## Abstract

**Background:** The advancement of wearable devices and growing demand of consumers to monitor their own health have influenced the medical industry. Health care providers, insurers, and global technology companies intend to develop more wearable devices incorporating medical technology and to target consumers worldwide. However, acceptance of these devices varies considerably among consumers of different cultural backgrounds. Consumer willingness to use health care wearables is influenced by multiple factors that are of varying importance in various cultures. However, there is insufficient knowledge of the extent to which social and cultural factors affect wearable technology acceptance in health care.

**Objective:** The aims of this study were to examine the influential factors on the intention to adopt health care wearables, and the differences in the underlying motives and usage barriers between Chinese and Swiss consumers.

**Methods:** A new model for acceptance of health care wearables was conceptualized by incorporating predictors of different theories such as technology acceptance, health behavior, and privacy calculus based on an existing framework. To verify the model, a web-based survey in both the Chinese and German languages was conducted in China and Switzerland, resulting in 201 valid Chinese and 110 valid Swiss respondents. A multigroup partial least squares path analysis was applied to the survey data.

**Results:** Performance expectancy ( $\beta=.361, P<.001$ ), social influence ( $\beta=.475, P<.001$ ), and hedonic motivation ( $\beta=.111, P=.01$ ) all positively affected the behavioral intention of consumers to adopt wearables, whereas effort expectancy, functional congruence, health consciousness, and perceived privacy risk did not demonstrate a significant impact on behavioral intention. The group-specific path coefficients indicated health consciousness ( $\beta=.150, P=.01$ ) as a factor positively affecting only the behavior intention of the Chinese respondents, whereas the factors affecting only the behavioral intention of the Swiss respondents proved to be effort expectancy ( $\beta=.165, P=.02$ ) and hedonic motivation ( $\beta=.212, P=.02$ ). Performance expectancy asserted more of an influence on the behavioral intention of the Swiss ( $\beta=.426, P<.001$ ) than the Chinese ( $\beta=.271, P<.001$ ) respondents, whereas social influence had a greater influence on the behavioral intention of the Chinese ( $\beta=.321, P<.001$ ) than the Swiss ( $\beta=.217, P=.004$ ) respondents. Overall, the Chinese consumers displayed considerably higher behavioral intention ( $P<.001$ ) than the Swiss. These discrepancies are explained by differences in national culture.

**Conclusions:** This is one of the first studies to investigate consumers' intention to adopt wearables from a cross-cultural perspective. This provides a theoretical and methodological foundation for future research, as well as practical implications for global vendors and insurers developing and promoting health care wearables with appropriate features in different countries. The testimonials and support by physicians, evidence of measurement accuracy, and easy handling of health care wearables would be useful in promoting the acceptance of wearables in Switzerland. The opinions of in-group members, involvement of employers,

and multifunctional apps providing credible health care advice and solutions in cooperation with health care institutions would increase acceptance among the Chinese.

## Introduction

### Background

The global market for wearable devices is growing at a remarkable rate [1]. The terms “wearable technology,” “wearable devices,” and “wearables” all refer to electronic technologies or computers incorporated into items of accessories and clothing, which can comfortably be worn on the body and enable users to collect and self-monitor their health vitals [2]. In this paper, we use the word “wearables” to represent the terms “wearable technology” and “wearable devices.” As the number of potential users continues to grow, wearables will have increasing sociological and cultural impacts [2]. Numerous global companies developing wearables in health care aim to target consumers in many countries. Nevertheless, the intention to accept and adopt wearables varies tremendously among consumers of different cultural backgrounds. It is evident that countries that differ greatly regarding their technological development, social structure, and usage habits have different levels of technology acceptance [3].

Some literature on the influential factors of consumers’ acceptance and adoption of health care wearables is available [4-12]. There are also some studies that focused on the differences in these influential factors in various national cultures with respect to technology acceptance [3,13,14]. However, there is a notable research gap concerning variation in the influential factors on consumers’ acceptance of health care wearables from distinct national cultures [5,6,11]. Based on this, the following research questions were formulated: What are the influential factors on consumers’ behavioral intention to adopt health care wearables? How different are the drivers of the behavioral intention to adopt health care wearables of Chinese and Swiss consumers?

The objective of this study was to investigate certain patterns of influential factors on usage intention of health care wearables by means of comparison of essential acceptance motives and usage barriers of Chinese and Swiss consumers. The different perceptions between Chinese and Swiss users were compared and are discussed in view of the differing national cultures of these two countries. Results of this study will have implications for global digital technology providers to develop and market wearables successfully across borders, as well as possible incentives that the insurers might offer with respect to lifestyle changes to enhance people’s health conditions effectively.

## Prior Research

### Theories and Models of Wearable Technology Acceptance

Technology acceptance is widely recognized as an aspect of understanding the approval, favorable reception, and continued use of newly introduced devices and systems [3]. Davis [15] developed the first technology acceptance model (TAM), in which perceived usefulness and perceived ease of use were shown to be two main factors affecting the attitude of a user toward new technologies. The TAM was subsequently expanded to include more factors influencing users’ acceptance of computer-related technologies. Recent studies have investigated technology acceptance on the part of consumers, particularly in the area of information technology. This is often performed in the context of the model of unified theory of acceptance and use of technology 2 (UTAUT2) introduced by Venkatesh et al [16]. In the UTAUT2 model, intrinsic motivation such as hedonic motivation and two aspects of consumer behavior, namely price value and habit, were added to the previous construct of UTAUT. The acceptance of medical technology intersects with intimate and personal aspects, and is therefore a highly sensitive topic that sets itself apart from the acceptance of information technology in general [3].

By examining the factors influencing mobile health technology acceptance, Rogers’ Protection Motivation Theory (PMT) [17] has been integrated into the health TAM [4]. Since health care wearables collect users’ personal health information on an ongoing basis, concern about data privacy risk increases. An individual’s decision to adopt health care wearable devices would involve an obvious privacy calculus, in which users may consider the tradeoff between perceived benefit and perceived privacy risk [5]. Based on this theory, various researchers have added and abandoned variables according to the characteristics of technology and the targeted user groups to predict a user’s intention to adopt health care wearables. Gao et al [6] developed an integrated framework comprehensively examining wearable technology acceptance in health care (WTAH) by combining the theories described above [18,19]. Gao et al [6] tested this framework through an empirical survey conducted in China with 462 qualified responses (users of health care wearables) and confirmed that the 8 predictors in their WTAH model, namely performance expectancy, hedonic motivation, effort expectancy, functional congruence, self-efficacy, social influence, perceived vulnerability, and perceived severity, positively influence an individual’s intention to adopt health care wearables; perceived privacy risk negatively affected an individual’s intention to adopt health care wearables. Among all factors, social influence and perceived privacy risk were the most significant predictors [6]. However, this survey was only

conducted in China, which did not consider the cultural differences between different countries [6]. Hence, testing whether the approved relationships are still held in other countries is necessary.

### ***Influence of National Culture on Technology Acceptance***

A country's cultural values influence technology acceptance [13]. Although the TAM has been used extensively when studying information technology adoption in Western countries, researchers noted that the TAM was not valid when applied to other cultures [13,20]. The UTAUT model was tested in non-Western cultures such as in Saudi Arabia [21], India [22], and China as compared to the United States [23]. These studies provided evidence that there is an interaction between the two phenomena of technology acceptance and national culture.

Several sets of dimensions have been developed to characterize the concept of national culture [24]. At present, at least 6 models of national cultures are widely cited and utilized in the management research literature [14]. These 6 culture models attempt to provide a well-reasoned set of dimensions to facilitate comparison of differing cultures. Among these models, Hofstede and Minkov [25] provided detailed guidelines to explain and measure cultural value differences applied to national culture. To date, these cultural dimensions have been the most commonly used variables for examining models cross-culturally [13,20,24,26]. McCoy et al [27] conducted a simple analysis of variance for each of Hofstede and Minkov's [25] cultural dimensions measured at the individual level across 8 countries. All of the F-scores obtained were significant at  $P < .001$ , which provides clear evidence of the existence of national culture (ie, the variance between groups is larger than the variance within groups) [27]. For this reason, this study primarily adopted the Hofstede and Minkov dimensions (hereafter referred to as "Hofstede's cultural dimensions") to describe, explain, and to a degree measure the difference in the national cultures of Chinese and Swiss consumers.

Hofstede's cultural dimensions [28] utilized a national level of analysis, whereas most TAMs were developed for an individual level of analysis. Ford et al [18] stated that it would be beneficial to consider national culture as a moderating variable, since this

might play an important role in comparing different populations. Alshare et al [13] confirmed this statement in their empirical study with samples from the United States, Chile, and the United Arab Emirates, showing that national culture dimensions represented by masculinity, power distance, individualism, and uncertainty avoidance moderate four relationships of an extended TAM. McCoy et al [29] showed that high power distance, high masculinity, low uncertainty avoidance, and high collectivism seem to nullify the effects of perceived ease of use or perceived usefulness in the TAM. Taken together, these studies suggested that national culture moderates relationships in the extended TAM, UTAUT, and other related models [13]. Following a similar reasoning, this study examined the moderating role of the national cultures of China and Switzerland with an adapted conceptual model of WTAH.

### ***Differences in National Culture Between the Chinese and Swiss***

The differences in the national cultures of China and Switzerland according to Hofstede's country comparison tool [30] are summarized in Table 1. According to Hofstede's [31] cultural dimension, Switzerland holds the cultural values of high individualism, moderately high uncertainty avoidance, moderately high indulgence, and low power distance. These contrast with the cultural values of the Chinese of low individualism (high collectivism), low indulgence (high restraint), moderately low uncertainty avoidance, and high power distance. Both countries have similarly high values of masculinity and long-term orientation. Multilingualism is an essential part of Switzerland's identity, with more than 64% of the population speaking German, and approximately 20% speaking French, 8% Italian, and 1% Romansh. Hofstede and Minkov [30] indicated that the German-speaking and French-speaking parts of Switzerland exhibit slightly different cultural values in the aspects of power distance and uncertainty avoidance, but are otherwise very similar with respect to the values of individualism, masculinity, long-term orientation, and indulgence. Therefore, only the cultural values of the German-speaking part of Switzerland were considered for this study.

**Table 1.** Cultural scores of China and Switzerland according to Hofstede and Minkov [30].

Cultural dimensions	China	Switzerland
Power distance	80	34
Individualism	20	68
Masculinity	66	70
Uncertainty avoidance	30	58
Long-term orientation	87	74
Indulgence	24	66

The cultural differences between the Chinese and the Swiss are additionally presented in Table 2, as mapped onto the "Big Five" dimensions in Nardon and Steer's [14] comparative study of all cultural models. Among these five dimensions,

"relationship with the environment" and "time orientation" are additional dimensions that were not explicitly mentioned by Hofstede.

**Table 2.** Country ratings of China and Switzerland in line with “Big Five” dimensions [14].<sup>a</sup>

Cultural dimensions	China	Switzerland
Relationship with the environment	Harmony	Mastery
Social organization	Collectivist+	Individualist
Power distribution	Hierarchical	Egalitarian
Rule orientation	Relationship-based	Rule-based+
Time orientation	Polychronic	Monochronic+

<sup>a</sup>All ratings are comparative, with a “+” sign indicating a stronger tendency toward a particular dimension.

## Methods

### Conceptual Model

To analyze influential factors for the intention to adopt health care wearables, and especially to distinguish the different perspectives between Chinese and Swiss consumers, a conceptual model was developed, which is illustrated in [Figure 1](#). This model was adapted from Gao et al’s [6] WTAH model, since it is one of the most comprehensive models that incorporates consumers’ behavioral intention on technology acceptance (UTAUT2), health behavior (PMT), and privacy calculus theories. The variables such as performance expectancy, hedonic motivation, effort expectancy, functional congruence, social influence, and perceived privacy risk are factors that influence the behavioral intention of consumers using health care wearables, which are adopted from the WTAH model. However, three other variables (self-efficacy, perceived vulnerability, and perceived severity) of the WTAH model based on the PMT were replaced by a single variable, “health consciousness,” in this study, for the following reasons.

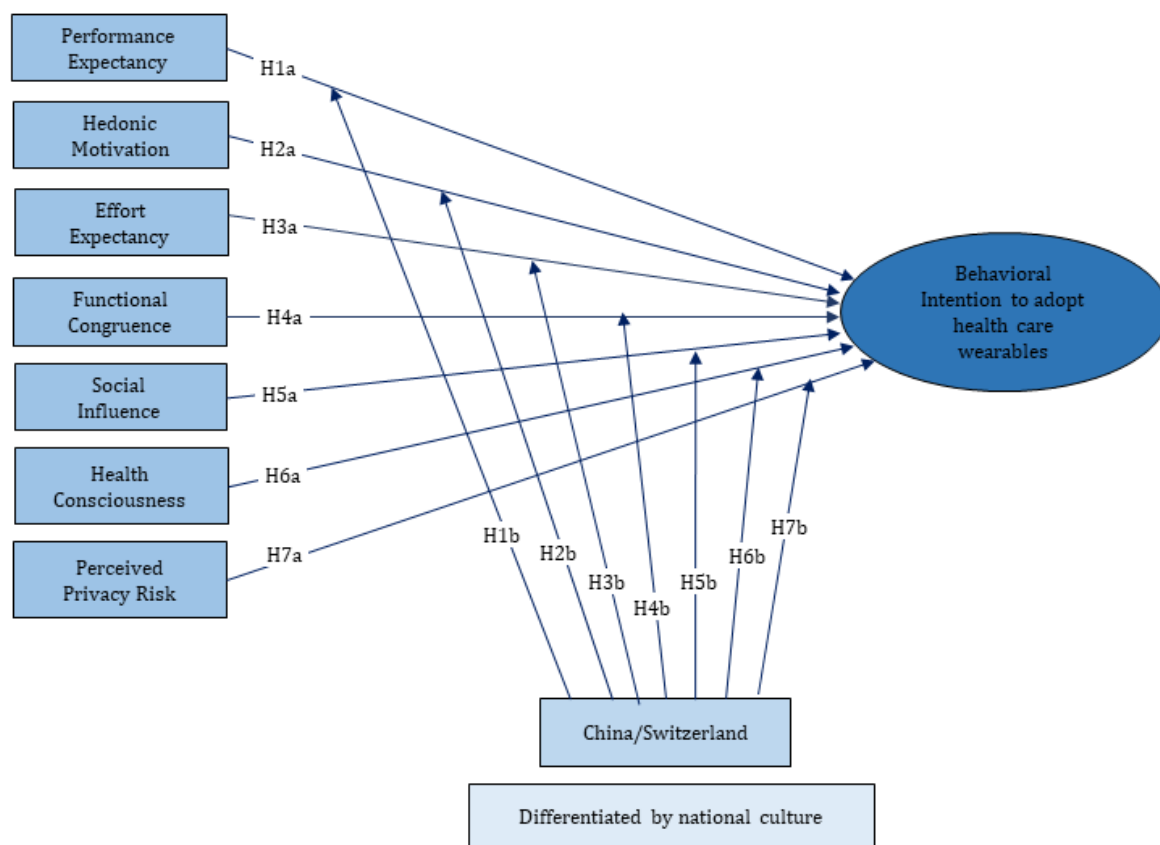

Perceived vulnerability refers to the possibility that one will experience a threat of certain diseases, whereas perceived severity represents the extent of the threat of certain diseases [4]. Sun et al [4] argued that the factors relevant to threat appraisal of PMT have only relatively weak (perceived vulnerability) or no (perceived severity) effects on behavioral intention to accept mobile technologies of health services. This is consistent with the meta-analysis results of Floyd et al [4,32]. Part of the health care wearables of focus in this study are consumer-grade devices that are typically used by relatively healthy members of the population who are interested in fitness/wellness. Therefore, the factors in the PMT model would not be suitable for measuring the acceptance of fitness/wellness

wearables, which constitute a significant portion of health care wearables. This was especially confirmed during the first round of the pilot study with the first version of the questionnaire, which included the variables of PMT. Some Swiss participants of the pilot study could not answer the related questions, and particularly could not distinguish the question with five different levels of a Likert scale, even when prompted with the situation that they would suffer from a certain disease and have poor knowledge about self-care regarding that disease. Self-efficacy is the belief in one’s ability to use health care wearables to monitor and improve their health condition [6]. The aspects related to this variable are partly covered by the variable effort expectancy, which was remarked as high by the test respondents in the first-round pilot study.

Health consciousness is conceptualized as the extent to which individuals have interest in and are aware of their own health conditions and well-being, and the extent to which a person maintains their own health [7]. A survey by the consulting firm MarketsandMarkets [33] described that the increasing health consciousness among people drives the growth of the wearable technology market. Cho et al [7] as well as Chen and Lin [8] confirmed that health consciousness has a significant direct effect on the perceived ease of use and usefulness of dietary and fitness apps. People’s behavior to maintain their health in the aspect of “health consciousness” covers the aspect of “self-efficacy.” Consequently, this study proposes that health consciousness represents people’s general health concern, awareness, and behavior instead of factors in the PMT.

The definitions of all factors in the proposed model are listed in [Table 3](#), which are adapted from previous published studies [6,7] with minor modifications in wording to fit into the health care wearables context.

**Figure 1.** Conceptual model.**Table 3.** Definitions of factors in the conceptual model.

Construct	Definition/Explanation
Performance expectancy	Degree to which adopting health care wearables will bring effectiveness to users in improving their health condition, which includes monitoring daily physical conditions, making personal health care plans, and reducing health-related threats.
Hedonic motivation	Pleasure or enjoyment derived from adopting and using health care wearables, such as enjoying the technical functions of the devices, sharing data with peers, and feeling of accomplishment after reaching the training goals.
Effort expectancy	Degree of perceived ease of using health care wearables, which includes wearing the device easily on the body, using other devices such as a smartphone to analyze the data, and understanding the data.
Functional congruence	Perceived suitability of health care wearables to fulfill the functional and basic product-related needs such as price reasonability, esthetics, and ergonomic design.
Social influence	Extent to which a user's decision-making is influenced by others' perceptions. These "others" include close relationships such as family members and close friends, important people such as employers or peers, professionals such as physicians, and technical specialists.
Health consciousness	Extent to which individuals have interest in and are aware of their own health condition and degree to which health concerns are integrated into their daily activities.
Perceived privacy risk	Perceived risk of reputation damage or other disadvantages by disclosing personal health data to people/organizations unwittingly.
Country China/Switzerland	Country dichotomy of China versus Switzerland distinguished by different national cultural values.
Behavioral intention	Users' formulation of conscious use or increasing use of health care wearables.

### Hypotheses Related to Influential Factors on Behavioral Intention

The effect of all of the independent variables (except for health consciousness) in this conceptual model were confirmed by

Gao et al [6] in their empirical study with Chinese respondents. As both Swiss and Chinese consumers were involved in this study, all of the influential factors in the conceptual model were tested with the entire group of valid respondents to evaluate

whether the relationships in this adapted model hold for both groups.

Based on this, the following hypotheses were drawn:

*H1a: Performance expectancy is positively correlated with an individual's intention to adopt health care wearables.*

*H2a: Hedonic motivation is positively correlated with an individual's intention to adopt health care wearables.*

*H3a: Effort expectancy is positively correlated with an individual's intention to adopt health care wearables.*

*H4a: Functional congruence is positively correlated with an individual's intention to adopt health care wearables.*

*H5a: Social influence is positively correlated with an individual's intention to adopt health care wearables.*

*H6a: Health consciousness is positively correlated with an individual's intention to adopt health care wearables.*

*H7a: Perceived privacy risk is negatively correlated with an individual's intention to adopt health care wearables.*

### **Hypotheses Related to Differences Between the Chinese and Swiss**

In the conceptual model, the country (China, Switzerland) distinguished by national culture acts as a moderating variable, which affects the influential degree of the above-mentioned independent variables and the individual's behavioral intention to adopt the wearables differently.

People in individualist cultures such as the Swiss culture pursue independence and freedom, and therefore advocate self-responsibility and self-reliance [31]. The opinions of close peers would not have much bearing on their decision to adopt wearables. By contrast, wearables enable them to live a more autonomous and freer lifestyle through self-monitoring of their health conditions (eg, not restricted by appointments with a physician, which was confirmed by Swiss interviewees). Therefore, performance expectancy of the Swiss on health care wearables might lead to higher intention to adopt health care wearables. Thus, we hypothesized:

*H1b: Performance expectancy has a greater impact on the intention to adopt wearable devices for Swiss consumers than for Chinese consumers.*

Swiss respondents exhibited a moderately high value of "indulgence," which means that they generally place a higher degree of importance on leisure time and having fun [31]. Pleasure or enjoyment derived from using health care wearables, such as enjoying the technical functions of the devices and the feeling of accomplishment after reaching the training goals, might cause the Swiss to have a higher intention to adopt health care variables. Therefore, we hypothesized:

*H2b: Hedonic motivation has greater impact on the intention to adopt wearable devices for Swiss consumers than for Chinese consumers.*

Ease of use of technology not only influences the user's motivation but also makes the technology more adaptive in the organization [20]. The individual Swiss consumer tends to solve technological problems by themselves much more than the Chinese consumer, who tends to live in a close community, taking support from the community for granted according to cultural value dimensions [14,20,31]. In addition, the high uncertainty avoidance value causes the Swiss to perceive new technology as more difficult, because the functions and consequences are uncertain [31]. Accordingly, perceived ease of handling health care wearables might have a greater impact on the behavioral intention of Swiss consumers. Therefore, we hypothesized:

*H3b: Effort expectancy has greater impact on the intention to adopt wearable devices for Swiss consumers than for Chinese consumers.*

The general income in China is dramatically lower than that in Switzerland, and this was clearly reflected in the sampling of this study. Thus, functional and basic product-related needs such as price reasonability, esthetics, and ergonomic design would have more impact on a Chinese consumer's intention to use health care wearables than a Swiss consumer's. Therefore, we hypothesized:

*H4b: Functional congruence has greater impact on the intention to adopt wearable devices of Chinese consumers than for Swiss consumers.*

With their generally collectivist values, Chinese consumers are more concerned about the maintenance of group cohesion, put more weight on the opinions of in-group members, and tend to assimilate their opinions or behaviors in their close community [31]. Researchers found that in collectivist countries, the positive effect of social influence on technology acceptance is stronger than that in individualist countries [34]. People in collectivist countries (ie, China) tend to seek out new information from their peers who have already adopted the technology, in contrast to people in individualist countries (ie, Switzerland), who tend to seek information on their own from formal/external sources [20].

The high power distance of Chinese consumers leads to the strong influence of superiors, employers, or authority on adopting wearables for health care or other purposes. For example, some Chinese companies distribute locally produced smartwatches to all of their employees as a kind of fringe benefit for health care. Through the encouragement, support, and influence of the local environment, Chinese consumers find it easy to be in a group of wearable users, which further fosters their intention to adopt the wearables. Therefore, we hypothesized:

*H5b: Social influence has greater impact on the intention to adopt wearable devices on the part of Chinese consumers than Swiss consumers.*

It is well known that the health care and insurance system in China is far from developed; health care providers are usually

overburdened with large volumes of patients and expenses for individuals are relatively high. The health-conscious Chinese might choose to pursue a healthier lifestyle through using wearables to track their health condition and avoid disease rather than going for treatment at a hospital after getting ill. This would save time and expenditures on health care. Therefore, we hypothesized:

*H6b: Health consciousness has greater impact on the intention to adopt wearable devices on the part of Chinese consumers than Swiss consumers.*

The high uncertainty avoidance of Swiss consumers might make them reluctant to engage with new technology and devices, and to exercise more discretion with personal information. They would perceive the privacy risk much higher than Chinese consumers, and demand clear regulations before adopting digital health care appliances, which might exert more of a negative influence on their intention to use wearables. Therefore, we hypothesized:

*H7b: Perceived privacy risk has greater impact on the intention to adopt wearable devices on the part of Swiss consumers than Chinese consumers.*

## Construction of Questionnaire

To validate the conceptual model and hypotheses, a quantitative research approach was employed by developing a written questionnaire. Several interviews were first held in Switzerland and China with current users of fitness and medical wearables to ensure the relevance and objectivity of the questions. The measurement items (see [Multimedia Appendix 1](#)) for the independent variables performance expectancy, hedonic motivation, effort expectancy, functional congruence, social influence, and perceived privacy risk, and the dependent variable behavioral intention in the questionnaire were adapted from Gao et al [6]; those for health consciousness were adapted from Michaelidou and Hassan [35]. A 5-point Likert scale was employed to measure the items. The questions regarding the cultural value dimension “individualism” were adopted from Hofstede and Minskova’s “Values Survey Module 2013 Questionnaire” [25].

Both variables of “nationality at birth” and “country of residence” were initially assessed to particularly ensure that Chinese living in Switzerland and Swiss living in China were not included in the valid samples, so that the country variable represents a distinct national culture to meet the requirement of reliability. Users and nonusers of health care wearables were included in the collected samples so that the different perceptions and attitudes of both groups (users with high propensity of intention and nonusers with low propensity of intention) were considered.

The questionnaire was translated from English into German and simplified Chinese. The translated versions were corrected by more than two native speakers in each language and have been back-translated. The German language was used for the Swiss questionnaire, as it covers more than 64% of the Swiss population.

Three rounds of pilot studies were conducted; since the measured items are all nonobservable variables, different understandings occur due to language barriers (English, German, and simplified Chinese) and divergent cultural backgrounds. The first pilot study round was conducted initially with 5 Swiss natives representing different age groups. Consequently, the variables of PMT in the WTAH model were replaced by health consciousness. The second and third rounds of pilot studies were conducted with 20 Chinese and 9 Swiss participants, through which the questions were adjusted in both languages a few times to ascertain that all items were formulated clearly, in logical sequences, relevant to the everyday lives of the respondents, and relatively easy to answer.

Smartwatches were selected as the representative health care wearables in this study because they combine the features of consumer and medical-grade devices [9,36]. Most smartwatches can monitor some human physiological signals and biomechanics, and thus act as fitness tracking devices that help users record their daily activities such as automatically recording workout times, tracking heart rates, step counts, and calories burnt [10]. With added apps and sensors, the new generation of smartwatches can further measure health vitals such as electrocardiography, glucose level, and blood pressure, as well as detect certain diseases such as arrhythmia and seizure [9,37]. Smartwatches are the most frequently purchased wearable devices worldwide currently and will continue to be in the near term [38].

## Data Collection

Both finalized questionnaires were distributed to the Chinese and Swiss populations using web-based survey tools and a snowball sampling method as a convenience sampling technique [39]. The German version, compiled in Survey Monkey, was distributed to Swiss consumers by email, with the request to forward the survey further to their colleagues and friends. The questionnaire was distributed in diverse industry and service companies, fitness centers, leisure and sport clubs, as well as in local communities. The Chinese version, designed in “Wen Juan Xing,” was distributed to Chinese consumers in mainland China by email and the social media platform WeChat with a requirement to share the survey. The collected samples were the responses to the survey from April 2 to April 24, 2019. Until the evening of April 24, 2019, 153 samples were collected from Switzerland and 203 samples were collected from 23 of 32 provinces and municipalities of mainland China (excluding Hong Kong and Macau).

## Data Analysis

First, a descriptive analysis was conducted related to the sample characteristics and the cultural values (individualism/collectivism) of the Chinese and Swiss. After validity assessments, *t* tests were conducted to compare mean differences in the constructs between the Chinese and Swiss samples. In the last step, the research model was tested using a multigroup partial least squares path analysis method.

## Results

### Sample Description

Among the 356 received responses, 13 incomplete samples that ended in the middle of the questionnaire were deleted, and 32 respondents with other nationalities (2 living in China and 30 in Switzerland) were excluded in the data analysis, being that

the moderating factor is a distinct culture of China and Switzerland. This resulted in a complete valid sample of 311 respondents with 201 Chinese respondents living in China and 110 Swiss respondents living in Switzerland. The sample characteristics are displayed in [Table 4](#), showing that the Chinese and Swiss samples represent the population of each country respectively against the current societal and economic backgrounds.

**Table 4.** Sample characteristics (N=311).

Variable	Chinese sample (n=201), n (%)	Swiss sample (n=110 <sup>a</sup> ), n (%)
<b>Gender</b>		
Male	89 (44.3)	52 (47.3)
Female	112 (55.7)	58 (52.7)
<b>Age (years)</b>		
16-25	8 (4.0)	10 (9.1)
26-40	72 (35.8)	33 (30.0)
41-55	56 (27.9)	33 (30.0)
56-70	38 (18.9)	29 (26.4)
>70	27 (13.4)	4 (3.6)
<b>Monthly income (US \$)</b>		
<500	16 (8.0)	2 (1.8)
501-1500	100 (49.8)	4 (3.6)
1501-3000	36 (17.9)	7 (6.4)
3001-5000	20 (10.0)	19 (17.3)
>5001	7 (3.5)	60 (54.5)
No information	22 (10.9)	17 (15.5)
<b>Highest education level</b>		
Apprenticeship	10 (5.0)	30 (27.3)
Senior high school	12 (6.0)	5 (4.5)
College	27 (13.4)	25 (22.7)
University <sup>b</sup> and above	143 (71.1)	43 (39.1)
No information	9 (4.5)	6 (5.5)

<sup>a</sup>One respondent did not answer the questions related to age, monthly income, and education, respectively, in the Swiss sample.

<sup>b</sup>Including universities of applied sciences.

### Difference in Cultural Values of the Chinese and Swiss

Following the 6 cultural dimensions of Hofstede [28], the biggest differentiation between the Chinese and the Swiss exists in the dimension of individualism versus collectivism (opposite of individualism), which was empirically examined in this study. Individualism is the degree to which people in a society are integrated into groups [31]. In a culture with individualistic values (like Switzerland), the ties between individuals are loose; that is, everyone is expected to look after themselves and their immediate family [31]. In cultures with a collectivistic value (like China), people are integrated from birth onward into strong, cohesive in-groups, often extended families that continue protecting them in exchange for unquestioning loyalty [31]. The issue addressed by this dimension is an extremely

fundamental one, relevant to all societies in the world [28]. In this study, the question items and calculation methods were based on Hofstede and Minkov's index formula [25]. The mean value of individualism for the entire Chinese population was 4.00 as compared to that of the Swiss at 46.24. Adding a constant of 20 to the mathematical means results in a value of 24.0 for the Chinese and 66.24 for the Swiss. This conforms almost exactly to Hofstede's original individualism values (20 vs 68) in [Table 1](#), which empirically confirms the distinguished cultural differences between China (low individualism) and Switzerland (high individualism).

### Validity Assessment

[Table 5](#) depicts the mean values and standard deviations of the constructs shown in [Figure 1](#). This table also includes the

reliability and validity statistics. The loadings of all reflective indicators were above .70 and significant, confirming item reliability. In line with this, the values of the composite reliability estimates revealed the internal consistency of the measurement instruments. The reliability estimates for behavioral intention to adopt health care wearables can also be regarded as satisfactory, because Hair et al [40] indicated that the true internal consistency reliability values usually lie between Cronbach  $\alpha$  and the composite reliability. In addition,

according to the values of the average variance extracted (AVE) statistic, the measurement showed convergent validity.

Based on the quotient of the square root of AVE on the diagonal and the correlation coefficient between constructs in the lines below, according to the Fornell-Larcker criterion [41], the square roots of AVE are larger than the correlation coefficient between constructs; thus, the discriminant validity of the measurement can ultimately be confirmed.

**Table 5.** Descriptive statistics, reliability statistics, and validity statistics.

Variable	Mean (SD)	Cronbach $\alpha$	Composite reliability	AVE <sup>a</sup>
Performance Expectancy	3.573 (0.806)	.869	0.919	0.791
Hedonic Motivation	3.438 (0.763)	.862	0.915	0.782
Functional Congruence	3.445 (0.678)	.713	0.836	0.631
Effort Expectancy	3.766 (0.803)	.900	0.937	0.833
Social Influence	3.034 (0.990)	.910	0.943	0.848
Health Consciousness	4.028 (0.577)	.806	0.803	0.590
Perceived Privacy Risk	3.393 (0.891)	.848	0.886	0.724
Behavioral Intention	3.129 (1.086)	.927	0.954	0.873

<sup>a</sup>AVE: average variance extracted.

### Differences Between Swiss and Chinese Participants in the Constructs

A *t* test was conducted to compare mean differences between the Chinese and Swiss samples in the constructs of the conceptual model.

As indicated in Table 6, the different responses of Chinese and Swiss respondents toward the variables performance expectancy, functional congruence, effort expectancy, social influence, behavioral intention, and the cultural value of individualism were significant. This indicates that Chinese respondents have higher performance expectancy on the presented wearables than Swiss respondents and are influenced more by their social environment. The moderate significant difference on effort

expectancy and functional congruence confirms that the Chinese consider health care wearables easy to use, and they pay more attention to additional functions such as comfort, esthetics, and price value. Differences between Chinese consumers and Swiss consumers toward hedonistic motivation, health consciousness, and perceived privacy risk were not significant. Both groups have quite high health consciousness, perceived privacy risk, and relatively high hedonistic motivation. From the significant differences between Chinese consumers and Swiss consumers in behavioral intention, it can be concluded that the Chinese clearly have more intention to use health care wearables than the Swiss. All of these distinctions are related to the cultural differences between Swiss and Chinese consumers according to cultural value dimensions.

**Table 6.** Comparing perceptions of the Chinese and Swiss (*t* test).

Variable	Chinese sample, mean (SD)	Swiss sample, mean (SD)	Mean difference	<i>P</i> value
Performance Expectancy	3.74 (0.76)	3.26 (0.79)	0.484	<.001
Hedonic Motivation	3.47 (0.73)	3.38 (0.82)	0.097	.29
Functional Congruence	3.50 (0.70)	3.34 (0.62)	0.168	.03
Effort Expectancy	3.84 (0.77)	3.63 (0.84)	0.215	.03
Social Influence	3.44 (0.84)	2.30 (0.80)	1.136	<.001
Health Consciousness	3.99 (0.61)	4.10 (0.50)	−0.108	.10
Perceived Privacy Risk	3.40 (0.91)	3.38 (0.85)	0.018	.86
Behavioral Intention	3.59 (0.80)	2.29 (1.40)	1.301	<.001
Individualism	4.004 (0.54)	46.24 (61.53)	−42.234	<.001

## Multigroup Partial Least Squares Path Analysis

The group-specific  $R^2$  value in the Chinese sample was 0.580 and that in the Swiss sample was 0.558, which revealed good explanatory power of the delineated model regarding the behavioral intention to adopt health care wearables.

Table 7 depicts the path coefficients according to the conceptional model (Figure 1). In view of hypotheses H1a-H7a and H1b-H7b, the results showed significant effects of performance expectancy, hedonistic motivation, and social influence on the behavior intention of consumers of health care

wearables in general. Performance expectancy, social influence, and health consciousness influenced the behavior intention of the Chinese significantly, whereas performance expectancy, hedonistic motivation, effort expectancy, and social influence had a significant influence on the behavior intention of the Swiss. Group-specific path coefficients showed a stronger influence of performance expectancy on the behavior intention of the Swiss than the Chinese and a stronger influence of social influence on the behavior intention of the Chinese than the Swiss. However, the results of the multigroup analysis indicated that these differences in the path coefficients were not significant when assessed at a level of  $P < .05$ .

**Table 7.** Group-specific path coefficients for each variable's influence on behavioral intention and multigroup analysis.

Variable	Path coefficient ( $P$ value) <sup>a</sup>			$P$ value for group differences in path coefficients
	Total sample	Chinese sample	Swiss sample

<sup>a</sup>Significance levels are based on a 5000 bootstrap run.

## Principal Results

The results above partially confirmed the proposed hypotheses. Among all of the predictors, performance expectancy, hedonistic motivation, and social influence affected behavioral intention positively, which support hypotheses H1a, H2a, and H5a, respectively. Effort expectancy, functional congruence, health consciousness, and perceived privacy risk did not affect behavior intention significantly, thereby rejecting hypotheses H3a, H4a, H6a, and H7a. Nevertheless, group-specific multigroup analysis with Chinese and Swiss samples indicated that hedonistic motivation and effort expectancy are significant predictors affecting the behavior intention of Swiss consumers positively, but do not affect that of Chinese consumers. By contrast, health consciousness is an important predictor affecting the behavior intention of Chinese consumers positively, but does not appear to have an effect on the behavior intention of Swiss consumers. Performance expectancy is a key factor affecting the behavior intention of both Chinese and Swiss consumers positively, but the degree of influence on Swiss consumers was higher than that on Chinese consumers. Social influence is another key factor affecting the behavior intention of both Chinese and Swiss consumers positively, but the degree of influence on Chinese consumers was higher than that on Swiss consumers. Country variable was not a moderator that differentiated the influence degree of functional congruence or perceived privacy risk toward behavior intention between Chinese and Swiss consumers. These results confirm hypotheses H1b, H2b, H3b, H5b, and H6b, but do not confirm hypotheses H4b and H7b.

## Discussion

### Main Findings

The  $R^2$  values in the total and subsample analyses indicate that the adapted WTAH model is a suitable conceptual model to assess behavioral intentions to use smartwatches as health care wearables. The multigroup analysis showed no significant differences between the Chinese and Swiss samples with respect to path coefficients. However, clear country-specific differences in the data were still found. First, the bootstrapping results within both samples clearly indicated that the relevance of the factors from the adapted WTAH model in the two sample groups differed. Performance expectancy and social influence appear to play a role in both sample groups to explain behavioral intention, whereas hedonistic motivation and effort expectancy were only key factors for the intention to use a smartwatch for the Swiss sample, and health consciousness only emerged as an important factor affecting behavioral intention for the Chinese sample. Functional congruence did not affect behavior intention in either sample. This could be explained by the fact that functional congruence comprises three items, wearing comfort, fashion, and price reasonability, which belong to three parallel aspects. Although intuitively all of these items relate closely with user intention, their consistency should be further checked.

Moreover, the mean values of perceived privacy risk were relatively high for both Chinese and Swiss consumers, but this was not validated as a significant predictor of the disinclination for consumers to use health care wearables, for consumers in general or for the specific group of Chinese or Swiss consumers.

One reason could be that smartwatches were used as the research object in this study, and consequently the related health data are not considered as critical and strictly confidential by users. Another reason could be that as a result of recent advancements in data privacy legislation, people are more familiar and confident with the data protection issue.

### Role of Cultural Values on Acceptability

These results can be explained by the differences in cultural values or social and health care systems between China and Switzerland, which are summarized in Table 8.

Chinese collectivist values and Swiss individualist values were confirmed empirically in this study. As collectivists, Chinese consumers search for information and support on wearables from people around them, attach more importance to others' opinions, and adapt to their peers. This explains the significantly higher values of effort expectancy, functional congruence, and social influence for the Chinese consumers in the *t* test. Chinese consumers, holding low uncertainty avoidance and "harmony" values toward their surroundings, normally embrace new technology and believe in its effectiveness, which can explain their higher performance expectancy value toward wearables than that of Swiss consumers.

**Table 8.** Influential cultural values on differences between China (CN) and Switzerland (CH).

Variables	Perceptions comparison ( <i>t</i> test)	Influence degree of country (group-specific path coefficients)	Explanatory cultural dimensions/social systems
Performance expectancy	CN > CH	CN < CH	CN: low IDV <sup>a</sup> ; low UAI <sup>b</sup> ; "Harmony" CH: high IDV; high UAI; "Mastery"
Hedonistic motivation	No difference	CN ns <sup>c</sup> CH sig <sup>d</sup>	CN: low IDV; low IND <sup>e</sup> CH: high IDV; high IND
Effort expectancy	CN > CH	CN ns CH sig	CN: low IDV; low UAI CH: high IDV; high UAI
Functional congruence	CN > CH	ns	CN: low IDV; low income CH: high IDV; high income
Social influence	CN > CH	CN > CH	CN: low IDV; low UAI; high PDI <sup>f</sup> CH: high IDV; high UAI; low PDI
Health consciousness	No difference	CN sig CH ns	CN: lack of developed health care and insurance system CH: importance on sport activities
Perceived privacy risk	No difference	CN ns CH ns	N/A <sup>g</sup>
Behavioral intention	CN > CH	N/A	CN: low IDV; low UAI; "Harmony" CH: high IDV; high UAI; "Mastery"

<sup>a</sup>IDV: individualism.

<sup>b</sup>UAI: uncertainty avoidance.

<sup>c</sup>ns: not significant.

<sup>d</sup>sig: significant.

<sup>e</sup>IND: indulgence.

<sup>f</sup>PDI: power distance.

<sup>g</sup>N/A: not applicable.

Swiss consumers showed significantly lower behavioral intention than Chinese consumers, which can be explained by their high value of uncertainty avoidance and "mastery" relationship with their surroundings (as compared to those of Chinese consumers). Because using wearables reduces social presence, this could accentuate the feeling of uncertainty. As a novel technology, the side effect, functionality, and measurement accuracy are quite uncertain. Swiss consumers in high uncertainty avoidance cultures will be less oriented toward using wearables than Chinese consumers in low uncertainty avoidance cultures [24]. Furthermore, the "mastery" value of Swiss consumers toward their environment/surroundings makes them inclined to stick with their habits and perceived correctness, which prevents them from trying new devices.

Although the mean values of health consciousness were high for both Chinese and Swiss respondents, it was not validated as a predictor that influences consumer intention to use wearables generally. Nevertheless, through group-specific analysis, health consciousness emerged as a significant predictor for behavior intention for the Chinese but not for the Swiss. The reason probably lies in the fact that Swiss consumers already spend more time on sport or wellness activities to enhance their health, and they generally have no further interest or time to invest in studying wearables for health purposes [7]. This is supported by Seiler and Hüttermann [11], who showed that 51% of nonusers (74% of the full sample) in their study expressed no need to adopt fitness wearables. By contrast, health-conscious Chinese consumers prefer to use wearables to help them track

their health, which is likely related to the underdeveloped health system in China with limited health care resources for such a large population; thus, Chinese consumers are open to more diverse and preventive possibilities.

### Limitations

Although some hypotheses were validated, and the criteria of objectivity, reliability, and validity were followed during the whole process of research, this study is subject to certain limitations, and the results should be interpreted with caution.

First, some variables of the conceptual model should be reorganized and reconsidered in future research. For example, health consciousness relates to many different concepts from health awareness, ranging from health concern to health activities. It influences the user's perception and intention of using wearables multilaterally. Health consciousness might be one of the predetermining factors for other variables such as performance expectancy, effort expectancy, and others, as investigated by some studies with controversial results [7,8]. Therefore, health consciousness should be examined in the future in different model structures. The country variable based on national culture was examined in this study as a moderating variable, which affects the relationship between predictors and outcomes. Cultural values influence many aspects (perception, attitude, intention) further to action. Thus, the country/cultural variables might also be predetermining factors for other predictors. In further research, the roles and distinction of cultural variables should be considered carefully and examined in different model structures as well.

Second, the control variables such as gender, age, education, and income might influence people's response patterns [42], which means that they can interfere with the predictors to affect a user's intention to adopt wearables. The control variables and user experiences were not considered in this study. The effect of control variables as moderators alone or as covariates with other moderators such as country/culture should be analyzed in the future.

Third, the external validity of the study is limited. A smartwatch was used as an example of health care wearables, which cannot be generalized to all types of medical wearable devices. In addition, the results cannot be generalized to other countries, as the survey was conducted in only China and Switzerland, and the cultural dimensions were only used to explain the difference between Chinese and Swiss consumers theoretically. It makes more sense to apply cultural values directly in the quantitative analysis in future research. For this purpose, effective methods of obtaining qualified scores of cultural values must be further explored.

Finally, a quantitative approach was applied to examine the conceptual model of this study, which could not provide specific information on certain types of users or devices. In future research, expert or focus group interviews could be conducted regarding a certain type of medical-grade wearable to gain more specific information.

### Comparison With Prior Work

This study is among the first to investigate the influential factors on intention to use health care wearables involving samples from two countries with quite different national cultures. Although most items of the conceptual model were adapted from the framework of Gao et al [6], in this study, the three predictors (self-efficacy, perceived vulnerability, and perceived severity) based on the PMT were replaced by a single variable: health consciousness. Thus, the findings cannot be compared with other studies directly.

Nevertheless, this study verifies that performance expectancy and social influence are the most influential factors on people's intention to accept health care wearables, which is in line with the results of Gao et al [6]. However, perceived privacy risk was not validated as a significant predictor influencing the behavior intention of consumers negatively, which contrasts with the results of Gao et al [6]. The main reason for this difference could be that more users adopting medical-grade devices were included in the samples of Gao et al's research because fitness/medical devices were examined as a moderator. This is not the case in our study regarding Chinese consumers, with smartwatches used as an example of health care wearables. Most smartwatch users might not be suffering from severe health problems at this stage. Hence, Chinese respondents might not consider revealing their health information as a privacy risk that would prevent them from using wearables in health care.

### Conclusions

This study examined the factors influencing people's behavioral intention to accept health care wearables, explored the different perceptions and using intention of Chinese and Swiss consumers, and explained the effect of national culture on these differences. These findings have practical implications for global wearables vendors and insurers to develop and promote health care wearables for consumers from various cultural backgrounds.

Performance expectancy and social influence were the most significant predictors that positively influenced consumer intention to adopt health care wearables. This result indicates that consumers are more affected by the perceived effectiveness of health care wearables and by other people's opinions. Thus, these factors should be given more attention when global companies develop and market health care wearables. For Switzerland, with cultural values of individualism and high uncertainty avoidance, the positive opinions of professionals such as physicians toward wearables and clearly demonstrated measurement accuracy would make Swiss consumers feel more confident with health care wearables. For China, with cultural values of collectivism and high power distance, the opinions of people in their surroundings (eg, peers, family, and friends) and the engagement of the Chinese working unit (eg, employers' social benefit) would increase the intention of Chinese consumers to adopt wearables.

Effort expectancy was shown to be an important driver for Swiss consumers to adopt health care wearables. Thus, the wearable devices should be easy to handle to attract Swiss consumers. This includes easy wearing of devices, along with easy analysis and interpretation of the data. Health consciousness emerged

as an important driver for Chinese consumers in adopting health care wearables. Thus, multifunctional apps providing feasible health care advice and solutions in cooperation with Chinese health care institutions are essential to attract Chinese consumers.

In addition, this study is one of the first to investigate intentions to adopt health care wearables from a cross-cultural perspective. It thus provides a theoretical foundation in terms of a conceptual model and survey methodology for future research in similar contexts with other countries and cultures.

## Acknowledgments

We would like to thank Yongsheng Yang, Beatrice Meyer, and Mischa Rupp for supplying personal information on using health care wearables in interviews, which served as the credible basis for questionnaire development. We would like to thank Altar Yilmazer, Elisabeth Schönwald, and Michaela Settelen for reviewing the language in the German questionnaire, and Zhiying Leng and Xu Yang for reviewing the language in the Chinese questionnaire. We would like to thank the many friends and colleagues who distributed the questionnaire in their social networks.

## Abstract

**Background:** The Brain Tumor Social Media (#BTSM) Twitter hashtag was founded in February 2012 as a disease-specific hashtag for patients with brain tumor.

**Objective:** To understand #BTSM's role as a patient support system, we describe user descriptors, growth, interaction, and content sharing.

**Methods:** We analyzed all tweets containing #BTSM from 2012 to 2018 using the Symplur Signals platform to obtain data and to describe Symplur-defined user categories, tweet content, and trends in use over time. We created a network plot with all publicly available retweets involving #BTSM in 2018 to visualize key stakeholders and their connections to other users.

**Results:** From 2012 to 2018, 59,764 unique users participated in #BTSM, amassing 298,904 tweets. The yearly volume of #BTSM tweets increased by 264.57% from 16,394 in 2012 to 43,373 in 2018 with #BTSM constantly trending in the top 15 list of disease hashtags, as well the top 15 list of tweet chats. Patient advocates generated the most #BTSM tweets (33.13%), while advocacy groups, caregivers, doctors, and researchers generated 7.01%, 4.63%, 3.86%, and 3.37%, respectively. Physician use, although still low, has increased over time. The 2018 network plot of retweets including #BTSM identifies a number of key stakeholders from the patient advocate, patient organization, and medical researcher domains and reveals the extent of their reach to other users.

**Conclusions:** From its start in 2012, #BTSM has grown exponentially over time. We believe its growth suggests its potential as a global source of brain tumor information on Twitter for patients, advocates, patient organizations as well as health care professionals and researchers.

## Introduction

Social media acts as one of the greatest facilitators of information, ideas, and discussions by creating a borderless global platform. As of April 2019, there are an estimated 3.5 billion active social media users who connect with people around the world at near-instantaneous speed [1]. Three of the largest global platforms are Facebook, WeChat, and Twitter with active user counts of 2.320 billion, 1.098 billion, and 330 million, respectively [2]. Given the ubiquity and integration of social media into everyday life, patients have taken to these platforms to share, connect, collaborate, communicate, and self-create online support communities, making it possible to circumvent traditional barriers to support groups (eg, geography, and lack of time, awareness, and transportation) [3,4].

Twitter makes it possible for unique Twitter users to follow each other, create unique posts, and interact through *tweets*—short messages limited to 280 characters [5]. Tweets can be accompanied by hashtags, which are words preceded by the octothorpe (#) symbol [6]. On Twitter, hashtags become a link that, when clicked, displays other tweets aggregated by the same topic [5,6]. Twitter describes hashtags as a way of categorizing tweets relevant to user's interest [6]. Recent studies have reported that patients increasingly use disease-specific hashtags as ad hoc support communities to share information and create meaningful connections [7,8]. In more recent years, disease-specific hashtags (including #BTSM [Brain Tumor Social Media hashtag]) have made it possible for clinicians and researchers to connect and communicate with patients and caregivers on areas of shared interest [8,9].

The #BTSM was founded in February 2011 by authors LS and CB [9]—2 brain tumor patients inspired by the success of other Twitter hashtag communities in oncology, notably Breast Cancer Social Media (#BCSM) [10]. LS and CB sought to make it easier for people in the brain tumor community to find each other and connect via Twitter, so they created #BTSM. In a blog post in 2013, LS described #BTSM as a *patient-run* Twitter community *not owned by any organization* [11].

LS and CB started a monthly tweet chat (an organized and moderated, live conversation on Twitter) operating under the Twitter account @BTSMchat in 2013. The #BTSM chat occurs on the first Sunday of every month and discusses broad topics of interest to the brain tumor community (eg, advance care planning, clinical trials, brain tumor representation in arts and entertainment) [11,12]. As of July 2020, @BTSMchat is formally organized by 5 patients, 1 caregiver, and 1 neuro-oncology clinician.

In this study, we examine #BTSM as a hashtag, and its role as an aggregator and technical facilitator of brain tumor conversations by identifying its key users and their interactions, and the type of information shared within this community since 2012. Furthermore, we report recent trends and developments within #BTSM.

## Methods

The data are all publicly available tweets with the #BTSM hashtag from January 1, 2012, to December 31, 2018, obtained via the Symplur Signals platform [13]. Information available includes user names and usage, tweet transcripts, and usage trends over time. Using R (version 3.5.3) [14], we generated descriptive statistics and visual output to provide insights into the overall use (growth) and demographic breakdown (eg, patient, doctor, researcher) of #BTSM users, along with trends and patterns about interactions between users of the #BTSM hashtag. We highlight #BTSM user engagement by describing the proportions of tweets that were retweets, replies, or mentions (ie, tweets that contain another Twitter user's name). To account for *passive consumption* of tweets featuring the #BTSM hashtag (ie, simply viewing a tweet without engaging with a retweet, reply, or mention), we report total impressions, which is the number of times a tweet has appeared in any user timeline or search result on Twitter [15]. Aggregate data on user engagement were collected to highlight the yearly share of tweet authorship among Symplur-defined user categories. To create a stack plot that focuses on proportions, the yearly raw count for user-specific tweets was transformed to represent yearly share. By representing count as a proportion, the users who generate the most tweets at any given year are presented.

To visualize the interactions between key #BTSM stakeholders, a network plot was created to visualize content sharing via retweets in 2018. Tweet transcripts from Symplur were first downloaded and merged to ensure that all nodes can be plotted and represented in the network. To create the retweet network plot, the open source software Gephi [16] (version 0.9.2) was used. To highlight the users with the most unique connections to other users based on having been retweeted, the color and size of their nodes were adjusted to visualize influential users by applying the outdegree setting on Gephi. Outdegree ranks nodes based on unique outward connections with other nodes [17], which in effect assigned bluer and larger nodes to users with more unique connections. Minor positioning adjustments were made to the network to ensure the readability of nodes and their labels. Additionally, we examined the impact of other hashtags on #BTSM activity in 2018.

## Results

### Content and User Descriptors

From 2012 to 2018, 59,764 unique Twitter users used the #BTSM hashtag in their tweets, amassing a total of 298,904 tweets (Table 1). Among these, 78.17% (n=233,658), 53.49% (n=159,884), and 5.19% (n=15,516) involved mentions, retweets, and replies, respectively. Many tweets included media, such as website links (42.00%, n=125,534) and media objects such as photos and videos (27.66%, n=82,679). The yearly volume of #BTSM tweets increased by 264.57% from 16,394 in 2012 to 43,373 in 2018, making #BTSM one of the most heavily trended medical hashtags in the Symplur platform. Those identified as patients generated the most #BTSM tweets (33.1%), followed by brain tumor advocacy organizations (28.8%), researchers (7.0%), caregivers (4.6%), and doctors

(3.9%; [Figure 1](#)). Although still low, the yearly use of #BTSM by doctors has increased over time from 1.3% to 8.6% between

2012 and 2018 ([Figure 2](#)). Persons defined as caregivers showed reduced use over time, declining from 14.2% to 2.4%.

**Table 1.** Key #BTSM user and tweet descriptors for 2012-2018.

Data descriptor	Total count
Unique users	59,764
<b>Tweets generated</b>	298,904
Tweets with mentions	233,658
Tweets that were retweets	159,884
Tweets with links	125,534
Tweets with media (photo, video)	82,679
Tweets that were replies	15,516
Total impression	2,284,771,009

**Figure 1.** Overall proportion of tweet authorship for 2012-2018.

**Figure 2.** A stacked plot showing the yearly proportion of tweet authorship among users for 2012-2018.

### Hashtags for Expanded Reach

We conducted a deeper analysis on #BTSM user participation and growth for the 2018 calendar year. May 2018 data revealed an increase in #BTSM activity generated by tweets combining both #BTSM and #BTAM, a hashtag created by the National Brain Tumor Society (NBTS) to celebrate the Brain Tumor Awareness Month (BTAM) [18]. Out of the 4620 #BTSM tweets in May 2018, roughly 44% contained #BTAM. Other hashtags combined with #BTSM in May 2018 included #BrainTumor, #BrainTumorThursday, #BrainTumorAwarenessMonth, and #Head2Hill2018 (a public policy advocacy day organized by the NBTS) [19].

In the second half of 2018, our exploratory data analysis found #SNO2018 linked to a mid-November surge in #BTSM activity. The annual meeting of the Society of Neuro-Oncology (SNO) was held in New Orleans, Louisiana, from November 15 to 18, 2018 [20]. The meeting's official hashtag, #SNO2018, was promoted and used by conference attendees to promote and share information and research at the event. Of the 140 #BTSM

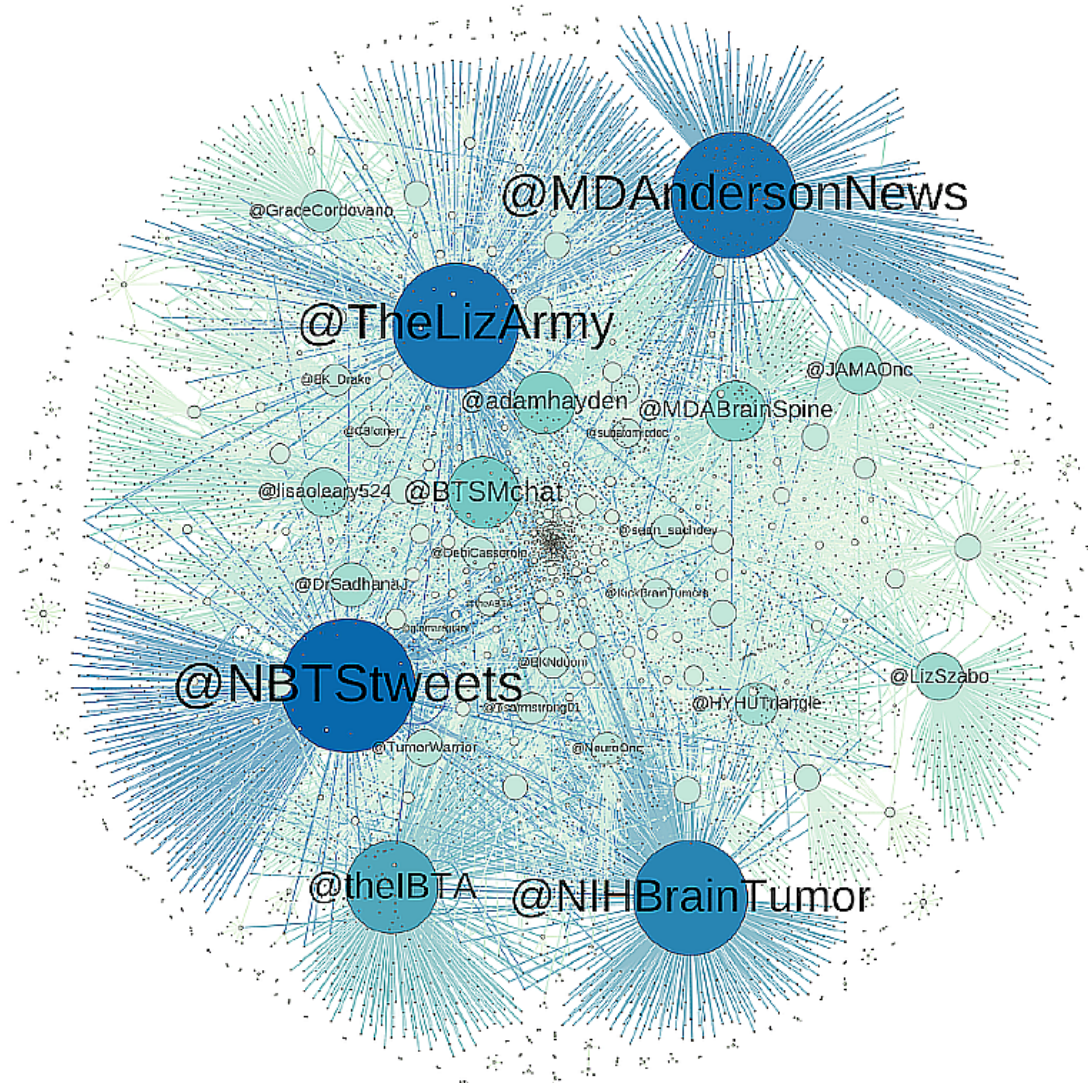

tweets in November 15-18, 85 (roughly 61%) also contained #SNO2018, which demonstrates the potential for neuro-oncology professionals to reach a majority of patient and caregiver audience on Twitter.

### Network Influencers

The 2018 network plot of retweets including #BTSM (Figure 3) identifies a number of key stakeholders from the patient advocate, patient organization, and medical researcher domains and reveals the extent of their reach to other people on Twitter. As indicated by their size and color, 6 of the most connected users in 2018 were @NBTStweets and @theIBTA (patient advocacy organizations), @MDAndersonNews and @NIHBrainTumor (health systems/brain tumor centers), @TheLizArmy (a brain tumor patient), and @BTSMchat (the patient-led community that hosts the monthly #BTSM tweet chats). Further analysis of the 2018 transcripts indicates that a substantial amount of Twitter interactions occurred in the first week of each month, corresponding to the monthly chat hosted by @BTSMchat (Table 2), and includes national and international individuals and organizations.

**Figure 3.** Social networks of most connected #BTSM users in 2018, by retweets.

**Table 2.** Topics Covered by @BTSMchat in 2018.

Month	Topic covered
January	Advance Care Planning
February	N/A <sup>a</sup>
March	Low-Grade Glioma Registry
April	What Does “Quality of Life” Mean to You?
May	Brain Tumor Awareness Month
June	Patient-Driven Symptom Tracking
July	Note to Self: What I Wish I Knew
August	Words Matter: Guilt & the Things We Tell Ourselves
September	Brain Tumors and the Media
October	Patient/Care Partner Relationships
November	Talking About Illness with Family and Friends
December	Breaking Down the Barriers to Clinical Trials

<sup>a</sup>@BTSMchat in February was on break.

## Discussion

This study finds that tweets including the #BTSM hashtag between 2012 and 2018 contained high degrees of Twitter user-to-user engagement where the vast majority of the tweets mentioned at least one other user on Twitter (eg, a reply to a tweet). Although we did not analyze the quality of information shared by users, the study found that sharing content such as website links and media (ie, sharing information) versus text alone corresponds to increased engagement with #BTSM tweets, with 27.66% and 42.00% of the tweets containing visual media (photos/videos) and website links, respectively. Twitter users do not just create unique messages, but also engage with other Twitter users by way of the #BTSM hashtag. As demonstrated in the network plot, major health care organizations (eg, MD Anderson, the National Institutes of Health [NIH], the International Brain Tumour Alliance) now play a central role in #BTSM communication by including the hashtag in their tweets. For future studies, different ways to weigh volume and unique connections, along with user clustering across the network, should be considered to give a more nuanced depiction of the network involved.

A limitation to this study is the focus on metrics that captures participation within #BTSM based on content generation and interaction, which ignores passive Twitter users who might otherwise rely on #BTSM for information without actively engaging through likes and retweets. Twitter users might be searching #BTSM for information without instigating any sort of active and thus trackable method of engagement (eg, tweeting, retweeting, replying, or liking #BTSM tweets). The @BTSMchat community organizers have attempted to track passive viewers during live tweet chats by prompting self-identification through this statement, "If you are here tonight to just listen, please tweet '#BTSM' so we know you're in the audience" [21]. To the best of our knowledge, we are not aware of any study that has thoroughly examined the extent of passive content consumption within #BTSM or any other disease-specific hashtags. Nevertheless, interaction with the #BTSM hashtag is captured by the total impression count of 2,284,771,009, the tally that any user has been served a content in their timeline or search results.

Throughout the year, major brain tumor events and medical conferences play valuable roles in expanding #BTSM's reach by introducing the brain tumor community on Twitter to the hashtag. In 2018, attendees and supporters of both BTAM and the Annual Meeting of the SNO heavily utilized #BTSM in their tweets along with other branded hashtags such as #BTAM and #SNO2018. Although it is unclear whether new Twitter users were converted into active #BTSM participants, tweets from any casual user may still be impactful for the awareness they bring to the larger brain tumor community.

One potential limitation for #BTSM growth is the somewhat older age noted for many persons diagnosed with brain tumors. For 2012-2016, the median age at diagnosis for brain and other central nervous cancers was 59 years in the United States [22], although data suggest that the majority of adults in the United States use some form of social media [23]. Among caregivers

of patients with childhood and early adolescent cancer, Facebook is the most commonly used social media platform over Twitter and Instagram [24]. Even on Twitter, childhood patient networks are also diffused across multiple hashtags such as #PedOnc (pediatric oncology), #PedPC (pediatric palliative care), #AYACSM (adolescent and young adult cancer social media), and #childhoodcancer. Figure 2 highlights that the proportion of tweets from caregivers has steadily decreased from roughly 14.2% in 2012 to 2.4% in 2018, thereby hinting at much-needed work to integrate patient caretakers into the #BTSM community for support and guidance. The observed decline could be related to the high mortality rate of people with malignant brain tumors, caregiver burnout, and the need to distance oneself from the brain tumor community after the death of a loved one [12]. A proactive method to promote #BTSM participation is to integrate more family members and caretakers to the community, and @BTSMchat organizers recruited a caregiver into their team in 2018. Compared to other disease-specific hashtags, family and caretaker involvement may be particularly important for #BTSM as patients with brain tumor are susceptible to cognitive deficits due to the tumor location.

As #BTSM and other disease-specific hashtags continue to expand, it is increasingly important to address the accuracy of health information shared on Twitter as it affects the public and may have patient safety implications. One way to address these issues is to increase the number of brain tumor stakeholders with a blue Twitter-verified profile badge, which Twitter describes as an authenticity indicator as a public interest account. As of April 1, 2020, the majority of #BTSM influencers identified by our network plot lacks this important badge. By increasing the number of verified accounts, it would be easier for the general public to vet individual accounts they might encounter, thereby increasing the likelihood of accurate information consumption among patients and survivors.

A key feature of #BTSM is the high involvement of national organizations and groups such as @BTSMchat in prompting conversations within the hashtag. By hosting a live, facilitated discussion on the first Sunday of each month, @BTSMchat creates an interactive space for various stakeholders within the brain tumor community (eg, patients, caregivers, clinicians, researchers) and forms a structure for sustained engagement. The @BTSMchat chat themes in 2018 ranged from large systemic issues (such as clinical trials and their failure to meet recruitment goals) to more personal topics (such as overcoming guilt, talking with family, holistic patient support through education and peer support, and discussing sensitive topics). @BTSMchat's identified future goals include (1) widening the lived experiences of tweet chat participants with a focus on social diversity, geographic diversity (rural vs urban), and diversity of central nervous system tumor experience; (2) partnering with moderators of brain tumor Facebook Groups by providing Twitter education and cross promoting the tweet chat; and (3) creating and curating resources for patients and care partners who want to pursue or deepen their participation in peer-to-peer support opportunities, including chat moderation, and through community education, conference attendance, public speaking, and research collaboration through traditional medical research pathways.

When social media platforms first entered the national consciousness, health care professionals could not grasp how these new forms of communication could apply to their work. It is now clear that the larger platforms such as Facebook, WeChat, and Twitter are here to stay. Twitter is a 14-year-old platform that continues to connect people not by personal relationship but rather by shared interests. It is only natural that patients, caregivers, clinicians, and researchers all with a shared interest in neuro-oncology would ultimately converge, share,

and form connections, because Twitter was designed to facilitate these forms of information exchange. It is interesting to note that #BTSM was created by patients who saw a needs gap and filled it, without the intervention of a health care structure and is sustained without formal institutional support.

We believe that the growth of the #BTSM hashtag highlights the potential of patient innovation through social media platforms, and serves as a global source of brain tumor information for all brain tumor constituents.

## Abstract

**Background:** PTSD Coach Australia is an app for serving and ex-serving defense members and was adapted for the Australian context in 2013 from PTSD Coach, which was created in the United States.

**Objective:** This study aimed to provide a user-centered evaluation of the app from the perspective of serving and ex-serving members of the Australian Defence Force.

**Methods:** Qualitative data were collected in response to questions to participants in 1 of 5 workshops (n=29) or in telephone interviews (n=24). Quantitative data were collected using the user version of Mobile Apps Rating Scale (uMARS).

**Results:** Analysis of the qualitative data demonstrated mixed support for the app. While some people found it extremely useful, especially as an adjunct to therapy, others pointed out limitations and cautioned against the app potentially triggering symptoms in people with PTSD. This perceived risk was usually found to stem from frustration with the app's functionality rather than its content. Participants spoke about the helpful and unhelpful aspects of the app and barriers to its use and made suggestions for improvement. Many participants encouraged its continued use and highlighted the need for it to be promoted more broadly, as many were not aware of it until they were invited to participate in this research.

**Conclusions:** PTSD Coach Australia was seen in a positive light by some participants, but others thought it had too much text and the potential to trigger a traumatic response in users with PTSD. A need to update the app was also a common comment as was the need to increase awareness of the app's existence.

**KEYWORDS**

PTSD; stress disorders, posttraumatic; self-management; evaluation, qualitative; health, veterans; armed forces personnel

## Introduction

Current research suggests that serving defense members have higher levels of posttraumatic stress disorder (PTSD) than

members of the general community [1]. However, perceived stigma and concerns about potential consequences of a diagnosis of mental disorder remain particularly important barriers to help seeking among serving defense members and veterans [2,3],

and self-management of symptoms is a more attractive alternative [2]. A partial solution to these challenges involves digital mental health resources. Web-based interventions for mental health issues have demonstrated benefits for self-management of a wide variety of problems, including PTSD [4]. Smartphone apps offer additional advantages over web programs because of their potentially constant accessibility and high community uptake [5,6]. While there is a wide range of mental health apps to support serving and ex-serving defense members [7], there is limited evidence about their acceptability and impact.

The United States Department of Veterans Affairs treatment providers developed the “PTSD Coach” app in 2011 in collaboration with veterans who had PTSD [8]. Subsequently, the Department of Veterans Affairs in Australia received permission to modify the app for use with an Australian audience. For example, audio was now read by people with Australian accents, Australian prevalence rates of PTSD were used, and some images were changed to reflect the Australian landscape. The resultant “PTSD Coach Australia” was jointly released by the Australian Departments of Defence and Veterans Affairs in February 2013.

There have been some evaluations of the original PTSD Coach app [9–11], including research suggesting its acceptability and benefit for self-management of posttraumatic stress symptoms [12,13]. However, it was not clear whether the Australian version of the app was well accepted and meeting the needs of Australian defense members. Hence, the aim of this research was to assess serving and ex-serving defense members’ perceptions of PTSD Coach Australia, using a combination of qualitative and quantitative methodologies. The research provided an opportunity to determine whether the app retained a high level of acceptability and perceived utility after being in use for several years and adapted to a different national context.

## Methods

### Ethical Approval

The study was approved by The Departments of Defence and Veterans’ Affairs Human Research Ethics Committee (DDVA HREC; E017/004), Queensland University of Technology Human Research Ethics Committee (1700000173), Greenslopes Research and Ethics Committee (17/17), and Townsville Mater Human Research Ethics Committee (E017-004); command approval for participation was obtained from all Australian defense forces.

### Participants

A total of 53 serving and ex-serving defense members volunteered to participate in workshops or telephone interviews. Of these 53 participants, 29 participants (n=8 serving, n=20 ex-serving, and n=1 unknown) took part in 1 of 5 user-experience workshops. Almost all were male (n=28; one indicated gender as “Other”). Of the workshop participants, 18 were from the Army, 4 were from the Air Force, 4 were from Navy, and 3 did not disclose the Australian Defence Force arm they served in. Of the 29 workshop members, 27 provided their age. The age range was 35–79 years (median 62, SD 12.4 years).

Only 3 of the workshop participants were aged under 40 years. The average service time was 14.1 (SD 10.5) years. Most (24/29, 83%) had been deployed, and the average number of deployments was 2.2 (SD 2.5). Of all workshop members, 20 (69%) had been deployed to warlike operations and 15 (52%) had been in a combat role. All had experienced at least one traumatic event in their lifetime, and all but 4 (85%) had received treatment for PTSD.

Further, 24 defense members (n=8 full-time serving, n=15 ex-serving, and n=1 reservist) participated in telephone interviews. Of these, 4 (17%) were female. Of the interview participants, 11 were from the Army, 8 were from the Navy, and 5 were from the Air Force. Their ages ranged from 31 to 80 years with an average age of 55.8 (SD 12.7) years, with only 1 interviewee under the age of 40 years. The average service time was 20.4 (SD 12.8) years. Most had been deployed (21/24, 88%), and their average number of deployments was 4.0 (SD 5.6). Of all telephone interview respondents, 14 (58%) had been deployed to participate in warlike operations and 11 (46%) had been in combat roles. All 24 reported experiencing a traumatic event in their life, and 10 (42%) had received treatment for PTSD.

### Procedure

Recruitment was undertaken through the Department of Veterans’ Affairs’ At Ease website, social media, and community support advisors; Department of Defence websites and newspapers; Defense-orientated organizations such as Mates 4 Mates, White Cloud, the Gallipoli Medical Research Foundation, Defence Families Australia, and the Defence Community Organisation; and treatment and support services including Greenslopes Private Hospital, the Veterans and Veterans Families Counselling Services (now Open Arms – Veterans & Families Counselling), PTSD Trauma Recovery Group Programs, Garrison Health Services, Part Two, Career Shift, Go2 Human Performance, and private practices. The use of focus groups and interviews is closely aligned with the protocol developed by Townsend and colleagues [14] for assessing user experience of digital health resources.

### Workshops

The 2-hour user-experience workshops involved 4–10 people and were facilitated by 2 members of the researcher team, including a registered psychologist with clinical training. Initially, participants were asked to open the app or download it if they had not used it before. Those without a smartphone were provided a smartphone or tablet with the app already loaded and given written instructions on how to download them in the future. After spending approximately 20 minutes investigating the app, they completed the user version of the Mobile Apps Rating Scale (uMARS) [15], which has 4 subscales (Engagement, Functionality, Aesthetics, Information) and 4 subjective quality items (Would you recommend the app? How many times would you use it? Would you pay for this app? Overall star rating). uMARS has been found to be a reliable and valid measure [15,16].

A focus group discussion was then facilitated by one of the research team members. Focal issues for all groups included

their overall experience of using the app, specific aspects of the app that were most and least helpful, what role (if any) the app may have in supporting people with trauma-related symptoms, potential barriers and enablers to its use, how these might be addressed, and how the app might be improved.

## Interviews

As conducting workshops around the country was not possible, telephone interviews were offered to increase participation from people in different geographical areas. As workshop facilitators were not on hand to assist with app download and exploration, participants who had not used the app in the past were given an opportunity to download it and become familiar with its content 2 weeks prior to the interview. This approach was also taken, as participants in interviews were likely to be using their phones for the interview, potentially the same device they were downloading the app onto. The individual 20- to 40-minute structured telephone interviews were conducted by registered psychologists with clinical training. Topics were the same as for the user-experience workshops. Interviews were audiotaped and continued until saturation of themes was obtained.

## Qualitative Data Analysis

All audio of the user-experience workshops and the interviews was professionally transcribed; themes were extracted from the data and grouped under the 6 questions posed, adhering to Braun and Clarke's [17] Thematic Analysis approach. Analysis

involved initially becoming familiar with the data through reading and re-reading transcripts and taking notes in the margins. Subsequent readings involved a process of constant comparison within the transcript and then between transcripts, combining notes into lower-order themes that were eventually grouped into higher-order themes. This approach focused on patterns of meaning across the whole group of participants and within subgroups (ie, serving and ex-serving defense members). Transcript data were supported by observational data, whereby notes were taken by facilitators about how participants were seen to be using the app.

## Expert Ratings of the App

Two raters, including the lead author on the paper regarding the development of the expert version of the Mobile Apps Rating Scale (MARS) [16], provided ratings of the app.

## Results

### Quantitative Ratings

Results of the uMARS and MARS are presented in Table 1. The app was rated moderately high on the uMARS, with its information and functionality being the most highly endorsed features. An expert rated aesthetics, subjective quality, and functionality somewhat lower than the uMARS mean for defense members, but otherwise the expert ratings were similar.

**Table 1.** Ratings of PTSD Coach Australia on the uMARS and MARS.

Subscales	uMARS <sup>a</sup> , mean (SD)	MARS <sup>b</sup> scores - Rater 1	MARS scores - Rater 2
<b>Objective subscales<sup>c</sup></b>			
Engagement	3.48 (0.63)	3.60	3.60
Functionality	4.09 (0.58)	3.75	3.25
Aesthetics	3.91 (0.67)	3.67	2.33
Information	4.10 (0.57)	4.71	4.33
Overall mean	3.87 (0.46)	3.93	3.38
<b>Subjective subscales<sup>c</sup></b>			
Subjective quality	3.54 (0.57)	2.50	3.25
Perceived impact	3.36 (0.97)	3.67	3.33

<sup>a</sup>uMARS: Mobile Apps Rating Scale (User Version).

<sup>b</sup>MARS: Mobile Apps Rating Scale.

<sup>c</sup>All uMARS and MARS items were rated on a 5-point scale: 1 - very poor, 2 - poor, 3 - average, 4 - good, 5 - excellent.

## Qualitative Responses

As the same 6 questions were posed to all workshop and interview participants, results are grouped according to the 6 questions. The themes were spoken about in every workshop group and by all interviewees.

### Knowledge and Experience of the App

Approximately half of the participants had used the app (most interviewees, but fewer workshop participants). Participants who had used the app (some of whom had used it for years) were generally introduced to it by their psychologist or

psychiatrist, or by the Veterans and Veterans Families Counselling Services (now known as Open Arms-Veterans & Families Counselling). It was seen as an app that was easily accessed and used: "Anyone can access it, the programme, and it was easy to use." Most interviewees also described having a positive experience with the app, finding it user-friendly, easy to navigate, and written in a clear and understandable language.

Some participants who had never used the app spoke with some self-deprecation: "I have no idea how to (use it), for idiots like myself" and "We're all dinosaurs." Most of these non-app users appreciated that the app might be useful if they had some digital knowledge, for example,

*If you know what you're doing, it would be effortless" and "It'd be helpful for people who know how to use one (app).*

Another participant said,

*I think for someone who's never used it before, I just need time to sit down on my own and go through it, and really try and understand how it all works, and then make some sort of opinion on it.*

Some participants observed that the purpose of PTSD Coach Australia may be unclear, given that it contains a self-assessment tool as well as strategies to manage symptoms. For example,

*...You need to define what you're going to use the application for. The application seems to me like it's got two purposes. One is to actually, 'Do I have PTSD?' and 'Here are the tools I need to manage PTSD.' To me, that can be dangerous in the fact that you don't want people to think that they have PTSD and then start manage, self-managing. What you prefer is that, um, you want people that have been diagnosed with PTSD and are using this as an additional tool to actually help manage their PTSD.*

### Helpful Characteristics

There were various aspects of PTSD Coach that were found to be helpful. One person explained that they liked the ability to put in reminders: "...so it gives me space to separate my mental health care from trying to remember everything else." Others commented that they "liked the quotes" referring to some being from "Janis Joplin and a Swedish proverb" that were "thought provoking." Participants generally appreciated the audios. For example, one participant said,

*I think going down the road, good to listen to, but also it allows you the opportunity to do it (listen) discreetly by just having your ear phones in," and another said, "I personally didn't read it, I listened to it.*

Others liked to read, so they could go back over material easily if needed.

Another aspect that seemed to be helpful was the ability to monitor stress:

*I've found it useful to let me know where my stress levels are...actually are.*

This feature had been used for a number of reasons, including to self-monitor. For example, if a person was not feeling great:

*Why (am I) such a cranky s\*\*t this week? And I'll look at it and I'll say: oh here I am, I'm up...I'm up here, um and calm down a little bit...so it was a little bit of a diagnostic tool for me*

Others used the stress monitoring feature when making a claim for veterans' support. For example,

*I've also used it (Subjective Units of Distress) as a tool to help in my claim and they've actually photographed my stress levels through the app.*

Many people commented positively about the amount of information. The learning function was seen to be most helpful for people who were not very aware of PTSD symptoms and how they may manifest:

*...the learning function is good. It will certainly help people that don't have any understanding or exposure to PTSD, so like family members and colleagues and that sort of thing.*

For those who had been in therapy, the information was not new, but could be a useful reminder. For example,

*I think there's plenty of information in there and you can spend as little or as much time in there just discovering what's out and about*

*Once you drill down into every folder and sub-folder there's a lot of info in there and it's just stuff that most people already know but it's good to have the reminder.*

Participants also commented on the "nice clinical feel" to give the app credibility: "it looks credible, it looks professional."

Explaining the self-assessment section was useful, an interviewee said,

*...so I can go back and, and have a look at that, in terms of how I might be feeling that day, if I've got something coming up, ... I guess it's a preparatory thing in my mind, to prepare myself for an environment that I may not feel comfortable in.*

People reported using this element to track their well-being such as "... (the app) helps identify how you're travelling."

Most participants who had used the app had accessed the Manage Symptoms and Self-Assessment sections. They found these helpful in managing their symptoms and to increase awareness of how they were feeling:

*...mostly using it to manage symptoms, like just to remind yourself. ...if you start thinking about all your crap, you can go on here and go, let's sort this out now instead of festering on it.*

Features aimed at assisting relaxation and sleep were generally seen to be positive:

*I've used it a fair bit just for sleep and relaxation...some of the sleep coaches and the relaxing sounds, and just grounding techniques and stuff like that.*

One participant said,

*I found it very straightforward, very intuitive...the font was great...the spoken instructions, and the sort of coaching was all very clear.*

Another participant said,

*...look honestly, a very useful tool, I've done it twice last week, and I'll probably do it again later today, and on those occasions where I think I might be feeling a bit down, I might use it, as well.*

Although some older participants in the workshops struggled with the technology, most of the older participants in the

interviews found the app easy to use. For example, one older participant said:

*...I was quite surprised when I went through this app, at how friendly it was. So, first up, it's a very friendly app. It's very easy to use. Pretty straight forward.*

This difference may in part have been due to interview participants having time to download the app pre-interview, whereas some workshop participants had never used technology before, let alone an app.

Consistent with the workshop data, some interview participants said that the app was not perceived as a standalone tool to manage symptoms of PTSD or to replace a mental health professional. Rather, it was seen as more appropriately used to reinforce learning and strategies introduced in therapy sessions.

*So, there's the app itself, I don't believe (it) is a sole source of solution.*

*...it's a good tool to help as well. I still think, you know, depending on the severity of the PTSD, they would need counselling and they would need, well, professional help...but it's a great little pocket tool to be able to you know, look at in times of crisis when you can't necessarily see a professional immediately.*

### **Least Helpful Characteristics**

Some participants did not like the app or found it unhelpful and frustrating when needing a quick strategy in a crisis situation. For example,

*Um, it became extremely frustrating. So then knowing how sometimes I feel when I have an attack, that wasn't good. It kept going skip, next, skip, next, skip, next. And I thought, well it's not really giving me any help.*

*I think when you're angry, reading something, and especially if you've got to read it, understand it, and put it into practice, is not the best way to do that. ...when I am annoyed, I have to read something two or three times before my brain comprehends it.*

Consistent with views expressed in the workshops, some interviewees with PTSD thought aspects of the app would trigger their symptoms:

*...with PTSD, you, it's a high degree and an instant degree of triggered frustration.*

Some participants experienced technical glitches with the app when they had difficulty downloading it onto their device, uploading songs and pictures, and listening to some of the audio. For example, one participant said,

*Bearing in mind that if you're vaguely thinking about this thing, it's gotta be a smooth entry, which in my case it wasn't.*

Some ex-serving defense members who had experience using apps and in particular, PTSD Coach Australia, voiced concerns addressing technical issues such as flexibility and the potential to personalize the app. For example, one participant's perception was as follows:

*I wanted to write a doctor's appointment (in it), there was no way for me to put it in.*

Another user agreed that the app “doesn't utilise all the capabilities of my (brand of phone).” Lack of flexibility was a widespread theme:

*Learn (from menu) is very important, that should be at the top, but for someone who has been using it for some months or years, they should be able to drag the learning component down at the bottom.*

A history function could also be used as a reminder of what a person was doing when they had a good day: activity icons could cue memories and be selected instead of reading and typing information in about activities undertaken during a good day. Some people suggested that the app was not as personalized as they would like and that different audiences (age groups, sex) needed different information or information communicated in different ways. If it were “...individualised and I can go – oh yeah that, that really resonates with me,” that was expected to increase uptake. Essentially, the app was seen to have outdated functionality when compared with current phone and tablet technology.

Some issues with the stability of the app's functions were identified. One person said,

*I was just trying to set reminders for things then (during a workshop) and I don't know if it's something to do with my phone but it just keeps shutting down every time I try and set a reminder.*

Further probing revealed the person was using a particular brand of Android phone, and some other users of the same brand of phone had the same experience. During the workshops, facilitators also noticed that histories were sometimes lost. For example, a participant did the assessment task, but the app would not let the user see the results—“I don't know where it went. Just disappeared.” This was frustrating, because using the app to monitor their health was seen as important.

Some participants saw the app as an agent of authority. For example,

*In the first paragraph it says... you agree to the terms and conditions. I went right through that front page, and nowhere is there a hidden panel or any sub-element of terms and conditions...I love how authority works.*

Another said the tone was suited to serving members because “they're telling you what to do, and it's like really, like being back in the army with your sergeant...” and a third explained, “as soon as you get out (of the military) you will not be told what to do.” Essentially the app was seen as “very militarized,” and that was a connection that many ex-serving members did not want.

Many people spoke about the density of information, for example: “I found the menus are wordy, lengthy, boring.” Color coding was a suggestion to “make it a little more accessible” such as having different colors for health, learning, and self-assessment. Others suggested increasing the density of information as a user progressed through the layers of the app:

*The first layer, so the initial layer, entry layer looks good, then your second layer, then once you step into the sub-elements, so tertiary and beyond, it then gets very overloaded.*

It was pointed out that this level of complexity and denseness of information was not helpful for people with a mental disorder. When becoming overloaded a person would “switch off and not really care about it.” Some people found that the denseness of information elevated their emotional arousal:

*There's a lot of reading in there, and I switched off. You know, black and white, black and white, read, read, read, reference to X, Y, Z. I don't care about X, Y, and Z, what does this bloody thing do? ... so, I switched off and went away, and had to calm down and then come back to it. It made me angry.*

For some people, the Self-assessment section seemed to evoke distress. For example,

*So I used the self-assessment and I got halfway through it and the questions were actually, for me they started to become disturbing, so I stopped.*

The Learn section of the app was seen as not thorough enough by some interviewees:

*...I must say my first reaction to it (Learn section) was, I thought, oh, this is pretty superficial, you know, what's PTSD, and how it develops, and how common is it...and the stuff like that.*

Others identified Soothing Pictures and Soothing Audio as least helpful:

*Now I've been through those resources that are listed, and basically found them, for me anyway...no use.*

As already noted, some participants found the inspiring quotes useful, but others did not; for example:

*Ah, yeah, it's the last thing I want (laughs)...I'm not into those touchy-feely things....I suppose it's just the word 'inspiring' sort of put me off straight away.*

There were also a number of comments about the app's design:

*(The) one that comes to mind most of all is the computer-generated voice. ...I found that to be, uh, um, not easy to understand, and also very impersonal.*

One person found “some of the text is actually overlaid on top of the scroll bar, the tool bar at the bottom.” Another said: “Once again, too much information. Text is too small.” This view was commonly asserted in both the telephone interviews and the workshop groups and was linked to unwanted emotions. For example,

*...to navigate through and looking at a small screen, I, if I spend more than 20 minutes, I just end up getting really angry with it.*

### **Potential Role of the App in Supporting People With Trauma-Related Symptoms**

Most participants who had used the app had done so with the help of their clinician. PTSD Coach Australia was seen by them as a positive adjunct to therapy: “...more helpful if you are

seeing a psychologist or psychiatrist.” However, as already mentioned, many participants commented about the potential for material to retrigger their symptoms. For example,

*You want to be careful you don't stir it all up...reliving it and rehashing it and all that. You know?*

Some people did not think using the app would “push people to get help,” whereas others thought recognizing symptoms through the app may spur people on to seeking help: “you say, s\*\*t this is happening to me so you're going to do something about it.” Many of the older participants thought it unlikely that they would access an app or that others from their cohort would, stating that when a person is experiencing symptoms of anxiety or depression “you'll want to talk to somebody that's going to give you advice...”

The dangers of self-diagnosis were also raised:

*People self-diagnose and they read the symptoms and say, yeah I have PTSD. You really have to go see an expert and psych to get information. You shouldn't do it yourself.*

A perceived lack of consistency in the content of the app with what clients were taught about PTSD and its management in therapy was also discussed as a retriggering feature:

*Well you know, me personally, I've come a long way from hating the world, and I'm comfortable with where I am now, and then I come in here and this (the app) contradicts what I'm being taught, which has made the world a better place for me. So that makes me confused, angry, emotional, frustrated.*

### **Potential Barriers and Enablers to the Greater Use of the App**

The main enabler to the greater use of the PTSD Coach Australia was that it is available for free, which was good “because I wouldn't pay for it.” A barrier for some was their lack of familiarity with technology in general and apps in particular. Some suggestions were offered to make access easier:

*Get the RSL [Returned Services League] to set up trainee workshops through their sub-branches...work in a group and kind of demystify it because it's actually quite simple when you know the trail.*

For many older (ie, Vietnam veteran) participants, the technology was foreign and using it was overwhelming.

Others pointed out that an app of this sort would be difficult to negotiate if they had additional physical complications such “as a stroke or a chronic illness such as Parkinson's.” Another suggested the app be available in “A DVD that you can just stick in...and watch and listen to it.” These quotes came from older participants and may further indicate discomfort with the technology. A lack of visible marketing of the app was noted.

The name of the app was raised by many participants, and the icon was also discussed. There were 2 issues in this theme. The first was that the app's title indicated that it was for people who have PTSD, but that the app could be used by a much broader population. The second issue concerned stigma. Having an icon

on their device that others may see (eg, on the train or bus) that suggests they had PTSD was considered to reveal personal information. Stigma regarding mental health was still seen as a problem, and more education was needed:

*If we can educate our new members and our current members, well, you know, there is still a lot of prejudice against mental health (problems) within Defence.*

The name of the app did not seem to be useful in breaking down that stigma. When asked what would stop someone using the app, one participant summed up the sentiment as, “shame, sense of shame.” When asked about potential barriers to use, others said,

*Just its name, PTSD Coach. I don't know what you could call it, but people don't want to be labelled.*

*My nephew wouldn't download it. My friends wouldn't download it. Uh, most people won't download it if it's called PTSD coach. ...if you call it Wellness Coach...*

Other suggestions for renaming it included “Mental Health Coach” but some doubted whether that would reduce perceived stigma. One suggested that the information screen “could say this can help if you are having trouble sleeping, if you've got anger issues, blah blah...”

Many participants stated that they could not find any other barriers or challenges in using the app, as it was informative and well set up: “...I haven't found it to be difficult at all. It's just been interesting...it's easy to read, it's easy to access and it's easy to understand.” Another participant said, “No barriers. I was fine. I can see that the app is useful ...when it's (used) in conjunction, obviously, with some sort of help as well.”

### Ways to Improve the App

The majority of participants stated that no improvements to the app were needed: “I think it's great. I think, for what it's meant to do, I think it's fantastic.” However, others suggested that including more strategies and interventions such as crisis intervention, mindfulness, mood tracking, and elements of exposure therapy would be beneficial: “So, as it stands now, the app can assist, but it wouldn't be able to assist through a crisis moment.” Another common subtheme was that participants suggested expanding information in the Learn section, for example, by including links to additional information, including videos with psychoeducation and presentations of techniques:

*(Include) a hyperlink to a webpage or something that may be able to help people if they want to do further research.*

*There should be, uh, there should be video examples, rather than trying to find written descriptions of how you deep breath.*

Most participants noted the need for increased awareness about the app and the need for its promotion to assist serving and ex-serving defense members who had experienced trauma:

*...how it can be used is by making people aware that it exists, seriously. I think that's the priority*

*...to actually send out a thing that says, “Here's a link to an app, and you can download it, and it doesn't cost you anything...”*

One person who described himself as belonging to the younger generation said,

*...it probably wouldn't hurt to have a YouTube video explaining what the purpose of it (is) and how to use it and how to maximise the benefit out of it.*

Rather than a video explaining how to use the app, others suggested

*...just a little video clip, a YouTube like video clip on it (the app itself). Nothing that takes up space or time, but just enough to get the gist of what's going on...maybe the odd skit.*

Using the app as a way of connecting with peers was suggested. When speaking about the possibility of the app being a platform for that purpose, one participant explained,

*A group amongst veterans is the strongest form of medicine you can have, the one-to-one with your peers.*

This potential function may also be a way of keeping track of each other; if a person had not heard from a peer for some time, it may prompt them to contact them to check how they were going.

Although many people liked the fact that they could load their own music and pictures, others suggested that “maybe having a library in there of pictures and sounds rather than having to upload your own into the system.” A younger participant said that he “liked that you could alter and change images to what you like. I had a bit of fun like, putting all my kids in.” However, there were some restrictions in the functionality of the app when trying to alter images for things like relaxation, for example, the app “doesn't allow you enough freedom to perhaps get something else off the internet without you having to do a separate action and then upload it to the app.” Others found some of the images insufficient; they were perceived as “a little bit sterile.” One participant was specific in his feedback about some of the images:

*...a picture of a person's head with brain cogs, okay it was clear, but I find it a bit offensive actually. It's like...I'm on the app that's gonna help me deal, I don't want to feel like I'm being analysed or I'm a nut case, or a statistic by the other icon with a line coming up and a lightning bolt going down.*

Some people remarked that the images on the app were not relaxing to them:

*There is a dog in a purple field in a yoga position...what I find is that is not relaxing, it's sort of more something like, you know, something a hippie would use.*

## Discussion

Many responses to PTSD Coach Australia by the serving and ex-serving defense members who participated in this research

were positive, with uMARS ratings in the “average” to “good” range and many positive comments. Most participants said the app was user-friendly, easy to navigate, and helpful in managing symptoms of PTSD. This feedback was consistent with studies evaluating the American version of the app [8,13,18,19]. Key components of the app (eg, Manage Symptoms, Find Support, and Learn) appeared to be maintaining the acceptability and perceived benefit that were observed in earlier research on its American version [18], and many participants continued to value the ability to track changes in stress or other symptoms. However, scheduling of reminders appeared less valued by some users than in past studies [12,18]. Inspiring quotes were generally but not universally valued.

Some participants suggested its use as an adjunct to face-to-face treatment rather than as a stand-alone tool. Consistent with broader evidence on the benefits of having a therapist or coach to guide and support the use of digital mental health tools [18], a pilot study comparing self-managed versus clinician-guided use of PTSD Coach found that clinician support appeared to increase the app’s symptomatic benefits [4], although both modes of application improved PTSD symptoms. Some participants also expressed concerns that self-managed use of the app may generate frustration or trigger trauma symptoms in some users and may not be well suited to crisis management. Improvements to the app’s functionality and reduction of text could avoid triggering frustration and distress in vulnerable users. A recent systematic review and rating of apps designed to assist with PTSD [20] noted the absence of safety planning in the PTSD Coach and PTSD Coach Australia apps. While the app has a listing of crisis services and an ability to set up individualized support contacts, additional safety planning within the app may be indicated.

Consistent with previous US research [8], many participants reported that the app was easy to use, although some wanted faster navigation to favorite tools. Many now found the app to have suboptimal functionality, have some out-of-date content, and lack engaging graphics and flexibility. These observations may reflect changes in user expectations. Importantly, current participants also experienced significant technical problems when using the app on some Android devices, suggesting that its updates had not kept up the pace with developments in

devices and software. Interestingly, previous research suggested that the app would appeal even to technology novices and older individuals [8], whereas (despite the passage of time) current respondents expressed the view that people who had little experience with digital technology may struggle with its use (and some saw this as applying to themselves). Some also noted that use of the app would be difficult for people with a physical disability or cognitive deficit and for those experiencing a heightened state of emotional arousal. Applying recent advances in app design and functionality could help address these issues.

While the availability of PTSD Coach Australia free of charge was seen as an enabler of its use, participants noted a lack of awareness of its existence, suggesting that greater promotion of the app was needed. Some participants proposed that this and other mental health apps could be discussed and used prior to deployments to assist with stress management.

A limitation in the current research was that the participants were predominantly older than the average age of currently serving personnel, which may limit the representativeness of findings in relation to use of the app by younger people. There was also a wide range of digital literacy regardless of age. A difference in the procedures used for interviews and workshops could be seen as a limitation: Interviewees were asked to download the app prior to the interview due to the likelihood of using the same device for the download as they used for the interview, whereas workshop participants examined the app at the start of the workshop, giving facilitators an opportunity to observe any difficulties they had in downloading or using the app. This difference in procedure may have resulted in workshop participants having a more recent experience with the app, although themes were consistent across the two approaches to data collection.

Overall, participants attested to the value of PTSD Coach Australia, and in particular, its potential benefit to both serving and ex-serving defense members who were receiving treatment for posttrauma reactions, and for those with less severe problems. While the app could be improved further, its current functionality was viewed mostly positively. A change in its name and increased promotion of the app could substantially improve its uptake and impact, in addition to an update of aesthetics and design to bring it in line with modern apps.

## Acknowledgments

This project was funded by the Department of Veterans’ Affairs (DVA MH EVAL 01/2016). Material presented in the paper is the responsibility of the authors and does not necessarily reflect the views of the Australian Government. We acknowledge the guidance of other steering committee members, including Michael Correll, Kate Henderson, Maureen Montalban, Tracey Noble, and Brian Riches, and the contributions of the Queensland University of Technology staff, including Professor Ross Young, Dr Madhavan Mani, Stoyan Stoyanov, Susan Lingard, and Daniel Krosch. ## Abstract

**Background:** During the COVID-19 pandemic, a number of conspiracy theories have emerged. A popular theory posits that the pandemic is a hoax and suggests that certain hospitals are “empty.” Research has shown that accepting conspiracy theories increases the likelihood that an individual may ignore government advice about social distancing and other public health interventions. Due to the possibility of a second wave and future pandemics, it is important to gain an understanding of the drivers of misinformation and strategies to mitigate it.

**Objective:** This study set out to evaluate the #FilmYourHospital conspiracy theory on Twitter, attempting to understand the drivers behind it. More specifically, the objectives were to determine which online sources of information were used as evidence to support the theory, the ratio of automated to organic accounts in the network, and what lessons can be learned to mitigate the spread of such a conspiracy theory in the future.

**Methods:** Twitter data related to the #FilmYourHospital hashtag were retrieved and analyzed using social network analysis across a 7-day period from April 13-20, 2020. The data set consisted of 22,785 tweets and 11,333 Twitter users. The Botometer tool was used to identify accounts with a higher probability of being bots.

**Results:** The most important drivers of the conspiracy theory are ordinary citizens; one of the most influential accounts is a Brexit supporter. We found that YouTube was the information source most linked to by users. The most retweeted post belonged to a verified Twitter user, indicating that the user may have had more influence on the platform. There was a small number of automated accounts (bots) and deleted accounts within the network.

**Conclusions:** Hashtags using and sharing conspiracy theories can be targeted in an effort to delegitimize content containing misinformation. Social media organizations need to bolster their efforts to label or remove content that contains misinformation. Public health authorities could enlist the assistance of influencers in spreading antinarrative content.

**KEYWORDS**

COVID-19; coronavirus; Twitter; misinformation; fake news; social network analysis; public health; social media

## Introduction

Since its detection in China in late 2019, SARS-CoV-2 has spread worldwide and been declared a pandemic, with negative effects on both human health and the global economy [1-3]. The dramatic consequences of the pandemic have led to the appearance of numerous conspiracy theories. One of the most successful theories linked 5G to the spread of the disease, leading to misinformation and the burning of 5G towers in the United Kingdom [4]. Other hoaxes have linked the severity of COVID-19 to the genetics of Spaniards and Italians or to vitamin D deficiency [5,6]. There has also been no shortage of hoaxes suggesting that chlorine dioxide can cure the disease [5].

In the first week of April 2020, another conspiracy theory emerged, which suggested that the pandemic was really an elaborate hoax. Drivers of this conspiracy theory argued that it could not exist because hospitals were empty or were operating as normal and therefore there were fewer COVID-19 cases than what had been reported. Its supporters also claimed that the severity of the disease had been exaggerated by the scientific community and the press. This then led to the encouragement of citizens to go to hospitals and film them to show that they were empty. The hashtag #FilmYourHospital was used when posting such videos on social media [7,8].

Misinformation is a matter of public concern. If citizens believe that COVID-19 is a hoax, they may be more eager for lockdown restrictions to ease and they may refuse future vaccines. Recent research has found that those who endorse or believe in conspiracy theories are less likely to adhere to government recommendations such as staying at home or keeping a safe distance between others [9]. The study also found that those who believed in conspiracy theories were also less likely to accept a future diagnostic test or vaccination [9]. In case of future outbreaks, it is important to understand the drivers behind this conspiracy theory so that future ones can be prevented and fought.

In this context, the aim of this study was to analyze the Film Your Hospital conspiracy theory that argued that COVID-19 is a hoax. Specifically, we set out to address the following questions:

1. Who were the drivers of this conspiracy theory on Twitter?
2. What online sources of information were used as evidence to support the theory, including the most retweeted tweets?
3. What was the ratio of automated accounts to organic accounts in the network?
4. What lessons can be learned to mitigate the spread of such a conspiracy theory in the future?

This study is the first empirical investigation into the #FilmYourHospital conspiracy theory and its novelty lies in the social network analysis, identification of influencers, identification of the most shared URLs and hashtags, and identification of genuine accounts as compared to bots. This study may have practical value for the development of recommendations for public health authorities.

## Methods

A computer running Microsoft Windows 8 was used to retrieve data in Microsoft Excel 2010 (Microsoft Corp) using the professional version of the social media analysis software NodeXL (Social Media Research Foundation, release code +1.0.1.428+), which provides access to Twitter's search application programming interface (API). The study retrieved data from a 7-day period from April 13, 2020, at 14:19 Coordinated Universal Time (UTC) to April 20, 2020, at 15:59 UTC. Users were included in the data set if they sent a tweet during the time the data was retrieved or were mentioned or replied to in these tweets. The keyword FilmYourHospital was used to retrieve data containing mentions of this phrase, including the hashtag #FilmYourHospital. There were 11,333 Twitter users within the network and they generated a total of 22,785 tweets, broken down as follows: 12,905 (56%) retweets, 2736 (12%) replies, 2425 (10.6%) mentions in retweets, 2194 (9.6%) mentions, and 2525 (11%) individual tweets.

Influential users, topics, and web sources were studied, and a social network analysis of the discussion was conducted with NodeXL, using a validated methodology used in previous research [4], which provided an understanding of the shape of the conversation [10-12]. In addition, a network graph was laid out using the Harel-Koren Fast Multiscale layout algorithm [11]. The graph's vertices were grouped by cluster using the Clauset-Newman-Moore algorithm. NodeXL uses Twitter's search API. URLs were automatically expanded within NodeXL. The Botometer tool [13] was used to find out the ratio of real to automated/bot accounts being used to tweet about this conspiracy. This was achieved by taking a 10% random sample of users who had sent original tweets and running the sample through Botometer. In understanding the network graph, the results build upon previous seminal research [14] that identified 6 network shapes and structures that Twitter topics may follow [11]: broadcast networks, polarized crowds, brand clusters, tight crowds, community clusters, and support networks. When analyzing popular websites within the network, the content was interpreted by reading the website or watching the video to which the tweet provided a link.

## Results

### Social Network Analysis

Figure 1 is a social network graph of the discussion surrounding the hashtag #FilmYourHospital. Each small color dot represents a user and a line between them represents an edge. Groups were formed around this topic based on how frequently users mentioned each other. There is an edge for each "replies-to" relationship in a tweet, an edge for each "mentions" relationship in a tweet, and a self-loop edge for each tweet that is not a "replies-to" or "mentions." The size of the nodes are ranked by their betweenness centrality score (BCS) [14], which measures the influence of a vertex over the flow of information between all other vertices under the assumption that information flows over the shortest paths among them. The graph highlights how a number of different communities tweeting about this topic formed on Twitter. It is important to note that the tweets

collected were based on the overall topic and could include a small amount of irrelevant content or users arguing against the conspiracy. The three largest groups (groups 1-3) appeared to be “broadcast groups,” where tweets received a high number of retweets. Group 5 was an “isolates group,” where a number of tweets were sent that did not contain mentions (including retweets). This particular shape appears when a user’s tweet does not contain an @ sign (ie, it is an original tweet expressing a view or opinion that does not refer to any other participant in the discussion). Table 1 provides an overview of the tweets (reworded for anonymity) that contained the most retweets according to the cluster they belonged to within the network.

In groups 1 and 2, we can see that the most retweeted post suggested that the public were being misled about hospitals

being empty and that hospitals were not busy or overrun, as had been suggested by the mainstream media. The tweet then called for users to film their hospitals to show this by using the hashtag #FilmYourHospital and for the hashtag to become a trending topic. This tweet was sent by a verified Twitter user. In group 3, the most popular tweet (posted in Spanish) called for users to watch the videos that were being posted on the #FilmYourHospital hashtag and “draw their own conclusions.” In group 4, the most popular tweet drew attention to an article posted by APNews, an American news agency. The tweet that was most popular in the fifth group drew attention to the #filmyourhospital hashtag. Table 2 provides an overview of the URLs that were most shared during this time.

**Figure 1.** Social network visualization of #FilmYourHospital.

**Table 1.** Most retweeted tweets in groups 1 to 5.

Group	Tweet	Retweet Count
1	<i>Been to two LA hospitals that are supposed to be jam-packed according to the mainstream media. Yet, they are EMPTY and very quiet! Wonder why they are lying to us. As we can't trust the news we should begin covering those – please send pictures of your hospital</i>	21,896
2	<i>Been to two LA hospitals that are supposed to be jam-packed according to the mainstream media. Yet, they are EMPTY and very quiet! Wonder why they are lying to us. As we can't trust the news we should begin covering those – please send pictures of your hospital</i>	21,896
3	<i>Watch the videos that are being published in the #FilmYourHospital tag and draw your conclusions</i>	2178
4	<i>The lame mainstream media has been reporting that the #FilmYourHospital can be traced to Qanon which is a far right group</i>	671
5	<i>Come on people – hospitals are empty – only queues are for shopping supplies. Corona is a Hoax</i>	50

10	[User handle removed for anonymity] placed in quarantine until May by filling the hospitals. Yesterday the Municipal Hospital of Tatuapé was empty. It is not to preserve lives, but to break São Paulo.	Removed for anonymity	17

In the first video, it is claimed the person speaking is a doctor, but the comments in the video and the office setting indicate that the person in the video may be a chiropractor. In the second video, a health worker notes that, on mainstream television, COVID-19 has been exaggerated and that all deaths in his hospital are being treated as COVID-19–related. The third most frequent URL shows a person who speaks against the conspiracy campaign and requests that people take the pandemic seriously. The fourth URL notes that polio outbreaks in Africa were caused by the mutation of a strain from a vaccine. The fifth URL linked to a news website critical of National Health Service (NHS) staff. Similarly, the sixth most popular URL linked to a tweet

that was critical of medical professionals posting videos of themselves dancing in hospitals on social media. The seventh most popular URL noted that the US army's Seattle Field Hospital closed after 3 days without treating any patients. The eighth most popular URL was a tweet that was critical of medical professionals using TikTok to create videos (the tweet was later deleted). The ninth most shared URL linked to a tweet that questioned why Twitter had removed the trending hashtag #FilmYourHospital. The tenth most shared URL came from a user who claimed that a certain hospital was empty. Table 3 provides insight into the most shared hashtags from this time period that were used alongside the #filmyourhospital hashtag.

The three most frequently used hashtags were #filmyourhospital, #emptyhospitals, and #filmyourhospitals. It was also interesting to see the hashtag #lamestreammedia, which appeared to be critical of the mainstream media. Other hashtags included

#endtheshutdown as well as the hashtag #plandemic, which refers to another viral conspiracy theory. Users sharing #endtheshutdown may have tried to use the conspiracy theory as an argument to end the lockdown.

**Table 3.** Most shared hashtags.

Hashtag	Count
filmyourhospital	13,984
emptyhospitals	1160
filmyourhospitals	1144
filmesuhoospital	1045
covid19	840
coronavirus	759
coronahoax	649
lamestreammedia	609
endtheshutdown	478
plandemic	441

## User Analysis

**Table 4** ranks influential users who have more than 100 followers by their betweenness centrality score. The followers column notes the number of followers the user had. The in-degree coefficient examines the number of inbound connections and is helpful in highlighting the users who are potentially the most trusted. The out-degree coefficient examines the number of outbound connections by users, which is useful in highlighting the number of accounts users were referring to.

The most popular account belonged to a user who identified as a Brexit supporter, followed by two citizens, one of whom was from Brazil. This user was particularly active during this time and had sent out a total of 154 tweets. A number of accounts (such as 6 and 7) appeared to be in support of the idea that COVID-19 is a hoax and these accounts posted a number of tweets using the #FilmYourHospital hashtag. Account number 6 was the most active and had sent out a total of 163 tweets. The most common type of account in the network belonged to citizens supporting this conspiracy theory. Donald Trump did

not tweet using the hashtag; however, he was a trusted node in the network, receiving a total of 310 inbound connections.

**Figure 2** presents results from Botometer, which was used to assess the frequency of automated accounts. The results indicated that the rate of automated accounts was low (9.2% of the sample), as the majority of accounts had a score of 0.1 to 0.9 (52% of the sample). The accounts scoring 4 or higher were further examined, as were those that had their tweets deleted. It was found that these accounts had sent 136 tweets during the studied time period, although the total combined number of tweets the bots had sent before their accounts were removed was 323,096. The high-probably bot accounts had received a total of 373,508 likes and had a combined total of 22,855 followers. **Table 5** highlights the most frequently used words that appeared in the user-bios of users who had a score over 4 and/or whose account was deleted.

It can be seen that high-probability automated accounts and/or deleted accounts contained the words “maga” and “trump” with the highest frequencies within their user bios.

**Table 4.** Influential users.

Rank	User	Betweenness centrality	Followers	In-degree	Out-degree	NodeXL Group in <a href="#">Figure 1</a>
1	Brexit supporter (UK)	14,153,758	1219	7	154	2
2	Citizen	12,085,093	194	695	2	1
3	Citizen	12,055,635	2679	631	2	3
4	President Donald Trump	11,194,004	77,802,730	310	0	2
5	George News	11,138,055	141,840	615	1	4
6	Citizen	7,948,257	191	16	163	2
7	Citizen	6,816,583	5904	0	78	6
8	Citizen	6,107,454	176	239	15	1
9	Nongovernmental organization	4,656,161	14,779	14	130	1
10	Citizen	3,616,519	1838	189	5	2

**Figure 2.** Assessing the number of bots on a scale from 0 to 5 using Botometer.**Table 5.** Top 5 most frequently used keywords in bios of users who scored 4 or over and whose account was deleted.

Rank	Word	Frequency
1	trump	7
2	maga	7
3	patriot	4
4	support	4
5	love	4

## Discussion

In regard to the first research question, this study found that the most frequent drivers of the #FilmYourHospital conspiracy theory appeared to be ordinary citizens; one of the most influential users is a Brexit supporter. Previous research on other COVID-19 conspiracies has also found that accounts that appeared to belong to citizens were the most influential [11]. Regarding the second research question, we found that YouTube was the information source most linked to by users. The most retweeted post belonged to a verified Twitter user, suggesting that Twitter tools aimed at identifying verified and trustworthy users do not always work. Regarding the third research question, related to automated accounts, we found that there was a low volume of bots in this social network analysis and a low volume of accounts that were deleted within the network.

YouTube was a popular platform for hosting content used to support this conspiracy. Certain tweets sharing the conspiracy theory also became very popular on Twitter. For instance, the tweet sent by the verified user contained a vast number of replies from other users indicating support of the view that COVID-19 is a hoax. Although our results found that some content had been deleted on Twitter and YouTube, there were still tweets and YouTube videos that remained online.

A number of recommendations can be made to attempt to combat the propagation of misinformation. First, as

recommended in previous research [15], public health authorities could use the hashtag and enlist the assistance of influencers to share the antinarrative (ie, reasons against the conspiracy). The majority of genuine (versus automated) accounts show the nature and popularity of the conspiracy. Second, bots would need to be countered in a more technical manner. It is important to note that most of them already existed before the beginning of this specific conspiracy theory, suggesting a broader problem. However, not all automated bots are set up for malicious purposes. Social media organizations could monitor for suspicious accounts set up to spread misinformation. Third, as our results show, the “citizen-based” #FilmYourHospital hoax should be countered with untargeted, trustworthy information, delivered from public health authorities as well as popular culture influencers (as mentioned above). Previous academic research suggests that explaining flawed arguments and describing scientific consensus to other people may help lessen the effect of misinformation about science [16]. Lastly, public health authorities and governments should enlist the help of the public in using the “report content” features across social media platforms. With a collective effort in rapidly reporting false and misleading information, a coordinated response would allow it to be detected and removed faster. This tactic may be more effective than the public engaging with the content, which may inadvertently raise its profile.

The network shape of this conspiracy theory differs from that of a conspiracy theory linking 5G and COVID-19, as that

theory's network had a large isolated group where users were tweeting without mentioning each other [11]. Conversely, in the FilmYourHospital network, there appear to be denser groups, indicating a larger volume of retweets and mentions. A reason for this is that certain tweets became very popular, were retweeted with high frequency, and received a large number of replies. This demonstrates that this conspiracy theory was larger in size, attracting more users and tweets: when comparing the 7-day time period of this study to that of the COVID-19 and 5G conspiracy [4], "FilmYourHospital" had almost double the number of tweets. The limitations of this study are that a 7-day time period was examined and Twitter's search API was used, which may exclude certain tweets. Future research could seek

to examine the locations of users that had tweeted using the hashtag and correlate this data with the re-emergence of COVID-19. Another important aspect to note is that there were also tweets that were irrelevant, such as ads, and some tweets might have been from users questioning the conspiracy theory. Not all tweets can definitively be interpreted as supporting the conspiracy. Future research could seek to conduct an analysis of tweets to ascertain the percentage of tweets that were related to the conspiracy. Future research could also seek to analyze the social networks of multiple conspiracy theories and look for potential commonalities with respect to key users and information sources.

## Abstract

**Background:** Despite the results of the Testosterone Trials, physicians remain uncomfortable treating men with hypogonadism. Discouraged, men increasingly turn to social media to discuss medical concerns.

**Objective:** The goal of the research was to apply natural language processing (NLP) techniques to social media posts for identification of themes of discussion regarding low testosterone and testosterone replacement therapy (TRT) in order to inform how physicians may better evaluate and counsel patients.

**Methods:** We retrospectively extracted posts from the Reddit community r/Testosterone from December 2015 through May 2019. We applied an NLP technique called the meaning extraction method with principal component analysis (MEM/PCA) to computationally derive discussion themes. We then performed a prospective analysis of Twitter data (tweets) that contained the terms low testosterone, low T, and testosterone replacement from June through September 2019.

**Results:** A total of 199,335 Reddit posts and 6659 tweets were analyzed. MEM/PCA revealed dominant themes of discussion: symptoms of hypogonadism, seeing a doctor, results of laboratory tests, derogatory comments and insults, TRT medications, and cardiovascular risk. More than 25% of Reddit posts contained the term doctor, and more than 5% urologist.

**Conclusions:** This study represents the first NLP evaluation of the social media landscape surrounding hypogonadism and TRT. Although physicians traditionally limit their practices to within their clinic walls, the ubiquity of social media demands that physicians understand what patients discuss online. Physicians may do well to bring up online discussions during clinic consultations for low testosterone to pull back the curtain and dispel myths.

## KEYWORDS

hypogonadism; natural language processing; Reddit; social media; testosterone replacement therapy; Twitter

## Introduction

The Testosterone Trials were a coordinated series of placebo-controlled, double-blinded trials intended to elucidate

risks and benefits of testosterone replacement therapy (TRT) in hypogonadal men [1-7]. Despite these recent trials, clinicians continue to be uncomfortable treating these men, in part due to unanswered questions related to cardiovascular outcomes and

cancer risk, as well as how TRT is portrayed in popular culture. Perhaps discouraged by conflicting information from physicians and traditional media, patients sometimes turn to social media platforms to discuss medical concerns with peers [8,9].

Interactive social media channels have emerged as potent resources for individuals to discuss health care concerns [9]. Reddit, an anonymous discussion platform with over 330 million monthly active users, serves as a popular internet destination for discussions of health-related topics [10]. The Reddit forum or subreddit r/Testosterone [11], which boasts over 30,000 active members, is devoted to answering questions, sharing personal accounts, and disseminating resources related to TRT and testosterone levels. Similar discussions occur on other social media sites, including Twitter, a microblogging platform with over 126 million daily active users [12].

We hypothesized that the content of online discussions about low testosterone can be classified into themes that may inform how physicians evaluate, counsel, and treat men with hypogonadism. Here, we apply quantitative natural language processing (NLP) techniques to identify dominant themes of discussions regarding low testosterone and TRT on social media.

## Methods

### Study Design and Sources of Data

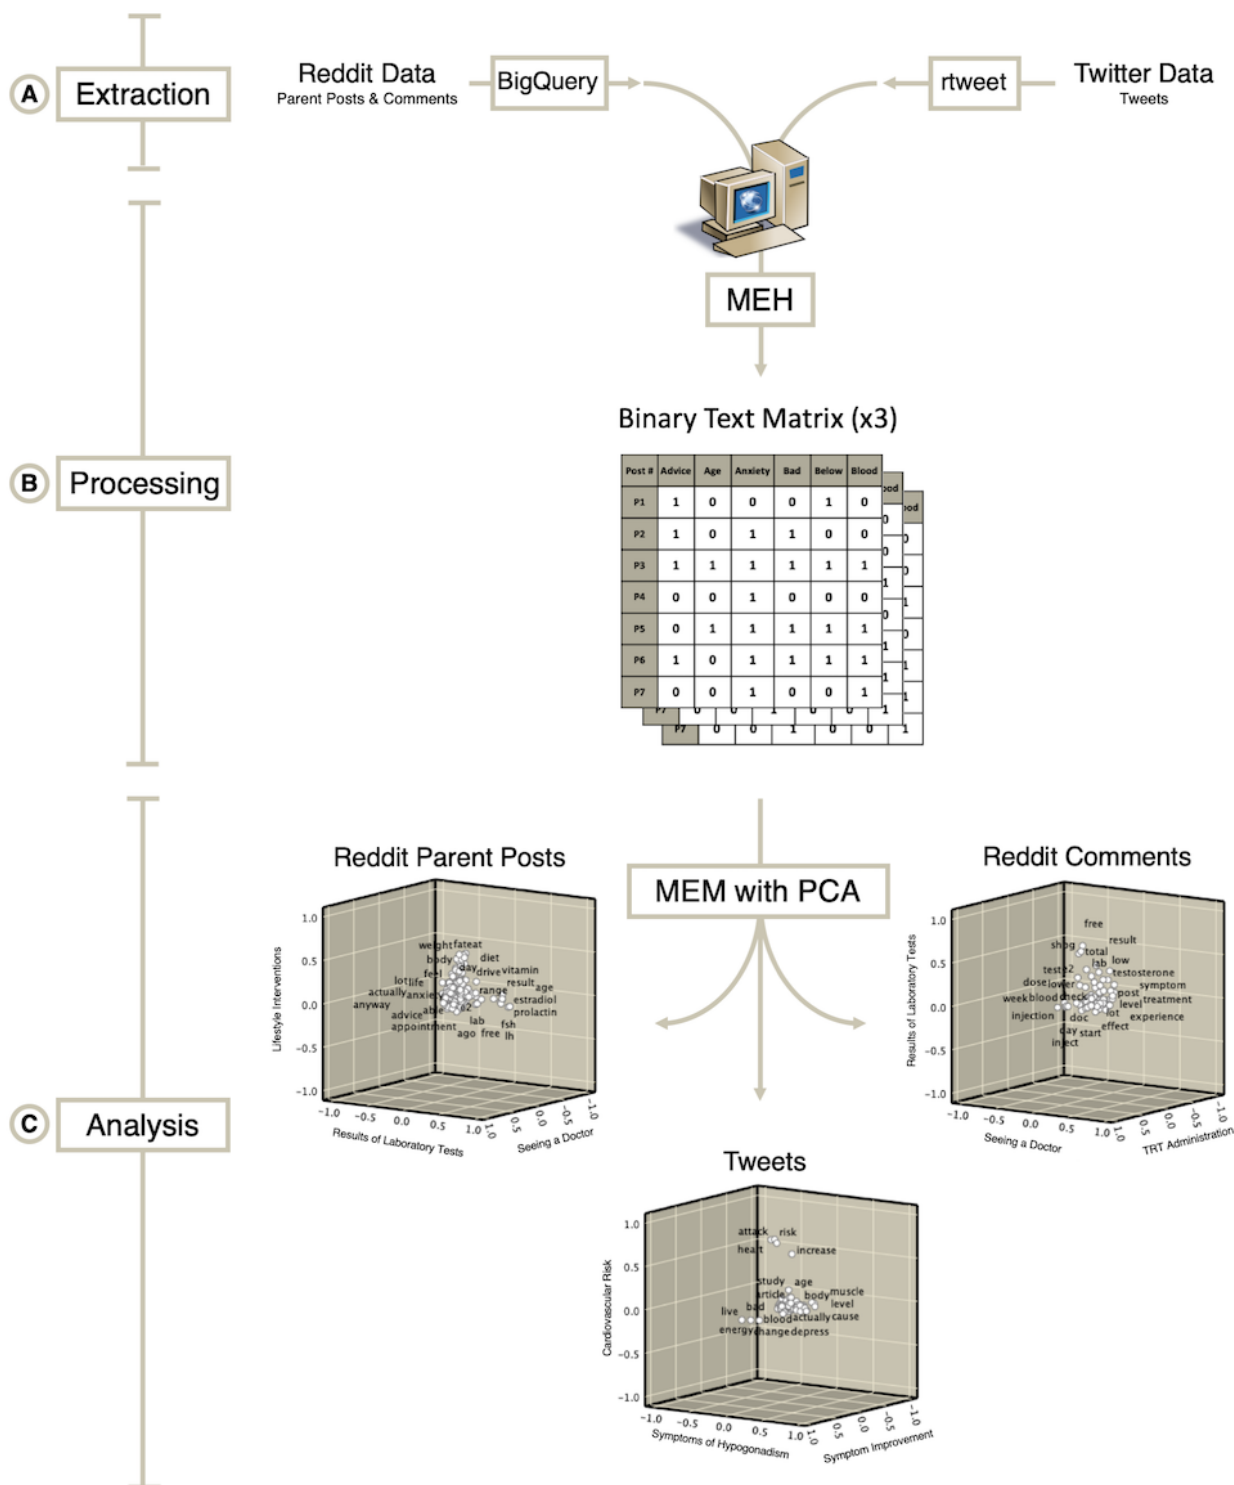

An overview of our methodology is presented in Figure 1. The study comprised three phases: extraction of data from social

media platforms (Figure 1A), automated organization of textual data (Figure 1B), and quantitative analysis of the textual data to identify dominant themes of the text (Figure 1C).

First, we retrospectively processed posts and comments from the Reddit community r/Testosterone from December 2015 through May 2019. Reddit data were extracted using BigQuery (Google LLC), an enterprise data analytics platform, from a dataset uploaded for public use [13] (Figure 1A). We evaluated both parent posts (the main post in a Reddit discussion) and comment posts (submitted in response to a parent post). We applied a word count criterion of >20 words for parent posts to exclude potential spam, deleted text, and posts composed only of links to other websites. As we anticipated the average word count of comment posts to be less, we used a more relaxed word count criterion of >5 words for comment posts.

Next, Twitter data (tweets) were collected prospectively from June through September 2019 using the rtweet application [14], which integrates tweets for processing in RStudio version 1.1.463 (RStudio PBC) (Figure 1A). We extracted tweets containing the terms low testosterone, low T, and testosterone replacement. We applied a word count criterion for tweets (>5 words per tweet), given the character count limitation imposed by the Twitter platform. Retweets (reposts of an identical, previously published tweet) were excluded from analysis.

**Figure 1.** Overview of methods: (A) extraction of Reddit and Twitter data using BigQuery and rtweet, respectively; (B) processing of raw text data using the meaning extraction helper to generate a binary text matrix for each data set; (C) meaning extraction method with principal component analysis generates word clusters for each dataset. Rotated component plots are shown with x-, y-, and z-axes representing the three clusters that capture the greatest variance of the data. MEH: meaning extraction helper; MEM: meaning extraction method; PCA: principal component analysis.

## Natural Language Processing Using the Meaning Extraction Method

Reddit parent posts, Reddit comment posts, and tweets from Twitter were separately subjected to an NLP technique called the meaning extraction method (MEM) [15] with principal component analysis (PCA). MEM/PCA tracks words that cluster

together to derive themes quantitatively [15]. This approach has been previously validated to reveal information about individuals' personalities, communication strategies, and behaviors [16,17].

To automate the MEM, we used the topic modeling application meaning extraction helper version 2 [18] to deconstruct each

post or tweet into its component words. Stop words (eg, articles, prepositions, and transitions) were filtered out. Remaining words were ranked by their frequencies of appearance in each post or tweet (Figure 1B). Words were then subjected to PCA with varimax rotation (Figure 1C) using SPSS Statistics version 25 (IBM Corporation). PCA identified clusters of words that frequently appeared together. Each word was conferred a factor loading, the correlation coefficient between the word and the cluster to which it belonged. Factor loading thresholds of  $>0.20$  are appropriate when performing PCA of text data to capture a sufficient proportion of the variance in the data [19,20]. We assigned a descriptive theme to each cluster based on the words within it.

### Subset Analyses on Key Topics of Interest

Given widespread interest and controversy regarding the potential associations of TRT with cardiovascular disease and prostate cancer risk, we sought to quantitate the appearance of these topics on Reddit and Twitter. Subset analysis was performed to determine the frequencies of the words prostate, cancer, PSA (prostate-specific antigen), heart, attack, stroke, cardiovascular, and death. Furthermore, to identify the degree to which individuals allude to seeking consultation with a health care provider, an additional analysis was performed to determine the frequencies of the relevant terms doctor, urologist, endocrinologist, and appointment.

### Statistical Validity of Principal Component Analysis

To assess applicability of PCA to each dataset, the Kaiser-Meyer-Olkin (KMO) statistic, a measure of sampling adequacy (values  $>0.60$  are adequate), and the Bartlett test for

sphericity, which tests if there are significant correlations among variables of interest, were calculated [21].

### Ethics

Consistent with previous investigations on social media data, this work was exempted by the institutional review board of the University of California, Los Angeles, as it involves publicly available data and does not involve human subjects.

## Results

### Total Number of Posts Extracted From Social Media

From the r/Testosterone community on Reddit, we retrospectively extracted 19,083 parent posts and 218,082 comment posts over the 42-month period of study. After exclusions, 12,665 parent posts and 186,670 comment posts remained. From Twitter, we prospectively extracted 7467 tweets over 4 months; 6659 tweets remained after exclusions.

### Natural Language Processing of Reddit Data

Using MEM for Reddit parent post and comment post data, we identified 5 factors, or thematic word clusters, that included words with factor loadings greater than 0.30 and 0.20, respectively (Tables 1 and 2).

The following themes emerged from NLP of Reddit data: seeing a doctor, results of laboratory tests, administration of TRT, and lifestyle interventions (both parent posts and comment posts); symptoms of hypogonadism (parent posts only); and TRT medications (comment posts only). Table 3 contains representative quotations that feature each Reddit theme. Some quotes have been abridged in the interest of space.

**Table 1.** Thematic clusters, word frequencies, and associated factor loading coefficients derived from the meaning extraction method with principal component analysis of parent posts from the Reddit community r/Testosterone (n=12,665).

Cluster and word	Factor loading coefficient	Frequency
<b>Results of laboratory tests</b>		
LH (luteinizing hormone)	0.72	13.2

**Table 3.** Representative quotations for each theme derived from the meaning extraction method. Asterisks are part of the quotations and do not refer to anything in the table.

Data source and theme	Representative quotation
<b>Reddit parent posts</b>	
<b>Results of laboratory tests</b>	<p>Here's what came up:</p> <p>FSH<sup>a</sup> 2.1 (1.5-12.4)</p> <p>LH<sup>b</sup> 5.6 (1.7-8.6)</p> <p>Prolactin 15.25 (4.04-15.2)*</p> <p>T, total<sup>c</sup> 311.1 (249-836)*</p> <p>SHBG<sup>d</sup> 33.3 (16.5-55.9)</p> <p>Free testosterone index 32.43 (35.0-92.6)*</p> <p>shbg and dheia still pending. I had to get these results because i have an appointment with neurosurgeon soon and he will need the labs and mri<sup>e</sup>.</p>
<b>Lifestyle interventions</b>	<p>Have been eating super clean. Working with a dietitian/personal trainer. Was dieting mostly high protein / low fat / low carb</p> <p>I work out all the time lifting heavy weights, 3 or 4 times a week on average. I eat a good diet, take my zinc, vitamin D, and get in my fats and essential fats.</p>
<b>Seeing a doctor</b>	<p>I know several people on trt<sup>f</sup>, but they all have the same doc...you walk in, tell him you want to get bigger, stronger, and faster, pay out of pocket for his blood test then buy your meds from his attached pharmacy. That's not what I want. I want to find out what's wrong without a preconceived bias.</p> <p>So I go to the appointment. And the specialist I saw (a urologist) said he wasn't the guy to see about this issue, and ended up referring me to another specialist.</p>
<b>Testosterone replacement therapy administration</b>	<p>T cyp<sup>g</sup> 200 mg/ml - 0.32 mL IM/SQ twice weekly (~130 mg/week)</p> <p>HCG<sup>h</sup> 500 IU SQ twice weekly to prevent testicular atrophy</p> <p>No AI<sup>i</sup> - low E2<sup>j</sup>, monitor</p> <p>DHEA<sup>k</sup> 25 mg every night</p> <p>So I don't know what to do? Take my AI and hope that my E2 is high? Or keep not taking my AI and hope things will get better?</p> <p>I literally can't hold out a week to get another blood test and also I can't afford it right now.</p>
<b>Symptoms of hypogonadism</b>	<p>All the normal symptoms: brain fog, mood swings, low libido, erectile dysfunction, inability to add muscle at the gym despite working out 3x a week.</p> <p>Symptoms: brain fog, very low energy level, lifelessness-zombie feeling most days, very lethargic, mood swings, easy to get angry, grumpy and annoyed at earliest, no libido/sex drive, ED<sup>l</sup>—less frequency, less powerful, minimal to no erections during sex, softer (haven't had sex in years)</p>
<b>Reddit comment posts</b>	
<b>Seeing a doctor</b>	<p>Many doctors—especially PCPs<sup>m</sup>—are not fluent in the endocrine system. They aren't supposed to be. Going to your primary care physician for hormone questions is a mistake. If you knew you had heart issues, wouldn't you go to a cardiologist?</p> <p>My PCP looked super confused and clueless as to what he was supposed to do for me. Doc made me do two more labs fasting to confirm then he referred me out to an endocrinologist. The endo made me do three more fasting labs and a testicular ultrasound to confirm.</p>
<b>Results of laboratory tests</b>	

Data source and theme	Representative quotation
<b>Testosterone replacement therapy administration</b>	<p>Honestly I don't think testosterone is your problem based on Sept 10th 2015 blood results. You have decent midrange total, and free testosterone. SHBG bounces around, so maybe it's a testing error.</p> <p>198 is low as hell for your dad, and even 450 for him would be low. Yours is lowish, but you have definite symptoms.</p> <p>75 mg E5D<sup>n</sup> (105 mg per week). Doesn't require an AI, doesn't give me side effects. I am at ~700 on trough days and feel pretty damn good.</p> <p>I had just moved to a standard TRT dose of Test Cyp, 100 mg/week. At 5'11", 172 lbs, and 17% body fat, taking 1 mg of Arimidex every day tanked my E2. Dropping down to 0.25 mg Arimidex once a week had the same effect.</p>
<b>Lifestyle interventions</b>	<p>Eat good food, lift heavy, and get sleep. Repeat for two years.</p> <p>TRT will not turn you into a bodybuilder. It may tone you a little bit (if everything is in check). But just saying "I eat good" literally means nothing. What are your macros? What's your diet? Etc?</p>
<b>Testosterone replacement therapy medications</b>	<p>HCG is a water-based peptide hormone that can be injected to replace the lost LH hormone that TRT shuts down. Without hCG, the LH receptors in the testes are no longer getting activated. The results: the testes shrink.</p> <p>Clomiphene. What a double-edged sword. First, Clomid will certainly have an effect on your testosterone levels. Usually, it is doses substantially higher than 12.5 mgs daily.</p>
<b>Tweets</b>	
<b>Symptoms of hypogonadism</b>	<p>Keeping your hormone levels up is a crucial part of #health. Low T can lead to all types of adverse effects: - weight gain/belly fat - #LowEnergy - low sex drive</p> <p>This, in turn, causes a lower sex drive, depression, reduced muscle mass, and low levels of energy. Erectile dysfunction is another symptom.</p>
<b>Cardiovascular risk</b>	<p>#Testosterone Replacement Therapy Lowers Heart Attack Risk</p> <p>Aging men with low testosterone levels who take testosterone replacement therapy (TRT) are at a slightly greater risk of experiencing an ischemic stroke</p>
<b>Symptom improvement</b>	<p>Starting testosterone replacement therapy and thyroid medication at the same time is quite the 1-2 punch to the system. Endless energy, great sleep, and able to lift weights heavier and longer.</p> <p>"My energy is back": how testosterone replacement therapy is changing men's lives</p>
<b>Derogatory comments and insults</b>	<p>That little cuck should be the poster boy for low T supplements</p>

Data source and theme	Representative quotation
	I was called effeminate and a low testosterone beta here for defending women's rights.

<sup>a</sup>FSH: follicle-stimulating hormone.

<sup>b</sup>LH: luteinizing hormone.

<sup>c</sup>T, total: total testosterone.

<sup>d</sup>SHBG: sex hormone binding globulin.

<sup>e</sup>MRI: magnetic resonance imaging.

<sup>f</sup>TRT: testosterone replacement therapy.

<sup>g</sup>CYP: cytochrome P450.

<sup>h</sup>HCG: human chorionic gonadotropin.

<sup>i</sup>AI: aromatase inhibitor.

<sup>j</sup>E2: estradiol.

<sup>k</sup>DHEA: dehydroepiandrosterone.

<sup>l</sup>ED: erectile dysfunction.

<sup>m</sup>PCP: primary care physician.

<sup>n</sup>E5D: every 5 days.

The highest frequency word occurrences among parent posts as determined by PCA were low (5484/12,665 [43.30%] of posts), week (5092/12,665, 40.20%), level (4382/12,665, 34.60%), and start (3635/12,665, 28.70%). Among comment posts, the highest frequency word occurrences were test (33,414/186,670, 17.90%), low (28,747/186,670, 15.40%), TRT (28,561/186,670, 15.30%), and week (24,267/186,670, 13.00%).

Parent post and comment post PCA accounted for 15.45% (1957/12,665) and 13.84% (25,835/186,670) of the total variance, respectively. KMO statistic was 0.91 for Reddit parent post data and 0.80 for Reddit comment post data, with Bartlett test <0.01, indicating that the Reddit data were appropriate for factor analysis using PCA.

### Natural Language Processing of Twitter Data

Similarly, MEM for Twitter data identified 4 factors, or thematic word clusters, with factor loadings greater than 0.25 (Table 4). The following themes emerged from NLP of tweets: symptoms of hypogonadism, cardiovascular risk, symptom improvement, and derogatory comments and insults.

The highest frequency word occurrences among tweets as determined by PCA were level (693/6659, 10.40%), male (426/6659, 6.40%), sex (213/6659, 3.20%), and increase (200/6659, 3.00%). Twitter PCA accounted for 9.01% (600/6659) of the total variance. KMO statistic was 0.61 for Twitter data, with Bartlett test <0.01, indicating that the Twitter data were appropriate for factor analysis using PCA. Of note, other studies using MEM/PCA have reported similar percentages of variance as those determined in our analysis of Reddit and Twitter data [22,23].

**Table 4.** Thematic clusters, word frequencies, and associated factor loading coefficients derived from the meaning extraction method with principal component analysis of tweets about low testosterone, low T, or testosterone replacement on Twitter (n=6659).

Cluster and word	Factor loading coefficient	Frequency
<b>Symptoms of hypogonadism</b>		
Muscle	0.54	1.9
Mass	0.48	1.2
Sex	0.41	3.2
Libido	0.39	1.0
Level	0.36	10.4
Drive	0.35	1.8
Fat	0.32	1.3
Hormone	0.31	2.7
Body	0.28	2.3
Weight	0.27	1.1
<b>Cardiovascular risk</b>		
Heart	0.76	1.1
Attack	0.76	1.1
Risk	0.73	2.1
Increase	0.62	3.0
<b>Symptom improvement</b>		
Change	0.69	2.2
Energy	0.69	2.9
Live	0.69	2.0
Life	0.21	2.1
<b>Derogatory comments and insults</b>		
Boy	0.58	2.3
Soy	0.56	2.4
Beta	0.42	2.8
Cuck	0.29	1.0
Male	0.23	6.4
Girl	0.22	1.0
Little	0.22	1.3

### Word Occurrences on Key Topics of Interest

Subset analysis was performed to determine word occurrence frequencies in three key topics of interest that relate to TRT: prostate cancer risk, cardiovascular disease risk, and seeking consultation with a health care professional. These data are presented in [Table 5](#).

In brief, over 1% of Reddit parent posts contain the terms prostate (143/12,665, 1.13%), cancer (143/12,665, 1.13%), PSA (210/12,665, 1.66%), or heart (175/12,665, 1.38%). Over a quarter of Reddit parent posts contain the term doctor (3235/12,665, 25.54%), while over 5% of parent posts refer to either a urologist (732/12,665, 5.78%) or endocrinologist (657/12,665, 5.19%). Frequencies of these terms were higher among Reddit posts than among tweets from Twitter.

**Table 5.** Subset analysis of word frequencies related to prostate cancer risk, cardiovascular disease risk, and seeking a health care consultation.

Concern associated with testosterone replacement therapy	Word frequency (%)		
	Reddit parent post	Reddit comment post	Tweet
<b>Prostate cancer risk</b>			
Prostate	1.13	0.36	0.63
Cancer	1.13	0.56	0.87
PSA <sup>a</sup>	1.66	0.25	0.06
<b>Cardiovascular disease risk</b>			
Heart	1.38	0.61	1.14
Attack	0.89	0.32	1.14
Stroke	0.23	0.13	0.86
Cardiovascular	0.13	0.13	0.44
Death	0.24	0.19	0.21
<b>Seeking health care consultation</b>			
Doctor	25.54	9.00	1.77
Urologist	5.78	1.36	0.20
Endocrinologist	5.19	0.97	0.17
Appointment	5.13	0.74	0.39

<sup>a</sup>PSA: prostate-specific antigen.

## Discussion

### Principal Findings

NLP techniques applied to unfiltered discussions on Reddit and Twitter offer a useful framework for understanding patient priorities outside the doctor's office. We found that men largely turn to social media to learn about symptoms of low testosterone, interpretation of personal lab results, practicalities of TRT, and body changes with treatment. Notably, cardiovascular risk was a major discussion theme, echoing concerns among prescribers, who may be deterred by continued ambiguity despite the publication of the Testosterone Trials. Although NLP analysis did not reveal prostate cancer as a notable theme, a number of posts included text related to this topic, suggesting that this may represent an important discussion point for a subset of online discussions related to TRT.

Our results underscore that patients are searching for medical guidance related to hypogonadism on social media, an environment where anecdotes predominate and advertising often masquerades as medical advice [24]. TRT prescriptions have risen almost 4-fold over the last two decades, which can be attributed, in part, to off-label indications and direct-to-consumer advertising [25]. Even beyond standard TRT, testosterone-boosting supplements with minimal data to support their efficacy are aggressively marketed and readily available online [26]. But still, social media represents an enormous opportunity for the medical community to improve how we engage with our patients and to do so in a meaningful and impactful way. Potential interventions that may inoculate against coercive direct-to-consumer marketing practices include disseminating high-quality, open-access information related to

hypogonadism. For example, Halpern et al [27] recently published a JAMA Patient Page article on hypogonadism. This single-page handout written in easily accessible language includes an infographic highlighting symptoms of hypogonadism and potential adverse effects of TRT, in addition to information related to etiology of hypogonadism and a discussion of potential cardiovascular and prostate cancer risks associated with TRT—all topics that emerged as major themes of discussion from our data.

Social media platforms, including Reddit and Twitter, create a space for patients not only to obtain answers to questions that they are either uncomfortable or unwilling to ask in a face-to-face clinical setting but also to connect with others going through similar experiences. However, not all health-related discussions online are productive. Twitter featured the theme of derogatory comments and insults, highlighting an undertone of stigma, which may compound existing barriers preventing men from accessing care [28]. In contrast, the seeing a doctor theme only emerged on Reddit, with more than 25% of parent posts mentioning the word doctor, compared with less than 2% on Twitter. This may reflect inherent differences among the two social media platforms, as Twitter is constrained by a strict character count limitation and is overall less anonymous, with discussants frequently using their true identities in their display usernames and account photos.

Although clinician engagement with the online hypogonadism community will become increasingly important in the coming years, improving the in-office clinical experience of our patients cannot be overemphasized. Our data reveal that many of the online discussions featured personal questions related to interpretation of lab results. This is consistent with a previous study exploring Reddit discussions of male factor infertility,

where nearly 20% of all posts featured a question related to personal semen analysis results [29]. Such discussions related to lab results cannot be addressed by disseminating a primer on hypogonadism and TRT, but instead demand the expertise of a clinician trained in managing male endocrinology and the related sexual, reproductive, and psychological comorbidities. Creating an in-office experience where men feel comfortable and safe to ask their questions and voice their concerns should be a priority for any outpatient clinical setting, but especially one that caters to men with suspected hypogonadism. Both outpatient primary care settings and urological outpatient clinics can learn from the success of the emerging multidisciplinary men's health clinic [30].

Here we offer valuable insight into primarily patient concerns in a forum that allows for honest and unfiltered patient feedback as it relates to these discussants' experiences with hypogonadism. Clinically, these data highlight that patients worry most about comorbidities, lifestyle factors impacted by low testosterone, and treatment options. While other aspects of hypogonadism can be discussed, these data highlight the most salient hypogonadism-related concerns for our patients. Additionally, this study can further improve on patients' in-office experiences by informing how physicians can lead discussions to highlight aspects of low testosterone that patients may feel are not being adequately addressed.

### Limitations

Our study is not without limitations. Although NLP techniques allowed us to analyze a large volume of discrete social media posts, generalizability of MEM is limited by the absence of

contextual valence (positivity or negativity). However, this does not impair overall thematic identification. Additionally, discussants who turn to social media for health care information may be different with respect to demographics, health care priorities, and information preferences compared with those who do not; our results should therefore be interpreted within this context [31]. It should also be noted that some individuals use social media as a platform to vent about their experiences with health care professionals as they relate to hypogonadism care. This is an important distinction to make because it may not necessarily represent a lack of communication between patients and their physician but rather a discussant's opportunity to share. Future studies may consider investigating to other Reddit communities, expanding Twitter search terms, or exploring other social media platforms.

### Conclusions

This study represents the first evaluation of the social media landscape surrounding hypogonadism and TRT using NLP techniques. Our analysis of more than 200,000 discrete social media posts revealed dominant themes of discussion, which may inform how physicians evaluate and counsel men with hypogonadism. Understanding the complex internet landscape of hypogonadism discussions represents the first step in creating well-informed and clinically meaningful change. Although physicians traditionally limit their practices to within their clinic walls, the ubiquity of social media demands that physicians engage patients where they are, including online. Practicing physicians may do well to bring up online discussions during clinic consultations, to pull back the curtain and dispel myths.

## Abstract

**Background:** The exposure and consumption of information during epidemic outbreaks may alter people's risk perception and trigger behavioral changes, which can ultimately affect the evolution of the disease. It is thus of utmost importance to map the dissemination of information by mainstream media outlets and the public response to this information. However, our understanding of this exposure-response dynamic during the COVID-19 pandemic is still limited.

**Objective:** The goal of this study is to characterize the media coverage and collective internet response to the COVID-19 pandemic in four countries: Italy, the United Kingdom, the United States, and Canada.

**Methods:** We collected a heterogeneous data set including 227,768 web-based news articles and 13,448 YouTube videos published by mainstream media outlets, 107,898 user posts and 3,829,309 comments on the social media platform Reddit, and 278,456,892 views of COVID-19-related Wikipedia pages. To analyze the relationship between media coverage, epidemic progression, and users' collective web-based response, we considered a linear regression model that predicts the public response for each country given the amount of news exposure. We also applied topic modelling to the data set using nonnegative matrix factorization.

**Results:** Our results show that public attention, quantified as user activity on Reddit and active searches on Wikipedia pages, is mainly driven by media coverage; meanwhile, this activity declines rapidly while news exposure and COVID-19 incidence remain high. Furthermore, using an unsupervised, dynamic topic modeling approach, we show that while the levels of attention dedicated to different topics by media outlets and internet users are in good accordance, interesting deviations emerge in their temporal patterns.

**Conclusions:** Overall, our findings offer an additional key to interpret public perception and response to the current global health emergency and raise questions about the effects of attention saturation on people's collective awareness and risk perception and thus on their tendencies toward behavioral change.

## Introduction

### Background

*In the next influenza pandemic, be it now or in the future, be the virus mild or virulent, the single most important weapon against the disease will be a vaccine. The second most important will be communication.*

This evocative sentence was written in May 2009 by John M Barry [1] in the early phases of what would soon become the 2009 H1N1 pandemic. In his essay, Barry summarized the mishandling of the deadly 1918 Spanish influenza, highlighting the importance of precise, effective, and honest information at the onset of health crises.

Eleven years later, the world is facing another pandemic. The cause is not a novel strain of influenza; however, unfortunately, Barry's words are still extremely relevant. In fact, as SARS-CoV-2 spreads worldwide and a vaccine may still be far in the future, the most important weapons to reduce the burden of the disease are nonpharmaceutical interventions [2,3]. Social distancing has become paramount, gatherings have been cancelled, and mobility within and across countries has been dramatically reduced. While these measures have been enforced to different extents across nations, they all rely on compliance. The effectiveness of these measures is linked to risk and susceptibility perception [4]; thus, the information to which citizens are exposed is of fundamental importance.

History repeats itself, and humanity appears to not be able to learn from its past mistakes. As happened in 1918, despite early evidence from China [5,6], the virus was first equated by many people with common seasonal influenza. As in 1918, many national and regional governments organized campaigns aimed at encouraging social activities (and thus local economies) while actively attempting to convince people that their cities were safe and that the spread of the disease was isolated in faraway locations. For example, the hashtag #MilanoNonSiFerma ("Milan does not stop") was coined to invite citizens in Milan to go out and live normally, while free aperitifs were offered in Venice. In hindsight, of course, it is easy to criticize the initial response in Italy. In fact, the country was one of the first to experience rapid growth of hospitalization [7]. However, the Mayor of London, 12 days before the national lockdown and a few days after the extension of the *cordon sanitaire* to the entire country in Italy, affirmed via his official Facebook page [8] that "we should carry on doing what we've been doing." More generally, in several western countries, news reports from other countries reporting concerning epidemic outbreaks were not considered to be relevant to the local situation. This initial phase aimed at conveying low local risk and boosting confidence in national safety was repeated, at different times, across countries. A series of surveys conducted in late February provide a glimpse of the possible effects of these approaches. These surveys report that citizens of several European countries, despite the grim news coming from Asia, were overly optimistic about the health emergency, placing their risk of infection at 1% or less [9]. As in 1918, countries that reacted earlier rather than later were

better able to control the virus, with significantly fewer infections [10-14].

History repeats itself; however, the context is often radically different. In 1918, news circulated slowly via newspapers, controlled by editorial choices; of course, news also spread by word of mouth. In 2009, we witnessed the first pandemic in the social media era. Newspapers and television were still very important sources of information; however, Twitter, Facebook, YouTube, and Wikipedia started to become relevant for decentralized news consumption, boosting of peer discussions, and spreading of misinformation. Currently, these platforms and websites are far more popular and integral parts of society, and they are instrumental sources of national and international news circulation. Together with traditional news media, these platforms and websites are the principal sources of information for the public. As such, they are fundamental drivers of people's perception and opinions and thus of their behaviors. This is particularly relevant for health issues. For example, approximately 60% of adults in the United States consulted web-based sources to gather health information [15].

Furthermore, some platforms are acknowledging their growing responsibility in media consumption and have introduced specific features to increase users' awareness and levels of information.

### Prior Work

With respect to past epidemics and pandemics, studies on traditional news coverage of the 2009 H1N1 pandemic highlighted the importance of framing and its effect on people's perception, behaviors (eg, vaccination intent), and stigmatization of cultures at the epicenter of the outbreak, as well as how these factors differ across countries and cultures [16-21]. During the Zika virus epidemic in 2016, public attention was synchronized across US states, driven by news coverage about the outbreak and independent of the real local risk of infection [22]. With respect to the COVID-19 pandemic itself, a recent study clearly showed how Google searches for *coronavirus* in the United States spiked significantly immediately after the announcement of the first confirmed case in each state [23]. Several studies based on Twitter data have also highlighted how misinformation and low-quality information about COVID-19, although limited overall, spread before the local outbreak and rapidly expanded once local epidemics started [24-26]. In the current landscape, this spread of misinformation has the potential to encourage irrational, unscientific, and dangerous behaviors. On the other hand, despite some important limitations [27], modern media has become a key data source to observe and monitor health. In fact, posts on Twitter [28-33], Facebook [34], and Reddit [35,36], page views in Wikipedia [37,38], and searches on Google [39,40] have been used to study, nowcast, and predict the spreading of infectious diseases as well as the prevalence of noncommunicable illnesses. Therefore, in the current full-fledged digital society, information is not only key to inform people's behavior but can also be used to develop an unprecedented understanding of these behaviors as well as of the phenomena driving them.

## Goal of This Study

The context in which COVID-19 is unfolding is very heterogeneous and complex. Traditional and social media are integral parts of public perception and opinions, and they have potential to trigger behavior changes and thus influence the spread of the pandemic. This complex landscape must be characterized to understand the public attention and response to media coverage. Here, we addressed this challenge by assembling a heterogeneous data set that includes 227,768 news reports and 13,448 YouTube videos published by traditional media, 278,456,892 views of topical Wikipedia pages, and 107,898 submissions and 3,829,309 comments from 417,541 distinct users on Reddit, as well as epidemic data in four different countries: Italy, the United Kingdom, the United States, and Canada. First, we explored how media coverage and epidemic progression influence public attention and response. To achieve this, we analyzed news volume and COVID-19 incidence with respect to volumes of Wikipedia page views and Reddit comments. Our results show that public attention and response are mostly driven by media coverage rather than by disease spread. Furthermore, we observed the typical saturation and memory effects of public collective attention. Moreover, using an unsupervised topic modeling approach, we explored the different topics framed in traditional media and in Reddit discussions. We show that while the attention of news outlets and internet users toward different topics is in good accordance, interesting deviations emerge in their temporal patterns. Also, we highlight that at the end of our observation period, general interest grew toward topics about the resumption of activities after lockdown, the search for a vaccine against SARS-CoV-2, acquired immunity, and antibody tests. Overall, the research presented here offers insights to interpret public perception and response to the current global health emergency and raises questions about the effects of attention saturation on collective awareness and risk perception and thus on tendencies toward behavioral change.

## Methods

### Data Set

#### News Articles and Videos

We collected news articles using News API, a service that allows free downloads of articles published on the internet in a variety of countries and languages [41]. For each country considered, we downloaded all relevant articles published on the internet by selected sources in the period from February 7 to May 15, 2020. We selected relevant articles by considering those citing one of the following keywords: *coronavirus*, *covid19*, *covid-19*, *ncov-19*, and *sars-cov-2*. Note that for each article, we could access the title, a description, and a preview of the full text. In total, our data set consisted of 227,768 news articles; 71,461 were published by Italian media, 63,799 by UK media, 82,630 by US media, and 9878 by Canadian media.

Additionally, we collected all videos published on YouTube by major news organizations in the four countries under investigation via their official YouTube channels using the official application programming interface (API) [42]. In this

process, we downloaded the titles and descriptions of all the videos and selected as relevant those that mentioned one of the following keywords: *coronavirus*, *virus*, *covid*, *covid19*, *sars*, *sars-cov-2*, and *sarscov2*. The reach of each channel (measured by the number of subscribers) varied drastically, from more than 9 million for CNN (United States) to approximately 12,000 for Ansa (Italy). In total, the YouTube data set consisted of 13,448 videos; 3325 were published by Italian channels, 3525 by UK channels, 6288 by US channels, and 310 by Canadian channels.

It is important to underline that while there is good overlap between the sources of news articles and videos, some do not match. This is due to the fact that not all news organizations have a YouTube channel, while others do not produce traditional articles. In [Multimedia Appendix 1](#), we provide a complete list of the news outlets and YouTube channels we considered.

#### Reddit Posts

Reddit is a social content aggregation website on which users can post, comment, and vote on content. It is structured in subcommunities (ie, subreddits) that are centered around a variety of topics. Reddit has already been proven to be suitable for a variety of research purposes, ranging from the study of user engagement and interactions between highly related communities [43,44] to postelection political analyses [45]. Moreover, it has been used to study the impact of linguistic differences in news titles [46] and to explore recent web-related issues such as hate speech [47] and cyberbullying [48] as well as health-related issues such as mental illness [49]; it also provides insights into the opioid epidemic [50].

We used the Reddit API to collect all submissions and comments published in Reddit under the subreddit r/Coronavirus from February 15 to May 15, 2020. After cleaning the data by removing entries deleted by authors and moderators, we retained only submissions with scores >1 to avoid spam. We removed comments with <10 characters and with >3 duplicates to avoid including automatic messages from moderators. The final data set contained 107,898 submissions and 3,829,309 comments from 417,541 distinct users.

To characterize the topics discussed on Reddit, we then selected entries with links to English-language news outlets. The contents of the URLs were extracted using the available implementation of the method described in [51], resulting in 66,575 valid documents.

Reddit does not provide explicit information about users' locations; therefore, we used self-reporting via regular expression to assign locations to users. Reddit users often declare geographical information about themselves in submissions or comment texts. We used the same approach described in [50], in which the use of regular expressions was found to be reliable, resulting in high correlation with census data in the United States; however, we acknowledge a potential higher bias at the country level due to heterogeneities in Reddit population coverage and user demographics. We selected all English-language texts containing expressions such as "I am from" or "I live in" and extracted candidate expressions from the text that followed the expressions to identify texts that

represented country locations. By removing inconsistent self-reporting, we were able to assign a country to 789,909 distinct users, among which 41,465 had posted at least one comment in the subreddit r/Coronavirus (13,811 from the United States, 6870 from Canada, 3932 from the United Kingdom, and 445 from Italy).

### Wikipedia Page Views

Wikipedia has become a popular digital data source to study health information-seeking behavior [52] and to monitor and forecast the spreading of infectious diseases [53,54]. Here, we used the Wikimedia API [55] to collect the number of visits per day to Wikipedia articles and the total monthly visits to a specific project from each country. We considered language to be indicative of a specific country, suggesting that the relevant projects for our analysis would be written in English and Italian (ie, *en.wikipedia* and *it.wikipedia*, respectively). We chose articles directly related to COVID-19 and those in the “See also” section of each page at the time of the analysis (February 7 to May 15, 2020), including country-specific articles (see [Multimedia Appendix 1](#) for the full list of webpages considered).

Except for Italian, where the language is highly indicative of the location, the number of visits to English pages is almost evenly distributed among English-speaking countries. To normalize the signal related to each country, we weighted the number of daily visits to a single article from a specific project  $p$ ,  $S_p(d)$ , with the total number of monthly visits from a country

$c$ , to the related Wikipedia project , such that the number of daily page views for a given Wikipedia project and country is:

$$(1) \quad \text{where the denominator is the total number of views of the specific Wikipedia project. The total volume of views on day } d \text{ from country } c \text{ is then given by the sum over all the articles } a \text{ and projects } p, \text{ namely:}$$

(2) 

### Media Coverage and Collective Web-Based Response

With our data set, we aimed to provide an overview of media coverage and a proxy of public attention and response. On the one hand, the study of news articles and videos enabled us to estimate the exposure of the public to information about the COVID-19 pandemic in traditional news media. On the other hand, the study of users' discussions and responses on social media (through Reddit) and information-seeking (through Wikipedia page views) allowed us to quantify the reaction of individuals both to the COVID-19 pandemic and to news exposure. As mentioned in the Introduction, previous studies showed the usefulness of social media, internet use, and search trends to analyze health-related information streams and monitor public reaction to infectious diseases [56-60]. Hence, we considered the volume of comments of geolocalized users on the subreddit r/Coronavirus to explore the public discussion in reaction to media coverage of the epidemic in the various

countries; meanwhile, we considered the number of views of relevant Wikipedia pages about the COVID-19 pandemic to quantify users' interest. It is important to stress that Reddit and Wikipedia provide different aspects of internet users' behavior and collective response. In fact, while Reddit posts can be regarded as a general indicator of the web-based discussion surrounding the global health emergency, the number of visits to COVID-19-related Wikipedia pages is a proxy of health information-seeking behavior. Health information-seeking behavior is the act by which individuals retrieve and acquire new knowledge about a specific topic related to health [61,62]; it is likely to be triggered on a population scale by a disrupting event, such as the threat of a previously unknown disease [63,64].

### Linear Regression Approach to Model Collective Attention

To analyze the relationship between media coverage, epidemic progression, and users' collective web-based response, we considered a linear regression model that predicts the public response for each country given the amount of news exposure. To include “memory effects” in the public response to media coverage, we also considered a modified version of this simple model, in which we weight a cumulative news articles volume time series with an exponential decay term [22]. Formally, we define the new variable as:

$$(3) \quad \text{where } \tau \text{ is a free parameter that sets the memory time scale and is tuned by comparing different variants of the linear regression with } \tau \in [1, 45] \text{ in terms of the adjusted coefficient of determination } R^2 [65] \text{ (results for the best } \tau \text{ are displayed). These two models were compared to a linear regression that considers only COVID-19 incidence to predict public collective attention. Then, the models considered are:}$$

$$\text{Model I: } y_t = \alpha_1 \text{incidence}_t + u_t$$

$$\text{Model II: } y_t = \alpha_1 \text{news}_t + u_t$$

$$\text{Model III: } y_t = \alpha_1 \text{news}_t + \alpha_2 \text{newsMEM}_t + u_t \quad (4)$$

where  $y_t$  can be the volume of Reddit comments of geolocalized users or of country-specific Wikipedia visits, and  $u_t$  is the error term. In [Multimedia Appendix 1](#), we provide more details on the model diagnostics and fitting procedure.

### Topic Modeling

Topic modeling has emerged as one of the most effective methods for classifying, clustering, and retrieving textual data, and it has been the object of extensive investigation in the literature. Many topic analysis frameworks are extensions of well-known algorithms that are considered to be state-of-the-art for topic modeling. Latent Dirichlet allocation (LDA) [66] is the reference for probabilistic topic modeling. Nonnegative matrix factorization (NMF) [67] is the counterpart of LDA for matrix factorization. Although there are many approaches to temporal and hierarchical topic modeling [68-70], we chose to apply NMF to the data set and then build time-varying intensities

for each topic using the publication dates of the articles. Starting from a data set  $D$  containing the news articles shared in Reddit, we extracted words and phrases with the methodology described in [71], discarding terms with frequencies  $>10$ , to form a vocabulary  $V$  with approximately 60,000 terms. Each document was then represented as a vector of term counts in a bag-of-words approach. We applied term frequency–inverse document frequency (TF-IDF) normalization [72] and extracted a total of  $K=64$  topics through NMF:

$$\| \mathbf{X} \|_F$$

(5)

where  $\| \cdot \|_F$  is the Frobenius norm and  $\mathbf{X} \in \mathbf{R}^{|D| \times |V|}$  is the matrix resulting from TF-IDF normalization, subject to the constraint that the values in  $\mathbf{W} \in \mathbf{R}^{|D| \times K}$  and  $\mathbf{H} \in \mathbf{R}^{K \times |V|}$  must be nonnegative. The nonnegative factorization was achieved using the projected gradient method with sparseness constraints, as described in [73,74]. The matrix  $\mathbf{H}$  was then used as a transformation basis for other data sets (eg, with a new matrix  $\mathbf{D}^{(t)}$ , we fixed  $\mathbf{H}$  and calculated a new  $\mathbf{X}$  according to Equation 5). For each topic  $k$ , we built a time series  $s_k$  for each data set  $D$ , where  $\mathbf{X}$  is the strength of topic  $k$  at time  $t$ . For the news outlets data set,  $\mathbf{X}$ , where  $D^{(t)}$  is the set of all documents shared at time  $t$  in news outlets. For Reddit, we weighted each shared document by its number of comments, and  $\mathbf{X}$ , where  $D^{(t)}$  is the set of all documents shared at time  $t$  in Reddit and  $c_i$  is the number of comments associated with document  $i$ . Finally, we defined the relevance  $R$  of a topic as the integral in time of the strength. Therefore, given  $t_0$  and  $t_f$  as the start and end of our analysis interval,  $\mathbf{X}$ . In Multimedia Appendix 1, we show that choosing  $K=64$  as the number of extracted topics provides a good balance between sufficient captured topic strength and good topic coherence.

## Results

### Impact of Media Coverage and Epidemic Progression on Collective Attention

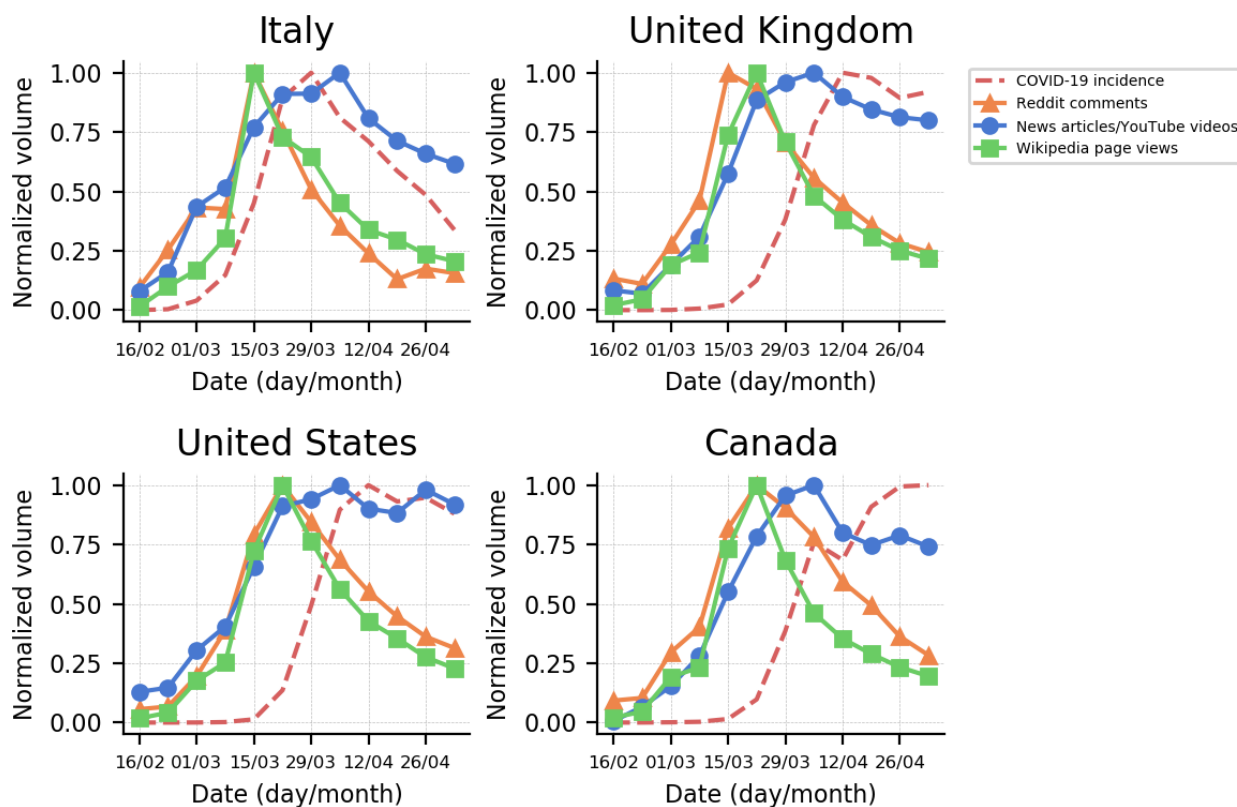

To answer the important question of how collective attention is shaped by news media coverage and epidemic progression, we started by comparing the weekly volumes of news stories and videos published on YouTube, Wikipedia page views, and

Reddit comments of geolocalized users with the weekly COVID-19 incidence in the four countries considered (Figure 1). It can be seen that as COVID-19 spread, both media coverage and public interest grew with time. However, public attention, quantified by the number of Reddit comments and Wikipedia page views, sharply decreased after reaching a peak, even though the volume of news stories and the incidence of COVID-19 remained high. Furthermore, the peak in public attention consistently anticipated the maximum media exposure and maximum COVID-19 incidence.

The correlation between media coverage, public attention, and progression of the epidemic is quantified in more detail in Table 1. The table shows that news coverage of each country is strongly correlated with COVID-19 incidence (both global and domestic) and slightly less correlated with the volumes of Reddit comments and Wikipedia views, which in turn are much less correlated with COVID-19 incidence (both global and domestic). This result was observed for all countries under consideration; it highlights how the spread of COVID-19 triggered media coverage as well as how public response was more likely to be driven by news exposure in each country than by the progression of COVID-19.

Beyond these observations, Figure 2 shows the share of citations of Chinese versus home country locations by Italian, UK, US, and Canadian news outlets before and after the first COVID-19 death occurred in those countries; the geographic locations were extracted from the text using the methods described in [75,76]. Interestingly, Italy is the only country where the news volume shows a higher correlation with domestic incidence than with global incidence (ie, news references to China). This suggests that Italian media coverage follows internal evolution more closely than global evolution, in contrast to other countries. This is probably due to the fact that Italy is the location of the first COVID-19 outbreak outside Asia. This observation is supported by Figure 2, which shows the citation share of Italian locations by Italian news media before and after the first COVID-19 death was confirmed in Italy on February 23, 2020. After this date, Italian locations represent about 74% of all places cited by Italian media (in our data set), with an increase of 45% with respect to the same statistics calculated before. Similar effects, although generally less intense, were observed in the other countries. Therefore, while media coverage is generally well synchronized with global COVID-19 incidence, the media attention gradually shifts toward the internal evolution of the pandemic as soon as domestic outbreaks erupt.

**Figure 1.** Normalized weekly volumes of news articles and YouTube videos, Reddit comments, and Wikipedia page views related to the COVID-19 pandemic and the incidence of COVID-19 in different countries.

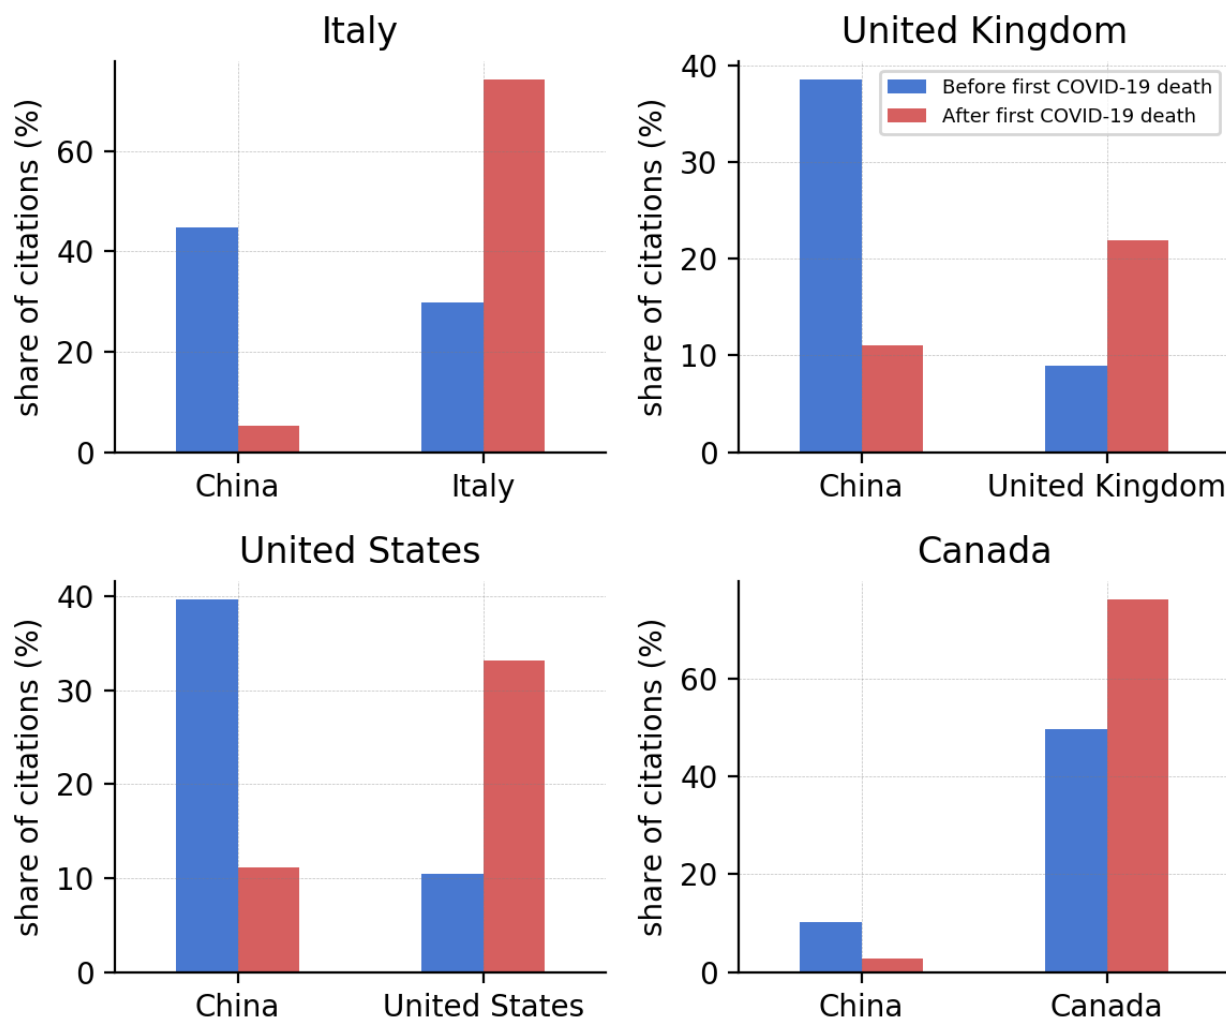

**Table 1.** Country-specific Pearson correlation coefficients for news coverage and global and domestic COVID-19 incidence, volumes of Reddit comments, and volumes of Wikipedia page views; domestic COVID-19 incidence and volumes of Reddit comments and Wikipedia views; and global COVID-19 incidence and volumes of Reddit comments and Wikipedia views.

<sup>a</sup>N/A: not applicable.<sup>b</sup>—: not determined.

**Figure 2.** Shares of citations of China versus home country locations by Italian, UK, US, and Canadian news outlets before and after the first COVID-19 death occurred in each country.

To more systematically explore the relationship between media coverage, public attention, and epidemic progression, we considered a linear regression model to nowcast the collective public attention for each country (quantified by the number of comments by geolocalized Reddit users or visits to relevant Wikipedia pages) using the volume of media coverage or the COVID-19 incidence as independent variables. We also included “memory effects” on the public attention by considering an exponential decaying term in the news time series [22]. We

compared the three models, where the independent variables are the domestic incidence, the news volume, and the news volume plus a memory term, using the adjusted coefficient of determination ( $R^2$ ) [65]. We found that the model that considered only COVID-19 incidence performed worse than the models that considered media coverage (Table 2). This enforces the idea that collective attention is mainly driven by media coverage rather than by COVID-19 incidence. In addition, we found that including memory effects improved the model performance.

**Table 2.** Adjusted  $R^2$  values for the three linear regression models applied to predict Reddit comments and Wikipedia page views ( $P < .001$ ).

Country	Model I		Model II		Model III	
	Reddit comments	Wikipedia page views	Reddit comments	Wikipedia page views	Reddit comments	Wikipedia page views
Italy	0.52	0.65	0.68	0.73	<i>0.82<sup>a</sup></i>	<i>0.79</i>
United Kingdom	0.27	0.27	0.72	0.74	<i>0.82</i>	<i>0.85</i>
United States	0.42	0.35	0.82	0.74	<i>0.89</i>	<i>0.82</i>
Canada	0.35	0.23	0.83	0.71	<i>0.90</i>	<i>0.82</i>

<sup>a</sup>Italics indicate the superior performance of Model III.

More formally, we compared Model I to Model III using the Cox test [77] for nonnested models, and we compared Model II to Model III using the  $F$  test [78] for nested models. In all cases we obtained  $P$  values  $<.001$ , providing strong statistical evidence that Model III actually outperforms the other models. Not surprisingly, the coefficients of the “memory effects” term reported in Table 3 are negative for all countries. This implies

that public attention actually saturates in response to news exposure and enables us to quantify the rate at which this phenomenon occurs.

In the next section, we will characterize the media coverage and internet users’ response more specifically in terms of content produced and consumed.

**Table 3.** Coefficient estimates (95% CI) for Model III (news plus memory effects). All coefficients are significant with  $P<.001$ .

Country	News		News plus memory effects	
	Reddit comments	Wikipedia page views	Reddit comments	Wikipedia page views
Italy	0.87 (0.60 to 1.14)	0.43 (0.29 to 0.58)	−0.41 (−0.59 to −0.23)	−0.15 (−0.26 to −0.04)
United Kingdom	0.95 (0.62 to 1.27)	0.99 (0.68 to 1.30)	−0.44 (−0.71 to −0.18)	−0.47 (−0.70 to −0.23)
United States	1.03 (0.79 to 1.27)	0.83 (0.58 to 1.09)	−0.51 (−0.77 to −0.24)	−0.46 (−0.73 to −0.19)
Canada	1.12 (0.89 to 1.36)	1.06 (0.67 to 1.44)	−0.40 (−0.59 to −0.22)	−0.45 (−0.72 to −0.18)

### Dynamics of Content Production and Consumption

While collective attention and media coverage are well correlated in terms of volume, the content and topics discussed by media and consumed by internet users may not be as synchronized [79,80]. To shed light on this issue, we adopted an unsupervised topic modeling approach to extract prevalent topics in the news articles mentioned and discussed on Reddit. Indeed, users on Reddit often post submissions containing news articles, and discussion unfolds in the comments under the submissions. Differently from the previous section and to provide a comprehensive overview of the topics discussed, in this section, we do not take any geographical context into account. However, in Multimedia Appendix 1, we provide some additional insights into the specific topics discussed by users in different countries.

We characterized the main topics discussed on Reddit by considering all submissions that included a news article in English. We then applied a topic modelling approach to the content of this news article set. Specifically, we extracted topics using NMF [67], a popular method for this type of task. In this way, we extracted the 64 most relevant topics in the news articles shared on Reddit. As a second step, we applied the model trained on the Reddit news to the set of articles published

by mainstream media. That is, we characterized the news published by media outlets in terms of the topics discussed on Reddit. This choice enabled us to directly compare the topics covered by the media to the public discussion around this news exposure. A complete list of the 64 topics extracted with the most frequent words is provided in Multimedia Appendix 1. We considered the number of articles published on a certain topic as a proxy of general interest of traditional media in that topic; meanwhile, we measured the collective interest of Reddit users by the number of comments under the news articles on a specific topic. Figure 3 shows an overview of the topics extracted and a comparison of the interest of media and Reddit users. We obtained a diverse and heterogeneous set of topics, including the global spread of the virus (Outbreaks, WHO [World Health Organization], CDC [US Centers for Disease Control and Prevention]); COVID-19 symptoms, treatment, hospitals and care facilities (Symptoms, Medical Treatment, Medical Staff, Care Facilities); the economic impact of the pandemic and responses from the governments to the upcoming crisis (Economy, Money); different societal aspects (Sports, Religious Services, Education); and possible interventions to mitigate the spread of the virus (Face Masks, Social Distancing, Tests, Vaccine).

**Figure 3.** Differences in interest percentage shares of different topics by traditional media outlets and Reddit users. For example, +2% on the x-axis indicates that traditional media dedicates proportionally 2% more attention to that specific topic than Reddit users. CDC: US Centers for Disease Control and Prevention; UK: United Kingdom; WHO: World Health Organization.

Overall, the levels of attention of traditional media outlets and Reddit users toward the different topics are in good accordance. Indeed, in Figure 3, we represent the difference between interest shares toward different topics in media and Reddit submissions. That is, we computed the percentage share of attention dedicated by news outlets and Reddit users to each topic, and we subtracted these two quantities. We observed a maximum absolute mismatch in interest share of 2.61%. However, we observed that Reddit users are slightly more interested in topics regarding health (Symptoms, Medical Treatment), nonpharmaceutical interventions and personal protective equipment (Social Distancing, Face Masks), studies and information on the epidemic (Research, Surveys, Santa Clara Study, CDC), and specific public figures such as Anthony Fauci. Interestingly, the Santa Clara Study topic refers to the discussion

about a controversial scientific paper suggesting that a much higher fraction of the population in Santa Clara County was infected with respect to what was originally thought [81]. Because the study suggested a lower mortality rate, the preprint was quickly leveraged to support protest against lockdowns [82]; meanwhile, substantial flaws have been detected in the scientific methodology of the paper [83].

The overview of topics presented here does not take temporal dynamics of interest into account. However, topics showing similar overall statistics may present a mismatch in temporal patterns. Hence, in the following, we take into account the temporal evolution of interest toward different topics. In Figure 4, we represent each topic as a single point: the x-coordinate and y-coordinate indicate the  $t_{1/2}$  when the topic reached 50% of its total relevance  $R$  in news outlets and on Reddit,

respectively, during the analysis interval. Therefore, topics in the bottom left region became relevant very early in the public discussion. Among these, we recognize themes centered on early COVID-19 outbreaks (ie, Chinese, Japanese, Iranian, and Italian outbreaks), events related to cruise ships, specific countries (ie, Israel, Singapore, and Malaysia), and topics regarding (early) health issues (ie, Symptoms, Confirmed Cases, and CDC). In contrast, topics in the top right region became relevant toward the end of the analysis interval (early May).

Reasonably, this region contains topics about the resumption of activities after lockdown (ie, Reopening), the feasibility and timing of a possible vaccine against SARS-CoV-2 (ie, Vaccine), and discussions regarding acquired immunity and antibody tests (ie, Immunity). All other topics are clustered around the end of March and mid-April 2020, which is the period in which the general discussion surrounding the COVID-19 pandemic increased sharply, as also shown in Figure 1.

**Figure 4.** Scatter plot with the 64 topics extracted via nonnegative matrix factorization. The x-axis and y-axis coordinates indicate when a topic achieved 50% of its relevance in news outlets and on Reddit, respectively, during our analysis interval. CDC: US Centers for Disease Control and Prevention.

Note that the diagonal in Figure 4 (plotted as a dashed line) separates topics according to their temporal evolution. Above and below the diagonal, we find topics in which interest on Reddit grows slowly and quickly, respectively, with respect to the media coverage. Therefore, above the diagonal, the interest of Reddit users is mainly triggered by media exposure, while below it, the interest grows faster and declines rapidly despite sustained media exposure. The top left and bottom right regions are empty, indicating that as a first approximation, temporal patterns of attention by traditional media and Reddit users are well synchronized; however, interesting deviations from the diagonal are observable. For example, above the diagonal, one can mainly find topics related to various outbreaks, economics,

and politics, for which the interest on Reddit follows the media coverage. Below the diagonal, we observe topics more related to everyday life, such as Schools, Medical Staff, Care Facilities, and Lockdown, for which the attention on Reddit accelerates with respect to media coverage and then declines rapidly. Note that our view of the topics discussed on Reddit is limited, as we only considered topics from news articles shared in submissions and did not explicitly take content expressed in comments into account. This ensures a proper comparison with the topics extracted from published news reports and explains the absence of points in the bottom right corner of Figure 4.

## Discussion

### Principal Results

In this work, we characterized the response of internet users to both media coverage and COVID-19 pandemic progression. As a first step, we focused on the impact of media coverage on collective attention in different countries, characterized as volumes of country-specific Wikipedia page views and comments of geolocalized Reddit users. We showed that collective attention was mainly driven by media coverage rather than epidemic progression, rapidly became saturated, and decreased despite media coverage and COVID-19 incidence remaining high. These results are in very good accordance with findings obtained in previous contexts related to epidemics and pandemics. Indeed, a similar media-driven spiky unfolding of public attention, measured through the information-seeking and public discussions of internet users, was observed during the 2009 H1N1 influenza pandemic [84,85], the 2016 Zika virus outbreak [86], influenza season [87], and more localized public health emergencies such as the 2013 measles outbreak in the Netherlands [88]. Our findings confirm the central role of the media, showing how media exposure is capable of shaping and driving collective attention during a national and global health emergency. Media exposure is another important factor that can influence individual risk perception as well [79,89-91]. The timing and framing of the information disseminated by media can actually modulate the attention and, ultimately, the behavior of individuals [2]. This becomes an even greater concern in a context where the most effective strategy to fight the spread of disease involves containment measures based on individuals' behavior.

Also, we showed how media coverage sharply shifted to the domestic situation as soon as the first death was confirmed in the home country. Arguably, this may have played an important role in individual risk perception. We can speculate that reframing the emergency within a national dimension can amplify the perceived susceptibility of individuals [92,93] and thus increase the adoption of behavioral changes [4,94]. Indeed, previous studies showed that at the beginning of February 2020, people were overly optimistic regarding the risks associated with the new virus circulating in Asia, and their perception sharply changed after the first cases were confirmed in their countries [9,95].

As a second step, we focused on the dynamics of content production and consumption. We modeled topics published in mainstream media and discussed on Reddit, showing that Reddit users were generally more interested in health, data regarding the new disease, and interventions needed to halt the spreading with respect to media exposure. By taking into account the dynamics of the extracted topics, we showed that while their temporal patterns are generally synchronized, the public attention to topics related to politics and economics is mainly triggered by media exposure, while the interest in topics more related to daily life increases on Reddit with respect to media coverage.

### Limitations

Of course, our research comes with limitations. First, we characterized the exposure of individuals to the COVID-19 pandemic by considering only news articles and YouTube videos published on the internet by major news outlets. However, individuals are also exposed to relevant information through other channels, with television being the most important [96]. Second, a 2013 Pew Internet Study found that Reddit users are more likely to be young men [97]; it was shown that around 15% of male internet users aged 18 to 29 years report using Reddit, compared to 5% of women in the same age range and 8% of men aged 30 to 49 years. Similarly, informal surveys proposed to users [98] showed that most respondents were males in their "late teens to mid-20s" and that female users were "very much in the minority." Furthermore, Reddit is much more popular among urban and suburban residents than among individuals living in rural areas [97]. In addition to sociodemographic biases, other studies have suggested that Reddit has become an increasingly self-referential community, reinforcing the tendency to focus on its own contents rather than external sources [99]. Thus, the perceptions, interests, and behaviors of Reddit users may differ from those of the general population. A similar argument can be raised for Wikipedia searches. Indeed, the use of the internet, especially for information-seeking purposes, can vary across people with different sociodemographic backgrounds [100-102]. Additionally, we extracted Reddit users' geographic location using a method based on regular expressions that has been successfully used in previous work [50]. However, because we have no ground truth data for comparison, we must consider the quality of location detection to be a possible limitation. Finally, our view on internet users' reactions is partial. Indeed, we did not consider other popular digital data sources, such as Twitter. The reasons for this choice are twofold. First, many studies have already characterized public response during current and past health emergencies through the lens of Twitter [25,58,60,85,86,103,104]. Second, several studies have reported a high prevalence of bots as drivers of low-quality information and discussions on COVID-19 on this platform [24,25,105-107]. Thus, careful and challenging additional steps would be necessary to isolate, identify, and distinguish organic Twitter discussions and reactions that originated from traditional media from those sparked by social bots. We leave this for future work.

### Conclusions

Our work offers further insights to interpret public response to the current global health emergency and raises questions about possible undesired effects of communication. On one hand, our results confirm the pivotal role of media during health emergencies, showing how collective attention is mainly driven by media coverage. Therefore, because people are highly reactive to the news they are exposed to at the beginning of an outbreak, the quality and type of information provided may have critical effects on risk perception and behaviors, which will ultimately affect the unfolding of the outbreak. However, we also found that collective internet attention saturates and declines rapidly, even when media exposure and disease circulation remain high. Attention saturation has the potential to affect collective awareness and perceived risk, which

ultimately affects the propensity toward virtuous individual behavioral changes aimed at mitigating the spread of disease. Furthermore, especially in the case of unknown viruses, attention saturation may exacerbate the spreading of low-quality information, which is likely to spread in the early phases of the outbreak when the characteristics of the disease are uncertain. Future work is needed to characterize the actual effects of attention saturation on human perceptions during a global health emergency. Our findings suggest that public health authorities should consider reinforcing specific communication channels, such as social media platforms, to compensate for the natural phenomenon of attention saturation. Indeed, these channels have the potential to create more durable engagement with people through a continuous loop of direct interactions. Currently, public health authorities are regularly issuing declarations on social media. However, the CDC did not even

have a Twitter account in 2009 during the H1N1 pandemic (the account was created in May 2010). While this is just one example, it underlines that the communication of these global health emergencies through social media platforms is relatively new. Therefore, there is great need to further reinforce these channels and engage people through them. Simultaneously, public health authorities should consider strengthening additional communication channels. One example of this is the participatory surveillance platforms that are appearing worldwide, such as Influenzanet, Flu Near You, and FluTracking [108-110], which can deliver in-depth targeted information to individuals during public health emergencies and promote the exchange of information between people and public health authorities; this has potential to enhance the level of engagement in the community [111].

## Acknowledgments

The authors would like to thank the startup company Quick Algorithm for providing the platform where the data collected during the COVID-19 pandemic were visualized in real time [112]. DP and MT acknowledge support from the Lagrange Project of the Institute for Scientific Interchange Foundation (ISI Foundation) funded by Fondazione Cassa di Risparmio di Torino (Fondazione CRT). MT acknowledges support from EPIPOSE (Epidemic intelligence to minimize COVID-19's public health, societal and economic impact) H2020-SC1-PHE-CORONAVIRUS-2020 call. MS and AP acknowledge support from the Research Project "Casa Nel Parco" (POR FESR 14/20 - CANP - Cod. 320 - 16 - Piattaforma Tecnologica "Salute e Benessere") funded by Regione Piemonte in the context of the Regional Platform on Health and Wellbeing. AP acknowledges partial support from Intesa Sanpaolo Innovation Center. The funders had no role in the study design, data collection and analysis, decision to publish, or preparation of the manuscript. NG acknowledges support from the Doctoral Training Alliance.

## Authors' Contributions

NG, MS, DP, AP, and NP conceptualized the study. NG, NP, AP, and MT collected the data. NG, AP, and FC performed analyses. NG, MS, and NP wrote the initial draft of the manuscript. NG and AP provided visualization. All authors (NG, NP, DP, MS, AP, MT, and FC) discussed the research design, reviewed, edited, and approved the manuscript.

## Abstract

**Background:** The death of George Floyd while in police custody has resurfaced serious questions about police conduct that result in the deaths of unarmed persons.

**Objective:** Data-driven strategies that identify and prioritize the public's needs may engender a public health response to improve policing. We assessed how internet searches indicative of interest in police reform changed after Mr Floyd's death.

**Methods:** We monitored daily Google searches (per 10 million total searches) that included the terms "police" and "reform(s)" (eg, "reform the police," "best police reforms," etc) originating from the United States between January 1, 2010, through July 5, 2020. We also monitored searches containing the term "police" with "training," "union(s)," "militarization," or "immunity" as markers of interest in the corresponding reform topics.

**Results:** The 41 days following Mr Floyd's death corresponded with the greatest number of police "reform(s)" searches ever recorded, with 1,350,000 total searches nationally. Searches increased significantly in all 50 states and Washington DC. By reform topic, nationally there were 1,220,000 total searches for "police" and "union(s)"; 820,000 for "training"; 360,000 for "immunity"; and 72,000 for "militarization." In terms of searches for all policy topics by state, 33 states searched the most for "training," 16 for "union(s)," and 2 for "immunity." States typically in the southeast had fewer queries related to any police reform topic than other states. States that had a greater percentage of votes for President Donald Trump during the 2016 election searched more often for police "union(s)" while states favoring Secretary Hillary Clinton searched more for police "training."

**Conclusions:** The United States is at a historical juncture, with record interest in topics related to police reform with variability in search terms across states. Policy makers can respond to searches by considering the policies their constituencies are searching for online, notably police training and unions. Public health leaders can respond by engaging in the subject of policing and advocating for evidence-based policy reforms.

policing; digital health; bioinformatics; public health; public interest; data mining; internet; search; trend; Google Trends

## Introduction

The death of George Floyd at the hands of police has resurfaced serious questions about police conduct in the United States that

has resulted in 1001 deaths of unarmed persons from 2013 through 2019 [1]. Despite widespread protests, public interest in police reform following George Floyd's death has not been quantified.

Data-driven strategies that identify and prioritize the needs of the public may engender a public health response to improve policing [2,3]. We argue tracking changes in aggregate internet searches is one such strategy, where the content of searches reflects the thoughts and behaviors of the public, the volume of searches reflect their priority, and the location of the search reflects the community [4-6]. This strategy has informed rapid public health responses across many domains, including responses to demand for unproven therapies during the COVID-19 pandemic [7], demand for HIV testing following Charlie Sheen's public HIV+ disclosure [8], interest in sexual harassment prevention and training following the #MeToo movement [9], and increased suicidal ideation during the initial airing of Netflix's 13 Reasons Why drama [10], to name a few. Moreover, once traditional data became available—in some cases years later—these example findings were confirmed [11,12], underscoring the validity of mining search histories. Similarly, public health leaders can survey internet search trends to rapidly detect public interest in and priorities for police reform.

Herein, we assess public interest in police reforms by mining aggregate internet searches and discovering the types of reforms being searched for by the public, both on the national and US state level (including Washington DC). Such reforms include police training, police unions, police militarization, and the qualified immunity doctrine that reduces the liability police officers face for potential misconduct [13]. To translate these trends into potential policy making, we quantified the police reforms most searched for by each state (including DC) and how each state's political culture reflected by results from the 2016 presidential election explained differences in searches.

## Methods

We monitored the fraction of daily Google searches (per 10 million searches) that included the terms “police” and “reform(s)” originating from the United States between January 1, 2010, through July 5, 2020. This strategy would capture “reform the police,” “best police reforms,” etc as markers for general interest in policing reforms. We also monitored searches containing the term “police” with “training,” “union(s),” “militarization,” or “immunity.” These searches were selected because they have been frequently cited by experts as avenues for reforms [14-16], and represent public prioritization of specific policing reform topics. Search rates were monitored both at the national and state (including DC) level.

### Quantifying the Impact of Mr Floyd's Death

Using historical search rates for each outcome (“police,” “reform[s],” “training,” “union[s],” “militarization,” or “immunity”), we forecasted a counterfactual scenario of expected search rates had Mr Floyd's death not occurred on May 25, 2020. The expected search rates were forecasted using an autoregressive integrated moving average (ARIMA) model,

selected by Hyndman and Khandakar's algorithm [17], fit to the historical search rates using all available data January 1, 2010, through May 24, 2020. The forecasted search rates were compared to observed search rates from May 25, 2020, through July 5, 2020, including computing the ratio of observed and expected search rates with bootstrap confidence intervals by day and cumulatively for the entire post period.

### Do Search Rates for Specific Police Reform Topics Differ Across States?

First, to assess which states had the greatest number of searches for any policy topic, we estimated the cumulative search rates by state for each policy topic, by summing the fraction of searches per 10 million for the entire post period (May 25, 2020, through July 5, 2020) and ranking states accordingly. Second, to identify which specific policy topics had the greater interest within each state, we estimated each state's total searches for any reform topic, by scaling the cumulative search volumes for each specific policy topic by the total cumulative search volume for all policy topics and ranking states accordingly. For each search query outcome, we contrasted any single state with the mean for all states and compared any two single or group of states by these percentages.

### Does Political Culture Impact Searches for Police Reform Policy Topics?

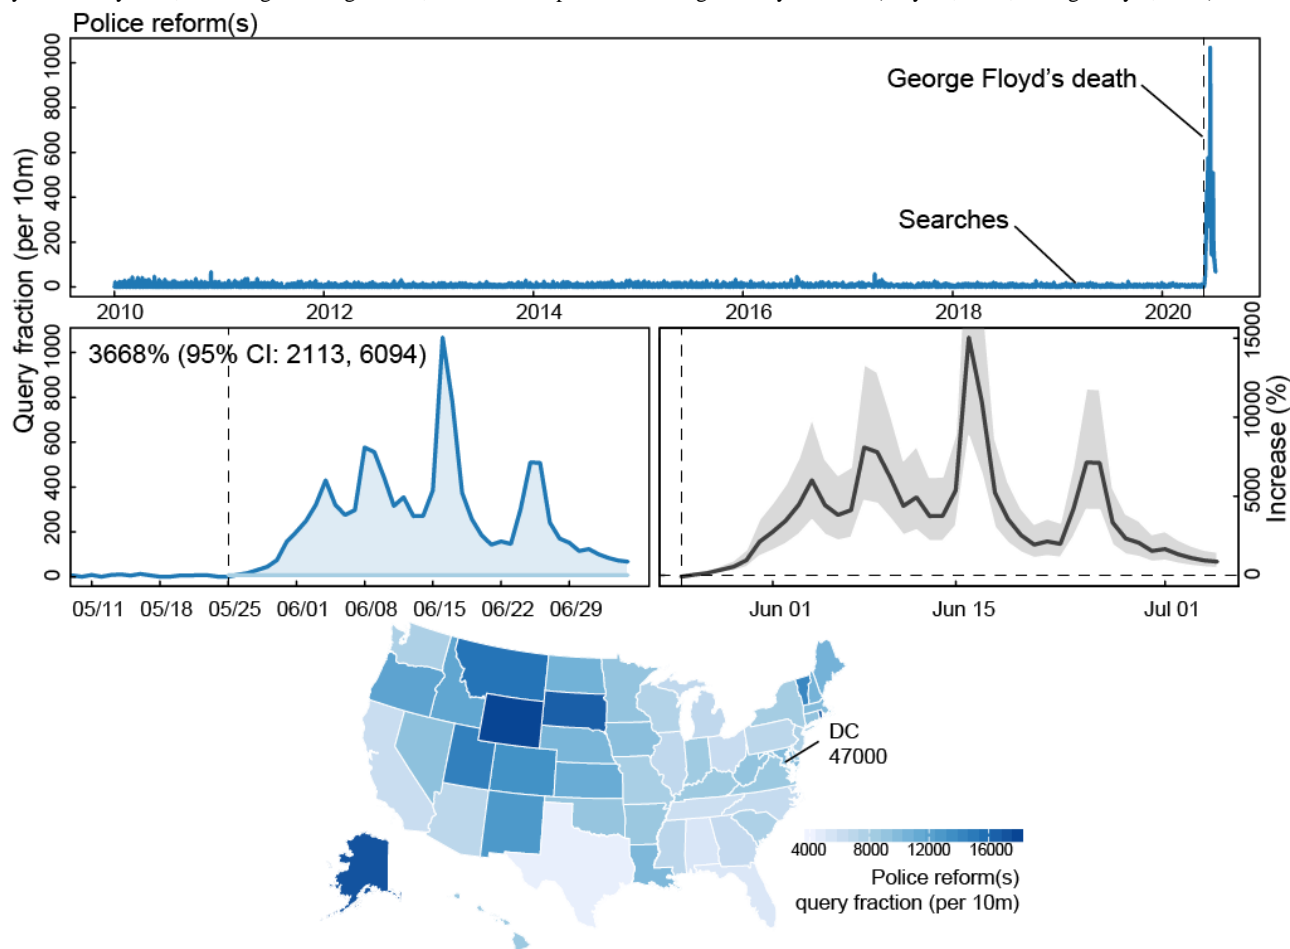

Given the political implications in policy making, we evaluated how political culture impacted searches for specific policy topics, by comparing cumulative search rates by state for each policy topic against their percent vote share for President Donald Trump during the 2016 election. While crude, the presidential percent vote share is often used as an indicator of the political culture of states, reflecting the strength of support or opposition to conservative or liberal policies [18]. For each, we estimated the breakdown of searches for police reform policy topics by states voting for Hillary Clinton or Donald Trump to evaluate any absolute relationships. Secondarily, we evaluated how more support of Trump predicts searches for police reform policy topics by plotting states by their search volume post Mr Floyd's death and percent vote share for Trump, and estimated the best fitting line including the slope of this line. All analyses were performed using R, version 3.5.1 (The R Project for Statistical Computing).

## Results

### Internet Searches for Police “Reform(s)”

The 41 days following Mr Floyd's death corresponded with the greatest number of police “reform(s)” searches ever recorded, with the highest daily fraction of all searches for “reform(s)” eclipsing the past high by over 150-fold (Figure 1). In absolute terms, this translated into about 1,350,000 total searches for police “reform(s).”

**Figure 1.** Internet searches for “police” and “reform(s)” following the death of George Floyd. Queries included all searches with the terms “police” and “reform(s).” Top panel shows the historic trends of reform searches in comparison to after Mr Floyd’s death. Middle panels show the percent increases in searches after Mr Floyd’s death (vertical dashed line is the day of the killing, May 25, 2020), and the bottom map shows the cumulative query fraction by state, including Washington DC, for the entire period following Mr Floyd’s death (May 25, 2020, through July 5, 2020).

Police “reform(s)” search rates cumulatively increased 3668% (95% CI 2113-6094) above expected levels and began increasing on May 25 with queries first eclipsing the past all-time high 5 days later (May 30) and ultimately setting the new record on June 16. During this time, local protests erupted (May 26), police officer Derek Chauvin was charged with third-degree murder and second-degree manslaughter over Mr Floyd’s death (May 29), protests went national (May 31), Mr Floyd’s brother testified at a House Judiciary Committee (June 10), Mr Rayshard Brooks’ death was recorded by video while struggling with police (June 12), and protests reached their peak (June 14) [19]. While queries declined, they remained significantly above expected levels through the last day of observation (July 5).

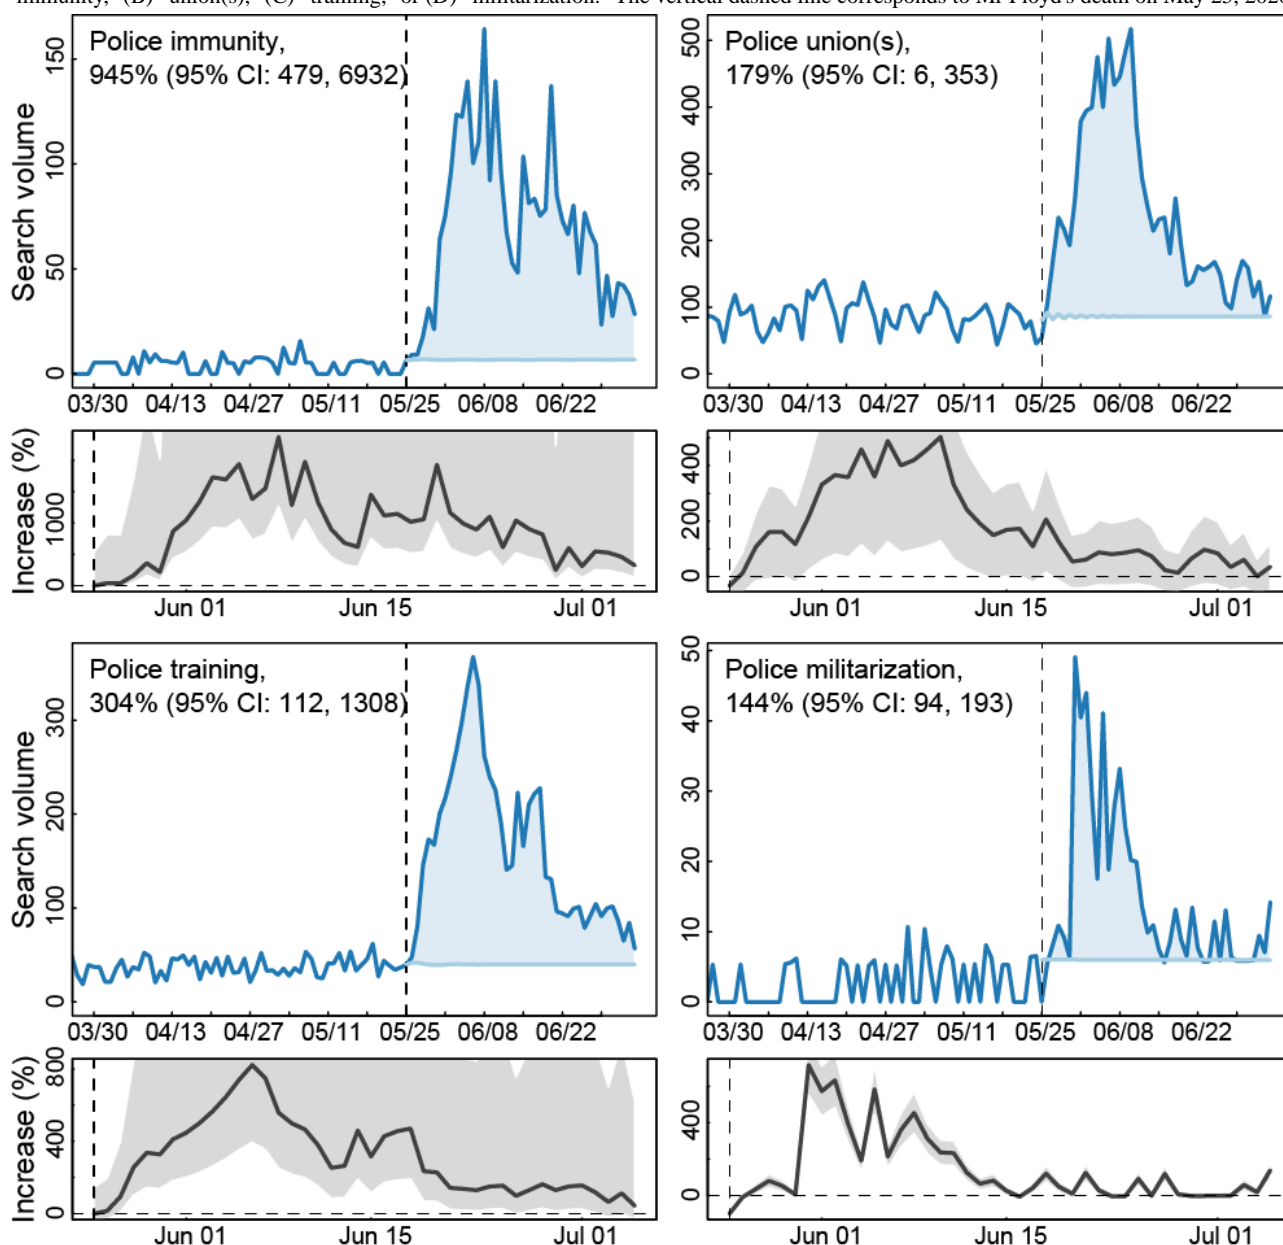

All states and Washington DC had statistically significant increases in search rates for police “reform(s).” By total volume, DC led all states with a total query fraction [QF] of 7300 per 10 million searches during the entire period after Mr Floyd’s death, more than 4.2-fold greater than the average for the states.

DC was followed by Alaska (QF=2760, 1.7-fold higher), Vermont (QF=2670, 1.65-fold higher), and Delaware (QF=2640, 1.64-fold higher). The states with the lowest cumulative search rates included Arkansas (QF=783, 55% below the mean), Maine (QF=1011, 41% below the mean), Kentucky (QF=1040, 40% below the mean), and Louisiana (1160, 33% below the mean).

### Internet Searches for Specific Police Reform Topics

Searches for specific reform topics also set new national benchmarks (Figure 2). Searches for “police” and “union(s)” eclipsed the past all-time highs by 4.5-fold, “training” by 4.8-fold, “immunity” by 53-fold, and “militarization” by 34-fold. Statistically, police “immunity” search rates were cumulatively 945% (95% CI 480-6932) higher than expected during the entire post period, followed by “training” (305%; 95% CI 112-1307), “union(s)” (179%; 95% CI 5.8-353), and “militarization” (144%; 95% CI 94-193). This translates into about 1,220,000 total searches for “union(s),” 820,000 for “training,” 360,000 for “immunity,” and 72,000 for “militarization.”

**Figure 2.** Internet searches for specific police reforms following the death of George Floyd. Queries included all searches with the terms “police” and (A) “immunity,” (B) “union(s),” (C) “training,” or (D) “militarization.” The vertical dashed line corresponds to Mr Floyd’s death on May 25, 2020.

By state, all states including DC had statistically significant increases in searches for specific reform topics after the killing of Mr Floyd, including police “union(s)” (led by Maine, Rhode Island, Wyoming, and West Virginia), “training” (led by Pennsylvania, DC, Minnesota, and Delaware), “immunity” (led by DC, North Dakota, New Mexico, and New Hampshire), and “militarization” (led by DC, New Hampshire, Nevada, and Colorado) (Figure 3). Search rates were somewhat correlated

by state across categories (overall intraclass correlation coefficient=0.31) and the 5 states with the lowest mean search rate across all outcomes after Mr Floyd’s death were Mississippi, Alabama, Tennessee, Texas, and Arkansas (southern states), and 72% (95% CI 64-84) lower than the 5 states with the highest search rate (DC, Pennsylvania, Minnesota, Maine, and Delaware).

**Figure 3.** Internet searches for specific police reforms following the death of George Floyd, by US state (including Washington DC). Queries included all searches with the terms “police” and (A) “immunity,” (B) “union(s),” (C) “training,” or (D) “militarization.” The value presented is the cumulative query fraction of searches for the focal terms relative to all searches per 10 million for the period after Mr Floyd’s death (May 25, 2020, through July 5, 2020). States are ordered by cumulative query fraction for “training.”

Within states, there were typically more searches for police “training” than any other reform topic, followed by police “union(s),” police “immunity,” and police “militarization” (Figure 4). Still, informative differences emerged in how states favored searching for one specific reform topic over another. In total, 33 states searched more often for police “training” than any other policy, including Alaska, Pennsylvania, Minnesota,

and New Jersey, averaging 76% of the total search volume for all 4 reform search topics. In 16 states, police “union(s)” was searched more often than any other topic, including Wyoming, Mississippi, South Dakota, and West Virginia, averaging 66%. Only 2 states searched more for police “immunity” (North Dakota and New Mexico), and no states showed increased searches for police “militarization” compared to all other topics.

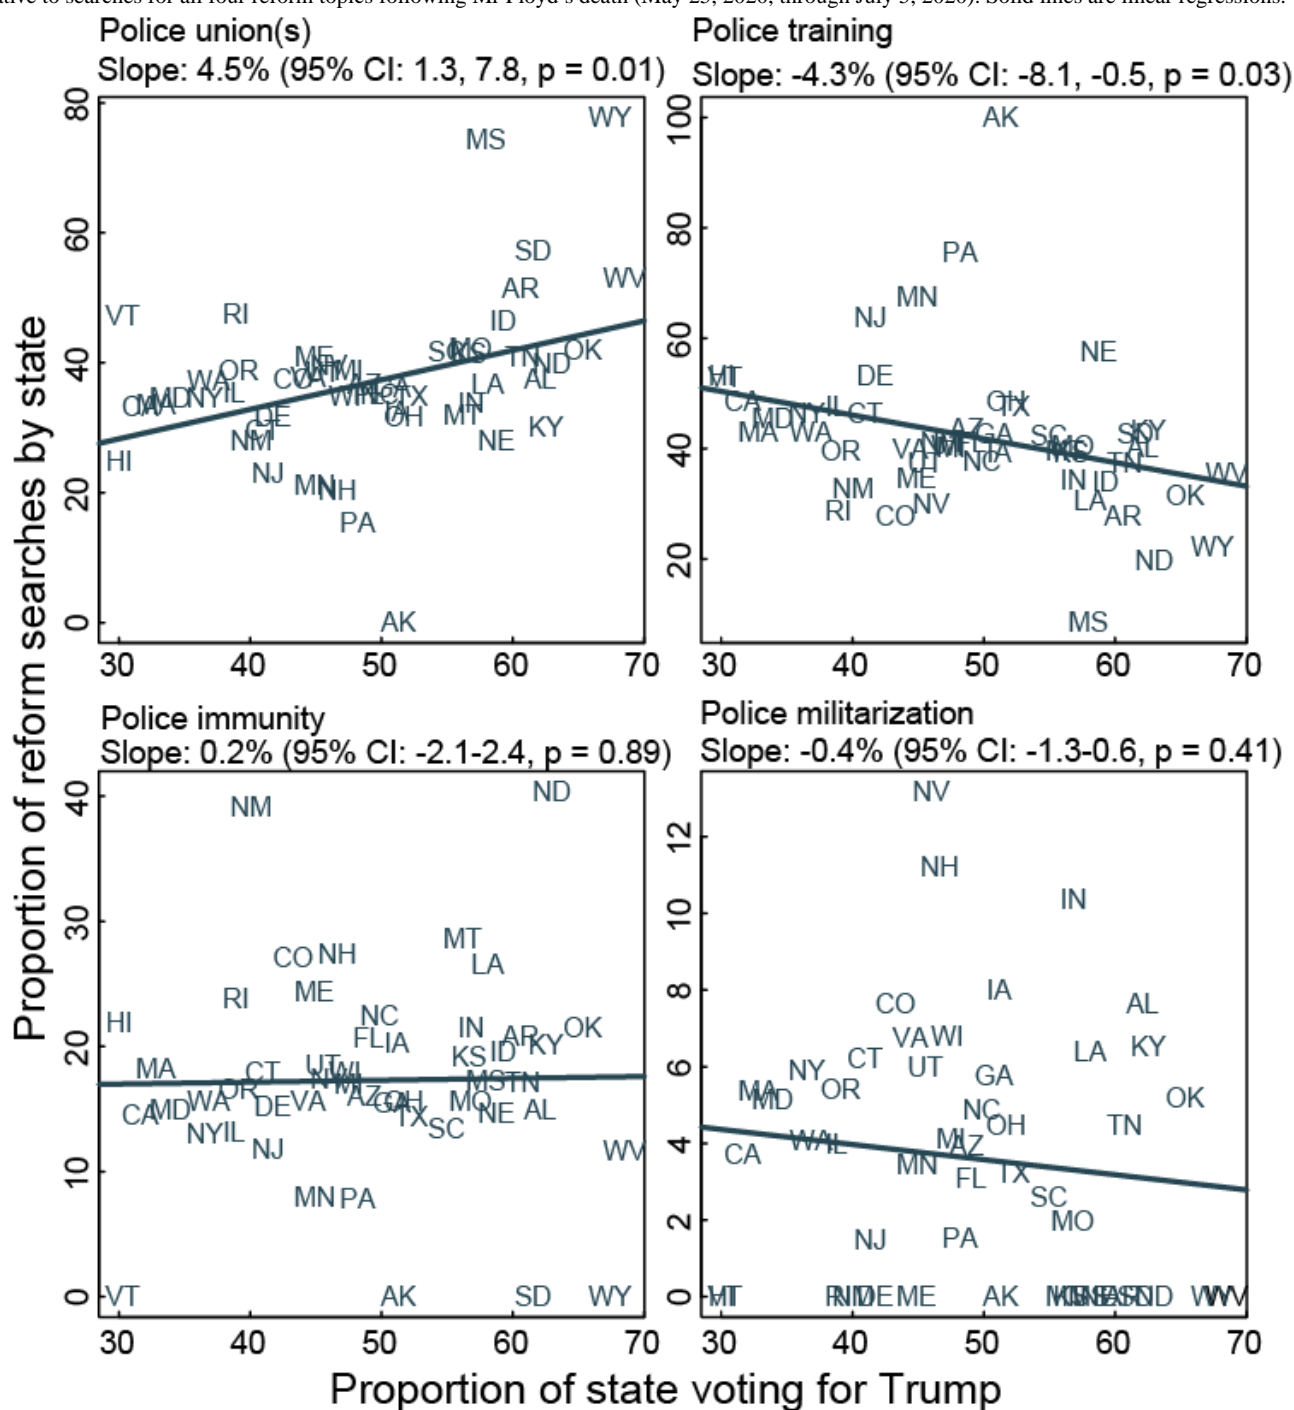

**Figure 4.** Internet searches for specific police reforms following the death of George Floyd, by US state (including Washington DC). Queries included all searches with the terms “police” and (A) “immunity,” (B) “union(s),” (C) “training,” or (D) “militarization,” normalized to the total volume of searches for all four topics by state following Mr Floyd’s death (May 25, 2020, through July 5, 2020). For instance, 37% for police “union(s)” in Alaska means that 37% of searches for “union(s),” “immunity,” “training,” and “militarization” combined were for “union(s).” States are ordered alphabetically.

Of the states won by President Trump during the 2016 presidential election, 57% searched more for police “union(s),” while 81% of states won by Secretary Clinton searched more for “training.” Increased vote share for Trump predicted a dose-response relationship with searches for police “union(s)” or “training” (Figure 5). A 10% increase in vote share for Trump predicted a 4.5% (95% CI 1.3-7.8) increase in cumulative

searches for police “union(s)” following Mr Floyd’s death. A similar increase in Trump vote share predicted a 4.3% (95% CI –8.1 to –0.5) decrease in cumulative searches for police “training.” Regardless of a vote preference for Trump or Clinton, states were no more or less likely to search more for police and “immunity” or “militarization” both absolutely and for a marginal change in vote share for Trump.

**Figure 5.** Internet searches for specific police reforms and electoral support for President Donald Trump. Figure shows the proportion of a state voting for Trump in the 2016 election against the proportion of searches for “police” and (A) “immunity,” (B) “union(s),” (C) “training,” or (D) “militarization,” relative to searches for all four reform topics following Mr Floyd’s death (May 25, 2020, through July 5, 2020). Solid lines are linear regressions.

## Discussion

The United States is at an acute historical juncture with record demand for police reforms sweeping the entire nation. Our results quantify the increasing public interest in police reforms, led by an interest in reforming police training followed by unions, immunity, and militarization nationally. In some states, there is a greater interest in reforming unions or immunity doctrines.

Determining what aspects of police reform to prioritize based on public interest is a challenging problem for elected officials.

We argue that monitoring the search queries of a population might clarify the needs and desires of a constituency in real time, especially when little other data is available. The increase in searches related to police reform indicates that the public is actively interested in police reforms, while searches for specific reform topics indicate a desire for leaders to explore these topics. Indeed, many of the reform topics searched for are backed by strong evidence. Restrictions on police unions that potentially advocate for the status quo and hinder reforms and curtailing police immunity that limit criminal and civil liability for police are both effective [20]. On the other hand, some reforms that may be inclusive of searches for “training” are more complex.

For example, reforms that implement training on procedural justice or the use of force is associated with less police violence [14], but racial sensitivity and implicit bias training are not associated with less police violence [21,22], even though unarmed Black individuals are more likely to be shot than unarmed White individuals [23]. In these cases, a search for training can serve as the basis for leaders to educate the public and seek additional feedback.

The latter raises a serious limitation of our approach; we cannot link search behavior to a policy preference or identify from whom queries originated. Regardless, searches can predict policy priorities on similar public safety issues, and they overcome many of the limitations that often delay traditional data gathering until the point that the data are no longer actionable [24,25]. Moreover, our focus is restricted to a few reform topics. Additional reform topics, such as body cameras (which have mixed empirical effect) [26] or limiting police funding (with unknown impacts and unanticipated effects) [27] can be studied using our approach. It is important that legislative leaders and policy makers listen to the voices of millions of constituents anonymously searching for solutions and consider policies inclusive of their reform interests as a starting point. Notably, the most high-profile police reform entitled “The Justice Act” proposed by Senator Tim Scott addressed training but did not address police unions, immunity, or militarization. Perhaps amendments to this proposed legislation might consider reforms targeting police unions, given that even in Mr Scott’s home state of South Carolina there were more searches related to police unions than training. Since most policy making occurs among states, decision makers there can rely on our results to identify policies that align with the interests of the public they serve. For instance, in North Dakota or New Mexico, policy makers might consider reforms to police immunity since that reform topic was searched more often than other topics. Extending our work to metropolitan areas can likewise inform more local responses.

While both the American Medical Association [28] and the American Public Health Association [29] have spoken out on police violence, the latter calling it a “public health crisis,” health researchers have done little to advance evidence-based police reforms. As of our writing, only 7 studies on PubMed

mention “police” and “misconduct” [30] and 10 mention “police” and “reform(s)” [31] in their title or abstract. This is not to say there is little scientific work on police reform (there is a tremendous literature [32–34]), but little of it has been conducted from a public health perspective or with the benefit of considering strategies popularized by other public health policy successes. For instance, public health advocates have achieved substantial policy reforms to curb deaths attributable to tobacco use [35,36].

Public health scientists, physicians, and other health professionals must do more. Research on policing is essential to public health practice and aligns with public health’s core mission: prevention. The health community has extensive experience studying relevant areas, including unintended medical errors and systematic bias, and can bring those insights to the topic of policing. Moreover, now is the time for health leaders to insist on evidence-based reforms and support science on police reforms that are responsive to the public’s needs.

One way to rapidly leverage science to inform policing is to turn to free and abundant big media data. Researchers could further mine internet search data to answer questions related to police practices. For instance, victims of nonfatal instances of police misconduct might search online for help and these digital tracings could be used to evaluate trends and the geographic distribution of misconduct in almost real time. A similar method is already in practice among health researchers who study drug or device adverse events [37,38] and HIV/AIDS, malaria, and tuberculosis in Africa [39]. Expanding the study of policing to other forms of big media data, including social media, online forums, and news media can similarly provide actionable insights.

Policy changes and public health research in police reform lags while public interest in policing reform is at an all-time high. Research that can help inform policies to improve policing should become a priority among the public health community, with our study serving as a demonstration and call to action. By offering to provide policy makers contemporary insights into policing reform topics their constituents have sought online, we hope that policy makers and elected officials will be inspired to act to prevent unnecessary deaths, like Mr Floyd’s.

## Acknowledgments

This work benefited from intramural support from the Division of Infectious Diseases and Global Public Health and the Center for Data Driven Health at the Qualcomm Institute, both with the University of California San Diego. This work is also supported by a grant from the National Institutes of Health (AI036214).

## Abstract

**Background:** Acne vulgaris is a common skin disease primarily affecting young adults. Given that the internet has become a major source of health information, especially among the young, the internet is a powerful tool of communication and has a significant influence on patients.

**Objective:** This study aimed to clarify the features of patients' interest in and evaluate the quality of information about acne vulgaris on the internet.

**Methods:** We compared the search volumes on acne vulgaris with those of other dermatological diseases using Google Trends from January 2004 to August 2019. We also determined the search volumes for relevant keywords of acne vulgaris on Google and Naver and evaluated the quality of answers to the queries in KnowledgeiN.

**Results:** The regression analysis of Google Trends data demonstrated that the patients' interest in acne vulgaris was higher than that for other dermatological diseases, such as atopic dermatitis ( $\beta=-20.33$ , 95% CI  $-22.27$  to  $-18.39$ ,  $P<.001$ ) and urticaria ( $\beta=-27.09$ , 95% CI  $-29.03$  to  $-25.15$ ,  $P<.001$ ) and has increased yearly ( $\beta=2.38$ , 95% CI  $2.05$  to  $2.71$ ,  $P<.001$ ). The search volume for acne vulgaris was significantly higher in the summer than in the spring ( $\beta=-5.04$ , 95% CI  $-9.21$  to  $-0.88$ ,  $P=.018$ ) and on weekends than on weekdays ( $\beta=-6.68$ , 95% CI  $-13.18$  to  $-0.18$ ,  $P=.044$ ). The most frequently searched relevant keywords with "acne vulgaris" and "cause" were "stress," "food," and "cosmetics." Among food, the 2 highest acne vulgaris-related keywords were milk and wheat in Naver and coffee and ramen in Google. The queries in Naver KnowledgeiN were mostly answered by a Korean traditional medicine doctor (53.4%) or the public (33.6%), but only 12.0% by dermatologists.

**Conclusions:** Physicians should be aware of patients' interest in and beliefs about acne vulgaris to provide the best patient education and care, both online and in the clinic.

## Introduction

### Background

The internet has spread widely since the 1980s and has become a powerful tool and route of communication. People increasingly use it to find information about health problems. According to the *Measuring the Information Society Report* from 2018 by the International Telecommunication Union, the internet usage rate in South Korea was 95.10% in 2018 [1]. According to 2018 internet usage statistics by the Ministry of Science and Information and Communications Technology of South Korea, the internet usage rate was 91.5% (46,124,694 persons), and the average daily internet usage time in South Korea was 2 hours 15 minutes [2]. As internet usage increases, the influence of the internet is also growing. According to the 2018 internet usage statistics by the Ministry of Science and Information and Communications Technology of South Korea, we use it for viewing movies, videos, and images (87.0%); shopping (62.0%); banking (63.7%); and communication through messengers (95.9%) [2]. In the face of the rapid expansion of smartphones, smartphones have made the internet more ubiquitous; we can get any information wherever we are, which contributes to the percentage of people using the mobile internet (90.4%) in 2018 in South Korea. In particular, young people actively use the internet to exchange their thoughts and get information, including medical and health care information. Among people aged in their 10s, 20s, and 30s, the ratios of people using the internet were 99.9%, 99.9%, and 99.9%, respectively, and those of people using the mobile internet were 98.7%, 99.9%, and 99.9%, respectively [2].

Acne vulgaris is a very common dermatological disease and the 8th most common disease worldwide; it is estimated to affect 633 million people globally [3,4]. It primarily affects young adults, mostly in their teens, 20s, and 30s [5]. Four mechanisms are considered important in the pathogenesis of acne vulgaris: (1) sebaceous hypersecretion, (2) hair follicle hyperkeratosis, (3) colonization of *Cutibacterium acnes*, and (4) inflammatory reactions [6]. External factors such as the environment are also known as important risk factors. Mechanical stimulation like friction, psychological stress [7], and excessive sweating have also been suggested as causes of acne vulgaris. Food is also a possible cause, but the relationship is still unclear, even though there are studies that show a relationship between acne vulgaris and food. The most commonly involved site of acne vulgaris is the face, followed by the neck, back, and chest. Clinically, various kinds of skin lesions are possible: comedon, papule, pustule, and nodule. Deep skin lesions can result in scars, and it is estimated that 95% of acne vulgaris patients have acne scars [8], which can induce serious psychosocial problems [4].

### Goal of This Study

Acne vulgaris is prevalent. It is observed in 80%-90% of adolescents and young adults, and it has high social interest because of its cosmetic sequelae and psychosocial problems. The purpose of this study was to clarify the features of patients' interest in and evaluate the quality of information about acne vulgaris on the internet. Therefore, we aimed to investigate public interest in acne vulgaris by assessing the search volume

of acne vulgaris-related keywords through the major search sites (Naver, Google) that are widely used in South Korea. In addition, we analyzed who answered questions about acne vulgaris on the internet and evaluated the answers posted on internet sites to investigate the accuracy of the information on the internet for public health.

## Methods

### Study Design

We used the search portal sites Naver and Google, which are among the most commonly used search sites in South Korea.

First, we compared the interest in acne vulgaris and other dermatological diseases by using Google Trends, a website that analyzes the popularity of top search queries in Google Search across various regions and languages. Google Trends provides a search volume index (0 to 100), which is the search volume relative to the total number of searches performed on Google. We compared the public interest in acne vulgaris to that of other dermatological disorders, such as atopic dermatitis or urticaria, as well as the yearly and seasonal trends in interest, using regression analysis of 15 years' worth of Google Trends data. From the regression analysis of Google Trends 90-day data, we looked at whether there is a difference between interest on weekends and on weekdays. To determine whether there is a correlation between Google Trends geographic data and personal income, private consumption, or composition of the population, we performed correlation analyses. Keywords used for the search were "acne vulgaris," "urticaria" (urticae or urtica were not included), and "atopic dermatitis" (atopic eczema was also included) in Korean.

Next, we compared search volumes using keywords for "acne vulgaris, treatment," "acne vulgaris, laser," "acne vulgaris, cause," "acne vulgaris, diet," and "acne vulgaris, cosmetics" in Korean in Google and Naver KnowledgeiN. We also sorted 500 answers by responders (dermatologist, general practitioner or specialist medical doctor, Korean medicine doctor, or general public) in Naver KnowledgeiN.

### Statistical Analysis

We used linear regression analysis to observe yearly trends and seasonal trends; correlation analysis to determine correlations between Google Trends geographic data and personal income, private consumption, or composition of population; and text mining to express the search volume of acne vulgaris-related keywords. The statistics program R 3.6.2 was used to analyze data, and  $P < .05$  was considered statistically significant.

## Results

### Acne Vulgaris is One of the Most Popular Dermatological Diseases on the Internet

The regression analysis of Google Trends data for 15 years demonstrated that patients' interest in acne vulgaris was higher than the interest in atopic dermatitis ( $\beta = -20.33$ , 95% CI  $-22.27$  to  $-18.39$ ,  $P < .001$ ) and urticaria ( $\beta = -27.09$ , 95% CI  $-29.03$  to  $-25.15$ ,  $P < .001$ ). Public interest in acne vulgaris has increased yearly ( $\beta = 2.38$ , 95% CI  $2.05$  to  $2.71$ ,  $P < .001$ ) and was higher

in summer than in spring ( $\beta=-5.04$ , 95% CI  $-9.21$  to  $-0.88$ ,  $P=.018$ ). But there was no significant difference between other seasons. For the temporal trends between weekends and

weekdays, the interest in acne vulgaris on weekends was higher than on weekdays ( $\beta=-6.68$ , 95% CI  $-13.18$  to  $-0.18$ ,  $P=.044$ ; Figure 1).

**Figure 1.** Temporal trends in searches for acne: (A) Google Trends time data (15 years). The search volume index (0 to 100) represents the search volumes relative to the total number of Google searches. (B) Google Trends time data (90 days). The horizontal bars indicate weekends.

### Seoul Has the Greatest Interest in Acne Vulgaris on the Internet Among Cities and Provinces

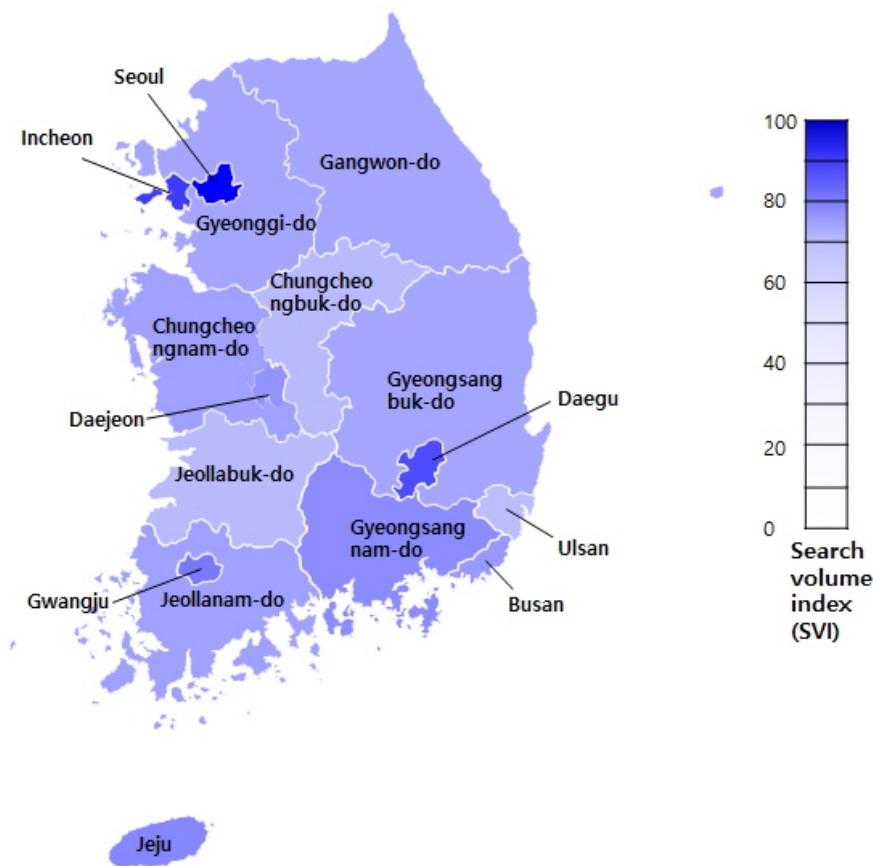

We also determined interest in acne vulgaris among cities and provinces through Google Trends geographic data. Seoul had the highest interest in acne vulgaris among cities and provinces, followed by Incheon and Daegu. Jeollabuk-do and

Chungcheongbuk-do had the lowest interest. There was no significant correlation between search volumes and personal income (correlation coefficient=0.30,  $P=.27$ ) or between search volumes and private consumption (correlation coefficient=0.37,  $P=.16$ ; Table 1; Figure 2). There was also no significant correlation between search volume and age (Table 2).

**Table 1.** Acne vulgaris search volume and personal income in cities and provinces.

Cities and provinces	Search volume	Personal income (annual, KRW)	Private consumption (annual, KRW)
Seoul	100	21,429,000	20,211,000
Incheon	91	17,550,000	14,486,000
Daegu	88	17,568,000	15,682,000
Gwangju	81	17,343,000	16,122,000
Jeju	79	17,464,000	15,107,000
Gyeongsangnam-do	78	16,864,000	14,735,000
Daejeon	77	18,454,000	16,286,000
Busan	76	18,332,000	16,208,000
Chungcheongnam-do	75	17,613,000	14,047,000
Jeollanam-do	75	15,938,000	14,112,000
Gyeonggi-do	74	18,580,000	15,786,000
Gyeongsangbuk-do	74	16,504,000	14,395,000
Gangwon-do	74	16,583,000	14,957,000
Ulsan	73	19,912,000	16,494,000
Jeollabuk-do	71	16,848,000	14,194,000
Chungcheongbuk-do	71	17,030,000	14,381,000

**Figure 2.** Regional trends in internet searches for acne.

**Table 2.** Acne vulgaris search volume and population composition in cities and provinces.

Cities and provinces	Search volume			Ratio of the population in the age range, %					
	2018	2017	2016	10s to 20s (2018)	10s (2018)	10s to 20s (2017)	10s (2017)	10s to 20s (2016)	10s (2016)
Seoul	100	100	89	23.60	8.76	23.76	9.08	23.94	9.41
Incheon	83	81	95	23.76	9.89	24.13	10.23	24.40	10.58

### Most Frequently Searched Relevant Keywords Were Cosmetics, Food, Laser, and Hormone

We searched Naver KnowledgeiN and Google for topics combined with “acne vulgaris” in 5 areas: treatment, cause, cosmetics, laser, and food (Table 3).

When comparing the number of search results from Naver KnowledgeiN with that from Google, Google had a greater number of search results: “acne vulgaris and cause,”

1,078,537/12,797,237, 8.4%, Naver and 11,718,700/12,797,237, 91.6%, Google; “acne vulgaris and food,” 257,137/5,740,137, 4.5%, Naver and 5,483,000/5,740,137, 95.5%, Google; “acne vulgaris and cosmetics,” 1,250,879/14,097,879, 8.9%, Naver and 12,847,000/14,097,879, 91.1%, Google; “acne vulgaris and treatment,” 277,918/2,035,700, 13.7%, Naver and 1,757,782/2,035,700, 86.3%, Google; and “acne vulgaris and laser,” 159,158/1,908,158, 8.3%, Naver and 1,749,000/1,908,158, 91.7%, Google.

**Table 3.** Frequently searched relevant keywords determined by text mining.

Topic	Naver	Google
<b>Acne and cause</b>		
Stress	371,735	1,520,000
Food	265,991	1,890,000
Cosmetics	29,249	6,630,000
<b>Acne and food</b>		
Milk	57,135	478,000
Flour	57,161	167,000
Coffee	27,005	1,460,000
Ramen	4285	1,370,000
<b>Acne and cosmetics</b>		
Toner	334,502	6,020,000
Lotion	332,153	814,000
Cleansing foams	57,135	472,000
Essences	68,667	1,250,000
<b>Acne and treatment</b>		
Lasers	168,750	1,250,000
Antibiotics	54,363	184,000
<b>Acne and laser</b>		
Fraxel laser	40,542	154,000
Photodynamic therapy	29,933	125,000
Toning laser	18,613	428,000
Intense pulsed light	16,379	280,000
LED	1378	316,000

### Information via the Internet Has Been Provided Mostly by Nonexperts

We sorted 500 answers by responders in Naver KnowledgeiN. The queries in Naver KnowledgeiN were mostly answered by Korean traditional medical doctors (267/500, 53.4%), but only 12.0% (60/500) by dermatologists, 33.6% (168/500) by the public, and 1.0% (5/500) by a general practitioner or a specialist medical doctor. The most common question about acne vulgaris was treatment (393/500, 78.6%), followed by cause (61/500, 12.2%), cosmetics (22/500, 4.4%), and laser (9/500, 1.8%).

## Discussion

### Principal Findings

People have greater interest in acne vulgaris than in other dermatological disorders, and patients' interest in acne vulgaris has significantly increased yearly. There were also significant differences in interest between cities and provinces. But there were no significant correlations between public interest and personal income, private consumption, or composition of the population. We selected acne-related topics that people would be curious about: cause, food, cosmetics, treatment, and laser. Among the foods, there were many searches for milk, wheat,

and coffee. Regarding lasers, Fraxel laser, photodynamic therapy (Naver), toning laser, and LED (Google) were of high interest. Answers to the questions on the internet were mostly provided by Korean traditional medical doctors (53.4%) or the public without expertise (33.6%) and only 12.2% by dermatologists.

Public interest in beauty has been increasing in South Korea. According to the International Society of Aesthetic Plastic Surgery, the size of the Korean plastic surgery market was estimated at about 5 trillion won in 2017, which was about a quarter of the world market, and the annual number of plastic surgeries per 1000 people was estimated at 13.5, making it first in the world [9]. The market size of the cosmetics and plastic surgery industries in South Korea has been growing [9,10], which could explain why the interest in acne vulgaris is high and increased much more abruptly than other dermatological disorders, such as atopic dermatitis. Another reason for this high interest may be that acne vulgaris mostly affects young people, who use the internet much more frequently.

People's lifestyles and thoughts are related to internet search volumes. Because acne vulgaris frequently affects young people who work or go to school on weekdays [5], the search volume for acne vulgaris was significantly higher on weekends than on weekdays. Conventionally, people might think that the higher their income, the more they care about their appearance, but

there was no significant correlation between public interest and personal income or private consumption. From this, we can see that people's interest in beauty is universal regardless of economic condition. Related to this finding, some studies have revealed that concern about physical appearance has no association with socioeconomic status [11].

The internet can probably help to identify etiology and epidemiology of disease [12]. It is known that acne vulgaris tends to get worse in the summer [13,14]. High temperatures can change sebum excretion [15], which can worsen acne vulgaris. Consistently, we found that the search volume for acne vulgaris was significantly higher in summer than in spring. Several studies have suggested that dairy products, chocolate, and hyperglycemic foods, such as ramen and flour, can exacerbate acne vulgaris [16-22]. Consistent with these studies, we found that people frequently searched for ramen, flour, chocolate, or milk along with acne vulgaris. Stress and hormones, which were frequently searched by the public on the internet, are also well known to exacerbate acne vulgaris [7,23-25]. Similarly, there are many other studies attempting to estimate epidemiology or track outbreaks of various kinds of diseases, such as influenza, cellulitis, cancer, and tuberculosis, by using the internet [12,26,27].

The power of mass media is extremely strong, even in the medical field [28,29]. In Figure 1A, there was a peak in search volume around the second week of October 2010, probably caused by news articles reported on October 13, 2010, from Korean major broadcasters such as MBC, SBS, or MBN that emphasized the relevance of food and acne vulgaris. In addition to conventional mass media, the internet, smartphones, and social media are also emerging as influential tools [30-32]. In 2010, there was an abrupt spread of smartphones in South Korea, which enabled people to get health information wherever they are and contributed to the peak of search volumes in 2010.

Physicians can use the powerful internet in the medical field [33]. First, through the internet, information about which the public is curious can be easily identified. Second, it can be a helpful tool for patient education because the internet is easily accessible and interactive and can provide media-based material, such as photos and videos. About this, especially in the field of skin cancer, several studies have shown that dermatologists can even effectively change people's skin-related health behavior through an internet intervention and can thus reduce the prevalence of skin diseases [34-36]. Through internet-based deep learning, diagnostic tools for skin cancer are even currently under development [37,38].

However, there is also the probability that false information could be provided, which can also be a major health risk. Much of the information was provided by nonexperts, such as the public or Korean traditional medical doctors, rather than by experts, that is, dermatologists, so the risk is high that false information might spread and endanger patients. Moreover, during data collection, we found manipulation for the purpose of promotion; in Naver KnowledgeiN, someone posted the same questions and adopted only one user as a best answer user. In this way, some people, if they have dishonest intentions, can spread misleading information very easily through the internet. Newspapers and TV news reports also have reported cases of adverse health effects because of incorrect medical information on the internet (Table 4). The Naver online café, Anaki, has greatly restricted the use of medicines for children and has even held chicken pox parties, causing a great deal of controversy. In addition, in the United States, conspiracy theories about vaccination spread on the internet, and the measles vaccination rate dropped significantly, which caused another measles pandemic [39]. As such, in the medical field, the internet has both aspects, in that helpful information can be provided to patients and yet wrong information can be provided and cause serious harm to patients.

**Table 4.** Risk cases for dissemination of unverified facts.

Source or harm	Example
Anaki	The Naver Café, with a membership as high as 60,000 people, caused problems with the dissemination of unfounded medical information, such as neglecting children's illness, refusing vaccinations, throwing chicken pox parties, and selling untested medicines.
Anyemo	This antivaccine movement website refused vaccinations without any reasonable evidence, which could cause pandemics of infectious diseases.
Measles epidemic in the United States	The measles epidemic in the United States has greatly increased because of the decrease in vaccination resulting from unfounded stories about vaccination spread through social media platforms such as Facebook.

## Limitations

There are several limitations to this study. First, Google Trends provides only a relative search volume index, not the absolute search volume, and does not provide a way to calculate the search volume index. Second, we could not find statistically significant factors affecting geographic differences. Personal income, personal consumption, and composition of the population had only weak positive correlations with acne vulgaris. Third, there are many advertisements about acne vulgaris, which might not represent the real interest of the public. Fourth, we could not analyze the exact accuracy of

information, but only estimate its quality through the ratio of who answered the questions in Naver KnowledgeiN. Last, it is not an interventional study. Further interventional studies are needed to measure the real effect of the internet in the real world.

## Conclusions

As part of patient education, we dermatologists need to correct wrong information. In addition, we can use the internet for patient education by launching official websites that provide accurate information about skin diseases or by operating dermatologists' Q&A sites. As such, we need to try both in and outside the office to understand people's interests and beliefs

in the internet space and try to intervene through the internet for patients with skin diseases. and smartphones to provide the best treatment and education

## Abstract

**Background:** The social media site Twitter has 145 million daily active users worldwide and has become a popular forum for users to communicate their health care concerns and experiences as patients. In the fall of 2018, a hashtag titled #DoctorsAreDickheads emerged, with almost 40,000 posts calling attention to health care experiences.

**Objective:** This study aims to identify common health care conditions and conceptual themes represented within the phenomenon of this viral Twitter hashtag.

**Methods:** We analyzed a random sample of 5.67% (500/8818) available tweets for qualitative analysis between October 15 and December 31, 2018, when the hashtag was the most active. Team coders reviewed the same 20.0% (100/500) tweets and the remainder individually. We abstracted the user's health care role and clinical conditions from the tweet and user profile, and used phenomenological content analysis to identify prevalent conceptual themes through sequential open coding, memoing, and discussion of concepts until an agreement was reached.

**Results:** Our final sample comprised 491 tweets and unique Twitter users. Of this sample, 50.5% (248/491) were from patients or patient advocates, 9.6% (47/491) from health care professionals, 4.3% (21/491) from caregivers, 3.7% (18/491) from academics or researchers, 1.0% (5/491) from journalists or media, and 31.6% (155/491) from non-health care individuals or other. The most commonly mentioned clinical conditions were chronic pain, mental health, and musculoskeletal conditions (mainly Ehlers-Danlos syndrome). We identified 3 major themes: disbelief in patients' experience and knowledge that contributes to medical errors and harm, the power inequity between patients and providers, and metacommentary on the meaning and impact of the #DoctorsAreDickheads hashtag.

**Conclusions:** People publicly disclose personal and often troubling health care experiences on Twitter. This adds new accountability for the patient-provider interaction, highlights how harmful communication affects diagnostic safety, and shapes the public's viewpoint of how clinicians behave. Hashtags such as this offer valuable opportunities to learn from patient experiences.

Recommendations include developing best practices for providers to improve communication, supporting patients through challenging diagnoses, and promoting patient engagement.

## KEYWORDS

social media; patient engagement; Twitter messaging; missed diagnosis; internet; physician patient relationship

## Introduction

Twitter is a social media platform for users to share 280-character posts. Globally, Twitter included an average of 145 million daily active users in 2019; [1] 22% of Americans use the platform [2]. Twitter serves as an appealing resource to 61% of American adults who look for web-based health information [3], of which 12% use Twitter or social networking to share health updates [4-6]. Patients and families can develop communities for specific medical conditions and health care-related education [7,8]. Health care professionals utilize Twitter for networking, disseminating medical information, policy and research, disease and health communication monitoring, and advocacy for specific issues [9-11]. By providing this open forum, Twitter enables novel forms of dialogue among and across patients, patient advocacy groups, and health care professionals.

Twitter *hashtags* are words or phrases that Twitter users include in their posts to demarcate posts by a common theme or content. The hashtag can be entered as a search term and demarcate a particular dialogue on the website; therefore, it is a method of indexing conversations. In October 2018, a hashtag titled #DoctorsAreDickheads emerged on Twitter. The term originated from a professional YouTube video maker, who posted a video on Twitter explaining that she had been diagnosed with Ehlers-Danlos syndrome and postural orthostatic tachycardia syndrome (POTS) [12]. After describing her 8-year-long process with various health care professionals to receive the diagnosis, she closed the video with the phrase, “doctors are dickheads.” As users began to respond, #DoctorsAreDickheads emerged as a viral hashtag; patients, caregivers, and health professionals responded to the phrase by sharing their own experiences and criticizing the use of the hashtag. As of July 2020, the hashtag had been used in a total of 37,624 tweets by 12,731 Twitter user accounts and is still in active use (personal communication with Symplur, August 7, 2020).

We sought to describe the concepts represented in this hashtag as part of a broader depiction of patient-driven communications about health. To this end, we conducted a qualitative, phenomenological analysis of this hashtag. Our goal was to describe the *who*, the *what*, and the *how* of this phenomenon: who is posting the hashtag (as per their health care-related role), what is being stated with this hashtag or what are the common medical conditions associated with the hashtag, and how dialogue and prevalent concepts related to it arose. These concepts highlight specific patient and clinician challenges that are voiced publicly on social media and will inform future efforts to improve the patient’s experience of care.

## Methods

### Data Collection

We reviewed all tweets with the hashtag using a report generated from Symplur, a health care social media analytics company [13]. The greatest peak of this hashtag was in late October 2018 (see [Multimedia Appendix 1](#) for the frequency of hashtags over time).

We then obtained tweets containing the hashtag dated between October 24 and December 31, 2018, comprising the predominant wave of use of the hashtag. We were able to obtain all tweets in this period, except for October 25, 2018, because of Symplur’s export limit of 2000 tweets at a time. In total, there were 9670 original tweets during the selected period, of which we were able to extract 8818. We randomly sampled 5.67% (500/8818) tweets for analysis using a random number generator. We selected 500 as the sample size based on a precedent social media analysis; Chan et al [14] demonstrated that a qualitative analysis of a sample of 540 tweets was sufficient to identify themes in how individuals understand and engage in health behaviors. We downloaded all tweets into Google Sheets spreadsheets (Google) for data abstraction and coding and used Microsoft Excel (Microsoft) for tabulation and thematic analysis.

### Data Processing of User Characteristics

We excluded tweets from abstraction if they were not in English, were nonsensical in content, or clearly posted by a bot (eg, had *bot* in the Twitter user profile). As Symplur exported the link to the original tweet, coders in the team reviewed the original Twitter post on the web and read the first tweet above or below the tweet of interest for context when necessary, as tweets can be either standalone comments or part of a conversation or *thread*. Team members abstracted the demographic role of Twitter users by reviewing the user profile and content of the tweet. For example, if a user described an experience while receiving medical care in their tweet, we abstracted their role as *patient*. If a user described themselves as an advocate for a clinical issue in their Twitter profile, we classified them as *advocate*. As there was a substantial overlap in role between *patient* and *patient advocate*, as evidenced by tweet content or profile, we developed a shared category called *patient or patient advocate*. The team also abstracted the clinical conditions mentioned in the tweets, for example, *depression* or *fibromyalgia*.

### Analysis of Themes

This was an interpretative phenomenological analysis, in which a *phenomenon* or lived experience is described by exploring the perspectives and shared meaning of those who have experienced it [15]. We sought to understand for whom, for what, and how

the *viral* hashtag #DoctorsAreDickheads became a way to frame and represent patients' lived experiences on Twitter. We used the iterative process known as a hermeneutic cycle, moving continuously between data collection, interpretation, and theorization and incorporating awareness of our subjective perspectives as researchers in order to develop a nuanced analysis of the phenomenon [16]. This helped us understand how patients interpolate their individual experiences into a wider discourse of patient experience through the hashtag #DoctorsAreDickheads.

Team members (AS, ZM, RC, JY, and JD) coded 20.0% (100/500) sampled tweets together and the remainder individually. Each team member first independently reviewed the content of 50 tweets, selecting a short *code* of a word or short phrase describing the conceptual topics represented in tweets with the hashtag #DoctorsAreDickheads. These codes ascribed what phenomenologically could be called the *essence* or the core meaning of a tweet. Afterward, the team compared codes into a preliminary codebook. The team then reapplied the preliminary codebook to the 50 previously coded tweets and then used it to code another 50 tweets independently. The team then met once more to review code application, discuss new codes, and begin the process of interpretation. Two research team members reconciled differences in code application for the initial 100 tweets that were coded by the entire research team. Once consensus and agreement had been established, we divided the remaining 400 posts among 5 members of the team and coded them independently using the codebook and developing new codes when necessary.

Throughout the process, team members wrote memos or notes to describe shared meaning from the individual codes. After all

remaining tweets were coded, the team sorted and categorized memos based on thematic content, developing an interpretive framework of the hashtag #DoctorsAreDickheads to result in final themes. When discussing possible themes, we also conducted frequency checks to prioritize the themes that were most frequently identified in the data. We aimed to identify all *meanings* of the phenomenon included in the sample; thematic saturation is not a priority in a phenomenological approach [17].

This study was reviewed by the University of San Francisco, California, institutional review board and categorized as *exempt*, with the approval number 19-27965.

## Results

### User Characteristics

Of the 500 tweets analyzed in our sample, 9 were excluded. Reasons for exclusion included being in a language other than English (n=2), written by a bot owing to having *bot* in the profile or nonsensical content (n=5), or containing no content (n=2). The sample included 344 independent Twitter users, with a median tweet frequency of 1 per user; 1 account had 7 posts, 1 had 20 posts, and 1 had 22 posts. In total, 50.5% (248/491) of tweets were posted by patients or patient advocates. Almost one-third or 31.6% (155/491) of tweets were posted by people in the other or unknown category. Health care professionals contributed 9.6% (47/491) of tweets; 4.3% (21/491) tweets were posted by caregivers, 3.7% (18/491) were posted by academics or researchers, and 1.0% (5/491) were posted by media or non-health care organizations. A list of roles identified in the coded sample is available in [Table 1](#).

**Table 1.** Characteristics of Twitter users posting the hashtag #DoctorsAreDickheads (N=491).

Demographics represented in the sample <sup>a</sup>	Values, n (%)
Patient and/or patient advocate	248 (50.5)
Health care provider	47 (9.6)
Caregiver and/or family member	21 (4.3)
Researcher or academic	18 (3.7)
Media, non-health care organization	5 (1.0)
Non-health care individuals or unknown or other	155 (31.6)

<sup>a</sup>Some Twitter posts pertained to multiple demographics.

In our sample, 60.2% (296/491) tweets mentioned a clinical condition. The most common condition mentioned was chronic pain (44 tweets). Mental health, musculoskeletal, and obstetrical or gynecologic conditions and procedures were also common. Ehlers-Danlos syndrome was the most common specific

condition, followed by fibromyalgia, chronic fatigue syndrome (also known as myalgic encephalitis), POTS, and mast cell activation syndrome. A full list of conditions is available in [Table 2](#).

**Table 2.** Clinical conditions mentioned in sample tweets (n=296).

Condition	Number of tweets
Chronic pain	44 (general pain: 38; fibromyalgia: 5)
Mental health	31

### Major Themes

We identified 3 core thematic results that were manifested in the experiences represented within our sample. Full definitions of each theme and additional exemplar quotes are found in [Table 3](#). Of note, we are publishing verbatim tweets with usernames

to give credit to Twitter users and their contributions to this discourse when possible. We obtained permission from cited users to publish these tweets. For tweets about which we received no response, we anonymized the content in accordance with recommendations regarding social media research [18].

**Table 3.** Major themes and definitions identified in the content analysis of the Twitter hashtag.

Theme	Definition	Example tweets
Belief and diagnosis	Describing experiences with medical providers being skeptical, dismissive, or “gaslighting”; this disbelief then causing delayed or incorrect diagnosis and/or medical harm	<ul style="list-style-type: none"> <li>“It took 10 years for my MS to be diagnosed. Doctors thought I was embellishing my symptoms and doing too much internet research. If they had spent that time listening, running the correct tests, and treating me, I might not be disabled to the point I am now. #DoctorsAreDickheads” (@VenusDoom14)</li> <li>“Two cardiologists dismissed my POTS as ‘nothing wrong’ or ‘it’s all in your head’ before the third one figured out my POTS. He’s a life-saver, but the other #DoctorsAreDickheads” (@Snarcoleptic_13)</li> <li>“this stings so hard when #DoctorsAreDickheads do this to you while gaslighting you about the psychosomatic nature of your symptoms” (@moniquedhooghe)</li> <li>“I went to an urgent care for what turned out to be pneumonia but had to spend half of the appointment being grilled over why I ‘think’ I have epilepsy. ‘Because the neurologist I’ve been seeing for a decade told me,’ was not good enough. #DoctorsAreDickheads” (@Jenny_Trout)</li> <li>“One doctor I went to, without even knowing me or my history, interrupted me while I was explaining my symptoms &amp; just said ‘You have a psychological condition.’ I said no I don’t.. &amp; he cut me off again &amp; said ‘Yes you do.’ #DoctorsAreDickheads (@d_vaz)</li> </ul>
Power inequity in the patient-provider interaction	Differential in power (due to medical hierarchy as well as misogyny, White supremacy, and ableism) affecting communication and behaviors between clinicians and patients	<ul style="list-style-type: none"> <li>“All I want is to be believed. To have people understand that when sick/stressed, I can’t pretend or act and so my intonation is flat. But they won’t. And, if I wasn’t hairy, if I didn’t have external ‘plumbing,’ this would be worse. #DoctorsAreDickheads” (@theAutistech)</li> <li>“Well, the time to care about my well-being is when I’m in the clinic, but physicians often will not. More often if they are men, and particularly more often if they’re white. This isn’t a stereotype, it’s established in the research. #DoctorsAreDickheads”</li> <li>“#DoctorsAreDickheads is being driven by people living with disabilities and activists that I know. I feel this so deeply – I’ve experienced this bullsh*t even if I’m closer to neurotypical – they confuse us and ignore our own knowledge about our bodies.”</li> <li>“Physicians have all the power. They could help us get better, but for all of us with chronic illness, they’ve traumatized us. We’re too scared to come in to be seen. You can’t get it unless you’ve lived it. #DoctorsAreDickheads”</li> </ul>
Metacommentary	Discussion about the rationale for and impact of this hashtag in public discourse	<ul style="list-style-type: none"> <li>“To all the people that are using #DoctorsAreDickheads first off all Get stuffed (<i>insert: crying laughing emoji</i>) our grouping all doctors into a group that in reality is only made up of like 1% of them. Now am I saying that all doctors are amazing? No but a lot of them work f**king hard and spend time helping others when they could be at home with there family” (@PineappleYT123)</li> <li>“People complaining about the #DoctorsAreDickheads hashtag because it contains a vulgarity... Do you know if patients use curse words (what I call “cuss words” from home) in a medical practice, they can be labeled ‘difficult’?” (@DrZackaryBerger)</li> <li>“I’m sorry, but #DoctorsAreDickheads is simply honest. Some doctors are rude, some are abusive, some are incompetent. Some are brilliant, but that doesn’t mean we can’t discuss the generally poor response to patients who raise issues.” (@WTBDavidG)</li> <li>“I’ve seen as many if not more medical professionals responding positively to #DoctorsAreDickheads in 24hr than I have to more polite debate in the last 8 months.” (@stendec6)</li> <li>“Decent doctors knows they are decent. They understand why the hashtag exists and why patients are suffering. They can deal with a few hurt feelings because they see the greater change that is possible when we stand up for ourselves #DoctorsAreDickheads” (@In-tactCervix)</li> <li>“So much trauma is due to us doctors. We learn best from our patients, but these lessons come too late. The stigma about weight isn’t something we talk about in our training. Let’s do better. #DoctorsAreDickheads”</li> </ul>

## Belief and Diagnosis

Patients and caregivers described a common experience of clinicians not listening, not believing, minimizing, or not valuing their accounts of illness. The experience of being disbelieved was often linked to experiencing an incorrect, delayed, or missed diagnosis. These diagnostic adverse events were associated with physical harm:

*Had terrible blood clots for several years—they said my legs were hurting from fibro and they couldn't do anything. Then I started having trouble breathing and we dashed to the ER. The clots had ended up spreading from my legs to my lungs.*

In addition to physical harm, others described emotional harm and guilt:

*I felt horrible. I was ruining all the holidays, and I could not do a single thing about it. I felt like a worthless piece of crap. And all because... the doctors didn't look at me, did not see my pain as valid. Even now, with my diagnosis.. it is hard... #DoctorsAreDickheads. [@WheelieNick]*

The narratives with this theme described prevalent gaslighting, meaning a manipulative tactic in which someone questions a person's perceptions, memories, and sense of reality. They also described egotistical behavior from clinicians, lording medical training or expertise over patients or being dismissive of patient input when their diagnosis or assessment was challenged:

*A doc told me that I had a cancer syndrome. I said no way – I had been in an accident right before my symptoms started. He told me, "I have an Ivy League degree, so don't ask questions." Turns out he was incorrect. No cancer. #DoctorsAreDickheads.*

Within this theme, we observed how patients countered the narrative of being dismissed by using #DoctorsAreDickheads to create a community where people are believed. In response to a thread in which a patient shared how they "sobbed . . . heaved with the realization that yet again (I'm) being gaslighted about (my) own damn body," another Twitter user responded:

*...please, consider the #DoctorsAreDickheads conversation. This hashtag shows that you're not on your own in this. It isn't just you imagining things. Look at all the people here who believe your words.*

## Power Inequity in the Patient-Provider Interaction

Twitter users described their experiences using this hashtag as a result of the power inequity and hierarchy in medical care. Clinicians hold power in decision making and medical orders, serving as *gatekeeper* for desired services. This included experiences where clinicians denied patient bodily autonomy:

*And then after I was finished having kids and wanted my tubes tied, the first two doctors I asked, refused. For non evidence based reasons. It took me 2.5 years to find a doctor who would. #DoctorsAreDickheads. [@MxPeachyKi]*

The power imbalance impacts communication, and a number of patients described being aware of what they felt they could

or could not say, or *self-edit* what they would express in the visit, to protect themselves from consequences that would affect their care:

*Honestly, if we suddenly go very silent and compliant, we're actually fighting back rage and tears bc we know damn well if we let it show you'll just label us hysterical and FIRE us as patients. Like we somehow serve YOU. #DoctorsAreDickheads. [@rhysfelis]*

Many of the accounts recounted experiences where patients felt that the clinicians were abusing their power. These experiences ranged from subtler, verbal diminishment of the patient experience to physical, verbal, and even sexual abuse and/or severely unethical care:

*cw: sexual assault I had many doctors actively try to cover up or push under the rug the fact that their coworker sexually assaulted me when I was 14. All these people are still practicing at a major hospital, including assaulter. Suffice to say those #DoctorsAreDickheads. [@atoradegay]*

Within this theme was a call for attention to how the patient or clinician power differential is compounded by structural inequities in society. Tweets addressed how White, cisgender, and neurotypical patients have more privileges in medical visits because of structural power imbalances. People of color, lesbian, gay, bisexual, transgender, queer individuals, and people living with disabilities described an intersectional experience, shaped from their identities as members of marginalized groups, in which there was a higher risk of a negative encounter or inappropriate care:

*My #DoctorsAreDickheads story: before I'm a physician, I'm a queer woman. Physicians, nurses, and everyone in healthcare have a long systemic history of abuse of power and broken trust with the LGBTQ+ community. My family & my community fear medicine because of it. Don't @ me. [@ShannonOMac]*

*THANK YOU. It was a little frustrating bc most of the participants were white and I didn't quite know how to articulate that #DoctorsAreDickheads is different when you have other marginalized IDs outside of being disabled or sick. [@Twitchyspoonie]*

## Metacommentary on Hashtag

Although much of the conversation using this hashtag focused on narratives of experiences with clinicians, there was also a *meta* conversation about the meaning of the hashtag's use on Twitter. This included the risks and benefits of using such an inflammatory term:

*Yes this #DoctorsAreDickheads represents poor experiences of care. We try to and should improve this if needed. But doctors are humans, patients, parents, and professionals. Attacking us is counterintuitive when we campaign for improvements. #twitter is this really helpful? [@dr\_nigel\_lane]*

Patient advocates noted that the hashtag got attention, precisely because it was sensational:

*The provocative hashtag #DoctorsAreDickheads drew people's attention to widespread, systemic medical maltreatment. A more polite hashtag couldn't have done this. [ @jeff\_says\_that ]*

Patients, advocates, and health care providers shared their frustration and hoped that this attention and dialogue would allow better understanding and possibly change:

*The medical professionals getting butthurt by #doctorsaredickheads need to read it for what it is - our cries to be treated as PEOPLE first, CONDITIONS second. A desire for inclusivity and a genuine desire to help IMPROVE patient care and the doctor-patient relationship. [ @Chrisa\_Hickey ]*

Within the metacommentary, a parallel hashtag emerged, *#DoctorIRspect*, used to share accounts of laudable or appropriate medical care. These tweets contained recommendations for improved communication during medical visits. Some tweets contained suggestions for engaging patients as partners in their care and system redesign to ensure more patient-centered care:

*So how do you become a #DoctorIRspect? It's really easy. If you have no clue what is going on, just say so. Tell us you don't know. That's all.*

*If you're not involving patients, I urge you to begin doing so. Heck, there are many patients that have experience in orchestrating such change within large medical spaces (insert: waving hand emoji) We're here with experience and even degrees. Hire us to help you. #DoctorsAreDickheads [ @GraysonGoal ]*

## Discussion

Our study paints a picture of patients living with chronic conditions, lacking power within the medical encounter, and turning to social media to share testimonies of being disbelieved and disrespected. Our study is the first empirical approach to analyze the phenomenon of this hashtag on Twitter, utilizing a random sample. Another response was an editorial piece, which concluded that the degree of rancor in the conversation would not aid in improving medical care [19]. Rare or challenging clinical syndromes were commonly mentioned, such as Ehlers-Danlos syndrome, chronic pain, and chronic fatigue syndrome, which have been seen in other analyses of medical topics discussed on Twitter [20,21]. Twitter may be an underutilized resource for understanding the patient's perspective and provider dynamics within the diagnostic pathway, particularly for challenging-to-diagnose conditions; social media data can be mined to monitor care quality and patient experience [22].

The connection between communication within the clinical encounter and the ability to make a correct and timely diagnosis was an unexpected finding. The hashtag *#DoctorsAreDickheads* highlighted how clinician engagement with patients is not just a matter of patient experience, but a priority for diagnostic safety. Patients shared how disrespectful treatment was connected to a missed, delayed, or incorrect diagnosis. Several previous studies on Twitter data found descriptions of

procedural, medication, and diagnostic errors [17,23]; our larger sample validates that patients can self-identify and report diagnostic adverse events. How information is conveyed or received is highly dependent on belief and respect throughout the encounter. Improvements are urgently needed in how clinicians communicate and how patients are involved in the diagnostic pathway [24,25].

The central takeaway from our analysis was how patients felt disempowered, disrespected, and disbelieved. Patients described a range of ways in which they are vulnerable during a health care encounter [26]. Beginning with the existing power differential between provider and patient, tweets described how patients enter the health care system struggling with active symptoms of illness or health needs and can be further burdened by bias, including racism, misogyny, or ableism in the medical system, or by previous traumatic experiences with health care. These vulnerabilities could lead to avoidance or *self-editing*, which hashtag users described as trying to behave like a *good patient* rather than continuing to share their knowledge or expertise in their condition. When experiencing mistreatment, patients are not engaged in sharing knowledge and expertise in their conditions, further reducing the quality of the clinical encounter. Our findings resonate with other works detailing the impacts of power and hierarchy in medicine, in which the lack of agency or respect further perpetuates harm [27,28].

In addition to describing harm from misdiagnosis, patients described assaultive behavior from health care professionals, ranging from hurtful comments (eg, ableist or sexist remarks, carelessness about prognosis) to egregious, unethical, or illegal acts (including sexual abuse). Traditionally, the patient-clinician interaction is private, with few witnesses. Should there be abuse, patients do not have clear-cut routes of action. In the climate of *#MeToo* and the Black Lives Matter movement, people in positions of power are being held to greater accountability for their behavior. As this hashtag demonstrates, Twitter provides greater transparency to clinician behaviors in a public forum.

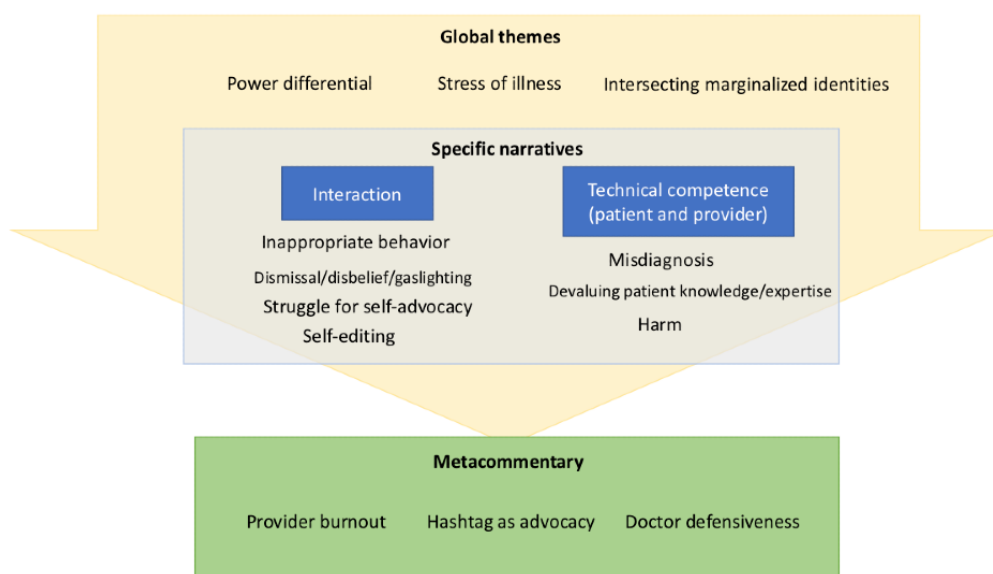

Using this hashtag, tweets demanded empathy on behalf of both clinicians and patients. Within the metacommentary theme, some hashtag users accused patients of exacerbating clinician burnout and mental illness. Patients and advocates responded by highlighting clinicians' privilege, encouraging them to be less defensive and listening to critiques. This opposition between patient needs and clinician burnout is a false dichotomy and speaks to the deeper shortcomings of a medical system that erodes empathy both for patients and for health care personnel. As health care systems continue to explore changes to improve quality and patient experience, work to achieve the quadruple aim is aligned with improving both clinician workplace satisfaction and patient experience [29]. Both patient and clinician wellness are priorities; however, the *#DoctorsAreDickheads* conversation shows how power differentials and limitations in the current health care system disproportionately impact patients, putting their needs in conflict with providers.

Figure 1 shows how the themes relate to each other. The direct experiences of gaslighting, minimization, and ignoring patient expertise (Theme 2) are couched in the overarching themes of

power differential, the burden of illness, and historically marginalized identities (Theme 1). In metacommentary, clinicians have responded both defensively and in support, and

patients and advocates noted the hashtag's utility to gain attention for advocacy for systemic changes (Theme 3).

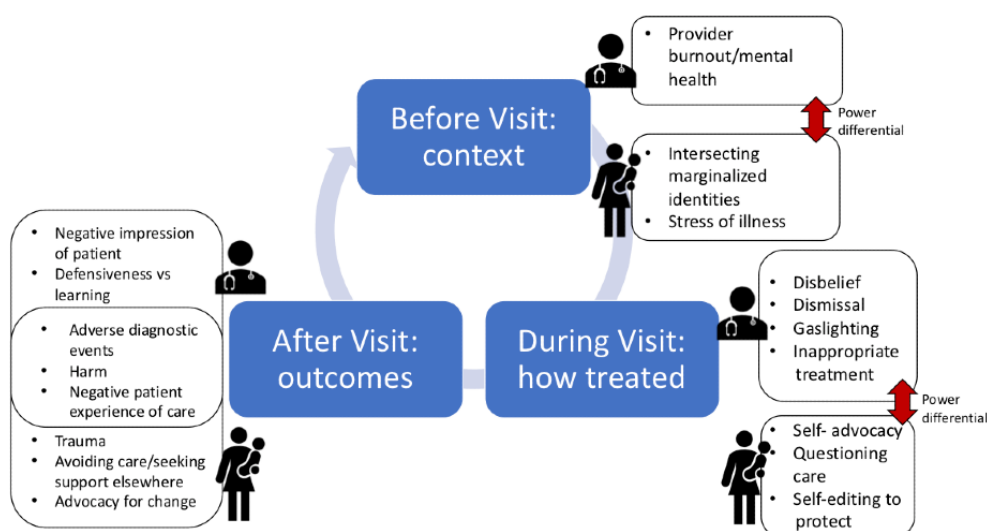

**Figure 1.** Map of major themes identified in Twitter hashtag.

We organized the experiences described in a process map of the patient and clinician encounter, showing how major themes function in a cyclical fashion (Figure 2). First, contextual factors, including the power differential, the patient's intersectional identity, and provider well-being, affect the clinical interaction before a visit. During the encounter, the power differential affects the interaction in which the clinician may disbelieve, devalue, or *gaslight* the patient, who may engage in various

coping behaviors such as self-advocacy, self-editing, or questioning care. In this interaction, downstream negative outcomes include misdiagnosis, medical harm, and negative patient experience or trauma. In this conceptual map, harmful outcomes are shared, highlighting the message of the #DoctorsAreDickheads hashtag as a call to action to improve outcomes for both patients and clinicians.

**Figure 2.** Cyclical process map of themes identified in Twitter hashtag.

Actionable recommendations for clinicians were provided with this phenomenon. First, clinicians can strive to diminish their defensiveness when patients share a negative experience. Second, there is the potential to improve how clinicians communicate in a clinical encounter. Trainings may improve clinician capacity to listen about a health concern, voice diagnostic uncertainty, even by stating "I don't know," and

accompany patients through challenging diagnoses or chronic conditions. Third, patients encouraged increased patient engagement within health care systems, such as through community advisory boards or hiring patients as consultants, to develop more patient-centered care systems [30].

## Limitations

Limitations of this study include a relatively small sample of events; however, our initial sample of 500 is similar to other qualitative analyses of social media posts [8,11]. Those who post on Twitter are not representative of all patients; however, given that 55.2 million people in the United States use Twitter, it is clear that Twitter's users are a sizable proportion of enrolled patients [31]. We do not know if patients who are higher utilizers of health care are more or less likely to post content on Twitter using this hashtag. Finally, we do not know detailed demographic information about Twitter users or their geographic location.

## Conclusions

Twitter and social media are growing platforms where patients discuss health care; this public forum holds clinicians to a higher

level of accountability and transparency. #DoctorsAreDickheads is an intentionally sensational hashtag, born out of frustration with health care interactions. The hashtag is meant to raise awareness of common negative patient experiences, particularly for those living with challenging, rare, and chronic conditions. Patients experience disbelief, mistrust, and lack of listening from their clinicians, which they link to delayed or missed diagnoses. Patients asked for a deeper recognition of the capacity and expertise they bring to the clinical visit and awareness of how power and bias affect the encounter. Although clinicians may feel resistant to concerns expressed through social media, patient advocates on Twitter advocate for system-level improvements to improve medical treatment and patient experience. By systematically exploring views expressed on these platforms, clinicians and health care leaders may identify important areas for improvement, such as improved communication during a challenging diagnosis.

## Abstract

**Background:** Older migrant patients with cancer face many language- and culture-related barriers to patient participation during medical consultations. To bridge these barriers, an eHealth tool called *Health Communicator* was developed in the Netherlands. Essentially used as a digital translator that can collect medical history information from patients, the Health Communicator did not include an oncological module so far, despite the fact that the prevalence of Dutch migrant patients with cancer is rising.

**Objective:** This study aims to systematically develop, implement, and conduct a pilot evaluation of an oncological module that can be integrated into the Health Communicator to stimulate patient participation among older Turkish-Dutch and Moroccan-Dutch patients with cancer.

**Methods:** The Spiral Technology Action Research model, which incorporates 5 cycles that engage key stakeholders in intervention development, was used as a framework. The *listen* phase consisted of a needs assessment. The *plan* phase consisted of developing the content of the oncological module, namely the question prompt lists (QPLs) and scripts for patient education videos. On the basis of pretests in the *do* phase, 6 audiovisual QPLs on *patient rights, treatment, psychosocial support, lifestyle and access to health care services, patient preferences*, and *clinical trials* were created. Additionally, 5 patient education videos were created about *patient rights, psychosocial support, clinical trials*, and *patient-professional communication*. In the *study* phase, the oncological module was pilot-tested among 27 older Turkish-Dutch and Moroccan-Dutch patients with cancer during their consultations. In the *act* phase, the oncological model was disseminated to practice.

**Results:** The *patient rights* QPL was chosen most often during the pilot testing in the *study* phase. Patients and health care professionals perceived the QPLs as easy to understand and useful. There was a negative correlation between the tool's ease of use and patient age. Patients reported that using the module impacted the consultations positively and thought they were more active compared with previous consultations. Health care professionals also found patients to be more active than usual. Health care professionals asked significantly more questions than patients during consultations. Patients requested to see the *patients' rights* video most often. Patients rated the videos as easy to understand, useful, and informative. Most of the patients wanted to use the tool in the future.

**Conclusions:** Older migrant patients with cancer, survivors, and health care professionals found the oncological module to be a useful tool and have shown intentions to incorporate it into future consultation sessions. Both QPLs and videos were evaluated positively, the latter indicating that the use of narratives to inform older, low-literate migrant patients with cancer about health-related topics in their mother tongue is a viable approach to increase the effectiveness of health care communication with this target group.

## Introduction

### Background

Migrant patients across the world are facing numerous adversities within the health care system. For instance, health care professionals communicate less adequately with migrant patients compared with nonmigrant patients [1], and their affective (ie, relating to psychosocial issues such as psychological support) and instrumental needs (ie, relating to more medically related issues such as being informed about treatments) are often not fully met [2]. Health care professionals particularly tend to overlook the importance of ensuring that migrant patients in language-discordant consultations comprehend all the information presented. This can induce dissatisfaction among migrant patients and their family members, ineffective consultation sessions, and ultimately worse patient health outcomes compared with language-concordant consultations [3]. In addition to language barriers, unresolved cultural barriers, such as culturally shaped beliefs about health and illness and communication styles, might also provoke migrant patients' perceptions of lack of health care professionals' respect, inability to participate in the decision-making process, and even perceived inequalities and discrimination in care quality [4-6].

The number of Dutch migrant patients with cancer is expected to triple within the next 20 years, mainly because of the aging of the first generation Turkish-Dutch and Moroccan-Dutch population [7]. However, cancer rates are still low among Dutch migrant patients with cancer; nevertheless, it becomes increasingly important to address language and cultural barriers to adequate health care professional-patient communication and enhance older migrant patients' participation during medical consultations in oncological care. Patient participation refers to "the extent to which patients produce verbal responses that have the potential to significantly influence the content and structure of the interaction as well as the healthcare professional's beliefs and behaviours" [8]. In particular, when it comes to the first generation Turkish-Dutch and Moroccan-Dutch patients with cancer, who often prefer to take along relatives to their consultation to bridge the language barrier instead of professional interpreters, there is a risk of relatives inhibiting patient participation during medical consultations because of culturally shaped beliefs about communication and treatment [9], resulting in providers not getting the patient information they need to provide good quality health care. Hence, interventions that address these barriers are urgently needed.

In general, patient-targeted intervention strategies that have been found to enhance patient participation significantly include coaching, providing educational materials, and having patients offer their opinions to their health care professionals [10,11]. An example of a successful intervention that employed the abovementioned strategies comes from Epstein et al [12]. The

results of this intervention, which was neither targeted at migrant patients nor meant to address language barriers, showed that more patient-centered communication took place during consultations with patients who received question prompt lists (QPLs) and individualized communication coaching, which assisted patients in identifying issues that needed to be addressed during consultation sessions, than during consultations with patients who did not receive these communication strategies. In addition, previous research indicated that a written QPL is beneficial to the communication and psychological and cognitive outcomes of patients with cancer [13].

However, Fukui et al [14] concluded that interventions need to be remodeled to align with the cultural characteristics of their participants to yield satisfactory results. In an intervention tailored to Americans, patients with cancer were provided with statistical information such as recurrence and survival rates. However, information related to the truth of illnesses in Japan was frowned upon among the Japanese participants. In the modified version, patients with cancer were given the liberty to ask for medical information in their own terms. Upon modification, more than 80% of Japanese patients with cancer expressed high satisfaction with the intervention, and no participants dropped out of the intervention compared with a 30% dropout rate in the American version of the intervention. Hence, the results of this study show that interventions must be culturally tailored to be effective.

### This Study

Given the lack of interventions tailored specifically to older Turkish-Dutch and Moroccan-Dutch migrant patients with cancer to combat the barriers they experience in communicating with their health care professionals [15,16], this study set out to systematically develop and implement an intervention to improve their participation and satisfaction with care. As the Turkish and Moroccan community has been growing as a result of migration, and recent figures have shown that they not only make up approximately 5% of the Dutch population but also account for being two of the fastest-growing populations in the last 5 years [17,18], we focused on older Turkish-Dutch and Moroccan-Dutch patients with cancer (>55 years). We developed an intervention, more specifically an oncological module, to be implemented in an existing Dutch eHealth tool called *Health Communicator*. The Health Communicator is a web-based digital tool that aims to resolve language barriers between non-Western patients with low Dutch language proficiency and their health care professionals. The Health Communicator is used to collect patient medical anamnestic data via digital questionnaires and to provide educational videos for patients in multiple languages about their illness. Although the Health Communicator includes medical history questionnaires and educational videos for various medical topics (eg, diabetes, pregnancy), it lacked a module specifically aimed at oncology patients, especially one systematically developed

for older Turkish-Dutch and Moroccan-Dutch migrant patients with cancer ([Multimedia Appendix 1](#)).

Our goal of implementing this new oncological module is further supported by evidence pointing toward the fact that older adults and Turkish-Dutch patients are more inclined to use media than interpersonal sources to gather health information, ranging from the television to the internet [19]. In a recent study, health care professionals have expressed positive attitudes and intentions to use the existing Health Communicator tool to increase patient participation (Yilmaz et al, unpublished data, 2020). Furthermore, older adults display more competence in recalling health information in an audiovisual format than a text-only format [20]. Hence, the overall aim of this study was to systematically develop, implement, and conduct a pilot evaluation of a web-based oncological module that can be integrated with the Health Communicator to stimulate patient

participation among older Turkish-Dutch and Moroccan-Dutch patients with cancer.

## Methods

The Spiral Technology Action Research (STAR) [21] model was used as the guiding framework for developing the oncological module. This model encourages several evaluation cycles among stakeholders, enabling continuous improvement of the intervention until it is finalized. To establish a high degree of relevance for target users, the model incorporates 5 guiding cycles that engage relevant community members in developing the intervention. These 5 cycles, *listen*, *plan*, *do*, *study*, and *act*, continuously weave technological and community development together [21]. In the following sections, we describe the steps taken in each phase with a special emphasis on the study phase and its results. [Table 1](#) provides an overview of the aims and actions during each phase.

**Table 1.** Overview of the phases, their aims, actions, and publications.

### Listen: Target Group Analysis

To identify existing findings on the needs of older migrant patients with cancer, a systematic literature review was conducted. The results of the literature review revealed that most non-Western ethnic minority patients with cancer and survivors have a high preference and need for information and shared or active participation. However, no information was available regarding the preferences and needs of our target population, Moroccan-Dutch and Turkish-Dutch older patients with cancer [22].

Given the limited findings in the literature regarding the needs of older Turkish-Dutch and Moroccan-Dutch patients with cancer, further in-depth interviews were conducted to determine the topics that need to be addressed within the oncological module. A total of 19 interviews were carried out with

Turkish-Dutch and Moroccan-Dutch patients with cancer and cancer survivors. Interviews were conducted by bilingual interviewers in patients' first language (ie, Turkish, Moroccan Arabic, or Berber dialects). Participants were recruited by reaching out to prominent figures within Turkish and Moroccan communities that work in the health sector and via snowball sampling. The results revealed unmet instrumental needs concerning the treatment of cancer and the health care system and unmet affective needs concerning psychosocial support and affective doctor-patient communication. Acceptance of the Health Communicator, which was studied based on concepts of the Technology Acceptance Model (TAM), revealed that patients thought that the Health Communicator would be useful to fulfill their unfulfilled needs, but ultimately did not intend to use the tool (Yilmaz et al, unpublished data, 2020).

Following patient interviews, 2 focus groups with general practitioners (GPs) and oncology nurses were conducted. Health care professionals were asked to reflect on the findings of the patient interviews, share their own experiences, and indicate the type of information they would like to receive from their patients to better fulfill their unmet needs. Although health care professionals acknowledged the most unmet instrumental and affective needs of patients that emerged from the interviews, they appeared not to be aware of patients' need for psychosocial support or misunderstandings surrounding clinical trial requests. Health care professionals also needed more information about patients' instrumental needs and the role of family members in the treatment process (Yilmaz et al, unpublished data, 2020). Overall, the patient interviews and focus groups with GPs and oncology nurses provided valuable insights into the content creation phases.

### Plan: Methodology Development

On the basis of the results of the target group analysis, 2 types of content, namely QPLs and narrative patient education videos, were created for the oncological module. QPLs are essentially structured question lists that aim to make it easier for patients to ask questions to their providers during consultations [13]. Typically, patients can look at these premade lists before the consultations and select the questions they would like to ask their health care providers during consultations. Selecting questions from a premade list is easier than formulating the questions on their own for the patients. In addition, selecting them before consultations decreases the risk of forgetting to ask them during consultations because of time pressure or other distractions. Narrative patient education videos that depict patient stories are increasingly used in health communication as they are shown to enhance learning, recall of information, and intentions to stimulate healthy behavior and attitudes [23]. They are especially suitable for relaying cancer-related information as they can transport the patient into the story and make it easier for them to identify with the positive role models in the videos [24]. In the methodological development phase, several pilot tests with patients and professionals were conducted for the QPLs and videos before moving on to the third phase where the prototype was built.

### Developing QPLs

On the basis of the emergent instrumental and affective needs of patients, 5 QPLs were developed. The content of the QPLs was not disease-specific (ie, not about breast cancer or other cancer types) but rather included topics relevant to general oncological care that addresses the issues that older migrant patients with cancer face during their illness, namely (1) patient rights, (2) lifestyle and access to health care services, (3) treatment, (4) psychosocial support, and (5) clinical trials. Each QPL consisted of 4 or 5 simple questions aimed at stimulating patients to ask more questions to their health care professionals and have a more active role during consultations (eg, "Can I discuss my problems in my mother tongue with someone sharing my culture?" and "Can I ask for a second opinion?"). In addition, to address health care professionals' instrumental needs, a sixth QPL was developed, which enabled them to learn more about patients' instrumental and decision-making preferences and

health behaviors (eg, "Are you using any medication bought from another country?" and "Who do you want, next to your doctor, to help you make healthcare decisions for you?"). Additional illustrations representing each question were developed to assist patients with low literacy.

All QPLs and accompanying illustrations were pilot-tested during in-depth interviews conducted with 11 older migrant patients with cancer and survivors (8 Moroccan and 3 Turkish; mean age 61.50, SD 9.36 years). Participants were recruited by reaching out to prominent figures within Turkish and Moroccan communities that work in the health sector and via snowball sampling.

Interviews were conducted by bilingual interviewers in the patients' first language (ie, Turkish, Moroccan Arabic, or Berber dialects). Patients evaluated each question and illustration for ease of understanding of the content and language (eg, "Do you understand this question?" and "Do you think this picture is a clear illustration of the question?"). Results showed that patients found the QPL questions easy to understand, whereas some illustrations were found to be too abstract. Patients had specific recommendations for word choices and requested increasing concreteness and familiarity of illustrations, such as adding headscarves to some of the female figures and removing abstract symbols. On the basis of their recommendations, revisions were made and incorporated in the *do* phase of our intervention development.

### Developing Videos

We created 5 scripts for each video. Similar to QPLs, the content of the videos addressed general oncological issues that older migrant patients with cancer typically face during their illness, namely (1) patient rights and access to health care services, (2) doctor-patient communication, (3a and 3b) psychosocial support, and (4) clinical trials. We created 2 separate scripts featuring a male and female patient as the main characters for the psychosocial support video. This was done to enhance identification with characters for both male and female patients. Each script was related to the experiences of an older migrant patient who survived cancer from the patients' point of view. The scripts incorporated actual experiences and specific language used by patients during interviews in the target group analysis phase as much as possible. All scripts were prepared in Dutch for health care providers and in Turkish, Moroccan Arabic, and Berber dialects for patients.

The scripts were pilot-tested with 8 older migrant patients with cancer (Turkish,  $n=3$ ; Moroccan,  $n=5$ ; mean age 63.75, SD 6.39 years) during individual in-depth interviews. Participants were recruited by reaching out to prominent figures within Turkish and Moroccan communities that work in the health sector and via snowball sampling. Interviews were conducted by bilingual interviewers in patients' first language (ie, Turkish, Moroccan Arabic, or Berber dialects). Patients evaluated each script on ease of understanding ("Can you understand everything said in the video/happening in the video easily?"), familiarity ("Does this story sound familiar to you?"), usefulness ("Do you find the information provided in the story useful?"), believability ("Do you find the information believable?"), emotions induced ("Does this story induce any emotion for you and if yes what

type of emotions?”), and level of identification with the main characters (“Can you put yourself in the shoes of the character in the story?”). Patients found the scripts easy to understand and reported very high familiarity, believability, and identification with the characters. They stated that they could see themselves in these stories and understand the emotions shared by the characters, and they also found them to be very useful for other patients.

We also tested the scripts in 2 separate focus group meetings with GPs ( $n=6$  [2 women and 4 men]; mean age 45.17, SD 11.89 years) and oncology nurses ( $n=5$ , all women; mean age 49.60, SD 12.16 years). The health care professionals evaluated the scripts on accuracy (“Is all the information provided in the script correct?”), the usefulness of the provided information (“How useful do you find the information in the script?”), and their willingness to share videos once they are available (“Would you share these videos with your patients in the future?”). The results showed that health care professionals found the scripts to be accurate and useful, and they expressed their intentions to use them in the future.

### **Do: Developing the Oncological Module Prototype**

On the basis of the results of the pilot tests with patients and health care professionals, we created a prototype for the oncological module. The prototype included 6 QPLs tested in the previous phase. We used voice actors and added audio support to the QPLs in Turkish, Moroccan Arabic, and Berber (Taraftit dialect), enabling (illiterate) patients to listen to the QPLs in their mother tongue.

Similarly, feedback on the scripts was incorporated, and 5 short videos (1.5–3.5 min long) featuring Turkish-Dutch and Moroccan-Dutch actors were filmed. Once again, voice actors narrated these stories in Turkish, Moroccan Arabic, and Berber (Taraftit). Scripts were largely based on patients’ answers during the interviews in the target group analysis. The first video addressed patients’ instrumental needs about patient rights (eg, right to informed consent) and access to health care services

(eg, dietitian, home care, psychological support). The second video included suggestions to improve GP-patient communication by encouraging patients to prepare before consultations, ask more questions, make use of interpreters, and inform the doctor about their affective needs. The third and fourth videos aimed to provide psychosocial support to patients. The videos acknowledged the negative emotions experienced by patients with cancer and tried to counter them by giving a positive but also realistic message of hope. Topics about self-care, such as the importance of good diet, social contacts, psychological and spiritual support, were incorporated into these videos. The final video aimed to clarify the misunderstandings surrounding clinical trial requests; the video emphasized that a request to join a clinical trial does not mean that the patient has no hope of treatment and that patients can take time to decide on joining these trials, can refuse to join without risking their relationship with their doctors, and can quit if they have accepted to join previously. Furthermore, information regarding the general aim of these trials was provided.

### **Study: Pilot Evaluation of the Oncological Module**

#### **Sample**

The oncological module was pilot-evaluated in practice among 27 Turkish-Dutch and Moroccan-Dutch older patients with cancer aged 50 years and older and cancer survivors (Turkish:  $n=15$ , 9 women, mean age 63.47, SD 2.59 years; Moroccan:  $n=12$ , mean age 63.33 years, SD 2.70 years) and their health care professionals (GPs and oncology nurses:  $n=12$ , mean age 53.50 years, SD 13.34 years; see [Tables 2](#) and [3](#) for sample characteristics). Dutch language proficiency was self-reported by patients on a 4-point scale (1=poor, 2=mediocre, 3=reasonable, and 4=good). Patients were recruited by first targeting their health care professionals; on the basis of snowball sampling, with the help of health care professionals who participated in the earlier phases of the study, we reached other health care professionals, who then invited their patients to participate in the study.

**Table 2.** Background characteristics of patients.

Demographics	Turkish (n=15)	Moroccan (n=12)	Total (n=27)
Age (years), mean (SD)	63.47 (2.59)	63.33 (2.70)	63.41 (9.55)

<sup>a</sup>No participants belonging to the category.

## Procedure

Before the beginning of the pilot testing with patients, all participating health care professionals received an hour-long individual training on how to use the oncological module. Patients evaluated the QPL content and use before their consultations in GP practices or hospitals by means of surveys that were verbally administered to patients in their mother tongue by bilingual trained interviewers. Interviewers presented patients with QPL themes in the oncological module and asked them to choose one or more QPLs that they would like to fill out. After choosing a theme (eg, patient rights), patients saw all available questions within that QPL (eg, “Can I record consultations?”) and selected the ones they wanted to discuss with their professionals during the consultation (Figure 1). Before the consultation started, patients evaluated their experience with the QPLs that they chose. Health care

professionals rated the usefulness and ease of use of QPLs at the end of the pilot study.

Following the QPL selection, patients and professionals consulted the same GP practice or hospital; 18 patients gave consent to have their consultations audio-taped. Patients who did not consent felt that the topics were too private and did not want anyone else to hear them, although their anonymity and confidentiality were guaranteed. After the consultations, patients completed a survey again, measuring their evaluation of the consultation.

After the consultations, the topics of all available narrative videos were briefly described to patients. Patients selected the videos they wanted to watch (Figure 2). Most of the patients preferred to receive videos on their smartphones. When this was not possible, patients requested that the videos were sent to patients’ family members’ phones. After patients watched the videos, phone interviews were conducted within a week, on

average, to assess how they perceived the videos. During the same phone interviews, patients were asked to rate the overall usefulness of the oncological module for improving their communication with their health care providers (ie, “Overall, this tool is useful to improve my communication with my

healthcare provider”). Health care professionals also responded to a similar question during the survey, which they filled at the end of their participation (ie, “The oncological module is useful in bridging communication barriers between migrant patients and their providers”).

**Figure 1.** Breakdown of question prompt lists selected by the patients in the evaluation study. Percentages reflect the percentage of participants that selected that question prompt list. Among the 27 participants, 10 selected 1 and 17 selected 2 question prompt lists. QPLs: question prompt lists.

**Figure 2.** Videos selected by the patients. Percentages reflect the percentage of participants that selected that video. 33% of patients selected 1 video, 22% selected 2 videos, 4% selected 3 videos, 19% selected 4 videos, and 11% selected 5 videos, amounting to an average of 2.27 (SD 1.59) videos requested per patient. GP: general practitioner.

## Measures

All survey items were measured using 5-point Likert scales (eg, 1=completely disagree, 5=completely agree; 1=very difficult, 5=very easy; and 1=very unsatisfied, 5=very satisfied).

### Patients' Evaluation of QPLs

After making their selection, patients assessed the ease of using the tool (both with and without assistance), ease of understanding QPL content and accompanying graphic images, and finally how convenient it was to choose QPLs before a consultation.

### Patients' Evaluations After Consultation

Patients' general satisfaction with the consultation was measured with 1 item (ie, “Overall, how satisfied are you with your consultation?”). Patients' perceptions of the informativeness and supportiveness of the health care professional were measured by 3 and 4 items, respectively, based on Street et al [25] (informativeness Cronbach  $\alpha=.84$ ; supportiveness Cronbach  $\alpha=.95$ ). Patients' attitudes toward the oncological module were measured with 2 items (using this tool “...made communicating with my doctor or nurse easier than usual” and “...had a positive influence on my consultation with my doctor or nurse”; Cronbach  $\alpha=.87$ ) and intention to use it again was measured

with 1 item (“I would like to use this tool again in the future”) [25].

Patients’ perceived participation during the consultation was measured using 5 items from Street et al [25] adaptation of the Lerman et al [26] perceived involvement in care scale (PICS; eg, “I asked my healthcare professional to explain the discussed topics in detail”; Cronbach  $\alpha=.82$ ). An additional question was used to measure the level of participation in comparison with previous consultations (ie, “I felt I could participate more than usual in this consultation”).

### Patient Participation

Patient participation was assessed with a self-developed codebook containing 2 measures: (1) relative talk for each person (ie, patient, health care professional, interpreter or companion) and (2) number and type of questions asked by patients, professionals, and interpreters or companion. In 11 of 18 consultations, an informal interpreter and/or companion was present; 8 consultations were held by nurses, 10 by GPs. Questions were divided according to the QPLs, except for clinical trials because this QPL could not be chosen because it was deemed irrelevant for GPs (ie, patient rights, treatment-related information, psychosocial support, lifestyle and access to health care services, patient information). In addition, a *miscellaneous* category was added to questions unrelated to these categories (eg, social questions, checking understanding, etc). The number of questions was counted per speech turn. If more than one question per turn was asked to address the same topic, this was counted as 1 question. Rhetorical questions were not addressed. Interpreters or companions’ questions that were a translation of a patient’s or professional’s questions were not counted.

### Patients’ Evaluation of the Narrative Videos

During the phone interviews, patients rated how easy it was for them to access (“How easy was it for you to access the videos”) and understand the videos (“The video was easy to understand”) and the usefulness (“The video was useful to improve my understanding of the topic about...”) and informativeness (“The video was very informative concerning the topic about...”) of each video that they had seen. The level of identification with the main characters in the narrative videos was measured with 4 items (Cronbach  $\alpha=.81$ ); 2 items were based on Murphy et al [24] and measured similarity and liking of the main characters. The other 2 items were based on the Cohen [27] identification scale and measured empathy for emotions experienced by the main characters. Finally, the patient’s intention to watch similar videos in the future was measured (ie, “In the future, would you like to watch videos that are similar to the ones that you watched?”) and whether they mentioned the videos to others (eg, friends, family members).

### Health Care Professionals’ Evaluation

After each consultation, health care professionals evaluated the participation of the patients during the consultation. To measure this, the same questions that patients responded to when reporting their participation were used. Specifically, these were the 5 items from the PICS (eg, “The patient asked me to explain the discussed topics in detail”; Cronbach  $\alpha=.74$ ) and the

additional question about comparison of the participation level (ie, “The patient participated more than usual in this consultation”). During the final survey study, health care professionals also evaluated the QPLs and narrative videos on perceived usefulness, ease of sharing with patients, and their intentions to use in the future.

### Analysis

Correlations between variables were calculated by running bivariate correlations using Pearson  $r$  as the correlation coefficient. The relative talk was measured by counting all words per person and calculating the word ratio. Question-asking was analyzed by means of descriptive analyses (mean and SD). Differences in the amount of question-asking were assessed using paired-samples  $t$  tests. The relationship between the first QPL topic choice by the patients and the number of questions asked by patients and health care professionals about that topic during consultations were assessed by simple linear regression analyses. Interrater reliability was calculated for 5 of 18 transcripts (27.7%; two-way mixed-effects model) and was 0.99 for professionals’ questions, 1.0 for patients’ questions, and 0.99 for interpreter or companions’ questions.

### Act

After the *study* phase was completed, a dissemination plan was devised in collaboration with the Dutch expertise center on migrant health care, Pharos, to distribute the oncological module to target audiences. First, to clearly communicate the goal of the oncological module, it was named the *Conversation Starter*. Next, the key organizations and actors that could help us reach health care professionals and older migrant patients with cancer were identified. Different newsletters highlighting the relevant parts of the Conversation Starter were prepared for these different audiences. Finally, a web version of the Conversation Starter that can be freely accessed without the Health Communicator application was created [28].

## Results

### Evaluation of QPL Content and Use

#### Patients

Overall, patients perceived the questions in the QPLs as easy to understand (mean 4.30, SD 0.65) and useful (mean 3.96, SD 0.72). Graphic images accompanying the QPLs were perceived as easy to understand (mean 3.75, SD 1.14). Patients found the usefulness of the images in aiding the understanding of the questions as neutral (mean 3.23, SD 1.27). Overall, participants found it relatively easy to use the QPL function in the oncological module (mean 3.54, SD 1.07). They had low confidence, although still neutral, about their ability to use the tool easily without any assistance (mean 3.19, SD 1.44). There was a strong negative correlation between the ease of using the tool and patient age. It was harder for older patients to use the QPLs ( $r=-0.48$ ;  $P=.01$ ), and they were also less confident in their ability to use the tool without any assistance ( $r=-0.67$ ;  $P<.001$ ). Approximately 70% of the patients reported that it was convenient for them to select the QPLs before their consultations (mean 3.85, SD 1.35). Similarly, younger age was

related to reporting more convenience in using the QPL function before consultations ( $r=-0.56$ ;  $P=.003$ ).

### Professionals

Health care professionals rated the QPLs as rather useful (mean 3.67, SD 1.07) and overall somewhat easy to use (mean 3.44, SD 0.96).

### Patient Participation

The mean consultation length was 14.09 min (SD 7.60; range 3.37–35.06 min). Professionals spoke, on average, most words (48.15%; range 166–2481), followed by patients (33.5%; range 130–2544), and interpreters or companions (18.35%; range 38–1672). The mean number of questions asked per consultation was 24.55 (SD 17.21; range 11–89). Professionals asked significantly more questions (mean 15.72, SD 9.36; range 3–43) than both patients (mean 4.56, SD 5.45; range 0–23;  $t_{17}=6.61$ ;  $P<.001$ ) and interpreters or companions (mean 4.28, SD 6.44; range 0–23;  $t_{17}=4.81$ ;  $P<.001$ ). The most asked questions were about treatment-related information (mean 9.89, SD 15.87), followed by questions on miscellaneous topics (mean 9.28, SD 4.34), patient rights (mean 2.17, SD 2.04), psychosocial support (mean 1.67, SD 2.97), and lifestyle and access to health care services (mean 1.50, SD 2.75). The least asked questions were about patient information (mean 0.06, SD 0.24).

### Relationship Between QPL Choice and Participation During Consultations

#### Patients

Overall, no significant relationship was found between the first QPL selection and the number of questions asked by patients during the consultation about that topic (patient rights:  $R^2=0.17$ ,  $b^*=0.12$ ;  $t_{16}=0.68$ ,  $P=.51$ ; 95% CI  $-0.267$  to  $0.517$ ; treatment:  $R^2=0.05$ ,  $b^*=-0.01$ ;  $t_{16}=-0.20$ ,  $P=.84$ ; 95% CI  $-0.058$  to  $0.048$ ; and psychosocial support:  $R^2=0.15$ ,  $b^*=-0.11$ ;  $t_{16}=-0.60$ ,  $P=.56$ ; 95% CI  $-0.502$  to  $0.279$ ). As there were not enough patients who selected the QPLs about lifestyle and access to health care services and patient preferences as their first choice, it was not possible to run the analyses to test these relationships.

#### Professionals

Similarly, we tested the relationship between patients' first QPL choice and the number of questions posed by health care professionals about that topic. The number of questions asked by the health care professionals in a given topic was marginally significantly predicted by the first QPL topic selected by the patients for patient rights ( $R^2=0.42$ ,  $b^*=0.14$ ;  $t_{16}=1.85$ ,  $P=.08$ ; 95% CI  $-0.021$  to  $0.309$ ) but not for treatment ( $R^2=0.09$ ,  $b^*=-0.01$ ;  $t_{16}=-0.37$ ,  $P=.72$ ; 95% CI  $-0.040$  to  $0.028$ ) and psychosocial support ( $R^2=0.15$ ,  $b^*=0.02$ ;  $t_{16}=0.61$ ,  $P=.55$ ; 95% CI  $-0.060$  to  $0.108$ ).

### Evaluation of Consultations

#### Patients

Overall, patients reported being highly satisfied with their consultations (mean 4.31, SD 0.55). They perceived their

providers as informative (mean 4.17, SD 0.57) and supportive (mean 4.34, SD 0.59). They also reported that using the module positively impacted consultations (mean 3.90, SD 0.55). Patients perceived themselves to be rather active during the consultations (mean 3.75, SD 0.84) and thought they were somewhat more active in comparison with previous consultations (mean 3.75, SD 0.79). Most (70%) of the participants reported that they would like to use the tool in the future (mean 3.85, SD 1.25). The age of the participants had a strong negative correlation with their wish to use the tool in the future ( $r=0.45$ ;  $P=.02$ ).

#### Professionals

Professionals' evaluation of the patients' participation revealed similar, although slightly lower scores. Professionals found patients to be slightly more active in asking questions and expressing themselves (mean 3.42, SD 0.70) and somewhat more active than their usual levels of participation (mean 3.61, SD 1.06). Both patients' and providers' evaluations were positively correlated for each of these measures ( $r=0.58$ ,  $P=.002$  and  $r=0.64$ ,  $P<.001$ , respectively).

### Evaluation of Narrative Videos

#### Patients

Patients rated the videos as easy to understand (mean 4.30, SD 0.47), useful (mean 4.00, SD 0.62), and informative (mean 4.20, SD 0.57). Identification with the characters in the videos was high (mean 3.93, SD 0.54). Patients were somewhat motivated to watch similar videos in the future (mean 3.55, SD 0.85). Around 30% of the patients talked about videos with others (ie, told their friends and family members that they watched them).

#### Professionals

Professionals rated the videos as useful (mean 3.92, SD 1.08). They were neutral about the ease of sharing the videos with their patients (mean 3.25, SD 1.06) and showed some intentions to share them (mean 3.42, SD 1.08).

### Overall Evaluation of the Oncological Module

Overall, patients found the tool to be useful in improving their communication with their health care professionals (mean 4.27, SD 0.88). Health care professionals rated the usefulness of the oncological module less favorable than the patients (mean 3.42, SD 1.16).

## Discussion

### Principal Findings

This paper elaborates on the development of an oncological module aimed at increasing patient participation between older migrant patients with cancer and their health care professionals. Using the STAR model as our framework, the module was developed with continuous input from relevant community members, namely older migrant patients with cancer, oncology nurses, GPs, and researchers. This multifaceted contribution allowed us to develop a multilingual intervention that received positive evaluations from both migrant patients with cancer and professionals. Patients most often chose the QPL for patient rights. Both patients and health care professionals perceived the QPLs as somewhat easy to understand and useful. The

correlation between the ease of using the tool and patient age was negative. Health care professionals asked significantly more questions than patients, whereas patients reported that using the module impacted the consultations positively and thought they were more active compared with previous consultations. Health care professionals echoed that patients were more active than usual. However, there were no significant relations between patients' first choice of QPLs and the number of questions asked about that topic during consultations. Patients requested to see the patients' rights video most often, and overall rated the videos as easy to understand, useful, and informative. Most of the patients reported that they like to use the tool in the future.

Aligned with the study by Walczak et al [29], migrant patients with cancer in this study evaluated the QPLs as easy to understand and quite useful. This is likely to be the result of the fact that the QPLs served the function of breaking down all cancer-related information that existed in small segments. By doing so, large chunks of information were labeled, which helped migrant patients to identify their concerns and needs more easily, thus preventing the possibility of experiencing cognitive overload [29]. Nonetheless, the evaluation became less positive with an increase in patients' age. The older the patient, the less easy they found using the tool, which might partly be explained by a decrease in one's cognitive competence over time and the digital divide (ie, a disparity in using digital technologies between young and old migrants and nonmigrants) [30-32]. To be readily able to adopt eHealth tools, older patients first have to be in a physically good condition and, second, be cognitively competent enough to develop internet literacy [33]. On the basis of the results of a systematic review, a suggested solution to help (older) migrant patients to better understand how QPLs work would be through incorporating a training component for patients [34]. In our intervention, only health professionals were trained. However, this—and even more in-depth training—is not sufficiently useful for patients because language barriers professionals are limited in their ability to pass on their training to patients. Therefore, a training component specifically targeted for patients is needed not only to ensure that the consultation sessions would be effectively guided by the QPLs but also to offer guidance for older migrant patients who might need help using the tool owing to old age [35]. This component can perhaps be added after each consultation session and shared with family members of the patient so that older migrant patients and their relatives are exposed to the tool more frequently, which in turn helps to increase their familiarity with the tool and enable relatives to help their older family members in using it.

Results collected to examine patient participation during the consultation sessions revealed that professionals were more active than patients in terms of leading the conversation and asking questions. A recent study revealed that patients' passive participation could be owing to the knowledge and language barriers they face [36], also indicated by the lack of relation between the choice of QPLs and the type of questions asked. Although an interpreter or a companion was present during most of the consultation sessions, it is still possible that the patients had a lack of understanding about the subject matters raised by the professionals and/or did not have the ability to ask questions

about the topics they indicated to want to discuss by their QPL choice because of an unresolved language barrier during the consultations. As a result of these barriers, there is a possibility that patients possessed insufficient competence to formulate the exact question or response they would like to make, especially when it comes to disagreeing with a statement proposed by the professional, as this requires more effortful processing, compared with simply agreeing with a statement [36,37]. As such, they may experience a lack of confidence and choose to refrain from making their point, thus generating fewer questions and talk, leading to a relatively passive outcome in terms of patient participation. As indicated by Cegala and Post [38], a lack of response from the patients' end hinders the active adoption of a more patient-centered communication from the professionals' end. This shows that there is a need for patients to be more empowered to secure a consultation session with active patient participation [38].

Given that the results indicated that most questions raised were about treatment-related information, a possible solution to tackle patients' passiveness would be through distributing information related to their cancer diagnosis in their native languages along with the QPLs before each consultation session, if they had a preference for this information. This approach can enhance patients' knowledge of the subject, which, in turn, allows them to become more confident in expressing their views and opinions about the professionals' suggestions and thus facilitate patient-centered communication, resulting in active patient participation. In addition, working with professional interpreters instead of nonprofessional interpreters during consultations is recommended, as most patient rights topics discussed during the consultations were related to patients' need for a professional interpreter. This will lead to better translations and enhance patients' understanding of the conversation [39,40], enabling more active participation during consultations.

The assessment of migrant patients with cancer of their QPL-incorporated consultation sessions was fairly positive, with patients expressing high satisfaction and concluding that the QPLs helped to impact their consultation sessions positively. Professionals' overall evaluation of patients' participation was less satisfactory, possibly because patients did ask fewer questions and contributed less to the conversation than they might have expected as a result of the intervention. On the other hand, for patients, the QPLs were able to help them identify topics of interest in a more direct manner, and, in turn, this helped professionals to formulate a clearer picture of their unmet instrumental and/or affective needs and prepare the consultation sessions based on this feedback. Although only marginally significant, the positive relationship between patients' choice of the patient rights QPL and health care professionals' questions about patient rights seems to lend some substantiation for this positive effect of QPLs, helping both parties to bring up the topic of patient rights more immediately during their consultation, thus increasing patient satisfaction with the consultation sessions [34]. Corresponding with previous research, this indicates that using QPLs allowed for more effective communication between patients and professionals, as indicated by the perceived higher than usual patient

participation, helping to improve the consultation sessions and encourage active patient participation [34,41].

Finally, both patients and professionals evaluated educational videos positively. Patients reported fairly high levels of identification with the characters in the narrative videos and expressed moderate intentions to watch similar videos in the future. High levels of identification with the character in the videos might likely have helped migrant patients with the ease of processing information presented because of sharing a common background with the characters [42]. Ultimately, this leads to more informed and empowered patients and, in turn, results in positive attitudes toward videos and better quality in health communication and care. What was especially interesting here was that the results reflected the patients showing more interest in narrative videos that covered the theme of patient rights in comparison with the other themes. This preference was also reflected in the selection of themes in the QPLs. Corresponding to previous research, this shows that there is a possibility that migrant patients often feel that they are not taken seriously, and to a certain extent, even discriminated against by their doctors [5,43]. Nonetheless, the precise concerns migrant patients might have concerning their rights are still scarcely researched and, thus, pointing to the fact that more empirical evidence is needed to understand inadequacies in the health care system for older migrant patients. Overall, this warrants that future research is needed to determine the underlying motivations and reasons behind choosing this theme.

### Study Limitations and Future Research

Although older migrant patients with cancer showed some intentions to use the oncological module in the future, the results indicated that older patients had concerns and expressed little ease and confidence in their ability to use the tools on their own, especially regarding using the QPLs. Again, this shows that training patients remains a crucial component of such intervention to be effective, as this study did not sufficiently target the issue of adopting and adhering to the eHealth tool, which is especially important among older adults because of their low internet self-efficacy [44]. Previous research has indicated that just short-term training can lead to successful information and communication technology adoption and outcomes for ethnically diverse older people [45]. In addition, future studies could incorporate the extended TAM and senior technology acceptance model (STAM) into the developmental process [44,46] instead of using the original TAM that was used in this study. The extended TAM sheds light on several spearheads, such as the amount of text used, page organization, and the incorporation of offline support to increase the perceived ease of use of an eHealth tool among older adults [44], whereas the STAM also incorporates age-related health and ability characteristics, such as gerontechnology self-efficacy [46]. Taking these additional factors suggested by the extended TAM

and STAM into consideration, this might further increase the tool's overall user-friendliness and lead to higher levels of perceived ease of use, usefulness, and intention to use.

Furthermore, as there is a dearth of research assessing digital literacy skills among older migrant patients, future studies are needed to gain more insight into their (lack of) competence to use new technologies in everyday life [47] and what is needed to enhance their skills. The results of such studies will help future intervention developers to gain a deeper insight into understanding what features are indeed appropriate and easy to use. The combination of incorporating the extended TAM and measuring older patients' digital literacy might help to produce higher levels of adoption and adherence to QPLs, which ultimately increases patient participation during the consultation sessions.

Another limitation of this study is related to the developmental process of the prototype. The STAR model was designed fundamentally to promote healthy behaviors among young adolescents by encouraging them to actively participate in the e-tool developmental process [48]. This involves all stakeholders being present in the discussions and decisions taken during all developmental phases. Although we did include patients in as many phases as possible, this approach was deemed unfeasible in the *do* phase when the prototype was developed, given the fact that our target group is rather vulnerable because of their sickness and old age. As the inclusion of people who represent different areas of expertise could increase the effectiveness of brainstorming sessions largely [49], future studies should explore the possibility and feasibility of inviting ethnic minority patients who are not ill yet or migrant patients' close relatives to take part directly in this phase of the intervention development. This could help eHealth developers to obtain a fuller picture of the attributes that can be added to the module and help maximize the customization of the tool for the target user.

### Conclusions

We conclude that QPLs make the oncological module a beneficial tool to assist health care professionals in question-asking during consultations and to better fulfill the instrumental and affective needs of older migrant patients with cancer. In addition, the use of narratives to inform older and low-literate migrant patients with cancer about health-related topics in their mother tongue is a viable approach to increase the effectiveness of health care communication with this target group. However, given that older migrant patients are less able to use the QPLs on their own, health care professionals should also look into the feasibility of adding a training component to offer offline guidance in navigating the QPLs. Finally, the oncology module developed in this study is a promising tool for both patients and health care professionals.

### Acknowledgments

The authors would like to thank all the participating patients, health care providers, and research assistants who made this project possible. The authors would also like to thank the reviewers for their valuable contributions, which helped us to improve this paper.

## Abstract

**Background:** In recent decades, advances in information technology have given new momentum to telemedicine research. These advances in telemedicine range from individual to population levels, allowing the exchange of patient information for diagnosis and management of health problems, primary care prevention, and education of physicians via distance learning.

**Objective:** This scientometric investigation aims to examine collaborative research networks, dominant research themes and disciplines, and seminal research studies that have contributed most to the field of telemedicine. This information is vital for scientists, institutions, and policy stakeholders to evaluate research areas where more infrastructural or scholarly contributions are required.

**Methods:** For analyses, we used CiteSpace (version 4.0 R5; Drexel University), which is a Java-based software that allows scientometric analysis, especially visualization of collaborative networks and research themes in a specific field.

**Results:** We found that scholarly activity has experienced a significant increase in the last decade. Most important works were conducted by institutions located in high-income countries. A discipline-specific shift from radiology to telestroke, teledermatology, telepsychiatry, and primary care was observed. The most important innovations that yielded a collaborative influence were reported in the following medical disciplines, in descending order: public environmental and occupational health, psychiatry, pediatrics, health policy and services, nursing, rehabilitation, radiology, pharmacology, surgery, respiratory medicine, neurosciences, obstetrics, and geriatrics.

**Conclusions:** Despite a continuous rise in scholarly activity in telemedicine, we noticed several gaps in the literature. For instance, all the primary and secondary research central to telemedicine was conducted in the context of high-income countries, including the evidence synthesis approaches that pertained to implementation aspects of telemedicine. Furthermore, the research landscape and implementation of telemedicine infrastructure are expected to see exponential progress during and after the COVID-19 era.

## Introduction

Advances in information and communication technologies (ICTs) have virtually reduced the world to a global village. The recent progress in ICTs has also shown incredible promise in addressing significant challenges in health care in disparate regions worldwide. Specifically, telemedicine ensures the provision of accessible, cost-effective, and specialized health care services in disparate areas. According to the World Health Organization (WHO), telemedicine pertains to the delivery of health care using different modalities embedded in the realms of information and communication technologies. It aims to advance health care, ranging from individual to population levels, by allowing exchange of patient information for diagnosis and management of health problems, primary care prevention, and education of physicians via distance learning [1]. Telemedicine is a new channel for health care services, which also enables opportunities to strengthen collaborative research.

The earliest evidence for telemedicine can be traced back to a clinical report published in *The Lancet* in 1879, which described the successful diagnosis of a child over the phone [2]. In addition, use of telegraphs was also evident in the American Civil War for transfer of mortality data and remote delivery of medical care [3]. A fine example of telemedicine was seen when, 20 years ago, the National Aeronautics and Space Administration monitored the astronauts' well-being during the Apollo mission to the moon. The modern form of telemedicine, however, appeared with the advent and maturation of the internet, which made possible the use of videoconferencing, high-quality data transfer, and distance learning platforms at a lower cost. The potential of telemedicine in strengthening health systems was also recently recognized by the WHO, leading to the establishment of the Global Observatory for eHealth in 2005 [1]. In 2009, the telemedicine module of the Global Observatory for eHealth mapped the development of telemedicine in 4 specialties of medicine—pathology, radiology, psychology, and dermatology—in 114 member states. This report found that the greatest development had been made in the provision of teleradiology services (33%) among the WHO member states, while 20% of the countries reported conducting a national review or evaluation of telemedicine. In addition, 50% of the member states reported that they had institutions dedicated to the development of telemedicine solutions [1].

The most recent report by the WHO, published in 2016, emphasized the role of eHealth in achieving universal health coverage [4]. The development of telemedicine was found crucial in the attainment of sustainable development goal 8, “achieve universal health coverage,” and goal 3, “ensure healthy lives and promote well-being for all at all ages,” thus ensuring health for all, regardless of creed, ethnicity, color, or finances. It also identified a rapid progress among its member states from 2010 to 2016. At least 83% of the countries had reported a mobile health (mHealth) initiative, widespread use of teleradiology (from 33% to 77%), telepathology or teledermatology (about 50%), and telepsychiatry (33%). In addition, e-learning initiatives were reported in 84% of countries and the use of national electronic health records in 47% of the member states, and 78% of the countries reported legislations

ensuring privacy of the electronic data. However, similar to the previous survey, very few countries had conducted evaluations of mHealth programs, which limits our understanding of the use of telemedicine, its barriers and facilitators, and which elements actually work [4]. These reports are a milestone in the field of telemedicine. However, these were dependent on data provided by government organizations and were heavily focused on government-run telehealth initiatives [4].

While the WHO-commissioned reports and evidence synthesis publications were indispensable in gauging worldwide infrastructure and legislation in telemedicine, scholarly research is a true marker for progress and evolution in every scientific field, and it is crucial to map research output in the field of telemedicine to determine prevalent research themes in order to guide policy makers and funders to improve or restrict flow of funding when required. Recognizing the importance of mapping progress in a field, scientists have devised several reproducible statistical methods that form the disciplines of bibliometrics and scientometrics. Scientometrics is defined as the “quantitative study of science, communication in science, and science policy” [5], and it helps evaluate the impact of journals, scientists, and institutions on the development and innovation of a scientific field.

Several studies published recently have used bibliometric methods to study progress in telemedicine, albeit in a very narrow context. For instance, Fatehi and Wootton [6] focused on delineating the use of different terminology to describe telemedicine, Groneberg et al [7] detailed the country-specific publication output and annual trends of publication and citation outputs, Gu et al [8] described the intellectual structure of telemedicine research by focusing on collaborative networks between different countries and authors, and Askari et al [9] provided an overview of the top 60 most frequently cited studies in telemedicine-specific journals. There is, however, a paucity of studies providing a holistic snapshot of advances in telemedicine from 2010 to 2019. The present analysis leverages the use of scientometric techniques to analyze publication output in the field of telemedicine worldwide, regardless of the government, industrial, or academic affiliations.

## Methods

### Bibliographic Search

An academic search of the Web of Science (WOS) core database was performed covering January 2010 to December 2019 to retrieve English language papers, using the following keyword: TS=(telemedicine). We restricted our search results to papers published in English only. The bibliographic records of these studies, including titles, abstracts, author details, affiliations, keywords, and citing references, were downloaded. We restricted our search results to the last 10 years to restrict our analyses in order to achieve a snapshot of recent research activity in telemedicine. The WOS core database was used for this academic search for two important reasons: it provides large coverage of over 20,000 peer-reviewed journals pertaining to 250 disciplines in health and social sciences and engineering and it is the only database that allows curation of citing

references of each indexed publication to allow cocitation analyses.

## Operational Definitions

Telemedicine literally means “healing at a distance.” However, there are no definitive definitions of telemedicine, with a recent review reporting over 104 peer-reviewed definitions found in the literature [10]. However, for the purpose of this scientometric investigation, we adapted a definition of telemedicine embodying 4 crucial elements: (1) provision of clinical support, (2) connection of users from different physical locations, (3) improved health outcomes, and (4) use of ICT [4,6].

## Knowledge Visualization Analyses

For analyses, we used CiteSpace (version 4.0 R5; Drexel University), which is a Java-based software that allows scientometric analysis, especially visualization of collaborative networks and research themes in a specific field [11,12]. The visualization of these collaborative networks in a discipline is based on the theory of cocitation, which posits that 2 documents share a cocitation relationship when they are cited together by another document [11,12]. For mapping of these networks, we ran network analyses using the cosine link reduction method and pathfinder networking scaling. Term sources were set as titles, abstracts, and author keywords, while nodes were set as cited references to delineate collaborative networks and cluster analyses. The time-splicing method was used to explore publications in 2 periods, 2010 to 2014 and 2015 to 2019, where each slice comprised the top 50 cited papers every year.

To obtain clusters or themes of research, we ran cluster analyses in which each cluster was termed according to publication keywords using 2 text-mining methods: term frequency-inverse

document frequency (TF-IDF) and log likelihood ratio (LLR). The first method, TF-IDF, uses terms that are weighted by term frequencies multiplied by inverted document frequencies [11,12]. LLR tests choose the most appropriate clustering label by assessing the strength of the bond between a term and a cluster [11,12]. A cluster is said to be parsimonious when it comprises a larger number of items and an acceptable silhouette and modularity value (Q). The silhouette value is a measure of how similar an object is to its own cluster (cohesion) compared with other clusters (separation) [11,12]. The value of Q and silhouette ranges between  $-1$  to  $1$ , where a value closer to  $1$  is considered acceptable.

Each paper is presented as a node and links between two nodes as edges. The collaborative network mapped from this analysis yields several important results. Any research study with centrality values  $\geq 0.1$  are considered influential in their collaborative networks. Citation rings show annual citation patterns, while purple nodes represent landmark theories or works that give rise to a new body of work. Citation bursts revealing short periods of high scholarly activity are presented as red rings. Based on these cues, researchers can identify important works in a field and important themes of research.

## Results

### Bibliometrics

Web of Science (core database) yielded 6896 publications from 2010 to 2019, with a total h-index of 87 and an average 10.64 citations per study. These were cited a total of 73,354 times by a total of 42,381 citing papers. There was an increasing trend in both the publication and citation output from 2010 to 2019 (Figure 1).

**Figure 1.** Trends of citations received by papers in telemedicine.

### Regional Trends in Telemedicine Research

Regionally, the highest publication output (in English) was contributed by high-income countries: the United States, Australia, England, Canada, and Germany. There were 2 middle-income countries, India and the People’s Republic of China, that also ranked in the top 10 for publication output. However, in terms of having a centrality score of 0.1 or greater, 6 countries—England, France, Belgium, Portugal, the People’s

Republic of China, and Greece—appeared to hold significant influence in worldwide collaborations in telemedicine. These countries are also presented as purple nodes in Figure 2 (ie, contributing groundbreaking research). These central nations, although mainly high-income countries, also formed collaborations with a number of low- and middle-income countries (LMICs), such as Ethiopia, Mali, Botswana, Nepal, Zimbabwe, Pakistan, and Uganda.

**Figure 2.** Regional collaborative networks in the area of telemedicine research. Peoples R China: People's Republic of China; USA: United States of America.

### Institutional Trends in Telemedicine Research

Among institutions, the top 9 contributing institutions in terms of publication output were based in the United States, including the University of California system (n=304), Harvard University (n=227), and the Pennsylvania Commonwealth System of Higher Education (n=152). Outside of the United States, the

University of Queensland in Australia was the fifth-highest contributing region. Institutions with centrality  $\geq 0.1$  included Columbia University, University of Queensland, University of Toronto, and Karolinska Institute. It is noteworthy that none of the top 9 US institutions in terms of publication output were deemed important in their collaborative networks (Figure 3).

**Figure 3.** Institutional collaborations in telemedicine research. CSIRO: Commonwealth Scientific and Industrial Research Organisation; Hlth: Health; Inst: Institute; Sci: Science; Univ: University.

### Discipline-Specific Trends in Telemedicine Research

An analysis of the Web of Science revealed that the disciplines of health care sciences and services ( $n=2338$ ) and medical informatics ( $n=835$ ) reported the highest number of publication items. However, a total of 19 disciplines had the greatest centrality values ( $\geq 0.1$ ). Most important innovations yielding a

collaborative influence were reported in the following medical disciplines, in descending order: public environmental and occupational health, psychiatry, pediatrics, health policy and services, nursing, rehabilitation, radiology, pharmacology, surgery, respiratory medicine, neurosciences, obstetrics, and geriatrics (Figure 4).

**Figure 4.** Discipline-specific trends in telemedicine research.

### Keyword Analysis in Telemedicine

A total of 106 research keywords were identified in the field of telemedicine, revealing the most-researched topics (Figure 5). From 2010 to 2019, 32 keywords appeared to have citation

outbursts showing the greatest research activity in telemedicine (Figure 6). The top 50 cited keywords in tandem with citation outbursts were divided into themes to identify the most frequently researched diseases, outcomes, study designs, and populations, shown in Table 1.

**Figure 5.** Research keywords in telemedicine research. acce: access; outcm: outcome.

**Table 1.** Research keywords in telemedicine by theme.

Theme	Most frequent keywords
Diseases	Diabetic retinopathy, stroke, depression, heart failure, rehabilitation, thrombolysis
Performance indicators	Feasibility, accuracy, reliability, barrier, adherence, satisfaction, performance, cost-effectiveness
Outcomes	Self-management, support, impact, diagnosis, education, mortality, quality of life, telemonitoring
Study design	Association, follow-up, meta-analysis, randomized controlled trials, implementation, prevalence
Disciplines	Telestroke, teledermatology, telepsychiatry, primary care
Setting	Home, internet, videoconferencing, communication, telecommunication, smartphone
Population	Veterans, United States, children

## Clusters of Research in Telemedicine From 2009 to 2014

From 2009 to 2014, a total of 2527 papers were published, which were cited by 141,702 references. These were analyzed to study landmark publications and clusters of research during

this period. There was a total of 228 nodes and 273 edges. Cluster analysis yielded a parsimonious network of clusters (Figure 7) with a modularity of 0.85 and silhouette value of 0.42. It yielded a total of 56 clusters, out of which 8 comprised at least 10 studies each and an acceptable silhouette value (range 0.85 to 1.0).

**Figure 7.** Clusters of research in telemedicine from 2009 to 2014.

## Acute Medicine

### Stroke

The zeroth cluster comprised 32 items with a silhouette value of 0.98, described by terms such as information technology (TF-IDF) and acute ischemic stroke and thrombolysis (LLR). The third cluster pertained to mobile stroke units (TF-IDF) and associated mortality and economic outcomes (LLR).

### Telecardiology

The second cluster pertained to telemonitoring at home (TF-IDF) for chronic diseases such as heart failure (LLR). The fifth cluster was focused on clinical management and home monitoring (TF-IDF) of pacemaker activity and implantable cardioverter defibrillator (LLR), especially in patients with myocardial infarction.

## Chronic Diseases

### Diabetes

Cluster 7 pertained to general practitioner-mediated telecardiology (TF-IDF) and user acceptance of this program (LLR). The sixth cluster pertained to nutrition in diabetes, especially in the context of the Columbia University Informatics for Diabetes Education and Telemedicine project.

### Telepsychiatry

The third cluster was defined as neuropsychological assessment (by TF-IDF method), focusing on posttraumatic stress disorder (PTSD) and cognitive behavioral therapy (LLR method).

### Respiratory Medicine

This cluster (the fifth cluster) pertained to self-management of chronic obstructive pulmonary disease (COPD) and its exacerbation (TF-IDF and LLR).

## Landmark Publications From 2009 to 2014

The period from 2009 to 2014 revealed 10 landmark publications pertaining to different themes, where most of the publications pertained to intensive care, especially stroke (Table 2) [13-16]. Audebert et al published 3 important studies [17-19] demonstrating the success of the telemanagement of stroke in rural hospitals in Bavaria, Germany. In a similar context, Schwamm et al [13] provided evidence for telestroke consultations via videoconferencing and Lilly et al [14] showed that the implementation of a tele-intensive care unit (ICU) intervention was associated with reduced adjusted odds of mortality and reduced length of hospital stay, as well as with

changes in best-practice adherence and lower rates of preventable complications. In their cross-sectional survey, Silva et al [16] described the status of telestroke programs in the United States. In addition, 2 important literature reviews were published during this period. Sood et al [10] improved our understanding of the theoretical underpinnings of modern telemedicine after a careful evaluation of 104 peer-reviewed publications, while Kahn et al [15] summarized the recommendations of a working group for the adoption of a standardized framework for the standardized conduct of tele-ICU studies. Lastly, May et al [20] described the complexity that exists in the scale-up of telemedicine programs, which is often underestimated, leading to their failures.

**Table 2.** Lessons learned from landmark publications from 2009 to 2014.

Author (year)	Study design	Theme	Disease	Lesson learned
Broens (2007) [21] <sup>a</sup>	Qualitative literature review	Implementation	N/A <sup>b</sup>	Determinants of successful implementation and scale-up of telemedicine programs. Important determinants of telemedicine programs include (1) technology, (2) acceptance, (3) financing, (4) organization, and (5) policy and legislation.
Schwamm et al (2004) [13]	Retrospective	Feasibility	Stroke	Telestroke consultation via videoconferencing improved care in 95% of the cases.
Silva et al (2012) [16] <sup>a</sup>	Cross-sectional survey	Barriers and facilitators	Stroke	Status of telestroke in the United States. The top 3 clinical needs met by telestroke were emergency department consultation (100%), patient triage (83.8%), and inpatient teleconsultation (46.0%).
Kahn et al (2011) [15] <sup>a</sup>	Working group statement	Guidelines	Intensive care	This working group meeting was convened to address methodological and knowledge gaps in the field. It proposed adoption of a common framework to facilitate standardized conduct of telemedicine studies in the ICU <sup>c</sup> .
Audebert et al (2005) [18]	Retrospective	Feasibility	Stroke	Telemedicine provided a cost-effective method to recommend use of thrombolysis among patients presenting with stroke in rural regions.
Lilly et al (2011) [14] <sup>a</sup>	Prospective stepped-wedge clinical trial	Effectiveness	Intensive care	Implementation of a tele-ICU intervention was associated with reduced adjusted odds of mortality and reduced length of hospital stay, as well as with changes in best-practice adherence and lower rates of preventable complications.
May et al (2003) [20]	Qualitative study	Implementation	N/A	Complexity exists at 4 discrete levels in any given telehealth context: implementation, adoption, translation, and stabilization. This complexity is often underestimated, leading to failed scale-ups.
Sood et al (2007) [10] <sup>a</sup>	Literature review	Theoretical underpinnings	N/A	Defined modern telemedicine after a careful review of 104 publications.
Audebert et al 2006 [17]	Prospective	Feasibility	Stroke	The telestroke concept promises better coverage of systemic thrombolysis in nonurban areas.
Audebert et al 2006 [19] <sup>a</sup>	Nonrandomized clinical trial	Trial	Stroke	Treatment in rural hospitals independently reduced the probability of a poor outcome compared with controls.

<sup>b</sup>N/A: not applicable.

<sup>c</sup>ICU: intensive care unit.

## Clusters of Research in Telemedicine From 2015 to 2019

From 2015 to 2019, a total of 4493 records were published, which were cited a total of 141,702 times. Cluster analyses yielded a parsimonious cluster network with a modularity of 0.69 and a silhouette value of 0.39. To get a snapshot of research themes in this period, we analyzed a total of 205 nodes with

345 edges. A total of 27 clusters of research in telemedicine were identified, out of which 12 had an acceptable silhouette value. In size, these clusters ranged from 8 to 23 studies, and modularity values ranged from 0.97 to 0.71. These clusters fell into 4 major themes: (1) clinical decision support systems, (2) reliability, (3) access to health care, and (4) medical conditions (Figure 8).

**Figure 8.** Clusters of research in telemedicine from 2015 to 2019.

### *Clinical Decision Support Systems*

The zeroth cluster pertained to clinical decision support systems to aid in self-management (TF-IDF), explored in the context of ulcerative colitis (LLR) and lung cancer (mutual information).

### *Reliability*

A total of 2 clusters (1 and 8) focused on reliability and interexpert agreement (TF-IDF) pertaining to telemedicine-aided diagnoses mediated by general practitioners (TF-IDF), especially in the field of teler dermatology (LLR).

### *Access to Health Care*

A total of 3 clusters (2, 3, and 9) pertained to this thematic area of telemedicine, defined by access to telemedicine in shortage areas (TF-IDF) to aid in the diagnosis of diabetic retinopathy. Rural health care was an important component of this research theme, where the issue of switching time between pediatric consultations was thoroughly researched.

### *Medical Conditions*

A total of 4 clusters (4, 5, 6, and 7) focused on both acute and chronic conditions, for instance, general practitioner-mediated mental health care, especially in PTSD. Cluster 5 pertained to telecardiology, in which heart failure, remote monitoring of pacemaker activity, and patient satisfaction were important areas of research. In accordance with research prior to 2015, acute ischemic stroke and thrombolysis were important research areas in telestroke. In the specialty of tele-ICU, the care of critically ill patients, especially those undergoing liver transplantation, and economic outcome were the most researched areas.

### *End Consumer Research*

Patient compliance, safety, and satisfaction were explored in 2 clusters (10 and 11).

### **Landmark Publications From 2015 to 2019**

This period of scholarly activity in telemedicine continued to be influenced by 4 studies published prior to 2015 [13,14,22-24], pertaining to tele-ICU, telestroke, tele-mental health, and facilitators and barriers to telemedicine. The majority of publications unique to this time period were literature reviews, systematic or otherwise (n=10), followed by retrospective studies (n=2) and a clinical trial (n=1). Major themes in this era were effectiveness and cost-effectiveness research (both primary and secondary). In addition, the connected health model of health care, which governs telemedicine, and the standardized framework for assessment of telemedicine commissioned by the European Commission were deemed central in these collaborative networks.

The most influential review in this period pertained to chronic diseases and was an evidence synthesis report on 141 randomized controlled trials relating to asthma, COPD, diabetes, heart failure, and hypertension [25]. It reported strong evidence of publication bias, with 108 randomized controlled trials reporting positive results and almost none reporting harm [25]. Wade et al [26] presented a systematic review regarding economic analysis of telemedicine and concluded that the delivery of health services by real-time video communication was cost-effective for home care and access to on-call hospital specialists.

Effectiveness research was conducted using both primary interventional and evidence synthesis approaches. For instance, Chaudhry et al [27] conducted a clinical trial and showed that telemonitoring did not improve outcomes among patients hospitalized for heart failure. In their reviews, Ekland et al [28] and Flodgren et al [29] examined effectiveness of telemedicine in multiple conditions [28,29]; Elbert et al [30] focused on effectiveness and cost-effectiveness for somatic

diseases and Hubley et al [31], on psychiatric diseases. Bashshur et al [32] examined 3 tracer diseases (heart failure, stroke, and COPD), which, when treated using telemedicine approaches, showed several markers of improvement, such as reduced hospital admissions and readmissions, length of hospital stay, and emergency department visits. Fierson et al [33] reviewed the currently available literature on telemedicine-based remote digital fundus imaging evaluations for retinopathy of prematurity and outlined pertinent practical and risk management considerations.

Kvedar et al [34] presented a model of care to make telemedicine an important part of the US health care system. He reported that

care processes in the United States are insufficient to address the mismatch in supply and demand of health care providers [34]. This review presented connected health as a new care model to improve patient care with telemedicine and telehealth. Kidholm et al [35], after synthesizing evidence from a stakeholders meeting, presented a framework for the assessment of telemedicine with 7 important domains: (1) health problem and description of the application, (2) safety, (3) clinical effectiveness, (4) patient perspectives, (5) economic aspects, (6) organizational aspects, and (7) sociocultural, ethical, and legal aspects. A summary of these publications is provided in Table 3.

**Table 3.** Lessons learned from landmark publications from 2015 to 2019.

Author (year)	Study design	Theme	Disease	Lesson learned
Wootton (2012) [25] <sup>a</sup>	Review	Evidence synthesis	Chronic diseases	This study presents an evidence synthesis report on 141 RCTs <sup>b</sup> pertaining to asthma, COPD <sup>c</sup> , diabetes, heart failure, and hypertension. There was strong evidence of publication bias, with 108 RCTs reporting positive results and almost none reporting harm.
Wade et al (2010) [26]	Systematic review	Economic analysis	— <sup>d</sup>	Delivery of health services by real-time video communication was cost-effective for home care and access to on-call hospital specialists, showed mixed results for rural service delivery, and was not cost-effective for local delivery of services between hospitals and primary care.
Chaudhry et al (2010) [27] <sup>a</sup>	Clinical trial	Effectiveness	Heart failure	Telemonitoring did not improve outcomes among patients hospitalized for heart failure.
Ekeland et al (2010) [28] <sup>a</sup>	Systematic review of systematic reviews	Effectiveness	—	Out of 80 included systematic reviews, 21 showed that telemedicine was effective, and 18 reported that evidence regarding telemedicine was limited and inconsistent.
Kvedar et al (2014) [34] <sup>a</sup>	Literature review	Model of health care	—	Care processes in the United States are insufficient to address the mismatch in supply and demand of health care providers. This review presented connected health as a new care model to improve patient care with telemedicine and telehealth.
Elbert et al (2014) [30]	Systematic review of systematic reviews	Effectiveness and cost-effectiveness	Somatic diseases	Out of 31 eligible reviews, 7 found eHealth to be clinically effective and cost-effective and 13 found it to be promising, while the rest found the evidence to be limited or inconsistent.
Bashshur et al (2014) [32] <sup>a</sup>	Systematic review	General review	Chronic diseases: heart failure, stroke, and COPD	The 3 diseases, when treated using telemedicine approaches, showed several improvements, such as reduced hospital admissions and readmissions, length of hospital stay, and emergency department visits.
Flodgren et al (2015) [29] <sup>a</sup>	Systematic review and meta-analysis	Effectiveness	Cardiovascular disease, diabetes, respiratory conditions, mental health or substance abuse conditions, conditions requiring a specialist consultation, comorbidities, urogenital conditions, neurological injuries and conditions, gastrointestinal conditions, neonatal conditions requiring specialist care, solid-organ transplantation, and cancer	There was high- to moderate-certainty evidence that there was no significant difference between telemedicine and usual health care in improving all-cause mortality and admissions to the hospital. There was some evidence of improved quality of life, lower HbA <sub>1c</sub> <sup>e</sup> among patients with diabetes, and decreased LDL <sup>f</sup> and blood pressure. Participants with different mental health and substance abuse problems reported no differences in the effect of therapy delivered over videoconferencing compared with face-to-face delivery.
Kidholm et al (2012) [35] <sup>a</sup>	Recommendations based on workshops with users and stakeholders of telemedicine, initiated by European Commission	Framework for assessment of telemedicine	—	There are 7 domains in MAST <sup>g</sup> : (1) health problem and description of the application, (2) safety, (3) clinical effectiveness, (4) patient perspectives, (5) economic aspects, (6) organizational aspects, and (7) sociocultural, ethical, and legal aspects.
Schwamm et al (2009) [13] <sup>a</sup>	See Table 2	See Table 2	See Table 2	See Table 2
Lilly et al (2011) [14] <sup>a</sup>	See Table 2	See Table 2	See Table 2	See Table 2

Author (year)	Study design	Theme	Disease	Lesson learned
Hilty et al (2013) [23] <sup>a</sup>	Review	Effectiveness	Mental health	This review reported that tele-mental health interventions are effective and improve access to care. More research is required on service models and ethical and cross-cultural aspects of tele-mental health.
Dharmar et al (2013) [22] <sup>a</sup>	Retrospective	Quality improvement	Pediatric critical care	Telemedicine consultations were associated with higher physician-rated quality of care and parent satisfaction.
Sanders et al (2012) [24]	Qualitative	Evaluation and barriers to adoption	Telehealth in general	This qualitative investigation examined barriers to participation and adoption of telehealth among people who withdrew from a UK-based clinical trial on telemedicine.
Fierston et al (2015) [33]	Review	Evaluation for retinopathy of prematurity	Retinopathy of prematurity	This report reviewed the currently available literature on RDTF-TM <sup>h</sup> evaluations for retinopathy of prematurity and outlined pertinent practical and risk management considerations.
Ashwood et al (2017) [36]	Retrospective	Effectiveness and cost-effectiveness	—	Direct-to-consumer telehealth may increase access to care but does not decrease spending; 12% of direct-to-consumer telehealth visits replaced visits to other providers, and 88% represented new use. Net annual spending on acute respiratory illness increased \$45 per telehealth user.
Hubble et al (2016) [31]	Systematic review	Effectiveness	Psychiatric diseases	A large evidence base supported telepsychiatry as a delivery method for mental health services. Future studies will inform optimal approaches to implementing and sustaining telepsychiatry services.

<sup>a</sup>Purple nodes in Figure 7 representing seminal work in the area of telemedicine.

<sup>b</sup>RCTs: randomized controlled trials.

<sup>c</sup>COPD: chronic obstructive pulmonary disease.

<sup>d</sup>Not available.

<sup>e</sup>HbA<sub>1c</sub>: glycated hemoglobin.

<sup>f</sup>LDL: low-density lipoprotein.

<sup>g</sup>MAST: model for assessment of telemedicine.

<sup>h</sup>RDTF-TM: telemedicine-based remote digital fundus imaging.

## Discussion

### Summary

This scientometric analysis presents an overview of scholarly work in the field of telemedicine in the last 10 years. It shows the transition of scholarly work in this field from teleradiology in the previous decade to mental health, stroke, and critical care medicine. Barriers and facilitators to successful implementation of telemedicine were also seen as an important area of research in telemedicine. Collaborative networks between regions and institutions revealed collaborative links between central global institutions and LMICs, showing a transfer of technology and expertise to disparate regions. Among the LMICs, China and India are emerging as big players in telemedicine.

### General Trends and Transcontinental Collaborations

Our analysis revealed a steadily increasing publication output and citation activity in the field of telemedicine, which is in consonance with previous literature [7,9,25,37,38]. In terms of regional output, a bibliometric assessment of literature in telemedicine from 1980 to 2013 showed that the top 5 countries in terms of publication output were the United States, the United Kingdom, Germany, Canada, and Australia, while China ranked tenth [37]. However, we opine that the centrality or influence of a particular entity in their collaborative networks and the volume of innovative work may be better indicators of progress

in a field. In this vein, England, France, Belgium, Portugal, the People's Republic of China, and Greece appeared to hold significant influence worldwide. Similarly, almost all of the top institutions with regard to publication output were from the United States, which reflects previous literature [7,9,25,37,38]. However, only 1 of the United States-based universities was found to be central in its domain. Top institutions were Columbia University, University of Queensland, University of Toronto, and Karolinska Institute.

Several of the top institutions were involved in collaborations with institutions from LMICs, indicating transfer of technology and expertise. This is an important endeavor, as studying the effectiveness and uptake of telemedicine may decrease disparities in these regions. Portugal, for instance, provides a good case study to examine collaborative networks between high-income and low-income countries. A transcultural pediatric telecardiology service has been established in several Portuguese-speaking African countries in collaboration with Portugal-based universities [39]. This program has been highly successful. For instance, in Angola alone, it has performed 32,685 outpatient teleconsultations (1998 to 2016), saving health system costs [39]. Another important endeavor includes echocardiography services through a telecardiology initiative being provided in Tanzania, Malawi, Mali, and Mozambique with a telereporting center in Italy [40]. On October 26, 2017, another impetus for telemedicine research and implementation

was provided by a resolution that created the Comunidade dos Países de Língua Portuguesa's Permanent Working Group on Telemedicine and Telehealth during the fourth Health Ministers Meeting of the Portuguese-Speaking Countries in Brasília [41].

### Transition of Research Themes

We noticed a transition in research themes in telemedicine during these periods. For instance, the WHO reports cited teleradiology services as being most prevalent worldwide. In line with this, Armfield et al [42], using text-mining approaches, reported that during the early period of telemedicine research from 1970 to 1995, teleradiology and telepathology were the most dominant fields, as well as the first fields to adopt telemedicine. In contrast, research trends in a more recent period (2009 to 2013) focused on cost-effectiveness, and the clinical and discipline-specific terms “diabetic” and “stroke” emerged in this period. Our analyses revealed that these themes progressed into the established fields of telecardiology, telestroke, and tele-ICU. Moreover, we also saw a rise in cost-effectiveness as well as implementation and feasibility research, which are very important aspects in the uptake of telemedicine. All the influential studies in our analyses pertained to these themes.

### Research Gaps and Recommendations for Future Work

Despite a continuous rise in scholarly activity in telemedicine, we noticed several gaps in the literature. For instance, all the primary and secondary research central to telemedicine was conducted in the context of high-income countries, including the evidence synthesis approaches pertaining to implementation aspects of telemedicine. In addition, patient confidentiality and ethical perspectives on the use of telemedicine were nonexistent in our analysis. Most of the telemedicine research in LMICs was driven in collaboration with high-income countries. There is a huge gap in needs-based analysis, eHealth literacy, and

inclusion of Indigenous end consumers and stakeholders in the design of telemedicine platforms in LMICs.

There were also no research clusters on improving eHealth literacy, especially in the context of use of telemedicine in LMICs. The lack of strengths, weaknesses, opportunities, and threats analyses, particularly in the evaluation of eHealth literacy among physicians, is a big factor in the failure of telemedicine. This was a major contributory factor in the failure of the Réseau en Afrique Francophone pour la Télémédecine (RAFT) telemedicine software platform in Angola, which enjoyed commitment from the Ministry of Health and local stakeholders but was not taken up by the participating physicians [43].

Telemedicine financing is a critical aspect for sustainability and most often not covered in studies. The development of telemedicine on a global scale will require more sophisticated business models. Additionally, telemedicine skills development is very seldom provided by medical schools.

Telemedicine is still in its infancy in LMICs, and there is a lack of clarity in several important aspects, such as the development and adoption of ethical standards, treatment protocols, and guidelines. Medical informaticians should liaise with health care centers, physicians, and medical ethicists to develop software promoting an ethos of confidentiality, privacy, and security during the sharing of sensitive data.

### Conclusion

The findings in this investigation suggest a rapid development in the field of telemedicine, albeit prior to the COVID-19 pandemic. We expect that the research landscape and implementation of telemedicine infrastructure may see exponential progress during and after the COVID-19 period. This is also echoed in the recent report by the American Medical Association, which predicts that “after COVID-19, \$250 billion in care could shift to telehealth, boosting research and infrastructural development” [44].

### Conflicts of Interest

None declared.

## Abstract

**Background:** Heart failure (HF) is a major public health issue in Canada that is associated with high prevalence, morbidity, and mortality rates and high financial and social burdens. Telemonitoring (TM) has been shown to improve all-cause mortality and hospitalization rates in patients with HF. The *Medly* program is a TM intervention integrated as standard of care at a large Canadian academic hospital for ambulatory patients with HF that has been found to improve patient outcomes. However, the cost-effectiveness of the *Medly* program is yet to be determined.

**Objective:** This study aims to conduct a cost-utility analysis of the *Medly* program compared with the standard of care for HF in Ontario, Canada, from the perspective of the public health care payer.

**Methods:** Using a microsimulation model, individual patient data were simulated over a 25-year time horizon to compare the costs and quality-adjusted life years (QALYs) between the *Medly* program and standard care for patients with HF treated in the ambulatory care setting. Data were sourced from a *Medly* Program Evaluation study and literature to inform model parameters, such as *Medly*'s effectiveness in reducing mortality and hospitalizations, health care and intervention costs, and model transition probabilities. Scenario analyses were conducted in relation to HF severity and TM deployment models. One-way deterministic effectiveness analysis and probabilistic sensitivity analysis were performed to explore the impact on the results of uncertainty in model parameters.

**Results:** The *Medly* program was associated with an average total cost of Can \$102,508 (US \$77,626) per patient and total QALYs of 5.51 per patient compared with the average cost of Can \$97,497 (US \$73,831) and QALYs of 4.95 per patient in the Standard Care Group. This led to an incremental cost of Can \$5011 (US \$3794) and incremental QALY of 0.566, resulting in an incremental cost-effectiveness ratio of Can \$8850 (US \$6701)/QALY. Cost-effectiveness improved in relation to patients with advanced HF and with deployment models in which patients used their own equipment. Baseline and alternative scenarios consistently showed probabilities of cost-effectiveness greater than 85% at a willingness-to-pay threshold of Can \$50,000 (US \$37,718). Although the results showed some sensitivity to assumptions about effectiveness parameters, the intervention was found to remain cost-effective.

**Conclusions:** The *Medly* program for patients with HF is cost-effective compared with standard care using commonly reported willingness-to-pay thresholds. This study provides evidence for decision makers on the use of TM for HF, supports the use of a

nurse-led model of TM that embeds clinically validated algorithms, and informs the use of economic modeling for future evaluations of early-stage health informatics technology.

## Introduction

### Background

Heart failure (HF) is a major public health issue with a worldwide prevalence of 26 million and 669,600 in Canada [1,2]. Half of those with a diagnosis of HF will die within 5 years, and up to 80% will die within 10 years [3-5]. Furthermore, flare-ups of HF symptoms occur often and can result in frequent hospitalizations, with more than 50% of individuals being readmitted within 6 months of discharge [6,7]. Reasons for rehospitalizations include incomplete treatment in hospitals, poor coordination of services or poor communication of care plans at discharge, inadequate access to services, poor patient education, failure to optimize therapies, and lack of long-term monitoring for early signs of worsening health [7]. HF-associated hospital admissions have been estimated to cost the Canadian health care system Can \$482 (US \$364) million in 2013, and the cost is expected to increase to Can \$720 (US \$543.14) million by 2030 [8].

It has been recommended that disease management interventions that enable patient empowerment, education, and clinical follow-up should be integrated within the system of care for patients with HF because these interventions have been associated with reduced hospitalization rates and improved quality of life (QoL) and survival [9]. In response, the *Medly* telemonitoring (TM) system and program, which was deployed to augment the existing standard of care at the Ted Rogers Centre for Heart Research at the University Health Network (UHN), was designed to shift traditional episodic care of HF to a more continuous paradigm where care is extended into the daily lives of patients rather than confined to health care institutions. This program enables patients to record symptoms and physiological measurements, including weight, blood pressure, and heart rate, which are then transmitted to a registered nurse coordinator who reviews and responds to alerts and serves as the first resource for patients. Overall, meta-analyses have shown that TM programs similar to *Medly* reduce all-cause mortality and hospitalizations when compared with the standard of care without TM [10-14]. However, other studies have also shown null or mixed results for TM [15-18]. Some of this uncertainty in effectiveness can be attributed to the heterogeneity of the studies, such as patient demographics, characteristic differences between the evaluated interventions, and quality of the trial [19].

The decision to implement interventions are often dependent on cost-effectiveness. However, there is a lack of economic evidence for TM stemming from the challenges associated with conducting economic evaluations owing to the heterogeneity and complexity of TM [20,21]. Specifically, diversity stemming from clinical conditions under study, technology, applications,

objectives, and context makes comparisons between telemedicine interventions difficult [21]. That said, a number of studies have been conducted that included evaluations of the financial impact of TM for patients with HF, with many reporting savings. However, most studies did not conduct a full economic evaluation [22-33], such as a cost-effectiveness or cost-utility analysis (CUA) [34]. Studies that included a full economic analysis did not evaluate the long-term effects of TM because time horizons of 18 months or less were used [35-37], or the studies were conducted outside of Canada [38-40]. This is owing to the lack of long-term Canadian economic evaluations of TM interventions for patients with HF, information on the life expectancy of this patient population, the possible fluctuations of health status over time, and the nuances of the Canadian population and health care system.

### Study Objectives

The objective of this study was to evaluate the long-term cost-effectiveness of TM for patients with HF within a Canadian context from a public health care payer perspective, referencing costing data and concepts from a TM program, *Medly*, implemented at a large academic hospital in Ontario, and data from the literature. Specifically, the central research question is as follows: What is the cost utility of the *Medly* program for patients with HF compared with the standard of care in Ontario? This question will be explored through the application of a microsimulation model.

## Methods

The methods used in this study follow the Consolidated Health Economic Evaluation Reporting Standards [41].

### Type of Economic Evaluation

A CUA was performed. A CUA was chosen because it allows for the effectiveness outcome to be comparable with that of other disease groups and across interventions, making it the gold standard for economic evaluations. Furthermore, there is utility evidence available for patients with HF, allowing for the use of quality-adjusted life years (QALYs) [34].

### Target Population

The target population was a cohort of ambulatory patients with HF from the UHN in Toronto, Canada, enrolled in the *Medly Program Evaluation* study. Table 1 presents information on the baseline patient characteristics and the missing data. Owing to the limitations associated with manual extraction of data from patients' clinical notes and inconsistent laboratory testing orders, there were considerable missing data. The nature of the missingness was not quantitatively analyzed, and it was assumed that the missing data were randomly distributed. The data reported correspond to the set of variables that were used in the

Seattle Heart Failure Model (SHFM), which is a multivariate Cox hazard model used to predict mortality [42-45]. As of June 31, 2019, 315 patients were enrolled in the program, based on

a joint decision between the patient and the cardiologist at either a follow-up outpatient visit or after an inpatient hospital stay.

**Table 1.** Baseline patient characteristics of the Medly Program Evaluation cohort (n=315; number of patients unless specified otherwise).

Characteristics	Overall	Missing, n
Age (years), mean (SD)	58.23 (15.43)	2
Proportion of females, n (%)	69 (22.0)	2
Proportion of ischemic etiology, n (%)	65 (28.5)	87
Proportion of beta blockers, n (%)	270 (89.4)	13
Proportion of aldosterone blockers, n (%)	215 (71.2)	13
Proportion of ARBs <sup>a</sup> , n (%)	82 (27.2)	13
Proportion of ACE <sup>b</sup> inhibitors, n (%)	137 (45.5)	13
Proportion of allopurinol, n (%)	41 (13.6)	13
Percentage LVEF <sup>c</sup> , mean (SD)	32.07 (13.62)	7
New York Health Association (average class), mean (SD)	2.36 (0.59)	13
Systolic blood pressure (mm Hg), mean (SD)	110.36 (17.91)	53
Percentage of lymphocytes, mean (SD)	22.18 (9.07)	52
Sodium (mEq/L), mean (SD)	137.73 (3.06)	33
Cholesterol (mg/dL), mean (SD)	154.77 (52.71)	83
Hemoglobin (g/dL), mean (SD)	13.33 (1.99)	52
Urate (mg/dL), mean (SD)	7.97 (2.70)	86
Weight (kg), mean (SD)	83.39 (20.04)	44
Furosemide-equivalent dose (mg/day), mean (SD)	99.57 (123.93)	16
Proportion of implantable cardioverter-defibrillators, n (%)	165 (56.5)	23

<sup>a</sup>ARB: angiotensin II receptor blocker.

<sup>b</sup>ACE: angiotensin-converting-enzyme.

<sup>c</sup>LVEF: left ventricular ejection fraction.

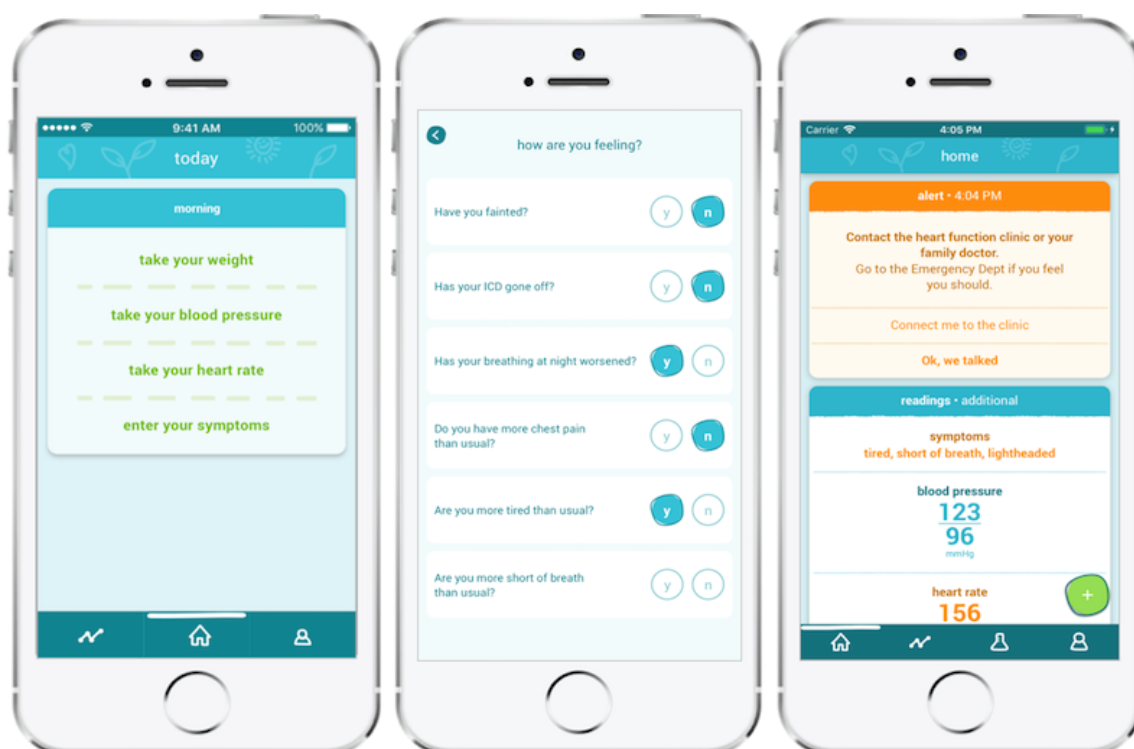

## The Intervention-Medly

In August 2016, the *Medly* program was deployed to augment the existing standard of care at the Ted Rogers Centre for Heart Research at the UHN. Patients are trained to use the technology, and the importance of taking daily readings is emphasized. Patients then use the intervention as long as there are clinical benefits as determined by both the clinician and the patient. The program is led by a registered nurse coordinator who reviews and responds to alerts and serves as the first resource for patients' clinical concerns or technical troubleshooting.

The main component of the program is the *Medly* smartphone app. Patients use the app to record their body weight, blood pressure, and heart rate and to answer a short yes or no questionnaire about their symptoms. Patients are asked to take these readings daily immediately after they wake up. These data are then processed by a clinically validated algorithm to interpret the readings relative to the patient's target thresholds set by the

most responsible HF physician [46]. If the algorithm determines that the recordings are within the target range, patients are presented with a prompt stating their HF is in a stable condition. If the algorithm deems that the readings are outside the target range and/or identify an abnormal trend in weight gain, the patient is prompted with self-care feedback such as taking an additional dose of their diuretic medication and to contact their care provider or to visit the emergency department (ED). [Figure 1](#) shows screenshots of some of the various interfaces with which patients interact. In addition to the self-care messages, the registered nurse coordinator receives the alert via email and triages the event. The nurse also responds to technical troubleshooting. A full-time nurse is projected to be able to manage approximately 500 patients through the *Medly* program. Alerts and all patient TM data can be viewed on the *Medly* clinical dashboard. Other features of the *Medly* app include graphical trends of specific measurements and an automated phone call to remind patients to take their daily measurements if it is past 10 AM (can be disabled per patient's request).

**Figure 1.** Medly app showing instructions for required readings (screen 1), the symptoms questionnaire (screen 2), and personalized self-care feedback (screen 3).

## Key Data Source

This study referenced the ongoing *Medly* program evaluation, which included multiple pre- and posttest analyses on patient-level impacts, patient adherence, and cost. Quantitative data analyses leverage data that were collected at the 6-month follow-up as a part of the standard of care, such as health care utilization and laboratory results from electronic patient records, while also using data from the TM system. The results of this study have been published in the study by Ware et al (2020) [47], and further details on the study can also be found therein.

## Comparators

In this analysis, the intervention group was a cohort of patients with HF enrolled in the *Medly* program. The comparator group consisted of patients with HF who received standard care, which does not include the use of TM. It was assumed that standard care was conducted according to the typical care practices in Ontario, which involves specialized multidisciplinary HF clinics, although care models may vary among clinics [48].

## Perspective

This analysis was conducted from the perspective of the public payer, namely the Ontario Ministry of Health because *Medly* is currently implemented in a publicly funded health care system.

## Time Horizon and Discounting

A time horizon of 25 years was adopted to determine the long-term cost and outcomes associated with *Medly* for the patient population with HF. Costs and outcomes were discounted

at an annual rate of 1.5%, as recommended by the Canadian Agency for Drugs and Technologies in Health [49].

## Model Framework, Conceptualization, and Technique

All analysis and model construction were conducted using RStudio [50]. The model consists of 7 mutually exclusive states: 4 states specific to HF severity, 2 states for hospitalization events, and 1 absorbing state for death. Patients with HF can alternate between a state of decompensation (or symptom exacerbation or functional capacity impairment) and a state of clinical stability. To capture this, the model was stratified by, and allowed for, transitions between New York Health Association (NYHA) functional classes. The NYHA functional classification is a common measure used by clinicians to classify the severity of symptoms in patients with HF, in which a higher class indicates worse health [51]. Hospitalizations mark a fundamental change in the natural history of HF with subsequent increased rehospitalizations and higher mortality rates as the patient's disease progresses [52,53]. A cycle length of 1 month was chosen to account for 30-day readmission rates common in the HF population [54]. As recommended by Naimark et al [55] for models that are relatively simple and have a cycle length of a month or less, a half-cycle correction was omitted.

The modeling technique chosen was a patient-level state-transition model, also known as a first-order Monte Carlo microsimulation. This model was appropriate because it can capture patient heterogeneity that is common in patients with HF and is also the preferred option for modeling chronic disease [56]. Figure 2 shows the conceptualization of the Markov model that was developed to represent an individual's progression of HF.

**Figure 2.** Conceptual representation of the microsimulation model structure. States 1 to 4 represent the transitions between New York Health Association classes. States 5 and 6 show transitions into and between hospitalization states. State 7 is an absorbing state representing death, where all states can transition to. NYHA: New York Health Association.

### Parameter Estimates

The values used in the model were based on a literature review. The values inputted into the model are conditional on patient characteristics. Patients with a more limited functional capacity by NYHA class have a higher risk of hospitalization [57-61]. In addition, the risk for readmission is highest within 30 days of hospital discharge [52]. As a patient's NYHA functional class can change over time, the probability of transitioning between classes was derived from the large-scale international SENIORS study [62,63]. All-cause mortality during hospitalization was based on the study by Yeung et al (2012) [64]. The SHFM was used to derive a survival curve for each patient over their lifetime, which is a multivariate Cox hazard model that has been validated on multiple cohorts of patients with HF [42-45].

### Generating Virtual Patient Profiles

To generate virtual patient profiles, a Cholesky decomposition was performed on a correlation matrix that describes the interdependence between patient characteristics [56]. The matrix was derived from a consolidated representative sample of 7125 patients with HF from the University of Washington, Prospective Randomized Amlodipine Survival Evaluation, Valsartan Heart Failure Trial, and Italian Heart Failure Registry [65] (Multimedia Appendix 1). Values for each patient characteristic were sampled from a multivariate normal distribution, defined by the *Medly Program Evaluation* cohort's mean and SD in Table 1 using the R-package "PoisBinOrdNonNor" [66,67].

Patient characteristics included clinical, pharmacological, device, and laboratory data, based on the SHFM developed by Levy et al (2006) [43].

### Effectiveness

The 2 primary outcomes that TM interventions for patients with HF aim to improve are all-cause mortality and all-cause hospitalization rates. The risk of all-cause hospitalization was based on evidence from the *Medly* program evaluation, which reported a relative risk (RR) of 0.753 (95% CI 0.634-0.879) for patients using *Medly* (Multimedia Appendix 1; All-cause hospitalization). Owing to the lack of an interdependent comparative group and small sample size of the *Medly* program evaluation, it was not possible to evaluate its effectiveness in reducing mortality. Therefore, the estimate was based on a meta-analysis of the effectiveness of TM for patients with HF by Yun et al (2018) [11]. This meta-analysis only included randomized controlled trials that defined TM as the transmission of biological information, such as body weight, heart rate, and blood pressure via telecommunication technologies. Owing to this strict inclusion criteria, it was deemed comparable evidence for the expected benefits that *Medly* users could experience. It was reported that TM users had an RR of 0.81 (0.70-0.94) for all-cause mortality compared with 416 of 3724 patients in the TM group to 483 of 3733 patients in the control group [11]. The study follow-up periods ranged from 3 months to 15 months, with 1 study having a 4 year follow-up. The meta-analysis also presented a subgroup analysis of only asynchronous interventions (ie, removal of real-time and

teleconferencing technologies), where an RR of 0.79 (0.66-0.94) was reported for all-cause mortality, which is similar to the primary analysis.

### Measurement and Evaluation of Health

Each state in the model has an associated utility value between 0 and 1. Utility values for each health state were derived on the basis of values from other health economic evaluations of HF

interventions. NYHA classes are commonly used to categorize patients with HF based on severity of symptoms, and studies have estimated utility values for each class [60,62,68,69]. All utilities and the sources of the values are presented in Table 2. To adjust for the decrease in the QoL patients experience when hospitalized [70], the patient utility value in the model was decreased by 0.059 in the hospitalization state, consistent with Sandhu et al (2016) [71].

**Table 2.** Model parameters conditional on New York Health Association (NYHA) class including living with heart failure costs (in Can currency), utilities, probability of hospitalization, and transitions between NYHA classes.

Description	NYHA <sup>a</sup> I	NYHA II	NYHA III	NYHA IV <sup>b</sup>	Source	Distribution
<b>Health care costs</b>

<sup>e</sup>N/A: not applicable.

### Resource Use and Costs

Health care utilization was based on data from the *Medly* program evaluation, and hospitalization and ED visit costs were derived from the Ontario Case Costing Initiative (OCCI) report for 2017-2018 using diagnosis codes I500, I509, and I501 [73]. The unit cost per outpatient visit was based on a paper outlining health care utilization for patients with HF over the last 6 months of their lives by Kaul et al (2006) [72] in a comparable health care system in Alberta. This was based on the provincial ambulatory care case mix group, which captures direct and

indirect functional center costs [75]. Physician fees for general practitioner (GP) visits were based on billing code A005 in Ontario's Schedule of Benefits [74]. The unit costs were multiplied by utilization data from the *Medly* program evaluation to calculate the monthly costs (Table 3). Median values for utilization were used because the distribution of health care utilization is typically left-skewed [76]. Monthly drug costs were incurred on the part of the public payer under the Ontario Drug Benefit program for patients aged 65 years and older. The

monthly drug costs were calculated on the basis of the costs reported in Kaul et al (2006).

Of note, the number of outpatient visits for both the intervention and comparator-simulated cohorts was limited to those that occurred at UHN because information outside of UHN's services

was unavailable at the time of the study. Furthermore, self-reported ED visits were used because UHN patient records may underreport the true number of ED visits as patients may live at some distance from UHN and may instead visit a community hospital for an emergency. Self-reported GP visits were used because UHN data do not record this information.

**Table 3.** Median health care utilization over 6 months before using Medly, unit costs per service (in Can currency), and associated distribution stratified by New York Health Association (NYHA) classes. N is the number of patients in each NYHA class.

Type of resource	Unit cost, mean (SD), Can \$	Source for unit cost	NYHA I health care utilization (n=44)	NYHA II health care utilization (n=166)	NYHA III health care utilization (n=93)	NYHA IV health care utilization (n=1)	Distribution

## Medly Costs and Deployment Models

Costs related to implementation and maintenance of *Medly* were provided by the *Medly* project management and development team (Table 4). The fixed costs associated with implementation were based on a system that delivers care to 1000 patients. The operational cost per patient included costs associated with asset management (technical and application support) and on-site frontline support for patients and clinicians, which was delivered via 2 registered nurse coordinators hired by the *Medly* program. Two registered nurses were included according to the *Medly* project management team's cost projections for 1000 patients. This is similar to what was reported by Ware et al (2020) [47], where approximately 300 patients were managed by 1 registered nurse coordinator. The variable cost per patient included the cost of the device and equipment, depending on the equipment that was loaned to the patient. The costs of the device and the equipment were based on a rental model. These costs were

adjusted for monthly costs according to the cycle length of the model.

The variable cost was based on a mix of models where users can fall into 1 of the 3 categories: Full Kit (FK), Bring Your Own Phone (BYOP), and Bring Your Own Everything (BYOE). An FK user refers to a user who was provided with all necessary equipment for the technology, which is currently funded by the *Medly* program, including a smartphone with a data plan, blood pressure monitor, weight scale, and licensing fee. A BYOP user brings their own phone and pays for their own data plan, but the blood pressure monitor, weight scale, and *licensing fee are provided by the Medly* program. The BYOE user brings their own equipment and is provided with just the licensing fee by the program. The reference case analysis uses a ratio of 2 FK:1 BYOP:2 BYOE, which was based on the number of each category of users in *Medly*'s current implementation. All costs were converted to 2019 Canadian dollars using Statistics Canada's Consumer Price Index to adjust for inflation [77].

**Table 4.** Parameter estimates not conditional on the New York Health Association class including hospitalization costs (in Can currency) and disutility, readmission rates, Medly costs (in Can currency), and Medly effectiveness estimates.

Parameters	Value	Source	Distribution
<b>Costs</b>			
Hospitalization cost per admission (Can \$), mean (SD)	8908 (16,867)	OCCI <sup>a</sup>	Gamma
Hospitalization length of stay days, mean (SD)	5.9 (11.2)	OCCI	Log normal
Medly fixed costs for site implementation	102,500	Medly program	Fixed

RR for morality	0.81 (0.70-0.94)	Yun et al (2018) [13]	Log normal

<sup>a</sup>OCCI: Ontario Case Costing Initiative.

<sup>b</sup>RR: relative risk.

## Reference Case Analysis

The expected values for all model parameters were used for the deterministic analysis. The cohort size was assumed to be 1000 patients. Each simulated patient progressed through the model twice until death; once as a patient using *Medly* and again as a patient receiving standard care. Each patient incurred costs and QALYs depending on the health state they were in. Total costs and QALYs were summed for both the *Medly* simulations and standard care simulations. From this, the average incremental cost-effectiveness ratio (ICER) per patient was computed using the following formula:

Monte Carlo standard errors were also reported to show how the results vary owing to patient heterogeneity and randomness introduced from patients transitioning to each state.

A second-order probabilistic analysis was also conducted to characterize the uncertainty in the deterministic results. Each parameter in the model was assigned a distribution based on the nature of the input parameter [56]. R-package “fitdistrplus” was used to fit negative binomial distributions for the health care utilization data from the *Medly* program evaluation via maximum likelihood estimation [78]. Details regarding how distributions were chosen based on Akaike Information Criterion and Bayesian Information Criterion scores are available in [Multimedia Appendix 1](#) ([11,54]; Curve fitting). Values were then randomly selected from the respective distributions and assigned as the input parameter. This process was repeated 1000 times. The results for each iteration were plotted on a cost-utility plane to visualize whether *Medly* was cost-effective, cost-saving,

cheaper, or dominated. The simulations were also plotted onto a cost-effectiveness acceptability curve (CEAC), where the proportion of simulations that resulted in an ICER under a range of willingness-to-pay (WTP) thresholds are plotted. A commonly used WTP threshold is Can \$50,000 (US \$37,718)/QALY [79,80].

## Scenario Analyses

### NYHA Functional Classes

Currently, most patients enrolled in the *Medly* program have HF that corresponds to NYHA functional classes II or III. For this scenario analysis, cohorts were generated for NYHA functional classes I, II, and III and simulated deterministically and probabilistically. NYHA functional class IV was not included because only 1 functional class IV patient was enrolled in the *Medly* program. Average ICERs per NYHA functional class were calculated in both the deterministic and probabilistic models, and CEAC curves were produced on a plot to visualize for which classes *Medly* was most likely to be cost-effective.

### Deployment Model

As mentioned, the *Medly* program currently offers 3 types of kits where the ratio of types of user is 2:1:2 for FK, BYOP, and BYOE, respectively. As the *Medly* program expands, understanding how the ICER changes when costs are shifted from the public dollar to the individual is informative to decision makers. Therefore, this analysis explored various proportions of user types. Specifically, each patient in the reference case cohort was randomly assigned FK, BYOP, and BYOE according to predefined ratios. The ratios of interest were 1:0:0 (100% FK), 1:4:5 (40% BYOP, 50% BYOE), and 0:0:1 (100% BYOE).

These were identified as all FK, mixed deployment, and all BYOE, respectively.

### Effectiveness

One-way deterministic analyses were also conducted to address the uncertainty associated with the estimates for *Medly*'s effectiveness in reducing all-cause hospitalizations (RR 0.63-0.88) and mortality (RR 0.70-0.94). Specifically, 95% CI for each estimate were inputted into the model, and the range of ICERs was presented.

## Results

### Reference Case Analysis

#### Deterministic Results

Over a 25-year time horizon, the average total costs were Can \$97,497 (US \$73,547.84) for the comparator group and Can \$102,508 (US \$77,327.93) for patients using *Medly*. The average total QALYs gained were 4.95 and 5.51 for the comparator group and *Medly* patients, respectively. When comparing the 2 groups, there was an incremental cost of Can \$5011 (US \$3780.10) with an incremental QALY gained of 0.566. This resulted in an ICER of Can \$8850 (US \$6676.09)/QALY (Table 5).

**Table 5.** Deterministic results of the reference case analysis.

Reference	Costs, Can \$ (US \$)	MCSE <sup>a</sup> , Can \$ (US \$)	QALYs <sup>b</sup>	MCSE	Incremental cost, Can \$ (US \$)	MCSE, Can \$ (US \$)	Incremental QALYs	MCSE	ICER <sup>c</sup> , Can \$ (US \$; \$/QALY)

Medly	102,508 (77,626)	3592 (2720)	5.51	0.13	5011 (3794)	2014 (1525)	0.57	0.05	8850 (6701)

<sup>a</sup>MCSE: Monte Carlo standard error.

<sup>b</sup>QALY: quality-adjusted life year.

<sup>c</sup>ICER: incremental cost-effectiveness ratio.

<sup>d</sup>N/A: not applicable.

### Probabilistic Results

On the basis of 1000 simulations of the reference case scenario in which each parameter was sampled from their respective distribution, 81.6% (816/1000) of the simulations showed that

*Medly* was costlier and more effective, whereas 17.3% (173/1000) showed that *Medly* was less costly and more effective (Figure 3). The CEAC in Figure 4 shows that 90.1% (901/1000) of the simulations resulted in an ICER below the Can \$50,000 (US \$37,718)/QALY threshold.

**Figure 3.** Cost-utility plane of 1000 iterations from the reference case probabilistic analysis. QALY: quality-adjusted life years.

**Figure 4.** Cost-effectiveness acceptability curve of reference case probabilistic analysis.

## Scenario Analyses

### NYHA Functional Classes

Table 6 presents the results of the NYHA functional class scenario analyses. As NYHA functional class increased, the

average total costs and incremental costs increased. In addition, as NYHA functional class increased, total QALYs per population decreased. This led to a decreasing trend in ICERs with increasing NYHA functional class.

**Table 6.** Deterministic results for New York Health Association classes I, II, and III.

The CEAC curves for NYHA functional classes I, II, and III are shown in Figure 5. At a WTP threshold of \$50,000 (US \$37,718), the probability of cost-effectiveness for NYHA functional classes I, II, and III was 90.5% (905/1000), 90.6% (906/1000), and 87.5% (875/1000), respectively.

**Figure 5.** Cost-effectiveness acceptability curve of the New York Health Association functional class scenario analyses. CEAC: cost-effectiveness acceptability curve; NYHA: New York Health Association.

## Deployment Models

Table 7 shows the results of the deployment model scenario analyses. As the only difference between scenarios was the total cost incurred by the *Medly* group, all comparator groups had the same average total costs and average total QALYs. The average total QALYs for patients using *Medly* were also the same for all scenarios. Moreover, as expected, when the proportion of FK users increased, so did the average total costs

for patients using *Medly*. This led to ICERs following the same trend.

The CEAC curves for each deployment model are shown in Figure 6. At a WTP threshold of Can \$50,000 (US \$37,718), the probability of cost-effectiveness for all BYOE, mixed model, and all FK was 92.9% (929/1000), 91.7% (917/1000), and 85.4% (854/1000), respectively.

**Table 7.** Deterministic results for each deployment model of *Medly*.

## Effectiveness Uncertainty

When the RR for mortality was set to its lower range, the ICER increased to Can \$18,556 (US \$13,997.90)/QALY (Table 8). When the RR for mortality was set to its upper range, *Medly*

became dominant (Table 8). When the RR for hospitalization was set to its lower range, *Medly* became dominant. When the RR for hospitalization was set to its upper range, the ICER increased to Can \$29,240 (US \$22,057.49)/QALY.

## Discussion

### Principal Findings

The purpose of this study was to assess the cost utility of the *Medly* program for patients with HF compared with the standard of care from a public payer perspective. The analysis showed that *Medly* had a high probability (90.1%) of being cost-effective at a WTP threshold of Can \$50,000 (US \$37,718)/QALY. The results also showed that cost-effectiveness improved in cohorts with more advanced HF. This is attributable to the higher health care utilization rates experienced in higher NYHA functional classes. Deployment models with larger proportions of patients bringing their own equipment to the *Medly* program were also shown to be more cost-effective owing to lower costs incurred by the program itself. Furthermore, the model itself was sensitive to the effectiveness parameters that informed the magnitude of the decrease in all-cause hospitalizations and mortality. However, the results of these analyses showed that *Medly* remains cost-effective even in scenarios with smaller clinical benefit, assuming a WTP threshold of Can \$50,000 (US \$37,718)/QALY [79,80].

### Study Implications

The significance of the study findings are 3-fold: (1) providing evidence for health care decision makers on the use of TM for HF, (2) supporting the use of a nurse-led model of TM using clinically validated algorithms within HF clinics, and (3) informing the use of economic modeling for future evaluation of early-stage health informatics technology.

Our study provided the *Medly* program with its first evaluation, where an economic perspective was considered. This added to the growing body of evidence associated with the program's value not only for patients and health care professionals but also for the health care system. As discussions about implementing the *Medly* program at other sites in Ontario continue among decision makers and stakeholders, this study directly contributes to their understanding of *Medly*'s cost-effectiveness. It enables a new perspective on the upfront costs involved with implementing the TM infrastructure and purchasing necessary equipment, relative to the total costs a patient with HF incurs over a lifetime. Such evidence alleviates some of the uncertainty around the risks in introducing a new model of care for patients with HF.

A key factor contributing to the cost-effectiveness of *Medly* was the high number of patients (500) that a single nurse could

manage, which is possible owing to the clinically validated algorithms that generate automatic clinical alerts and self-care messages. Other studies have reported a concern regarding increased clinical workload associated with incompatibility of the TM program with existing workflows, including management of and responding to alerts [81-83]. To mitigate the increased physician workload, the *Medly* program relies on a registered nurse coordinator and a rule-based algorithm [46] as a patient's first point of contact, decreasing dependency on cardiologists. The registered nurse had the necessary skills to manage patient concerns and involved cardiologists as required. This nurse-led strategy presents a model of care that could be scalable to other hospitals.

Our study provides a case study on the use of multiple data sources and methods to develop a decision model for an early-stage health informatics intervention where knowledge gaps existed. As the purpose of this study was to evaluate the potential long-term effects of the *Medly* program in the management of patients with HF, the use of various data sources and modeling techniques are indispensable. This study was successful in developing a flexible algorithm based on the Cholesky decomposition method that was able to generate representative hypothetical cohorts of patients with HF according to the needs of the analysis [56]. An example of the algorithm's flexibility to adapt to the needs of the analyses was the ability to generate hypothetical patient cohorts for NYHA classes I, II, and III while maintaining the individual differences between patients within each class. Our study also successfully implemented a highly validated multivariate Cox model, the SHFM [42-45], within our algorithm to predict the survival of each generated patient over their lifetime. As the purpose of this study was to understand the *long-term effects of the Medly* program, the inclusion of the most validated predictive model for HF survival was logical [84]. The use of the SHFM provided a link for the survival probabilities derived in our model to a larger body HF research around predictive modeling. As mentioned, this was similar to the study by Reed et al (2015) [42], in which the SHFM was used as its underlying prognosis model and correlated health care costs and utility values via regression techniques [42,85,86].

### Comparison With Other Work

Other studies have investigated the cost-effectiveness of other types of TM in HF, where data are transmitted to medical staff. The study by Thokala et al (2013) [38] compared TM with usual care from the public payer perspective and found TM to be cost-effective at £11,873/QALY gained in 2011 (equivalent to Can \$19,996 (US \$15,084.18)/QALY gained in 2018) using a two-state (alive or dead) cohort-based Markov model over a 30-year time horizon. This relatively higher ICER than ICER in our study, which could be attributed to various factors, such as the lower cost of hospitalizations (£1529.97-£2514.49), led to less cost-saving per hospitalization. Furthermore, model structures differed between the study by Thokala et al [38] and our study, in which different health states and transition probabilities were used. A study by Liu et al (2016) [40] also broadly compared TM with standard care from the payer perspective in the United States and found cost-savings for specific scenarios. This included patients who were intermediate

and high-risk over 1- to 5-year time horizons. These results differ from our study owing to different model structures and transition probability parameters. The health states in the model developed by Liu et al (2016) were based on the number of past hospitalizations. In addition, hospitalization rates were conditional on both NYHA functional class and number of past hospitalizations, where the associated monthly probabilities for hospitalizations were much higher than those used in our study. This increased rate of hospitalizations in combination with the larger treatment effect size in reducing mortality and hospitalizations can be attributed to the cost-saving results [40]. A study by Grustam et al (2018) [39] compared TM with usual care for patients with HF from the public payer perspective within the Trans-European Network-Home-Care Management System using data from its original publication and other sources. This resulted in an ICER of €2,479/QALY gained in 2015 (Can \$18,145 [US \$13,687.86] in 2018), which was relatively higher than that reported in our study. The difference in our results can be attributed to the different methods used to model HF and measure effectiveness. The effectiveness of TM in the study was not defined by the risk for all-cause mortality and hospitalization events. Rather, effectiveness was measured by the decrease in probabilities of transitioning to more severe NYHA functional classes and the dead state based on an extrapolation from their database of patients with HF using TM [39].

### Limitations

As with any modeling exercise, it is important to understand the limitations around data availability and assumptions. First, owing to the lack of long-term studies, the trajectory of the effectiveness of TM was unknown and was assumed constant over the patient's lifetime. It is not known if effectiveness changes over time, which may affect the results of this study. Another limitation was the assumption that patients used *Medly* over the entirety of the model. It has been reported that clinicians have not established a generalizable duration of enrollment into the program [87]. Patients may be enrolled into the program for a period of time and be off-boarded after they have learned the necessary self-care behaviors for HF and no longer require the assistance of the technology. This could decrease the costs of the intervention. In addition, caution should be exercised when interpreting data from the *Medly* program evaluation because patients are enrolled in the program based on a joint decision between the clinician and the patient, which could lead to selection bias. Without strict enrollment criteria and end time points, patients may be less sick than the average patients with HF, making results less generalizable. Another limitation was that it was assumed that the *QoL of patients using Medly* was same as that of patients in the comparator group. However, evidence from the *Medly* program evaluation [47] and past literature [88] indicates that QoL improves when patients use *Medly*. As QoL in these studies was measured using HF-specific scoring tools, translation of the improved QoL to utility values used in this study was not feasible because the QALY is derived from the EuroQol-5 Dimension instrument [89]. This likely underestimated *Medly's* total QALYs gained. In addition, health care utilization data used to inform parameters in this study were based on the *Medly* program evaluation, which relied on

a relatively small sample of patients, self-reported ED and GP visits, and a database that was limited to events that occurred at 1 hospital. This early-stage evidence on baseline health care utilization in patients with HF may underestimate or overestimate the actual health care utilization of an HF population, which could alter the results of the study.

## Conclusions

The *Medly* program was found to be a cost-effective solution given the widely cited WTP thresholds of Can \$50,000 (US \$37,718)/QALY for patients with HF when implemented within a multidisciplinary HF clinic in Ontario. This is the first

Canadian economic evaluation of TM for HF using a cost-utility approach, and one of the few studies to use a long-term time horizon. The significance of this study includes providing evidence for health care decision makers on the use of TM for HF, supporting the use of a nurse-led model of TM within HF clinics, and informing the use of economic modeling for future evaluations of early-stage health informatics technology. Given the substantial impact of HF on patients' QoL and burden on health care resources, expanding access to TM programs may be an important mechanism to improve HF disease management and patient outcomes.

## Conflicts of Interest

HR and ES are considered inventors of the *Medly* system under the intellectual property policies of the UHN and may benefit from future commercialization of the technology by UHN.

## Abstract

**Background:** Implementing digital health technologies is complex but can be facilitated by considering the features of the tool that is being implemented, the team that will use it, and the routines that will be affected.

**Objective:** The goal of this study was to assess the implementation of a remote-monitoring initiative for patients with chronic obstructive pulmonary disease in Ontario, Canada using the Tool+Team+Routine framework and to refine this approach to conceptualize the adoption of technologies in health care.

**Methods:** This study was a qualitative research project that took place alongside a randomized controlled trial comparing a technology-enabled self-monitoring program with a technology-enabled self- and remote-monitoring program in patients with chronic obstructive pulmonary disease and with standard care. This study included interviews with 5 remote-monitoring patients, 3 self-monitoring patients, 2 caregivers, 5 health care providers, and 3 hospital administrators. The interview questions were structured around the 3 main concepts of the Tool+Team+Routine framework.

**Results:** Findings emphasized that (1) technologies can alter relationships between providers and patients, and that these relationships drove the development of a new service arising from the technology, in our case, and (2) technologies can create additional work that is not visible to management as a result of not being considered within the scope of the service.

**Conclusions:** Literature on the implementation of digital health technologies has still not reconciled the importance of interpersonal relationships to conventional implementation strategies. By acknowledging the centrality of such relationships, implementation teams can better plan for the adaptations required in order to make new technologies work for patients and health care providers. Further work will need to address how specific individuals administering a remote-monitoring program work to build relationships, and how these relationships and other sources of activity might lead to technological scope creep—an unanticipated expanding scope of work activities in relation to the function of the tool.

## Introduction

The digital health market continues to expand, with projected growth from US \$79 billion in 2015 to an estimated value of US \$206 billion in 2020 [1]. This growth is driven, in part, by the fact that many patient-facing digital health technologies, such as remote monitoring, have shown potential for positive effects on patient health and health care provider performance, such as enhanced chronic disease management and enhanced access to care [2,3]. However, despite some demonstrated successes with digital health technologies, positive results remain sporadic and difficult to achieve [4].

The implementation of digital health technologies remains an extremely complex area of health system improvement, and remote monitoring has served as an important example of the challenges associated with encouraging the meaningful use of technologies in routine care [5,6]. The need for patients to feel comfortable with a given technology in addition to the health care provider team engaging in remote care delivery creates additional barriers to successful adoption [7,8]. Furthermore, many technologies are advertised to be “plug and play,” suggesting there should be no barriers to their immediate use when, in fact, much local adaptation is required for them to be incorporated into users’ everyday lives [9]. These observations illustrate the persistent and unresolved issues associated with determining both the mechanisms through which remote monitoring works for users and the optimal strategies to promote implementation.

Unsuccessful implementation of technologies such as remote monitoring is a result of several complex influences [10], including poor alignment with the main objective of the health care organization, poor training of staff, nonalignment of procurement models, or noninteroperability of the technology with existing systems [11,12]. Over the past 10 years especially, methods and frameworks have been developed to support better implementation of technological tools in health care settings [10,13,14]. Many of these approaches have been rooted specifically in theories of implementation science, including the Consolidated Framework for Implementation Research [15] and the Normalization Process Theory [16]. Theories of implementation science have been important in clarifying the conceptual dimensions requiring consideration in technology implementation initiatives. However, we suggest they have done less to clearly articulate the most important links between the adoption of a technology and the redesign of the service into which a technology is being implemented.

This basic point formed the motivation for previous work by our research team to present an approach to the adoption of digital health technologies that emphasizes the links between technological innovations and service innovations, informed by a service design perspective [17]. Service design is an approach to the improvement or establishment of services that takes the entire service as the primary focus, emphasizing the importance of user experience and the realities of service delivery for health care providers and other staff [17]. In our past work, we formulated the objective of service design: to “carefully plan and promote the coordinated action required to

execute a high quality health care service [17].” In this way, service design considers a technology for its contributions to a service more generally by focusing less on the adoption of the technology itself and more on its contributions to the work required to deliver an excellent service overall.

The recently developed Tool+Team+Routine framework [17] outlines a service design approach to innovation adoption that includes (1) identifying the value propositions of a given tool, (2) considering the implications of the tool for team relationships, and (3) explicitly addressing the new routines required in the technology-informed reconfiguration of the service. Although this approach is based on past empirical research examining this alternative approach to technology adoption, the Tool+Team+Routine framework is a simple heuristic that has not yet been subject to critical examination [17].

The goals of this study were two-fold. First, to apply the Tool+Team+Routine framework to interpret the results of the implementation of a remote-monitoring initiative for patients with chronic obstructive pulmonary disease (COPD) in Ontario, Canada, in order to generate insights that inform potential improvements to the Tool+Team+Routine framework. Second, to identify insights pertaining to the influences that drive adoption of remote-monitoring technologies specifically.

## Methods

### Study Setting

This is a qualitative substudy of a randomized controlled trial [18]; both the randomized controlled trial and this qualitative study were conducted at a community-based hospital in a large city in Ontario, Canada, within a respiratory center that treats patients with COPD. The randomized controlled trial investigated the effectiveness of implementing a technology-enabled self-monitoring program or a technology enabled self- and remote-monitoring program in a COPD patient population compared to standard care. Both the self-monitoring and the remote-monitoring groups used the Cloud DX Connected Health Kit as the monitoring tool [19]. This tool consisted of a tablet and multiple smaller devices to measure physiological vitals and to complete surveys on objective COPD symptoms. The tablet notified patients whenever their readings exceeded their personal thresholds.

All patients from both groups were also provided with a paper-based action plan, which they could follow whenever they received such notifications. The vitals and questionnaire answers from the remote-monitoring group were monitored by the project lead who is also a respiratory therapist. If it was thought to be necessary by the respiratory therapist, based on the vitals or the questionnaire answers, the patient was contacted directly. In addition, the project lead called each remote-monitoring patient once a week.

The study was approved by Markham Stouffville Hospital and Women’s College Hospital research ethics boards in Ontario, Canada.

## Participants

We included 8 patients with COPD (5 from the remote-monitoring group and 3 from the self-monitoring group), 5 health care providers, and 3 hospital administrators (herein referred to as hospital managers). One remote-monitoring patient and 1 self-monitoring patient were interviewed together with their caregiver. Participants were purposefully sampled in order to capture a meaningful and varied range of views on the program from the parties most intensively involved in its implementation. The patients were recruited by a respiratory therapist at the host site and were selected from the randomized controlled trial's group of participants. These patients' contact details were passed onto the research team. The patients were contacted for participation by the principal author (FvL), either over the phone or through email. Prior to the interview, all participants provided informed consent to participate and were informed that they could decline or withdraw from the study at any time without any consequence to their health care. Written or verbal consent was obtained from all participants by the principal author (FvL) at the start of the interview. All patients had moderate (Global Initiative for Chronic Obstructive Lung Disease level 2) to very severe (Global Initiative for Chronic Obstructive Lung Disease level 4) COPD [20]. Patients' demographics were obtained from the randomized controlled trial's onboarding questionnaires.

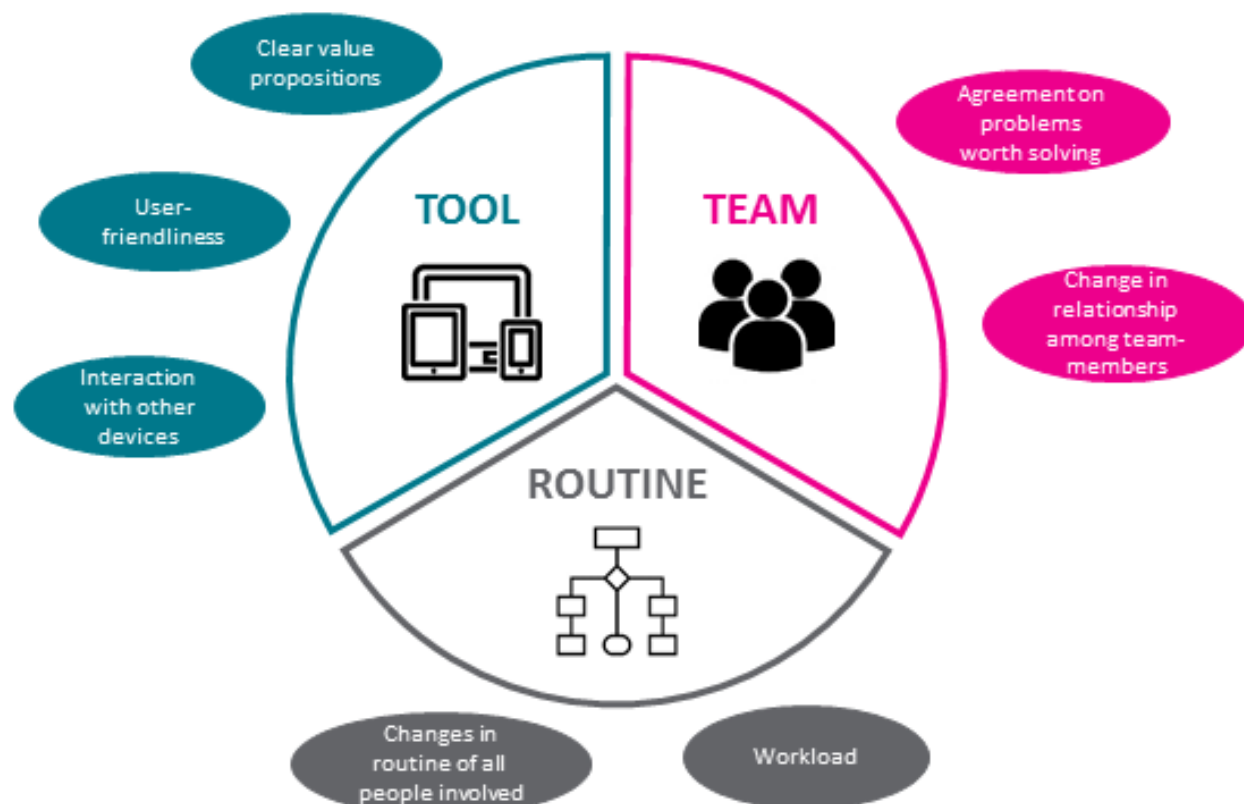

## The Framework

The framework used in this research study was the Tool+Team+Routine framework [17]. Unlike other implementation frameworks, this framework focuses explicitly on service design. Some key ideas that characterize service design in health care are

1. Focus on all the changes to services that are required when introducing a new digital health tool in a health care delivery process.
2. A technology is not immutable; it may need to be modified in order to be of most use to the health care delivery process.
3. There needs to be clear value to all stakeholders, so-called *value propositions* [21]. Ideally, the new service improves one or more factors of the health care quadruple aim—enhancing patient experience, improving population health, reducing costs, and improving the work life of health care providers [22].

Implementing these principles of service design in health care, the Tool+Team+Routine framework is a simple, heuristic approach for introducing new digital health tools to a health care delivery process, or re-designing the delivery process overall and focuses on 3 main factors (Figure 1; Table 1).

**Figure 1.** Visual representation of the main factors in the Tool+Team+Routine framework.

**Table 1.** Tool+Team+Routine framework.

Factor	Description	Questions
Tool	Determines how useful and acceptable the technology is	Are the value propositions clear for all the stakeholders that will use the tool? Is the tool user-friendly? In what way does the tool interact with other devices?
Team	Investigates what changes will occur to the whole team and the way they interact with each other	Does the whole team agree on the problem to be solved by the technology? How does the introduction of the new system change the relationships among team-members, including changed relationships between patient and health care provider?
Routine	Considers in what way people's routines change when the new system is introduced	What other changes will occur in the routines and day-to-day lives of all the people involved—intentionally or unintentionally—when the new system is introduced?

## Data Collection Methods

Participants were interviewed by the principal author (FvL). The interviews were semistructured and contained questions pertaining to the 3 main concepts of the framework. Each group of participants (patients, health care providers, and hospital managers) were interviewed using a different interview guide. Interviews lasted 30 to 60 minutes. All patient interviews were conducted over the phone. The interviews with the health care providers and hospital managers were conducted in person, except for 2 that were conducted by phone. All interviews were audiorecorded and transcribed verbatim. The transcripts were anonymized and deidentified.

## Data Analysis

The interview data were analyzed using thematic analysis methods [23,24]. The first 2 transcripts were analyzed and coded individually by the principal author and 2 other members of the research team. The codes were then compared and discussed which informed the development of a code book that was used to code 3 other transcripts. Thereafter, the code book was

discussed again between the same 3 researchers, which resulted in the revised code book. This method was used to ensure the members of the research team contributing to the analysis agreed on the relevance and definitions of the codes being used. The remaining transcripts were analyzed and coded by the principal author using the revised code book. Any necessary changes to the coding of the first 5 transcripts that resulted from the revised code book were made as well, through regularly occurring analysis meetings between 4 authors on the study team.

## Results

### Overview

**Table 2** provides an overview of the patients and caregivers who participated.

**Table 3** provides an overview of the health care providers and hospital managers who participated. The tables provide the overall attitude toward the program (negative, neutral, mixed, or positive) as gleaned from participant interviews.

**Table 2.** Patients and caregivers who participated.

Participant	Study arm (remote or self-monitoring)	Gender	Age (years)	Interviewed with caregiver	Overall attitude toward program
P1	Remote monitoring	Male	73	No	Positive
P2	Remote monitoring	Female	89	No	Positive
P3	Self-monitoring	Female	69	No	Neutral
P4	Remote monitoring	Female	72	No	Neutral
P5	Remote monitoring	Male	65	No	Positive
P6	Self-monitoring	Female	75	No	Positive
P7	Remote monitoring	Male	73	Yes	Positive (patient); positive (caregiver)
P8	Self-monitoring	Female	81	Yes	Neutral (patient); positive (caregiver)

**Table 3.** Overview of the health care providers and hospital managers who participated.

Participant label	Job title	Level of interaction with Cloud DX <sup>a</sup>	Overall attitude toward program
HCP 1	Physician	3	Positive
HCP 2	Physician	3	Neutral
HCP 3	Allied health professional	5	Mixed
HCP 4	Allied health professional	5	Positive
HCP 5	Allied health professional	4	Positive
HM 1	Senior manager	2	Positive
HM 2	Manager	2	Positive
HM 3	Senior manager	1	Positive

<sup>a</sup>Levels—1 (very little): no interaction with the Cloud DX data on a daily basis and little to moderate understanding of the tool; 2 (little): no interaction with the Cloud DX data on a daily basis but moderate to high understanding of the tool; 3 (moderate): regular indirect interaction with the Cloud DX data but not involved in daily monitoring of patients; 4 (high): daily direct interaction with the Cloud DX data but not involved in daily monitoring of patients; 5 (very high): daily monitoring of patients with the Cloud DX tool and data.

In the sections below, qualitative descriptions of the results that emerged from the interviews are given. These results are structured around the 3 main themes of the framework: *Tool*, *Team*, and *Routine*. Verbatim quotations are labeled with the role of the participant and their study arm (for patient and caregiver participants) or their role and level of interaction with the Cloud DX tool (for health care provider and hospital manager participants).

### Attitude Toward the Project

Within all stakeholder groups, the attitude toward the project was mainly positive. Of the remote-monitoring patients, 4 out of 5 viewed the program as positive; the fifth had a neutral attitude toward the program. Of the self-monitoring patients, 1 out of 3 viewed the program as positive; the other 2 had neutral feelings about it. The 2 caregivers were both positive about the program. Within health care provider and hospital manager groups, attitudes toward the program were more nuanced. All 3 hospital managers showed positive attitudes toward the program. Of the health care providers, 3 out of 5 showed positive attitudes as well; the other 2 had mixed feelings about the program. These are elaborated.

### Tool: Value Propositions in a Technology-Push Project

Stakeholders' perceptions of the value of the tool varied and were characterized by the fact that the implementation project was structured using a *technology-push* approach. In this case, a team of managers and providers from 2 different health care organizations established a project agreement with the vendor, securing funding to support an evaluation of the tool in a hospital environment. One manager explained expectations for the project:

*I think [the technology] is allowing patients to catch their symptoms, uh sooner so they can start treatment before they get really sick. I think it's keeping them away from the emergency department and it should be decreasing the number of admissions... So, decreasing admissions to hospital, overall, it's gotta be improving their quality of life. [Senior manager, very little interaction]*

Only after the funding was in place and the agreement to complete the project was secured did the project team seek to engage the health care providers who would be using the tool in the newly established model of care. As a result, not all health care providers saw value in the tool, leading some to resist engaging with the technology in a meaningful way.

Resistance to engaging with the technology and its outputs was reported by some of the respiratory physicians who were involved in the care of patients enrolled in the program. One physician stated:

*I was very skeptical when the study was first started because uh, a lot of the times, these sort of home monitoring or self-monitoring or other programs kind of invent the technology first before asking a lot of important clinical questions of whether it's actually gonna be of benefit or uh, examining why patients actually have exacerbations or the mechanisms and then it's sort of just implemented into this study and then we see what happens, so, it's uh, a bit of the uh, cart before the horse kind of scenario [Physician, moderate interaction]*

This quotation illustrates the general lack of engagement with the tool among some physicians primarily as a result of feeling that the tool does not solve a direct clinical need (although the lack of time physicians have for such initiatives is also clearly acknowledged). The primary example of this was that vitals data, such as blood oxygenation saturation, which are a primary data output of the tool for health care providers are known to be a poor predictor of exacerbations of COPD. Physicians were not satisfied with the effort to establish a meaningful use case for the tool after the decision to move forward with the project was made. This created a scenario where physicians had widely varying levels of engagement with the lead respiratory therapist who provided them with information about the outputs of the tool in order to inform their approach to care.

In this initiative, the physicians were not actually required to interact directly with the tool. Instead, a respiratory therapist was responsible for communicating with patients by phone regarding the tool and managing the inputs arising from patient

data being collected at home. This respiratory therapist would communicate with physicians when remote-monitoring data from patients under their care suggested that some form of physician follow-up would be appropriate. Although the respiratory therapist had reservations about the workload implications of the tool, this person believed there would be a benefit for certain patients:

*So the program I think it's helping patients, ehm, better understand their condition, or at least some of the patients. Perhaps not all of them. And helping them to recognize when they're getting sick so that they can get treatment, either sooner or more appropriately... I would say that some patients did, or were good self-recognizers [already] and those are patients who have come to the hospital one or two times before because they had experienced [an exacerbation]... However those who haven't had many experiences with exacerbations, it helps them better recognize it. [Allied Health Professional, very high interaction]*

The patients and caregivers interviewed for the study reported some technology-related challenges that might be expected when adopting new digital tools for the first time. However, many participants reported generally positive sentiments about the tool and its adoption into their everyday lives. One patient, a woman in her 70s who lived alone, stated:

*The tablet gave me, just that confidence because I could see that my blood pressure was in normal range though I kind of figured that. And then my oxygen levels, I didn't know about my oxygen level and then, once I, I got to reading my oxygen levels, everything seems to be fine. So that, that was just, I don't know, just a report back to myself saying "Hey, you're not too bad at all" [Patient, remote monitoring]*

Another patient described an instance where her decision to seek out emergency services was directly informed by the tool. Although this example is not directly related to a patient's experience of COPD, people living with COPD often experience co-occurring conditions such as atrial fibrillation.

*[Respondent:] ... my heart was beating too fast and because I had the, eh, or it was getting, although it was indoors it seemed to be getting very dark and, I had ehm, and my blood pressure I don't know, I don't know what my blood pressure was but my pulse was, was going about a hundred and, at a hundred and seventy beats a minute and, I realised that was way too fast and I felt sort of dizzy so I went into emerge that time...*

*[Interviewer:] Alright. (.) So, did you feel like the Cloud DX tablet helped you at [that] incident?*

*[Respondent:] Yes, because like I didn't, I was, I guess I was sort of dizzy I didn't realize my pulse, when I saw my pulse was so high I knew I had to do something about it. Otherwise, I might not have gone in and I don't what would've happened then. [Patient, remote monitoring]*

In summary, although the value propositions of the tool were not immediately clear to all stakeholders, those who engaged with the tool directly did feel the tool was valuable for the management of COPD, at least in certain cases. However, the primary value that appeared to be offered by the program arose not from the tool per se but from the relationship between patients and the respiratory therapist responsible for administering the program. We explore this point in the next section.

### Team: The Role of Relationships in the Reconfigured Service

The relationships between members of the health care team did not change in meaningful ways as a result of the implementation of the tool and the establishment of the remote-monitoring service. The respiratory therapist who administered the program was the primary point of contact for patients and would notify physicians, when appropriate, regarding issues arising for patients under their care. This process was not substantially different from how these providers communicated previously, as respiratory therapists had opportunities to interact with some patients before the beginning of this project in the context of a community-based exercise program and as recurring patients at the Centre for Respiratory Health and would communicate with physicians under similar circumstances as during the remote-monitoring project.

The relationships that were most important were those between the respiratory therapist administering the program and the patients enrolled in the program. Specifically, the relationships between the respiratory therapist and patients in the remote-monitoring program deepened and became an important component of the patients' overall care. Many remote-monitoring patients spoke about the importance of this particular respiratory therapist for the value they experienced with the program, viewing the respiratory therapist not only as a source of information related to the tool itself, and COPD more generally, but as a person capable of supporting patients in solving health-related challenges of virtually any kind. The respiratory therapist corroborated this view by indicating that she had a good relationship especially with patients in the remote-monitoring group of the project:

*So a lot of the patients call me because they know I'll answer and it's just to help get a prescription filled or sort of some other issue that they're having... cause they know I'll answer and have access to their physicians. They'll call me over calling [the doctor's] receptionist... Which maybe isn't good, but, is also kind of good for [patients] because they feel more comfortable. Cause the relationship is there. [Allied Health Professional, very high interaction]*

Patients also reported the importance of being able to make contact with the respiratory therapist when questions arose regarding their health and health care. When asked what the most useful feature of the technology was, one patient stated:

*Well, the point that you can, ehm, call somebody whenever you have a question, like [the respiratory therapist] you know. It's very helpful because you*

*have somebody to talk to about whatever the problem is. Whether it's your breathing or your heart or what.*  
[Patient, remote monitoring]

These examples illustrate a fundamental mechanism by which the newly established service exhibited value for patients in the remote-monitoring group: through the relationship with the respiratory therapist administering the program. In this sense, although the tool was able to support the development of confidence and elicit appropriate responses to changing symptoms for patients across both self-monitoring and remote-monitoring groups, the value of the program extended beyond supporting the ability of patients to manage their COPD independently for the remote-monitoring group; it evolved to include a hidden care coordination function that was being performed by the respiratory therapist.

This care coordination function was not intended to be a part of the program from the outset and could be viewed as being a function of technological scope creep as a result of this respiratory therapist's strong relationships with patients. Specifically, we use *technological scope creep* to refer to the unanticipated expanding scope of the respiratory therapists' work activities in relation to the function of the tool. The positive relationship between the respiratory therapist and remote-monitoring patients perhaps boosted their engagement with the tool but also fundamentally changed the nature of the remote-monitoring program. It was no longer simply a matter of monitoring vital signs and symptoms related to COPD, but at least for some patients, became a strategy to coordinate and access health services well beyond the original boundaries of the program. This technological scope creep is one component of the ways in which routines evolved as the program was implemented, which is addressed in the final section of the findings.

### Routine: Routines of Care and Hidden Work

The demand for changes in routines of care was very different for the different people involved in the project. For physicians, they had to change virtually nothing, and independently chose whether or not to act upon any information provided by the respiratory therapist administering the project. This meant that some physicians would act directly on the information provided and reach out to patients to follow up, whereas others would simply note the information but proceed with their usual approach to care.

Patients underwent a learning process as they came to interact with the new tool that became a part of their home environment during the project period. Although patients suggested that the learning process was a challenge in some cases, ultimately, the everyday use of the tool was viewed as largely unproblematic. One patient explained:

*... I would make sure to get up a few minutes earlier than the time I needed to be up and kind of on my way out, to make sure I do have the time to do it. It's not a big deal.* [Patient, self-monitoring]

In contrast to the relative ease experienced by physicians and patients, the respiratory therapists directly involved in the new program experienced drastic changes to their routines. In a

sense, these changes were obvious and expected, as both respiratory therapists appointed to the program were fully aware that the program was just being established and represented net new work. However, the nature of the work they were ultimately required to carry out was not clear to them in advance. Two examples illustrate this point: extra documentation requirements and the growing communication demands arising from patient input through the tool.

In relation to documentation, the respiratory therapists were initially required to chart patient notes in the tool's record system related to any care-related activity that took place through the tool. However, it quickly became apparent that this meant double charting and would not be sustainable were the program to become a part of usual care. One respiratory therapist described this as follows:

*What we did was we actually charted in some of the patients' notes on the Cloud DX project, sort of things that we thought were relevant. But then we found out we were actually double charting. Ehm, because we would have to chart in, you know, the EMR system. And so, I think that, you know, if it could be integrated into the system, like at the hospital, ehm that would be awesome. But at, at present, during the study, we, you know, we had to sort of do extra work just cause it wasn't integrated.* [Allied health professional, very high interaction]

In this case, the known challenge of the lack of interoperability led to excessive workload on the part of the health care providers administering the program.

In relation to the communication demands arising from the program, these extended beyond the issue of patients calling the respiratory therapist for support in coordinating care more generally. The respiratory therapist also received calls related to technological challenges that were supposed to be directed to the vendor. Furthermore, the respiratory therapist would receive notifications indicating an exacerbation based on data that had been incorrectly entered and would need to call patients to follow up on those notifications only to discover that something had gone wrong in the data collection process (eg, they had responded to a survey incorrectly or the blood pressure cuff was not tightened properly). The respiratory therapist administering the program stated:

*I can tell you that, ehm, in the remote monitoring group I had 116 incoming calls in 6 months and the self-monitoring group I had like 134 incoming calls in six months. So the total is, what, 240? So the remote-monitoring called me a little less than the self-monitoring. Ehm, and then I further broke that down into the reason for them calling and I'd say it's like 77 were technological in the remote-monitoring and like 80 or so were technological [in self-monitoring]. And then the next highest one was just general health inquiries. Yeah, so, it's, it's mostly tech issues that they're calling about. And they are told to call [the vendor], they just feel more comfortable calling me. And I generally just push it over to [the vendor]. In addition to those incoming*

*calls, I had the notifications to respond to. So [sighs] I think in the three months for the remote monitoring group I had something, like, close to 300 notifications in six months, to respond to. [Allied health professional, very high interaction]*

The additional workload represented by these new routines was also not anticipated by managers. A manager responsible for considering the workload implication and sustainability of the program in the longer term commented:

*[An important question is] if it's something that's sustainable and how do we integrate it into the day to day clinic activities? This study did not address that. So that will be something we'll have to figure out. [Senior manager, little interaction]*

These instances of additional workload represent the establishment of new routines of care that were not anticipated at the outset of the program. These new routines quickly filled the time of the respiratory therapists responsible for the program, and added demands that would not be sustainable if the resources for staffing were held constant in the long-term. This finding represents the hidden work of technology implementation and remote-monitoring tools, which is not visible in advance of a program and might not be visible at all unless explicitly examined during the evaluation process.

## Discussion

### Principal Findings

Our findings direct attention toward two primary insights. Each insight helps to address the two primary objectives of our paper, which were to advance the Tool+Team+Routine heuristic for the adoption of digital health technologies and to clarify mechanisms by which remote monitoring may exert its value for patients. The first insight is the significance of interpersonal relationships for the functioning of this particular digital health technology in the context of delivering a comprehensive service of remote monitoring. The second is the expansion of routines of care and what we refer to as technological scope creep—the growing demands of health care providers' everyday work as the technology requires new actions to fulfil newly generated demands.

### The Role of Relationships in Remote-Monitoring Initiatives

In our study, we found that one of the features of the service that most drove the successful engagement of patients with the technology was the relationship between the respiratory therapist administering the program and the patients who were enrolled. This finding resonates strongly with previous research [10,25] on the mechanisms by which digital health services have their effects. Vassilev et al [26] completed a realist review of the literature examining the specific causal mechanisms influencing the effectiveness of telehealth programs and found relationships to be one of three crucial mechanisms. They explained that new technologies introduce “new sources of relationality [26],” and thereby, “restructure existing relationships [26].”

In support of previous literature [7], our findings outline the value of such interpersonal relationships between the provider administering the program and the patients using the technology for the successful adoption of the service overall. In relation to the Tool+Team+Routine framework, this is an important point to emphasize; it is not just that such relationships enhance the adoption of the new technology, but that the relationships drive the development of an actual service arising from the technology itself. The technology is one component of a new program but relies on many other interacting components to become a part of a successfully delivered service (including people, technologies, and newly established processes).

In the context of service design, the adoption of new technologies stands to influence interpersonal relationship in at least two distinct ways. First, the technology might influence relationships among health care providers as they are required to collaborate in different ways than they previously had. We did not find this to be the case in our study, likely because the expectations that different health care providers had for one another did not change throughout the study period. However, this change to relationships among health care providers remains a possibility [25]. Second, the mechanisms by which the technology has its effects for patients are themselves determined in part by the quality of the relationships established between patients and the provider administering the program, and in this case, mediated by the technology. Emphasizing these relationships represents an important conceptual development for the Tool+Team+Routine heuristic, placing relationships in a more prominent position when taking a service design approach to promoting the adoption of technology-enabled service innovations. This point also reinforces the finding in the literature that the interpersonal relationship between the patient and the health care providers is a primary consideration in the effort to understand the ways in which remote monitoring has its effects [25].

### Technological Scope Creep

The second important finding emerging as an important direction for future research in our study is the phenomenon of technological scope creep. This point relates specifically to the *routine* element of the Tool+Team+Routine heuristic in a service design context, as it refers to changes in the routines of providers who must interact with the technology in ways that were not predicted at the outset. Furthermore, these newly added routines, in our study, were not accounted for in the time allocations assigned to providers responsible for administering the program via the technology, even though they might add additional value for patients. This point raises an important issue for the Tool+Team+Routine heuristic: in the effort to promote adoption of technologies for new services or service re-design, explicit effort should be made to anticipate technological scope creep and the demand for new routine practices that were not expected of the technology at the outset.

This point resonates with past work outlining how routine work practices change when new technologies are adopted [16,27,28]. However, past work has primarily emphasized the point that technologies restructure service arrangements [29]. We acknowledged this point in our past work [17] but extend this

point now to acknowledge that even where work restructuring is explicitly anticipated in technology adoption projects, new technologies have a further potential to produce new work that is hidden from the view of management and evaluation as a result of not being considered as falling within the scope of the service itself. The technology evaluated in this study was intended to enable remote and self-monitoring of patients related specifically to COPD; however, patients ended up using the service as a general care coordination service. As a result of the relationships with the primary program administrator (the respiratory therapist), the scope of the service expanded to include this more general care coordination function. In effect, as a result of technological scope creep, the service itself expanded from its original function to take on a broader set of functions.

### Strengths and Limitations

This paper has applied a previously reported framework [17] to understand the implementation of a remote-monitoring

technology into a health care environment. Although the patient participants recruited for this study might not reflect the needs and opinions of the entire COPD population, the sample of patients included provided in-depth insight into the value of the tool in the context of the service.

### Conclusions

The observations arising from our findings advance the Tool+Team+Routine heuristic for use in service design activities that involve technology adoption in health care services. Deep thinking about how the specific individuals administering the program will work to build relationships and how those relationships and other sources of activity might lead to technological scope creep present two often unanticipated challenges when implementing digital technologies in health care. Future work can reconcile these important influences on technology adoption and will examine strategies to account for them in advance of initiating technology implementation projects using a service design approach.

### Acknowledgments

We gratefully acknowledge all the participants who took part in the study. This work was supported by Ontario Centres of Excellence Health Technologies Fund (grant number 27009). The grant supported personnel and materials related to the implementation of the technology into the clinic and the evaluation of the intervention.

### Conflicts of Interest

None declared.

## Abstract

**Background:** Visual field defects are a common consequence of stroke, and compensatory eye movement strategies have been identified as the most promising rehabilitation option. There has been a move toward compensatory telerehabilitation options, such as the Durham Reading and Exploration (DREX) training app, which significantly improves visual exploration, reading, and self-reported quality of life.

**Objective:** This study details an iterative process of liaising with stroke survivors, carers, and health care professionals to identify barriers and facilitators to using rehabilitation tools, as well as elements of good practice in telerehabilitation, with a focus on how the DREX package can be maximized.

**Methods:** Survey data from 75 stroke survivors informed 12 semistructured engagement activities (7 focus groups and 5 interviews) with 32 stroke survivors, 10 carers, and 24 occupational therapists.

**Results:** Thematic analysis identified key themes within the data. Themes identified problems associated with poststroke health care from both patients' and occupational therapists' perspectives that need to be addressed to improve uptake of this rehabilitation tool and telerehabilitation options generally. This included identifying additional materials or assistance that were required to boost the impact of training packages. The acute rehabilitation setting was an identified barrier, and perceptions of technology were considered a barrier by some but a facilitator by others. In addition, 4 key features of telerehabilitation were identified: additional materials, the importance of goal setting, repetition, and feedback.

**Conclusions:** The data were used to try to overcome some barriers to the DREX training and are further discussed as considerations for telerehabilitation in general moving forward.

**KEYWORDS**

telerehabilitation; vision; barriers; facilitators; technology

## Introduction

Visual impairments occur in about 65% of stroke survivors [1], with a large proportion of these experiencing partial visual field loss [2] (eg, blindness in a part of their visual field). For such individuals, visual restoration is limited [3]. Partial visual loss can be debilitating, with those who experience it having problems completing activities of daily living [4], an unwillingness to leave the home [5], and an increased risk of falling [6]. Individuals also have their driving licenses revoked, further reducing their independence, and can consequently become more isolated, reliant on support, and depressed [5,7-9]. Overall, people with visual field defects demonstrate poorer functional outcome [10], impaired vision-related quality of life [11], and reduced engagement in rehabilitation [12]. With improving stroke survival rates [13], an increasing number of stroke survivors are living with the long-term consequences of partial visual loss. Therefore, providing effective and accessible treatment for such individuals is important in order to significantly reduce their disability.

The uptake of technology among older people is relatively high, with 48% of those aged 55 years or older owning a tablet computer in 2017 and 8.1 million 55- to 64-year-olds in the United Kingdom using apps regularly [14]. Furthermore, telerehabilitation, the provision of rehabilitation services (therapeutic intervention, progress monitoring, education, training, etc) at a distance via electronic information and communication technologies [15], has been identified as a credible, potentially cost-effective future direction for health and social care [16,17]. Despite this, there is still a significant contingent of stroke survivors who distrust telerehabilitation, as they fear reduced quality of care [17]. Previous evidence has shown that motivation is a significant factor in improving engagement with home-based rehabilitation tools [18]. At present, only a limited number of studies exist regarding the effectiveness of telehealth-based digital interventions [19]. For these reasons, it is important to examine factors that could increase their uptake.

The most common form of telerehabilitation employed to address visual loss is computer-based compensatory training, which teaches stroke survivors adaptive eye movement strategies to cope more effectively with visual loss. Durham Reading and Exploration Training (DREX) is one such version of this training, taking the form of a free, multiplatform app and significantly improving visual exploration, reading, and quality of life [20] (see [Multimedia Appendix 1](#) for further details). We report findings from our 2-stage study with stroke survivors, carers, and health professionals, which explored potential barriers and facilitators to the use of DREX and perceptions about key features for telerehabilitation packages. Stage 1 described key findings from a survey identifying the key elements of patients' stroke experiences. In stage 2, these elements were addressed through a process of liaising with key stakeholders (stroke survivors, carers, and occupational therapists) to understand experiences of this specific tool (DREX) and adjusting the training package in response to the issues identified, thereby improving the potential for training uptake and user experience.

## Methods

### Recruitment

A snowball sample of 75 UK-based stroke survivors with partial visual loss completed the survey (mean age 63.77 years). The survey was distributed in an online format via prominent stroke Facebook groups (n=66; mean age 57.00 years) or as a paper version upon request (n=9; mean age 66.78 years).

Stroke survivors for interviews and focus groups were selected through opportunity sampling based on geographical location (region of North East England). A total of 32 stroke survivors (18 men; aged 43-83 years, mean age 62.28 years), 10 carers (7 women; 41-75 years, mean age 54.70 years), and 24 occupational therapists (19 women; 22-45 years, mean age 31.13 years) were involved in either focus groups (n=7) or interviews (n=5). Engagement activity characteristics are displayed in [Table 1](#).

**Table 1.** Characteristics of stakeholder engagement activity.

<sup>a</sup>N/A: not applicable.

## Design

This qualitative study was part of a larger study investigating barriers and facilitators in stroke rehabilitation in general. This data subset explores the interaction between DREX and specific issues in relation to poststroke visual field defects. Full project data and materials can be found on the Open Science Framework [21]. This study was divided into 2 stages. In stage 1, a short survey was used to identify the barriers and facilitators from the stroke survivors' experiences. Stage 1 data informed the second stage, which aimed to quantify the extent of the major themes identified. Interviews and focus groups were conducted with stroke survivors, carers, and occupational therapists in a semistructured manner to understand the specific impact of these barriers and facilitators and the factors perceived as important within telerehabilitation. Stroke survivors were recruited via Stroke Association groups in the northeast of England and could participate in either a focus group or an interview. Participants had to be at least 18 years old and able to give informed consent. Stroke survivors with communication difficulties were not excluded if they had capacity for consent; however, no stroke survivors reported communication difficulties. The information gathered from these activities was used to generate changes to the DREX package to increase accessibility. Ethical approval was provided by the Durham University Psychology Department Ethics Committee and the study was conducted in accordance with the Declaration of Helsinki.

### Stage 1: Survey

Full survey details can be found in [Multimedia Appendix 2](#). Survey data were analyzed to inform key points of interest for discussion within stage 2.

### Stage 2: Focus Groups and Interviews

Survey data permitted the construction of a semistructured interview protocol (see [Multimedia Appendix 3](#) for the interview

schedule), which probed further information from a number of identified areas. Specifically, stroke survivors and carers responded to questions regarding their everyday difficulties, rehabilitation journey, experiences with technology, motivation, and levels of support. Occupational therapists were also asked about their experiences, but with a greater focus on understanding the barriers and facilitators they experience in supporting stroke survivors and their views on the use of technology in poststroke visual rehabilitation.

Stroke survivor focus groups were carried out at one of 5 venues: Age UK Roundhouse Ashington Stroke Group, Gateshead Stroke Association Stroke Group, Newton Aycliffe Stroke Group, Teesside Stroke Club, and Stockton-On-Tees Happy Talk Stroke Club. Interviews were carried out in a quiet room in the survivor's home. The 2 focus groups with occupational therapists took place with the stroke teams at the University Hospital of North Tees and Northumbria Hospital. Discussions were audio recorded with consent.

Focus groups were facilitated by the primary author (an experienced qualitative researcher with clinical experience). Initially, the project and focus group aims were outlined and the participants introduced. The notion of facilitators and barriers were explained, and participants were given the opportunity to discuss their own expectations and clarify any miscommunications. Carers were encouraged to let the stroke survivors give their views first but were also given the opportunity to discuss their own experiences. All participants communicated verbally. The focus groups and interviews were semistructured, with 6 open questions used to stimulate discussion and follow-up questions used depending on responses. The 2 focus groups conducted with occupational therapists instead focused on the DREX training package and how it could be improved, current rehabilitation techniques implemented by therapists dealing with poststroke visual loss, and additional materials that could assist therapists. Focus groups and interviews lasted approximately 60 minutes.

Qualitative methods have proved particularly suitable for the analysis and interpretation of focus group data [22]. Thematic analysis was used [23] to work through the data until a small number of themes that described the data set were identified. Data were managed using Microsoft Word. Specific information regarding the data coding process can be found in [Multimedia Appendix 4](#).

## Results

### Stage 1: Survey Data

Stroke survivors identified family, carers, and occupational therapists as best placed to support them in their recovery. Therefore, these stakeholder groups were included as participants in stage 2. Additionally, confidence with technology and the internet was found to decline increasingly with age, while fear of making mistakes rose. Finally, face-to-face support

was identified as the most useful factor in rehabilitation. A full discussion of these results can be found in [Multimedia Appendix 5](#).

### Stage 2: Interview Data

#### *Qualification and Quantification of Barriers and Facilitators Identified by Participants*

There were 2 main themes and several subthemes that were identified by stroke survivors as factors that act as barriers to using telerehabilitation, while 1 main theme with 1 subtheme was identified as a facilitator. In addition, 4 key features were identified by participants for those designing and creating e-therapies for stroke survivors. These themes are presented in [Textbox 1](#) and discussed below, illustrated with verbatim transcripts. Interestingly, technology was seen as both a barrier and a facilitator, so these are discussed together.

**Textbox 1.** Factors identified by stroke survivors, carers, and occupational therapists as acting as barriers or facilitators in the use of telerehabilitation in stroke and the key features identified as important for telerehabilitation.

<b>Barriers</b>	
1. Acute ward rehabilitation	<ul style="list-style-type: none"> <li>Limited occupational therapy time</li> <li>Acute patient readiness</li> </ul>
2. Perceived disadvantages of technology	<ul style="list-style-type: none"> <li>Confidence</li> <li>Lack of interest</li> <li>Lack of personal contact</li> </ul>
<b>Facilitators</b>	
1. Technology and the internet as a perceived advantage	<ul style="list-style-type: none"> <li>YouTube</li> </ul>
<b>Key features for rehabilitation</b>	
1. Additional resources	
2. Goal setting	
3. Feedback	
4. Repetition	

### *Acute Ward Rehabilitation as a Barrier*

Occupational therapists discussed the limited time they have with stroke survivors in acute settings as a barrier in their rehabilitation. Therapists praised the idea of having a form of therapy they could leave with a stroke survivor to use as and when they want without requiring therapist supervision and time:

*It's also good as well because like obviously we can only provide so much time as well with rehab but if we can give the patient that to do when we're not there then if they're doing even an hour every other day then its brilliant. Sometimes we give them things*

*to do and think, "Are they going to do it or not?" but something like that they know it's there, they do it, log on.*

However, occupational therapists also identified that even with prior technological experience, the use of technology on acute wards was often too big a jump for many stroke survivors:

*I think one of the reasons our use of DREX hasn't been as much as we'd like or anticipate has partly been the whole problem of how ready they are for some of this in the acute phase, and I think that can run over into the acute phase at home as well. That applies to DREX but also applies to some of the other rehab activities we apply to patients. And it's about,*

*if possible, increasing the option to grade patients into it. I often find with my patients on the ward, DREX is just too big of a jump for them. That even if they've got some tech knowledge beforehand the assessment is a big jump for them straight away.*

### Perceptions of Technology

A key factor discussed across all focus groups was technology, specifically if and how it is used by stroke survivors. There was a clear dichotomy between those who perceived technology as a positive aspect of rehabilitation and those who viewed it negatively.

### Technology as a Barrier to Telerehabilitation

Within this overarching theme of technology as a barrier, 3 key reasons were identified by stakeholders as to why they felt technology was not useful. The primary subtheme was confidence with technology; a large number of the stroke survivors talked about loss of confidence post stroke, which seriously impacted their life. Those who were previously technophobic reported having little confidence to learn something new:

*Facilitator: Would you ever want to use the internet or need to use the internet?*

*Participant: I don't think so, no, I don't really think so. It would be handy for some things but the amount of learning it would take...*

In addition to this, even those who were previously comfortable using technology reported becoming less confident after their stroke:

*I use it. Far less than I used to though. I used to be really comfortable on the internet but now I just stick to basics of where I'm comfortable and I wouldn't go exploring online at all now. I just use Amazon, Facebook, that's it. I haven't got the wherewithal that I used to. I used to be very switched on. Now I'm only half switched on.*

One aspect of confidence that stroke survivors discussed was fear, for example, fear of making a mistake while online. This was also echoed in a carer's responses, who similarly felt fearful letting their partner online because of the potential ramifications of errors:

*Participant: I'm just frightened of making a mistake. I think that's my biggest worry. One time I would just go on the internet and do my shopping on the internet. Now I'm frightened if I order 19 of something.*

*Carer: I haven't got the confidence to let him [use the internet] because if he gets into trouble on it I'm [in trouble]!*

A second subtheme was level of interest; some stroke survivors were not interested in accessing technology. This was encapsulated in one participant's response:

*I didn't have an interest then, I haven't got an interest now.*

It is important to understand that individuals may be reluctant to use technology purely because they have previously not had to use it and do not see a need now.

A third subtheme relating to disadvantages of technology was stroke survivors not appreciating the lack of personal contact. Some stroke survivors viewed the emergence of everything being done online, including rehabilitation, as a barrier in their rehabilitation journey:

*The other thing as well is everything is done on the internet, there's no personal contact. I think sometimes you need to break that barrier down.*

### Technology as a Facilitator for Telerehabilitation

Although some stroke survivors viewed technology as a barrier, others spoke about the benefits of technology and its positive impact:

*Technology has been my saviour.*

Specific positives were attributed to the accessibility of certain technology. Particular mention was made of YouTube and the advantage of being able to watch an online video repeatedly:

*YouTube videos would help teach me stuff because the beauty of YouTube is I can play it again and again and again.*

### Key Features of Telerehabilitation Packages

#### Additional Resources

After discussion with occupational therapists, it became apparent that there was no fixed activity provided for stroke survivors with visual loss to complete on acute wards, resulting in the time-consuming process of therapists creating their own materials. This led to therapists discussing the specific tools and materials they could use:

*So that's something we're already doing, not in the same format. So it's more paper based so it doesn't move up and it's not...we just make them ourselves as well. It's not as content heavy, it's not moving through space the way the app is with having to keep up and that.*

One theme that emerged was a need for stroke survivors to be provided with opportunities to better understand the requirements of the training packages used in telerehabilitation and the need for tools that could assist occupational therapists in delivering effective therapy in acute wards.

#### Goal Setting

Stroke survivors described the positive nature of setting goals in their rehabilitation and how this aided their rehabilitation in general:

*[I] think to myself I'm going to improve...again it was that 4%, 8%, 10%, 12%.*

Generally, goal setting is a good motivator and its inclusion in telerehabilitation provides stroke survivors with further motivation to undertake exercises above and beyond their rehabilitative benefit.

## Feedback

Feedback was highlighted by occupational therapists as critically important to rehabilitation, with stroke survivors feeling more positive and having a sense of achievement after receiving progress feedback:

*[Feedback] gives you that boost, doesn't it. They can say, "I'm improving." Because you like to know if you're improving.*

## Repetition

Stroke survivors discussed the positive aspects of repetition in their rehabilitation. One patient discussed the benefits of being able to do things repeatedly, as with his memory issues, this was the only way he could function independently:

*Facilitator: So for you, do you think the repetition...because obviously the tasks themselves are extremely repetitive. You're doing the same kind of training over and over again. Is that something that works really well for you?*

*Patient: Yeah because it takes me a while to get a hang of it and then I'm ahead of the game. Repetition is the secret of running my life.*

## Applications of These Findings to DREX

Participant responses highlighted a range of issues in the application of telerehabilitation for stroke survivors with visual field defects. We outline alterations made to the DREX training package in order to directly address these issues.

In liaison with occupational therapists, we created a dossier of paper-based tasks for use by stroke survivors who are not currently able to access the training. The tasks are paper-based versions adapted from the training exercises in the DREX app and provide an intermediary form of compensatory training for acute ward use. This tackles several identified issues, including alleviating some of the time pressure on therapists, since they do not have to do this task anymore, and addressing patient readiness for telerehabilitation by providing a simplified form. It could also be a starting point for those lacking confidence or interest in technology by familiarizing them with the tasks in a different format first. Therapists have begun trialing these resources at several local National Health Service trusts and have found them helpful:

*I can imagine a lot of people that it will be a real lifeline for because, you know, we run to the photocopy [sic], get our bits of paper, we make stuff up ourselves for them to do.*

Furthermore, working with stroke survivors and therapists, we updated user guides and website information to provide a more accessible service to key stakeholders. These user guides have also been printed and provided to therapists in acute settings to avoid having to use technology to access them, which may be a barrier to some. Furthermore, in accordance with an identified facilitator, a YouTube channel was created that included task demonstration videos. Such additional resources were designed to help alleviate some concerns that users experience regarding unknown technology, and we know that the videos viewed more often are those that correspond to some of the more difficult

aspects of navigating the training, indicating that they are a tool that can aid this.

Given the importance of feedback in rehabilitation, the delivery of this within the DREX training was improved; users now receive a speed and accuracy score after every training block. This allows them to effectively track their progress over the course of training. However, we are continuing to investigate ways to improve the feedback provided. Although stroke survivors have responded well to receiving feedback, therapists believed the feedback delivery could be improved. Therapists felt one-to-one monitoring of stroke survivors' feedback would further help stroke survivors understand how they are progressing and challenge them to continually improve.

*I thought it might be quite helpful to sit down with someone and go through it afterwards to say, "How did you find this," and "Well this is what it's shown." "This is what you've done really well" or "This part shows that's what you're saying is really difficult." For some people it might be really helpful to have those conversations in some more detail.*

Delivery of feedback is an extremely important factor in the success of rehabilitation in clinical populations, and this factor was no less understated in the responses of occupational therapists. This provides an interesting point in the move toward telerehabilitation, as this personalized delivery may be lost.

## Discussion

### Principal Findings

Through interviews with key stakeholder groups involved in stroke survivor rehabilitation, this study identified several facilitators and barriers to telerehabilitation. A general lack of confidence with technology, the perceived fear of using telerehabilitation, and the reduced face-to-face contact that a move toward more technological solutions in rehabilitation would bring were highlighted as the main issues stroke survivors faced. Initial in-person visits are one way to alleviate initial fear, as they can facilitate stroke survivor engagement and motivation in the rehabilitation process [24].

Telerehabilitation has been shown to have positive outcomes in motor consequences of stroke, health outcomes, carer support, and health professional satisfaction, albeit evidence quality was recognized to be poor [25]. The present study, therefore, thoroughly addresses the issues that stroke survivors with visual impairment face when using telerehabilitation.

On the basis of the work presented here, we recommend that several core issues be considered in the development and delivery of telerehabilitation. Compensatory training for poststroke visual field rehabilitation is repetitive in nature, which is why it works. It is important to ensure that such tools provide repetition in the most accessible way to ensure that repetition does not result in disengagement. Feedback and goal setting are important considerations when creating telerehabilitation, as they can improve engagement and motivation, but it is also important to provide a tangible progress update. In DREX, goals are set by the individuals based on feedback received when training. Previous studies have highlighted the motivational

benefit of individual goal commitment and goal setting on successful performance in other tasks [26]. As such, introducing goal-setting elements and feedback mechanisms into future telerehabilitation for stroke survivors would be beneficial, especially tailored programs that allow final goals (eg, overall aim) and interim goals (eg, daily target) to be determined.

In order to make telerehabilitation as accessible as possible for the majority of individuals, it would be valuable to consider intermediary steps and additional resources that can aid in intervention delivery. Using a multimodal approach (eg, paper, text, audio, visual elements, etc) enables these resources to be understood and used by all stakeholder populations. Engaging with key users prior to and during the development of telerehabilitation packages can ensure the creation of tools that are of maximum effectiveness and accessibility. For example, if during the acute phase of rehabilitation, perceptions of technology are identified as a barrier, then intermediary steps can be put in place to alleviate concerns and assist in the eventual uptake of the telerehabilitation tool. Additionally, training and education of users and key stakeholders involved in the application of telerehabilitation is an important

consideration previously found to lead to more effective treatment [27].

## Conclusions

In summary, this study identified several facilitators and barriers to telerehabilitation from the perspectives of the key stakeholders involved in stroke survivor rehabilitation, and it gathered opinions regarding key features required in telerehabilitation. This process has not only given a voice to the key populations directly involved in the rehabilitation process but also developed an understanding of the most important factors in developing a successful and engaging telerehabilitation tool to improve accessibility and usability. More generally, the issues highlighted by all of the populations engaged with show the need to address the disparity between acute care and the mountainous step to what comes next. An intermediary support phase may negate many of the identified barriers in stroke populations and deflect the fear that telerehabilitation reduces quality of care. Using the mitigations outlined will result in a more personalized recovery program for all stroke survivors.

## Abstract

**Background:** Electronic patient questionnaires are becoming ubiquitous in health care. To address care gaps that contribute to poor asthma management, we developed the Electronic Asthma Management System, which includes a previsit electronic patient questionnaire linked to a computerized clinical decision support system.

**Objective:** This study aims to identify the determinants (barriers and enablers) of patient uptake and completion of a previsit mobile health questionnaire.

**Methods:** We conducted semistructured interviews with adult patients with asthma in Toronto, Canada. After demonstrating the questionnaire, participants completed the questionnaire using their smartphones and were then interviewed regarding perceived barriers and enablers to using and completing the questionnaire. Interview questions were based on the Theoretical Domains Framework to identify the determinants of health-related behavior. We generated themes that addressed the enablers and barriers to the uptake and completion of the questionnaire.

**Results:** In total, 12 participants were interviewed for saturation. Key enablers were as follows: the questionnaire was easy to complete without additional knowledge or skills and was perceived as a priority and responsibility for patients, use could lead to more efficient and personalized care, completion on one's own time would be convenient, and uptake and completion could be optimized through patient reminders. Concerns about data security, the usefulness of questionnaire data, the stress of completing it accurately and on time, competing priorities, and preferences to complete the questionnaire on other devices were the main barriers.

**Conclusions:** The barriers and enablers identified by patients should be addressed by developing implementation strategies to enhance e-questionnaire use and completion by patients. As the use of e-questionnaires grows, our findings will contribute to implementation efforts across settings and diseases.

## Introduction

### Background

Asthma affects approximately 7.7% of adults in the United States and carries an annual economic burden exceeding US \$50 billion [1,2]. As in many other common chronic diseases, large gaps between guideline-recommended care and real-world care continue to exist in asthma [3,4].

Patient-facing electronic health questionnaires represent a promising strategy to address clinical care gaps, as they engage patients in taking a more active role in their care, increase efficiency by reducing data acquisition burdens on clinicians, and collect data that can be directly processed through computerized decision support system (CDSS) algorithms and then integrated into point-of-care electronic health records (EHRs) for clinicians [5]. With the dramatic rise in smartphone ownership in the United States [6] and a shrinking *digital divide* [7], mobile health (mHealth) previsit questionnaires have emerged as a commonly used strategy across primary and specialty care settings [8-11]. However, little is known about patient perceptions of these questionnaires and their actual uptake and what strategies can be leveraged to drive their use. It is of great importance to understand the user's perceived barriers and enablers to use mHealth technology to maximize its success [12].

Our team developed the Electronic Asthma Management System (eAMS), a point-of-care CDSS, to bridge key care gaps in the management of asthma in primary care settings [5]. The eAMS consists of a previsit electronic patient questionnaire that collects asthma-related parameters and a CDSS that receives and processes questionnaire data to produce guideline-based decision support (asthma control level, corresponding medication change recommendations, and a self-management tool called an asthma action plan (AAP) [4] integrated into the EHR in real time). In a 2-year interrupted time series study involving 890 patients and 237 clinicians, the eAMS significantly improved the frequency of asthma control assessment, the ratio of controller to reliever medication prescriptions, and delivery of AAPs to patients [5]. However, the previsit questionnaires were used by only 61.2% (551/890) of patients [5]. A detailed uptake analysis identified several quantitative predictors of questionnaire uptake [13].

### Objectives

In this study, we sought to identify the determinants (barriers and enablers) of uptake and completion of the eAMS mHealth previsit patient questionnaire, with a view to tailoring targeted strategies to overcome barriers and leverage enablers to drive patient usage. Given the growing popularity of mobile patient questionnaires, we identified themes that would be broadly relevant across such systems.

## Methods

### Recruitment

This was a qualitative study. Patients were recruited from the St. Michael's Hospital's Respiratory Patient Database via

telephone or email, and each provided informed written consent. We included adults (aged  $\geq 18$  years) with a clinical diagnosis of asthma, who were able to speak and write English, and who owned a smartphone. Each participant received a Can \$50 (US \$38) gift card for participating in the study. Ethics approval for the study was obtained from the Research Ethics Boards at Ryerson University and St. Michael's Hospital.

### Sample Size

For theory-based interview studies, Francis et al [14] recommended a minimum of 10 interviews, followed by an initial analysis, and up to an additional 3 interviews or fewer if data saturation (ie, no new themes generated) is achieved before that. Accordingly, we sought to interview at least 10 participants and up to 3 more pending interim analyses for data saturation.

### Interview Procedure

All interviews were conducted by 3 members of the research team trained in conducting qualitative interviews. Interviews were audio recorded and transcribed verbatim. After consent was obtained, participants were asked to complete a data collection form for background information (demographics, asthma-related information, and smartphone usage). Given that group sessions featured direct use of the eAMS questionnaire, each participant was asked to bring his or her own smartphone and was emailed a link to the questionnaire at the start of the session. We then explained and demonstrated the functions, role, and workflow of the questionnaire (including information transmission to the clinician's CDSS) and asked participants to independently complete the questionnaire on their device.

The questionnaire takes 5 to 10 min to complete and poses a series of questions that determine guideline-based asthma control levels, identify the individual's asthma symptoms and triggers (eg, sports, activities, location), and elicit current medication use. We created a web-responsive version of the tablet-based waiting room questionnaire that was used in the original eAMS study [5]. The original questionnaire's design and testing process are described in detail elsewhere [15,16]. Briefly, the questionnaire was designed based on the best principles for touch questionnaire usability [16], and both its content and usability were optimized through patient feedback in a rapid cycle design process (with summative qualitative analysis) involving 20 patients with asthma sampled purposively to represent a broad range of ages and electronic technology and touch device experience. The questionnaire achieved an *excellent* System Usability Scale score of 84.2 (SD 14.7). The System Usability Scale is a 10-item Likert scale questionnaire that has been used widely to measure the perceived effectiveness of, satisfaction with, and system efficacy of technological apps [15-17].

Immediately after completing the questionnaire, participants were asked specific questions related to the barriers and enablers to complete the questionnaire in a real-world setting. The described real-world workflow included downloading an app to their smartphone or tablet and accessing the questionnaire through this app for up to 1 week before their doctor's appointment (up to and including in the waiting room immediately before the appointment). The interview guide was

based on the Theoretical Domains Framework (TDF), an integrative framework comprised of 14 theoretical domains derived from 33 validated health and social psychology theories and 128 constructs that may drive and explain health-related behavior change from a psychological perspective [18,19]. The TDF is a comprehensive approach to understanding the determinants of behaviors in health care professionals and patients; it has been applied successfully for this purpose across diverse diseases and health care settings; and it has emerged as a standard for barrier and enabler measurement in implementation research [20]. The 14 theoretical domains include (1) knowledge; (2) skills; (3) social/professional role

and identity; (4) beliefs about capabilities; (5) optimism; (6) beliefs about consequences; (7) reinforcement; (8) intentions; (9) goals; (10) memory, attention and decision processes; (11) environmental context and resources; (12) social influences; (13) emotions; and (14) behavioral regulation [20]. The interview guide was designed to explore which domains in the TDF were relevant for the targeted behavior (ie, completion of the eAMS questionnaire before the clinical visit) and how each of those domains influenced this behavior [20]. [Table 1](#) describes the 14 TDF domains [19] and associated interview questions.

**Table 1.** Theoretical Domains Framework: theoretical domains and associated questions.

Theoretical Domains Framework domain	Definitions	Example interview questions
Knowledge	An awareness of the existence of something	<ul style="list-style-type: none"> <li>Having seen the questionnaire, do you need more information? What would need to be in place for you to do this questionnaire before seeing your doctor?</li> </ul>
Skills	An ability or proficiency acquired through practice	<ul style="list-style-type: none"> <li>What types of training, if any, would have been required to help you to complete the questionnaire?</li> </ul>
Social/professional role and identity	A coherent set of behaviors and displayed personal qualities of an individual in a social or work setting	<ul style="list-style-type: none"> <li>Do you feel it is part of your responsibility to complete this questionnaire? Do you think this is something you should do?</li> </ul>
Beliefs about capabilities	Acceptance of the truth, reality, or validity about an ability, a talent, or a facility that a person can put to constructive use	<ul style="list-style-type: none"> <li>How easy or difficult was it to complete the asthma questionnaire? What parts of the questionnaire were easy or difficult to complete? How confident were you in your ability to complete the questionnaire?</li> </ul>
Optimism	The confidence that things will happen for the best or that desired goals will be obtained	<ul style="list-style-type: none"> <li>How likely do you think it is that completing the asthma questionnaire would lead to better management of your asthma by your doctor?</li> </ul>
Beliefs about consequences	Acceptance of the truth, reality, or validity about outcomes of a behavior in a given situation	<ul style="list-style-type: none"> <li>What do you think are the benefits of completing the asthma questionnaire? What are the good things that can happen as a result of completing the asthma questionnaire?</li> </ul>
Reinforcement	Increasing the probability of a response by arranging a dependent relationship, or contingency, between the response and a given stimulus	<ul style="list-style-type: none"> <li>Are there any good experiences that you have had with your asthma management that would increase your likelihood of completing the asthma questionnaire?</li> </ul>
Intentions	A conscious decision to perform a behavior or a resolve to act in a certain way	<ul style="list-style-type: none"> <li>Is completing the questionnaire something you plan to do if you are asked to complete the questionnaire in the future?</li> </ul>
Goals	Mental representations of outcomes or end states that an individual wants to achieve	<ul style="list-style-type: none"> <li>How much of a priority would it be to complete the asthma questionnaire before you see your doctor, compared to other priorities?</li> </ul>
Memory, attention and decision processes	The ability to retain information, focus selectively on aspects of the environment, and choose between 2 or more alternatives	<ul style="list-style-type: none"> <li>Is completing a questionnaire before seeing a doctor something you usually do? Would you remember to complete the questionnaire?</li> <li>When could you see yourself forgetting to complete the questionnaire? Why? What could help to prevent this?</li> <li>Would a text or email message 1 week before your appointment be a sufficient reminder?</li> </ul>
Environmental context and resources	Any circumstance of a person's situation or environment that discourages or encourages the development of skills and abilities, independence, social competence, and adaptive behavior	<ul style="list-style-type: none"> <li>Is there anything that might influence whether or not you would complete the questionnaire? (eg, Wi-Fi availability, equipment to complete, links broken, time, competing tasks, etc)</li> </ul>
Social influences	Those interpersonal processes that can cause individuals to change their thoughts, feelings, or behaviors	<ul style="list-style-type: none"> <li>Who would influence you to complete the questionnaire? (eg, family member, doctor, etc)</li> </ul>
Emotions	A complex reaction pattern, involving experiential, behavioral, and physiological elements, by which the individual attempts to deal with a personally significant matter or event	<ul style="list-style-type: none"> <li>Tell me how you feel about completing the asthma questionnaire before you see your doctor. Are you worried, or do you have any concerns about completing the questionnaire?</li> </ul>
Behavioral regulation	Anything aimed at managing or changing objectively observed or measured actions	<ul style="list-style-type: none"> <li>Can you think of a plan for how you would ensure that you complete the asthma questionnaire before your appointment?</li> </ul>

## Data Analysis

Participant characteristics were summarized in detail. In total, 2 trained qualitative analysts (JY and SS) independently coded transcripts into the 14 TDF domains (using directed content analysis) [21]. They first coded 2 transcripts independently and together defined a consensus coding scheme (ie, codes, definitions of codes, examples of quotes under each code). This coding scheme was used to independently code the remaining transcripts (using NVivo 12 software, QSR International). The coders met on a regular basis to discuss discrepant codes, which were resolved through consensus. For each coded quote, the analysts generated a statement that reflected the core belief expressed by that response (a *belief statement*) [20]. These statements were grouped into themes that suggested significant influence on the uptake of the questionnaire. In instances where a single domain allocation agreement could not be reached, the statement was placed in both pertinent domains [20]. Emerging themes and belief statements were verified by each analyst and adjusted for consensus. To ensure the trustworthiness of the data, the analysts used memos during the coding process and developed an audit trail to track progress and enable easy reference to the primary data at a later time, if necessary. TDF domains that were considered of high importance were those with (1) belief statements in the domain that had relatively high

frequencies (ie, more than one-third of respondents identified the belief), (2) conflicting beliefs in the domain (ie, where participants identified opposing beliefs), and (3) evidence of strong beliefs in a domain that is believed to directly impact uptake (as determined by the consensus of research team members) [20,22]. Verbatim quotes along with their categories and themes were used to support the belief statements.

## Results

### Overview

Data were collected from June 2018 to April 2019. Of the 21 patients who were approached to participate, 12 were recruited and consented to be interviewed. We performed an interim analysis after the first 10 interviews and coded each transcript thereafter until saturation. Saturation was achieved after another 2 interviews, for a total of 12 interviews.

### Participant Characteristics

Participant characteristics are summarized in Table 2. All participants were aged  $\geq 31$  years, 58% (7/12) of the participants were female, and a majority had a college education or higher. All participants used their smartphones frequently during the day for a variety of purposes. Each face-to-face interview lasted approximately 45 min.

**Table 2.** Participant characteristics (n=12).

Variable	Values
<b>Age (years), n (%)</b>	
25-30	0 (0)
31-40	3 (25)
41-50	3 (25)
51-60	2 (17)
≥60	4 (33)

<sup>a</sup>OS: operating system.

<sup>b</sup>Android OS: included phones manufactured by Samsung, Huawei, LG, and OnePlus.

## Relevant Theoretical Domains

Participants spent an average of 9.6 (SD 5.2) min to complete and review the questionnaire before the interview. All 14 TDF domains were identified as relevant. Most of the belief statements focused on enablers to use the questionnaire. A summary of the 14 TDF domains, related belief statements, and participant quotes is provided in [Multimedia Appendix 1](#).

## Enablers

Overall, the majority of participants indicated that the eAMS questionnaire was easy and straightforward to complete, with no training required (knowledge, beliefs about capabilities, and skills). Most participants stated that they would complete the questionnaire on their phone if they were given that option (intention). Completion of the questionnaire was viewed by participants as important and a priority (goals). Having the

option to complete the questionnaire on their own time was considered a benefit to participants (environmental context and resources):

*I think it's more relaxed which makes the patient feel easier and there's no rush. Like okay, you're doing the questionnaire and somebody comes to the door or you can just go answer the door, and then go back to the questionnaire, or be doing the questionnaire at 3 o'clock in the morning if you want... [P1003]*

Several participants reported that their prior experiences with poor disease control motivated them to use the tool (reinforcement), and the majority of participants reported that it was their responsibility to complete the questionnaire to enhance their level of care (social/professional role and identity):

*I feel it is [my responsibility] because the way I look at it, the more information my doctor has about what's going on with me, the better he or she is able to help me manage my symptoms and cope. [P1004]*

Most participants described benefits to completing a patient questionnaire before their medical appointment, including that their primary care physician would have a more thorough understanding of their condition and that this would translate into better health care and disease control (eg, this would inform their self-management plans; beliefs about consequences). Participants also indicated that completing the questionnaire would enhance their understanding of their own disease control (beliefs about consequences):

*I think from the patient's perspective, it would give them more insight as to what's happening because they actually have to think about what their symptoms are and what they're doing to help the asthma, so therefore, they can bring that information to the doctor. [P1008]*

More than half of the participants felt that receiving a reminder from the doctor's office via email, text, or phone before their appointment would ensure that the questionnaire would be completed (behavioral regulation, memory, attention and decision processes; environmental context and resources).

## Barriers

Several participants mentioned that competing priorities might influence whether they would complete the questionnaire in advance of their medical appointment (environmental context and resources):

*I have my two personal emails. I have 4 different work emails that I have to go through every day. Like it's swamped with these things. [P1003]*

Some would have preferred to complete the questionnaire on a larger device (eg, computer, iPad; environmental context and resources) or on paper. Barriers to using the questionnaire also included conflicting beliefs. A small number of participants felt that completing the questionnaire would not help them to understand their asthma nor lead to better asthma control (beliefs about consequences). Several participants expressed concerns about web-based security of questionnaire data and whether they could complete the questionnaire correctly (emotions).

## Discussion

### Principal Findings

To our knowledge, this is the first study to formally assess barriers and enablers to patient use of an mHealth questionnaire and the first to apply the validated TDF for this purpose. In identifying the determinants of uptake of the eAMS patient questionnaire, we identified constructs that are likely applicable to mHealth questionnaires across diseases.

First, we noted that factors relating to the content, format, and usability of the questionnaire itself were mostly perceived favorably and characterized as enablers to its use, as opposed to barriers. Specifically, most users did not believe that they needed extra training in the form of external knowledge or skills to complete the questionnaire (knowledge and skills) and clearly indicated that they were capable of completing it as required (beliefs about capabilities). This is likely a direct consequence of the user-centered approach taken in questionnaire development, whereby both content and format were serially improved in response to user feedback in focus group settings [15,16]. Indeed, Sun et al [23] previously reported that perceived ease of use is positively associated with behavioral intention to use mHealth systems. Accordingly, our findings reinforce the value of the integrated knowledge translation approach [24] in general and of rapid cycle design in particular, whereby end user engagement at an early stage of development is critical to ensure that the intrinsic features of a tool are conducive to later uptake [25]. Yet, it should be noted that 2 participants indicated that some users might require telephone or in-person support during questionnaire use (environmental context and resources), and it is likely that universal and sustainable adoption of any such mobile questionnaire will require investment in some form of technical support for a small number of users [26], even if they own a smartphone. As noted, the questionnaire completion rate was only approximately 60% in our previous study, which required patients to complete the questionnaire on a waiting room-based tablet [5]. In this study, the use case involved completion on their own device, up to 1 week in advance of the appointment, and patients indicated that both the ability to complete it on their own time schedule and in their own physical space were facilitators (environmental context and resources). This preference for e-questionnaire completion at home as opposed to within a health care facility was also noted in a previous study [27]. This suggests that questionnaire modalities that are limited to the waiting room environment, such as tablets or kiosks, may be less favorable. However, the advance completion approach would not be able to leverage typical prompts and reminders used in the waiting room environment (both human [eg, receptionist] and visual [eg, waiting room posters]). Correspondingly, some patients believed that they might fail to complete the questionnaire because of barriers presented by a lack of time or competing day-to-day priorities (environmental context and resources), and others indicated that they might simply forget (memory, attention and decision processes). Although some patients noted that they could set a calendar or personal email or device reminder (behavioral regulation), the vast majority indicated that a *friendly* (external) reminder would be a key facilitator (memory, attention and

decision processes), with preferred modalities being email or SMS text message (environmental context and resources). In summary, the balance of our findings suggests that completion at home on a personal device is preferable but that electronic reminders should also be incorporated into any e-questionnaire implementation plan. Given that health practitioners were the most commonly reported influencers who could drive usage (social influences), invitations and reminders should ideally be addressed from the patient's own health care provider.

As for the mode of delivery of the questionnaire, most users preferred the electronic system to a conventional paper-based questionnaire, although it is of note that 2 participants would have preferred paper (environmental context and resources). Several previous studies have similarly reported that most patients, across conditions, prefer an e-questionnaire to a paper-based one. [28-30]. Barentz et al [29] found that a preference for e-questionnaires was greatest in younger and more educated patients. Although our study included participants across a wide age spectrum, most were highly educated (10/12, 83% had a college education or higher), which may have contributed to this finding. It is also of note that some participants would prefer using a larger device, such as a personal computer or laptop (environmental context and resources). This supports previous observations that mobile apps should not exist in isolation [26]; any such mHealth questionnaire should be complemented by both a conventional website and tailored or web-responsive content accessible across platforms [26].

The vast majority of participants in our study felt that it was part of their responsibility to complete the questionnaire before their appointment (social/professional role and identity). Indeed, given a gradual movement away from the conventional unidirectional model of care (provider to patient) toward a bidirectional model with direct patient engagement and shared decision making over the last decade [31], it is not surprising that many patients perceived completion of a previsit questionnaire as a natural part of the health care interaction. Not only do studies suggest that a majority of patients would prefer to have an active role in their health care [32] but that such participation is associated with improved health outcomes [33]. This perceived responsibility was complemented by the perceived benefits of completing the questionnaire (beliefs about consequences). Some participants believed that completing the questionnaire before their medical appointment would benefit their physician by facilitating history taking and saving time. This finding is similar to that of Howell et al [27], who reported that a desire to reduce consultation time and enhance clinic efficiency motivated patients to complete a preoperative tablet-based questionnaire. Other direct benefits of questionnaire use mentioned by our participants included improving their own understanding of their disease and enabling both more personalized care (eg, a personalized AAP) and a higher quality of care. This perception of higher quality care was also the driving factor behind goal setting and prioritizing questionnaire completion (goals). Given that these factors appear to be strong enablers, patient-facing messaging at the time of an

e-questionnaire rollout could reinforce a sense of patient responsibility and these myriad benefits of completing such a questionnaire in an effort to drive usage.

Some participants also noted that their own previous experience with poor health outcomes acted as facilitators by enabling them to recognize the importance of completing the questionnaire (reinforcement). Correspondingly, previous work has shown that perceived health threats predict patient intentions to use smartphone-based health technology [34]. This facilitator may be particularly relevant in diseases that are characterized by episodic flares, such as asthma [35], chronic obstructive pulmonary disease [36], and congestive heart failure [37] and can also be leveraged in patient-facing messaging to drive usage.

Although the vast majority of participants indicated that they would ultimately complete such a questionnaire (intentions), certain barriers and strategies to address them are worth noting. Some participants were not convinced that their questionnaire responses would ultimately prove useful (optimism). This barrier to uptake has been echoed in previous eHealth literature, particularly among older adults concerned about *getting it wrong* [26]. Similarly, some participants expressed concerns about the stress of completing the questionnaire on time and accurately (emotions). These findings suggest that it would be important for any e-questionnaire to include an option to skip questions, and to include response options such as "I don't know" or "I'm not sure." Additional messaging could explain that missing answers and data entry errors are acceptable, that patients are simply being asked to "do their best," and that clinicians will verify and complete data where required. Another concern raised by one participant was the risk of a data security breach (emotions). Indeed, patient concerns about data security are a well-described barrier to the use of social media [38], mHealth apps [39], and eHealth questionnaires in particular [26,27]. These concerns can be addressed upfront through transparent terms of use, privacy, and data policies as well as through opt-out clauses for users. Ideally, a formal privacy impact assessment and threat risk assessment should be performed. Although the cost of formal analyses may be prohibitive for small organizations, some jurisdictions are facilitating this process for developers, such as the National Health Service (NHS) in the United Kingdom, through the NHS Health Apps Library [40].

## Practice Implications

Our findings consisted mostly of enablers to using the e-questionnaire and were identified across participants, and many were supported by the literature in parallel areas. On the basis of these findings, we were able to suggest simple solutions that might drive questionnaire usage. A summary of these identified barriers and enablers and corresponding optimization strategies to address and leverage them are provided in Table 3. These strategies are rooted in concepts related to behavior change techniques (BCTs); however, as a next step, we will employ a formal process (ie, a behavior change matrix) to identify BCTs that will be mapped onto these relevant TDF domains (ie, modifiable barriers and enablers) [41,42].

**Table 3.** Practice implications for uptake and completion of the Electronic Asthma Management System questionnaire based on identified enablers and barriers.

Identified barrier and enabler	Corresponding system optimization strategy
<ul style="list-style-type: none"> <li>Competing priorities may impede questionnaire completion before appointment (barrier: environmental context and resources)</li> </ul>	<ul style="list-style-type: none"> <li>Reinforce that questionnaire takes only 5 to 10 min to complete and can be done at any time before appointment</li> <li>Provide a reminder to administrative staff at the time of appointment to identify patients who have not completed the questionnaire and prompt them to complete it in waiting room</li> </ul>
<ul style="list-style-type: none"> <li>Preference to complete questionnaire on a larger device (barrier: environmental context and resources)</li> </ul>	<ul style="list-style-type: none"> <li>Develop a web-responsive version of the questionnaire, optimized for completion on large tablets, laptops, and desktop computers</li> </ul>
<ul style="list-style-type: none"> <li>Questionnaire completion will enhance one's understanding of one's own disease control (enabler: beliefs about consequences)</li> <li>Questionnaire completion would not help one to better understand their asthma (barrier: beliefs about consequences)</li> </ul>	<ul style="list-style-type: none"> <li>Position the questionnaire app as part of a general educational tool for asthma by developing dedicated web-based educational content that users can access simultaneously through the same app</li> </ul>
<ul style="list-style-type: none"> <li>Prior experiences of poor disease control motivated questionnaire completion (enabler: reinforcement)</li> <li>Questionnaire completion would not lead to better asthma control (barrier: beliefs about consequences)</li> </ul>	<ul style="list-style-type: none"> <li>Include patient-facing messages describing the personal impact of poor disease control, how doing the questionnaire will lead to an AAP<sup>a</sup>, and how an AAP has been shown to reduce symptoms of poor control</li> <li>Enhance the questionnaire app by providing access to the AAP itself through the app</li> </ul>
<ul style="list-style-type: none"> <li>It is part of one's responsibility to complete the questionnaire to enhance their care (enabler: social/professional role and identity)</li> <li>Questionnaire completion leads to the physician having a more thorough understanding of one's condition, translating into better health care and disease control (enabler: beliefs about consequences)</li> </ul>	<ul style="list-style-type: none"> <li>Ask each user's <i>own</i> health care provider (physician or nurse practitioner) to send a message to patients emphasizing the following: <ul style="list-style-type: none"> <li>This is a role that they would like the patient to play in their own care</li> <li>Completing this will enable them to better understand the patient's disease and to offer better care</li> </ul> </li> </ul>
<ul style="list-style-type: none"> <li>Concerns about web-based security of questionnaire data (barrier: emotions)</li> </ul>	<ul style="list-style-type: none"> <li>Conduct a formal privacy impact assessment and threat risk assessment and clearly communicate this robust security approach to users</li> </ul>
<ul style="list-style-type: none"> <li>Concerns about whether one can complete the questionnaire correctly (barrier: emotions)</li> </ul>	<ul style="list-style-type: none"> <li>Provide patients with options to skip questions and responses and ensure availability of telephone and email technical support</li> </ul>
<ul style="list-style-type: none"> <li>A reminder would ensure that the questionnaire would be completed (enabler: behavioral regulation, memory, attention and decision processes; environmental context and resources)</li> </ul>	<ul style="list-style-type: none"> <li>Include <i>friendly</i> reminders via automated phone call, email, or text message to complete the questionnaire (and allow personalization of reminder preferences at the time of patient registration)</li> </ul>

<sup>a</sup>AAP: asthma action plan.

## Limitations

Our study applied a validated, theory-based methodology to identify and classify barriers and enablers and sampled a diverse population (varied ages and smartphone operating system types). Smartphone ownership is approaching universality in industrialized nations, and we expect that most patients would complete such a questionnaire on a smartphone; however, our results are not pertinent to users without a smartphone who would have to access the system through a web-based, web-responsive questionnaire at home or on a tablet device made available for this purpose in the clinic setting. Recruitment of participants from a quaternary care center may also limit generalizability to other settings. Given that patients with asthma prefer a collaborative role in managing their illness, across a range of asthma severity levels [43], we do not believe that the

severity of the disease itself would influence the barriers and enablers that we identified, with the exception of previous poor health outcome experiences acting as a facilitator.

## Conclusions

In this study, we formally identified barriers and enablers in the uptake of a patient-facing mHealth questionnaire. We believe that our findings are broadly relevant to the rapidly growing use of e-questionnaires across health disciplines. Where possible, we suggested strategies that can be used to address barriers and leverage enablers. Future studies are recommended to employ a formal process (ie, a behavior change matrix) to identify behavior change strategies and techniques that are mapped onto the relevant TDF domains (ie, modifiable barriers and enablers) [41,42] and test their impact on actual questionnaire uptake.

## Acknowledgments

The authors would like to thank the participants for providing extensive feedback on the e-questionnaire. This study was funded by the Lung Association Provincial Grant-in-Aid/National Grant Review competition. AK is supported by the Thorpe Family Fellowship in Respiratory Medicine at St. Michael's Hospital. SG is supported by the Michael Locke Term Chair in Knowledge Translation and Rare Lung Disease Research. Funders had no role in the design of the study; in the collection, analysis, or interpretation of data; or in manuscript preparation.

## Conflicts of Interest

SG owns the intellectual property associated with eAMS and the eAMS questionnaire and would have an ownership interest in any commercial enterprise derived from this system. Other authors report no potential conflicts of interest.

## Abstract

**Background:** Reporting cumulative antimicrobial susceptibility testing data on a regular basis is crucial to inform antimicrobial resistance (AMR) action plans at local, national, and global levels. However, analyzing data and generating a report are time consuming and often require trained personnel.

**Objective:** This study aimed to develop and test an application that can support a local hospital to analyze routinely collected electronic data independently and generate AMR surveillance reports rapidly.

**Methods:** An offline application to generate standardized AMR surveillance reports from routinely available microbiology and hospital data files was written in the R programming language (R Project for Statistical Computing). The application can be run by double clicking on the application file without any further user input. The data analysis procedure and report content were developed based on the recommendations of the World Health Organization Global Antimicrobial Resistance Surveillance System (WHO GLASS). The application was tested on Microsoft Windows 10 and 7 using open access example data sets. We then independently tested the application in seven hospitals in Cambodia, Lao People's Democratic Republic, Myanmar, Nepal, Thailand, the United Kingdom, and Vietnam.

**Results:** We developed the AutoMated tool for Antimicrobial resistance Surveillance System (AMASS), which can support clinical microbiology laboratories to analyze their microbiology and hospital data files (in CSV or Excel format) onsite and promptly generate AMR surveillance reports (in PDF and CSV formats). The data files could be those exported from WHONET or other laboratory information systems. The automatically generated reports contain only summary data without patient identifiers. The AMASS application is downloadable from <https://www.amass.website/>. The participating hospitals tested the application and deposited their AMR surveillance reports in an open access data repository.

**Conclusions:** The AMASS is a useful tool to support the generation and sharing of AMR surveillance reports.

## KEYWORDS

antimicrobial resistance; surveillance; report; data analysis; application

## Introduction

Generating and sharing antimicrobial resistance (AMR) surveillance reports are fundamental elements of actions against AMR infections at local, national, and international levels. Information on patterns of antimicrobial susceptibility is important to guide empiric choice of therapy, monitor resistance trends, and detect outbreaks of AMR infections at the local level [1-3]. Combining data and reports at the national level provides evidence to inform the implementation of national action plans, decide on resource allocation for interventions, and monitor the impact of those interventions [3-5]. The Review on AMR chaired by Jim O'Neill estimated that 700,000 global deaths are attributable to AMR infections each year (including bacterial infections and tuberculosis) [1,6], and they have an enormous global impact [7,8]. While this represents a very rough estimate subject to well-documented limitations [1,9,10], the report importantly highlighted the need for improved AMR surveillance.

Methods to analyze data and generate AMR surveillance reports are gradually being standardized worldwide [3,11-15]. Recently, the World Health Organization (WHO) launched the Global Antimicrobial Resistance Surveillance System (GLASS) with a defined protocol for AMR surveillance data collection for certain high-priority pathogens and resistance phenotypes [2,11,16]. In general, it is recommended that (1) repeat isolates of a given bacterial species from individual patients should be removed from the calculations and (2) data should be stratified by origin of infection (community or hospital) whenever possible [11,15]. A simple deduplication process is to include only the first isolate of a species per patient per specimen type per survey period in the report [3,11]. The origin of infection

is defined by using specimen collection date, location type (inpatient or outpatient setting), and hospital admission date for inpatient isolates as a proxy to define where the infection was likely contracted (community or hospital) [3,11].

Even in areas where AMR surveillance data are available, there are many barriers to utilizing such data [17]. Many hospitals in low and middle-income countries (LMICs) lack the time and resources needed to analyze the data (particularly to deduplicate and validate the accuracy of the summary data), write reports, and release the data or reports [17]. There are open-access laboratory information systems (LISs) [18] and microbiology laboratory database software, including WHONET [19], that are useful for recording and analyzing the data, and generating figures to support the generation of AMR surveillance reports for hospitals in LMICs. Most of these systems have limited ability to generate summary reports for immediate use and be operated by nontechnical staff. In addition, to generate AMR surveillance reports stratified by the origin of infection, additional data on hospital admission are frequently needed [20-23]. This is because hospital admission dates are not generally collected in microbiology laboratory data files. In many hospital settings, microbiology and hospital admission data are held in separate computers or systems with restricted access. Even in high-income countries, many hospitals lack well-trained clinical microbiologists, epidemiologists, or data experts with adequate skills in statistical software (such as R, SAS, SPSS, and STATA) to merge and deduplicate data in the separated databases and generate reports stratified by the origin of infection.

Here, we developed an application termed the AutoMated tool for Antimicrobial resistance Surveillance System (AMASS), which can support a local hospital to independently analyze

routinely collected electronic data and rapidly generate AMR surveillance reports. We tested the AMASS in seven hospitals in Cambodia, Lao People's Democratic Republic, Myanmar, Nepal, Thailand, the United Kingdom, and Vietnam, and deposited the report from each hospital in an open-access platform.

## Methods

### Design of the Application

The tool operates by reading and processing the raw data files to automatically produce AMR surveillance reports. The application was designed to be open access, user friendly, and highly compatible with readily available data sets at local hospitals, and have high data security. To ensure the tool is fully open access and can run in a standalone inexpensive computer even without internet access, we built the application in R (version 3.6.2; R Project for Statistical Computing), which is a

free software environment. We then gave the application a user-friendly interface, which only requires double clicking on the application file to run the automation without the need to understand the R program. We decided to include both R portable (version 3.4.3; R Project for Statistical Computing) and RStudio (version 1.1.423; RStudio, Inc) within the downloadable package so that the application can run without the need to install R or any program prior to running the application. We designed the application so that it reads raw data files in either CSV or Excel format as many hospitals in LMICs can export their data in one of these formats [17]. Hospitals that store microbiology data and hospital data in software, such as WHONET [19], can export data in CSV or Excel format. During the development process, we revised the R codes repeatedly to ensure that the application would produce easy-to-use and easy-to-share outputs. Table 1 documents the features that we focused on when designing the application [24,25].

**Table 1.** Features of the AutoMated tool for Antimicrobial resistance Surveillance System (AMASS).

Feature	Description
Open access	<p>The AutoMated tool for Antimicrobial resistance Surveillance System (AMASS) is open access and can be downloaded [24,25].</p> <p>The AMASS was developed using R, which is a free software. In the download package for the AMASS (AMASS.zip), there is a folder that contains R-portable and RStudio, which support data processing and analysis to generate the antimicrobial resistance (AMR) surveillance report automatically.</p> <p>The AMASS is under CC-BY 4.0 license. Users can share (copy and redistribute the material in any medium or format) and modify the R codes of the AMASS under the terms and conditions of the Creative Commons license.</p>
User friendly	<p>The AMASS can be run by double clicking on the application icon. Data analysis and AMR surveillance report generation are automated by the AMASS application.</p> <p>Data cleaning, deduplication, and analysis are performed rapidly (it takes about 1-3 minutes to automatically produce an AMR surveillance report using example data sets provided in the AMASS package).</p> <p>No additional program or software is needed. All the essential software is stored in the AMASS package and will operate automatically after double clicking the application file (AMASS.bat).</p> <p>Users do not need to understand R program or write any codes to run the AMASS application.</p>
Highly compatible	<p>The AMASS works with raw data files in either CSV or Excel format, which can be commonly exported from WHONET and other software, programs, or data management systems used for microbiology data and hospital admission data.</p> <p>The AMASS uses data dictionary files (in Excel format) to accommodate data exported from different software, programs, or systems that may have different ways to name data variables and data values.</p> <p>The AMASS dictionary files can be reused by users in the future (eg, monthly, quarterly, and yearly) if the structures of the new raw microbiology data file and hospital admission data file remain unchanged.</p> <p>The AMASS uses a tier-based approach based on availability of raw data files to generate reports. Users with limited data availability (eg, microbiology data with only culture positive results) can still utilize the deduplication and report generation functions of the AMASS. Users with additional data (eg, microbiology data with culture negative results and hospital admission date data) will receive additional reports (eg, sample-based surveillance reports with stratification by infection origin).</p>
High data security	<p>The AMASS does not require the internet for operation. Users do not have to transfer raw individual data (which may contain identifiable information) to any institution outside of the hospital to analyze the data and generate the reports. The AMASS can be run on a standalone computer within the local hospital under local data security. Hence, the AMASS does not increase any risks of breaching individual patient data confidentiality.</p>
Easy-to-use outputs	<p>The automatically generated AMR surveillance report is in PDF format, which is easy to print, read, and share within and outside the hospital.</p>
Easy-to-share outputs	<p>The report (in PDF format) and aggregated summary data files (in CSV format) contain no individual-level patient data and can be readily shared with national and international organizations.</p>

A schematic overview of input data, data processing, statistical analysis, and output is shown in [Multimedia Appendix 1](#). In brief, input data are microbiology data files (in CSV or Excel format) with or without hospital data files, which can be exported from WHONET or a LIS with data export capacity. The data processing and analysis algorithms, including data deduplication, were developed based on the WHO GLASS recommendations [2,11]. The reports were designed to have a format similar to that of the WHO GLASS 2018 report [14].

The application deduplicates the data by including only the first isolate per sample type per pathogen per survey period for each patient [11]. The application currently includes only blood specimens and the following eight pathogens: *Acinetobacter* spp., *Escherichia coli*, *Enterococcus* spp., *Klebsiella pneumoniae*, *Salmonella* spp., *Staphylococcus aureus*, *Streptococcus pneumoniae*, and *Pseudomonas aeruginosa*. Both *Enterococcus* spp. and *P. aeruginosa* were added on top of the six priority pathogens described by the WHO GLASS for bacteremia [2,26] because both pathogens are common causes of bacteremia [15,20], and were included in the 2015 global priority list of AMR bacteria [26]. The list of pathogen-antibiotic combinations was modified from the WHO GLASS ([Multimedia Appendix 2](#)). Infections are stratified into community-origin or hospital-origin infections using hospital admission dates and specimen collection dates, when available [2,11]. Patients with the first specimen culture positive for the pathogen taken in the outpatient setting or on the first or second day of hospitalization are classified as having community-origin infection [2,11]. Patients with the first specimen culture positive for the pathogen taken on hospital day three or later are classified as having hospital-origin infection [2,11]. Alternatively, in cases where users have data on the origin of infection assigned by the attending physician or infection control team of the hospital, the AMASS can instead use those categorizations to stratify the infection into community-origin or hospital-origin infection. Prevalence and incidence rates are estimated based on the recommendations of the WHO GLASS ([Multimedia Appendix 3](#)) [2,11]. An additional report on mortality involving AMR and non-AMR infections is generated when mortality data are available in the hospital admission data file. The term “mortality involving AMR and antimicrobial-susceptible infections” is used because the mortality reported in the hospital admission data represents mortality from any cause, not necessarily attributable to AMR [1]. This measure of mortality includes deaths caused or contributed by other underlying and intermediate causes. Therefore, the term “involving AMR infections” is used, in accordance with the term used by the UK Office for National Statistics [27,28]. The AMASS used the Wilson method to estimate the confidence intervals for proportions.

### Example Data Sets

Two example data sets are provided in the downloadable package of the AMASS application. The first example data set is the open-access demonstration file from WHONET [19]. The second example data set is a synthetic data set generated for the AMASS. The second example data set was created to represent a large data set from a 1000-bed hospital, containing both microbiology and hospital admission data. A detailed description

on how the second example data set was generated is provided in [Multimedia Appendix 4](#). In brief, two synthetic data files (microbiology\_data.xls and hospital\_admission\_data.xls files) were generated based on the summary data in the AMR surveillance report from 2015 of Sunpasitthiprasong Hospital, Ubon Ratchathani, Thailand. Variables in the microbiology data file include hospital number, specimen type, specimen collection date, culture result, and antibiotic susceptibility testing result, and each row contains information for each specimen. Variables in the hospital admission data file include hospital number, age, sex, admission date, discharge date, and in-hospital discharge outcome. All data were randomly generated using STATA 15.1 (StataCorp).

### Testing the AMASS Using Hospital Data

The following seven hospitals participated in the study: Angkor Hospital for Children in Cambodia, Mahosot Hospital in Lao People's Democratic Republic, North Okkalapa General and Teaching Hospital in Myanmar, Patan Hospital in Nepal, Sunpasitthiprasong Hospital in Thailand, St Thomas' Hospital in the United Kingdom, and Hospital for Tropical Diseases in Vietnam. The hospitals were selected because microbiology data are collected routinely, and they have prior experience in data quality controls. Moreover, the hospitals varied in the LIS used for data storage and are good examples to demonstrate the practicality and usability of the AMASS in different settings, to a wider audience. The study was approved by the Oxford Tropical Research Ethics Committee, University of Oxford, and local Ethics Committees. CL corresponded with the participating hospitals and demonstrated how the application operates using the example data files. The local hospital staff operated the application using their local data by themselves. All microbiology and hospital data were stored independently within their hospital computers under their local data protection standards. Automatically generated reports and anonymous summary data from each hospital are publicly available and deposited in data repositories with permission from each hospital.

## Results

### Overview of the AMASS

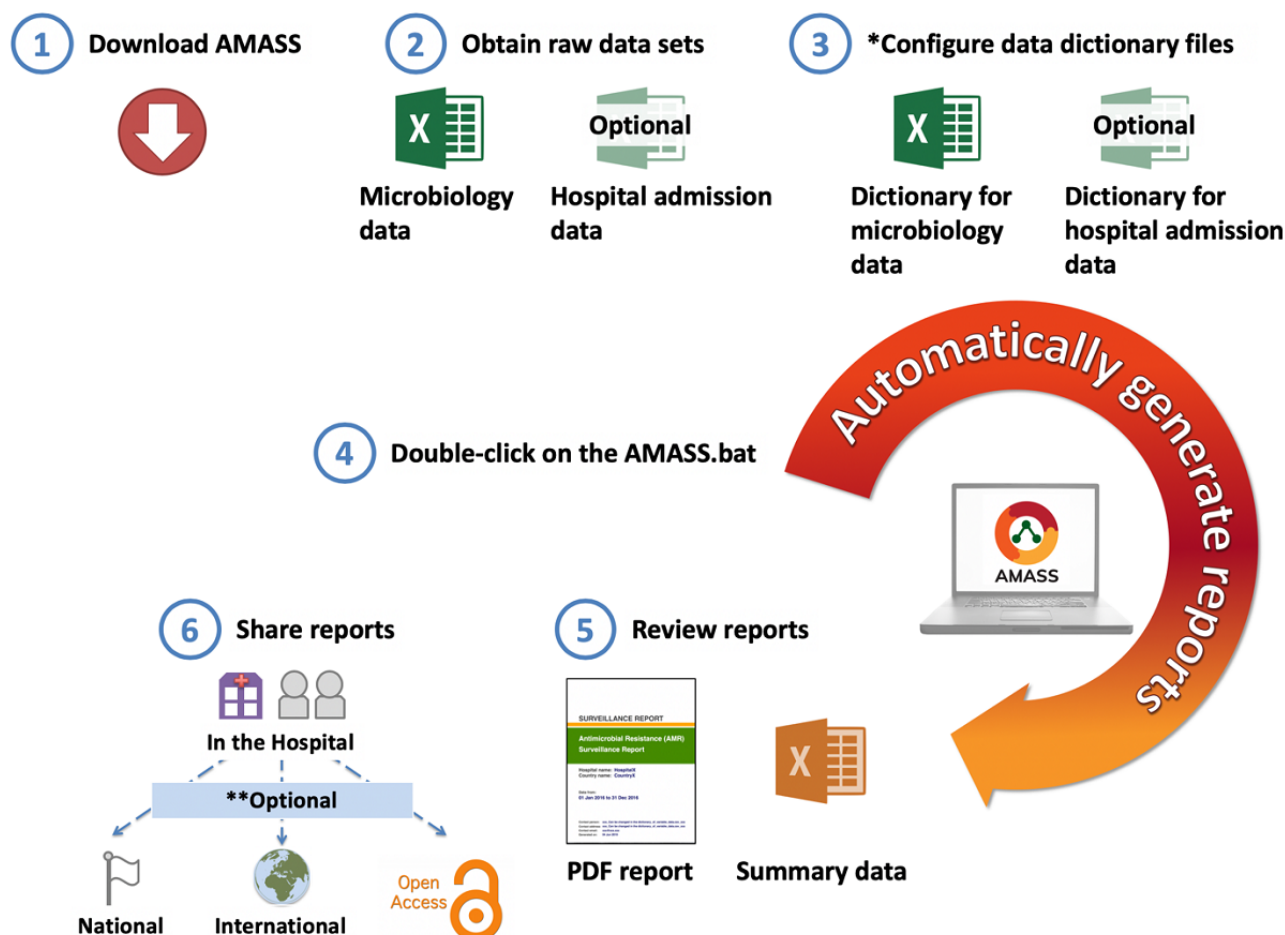

The AMASS application has been developed to support clinical microbiology laboratories to automatically analyze hospital local data files (in CSV or Excel format) and generate AMR surveillance reports (in PDF and CSV formats) promptly. Six steps are followed to generate the AMR surveillance reports ([Figure 1](#) and [Multimedia Appendix 5](#)). First, download the AMASS package from the website [24]. Second, obtain the routinely collected raw microbiology data file and, if available, hospital admission data file, and then, save the data files in the folder of the AMASS application. Third, configure data dictionaries. Two data dictionaries are provided to accommodate different ways of naming variables (eg, sex and gender) and data values (eg, M and F, or male and female). The functioning of the data dictionaries is described in more detail in the “Illustration on How to Use the AMASS” section. Fourth, double click on the AMASS.bat file to run the application. Fifth, review and validate the AMR surveillance reports (generated

in PDF format) and the anonymous summary data (generated in CSV format). Sixth, share the reports within the hospital, especially with the local infection control team. The reports and anonymous summary data contain no patient identifiers.

Therefore, users may share the reports and anonymous summary data with national and international organizations or make the reports and anonymous summary data open access. The key features of the AMASS are listed in [Table 1](#).

**Figure 1.** Conceptual flow of the AutoMated tool for Antimicrobial resistance Surveillance System (AMASS). Step 1 (download the AMASS) and step 3 (configure data dictionary files) are one-time steps. Step 2 (obtain data), step 4 (run the AMASS), step 5 (review report), and step 6 (share report) are ongoing steps that users could repeat regularly (ie, monthly or quarterly). \*Two data dictionary files (in Excel format) are provided to allow the application to understand how variables and values of each variable are named in the raw data files in different settings. Those data dictionary files can be reused in the subsequent runs of the AMASS, as long as how variables and values of each variable are named in the raw data files remain the same. Details on how to configure the data dictionary can be found in [Figure 2](#) and [Multimedia Appendix 6](#). \*\*The antimicrobial resistance (AMR) surveillance report and summary data generated contain no patient identifiable information. The decision to share the report and summary data to national or international AMR organizations is solely up to the jurisdiction of the hospital.

## Illustration on How to Use the AMASS

### Input Requirements

To align with formats of commonly exported microbiology data and hospital admission data, the AMASS reads data files in both CSV and Excel formats. The microbiology data need to be in a wide format, meaning that each row should contain data from a single clinical isolate. The key variables required for the microbiology data file include patient identifier, specimen collection date, specimen type, culture result, and antimicrobial susceptibility test interpretation per antibiotic. The hospital admission data file is optional but, if available, also needs to be in a wide format. The key variables needed for the hospital admission data file include patient identifier, admission date, gender, age, and, if possible, in-hospital discharge outcome. The current version of the AMASS uses the Gregorian calendar

and requires the date to be in the order of day, month, and year in any format (ie, either text [English] or numeric).

There are two data dictionary files provided for the users to accommodate different ways of naming data variables and data values ([Figure 2](#)). The first data dictionary file (`dictionary_for_microbiology_data.xls`) is for the microbiology data file. For example, the AMASS uses the variable name “hospital\_number” as a patient identifier (Row 3, Column A of the data dictionary file). In cases where the raw microbiology data file uses a different name for the patient identifier (eg, hn), users would need to fill “hn” in the data dictionary file (Row 3, Column B of the data dictionary file). This allows the AMASS application to know that the variable “hn” of the raw microbiology data file is the patient identifier (ie, “hospital\_number”). The second data dictionary file (`dictionary_for_hospital_admission_data.xls`) is for the hospital admission data file, which is to be used likewise. [Multimedia](#)

Appendix 6 presents a step-by-step tutorial on how to use and configure the data dictionaries.

**Figure 2.** An example of how to complete a data dictionary file. For a first-time user, the user may need to complete a data dictionary file by filling in variable names used in the raw data files into the data dictionary files (eg, arrow A). This is to allow the AutoMated tool for Antimicrobial resistance Surveillance System (AMASS) to understand that the variable “hospital\_number” used by the AMASS is named as “hn” in the user’s raw microbiology data file. Thereafter, users need to enter how data values are named in their raw data files (e.g. arrow B). This is to allow the AMASS to understand that the data value named “blood\_specimen” is named as “blood” in user’s raw microbiology data file. Please note that the contents in the first column of the data dictionary file must remain unchanged. Users can add new rows but the content in the cell in the first column must not be changed. For example, users can define that both “*E. coli* (ESBL-producing strain)” and “*Escherichia coli*” in their raw microbiology data file mean “organism\_escherichia\_coli” by the AMASS. The example data dictionary files shown in the figure are available in the Example\_Dataset\_2 folder (within the AMASS download package).

**An example dictionary for microbiology data file**

A	B	C	D
"Don't change content in this column, but you can add rows with the same content if needed"			
"Change content in this column to represent how variable names, antibiotic names, or variable values are written in your raw microbiology data file"		Requirements	Explanation
1	Variable names used in AMASS	Variable names used in your microbiology data file	
2	hospital_number	hn	Required
3	specimen_collection_date	spcdate	Required
4	specimen_type	spctype	Required
5	organism	organism	Required
6	infection_origin		Optional
7	Data values described in AMASS	Data values used in your microbiology data file	
8	blood_specimen	blood	Required
9	organism_no_growth	no growth	Required

**An example microbiology data file**

**Arrows:**

- A: Points from the dictionary to the data file (e.g., from 'hn' in the dictionary to 'hn' in the data file).
- B: Points from the dictionary to the data file (e.g., from 'blood' in the dictionary to 'blood' in the data file).

### Outputs Generated by the AMASS

The AMR surveillance reports generated from the AMASS are illustrated using the two open-access example data sets provided within the download package. Multimedia Appendices 7 and 8 contain AMR surveillance reports generated from the first and second example data sets, respectively. Multimedia Appendix 5 illustrates how to test the AMASS using example data sets in a step-by-step fashion.

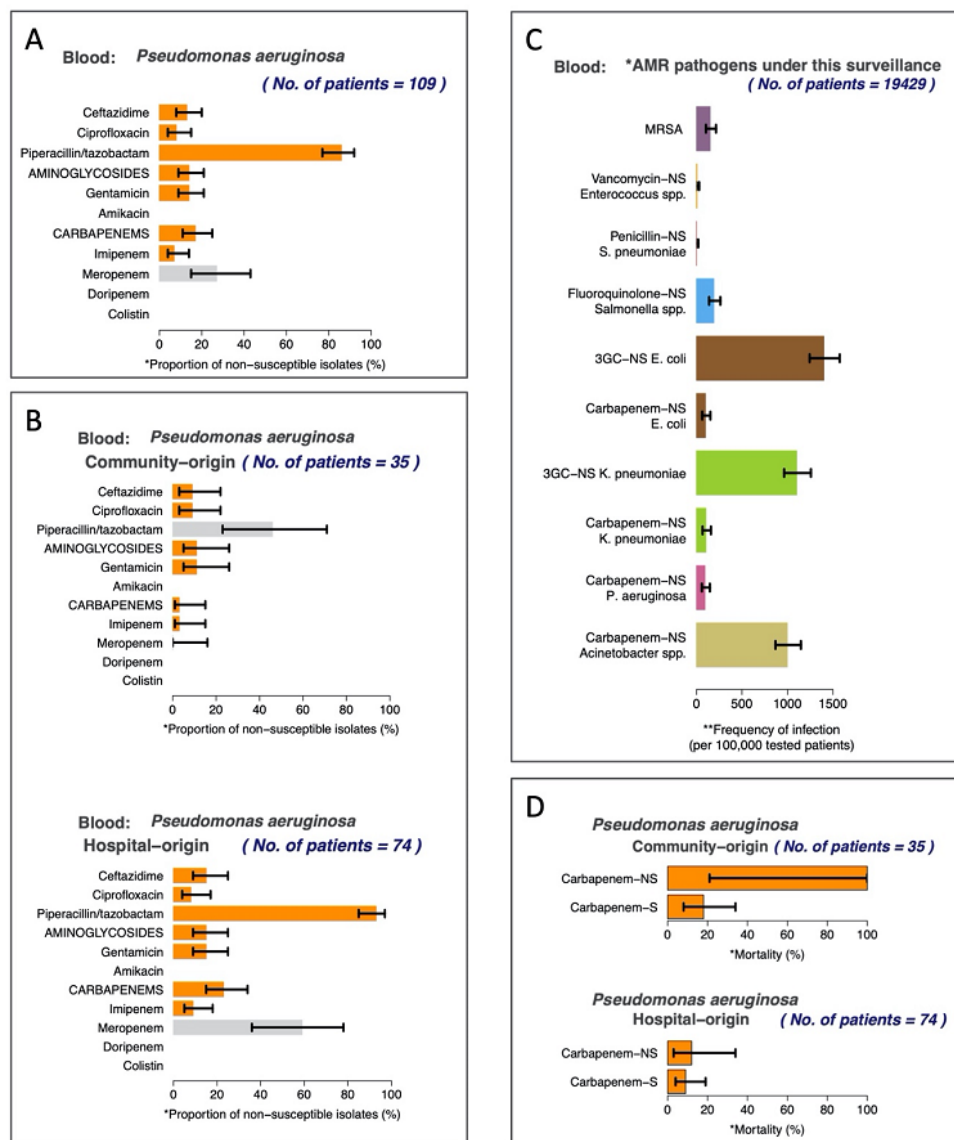

In short, the automatically generated report on AMR surveillance contains the following six sections (Figure 3): (1) data overview; (2) an isolate-based report; (3) an isolate-based report with stratification by origin of infection; (4) a sample-based report; (5) a sample-based report without stratification by infection; and (6) mortality involving AMR and antimicrobial-susceptible infections.

The AMASS uses a tier-based approach. When only the microbiology data file with the results of culture positive samples is available, only section one and two are automatically generated for users (as shown in Multimedia Appendix 7,

generated from the first example data set). Section three is generated only when data on admission dates are available. This is because these data are required for stratification by the origin of infection. Section four is generated only when data of culture negative specimens (no microbial growth) are available in the microbiology data file. This is because these data are required for the sample-based approach. Section five is section four stratified by the origin of infection and is generated if admission date data are also available. Section six is generated only when mortality data are available (as shown in Multimedia Appendix 8, generated from the second example data set).

The AMASS also generates two log files. The first log file (generated in PDF format) is for users to validate the input data used by the AMASS to generate the AMR surveillance report. It contains information such as the total number of records analyzed, age distribution, number of missing values, and total number of isolates per organism in the raw microbiology data file. The second log file (generated in plain text format) could be used for consultation with R users, statisticians, or the AMASS development team in case of any technical issue when running the AMASS.

**Figure 3.** Examples of figures automatically generated by the AutoMated tool for Antimicrobial resistance Surveillance System (AMASS). All figures are from the report (Multimedia Appendix 8 Multimedia Appendix 8) automatically generated by the AMASS application using an example data set provided in the download package. Figure 3A represents the overall proportion of nonsusceptible (intermediate and resistant) isolates in an isolate-based report (section two in the report). Figure 3B represents the proportion of nonsusceptible isolates stratified by the origin of infection (section three in the report). Figure 3C represents the frequency of bloodstream infections per 100,000 tested patients (section four in the report). Figure 3D represents mortality involving antimicrobial-resistant and antimicrobial-susceptible bloodstream infections (section six in the report).

### Testing the AMASS Using Hospital Data

The AMASS was tested in seven hospitals in seven countries (Figure 4). The hospitals varied in data availability, data structure, naming of the variables, and definitions for data values (Multimedia Appendix 9). Overall, the proportions of patients

having *Escherichia coli* bacteremia caused by third-generation cephalosporin-resistant isolates ranged from 19% to 85%. The incidence rates of *Escherichia coli* bacteremia caused by third-generation cephalosporin-resistant isolates ranged from 283 to 2737 per 100,000 tested patients among participating hospitals with available data on negative cultures.

**Figure 4.** A map of participating hospitals and examples of summary data from the automatically generated antimicrobial resistance surveillance reports. The reports and summary data from St Thomas' Hospital, Patan Hospital, North Okkalapa General and Teaching Hospital, Mahosot Hospital, Sunpasitthiprasong Hospital, Hospital for Tropical Diseases, and Angkor Hospital for Children are open access [28-34].

All participating hospitals deposited their output files and their data dictionary files at figshare [29-35]. Angkor Hospital for Children, North Okkalapa General and Teaching Hospital, and Sunpasitthiprasong Hospital had all six sections of the AMR surveillance report, as microbiology and hospital admission data, data on negative cultures, and in-hospital discharge outcome data were available. Mahosot Hospital and Patan Hospital had sections one and two of the AMR surveillance report, as only microbiology data on positive cultures were available to test in the AMASS. St Thomas' Hospital had sections one, two, three, and six of the AMR surveillance report because negative culture data were not available to test in the AMASS. Hospital for Tropical Diseases had sections one, two, and four available, as hospital admission data were not available to test in the AMASS.

Data storage systems varied across the hospitals. Angkor Hospital for Children used the ACORN LIS that is based on the Microsoft Access program [36]. Mahosot Hospital used a local LIS that is also based on the Microsoft Access program [37]. Sunpasitthiprasong Hospital used the MLAB program [38]. St Thomas' Hospital used ICNET [39], which is a commercial clinical surveillance software package. North Okkalapa General and Teaching Hospital used WHONET 2019 (modernized version of WHONET 5.6) [19]. Patan Hospital and Hospital for Tropical Diseases used an in-house LIS based on the MySQL system. Inputting data dictionary files for the first time took about 1 to 3 hours. However, the data dictionary files could be stored and reused when the raw microbiology data file or hospital admission data file was revised or updated. North Okkalapa General and Teaching Hospital used the data dictionary file from the example data set (in the Example\_Dataset\_1\_WHONET folder), which was generated to comply with WHONET exported data (in .XLSX format; [Multimedia Appendix 10](#) illustrates how microbiology data were exported from WHONET 5.6). This saved the time and effort needed to complete the data dictionaries for the hospital.

We found that the AMASS took about 1 to 3 minutes to run and automatically generate an AMR surveillance report using

local data and local hospital computers. The AMASS works on Microsoft Windows 10 and with data containing a non-English (Latin and non-Latin characters) language. For example, “blood\_specimen” was recorded as “☒” in the raw microbiology excel file at Hospital for Tropical Diseases, Vietnam. As another example, “male” was recorded as “☒” and “female” was recorded as “☒” in the raw hospital admission excel file at Sunpasitthiprasong Hospital, Thailand. By completing data dictionary files, users could use the AMASS to analyze the data and generate the AMR surveillance report even though the raw data were recorded in a local language.

All participating hospitals had previous experience in data verification and in AMR surveillance report validation. All participating hospitals were familiar with the recommendations of the Clinical and Laboratory Standard Institute (CLSI) and European Committee on Antimicrobial Susceptibility Testing (EUCAST) on antimicrobial susceptibility testing (AST) data verification. Additionally, all participating hospitals were familiar with validating summary data by comparing the summary data automatically generated by the AMASS with manual calculations.

Users' suggestions for improvement were received when the investigation team visited the participating hospitals. The users expressed a need for including other clinical specimen types (eg, urine samples) and a function to support data verification or provide a list of isolates with unusual AST profiles. This is because a data verification function is not currently available in many in-house LISs. Users also expressed the need for a way to import multiple data files and different data formats, particularly the long format (ie, each row represents an AST result obtained from each antibiotic against each isolate). This is because the data exported from automated machines for AST testing are commonly in the long format and it takes time to integrate the data from the automated AST machines and from disk diffusion AST results. Users also noted that the requirement to manually export data from the existing LIS can be tedious

and time consuming to perform on a regular basis, and automation that can bypass the data extraction step would be useful.

## Discussion

We developed an open-access, offline, and easy-to-use application, AMASS, which allows hospitals, especially in LMICs, to automatically generate AMR surveillance reports from routinely collected electronic microbiology data. Seven hospitals used the AMASS, and shared their reports and summary data files by depositing them in an open-access data repository website. We propose that routine generation and sharing of AMR surveillance reports (ie, cumulative antimicrobial susceptibility reports or antibiograms) in open-access data repositories from hospitals with a microbiology laboratory should be supported worldwide [40].

The AMASS empowers data sharing by reducing the time and effort needed to prepare the summary data and reports without increasing the risks of breaching individual patient data confidentiality. This is because the AMASS can analyze the data and generate the reports promptly without needing to transfer raw data files to any party outside of the hospital. The autogenerated AMR surveillance reports are in PDF format, which can be reviewed and shared locally and immediately. This is important to improve the understanding of the local AMR burden and to inform local patient management. The PDF report and summary CSV files contain no individual patient-level information and can be shared with national and international organizations to support action plans on AMR. Any attempt to compare AMR surveillance reports among different hospitals should be done cautiously, as factors, including the type of hospital, blood culture utilization rates and practices, and patient characteristics, may influence the estimated prevalence and incidence rates of AMR infections [12-14]. An AMR surveillance report should clearly present the denominators used to calculate incidence rates. Selecting an appropriate denominator that represents the local setting is important for estimating the incidence rate of AMR, but remains challenging [41]. The AMASS calculates the total numbers of tested populations and uses them as denominators in section four and section five of the output report based on the WHO GLASS recommendations, and these denominators will not be available without data on negative cultures.

The AMASS uses currently recommended analytical approaches to generate the summary data and reports. The entire code is open access, verifiable, and modifiable. The AMASS can also be expanded and tailored based on local requirements. For instance, notifiable bacterial infections that are important for a local setting can be included by revising the R code provided in the AMASS package. Analytical methods can also be constantly updated and improved over time.

The AMASS is an add-on automatized report-generating tool that can be easily used, even by hospital users with limited information technology skills. It does not replace WHONET, LISs, quality assurance programs, or antimicrobial surveillance systems (including the WHO GLASS). The AMASS therefore differs from the “Macros and Excel Reports” function of

WHONET, which allows users to regularly generate reports on screen and export data as Excel files using macro language (ie, a series of written study parameters generated automatically through the WHONET user interface grouped together) [19]. In contrast, the AMASS is designed to automatically compile summary results of multiple organisms into a single report. The current version of the AMASS does not support quality improvement or alert individuals to unexpected antibiogram results, which WHONET is capable of doing [19]. Thus, while WHONET is an appropriate choice for the main software package for microbiology laboratories in LMICs to capture and store microbiology data and to export data for the WHO GLASS [19], the AMASS provides important additional functionality [19].

Verifying individual AST results and validating summary data in the reports (including those generated by the AMASS) remain major barriers to the generation of accurate surveillance data on AMR. Only verified AST results on each patient's isolate should be used in the data analysis [12-14]. WHONET and few LISs include functions that automatically check the results to ensure that they appear reasonable or alert users to confirm unusual results (eg, amikacin resistance coexisting with gentamicin and tobramycin susceptibility in *E. coli* is unusual, and data on such cases should be verified) [12-14,19]. In addition, it is important to validate the calculations of any analytical software used to generate the summary data and reports. We recommended that users of the AMASS perform manual validation (such as printing a line listing of all isolates of the species to cross-check with the reports), particularly when the program is used for the first time [12-14]. Users should also understand that the precision of the estimate is based on the sample size, which is illustrated by estimated confidence intervals. In addition, the representativeness of the summary cumulative AST data could be impacted by the sampling strategy used, particularly if blood culture is mainly performed for patients with treatment failure or prolonged hospitalization [11,12,14]. Nonetheless, generating AMR surveillance reports from existing microbiology databases could be the first step for hospitals in LMICs to understand and validate their own data, and support quality control programs at the local level.

Local hospitals must not be discredited because of the statistics in any AMR surveillance report, as possible criticism could be a barrier to data sharing [42]. Negative criticism of the data shared by local hospitals needs to be avoided. It is inevitable for errors to occur in any data set, especially in settings with limited resources and experience on quality assurance and data validation. Tools for data validation should be provided to local hospitals, and the statistics in an AMR report should act as a guide on the direction of improving data quality control, data validation, and infection prevention and control. Credit should be given to the hospitals that share their local AMR data and reports on an open-access data repository platform. Data repository platforms, such as figshare, allow flexibility on updating the data and revising the AMR surveillance reports with appropriate version controls by local hospitals. Publishing open-access AMR data on data repository platforms provides a digital object identifier (DOI) that should be used for data citation [43].

The AMASS has a number of limitations. First, the AMASS is not applicable for hospitals that only store data in paper forms. Second, the AMASS cannot work with raw microbiology data files that are not in a wide format or combine many files in multiple formats. For example, raw microbiology data file where each row contains data of each antibiotic susceptibility result for one single specimen. Third, the current version of the AMASS can only analyze microbiology data that include antimicrobial susceptibility test interpretive categories (susceptible, intermediate, and resistant) based on guidelines that the local hospital uses. Fourth, the AMASS cannot automatically validate the reliability of the data that are imported into the application and used for analysis. Data verification and quality checks will be included in future versions of the application. Fifth, the AMASS was tested with only few data sets that included non-English languages, and further testing on data with other languages may be needed. The current version

of the AMASS has been tested on Windows 10 and 7 and may not work on other operating systems. Sixth, the current version of the AMASS cannot provide options to export the AMR surveillance report in different formats (ie, in document or text format). However, users can reuse the summary statistics, which are saved in CSV format under the ResultData folder. Finally, feedback from participating hospitals was not formally evaluated. Studies evaluating the barriers, facilitators, and utilities of supporting applications, such as the AMASS, to generate AMR surveillance reports are needed.

In conclusion, the AMASS can be used to support hospitals with microbiology laboratories in analyzing routinely collected data and generating reports with minimal resources and expertise required. This may empower individual hospitals to contribute to the understanding of and actions on AMR in local settings and maximize the utility of local data.

---

## Acknowledgments

We thank all hospitals that participated in the AMASS project. We thank Dr Thet Wai Nwe from the Central Epidemiology Unit of Myanmar and Dr Htay Htay Tin from the National Health Laboratory of Myanmar for their comments on the AMASS. We also thank Dr Kyi Soe, who is the Senior Medical Superintendent of North Okkalapa General and Teaching Hospital, for his support for the AMASS and for hosting the AMASS training workshop at the hospital. We thank Professor Frank Smithuis and Dr Aung Pyae Phyo from Myanmar Oxford Clinical Research Unit (MOCRU) for their support on the AMASS project. We thank Professor Paul Newton and Professor David Dance from the Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit (LOMRU) for their support on the AMASS project. We thank Ronas Shakya from Patan Hospital, Nepal for technical assistance. We thank Joe Hessel from the Diagnostic Microbiology Development Program for comments on the AMASS. We thank Chotipong Chaisiripreeyakul, Techat Totemchokchaikarn, Sitthinun Pasirichusaree, and Papitchaya Achavakulthep for the tutorial videos on the AMASS. Mahidol Oxford Tropical Medicine Research Unit (MORU) is funded by the Wellcome Trust (grant: 106698/Z/14/Z). Oxford University Clinical Research Unit (OUCRU) is funded by the Wellcome Trust (grant: 106680/B/14/Z). The investigators are funded by the Wellcome Trust (CLim is funded by a Training Research Fellowship [grant: 206736] and DL is funded by an Intermediate Training Fellowship [grant: 101103]). BC is funded by the UK Medical Research Council and Department for International Development (grant: MR/K006924/1). The funders of the investigators and study had no role in the study, data collection, data analysis, data interpretation, or writing of the manuscript. The corresponding authors had the final responsibility for the decision to submit for publication.

---

## Authors' Contributions

CLim and DL conceptualized, designed, and developed the AMASS, and wrote the original draft. TM, VC, MTA, AK, PTe, RB, and LNPH tested the AMASS, curated data, and reviewed reports generated from the AMASS using local data. JS, PTu, EA, RvD, HNL, CLing, SH, SI, SD, TW, VH, WS, YLM, TLV, HHH, MM, MV, BB, JE, SP, GT, ND, and BC reviewed and interpreted the reports. All authors participated in drafting, editing, and revising the final manuscript.

### Multimedia Appendix 1

An overview of the flow of data processing and analyses performed by the AutoMated tool for Antimicrobial resistance Surveillance System (AMASS).

[DOCX File, 242 KB - [jmir\\_v22i10e19762\\_app1.docx](#)]

---

### Multimedia Appendix 2

The list of pathogen-antibiotic combinations modified from the World Health Organization Global Antimicrobial Resistance Surveillance System priority list and included in the AutoMated tool for Antimicrobial resistance Surveillance System (AMASS).

[DOCX File, 31 KB - [jmir\\_v22i10e19762\\_app2.docx](#)]

---

### Multimedia Appendix 3

The methods to estimate prevalence and incidence rates were based on the recommendation of the World Health Organization Global Antimicrobial Resistance Surveillance System.

[DOCX File, 29 KB - [jmir\\_v22i10e19762\\_app3.docx](#)]

#### Multimedia Appendix 4

Simulating hypothetical data sets.

[DOCX File, 27 KB - [jmir\\_v22i10e19762\\_app4.docx](#)]

#### Multimedia Appendix 5

How to run the AutoMated tool for Antimicrobial resistance Surveillance System (AMASS) using example data files.

[DOCX File, 26 KB - [jmir\\_v22i10e19762\\_app5.docx](#)]

#### Multimedia Appendix 6

How to configure the data dictionary files.

[DOCX File, 26 KB - [jmir\\_v22i10e19762\\_app6.docx](#)]

#### Multimedia Appendix 7

AMR surveillance report generated from the first example data set.

[PDF File (Adobe PDF File), 44 KB - [jmir\\_v22i10e19762\\_app7.pdf](#)]

#### Multimedia Appendix 8

AMR surveillance report generated from the second example data set.

[PDF File (Adobe PDF File), 124 KB - [jmir\\_v22i10e19762\\_app8.pdf](#)]

#### Multimedia Appendix 9

The list of participating hospitals.

[DOCX File, 30 KB - [jmir\\_v22i10e19762\\_app9.docx](#)]

#### Multimedia Appendix 10

How to export data from WHONET 5.6 (2019) in an Excel format that can be used by the AutoMated tool for Antimicrobial resistance Surveillance System (AMASS).

[DOCX File, 2846 KB - [jmir\\_v22i10e19762\\_app10.docx](#)]

## Abstract

**Background:** Collectively, an estimated 5% of the population have a genetic disease. Many of them feature characteristics that can be detected by facial phenotyping. Face2Gene CLINIC is an online app for facial phenotyping of patients with genetic syndromes. DeepGestalt, the neural network driving Face2Gene, automatically prioritizes syndrome suggestions based on ordinary patient photographs, potentially improving the diagnostic process. Hitherto, studies on DeepGestalt's quality highlighted its sensitivity in syndromic patients. However, determining the accuracy of a diagnostic methodology also requires testing of negative controls.

**Objective:** The aim of this study was to evaluate DeepGestalt's accuracy with photos of individuals with and without a genetic syndrome. Moreover, we aimed to propose a machine learning-based framework for the automated differentiation of DeepGestalt's output on such images.

**Methods:** Frontal facial images of individuals with a diagnosis of a genetic syndrome (established clinically or molecularly) from a convenience sample were reanalyzed. Each photo was matched by age, sex, and ethnicity to a picture featuring an individual without a genetic syndrome. Absence of a facial gestalt suggestive of a genetic syndrome was determined by physicians working in medical genetics. Photos were selected from online reports or were taken by us for the purpose of this study. Facial phenotype was analyzed by DeepGestalt version 19.1.7, accessed via Face2Gene CLINIC. Furthermore, we designed linear support vector machines (SVMs) using Python 3.7 to automatically differentiate between the 2 classes of photographs based on DeepGestalt's result lists.

**Results:** We included photos of 323 patients diagnosed with 17 different genetic syndromes and matched those with an equal number of facial images without a genetic syndrome, analyzing a total of 646 pictures. We confirm DeepGestalt's high sensitivity (top 10 sensitivity: 295/323, 91%). DeepGestalt's syndrome suggestions in individuals without a craniofacially dysmorphic syndrome followed a nonrandom distribution. A total of 17 syndromes appeared in the top 30 suggestions of more than 50% of nondysmorphic images. DeepGestalt's top scores differed between the syndromic and control images (area under the receiver operating characteristic [AUROC] curve 0.72, 95% CI 0.68-0.76;  $P < .001$ ). A linear SVM running on DeepGestalt's result vectors showed stronger differences (AUROC 0.89, 95% CI 0.87-0.92;  $P < .001$ ).

**Conclusions:** DeepGestalt fairly separates images of individuals with and without a genetic syndrome. This separation can be significantly improved by SVMs running on top of DeepGestalt, thus supporting the diagnostic process of patients with a genetic syndrome. Our findings facilitate the critical interpretation of DeepGestalt's results and may help enhance it and similar computer-aided facial phenotyping tools.

facial phenotyping; DeepGestalt; facial recognition; Face2Gene; medical genetics; diagnostic accuracy; genetic syndrome; machine learning

## Introduction

### Background

Although individual genetic diseases are rare, they collectively affect an estimated 5% of a population [1]. Thus, these diseases represent a major challenge for health care systems, as it usually requires highly specialized knowledge to propose a specific genetic diagnosis. Assessing the facial phenotypes of patients with genetic syndromes is key to this diagnostic process [2]. Traditionally performed by a physician, the advents of computer vision and machine learning in medicine enable rapid and automated assessment of a patient's facial traits [3,4]. Numerous facial phenotyping systems have been developed with the potential to aid the diagnostic processes in medical genetics [5-12]. DeepGestalt, the neural network behind Face2Gene CLINIC, which was trained on more than 17,106 images, is thus far the best-investigated and most convenient to use application [11]. Several studies assessed the algorithm's sensitivity, suggesting that it is of a certain quality [11,13-38]. These tests predominantly analyzed images of patients diagnosed with a genetic disorder known to show characteristic facial features. This appears reasonable as DeepGestalt is designed to identify such syndromes. However, it might introduce a bias in conclusions of the system's everyday clinical use since not all individuals seen in a real-life setting belong to the group of patients included in previous studies of DeepGestalt. This may be because (1) the featured syndrome is yet to be analyzed by the system; (2) an individual features a syndrome not associated with a characteristic facies; or (3) an individual has no syndrome at all.

In addition to such evaluations of DeepGestalt's sensitivity, there is a need for studies on its specificity when tested on individuals without craniofacial dysmorphism. As DeepGestalt is not designed to suggest the class label "inconspicuous face" [11], evaluating its clinical specificity is not too trivial a task. Some studies tested the ability of DeepGestalt's methodology to distinguish between facial images with and without a genetic syndrome by constructing user-specific neural networks trained on healthy control images and on images of limited numbers of well-selected genetic disorders using Face2Gene RESEARCH

[20,26-28,30,32,34,39-41]. Their results suggested that neural networks such as DeepGestalt may have the potential to differentiate between the 2 classes and may thus be used in diagnosing patients in medical genetics. Such a test could be applied at different stages of the diagnostic process. Patients who want to know if genetic counseling is necessary could use it as a triage test to check whether a suspicion of a genetic disease is justified. Physicians and other medical professionals could similarly use such a test on patients suspected of having a genetic syndrome to narrow down the range of possible diagnoses. Geneticists could use it as an add-on test to further confirm a diagnosis, for example, in the presence of a variant of unknown significance.

### Objectives

We aimed to systematically benchmark DeepGestalt's power to discern images of individuals with a dysmorphic genetic syndrome from images of healthy control individuals. For this purpose, we tested the basic prerequisite for the diagnostic usefulness of DeepGestalt, that is, to yield different scores in persons with a conventionally established diagnosis of a genetic syndrome than in persons without a genetic syndrome ( $H_1: \mu_{\text{syndromic}} \neq \mu_{\text{healthy}}$ ). We also determined DeepGestalt's capacity to distinguish those images by measuring its area under the receiver operating characteristic (AUROC) curve. Furthermore, we aimed to develop and test a machine learning-based approach to improve DeepGestalt's accuracy.

## Methods

### Selection and Analysis of Portrait Photos

#### Study Design

To be included in this study, portrait photos had to depict the entire frontal face (from hairline to chin showing both eyes) and no artifact other than glasses. To achieve a vertical positioning of the face, the images were cropped and rotated if necessary. A convenience sample of online accessible images was collected between September 2019 and December 2019, using a methodology adjusted from Ferry et al [8]. Pictures photographed by us were taken at the 2018 meeting of the

Elterninitiative Apertsyndrom und Verwandte Fehlbildungen eV, a parents' initiative on Apert syndrome and related disorders in Germany, after obtaining written informed consents as approved by the ethics committee of the Charité – Universitätsmedizin Berlin (EA2/190/16). Image inclusion was planned before conducting analysis by DeepGestalt. A sample size of the positive and negative class of 105 (N=210) was calculated using G\*Power, version 3.1.9.7 (effect size 0.5;  $\alpha=.05$ ; power 0.95; allocation ratio 1).

### Defining Reference Phenotypes

Only images of individuals reported to be clinically or molecularly diagnosed with a genetic syndrome were labeled as syndromic. When no syndrome was reported and no facial gestalt suggestive of a syndrome was observed, as judged by physicians working in medical genetics, images were labeled as “healthy.”

### Computer-Aided Facial Phenotyping

Computer-aided facial phenotyping was performed using DeepGestalt version 19.1.7, accessed via Face2Gene CLINIC (FDNA Inc). Neither the class labels nor diagnoses were passed to DeepGestalt. No other phenotypic information but 1 portrait photo per case was entered into the system. DeepGestalt's training set was tested not to contain duplicates of images used in this study, as described previously [42].

### Danyel Cohort

The Danyel cohort, originally described by Danyel et al [30], comprises 116 healthy control images.

### Syndromic Cohort

This cohort comprises frontal facial images of 17 syndromes. We planned to collect the same number of images for each of these syndromes. A total of 16 of these syndromes were chosen from the 201 distinct suggestions in DeepGestalt's top 30 results lists of the Danyel cohort. Syndromes of different frequencies ranging from 76% (frequently suggested) to 1% (rarely suggested) were selected. In descending order of frequency, these syndromes are as follows: Fragile X syndrome (OMIM: #300624), Angelman syndrome (OMIM: #105830), Rett syndrome (OMIM: #312750), Phelan-McDermid syndrome (OMIM: #606232), Klinefelter syndrome, Beckwith-Wiedemann syndrome (OMIM: #130650), 22q11.2 deletion syndrome (OMIM: #611867), Sotos syndrome (OMIM: #117550), Noonan syndrome (OMIM: PS163950), Loeys-Dietz syndrome (OMIM: PS609192), Williams-Beuren syndrome (OMIM: #194050), Rubinstein-Taybi syndrome (OMIM: PS180849), achondroplasia (OMIM: #100800), Wolf-Hirschhorn syndrome (OMIM: #194190), Pallister-Killian syndrome (OMIM: #601803), and Treacher Collins syndrome (OMIM: PS154500). In addition, we chose Apert syndrome (OMIM: #101200), which was not implied in the Danyel cohort.

### Matched Control Cohort

Each photo of the syndromic cohort was matched to an image of an individual without a genetic syndrome by age, sex, and ethnicity to build a cohort of an equal number of control images.

## Statistical Evaluation and Classification Experiments

Face2Gene CLINIC returns DeepGestalt's top 30 syndrome suggestions. DeepGestalt associates each suggestion with a Gestalt score [11]. The syndrome suggestions' frequencies, scores, and ranks were statistically evaluated.

### Feature Extraction and Vector Construction

All images were labeled by class (syndromic vs healthy). Vectors were built to hold an attribute for any of the syndromes suggested at least once in DeepGestalt's top 30 suggestions. To construct a vector for a given photo, the 30 highest Gestalt scores were assigned to their respective attributes; and the remaining attributes were set to 0 (s. matrix.txt in [Multimedia Appendix 1](#)).

### Classification

To differentiate between syndromic and healthy portrait photos, we trained linear support vector machines (SVMs) using the LinearSVM class of scikit-learn, version 0.21.3, with default parameters in Python 3.7. To avoid overfitting, training and testing were performed using a leave-1-out classification scheme. Since ethnic background is a possible confounder of DeepGestalt [15,22,26,29,33], we designed classification experiments based on all images, images of White persons, and those of persons with other ethnicities, to benchmark the influence of ethnicity on SVM performance.

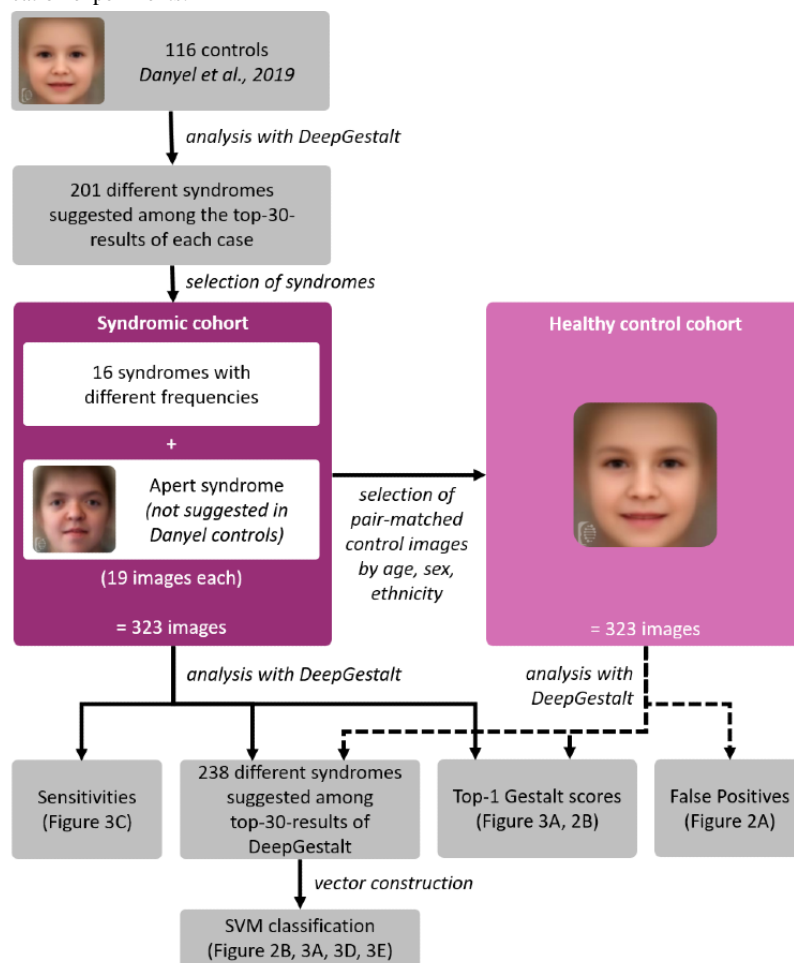

To test a possible influence of the number of top ranks considered, classification of all images was run 30 times with the number of considered top Gestalt ranks, ranging from 1 to 30.

### Statistical Analysis

Scores of the syndromic and healthy control cohort were tested to be different using a 2-sided, independent Welch *t* test. Difference of receiver operating characteristics (ROCs) was tested using a DeLong test. Classification performance was assessed using Matthews correlation coefficient (MCC). All statistical tests were performed in Python 3.7; the code can be found in [Multimedia Appendix 1](#).

### Data and Code Availability

The data and code can be found in [Multimedia Appendix 1](#). For reasons of data protection, all data were cumulated (where possible), deidentified, and minimized. Facial images depicted in [Figure 1](#) show computer-generated composite masks and not real individuals. In [Multimedia Appendix 1](#), file data.txt describes the diagnosis, age, sex, and ethnicity of persons in the analyzed set of images; and file matrix.txt contains DeepGestalt's output vectors as used for this study. Files differentiator.py and reproduce.py may be used for reproducing the statistical results of this study. Further information may be found in file readme.txt ([Multimedia Appendix 1](#)).

**Figure 1.** Workflow of classification experiments.

## Results

### Included Images

We could include 19 images for each of the 17 syndromes in the syndromic cohort. A total of 83% (272/323) of these images were of White persons (file data.txt of [Multimedia Appendix 1](#)). Images from the syndromic cohort were matched to 323 images forming the matched control cohort, resulting in a total number of 646 analyzed photos ([Figure 1](#)).

### Frequencies and Scores of Suggested Syndromes in Control Individuals

DeepGestalt suggested 238 different syndromes among the top 30 suggestions of the matched control cohort. One syndrome was suggested in more than 80% of the cases (Fragile X syndrome, 82%), 6 syndromes in 70%-80% of the cases; 4 syndromes in 60%-70% of the cases; 6 syndromes in 50%-60% of the cases; 6 syndromes in 40%-50% of the cases; 11 syndromes in 30%-40% of the cases; 15 syndromes in 20%-30% of the cases; 29 syndromes in 10%-20% of the cases; and 160 syndromes at least once in less than 10% of the cases ([Figure 2A](#)).

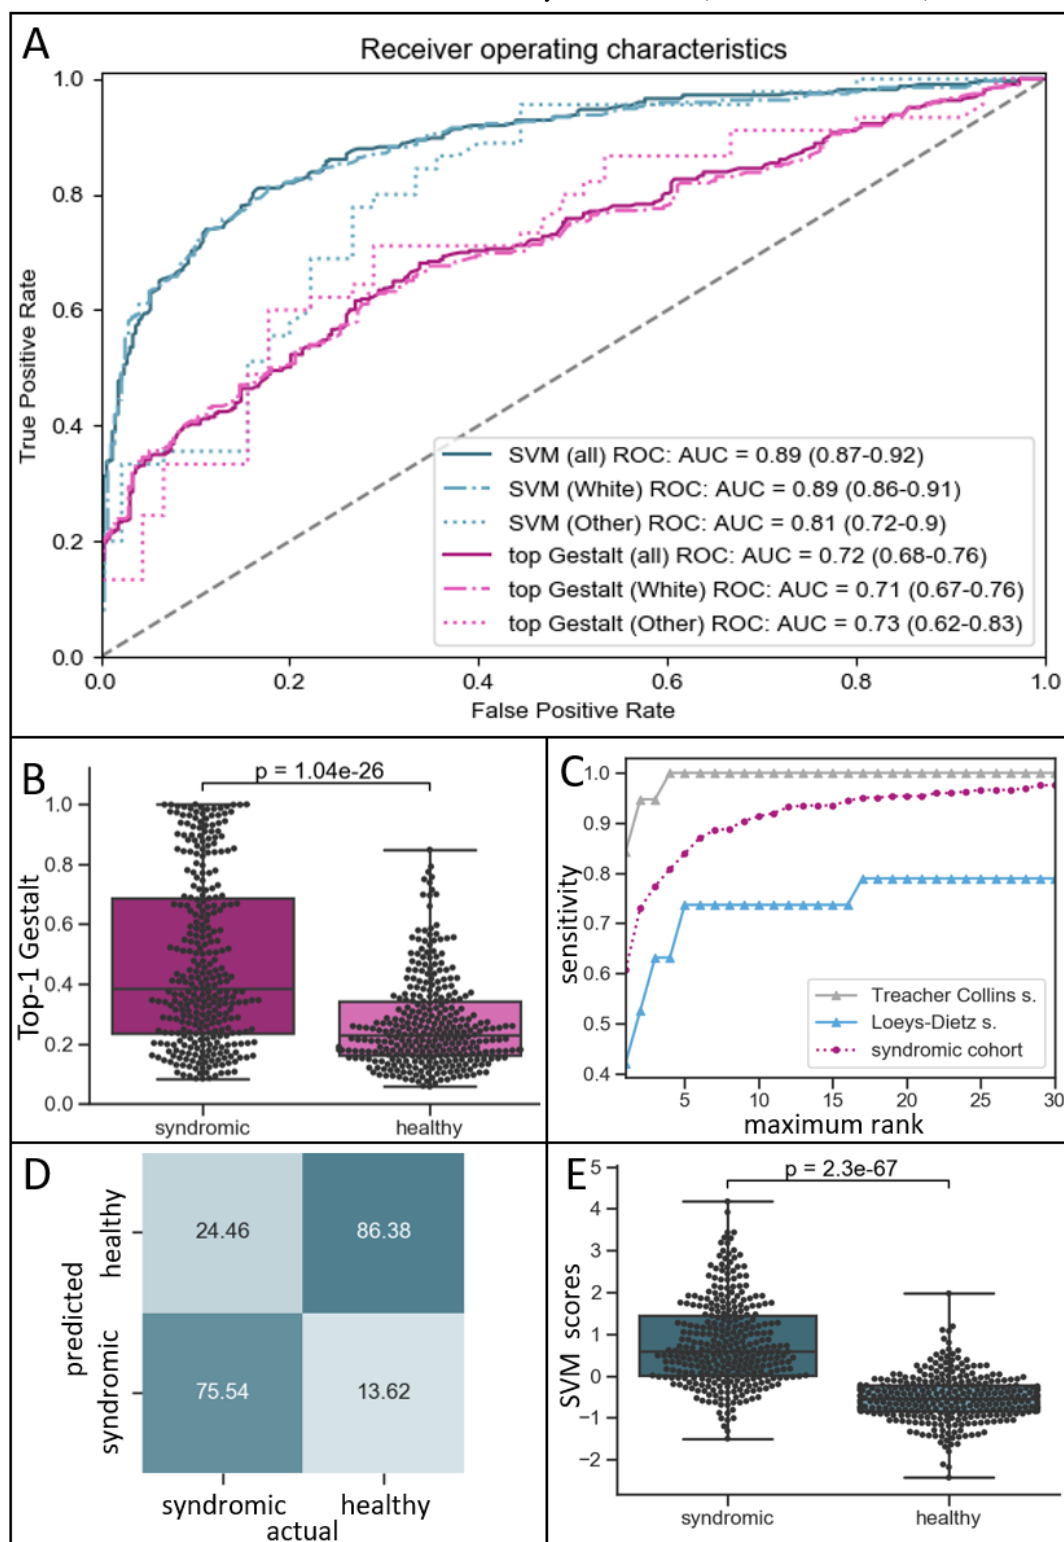

**Figure 2.** (A) Frequency of syndromes suggested by DeepGestalt in more than 20% of the matched control cohort's top-30-results lists. Colors indicate frequency percentages. (B) Number of images correctly classified as "syndromic"; colors relate to (A) and gray indicates <20%.

The highest first-rank Gestalt score of the matched control cohort amounted to 0.85, and the lowest, to 0.06, with a mean of 0.27 (SD 0.15). First-rank Gestalt scores of the syndromic cohort (highest 1.0; lowest 0.08; mean 0.47, SD 0.28) and the matched control cohort appeared to be separable with an AUROC of 0.72 (95% CI 0.68-0.76) (Figure 3A). Notably, this

was found for both tested ethnic groups (Figure 3A, Multimedia Appendix 2), White persons only (AUROC 0.71, 95% CI 0.67-0.76;  $P < .001$ ), and persons of other ethnicities only (AUROC 0.71, 95% CI 0.62-0.83;  $P < .001$ ). Separability of the 2 cohorts is evident and significant ( $P < .001$ ), as shown in Figure 3B.

**Figure 3.** (A) Receiver operating characteristic (ROC) curves: dashed line indicates random ROC curve; note that support vector machine (SVM) scores yield higher areas under the ROC curves (AUROCs) than their respective raw first-rank Gestalt scores. (B) Distribution of first-rank Gestalt scores in the syndromic cohort and the matched control cohort (healthy). (C) Sensitivities of DeepGestalt (X-axis: number of considered top ranks). Dark-purple circles: average of syndromic cohort; gray triangles: 19 images with Treacher-Collins syndrome; blue triangles: 19 images with Loeys-Dietz syndrome. (D) Distribution of SVM scores in the syndromic cohort and the matched control cohort; note: improved separability as compared to B. (E) SVM classification results based on the entire matched control cohort and syndromic cohort (threshold SVM score: 0).

### Sensitivity of DeepGestalt

DeepGestalt's average top 10 sensitivity in the syndromic cohort amounted to 91%, varying between the 17 tested syndromes (Figure 3C, Multimedia Appendix 3). Interestingly, DeepGestalt

was sensitive independent of ethnicity (White persons only, 90%; persons of other ethnicities only, 97%). A total of 7 syndromes reached a top 10 sensitivity of 100% (Fragile X, Noonan, Phelan-McDermid, Rett, Sotos, Treacher-Collins, and Williams-Beuren syndromes). DeepGestalt performed worst

for Loeys-Dietz syndrome, with a top 10 sensitivity of 74% (Figure 3C).

### Performance of the SVM

Sensitivities of binary SVM classification differed between syndromes (Figure 2B). All images of individuals with Apert syndrome, Wolf-Hirschhorn syndrome, and Williams-Beuren syndrome were correctly classified as being syndromic. The SVM performed worst on the 19 images of individuals with Klinefelter syndrome, correctly classifying only 7 of them as syndromic.

Binary SVM classification of DeepGestalt's output achieved an increased separability of syndromic images and healthy controls as compared to top Gestalt scores with an AUROC of 0.89 (95% CI 0.87-0.92) (Figure 3A). Again, this was true in both tested ethnic groups (Figure 3A), for photos of White persons (AUROC 0.88, 95% CI 0.86-0.91;  $P < .001$ ) and those of persons of other ethnicities (AUROC 0.79, 95% CI 0.62-0.83). However, difference in ROCs was not significant in the latter ( $P = .13$ ). SVM classification performance improved with an increasing number of considered ranks. Using the top 30 Gestalt scores showed the best MCC (0.63), as shown in Multimedia Appendix 4, with a sensitivity of 75.54% and a specificity of 86.38% (Figure 3D). Separability was significant ( $P < .001$ ) (Figure 3E).

## Discussion

### Classification of Images of Individuals Without a Genetic Syndrome

To our knowledge, this is the first study to systematically analyze DeepGestalt's behavior on portrait photos of individuals without a genetic syndrome. For these images, we show that DeepGestalt's syndrome suggestions follow an interesting distribution. Certain syndromes are implied as differential diagnoses with a considerably high likelihood. Among these were Fragile X, Klinefelter, Rett, and Angelman syndromes, which were suggested in more than 3 quarters of the matched control cohort. In contrast, syndromes such as Treacher-Collins syndrome and Wolf-Hirschhorn syndrome were implied very rarely.

DeepGestalt cannot assign the class label "inconspicuous." Yet, DeepGestalt's scores are used to help judge the presence of a given syndrome. Based on a high maximum Gestalt score, a user could assume that the individual depicted in an entered image is likely to have a syndrome. Likewise, one is tempted to assume that a low maximum Gestalt score makes an underlying syndrome unlikely. Indeed, the mean of first-rank Gestalt scores is higher in images depicting syndromic facies than in images of individuals without a genetic syndrome. Similarly, scores higher than 0.85 appear to be specific indicators of a syndromic facies, and those lower than 0.08 are not suggestive of a genetic syndrome. However, these specific values are very rare. Gestalt scores alone are only fairly sufficient for judging the presence or absence of a genetic syndrome with facial dysmorphism since the distributions of the highest Gestalt scores of the syndromic and matched control cohort greatly overlap. We show that this problem can be

reduced by considering both top Gestalt scores and the actual list of suggested syndrome matches. The boost in discriminatory power is illustrated by the increase of the respective AUROCs. Although DeepGestalt cannot directly assess the presence/absence of a syndromic facies, machine learning-based tools (eg, SVMs) built on top of DeepGestalt may be used for this purpose.

It is noteworthy that we achieved promising results with a comparably low number of samples and a low complexity classification model with default hyperparameters. We assume that the quality and complexity of future classifiers will improve as more data will become available. Increasing the number of top ranks considered for vector construction increased the performance of the SVM. However, the number of DeepGestalt's suggestions accessible via Face2Gene CLINIC is limited to 30 suggestions. We hypothesize that using more than just the 30 top ranks for vector construction might further boost classification performance. We classified DeepGestalt's output to predict the presence of a syndromic facies. We also suggest evaluating classification performance based on DeepGestalt's input vectors.

### Potential Confounders

Until now, differences in the diagnostic performance of DeepGestalt, which arise due to the ethnicity of the person depicted, have been evaluated using DeepGestalt's sensitivity. Studies of earlier versions of DeepGestalt showed that its sensitivity is dependent on the ethnic background in certain syndromes [15,22]. Studies of more recent versions of DeepGestalt suggested that ethnicity had no major influence on its sensitivity [26,29]. In our set of syndromic images, DeepGestalt's sensitivity is remarkably high, which is in line with the previous studies highlighting DeepGestalt's good general sensitivity [11,36,42]. This high sensitivity of DeepGestalt was confirmed for both groups of images, those of White persons and those of persons of other ethnicities. Improvement of distinguishability of images of individuals with and without a genetic syndrome appeared to be stronger in the group of photos of White persons than in the group of photos of persons of other ethnicities. However, we assume that this is caused by the limited sample size of images of non-White persons in our data set. We believe that our approach is also applicable to populations comprising predominantly other ethnicities.

The SVM had difficulties classifying images of patients with syndromes that were frequently suggested in healthy controls. Possible explanations for DeepGestalt's output to be similar in controls and individuals with these syndromes could be as follows: (1) such syndromes have only mild characteristic facial features; (2) they have a typical facial gestalt, which is present only in some but not all affected individuals; or (3) they have no typical facies at all. For example, not all patients with Loeys-Dietz syndrome exhibit distinctive facial features [43], and the facial appearances of males with Klinefelter syndrome show no commonly observed characteristics [44].

## Further Research

Further research is necessary to determine DeepGestalt's capacity to distinguish individuals with and without a genetic syndrome when combined with other sources of information, such as genetic test results and nonfacial phenotypic information. We suggest including additional scores that are based on both phenotype and genotype (eg, prioritization of exome data by image analysis [PEDIA] scores [42]) in future classifiers of the presence/absence of a syndromic facies.

The increasing use and quality of facial phenotyping software in clinical genetics should also be accompanied by an ethical evaluation of these systems [45]. This affects issues such as the automation of medical diagnostic action, the sharing of (potentially identifiable) data, and a potentially altered doctor-patient relationship. In particular, a systematic analysis

of the patient perspective on the use of computer-aided facial analysis methodologies in clinical genetics is lacking so far.

We believe that our findings will help improve future versions of DeepGestalt and similar systems and are crucial when interpreting Face2Gene's results in the clinical routine. In particular, we recommend providing users with the false-positive rates of each suggested syndrome.

## Conclusion

DeepGestalt is a computer-aided facial phenotyping tool that showed promising results for detecting a potentially syndromic facies. It yields higher first-rank scores in individuals with a genetic syndrome than in those without a diagnosis of a genetic syndrome. Its output may be classified to improve this detection. The exact stage to use DeepGestalt during the diagnostic makeup of individuals with a suspected genetic syndrome remains to be determined. Primarily, it should be used by expert geneticists.

## Acknowledgments

We thank the members of the Elterninitiative Apertsyndrom und Verwandte Fehlbildungen eV, a parents' initiative on Apert syndrome and related disorders in Germany, for the contribution of their images, and Yaron Gurovich and Nicole Fleischer of FDNA Inc for technical assistance in checking DeepGestalt's training set for duplicate images used in this study. MAM is a participant in the BIH Charité Digital Clinician Scientist Program funded by the Charité – Universitätsmedizin Berlin and the Berlin Institute of Health. We acknowledge support from the German Research Foundation (DFG) and the Open Access Publication Funds of Charité – Universitätsmedizin Berlin.

## Authors' Contributions

JTP, NH, and MAM designed the study. JTP, NH, MD, JE, ATAP, and MAM collected the data. SM, MS, DH, and CEO provided insights that were critical for the interpretation of data. MAM implemented the Python code with support from PH. PH and MAM performed the statistical analysis. JTP, NH, CEO, and MAM wrote the manuscript with approval of all the authors.

## Abstract

**Background:** Stress is a risk factor associated with physiological and mental health problems. Unobtrusive, continuous stress sensing would enable precision health monitoring and proactive interventions, but current sensing methods are often inconvenient, expensive, or suffer from limited adherence. Prior work has shown the possibility to detect acute stress using biomechanical models derived from passive logging of computer input devices.

**Objective:** Our objective is to detect acute stress from passive movement measurements of everyday interactions on a laptop trackpad: (1) *click*, (2) *steer*, and (3) *drag and drop*.

**Methods:** We built upon previous work, detecting acute stress through the biomechanical analyses of canonical computer mouse interactions and extended it to study similar interactions with the trackpad. A total of 18 participants carried out 40 trials each of three different types of movement—(1) *click*, (2) *steer*, and (3) *drag and drop*—under both relaxed and stressed conditions.

**Results:** The mean and SD of the contact area under the finger were higher when clicking trials were performed under stressed versus relaxed conditions (mean area:  $P=.009$ , effect size=0.76; SD area:  $P=.01$ , effect size=0.69). Further, our results show that as little as 4 clicks on a trackpad can be used to detect binary levels of acute stress (ie, whether it is present or not).

**Conclusions:** We present evidence that scalable, inexpensive, and unobtrusive stress sensing can be done via repurposing passive monitoring of computer trackpad usage.

## Introduction

### Overview

Several health risks such as cardiovascular disease and immune deficiencies, which can diminish the quality of life and shorten life expectancy [1], are linked to repetitive daily acute stress (ie, short-term response to a perceived threat or challenge [2,3]). Stress can also have a profound impact on cognitive and emotional well-being. Advances in wearable technology enable affective and cognitive state measurements. Still, wearable devices can suffer from high attrition and low adoption, in general, and getting stable stress measurements “in the wild” (eg, heart rate variability [HRV] and electrodermal activity [EDA]) remains challenging.

Previous lab studies have shown that data from interactions with everyday devices, such as computer mouse movements, keyboard pressure, smartphone touch, and key swipes, or even the steering wheel of a car, can be used in an unobtrusive and scalable way to detect the presence of acute stress [4-8]. To the best of our knowledge, this paper presents the first work showing the feasibility of detecting acute stress from interactions with laptop computer trackpads.

There are several billion personal computing devices (PCDs) deployed in the world, and this number increases by around 300 million every year [9]. Laptops, or notebooks, represent the largest (42%) and the fastest-growing segment [9] among PCDs.

Most laptop users prefer the trackpad over an external mouse, for improved mobility or due to space limitations. Investigating biomechanics and motor control of finger dynamics during trackpad use can lead to reliable detection of acute stress, especially for long-term unobtrusive continuous monitoring. We propose two research questions (RQs):

1. RQ1: Can we assess differences between stress versus relaxation through changes in the damping ratio ( $\Gamma$ ) and damping frequency ( $\omega$ ) of a mass-spring-damper (MSD) model derived from finger strokes on a laptop trackpad, similar to our previous study on a computer mouse [4]?
2. RQ2: Are there differences between stress and relaxation in other metrics of finger dynamics, such as contact area, velocity, and acceleration, which are theoretically linked to muscle tension?

We conducted a within-subjects study (N=18) counterbalancing relaxed and stressed conditions. Subjects performed 40 trials each of three canonical computer tasks using a trackpad, namely, *clicking*, *steering*, and *drag and drop* (see Table 1 and Figure 1), similar to what Sun et al did with a computer mouse [4]. We focused our analyses on metrics derived from finger dynamics. Our results confirm a significantly higher mean and SD of the contact area under the finger for the tasks performed under stress compared to relaxed conditions, even among the initial 10% of the data (ie, 4 out of 40 *clicks*) from *clicking* trials. To the best of our knowledge, this is the first systematic study that links acute stress to finger strokes on the trackpad of a laptop device.

**Table 1.** Different task configurations by varying the distance and width parameters.

Task type	Distance by configuration, pixels					Width by configuration, pixels			
	1	2	3	4	5	1	2	3	4
Click	64	128	256	512	1024	8	16	32	64
Drag and drop	64	128	256	512	1024	16	32	64	128
Steer	64	128	256	512	1024	8	16	32	64

**Figure 1.** Computer tasks used in the study: (1) *click*, (2) *steer*, and (3) *drag and drop*. Different combinations of width (W) and distance (D) were randomly presented (see Table 1). In the *click* trials, subjects had to click anywhere on the blue rectangle first and then the yellow rectangle. In the *steer* trials, subjects had to hold down the left key and steer across the distance between the two rectangles. In the *drag-and-drop* trials, subjects had to click on the green rectangle, hold it, drag it, and then drop it over the red rectangle.

## Background

### Stress Measurements

Stress can be measured via self-reports or physiological signals. Self-reported stress (SRS) can be measured through the Perceived Stress Scale (PSS) [10,11]. Typically, a simplified version with a single 11-item scale of stress, ranging from 0 to 10, is used in repeated-measure studies [4,12]. Although subjective responses are commonly used, they are not precise and suffer from response bias and noncompliance [13], making them impractical for long-term monitoring.

Complementarily, physiological measurement of stress can be done by an indirect observation of the autonomic nervous system (ANS) signal [14]. A popular metric is EDA [15,16]. EDA, formerly known as the galvanic skin response, is a measurement of skin conductance due to the activation of the eccrine sweat glands, which are only innervated by the sympathetic nervous system (SNS). The SNS is one of the branches of the ANS linked to the “fight or flight” response, the coordinated response by the body organs to a threat signal (ie, stressor). High average levels and an increase in skin conductance responses (SCRs) (ie, the number of EDA peaks) are associated with stress [16]. Another popular measure is HRV, which is the measurement of the time variation between R-R peaks of an electrocardiogram (ECG) signal due to the sinusoidal arrhythmia [14]. EDA and ECG can be obtained in ambulatory settings using wearable devices. However, these sensors are obtrusive, leading to dropout, and are also affected by motion artifacts. In this paper, we validated our stressor with SRS and EDA.

### Links Between Stress, Motor Control, and Muscle Tension

Previous research suggests that hormones and neurotransmitters released during heightened stress arousal can influence motor output [17]. Noteboom et al [17] carried out a precision task that required a submaximal isometric pinch grip. Their research found that the steadiness in electromyography (EMG) activity in the first dorsal interosseous (FDI) muscle of the hand (see Figure 2), and the flexor digitorum superficialis muscle of the forearm, was increased during stress, especially in those with moderate anxiety trait compared to those with low anxiety trait. Laidlaw et al [18] measured the motor unit activity using intramuscular EMG recordings in the FDI during a pinch grip task. They concluded that increased variability of motor unit discharge is associated with reductions in steadiness. Coombes et al [19] showed that the force production in wrist and finger extensor muscles was increased during continuous exposure to unpleasant stimuli, compared to neutral stimuli, for a voluntary bimanual maximal isometric contraction task. Arnich et al [20] showed that nervous or anxious individuals have higher levels of movement variability while sitting (ie, a higher center of pressure dispersion on the seat). These studies provide evidence on how acute stress can influence variability while performing a motor task.

Additionally, various studies have shown that acute mental stress increases muscle tension in the neck, forehead, and arms [21-24]. The shoulder's trapezius muscle [25], as well as biceps and triceps [26], have shown direct changes due to mental arithmetic tasks. In this study, we used two types of biomechanical metrics: those that are influenced by changes in muscle tension and motor control variability due to stress.

**Figure 2.** Main muscles activated when using computer input devices: mouse and trackpad.

### ***Effects of Stress on the Manipulation of Computer Input Devices***

Sun et al [4] showed a direct correlation between stress, muscle tension, and movement of a computer mouse by approximating the mouse movement trajectories as a step response of an MSD system. They calculated the  $\Gamma$  and  $\omega$ , both of which were higher under stress. Hernandez et al showed a higher contact area with the surface of a capacitive mouse under stressful conditions compared to relaxed conditions [6]. Wahlstrom et al [27] showed that muscle activity in the right extensor digitorum (ED) and right trapezius muscles were greater in stressed situations evoked by time pressure and verbal provocation while working with a computer mouse. Carneiro et al [28] showed that acceleration and mean and maximum intensity (aka, pressure) of touch when interacting with touchscreen devices were higher under stressful conditions. While not the same as stress, Gao et al [7] showed that the velocity and contact area of the finger strokes during the *frustrated* state in comparison to the *relaxed* state were among the main features used in a machine learning (ML) prediction model of *frustration* during game-playing interactions on an iPod. To the best of our knowledge, there is no prior research on systematic stress detection using finger dynamics during laptop trackpad use.

### ***Biomechanics of Trackpad Versus Mouse Usage***

It is important to understand the biomechanical differences between trackpad and mouse use [29]. Direct comparisons between methods and metrics used with a computer mouse may not be feasible for a trackpad. Mouse use primarily triggers the large trapezius muscles for moving the entire arm leading to

horizontal and vertical movement of the cursor on the screen [29]. Although both mouse and trackpad movements use the ED muscle for *clicking*, trackpad displacement mainly involves the rather small FDI hand muscle [29]. Figure 2 shows the relative sizes of the muscles of the arm and hand.

In comparison to the trackpad, mouse use induces larger shoulder abduction and smaller elbow flexion [29]. Trackpad use requires a more static posture of the upper arm to maintain stabilization of the hand but a more rigorous movement of fingers [29]. Stress detection via an approximation of muscle tension [4] benefits from more muscle activity. However, the absolute level of muscle activity in the FDI during trackpad usage is low compared to that in the bigger trapezius muscle during computer mouse usage [29,30]. As a result, it could be hard to rely on muscle tension and stiffness to infer stress using trackpad versus mouse data [4,27].

## ***Methods***

### ***Subjects***

We recruited 22 subjects (10 males [45%] and 12 females [55%]), with ages ranging from 19 to 68 (mean 37, SD 16), not screened for preferences in using a computer mouse or trackpad. We eliminated 4 subjects for whom our stressor did not have any effect on SRS, leaving a total of 18 subjects (8 males [44%] and 10 females [56%]). Of the remaining 18 subjects, 11 (61%) reported using a computer mouse and 9 (50%) reported using a laptop trackpad daily. The mean self-reported daily usage duration of the laptop trackpad (mean 2.6, SD 3.1 hours) was significantly lower ( $t_{17}=2.1$ ,  $P=.03$ ) than that of the computer

mouse (mean 5.2, SD 3.1 hours). Subjects provided written informed consent before participation and were given US \$20 gift cards for their participation. The study was approved by the Institutional Review Board of Stanford University.

### Apparatus

The experiment was performed in an office setting without any distractions. We used a 15-inch 2015 MacBook Pro (Apple Inc) (see Figure 3) equipped with a 140×70-mm Force Touch trackpad with sensitivity preset to a default value of 1.0. An

overhead camera captured hand movement, and our logging software captured trackpad and cursor activity. The logger was implemented in C and Swift (Apple Inc) using Apple's *MultiTouchSupport* framework. It recorded coordinates rounded to the nearest hundredth of a millimeter with an average sampling rate of 8.17 milliseconds (SD 3.75), multiple finger touches marked with ID numbers, contact shape under the finger (ie, major and minor axes of the ellipse), interaction type (ie, touching, dragging, etc), and pressed state (ie, active or inactive).

**Figure 3.** Apparatus: a 15-inch 2015 MacBook Pro (Apple Inc) with a passive movement logger teamed with an overhead camera for the ancillary recording of hand movement.

### Stimuli

The stimuli consisted of *Relaxation* and *Stressor* phases replicated from prior studies [4,5]. During the *Relaxation* phase, we instructed subjects to breathe deeply while viewing a soothing video, which is recommended over doing nothing [31]. The acute *Stressor* phase consisted of an arithmetic cognitive stressor combined with social evaluation (ie, the presence of an experimenter continuously observing and correcting if the subject made a mistake), derived from the Trier Social Stress Test [32], and enhanced with a biased financial stimulus. The test required subjects to perform a series of subtractions out loud (eg, subtract 13 from 2017, and so forth) under the scrutiny

of the experimenter. If the subject made a mistake, or if he or she took more than four seconds to respond, the experimenter asked the subject to start again from 2017. The subject was offered an additional US \$1 for every 10 consecutive arithmetic operations performed correctly, but only US \$1 was to be deducted for each mistake. All subjects made mistakes that made them “lose” money, but after debriefing, they all received full compensation. The financial part of the stimulus based on performance could have been more frustrating than stressful for some subjects. However, it was added, as was done in our previous study [4], since frustration can further exacerbate acute stress.

## Experimental Tasks

All subjects performed three types of tasks—*click*, *steer*, and *drag and drop* (see Figure 1)—as in our previous study using the computer mouse [4]. Five different distance (D) and four different width (W) configurations were used for each of the three task types, resulting in a total of 20 configurations per

task (see Table 1) [4]. Users performed two trials per configuration within each task type (see Figure 4). Tasks of the same type were grouped to prevent performance differences due to subjects needing to adjust to different task types. In total, each experimental condition, *tStressed* (stressed task) and *tRelaxed* (relaxed task), had 120 trials (3 task types × 40 trials).

**Figure 4.** Example of distribution of different task types across different subjects.

Subject No.	Task Type 1	Task Type 2	Task Type 3
A1	Click1, Click2, ....., Click40	Drag1, Drag2, ....., Drag40	Steer1, Steer2, ....., Steer40
A2	Drag1, Drag2, ....., Drag40	Steer1, Steer2, ....., Steer40	Click1, Click2, ....., Click40
⋮			
B9	Steer1, Steer2, ....., Steer40	Click1, Click2, ....., Click40	Drag1, Drag2, ....., Drag40

## Experimental Design

### Testing Procedure

The experiment consisted of four distinct phases (see Figure 5):

1. *Baselining and Relaxation*: a 5-minute phase designed to normalize the effects of any stressors, including any external factors, and to bring the subject to a baseline level.
2. *tRelaxed*: an approximately 7-minute phase (mean 6.8, SD 1.7 minutes) during which subjects were instructed to perform the randomized tasks—*click*, *drag and drop*, and *steer* (see Figure 1)—as quickly and accurately as possible.
3. *Stressor*: a 5-minute stress-inducing phase.

4. *tStressed*: an approximately 7-minute phase (mean 6.8, SD 1.5 minutes) during which subjects were instructed to perform the randomized tasks—*click*, *drag and drop*, and *steer* (see Figure 1)—as quickly and accurately as possible.

The 18 subjects were assigned to one of the two counterbalanced arms: *Relax-Stress* (3 males [17%] and 5 females [28%]) and *Stress-Relax* (5 males [28%] and 5 females [28%]) (see Figure 5). The *Stress-Relax* arm required an additional baselining phase, before *tRelaxed*, to normalize the effects of external factors. Subjects wore an E4 wristband (Empatica Inc) to measure EDA in their nondominant hand and provided perceived self-reported *stress*, *tension*, and *concentration* levels on a scale of 0-10, before and after each phase (see Figure 5).

**Figure 5.** Study procedure with (A) *Relax-Stress* and (B) *Stress-Relax* counterbalanced arms. The *Relax* part is shown with a green transparent box and the *Stress* part is shown with a red transparent box. Data were collected at self-report marker (SR) time points 0-5. \*For the *Stress-Relax* arm, before the stressor phase, a baselining phase was carried out to normalize the effects of external factors. *tRelaxed*: relaxed task; *tStressed*: stressed task.

## Data Processing

### Self-Report and Ancillary Data

SRS was assessed using a simplified version of the PSS [11], an 11-point scale question—“What is your current level of stress?” where responses ranged from *Low* (0) to *High*

(10)—immediately after completion of each phase (see Figure 5). To verify that the stressor did not induce cognitive alterations, we assessed perceived *concentration*, ranging from *Low* (0) to *High* (10), and measured *trial completion time*. Finally, we captured ancillary data on perceived muscle *tension*, ranging from *None* (0) to *High* (10). Self-report markers (SRs)

in Figure 5 show the time points during the experiment where these data were collected. To estimate the self-reported metrics *during* any phase, the before and after values were averaged for that phase. For example, the average of SR4 and SR5 values for stress for subjects in arm A (see Figure 5) gave us an estimate of the SRS value *during* the *tStressed* phase.

All self-reported metrics were min-max normalized across the four phases—*Relaxation*, *Stressor*, *tRelaxed*, and *tStressed*—unless stated otherwise. For normally distributed data, where the Shapiro-Wilk test was not significant, we applied a 1-tailed paired *t* test. Otherwise, we applied a 1-tailed Wilcoxon signed-rank test. We used 1-sided comparisons, as we had prior knowledge about the expected direction of changes in the different metrics, and the stressor task we used has already been shown to be effective in inducing stress in prior studies [4,5,32]. Effect sizes (Cohen *d*) are provided for within-group changes for primary measures, where Cohen *d* values between 0.20 and 0.49 indicate a small effect, values between 0.50 and 0.79 indicate a medium effect, and values of 0.80 and above indicate a large effect [33]. For any bivariate correlations, we used the Pearson correlation coefficient for normally distributed data; otherwise, we used Spearman rho.

Out of 22 subjects, 4 (18%) showed no change in SRS across the two extreme phases—*Stressor* and *Relaxation*—and were excluded from all analyses, leaving a working set of 18 subjects.

### EDA Processing

We eliminated 3 of the 18 subjects (17%) before the analysis, leaving a total of 15 subjects (83%) for EDA analysis: 1 subject did not have a signal due to loose contact, another had an anomalous signal above 20  $\mu$ S [34], and 1 had more than 5% noisy 5-second epochs estimated with the *EDA Explorer* [35]. For the remaining 15 subjects, EDA signals were filtered using a 6th-order 1-Hz low-pass Butterworth filter [36]. Then, using Ledalab, version 3.2.5 [37], we obtained the tonic mean, phasic

mean, and the number of SCR peaks with an amplitude above 0.01  $\mu$ S. Only data from *tRelaxed* and *tStressed* phases were considered for the EDA analyses.

### RQ1: MSD Model Evaluation

We modeled trackpad finger trajectories using a linear predictive coding (LPC) inverse filtering technique [38] as in Sun et al, who successfully modeled the arm movement as an approximation of a step response of a single-degree-of-freedom MSD system [4]. The LPC approximation for the MSD model has been used in several other studies, like in our previous work using steering wheel data [5] and also by Guo et al [39], using data from touchpad interactions. However, unlike mouse movements, which are primarily continuous and more standardized across subjects, there are many quirks in the way different individuals interact with the trackpad. Since subjects were given the freedom to use the trackpad as normally as possible, we observed that 17 out of 18 subjects (94%) used multiple fingers from their dominant hand, and/or used fingers from both hands (see Figure 6), creating many discontinuities in the finger strokes during each trial (see Figure 7). Across all subjects, a mean of 38.0% (SD 13.9) of the trials had at least one gap in the continuity of the finger stroke because subjects either used multiple hands (see Figure 6, A), multiple fingers (see Figure 6, B), or even the same finger, but the finger hovered on the trackpad. We used our ancillary videos to observe this behavior, as it was impossible to use logger data alone to verify that the subject used the same finger multiple times or separate fingers during one trial.

We identify gaps (see Figure 7, A) by searching for large variations in x or y coordinates and keeping points that represented the largest continuous movement of the underlying stroke (see Figure 7, B—green trace). We fitted an approximation to the MSD model [4] to this stroke and extracted  $\Gamma$  and  $\omega$  for the horizontal x-direction, which contained most of the displacement information for our tasks.

**Figure 6.** (A) multiple hands or (B) multiple fingers being used while interacting with the trackpad.

**Figure 7.** Example traces from a *click* trial. (A) Multiple traces at the same time (see between 4.6 and 5.0 seconds) suggests the use of multiple fingers from the same or different hands at the same time. The gap between 5.70 and 5.75 seconds indicates that the subject lifted his or her finger and then placed the same or another finger back. (B) Identifying the largest stroke (green trace) and other ancillary strokes due to the use of different fingers (orange and red traces). X represents the horizontal movement on the trackpad.

## RQ2: Measurements of Finger Dynamics From Trackpad Interactions

Under stress, wrist and forearm muscles present changes in mean force production [19] and motor control variability [17]. Therefore, we measured mean and SD values for three typical finger dynamics measurements: velocity, acceleration, and contact area under the finger. We kept all strokes and sub-strokes for every trial by identifying the gaps between partial movements (see Figure 7, B) and averaged their metrics for each trial. We estimated the contact area of the ellipse ( $\pi \times a \times b$ ) between the finger and the trackpad using the major axis (a) and minor axis (b) provided by the logger. We calculated finger velocity by differentiating position information and finger acceleration by differentiating velocity information. We used only horizontal (x-direction) displacement data, which contained most of the information for our tasks.

## Statistical Modeling and Sensitivity Analysis

First, we evaluated a *Mixed Task* omnibus model independent of specific task types—*click*, *drag and drop*, and *steer*—and task configurations ( $W \times D$ ). Values for each task type were obtained by averaging across all configurations and repetitions (ie, 40 trials) for each of the *tStressed* and *tRelaxed* phases for each subject. Then, a single value for each *tStressed* and *tRelaxed* phase was obtained after averaging across all three task types for each subject. Variables with significant differences across the *tStressed* and *tRelaxed* phases in the *Mixed Task* model were further examined using *Task-Specific* models. To

avoid inflation, we applied Bonferroni correction ( $0.05/3 = 0.017$ ) for *Task-Specific* models. Finally, for the type of task with the most significant difference, we applied a sensitivity analysis comparing the *initial* 10% (ie, 4 trials out of 40) of data across the *tStressed* and *tRelaxed* phases. We also carried out post hoc power ( $\beta$ ) analyses on all finger dynamics measures that were found to be significant. Additionally, to check if the order of stress-relax condition has any effect, we investigated the *Order* (ie, A vs B; see Figure 5)  $\times$  *Condition* (ie, stress vs relax) interaction effect using analyses of variance on all finger dynamics measures that were found to be significant.

## Results

### Mental Stress Validation

#### SRS and Tension Metrics

On average, the SRS was significantly higher during the *Stressor* phase (mean 0.56, SE 0.04) compared to the *Relaxation* phase (mean 0.15, SE 0.03) ( $Z_{17}=3.72$ ,  $P<.001$ ). The SRS was also significantly higher during the *tStressed* phase (mean 0.72, SE 0.03) compared to the *tRelaxed* phase (mean 0.23, SE 0.04) ( $t_{17}=13.06$ ,  $P<.001$ ). Figure 8 shows a comparison of min-max normalized SRS values for the four phases of the experiment. Table 2 shows the average raw SRS values at the end of the *Relaxation*, *tRelaxed*, *Stressor*, and *tStressed* phases. It can be observed that SRS levels go down over time during the *tStressed* phase.

**Figure 8.** Levels of min-max normalized self-reported stress. Error bars represent SE. *tSRelaxed*: relaxed task; *tStressed*: stressed task.**Table 2.** Average raw self-reported stress values across all subjects at the end of different phases.

Time point	Mean (SE)
End of <i>Relaxation</i> phase	2.27 (0.42)
End of <i>tRelaxed</i> <sup>a</sup> phase	3.78 (0.42)
End of <i>Stressor</i> phase	6.22 (0.61)
End of <i>tStressed</i> <sup>b</sup> phase	4.50 (0.42)

<sup>a</sup>*tRelaxed*: relaxed task.<sup>b</sup>*tStressed*: stressed task.

In addition to SRS, we found that the perceived *tension* was significantly higher *during Stressor* (mean 0.52, SE 0.05) versus *Relaxation* (mean 0.09, SE 0.02) ( $Z_{17}=3.59$ ,  $P<.001$ ) phases and *during tStressed* (mean 0.78, SE 0.03) versus *tRelaxed* (mean 0.29, SE 0.04) ( $t_{17}=11.79$ ,  $P<.001$ ) phases. Furthermore, perceived *tension* and SRS were highly correlated ( $r=.74$ ,  $P<.001$ ).

No statistical differences ( $t_{17}=0.58$ ,  $P=.29$ ) were observed for *trial completion time* between *tRelaxed* (mean 2.04, SE 0.14 seconds) and *tStressed* (mean 2.10, SE 0.13 seconds). Additionally, we found no statistically significant differences for perceived *concentration* *during Stressor* versus *Relaxation* phases ( $Z_{17}=1.46$ ,  $P=.07$ ), and *tStressed* versus *tRelaxed* phases ( $Z_{17}=0.56$ ,  $P=.28$ ). This shows that our stressor elicited an affective response as opposed to a response due to changes in cognitive performance.

### Physiological Stress

All metrics for EDA were significantly higher. Mean phasic EDA *during tStressed* (mean 0.040, SE 0.015 S) compared to *tRelaxed* (mean 0.020, SE 0.006 S) was higher ( $Z_{14}=2.33$ ,  $P<.01$ ); mean tonic EDA *during tStressed* (mean 4.223, SE 1.389 S) compared to *tRelaxed* (mean 2.057, SE 0.806 S) was

higher ( $Z_{14}=3.181$ ,  $P<.001$ ); and the number of EDA *peaks* (ie, SCR events) *during tStressed* (mean 68.2, SE 16.9) compared to *tRelaxed* (mean 40.4, SE 11.7) was higher as well ( $Z_{14}=2.86$ ,  $P<.01$ ).

Overall, both SRS and EDA evaluations showed that our stressor was effective in inducing acute stress, as planned.

### Trackpad Interactions

#### Mixed Task Models

Both the mean and SD of contact area under the finger were significantly different between *tRelaxed* and *tStressed* phases with large effect sizes (Cohen  $d>0.8$ ) and large post hoc power ( $\beta>97\%$ ) (see Table 3). The mean and SD of velocity and acceleration, as well as the two LPC-approximated biomechanical MSD parameters ( $\Gamma$  and  $\omega$ ), were not significantly different. Paired *t* tests were carried out for all these measures except for  $\Gamma$ , for which a Wilcoxon signed-rank test was carried out. For mean contact area, the *Order*  $\times$  *Condition* interaction effect was not significant ( $F_{1,32}=1.87$ ,  $P=.18$ ). However, for the SD of contact area, the interaction effect was significant ( $F_{1,32}=11.17$ ,  $P<.01$ ), suggesting that the *Order* of the conditions did have a significant effect on the overall SD of the contact area across the two *Conditions*.

**Table 3.** Summary of descriptive statistics between *tRelaxed* and *tStressed* phases for the Mixed Task model.

Measure	<i>tRelaxed</i> <sup>a</sup> , mean (SE)	<i>tStressed</i> <sup>b</sup> , mean (SE)	<i>t</i> test (17)	Z test (17)	<i>P</i> value	Cohen <i>d</i>
<b>Normalized velocity</b>						
Mean	0.47 (0.16)	0.49 (0.12)	0.50	N/A <sup>c</sup>	.31	0.15
SD	0.39 (0.14)	0.47 (0.20)	1.42	N/A	.09	0.48
<b>Normalized acceleration</b>						
Mean	0.35 (0.15)	0.43 (0.18)	1.36	N/A	.10	0.49
SD	0.31 (0.17)	0.42 (0.17)	1.54	N/A	.07	0.64
<b>Normalized area</b>						
Mean	0.40 (0.18)	0.55 (0.16)	2.18	N/A	.02 <sup>d</sup>	0.87
SD	0.39 (0.17)	0.53 (0.13)	2.08	N/A	.03	0.92
<b>Mass-spring-damper model</b>						
$\Gamma$ (damping ratio)	0.538 (0.007)	0.540 (0.006)	N/A	0.11	.46	0.09
$\omega$ (damping frequency) (rad/s)	0.256 (0.006)	0.261 (0.005)	1.21	N/A	.12	0.17

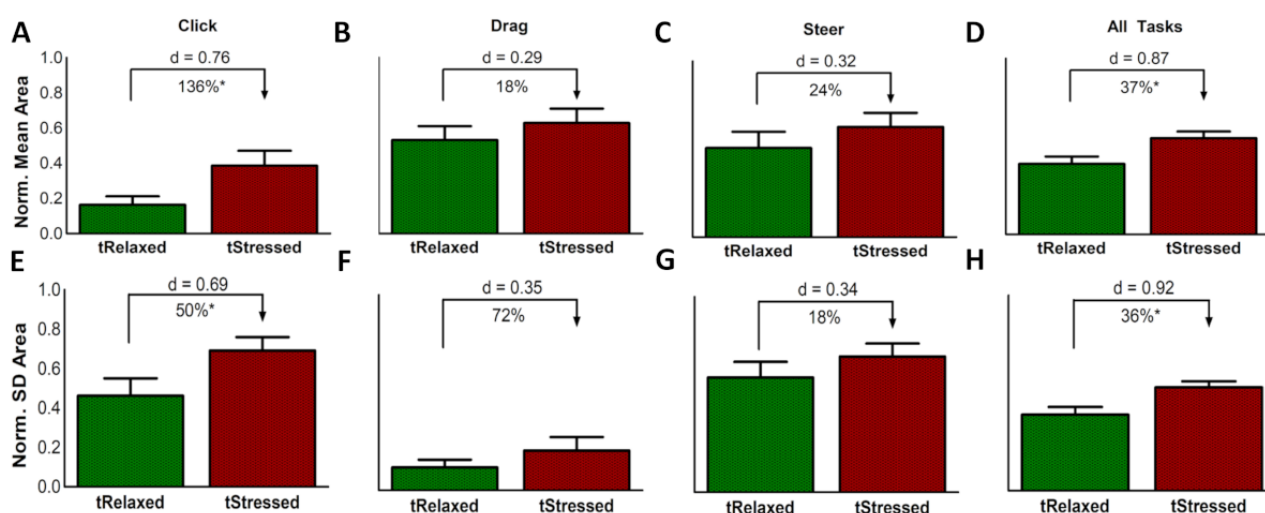

<sup>a</sup>*tRelaxed*: relaxed task.<sup>b</sup>*tStressed*: stressed task.<sup>c</sup>N/A: not applicable.<sup>d</sup>Italicized values indicate significance ( $P < .05$ ).

### Task-Specific Models

Task-Specific models for mean and SD of the contact area under the finger (see Figure 9) were performed for all three task types. Significant differences ( $P < .02$ ) between *tStressed* and *tRelaxed*

were observed for *click* tasks only, both for mean area ( $Z_{17}=2.37$ ,  $P=.009$ ,  $\beta=91\%$ ) and for SD of the area ( $Z_{17}=2.33$ ,  $P=.01$ ,  $\beta=86\%$ ). Overall, *click* tasks (see Figure 9, A and E) show large percentage differences between *tRelaxed* and *tStressed* phases.

**Figure 9.** Bar plots (Mean  $\pm$  SE), effect size (Cohen *d*), and the percentage difference between *tRelaxed* (relaxed task) and *tStressed* (stressed task) phases of (A, E) *click*, (B, F) *drag*, (C, G) *steer* tasks, and overall combining (D, H) *All Tasks* (Mixed Task model) for both mean and SD of contact area, respectively. (\*) for click indicates  $P < .05/3 = .017$  (Bonferroni correction), and (\*) for *All Tasks* indicates  $P < .05$ .

The interaction effects for mean and SD of contact area during *click* tasks were not significant (mean area:  $F_{1,32}=0.00$ ,  $P=.98$ ; SD area:  $F_{1,32}=1.39$ ,  $P=.25$ ). We also evaluated the interaction effects for SD of the contact area for *drag* and *drop* ( $F_{1,32}=1.82$ ,  $P=.19$ ) and *steer* ( $F_{1,32}=4.48$ ,  $P=.04$ ), the latter of which was significant, suggesting that the significant interaction in SD of the contact area variable in the Mixed Task model (see the Mixed Task Models section) is mainly due to significant interaction

effect only in *steer* task trials. Overall, our results suggest that finger dynamics from *click* tasks alone, which are the most common computer interactions (see Discussion section), and are unaffected by *Order* effects, can be used as robust measurements to detect acute stress.

## Sensitivity Analyses

### Data Reduction

In this section, we focus on *click* data, which was the only task type contributing to the overall differences in the *Mixed Task* model. We started looking for data closest to the stressor (ie, the *initial* 10% [4 *clicks* out of 40]), and we intended to explore bigger segments (ie, 20%, 30%, etc) in case we did not find a signal sufficient to detect acute stress across the two conditions.

To our surprise, with only 4 *clicks*, we could see a significant difference across the two phases (see [Table 4](#)). This result may be because the effect of the stressor is higher earlier during the *tStressed* phase, and it decays over time (see [Table 2](#)). Similar sensitivity results have been observed in other biomechanical models of stress [5]. Neither of the two variables mentioned in [Table 4](#) showed any significant interaction effect (mean area:  $F_{1,32}=0.00$ ,  $P=.99$ ; SD area:  $F_{1,32}=0.50$ ,  $P=.49$ ), which reconfirms that *click* tasks are not influenced by *Order* effects.

**Table 4.** Summary of descriptive statistics between *tRelaxed* and *tStressed* phases pertaining to only the initial 10% of click trials.

Measure	No. of <i>clicks</i> (N=40), n (%)	<i>tRelaxed</i> <sup>a</sup> , mean (SE)	<i>tStressed</i> <sup>b</sup> , mean (SE)	<i>t</i> test (17)	<i>P</i> value	Cohen <i>d</i>	$\beta$ , %
Mean area (mm <sup>2</sup> )	4 (10)	270.9 (6.3)	284.6 (8.1)	2.81	<.01 <sup>c</sup>	0.44	56
SD area (mm <sup>2</sup> )	4 (10)	16.7 (1.6)	21.2 (1.3)	2.88	<.01	0.73	91

<sup>a</sup>*tRelaxed*: relaxed task.

<sup>b</sup>*tStressed*: stressed task.

<sup>c</sup>Italicized values indicate significance ( $P<.05$ ).

### Click Rate Manipulation

Our original manipulation generated *click* trials at a rate of roughly 1 *click* per 3.5 seconds: 40 *click* trials were completed in an average of 136 seconds (SD 31). To create a scenario in which the *clicks* are obtained at a slower rate, which could also be plausible in the wild, we tested the artificially slowest rate by decimating the samples, using only 10% of the data distributed across the entire range of the production of the *click* trials. We picked the first, the last, and 2 random *click* trials from 1 to 40, in this way simulating a scenario in which *clicks* are generated once every ~45 seconds. As it turns out, both area measures were still significantly different across two stress conditions. The mean of the mean area for *tStressed* was 277 mm<sup>2</sup> (SE 8.61) and for *tRelaxed* was 267 mm<sup>2</sup> (SE 6.4) ( $t_{17}=2.07$ ,  $P=.03$ ,  $d=0.32$ ,  $\beta=37\%$ ). The mean of the SD area for *tStressed* was 22 mm<sup>2</sup> (SE 1.8) and for *tRelaxed* was 18 mm<sup>2</sup> (SE 1.5) ( $t_{17}=1.86$ ,  $P=.04$ ,  $d=0.54$ ,  $\beta=71\%$ ). Further, no significant interaction effect was found for either of these two measures as well (mean area:  $F_{1,32}=0.14$ ,  $P=.72$ ; SD area:  $F_{1,32}=1.98$ ,  $P=.17$ ).

### Individual Differences

When looking at individual differences for all tasks, 12 out of 18 (67%) participants showed an expected increase in either the mean or the SD of the area under the finger. For the initial 10% (ie, 4 out of 40 *clicks*), 13 out of 18 (72%) subjects had changes in the expected direction for either mean or SD (see [Figure 10](#)). Participants A1, A4, B10, B1, and B3 showed an opposite trend for the mean area (see [Figure 10, A](#)), while participants A10, A2, A5, B3, and B7 showed an opposite trend for SD area (see [Figure 10, B](#)). Subject B3 showed an opposite trend for both measures. If we were to consider a hard evaluation where both metrics must occur at the same time, we would see 11 out of 18 (61%) subjects satisfying the expected change. However, if we were to detect stress whenever either of the two measures has the right trend, we would detect stress changes in 17 out of 18 (94%) subjects. This latter approach is plausible, as both measurements are theoretically linked to changes in either muscle tension or motor control alterations due to stress (see section RQ2: Measurements of Finger Dynamics From Trackpad Interactions).

**Figure 10.** Individual differences for (A) mean and (B) SD of the contact area under the finger across the initial 10% of the *click* trials. *tRelaxed*: relaxed task; *tStressed*: stressed task.

## Discussion

### Principal Findings

Enabling precision health and effective stress management regimes are dependent on the evolution of ubiquitous real-time stress sensors and algorithms. An ideal scenario would be to passively obtain data from everyday use devices, rather than having people wear sensors or answer survey questions. In this study, we aim at assessing the feasibility of using passively obtained laptop trackpad data to detect acute stress. We present evidence that binary levels of acute stress (ie, whether it is present or not) can be detected from finger strokes alone.

In response to RQ1, we found out that our approximation to an MSD model, previously used with data from the computer mouse [4], cannot be used directly on trackpad data. Our analyses provide new insights into the complexity of the use of finger stroke data from trackpad operations for applying an MSD model. Unlike a computer mouse, handling a laptop trackpad is subject dependent. Some people may employ multiple hands and/or multiple fingers to perform the same tasks. This creates challenges to process the data due to the gaps present in the strokes and the difficulty of obtaining a clean intentional segment of data, with a clear *beginning* and *end*, required to get meaningful MSD results. These limitations leave little useful data for analysis, and we did not observe a difference in either of the two MSD parameters ( $\omega$  and  $\Gamma$ ) between the *tRelaxed* versus *tStressed* phases. However, our analyses were restricted to the largest stroke per trial. It is possible that in the wild, where we can collect larger amounts of data that would allow us to extract valid displacement segments, an MSD approach may still be useful to assess changes due to muscle tension under acute stress.

Our RQ2's results are encouraging, showing the robustness of the mean and SD of the finger contact area as a stress sensor. Both metrics were higher during the *stressed* tasks as compared to the *relaxed* tasks. We show that as few as 4 *click* trials per subject are sufficient to see a significant difference, which is promising for longitudinal studies. Overall, we present evidence of the use of the finger contact area from laptop trackpad measurements to detect acute stress while performing common computer tasks.

### Acute Stress Detected Using Click Finger Dynamics

This is the first study showing that the mean and SD of the contact area under the finger on a trackpad are higher under stress compared to a relaxed state (ie, *Mixed Task* model). Theoretically, the mean value is related to mean force production [19] and higher variability [17] under stressful situations in the wrist and forearm muscles. There may be other underlying mechanisms (eg, changes in hand or body posture [40]) through which stress may influence finger dynamics, and future studies should monitor those variables as well. In the *Task-Specific* model, differences in mean and SD of the contact area under the finger were different for *click* trials. If combined, mean *or* SD, we could detect up to 94% of acute stress events. This is encouraging because *clicking* tasks represent nearly 70% of all computer mouse events in a typical day [41].

With just the initial 10% of *clicking* trials (ie, 4 *clicks* out of 40), we could still see small and medium effect size differences in mean and SD of the contact area under the finger. Since *click* trials were not always carried out right after the stressor, the difference is not due to ordering effects; here we are referring to ordering of *click*, *steer*, and *drag and drop*, and not the ordering of *stress-relax* conditions. We attribute the strength of using so little data to the proximity to the stressor, as there is a clear decay of stress over time, which would clearly affect values averaged over longer periods. Furthermore, we simulated a scenario where *clicks* are produced at a different rate (ie, going from 1 *click* produced every ~3.5 seconds to every ~45 seconds). We obtained significant results even for the lowest *click* productivity we could simulate with our data (1 *click*/45 s). In a separate pilot study, collecting computer mouse data “in the wild,” we have seen that a typical user may generate a *click* every 10-30 seconds, and at least 1000 *clicks* are generated in any given working day. Thus, we feel confident we can use our findings as the basis for a passive, continuous, scalable, inexpensive, and unobtrusive stress sensor. In the wild, of course, changes in muscle tension would not only be due to affective (ie, ANS) processes but also due to cognitive processes (see Potential Interaction Effects With Task Performance section). Ultimately, a reliable “in the wild” stress detection system would have to combine multiple modalities, such as biomechanical, behavioral, and physiological sensors, as well as contextual information.

### Potential Interaction Effects With Task Performance

Mean and SD of finger velocity and acceleration were similar across the two phases, as well as *trial completion time*. This reconfirms that our stressor did not change the cognitive performance of the subjects but only their affective state. However, the relationships between stress, velocity, and acceleration may not be simple. For example, one may say that under a stressful situation, a user may want to move the fingers with higher velocity and/or acceleration; however, after a certain point, it will also start affecting the accuracy of this fine motor control task [42]. Thus, the user may not use higher velocities and/or acceleration under stress. Further studies with different elicitations to modify the performance rewards must be performed to observe interaction effects between these variables.

### Contrasting With Other Touch Technologies

At least two studies have shown higher finger pressure under stress [28] and under frustrating [7] conditions while using touchscreen devices. However, the usage and handling of touchscreen devices are not the same as that of a trackpad, in terms of fine and precise interaction [43]. The capacitive technologies used in touchscreens and trackpads are different in terms of how much pressure needs to be applied: typically, the trackpad requires stronger pressure [43]. Additional research would be needed to determine if our finger dynamics from contact area (ie, mean and SD) can be translated to other types of touch-sensitive devices.

### Limitations

Our study has four limitations related to sample size, stressor effect size, apparatus, and assumptions for modeling. First,

because of the small sample size ( $N=18$ ) we could not investigate the effects of age, gender, length of experience with trackpads, and frequency of day-to-day usage of trackpads. We also could not build reliable predictive models (eg, using different ML techniques), which could parse out the importance of various features in predicting acute stress. Second, given the mild nature of the stressor, not all users (18/22, 82%) responded to our manipulation. Nevertheless, this level of efficacy is expected for a mild stressor and in line with our prior study [6]. Third, although we do not expect the behavior of users to be fundamentally different across different laptops, our experiment should be revalidated on other models of trackpads. Fourth, using finger contact area as a proxy to pressure assumes a linear relationship between the two. However, factors like the angle of the finger can also influence this relationship. Since the time of the data collection for this study, Apple has updated the *MultiTouchSupport* framework, and it now also provides information about pressure and capacitance density underneath the fingers. Additional models collecting this new data would be quite useful to strengthen the precision of our detection method further.

### Future Directions

We plan to expand current results by running lab experiments with larger sample sizes; by logging other actions performed using trackpads, such as scrolling and multiple finger gestures; and by collecting other behavioral metrics, such as *click* production rate, the timing between *clicks*, etc. Once we collect more data, both in the laboratory settings and “in the wild,” we aim at building predictive models that include both biomechanical and behavioral metrics to increase the accuracy and specificity of stress prediction in real time.

As we move out of the lab, we will explore ways to carry out longitudinal studies collecting data from our passive loggers across devices (ie, mice, trackpads, touchpads), contextual data, and stress “labels” obtained from empirical sampling methods or physiological measurements. As we accumulate richer and bigger datasets, we plan to investigate data-intensive unsupervised and supervised ML methods to optimize data collection, preprocessing, and prediction. For example, we plan to investigate algorithms to parse types of events and movements (eg, *clicks*, *drag and drop*, etc) or to select segments that may have the right morphology to derive biomechanical features (eg, MSD parameters, contact area, etc). Ultimately, we hope that our lab and field findings can help select the appropriate behavioral, biomechanical, contextual, and perceptual features (ie, feature engineering) to train ML systems to be able to detect stress levels throughout the day.

### Conclusions

The current methods for sensing stress are often inconvenient, expensive, or suffer from limited adherence. In this lab study, we show the efficacy of repurposing signals from a laptop trackpad to detect acute mental stress. We showed that with a handful of *click* events, we could use the mean and SD of the finger contact area to obtain a binary estimation of acute stress (ie, whether it is present or not). We validated our sensing models against well-known stress metrics such as self-reports and EDA. Complementarily, we validated that we did not elicit performance or cognitive confounds that may affect our affective stress elicitation. These results provide a firm baseline toward our future goal of deploying our algorithms in the wild, leveraging the trackpad as a potential unobtrusive, scalable, continuous, and inexpensive stress sensor.

### Acknowledgments

We appreciate the financial support provided by the late Prof Sam Gambhir, the Precision Health and Integrated Diagnostics Center, Prof Sarah L Billington, and Prof James A Landay, as well as the advice provided by Dr Jean Costa. [Figure 2](#) was licensed from QA International, science photo library, and labels were added to the four muscles.

### Conflicts of Interest

None declared.

## Abstract

**Background:** Screening for influenza in primary care is challenging due to the low sensitivity of rapid antigen tests and the lack of proper screening tests.

**Objective:** The aim of this study was to develop a machine learning-based screening tool using patient-generated health data (PGHD) obtained from a mobile health (mHealth) app.

**Methods:** We trained a deep learning model based on a gated recurrent unit to screen influenza using PGHD, including each patient's fever pattern and drug administration records. We used meteorological data and app-based surveillance of the weekly number of patients with influenza. We defined a single episode as the set of consecutive days, including the day the user was diagnosed with influenza or another disease. Any record a user entered 24 hours after his or her last record was considered to be the start of a new episode. Each episode contained data on the user's age, gender, weight, and at least one body temperature record. The total number of episodes was 6657. Of these, there were 3326 episodes within which influenza was diagnosed. We divided these episodes into 80% training sets (2664/3330) and 20% test sets (666/3330). A 5-fold cross-validation was used on the training set.

**Results:** We achieved reliable performance with an accuracy of 82%, a sensitivity of 84%, and a specificity of 80% in the test set. After the effect of each input variable was evaluated, app-based surveillance was observed to be the most influential variable. The correlation between the duration of input data and performance was not statistically significant ( $P=.09$ ).

**Conclusions:** These findings suggest that PGHD from an mHealth app could be a complementary tool for influenza screening. In addition, PGHD, along with traditional clinical data, could be used to improve health conditions.

## Introduction

With the increasing popularity of mobile health (mHealth), a considerable amount of health-related data are now generated and accumulated outside of hospitals [1-3]. These health-related

data cover a wide range of quantitative variables, such as physical activity, blood glucose levels, blood pressure, heart rate/rhythm, and oxygen saturation along with a range of qualitative data, such as mood-related symptoms, food intake, medication use, and sleep patterns. Even data from social media posts or search engine queries may be included [4]. These kinds

of health-related data are categorized as patient-generated health data (PGHD) and defined by the Office of the National Coordinator for Health Information Technology as “health-related data—including health history, symptoms, biometric data, treatment history, lifestyle choices, and other information—created, recorded, gathered, or inferred by or from patients or their designees (i.e., care partners or those who assist them) to help address a health concern” [5].

Many studies have shown that PGHD have various potential benefits for health care. For example, PGHD may help patients with chronic diseases like diabetes or hypertension take better care of themselves by delivering continuous monitoring and support with more personalized treatment planning [6-9]. PGHD are also beneficial for remote monitoring of patients’ postsurgical pain or chronic pain and have been found to more accurately assess the psychoemotional status of patients [10-12]. Another example of PGHD use is forecasting contagious diseases. Some research has shown that influenza [13-15] and Middle East respiratory syndrome (MERS) [16] outbreaks could be predicted using search engine query data, including Google Flu Trends and social media posts. In addition to these indirect methods, a website or smartphone app through which patients directly report their symptoms can also be used to detect epidemics [17,18].

Although influenza outbreaks can be predicted using PGHD, the diagnosis or screening of individual patients has been conducted using traditional medical devices, such as the rapid influenza antigen test or reverse transcription–polymerase chain reaction (RT-PCR). The rapid influenza diagnostic test (RIDT) has mainly been used as a diagnostic test because of its reduced processing time and easy accessibility [19]. However, due to the low sensitivity of the RIDT, it is insufficient to serve as a screening test for influenza [20-22]. Due to this concern, influenza treatment with antiviral medication has been prescribed for suspected influenza cases, based on clinical judgment, even when the RIDT showed a negative result. Influenza-like illness (ILI) case definition is one of the symptom-based screening methods of suspected cases, but it has been reported to have limited sensitivity despite its loss of substantial specificity [23].

Fever is regarded as the most distinctive symptom of influenza. Due to the lack of other distinguishable symptoms, it can be challenging to differentiate influenza from other diseases [24,25]. Recently, deep learning approaches have been reported to exceed classical statistical methods for predicting the outcomes of an individual patient using time series data, such as inpatient data [23,26]. In this study, we propose a deep learning method for influenza screening by combining epidemiological information and PGHD from an mHealth app. These results were then compared with the patients’ diagnostic findings.

## Methods

### Data Collection

We retrospectively collected log data from the Fever Coach app, which is available on Android and iOS [27]. Fever Coach is a fever management app that uses the self-reported data of its users (Figure 1).

The data were collected from January 2017 to December 2018. A total of 480,793 users entered 28,010,112 records. During the same period, the number of users diagnosed with influenza at a clinic was 16,432. In 2017 and 2018, 3583 and 12,849 users were diagnosed with influenza, respectively. The log data included body temperature, volume, type and form of antipyretic drugs or antibiotic drugs, sex, age, weight, symptoms, and memos. The users of Fever Coach agreed that their deidentified data could be used for research purposes, and the institutional review board of Samsung Medical Center waived informed consent.

We collected the daily mean temperature, daily maximum temperature, daily minimum temperature, daily mean dew point, daily mean relative humidity, and daily mean pressure data between January 2017 and December 2018 from the Korea Meteorological Administration information portal. The observation point was Seoul 108 [28].

Korea Center for Disease Control (KCDC) produces a weekly influenza-like illness report every Tuesday using data received from public health centers during the previous week. These data were collected for the period of January 2017–December 2018 [29].

**Figure 1.** Screenshots of the Fever Coach app.

## Data Preprocessing

All of the log data, separated by user ID and year, were then split into episodes. The episodes were defined as the set of consecutive days containing the day the user was diagnosed with influenza or another disease. For example, if a user was diagnosed with influenza on February 23, 2018, and recorded his or her body temperature between February 21, 2018, and February 24, 2018, these days were considered to be 1 episode. If the user logged another record 24 hours after his or her previous record, it was considered to be a new episode. [Table 1](#) shows examples of episode separation.

Each episode must contain information about the user's age, gender, and weight. Users were divided into 4 age groups—0-2 years, 2-5 years, 6-12 years, and  $\geq 13$  years—to avoid possible overfitting according to age, as age is one of the key factors of influenza propagation. Any episode without age, gender, and weight was excluded. Moreover, any episode not containing at least 1 fever data point was excluded.

We then calculated the app-based weekly influenza surveillance from the influenza-diagnosed episodes each year. The app-based weekly influenza surveillance was defined by the weekly number of reported influenza cases divided by the total number of annually reported influenza cases in the same year. For example, if there were 3000 reported influenza cases in 2018 and 300 weekly reported influenza cases in week 49 of 2018, the app-based surveillance for week 49 of 2018 was 0.1. We calculated this value every week for each year and then added

this value to the corresponding episode. If each episode had multiple days, we used the first day of each episode as the representative value, considering that the incubation period of influenza is 1 to 4 days [30,31]. Our week-numbering was based on the ISO week-date system [32]. The app-based weekly influenza surveillance data are in [Multimedia Appendix 1](#).

We also added meteorological data from the Korean Meteorological Administration. As before, we used values corresponding to the first day of each episode. We added KCDC laboratory surveillance as well, but this time we used values corresponding to 1 week before the first day of each episode. Due to the reporting delay of the KCDC surveillance, we could not use values corresponding to the same week.

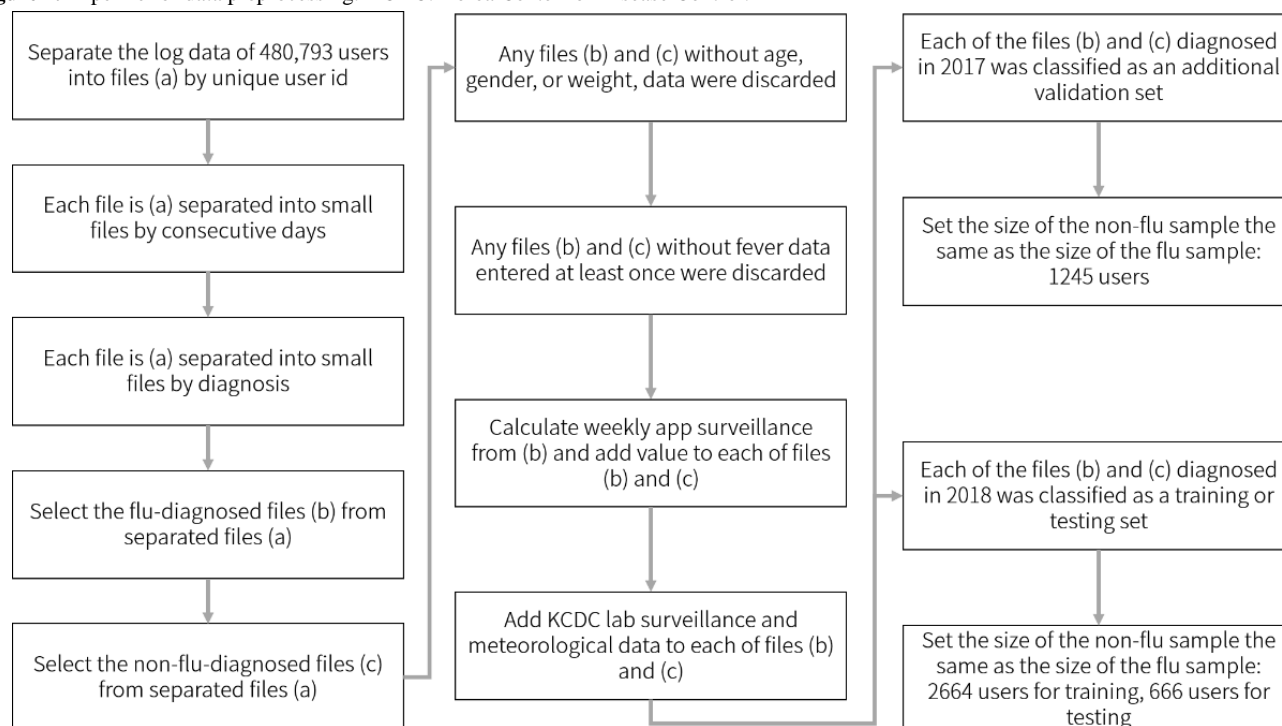

Finally, as the log data we collected had more noninfluenza episodes than the influenza episodes, we set the number of the noninfluenza episodes to be the same as the influenza episodes each year. Data from 2018 were used for training and hyperparameter tuning, and those data were randomly split into the training set (2664/3330, 80%) and the test set (666/3330, 20%). A 5-fold cross-validation was used on the training set. Considering that the influenza epidemic is slightly different each year, we prepared an additional validation set. Although our training/test sets included the data collected in 2018, the additional validation set included the data collected in 2017 that had a different distribution of weekly reported influenza cases. As with the training/test set, the additional validation set was also adjusted to 50:50 for influenza and noninfluenza episodes. [Figure 2](#) summarizes the overall pipeline for data preprocessing.

## Deep Learning Model and Training Hyperparameters

We used GRU-D as our baseline model [26]. GRU-D is a modified design of the gated recurrent unit (GRU) neural network structure based on a recurrent neural network. Unlike in the GRU, the mask and timestamp were combined together, and input was manipulated to 3-channel data. Since Fever Coach data were characterized by a variety of missing values, we considered that the mask system of the GRU-D structure would be effective in our experiment. Backpropagation was not performed for the masked data; therefore, it did not update parameters. The input data were manipulated to 3-channel data, which were concatenated with a timestamp and masked as previously described. Thus, the shape of the matrix  $X_{\text{input}}$  was  $3 \times D \times T$ , where  $D$  is the number of variables for each experiment, and  $T$  is the maximum number of time series. We used  $T=70$  in the experiment in that the maximum count of the input data in 1 episode was 70. The maximum number of variable dimensions in our experiment was 16 (4 for age, 6 for meteorological data, and 1 each for sex, weight, influenza surveillance, app-based surveillance, antibiotic administration, and antipyretics administration). We performed 3 experiments using different combinations of variables. First, we used the

entire 16 dimensions (7 variables) for inputting the model, and 2 additional experiments were performed to evaluate the effect of the input variables on performance. The second experiment was performed with the same conditions as the first, except a single variable was removed, which brought the number of variables to 6. The third experiment was similar to the first as well, except for the addition of 1 variable out of the 3 (body temperature, antipyretics administration, and antibiotic administration). We used binary cross-entropy as a loss function, and we used accuracy as an evaluation metric to choose the best model. All hidden states were initialized to 0. We used the optimizer, rectified adaptive moment estimation, with a learning rate of 0.0001 [33]. The total number of epochs was 50. The softmax function was used as an activation function. We used a dropout of 0.01 to prevent overfitting. All the input variables were normalized to have a mean of 0 (SD 1). The codes are publicly available at a GitHub repository [34].

## Results

The total number of episodes obtained was 6657. Out of these 6657 episodes, 3326 were diagnosed with influenza. The average and SD of each episode length were 29.24 (SD 21.79). Table 2 summarizes the general characteristics of the processed data.

**Table 2.** General characteristics of the data set.

Variables	Year 2017	Year 2018
<b>Body temperature</b>		
Average number of inputs	15.05	20
Variance in the number of inputs	16.32	18.29
<b>Antipyretic administration</b>		
Average number of inputs	4.578	6.040
Variance in the number of inputs	4.685	24.03
<b>Antibiotic administration, n</b>		
At least 1 antibiotic administration	372	4705
No antibiotic administration	2118	1952
<b>Age (years), n</b>		
0 to 2	886	2529
2 to 5	1328	3564
5 to 12	262	479
Older than 12	14	85
<b>Sex, n</b>		
Male	1246	3348
Female	1244	3309

Based on the GRU-D, the proposed screening algorithm used PGHD (body temperature records, antipyretic drug administration records, and antibiotic drug administration records), app-based surveillance, and meteorological data as the input variables. The area under the receiver operating characteristic (AUROC) curve of the test data set was 0.902, with an accuracy of 82.43% (95% CI 80.28%-84.44%), a

sensitivity of 84.20% (95% CI 81.07%-87.00%), a specificity of 80.92% (95% CI 77.85%-83.73%), a positive predictive value (PPV) of 79.05% (95% CI 76.38%-81.50%), and a negative predictive value (NPV) of 85.69% (95% CI 83.26%-87.83%). The confusion matrix and the receiver operating characteristic (ROC) curve are shown in [Figures 3](#) and [4](#), respectively.

**Figure 3.** Confusion matrix for the test set and the additional validation set.

Confusion Matrix					
Test Set			Additional Validation Set		
	Predicted Positive	Predicted Negative		Predicted Positive	Predicted Negative
Actual Positive	581	97	Actual Positive	951	172
Actual Negative	137	517	Actual Negative	241	976

**Figure 4.** Receiver operating characteristic (ROC) curve illustrating the screening ability of the model. The red line shows a random guess, the blue line is the result of the test set collected in 2018, and the orange line is the result of additional validation using data from 2017. AUROC curve: area under the receiver operating characteristic curve.

Considering that the influenza epidemic is slightly different each year, we prepared additional validation set as described in the methods section. For the additional validation set, we achieved an area under the curve (AUC) of 0.8647, an accuracy of 77.99% (95% CI 76.31%-79.61%), a sensitivity of 82.35% (95% CI 79.91%-84.61%), a specificity of 74.79% (95% CI 72.46%-77.02%), a PPV of 70.57% (95% CI 68.59%-72.47%), and an NPV of 85.24% (95% CI 83.47%-86.84%).

We also attempted to evaluate the effect of the input variables on performance in 2 ways. First, we removed them one at a time from all variables. Second, we added them one at a time from baseline variables. To remove them one by one, we first trained the model using all 10 input variables and measured the

performance at that time. We then removed 1 input variable and trained the model on the same data set using a total of 9 input variables and measured the performance. We obtained a total of 10 results and summarized them in Table 3. For example, the second row means all variables except fever were used. As a result, the app-based surveillance turned out to be the most influential variable, even though it had little effect on specificity. The second most influential variable was the meteorological observation data. Interestingly, KCDC surveillance data did not seem to have a significant impact. The meteorological factors and app-based surveillance seemed to compensate for the exclusion of the KCDC surveillance data from the input variables.

**Table 3.** The effects of the removal of each variable from the analysis. “—<Variable>” means that the variable was singularly removed from the list of variables for the corresponding experiment.

Another experiment was conducted to observe the performance changes by defining the base features and adding the variables one at a time (Table 4). The baseline features used were body temperature and the antipyretic and antibiotic drug data. We repeated the analysis by adding each variable to the base features and observing the performance. In each experiment, a total of 4 input variables was used. Consequently, gender data were found to slightly decrease the AUC performance ( $-0.02$ ), but there was no significant difference between the baseline performance and the performance modified by the addition of

gender. Weight and age also displayed no significant differences. For the variables of meteorological data, app surveillance, and KCDC laboratory surveillance, each significantly improved the performance ( $P < .001$ ). There was no significant difference between the performance of "baseline features + app surveillance" and that of "baseline features + meteorological data" ( $P = .48$ ). Similarly, there was no significant difference between the performance of "baseline features + app surveillance" and that of "baseline features + KCDC laboratory surveillance" ( $P = .46$ ).

**Table 4.** Effect of each variable on the analysis. The baseline included body temperature, antipyretic drug, and antibiotic drug data. "+<variable>" means that the variable was added to the baseline for the analysis and then removed for the next analysis (noncumulative addition).

Variable	Sensitivity	Specificity	AUROC <sup>a</sup>	Accuracy	NPV <sup>b</sup>	F <sub>1</sub>

Finally, we looked at the correlation between the duration of the input data and the screening performance. Figure 5 describes the association between the duration of body temperature records and the screening performance. We initially assumed that the prediction would be more accurate if the user entered more data.

However, in reality, no correlation was found between the duration of the input data and the screening performance. Spearman rank correlation coefficient was 0.0916. Thus, the association was not considered to be statistically significant.

**Figure 5.** Screening performance versus the number of body temperature records. The y-axis shows the percentage of accuracy, and the x-axis refers to the number of body temperatures entered by the user.

## Discussion

With this study, we investigated the possibility of screening for influenza using PGHD, such as body temperature and medication records collected from an mHealth app.

At the beginning of this study, we did not know whether body temperature would change when antipyretics were administered, or if body temperature alone was more important. Although fever is a major symptom of influenza, it is impossible to diagnose influenza using only body temperature changes [24,25]. Therefore, we hypothesized that patients with influenza would respond more slowly to antipyretics. To test this hypothesis, we specifically looked at the difference between the performance of the model with and without antipyretic administration. There was a greater change in performance when the antipyretic dose records were removed from the input variable than when only the body temperature was removed. Based on these results, we conclude that the model works as expected. Antibiotic administration records are another variable that we considered important. We expected that the antibiotic administration records and antipyretic administration records would have similar effects, but antibiotic administration records appeared to limit the performance. This might have been due to the ineffectiveness of antibiotics or unnecessary prescription of antibiotics. In our data, 1952 of all 6657 users were prescribed antibiotics, and 674 of those who were prescribed drugs were diagnosed with diseases other than influenza.

Body temperature is known to be one of the most important symptoms of influenza. However, its effect on the model was not as strong as we expected. A temperature higher than 38.3 °C was recorded at least once during 97.42% (6485/6657) episodes in our data. This shows that the majority of users used the app when their children had a fever, which was the original purpose of the app. Among the episodes, 50.82% (3296/6485) were those of influenza, and 49.18% (3189/6485) were due to other conditions. The mean and variance of body temperature in the patient group diagnosed with influenza were 38.1519 °C and 0.8611 °C, respectively; and the mean and variance of body temperature with other conditions were 38.0449 °C and 0.8367 °C. There was a significant difference between the 2 groups ( $P < .001$ ). We speculate that because the app focused on fever, the predictive power of body temperature for influenza was diminished.

One interesting finding was the effect that sex had on specificity. Although some studies have shown that there is a difference in

influenza prevalence by gender, our data found that the sex ratio was almost equal, with 1677 males and 1660 females diagnosed with influenza. Moreover, when we excluded sex from the input variables, the accuracy and  $F_1$  measure did not significantly change. We obtained similar results by repeating the ablation study. Therefore, further research may be needed to clarify this point.

In summary, age, weight, and gender had little effect on the screening performance. App-based surveillance has greatly improved the screening performance and is nearly identical to using KCDC laboratory surveillance or meteorological data, which are frequently used as indicators of influenza outbreaks.

This study has several limitations. First, the training and validation data used were self-reported by the patients. Most users reported their diagnosis using their smartphones; thus, these data were not reported by clinicians. Therefore, we cannot ascertain that the same results would be recorded if hospital-generated data were used. Also, primary care doctors usually use the RIDT instead of RT-PCR to diagnose influenza. As the RIDT has low reliability, our ground truth label may be noisy. For the deep learning model, if the character of the data on deployment is slightly different from that of the training data, it is difficult to achieve the expected performance on validation due to the difficulties in analyzing the effect of the data distribution and input variables on the model [35]. Since the data did not include laboratory results, they are difficult to use in a clinical setting or for general epidemiological analysis; and we expect that the application of limited screening tests through the Fever Coach app will be possible with further research. We are planning to conduct a prospective observational study to address these limitations. Second, various methods were used to measure body temperature. Some of the app users used axillary instead of tympanic temperatures. As there are no primary blood vessels in the axilla, the axillary temperatures are less accurate. This may have influenced the performance of the model.

Screening for influenza can be challenging due to the low sensitivity of rapid antigen tests and the lack of proper screening tests. In this study, we developed a deep learning-based screening tool using PGHD obtained from an mHealth app. The experimental results confirm that PGHD from an mHealth app can be a complementary tool for screening for influenza in individual patients. Since our digital approach can screen patients without physical contact, this approach could be quite beneficial in screening new contagious diseases.

## Authors' Contributions

HC implemented the code and performed the experiments. MK and JC manipulated the raw data for preprocessing and designed the experiments. JS provided the data and designed the experiments. SYS designed the experiments and supervised the study. All authors wrote the manuscript and discussed the results. HC and MK equally contributed to this work. JS and SYS are co-corresponding authors.

## Conflicts of Interest

SYS holds stocks in Mobile Doctor, which created the app Fever Coach. SYS also holds stocks in Hurraypositive and Mune, serves as an outside director in Life Semantics, and is a partner of Digital Healthcare Partners. MK is Chief Medical Information

Officer of Mobile Doctor and has equity in Mobile Doctor. SJW is the founding member and Chief Executive Officer of Mobile Doctor. SJW is also Chief Executive Officer of Aim Med and a partner in Digital Healthcare Partners. JC was an internship researcher for Mobile Doctor.

## Multimedia Appendix 1

App-based surveillance calculated from user input data.

## Abstract

**Background:** Information has been identified as a commonly unmet supportive care need for those living with cancer (ie, patients and their friends and family). The information needed to help individuals plan their lives around the consequences of cancer, such as the receipt of health care, is an example of an important informational need. A suitable theory to guide the development of interventions designed to meet this informational need has not been identified by the authors.

**Objective:** The aim of this study is to generate a grounded theory capable of guiding the development of interventions designed to assist those living with cancer in meeting their informational needs.

**Methods:** Classic grounded theory was used to analyze data collected through digitally recorded one-on-one audio interviews with 31 patients with cancer and 29 friends and family members. These interviews focused on how the participants had accessed and used information to plan their lives and what barriers they faced in obtaining and using this information.

**Results:** The theory that emerged consisted of 4 variables: personal projects, cancer as a source of disruption to personal projects, information as the process of accessing and interpreting cancer-related data (CRD) to inform action, and CRD quality as defined by accessibility, credibility, applicability, and framing. CRD quality as a moderator of personal project disruption by cancer is the core concept of this theory.

**Conclusions:** Informational resources providing accessible, credible, applicable, and positively framed CRD are likely key to meeting the information needs of those affected by cancer. Web-based informational resources delivering high-quality CRD focused on assisting individuals living with cancer in maintaining and planning their personal projects are predicted to improve quality of life. Research is needed to develop and integrate resources informed by this theoretical framework into clinical practice.

## Introduction

### Background

One of the most commonly reported unmet supportive care needs of those facing cancer, including patients [1-4] and their friends and family [5-7], is for information. Common informational needs include those related to prognosis, how to care for someone with cancer, and the benefits and toxicities of treatment [2,8-14]. Unmet information needs are associated with decreased treatment adherence [15,16], increased health care costs [17-19], anxiety [20,21], and depression [20].

In a previous study conducted by the lead author (MT) [22] it was identified that the diagnosis of malignancy resulted in widespread interruption to the lives of those affected by cancer. This study used grounded theory [23,24] to analyze data from 43 semistructured interviews conducted with 18 patients who had been recently diagnosed with cancer and 15 friends and family in Manitoba, Canada. One conclusion from this study was that to support individuals affected by cancer, information is needed that supports them in planning the activities necessary for maintaining participation in the relationships and projects they established before diagnosis—such as those with family, friends, and their work—both in the short and long term. Addressing this finding was a major motivator for the work presented in this study.

Health information-seeking behavior (HISB) is a field of research encompassing how those affected by illness utilize health information. Important areas of study within HISB include how individuals seek, use, and share information [25-27]. The HISB literature can be broadly divided into 3 main categories: (1) coping with health situations, (2) involvement in shared medical decisions, and (3) behavior change and preventative behavior [25,27]. In their concept analysis of HISB, Lambert and Loiselle [27] identified that one goal of the individual engaging in HISB is to better understand what to expect. They identify that HISB serves to “increase predictability” [27] and may assist with “anticipating the sequence of events” [27] that will likely take place. These goals of HISB are consistent with the informational need identified in the study leading up to this work: that information is essential to helping individuals know what to expect in the future so that they can effectively plan how to live their lives [22].

The factors that affect HISB are complex, as illustrated by the examination of the Miller Behavioral Style Scale (MBSS) [26-28] and the model of health information acquisition (HIA) [26,27,29], both of which are utilized in the HISB literature [26,27]. The MBSS is a validated scale [28,30] useful for characterizing individual information-seeking styles in response to both *physical and psychological stress* [28]. The MBSS categorizes individuals as either information seekers (high monitors) or information avoiders (low monitors) [28,30]. High monitors are more likely to seek out information to cope with stressors, whereas the response of low monitors is to avoid information [28,31,32]. The HIA, developed by Freimuth et al [29] from their work with the National Cancer Institute's telephone-based Cancer Information Service [26], predicts that the decision to seek information involves a cost-benefit analysis.

The expected benefit of information is weighed against the effort to seek additional information [26,27,29] in terms of cost considerations such as “financial and time expenditures, frustration, confusion, [and] emotional distress” [29]. Together, the MBSS and the HIA suggest that both intrinsic and external variables impact an individual's ability to access and use health information to plan around the receipt of health care. This conclusion is supported by the wealth of empirical evidence, including multiple systematic reviews [1,5,7,33-40], consistently correlating specific demographic factors (eg, age, gender, education) [33,41,42] with various types of information-seeking behavior [27,43] and health information needs [5,35].

In the context of cancer, it is not clear how to optimally design interventions to support individuals in obtaining the health information that is most useful for them. In general, using theory to guide intervention design results in better outcomes [44,45]. The application of theory in intervention design facilitates the identification of key constructs to be included in the intervention, potentially resulting in a stronger effect [46]. In addition, the results of testing theory-based interventions provide valuable feedback about the accuracy of the theory [23,46], furthering the understanding of the contextual area under study and facilitating modification of the theory to enhance its accuracy [23].

Multiple theories have been used to guide both the understanding of HISB [26,27] and the development of interventions [37]. Importantly, besides the model of HISB by Longo [47,48] and the HIA by Freimuth et al [29,48], few theoretical frameworks regarding HISB have been developed within the context of cancer. In addition, although existing theories in the HISB literature facilitate understanding and explanations of HISB patterns, the utility of these theories for developing interventions is not clear. For instance, although existing theoretical frameworks employed in the HISB cancer context [29,47-49] describe a cost-benefit relationship in terms of whether an individual will search for additional information, they do not provide guidance in terms of how to structure interventions for those affected by cancer to minimize the cost and maximize the benefit of information seeking. A theoretical framework that addresses this gap in the literature is thought to be valuable for developing interventions that address the informational needs of those living with cancer [1,4,11,12,14,15,35,38,48]. Such a framework would be capable of informing the development of interventions that support individuals in planning their lives around the short- and long-term consequences of cancer, including the receipt of treatment and altered life expectancy [22,50].

### Objectives

The objective of this study is to develop a grounded theory capable of guiding the creation of informational resources designed to assist individuals living with cancer in meeting their informational needs by minimizing the cost and maximizing the benefit of information seeking.

## Methods

### Study Approach

This study used classic grounded theory (CGT), a method for discovering theory through iterative data collection and analysis [51-53]. CGT has been identified as a method for uncovering latent behavioral patterns and generating theory capable of guiding practical action for problem solving [54]. This was one reason that CGT was considered the ideal method for this study as the objective required a theory that operationalized (1) why information related to cancer is important for supporting individuals affected by it and (2) how information about cancer can be optimally provided to improve the lives of those affected by it. Both questions assume that shared patterns of behavior exist among those affected by cancer.

### Study Procedures

The study procedures, including the study design, data collection, analysis, and drafting of the report, were conducted primarily by the lead author, who was completing a medical oncology fellowship during the first year of the study and enrolled in a PhD graduate program as well as in active independent clinical practice as a medical oncologist for the subsequent portion of this study. The second and fourth authors provided methodological support in conducting and presenting the grounded theory analysis. The third author provided general research expertise and contextual expertise regarding clinical oncology practice.

### Ethical Considerations

Approval for this study was obtained through the Health Research Ethics Board of Alberta (Study ID: HREBA.CC-17-0365) before the initiation of recruitment, data collection, and data analysis.

### Recruitment

Patients were recruited using posters and invitation letters from a large outpatient cancer facility in Western Canada. Interested patient participants contacted the lead author or primary investigator who provided further details of this study, including its methods, objectives, risks, benefits, and obtained written consent. The patient participants were invited to approach any friends and family to participate in this study as secondary participants. This study was open to all patients aged 18 years or older who had received oncology care. Friends and family participants aged 18 years or older were welcome to participate. Exclusion criteria were limited to not being able to communicate in English and being aged below 18 years. Incentives for participation included being eligible to win one of four Can \$25 (US \$18.79) gift certificates.

The rationale for inclusion of both friends and family participants as well as patient participants in this study was three-fold. First, it was assumed that, besides instances where patients were receiving medications affecting their cognition or had severe neurological sequelae of their cancer, such as a debilitating brain metastasis, there would be no psychological or sociological phenomena differentiating the processes of information seeking and use for those diagnosed with cancer

from their family and friends. Therefore, the concepts and resulting theory that would emerge would likely be valid for both friends and family as well as patients. Second, it is recognized that informal caregivers are often left behind when it comes to supportive care research, including research related to information needs. Although the theory that was expected to emerge would likely be applicable to both groups, without including both patients and friends and family in the study, the validity of the theory for the group not included would likely be questioned. Finally, the contrasting perspectives of friends and family and patients were expected to provide extremely useful data for the purposes of constant comparison, ensuring that theoretical saturation occurred [23,24].

### Data Collection

After obtaining written consent, all participants completed a demographic questionnaire (Multimedia Appendix 1). A review of the electronic medical charts of patient participants was performed to facilitate the identification of details that were not readily available outside of a thorough interview in the style of detailed medical and treatment history. The data from the chart review and questionnaires were compiled into a database to assist with theoretical sampling, an iterative sampling technique to ensure theoretical coverage and heterogeneity [23,24]. For instance, patients were initially interviewed as they were recruited, resulting in a predominance of patients >50 years of age with breast and colorectal cancer being interviewed. Therefore, the database was used to identify and select participants for interviews who were primarily younger patients with less common malignancies. This was important to ensure that the emerging concepts were adequately informed by data from individuals likely to have had contrasting experiences.

All interviews were semistructured (Multimedia Appendix 2), face to face, and audio recorded. The interviews were carried out in participants' homes, apart from 3 interviews conducted over the phone. Interviewees were encouraged to stop the interview at any point if they were no longer comfortable proceeding or needed a break; in addition, they were provided with contact information for psychosocial support available through the cancer center. The interviews with participants took place separately, except for 7 interviews where the patients and their friends and family wanted to be interviewed together. Participants were interviewed once; no repeat interviews were conducted. The audio recordings from the interviews were transcribed by a professional transcriptionist as soon as possible after each interview to facilitate ongoing and iterative data analysis. The average interview length was 53 min overall, 1 hour and 4 min for interviews involving patients, and 36 min for interviews with only friends and family participants. Participants who participated in interviews were offered a 24-hour parking pass to the cancer center.

### Data Analysis

Data analysis using constant comparison was carried out in keeping with the CGT [51]. Data analysis and data collection occurred in an iterative manner, beginning once the first interview was transcribed. Coding, memoing, and theory generation were guided by comparing coded incidents and intentionally selecting participants and interview questions

likely to result in data being collected that would contrast with previously collected data, providing new insight to guide the emerging theory [51]. Data collection ceased when data saturation occurred, whereby no new data emerged from the ensuing interviews. The initial stage of coding the collected data (ie, open coding) resulted in a coding schema emerging and the identification of a core category. This facilitated the next stage of the CGT analysis (ie, selective coding), where the theory began to emerge around the coding categories (ie, variables) associated with the consequences of access to the information that participants identified as being helpful or

unhelpful. The final stage of the CGT analysis (ie, theoretical coding) involved coding to finalize theoretical links between the categories connecting the challenges faced by the participants, their experience with cancer, and information.

## Results

### Participant Characteristics

A total of 37 patients and 36 friends and family consented to be contacted for interviews, with 31 patients and 29 friends and family (Table 1) completing interviews.

**Table 1.** Interviewed participants' demographics (n=60).

Interviewed participants	Values
<b>Interviewed primary participants (n=31)</b>	
Age (years), mean (range)	60 (29-81)
<b>Gender, n (%)</b>	
Male	14 (45)
Female	17 (55)
<b>Initially curative at the time of diagnosis, n (%)</b>	
Yes	26 (84)
No	5 (16)
<b>Currently curative (at the time of interview), n (%)</b>	
Yes	19 (61)
No	12 (39)
<b>Malignancy type, n (%)</b>	
Colorectal	8 (26)
Noncolorectal gastrointestinal malignancy	5 (16)
Breast	9 (29)
Melanoma	5 (16)
Hematologic malignancies	3 (10)
Osteosarcoma	1 (3)
<b>Interviewed secondary participants (n=29)</b>	
Age (years), mean (range)	56 (27-83)
<b>Relationship with the primary participant, n (%)</b>	
Spouse	17 (59)
Child	3 (10)
Sibling	2 (7)
Parent	2 (7)
Friend	5 (17)

The sample of patients who completed the interviews was relatively balanced in terms of gender and included patients with ages ranging from their late 20s to early 80s. Importantly, there was a mix of patients who were being treated with curative intent, as well as those being treated noncuratively for de novo or recurrent metastatic disease, suggesting a wide range of cancer experiences. In terms of friends and family interviewed, ages were similar to patients, likely reflecting the high number of spouses who were included in the interviews.

### The Grounded Theory of Information Access and Use

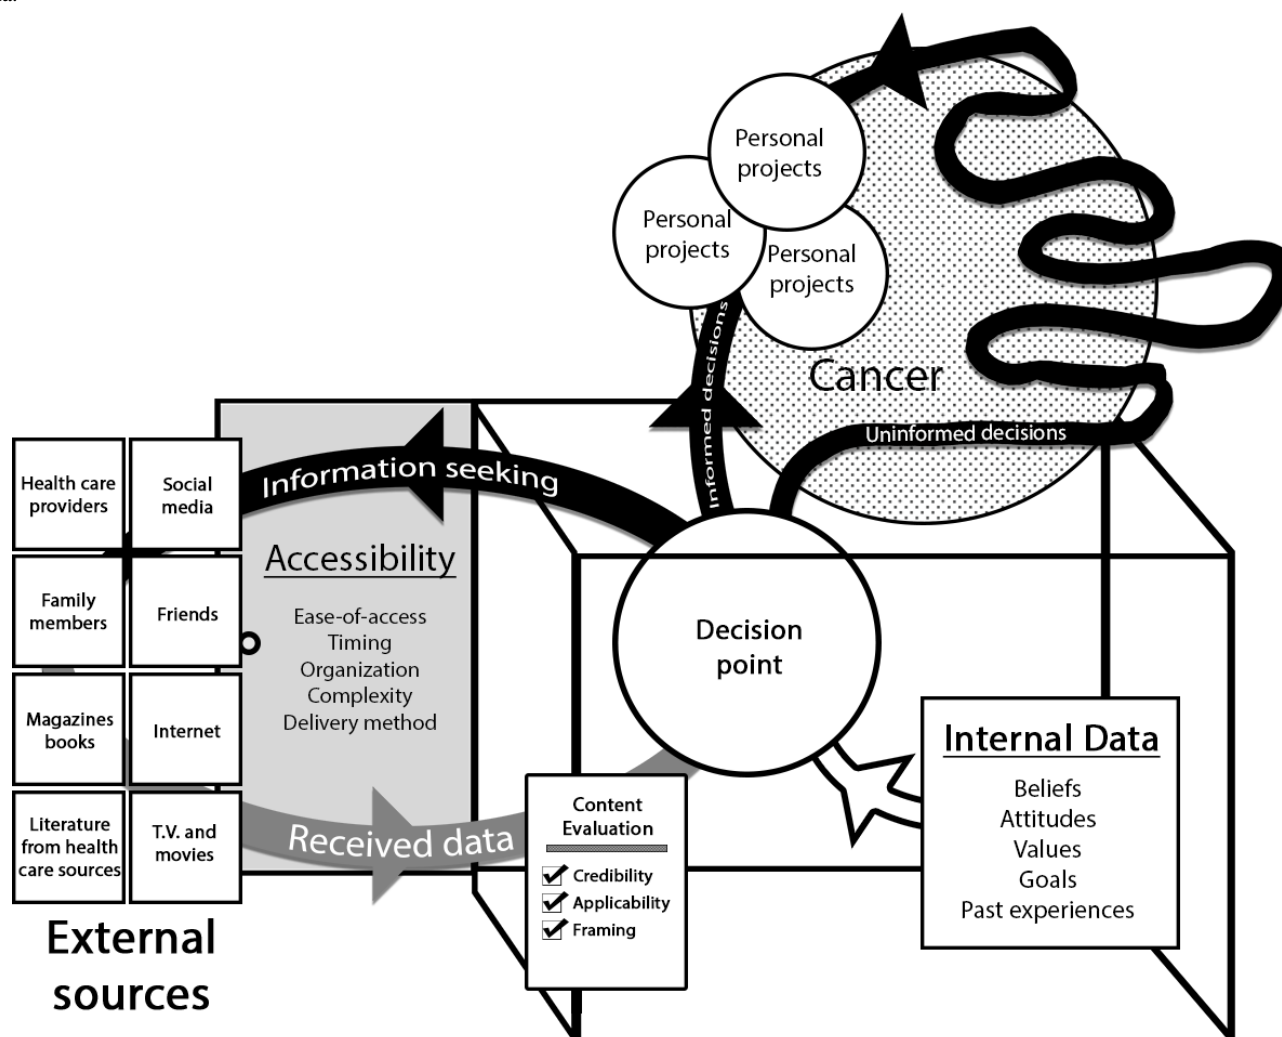

The primary finding, or core variable [51], was that the quality of cancer-related data (CRD) that patients and their friends and family received impacted their ability to plan their lives around the consequences of the malignancy diagnosis. The theory consists of 4 interrelated concepts: (1) personal projects, (2) the cancer project, (3) information as the process of receiving and

interpreting data to inform action, and (4) the quality of CRD received.

At the conclusion of this study, information was understood as the process of informing action based on the CRD that patients and their friends and family received about cancer. For those affected by cancer, CRD came from multiple sources, including health care providers, family, friends, and the internet. CRD from health care providers were the most credible and applicable; however, access to health care providers was often limited to clinical visits where the uptake of the CRD was

limited. CRD found on the internet were readily accessible and provided an opportunity for repeated access. Received CRD are interpreted in the context of internal data, including the individual's personal values, how the individual understands their life story, goals for the future, and previously obtained CRD. This process informs the individual's actions related to managing cancer or their personal projects (eg, career, raising children, being physically fit). The concepts that comprise the theory are described in the following subsections. A graphical model of the theory is presented in Figure 1.

**Figure 1.** A graphical model of the theory of information access and use. The theory suggests that a cancer diagnosis is disruptive, in part, because it decreases the ability of an individual to effectively make decisions about how to invest their time and energy into their personal projects. This is due to a resulting lack of certainty about what to expect, both in terms of the cancer itself and how the consequences of cancer, such as treatment and altered life expectancy, will affect their personal projects. Information is understood as a process involving receiving data about cancer and interpreting it to increase the certainty of the outcome of different actions. High quality data, defined as data that is accessible, credible, applicable, and positively framed, enhances decision-making support and results in improved engagement with personal projects. The dark black arrowed lines represent aspects of the information/action continuum in which energy and time is diverted between personal projects and seeking information. The indirect winding line titled “uninformed decisions” illustrates the inefficient use of an individual's finite energy and time when decisions are not informed by high-quality cancer data.

### Personal Projects: The Context of Cancer

Personal projects refer to the collection of activities that an individual invests a significant amount of energy and time in over a prolonged period of their life. The following quote demonstrates how time and energy shift from one personal

project (eg, child rearing) to another (eg, the project of being healthy) over the course of a lifetime:

*I worked and I [raised] the kids and I was very involved, and I volunteered a ton and then once they graduated it was my turn. And I started to do things for me and get myself healthy and eat healthy and all that. [Patient 1]*

The personal projects of the participants created a unique context for each individual to face the challenges of the cancer experience. Each participant had a unique group of ongoing personal projects, allotting different amounts of time and energy to each, and each was ascribed with unique meaning. Importantly, before diagnosis, these personal projects—and the activities and roles that comprised them—were what the participants invested their time and energy in.

### **Cancer: A New Disruptive Project**

The personal projects of the participants were disrupted following the malignancy diagnosis. Energy and time were diverted from preexisting personal projects to managing the consequences of the cancer diagnosis. Some participants described being able to continue with most aspects of their personal projects but were unable to plan how these would fit into the future. This was because the necessary details that would facilitate planning, such as prognosis or the time and energy commitment needed for treatment, were not made clear for weeks, or even months, after the initial diagnosis. Others described that following the diagnosis, their personal projects essentially halted:

*I was given the diagnosis, sent to the [hospital ward] and then I was in there for over I think it was two weeks or something or longer. [Patient 15]*

For friends and family, disruption to personal projects was related to the amount of support they provided to the individual who received the malignancy diagnosis. A partner of a patient described the disruptive effect of cancer as follows:

*Well obviously, it's been life altering. I guess it's – it's certainly changed what the priorities are in our short term, midterm and long-term activities. ...because like the first priority is always caring for [spouse] making sure [they] get the right [treatment]. [Friends and Family 15]*

In this example, priorities were understood to relate to the relative energy and time that the participant planned to invest in various projects. In contrast, a participant identified as a friend to a primary participant but not as a central member of the patient's support network indicated that the malignancy diagnosis was not disruptive to their personal projects stating:

*I avoid the issue of [their] illness. ...I don't make [them] sick. [Friends and Family 26]*

### **Information: Definition and Function**

At the conclusion of this study, information came to be understood as a multistage process, with steps occurring both externally and internally to the individual. The process participants described included searching for, receiving, and interpreting data related to cancer (ie, CRD) to inform action related to their personal projects and managing cancer. CRD came in many forms, including through conversations with health care providers, friends and family, web searches, and personal experiences. Participants also described actively searching for CRD, using time and energy that would otherwise be used for their personal projects, to understand the diagnosis and its consequences. For instance, one participant described

searching for CRD and using them to answer questions related to the project of raising a family following the malignancy diagnosis:

*But at the start, 'cause I was so scared, I thought "oh my God, I have these little kids that I have to raise" you know? I have a long haul ahead of me, like I got to get through this. What can I do that's going to help benefit me in the long run? [...] what things are going to benefit me health wise? That's going to... help me get through this? [Patient 2]*

This participant went on to describe finding books and other resources that contained CRD that were helpful in navigating the challenges of being a parent while dealing with the consequences of the malignancy.

In contrast to the CRD that were actively sought out, CRD were also obtained passively through sources such as TV shows, news, and casual conversations with friends and family and from clinical encounters with physicians and nurses. In addition, participants indicated that although much of the CRD that they used were obtained from external sources, they also identified internal sources of CRD. For instance, personal knowledge gained from previous cancer experiences with family and friends was identified as an important source of CRD.

After CRD were accessed, participants described using it to guide both small-scale decisions, such as the day-to-day logistical coordination of the activities related to a single personal project (eg, taking time off work to provide transportation to a patient), and large-scale decisions, such as those that would affect all of an individual's personal projects:

*[...] if I had had a better idea about what the progression, the path [forward] is going to be - that would be helpful for me. [...] And I want to plan, right now I want to plan 6 months, I want to plan a year from now. [...] Because of this situation I'm going to be leaving my job and [moving] and to the extent possible I'd like to know, this sounds terribly selfish, but there's a little bit of: how does this affect me? [Friends and Family 27]*

### **Quality CRD: Accessibility, Credibility, Applicability, and Framing**

To understand how information could be optimally provided to those affected by cancer, many of the study interviews included a focus on how CRD had been provided through the cancer center or by clinicians, whether these CRD were helpful, and discussions about how CRD could be better provided. Through this exploration, and the many contrasting examples provided by the participants, 4 themes defining the quality of CRD were identified: accessibility, credibility, applicability, and framing.

#### **Accessibility**

Accessibility refers to how CRD are made available to individuals and is characterized by *ease of access, timing, organization, complexity, and delivery method*.

### Ease of Access

Some external CRD sources can have limited accessibility, whereas others can be repeatedly and conveniently accessed. Health care providers and cancer centers are sources of CRD that have limited access. Participants described CRD available through clinic visits, support groups, and education sessions as being accessible only in certain locations and at certain times. As a result, the CRD provided were not always able to be effectively received. One participant described the experience of comparing the details that they recalled from clinician visits with a friend who had been present for the visits and had been taking notes:

*I still haven't been to a single appointment without bringing someone with me. [...] every single car ride home [when we discuss the appointment] it was like we were in two different [doctor's visits].* [Patient 30]

Resources that could be accessed repeatedly, such as printed materials or the internet, allowed participants to access and interpret CRD at their own pace. The internet was a highly accessible source of CRD for many participants. One patient participant described being confused about the prognosis of their breast cancer despite receiving prognostic CRD from a physician. The participant used Google to gather additional CRD as the physician was not readily available to provide further clarification. The participant eventually decided to accept the treatment that had been recommended after learning through the internet that their breast cancer is a “more aggressive type so that's kind of scary, but then there's the treatment for a year that's supposed to balance it out” (Patient 29).

### Timing

For CRD sources with limited access, participants needed to be able to receive them when they were available. Timing refers to issues where individuals are simply not able to receive CRD even if they are physically presented with CRD. One friend and family participant described an instance of poor timing when CRD was shared with a loved one who was in the hospital and recovering from cancer surgery:

*Well, he was on hard drugs. So I couldn't – like he is stoned, when he was in the hospital. And they are throwing a ton of information at him that I am having a hard time grasping and retaining and so he doesn't have a hope in hell of getting it.* [Friends and Family 3]

### Organization

Organization affects how efficiently individuals are able to identify what content of the provided CRD is relevant to them. One participant described the experience of receiving a printed package of CRD from the cancer center, and the subsequent investment of energy and time to identify what was important:

*[...] it was a lot of brochures and then for me it was about weeding out what was important and relevant, so I just focused on like overall what's going to happen with chemo and then just hone in on like [the patient's type of cancer]. Not that anything – like it's not like the other things aren't relevant but [I had to*

*focus on] what I could like absorb [and] what I needed to know.* [Friends and Family 22]

### Complexity

The complexity of the CRD being shared also affected participants' ability to interpret it. One participant described receiving CRD with technical medical content as “good, but you can only give so much to a laymen and they're not going to understand the rest of it like, it can only be so difficult” (Friends and Family 15). Another participant described the amount of time and energy required to navigate through complicated treatment decisions that had been offered by the medical oncologists. The participant described having multiple “family group meetings” (Friends and Family 9) in which the members of the family would sit in the patient's living room and repeatedly play the recording of the doctor's visit, trying to understand the CRD that were shared in the consultation to make decisions both regarding medical management and how to plan their lives around the data received.

### Delivery Method

The method of delivery was also important in terms of participants' ability to access CRD. Different formats of delivery, such as face-to-face discussions with clinicians, education sessions at the cancer center, and internet content, resulted in differences in terms of ease of access. Participants also expressed relative differences in their comfort in each format. Text-based CRD were universally described as helpful. However, some individuals expressed issues with retrieving internet content (“I don't do the computer” [Patient 3]) or a preference for reading things on paper as opposed to on a computer or smartphone screen.

### Credibility

Participants described receiving CRD from their health care providers, friends, family, the internet, TV, and other cancer survivors. The usefulness of these CRD was related to the credibility (ie, reliability) of the source.

CRD received from health care providers, including handouts and brochures, were generally considered credible. Oncology specialists, including physicians and nurses, were identified as being the most credible sources of CRD. They were described as being able to anticipate questions and provide answers without even being asked, capable of providing reassurance, and answering the patient's questions based on “where [the patient was] coming from” (Patient 7). General practitioners or family physicians were also considered credible sources; however, several participants indicated that they received little CRD about their cancer from their general practitioner. One participant indicated that they did not trust anything from the general practitioner stating that the general practitioner had “missed the diagnosis [of malignancy] for many years” (Patient 1). Although participants described various degrees of trust in internet sources of CRD, websites such as the Canadian Cancer Society's website were identified as highly credible.

Cancer survivors, defined here as those with a personal diagnosis or the close friend or family member of someone with a diagnosis [55], were also credible sources of CRD. Survivors provided practical, real-world knowledge about how to manage

the consequences of cancer. Participants described “comparing notes” (Patient 12) about where to source complementary products such as hand creams and how to plan for certain treatments. In addition, survivors who had been diagnosed with cancer decades earlier and were still alive existed as CRD that a malignancy diagnosis was not necessarily a death sentence:

*Since I have seen people stay over 10 years with [specific type of cancer], I'm hoping I will stay about 10 years [...]. I met a woman who told me “oh, this is my 10th year” [...]. So I believe that if some people can survive it then I will.* [Patient 10]

Participants also described CRD from sources that were not credible. They described interactions with well-meaning friends and family who provided CRD about conspiracy theories and unproven controversial treatments. These examples of CRD were described as “uncomfortable noise” (Patient 30) requiring time and energy to evaluate both its credibility and how best to manage the relationship with its source.

### Applicability

Although participants described the CRD obtained from health care providers as highly credible, the data were not always applicable. Participants described receiving general information packages about nutrition and managing side effects but finding these of limited use or even a source of potential distress. One participant who was receiving immunotherapy described receiving a list of potential side effects of treatment from the medical team providing treatment. The participant described reading through the list and feeling anxious about the potential side effects only to become frustrated when at the bottom of the list it said that immunotherapy patients should “ignore [the list of side effects] and just call the triage number” (Patient 17).

Many participants described receiving CRD from the TV and the internet. CRD from these sources presented challenges for the participants as they were a potential source of fear. One participant described being: “worried about how bad [chemotherapy] was going to be” based on “pictur[ing] it from TV and stuff. Like people just puking all the time” only to find that “nausea was hardly a problem” [Patient 31].

Personal experience provided a source of internal CRD considered to be extremely applicable. Participants, including patients and those supporting them, described that as they gained personal experience with receiving medical care, they were able to find a “rhythm” (Patient 31) as they knew what to expect. This allowed them to become increasingly able to plan activities related to their personal projects, such as their work or other relationships. However, each new challenge, such as an unfamiliar treatment, procedure, or symptom, had the potential to interrupt this rhythm, causing disruption until a new rhythm could be established.

### Framing

Whether CRD were framed in a *positive* way also affected participants' ability to use the data. *Positive framing* involves communicating information in an honest manner that (1) also highlights the best possible outcome including exceptional outliers and (2) provides options for moving forward. Even when the odds were seemingly against them, participants

stressed the importance of focusing on positive outcomes and what they, or clinicians, could do to optimize the situation:

*Maybe they're not right with me. Maybe I'm one of the 5%, because I exercise or whatever... I can pretend that maybe I'm one of the [few] that will beat this, to some degree, not beat it forever, but go a little longer than they told me.* [Patient 1]

*You don't want someone telling you, you're for sure going to have, you know, a really bad rash on your hands and feet. You want someone saying, you might have a bad rash on your feet **and this is what you do about it.*** [Patient 2]

*They've been amazing, everybody. And helpful, and encouraging. [...] They haven't been negative about [it], they've just said that there is no cure for this yet.* [Patient 8]

*I guess the negative part to me is – cause I've heard and seen people that [say] “well I have cancer so I'm going to die, I know that whether it's five years down the road, I'm going to die.” [...] The negative part is “I'm going to die” you know?* [Patient 21]

## Discussion

### Interpretation of Findings

A classic definition of information is “a difference in matter-energy which affects uncertainty in a situation where a choice exists among a set of alternatives” [29,56]. Benner [57] suggests that illness and losses such as death “can disrupt (if not shatter) one's taken-for-granted world” and that recovery comes both from “curing the body” [57] and through (re)integration of the self into “his or her particular world” [57]. The theory that emerged in this study links an individual's ability to remain integrated in a world changed by cancer, through maintenance of connection with personal projects to their ability to access helpful information in a way that does not result in further disruption to their life.

The risk benefit consideration identified in existing theories, such as the HIA [29] and the theoretical framework of HISB by Longo et al [47], identifies that an important step in the information process is deciding whether additional information should be sought (ie, cost-benefit analyses). Similarly, this study identified that the cost of seeking CRD is two-fold. First, seeking CRD was an activity that diverted time and energy from personal projects. Second, the cost of basing expectations and making decisions on CRD that are inaccurate is not negligible, as exemplified by the quotes provided in the Applicability subsection in the *Results* section. Interventions structured on the 4 components of high-quality CRD outlined in this study, including accessibility, credibility, applicability, and framing, are likely to minimize the cost and maximize the benefit of health information seeking for those living with cancer.

### Extending the Theory—A Deeper Grounding of Accessibility and Time

An important component of the information process, in addition to seeking, receiving, and ultimately acting on CRD, occurs

between when CRD are received and action occurs. Although the process of interpreting CRD to inform action was not explored explicitly in this study, insights can be gained by examining the findings of this study in conjunction with the existing literature. First, participants in this study indicated that some of their decisions regarding treatment and their personal lives were based on limited or inaccurate CRD. Second, as participants shared and reflected on their cancer journey they both reflected feeling and displayed anger, sadness, joy, and a wide range of other emotions. Both observations are congruent with the existing literature regarding the challenges individuals living with cancer face in obtaining useful information [1-4,9,11,12,14,15,38,39,42,50] and the significant role emotions play during the cancer experience [58,59]. The role of emotions in decision making has been well documented, with both theory and empirical data supporting that emotions affect decision making in different ways [60,61]. For instance, fear is associated with the interpretation of greater risk, whereas anger is associated with less perceived risk [60,61]. In addition, research supports that individuals revert to less emotional states as time passes from the inciting stressor, resulting in decision making that is less reactive, and instead guided by reasoning that is more rational, better reflecting the individual's personal values [60,62].

The insights gained from the data regarding emotions and decision making is important because they add depth to the concept of accessibility and the subconcept of timing that emerged from this theory. On the basis of the theoretical and empirical data regarding emotion and decision making [60,61], for CRD to be useful, they must be provided well in advance of decision making to increase the probability that decision making will be interpreted in a nonemotionally heightened state. Although there is limited empirical evidence to support this conclusion in the cancer context, the literature regarding patient decision aids (PDAs) is informative. PDAs consist of questionnaires or informational packages provided to patients to assist them in better understanding and engaging with medical decision making [19,63]. In a recent Cochrane Systematic Review, although not directly compared in any of the studies reviewed, PDAs provided before consultation compared with usual care appeared to have a positive impact on patient's accurate perception of risk compared with PDAs provided during consultation (risk ratio 2.25, 95% CI 1.65-3.07 vs risk ratio 1.79, 95% CI 1.28-2.52, respectively) [19]. If fear is indeed associated with inaccurate risk perception [60,61], then this trend suggests that endeavors to understand the role of early provision of high-quality CRD to patients with cancer and those supporting them, guided by the intention of reducing fear and improving decisional quality, may be fruitful.

### ***From Theory to Innovation***

The theory that emerged in this study is useful because it identifies guiding concepts for developing high-quality CRD. Providing CRD that are accessible, credible, applicable, and positively framed is predicted to minimize the cost and maximize the benefit of information seeking. On the basis of what was shared by the participants in the interviews and the resulting theory, it is expected that the internet will be the primary delivery method of any novel informational intervention

informed by this study. Although universal access to the internet is not a reality, with barriers to access existing for some groups such as those of low socioeconomic status [64], it is estimated that approximately 90% of North Americans have internet access [65], with rates of internet usage in seniors (aged 65 years and older) being over 70% in some areas [65]. As identified in this study and in the HISB literature in general [66,67], the internet circumnavigates common issues with accessibility, such as the need to travel or being available only during business hours and the requirement of appointment times to receive information [67]. In other words, it facilitates access to CRD in a way that minimizes the cost to the individual and their personal projects.

Perhaps the biggest challenge with providing highly accessible internet-based CRD is ensuring that it is adequately applicable to "assist with anticipating the sequence of events that will likely take place" [27]. It is plausible that an inversely proportional relationship exists between applicability and accessibility. For instance, in this study health care providers were identified as providing the most applicable information, yet they could only be accessed through an appointment taking place at the cancer center. The internet, on the other hand, was very accessible, but many participants identified not being sure of what information was relevant to them. Similar findings have been reported elsewhere [68,69]. Taken together with the theory that emerged, this relationship suggests that any novel online informational intervention should be integrated with and informed by local clinical practice patterns.

Given the current state of oncology practice, developing informational interventions that deliver high-quality CRD is likely possible. Contemporary clinical oncology practice relies on evidence-based, guideline-informed practice. A recent retrospective analysis of the Surveillance, Epidemiology, and End Results Program-Medicare database identified deviations from guideline recommendations in the metastatic breast cancer setting occurring only 18% of the time [70]. Similar findings in the early breast cancer population have been observed [71], supporting that, at least within the breast cancer context, care is relatively standardized in many centers. Standardization of care means that informational content can be developed that is capable of being both applicable to those in any given cancer context, providing information that helps them predict what to expect. This is because standardization likely facilitates the production of informational content that can be specific about what is going to happen regarding any given process. In contrast, when there is little standardization, specific management details, such as which clinicians will be involved, the treatments that will likely be offered, or the timing of these treatments, may quickly become inaccurate or unreliable, resulting in confusion and distress for individuals using those details to plan their lives. In addition to standardization, internet-based patient portals, which connect patients with cancer to their health care data such as consultation reports, imaging, laboratory values, and informational support, are being established at an increasing number of cancer centers [66,72-74]. This also supports that clinical integration of online informational resources delivering high-quality CRD is possible. Given that the hurdles of applicability and accessibility can be overcome, understanding

how best to meet specific content needs is an important next step on the path to improving the cancer experience.

### Clinical Implications

The theory that emerged in this study informs current clinical practice in several ways. First, it highlights that clinicians are an important source of CRD. The CRD they provide is considered to be both highly credible [68] and applicable by those affected by cancer. However, the observed limitations associated with health care providers as an information source include accessibility and framing. Clinicians are encouraged to be mindful of *overloading* patients and their informal caregivers. The theory that emerged here supports that providing CRD to patients when they are emotionally overwhelmed, physically exhausted, or impaired by medication is not effective. The concept of accessibility highlights one benefit of patients having access to recordings of their visits with health care providers [75], as this intervention allows the CRD shared by health care providers to be carefully reviewed at a time that best suits the patient and their informal caregivers. With regard to framing, it has been reported elsewhere that identifying what the clinician can do for the patient, including treatment options, is an important aspect of sharing bad news [76-78]. On the basis of the findings of this study, clinicians are also encouraged, when appropriate, to empower patients and informal caregivers following bad news discussions by helping them identify ways to help themselves. This may include assisting with realistic goal setting and identifying activities that the patient and informal caregivers can engage in that will improve their situation in a meaningful way, whether directly related to the disease outcome or not.

### Research Implications

It is anticipated that this theory will be useful in guiding the development of novel interventions by providing a framework of key considerations for maximizing the benefit of information seeking in the cancer context. However, it does not provide explicit guidance on content to be included in a novel resource or the format of that content. Although the information needs of those affected by cancer are well characterized, it is not clear from the literature what specific content and resources would be most helpful for meeting those needs. Researchers are encouraged to build on this study and engage with those affected by cancer as partners [79] to systematically identify the content and method of delivery that is most helpful to those navigating the cancer journey, both in general and in specific contexts not limited to geography, culture, age, gender, sexuality, education, and income.

### Limitations

This theory was generated by engaging with adult patients and their friends and family, without exclusion on the basis of cancer type, stage, or treatment intent. The sampling approach focused

on obtaining diverse, contrasting perspectives and experiences [51,80]. It is expected that, through the constant comparative method used in this grounded theory study, the emerging theoretical framework will be applicable across the general cancer context. However, specific demographic and cultural groups were not focused on, as this was not within the scope of this study. It is certainly plausible that the concepts, such as the components of high-quality CRD that emerged from this study will be of varying relevance in different populations. For instance, it is plausible that accessibility may be more important for persons with hectic schedules—such as young adults balancing establishing a career, growing a young family, maintaining a social schedule, and facing the challenges of a new cancer diagnosis—compared with individuals with fewer competing commitments. In addition, although the interpretation of CRD is presented here as a personal process, it has been demonstrated that some individuals may prefer to involve various members of their community, including elders, extended family, and/or spiritual leaders in decision making [81,82]. These 2 observations serve as a reminder that theory is not a substitute for engaging with the expected end users when developing interventions intended to help improve their cancer experience [83]. Finally, as this research study was conducted in the context of the cancer experience in Western Canada, it is certainly possible that how this framework applies to other areas in Canada, and the world for that matter, may differ. Researchers and clinicians are encouraged to explore how the framework presented here can be modified to best reflect the context of living with cancer in their area [23].

### Conclusions

The objective of this study is to develop a theoretical framework grounded in the cancer experience capable of guiding the development of informational resources. The framework that emerged links the quality of CRD received to the impact that the cancer diagnosis has on an individual's life. The theory comprises 4 variables: personal projects, cancer as a project that interferes with existing personal projects, information as the process of receiving and processing CRD to inform action, and CRD quality. Key features of high-quality CRD include accessibility, credibility, applicability, and framing. On the basis of this theory, the internet is foundational for delivering highly accessible information interventions. Clinicians are encouraged to consider accessibility and framing in how they provide information to those they care for. Future directions for research are expected to include engaging with those affected by cancer as partners to develop and integrate informational interventions based on this theory into clinical care. Interventions informed by this theoretical work are expected to help individuals remain effectively engaged with the personal projects in their lives following a cancer diagnosis and minimize the disruptive impact of the cancer diagnosis on patients and their informal caregivers by decreasing the cost of obtaining useful information.

### Acknowledgments

The authors would like to acknowledge the participants of this study who graciously shared their time, the details of their cancer experience, and their wisdom for the benefit of others.

## Abstract

**Background:** *Herd immunity* or *community immunity* refers to the reduced risk of infection among susceptible individuals in a population through the presence and proximity of immune individuals. Recent studies suggest that improving the understanding of community immunity may increase intentions to get vaccinated.

**Objective:** This study aims to design a web application about community immunity and optimize it based on users' cognitive and emotional responses.

**Methods:** Our multidisciplinary team developed a web application about community immunity to communicate epidemiological evidence in a personalized way. In our application, people build their own community by creating an avatar representing themselves and 8 other avatars representing people around them, for example, their family or coworkers. The application integrates these avatars in a 2-min visualization showing how different parameters (eg, vaccine coverage, and contact within communities) influence community immunity. We predefined communication goals, created prototype visualizations, and tested four iterative versions of our visualization in a university-based human-computer interaction laboratory and community-based settings (a cafeteria, two shopping malls, and a public library). Data included psychophysiological measures (eye tracking, galvanic skin

response, facial emotion recognition, and electroencephalogram) to assess participants' cognitive and affective responses to the visualization and verbal feedback to assess their interpretations of the visualization's content and messaging.

**Results:** Among 110 participants across all four cycles, 68 (61.8%) were women and 38 (34.5%) were men (4/110, 3.6%; not reported), with a mean age of 38 (SD 17) years. More than half (65/110, 59.0%) of participants reported having a university-level education. Iterative changes across the cycles included adding the ability for users to create their own avatars, specific signals about who was represented by the different avatars, using color and movement to indicate protection or lack of protection from infectious disease, and changes to terminology to ensure clarity for people with varying educational backgrounds. Overall, we observed 3 generalizable findings. First, visualization does indeed appear to be a promising medium for conveying what community immunity is and how it works. Second, by involving multiple users in an iterative design process, it is possible to create a short and simple visualization that clearly conveys a complex topic. Finally, evaluating users' emotional responses during the design process, in addition to their cognitive responses, offers insights that help inform the final design of an intervention.

**Conclusions:** Visualization with personalized avatars may help people understand their individual roles in population health. Our app showed promise as a method of communicating the relationship between individual behavior and community health. The next steps will include assessing the effects of the application on risk perception, knowledge, and vaccination intentions in a randomized controlled trial. This study offers a potential road map for designing health communication materials for complex topics such as community immunity.

## KEYWORDS

community immunity; herd immunity; vaccination; vaccine hesitancy; avatar; web application

## Introduction

### Background

*Herd immunity* or *community immunity* refers to the reduced risk of transmission of infection among susceptible individuals in a population through the presence and proximity of immune individuals. Community immunity (the term we use throughout this paper) works by breaking the chain of transmission and decreasing the probability of contact with an infectious agent, thereby preventing the spread of infectious agents in susceptible populations [1,2]. High vaccination coverage is generally needed to achieve this protection at the population level [3]. Decisions not to vaccinate affect population-level vaccine coverage and can result in outbreaks of vaccine-preventable diseases by pushing the vaccine coverage rate below the community immunity threshold [4-6].

Although some research suggests that people's immunization decisions are primarily influenced by perceived benefits and harm at the individual level rather than those at the community level [7], other studies have suggested that improving the understanding of community immunity may lead to an increase in the intention to be vaccinated [8-10].

Community immunity is a challenging concept to convey. It depends on multiple factors, namely, vaccine effectiveness and coverage, whether or not susceptible individuals form clusters, timing of vaccine administration (ie, delayed vaccination results in longer periods of susceptibility and therefore increased likelihood of infection), and the presence or absence of serotype replacement [11]. It is also affected by historical rates of vaccination coverage where there are potential immunity gaps among people in specific age groups (eg, adolescents and young adults for MMR [measles, mumps, and rubella] vaccines). Possibly because the interplay between all these variables is complicated, people demonstrate an uneven understanding of

the connection between individual-level vaccination behavior and community-level risk and benefits [12].

A systematic review identified visualization as a promising avenue for communicating the complex concept of community immunity [13]. By visualization, we mean the visual presentation of data or information. Visualization is a powerful communication mechanism because it enables people to rapidly understand complex information [14]. In this paper, we use the term *visualization* to refer to a brief narrated animation about community immunity. We use the term *application* when referring to a complete web-based application, combining the visualization with an interactive section in which people make their own avatars.

### Objectives

In this study, we seek to iteratively develop an application about community immunity that would be understood by people with varying levels of education and to assess and optimize people's cognitive and emotional responses to the application. Our focus included emotions because emotions influence people's decisions [15-17], including health decisions [18-20], and specifically vaccination decisions [21,22].

Our study aims to determine (1) whether and how people attend to different visual elements to explain the concept of community immunity (what is community immunity and how it works), (2) whether these elements are understandable, and (3) whether people understand how community immunity safeguards people, especially vulnerable populations who cannot be vaccinated or who may not respond to vaccines owing to their age or suppressed immune system.

## Methods

### Ethics Approval and Consent to Participate

This project was approved by 'Comité d'éthique de la recherche en sciences de la santé' ethics committee of Laval University

(approval no: 2017-137 R-2/15-07-2019). All participants provided written informed consent.

### Concept Map

Before designing the first prototype, our multidisciplinary team began by developing a concept map [23] of what the prototype should convey ([Multimedia Appendix 1](#)). Concept maps are defined as tools for organizing and representing knowledge [24] or a graphical representation of different concepts and the relationship between those concepts [25]. Our concept map was used to organize the underlying content presented in the visualization within three major themes: (1) community, (2) infection, and (3) vaccines. We expanded and refined the components of each theme throughout the study in response to participants' feedback. The theme *community* included content about how a community is made up of individuals, including vulnerable people living among other individuals. The theme *infections* included content about how different pathogens cause different infections and spread at different rates. The theme *vaccines* included content about how effective vaccines may or may not be, how some vaccine effectiveness may wane over time, and how different diseases require different vaccine coverage to prevent the spread of infection and to create community immunity.

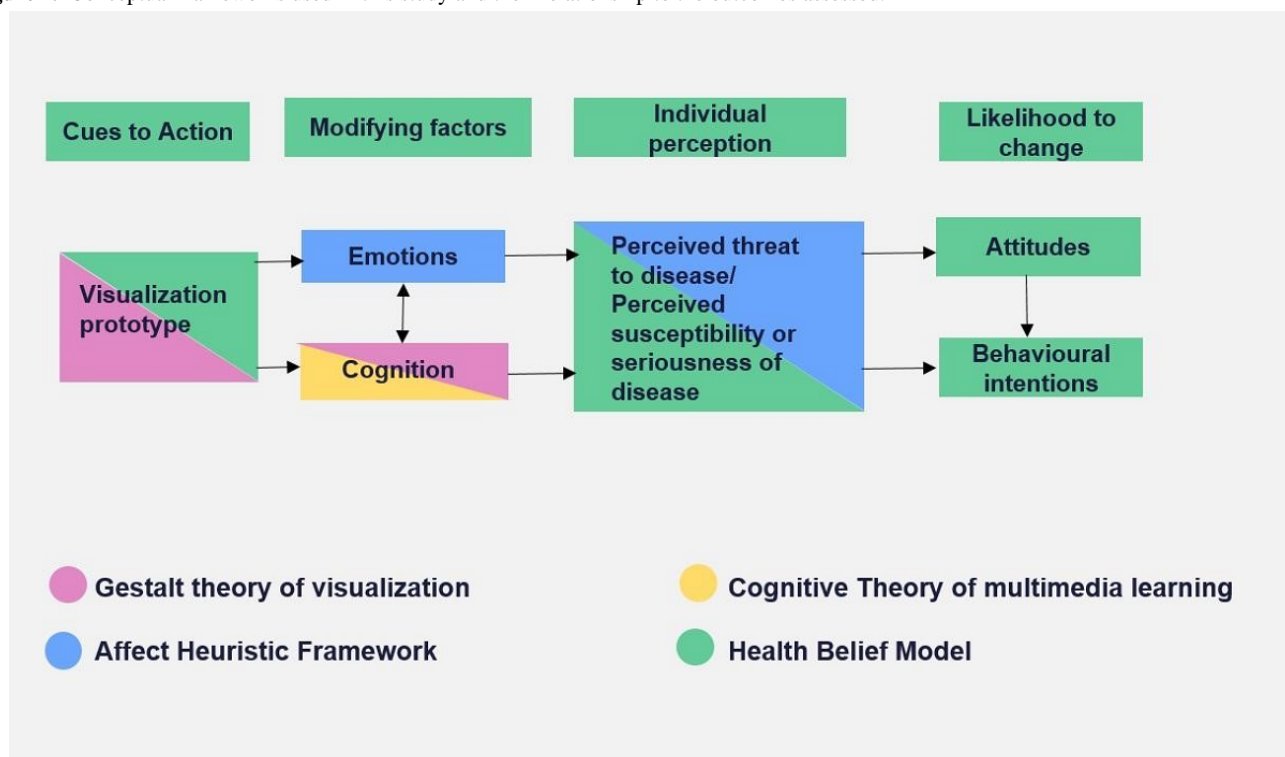

### Overall Approach

We developed our prototype application according to the concept map and predefined our communication goals for each element of the prototype. Each element of the prototype was linked to what it was intended to convey in the concept map, and what cognitive and/or affective (emotional) responses we aimed to evoke among participants. Across multiple iterative cycles ([Multimedia Appendices 2-5](#)), we then measured participants' responses to assess the extent to which each element of our application met its associated communication goals. In each cycle, we further sought to understand participants' needs, strengths, and limitations; observe how they attended to visual elements and colors; and identify potential improvements that could be made to the application.

### Framework

To design our application and interpret people's responses, we developed an integrated framework, as shown in [Figure 1](#), combining four existing frameworks or models: (1) the *Health Belief Model* [26], (2) *Gestalt visual principles* [27], (3) the *Cognitive Theory of Multimedia Learning* [28,29], and (4) *Affect Heuristic* [30,31].

**Figure 1.** Conceptual frameworks used in this study and their relationship to the outcomes assessed.

We selected the *Health Belief Model* [26] as the most likely framework to help us understand potential health behavior as a result of exposure to our intervention. This model has been developed and used to assess behavioral changes among people. However, this model hypothesizes that the intention or likelihood of an individual to take action stems from individual perception, and there is less detail regarding how such perceptions are shaped by different cues to action. We augmented this model to better understand the antecedents of

perception by using *Gestalt visual principles* to inform the design of our visualization. Gestalt visual principles emphasize that the whole cannot be determined by simply knowing the individual pieces but emerges through how the pieces are combined or structured. These principles can be used to understand how the structure, configuration, or layout of elements in a visualization influence how people perceive the visualization. For example, the figure-ground principle describes how humans perceive objects or figures according to the contrast

between elements and their backgrounds, and the proximity principle describes how images or figures located near each other are considered as a part of the same group, whereas objects apart are perceived as separate. Gestalt visual principles can thus help predict the effects of spacing, timing, and configuration when presenting information visually [32]. The *Cognitive Theory of Multimedia Learning* describes how people learn via two channels—auditory and visual—and use both together to build mental representations from words (audio) and images (visual) [28,29]. Finally, the *Affect Heuristic* provides an explicit framework for how the experiential system influences decisions via affect and emotions. The experiential system encodes reality in images, metaphors, and narratives, to which people have affective responses [31]. The Affect Heuristic helps structure analyses of emotions in response to the visualization.

Our guiding methodological framework was that of a user-centered design [33] in which potential users are consulted early and often, with their responses to prototype versions serving to help guide iterative improvements of the intervention or tool.

### Study Participants and Setting

Across all four study cycles, we recruited participants who were aged 18 years or older, had either no vision problems or corrected vision problems (eg, using eyeglasses or contact lenses), and were able to provide written informed consent, read and understand French or English, and use computers. In cycles 1, 3, and 4, we recruited participants to come to our university-based human-computer interaction laboratory by sending invitations to a university-wide listserv directed at all students, staff, and others. In cycle 2, we recruited participants in person by approaching them at a university-based cafeteria. In cycle 3, in addition to the listserv recruitment, we also recruited participants in person at a public library and two shopping malls located in areas of the city whose postal codes are associated with more diverse educational backgrounds. An incentive of either Can \$10 (US \$7.46; cycles 1, 2, 4) or Can \$20 (US \$14.92; cycle 3) was offered for their time and any transportation costs incurred. In cycle 3, we offered a larger incentive because, after viewing our visualization, participants subsequently interacted with materials developed for other studies, meaning that the individual sessions were of a longer duration.

### Psychophysiological Measurement

Design cycles 1, 3, and 4 used four psychophysiological data collection methods: eye tracking, galvanic skin response, electroencephalogram (EEG), and facial emotion recognition. We used eye tracking to determine what people were looking at and to measure participants' visual attention [34]. We used galvanic skin response to determine when participants experienced peaks in emotional arousal [35]. Such peaks indicate instances of strong emotions. We expected the visualization to elicit strong emotions when, for example, something alarming happened, such as a vulnerable person getting infected with a contagious disease. We used facial emotion recognition software to assess emotional valence (ie, whether emotions were positive or negative) [36]. We expected participants' emotions to be positive when the visualization depicted positive things happening, for example, community immunity being achieved and protecting community members, and to be negative when the visualization depicted negative things happening, for example, an infection spreading in the community. We used EEG to assess participants' cognitive workload and engagement while looking at the information provided in the visualization [37]. We aimed for participants to experience higher engagement when interacting with the visualization without exceeding a cognitive load threshold above which they might be less likely to process new information.

### Apparatus and Procedures

As shown in Figure 2, participants sat in a stationary chair in front of a desk with a mobile eye tracker (Tobii X2-30) and a webcam mounted on the computer monitor, a keyboard, a mouse, and computer speakers. A member of the research team explained each participant-worn device while placing it. These participant-worn devices were a portable galvanic skin response apparatus (Shimmer Sensing Shimmer3 GSR+) worn on the participant's nondominant hand and an EEG (Advanced Brain Monitoring B-Alert X-Series) fitted on the participant's head, using a gel on the electrodes. We followed standard procedures for each device's calibration [38-41]. Data streams for all devices were synchronized and saved using the iMotions Attention Tool version 7 (cycle 1) or version 8 (cycles 3 and 4) [42].

**Figure 2.** Human-computer interaction laboratory apparatus.

### Verbal Feedback

We complemented psychophysiological data on participants' nonverbal reactions with brief verbal feedback. Using semistructured interview questions ([Multimedia Appendices 6-8](#)), we asked participants to summarize in their own words what they saw in the visualization, what message it aimed to convey, and anything they found confusing or unclear. They

were also asked questions about how to improve the visualization or personalized avatar building. If their explanation about the visualization indicated that they may have missed some visual elements, we probed for more specific information on how to improve those visual elements. We recorded responses using an audio recorder and took notes. [Table 1](#) shows the summarized study design.

**Table 1.** Summarized study design.

Cycles	Study setting	Sample size	Method for data collection
First cycle	University-based human-computer interaction laboratory via university-wide listserv (email)	n=8	Psychophysiological measurement and verbal feedback
Second cycle	University-based cafeteria (by approaching them)	n=11	Verbal feedback
Third cycle	<ul style="list-style-type: none"> <li>University sample: university-based human-computer interaction laboratory via university-wide listserv (email)</li> <li>Community sample: a public library and two shopping malls (by approaching them)</li> </ul>	<ul style="list-style-type: none"> <li>University sample: n=49</li> <li>Community sample: n=34</li> </ul>	Psychophysiological measurement and verbal feedback
Fourth cycle	University-based human-computer interaction laboratory via university-wide listserv (email)	n=8	Psychophysiological measurement (eye-tracking only) and verbal feedback

### Analysis

Our analytical aim was to assess whether the application achieved its communication goals. To analyze *psychophysiological measurements*, we examined participants' reactions to each element according to its associated communication goal. We first identified the periods of each element in the visualization according to the voice-over timing. We assessed whether the participant was visually attending to each element by defining an area of interest for each element (eg, a rectangular region around a symbol) and examining whether the participant had any eye fixations of 200 ms or more

in that area of interest. Fixations are described in the literature as lasting from 100 to 500 ms [43,44], 150 to 600 ms [45], or as low as 100 ms but *typically 200 to 600 ms* [46]. We selected 200 ms to maximize the likelihood of detecting fixations among people viewing a rapidly moving visualization while avoiding contaminating our data with shorter pauses in eye movement that might not indicate the person extracting any visual information. During the times when the element was present, we then also examined galvanic skin response, facial emotion, and EEG data as predefined for each communication goal. To analyze the galvanic skin response, we used an algorithm to detect peaks in arousal [47]. Previous literature suggests that

this algorithm performs well in detecting such peaks [48,49]. To account for known lags in galvanic skin response (ie, the fact that skin response lags behind experience of heightened arousal by 3 to 5 s [50]), we inspected data for peaks in arousal during the defined time for each communication goal and for an additional 5 s afterward. The existence of such peaks would indicate that the participant experienced a heightened emotion of some kind while that element was displayed. For instance, in the first cycle, some participants showed a peak in arousal when the visualization showed vulnerable people getting infected. To analyze facial emotions, we used the facial recognition software FACET (Emotient) within the iMotions Attention Tool [51]. This software uses algorithms to translate the movement of facial features, such as eyes, eye corners, brows, mouth corners, and nose tip, into classifications of emotional valence. Recent work suggests that this automated facial-expression analysis software performs well for detecting emotional states [52,53]. We inspected the aggregated data for the number of occurrences across all respondents, and for any positive, negative, or neutral emotional valence elicited by the visualization. To analyze the EEG data, we used algorithms to estimate participants' cognitive workload and engagement [39]. Cognitive workload indicates the extent to which working memory is being used. Engagement indicates a participant's attentiveness while watching the visualization. Previous studies have validated these algorithms for measuring cognitive workload and engagement [54-56]. Cognitive workload is reported on a continuous scale from 0 to 1, with 0 to 0.4 classified as boredom, 0.4 to 0.7 as optimal workload, and 0.7 and above as information overload. Engagement levels are also reported on a continuous scale from 0 to 1, with 0 to 0.1 classified as sleepiness and drowsiness, 0.3 as distraction, 0.6 as low engagement, and 0.6 to 1 as high engagement. A summary score was computed by averaging values for each communication goal across all participants. For cycles with fewer than 10 participants, we examined emotional valence and EEG data at the individual level only. For cycles with 10 or more participants, to summarize data while continuing to weigh data from each participant equally, we calculated the mean valence, cognitive load, and engagement for each participant for each element, and then computed summary statistics and indices of dispersion across all participants. When these mean values were normally distributed across participants, our summary statistic was a global sample mean and our index of dispersion was a sample SD. When these mean values were skewed across participants, our summary statistic was a global sample median and our index of dispersion was an IQR. In addition to analyses by area of interest, we also inspected the heat maps of full screens. Heat maps are visual representations of data showing the relative intensity of participants' visual attention to see where participants are looking at the most.

To analyze *verbal feedback*, two independent analysts (HH and EP) examined the responses independently and assessed the extent to which responses aligned with communication goals for each cycle by deductively comparing participant responses to our detailed concept maps. Any disagreement was resolved through discussion with the senior author (HW). We noted anything that failed to align with communication goals or was confusing to participants to guide changes for the next cycle.

After collecting data for each cycle, the first author (HH) compiled and reviewed data with coauthors (EP and MTB), summarized problems, and drafted recommendations. These recommendations were then discussed with the senior author (HW) and, when necessary, the larger team (remaining authors) to determine changes for the next cycle.

## Iterative Cycles

### First Cycle

Our multidisciplinary team developed the first version of a visualization based on epidemiological evidence that we had organized in the concept map. We prespecified communication goals for different visual design elements (ie, what we wanted to convey with each element of the visualization and how we expected people to respond). We used four devices (Figure 2) and brief verbal feedback (audio-recorded) to assess participants' interpretations and reactions to the content of the visualization. After viewing, the participants described the visualization in their own words. They were also asked the following questions: What do they think this visualization wants to convey? Is there anything in the visualization that they find unclear or confusing?

### Second Cycle

We developed a revised version of the visualization based on participants' feedback in the first cycle. We predefined our communication goals for the second cycle (Multimedia Appendix 9) and refined the concept map by adding how different diseases spread differently (pertussis, measles, and influenza as test case) and that different diseases require a different number of vaccine doses (eg, a single dose, multiple, booster, or annual doses). The visualization showed how different parameters (eg, vaccine coverage and intracommunity contact) can influence community immunity. We audio-recorded a brief verbal feedback.

### Verbal Feedback

In this cycle, we only used audio-recorded verbal feedback (no psychophysiological measurements were used in this cycle [Table 1]) to assess participants' interpretations of the visual content and their suggestions to improve it. We chose this method to increase the richness of verbal responses for each visual element. We asked participants to describe their understanding of the visualization, how vaccines work to protect people from diseases, what it means to be immune, and if there was anything confusing or unclear in the visualization. We showed images from the visualization to participants and asked specific questions (eg, what do the icons of the older woman and the baby represent in this visualization? What do the images of viruses causing different diseases represent?). We also asked participants about different terms used to explain community immunity, that is, herd immunity, community immunity, and community protection and which term they prefer.

### Third Cycle

We developed a third version of a visualization based on participants' feedback in the second cycle. We used the same techniques as in the human-computer interaction laboratory described earlier, along with verbal feedback. The third cycle was tested in two different settings: a university and different

locations in a community setting (two shopping malls and a public library). We predefined the communication goals for the third cycle (see [Multimedia Appendix 10](#) for university sample and [Multimedia Appendix 11](#) for community sample). We asked participants to describe, in their own words, the visualization shown to them. We included a larger number of participants in this cycle, as our visualization was closer to launch and we wanted to make sure that it was easily understood and that people grasped the concept of community immunity. We also wanted to test if our communication goals were achieved among people with varied levels of education.

#### **Fourth Cycle**

By the fourth cycle, the content of our visualization had achieved nearly all predefined communication goals. However, one major issue remained. Up to this cycle, we had used generic avatars in our visualization. On the basis of data from previous cycles, we were concerned about the extent to which people could identify with the generic avatars presented in the visualization. Therefore, we developed an additional piece in which people were asked to build their own communities by making personalized avatars (their own, 2 vulnerable people in their community, and 6 avatars of people around them who could be family members or coworkers). We added this feature so that people could better identify with the avatars that were subsequently integrated into our application to explain community immunity. We asked participants to provide critical feedback on the process of creating their own avatars and

building their own communities. In this cycle, we focused on three questions related to the new features: (1) Was an onboarding tutorial describing how to build avatars a useful addition? (2) Was it easy to build the avatars? and (3) Was the length of the avatar-building process reasonable? We further asked what participants thought of the avatar-building options, including the accessories and color palettes for skin tone and hair color. Participants also described the application in their own words. We only used the eye-tracking device in this cycle to assess visual attention.

## **Results**

### **Study Participants**

A total of 110 eligible participants across the four cycles (cycle 1 [n=8], cycle 2 [n=11], cycle 3 [n=83], and cycle 4 [n=8]) participated in the study ([Table 2](#)). Overall, 61.8% (68/110) of the participants were women and 34.5% (38/110) were men; 3.6% (4/110) did not report their gender. The mean age was 38 years (SD 17). Furthermore, 96.3% (106/110) of the participants spoke and understood French, 29.0% (32/110) spoke and understood English, whereas 3.6% (4/110) did not report the language spoken. More than half of the participants (65/110, 59.0%) had a university-level education. Most participants (85/110, 77.2%) reported no physical disability, 16.3% (18/110) reported some form of disability, and 2.7% (3/110) preferred not to answer. Across the 110 participants, 3 (2.7%) did not complete the sociodemographic questionnaire.

**Table 2.** Sociodemographics of each cycle.

Demographic characteristic	First cycle (n=8)	Second cycle (n=11)	Third cycle (university sample; n=49)	Third cycle (community sample; n=34)	Fourth cycle (n=8)	Across all cycles (N=110)

## First Cycle

### Findings From This Cycle

We obtained psychophysiological data from 6 of 8 participants and qualitative verbal feedback from 8 of 8 participants. There were missing psychophysiological data for 2 participants because of technical issues with the devices. Specifically, we had problems initializing the EEG.

As described in Table 3, the design elements of the visualization achieved their communication goals to varying degrees. All participants (8/8) reported that people in clusters of hexagons represented members of the community. Most participants (7/8) reported that a yellow background indicated vulnerable people,

and 6 of 6 participants responded psychophysiological in desired ways, that is, peaks in arousal, and high engagement when a vulnerable person became infected. All participants (8/8) reported that red connecting lines represented the spread of infection. Half of the participants (3/6) did not visually attend to the appearance of a thick blue band indicating community immunity upon its appearance. When questioned about its meaning, most participants (6/8) reported that the blue band around vulnerable people meant community immunity, whereas 2 of 8 participants interpreted it as some sort of linkage between the older woman and the baby. All participants (8/8) explicitly mentioned in their explanation that when enough people were vaccinated, this created a protective barrier of community immunity to prevent the spread of infection. Overall, all

participants had a neutral (6/6) facial expression when community immunity was explained in the visualization.

### ***Changes for the Next Cycle***

A number of aspects of the first version of the visualization needed improvement. First, only a few participants (1/6) visually attended to the appearance of the central avatar, and only half of the participants (4/8) reported that the central avatar represents them. Second, most people (5/8) did not understand that the avatars around them could be others they see often but who are not members of their immediate family, for example, coworkers. To address these two issues, for the next cycle, we presented the center avatar, immediate family members, colleagues, and other regular contacts in the same visual frame by zooming in and out. Third, participants showed either low engagement (2/6) or drowsy or unengaged (4/6) when an infection first entered the community. To address this, rather than having the infection simply appear, we used a red line to

visually represent the entry and spread of infection in the community. Fourth, participants (8/8) suggested that the visualization came across as a simple promotion of immunization rather than explaining how community immunity works. Although these concepts are interrelated in the sense that community immunity requires sufficient numbers of people to be immunized, our goal was to explain community immunity. To address this issue, we increased the focus on community immunity in the narration of our visualization. In discussing this latter change among our team, we identified a need to test the terms herd immunity, community protection, and community immunity by asking participants in the next cycle about their reactions to each of the three terms. In our team discussions, we also identified the need for new visual elements about different viruses (using measles, pertussis, and influenza as examples) to explain in greater detail why different diseases require vaccine doses and schedules.

**Table 3.** The communication goals set for the first cycle of visualization.

S. no.	Design element or a concept	Message design elements intended to convey in the visualization (desired interpretation and/or reaction)	What users reported when viewing these design elements (verbal feedback; n=8)	How users reacted to these design elements (psychophysiology; n=6)
1.		The avatar represents the participant.	Of 8 participants, 4 reported that the avatar represents them. The other 4 participants interpreted it as representing a person, but not them.	Of 6 participants, 1 visually attended to the appearance of the avatar. Overall valence was positive across the 6 participants.
2.		The hexagonal shape represents a unit.	Of 8 participants, 2 reported that each hexagonal shape was a separate unit. The other 6 participants interpreted it as an unspecified symbol or a honeycomb.	N/A <sup>a</sup> (no psychophysiology data specific to this visual element).
3.		A person in a hexagonal shape around the central avatar represents the participant's regular contacts (family members, friends, neighbors, or colleagues).	Of 8 participants, 3 reported that a person in hexagonal shape was a member of their community; 5 participants interpreted it as their family member.	N/A (no psychophysiology data specific to this visual element).
4.		<ul style="list-style-type: none"> <li>Icon of an older woman and a baby represents vulnerable people or those with fragile immune systems (eg, patients with cancer).</li> <li>High arousal and visual attention were expected when vulnerable people appeared in the visualization.</li> </ul>	All participants (8/8) reported that an older woman and a baby in the visualization represent vulnerable people.	Of 6 participants, 4 visually attended when vulnerable people appeared in the visualization. Of 6 participants, 3 showed a peak in arousal when vulnerable people appeared.
5.	Yellow color behind <i>baby</i> and <i>an older woman</i>	Yellow color signals vulnerable people.	Of 8 participants, 7 reported that yellow color signals vulnerable people; 1 participant did not pay attention to the yellow color in the visualization.	N/A (no psychophysiology data specific to this visual element).
6.		Red color signals diseased or infected; blue color signals vaccinated or protected; gray color signals susceptible to disease or infection	<ul style="list-style-type: none"> <li>All participants (8/8) reported that the red color in the visualization represents disease, infection, or danger.</li> <li>All participants (8/8) reported that the blue color in the visualization signals being safe from diseases or vaccinated.</li> <li>Of 8 participants, 6 reported that gray color signals being susceptible to disease/infection or not vaccinated; 2 interpreted gray color as people who can be vulnerable.</li> </ul>	N/A (no psychophysiology data specific to this visual element).

S. no.	Design element or a concept	Message design elements intended to convey in the visualization (desired interpretation and/or reaction)	What users reported when viewing these design elements (verbal feedback; n=8)	How users reacted to these design elements (psychophysiology; n=6)
7.	When infection first enters the community.	High arousal, engagement, and visual attention were expected when the visualization shows when the infection first enters the community.	No comments recorded.	<ul style="list-style-type: none"> <li>Of 6 participants, 3 visually attended when infection first entered the community.</li> <li>Of 6 participants, 2 showed a peak in arousal when infection first entered the community.</li> <li>No participants (0/6) were most likely to be in a high-engagement state when the infection first entered the community; 2 of 6 participants were most likely to be in a low-engagement state; 4 of 6 participants were most likely to be in a drowsy (unengaged) state.</li> </ul>
8.	When the central avatar gets infected.	High arousal, engagement, and visual attention were expected when the visualization shows the central avatar representing the participant getting infected.	No comments recorded.	<ul style="list-style-type: none"> <li>Of 6 participants, 1 visually attended when the avatar got infected.</li> <li>Of 6 participants, 4 showed peaks in arousal when the avatar got infected.</li> <li>Of 6 participants, 4 were most likely to be in a high-engagement state when the avatar got infected.</li> </ul>
9.		<ul style="list-style-type: none"> <li>Red connecting lines represent the spread of infection.</li> <li>High arousal, engagement, and visual attention was expected when the visualization showed red connecting lines indicating the spread of infection.</li> </ul>	All participants (8/8) reported that red connecting lines indicate the spread of infection.	<ul style="list-style-type: none"> <li>Of 6 participants, 1 visually attended to red connecting lines.</li> <li>Of 6 participants, 1 showed peak in arousal when red connecting lines appeared.</li> <li>All participants (6/6) were most likely to be in a high-engagement state when red connecting lines appeared.</li> </ul>
10.	When the vulnerable people get infected.	High arousal, engagement, and visual attention were expected when the vulnerable people got infected.	No comments recorded.	<ul style="list-style-type: none"> <li>Of 6 participants, 3 visually attended when vulnerable people got infected.</li> <li>All participants (6/6) showed a peak in arousal and a negative valence when vulnerable people got infected.</li> <li>All participants (6/6) were most likely to be in the state of high engagement when vulnerable people got infected.</li> </ul>
11.	When community immunity was explained	<ul style="list-style-type: none"> <li>Participants' explanations include the concept of community immunity.</li> <li>High arousal, visual attention, and positive valence was expected when the visualization demonstrated the concept of community immunity.</li> </ul>	All participants' (8/8) explanations include the concept of community immunity, that is what it is and how it works.	<ul style="list-style-type: none"> <li>Of 6 participants, 4 visually attended when community immunity was explained.</li> <li>Of 6 participants, 4 showed peak in arousal when community immunity was explained.</li> <li>Overall facial expression was neutral across the 6 participants.</li> </ul>
12.				

S. no.	Design element or a concept	Message design elements intended to convey in the visualization (desired interpretation and/or reaction)	What users reported when viewing these design elements (verbal feedback; n=8)	How users reacted to these design elements (psychophysiology; n=6)
		<ul style="list-style-type: none"> <li>Thick blue band around vulnerable people indicates community immunity.</li> <li>High engagement and visual attention was expected when the thick blue band appeared around vulnerable people.</li> </ul>	Of 88 participants, 6 reported that the thick blue band around vulnerable people represents community immunity, which protects them from getting infected.	<ul style="list-style-type: none"> <li>Of 6 participants, 3 visually attended when the blue line appeared around vulnerable people.</li> <li>All participants (6/6) were most likely to be in a high-engagement state when the blue line appeared around vulnerable people.</li> </ul>
13.		<ul style="list-style-type: none"> <li>Blue lines spreading out from vaccinated people indicate the community immunity.</li> <li>High engagement was expected when blue lines appeared indicating the community immunity.</li> </ul>	All participants (8/8) reported that blue lines spreading out from vaccinated people show the protective barrier that is community immunity.	All participants (6/6) were most likely to be in a high-engagement state when blue lines appeared indicating the community immunity.
14.		The cluster of hexagons represent different communities.	All participants (8/8) reported that clusters of hexagons represent different communities.	N/A (no psychophysiology data specific to this visual element).
15.		The avatar in the cluster of hexagons represents members of the community.	All participants (8/8) reported that the avatar in the clusters of hexagons represents members of the community.	N/A (no psychophysiology data specific to this visual element).
16.		The gray outline around the cluster of hexagons indicates a group or members of the same community.	Of 8 participants, 6 reported that the gray outline indicates the group or members of the same community.	N/A (no psychophysiology data specific to this visual element).
17.		<ul style="list-style-type: none"> <li>The orange outline showed the participant's community.</li> <li>High engagement was expected when an orange outline appeared around their community.</li> </ul>	Of 8 participants, 7 interpreted the orange outline as their community.	<ul style="list-style-type: none"> <li>Of 6 participants, 3 visually attended when the orange outline appeared around their community.</li> <li>All participants (6/6) were most likely to be in a high-engagement state when the orange outline appeared around their community.</li> </ul>

<sup>a</sup>N/A: not applicable.

## Second Cycle

### Findings From This Cycle

The second version of the visualization achieved most of its communication goals. [Multimedia Appendix 9](#) provides details analogous to those provided in [Table 3](#) for the first cycle. All participants (11/11) reported that the people in the hexagon represent members of their community or people with whom they were in daily contact, the *older woman* and the *baby* in the visualization represented vulnerable members of the community, and the hexagons represented individuals. Most participants (7/11) reported that the visualization communicated that vaccines are not perfect, and nearly all reported that some vaccines require multiple doses or booster shots to work (10/11). All participants' (11/11) responses showed that they understood the use of colors to signal vulnerability and infection such as a yellow background indicating vulnerable people, and that red

color showed propagation of the disease. All participants (11/11) reported that community immunity safeguards vulnerable people, that is, when sufficient number of people around them were vaccinated, whereas lower vaccine coverage puts communities and the people within them, especially vulnerable populations, at risk of becoming sick. Participants indicated that the term *community immunity* best conveyed the concept compared with terms *herd immunity* (which implies herds of animals) or *community protection* (which participants indicated evoked images of protection via firearms.) Few (2/11) participants reported that the color blue indicated immunity, and none (0/11) showed understanding that the color gray indicated susceptibility to infection. Some participants reported that diseases differ (3/11) and spread at different rates (3/11). Few participants (2/11) reported vaccine-induced immunity, whereas none reported the concept of natural immunity (0/11). Some participants (3/11) reported the role of vaccine

effectiveness in creating community immunity, whereas others did not.

### *Changes for the Next Cycle*

Aspects of the visualization that needed to be improved included conveying that the color blue means being vaccinated or immune, the color gray means being susceptible, and focusing attention on the fact that different diseases spread at different rates. In addition, the visualization did not yet help participants understand the role of vaccine effectiveness in community immunity or distinguish between natural immunity and vaccine-induced immunity. Participants further suggested that the visualization was too long and provided too much information to retain. In the third cycle, we kept the colors blue and gray but explained their meaning in the narration. We removed the images representing different viruses but kept the narration explaining how different infections spread at different rates, illustrating it with infection spread. We further added depictions of different vaccine coverage for different diseases to show how community immunity prevents the spread of infection. We removed images illustrating natural and vaccine-induced immunity and different vaccine doses, and instead wove this information into the narration illustrated by a single image of immunity. We shortened the visualization for the next cycle to about 2 min and used the term community immunity in the narration.

### **Third Cycle**

#### *Findings From This Cycle*

The third cycle mostly achieved its communication goals (see [Multimedia Appendix 10](#) for university sample and [Multimedia Appendix 11](#) for community sample). A total of 83 participants (university sample:  $n=48$ ; community sample:  $n=34$ ) participated in our third cycle. Most participants (51/83, 61%) reported that the *older woman* and *the baby* represented vulnerable people or those with fragile immune systems (eg, patients with cancer). Most participants' (60/83, 72%) verbal feedback summarizing the visualization included the point that vaccines prevent the spread of infection. Most participants (42/83, 50%) reported that community immunity safeguards everyone, some participants (34/83, 41%) reported that the thick blue band around an *older woman* and *the baby* demonstrated community immunity protecting vulnerable population and that an individual's decision to get vaccinated or not has an impact on other people in their community (36/83, 43%). Most participants visually attended to all communication goals in a desired way; for example, nearly all participants (80/83, 96%) visually attended when the contagious disease spread to vulnerable

people, when vaccines wane over time (74/83, 89%), and when community immunity safeguards everyone (81/83, 97%). Overall, across all 83 participants, people were likely in a state of high engagement and optimal workload during the explanation of how community immunity safeguards everyone.

### *Changes for the Next Cycle*

Results from this cycle suggested that participants mostly understood the information presented in the visualization. However, some wording was unclear, so we made changes to the script to clarify it. For example, in the portion of the animation explaining how vaccines' effectiveness wanes over time, we changed the script from, *They don't work every time, and can wane over time*, to, *their protection can fade over time*. We also changed the order of some design elements to better align with how people appeared to understand the information during testing. For example, rather than first presenting how different diseases spread at different rates and then explaining community immunity, we changed these to present community immunity first, facilitating the explanation of why some diseases need more people to be vaccinated to create community immunity. Most importantly, until this cycle, we used generic avatars in the visualization. However, the generic avatars continued to be difficult for participants to interpret. To personalize the avatars so that people could better identify with them, we added a functionality so that people could build their own communities by making an avatar for themselves, 2 avatars for vulnerable people in their community, and 6 avatars of other people they see regularly, such as family members or coworkers. These personalized avatars were then integrated into our visualization to help participants better understand and respond emotionally to the idea of family members, friends, or other close contacts being vulnerable and at risk of infection.

### **Fourth Cycle**

We tested the last version of the application with 8 participants. All participants (8/8) reported what community immunity was and how it worked. Participants found the tutorial on how to create avatars confusing and preferred to make avatars by reading instructions. All participants (8/8) were able to easily create avatars by following step-by-step instructions, without a tutorial. All participants liked the color palettes for skin tone and hair colors. A participant suggested adding different accessories with options such as caps, hats, and a hijab to include more culturally diverse and realistic avatars.

The key findings of all cycles and major changes implemented are summarized in [Table 4](#).

**Table 4.** Key findings of all cycles.

Cycles	Key communication goals achieved	Key communication goals not achieved	Summary of psychophysiological data (where applicable)	Summary of how issues were addressed in the next cycle
First cycle	<ul style="list-style-type: none"> <li>Nearly all participants reported that the color yellow represents vulnerable people.</li> <li>Most participants reported that the blue band around vulnerable people meant protection.</li> <li>All participants reported that the avatars in the cluster of hexagons represent members of the community.</li> </ul>	<ul style="list-style-type: none"> <li>Most participants did not understand that the central avatar represents them.</li> <li>Some participants did not understand that the avatars around them could include nonfamily contacts, for example, coworkers.</li> <li>All participants understood the purpose of visualization as promoting immunization rather than explaining the concept of community immunity.</li> </ul>	<ul style="list-style-type: none"> <li>Most participants visually attended to the appearance of vulnerable people.</li> <li>Most participants had peaks in arousal and showed high engagement when avatars got infected.</li> <li>All participants showed high engagement when red lines showed the spread of infection.</li> <li>Most participants visually attended, and all participants had peaks in arousal and showed high engagement when vulnerable people got infected.</li> <li>Most participants visually attended and had peaks in arousal when community immunity was explained.</li> <li>All participants showed high engagement when blue lines around people spreading out from vaccinated people showed community immunity.</li> </ul>	<ul style="list-style-type: none"> <li>We presented the center avatar, immediate family members, colleagues, and communities in the same visual frame by zooming in and out.</li> <li>We removed the term immunization in the narration script and focused more on community immunity.</li> <li>We decided to test the terms herd immunity, community protection, and community immunity by asking participants which term they relate to and prefer.</li> <li>We added a question to be asked in the next cycle about the shape of hexagons presented in the visualization.</li> <li>We added a new design element in the next cycle explaining how different viruses (eg, measles, pertussis, influenza) spread at different rates and require different vaccine schedules.</li> </ul>
Second cycle	<ul style="list-style-type: none"> <li>All participants reported that yellow signaled vulnerability.</li> <li>All participants reported that red signaled infection.</li> <li>All participants reported that hexagons represent people.</li> <li>Nearly all participants reported community immunity safeguards vulnerable people when sufficient people around them are vaccinated.</li> <li>All participants preferred the term community immunity over herd immunity or community protection.</li> </ul>	<ul style="list-style-type: none"> <li>Few participants reported that blue meant vaccinated or immune.</li> <li>No participants reported that gray meant susceptible.</li> <li>Most participants did not report that different diseases spread at different rates.</li> <li>Most participants did not report the role of vaccine effectiveness in community immunity.</li> <li>Few participants reported vaccine-induced immunity.</li> <li>None of the participants reported accurate understanding of natural immunity.</li> <li>All participants suggested that the visualization should be shorter.</li> </ul>	<ul style="list-style-type: none"> <li>N/A<sup>a</sup></li> </ul>	<ul style="list-style-type: none"> <li>We removed images of viruses but retained in the narration explanation of how different infections spread at different rates.</li> <li>We added images about different levels of vaccine coverage to achieve community immunity for different diseases.</li> <li>We removed images about different vaccine doses and natural and vaccine-induced immunity.</li> <li>We shortened the visualization to about 2 min and used the term community immunity.</li> </ul>

Cycles	Key communication goals achieved	Key communication goals not achieved	Summary of psychophysiological data (where applicable)	Summary of how issues were addressed in the next cycle
Third cycle	<ul style="list-style-type: none"> <li>• Most participants reported that the older woman and baby avatars represent vulnerable people or those with fragile immune systems.</li> <li>• Most participants reported that vaccines prevent the spread of infection.</li> <li>• Most participants reported that community immunity safeguards everyone.</li> <li>• Some participants reported that the thick blue band around an older woman and the baby shows community immunity protecting vulnerable populations.</li> <li>• Some participants reported that their decision to get vaccinated or not has an impact on other people in their community.</li> </ul>	<ul style="list-style-type: none"> <li>• Nearly all participants found it difficult to identify with the generic avatars.</li> </ul>	<ul style="list-style-type: none"> <li>• Some participants had peaks in arousal when the avatar first appeared.</li> <li>• Most participants had peaks in arousal when the vulnerable population was explained in the visualization.</li> <li>• Some participants had peaks in arousal when the infection first entered the community in the visualization.</li> <li>• Most participants visually attended when the community immunity was shown, along with how it safeguards everyone.</li> <li>• Overall, participants showed high engagement and an optimal workload throughout the visualization.</li> </ul>	<ul style="list-style-type: none"> <li>• We added a functionality for people to build their own avatars and their own communities.</li> </ul>
Fourth cycle	<ul style="list-style-type: none"> <li>• All participants reported an accurate understanding of what community immunity is and how it works.</li> <li>• All participants reported that community immunity safeguards vulnerable people and everyone in the community.</li> <li>• All participants reported that some infections spread faster and need enough people to get vaccinated to prevent the spread of infections.</li> <li>• All participants found it easy to create avatars by following instructions without a tutorial.</li> <li>• All participants liked the palettes for skin and hair colors.</li> </ul>	<ul style="list-style-type: none"> <li>• For all participants, the avatar creation tutorial was confusing. They preferred to make avatars just by reading the step-by-step instructions.</li> <li>• A participant suggested adding additional accessories such as caps, hats, hijab, and other head and hair coverings.</li> </ul>	<ul style="list-style-type: none"> <li>• Nearly all participants visually attended to the avatar creation elements, including written instructions.</li> </ul>	<ul style="list-style-type: none"> <li>• Head and hair covering options (caps, hats, hijab, turban) were added.</li> </ul>

<sup>a</sup>N/A: not applicable.

In [Table 4](#), we summarize quantitative findings by referring to all participants when 100% of participants exhibited this; nearly all: 80% to 99%; most: 50% to 79%; some: 25% to 49%; few: 1% to 24%; no participants: 0%.

## Discussion

### Principal Findings and Comparison With Previous Literature

Considering our study as a whole, we observed three principal findings. First, visualization does indeed appear to be a promising medium for conveying what community immunity is and how it works. Our project builds on the limited previous literature on visualization to convey the concept of community immunity. On the basis of our systematic review [13], Betsch et al [10] are the only team to have developed and evaluated such an interactive visualization. Their visualization increased vaccination intentions and demonstrated the promise of this

medium for conveying the concept of community immunity. We built on this by adding personalization to increase the user's identification with the avatars, a voice-over to increase learning, especially among people with lower literacy, and a focus on the protection of vulnerable members of a community. In addition to previous research by Betsch et al [10,57], other studies have also pointed to the potential advantages of using visualization and videos to convey the concept of community immunity [58,59].

Second, our study shows that by involving users in iterative cycles during the design process, it is possible to create a relatively short and simple visualization that conveys a mathematically complex topic. This aligns with previous literature suggesting that visualizations can support people in understanding complex concepts [60-62], and users' involvement in the design process can facilitate an understanding of the information [63].

Finally, our study shows that considering emotion during the design process can help inform the final design of the intervention. Emotions play an important role in health decision making [17], especially when deciding on behalf of loved ones [64], as is the case when deciding about vaccinating one's children [65]. To the best of our knowledge, no previous study has considered emotions in developing a tool to explain community immunity [13]. In keeping with the Affect Heuristic within our framework, our study explicitly considered emotion, as expressed in verbal feedback and measured with psychophysiological data. According to Peters et al [66], affect has four possible functions in health communication and decision making. Affect can directly influence decisions according to a person's subjective sense of the *goodness* or *badness* of options; it can function "as a spotlight" to direct a person's attention toward information, which, in turn, shapes their judgments and decisions; it can motivate information processing and behavior; and it can help people trade-off between concepts that are difficult to compare directly. Because our application is designed primarily to convey a complex concept to inform decisions, we focused on affect's function as a spotlight and adapted our application to better provoke emotional reactions to key information, such as the vulnerability of some community members. Attending to data about participants' emotions throughout the design process therefore helped us carefully adapt our application to the way people perceive and use information to make health-related or other decisions.

### Limitations

This study has four main limitations. First, study participants were primarily French-speaking people in Quebec City, Canada, predominantly women, and many had a relatively high level of education. Our recruitment materials for different cycles mentioned that the study was about vaccination or health, which may have contributed to the over-representation of women in our university-based samples. Women seek health services more frequently than men [67] and are the overwhelming majority

of participants in studies on childhood vaccine decision making [68]. To address this, in our largest cycle (third cycle), we expanded our recruitment strategy to include community-based settings. By deliberately recruiting a large subsample from a population that was more likely to include men and more likely to include people with lower levels of education, we were better able to ensure that the final design would be appropriate for a broad audience. However, despite our best efforts to diversify our study sample, our results may not be generalizable to other populations. Second, our application currently requires that users be able to visually perceive presentations on a screen. Further work will ensure accessibility for people who are blind or visually impaired. Third, building avatars and launching an application requires a certain level of computer literacy, meaning that the application will not necessarily serve people who are uncomfortable using or unable to use computers. Finally, the studies included people who were specifically recruited to participate in a study. It remains to be seen whether people are willing to view a 2-min visualization of community immunity outside of a study setting.

### Conclusions

Our application shows promise as a method of conveying the concept of community immunity to a broad range of members of the general public. This study has practical implications regarding how to design health communication materials about complex topics, such as community immunity, and other concepts that combine individual and population benefits and harms, such as antibiotic resistance, health resource allocation, and interventions during epidemics. Applications with personalized avatars may be more effective than abstract visual representations or text-based explanations to help people understand their personal role in population health. Further research could evaluate the specific effects of personalization. Our future work will test our application in a web-based randomized controlled trial to assess its effects on risk perception, knowledge, and vaccination intentions.

### Acknowledgments

The authors gratefully acknowledge the contributions of Mehdi Aouami and Rosalie Baker for designing the first version of their prototype and Professor Frédéric Lepinay (Design School of Laval University), Dr Ruth Ndjaboue (epidemiologist and postdoctoral fellow at Laval University), Dr Bryna Warshawsky (Public Health Physician at Public Health Ontario), and other colleagues for their constructive comments on an earlier version of prototypes to improve our design. We thank Donovan Aziaka, Magniol Noubi, and Nadège Touko Toudjeu for programming the final version of the application and making it ready to launch. This study was funded by the Canadian Institutes of Health Research (grant number FDN-148426, 2016-2021, principal investigator: Witteman). The CIHR had no role in determining the study design, the plans for data collection or analysis, the decision to publish, or the preparation of this manuscript. During this study, HW received salary support from Fonds de Recherche du Québec—Santé (Research Scholar Junior 1, then Junior 2 Career Development Awards) and from a Canada Research Chair (Tier 2) in Human-Centred Digital Health.

### Authors' Contributions

HH and HW contributed to the design of the study. HH, EP, and MB contributed to data collection. HH, EP, MB, DA, MN, NT, and HW helped in designing and programming the application. HH and HW drafted the first version of the article. DA, JB, CC, ED, MD, TG, AG, EK, SM, MN, RO, EP, JP, JR, BS, AS, NT, MB, KW, JL, and DR critically revised the article and approved the final version for submission for publication. HH and HW had full access to all the data in the study and had final responsibility for the decision to submit for publication.

## Abstract

**Background:** In England, almost all general practices (GPs) have implemented GP online services such as electronic personal health records (ePHRs) that allow people to schedule appointments, request repeat prescriptions, and access parts of their medical records. The overall adoption rate of GP online services has been low, reaching just 28% in October 2019. In a previous study, Abd-Alrazaq et al adopted a model to assess the factors that influence patients' use of GP online services in England. According to the previous literature, the predictive power of the Abd-Alrazaq model could be improved by proposing new associations between the existing variables in the model.

**Objective:** This study aims to improve the predictive power of the Abd-Alrazaq model by proposing new relationships between the existing variables in the model.

**Methods:** The Abd-Alrazaq model was amended by proposing new direct, mediating, moderating, and moderated mediating effects. The amended model was examined using data from a previous study, which were collected by a cross-sectional survey of a convenience sample of 4 GPs in West Yorkshire, England. Structural equation modeling was used to examine the theoretical model and hypotheses.

**Results:** The new model accounted for 53% of the variance in performance expectancy (PE), 76% of the variance in behavioral intention (BI), and 49% of the variance in use behavior (UB). In addition to the significant associations found in the previous study, this study found that social influence (SI) and facilitating conditions (FCs) are associated with PE directly and BI indirectly through PE. The association between BI and UB was stronger for younger women with higher levels of education, income, and internet access. The indirect effects of effort expectancy (EE), perceived privacy and security (PPS), and SI on BI were statistically stronger for women without internet access, patients with internet access, and patients without internet access, respectively. The indirect effect of PPS on BI was stronger for patients with college education or diploma than for those with secondary school education and lower, whereas the indirect effect of EE on BI was stronger for patients with secondary school education or lower than for those with college education or a diploma.

**Conclusions:** The predictive power of the Abd-Alrazaq model improved by virtue of new significant associations that were not examined before in the context of ePHRs. Further studies are required to validate the new model in different contexts and to improve its predictive power by proposing new variables. The influential factors found in this study should be considered to improve patients' use of ePHRs.

## Introduction

### Background

An electronic personal health record (ePHR) has been defined by the Markle Foundation as “an electronic application through which individuals can access, manage and share their health information, and that of others for whom they are authorized, in a private, secure and confidential environment” [1]. Several services can also be provided by more advanced ePHRs, such as requesting repeat prescriptions, booking appointments, viewing test results, and messaging providers [2-4]. ePHRs have the potential to empower patients [5,6], improve patient self-management and medication adherence [7,8], enhance the rapport and communication between patients and health care providers [9,10], ease access to health services [11,12], avoid duplicated tests and medical images [9,11], and decrease adverse events [4,9,11,13].

In England, almost all general practices (GPs) have implemented GP online services, that is, ePHRs that allow people to schedule appointments, request repeat prescriptions, and access coded information in their medical records, such as demographics, medications, allergies, and test results [14]. The number of providers offering GP online services is growing [15].

### Research Problems and Aims

Despite the aforementioned potential benefits of ePHRs, the overall adoption rate of GP online services has been low, reaching just 28% in October 2019 [16]. To improve the adoption and implementation of ePHRs, it is important to identify the factors that influence individuals' use of the system [17-23]. A recent systematic review of 97 studies found that more than 150 factors could affect patients' acceptance and adoption of ePHRs [24]. Unfortunately, none of these studies were carried out in the United Kingdom and included a number of shortcomings, namely, few studies were theory based [21,25-28], many focused on factors affecting patients' intention to use ePHRs instead of actual use [29-32], many assessed factors affecting self-reported use rather than actual use [28,33-36], almost all examined independent and dependent variables at one point in time using the same data collection instrument and were therefore at risk of common method bias [26,33,37], and almost all the studies did not differentiate between factors affecting initial use and continuing use of ePHRs. Therefore, Abd-Alrazaq et al [38] conducted a cross-sectional survey to assess the factors that influence patients' use of ePHRs in England. The study identified several significant factors (performance expectancy [PE], effort expectancy [EE], perceived privacy and security [PPS], behavioral intention [BI], and some moderators), which were able to predict 48% of the variance in use behavior (UB). On the basis of previous research, we propose an amended model

that we expect will predict UB more accurately. This study aims to improve the predictive power of the Abd-Alrazaq model by proposing new relationships between the variables existing in the model.

### Theoretical Foundation

In a previous study [38], the Unified Theory of Acceptance and Use of Technology (UTAUT) [39] was selected from 12 models as the theoretical foundation. The selection process was based on 6 predefined criteria: 4 criteria related to the goodness of the theory (ie, logical consistency, explanatory power, falsifiability, and parsimony), and 2 criteria related to the applicability of the theory on the phenomena of interest (ie, population and type of behavior). [Multimedia Appendix 1](#) [27,29,37,39-65] elaborates on the selection process of the appropriate theory. Abd-Alrazaq et al [38] adapted UTAUT to the context of ePHRs by removing experience and voluntariness and adding PPS, education, income, and internet access to the model ([Multimedia Appendix 2](#)). Their justifications for these adaptations are provided in [Multimedia Appendix 3](#).

Given that the study did not find a significant association between social influence (SI) and BI, the authors recommended that researchers examine other associations of SI [38]. Several studies have found that SI positively affects PE [66-68]. In other words, individuals who perceive that using technology is recommended by those important to them are more likely to perceive that the technology is useful. Therefore, this study proposes that SI directly affects PE and indirectly affects BI through PE.

The 2019 Abd-Alrazaq model [38] could be criticized for failing to hypothesize that facilitating conditions (FCs) are associated with BI. This argument is in line with the findings of Venkatesh et al [69], who proposed this relationship in the extended Unified Theory of Acceptance and Use of Technology (UTAUT2) framework, which is suitable for the consumer context [69]. Several studies have found that FCs are also associated with PE [70-72]. Accordingly, this study proposed that FCs directly affect both PE and BI and indirectly affect BI through PE.

The study by Abd-Alrazaq et al [38] also highlighted the need to assess the effect of moderators on indirect relationships (ie, moderated mediation) in the context of ePHRs. To address this recommendation, this study hypothesized that all mediating effects are moderated by sex, education, income, and internet access. To the best of our knowledge, no studies have assessed the moderating effects of these variables on the relationship between BI and UB. Thus, we explored the moderating effect of age, sex, education, income, and internet access on the relationship between BI and UB. Our proposed model and hypotheses are presented in [Figure 1](#) and [Table 1](#), respectively. The conceptual definitions of the constructs in the proposed model are presented in [Multimedia Appendix 4](#).

**Figure 1.** The proposed conceptual model.

**Table 1.** The proposed research hypotheses.

Hypothesis #	Hypothesis
H1	PPS <sup>a</sup> positively affects PE <sup>b</sup> .
H2	PPS positively affects BI <sup>c</sup> .
H3	PPS indirectly and positively affects BI through PE.
H4	The positive relationship between PPS and PE is moderated by age, sex, education, income, and internet access, such that the influence is stronger for older women with a higher level of education and lower income and with internet access.
H5	The positive relationship between PPS and BI is moderated by age, sex, education, income, and internet access, such that the influence is stronger for older women with a higher level of education and lower income and with internet access.
H6	The indirect effect of PPS on BI is moderated by sex, education, income, and internet access, such that the influence is stronger for women with a higher level of education and lower income and with internet access.
H7	EE <sup>d</sup> positively affects PE.
H8	EE positively affects BI.
H9	EE indirectly and positively affects BI through PE.
H10	The positive relationship between EE and PE is moderated by age, sex, education, income, and internet access, such that the influence is stronger for older women with a lower level of education and income and without internet access.
H11	The positive relationship between EE and BI is moderated by age, sex, education, income, and internet access, such that the influence is stronger for older women with a lower level of education and income and without internet access.
H12	The indirect effect of EE on BI is moderated by sex, education, income, and internet access, such that the influence is stronger for women with a lower level of education and income and without internet access.
H13	SI <sup>e</sup> positively affects PE.
H14	SI indirectly and positively affects BI through PE.
H15	The positive relationship between SI and PE is moderated by age, sex, education, income, and internet access, such that the influence is stronger for older women with a lower level of education and income and with internet access.
H16	The indirect effect of SI on BI is moderated by age, sex, education, income, and internet access, such that the influence is stronger for older women with a lower level of education and income and with internet access.
H17	FCs <sup>f</sup> positively affect PE.
H18	FCs positively affect BI.
H19	FCs positively affect UB <sup>g</sup> .
H20	FCs indirectly and positively affect BI through PE.
H21	The positive relationship between FCs and PE is moderated by age, sex, education, income, and internet access, such that the influence is stronger for older women with a lower level of education and income and without internet access.
H22	The positive relationship between FCs and BI is moderated by age, sex, education, income, and internet access, such that the influence is stronger for older women with a lower level of education and income and without internet access.
H23	The positive relationship between FCs and UB is moderated by age, sex, education, income, and internet access, such that the influence is stronger for older women with a lower level of education and income and without internet access.
H24	The indirect effect of FCs on BI is moderated by age, sex, education, income, and internet access, such that the influence is stronger for older women with a lower level of education and income and without internet access.
H25	The indirect effect of FCs on UB is moderated by age, sex, education, income, and internet access, such that the influence is stronger for older women with a lower level of education and income and without internet access.
H26	PE positively affects BI.
H27	The positive relationship between PE and BI is moderated by age and sex, such that the influence is stronger for younger men with a lower level of education, higher income, and internet access
H28	BI positively affects UB.
H29	The positive relationship between BI and UB is moderated by age, sex, education, income, and internet access, such that the influence is stronger for younger women with a higher level of education and income and with internet access.

<sup>a</sup>PPS: perceived privacy and security.<sup>b</sup>PE: performance expectancy.<sup>c</sup>BI: behavioral intention.

<sup>d</sup>EE: effort expectancy.

<sup>e</sup>SI: social influence.

<sup>f</sup>FC: facilitating condition.

<sup>g</sup>UB: use behavior.

## Methods

### Study Design and Setting

This study used secondary data analysis from data collected by Abd-Alrazaq et al [38] using a cross-sectional survey of 4 West Yorkshire GPs (Multimedia Appendix 5). Health Research Authority approval was granted before starting data collection (REC reference: 17/SC/0323).

### Measurement

All variables except UB were measured using self-administered questionnaires. The questionnaires were composed of 29 questions adopted from previous research (Multimedia Appendix 6). A panel of experts evaluated the face validity and content validity of the questions, and based on their suggestions, the questionnaire was amended and sent via email to 37 patients for pilot testing. The questionnaire was subsequently amended slightly because of the issues reported by patients (Multimedia Appendix 7). UB was measured objectively using system logs by extracting data on the number of times that each participant logged into the system during the 6 months after completing the questionnaire. One open-ended question was added to the questionnaire to obtain qualitative data that enabled the exploration of additional factors. The qualitative data were analyzed using thematic analysis, and the results have been reported elsewhere.

### Recruitment

A convenience sampling approach was used to recruit patients. Patients were eligible to participate if they were living in England, were registered at 1 of the 4 GP practices, were aged 18 years or older, and had not used GP online services before (nonusers). The questionnaire was delivered to eligible participants visiting 1 of the 4 GP practices during the study period. Data on participants' use of GP online services were extracted from the system logs after 6 months of completing the questionnaire.

### Statistical Analysis

Before assessing the proposed model, it is a prerequisite to check normality [73,74], linearity [73], multicollinearity [73], and common method bias [75,76]. Univariate normality was examined by assessing skewness and kurtosis [73,77]. This study checked the linearity between each proposed relationship using scatterplot graphs [73] and the curve estimation procedure [78]. Multicollinearity was assessed in this study using tolerance, which refers to the proportion of the variability of one predictor that is unexplained by other predictors [73,77]. We checked the common method bias using Harman single-factor test [75]. All the aforementioned analyses were carried out using SPSS v.22 (IBM).

The theoretical model and hypotheses were examined using structural equation modeling (SEM). In SEM, models consist

of 2 elements: a measurement model in which the relationships between observed variables and latent variables are examined, and a structural model in which the relationships proposed among the latent variables are assessed [73,79]. Although the measurement model in this study is identical to the original study [38], it was reassessed just for the sake of completeness. The measurement model was examined in terms of 3 aspects: model fit, construct reliability, and construct validity [73,77]. The structural model was then assessed for model fit, predictive power, and strength of relationships [77,79,80]. The strength of relationships was tested using different approaches depending on the type of the proposed effect. To be more precise, path coefficients were checked to examine direct effects [81]. Mediating effects were examined by assessing the indirect effects of using bootstrapping. The moderating effect for the metric moderator (ie, age) was examined using the interaction effect method [73,82]. The moderating effects for the nonmetric moderator (sex) were tested using multigroup SEM [73,74,82]. Moderated mediating effects were assessed using multigroup SEM for indirect effects. All analyses were conducted using the Analysis of Moment Structures v.24 (IBM) software.

## Results

### Participants' Characteristics

The response rate was 78.0% (624/800). As shown in Multimedia Appendix 8, the mean age of participants was 44.2 (SD 1.89) years. Most participants were White (498/624, 79.8%) and had internet access (528/624, 84.6%). About half of the sample (284/624, 45.5%) had an income level of less than US \$25,000 per year. The most prominent education levels among respondents were bachelor's degrees (174/624, 27.9%), college or diploma (165/624, 26.4%), and secondary school (147/624, 23.6%). There were no significant differences between participants and the target population in terms of age, sex, and ethnicity ( $P=.21$ ,  $P=.06$ , and  $P=.64$ , respectively; Multimedia Appendix 8). Thus, the risk of nonresponse bias is minimal.

### Normality, Linearity, Multicollinearity, and Common Method Bias

Histograms presented in Multimedia Appendix 9 show no severe skewness and kurtosis for all items. This finding was confirmed by the absolute values of skewness and kurtosis, which were considerably less than the cutoff points of 3 and 10, respectively [77] (Multimedia Appendix 10).

According to the scatterplots shown in Multimedia Appendix 11, there was an indication of possible nonlinearity for only 2 relationships: the effect of BI and FCs on UB. However, the results of the curve estimation procedure showed that the F values for all proposed relationships in the linear model were significant and higher than the F values of the proposed relationships in the 10 nonlinear models, indicating that all proposed relationships between variables are linear (Multimedia Appendix 12).

As shown in [Multimedia Appendix 13](#), all values of tolerance are within the predetermined cutoff point ( $\geq 0.2$ ) [83], indicating that there is no serious multicollinearity between independent variables.

With regard to the common method bias, 5 factors emerged from the Harman single-factor test; a single factor was able to explain less than half of the variance (47.3%; [Multimedia Appendix 14](#)). This means that there are no concerns regarding the presence of the common method bias in this study.

## Measurement Model

### Model Fit

Nine indices were used to assess the absolute model fit (chi-square/df, goodness-of-fit index, adjusted goodness-of-fit index, root mean square error of approximation, p of Close Fit, and standardized root mean square residual) and incremental fit (normed-fit index, comparative fit index, and Tucker-Lewis index) [73,77]. Given that the measurement model in this study is identical to the modified measurement model in the original study, the results of the fit indices were the same between the 2 studies and were within their suggested levels ([Multimedia Appendix 15](#)). This indicates that the measurement model adequately fits the collected data.

### Construct Reliability

Three measures were used to assess the construct reliability: Cronbach alpha ( $\alpha$ ), composite reliability (CR), and average variance extracted (AVE). Yielded values of  $\alpha$ , CR, and AVE for each construct were within their recommended values of  $\geq .70$ ,  $\geq .70$ , and  $\geq .50$ , respectively ([Multimedia Appendix 16](#)) [73,77]. This means that the measurement items are consistent and reproducible in measuring what it is assumed to measure.

## Construct Validity

Two components of construct validity were examined in this study: convergent validity and discriminant validity [73,77]. The convergent validity was examined by checking factor loadings and the AVE [73]. As shown in [Multimedia Appendix 17](#), the values of factor loading and AVE for all items considerably exceeded the thresholds of .70 and .50, respectively [73]. These results indicate that each item relates strongly to the latent variable that it is assumed to measure.

Discriminant validity was assessed by checking intercorrelation coefficients, comparing the square root of AVE with the intercorrelation coefficients, and comparing loadings and cross-loadings [73,77,81]. [Multimedia Appendix 18](#) shows that the intercorrelation coefficients (off-diagonal values) are located within acceptable ranges ( $< .85$ ) [84]. Furthermore, each value of the square root of AVE for a construct (values on the diagonal) is higher than all intercorrelation coefficients between that construct and each other construct ([Multimedia Appendix 18](#)). As shown in [Multimedia Appendix 19](#), the loading of each item on its construct was higher than the cross-loadings in rows and columns. The results of the three measures indicate that items of each construct are not related to the other constructs that it is not supposed to measure; therefore, the measurement model has acceptable discriminant validity.

## Structural Model

### Model Fit and Predictive Power

The indices that were used to assess the fit of the measurement model were used again to assess the fit of the structural model. As shown in [Multimedia Appendix 20](#), all fit indices were within the recommended values, indicating that the structural model adequately fits the collected data. The model was able to predict about 0.53 of the variance in PE, 0.76 of the variance in BI, and 0.49 of the variance in UB ([Figure 2](#)).

**Figure 2.** Structural model estimates.

### Strengths of Relationships

#### Direct Effects

As seen in Figure 2 and detailed in Table 2, all proposed direct effects were statistically significant, except for the effect of FCs on BI ( $\beta=.05$ ,  $P=.08$ ). Specifically, PPS was significantly associated with PE ( $\beta=.39$ ) and BI ( $\beta=.23$ ). The paths from EE

to PE and BI were statistically significant ( $\beta=.25$  and  $\beta=.15$ , respectively). There was a statistically significant relationship between SI and PE ( $\beta=.13$ ). FCs were significantly associated with PE ( $\beta=.13$ ) and UB ( $\beta=.25$ ). The relationship between PE and BI was statistically significant ( $\beta=.57$ ). BI and UB were significantly associated ( $\beta=.76$ ). To sum up, the following hypotheses were supported: H1, H2, H7, H8, H13, H17, H19, H26, and H28 (Table 2).

**Table 2.** Results of the direct effects.

Hypothesis #	Path	Standardized estimate ( $\beta$ )	95% CI	P value
H1	PPS <sup>a</sup> →PE <sup>b</sup>	.39	0.32 to 0.46	<.001
H2	PPS→BI <sup>c</sup>	.23	0.17 to 0.29	<.001
H7	EE <sup>d</sup> →PE	.25	0.18 to 0.32	<.001
H8	EE→BI	.15	0.10 to 0.21	<.001
H13	SI <sup>e</sup> →PE	.13	0.04 to 0.22	<.001

H28	BI→UB	.53	0.47 to 0.58	<.001

<sup>a</sup>PPS: perceived privacy and security.<sup>b</sup>PE: performance expectancy.<sup>c</sup>BI: behavioral intention.<sup>d</sup>EE: effort expectancy.<sup>e</sup>SI: social influence.<sup>f</sup>FC: facilitating condition.<sup>g</sup>UB: use behavior.**Mediating Effects**

With regard to the mediating effects, results showed that PE significantly mediated the effect of PPS, EE, SI, and FCs on BI

( $\beta=.22$ ,  $\beta=.14$ ,  $\beta=.09$ , and  $\beta=.07$ , respectively; Table 3). Accordingly, H3, H9, H14, and H20 were supported in this study.

**Table 3.** Results of the mediating effects.

Hypothesis #	Indirect effect	Standardized estimate ( $\beta$ )	95% CI	P value
H3	PPS <sup>a</sup> →PE <sup>b</sup> →BI <sup>c</sup>	.22	0.18-0.28	<.001

<sup>a</sup>PPS: perceived privacy and security.<sup>b</sup>PE: performance expectancy.<sup>c</sup>BI: behavioral intention.<sup>d</sup>EE: effort expectancy.<sup>e</sup>SI: social influence.<sup>f</sup>FC: facilitating condition.**Moderating Effects**

With respect to the moderating effects, the effect of EE and FCs on BI statistically increased with increasing age ( $P=.03$ ,  $P<.001$ ,

respectively; Table 4). In contrast, the effect of PE on BI and the effect of BI on UB statistically decreased with increasing age ( $P<.001$ , for both moderating effects).

**Table 4.** Results of the moderating effect of age.

Hypothesis #	Interaction effect	Standardized estimate ( $\beta$ )	<i>P</i> value

<sup>a</sup>PPS: perceived privacy and security.<sup>b</sup>PE: performance expectancy.<sup>c</sup>BI: behavioral intention.<sup>d</sup>EE: effort expectancy.<sup>e</sup>SI: social influence.<sup>f</sup>FC: facilitating condition.<sup>g</sup>UB: use behavior.

Concerning the moderating effects of sex, the association between PE and BI was statistically stronger for men than for women ( $\beta=.59$  vs  $\beta=.50$ ,  $P=.004$ ; Table 5). The path from BI to UB was statistically stronger for women than for men ( $\beta=.53$  vs  $\beta=.03$ ,  $P=.001$ ).

**Table 5.** Results of the moderating effect of sex.

Hypothesis #	Hypothesized path	Men		Women		<i>P</i> value for chi-square difference test

<sup>a</sup>PPS: perceived privacy and security.<sup>b</sup>PE: performance expectancy.<sup>c</sup>BI: behavioral intention.<sup>d</sup>EE: effort expectancy.<sup>e</sup>SI: social influence.<sup>f</sup>FC: facilitating condition.<sup>g</sup>UB: use behavior.

In relation to the moderating effect of education (Tables 6-8), the association between EE and PE was statistically stronger for the “secondary school or lower” group than for the “bachelor or higher” group ( $\beta=.31$  vs  $\beta=.01$ ,  $P=.049$ ). The association between EE and BI was statistically weaker for the “bachelor or higher” group than for the “secondary school or lower” group ( $\beta=-.08$  vs  $\beta=.13$ ,  $P=.04$ ) and for the college group ( $\beta=-.08$  vs  $\beta=.12$ ,  $P=.02$ ; Tables 6-8). The path from FCs to UB was statistically stronger for the “secondary school or lower” group

than for the college group ( $\beta=.38$  vs  $\beta=.29$ ,  $P=.003$ ) and the “bachelor or higher” group ( $\beta=.38$  vs  $\beta=.21$ ,  $P=.03$ ). The relationship between BI and UB was statistically stronger for the “bachelor or higher” group than for the “secondary school or lower” group ( $\beta=.48$  vs  $\beta=.14$ ,  $P<.001$ ) and the college group ( $\beta=.48$  vs  $\beta=.39$ ,  $P=.003$ ). The relationship between BI and UB was statistically stronger for the college group than for the “secondary school or lower” group ( $\beta=.39$  vs  $\beta=.14$ ,  $P<.001$ ).

**Table 6.** Results of the moderating effect of education level (secondary school vs college).

### Moderated Mediating Effects

With regard to the proposed moderated mediations, the indirect effects of EE and SI on BI were statistically stronger for women than for men ( $P=.03$  and  $P=.01$ , respectively; Table 13). The indirect effect of PPS on BI was stronger for patients with college or diploma compared with those with secondary school and lower (Tables 14-16). In contrast, the indirect effect of EE on BI was stronger for patients with secondary school or lower

than for those with college or diploma (Tables 14-16). There was no moderating effect of income on all indirect effects (Tables 16-19). As shown in Table 20, the indirect effect of PPS on BI is statistically stronger for patients with internet access ( $P<.001$ ). The indirect effect of EE on BI was statistically stronger for patients without internet access ( $P=.03$ ). Accordingly, the following hypotheses were partially supported: H6, H12, and H16.

**Table 13.** Results of the moderating effect of sex on indirect paths.

## Discussion

### Principal Findings

This study aimed to improve the predictive power of a model proposed by Abd-Alrazaq et al [38] by proposing and examining new relationships between the variables existing in that model. The predictive power of the new model was slightly higher than that of the Abd-Alrazaq model for PE (53% vs 51%) and UB (49% vs 48%), but it was exactly the same in both models for BI (76%).

With regard to the direct effects, there was no considerable difference between the new model and the Abd-Alrazaq model for the following paths PE→BI (0.57 vs 0.57), EE→BI (0.15 vs 0.16), PPS→BI (0.23 vs 0.24), FCs→UB (0.25 vs 0.25), and BI→UB (0.53 vs 0.53). Compared with the Abd-Alrazaq model, the current model showed a considerable decrease in the effect of EE (0.25 vs 0.34) and PPS (0.39 vs 0.49) on PE; however, both paths were still significant in the current model. This decrease resulted from proposing 2 new predictors for PE (ie, SI and FCs) in the current model, which were significant. The only direct path that was nonsignificant was FCs→BI in the current model. This finding is in line with the findings of a study conducted by Tavares and Oliveira, who did not find a significant association between FCs and BI to use ePHRs [40]. Venkatsh et al [39] attributed this nonsignificant path to the fact that this effect disappears when a model includes both PE and EE.

Compared with the Abd-Alrazaq model, the current model showed a decrease in the indirect associations between BI and each of EE (0.15 vs 0.20) and PPS (0.22 vs 0.28) through PE. However, both indirect effects are still significant in the current model. This decrease resulted from proposing 2 new predictors for PE (ie, SI and FCs) in the current model. Two new indirect paths were found SI→PE→BI and FCs→PE→BI. This means that patients who perceive that important others believe they should use GP online services are more likely to perceive it as a useful system; therefore, they are more likely to intend to use it. Furthermore, patients who believe that an organizational and technical infrastructure exists to support the use of GP online

services are more likely to perceive it as a useful system and are therefore more likely to intend to use it.

All proposed moderating effects that are common between the new model and the Abd-Alrazaq model were comparable between both models. In addition to the significant moderating effects found in the Abd-Alrazaq model, this study found that the association between BI and UB is significantly moderated by age, sex, education, income, and internet access and that the association between EE and PE is moderated by education. Specifically, the association between BI and UB is stronger for younger women with higher levels of education, income, and internet access, and the association between EE and PE is stronger for patients with lower levels of education.

With regard to the moderated mediations proposed in the new model, this study found that the indirect effect of EE on BI through PE was statistically stronger for women without internet access. The indirect effect of PPS on BI was stronger for patients with college education or diploma compared with those with secondary school education and lower, whereas the indirect effect of EE on BI was stronger for patients with secondary school or lower than for those with college education or diplomas. Furthermore, the indirect effect of SI on BI through PE was stronger for patients without internet access. Last but not least, the indirect effect of PPS on BI through PE was statistically stronger for patients with internet access.

### Theoretical and Practical Contributions

This study is one of the very few theory-based studies conducted to identify the factors that affect patients' use of ePHRs or patient portals [21,25-27]. The predictive power of the new model (49%) is higher than that of the previous models proposed in our previous study (48%) and other studies conducted in the context of ePHRs: Tavares and Oliveira (26.8%) [40] and Hsieh (42.7%) [85]. Moreover, the predictive power of the new model is higher than that of the original UTAUT model (48%) [39]. Accordingly, this study contributes to the literature by providing the most predictive model to explain the adoption of ePHRs to date.

To the best of our knowledge, this is the first study in the context of ePHRs that examined the direct effect of SI and FCs on PE, their indirect effects on BI through PE, the moderation effects on the association between BI and UB, and the moderated effects on indirect relationships. This extends our understanding of the complex associations between the factors that affect the adoption of ePHRs.

In addition to the practical contributions reported in the previous study [38], this study provides some contributions based on the newly proposed relationships. People who are important to patients (eg, family members, friends, physicians, and caregivers) can play an important role in enhancing their perceived usefulness of the system and their intention to use it. The influence of these important people is more evident on women than on men. Interventions aimed at increasing the uptake of online access could harness the influence of such individuals to encourage patients to use such services. For example, GPs could prompt the recurrent users of the system to become ePHR champions and speak to their friends or family members about their experiences. GPs could also train practice staff to offer these services to their patients routinely in their communications, and campaigns aimed at increasing ePHR uptake could use social influencing techniques, such as celebrity endorsements. As FCs are directly associated with perceived usefulness of ePHRs, and this, in turn affects BIs, steps should be taken to improve the degree to which patients believe that an organizational and technical infrastructure exists to support their use. For example, the National Health Service app has demonstrated an efficient infrastructure supporting the patient registration process, which enables patients to sign up to access their records online without needing to visit their GP surgery [15]. Instead of registration requiring patients to show evidence of their identity to practice staff, they can instead register by uploading a photograph of identifying documentation and taking a short selfie video on their mobile device. Other potential approaches to targeting FCs include the provision of online educational materials, 24/7 technical support, or drop-in training sessions at GP practices.

### Research Limitations

The proposed model was examined using data collected from 4 GP practices that have implemented the same system (SystemOnline); therefore, our findings may not be generalizable to other systems (eg, Patient Access and i-Patient). Nonetheless, the findings may still be applicable to other ePHRs because all participants were nonusers, and these systems offer the same services to the patients. Consequently, participants would be unlikely to have different perceptions of the different systems.

This study focused on the factors that influence the initial use of ePHRs, given that the system is new in England and has a low adoption rate. Thus, the generalizability of the findings in the context of the continuing use of ePHRs is limited. Given that the study used secondary data, it was not possible to assess the effect of new factors, such as those recommended by Abd-Alrazaq et al [38].

Sampling bias may be a concern in this study owing to the convenience sampling technique used to recruit the participants [37,86]. This study showed that there was no statistically significant difference between the participants and nonparticipants in terms of age, sex, and ethnicity. Accordingly, our findings may be generalizable to GPs, similar to the 4 GPs in this study.

### Recommendations for Future Research

The applicability of the proposed model to other contexts should be examined in further studies. Specifically, researchers may assess the applicability of the model to other providers of GP online services (eg, Patient Access), specific platforms (eg, mobiles, tablets, and computers), other settings (eg, hospitals), and other cities or countries.

Further studies are required to validate the new significant associations proposed in this study, such as SI→PE, FCs→PE, and SI→PE→BI. In addition, future studies should endeavor to improve the predictive power of the current model by adding other factors such as awareness of the system, health status, perceived severity, patient satisfaction, and patient activation level.

It is well known that the eventual success of information technology depends on continued use more than initial use [33,87-89]. There is a lack of studies that have assessed factors affecting the continuing use of ePHRs or even consumer health information technologies (CHITs). Therefore, we prompt researchers to develop and examine a theoretical model that explains the variables affecting the continuing use of ePHRs and CHITs.

This study did not assess series mediations, such as the indirect effect of EE on UB through PE and BI (ie, EE→PE→BI→UB). Furthermore, to the best of our knowledge, such effects have not been examined in previous studies in the context of ePHRs and CHITs. This highlights a need to assess such effects.

### Conclusions

This study slightly improved the predictive power of the Abd-Alrazaq model. More importantly, the improved model showed new significant relationships that were not examined before in the ePHR context, such as the direct effect of SI and FCs on PE, their indirect effects on BI through PE, moderation effect of age, sex, educational level, income, and internet access on the association between BI and UB, and the moderating effects on some indirect relationships. These findings extend our understanding of the complex associations between factors affecting the adoption of ePHRs. The predictive power of 49% indicates that there are other, as yet unidentified, factors that affect the use of ePHRs. Further studies are required to validate the new model in different contexts and to improve its predictive power by proposing new factors. Interventions could focus on the role of significant others (eg, health care professionals, friends, and family members) in influencing web access usage, for example, by discussing the potential benefits of such services with patients.

## Acknowledgments

The authors would like to thank Dr Peter Gardner and Dr Tracey Farragher for their supervision during the study and Dr Hamish Fraser for his help in the initial stages of the study, especially for his contribution to the development of the study design and setting up links with practices.

**Abstract**

**Background:** As health care organizations strive to improve health care access, quality, and costs, they have implemented patient-facing eHealth technologies such as personal health records to better engage patients in the management of their health. In the Kingdom of Saudi Arabia, eHealth is also growing in accordance with Vision 2030 and its National Transformation Program framework, creating a roadmap for increased quality and efficiency of the health care system and supporting the goal of patient-centered care.

**Objective:** The aim of this study was to investigate the adoption of the personal health record of the Ministry of National Guard Health Affairs (MNGHA Care).

**Methods:** A cross-sectional survey was conducted in adults visiting outpatient clinics in hospitals at the Ministry of National Guard Health Affairs hospitals in Riyadh, Jeddah, Dammam, Madinah, and Al Ahsa, and primary health care clinics in Riyadh and Qassim. The main outcome measure was self-reported use of MNGHA Care.

**Results:** In the sample of 546 adult patients, 383 (70.1%) reported being users of MNGHA Care. MNGHA Care users were more likely to be younger ( $P<.001$ ), high school or university educated ( $P<.001$ ), employed ( $P<.001$ ), have a chronic condition ( $P=.046$ ), use the internet to search for health-related information ( $P<.001$ ), and use health apps on their mobile phones ( $P<.001$ ).

**Conclusions:** The results of this study show that there is substantial interest for the use of MNGHA Care personal health record with 70% of participants self-reporting use. To confirm these findings, objective data from the portal usage logs are needed. Maximizing the potential of MNGHA Care supports patient engagement and is aligned with the national eHealth initiative to encourage the use of technology for high-quality, accessible patient-centered care. Future research should include health care provider perspectives, incorporate objective data, employ a mixed-methods approach, and use a theoretical framework.

## KEYWORDS

patient portal; personal health record; eHealth; Middle East; Saudi Arabia

## Introduction

There has been exponential growth in internet penetration globally, including in Saudi Arabia where the internet penetration rate is 93% and that of social media is 72% [1]. Living in the digital age, an increasing number of patients are empowered, computer-literate, and have access to the internet. With advances in health information technology and the now ubiquity of the internet, patients have access to health information and are expected to engage in their care in new ways. Consumer-based health apps have been developed to “transform the paternalistic model of health care into one that is responsive to consumer needs and treats each individual as a copilot in a life-long health care process” [2].

The eHealth movement, which is the delivery of health services and information through the internet or related technology, has been broadly promoted to improve the health status of patients [3,4]. Patient-facing tools have been endorsed by the Institute of Medicine and the World Health Organization to encourage patient- and person-centered care by facilitating patient involvement in medical decision-making [5,6]. The use of digital information for disease and health-related tracking is widespread and considered an “essential and important element in the health care sector” [7]. Innovative eHealth technologies such as personal health records (PHRs) are leveraged to support patients in becoming empowered. Health care organizations adopt PHRs to increase patient engagement in the drive to meet the triple aims of health care: increase access, reduce cost, and improve quality of care [8-10].

PHRs are either standalone, tethered, or integrated [11]. A standalone PHR is owned by the patient and allows a person to “access and coordinate their lifelong health information” [12]. A tethered PHR, or patient portal, is connected to an organization’s electronic health record (EHR) and allows patients to access information from their medical records [13]. An integrated PHR contains patient information from various sources such as pharmacy data, insurance claims, and an EHR. PHR features vary among health care organizations. Basic PHR features include viewing lab results, requesting prescription refills, and scheduling appointments [8,14,15]. More advanced PHR features include personal health-related reminders, secure messaging, eVisits, and social networking [16]. Since the terms “PHR” and “patient portal” have been used interchangeably in

the literature, we here consider the two terms to be synonymous [9].

PHRs are designed to increase patient engagement in managing their health, increase care coordination, and to encourage patient empowerment [16-18]. Engaged patients monitor and update their medication and there is potentially more treatment concordance, leading to positive health outcomes [17,19]. Patient engagement is increasingly recognized as a vital component of safe, person-centered care [6]. Providing patients with access to their EHRs through a PHR is a method for health care systems to promote engagement [20].

Previous studies have shown that PHR use has positive effects on patient adherence, patient self-management skills, and clinical outcomes [16,19,21]. Wade-Vuturo et al [21] found that patients with diabetes mellitus who used a patient portal had better patient-provider communication, more satisfaction with care, greater self-management behaviors, and improved clinical outcomes (ie, hemoglobin A1c, hospital admissions, and emergency room visits). The PHR could bridge the gap due to the limited time and planning devoted to addressing chronic needs since acute issues are the focus of health care visits [22]. Despite the proposed benefits and consumer interest in PHRs, various studies have shown limited adoption and use [8,9,23-25]. According to Abd-Alrazaq et al [8], PHR adoption ranged from 0.13% in the United Kingdom to 10% in the United States.

PHRs are relatively new in the Middle East with less than 12% of health care organizations in the Arab world offering them [26]. Health care organizations in the Kingdom of Saudi Arabia (KSA) have only recently begun to implement PHRs. As with many developed countries, the KSA has invested substantial resources in the implementation of eHealth systems to reduce health care costs and improve care with 4 billion Saudi Arabian Riyals (SAR; US \$1.1 billion) allocated by the government to improve eHealth [27]. The KSA has dedicated enormous funds to enhance national health care systems. To that end, the health care system is one of the priority areas of the National Transformation Program 2020 and Saudi Vision 2030, aiming to provide the highest quality of health care services to the citizens and residents while providing sufficient and efficient health care. The national eHealth initiative focused on improving the quality and efficiency of health care services by enhancing a patient-centered health care culture and increasing patient involvement in their care through technology [28]. In line with

the KSA's eHealth agenda, research on eHealth tools such as PHRs has grown [18,29-32].

The main objectives of this study were as follows: (1) to examine the prevalence of PHR use by region, (2) to categorize the PHR features used most frequently, and (3) to identify predictors of PHR adoption by patients. In addition, comparisons were made between portal users and nonusers according to (1) demographic and clinical characteristics, (2) access to and use of the internet, (3) health literacy and self-reported health status, and (4) online health-related information-seeking behavior.

Research into the actual use of the PHR focusing on the users and features accessed will lay the foundation for future developments of the system and targeted efforts to motivate patients to adopt its use. To reap the proposed benefits and maximize the return on investment, research must be conducted with an eye toward contextual factors and finding methods to promote initial and sustained PHR use among all patient populations.

## Methods

### Study Setting

The Ministry of National Guard Health Affairs (MNGHA) is a large tertiary health care system established in 1983 to provide state-of-the-art medical care to the National Guard's soldiers and their dependents in all regions across the KSA [33]. The MNGHA is a leader in health care services in the Middle East. As a health care leader, MNGHA implemented its PHR known as MNGHA Care in 2018. Some of the features available in MNGHA Care include scheduling appointments, requesting medical reports, viewing radiology reports, checking laboratory results, requesting prescription refills, and providing vaccination reminders. MNGHA Care allows patients to upload personal

health information such as weight, blood pressure, blood sugar, and exercise details. There is also a self-assessment feature where patients can enter information on pain control, performance status, and quality of life. In addition, it contains links to health educational information. MNGHA Care is a powerful tool that is expected to increase health awareness and promote positive health outcomes [34].

### Study Design

A cross-sectional survey design was used. An online survey was constructed and administered through QuestionPro. The study was conducted from December 2019 to February 2020.

### Sample

The target population consisted of adults who visited the outpatient waiting areas at Imam Abdulrahman Bin Faisal Hospital in Dammam, King Abdulaziz Medical City in Riyadh, King Abdulaziz Medical City in Jeddah, Prince Mohammad Bin AbdulAziz Hospital in Madinah, King Abdulaziz Hospital in Al Ahsa, and the primary health clinics in Riyadh and Qassim. The study was carried out at each site independently with each site's research team. Patients or their caregivers were eligible to participate if they were aged 18 years and older and able to read and understand either Arabic or English.

### Sampling Strategy

Stratified random sampling with proportionate allocation was used to draw samples from the study population. The approximate number of patients seen daily in each city was used to determine the target sample for each site. Table 1 shows the proportionate allocation by city with the sample selected in proportion to the size of the population. Since no sampling frame was available, the biostatistician generated a random day and time schedule to be used by each site when beginning data collection.

**Table 1.** Proportionate allocation by region.

Region	Approximate number of patients/day	Minimum N
Dammam	250	27
Riyadh	1120	139
Jeddah	850	75
Medina	200	22
Al Ahsa	750	80

### Sample Size

The effect size was based on 40% internet usage for Usenet, listserv, discussion forums, internet phone, and streaming audio music [35]. This effect size was then applied to find the optimal sample size to detect a proportion of the Saudi population using the internet with a predefined accuracy. We assumed the minimum weekly visit frequency as the population to calculate the overall sample sizes. We further adjusted the sample size according to the proportion of daily visits in each region. With the above assumptions, the study required at least 364 complete records to estimate the proportion at a 95% confidence limit and within 5% precision.

### Participant Recruitment

Each research site used the survey time points and days from the table prepared prior to study initiation. A member of the research team recruited participants in the outpatient pharmacy waiting areas and used a password-protected device to allow the participants to access the survey through QuestionPro, provide consent, and complete the survey. All participants were informed about the study purpose, and were assured anonymity and confidentiality of the information collected. The research team member approached the subjects at randomly selected time points during active working hours until the minimum sample size requirement for the center was reached.

## Instrument

This study used a questionnaire developed by the lead author based on a literature review. The questionnaire contained 41 questions covering demographics, health status, satisfaction with health care, health literacy, mobile phone and internet usage, online health-related information-seeking behavior, and MNGHA Care. There were 13 statements rated on a Likert scale related to MNGHA Care use included but not analyzed for this study. The authors reviewed the questions to ensure readability and appropriateness. The questionnaire was forward-translated by native Arabic speakers and was back-translated by a professional translator and compared to the original. Before study initiation, a pilot test was performed in 20 volunteers at Imam Abdulrahman Bin Faisal Hospital with slight modifications made.

## Measures

Demographic and clinical characteristics were collected to describe the study sample and were self-reported. Demographic characteristics included health care facility, age, gender, marital status, educational level, employment status, and monthly household income. Clinical characteristics included the presence of a medical condition, number and type of medical conditions, self-reported health status, recent hospitalization (<6 months), recent emergency department visit (<6 months), and satisfaction with health care.

To characterize mobile phone and internet usage, one question was asked about smartphone ownership and another question was asked about the frequency of internet use.

Previous researchers have identified a link between health literacy and technology use [36,37].

Therefore, a single-item health literacy screener was used with the following question: “How often do you need to have someone help you when you read instructions, pamphlets, or other written material from your doctor or pharmacy?” [38].

Four questions were related to internet use for seeking health information: (1) Do you use the internet to search for medical information? (2) Are you a member of an online health community? (3) Do you discuss health issues on social media (eg, Facebook, Twitter)? (4) Do you use health apps on your mobile phone?

## Outcome

The outcome variable was the patient-reported use of the PHR, operationalized by asking the patients whether or not they used MNGHA Care.

## Ethics Statement

All participants were informed about the aim of the study and their right to not answer any question they felt uncomfortable answering. The study was approved by the Institutional Review Board (RD19/002/D) at King Abdullah International Medical Research Center in Riyadh, Saudi Arabia.

## Data Analysis

The raw data were downloaded from QuestionPro into Microsoft Excel and were analyzed using SAS 9.4. The proportion of PHR users with the corresponding 95% confidence limit was calculated using the Wilson score method. Descriptive analysis was used to summarize the categorical variables as frequency and percentage and continuous variables as mean and standard deviation. For reporting convenience, the continuous variables were grouped and the frequency and percentage are reported in each group. Further, we compared the relative frequency distribution of all variables across PHR users and nonusers. The chi-square test was used to measure the significance of the association between individual covariates and PHR usage. Finally, multiple logistic regression was used to estimate the odds ratio and the corresponding 95% confidence limit. Throughout the study, we considered any *P* value less than .05 as evidence for a significant result.

## Results

### Sample Characteristics

The baseline characteristics of the participants are shown in Table 2. A total of 546 participants agreed to complete the survey. Most of the participants were men, married, employed, and university graduates. The mean age was 37.39 (SD 11.23) years. The estimated monthly income was greater than 5000 SAR/month (US \$1333/month) for 68.0% (335/493) of the participants. Most participants rated their health as very good or excellent. The majority reported only one medical condition. The most frequently reported medical conditions were diabetes, hypertension, and asthma or chronic obstructive pulmonary disease. About a quarter of the sample reported being hospitalized and approximately half had visited the emergency department in the previous 6 months. All patients were either satisfied or very satisfied with their health care. Most patients either never or rarely need help with reading materials from their physician or pharmacist.

**Table 2.** Baseline demographics of participants (N=546).

Variable	n (%)
<b>Age (years)</b>	
18-29	133 (26.3)

## Internet Use and Online Health Information–Seeking Behavior

Table 3 shows data from the survey related to internet use and online health information–seeking behavior. An overwhelming majority of the participants reported using a smartphone and

accessing the internet several times a day. A large majority also reported using the internet to search for medical information. However, relatively few participants reported being a member of an online health community or discussing health issues on social media. Over half the participants use health apps on their mobile phones.

**Table 3.** Internet use and online health information–seeking behavior (N=546).

Internet use category	n (%)
Smartphone use	516 (94.5)
<b>Frequency of internet use</b>	
Several times a day	442 (81.0)
About once daily	30 (5.5)
A few times per week	19 (3.5)
A few times per month	22 (4.0)
Rarely or not at all	29 (5.3)
Use the internet to search for medical information	381 (69.8)
Member of online health community	44 (8.1)
Discuss health issues on social media	101 (18.5)
Use health apps on your mobile phone	299 (54.8)

## MNGHA Care Use

Of the 546 participants, 460 (84.7%) were aware of MNGHA Care. As shown in Table 4, most participants were made aware of MNGHA Care through someone from the organization—health care provider or other hospital staff—followed by a family member. Of the 460 participants aware of the PHR, 383 (83.3%) reported using it. The health care facilities were classified into the central (Riyadh and Qassim), eastern (Al Ahsa and Dammam), and western (Jeddah and Madinah) regions. There was a statistically significant difference in use by region ( $P<.001$ ): central region (182/383, 47.5%), eastern region (109/383, 28.5%), and western region (92/383, 24.0%). In response to the question “How long have

you been using MNGHA Care?”, the majority of respondents (267/383, 69.7%) reported using it for the past 12 months with most (160/383, 41.8%) using it only within the last 6 months. Most participants reported using MNGHA Care a few times a month (210/383, 54.8%) to rarely (119/383, 31.1%). PHR features accessed by the participants are shown in Figure 1. Scheduling appointments was the feature used most frequently in all regions. In the western region, use of the PHR to check laboratory results was quite low (6.5%) compared to that reported in the eastern region (48.6%) and central region (34.1%). Prescription refill requests were used the most in the eastern region (38.5%), followed by the western region (22.8%) and central region (15.9%).

**Table 4.** Source of MNGHA Care recommendation among users (N=383).

Recommender	n (%)
Health care provider	179 (46.7)
Other hospital staff	41 (10.7)
Family	90 (23.5)
Friends	47 (12.3)
No one	20 (5.2)

**Figure 1.** MNGHA Care features accessed by region.

Table 5 shows a comparison of the baseline demographics between MNGHA Care users and nonusers. There were statistically significant differences between the groups with respect to age, educational level, and employment status.

MNGHA Care users were younger (18-39 years), had a high school or university education, had at least one medical condition, and larger monthly household incomes relative to those of nonusers.

**Table 5.** Demographic characteristics of personal health record (PHR) users and nonusers.

Characteristic	PHR user, n (%)	PHR nonuser, n (%)	<i>P</i> value
<b>Age group (N=487)</b>			.001
18-29 years	102 (33.0)	30 (21.3)

<sup>a</sup>PHR: personal health record.

Table 8 shows the logistic regression results assessing the influence of various participant characteristics on MNGHA Care use. Of the 9 predictor variables, only 3 were statistically significant: educational level, use of the internet to search for health-related information, and use of health apps on the mobile phone. Although higher educational level was associated with more frequent PHR use, this relationship was only statistically

significant for patients with a high school education, who had a 4.08-times higher odds of using the PHR compared with those having an elementary education ( $P=.002$ ). Patients who use the internet to search for health-related information had a 2.4-times higher odds of using the PHR ( $P=.005$ ). Finally, patients who use health apps on their mobile phones had a 2.1-times higher odds of using the PHR ( $P=.008$ ).

## Discussion

### Principal Findings

In the sample of 546 adult patients, 383 (70.1%) reported being users of MNGHA Care. The central region (Riyadh and Qassim) had higher use (83.4%) than the western (Jeddah and Madinah, 59.4%) or eastern (Dammam and Al Ahsa, 64.1%) regions. There were 460 participants (84.6%) who were aware of the PHR. Of those, the majority (83.3%) reported using MNGHA Care. Despite the high penetration of internet (93%) and social

media (72%) use in the KSA, few participants reported being a member of an online health community (8.0%) or discussing health issues on social media (18.6%), whereas a high proportion of participants reported using the internet to seek health information [1]. Other researchers in the KSA have found a growing interest in patients using online social networking for health-seeking purposes [39-41].

Prior to the implementation of MNGHA Care in 2018, Al-Sahan and Saddik [31] conducted a study among 424 patients in the outpatient setting at MNGHA Riyadh to gauge the acceptance of the PHR. In their study, most patients were interested (25.2%)

or very interested (60.6%) in a PHR. The results of this study appear to be concordant with these previous findings, even though their sample was predominantly female (68.2%) with the majority having no medical condition (68.2%). Technology use was also evaluated, demonstrating high internet use (95.9%), smart device use (92.2%), and computer use (80.7%), with only 15.9% accessing patient electronic services from the MNGHA website (15.9%). Our study showed similar findings with 94.5% having a smartphone and 81% using the internet several times a day.

MNGHA Care users were more likely to be younger (18-39 years of age), high school or university educated, employed, users of the internet to search for health-related information, and users of health apps on their mobile phones. Most PHR studies have been conducted in Western countries and have noted differences in PHR use by age, gender, and ethnic background, with people of a lower socioeconomic status using PHRs less often [19,42-47]. In the systematic review conducted by Abd-Alrazaq et al [8], the factors positively associated with use of a PHR were awareness of the PHR, perceived ease of use, perceived usefulness, internet access, income, and education level. Our study also showed a positive association of PHR use with awareness, internet access, income, and educational level.

Our results indicated that increasing age is associated with lower odds of using the PHR. This is consistent with the existing literature [44,46,48-51]. Even though older patients have more chronic conditions and are in the greatest need of support in disease self-management, many do not use a PHR for a variety of reasons. Disparities in PHR use by age have frequently been cited in the literature with many studies showing that older individuals are less likely to use a PHR. Confounding factors include low computer literacy, low eHealth literacy, or less inclination to use technology, ultimately leading to more difficulties with advanced technologies such as PHRs [17,32,48]. In a study using a simulated PHR in adults aged 40 years and above, the authors concluded that adults with age-related declines in reasoning and cognitive abilities were more likely to have difficulties completing more complex health management tasks using a PHR [52]. In a study conducted in Saudi Arabia using a simulated PHR to perform various health management tasks, the authors found an increased probability to watch the help video with each 1-year increase in age, but did not note difficulties by age in completing simple compared to complex tasks [32]. The authors suggested embedding aids such as help videos in PHRs to improve the comprehension of numeric health information [53]. Special considerations should be made in the design of a PHR with targeted training sessions for the older population. Allowing patients to participate in the design of the PHR through focus groups is a strategy employed by some health care organizations [50].

Another area where the digital divide has been evident with the use of PHRs relates to education level [9,42,54]. Our study showed that a high school or university education was associated with use of the PHR; however, there was no difference in use for those with a postgraduate degree. This is inconsistent with previous research, which has shown increasing PHR use with higher levels of education. In the systematic review conducted by Zhao et al [9] examining barriers and facilitators to PHR

use, the authors recognized that one of the most common barriers is lack of a user-friendly interface. They identified 17 studies that mentioned redesigning the PHR and patient portal interfaces so that they are “easy-to use, easy-to-navigate interfaces and simpler language” [9]. Honein-AbouHaidar et al [26] evaluated the acceptance of the patient portal in Lebanon and noted the importance of simplifying and tailoring messages to the target population. Focusing on the patients and how the information is presented in the PHR will prevent the widening of health disparities.

Other studies have found that patients with chronic medical conditions are more frequent PHR users than those without [26,44,51,55]. In this study, 389 (71.9%) of the participants had a medical condition, 265 (68.1%) of whom reported using MNGHA Care. Similar to the literature, patients with a chronic medical condition had a higher prevalence of PHR use. Diabetes mellitus was the most frequently reported medical condition in our participants. Numerous studies have evaluated PHR use in this population to improve diabetes care, increase self-management, and optimize health outcomes [14,21,37,49,56-61]. Belcher et al [29] conducted a 12-week study in 31 patients with diabetes mellitus in the eastern province of Saudi Arabia who were sent twice-weekly messages through the patient portal. They found a reduction in hemoglobin A1c (11% to 9%) and fasting blood sugar (198 to 173 mg/dL). Secure messaging, a feature not available in MNGHA Care, has been associated with improved glycemic control in studies of PHR use in patients with diabetes mellitus [13]. In the study by Al Sahan and Sadek [31], 74.1% of participants reported a desire to communicate with a physician. Since patients showed an interest in secure messaging and studies have shown positive patient outcomes, it may be the right time to consider adding this feature in phases across the organization to support patient-centered communication.

This study showed that the MNGHA Care feature used most commonly was appointment scheduling (83.0%). In the study by Al Sahan and Sadek [31], participants were interested in accessing laboratory results (91.7%), radiology results (82.9%), and appointment scheduling (90.5%). With real-world use, our participants underutilized the features for managing personal health information (28.5%), checking laboratory results (31.6%), and requesting prescription refills (24.0%). Although the previous study showed a high level of patient interest in specific PHR features 2 years before MNGHA Care was implemented in the organization, utilization was less than would be expected after the implementation. Indeed, interest in PHRs and their features has been found to be higher than the actual adoption, with 80% of US respondents surveyed indicating interest in PHRs but only 2.2% of the population actually used a PHR [53]. Having the technology available is one challenge to be overcome but it is also necessary to monitor the process, find ways to connect patients to the technology, and investigate their concerns regularly postimplementation.

An explanation for the low percentage of participants requesting prescription refills is that the pharmacies in each region chose when to activate this feature. Not all pharmacies in all regions had activated the refill function at the time of performing this study. With respect to checking laboratory results and managing

personal information, patients may have disliked the interface or had problems interacting with the system. Zhao et al [9] highlighted the need for health care providers to work with patients and demonstrate the features as a way to increase the value of the PHR from the patients' perspective. There also could have been differences in the way the PHR was rolled out in each region. The central region possibly implemented more strategies aimed at encouraging patient awareness compared to the other regions. Finally, it is recognized that health care providers play an influential role in endorsing PHR use [8,9,44,47]. This is evident in our study, in which the health care provider (47.9%) or hospital staff (10.8%) was responsible for recommending the use of MNGHA Care to most participants. For better utility of the PHR, all health care providers and staff need proper training to support their patients. It is hoped that an impact of this study will be to disseminate information on the availability and benefits of the PHR and its various functions to patients and health care providers.

### Limitations

A major limitation of this study is the use of only self-reported data. Several biases are associated with self-reported data, including social desirability, recall, and nonresponse bias [62]. There may have been overreporting of PHR use by participants because they felt that this was the answer expected of them. In the systematic literature review and meta-analysis conducted by Fraccaro et al [25], the researchers found an adoption rate of 71% in controlled experiments and 23% in real-world experiments. In a cross-sectional study conducted in the Netherlands, there was a 32.1% adoption rate [44]. Objective PHR data from system usage logs can be used along with self-reported data; however, such data were not available to the research team for this study. Systems data would provide information on the total MNGHA population registered to use the PHR, patient logins, and use of specific features. In addition,

those who agreed to participate may have been more likely to use MNGHA Care compared with those who did not participate, resulting in skewed results. Another limitation is the use of only a quantitative approach for analysis. This study would have benefited from combining quantitative data with qualitative data in a mixed-methods approach. The advantage would be gaining greater insight into patient acceptance and concerns with use of MNGHA Care. Such analysis would allow for a more in-depth examination of some of the barriers and facilitators to adoption within the KSA. Another limitation is that the study was conducted in a single health system. However, the large sample size of patients from across the country who were visiting different departments should increase the generalizability of the findings. Finally, the lack of a theoretical framework possibly limits the interpretation of interrelationships between patient factors and PHR characteristics.

### Conclusions

The results of this study show that there is a great deal of interest in use of MNGHA Care with 70% of participants self-reporting use. To our knowledge, this study is the first to report on the adoption of a PHR in a real-world setting in the KSA. To confirm these findings, objective data from the portal usage logs are needed. With the COVID-19 pandemic, the entire world is learning many lessons as the eHealth landscape transforms rapidly. One lesson we are learning is how to engage in health care remotely and efficiently via electronic apps. Remote personal health engagement has become the new normal. Maximizing the potential of MNGHA Care supports patient engagement and is aligned with the national eHealth initiative to encourage the use of technology for high-quality, accessible patient-centered care. Future research should include health care provider perspectives, incorporate objective data, employ a mixed-methods approach, and use a theoretical framework.

### Acknowledgments

The authors would like to thank the data collectors Aliya Najeeb Balbaid, Raneem Mohammad Aljohani, Faten Mohammed Alasiri, Mahmoud Ismail Nouh, and Ismail Hasanin. We also greatly appreciate the assistance of the research coordinators Nadia Alotaibi, Mohammed Al Arab, and Dr. Shahinaz Bashir. Finally, we thank Marjorie Palcat for her administrative assistance at King Abdullah International Medical Research Center, Dammam.

### Conflicts of Interest

None declared.

## Abstract

**Background:** eHealth technologies aim to change users' health-related behavior. *Persuasive* design and system features can make an eHealth technology more motivating, engaging, or supportive to its users. The Persuasive Systems Design (PSD) model incorporates software features that have the possibility to increase the persuasiveness of technologies. However, the effects of specific PSD software features on the effectiveness of an intervention are still largely unknown. The Perceived Persuasiveness Questionnaire (PPQ) was developed to gain insight into the working mechanisms of persuasive technologies. Although the PPQ seems to be a suitable method for measuring subjective persuasiveness, it needs to be further evaluated to determine how suitable it is for measuring perceived persuasiveness among the public.

**Objective:** This study aims to evaluate the face and construct validity of the PPQ, identify points of improvement, and provide suggestions for further development of the PPQ.

**Methods:** A web-based closed-ended card-sort study was performed wherein participants grouped existing PPQ items under existing PPQ constructs. Participants were invited via a Massive Open Online Course on eHealth. A total of 398 people (average age 44.15 years, SD 15.17; 251/398, 63.1% women) completed the card sort. Face validity was evaluated by determining the item-level agreement of the original PPQ constructs. Construct validity was evaluated by determining the construct in which each item was placed most often, regardless of the original placement and how often 2 items were (regardless of the constructs) paired together and what interitem correlations were according to a cluster analysis.

**Results:** Four PPQ constructs obtained relatively high face validity scores: perceived social support, use continuance, perceived credibility, and perceived effort. Item-level agreement on the other constructs was relatively low. Item-level agreement for almost all constructs, except perceived effort and perceived effectiveness, would increase if items would be grouped differently. Finally, a cluster analysis of the PPQ indicated that the strengths of the newly identified 9 clusters varied strongly. Unchanged strong clusters were only found for perceived credibility support, perceived social support, and use continuance. The placement of the other items was much more spread out over the other constructs, suggesting an overlap between them.

**Conclusions:** The findings of this study provide a solid starting point toward a redesigned PPQ that is a true asset to the field of persuasiveness research. To achieve this, we advocate that the redesigned PPQ should adhere more closely to what persuasiveness is according to the PSD model and to the mental models of potential end users of technology. The revised PPQ should, for example, *enquire if* the user thinks anything is done to provide task support but not *how* this is done exactly.

eHealth; behavior change support systems; card sort; perceived persuasiveness; persuasive systems design; mental model; questionnaire evaluation

**Introduction**

Owing to the increasing pressure on health care systems, an increasing number of health-related interventions are making use of technology. This is also referred to as eHealth: the use of technology to support health, well-being, and (the organization of) health care [1]. Many eHealth technologies aim to change their users' health-related attitudes or behaviors. A known pitfall of such technologies is that users stop using them rather quickly or do not use the technology as intended by the developers [2]. This issue of nonadherence can limit the effectiveness of technology because of the dose-response relationship, that is, the more a technology is used, the more effective it is [2]. Furthermore, limited use of technology also hampers sustainability. To deal with this downside of eHealth, it is pivotal that users of eHealth technologies are continuously motivated and engaged by the technology itself. To that end, eHealth technologies can make use of certain design and system features that can make technology more motivating, engaging, and supportive to its users, in turn helping them become *persuasive* eHealth technologies [3-7]. Persuasive (eHealth) technologies may be defined as "computerized software or information systems designed to reinforce, change or shape attitudes or behaviors or both without using coercion or deception" [8]. Despite the potential benefits of persuasion, insight into whether, why, for whom, and how persuasive eHealth technology works remains limited. Most of the existing research has focused on whether persuasive eHealth technology as a whole is effective, which provides little insight into what it is that makes it effective and what the role of persuasiveness is [9]. Thus, there is a need to open the black box of persuasive eHealth technologies to gain insight into whether and how persuasive technology actually increases adherence and whether persuasiveness is related to the effectiveness of such technologies.

**How Does Persuasion Work?**

Although we currently have a broad sense of which persuasive strategies are preferred by certain user groups (eg, based on personality traits, age, or gender) [10-14], more research is needed to unravel why and how persuasive technologies work for different types of users. To evaluate the effect of persuasion, we need to gain insight into whether technology users actually experience the included persuasive software features (eg, personalization and social comparison) as persuasive. After all, the persuasive strategies that designers apply in the software may not be perceived as such by the users [15]. It has been stated that the persuasive powers of a technology are determined by an individual's subjective evaluation of that technology and its impact on the self [16]. This highlights the importance of the subjective experience of persuasiveness as opposed to merely checking whether certain persuasive features are present according to the researchers or developers of the technology. It would therefore be extremely helpful for persuasive technology researchers and developers to have an instrument at hand that

enables them to reliably check the persuasive aspects of technologies, not from a designer's perspective but from a user's perspective. This would not only support developers in making their designs more persuasive but also provide the necessary step to evaluate whether technology increases adherence and effectiveness through the persuasiveness of the technology as theorized.

**Toward Designing Persuasive Technologies**

For developers and designers, the Persuasive Systems Design (PSD) model was created as a guideline for the development of persuasive eHealth technologies [17]. It provides 4 categories of software features that can be applied to persuasive systems: *primary task support*, *dialogue support*, *social support*, and *credibility support* [17] (Table 1). The model posits that all these features have the ability to increase the persuasiveness of technologies. However, as previously indicated, the effects of specific software features on the persuasiveness of an intervention are still largely unknown. Thus, measuring persuasion would require a measurement tool to evaluate the subjective (*perceived*) persuasion of a technology for the individual user. There are 3 newly developed questionnaires that might play a role in achieving this goal. First, there is the Persuadability Inventory [18]; this is a questionnaire aimed at measuring how susceptible an individual is to certain persuasive strategies such as rewards or social comparison. Although this is an interesting focus area, it does not measure the effects of specific software features on different individuals and, therefore, cannot be used for evaluating the persuasiveness of a system. The second related questionnaire is the Persuasive Potential Questionnaire [19]. This questionnaire is aimed at measuring the potential of different systems to persuade users, especially at the stage when the system is not fully developed. As such, it also does not evaluate the effect of specific software features within a system and seems to focus on how persuadable an individual is. Therefore, this questionnaire seems ill suited for the goal of evaluating the persuasiveness of a system. The third questionnaire is the Perceived Persuasiveness Questionnaire (PPQ) [16,20]. The PPQ is a 31-item scale that assesses perceived persuasiveness according to the 4 categories of the PSD (primary task support, dialogue support, social support, and credibility support) and the 4 related constructs: unobtrusiveness, effort, effectiveness, and (overall) perceived persuasiveness [16,20].

Although the goal of the PPQ is not clearly articulated in the first papers that it appeared in, it has been used to evaluate how users perceive the persuasiveness of a certain system (a digital weight loss intervention) and how the different included constructs relate to each other within a structural equation model. Later studies have used the PPQ to evaluate the persuasive effects of different virtual agents [21] in a web-based weight loss intervention [22] and in an antibiotic information app for nurses [23]. Thus, the questionnaire has been applied to evaluate interventions as a whole or specific persuasive elements within such interventions, and it has been applied to

the general public and health care professionals as well. Overall, as the intent of the PPQ is to measure perceived persuasiveness, it is interesting to evaluate to what extent the scale can be used to assess the perceived persuasiveness of technologies.

Therefore, this study addresses questions related to how to evaluate and measure the dimensions of persuasion in eHealth. The PPQ is recognized as a promising low-threshold instrument to measure perceived persuasiveness among a heterogeneous set of people [16,20]. However, to live up to its potential, it is important to evaluate whether the PPQ truly matches the underlying PSD model and the mental models of its broad range of potential target groups [15,24]. A mental model is a person's simplified representation of how something works in the real world. As the PPQ focuses on how persuasiveness is *perceived*, it is even more essential that its items actually match its users' mental models. Consequently, this study aims to evaluate the

face and construct validity of the PPQ constructs to identify points of improvement for a potentially updated version. To achieve this, a broad target group with an interest in eHealth was asked to evaluate the face and construct validity of the PPQ constructs by means of a card-sort study. This provides insight into the extent to which the PPQ items are grouped under the PPQ constructs as intended by its developers and as such provide face validity. Furthermore, we explore the extent to which participants see the constructs included in the PPQ as separate from each other and the items as fitting with each other, which provides information on construct validity. Together, this provides insight into whether the PPQ items are capable of rendering a valid impression of a technology's perceived persuasiveness and whether the PPQ items match the mental models of the users of the technology. The outcomes of this study can be used to establish whether any changes are needed to the PPQ constructs and items.

**Table 1.** Overview of the categories of the Persuasive Systems Design model.

Category	Description	Examples of design features
Primary task support	What the technology does to support the user in carrying out his primary task	Reduction, tunneling, tailoring, personalization, self-monitoring, simulation, rehearsal
Dialogue support	How the technology supports its users via computer-human communication	Praise, rewards, reminders, suggestions, similarity, liking, social role
Social support	How the technology uses social influence to motivate its users	Social facilitation, social comparison, normative influence, social learning, cooperation, competition, recognition
Credibility support	How the technology's design contributes to instilling trust in its users	Trustworthiness, expertise, surface, credibility, real-world feel, third-party endorsements, verifiability

## Methods

### Design

Traditionally, the card-sorting methodology is used to create and evaluate a fit between an information structure and the mental models of its target group such that it enables them to easily find, interpret, and apply information [25-27]. However, previous research has indicated that it can also yield valuable insights into how mental models fit with other kinds of structuring of information, such as the items of a questionnaire [28].

Specifically, in this study, we applied the card-sort methodology to evaluate the face and construct validity of a questionnaire. The questionnaire's face validity refers to the extent to which its items subjectively (at first glance) seem to actually cover the constructs they are intended to measure [29]. In the card sort, this was ascertained by evaluating how many participants had grouped each individual item in the intended construct. The questionnaire's construct validity represents the extent to which the included items are actually related to each other and the construct they intend to measure [30]. In the card sort, this was evaluated by analyzing how the items are grouped and placed in constructs by the respondents themselves, according to their own mental models regardless of the constructs that the items originally belonged to. This cross-sectional study used a closed-ended card sort to evaluate the face and construct validity of the PPQ. In this type of card-sort study, the categories that have to be used to group items have already been defined

beforehand. During the card-sort study, participants were asked to sort cards with, in this case, questionnaire items into the PPQ constructs (primary task support, dialogue support, perceived credibility, perceived social support, perceived unobtrusiveness, perceived persuasiveness, perceived effort, perceived effectiveness, and use continuance) in a way that was logical or meaningful to them. The resulting groups render information about the participants' mental models concerning these constructs, including an agreement or disagreement among users [31].

### Participants

Participants were invited to join the study via a Massive Open Online Course (MOOC) on *eHealth: Combining Psychology, Technology and Health* that was hosted by the research group of the authors of this paper [32]. Anyone with an interest in eHealth technology can join the MOOC, free of charge. It is targeted at an international audience via the FutureLearn platform [33]. Participants of the MOOC were invited to participate in the fourth week (of a total of 6 weeks) of the MOOC. This week of the course was entirely focused on the persuasive design of eHealth technology. In addition, at that point of the web-based course, participants had already finished reading and practicing with information about eHealth, human-centered design, and behavior change. This means that they had acquired at least some basic knowledge about eHealth and persuasive design. After completing the lessons of week 4, participants were presented with a short introductory text including disclosure about the research ([Multimedia Appendix](#)

1). They were invited to participate on a voluntary basis in this study. Data were collected during 10 runs of the MOOC, which ran from May 23, 2016, to December 8, 2019. A total of 12,439 people actively participated in the MOOC during this time span. A total of 602 people started filling in the questionnaire, of which 398 (251/398, 63.1% women; 147/398, 36.1% men) completed the study and were included. The average response rate per MOOC run was 3.35% (398/11,880) of the active learners of the MOOC. The participants' mean age was 44.15 years (SD 15.17) with participants' age ranging from 18 to 81 years. Most participants (288/398, 72.4%) were *somewhat familiar* with eHealth. However, despite having joined the MOOC, some (17/398, 4.3%) participants indicated that they were not familiar with eHealth at all. The first participant completed the card sort on June 11, 2016, and the last participant completed the card sort on June 25, 2019. Most (121/398, 30.4%) of the participants had joined the MOOC during its very first run. Participants' data were included in the data analysis if all demographic questions were answered and the card sort was completed.

## Materials and Procedure

All participants received an explanation of the background, purpose, and methodology of the study. Optimal workshop software [34] was used for this study. This software allowed us to inquire about the participants' demographics (ie, gender, age, and familiarity with eHealth) and complete the card sort at a single (web) location. The software provided participants with instructions on how to perform the card sort and how to sort the

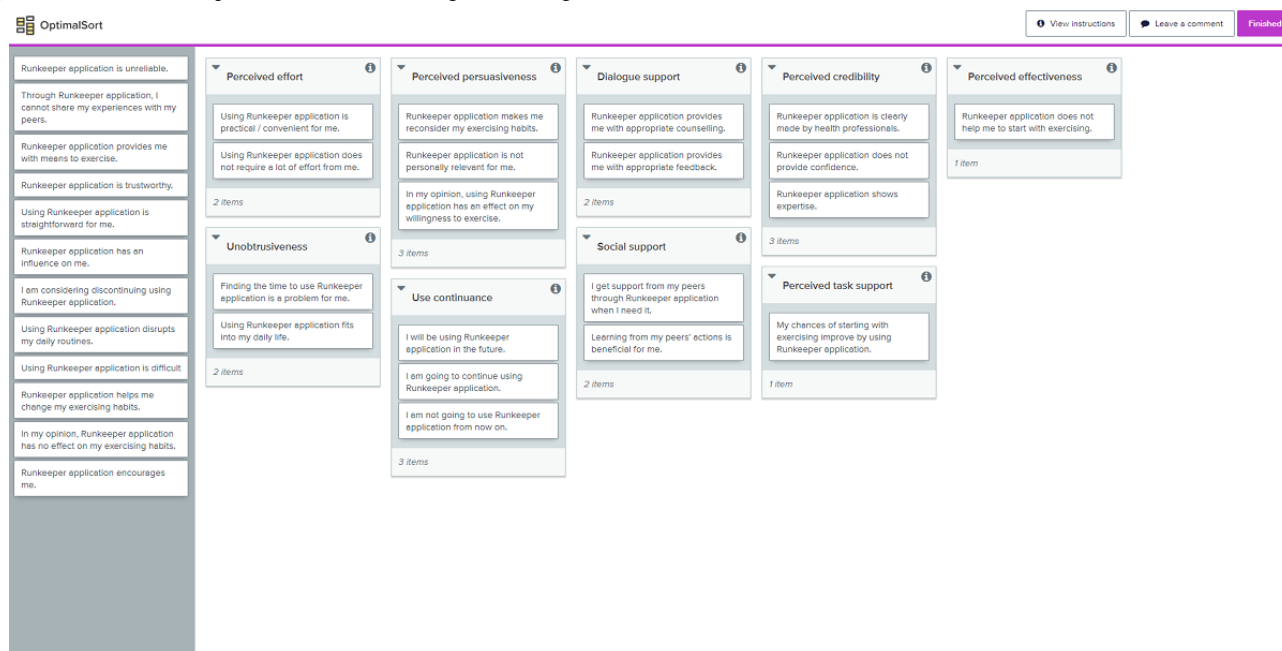

cards by a simple drag-and-drop functionality. Screenshots of the card-sort software used are provided in [Multimedia Appendix 2](#). [Figure 1](#) portrays the instructions page; [Figure 2](#) shows a screenshot during the actual sorting task.

The focal point of this study's card sort was the PPQ. Overall, the PPQ consists of 31 items divided over 9 constructs. The constructs, their meaning, and an example item are provided in [Table 2](#). A complete overview of the PPQ constructs and their items is provided in [Multimedia Appendix 3](#). To make the items easier to interpret and less abstract, for this study, the PPQ items were formulated around an existing, well-known eHealth technology: the Runkeeper app [35]. However, the items can be adapted to fit other persuasive technologies. Participants did not need to actively work with the Runkeeper app; it was merely used as a way to concretize the PPQ constructs. For example, it allowed a card to state "Runkeeper application does not help me to start with exercising" rather than "XYZ does not help me change [target behavior]."

During the card sort, the participants were asked to *drag and drop* all PPQ items onto the PPQ constructs to group them into a meaningful collection of items. They were assured that there were no right or wrong answers and to *just do what comes naturally*. It was explained to them that they could see the definition of each PPQ construct by hovering the mouse over it. During the card sort, the software ensured that participants had to select a single construct to place an item in. Completing the card-sort task took the participants an average of 10.55 min (SD 8.03).

**Figure 2.** Screenshot of OptimalSort software during card sorting task.**Table 2.** Short overview of Perceived Persuasiveness Questionnaire constructs and examples of their items.

PPQ <sup>a</sup> construct (abbreviation)	Short description	No. of items	Example of an item
Primary task support (TASK)	Whether the technology helps to achieve the goal	3	Runkeeper helps me change my exercising habits
Perceived dialogue support (DIAL)	Whether the technology provides feedback and guidance to the user	3	Runkeeper provides me with appropriate counselling
Perceived credibility (CRED)	The perceived reliability and trustworthiness of the technology	5	Runkeeper is clearly made by health professionals
Perceived social support (SOCI)	Whether the technology allows the user to share with and learn from their peers	3	I get support from my peers through Runkeeper when I need it
Perceived persuasiveness (PERS)	Whether users think that the technology is valuable and has an influence on them	3	Runkeeper has an influence on me
Perceived unobtrusiveness (UNOB)	How disturbing the technology is to daily life	4	Using Runkeeper disrupts my daily routines
Perceived effort (EFO)	The endeavor that the technology entails	3	Using Runkeeper is difficult
Perceived effectiveness (EFFE)	The efficacy of the technology	3	My chances of starting with exercising improve by using Runkeeper
Use continuance (CONT)	Willingness of users to adopt the technology in the future	4	I will be using Runkeeper in the future

<sup>a</sup>PPQ: Perceived Persuasiveness Questionnaire.

## Data Analysis

All card-sort data were exported into an Excel spreadsheet (Microsoft) that was specifically developed for the analysis of card sorts [36]. This spreadsheet was extended, adapted, and used in this study and previous research from our research group [24,26,37].

Face validity was evaluated by determining the item-level agreement of the original PPQ constructs. This was done by evaluating how many participants had grouped each individual item in the intended construct by means of descriptive statistics. As a second step for the data analysis, the focus was on construct

validity of the PPQ constructs. It is of interest to see how the items are grouped and placed in constructs by the respondents themselves, according to their own mental models, regardless of the constructs that the items originally belonged to.

Third, we performed a more in-depth analysis by exploring how often any 2 items (regardless of the constructs) were paired together and by measuring interitem correlations (a measure of how consistently the items of that construct are grouped together). To study the items' coherence regardless of the clusters, we performed a cluster analysis of the items. These analyses provide insight into which items were perceived as

measuring a similar construct. We performed a hierarchical cluster analysis (intervals based on squared Euclidian distance) using IBM SPSS 24.

## Results

### Face Validity—Item-Level Agreement in the Original PPQ

The first research question focused on the face validity of the PPQ constructs, revolving around the question of the extent to which the participants' sorts fit the original PPQ constructs. Item-level agreement on these constructs is shown in [Table 3](#).

Some of the original PPQ constructs demonstrated a relatively strong (average >50%) item-level agreement, indicating that most of the participants grouped the *correct* items within these constructs. Agreement about the items of the constructs perceived social support, use continuance, perceived credibility, and perceived effort was high. On the other hand, item-level

agreements for the constructs perceived task support, perceived dialogue support, perceived usefulness, perceived persuasiveness, and perceived effectiveness were relatively low. Agreement on these items was more diffused with respondents frequently mingling with these constructs. Some interesting observations from [Table 3](#) are as follows:

- The items of the perceived task support construct were grouped relatively often into the constructs of perceived persuasiveness and perceived effectiveness.
- The items of perceived dialogue support were grouped relatively often under perceived task support.
- The items of perceived unobtrusiveness were also grouped under perceived effort.
- The items of perceived persuasiveness were also grouped relatively often under perceived effectiveness and perceived task support.
- The items of perceived effectiveness were most frequently also grouped under the construct perceived persuasiveness and perceived task support.

### Optimal Item-Level Agreement

As a second step, focusing on construct validity, we calculated in what constructs the items were most often placed regardless

of the original placements of the items. An overview of the average agreement within the constructs for the original constructs versus the constructs as they should be according to popular placements is given in [Table 4](#).

**Table 4.** Overview of the agreement within the original constructs versus popular placement constructs.

Construct	Average agreement within the original PPQ <sup>a</sup> constructs	Average agreement within constructs as defined by popular placement
Perceived task support	33.7	73.7
Perceived dialogue support	48.7	73.7
Perceived credibility	74.8	74.8
Perceived social support	84.7	84.7
Unobtrusiveness	51.0	56.3
Perceived persuasiveness	39.3	42.5
Perceived effort	61.7	56.0
Perceived effectiveness	44.3	41.8
Use continuance	77.3	77.3

<sup>a</sup>PPQ: Perceived Persuasiveness Questionnaire.

According to popular placement ([Table 5](#)), the items of the constructs perceived task support and perceived dialogue support should be merged into a single category with a high average agreement (>70%). This merged category showed much higher agreement than the items within the separate constructs according to the original PPQ. Existing constructs with high agreement according to popular placement were perceived credibility support, perceived social support, and use continuance. All these constructs had the same average

agreement as when using the original placement, with their items remaining unchanged. Agreement with popular placement for unobtrusiveness and perceived persuasiveness was somewhat higher than agreement within these constructs of the original PPQ. Simultaneously, agreement with popular placement for perceived effort and perceived effectiveness was slightly lower than agreement within the original PPQ. For all these constructs and for the merged construct, the composition of items would have to change based on popular placements.

**Table 5.** Popular placement matrix.

### Cluster Analysis of the Items

The results described in the sections *Face Validity—Item-Level Agreement in the Original PPQ* and *Optimal Item-Level*

*Agreement* have indicated that some changes in the PPQ would be advisable based on the mental models of the participants. In the following section, we therefore performed an additional cluster analysis of the items to study their coherence regardless

of the constructs. [Multimedia Appendix 4](#) shows an item-item matrix of correlations. Within the table, we indicate which construct most of the items in each cluster belong to. There are 3 relatively strong clusters that are identical to the original perceived credibility support, perceived social support, and use continuance. However, the placement of the other items was much more spread out over the other clusters ([Multimedia Appendix 4](#)). Some interesting observations are as follows:

- The original perceived effort and perceived unobtrusiveness could still be found unchanged in the item-item matrix. However, the items of perceived effort also showed overlap with 2 other items (items 28 and 1) that were mainly grouped in the latter. Merging the 2 constructs would lead to an interitem correlation of 0.898, which is slightly lower than perceived effort and higher than perceived unobtrusiveness.
- On the basis of cluster analysis, the original construct of perceived dialogue support could be reduced to only 2 items. This change slightly improved the interitem correlation from 0.715 to 0.731.
- The items of the original constructs perceived task support, perceived effectiveness, and perceived persuasiveness showed rather strong overlap and were grouped into a single cluster.
- One item of perceived dialogue support (item 11) had been moved to a left over cluster alongside item 24, which was originally part of perceived task support.

## Discussion

### Principal Findings

This study set out to evaluate the PPQ by means of a card sort of its items to determine whether the current version of the PPQ can be used to assess the overall perceived persuasiveness of a technology according to the mental model of its users. The results show that some constructs within the PPQ seem to have high face and construct validity in their current form (ie, perceived credibility, social support, and use continuance), whereas other constructs (ie, perceived task support, perceived dialogue support, perceived effort, unobtrusiveness, effectiveness, and persuasiveness) have less face validity and overlap with other PPQ constructs. It appears that the PPQ in its current form does not fit the mental models of the participants, which sheds doubt on the usefulness of the scale to assess perceived persuasiveness because of the subjective nature of this concept. The results of this study provide a first step toward a thorough redesign of the PPQ to more robustly and validly measure constructs related to perceived persuasiveness in a manner that fits the perceptions and experiences of its potential users.

First, it is noticeable that the constructs perceived task support and perceived dialogue support show strong overlap. Both constructs are part of the PSD model but differ in their theoretical underpinning, meaning, and effect [16,17]. However, it seems as if the items are not able to distinguish between the constructs. The PPQ should be able to make a distinction

between these constructs as their theoretical aims differ from one another: perceived task support covers the features of the technology that aim to support its user in achieving its goals, whereas perceived dialogue support covers computer-human interactions that are enabled by the technology [16,17]. In line with this, it has been shown that the effect of including elements of perceived task support and perceived dialogue support in technologies is different; for example, perceived dialogue support has been shown to be related to adherence, although this relationship was not found for perceived task support. Thus, the items within these constructs need to be redefined to enable adequate measurement of these distinct constructs. When looking at the items, it is apparent that the conceptual level of the items in the different constructs varies. For perceived task support, the items are aimed at the overall goal of the concept (eg, “Runkeeper helps me change my exercising habits”), whereas for perceived dialogue support, the items are framed on separate elements within the concept of perceived dialogue support (eg, “Runkeeper provides me with appropriate counseling”). It might be that the focus on separate elements in perceived dialogue support does not sufficiently address the overall goal of the category, in this case supporting the dialogue between the system and the user. Therefore, we suggest redefining all items of the PPQ such that they represent a similar level of abstraction, focusing on the purpose of the construct rather than on how it might have been applied in a technology.

Second, the constructs perceived effort and perceived unobtrusiveness also show strong overlap. Ideally, the PPQ should include all constructs that are part of a technology’s persuasiveness. However, it should omit constructs that seem to predict rather than being a part of persuasiveness. Perceived effort revolves around how strenuous it is to use the technology, regardless of its context. In addition, perceived effort is seen to be part of usability, which is a precondition for persuasion but not persuasion itself [16]. Therefore, we argue that perceived effort should not be a part of the PPQ. Perceived unobtrusiveness, on the other hand, concerns the extent to which the technology can be used as a *seamless part of daily routines* [16]. From many previous studies, we know that the success of a technology not only depends on the technology itself but also on its fit with the use context [38,39]. A main way of technology to be persuasive is, therefore, to increase the fit of the technology in daily life and by improving the way in which it is integrated into the work or thought process of its users. Therefore, we advocate that perceived unobtrusiveness should remain part of the PPQ and that *unobtrusiveness support* might even be seen as a fifth category of the PSD model.

Third, perceived effectiveness, perceived persuasiveness, and (to a lesser extent) perceived task support display strong overlap. This might be explained by the fact that they all cover the technology’s support toward achieving one’s goals. However, it is noticeable that of these constructs, only perceived task support is part of the PSD model. Furthermore, the construct of perceived task support is focused on how supportive the technology is, whereas perceived effectiveness and perceived persuasion are concerned with the extent to which technology-driven support has actually contributed to a behavior change. As the latter two are more of an outcome measure of

persuasion than a form of persuasion itself, we advocate that they should not be part of the PPQ. For perceived persuasiveness, this is also confirmed in the literature, where perceived persuasiveness was shown to be the result of perceived task support, perceived dialogue support, perceived credibility, and perceived unobtrusiveness. Yet, perceived persuasiveness itself did not influence any variables except the (intended) use of the technology, suggesting that it is an outcome rather than a part of persuasion [16]. This confirms our belief that perceived persuasiveness should merely be seen as an outcome of persuasion, rather than being part of it. Moreover, it seems peculiar to have a construct called perceived persuasiveness as a part of a questionnaire with the same name. This suggests that the other constructs are not part of the same theoretical concept and should thus not be included in the questionnaire.

Fourth, the construct use continuance has and maintains strong face and construct validity. However, following the same reasoning as described above, it is questionable whether this construct is part of perceived persuasion or is more of an outcome or effect of perceiving persuasion. Moreover, we argue that use continuance would be a measure of adherence rather than persuasion and therefore advocate that it should not be part of the PPQ.

### Using a Card-Sort Study to Evaluate the Questionnaire

In this study, we opted to use the card-sort method to investigate the face and construct validity of the PPQ instead of more traditional methods such as interviews and focus groups. A large advantage of the card-sort method is that the data of more people can be combined in a robust and statistical manner, more so than using qualitative methods [40]. In this manner, we could statistically analyze whether participants agreed with the original grouping of the PPQ items and which items were clustered together in new user-centered concepts. A disadvantage of the card-sort method is that the reasoning behind participants' clustering is not taken into account, whereas in a qualitative study, a researcher is able to focus on this more. Therefore, a conscious decision on which method to use in a particular context should be made.

Although the card sort yielded many valuable results in this study, it would also have been useful to use this closed-ended card sort at an earlier stage: during the development of the PPQ, before its release. In this manner, a card sort can be used to verify whether assumptions made by the researchers on the structure of the questionnaire and clustering of the items are in line with the users' mental models. Consequently, card sorting is not merely a suitable method to evaluate existing questionnaires but can also be used as a development tool when creating new questionnaires.

Furthermore, in this study, prospective end users of the PPQ were invited to participate in the card sort study. An advantage of this approach is that the resulting structure of a questionnaire fits the mental models of users, who might lack the necessary expertise to make decisions based on theoretical underpinning of the constructs. Consequently, we recommend combining user-based card sorts with expert-based card sorts to combine both perspectives, resulting in a theory-based and user-centered questionnaire.

Finally, in this study, we used a closed-ended card sort, which means that the *final* categories were presented to the users. For a new and improved version of the PPQ, in a later stage of development, an open-ended card sort might be used, in which participants are asked to cluster items together individually and provide them with a label of their own choice to cross-reference the construct validity.

Overall, card sort is a very promising method for questionnaire construction and evaluation. However, more research that applies this method and reflects on its benefits and barriers is required to study its full potential at every stage of questionnaire development, redesign, and evaluation.

### Future Research

Further steps must be taken to redesign and validate the PPQ. First, an expert evaluation of the concept of perceived persuasiveness should be carried out to assess what subconstructs need to be included in this broad concept and which items can be used to assess these subconstructs. Second, measures such as Cronbach alpha and interitem correlations are relevant for its reliability, and a factor analysis is needed to evaluate its (convergent and divergent) construct validity. Furthermore, the predictive validity of the PPQ for adherence or effectiveness should be investigated.

Following such research, it would be highly relevant to also explore the relatedness of perceived persuasiveness with other factors, such as engagement [41], adherence [42] and the effectiveness of technologies. This would allow future research to address the following relevant questions: To what extent does perceived persuasiveness matter? Does it actually make its users more adherent? Does it actually improve the effects that are achieved through using the technology? Can the PPQ be used at early stages during the developmental stages of eHealth technologies to make them as persuasive as possible?

### Strengths and Limitations

A strength of this study is that the PPQ is assessed from the user perspective and insight is yielded in the mental models of users for this valuable concept. However, the card sort method did not allow us to assess the theoretical content validity of the scale and the subconstructs. The results showed that this is a step that still needs to be taken. However, this study did allow us to explore whether the PPQ holds enough potential value to invest more resources in a more extensive validation process.

The results of this study should be interpreted with caution. First, the participants of this study were no experts in the field of persuasion. Thus, although definitions of the constructs were provided, it is not certain whether they had enough skills to truly grasp the meaning of the PPQ constructs and items. However, the choice to include these nonexperts as participants was a conscious one. After all, the PPQ is intended to be filled in by technology users just like them, not by experts in the field of persuasion.

Simultaneously, because of the highly international nature of the participants, it is not known if language barriers might have influenced the results. However, given the fact that the participants were recruited via an English language MOOC, it

can be assumed that their English language skills are at least sufficient to understand the meaning of written text.

Finally, it is noticeable that the participants were not as consistent in their groupings as they could have been. For example, items 25 and 12 are reversed versions of the same item but are not most frequently grouped together (by only 131/398, 32.9% of the respondents). However, this could also be a symptom of the overlap that participants perceived between different constructs.

## Conclusions

In summary, we believe that the original PPQ in combination with the findings of this study, provide a solid starting point toward a redesigned PPQ that is a true asset to the field of persuasiveness research. It has the potential to contribute to answering the all-important question of *what works when for whom*. However, to be able to achieve this, we advocate that the redesigned PPQ should adhere more closely to what

persuasiveness is and to the mental models of potential end users of technology.

In its current form, the PPQ covers many broad constructs, with items that are very specific and diverse. We suggest altering the items to be less focused on details and specific design features and more focused on what the technology is intended to do per category of the PSD model. In other words, the PPQ should enquire *if* the user thinks anything is done to provide task support, but not *how* this is done exactly. This would also increase the reliability and external validity of PPQ measurements. After all, considering the breadth of technologies and the endless varieties of possible target groups, aims, and contexts of these technologies, it is nearly impossible to cover all possible ways of providing (for example) task support. Therefore, there is a need for a new, more abstract version of the PPQ that closely matches the concept of perceived persuasiveness and fits with the mental models of its users.

## Abstract

**Background:** Virtual reality (VR) exergaming has the potential to target sedentary behavior. Immersive environments can distract users from the physical exertion of exercise and can motivate them to continue exergaming. Despite the recent surge in VR popularity, numerous users still experience VR sickness from using head-mounted displays (HMDs). Apart from the commonly assessed self-reported symptoms, depth perception and cognition may also be affected. Considering the potential benefits of VR exergaming, it is crucial to identify the adverse effects limiting its potential and continued uptake.

**Objective:** This study aims to investigate the consequences of playing one of the most popular VR exergames for 10 and 50 min on aspects of vision, cognition, and self-reported VR sickness.

**Methods:** A total of 36 participants played an exergame, called Beat Saber, using an HMD. A repeated measures within-subject design was conducted to assess changes in vision, cognition, and well-being after short (10 min) and long (50 min) durations of VR exposure. We measured accommodation, convergence, decision speed, movement speed, and self-reported sickness at 3 test periods—before VR, immediately after VR, and 40 min after VR (late).

**Results:** Beat Saber was well tolerated, as there were no dropouts due to sickness. For most participants, any immediate aftereffects were short-lived and returned to baseline levels after 40 min of exiting VR. For both short and long exposures, there were changes in accommodation ( $F_{1,35}=8.424$ ;  $P=.006$ ) and convergence ( $F_{1,35}=7.826$ ;  $P=.008$ ); however, in the late test period, participants returned to baseline levels. Measures on cognition revealed no concern. The total simulator sickness questionnaire (SSQ) scores increased immediately after VR ( $F_{1,35}=26.515$ ;  $P<.001$ ) and were significantly higher for long compared with short exposures ( $t_{35}=2.807$ ;  $P=.03$ ), but there were no differences in exposure duration in the late test period, with scores returning to baseline levels. Although at a group level, participants' sickness levels returned to baseline 40 min after VR exposure, approximately 14% of the participants still reported high levels of sickness in the late test period after playing 50 min of Beat Saber. We also showed that the participants who experienced a high level of sickness after a short exposure were almost certain to experience a high level of symptoms after a longer exposure.

**Conclusions:** Irrespective of the duration of exposure, this study found no strong evidence for adverse symptoms 40 min after exiting VR; however, some individuals still reported high levels of VR sickness at this stage. We recommend that users commit to a waiting period after exiting VR to ensure that any aftereffects have deteriorated. Exergames in HMDs have the potential to encourage people to exercise but are understudied, and the aftereffects of exergaming need to be closely monitored to ensure that VR exergames can reach their full potential.

## Introduction

### Background

Exergaming combines exercise and gameplay into a virtual environment with the intention of promoting greater physical activity among users. Exergaming is a valid method for targeting sedentary behaviors in children, adolescents [1], and adults [2,3]. The physiological health benefits of exergames are comparable with exercise such as running and aerobic dancing [1]. Several studies show that some people get greater enjoyment and feel more positive toward exergaming compared with other forms of physical exercise [1,4,5]. Greater enjoyment of exercise and adherence are linked to the psychological experience of flow during physical activities [6]. Exergaming facilitates the flow experience by providing an opportunity to become easily absorbed in the goals and challenges in the game [7,8]. A combination of physiological and psychological benefits of physical activities makes exergaming an appealing strategy to encourage sedentary people to exercise.

A potentially promising avenue to boost the effectiveness of exergaming is virtual reality (VR). One main reason why exergaming is so successful is that it can distract the user from the physical exertion of exercise [4,9]. Users become deeply involved in the game (flow state) and are more motivated to continue engaging in the tasks and narrative of the game even if it requires physical and mental effort. When it comes to involvement and absorption, VR excels in this domain. By offering a combination of realistic 3D environments, immersive 360° spaces, and body tracking, these features allow users to feel like they exist in the virtual world and are ready to face all the challenges and experiences it affords. Typically, presence is not a prerequisite for exergames but can provide added benefits [9]. However, in VR, presence is the cornerstone of a successful virtual experience, with greater presence leading to better task performance and stronger physiological responses compared with other screen-based activities [10-12]. Similarly, immersion and presence in VR exergames play a major role in the motivation of users and their continued engagement [9].

Reviews of VR exergames are an important indicator of user attitudes and receptivity of using VR experiences as a motivator to exercise. A recent study [9] examined reviews of popular VR exergames to identify the positive and negative factors contributing to their continued engagement. Generally, users said that they enjoyed immersive exergames that distracted them from the intensity of the exercise and felt that VR games, such as Beat Saber, provided a similar level of physical activity they would typically get from exercising in the real world [9]. Negative reviews identified *motion sickness* as a hindrance to their in-game performance and perceived enjoyment [9].

*Motion sickness*, or VR sickness, has plagued VR since its early days. While the VR industry has seen a surge in accessibility, greater reliability, and lower prices even for casual consumers, many users are still affected by symptoms of VR sickness [13-15]. High levels of VR sickness symptoms such as nausea, disorientation, and visual disturbances have been estimated to result in an average dropout rate of 15.6% [14]. VR sickness has been shown to decrease or break presence [10,11], impact

motivation and enjoyment [9,16], and influence task performance [17-19]. Apart from the commonly assessed self-reported symptoms, depth perception and cognition may also be affected when users experience VR sickness [15,20,21]; however, little is known about these aftereffects. Considering the potential benefits of serious VR gaming, it is crucial to better understand the adverse effects that limit its potential and continued uptake.

There is no consensus on the etiology of VR sickness [22-24]. One prominent theory is the mismatch between virtual and real worlds. A visual-vestibular conflict can be introduced in VR when the visual experience does not match the physical or bodily experience [13,25]. The integration of visual and vestibular (ie, bodily) sensations plays a fundamental role in an individual's ability to move about and interact with their environment [26,27]. If there is a conflict between visual and vestibular sensations relayed back to the brain, an individual may experience a disturbance in sensory integration leading to the occurrence of motion sickness symptoms such as nausea or disorientation. An individual may also experience an increase in oculomotor symptoms resulting from vergence-accommodation conflicts from HMDs [15,20,28]. Vergence and accommodation are essential oculomotor functions that facilitate the accurate use of depth cues [15]. It is unclear whether vergence-accommodation conflicts are responsible for VR sickness in certain individuals or whether it compounds the severity of sickness symptoms.

Considering the factors that induce VR aftereffects, it is clear that both content and device characteristics play a key role in the onset and progression of VR sickness. To address the role of content, the Oculus store (Facebook Technologies LLC, 2012) includes comfort ratings for most VR games, which are either rated *comfortable*, *moderate*, or *intense* to warn users of potential adverse side effects [29]. These ratings are based on the amount of camera movement, user motion, and occasional disorienting content that can be perceived under a typical experience. However, these ratings do not factor in the length of the experience and how longer exposures may contribute to VR aftereffects [14,30]. Similarly, device manufacturers of HMDs address VR sickness or side effects in their instruction manuals and make safety recommendations for VR usage [31-33]. These safety guidelines are reliant on the self-assessment of their users to gauge the symptoms of VR sickness. Recommendations for VR usage durations range from 30 min to hour-long exposures, and some devices do not specify but leave it up to the user to decide [31-33]. As VR is highly immersive, users can easily lose track of time, resulting in longer exposure times. Research shows that longer exposures lead to a higher prevalence of serious self-reported symptoms [14,30]. Publicly available research supporting manufacturer recommendations for VR exposure durations is limited.

Research investigating the impact of VR exposure duration primarily focuses on self-reported symptoms and shows that the length of time spent in VR is a critical factor in the development and severity of aftereffects [14,34,35]. However, a recent review suggests that the relationship between VR content and exposure duration may not be straightforward [14]. The authors found that lower self-reported symptoms were

recorded for exposures less than 10 min compared with longer VR studies between 10 and 20 min. Intriguingly, studies that were longer than 20 min on average reported less severe symptoms than studies between 10 and 20 min. The authors suggested that the distribution of the types of VR content (ie, 360° videos, game, minimalist, scenic) in each of the time categories may have contributed to this nonlinear pattern of results [14]. There are few studies that directly compare aftereffects in the same content with shorter and longer exposure durations. Hence, it is difficult to answer the question of whether users who experience short exposures to a particular VR content will experience similar or worse symptoms for longer exposures with the same content.

Another important safety issue to consider is the duration of aftereffects after exiting VR and the impact the duration of aftereffects may have on recovery. There is a gradual degradation of VR sickness symptoms, and it is often recommended that users experiencing symptoms stop VR and wait until they have recovered [32,36]. The duration of these symptoms may vary depending on the time spent in VR and the initial severity of symptoms [34,37]. A recent review suggests that although there is an increase in symptoms with exposure durations, the persistence of aftereffects varies considerably from short periods of time (10 min) to longer periods (4 hours) [34]. Furthermore, recovery from aftereffects may take longer if a user experiences severe symptoms [34].

## Objectives

With the growth in VR exergaming and entertainment, an increasing number of people will likely experience symptoms from longer exposures. Using a popular VR exergame, this study addresses the influence of exposure durations on a user's well-being, and on aspects of vision and cognition. One of the most successful commercial VR exergames is called Beat Saber, with over 2 million copies sold worldwide [38]. According to the Virtual Reality Institute of Health and Exercise [39], the time spent playing Beat Saber is comparable with the energy spent playing tennis in the real world. Therefore, Beat Saber provides a compelling test case for studying the aftereffects of VR exergaming. This study examined VR aftereffects from exergaming through long (50 min) and short (10 min) exposure durations. For both exposure durations, measures of near-point convergence and accommodation, reaction times, and self-reported symptoms were taken before, immediately after VR, and 40 min after VR (late measurements).

## Methods

### Participants

A power analysis [40] was performed using a medium effect size (0.54) from the average effect sizes for vision and cognitive tests in Szpak et al [11]. Accordingly, the power analysis for a one-sample *t* test (difference from constant) with  $\alpha=.05$  and  $1-\beta=.80$  suggested that a minimum sample of 29 participants was required. We tested all participants who signed up when the study was advertised, which resulted in a total of 44 participants.

A total of 44 English-speaking participants were recruited and provided informed consent for participation. Participants were reimbursed AUD \$20 (USD \$14.6) per hour of participation. One participant withdrew (*male*) from the study, which was not due to VR sickness, and another 7 participants (*male*=5; *female*=2) were excluded because of stereoacuity of 100 arcseconds or worse. The remaining 36 participants (*male* 21; *female*=15) were included in the main analyses (mean age 20.55, SD 2.29 years). Of these 36 participants, 17 (47%) self-reported to play computer/console games on a weekly or daily basis, 50% played on a monthly basis or less, and 1 person did not specify. The average total Motion Sickness Susceptibility Questionnaire Short-form (MSSQ-short) score was relatively low at 8.97 (SD 6.14) compared with other studies and norm data [25,26]. The Human Research Ethics Committee at the University of South Australia granted ethics approval for this study.

### Materials and Apparatus

#### Virtual Reality Setup

A commercially available HTC Vive Pro HMD was used to administer a VR rhythm exergame—*Beat Saber* (developed by Beat Games). Beat Saber was selected because it is a best-selling exergame with a large user base and it offers a high-quality, responsive, and enjoyable game that participants could engage with for at least 60 min. A high-end laptop with an Intel Quad-Core i7-7820HK processor at 2.90 GHz, 16 GB RAM, and an Nvidia GeForce GTX 1080 8 GB graphics card, which ensures that participants experience the game at optimal performance. Using motion tracking, Beat Saber simulates handheld controllers as light sabers, whereby users slash targets and must actively avoid incoming obstacles to the rhythm of the beat. The game provided haptic, auditory, and performance feedback, thereby giving participants an immersive experience.

#### Visual Measures

Stereo vision, near vision, and distance vision were measured to screen participants' visual and stereoacuity. The Snellen [41] and Fonda-Anderson [42] charts were used to assess distance vision and near vision, respectively. The Butterfly Stereo Acuity test (Vision Assessment Corporation, 2007) was utilized to ensure participants could see the virtual environment correctly. Furthermore, accommodation and vergence were measured to investigate changes in participants' depth perception and vision. The Royal Air Force (RAF) near-point rule [43] was used to assess the near point of convergence and the near point of accommodation before and after VR exposure. The RAF near-point rule is composed of a 500-mm ruler-like square tube with a slider attachment bracketing a 4-sided rotating cuboid. In this study, we used only 2 of the 4 sides: the Times Roman typeface to measure accommodation and a small black dot to measure convergence. At one end of the RAF rule, there is a plastic 60-mm V-shaped cheek rest to comfortably sit on a participant's cheek and fit around his or her nose [43]. Participants' accommodation and vergence measurements were measured in millimeters.

### Cognitive Measures

The CANTAB 5-choice reaction time task (RTI) was administered on an iPad 2 using the CANTAB app [44]. The CANTAB version of the 5-choice RTI focuses on measuring participants' speeded responses so that movement and cognitive factors are dissociable. The 5-choice RTI requires a participant to monitor 5 locations. The RTI consists of a circle (button) on the lower half of the screen and 5 circles on the top of the screen. The participant must press the button located at the bottom of the screen and wait for a yellow dot to appear in any of the 5 circles on the top of the screen. When a yellow dot appears, the participant must release the button and touch the yellow dot (target stimulus) as quickly as possible. The reaction time for this task comprises 2 components: decision and movement speed. In this study, decision speed is the median duration from the time the target stimulus appeared to the moment the participant released the button. The movement speed is the median duration of the release of the button to the touch of the target stimulus. Only correct responses were used to calculate these components.

### Self-Report Questionnaires

The MSSQ-short was employed to measure how susceptible participants are to motion sickness [45,46]. The MSSQ-short [46] has a high correlation with the long version ( $r=0.93$ ) [45,46] and has an internal consistency of  $\alpha=.91$  [46].

The Simulator Sickness Questionnaire (SSQ) [47] is the most commonly used questionnaire in simulator and VR studies [14,25] and has a good internal consistency  $\alpha=.87$  [48]. The SSQ was used in this study to measure self-reported symptoms of VR sickness [47,49]. The SSQ comprises a 16-symptom inventory with a 4-point rating scale from 0 (none) to 3 (severe). Each symptom cluster was divided into 3 categories: nausea, oculomotor, and disorientation. The nausea cluster comprises 7 symptoms associated with feelings of stomach sickness, such as increased salivation, burping, and stomach awareness. The oculomotor cluster consists of 7 symptoms related to eyestrain,

fatigue, and focus. The disorientation cluster includes 7 symptoms related to dizziness and vertigo. The 3 subscales include overlapping symptoms from the other subscales. Raw scores are weighted differently for total scores and the subscales [12,38,39].

### Procedure

First, each participant was given verbal instructions and guided through the consent process. All participants were screened to ensure that they had normal vision and stereoacuity using the Butterfly Stereo Acuity test, the Snellen chart, and the Fonda-Anderson chart. Participants completed several questionnaires that included questions regarding demographics (eg, age, gender, handedness), gaming experience, vision history, and motion sickness susceptibility (MSSQ-short).

At baseline, participants' accommodation and convergence were measured with the RAF rule, and they also completed the CANTAB RTI on an iPad and paper-based SSQ. Participants were then immersed in a VR exposure that required them to play Beat Saber using the HTC Vive Pro HMD. During this time, participants had either a 10-min or 50-min exposure in the VR. All participants completed both a 10-min and 50-min exposure on 2 separate days. The order of exposure duration was counterbalanced across participants.

Participants were instructed to play the in-game tutorial to understand how the game is played. The tutorial was completed only during the participant's first intervention period. Once the tutorial was completed, the researcher explained that participants had an opportunity for *free play*, that is, they could play the game at their leisure and choose any song and difficulty of their choice.

Immediately after each VR exposure, participants completed the same measures they completed before VR in the following order: accommodation, vergence, RTI, and SSQ. Participants then had a 20-min break and, finally, completed these same measures in a late test period 40 min after VR exposure (Figure 1).

**Figure 1.** The study design of both days of participation. One square represents 5 min. Dark gray squares represent assessment periods, light gray squares represent virtual reality (VR) exposure, and white squares show when participants took a 20-min break. The order of short and long VR exposures on days 1 and 2 was counterbalanced between participants.

#### Short exposure

#### Long exposure

### Analyses

The following analyses used difference scores that were calculated for all measures to demonstrate the change from baseline to immediate or late measurements. All difference

scores were analyzed with the repeated measures analysis of variance with test periods (immediate and late) and exposure durations (10 min and 50 min) as within-subject factors. Bonferroni corrections were employed for all planned pairwise post hoc comparisons. Furthermore, one-sample *t* tests were

performed to determine whether the difference scores significantly changed from zero, that is, represent a significant difference from baseline (Table 1). Alluvial plots were generated from weighted SSQ scores and categorized from a modified version of Kennedy et al [49], resulting in the following 3 sickness levels: low (0-10), mid (>10 to 20), and high (>20).

## Results

Participants' data are available on the Open Science Framework [50].

### Visual Measurements

For accommodation measurements, there was a significant main effect of the test period ( $F_{1,35}=8.424$ ;  $P=.006$ ; partial  $\eta^2=.0.194$ ), with larger accommodation changes immediately after VR (mean 12.43, SE 3.06) compared with the late (mean 4.10, SE 1.92) measurement test period (Figure 2). There was no effect of the exposure duration ( $F_{1,35}=2.974$ ;  $P=.09$ ; partial  $\eta^2=.078$ ), and the interaction was not significant ( $F_{1,35}=0.035$ ;  $P=.85$ ; partial  $\eta^2=.001$ ).

For convergence measurements, there was a significant main effect of test period ( $F_{1,35}=7.826$ ;  $P=.008$ ; partial  $\eta^2=.0.183$ ) with larger convergence changes immediately after VR (mean 13.68, SE 3.65) compared with the late (mean 5.00, SE 2.93)

measurement (Figure 2). There was no effect of the exposure duration ( $F_{1,35}=2.159$ ;  $P=.15$ ; partial  $\eta^2=.0.058$ ), and the interaction was not significant ( $F_{1,35}=1.334$ ;  $P=.26$ ; partial  $\eta^2=.0.037$ ).

### Cognitive Measurements

The CANTAB 5-choice RTI captured both decision times and movement speeds. Accordingly, these components were analyzed separately to determine which aspect of the reaction speeds may be affected by VR.

Regarding decision times, there was a significant main effect of the test period ( $F_{1,35}=4.671$ ;  $P=.04$ ; partial  $\eta^2=.118$ ) with larger changes (slower reaction times [RTs]) in the decision speed immediately after VR (mean 4.472, SE 2.229) compared with the late (mean .257, SE 2.638) measurements (Figure 3). There was no effect of the exposure duration ( $F_{1,35}=0.440$ ;  $P=.51$ ; partial  $\eta^2=.0.012$ ), and the interaction was also not significant ( $F_{1,35}=0.668$ ;  $P=.42$ ; partial  $\eta^2=.0.019$ ).

Regarding movement times, there was no main effects of the test period ( $F_{1,35}=1.506$ ;  $P=.23$ ; partial  $\eta^2=.0.041$ ) or the exposure duration ( $F_{1,35}=0.206$ ;  $P=.65$ ; partial  $\eta^2=.0.006$ ), and the interaction was not significant either ( $F_{1,35}=0.784$ ;  $P=.38$ ; partial  $\eta^2=.0.022$ ; Figure 3).

**Figure 2.** Raincloud plots for accommodation (left) and vergence (right) measures showing the different test periods and virtual reality exposure times. Positive and negative scores, respectively, indicate an increase (further) or decrease (nearer) change in accommodation or vergence from baseline measurements.

**Figure 3.** Raincloud plots for the cognitive 5-choice reaction time task showing reaction time (RT) difference scores for the different test periods and virtual reality exposure times. This task captures both decision speeds (left) and movement speeds (right). Positive and negative scores indicate the participant's RTs becoming slower or faster from baseline measurements. RT: reaction time.

## SSQ

Total SSQ scores and subscales (nausea, oculomotor, and disorientation) were weighted according to Kennedy et al [47]. Difference scores were calculated from these weightings. Alluvial plots were created to visualize changes in SSQ symptom levels in participants across the different exposure times and test periods (Figure 4).

For total SSQ difference scores, there was a significant main effect of the test period ( $F_{1,35}=26.515$ ;  $P<.001$ ; partial  $\eta^2=0.431$ ), with larger changes immediately after VR (mean 9.869, SE 1.952) compared with the late measurement (mean  $-0.052$ , SE 1.272; Figure 5). There was also an effect of exposure ( $F_{1,35}=4.816$ ;  $P=.04$ ; partial  $\eta^2=0.121$ ), with a 50-min VR

exposure (mean 7.220, SE 2.038), leading to larger changes than a 10-min exposure (mean 2.597, SE 1.280). The significant interaction ( $F_{1,35}=4.738$ ;  $P=.04$ ; partial  $\eta^2=0.119$ ) was followed up with a number of post hoc paired  $t$  test comparisons. They showed that for 10 min of VR, immediate measurements (mean 6.026, SE 1.325) were significantly different from late measurements (mean  $-0.831$ , SE 1.325;  $t_{35}=3.868$ ;  $P=.002$ ). Comparisons for 50 min of VR showed that immediate measurements (mean 13.713, SE 2.878) and late measurements (mean 0.727, SE 2.037) were also statistically different ( $t_{35}=4.522$ ;  $P<.001$ ). A comparison of the immediate measurements between the 10 min and 50 min sessions of VR were also significantly different ( $t_{35}=2.807$ ;  $P=.03$ ) from each other. However, the late measurements taken after 10 min and 50 min of VR were not significantly different ( $t_{35}=0.675$ ;  $P=.99$ ).

**Figure 4.** Alluvial plots showing how participants' flow from one virtual reality sickness category to another on the basis of exposure duration and test period. Bars indicate the percentage of participants who are in each of the high, mid, and low virtual reality sickness symptom categories for 10-min and 50-min exposures. Left and right panels show the flow of the categories for the immediate and late test period, respectively.

**Figure 5.** Raincloud plots for the total Simulator Sickness Questionnaire and subscale difference scores showing test periods and exposure duration. Positive and negative scores, respectively, indicate an increase and decrease in sickness symptoms compared with baseline. SSQ: Simulator Sickness Questionnaire.

For nausea difference scores, there was a significant main effect of the test period ( $F_{1,35}=22.379$ ;  $P<.001$ ; partial  $\eta^2=0.390$ ), and the effect of the exposure duration ( $F_{1,35}=4.549$ ;  $P=.04$ ; partial  $\eta^2=0.115$ ) and the interaction was also significant ( $F_{1,35}=4.334$ ;  $P=.045$ ; partial  $\eta^2=0.110$ ; Figure 5). Paired  $t$  test comparisons showed that for 10 min of VR, immediate measurements (mean 1.590, SE 1.496) were significantly different from late measurements (mean  $-2.385$ , SE 1.441;  $t_{35}=2.667$ ;  $P=.048$ ). Comparisons for 50 min of VR showed that immediate (mean 8.480, SE 2.336) and late measurements (mean  $-0.530$ , SE 1.419) were also statistically different ( $t_{35}=4.261$ ;  $P<.001$ ). A comparison of immediate measurements between the 10 min and 50 min sessions of VR were also significantly different ( $t_{35}=2.745$ ;  $P=.04$ ) from each other. However, the late measurements taken after 10 min and 50 min of VR were not significantly different ( $t_{35}=0.827$ ;  $P=.99$ ).

For oculomotor difference scores, there was a significant main effect of the test period ( $F_{1,35}=21.173$ ;  $P<.001$ ; partial  $\eta^2=0.377$ )

and the effect of the exposure duration failed to reach significance ( $F_{1,35}=3.795$ ;  $P=.06$ ; partial  $\eta^2=0.098$ ); however, the interaction was significant ( $F_{1,35}=4.817$ ;  $P=.04$ ; partial  $\eta^2=0.121$ ; Figure 5). Paired  $t$  test comparisons showed that after 10 min of VR, immediate measurements (mean 5.263; SE 1.677) were significantly different from late measurements (mean  $-0.632$ , SE 1.329;  $t_{35}=3.500$ ;  $P=.004$ ). Comparisons for 50 min of VR showed that immediate (mean 12.002, SE 2.587) and late measurements (mean 0.211, SE 2.229) were also statistically different ( $t_{35}=4.128$ ;  $P<.001$ ). A comparison of immediate measurements between the 10 min and 50 min sessions of VR were also significantly different ( $t_{35}=2.652$ ;  $P=.048$ ) from each other. However, the late measurements taken after 10 min and 50 min of VR were not significantly different ( $t_{35}=0.388$ ;  $P=.99$ ).

For disorientation difference scores, there was a significant main effect of the test period ( $F_{1,35}=19.875$ ;  $P<.001$ ; partial  $\eta^2=0.362$ ) but no effect of the exposure duration ( $F_{1,35}=2.577$ ;  $P=.12$ ;

partial  $\eta^2=0.069$ ) and no interaction ( $F_{1,35}=1.628$ ;  $P=.21$ ; partial  $\eta^2=0.044$ ; Figure 5).

In Table 1, a summary of one-sample  $t$  tests is reported to establish whether the difference scores for each measure

significantly changed from zero, that is, represent a significant difference from baseline. Several visual, cognitive, and self-reported measures demonstrated changes from baseline immediately after VR; however, at the group level, all changes returned to preexposure levels at late test periods.

**Table 1.** One-sample  $t$  tests summarizing the measures that are significantly different from zero (baseline) for both test periods (immediate and late) and exposure duration.

## Discussion

### Summary of Findings

This study aimed to investigate the consequences of playing one of the most popular active VR games for 10 min and 50 min on aspects of vision, cognition, and self-reported VR sickness. There were no dropouts due to sickness in this study. Given that the average dropout rate for a VR study using an HMD is approximately 15.6% [14], this suggests that Beat Saber was well tolerated. A low dropout rate is only one indicator of

sickness, and aspects of vision, cognition, and self-reported sickness are discussed in detail in the following sections.

### Visual Measures

Irrespective of the exposure duration, both accommodation and convergence significantly changed immediately after VR compared with baseline measurements. However, the visual measures returned to baseline levels 40 min after exiting VR, suggesting that changes to accommodation and vergence were relatively short-lived.

Interestingly, the exposure duration did not influence any visual measure, suggesting that observable changes in accommodation and vergence did occur within the first 10 min of VR exposure and did not significantly change for exposures up to 50 min. Changes in convergence and accommodation observed after VR are likely to result from the perception of conflicting depth cues in HMDs. Convergence and accommodation are oculomotor functions necessary to achieve a single and clear focus on near objects, respectively. Hence, blur and disparity are essential retinotopic cues assisting accommodation and convergence to achieve a more precise fixation on a near object [51]. Typically, under natural viewing conditions, vergence and accommodation function together in a feedback loop so that changes in one mechanism will lead to concurrent changes in the other. However, in HMDs, vergence and accommodation may be decoupled [15,28], leading to an uncertainty associated with retinotopic cues for depth perception [52,53] and potentially to a range of concomitant symptoms such as headaches, sore eyes, fatigue, and double vision. Although our participants did not report any concurrent clinical visual impairments, it is worth noting that several participants reported large oculomotor changes in both immediate and late test periods (Figure 2). Large oculomotor changes after VR may influence an individual's depth perception in the real world [53], but the risks associated with these changes are not well understood.

### Cognitive Measures

In this study, we assessed whether the ability to react quickly to stimuli is affected after immersion in VR. The time required to initiate motor movements (ie, decision time) was not statistically different from the decision times before VR exposure at either test period (Figure 3). Notably, the participants were slightly faster at the late test period compared with the immediate test period. However, given that the decision times at either of these test periods were not different from their baseline measures (Table 1), this finding remains to be an interesting observation at this stage.

The investigation of the motor movement times (ie, time from button release to the touch of stimuli) revealed no concerns. In fact, after playing Beat Saber for 10 min, participants' movement speeds immediately after VR exposure were slightly faster than before the VR exposure (Figure 3). Whether this improvement is related to practicing fast-paced motor movements required in the game remains to be established. The fact that the observed positive effects were short-lived ties in with research in the field of aerobic exercise, which found that effects of exercise on reaction times disappear quickly after exercise cessation [54]. This study cannot answer the question about the possibility of positive long-term cognitive effects with repeated VR gaming. However, there is research showing that gamers have greater attentional control compared with nongamers [55]. Furthermore, frequent gamers are better at filtering out distractors and have been shown to outperform nongamers on a range of perceptual and attentional tasks [55,56]. Considering the differences between screen-based gaming and VR gaming, it would be interesting to explore whether frequent VR gamers also exhibit a similar attentional advantage.

The literature on the immediate effects of VR exposure on the ability to react quickly to stimuli is highly inconsistent. Some researchers find negative reaction time aftereffects [19,57-59], and others show positive (faster) effects on reaction times [60]. The type of content, the time in VR, and the method of RT measurements are key reasons for the inconsistent results. Notably, although there is inconsistency across studies, the reported positive or negative effects of VR exposure on RT are typically under 50 ms. The degree to which such relatively small changes would have any real-world consequences for activities such as driving is unclear. In simulated driving studies, researchers suggest that the average braking time needs to be between 700 ms and 1200 ms to reduce the negative impact of a collision [61].

### Self-Reported VR Sickness

Self-reported VR sickness scores were higher immediately after VR than 40 min after exiting VR. Immediately after VR, participants reported more nausea, oculomotor, and disorientation symptoms compared with preexposure levels. The reported symptoms returned to preexposure levels during the late testing period.

Longer VR exposure (ie, 50 min vs 10 min) led to more symptoms immediately after VR (Figure 5). The exception was the disorientation subscale, which was not modulated by the exposure duration. An increase in nausea symptoms was observed after 50 min but not after 10 min of VR exposure (Table 1). For all other self-reported measures, 10 min of VR was sufficient to observe an increase in symptoms. All symptoms returned to baseline levels after 40 min of exiting VR (Table 1). During the late test period, the number of reported symptoms was no longer modulated by the duration of the VR exposure.

Although an increase in SSQ scores for longer exposure durations is consistent with the VR literature, few studies have examined VR sickness in HMDs, which makes it difficult to evaluate the role of intense exercise in reporting symptoms. However, considering that there is an overlap between symptoms of VR sickness and symptoms of intense cardio exercise (ie, fatigue, disorientation, sweating, and in some cases nausea), it can be challenging to identify VR sickness during an intense workout in VR. Perhaps more research with VR exergames is needed to better understand the relationship between the exposure duration, VR sickness, and the intensity of physical activity.

### Does the Lack of Prolonged Aftereffects Mean There Is Nothing to Be Concerned About?

Overall, this study found no strong evidence for adverse symptoms of concern 40 min after VR exposure, irrespective of whether people played Beat Saber for 10 or 50 min. However, our findings should *not* be taken as evidence for a clean bill of health for playing VR exergames. Primarily, our participants comprised a young and healthy student population with a below-average history of motion sickness. Hence, it is unclear whether the current findings will hold for the elderly and people with high susceptibility to motion sickness. It is important to keep in mind that the lack of difference between baseline scores

and 40 min after VR is based on group averages. Closer inspection of individual data (Figures 2 and 5) reveals that individual participants still report adverse symptoms that are higher than their baseline scores. Case in point, approximately 1 out of 7 participants (approximately 14%) may still score *high* on the SSQ 40 min after playing Beat Saber for 50 min (Figure 4). The *high* category in this study is based on the study by Kennedy et al [49], who proposed that scores over 20 are indicative of a problem simulator. However, the degree to which a high SSQ score impacts everyday activities is unclear. The link between scores on the SSQ and real-world performance decrements is not understood and constitutes a critical gap in knowledge for advancing the safe use of VR.

We did not follow up with participants after the late measurements and did not know how symptoms developed after the experimental session ended. It is important to note that the peak of symptoms in an individual is not always observed in or immediately after VR. Some users may experience severe latent symptoms occurring up to 24 h later [30,36,62]. There are many challenges with monitoring participants' hours after a VR experiment such as how long should one follow up with participants, what is the best method for measuring latent effects, and should symptoms be weighted higher if they occur hours after VR. Furthermore, when following up with participants' hours later, it is more difficult to establish a causal relationship between their symptoms and VR. For example, headaches and fatigue are symptoms of VR sickness but can also occur for many other reasons not related to VR, that is, dehydration, hunger, and exertion, making it difficult to track the progression of symptoms for each individual.

Individual differences such as age, HMD fit, postural stability, and motion sickness susceptibility may contribute to the likelihood of a person experiencing VR sickness in HMDs [14,63,64]. The alluvial plot (Figure 5) shows subgroup patterns on the relationship between the levels of symptoms and the exposure durations immediately after exiting. When experiencing a high level of symptoms after a short 10-min exposure, a participant was almost certain to also experience a high level of symptoms for a longer 50-min exposure on a different day. Around half of the participants experiencing midlevels or no/low symptoms immediately after a 10-min exposure reported the same level of symptoms after longer exposure durations. The other half of the participants in these categories experienced worse symptoms for a longer 50-min exposure. Experiencing symptoms after short periods in VR may be an indicator of whether an individual may experience serious symptoms after longer exposure periods. There is some evidence to suggest that short repeated exposures may reduce a user's experience of VR sickness in subsequent exposures [65-67], but this strategy may not work for everyone. Additionally, taking more frequent breaks [31-33] could be explored as a strategy to mitigate symptoms.

## Limitations

We used the currently most popular VR exergame; however, to what extent these findings hold for other games is unknown. One major challenge when comparing aftereffects from different VR experiences is the role content has on the progression and

severity of symptoms. For example, several studies have compared sickness symptoms across multiple VR experiences and found that some content induces VR sickness and other content leads to no/minimal symptoms [37,59]. High levels of motion have consistently been shown to increase nausea, disorientation, and oculomotor disturbances [21,37,58]. Other factors such as scene complexity [68], presence [10,11], and locomotion [69] have also been suggested to play a role in the development of VR sickness.

In our Beat Saber study, there was a high level of both visual stimulation and user movement, which would have increased with the level difficulty. Participants were able to select any song or level of difficulty. By directing their own gameplay, participants could choose which levels they felt challenged by. A limitation of this study is that we did not monitor in-game performance, which may have been insightful. If the choice of difficulty increased the visual motion in the exergame, this may have also had an impact on the likelihood of a person experiencing symptoms. Future VR studies should consider how the variation in gameplay may impact sickness outcomes and measure in-game performance if possible.

VR exergames that require physical activity from the user will have higher levels of user movement and visual stimulation, which may contribute to VR sickness. A recent VR bike simulator study [57] found that participants using an HMD displayed substantially higher SSQ scores than participants using a large screen. In their study, SSQ scores increased with the exposure duration and simulated motion [57]. Although HMDs may be a more immersive option for exergames, HMDs may also lead to higher levels of sickness relative to screen-based exergames. If the simulated motion is a major factor leading to VR sickness in exergames, then congruent visual and user motion will likely be better tolerated. A call for more research is needed to investigate the relationship between simulated motion and VR sickness in exergames.

A wide range of possible VR aftereffects exist, and this study only investigated some of them (vision, reaction time, and self-reports). It remains to be established whether or how other symptoms, such as changes in balance, depth perception, and motion drowsiness (sopite symptoms), may have also been affected. This study also targeted a young and healthy group of participants, and it is possible that an older sample may experience different symptoms or challenges when exergaming. There are no clear guidelines and thresholds identifying who will be at risk after using provocative VR applications and what to do if users experience atypical symptoms.

## Conclusions

VR sickness in exergames, particularly in HMDs, is understudied. On the basis of the data in this study, we can make two suggestions for the safe use of VR. First, we recommend that users trial a brief session in VR before committing to longer exposures. Our research shows that if a user experiences a high level of symptoms after a short exposure, they he or she will likely experience similar or worse symptoms for longer exposures. Users with high symptoms for shorter exposures may attempt to take frequent breaks and habituation strategies but should still be cautious as these approaches may not work

for everyone. Second, we recommend that users commit to a waiting period after exiting VR. During this waiting period, users should withdraw from activities that may pose a risk to injury in the event that a person has VR aftereffects, for example, driving a car. In our study, a 40-min wait period was sufficient for most people's symptoms to return to baseline levels. Since content plays a major role in the development of

VR sickness, more research is needed to clarify the relationship between VR sickness, the exposure duration, and the minimum waiting times for different exergames before participants should return to activities that pose an increased risk of injury and accident. Given the increasing popularity of VR exergames and the potential implications of VR aftereffects, it is essential that research in this area continues to propagate.

## Acknowledgments

AS and TL worked together in the conceptualization of this research and wrote the manuscript. SM was involved in data collection and assisted in editing the final drafts of the manuscript. TL was supported by the National Health and Medical Research Council Dementia Research Leadership Fellowship (GNT1136269).

## Abstract

**Background:** Patients are increasingly taking an active role in their health. In doing so, they combine both mass and interpersonal media to gratify their cognitive and affective needs (ie, convergence). Owing to methodological challenges when studying convergence, a detailed view of how patients are using different types of media for needs fulfillment is lacking.

**Objective:** The aim of this study was to obtain insight into the frequency of reported convergence, how convergence affects what posters write online, motives for posting, and the needs posters are trying to fulfill.

**Methods:** Using a hybrid method of content analysis and supervised machine learning, this study used naturally available data to fill this research gap. We analyzed opening posts (N=1708) of an online forum targeting cancer patients and their relatives (Kanker.nl).

**Results:** Nearly one-third of the forum opening posts contained signs of convergence in mass or interpersonal media. Posts containing mass media references disclosed less personal information and were more geared toward community enhancement and sharing experiences compared to posts without convergence. Furthermore, compared to posts without signs of convergence, posts that included interpersonal media references disclosed more personal information, and posters were more likely to ask for the experiences of fellow users to fulfill their needs. Within posts containing signs of convergence, posts including interpersonal media references reported fewer shortages of information, disclosed more information about the disease, and were more active in seeking other posters' experiences compared to posts containing mass media references.

**Conclusions:** The current study highlights the intertwining of media platforms for patients. The insights of this study can be used to adapt the health care system toward a new type of health information-seeking behavior in which one medium is not trusted to fulfill all needs. Instead, providers should incorporate the intertwining of sources by providing patients with reliable websites and forums through which they can fulfill their needs.

## Introduction

**Background**

Patients have the need to know and understand (ie, cognitive needs) and the need to feel acknowledged and understood (ie,

affective needs) [1]. Currently, patients take an active role in the management of their health, and in doing so they combine mass and interpersonal communication to gratify their cognitive and affective needs (hereafter referred to collectively as “needs”) [2]. By using mass and interpersonal communication, patients engage in a process that is called “convergence” [3-5].

According to Kreps [3], convergence can be defined as “the sequence of impersonal to interpersonal interactions” (p. 519; type 1 convergence) or the “conduct of interpersonal and peer discussions about health-related issues in virtual discussion spaces of various kinds” (p. 521; type 2 convergence). We adapted and broadened this definition to include convergence between and within mass or interpersonal communication for the current study. That is, we consider convergence as a process in which either one mass communication source and one interpersonal communication source (intermedium convergence) or two mass communication sources (intramedium convergence) are being used to fulfill the user’s needs. For example, patients learn about their disease through a consultation with a medical expert (interpersonal communication) and then validate the advice of the medical expert by visiting a website (mass communication; intermedium convergence) [6-8]. An example of intramedium convergence is the use of treatment experience from a fellow patient’s blog post in one’s own blog post.

These examples show how patients use mass and interpersonal communication to fulfill their needs. However, research into this topic often focuses on one singled-out communication source. As a consequence, current research does not provide insights into how communication sources affect each other and how needs differ depending on the sources used. Answering these questions is important since patients have different communication sources at their disposal. In particular, when it comes to online health information, patients often struggle to understand the complex information online, have difficulties in assessing whether the information is reliable, and might feel overwhelmed or experience information overload [9,10]. Therefore, patients and medical experts should work together in providing, validating, and discussing information. To determine which (online) source fits best, insights are needed on how patients combine sources and how the combination of sources affects needs. Ultimately, part of the costly and limited time of the medical expert could be used for referring to sources that can reliably fulfill part of the patients’ needs.

One explanation for the research gap on how patients combine multiple sources to fulfill their needs can be found in the methodological challenges faced when studying this process. The scarce research in health communication in which both mass and interpersonal communication are taken into account tends to rely on more traditional research methods such as surveys [11,12], interviews [13], and focus groups [14]. These methods can be affected by selection bias, recall bias, and social desirability [11]. By using a hybrid method consisting of content analysis and supervised machine learning (SML), the limitations of these traditional methods can be surmounted [15]. The hybrid method combines a content analysis of real-life communication and SML. We use natural unsolicited data (ie, data that are not obtained as part of research but are instead compiled by the user writing at the time their needs arose). The benefit of this method is that large amounts of already existing natural data can be used to study the current topic.

A good starting point is the analysis of data from online health forums targeting patients. Forums provide a natural database of people’s online activities. In forum opening posts, posters often provide information about their situation at the time of

writing, which often includes previously used communication (ie, signs of convergence), the outcome of this communication effort (ie, motives to start the forum post), and the needs they are trying to fulfill. Additionally, background information about the poster is often included (eg, stage and type of the disease, and whether the poster him/herself or a family member has been diagnosed with the disease) [3,16]. Thus, by using this hybrid method, we are able to gain more insight into how often patients combine mass and interpersonal communication, the reason as to why they engage in convergence, which need they are trying to fulfill, and whether the content of forum posts differs based on the communication sources they used prior to writing the post. The following research aim was central in the present study: What signs of convergence can be detected in forum opening posts, how frequently does convergence occur, what kinds of needs are patients trying to fulfill by engaging in convergence, and how do forum post characteristics (ie, motives, information about the poster, and needs) differ for different kinds of convergence?

In this study, we used forums in the context of cancer. Cancer patients are confronted with many questions and uncertainties during their illness [17,18]. Furthermore, online platforms such as forums and interpersonal communication with a health care provider are the two most important sources of information for cancer patients [19].

## Interpersonal Communication

In general, most patients consider medical experts to be the most trusted source of information [20]. In a review, Shea-Budgell and colleagues [20] highlighted that patients place a high level of trust in medical experts owing to their expertise on topics that patients find most important, including treatment, screening, testing, and detection. Furthermore, their medical and informational training and, to a lesser degree, the emotional support they provide during a consultation are mentioned as factors that instill confidence [21-23]. Nevertheless, between 40% and 90% of patients report unmet needs after their consultation with a medical expert [24,25]. Multiple reasons can be given for these unmet needs. Patient-related reasons include unmentioned concerns, a lack of trust in a particular medical expert, and information overload [26]. Examples of medical expert–related concerns are time constraints and a lack of experience [27]. Therefore, patients also rely on other sources for needs fulfillment, such as online forums. Patients expect their medical experts to discuss the content they found via other sources and to offer their professional take on it [28]. By discussing online health information with their provider, patients engage in intramedium convergence.

## Online Forums

Online forums are often used by patients and their relatives and can be considered as virtual communities. Virtual communities exist in many different areas, cover many topics, and connect groups with a variety of shared characteristics. In this study, we adopt the definition of Rheingold [29], who states that virtual communities are “social aggregations that emerge from the Net when enough people carry on those public discussions long enough, with sufficient human feeling, to form webs of personal relationships in cyberspace.” Many patients encounter various

needs and use multiple communication sources to fulfill these needs. As a result, these patients are active in online forums while also often having contact with other sources such as medical experts [30]. Patients use these platforms to gain understanding about their disease but also to connect and exchange experiences and support with others in comparable situations [7,8,31]. By encouraging and enabling active participation (eg, by opening a thread on a topic that is personally relevant), forums have the potential to provide different types of support to the user, such as to receive the support of their peers, to feel empowered through information provision, and to recognize themselves in stories from peers and thereby feel less isolated [11,32]. The malleability of forums in addressing patients' needs and the ability to do this at any time might be a key reason why patients turn to these forums.

### Convergence and Underlying Motives

Many patients decide to combine multiple sources to fulfill their needs. Generally, 25% to 83% of patients search for online health information before or after a consultation with their medical expert [33-36]. Patients seem to use online health information in addition to a consultation to prepare themselves [13], to complement the information given by the medical expert [13,24,25], as well as to validate or challenge the information given by the medical expert [13].

To understand why patients use multiple sources, the optimal matching model can be used [37,38]. This model states that to fulfill patients' needs, these needs should be matched with the right type of support. For example, if the patient feels the need to prepare for a consultation or wants to complement, validate, or challenge the information that is given by the medical expert, this need can be fulfilled by gathering factual information from other sources. By contrast, if the patient feels lost and alone, this need might not be fulfilled by receiving information about the upcoming treatment but rather by receiving emotional support that helps with the emotional aspects of being sick. According to the optimal matching model, patients actively choose the communication channel that they believe has the highest potential to fulfill their current needs. A patient who feels that they should prepare for the consultation is more likely to choose online medical libraries to fulfill these needs, whereas a patient who feels lost will more likely turn to online health forums and blogs, on which interaction with fellow patients is possible [3,31,39-41]. This exploratory research contributes to the optimal matching theory by identifying whether and how patients fulfill their needs by using multiple sources at their disposal and how these sources are intertwined.

### Research Questions

In summary, we believe that forum posts provide a natural database of peoples' communication activities, and these forum posts can offer an opportunity to gain a better understanding of the interplay between communication channels. Therefore, our first research question (RQ1) is proposed as follows: What is the frequency of signs of convergence in forum opening posts? Furthermore, these forum posts can provide a natural registration of the motives for using different media (eg, after seeing a doctor or reading online health information) to fulfill specific needs. Therefore, research question 2 (RQ2) is proposed as follows:

What needs are patients trying to fulfill by opening a forum post? By using a hybrid method to analyze these forums, we are able to also capture other relevant information such as the disclosure of information about the poster and the motive for posting [3,16]. These aspects are important for providing insight into how users in different situations gratify their needs or the needs of relatives by using multiple sources. Therefore, we propose research question 3 (RQ3) as follows: How do motives (3a), information about the poster (3b), and the needs (3c) differ for different types of convergence?

## Methods

### Study Design

We used a hybrid method consisting of a classic social science method (ie, the framework method [42]) and a newer computational social science method (ie, SML). The benefit of this approach is two-fold. First, this method allows us to combine unique features from both approaches. On the one hand, the framework method starts from a theory-based codebook (ie, the use of sensitizing concepts) and is then further developed through an iterative process of (open) coding on a subsample of the data. On the other hand, the coded subsample can then be used to label the whole sample with codes and categories using SML, thereby allowing us to move from open-coded data on a subsample to data that are suitable for quantitative analysis based on the complete dataset, allowing researchers to analyze sample sizes that were impossible to code manually. Second, SML allows us, as well as other researchers and practitioners, to (re)use the trained model on a different dataset or for practical applications. The reuse of the algorithms makes cost-efficient longitudinal research into convergence possible since the models can automatically and consciously be applied to new data.

### Data

We used data retrieved from cancer patients and relatives on the online forum Kanker.nl [43] in the Netherlands. Cancer is the most common disease, with a yearly incidence rate of 439.2 per 100,000 men and women (18,078,567 in 2018) and a yearly rate of 163.5 per 100,000 people dying from cancer (9,555,027 in 2018) [44]. Furthermore, cancer patients and their relatives experience multiple visits with a medical expert and face many questions and uncertainties. In the Netherlands, Kanker.nl is one of the largest and best-known Dutch websites for cancer-related information within an online community [43].

Users are required to register and must provide their name and a valid email address. Participants of all platforms within Kanker.nl give (standard) consent for using their data for research when they register. Ethical approval for the current study was provided by the ethical committee of University of Amsterdam (2016-PC-7547).

For the complete dataset, first, all forum entries (N=9573) were extracted. Second, only the opening posts of the threads were selected (n=1708). The opening posts were chosen because they are most likely to contain a description of the situation and the need the user wants to fulfill. The median number of words for

each thread opening was 608.05 (range 3-20,649). The threads were created between April 2013 and November 2016.

### Phase 1: Framework Method

Of all 1708 thread openings, a random sample of 306 posts (17.92%) was manually coded by the first author (RS) in multiple iterations. First, using two sensitizing concepts derived from the literature (ie, information sources and motives for searching health information), 100 posts were open-coded on signs of convergence (RQ1), motives for opening a forum thread (RQ2), sought-after need (RQ3), and personal characteristics (RQ3); in total, 583 different codes were used for the constructs needed to answer RQ2 and RQ3. Second, these open codes were merged into overarching, latent categories. For example, the distinctions between different medical experts such as general practitioners, oncologists, and nurses were merged into a

medical expert category. Third, the codebook and categories were evaluated on completeness during research meetings with the coauthors (AL, RV, JvW). As a result, several categories were merged again, and more specific categories were added. This process resulted in the following categories: convergence, motive for posting, information on poster, and needs (see [Table 1](#) for the codebook). Fourth, the updated codebook was evaluated by the first author and a trained coder (RS and MB) who double-coded 20% of the sample. The intercoder reliability was good (Lotus range 0.98-1.00); Lotus and standardized Lotus scores are displayed per category in [Table 2](#). Fifth, all 306 exported thread openings were manually coded by the first author (MB) using the codebook. Finally, the manually coded posts were transformed by the first author (MB) into binary variables to be used in the second phase.

**Table 1.** Overview of categories and codes analyzed.

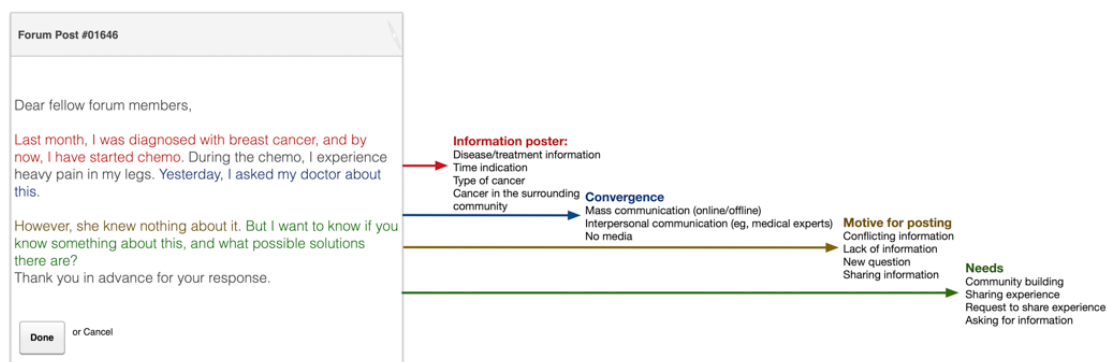

Codes/classifiers	Description	Example
<b>Convergence</b>		
Mass communication	(1) online and (2) offline media. Mass communication was coded as such when communication channels such as internet sources (ie, online) and television and newspapers (ie, offline) were mentioned.	"[...] on a website I read that [...]"; "This article in today's newspaper [...]"
Interpersonal communication	Interpersonal communication was coded as such when one of the following communication sources was mentioned: (1) medical experts (eg, general practitioner, nurse, surgeon), (2) fellow patients, (3) family members, or (4) others.	"My doctor told me that [...]"; "According to my mother [...]"
No media	Posts contained no references to other media.	"I was wondering if any of you knows something about [...]"
<b>Motive for posting</b>		
Conflict	Information is received from a medium that is contradictory to information previously acquired from another medium or contradictory to held beliefs. Resolving this discrepancy is a motive to open a forum thread.	"[...] My doctor told me this treatment is not an option for me, but I heard lots of stories that it was successful [...]"
Shortage of information	Poster indicates that (s)he received little or no information regarding a topic. To fill this information gap, a forum thread is opened.	"[...] There was no time during the consultation to discuss the trajectory of this alternative [...]"
New question	Poster indicates that as a result of information provided during the mentioned communication effort, (s)he has new (follow-up) questions. Answering these questions is a motive for opening a thread.	"[...] the doctor mentioned this medicine can have a lot of side effects, but is it common to experience them?"
Sharing information	Poster wants to share the information/content that was received during the previous communication effort on the forum.	"I read this [website] and thought it might be useful for all of you".
<b>Information on poster</b>		
Disease or treatment information	Specific stages of the disease (eg, stage one) or treatment (eg, after surgery) were described in the post.	"[...] I'm diagnosed with stage one breast cancer"; "[...] After surgery I noticed that [...]"
Time indication disease or treatment	Diseases or treatments that were mentioned at the "disease or treatment information" stage are further specified with a time indicator.	"One year after my surgery, I went back to the hospital [...]"
Type of cancer	Type of cancer is mentioned by the poster.	"I have been diagnosed with lung cancer"
Cancer in the surrounding community	The poster him/herself did not receive a diagnosis but someone close to him or her has.	"My husband has been sick for a few years now, I wonder [...]"
<b>Needs</b>		
Community building	The post is meant as a conversational starter, including rhetorical questions and a direct call for discussion. All without asking for experiences or advice.	"What is your opinion about the quality of care in the Netherlands?"
Sharing experiences	The poster is sharing experiences about the treatment or psychosocial aspects surrounding (living with) cancer.	"For me, this kind of treatment worked very well without too many side effects" or "For me, it worked to limit the number of social activities in a week".
Asking experiences	The poster invites other forum members to share their experiences about a certain topic.	"Who has experience with this?"
Asking for information	The poster asks for more information about a certain topic or asks for referrals to sources where this information can be obtained.	"Who knows where I can find more information about this?"

**Table 2.** Intercoder reliability using Lotus and standardized Lotus (S-Lotus) coefficients per variable.

Concept	Lotus	S-Lotus
<b>Convergence</b>		
Mass communication	1.00	1.00
Interpersonal communication	1.00	1.00
No media	1.00	1.00
<b>Specification of convergence</b>		
Online	1.00	1.00
Offline	1.00	1.00
Medical expert	1.00	1.00
Fellow patients	1.00	1.00
Family members	1.00	1.00
Others	1.00	1.00
<b>Motive for posting</b>		
Conflict	1.00	1.00
Shortage of information	1.00	1.00
New question	0.98	0.96
Sharing information	0.98	0.96
<b>Information on poster</b>		
Disease or treatment information	1.00	1.00
Time indication disease or treatment	1.00	1.00
Type of cancer	0.99	0.97
Cancer in the surrounding community	1.00	1.00
<b>Needs</b>		
Community building	1.00	1.00

Asking experience	1.00	1.00
Asking information	0.99	0.97

## Codebook

Table 1 contains the categories and codes that were coded during the SML phase. These variables were coded as 0 (not present)

**Figure 1.** Example of extraction of concepts from forum posts.

or 1 (present). Figure 1 shows a fictitious example of the extracted concepts from the forum opening posts.

## Phase 2: SML

We used SML to train classifiers for the references to mass or interpersonal communication (see [Multimedia Appendix 1](#) for a detailed description of the SML phase). A sample of 685 manually coded opening posts (in two rounds) was used as input for SML. This sample was split into a training set ( $n=548$ ) and a test set ( $n=137$ ) using an 80-20 split. Using Scikit-Learn [45], the data were preprocessed (see [Multimedia Appendix 1](#) for a detailed overview), and the classifiers were trained using different algorithms such as support vector classification, stochastic gradient descent, multinomial naïve Bayes, gradient boosting, and passive aggressive classifier. This was done to evaluate which algorithm would have the best performance for each concept it was trained to predict. In this process, we adopted a grid search strategy, which tests different combinations of parameters for each algorithm as well as different options for preprocessing the data.

The quality of the classifiers was assessed based on precision, recall, and F1 scores for their predictions of cases in which the category was present (ie, for cases in which the reference to mass or interpersonal communication was 1). Precision gives the proportion of the automatically assigned labels that correspond with the human-labeled data. Recall gives the proportion of the true labels that are found automatically. This often results in a tradeoff between the scores of precision and recall; for example, in cases of higher recall, the chance that some of the recalled data are false positives grows, and the precision score consequently goes down. F1 scores are the harmonic mean of the recall and precision. Stochastic gradient descent proved to have the best performance in predicting the classifiers convergence mass media and convergence interpersonal media (recall<sub>interpersonal</sub>=0.76, precision<sub>interpersonal</sub>=0.96, F1=0.85; recall<sub>massmedia</sub>=0.86, precision<sub>massmedia</sub>=0.92, F1=0.89). See [Multimedia Appendix 2](#) for the complete confusion matrix. These classifiers were applied to the complete dataset of opening posts ( $N=1708$ ) to create a subsample of opening posts that were likely to contain signs of convergence ( $n=771$ , 45.14%).

## Phase 3: Manual Coding Convergence Posts

To ensure the validity of the automatically assigned classifiers, the created subsample of posts was checked for correctness. Of the automatically labeled posts containing signs of convergence ( $n=771$ ), 245 posts (31.78%) did not contain signs of convergence after manually checking, and were coded as “no media.” Next, the subsample of posts was manually coded by the first author (MB) using the codebook for the remaining categories (see [Table 1](#)).

## Analysis

Before running the analysis, all independent variables were tested on possible issues due to multicollinearity. Only issues concerning time since diagnosis, stage of the disease, and type of disease ( $r_{\text{time-stage}}=0.82$ ,  $r_{\text{time-type}}=0.92$ ) were found; thus, these items were taken together as “disclosure of information about the disease” (eigenvalue=2.71;  $R^2=0.90$ ;  $\alpha=.95$ ).

RQ1 and RQ2 were answered using descriptive analyses. To compare the outcomes on the dependent variables between posts containing different signs of convergence (RQ3), two multinomial logistic regression analyses were conducted. In these two analyses, the referenced communication channels were the dependent variables (ie, no media, mass communication, or interpersonal communication). The first regression used no media as the reference category with information on poster and needs as the independent variables. Since the category “motive” was not applicable to the “no mass” or “interpersonal media” category, motive was omitted from this analysis. However, to pinpoint the differences between posts containing signs of convergence, motive, information on poster, and needs were included in the second regression analysis, in which mass communication was used as the reference category. The outcomes of these analyses are displayed as the odds ratios (OR). An  $R$  value of 1 indicates no differences in probability between the groups compared, whereas a value  $>1$  represents an increased probability and a value  $<1$  represents a decreased probability [46].

## Results

### Signs of Convergence in Forum Posts

The results showed that 30.80% of the complete sample of forum opening posts ( $n=526$ ) contained signs of convergence. These were divided into mass communication (324/526, 61.6%) and interpersonal communication (202/526, 38.4%). In the following sections, these categories will be described in more depth.

Of all mass communication references ( $n=324$ ), 274 (84.6%) referred to online sources (eg, other members’ profiles or blogs, news media articles concerning cancer [patients], and health information websites). Of all posts with mass communication references, 214/324 (66.1%) posts contained references to a website. Offline mass communication was referenced 49 (15.1%) times, which included references to printed newspapers, books, and television.

Of all interpersonal communication posts ( $n=202$ ), 162 references (80.2%) were made to medical experts (eg, oncologists, nurses, and general practitioners) and 14 references (6.9%) were made to family members. These include family members who either had personal experiences with the disease or provided information they received via other sources. Fellow patients who provided information offline were referenced 3 times (1.5%) and 22 references (10.9%) were made to communication events with other people. Often, these events consisted of work-related relationships (eg, employers, insurers, and rehabilitation agents).

With respect to RQ1, almost one-third of all forum opening posts contained signs of convergence and thus included references to either mass or interpersonal communication. When referencing mass communication, mainly online sources were mentioned, whereas for interpersonal communication, medical experts were most often mentioned.

## Posters' Needs

Of all 771 opening posts containing signs of convergence, 344 posts (44.6%) represented the need of asking for experiences regarding a specific treatment (eg, medicine, procedure) or experiences regarding (dealing with) the (emotional) effects of living with cancer (ie, dealing with side effects, reintegration into society, and body image). This was followed by forum opening posts related to community building (266/771, 34.5%). In these cases, the poster started a discussion about a particular topic such as developments in the medical sector, with or without a URL to a news story (online). The third-largest need to open a forum thread was to share one's personal experience. Overall, 143/771 (18.6%) of the posts featured this need. Finally, in 72 of the 771 opening posts (9.3%), the poster directly asked for sources to find more factual information on a particular topic such as (alternative) treatment options. Therefore, to answer RQ2, the main need for patients to be fulfilled, as reflected in forum openings post, is that of asking for information related to experiences. This need is followed by that of enhancing the community, sharing one's experiences, and asking for factual information.

## Differences in Posts for Different Kinds of Convergence

The first multinomial logistic regression model contained the variables from the categories information on poster and needs (adjusted  $R^2=0.30$ ,  $\chi^2_{12}=-563.27$ ,  $P<.001$ ; Table 3). In posts referencing mass communication, the disclosure of

disease-related information was 89% less likely to occur compared to posts that did not include a reference to mass communication. In contrast, posts including references to interpersonal communication had a 156% higher likelihood of featuring the disclosure of disease-related information (Table 3) compared to posts containing no references to media. These outcomes mean that the chance of disclosing disease-related information in forum posts in which interpersonal communication is mentioned is higher compared to that of forum posts with no signs of convergence and is lower for posts that include references to mass communication.

When considering the needs posters might have for opening a forum thread, differences in needs within different types of convergence were found. Higher likelihoods were found for posts including references to mass communication compared to posts containing no signs of convergence for the needs: community building, sharing experiences, and asking for information. This means that after mass communication exposure, posts have a 373% higher likelihood of containing the need to share the post for community building, a 291% higher likelihood of containing the need to share one's experience with others, and a 188% higher likelihood of asking for more information compared to no exposure to mass or interpersonal communication. Posts containing references to interpersonal communication had a 268% higher likelihood of displaying the need to ask fellow patients for their experiences compared to posts containing no signs of convergence.

**Table 3.** Differences between posts containing signs of convergence and posts without (reference category=no media).

Variable	Mass			Interpersonal		
	OR <sup>a</sup>	P value	95% CI	OR	P value	95% CI
<b>Information on poster</b>						
Disclosure of information about the disease	0.11	<.001	0.06-0.20	2.56	.009	1.26-5.20
Cancer in surrounding	1.08	.85	0.50-2.29	1.51	.10	0.92-2.49
<b>Needs</b>						
Community building	4.73	.002	0.92-2.49	0.21	.06	0.04-1.10
Sharing experiences	3.91	.003	1.59-9.59	1.71	.21	0.75-3.89
Asking for experiences	1.30	.58	0.52-3.30	3.68	.004	1.50-8.99
Asking for information	2.88	.04	1.04-7.98	1.91	.23	0.67-5.46

<sup>a</sup>OR: odds ratio.

The second multinomial logistic regression models contained the variables from the categories motive, information on poster, and needs (adjusted  $R^2=0.77$ ,  $\chi^2_{20}=-185.40$ ,  $P<.001$ ; Table 4). Within the category motive, in posts referencing interpersonal communication, a shortage of information was 81% less likely to be the reported outcome of the communication effort compared to posts referencing mass communication. Furthermore, within the category information on poster, posts referencing interpersonal communication were 2015% more likely to disclose information about the disease compared to posts referencing mass communication. Within the category needs, posts containing interpersonal communication were 93% less likely to display community building as a need of the post

compared to posts referencing mass communication. Furthermore, posts referencing interpersonal communication had a 227% higher likelihood of asking for other posters' experiences compared to posts referencing mass communication (OR 3.27,  $P=.04$ ).

To answer RQ3, compared to intramedium convergence, intermedium convergence posts are less likely to be motivated by a shortage of information and are more likely to contain information about the poster's condition. Furthermore, again compared to intramedium convergence, intermedium convergence is more likely to display the need for experiences and is less likely to exhibit a need for community building.

**Table 4.** Differences between posts containing signs of interpersonal convergence (reference category=mass communication).

Variable	OR <sup>a</sup>	P value	95% CI
<b>Motive</b>			
Conflict	2.77	.07	0.92-8.29
Shortage of information	0.19	.006	0.06-0.63
New questions	0.83	.69	0.30-2.23
Sharing of information	0.39	.11	0.12-1.24
<b>Information on poster</b>			
Disclosure of information about the disease	21.15	<.001	9.39-47.62
Cancer in surrounding	1.49	.36	0.64-3.47
<b>Needs</b>			
Community building	0.07	.004	0.01-0.44
Sharing experiences	0.65	.47	0.20-2.10
Asking for experience	3.27	.04	1.01-10.57
Asking for information	0.77	.70	0.20-2.90

<sup>a</sup>OR: odds ratio.

## Discussion

### Principal Findings

This study provides more insight into (the occurrence of) convergence using natural unsolicited data. Overall, intramedium and intermedium convergence resulted in posts containing different content and aiming to fulfill different needs. We found that nearly one-third of all forum opening posts in our sample contained signs of convergence by referencing either mass or interpersonal communication in the post. For intramedium convergence, online sources such as websites, forums, and online news articles were most often mentioned, frequently accompanied by a link to that source. In this way, posters seem to fulfill their need to help build the online community and initiate a discussion or to share experiences. Posts containing intermedium convergence often included references to a consultation with a medical expert. In these posts, users reported less shortage of information, disclosed more about themselves, and asked for more experiences from other users compared to posts containing intramedium convergence.

Our findings further emphasize the frequency of reported convergence and how intertwined these sources are. The main interpersonal communication source that was mentioned in the posts was that of a medical expert. This outcome is in line with previous research in which the medical expert, together with the internet, is named as the most important source of information for patients [19,23,47]. We found that one-third of the posts contained signs of convergence. The number of patients who use more than one medium is likely to be higher for two reasons. First, we only looked at specific types of convergence occurring in forum posts; however, based on previous research (eg, [35]), we know that signs of convergence also occur at the medical encounter and that different types of convergence exist. For example, during medical encounters, patients could discuss a forum they have read before the

consultation and thus engage in intermedium convergence (online forum-medical expert) or engage in intramedium convergence (ie, medical expert-medical expert) by referencing a medical expert during the consultation who provided a second opinion.

Second, we only coded explicit signs of convergences, whereas previous research also shows that patients implicitly mention different sources [48]. One aspect that is unique to this study is that although previous studies often examined both sources independently, the current results show how interdependent these sources are and how they are likely to continue to merge in the future. For example, a poster who recently had an appointment with a medical expert may have received a lot of information (convergence). After interpersonal communication, there is a lower likelihood that the patient experienced a shortage of information (motive). However, the patient might have missed information about how other patients experienced the situation, which motivates the patient to go online, write about their situation, and ask fellow patients for their experiences (need). According to the optimal matching theory [38], patients actively choose a medium that likely fulfills their needs.

In the context of support, some patients actively start participating in forums to find information that only fellow patients can provide—their experiences [14,49,50]. Our results also highlight the importance and added value of studying information sources in an interdependent context instead of independently. In light of the increased availability of different types of information on platforms, the internet seems to be a promising venue to fulfill needs that are not fulfilled during a consultation. Taking the notion of the optimal matching theory further, one could argue that it should not be a problem if patients report unmet needs based on their exposure to one medium, as another medium might be better able to fulfill these unmet needs. However, the medical expert and patient should

work together to make sure credible sources of information are known and available to the patient to fulfill their needs.

Based on our results, posters seem to require information provided by other patients combined with the information provided by the medical experts. Forums can be used to gain access to the experiences of fellow patients without the medical expert being an intermediary in this process. Users thereby benefit from both the expertise garnered during consultations with the medical expert and the experiences of fellow patients [51]. Eysenbach and colleagues [50] already highlighted that providing, receiving, and reading experiences from fellow patients is one of the main functions of social support communities. The current study shows how patients use health forums in a broader context of multiple available sources.

Because websites are easily shared and embedded in online tools such as online forums, the current study found many references to mass communication in general and online sources in particular. Mass communication is likely to be shared with members of the community to sustain and to inform the community through what is called “community building.” Community building creates a feeling of being part of a community and therefore fights the feeling of being alone, which in turn can emotionally support the patient [52].

### Limitations and Future Research

We posited that using a hybrid method on natural data could be a useful tool in meeting the challenges faced in studying convergence (ie, circular process, biased data when trusted on solicited recall data). Although we successfully analyzed indicators for convergence using forum data, some shortcomings must be acknowledged to advance future research. Despite the merits in using unsolicited data, not all aspects of convergence could be studied. First, we could only detect explicit signs of convergence. It would be a safe assumption to imagine convergence occurring in implicit ways as well, such as by simply posting a question without stating the events leading up to the post. Furthermore, convergence could only be measured when mass or interpersonal communication led to posting on a forum. However, posting online or reading posts and responding to these posts could lead to convergence elsewhere. By only studying online forum posts on one particular website, these types of convergence could not be measured. Although this would result in an underestimation of convergence instead of an overestimation, future research could address these types of convergence. Content analysis (on videotaped consultations) can, for instance, be combined with surveys to investigate patients’ (unmet) needs when they communicate and to gain insight into how patients use communication sources to cope with their needs. The online environment would be a logical place to administer these surveys since this environment does not require actual tracking; instead, log data and prompted surveys could minimize intrusion and reliance on recall. Finally, using natural data restricted the possibility to control for differences in personal characteristics of the poster because these variables are not known. Based on previous studies, we know that the way patients use online forums changes over time [53]. We did not account for these individual differences. Future studies could gather data from multiple forum messages and

profiles to extract information on the time of diagnosis, number of posts by the user, and type of disease to gain insight into these concepts.

SML was applied to create a subsample of posts containing signs of convergence. This approach resulted in a significantly smaller sample that had to be manually coded. If studies are interested in latent communication concepts such as the needs or motives of patients, researchers should take into account the time and effort needed to code a substantial part of their data as input for the SML, still without a guarantee that these latent construct can be reliably predicted. In an early phase of their study, researchers should decide on the role of SML in their project based on the number of positive cases per classifier and the initial SML results. Instead of coding a large portion of their data in the hope to obtain reliable classifiers for all constructs, reliable classifiers can be used in an early phase as a filter on the complete dataset to create a small subdataset that can be coded by hand.

The current study introduced two possible forms of biases. First, our sample consisted of posts from one forum on a highly trusted Dutch cancer website. Users on this forum might differ from the general cancer population in that they must have the skills to go online and register before using this forum. Furthermore, the fact that these patients opened a forum post could be an indication that they experienced a problem during a previous communication (eg, a shortage of information or conflicting information during the consultation with their medical expert). Therefore, the results might not be representative of all cancer patients, and the needs and motives found could be an overestimation of the unmet needs in this population. However, a complete export of all of the content of a platform with the informed consent of all users is still difficult to obtain, thus illustrating the uniqueness of our study. While the reported unmet needs might be an overestimation, these unmet needs still exist and will likely continue to exist. Therefore, scholars, medical experts, and (cancer) patient associations should work together to make convergence as easy as possible and try to incorporate alternative sources of information into the medical trajectory. For example, a leaflet or a website hosted by the hospital can provide patients with reliable sources but also well-known forums in which patients can exchange experiences and find support.

The second possible bias could have been created during the SML process. The SML algorithm that was used to create a sample of the posts used for the analysis might have caused a bias in the reference category. We manually created the reference category in which no signs of convergence were present. However, it is possible that the original algorithm marked these posts as false positives based on some shared content characteristics. This process might have led to differences between these false positives and the posts without signs of convergence in the corpus (ie, dataset) that were left out of the analysis. As a result, the reference sample might not completely be representative of the posts without signs of convergence. However, most of the main results are from a comparison between mass and interpersonal communication. These two samples were created by a combination of SML and manual checking; therefore, the above-described bias does not

play a role. To overcome this possible bias, future research could either randomly create a sample as the reference category or possibly compare the reference category that was created through machine learning to a random sample before running the analysis.

## Conclusions

To conclude, convergence is an important concept that represents the natural flow of patients' information-seeking behavior between and within interpersonal and mass communication. Understanding how patients use different

communication channels is essential to improving health care by providing guidance to patients who are trying to fulfill their needs. A better understanding of the conditions (ie, whether the information is discussed and in which way) under which the convergence of interpersonal and mass media results in positive patient outcomes might be the key to enhancing information provision to patients and in turn increasing patients' wellbeing. In doing so, providers should take a proactive role in discussing online information-seeking with patients and referring patients to the right sources that best meet their needs.

## Abstract

**Background:** A “concerning post” is a display of a user’s emotional crisis on a social media platform. A better understanding of concerning posts is relevant to suicide prevention, but little is known about social media users’ attitudes and responses to concerning posts. Military veterans in the United States are disproportionately affected by suicide, often use social media, and may have exposure to individuals with elevated suicide risk via concerning posts.

**Objective:** The objective of the study was (1) to obtain insight into whether and how US military veterans respond to members of their social network on social media (ie, “friends”) who are experiencing substantial emotional distress, and (2) to identify potential interventions that could assist in users’ response to concerning posts.

**Methods:** We recruited veterans through Facebook and conducted semistructured interviews with 30 participants between June and December 2017. We used a summary template for rapid analysis of each interview, followed by double-coding using a codebook based on topic domains from the interview guide. Members of the research team met regularly to discuss emerging patterns in the data, generate themes, and select representative quotes for inclusion in the manuscript.

**Results:** Veterans were reluctant to disclose emotional and health issues on Facebook, but they were open to reaching out to others’ concerning posts. There was a complex calculus underlying whether and how veterans responded to a concerning post, which involved considering (1) physical proximity to the person posting, (2) relationship closeness, (3) existing responses to the post, and (4) ability to maintain contact with the person. Veterans desired additional training, backed by community-based veteran organizations, in how to respond to concerning posts from peers.

**Conclusions:** There is a need to incorporate features that will help veterans effectively respond to concerning posts from peers into suicide prevention training and to expand access for veterans to such training.

concerning post; social media; suicide prevention; gatekeeper training; military veterans

## Introduction

As social media has become embedded into our daily lives, researchers have taken on the task of unpacking its myriad implications for our health. Studies of social media have often focused on examining psychosocial harms from exposure to social media, such as loneliness [1], negative social comparisons [2], and worsening of mental health status [3]. Perhaps because of negative public and scientific perceptions of social media, less attention has been paid to identifying ways that social media could be used to improve mental health [4]. In reality, both positive and negative consequences of social media coexist and are influenced by how individuals—and society collectively—interact using social media.

An especially delicate but important health concern in the social media landscape is suicide prevention. Suicidal individuals are more likely than nonsuicidal individuals to spend time online [5]. Expressions of suicidal ideation on social media have been widely reported and, at times, are followed by suicidal behavior [6,7]. Disclosures of emotional distress on social media reflect real-life concerns, with studies showing links between depressive language in Facebook posts and self-reported symptoms of depression and medical record–confirmed diagnoses of depression [8,9]. Even more visible to the public are media reports about suicide, which are relatively common on social media compared with reports of deaths from other causes [10]. Analysis of Twitter data has found that large reactions to this reporting, measured through increased mentions after the death of a celebrity by suicide, are linked to subsequent increases in deaths by suicide [11].

Amidst this contemporary reality, the notion of a “concerning post” has emerged, which we define as a display of a user’s emotional crisis or other indication of an acute mental health concern on a social media platform. Little is known about individuals’ attitudes and responses to concerning posts. Among the available studies, results have conflicted at times. For instance, one study found that youth lacked confidence in how to respond to a concerning post [12], while another study found that sharing emotional distress activated supportive responses [13].

While much of the research in this area has focused on youth, military veterans are another key target population for suicide interventions. Veterans in the United States are disproportionately affected by suicide. Their rate of suicide is 50% (1.5 times) higher than that of nonveterans, according to the most recent available data [14]. Suicide exposure (knowing someone who has died by suicide) is also very common and may occur via social media; an estimated 57% of veterans [15] and 65% of National Guard personnel [16] have been exposed to suicide. Social media plays an important role in maintaining veterans’ social networks, with one contributor being the physical separation from family and friends that occurs during deployment or active duty, as well as separation from their servicemember peers after leaving the military. Social media serves to sustain connection and communication over time and in particular through periods of transition [17].

Using data from interviews with veterans who use social media, our objectives in this study were (1) to obtain insight into whether and how veterans respond to “friends” and family members on social media who are experiencing substantial emotional distress, and (2) to identify potential interventions that could assist veterans in responding to concerning posts.

## Methods

### Setting and Sample

This research was conducted as part of a mixed-methods study focused on understanding opportunities to use social media platforms, particularly Facebook, to reach and provide support to veterans at risk of psychiatric problems. We interviewed Operation Enduring Freedom, Operation Iraqi Freedom, and Operation New Dawn veterans with a service separation date after October 1, 2001, who were in the metropolitan area of Portland, Oregon, United States. Thirty participants were interviewed—a number chosen based on the literature, feasibility, and our research team’s experience reaching thematic saturation with such a sample size [18,19].

### Data Collection

Participants who had responded to Facebook advertisements and completed an online survey were eligible for participation in the current study. The survey that was administered has been previously described [20,21]; in brief, it included items on sociodemographic characteristics, frequency of social contact, use of social media platforms, screening for psychiatric problems and health service utilization, and interest in potential online interventions for social support and suicide prevention. Among participants who used Facebook daily, we purposively sampled veterans that varied in the extent to which they used the Department of Veterans Affairs for their health care and varied in their interest in learning more about suicide prevention.

Fifty individuals were contacted to participate, and 30 of them completed an approximately 40- to 60-minute interview between June and December 2017. Twenty-three interviews were completed in person; the remaining seven interviews were conducted over the phone, which allowed for participation by individuals who could not present in person to participate in the study. Two research team members (HM and AT) conducted the interviews using a semistructured interview guide (Multimedia Appendix 1). Questions were organized into three primary domains: (1) participants’ social media use and preferences, (2) discussion of health issues on social media, and (3) suicide prevention in a social media context (including experiences with concerning posts and preferences related to suicide prevention training). Interviews were audio recorded and transcribed.

### Data Analysis

Survey responses were used for participants’ descriptive characteristics. For qualitative analysis, we first created a summary template for rapid analysis of each interview [22,23]. We then created a codebook based on topic domains from the semistructured interview guide and informed by notes from the summary templates. Two research assistants (RB and WS) coded the interviews using qualitative analysis software (Atlas.ti;

ATLAS.ti Scientific Software Development GmbH) for data management. As the primary coder, RB met weekly with the lead investigator (AT) to discuss general impressions and emergent themes. As the secondary coder, WS reviewed the primary coding, adding any codes that may not have been applied, with the goal of ensuring robust coding. AT adjudicated coding disputes as needed. Members of the research team (AT, RB, WS, SD, and SO) met regularly to discuss emerging patterns in the data, generate themes, and select representative quotes for inclusion in the manuscript. We assigned pseudonyms to the participants to maintain confidentiality.

## Results

### Principal Findings

A summary of participants' characteristics is presented in Table 1. The 30 participants (23 men, 7 women) came from all military branches, with 3 participants serving in two branches over their careers. The average age of participants was 41 years (range 24–64 years), 73% (22/30) were White, 60% (18/30) were married, and 57% (17/30) had a college or postgraduate degree. In terms of their mental health, 5 of 30 (17%) participants received a score of 3 or greater on the Patient Health Questionnaire-2, which is indicative of a positive screen for major depressive disorder [24]; 15 of 30 (50%) participants had considered suicide, and 5 of 30 (17%) participants had previously attempted suicide. While 90% (27/30) of participants used Facebook several times a day, the majority never or rarely used social media for sharing information about their health (23/30, 77%), symptoms such as mood swings, depression, anxiety, or sleep problems (21/30, 70%), or thoughts about suicide or self-harm (28/30, 93%).

Veterans were reluctant to disclose emotional and health issues on social media but were open to reaching out in response to others' concerning posts. Interviews revealed multiple reasons for veterans' reluctance to share negative emotional states or information about their health. First, Facebook was viewed as a venue for positive self-presentation; thus, they were disinclined to use it as a place to "air dirty laundry." Second, when veterans did need support, they usually preferred to obtain it from other avenues in the "real world" that involve "person-to-person interaction," or they preferred to be self-reliant. Also, veterans believed that sharing personal health information was "risky" to their privacy. Lastly, participants noted that Facebook friends were not necessarily "real friends."

While most veterans were cautious about disclosing their own health issues, a number of veterans were understanding of others who chose to post about health issues. One participant summarized this distinction:

*I think for some people they find that they can post about their bad day, and they get a bunch of people "like" it, a bunch of people put the sad face on, a*

*bunch of people say, "You're amazing. You're brilliant. You go girl." That kind of thing. I've definitely seen a ton of people do that, but at the same time I would never do that. And it's not like I don't want support, but I feel like I would be negatively judged for that. [Oscar]*

Further, many veterans were open to responding when others disclosed personal information in a post, particularly emotional struggles or suicidality.

*I've seen other friends do it, and I've come to the aid of other friends because they have shared it on Facebook out in the open just to their timeline or whatever. I've also helped friends who have reached out to me personally and [sent] Facebook messages and said, "I'm having this crisis. I can use some words of encouragement or some words of advice or some help just in general." [Bryan]*

Participants identified a post as concerning in several ways. Most obviously, this was direct language expressing emotional distress, particularly when the distressed person had a known mental health condition (eg, post-traumatic stress disorder or an anxiety disorder), when the person was acting out of character (eg, getting rid of their possessions), or if the person had one or more recent psychosocial stressor, such as divorce/breakup, death of a loved one, or loss of a job. Several veterans also expressed a feeling of concern without an identifiable cause, noting, for instance, "[The post] just seems off" [Seth]. Veterans occasionally did not interpret a post as concerning if they felt the post was "venting" [Natasha] or that the person was seeking attention.

There was a complex calculus behind whether and how individuals responded to a concerning post. Once veterans had determined a post to be concerning, they wanted to be there for a peer in distress, but they did not always know if and how they should respond. Before they reached out, veterans went through a series of considerations. Elements of this complex calculus included (1) physical proximity, (2) relationship closeness, (3) existing responses to the post, and (4) ability to follow up with the person in crisis. While the weight given to each consideration varied across situations and circumstances, each factor influenced decisions related to whether veterans responded, how they chose to reach out, and how urgently and directly they responded.

When a friend posted something on Facebook that appeared to indicate suicidal ideation, participants reported that the preferred response was to attempt to make direct, one-on-one contact to talk with the friend. This direct contact could be through Facebook itself (using a private message), email, a phone call or text, or meeting up in person. Multiple methods of contact could be combined, typically with the goal of having the online contacts lead to an in-person contact.

**Table 1.** Summary of participants' demographic, clinical, and social media use characteristics (N=30).

Characteristics	Mean (range)	n (%)
<b>Demographic characteristics</b>		
Age (years)	41 (24-64)	
Gender		
Male		23 (77)
Female		7 (23)
Race/ethnicity		
White		22 (73)
Hispanic		3 (10)
American Indian/Alaska Native		2 (7)
Asian		3 (10)
Educational attainment		
High school or high school equivalency certificate		1 (3)
Some college		9 (30)
Technical or vocational school		3 (10)
College graduate		11 (37)
Postgraduate		6 (20)
Marital status		
Single, never married		7 (18)
Divorced		4 (13)
Separated		1 (3)
Married		18 (60)
Military branch <sup>a</sup>		
Army		11 (37)
Marine Corps		9 (30)
Navy		6 (20)
Air Force		5 (17)
Coast Guard		2 (7)
<b>Clinical characteristics</b>		
Patient Health Questionnaire-2 score	1.5 (0-4)	
0		11 (37)
1		2 (7)
2		12 (40)
3		2 (7)
4		3 (10)
History of serious suicidal ideation <sup>b</sup>		
Yes		15 (50)
No		15 (50)
Number of prior suicide attempts <sup>c</sup>		
0		25 (83)
1		2 (7)
2		2 (7)

Characteristics	Mean (range)	n (%)
3		0 (0)
4		1 (3)
<b>Social media use</b>		
How often do you visit or use Facebook?		
Several times a day		27 (90)
Once a day		2 (7)
A few times a week		1 (3)
How often do you use any social media website to do the following:		
Share symptoms such as mood swings, depression, anxiety, or sleep problems?		
Never		14 (47)
Rarely		7 (18)
Sometimes		4 (13)
Usually		4 (13)
Always		1 (3)
Share information related to your health?		
Never		10 (33)
Rarely		13 (43)
Sometimes		5 (17)
Usually		2 (7)
Always		0 (0)
Share thoughts about suicide or hurting yourself in some way?		
Never		26 (87)
Rarely		2 (7)
Sometimes		2 (7)
Usually		0 (0)
Always		0 (0)

<sup>a</sup>Total is greater than 100% because three participants served in two branches.

<sup>b</sup>Survey item asked, "Have you ever seriously considered attempting suicide at some point in your life?"

<sup>c</sup>Survey item asked, "How many times in your life have you attempted suicide?"

## Physical Proximity

When veterans saw a concerning post on Facebook, one of the first considerations for how they chose to respond was their physical proximity to the individual in distress. If the friend was within a reasonable travel distance, veterans often indicated it was optimal to visit them or call immediately to arrange an in-person meetup as soon as possible. If a friend expressed loneliness or concerning thoughts, participants felt responding through Facebook alone was insufficient. By meeting up in person, veterans felt that they could "get them out and let them know that there are still people for them" [Jamie] and "read more in a person by watching their body language" [Robert]. If the friend was not in close proximity and the level of concern was high, some veterans noted that they might try to get a next-of-kin or other person who was physically closer to check in on the friend.

*Depends on physical proximity, if it's somebody within driving distance, within a few hours I'll be at their house banging on the fucking door. If not, there's going to be phone calls and emails and text messages and that's the way I would react. [Alyssa]*

## Relationship Closeness

Veterans varied in their responsiveness to concerning posts depending on the closeness of their relationship with the person in crisis. For instance, if the concerning post was from an acquaintance or someone that was on the periphery of their life, they were more likely to respond in a less direct or less immediate fashion.

*I'll send them the phone number for the veteran's suicide hotline, that's really about as far as I'm willing to go unless I know the person. [Andrea]*

*If I don't know them personally, I try to give an encouraging thought. [Natasha]*

For a close relationship, efforts to respond were more direct and more intensive. One veteran said that in the case of a close friend or family member, he would respond as follows:

*I probably wouldn't even be on social media in that case. I would've just gone to the person and, you know, physically gone to see them.* [Conrad]

For relationships that fall somewhere between acquaintance and close friend or family, participants tended to communicate their availability but ultimately left the onus of further connection on the person in crisis. These efforts were often made under the assumption that there was someone closer who could help the person in crisis but also acknowledged that they were unsure of this and were thus willing to provide support if needed.

*...you can reach out to them and just give them a little love and then you instant message him and say, "Here's my phone number and call me if you need to."* [Jerry]

### Existing Responses to the Post

A third consideration in the response calculus related to the interactions and activity in response to a concerning post, including "likes," comments, and shares that were visible to others. Often, the timing of the post relative to when it was being seen was a factor. Veterans stressed the importance of timing for two reasons: first, the circumstances surrounding the crisis may have changed, and second, others may have already intervened.

*I've seen it a couple times or I've been, for lack of better term, late to the conversation and you've seen other people comment before that and someone said, "Hey, I've talked to 'em.'"* [Neal]

Recognizing that timing of a post and actions by others might have resulted in resolution by the time they saw a concerning post, participants also described assessing if there had already been direct and supportive responses to the friend when deciding if they should respond.

*I'm usually not the first person to come along by it, so usually I'll check the comment section and see what's being done. Typically, someone will comment and then they'll say: I've got ahold of them, or got them talking.* [Richard]

*And after somebody posts, there's some likes and dislikes and maybe a "hey, what's up, call me." I imagine in those situations there's four or five personal conversations going on with that person. And then they decide who is understanding the situation, talk with them.* [Yolanda]

### Ability to Follow Up

Some veterans emphasized both the need to initially reach out and the importance of following up with a friend in crisis. Veterans who discussed the importance of follow-up considered whether they had the capacity to continue to maintain contact and actively provide support.

One veteran responded that she had a friend who posted on Facebook "reaching out about how lonely they were." She went on to say the following:

*...they're obviously looking for that public acknowledgment, so, I did that. And kept it... you know, more... general, I guess, and supportive, and then, messaged them more. You know, specifically relating to it and then scheduling a follow-up visit with them.* [Jamie]

She let the friend know they weren't alone and scheduled a time to meet up with them.

*...it was the next day or something. Just for a quick coffee date, you know, just to get them out and let them know that there are still people for them.* [Jamie]

*...you don't just listen and walk away. You still have to follow-up with them and keep talking with them. It might not even be someone that you actually really know, but if you come across someone in that state of mind, it's usually kind of obvious that something's not quite right so don't ignore them.* [Bryan]

### Suicide Prevention Training

Veterans desired suicide prevention training that would prepare them to assist others in emotional crisis. The suggestion for training on how to respond to concerning posts, specifically if suicidal ideation was suspected or indicated, was raised by participants as well as asked about by the interviewer. Veterans indicated a desire for training in suicide prevention skills to help a peer in crisis. A common reason they cited for wanting training was a sense of being unprepared to assist others in crisis or even worry about exacerbating the situation.

*I have no idea what to say but just trying to make myself available, trying to say as little damaging stuff as I can... It's mostly that I have no idea what should I do to help? ...I got pretty much nothing else.* [Alyssa]

*I don't know how to sometimes get the point across to them without sounding judgmental.* [Lynn]

### Training as an Ongoing Process

Even veterans who indicated having prior suicide prevention training, often during military service, felt that the training was inadequate or insufficient. This seemed especially vital for veterans who were interested in helping others but worried about how to initiate conversations with more socially distant individuals.

*Would I want more? Yes. Just to let me know I've got the basics down. I'm not a licensed mental health professional so I can't go about helping them solve their problems, but I can get [someone in crisis] in the right direction.* [Edward]

*I'd like to recognize more warning signs, and I would like to have some conversation items that I could take as far as how to talk about it, or how to bring it up.* [Lewis]

### Preferred Features for Suicide Prevention Training

Veterans identified two features of suicide prevention training that would make it especially appealing. First, training sponsored or delivered by community-based veteran organizations was believed to “carry more weight” [Neal] and be “a good source of credibility” [Edward]. Many participants who followed at least one veteran-centric Facebook page or group (eg, Dysfunctional Veterans, Lift for the 22, Gulf War Veterans, etc) felt these groups could act as trusted sponsors of suicide prevention training. One veteran described the kind of support he’s encountered in one such private Facebook group:

*...every 22nd of every month, we do a check in. We'll post a thing, check in with our veteran friends because it comes out that there's 22 vets that commit suicide every day. And we started a program called "22 to None," so we support each other. I've made a couple friends with some other vets, and other Navy vets. And, one guy... he told me, gave me his number, he says you ever start feeling really bad, give me a call. He was a trained counselor as well. [Keith]*

Second, veterans were most willing to receive training targeted at helping their veteran peers. Their shared experiences, military background, and camaraderie as a result of service made a difference in their level of comfort and trust when talking about the topic of suicide with other veterans.

*It's very easy for me to have a relationship or an exchange of information between another person who's in the service. It's easier than it is for me to sometimes talk with my wife, or members of my family because they don't have that background like we have—those who've served. [Meghan]*

*Have you ever had two different people tell you the same piece of information? One is Bob who you don't really know particularly well, but the other one is somebody who is close to you—you know and respect—they repeat that same information, you place a lot more weight on it. With somebody who you've had a lot of those shared experiences with, I may not know them particularly well, but they've been in the same places I have, they've faced the same problems I've had, and if they say that this is helpful, I place a lot more weight on it. [Alyssa]*

## Discussion

### Principal Findings

In the daily course of their lives, veterans are likely to encounter others in emotional crisis, and this can manifest through concerning posts on social media platforms such as Facebook. When presented with a concerning post, veterans go through a complex calculus—involving an assessment of physical proximity, relationship closeness, activity on the post, and ability to follow-up—which informs the extent and manner in which they reach out to provide support. The order of the complex calculus and the weight of each element varies in each situation. Veterans are often inclined to help their peers in some way, but they often feel unprepared as to how to respond to a concerning

post. Given these circumstances, veterans desire suicide prevention training that extends beyond what they received during military service. They seek additional training that is germane to responding to concerning posts on social media, backed by community-based veteran organizations, and tailored to providing assistance to their veteran peers.

### Links to Existing Research on Social Media and Suicide Prevention

Our finding that veterans are thoughtful and potentially motivated to respond positively to concerning posts suggests a key exception to prior research on displays of negative emotions on social media. Experimental and observational studies have shown that emotions are transmitted through social media posts [25,26]. Individuals who frequently post on social media are more likely to post about health issues and to have a diagnosis of depression [27]. Moreover, early research on Facebook posting suggested that depressed individuals see the platform as an appealing venue for self-disclosure, but their posts are often met with undesirable responses due to the negativity of the posts [28]. It may be that military culture around altruism and stewardship toward veteran peers (eg, taking care of “our own,” leaving no one behind, etc) [29] contribute to the positive intentions we found toward responding to concerning posts. Our findings also comport with research showing that individuals often fear personal expressions of vulnerability but tend to react more positively to those who express it [30].

### Training Models Applicable to Social Media–Based Suicide Prevention Training

Our findings complement the use of two education and training intervention models in the literature: gatekeeper training and bystander education. Both gatekeeper training and bystander education train individuals to recognize the signs of crisis and develop skills to triage such a situation and assist with accessing subsequent professional assistance [31,32].

Gatekeeper training has been specifically designed to support “upstream” suicide prevention. Reviews have found evidence of gatekeeper training’s ability to increase knowledge and foster self-efficacy and other beliefs adaptive to suicide prevention [32]. In a recently published pilot intervention, a gatekeeper training approach helped prepare adults to support American Indian and Alaska Native youth who post or view concerning messages on social media [33]. Bystander interventions, also called bystander education, have been primarily used for prevention of sexual violence, and they emphasize a five-step model: (1) awareness of an issue that requires intervention; (2) identifying when the bystander should intervene; (3) deciding to take responsibility; (4) deciding how to help; and (5) taking action [31]. Education about all five steps is meant to increase the likelihood of a bystander taking action at multiple time points. Both of these educational approaches would seem highly applicable to craft training for veterans and others in how to identify and respond to concerning posts. Gatekeeper training and bystander education might be strengthened if future research identifies how expressions of vulnerability and peer support could normalize help-seeking and dialogue about suicide.

## Limitations

Our findings are constrained by several study limitations. Participants were recruited from a sample of locally recruited veterans from Facebook, and thus our findings may not be entirely generalizable to veterans nationally, individuals less inclined to participate in research or to use Facebook, or individuals who have experiences on other social media platforms. The last constraint is particularly relevant given rapid shifts in the social media landscape. There are other facets of Facebook posts, such as posts within private Facebook groups or automatic identification of concerning posts using machine learning models [34], that were beyond the scope of this study but merit closer investigation as part of a larger social media

suicide prevention strategy. Finally, as with all qualitative work, we took participants on their word that they accurately represented themselves and their experiences.

## Conclusions

Social media is an important venue through which many connect with their social network. One consequence of this, particularly among veterans who are disproportionately affected by and exposed to suicide, is encountering concerning posts. Our findings call for expanding access to ongoing suicide prevention training opportunities—in partnership with community-based veteran organizations—and incorporating features into existing suicide prevention training programs that will help veterans in their response to concerning posts from their veteran peers.

## Acknowledgments

This project was supported, in part, by a Career Development Award to Dr Teo from the Veterans Health Administration Health Service Research and Development (CDA 14-428) and the Health Service Research and Development Center to Improve Veteran Involvement in Care (CIVIC) (CIN 13-404). This project was also supported by awards received by Dr Teo from the Collins Medical Trust Research Grant and the Medical Research Foundation of Oregon New Investigator Grant (1603). The authors wish to thank Ms Heather Marsh, at CIVIC, for her assistance.

## Abstract

**Background:** Home hospitalization is widely accepted as a cost-effective alternative to conventional hospitalization for selected patients. A recent analysis of the home hospitalization and early discharge (HH/ED) program at Hospital Clínic de Barcelona over a 10-year period demonstrated high levels of acceptance by patients and professionals, as well as health value-based generation at the provider and health-system levels. However, health risk assessment was identified as an unmet need with the potential to enhance clinical decision making.

**Objective:** The objective of this study is to generate and assess predictive models of mortality and in-hospital admission at entry and at HH/ED discharge.

**Methods:** Predictive modeling of mortality and in-hospital admission was done in 2 different scenarios: at entry into the HH/ED program and at discharge, from January 2009 to December 2015. Multisource predictive variables, including standard clinical data, patients' functional features, and population health risk assessment, were considered.

**Results:** We studied 1925 HH/ED patients by applying a random forest classifier, as it showed the best performance. Average results of the area under the receiver operating characteristic curve (AUROC; sensitivity/specificity) for the prediction of mortality were 0.88 (0.81/0.76) and 0.89 (0.81/0.81) at entry and at home hospitalization discharge, respectively; the AUROC (sensitivity/specificity) values for in-hospital admission were 0.71 (0.67/0.64) and 0.70 (0.71/0.61) at entry and at home hospitalization discharge, respectively.

**Conclusions:** The results showed potential for feeding clinical decision support systems aimed at supporting health professionals for inclusion of candidates into the HH/ED program, and have the capacity to guide transitions toward community-based care at HH discharge.

## Introduction

### Home Hospitalization and Early Discharge at the Hospital Clinic of Barcelona

Home hospitalization (HH)/early discharge (ED) programs [1-6] show substantial site heterogeneities in terms of service workflows and organizational aspects. However, overall, they have demonstrated maturity and health care value generation [7] such that it is well accepted that HH/ED constitutes an effective alternative to inpatient care for a select group of patients requiring hospital admission.

The characteristics of the deployment and adoption of the HH/ED program at Hospital Clinic of Barcelona (HCB) were recently described in a report [8]. In this report, HH/ED is defined as a service providing acute, home-based, short-term, complex interventions aimed at substituting conventional hospitalization fully with HH [7,9] or partially with ED [10]. The service at HCB is delivered by trained hospital personnel, and it is provided for a period of time that is not longer than the expected length of hospital stay for the patients' diagnostic related groups involved [11]. The Hospital retains the entire clinical, fiscal, and legal responsibilities. Virtual beds are used to support the required administrative and clinical processes. The report concluded that HH/ED for acute medical and surgical patients in a real-world setting was safe, generated healthcare efficiencies, and was well accepted by 98% of patients and professionals [8]. Moreover, the study stressed the potential of HH/ED to strengthen care coordination between highly specialized hospital-based care and home-based services involving different levels of complexity [8].

Currently, the HH/ED program at HCB is a mainstream, mature service that is offered 24 hours a day, 7 days a week, all year round, with 48 virtual beds available per day. It is the first choice for eligible patients requiring hospital admission when attended in the Emergency Department, and it serves the entire Health district of Barcelona Eixample-Esquerra, which has 540,000 inhabitants.

It is well accepted that the key health outcomes that define the success of hospitalization at home [8] are mortality and unplanned emergency room consultations that lead to in-hospital admissions, either during the home hospitalization episode or during the 30-day period after discharge. This study relies on the assumption that multisource predictive modeling facilitating clinical decision support at 2 key time points—(1) at entry, and (2) at HH/ED discharge—could be useful to enhance service outcomes. Risk assessment at entry may contribute to reducing undesirable events during the episode of HH/ED, whereas the assessment of unexpected events after discharge will likely contribute to improving transitional care [12,13] and better definition of personalized care pathways within a care continuum scenario [14].

### The Use of Multisource Predictive Modeling for Enhanced Risk Assessment

This study was designed to elaborate and assess the potential of a machine learning approach to the prediction of mortality and hospital admission at entry and at discharge from HH/ED.

A key specificity of the study is the use of various data sources to estimate the 2 outcomes, mortality and hospital re-admission, as conventional inpatient care. In addition to classical clinical and biological information obtained from electronic medical records (EMR), we have also considered the inclusion of Catalan population–health risk assessment scoring, known as Adjusted Morbidity Groups (GMA) [15,16], and purposely collected data on patients' performance and frailty.

The GMA is an open, publicly owned algorithm that does not rely on expert-based fixed coefficients. Such characteristics provide a high degree of flexibility for multisource predictive modeling and good potential for transferability to other sites, as demonstrated through its validation and current use in 13 of the 17 health regions in Spain, encompassing approximately 38,000,000 citizens [15]. It is fully operational since 2015 for health policy purposes and for clinicians in primary care workstations, providing yearly updated risk stratification with a population health orientation. It takes into account multimorbidity and complexity, that is, impact on health care, using data across health care tiers stored in the Catalan Health Surveillance System.

The approach adopted in this study was based on the hypothesis that the application of holistic strategies for subject-specific risk prediction and stratification, which consider multisource covariates influencing patient health, could increase predictive accuracy and facilitate clinical decision-making based on sound estimates of individual prognosis [17]. Developed predictive models were evaluated on a real-world database, which included all cases admitted to HH/ED at HCB from January 2009 to December 2015.

## Methods

### Dataset

Retrospective data from 1936 patients admitted to the HH/ED program at HCB from January 2009 to December 2015 (Table 1S in [Multimedia Appendix 1](#)) were considered in the analyses carried out to elaborate the predictive modeling of mortality and hospital re-admission at 2 time points: (1) at entry into HH/ED, and (2) at discharge from the HH/ED program. HH/ED at HCB is run as a transversal program, under the responsibility of the medical and nurse directors of the Hospital, serving the different clinical specialties. Patients included in the HH/ED show a broad spectrum of primary diagnoses, as displayed in Table 1S in [Multimedia Appendix 1](#).

The potential covariates considered for predictive modeling purposes (Table 2S in [Multimedia Appendix 1](#)) encompassed 3 dimensions: (1) standard clinical and biological information obtained from EMRs; (2) patients' functional performance and frailty data, specifically collected to characterize these patients; and (3) GMA scoring indicating multimorbidity, complexity, and patients' allocation into the population–health risk stratification pyramid.

### Ethical Approval

The Ethical Committee for Human Research at HCB approved the study, and all participants signed an informed consent prior

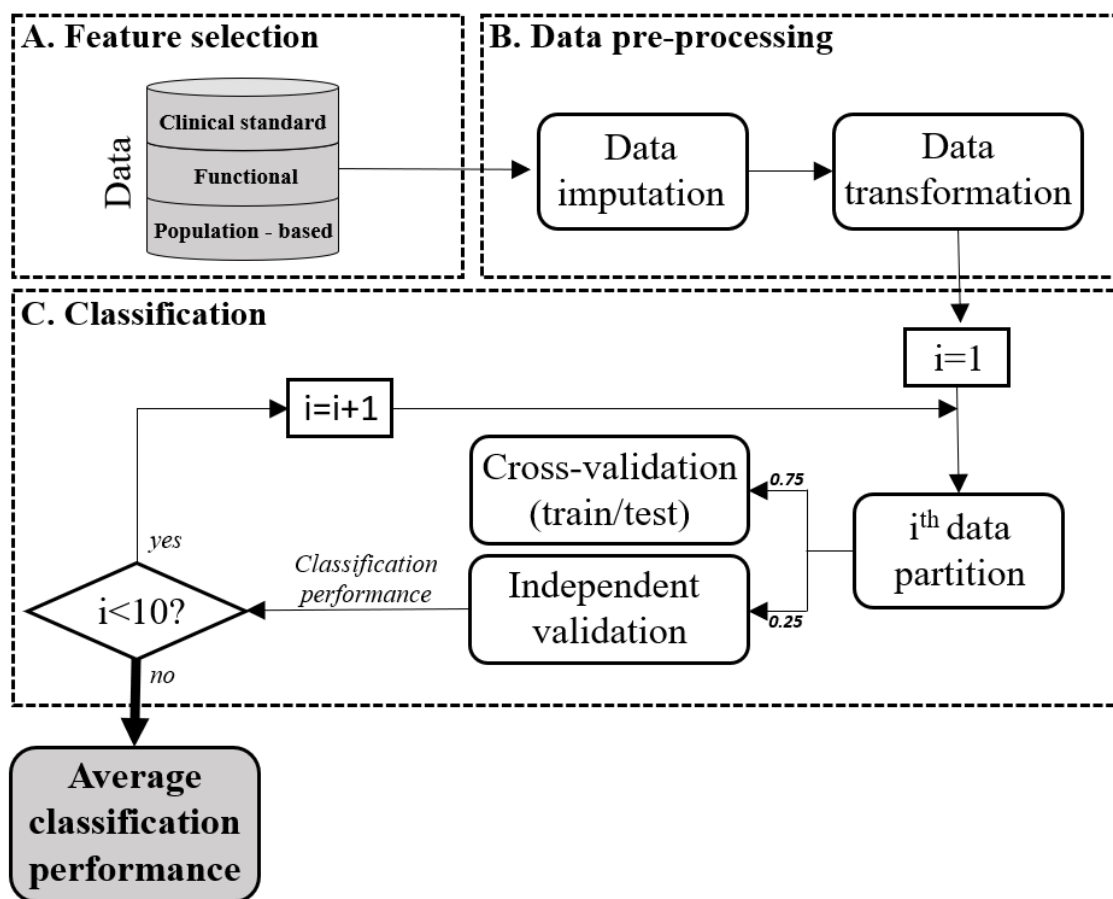

to any procedure. The program was registered at ClinicalTrials.gov: NCT03130283.

### Predictive Analytics Workflow

Figure 1 illustrates the global methodology proposed to identify patients at risk of re-admission or death after HH discharge; the

elaboration of predictive modeling followed 3 successive steps: (1) feature selection, (2) data preprocessing, and (3) classification.

**Figure 1.** Predictive analytics workflow, composed of 3 main steps: (A) feature selection, (B) data preprocessing, and (C) classification.

### Feature Selection

Feature selection refers to different processes involving data cleaning, selection of variables to be considered for predictive modelling, as well as selection of the final set of patients included in the analyses.

### Data Preprocessing

In order to handle the impact of missing values, a robust method was designed for mixed-type data imputation. To this end, the missForest algorithm was applied to the whole dataset [18]. Moreover, we applied a rediscretization of some categorical variables to avoid under-represented categories.

### Classification

Different strategies were considered for the elaboration of predictive models in this study. Specifically, 3 of them were explored in detail (Multimedia Appendix 1); that is, logistic regression and 2 machine learning approaches: a decision tree and random forest classifiers.

For model training, the dataset was 10-times divided in (1) a training subset, taking 75% of randomly selected cases, and (2) a validation subset with the remaining 25% of cases. For each

data partition, the model was trained using 4-fold cross-validation on the training subset. As successful cases (ie, survivors not requiring hospital admission) were far superior in number, the effect of class imbalance was reduced by applying a random stratified-sampling strategy [19].

Model performance was assessed by computing the area under the receiver operating characteristic curve (AUROC), sensitivity, specificity, and score metrics in the validation subset. Score is a measure of prediction accuracy and is defined as the weighted harmonic mean of the sensitivity and specificity of the model. The final performance of the models was assessed as the average performance of all independent validations.

As indicated above, the methodology was applied to predict 2 types of events: (1) mortality, and (2) in-hospital admission until 30-days after HH/ED discharge. Risk assessment was conducted in 2 different scenarios: (1) at entry into the HH/ED program, and (2) at discharge. Accordingly, the analyses led to 4 different risk models (RM): (1) RM1 accounts for predicting the need for conventional hospitalization at entry into the HH/ED program; (2) RM2 predicts mortality during the study period assessed at entry; (3) RM3 refers to predictive modeling of conventional hospital admissions assessed at HH/ED

discharge; and (4) RM4 predicts mortality during the study period assessed at HH/ED discharge. The risk of mortality and re-admission during HH at entry was not assessed due to the scarcity of unsuccessful cases during HH/ED.

## Results

### Study Population

All 1936 patients admitted to the HH/ED program at HCB during the study period were included in the research. However, the analyses conducted in the study were based on 1925 cases; 4 cases were discarded for having unrecoverable wrong data and 7 for having missing mandatory data. The mean age of the study group was 70.85 (SD 14.88) years; 1201 (62.4%) were men and 724 (37.6%) were women. The list of main diagnoses is depicted in Table 1S in [Multimedia Appendix 1](#). Up to 64 variables, grouped into the 3 categories indicated above, were considered in the analyses (Table 2S in [Multimedia Appendix 1](#)).

To characterize different subpopulations of risk, patients were classified as undergoing successful and unsuccessful home

hospitalization stays based on their re-admission and mortality during the study period and 30 days after hospital discharge ([Tables 1-2](#)). Of the 1925 patients admitted to the HH/ED program, 3 (0.2%) patients died and 96 (5.0%) cases were eventually readmitted to the hospital due to complications of heterogeneous origin during HH/ED. Of the remaining 1922 patients, within 30 days after HH/ED discharge, 37 (1.9%) patients died and 210 (10.9%) cases were identified as falling into the unsuccessful groups when analyzing re-admission risk. [Tables 1](#) and [2](#) summarize the baseline characteristics of both study groups, according to mortality and re-admission, respectively.

Mortality was higher in elderly ( $P<.001$ ) and comorbid patients, GMA ( $P=.02$ ), and the Charlson Comorbidity Index ( $P=.001$ ), especially in those with cardiovascular ( $P<.001$ ) and oncologic disorders ( $P=.019$ ). Mortality was lower in postoperative patients ( $P<.001$ ) and in those with respiratory diseases ( $P=.005$ ). Interestingly, in-hospital re-admission was only slightly associated with higher age ( $P=.003$ ) and a major complexity of comorbid conditions, GMA ( $P<.001$ ), and the Charlson Comorbidity Index ( $P<.001$ ), without well-defined associations with the characteristics of the main diagnosis.

**Table 1.** Clinical characteristics of successful and unsuccessful home hospitalization (HH) cases (n=1925) based on mortality.

Patient characteristics	Successful cases (n=1885)	Unsuccessful cases during HH (n=3)	Unsuccessful cases 30 days after HH discharge (n=37)	P value <sup>a</sup>
Age, mean (SD)	70.7 (14.9)	89.3 (15.1)	77.9 (10.6)	<.001
<b>Sex, n (%)</b>				
Male	1181 (62.7)	1 (33.3)	19 (51.3)	.145

<sup>a</sup>P values were calculated comparing successful and unsuccessful groups during the full period.

### Predictive Modeling

Different modeling approaches were considered for this purpose, including logistic regression, decision trees, and random forests. The averaged AUROC of each modeling approach that was considered is presented in [Table 3](#).

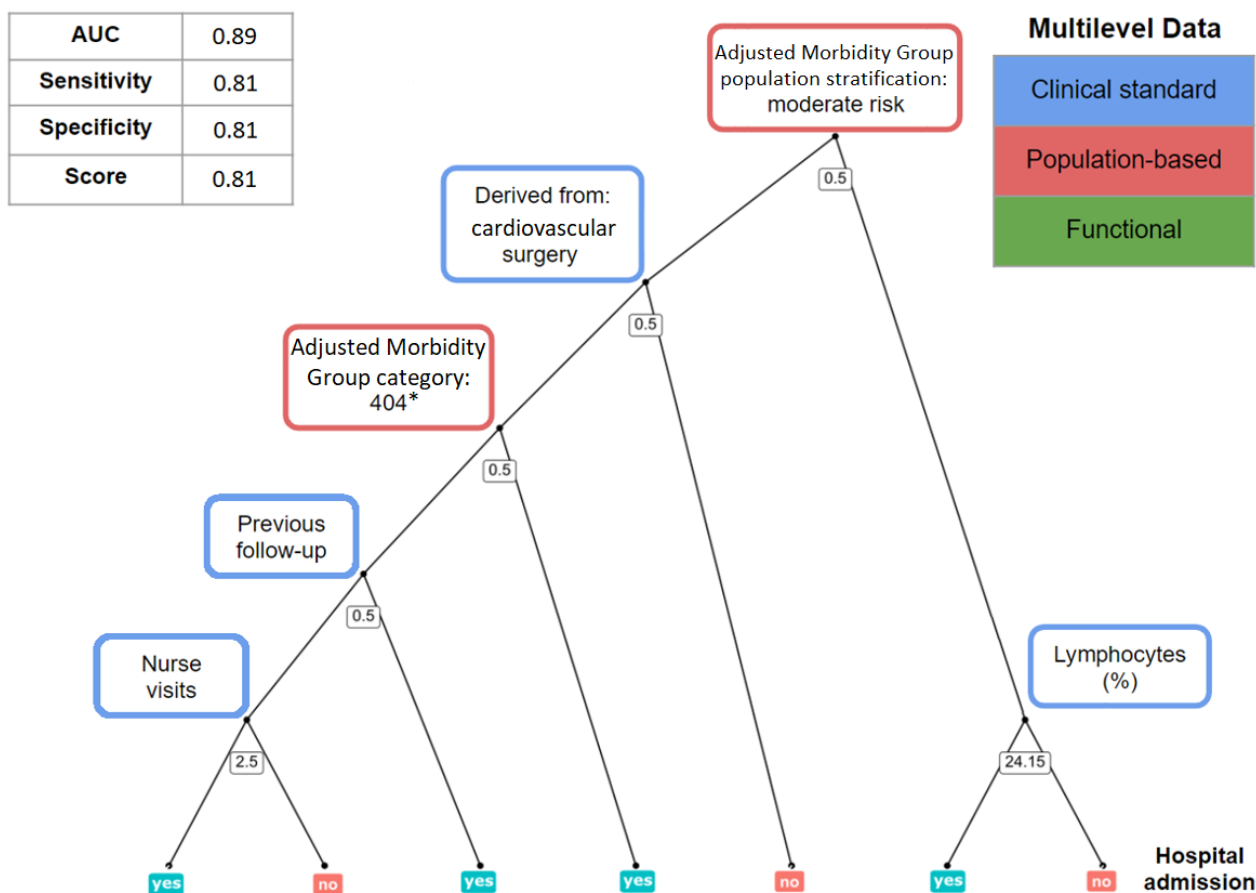

Among the different modeling strategies developed, random forest classifier ([Figure 2](#)) showed the best performance averaged over the 4 risk scenarios.

[Table 4](#) summarizes the performance of the 4 predictive models proposed in the study for in-hospital admission (RM1 and RM3) and for mortality (RM2 and RM4); [Multimedia Appendix 2](#) depicts the relative weight, expressed as the mean decrease in accuracy (MDA) [20], of the 10 most relevant variables for each of the 4 predictive models.

**Table 3.** Area under the receiver operating characteristic curve (AUROC; sensitivity/specificity) performance of the modeling strategies explored.

Model	Mean AUROC (sensitivity/ specificity)	RM1 AUROC (sensitivity/ specificity)	RM2 AUROC (sensitivity/ specificity)	RM3 AUROC (sensitivity/ specificity)	RM4 AUROC (sensitivity/ specificity)
Logistic regression	0.58 (0.54/0.57)	0.65 (0.68/0.58)	0.54 (0.50/0.59)	0.59 (0.61/0.52)	0.54 (0.38/0.58)
Decision tree	0.59 (0.81/0.47)	0.62 (0.82/0.43)	0.64 (0.88/0.51)	0.57 (0.64/0.42)	0.64 (0.88/0.52)
Random forest	0.80 (0.75/0.71)	0.71 (0.67/0.64)	0.88 (0.81/0.76)	0.70 (0.71/0.61)	0.89 (0.81/0.81)

**Figure 2.** Overview of the predictive modeling strategy taking, as an example, prediction of re-admission at home hospitalization discharge. Upper-left table: metrics used for model performance assessment; AUC: area under the receiver operating characteristic curve. Center figure: representation of 1 decision tree using a random subset of features; on the nodes, threshold values for each variable determine the path from the root to the leaves (0.5 for Boolean variables), moving toward the left when the decision rule is met; on a random forest model, final predictions are averaged over multiple decision trees. Upper-right table: 3 categories of data that are included in the models. \*GMA category 404; 40: patient with active neoplasms; 4: high complexity conditions (percentile between 0.85 and 0.95).

**Table 4.** Average results of the performance of the 4 home-hospitalization/early discharge (HH/ED) predictive risk models (RM).

Model	AUROC <sup>a</sup> , mean (SD)	Sensitivity, mean (SD)	Specificity, mean (SD)	Score, mean (SD)
Readmission risk at HH/ED admission (RM1)	0.71 (0.03)	0.67 (0.06)	0.64 (0.05)	0.66 (0.03)
Readmission risk at HH/ED discharge (RM3)	0.70 (0.02)	0.71 (0.06)	0.61 (0.05)	0.66 (0.03)
Mortality risk at HH/ED admission (RM2)	0.88 (0.04)	0.81 (0.09)	0.76 (0.04)	0.78 (0.06)
Mortality risk at HH/ED discharge (RM4)	0.89 (0.04)	0.81 (0.12)	0.81 (0.05)	0.81 (0.06)

<sup>a</sup>AUROC: area under the receiver operating characteristic curve.

For risk of in-hospital admissions (Multimedia Appendix 2, panels A and C), multimorbidity (expressed as GMA scoring) showed the highest predictive impact, followed by red cell distribution width (RDW). Other top predictors were polypharmacy, body mass index (BMI), a few biological variables (blood cells characteristics and glucose), and physical and mental status.

For risk of mortality (Multimedia Appendix 2, panels B and D), RDW and physical status at entry (assessed using the SF-36 questionnaire [21]) showed the highest impact in the models.

Notably, enriching the model with information acquired during HH/ED (Multimedia Appendix 2, panels C and D), several

variables gained importance, such as hospital admissions during HH/ED, length of current hospitalization period, and nursing home visits.

## Discussion

### Principal Findings

The current research has developed and internally validated 4 machine learning algorithms predicting the risk of in-hospital admission and mortality for patients undergoing home-based hospitalization until 30-days after discharge from the service at HCB, from 2009 to 2015. Predictions of the 2 undesirable

events were performed at 2 specific time points: at entry and at discharge from home-based hospitalization.

The study design was formulated and adopted under the hypothesis that robust predictions could be useful for clinical decision making: (1) to decide patients' admission into the HH/ED service (RM1 and RM2); and (2) to personalize care paths for transitional care, as well as for enhanced vertical integration between specialized care and community-based services, both at patients' discharge from HH.

A unique aspect of this research is that predictors considered in the analyses encompass 3 different categories of variables (Table 2S in [Multimedia Appendix 1](#)): (1) clinical data and biological information [22-24] extracted from patients' electronic medical records; (2) additional variables often not considered in the clinical records specifically collected in the research protocol to reflect patients' functional capacities and health care resources; and (3) information from GMA, the population-based, health-risk assessment tool developed and implemented in Catalonia (ES) [15,16,25].

We understand that the multisource approach adopted in this research was the most appropriate to elaborate predictive modeling in a highly heterogeneous group of patients undergoing HH/ED, in terms of clinical diagnosis and frailty status [8]. The results depicted in [Table 4](#), in terms of AUROC and score values, indicate the reasonably good performance of the predictive models as compared to recent studies on similar scenarios [26], demonstrating the feasibility of the proposed approach and leveraging the advantages of applying machine learning in clinical risk prediction contexts in front of more traditional approaches based on standard multiple regression analyses [27]. Moreover, [Multimedia Appendix 2](#) (panels A-D) shows a high relative contribution of variables usually not considered to be of clinical standard or relevant biological information recorded in the EMR. Overall, our results indicate that our multisource approach significantly contributes to enhanced health risk assessment with a potentially high impact on clinical decision support.

### Limitations of the Study and Lessons Learned for Clinical Application

We have not been able to identify literature on predictive modeling specifically addressing HH/ED. It may partly be due to the heterogeneity of orientations and characteristics of the ongoing HH/ED programs among sites. This fact constitutes a limitation regarding the potential for generalization of the results of this research to other sites. However, we understand that the multisource approach undertaken in this study shows enormous potential for risk assessment regarding mortality and early re-admissions of hospitalizations in general, and may show high applicability beyond the field of HH/ED. The predictive modeling undertaken in the study should be useful for defining the characteristics of personalized care paths of transitional care after hospital discharge. As indicated above, the results can have a high impact on shaping the interactions between specialized and community-based care in patients with high risk for hospital re-admissions.

A major general limitation of machine learning approaches such as the one proposed here is the fact that they can be considered "black-box" solutions, difficult to interpret by clinicians. Our work, however, is based on random forest models that provide interpretable information regarding variable importance ([Multimedia Appendix 2](#), panels A-D) and even model visualization, thus facilitating the understanding of their predictions. We believe that the clinical interpretation of the predictors may require different approaches; for example, variables like age and diagnosis should be individually assessed for clinical judgment, while others, like the different GMA parametrization (including the Charlson Index), should be assessed by taking the category as a whole (and likewise, abnormalities in some blood test variables). On the other hand, this study indicates that the impact of patients' functional status on outcomes is high. However, some of the measurements included in this category are not scalable in the clinical scenario (ie, SF36). Therefore, our results clearly indicate that surrogates with higher applicability [28,29] should likely be considered for inclusion in real-life clinical settings. This could be achieved through patients' self-tracking equipment (ie, apps) that provides information on different dimensions characterizing the functional performance of the patient, namely physical and psychological status, wellbeing, activation, etc.

It is acknowledged that the generalization of the use of new clinical scores generated from predictive modeling needs external validation on other patient cohorts or in different timeframes, and even on the development of impact studies in real-world settings [30]. Apart from being costly, such a validation process can show limitations partly due to rapidly evolving clinical environments, as is the case for HH/ED at HCB, expanded to the entire health district of Eixample-Esquerra during 2018. The new scenario implies great changes in the clinical environment, patients' characteristics, and data sources prompting the need for designing dynamic models in the context of learning health systems (LHS) [31,32]. It is of note that within a mature digital health scenario, the multisource predictive modeling approach could be enriched with other sources of data, such as patient self-reported data and data from social care. The lack of digital maturity of the current ecosystems constitutes a limiting factor for now, but in the near future, risk assessment tools are expected to improve in terms of robustness, potential for generalization of the results, and incorporation of a dynamic predictive approach.

### Steps Toward Dynamic Learning Health Systems

There is little doubt about the high potential shown by the digital transformation of health as part of a large-scale adoption of integrated care. It is acknowledged, however, that practical applications of this vision face major limitations when it comes to accessing and mining health data stored in distributed silos of information. However, it seems clear that integrating and analyzing highly complex data would open new avenues for digital health in the clinical arena.

The integration of biomedical research information systems with in-place electronic health records in hospitals and in primary care centers having interoperability with patients' self-tracking information would enable the development of

innovative, dynamic predictive modeling approaches, opening up entirely new and fascinating scenarios for an interplay between clinical practice and biomedical research [33,34]. We have identified 4 main interrelated enablers of this scenario [15,17,35]: (1) cloud-based tools and services allowing secure analysis of patient-centric distributed and multi-disciplinary health-related information; (2) systems medicine approaches to generate clinical predictive modeling to feed clinical decision support systems and patient decision support systems; (3) implementation and evaluation strategies for real-world implementation and assessment of cloud-based services, and (4) governance, regulatory aspects, and service adoption throughout the health care systems; these are all key to harnessing the strengths and opportunities of LHS.

Combined actions involving organizational changes with the engagement of all stakeholders, selective adoption of novel biomedical and digital tools, and the achievement of financial sustainability through enhanced accountability and entrepreneurial actions should pave the way toward the transition to LHS.

## Conclusions

This study proves the potential of the proposed multisource machine-learning models for the prediction of risk of re-admissions and deaths in patients undergoing home-based hospitalization in a real-world setting. Further steps beyond this study include the development of dynamic clinical decision support systems allowing progression towards sustainable patient-centered health care services.

## Abstract

**Background:** In England, national safety guidance recommends that ciclosporin, tacrolimus, and diltiazem are prescribed by brand name due to their narrow therapeutic windows and, in the case of tacrolimus, to reduce the chance of organ transplantation rejection. Various small studies have shown that changes to electronic health record (EHR) system interfaces can affect prescribing choices.

**Objective:** Our objectives were to assess variation by EHR systems in breach of safety guidance around prescribing of ciclosporin, tacrolimus, and diltiazem, and to conduct user-interface research into the causes of such breaches.

**Methods:** We carried out a retrospective cohort study using prescribing data in English primary care. Participants were English general practices and their respective EHR systems. The main outcome measures were (1) the variation in ratio of safety breaches to adherent prescribing in all practices and (2) the description of observations of EHR system usage.

**Results:** A total of 2,575,411 prescriptions were issued in 2018 for ciclosporin, tacrolimus, and diltiazem (over 60 mg); of these, 316,119 prescriptions breached NHS guidance (12.27%). Breaches were most common among users of the EMIS EHR system (breaches in 18.81% of ciclosporin and tacrolimus prescriptions and in 17.99% of diltiazem prescriptions), but breaches were observed in all EHR systems.

**Conclusions:** Design choices in EHR systems strongly influence safe prescribing of ciclosporin, tacrolimus, and diltiazem, and breaches are prevalent in general practices in England. We recommend that all EHR vendors review their systems to increase safe prescribing of these medicines in line with national guidance. Almost all clinical practice is now mediated through an EHR system; further quantitative research into the effect of EHR system design on clinical practice is long overdue.

## Introduction

Over 1.1 billion prescriptions are issued through primary care in England each year, at a cost of £8.8 billion in 2018 [1]. The overwhelming majority of these prescriptions are generated

through an electronic health record (EHR) system [2], where the clinician selects a medicine from a “picking list,” specifies directions (eg, “once daily”), and then signs the prescription either electronically or on a printed copy. All National Health Service (NHS) practices use one of four EHRs made available through NHS Digital [3]. We have previously described a small

design choice in an EHR medicines selection screen that costs the NHS approximately £9.5 million in one year across a wide range of drugs [4,5].

Tacrolimus and ciclosporin are used in organ transplantation and other conditions, such as rheumatoid arthritis, psoriasis, and severe atopic dermatitis. Both medicines have a narrow therapeutic window: minor differences in blood levels have the potential to cause graft rejection reactions, and switching between tacrolimus products has been associated with reports of toxicity and graft rejection. Therefore, the Medicines and Healthcare products Regulatory Agency (MHRA) recommends that tacrolimus and ciclosporin are prescribed and dispensed by brand name [6,7]. Similarly, diltiazem—a calcium channel blocker commonly used for conditions such as angina and mild-to-moderate hypertension—should be prescribed and dispensed by brand for preparations containing greater than 60 mg, as different brands of modified-release formulations with over 60 mg diltiazem may not have the same clinical effect [8].

Our team delivers OpenPrescribing.net, a publicly funded and openly accessible data explorer for NHS primary care prescribing, with 135,000 unique users in the past year. OpenPrescribing.net supports bespoke data queries alongside numerous predefined standard measures for safety, cost, and effectiveness, with data shared for every practice in England. Two of these standard measures assess compliance with the guidance to prescribe a branded preparation of ciclosporin, tacrolimus, and diltiazem (over 60 mg). Through our prior knowledge around EHR design, as clinicians and researchers engaged with software development, we suspected there may be a relationship between choice of EHR system and breaches of this safety guidance.

We therefore set out to describe and map variation between practices and their parent clinical commissioning groups (CCGs) in breaches of safe prescribing guidance for ciclosporin, tacrolimus, and diltiazem (over 60 mg), and assess the impact of EHR choice on the proportion of safety breaches. Having identified one EHR system as being strongly associated with safety breaches, we conducted user testing to explore the causes of this association. We aimed to produce a rapid report to

support further investigations and any required software modifications to the EHRs, in light of the patient safety risk.

Methods

Study Design

This study is a retrospective cohort study in prescribing data from all English NHS general practices and CCGs, complemented with data on EHR deployment from NHS Digital, as well as in user testing of two commonly used EHRs by a senior pharmacist.

Data Sources

We extracted data from the OpenPrescribing.net database. This imports openly accessible prescribing data from the large monthly files published by the NHS Business Services Authority, which contain data on cost and items prescribed for each month, for every typical general practice and CCG in England since mid-2010 until May 2019 [9]. The monthly prescribing datasets contain one row for each different medication and dose, in each prescribing organization in NHS primary care in England, describing the number of items (ie, prescriptions issued) and the total cost. These data are sourced from community pharmacy claims data and, therefore, contain all items that were dispensed. We extracted all available data for typical general practices, excluding other organizations such as prisons and hospitals, according to the NHS Digital dataset of practice characteristics and excluded practices that had not prescribed at least one item per measure. We excluded all other organizations such as prisons and hospitals. Data on which EHR was deployed in each practice were extracted from a monthly file that is circulated by NHS Digital to interested parties and is available on request [9].

Prevalence of Safety Breaches by General Practices in Implementation of Brand Prescribing of Ciclosporin, Tacrolimus, and Diltiazem

We measured the number of safety breaches and created practice-level deciles at each month for the measure [10] (see Table 1) of proportion of brand prescribing of ciclosporin, tacrolimus, and diltiazem (over 60 mg).

Table 1. OpenPrescribing measures of generic ciclosporin, tacrolimus, and diltiazem prescribing.

Measure	Definition (full technical definitions are available on GitHub [10])
Ciclosporin and tacrolimus	Total items of generic ciclosporin and tacrolimus preparations, as a proportion of total items of all ciclosporin and tacrolimus items. These medicines are grouped due to them having similar uses and covered by similar safety alerts by the Medicines and Healthcare products Regulatory Agency (MHRA).
Diltiazem	Total items of generic diltiazem modified-release preparations, as a proportion of total items of all diltiazem modified-release items (over 60 mg).

Variation in Safety Breaches by Electronic Health Record

We measured the proportion of safety breaches for prescribing of ciclosporin, tacrolimus, and diltiazem for each of the four principal EHRs.

Influence of Principal Electronic Health Record on Breaches of Safety Guidance

We conducted mixed-effects logistic regression to determine the effect size of the EHR used and the extent to which CCG membership and other factors affected these estimates. The independent variable was each prescription as a binary choice between generic and branded, while the main fixed-effect variable was EHR vendor, with CCG membership as a random

effect. Other practice factors were selected *a priori* based on their reasonable availability, as well as clinical judgement. These were as follows: percentage of patients over 65 years of age, percentage of patients under 18 years of age, percentage of patients with a long-term health condition, dispensing practice status, single-handed practice status, ruralness or urbanness of practice location, and index of multiple deprivation. Where data for predictor variables were missing, these practices were excluded from the regression.

### Electronic Health Record System User-Interface Evaluation

One senior pharmacist issued prescriptions in the EMIS and SystmOne computer systems to a test patient and observed the prompts. These two systems hold 95% of the EHR-use market share in general practices in England.

### Software and Reproducibility

Data management was performed using Python, version 3.7 (Python Software Foundation), and Google BigQuery, with analysis carried out using Stata 13.1 (StataCorp) and Python. Data, as well as all code for data management and analysis, is archived online in a public, open access repository on GitHub [11].

### Patient and Public Involvement

Our website, OpenPrescribing.net, is an openly accessible data explorer for all NHS England primary care prescribing data, which receives a large volume of user feedback from professionals, patients, and the public. This feedback is used to refine and prioritize our informatics tools and research activities. Patients were not formally involved in developing this specific study design.

### Ethical Approval

This study uses open, publicly available data and data that are publicly available from NHS Digital on request; therefore, no ethical approval was required.

## Results

### Prevalence of Safety Breaches

In 2018, 316,119 of the 2,575,411 (12.27%) prescriptions for ciclosporin, tacrolimus, and diltiazem (over 60 mg) breached prescribing safety guidance. Of practices that prescribed ciclosporin or tacrolimus at least once, 2241 out of 5439 (41.20%) breached safety guidance, while 5777 practices out of 7186 (80.39%) breached safety guidance with regard to diltiazem. The ratio of safety breaches as a proportion of all prescribing for these items for practices was 12.28% (292,331/2,380,128) (10th-90th percentile range = 0%-47%) for diltiazem and 12.18% (23,788/195,283) (10th-90th percentile range = 0%-67%) for ciclosporin and tacrolimus.

### Variation in Safety Breaches by Electronic Health Record

The mean values for the ciclosporin and tacrolimus safety breaches and for the diltiazem safety breaches as a proportion of all prescribing for the respective items from January 2016 to May 2019 are shown in Figures 1 and 2, respectively. The rate of breaches was consistently highest in EMIS practices, and in 2018, 18.81% (16,521/87,828) of all ciclosporin and tacrolimus prescriptions issued from the EMIS EHR system breached safety prescribing safety guidance, while 17.99% (209,371/1,163,578) of all diltiazem (over 60 mg) prescriptions breached safety guidance.

**Figure 1.** Mean values for the ciclosporin and tacrolimus safety breaches as a proportion of all prescribing by electronic health record (EHR).

**Figure 2.** Mean values for the diltiazem safety breaches as a proportion of all prescribing by electronic health record (EHR).

The results of the logistic regression are shown in [Table 2](#). When generating a diltiazem (over 60 mg) prescription, practices using the EMIS EHR system were around 4 times more likely to prescribe in breach of guidance with regard to diltiazem than practices using SystmOne, with a similar size of effect for ciclosporin and tacrolimus breaches. Practices using Microtest and Vision EHR systems were substantially less likely to breach safety guidance, although these practices make up a relatively

small proportion of practices. Adjusting for CCG membership as a random effect had little effect on these estimates, although CCG membership was still responsible for a high proportion of the variation in propensity to prescribe generically: 16.4% for diltiazem and 8.4% for ciclosporin. Other factors had even less of an effect on the estimates, though some factors were weakly associated with the propensity to prescribe in breach of guidance (see [Multimedia Appendix 1](#)).

**Table 2.** Ciclosporin, tacrolimus, and diltiazem prescribing measures stratified by electronic health record (EHR) system along with odds ratios (ORs) from a univariable and multivariable logistic regression model.

Medicine and EHR systems	Breaches of safety guidance (%), mean	Univariable logistic regression, OR (95% CI)	Mixed-effects logistic regression <sup>a</sup> , OR (95% CI)
<b>Diltiazem</b>			
EMIS	22.7	Reference	Reference
Microtest	1.0	0.045 (0.039-0.052)	0.051 (0.044-0.060)
SystmOne	7.0	0.252 (0.249-0.254)	0.239 (0.235-0.243)
Vision	12.0	0.462 (0.451-0.473)	0.300 (0.290-0.309)
<b>Ciclosporin and tacrolimus</b>			
EMIS	23.2	Reference	Reference
Microtest	6.1	0.103 (0.072-0.148)	0.161 (0.107-0.242)
SystmOne	7.8	0.238 (0.230-0.247)	0.271 (0.256-0.287)
Vision	10.8	0.378 (0.346-0.412)	0.219 (0.195-0.247)

<sup>a</sup>Adjusted for clinical commissioning group (CCG) membership as a random effect, percentage of patients over 65 years of age, percentage of patients under 18 years of age, percentage of patients with a long-term health condition, dispensing practice status, single-handed practice status, ruralness or urbanness of location, and index of multiple deprivation.

## Electronic Health Record System User-Interface Evaluation

### EMIS

On reviewing the medicines-selection screen, it was observed that when searching for a medicine by its brand name, EMIS always presents the generic version of the medicine as priority in the medicines-picking list; this represents a breach of safety guidance for ciclosporin, tacrolimus, and diltiazem (over 60 mg). Warnings are presented to prescribers to prescribe by brand when a generic version of these medicines is selected; however, these warnings appear alongside multiple other warnings such as interactions with other medications. These warnings take the form of a *pop-up* box, which can be easily overridden allowing the generic version of all three medicines to be issued.

### SystmOne

When the search terms “ciclosporin,” “tacrolimus,” or “diltiazem” were entered, no results were returned, encouraging a user to search by brand names in line with safety guidance. However, in another part of the user-interface screen there is a separate tick-box, “non-prescribable.” When ticked by a user, input of the search terms “ciclosporin,” “tacrolimus,” or “diltiazem” does return results, allowing selection of the generic medicine in breach of safety guidance. A single, stand-alone *pop-up* is presented if the user proceeds, warning of the importance of brand prescribing. This is in contrast to EMIS, where it is presented alongside other clinical warnings.

## Discussion

### Principal Findings

A total of 2,575,411 prescriptions were issued in 2018 for ciclosporin, tacrolimus, and diltiazem (over 60 mg); of these, 316,119 prescriptions breached NHS safety guidance (12.27%). Breaches were most common among users of the EMIS EHR system ( $n=3888$ ; December 2018), but breaches were observed in all EHR systems.

### Strengths and Weaknesses

We included all typical practices in England, thus minimizing the potential for obtaining a biased sample. We used prescribing data derived from pharmacy claims data used to calculate the transfer of funds from CCGs to dispensing pharmacies: all parties are motivated to ensure the accuracy of this data. We excluded a small number of settings such as walk-in centers, which typically do not issue repeat prescriptions for medicines, and where no data on EHR usage is available. The data does not distinguish which prescriptions may have been written by hand without EHR generation; however, as 74% of prescriptions are transmitted electronically [2] and many more are generated electronically and then printed on paper, we do not expect this to substantially affect our results. Our data do not include hospital medicines data, but we do not expect the same issue associated with EHR system design to occur in hospitals, as medicines are procured differently and the use of electronic prescribing and EHRs in secondary care in England is limited [12]. Observation of EHR systems was limited to one 30-minute session on each EHR system with limited scenarios in a single

location. EHRs can be manually adapted and defaults set locally; compliance with safety guidance may, therefore, differ between individual practices even with the same EHR systems. Additionally, practices may have secondary decision support software systems providing information and prompts, which may affect breaches.

One caveat regarding clinical impact is that the available data reflect prescribing and not dispensing: in England, when medicines are prescribed generically, pharmacies are entitled to dispense a brand, and some pharmacists may try to ensure they dispense the same brand that the patient previously received; however, pharmacists are likely to be blocked in this by lack of access to the patient record and, commonly, by the absence of information on specific brands in the patient's record [13]. Additionally in England, CCGs employ teams of pharmacy professionals who in some areas may have made concerted manual effort to amend repeat prescriptions following audit. In any case, occasional remedial interventions do not affect the key observation that EHR systems strongly predict safety breaches among prescribing clinicians.

### Findings in Context

We are aware of no prior work on the prevalence of safety breaches around use of ciclosporin, tacrolimus, and diltiazem; however, incomplete implementation of this important national prescribing safety recommendation is consistent with extensive prior work showing incomplete or slow adoption for other national prescribing guidance [14–16]. To our knowledge, we are the first group to use natural variation in prescribing behavior between EHR systems to identify, explain, and address suboptimal prescribing using national data. One small study involving 90 general practices in the Netherlands did find an association between prescribing safety and EHR systems with regard to prescribing of gastroprotective agents to prevent side effects of anti-inflammatory medicines [17]. A 2017 systematic review [18] identified 34 relevant studies exploring the role of computerized systems in suboptimal prescribing. However, none used quantitative methods to compare different systems, instead relying on questionnaires to interrogate clinicians about their experiences of EHRs, qualitative research observing or interviewing clinicians, and descriptions of clinicians' spontaneous reports on errors and safety issues in EHR systems.

Various small studies have aimed to evaluate the impact of a single specific new change to a computerized prescribing system, as a behavioral intervention to increase the probability of a desired choice being made by clinicians using the system [19–23]. Despite evidence for effectiveness from *pop-ups*, *alert fatigue* has also been described, whereby large numbers of pop-ups can result in salient messages being ignored or disabled by prescribers [24]. One small mixed methods study involving the EMIS EHR system found that only three pop-ups from 117 alerts resulted in the general practitioner checking, but not altering, the prescription [25].

### Policy Implications and Interpretation

Breaches of safety guidance around diltiazem, ciclosporin, and tacrolimus can expose patients to avoidable clinical risk. This is especially important in the case of organ transplantation,

where failure to adhere to the safety guidance assessed in our analysis has resulted in organ rejection [7]. The current World Health Organization challenge on medication safety encourages countries to reduce medication errors by 50% by 2022; our finding represents a clear example of an error amenable to change [26]. We strongly recommend that picking-lists be configured in line with best practice guidelines, and that compliance with this be audited by national organizations such as NHS Digital and NHSX. The US National Coordinator for Health Information Technology has made similar recommendations [18,27,28]. For the specific safety issue raised by our analysis, the mandated medicines data standard for the NHS, the Dictionary of Medicines and Devices (dm+d), already includes a field that can be used to mandate branded prescribing where this is required by safety guidance; indeed, it is likely that this field triggers the pop-up warnings described above.

### Future Research

We are concerned by the relative absence of applied practical research around the EHR systems used by clinicians to store information, retrieve relevant information rapidly when assessing a patient, and implement specific clinical actions, such as ordering a test or prescribing a treatment. Health care activity is increasingly computerized, and EHR software is likely to exert a very substantial influence on the way that modern medicine is practiced, in the same way that the rapid explosion in social media usage has changed the ways that people interact socially [29]. We can find no previous attempts to evaluate the impact of EHR system design on clinical practice by analyzing variations between organizations using different EHR systems. In our view, questions of how best to represent, retrieve, and present knowledge about patients to clinicians—and the impact this can have on patient care—should

be a key priority for funders and researchers in “digital health.” The NHS and health care systems around the world spend large sums of money on EHR systems [30] and there is substantial room for collaborative improvement to make clinical care safer, cheaper, and more effective. Since sharing our preprint version of this paper, EMIS have implemented a change to their EHR system to address our findings and we will evaluate the effectiveness of this change in 12 months’ time.

There is also a role for open standards in this work. We are aware that in most general practices, complementary decision support systems are deployed alongside the core EHR system, to support medicines-optimization activity and other aspects of quality improvement [31-33]. However, we have been repeatedly blocked from researching the impact of these pop-ups on routine prescribing, as there is no national framework or data detailing which pop-ups are implemented in each setting, and we have been unable to access the data by private negotiation. NHS commissioners and leaders are also blocked from routinely monitoring which pop-ups are implemented across the NHS and from defining or deploying pop-ups nationally. In our view, this represents a failure to set standards and ensure the proportionate and secure data sharing necessary to evaluate and improve patient safety.

### Summary

National guidance on safe prescribing for ciclosporin, tacrolimus, and diltiazem is commonly breached, and the prevalence of safety breaches is strongly influenced by the brand of EHR system. We recommend that EHR vendors immediately review their systems to mandate safe prescribing of these medicines in line with national guidance. We also recommend that more data and funding be made available to support research into the impact of EHR system design on clinical practice.

### Acknowledgments

We are grateful to Peter Inglesby and Dave Evans for their contributions to maintaining databases and the OpenPrescribing website. We are grateful to wider NHS colleagues for discussions that have informed our work on this topic. No specific funding was sought for this work. BG’s work on clinical informatics has been supported by the National Institute for Health Research (NIHR) Biomedical Research Centre, Oxford; NHS England; the Health Foundation (Award Reference Number 7599); the NIHR School of Primary Care Research (SPCR) (Award Reference Number 327); the NIHR Applied Research Collaboration Oxford and Thames Valley; Health Data Research UK; and policy work by the Mohn-Westlake Foundation. Funders had no role in the study design; in the collection, analysis, and interpretation of data; in the writing of the report; or in the decision to submit the article for publication.

### Authors' Contributions

All authors conceived the study and designed the methods. BMK, SB, and AW analyzed the data. BMK, HC, and BG drafted the manuscript. All authors contributed to and approved the final manuscript. BG supervised the project and is guarantor.

### Conflicts of Interest

All authors have completed the International Committee of Medical Journal Editors (ICMJE) uniform disclosure form available at the ICMJE website [34]. BG has received research funding from the Laura and John Arnold Foundation, the Wellcome Trust, the Oxford Biomedical Research Centre, the NIHR Applied Research Collaboration Oxford and Thames Valley, the NHS NIHR SPCR, the Health Foundation, Health Data Research UK, the Mohn-Westlake Foundation, and the World Health Organization; he also receives personal income from speaking and writing for lay audiences on the misuse of science. RC, AW, HC, and SB are employed on BG’s grants for OpenPrescribing. BMK is seconded to the DataLab from NHS England. The views expressed

in this publication are those of the authors and not necessarily those of the NIHR, NHS England, or the Department of Health and Social Care.

## Abstract

**Background:** Fractures as a result of osteoporosis and low bone mass are common and give rise to significant clinical, personal, and economic burden. Even after a fracture occurs, high fracture risk remains widely underdiagnosed and undertreated. Common fracture risk assessment tools utilize a subset of clinical risk factors for prediction, and often require manual data entry. Furthermore, these tools predict risk over the long term and do not explicitly provide short-term risk estimates necessary to identify patients likely to experience a fracture in the next 1-2 years.

**Objective:** The goal of this study was to develop and evaluate an algorithm for the identification of patients at risk of fracture in a subsequent 1- to 2-year period. In order to address the aforementioned limitations of current prediction tools, this approach focused on a short-term timeframe, automated data entry, and the use of longitudinal data to inform the predictions.

**Methods:** Using retrospective electronic health record data from over 1,000,000 patients, we developed Crystal Bone, an algorithm that applies machine learning techniques from natural language processing to the temporal nature of patient histories to generate short-term fracture risk predictions. Similar to how language models predict the next word in a given sentence or the topic of a document, Crystal Bone predicts whether a patient's future trajectory might contain a fracture event, or whether the signature of the patient's journey is similar to that of a typical future fracture patient. A holdout set with 192,590 patients was used to validate accuracy. Experimental baseline models and human-level performance were used for comparison.

**Results:** The model accurately predicted 1- to 2-year fracture risk for patients aged over 50 years (area under the receiver operating characteristics curve [AUROC] 0.81). These algorithms outperformed the experimental baselines (AUROC 0.67) and showed meaningful improvements when compared to retrospective approximation of human-level performance by correctly identifying 9649 of 13,765 (70%) at-risk patients who did not receive any preventative bone-health-related medical interventions from their physicians.

**Conclusions:** These findings indicate that it is possible to use a patient's unique medical history as it changes over time to predict the risk of short-term fracture. Validating and applying such a tool within the health care system could enable automated and widespread prediction of this risk and may help with identification of patients at very high risk of fracture.

**Introduction**

Fractures due to osteoporosis and low bone mass are associated with a significant personal, clinical, and economic burden. These fractures are common; the risk of sustaining such a fracture increases with age, and their incidence is expected to increase worldwide as the population ages [1-11]. In the United States, an estimated 1 in 2 women and 1 in 4 men over 50 years of age will experience such a fracture [12-14]. However, there remains a significant diagnosis and treatment gap for osteoporosis [1,2,4,12]. When these fractures occur, they often result in a loss of independence for patients and can lead to functional disability, lower quality of life, and increased mortality [5,15-38]. Given this substantial burden and unmet need for interventions, it is critical to identify patients at risk of fracture, as effective management of risk can prevent these deleterious outcomes.

Several fracture risk prediction tools have been developed for clinical use. The most commonly used tools are the University of Sheffield Fracture Risk Assessment Tool, known as FRAX [39], and the Garvan Institute of Health Bone Fracture Risk Calculator (GIH-BFRC) [40]. Both tools use a set of cross-sectional clinical risk factors to evaluate fracture likelihood, and typically require manual data entry to perform the predictions. The performance of both methods varies greatly in real-world analyses; this variance is partially explained by study population and design and predicted fracture outcome (hip vs other osteoporotic fractures). In a review [41], 12 studies of FRAX showed an average area under the receiver operating characteristics curve (AUROC) of 0.65 (SD 0.038) when predicting major osteoporotic fractures without including bone mineral density in the model, and similar results were shown for GIH-BFRC [41]. These commonly used risk assessment tools estimate 5- and 10-year fracture risk but do not provide estimates of 1- to 2-year risk [42-45].

Increased risk of fracture in the next 1-2 years is not routinely assessed in clinical practice, despite the existence of rapid-acting preventative therapeutics [8,46,47]. Although methods for predicting short-term risk have been explored [48-50], they have not yet been widely clinically accepted. Furthermore, these models are limited to a specific set of cross-sectional information, some of which may not readily be available. Thus, there remains a need to further develop a fracture risk prediction tool that predicts on a short-term time frame in order to facilitate identification of patients at high risk. While there are published examples [51-53] applying artificial intelligence to fracture and osteoporosis risk, these approaches focus either on imaging data [51] or on cross-sectional data for long-term predictions [52,53]. To our knowledge, there is no existing method that applies deep learning to sequential patient data for predicting fracture risk.

To address these unmet needs, we developed *Crystal Bone*, a machine learning approach that leverages techniques typically applied in natural language processing. However, rather than applying these methods to text-based data, we applied them to longitudinal data contained in electronic health records. Specifically, we focused on diagnosis codes (International Classification of Diseases; ICD), treating each code as a word and sequences of codes as stories. The goal of this study was to evaluate the ability of these natural language processing-based models to learn patterns associated with increased short-term (ie, 2-year) fracture risk. The results of our analyses suggest that not only does this unique longitudinal method produce accurate short-term fracture risk predictions, but also that the approach can help fulfill the unmet need that exists in fracture-risk identification.

**Methods****Data Background**

We used subsets of the Optum deidentified electronic health record data set, which contains comprehensive longitudinal electronic health record data for 91 million patients from over 140,000 providers (as of March 2018) from the United States. The subsets, which contain bone health and pan-therapeutic populations respectively, cover the time from January 1, 2007, through December 31, 2018 (Optum, email communication, August 2019).

The bone health subset was obtained by filtering for patients with osteoporosis, fractures, or bone-related medications ( $n=6,329,986$ ). In the period covered by the data set, the fracture incidence rate (ie, the proportion of fractures among all events detected, which may include multiple fractures per person) was 39% in the population over 50 years of age. The bone health data set was primarily used for training the model.

The pan-therapeutic data set represented a random sample of 5% of the overall Optum electronic health record data set and contained patient data ( $n=3,476,219$ ) with no filtering for any specific comorbidities or treatments; this dataset had a fracture incidence rate of 8.5% in the population over 50 years of age. Because the sample was drawn from such a large population, the pan-therapeutic data set was assumed to be broadly representative of the US population. As such, we performed all model evaluations on a testing sample from this data set (a holdout data set), to better understand the generalizability of the model in a real-world setting.

**Ethical Approval**

Since this was a retrospective study using deidentified data, patients were not required to actively participate in the study. Therefore, neither informed consent of patients nor institutional review board approval was required.

## Data Engineering and Cohort Selection

The cohort consisted of patients who were at least 50 years of age at the time of their event; this criterion was chosen to reduce the data to a population that is more susceptible to fractures associated with osteoporosis and low bone mass. For fracture patients, an event is the date of occurrence of any qualifying fracture. Qualifying fractures are defined by a set of rules based on those used by Wright et al [54] for identifying novel and relevant fracture events in claims data. For nonfracture patients, an event is the date of the last recorded diagnosis of any kind in the data set. We describe further details of the fracture identification process in [Multimedia Appendix 1](#).

We further filtered our cohorts for patients with at least 2 years of medical history leading up to their respective events. Applying these parameters limited the bone health cohort to 3,408,494 patients and the pan-therapeutic cohort to 700,315 patients.

We applied sliding windows to the data ([Figure 1](#)), where each event could have up to 5 windows, and each window was a historical sequence defined as the list of chronologically ordered ICD codes in the 2 years leading up to an event. These historical sequences were then used to predict risk of fracture within a 2-year horizon (a 1-year horizon was also explored, see [Multimedia Appendix 1](#)). As shown in [Figure 1](#), some windows were dropped from the analysis due to incomplete or potentially overlapping coverage. Additionally, windows that occur more than 2 years before a fracture event were labeled as nonfracture windows. The motivation for this approach was to provide the algorithm with multiple unique code sequences leading up to the same event that may reflect changes in risk at various times within the given time horizon. Furthermore, the fixed window size provided a consistent timeframe for prediction as opposed to varying lengths of time for each patient, which would have occurred if patients' complete code histories were used. Further details regarding the motivation and methodology of this approach are in [Multimedia Appendix 1](#).

**Figure 1.** Sliding window algorithm schematic. This schematic depicts the sliding window algorithm for a multifracture and nonfracture patient. Dx: diagnosis; ICD: International Classification of Diseases.

### Sample Fracture Patient Windows:

### Sample Non-Fracture Patient Windows:

There was no additional filtering based on specific diagnoses or comorbidities. For each qualifying patient, the algorithms utilized all available ICD codes in the historical sequences described above. Only the codes that occurred fewer than 5 times in the full cohort were excluded, as these codes were too rare to be included in the diagnosis code vocabulary.

## Data Sampling

Before model training, we generated a 70:30 random split of the pan-therapeutic data, representing training and holdout subsets. Since the pan-therapeutic data set is highly imbalanced, with a fracture event incidence of only 6.5% after applying the sliding window algorithm, we oversampled additional fracture windows from the bone health data set to achieve a balanced

(50:50) training set for modeling. This oversampling training paradigm was replicated for all models. The holdout set remained untouched, with the original distribution of fractures.

## Modeling Approaches

### Overview

Crystal Bone was inspired by techniques that are typically applied in natural language processing. However, instead of applying these techniques to text-based data, we applied them to sequences of ICD codes. Correspondingly, each ICD code was analogous to a word, and each sequence of ICD codes was analogous to a document. To this end, we implemented 2 distinct frameworks: (1) ICD code vectorization and long short-term

memory networks, and (2) patient-level vectorization and extreme gradient boosting decision trees. Both approaches utilize sequences of ICD codes as inputs. The ICD code vectorization and long short-term memory framework undertakes this task by first learning semantic definitions for the codes, then evaluating the sequence of definitions through a deep learning network.. The patient-level vectorization and extreme gradient boosting modeling framework employs a similar approach; however, rather than embedding individual ICD codes, it embeds the entire ICD code sequence for each patient, thereby learning “summaries” of patient sequences. This framework produces a prediction by feeding these summaries through a decision tree classifier. The model parameters were tuned to optimize AUROC; details of this process are provided in [Multimedia Appendix 1](#).

### ***Framework 1: ICD Code Vectorization + Long Short-Term Memory***

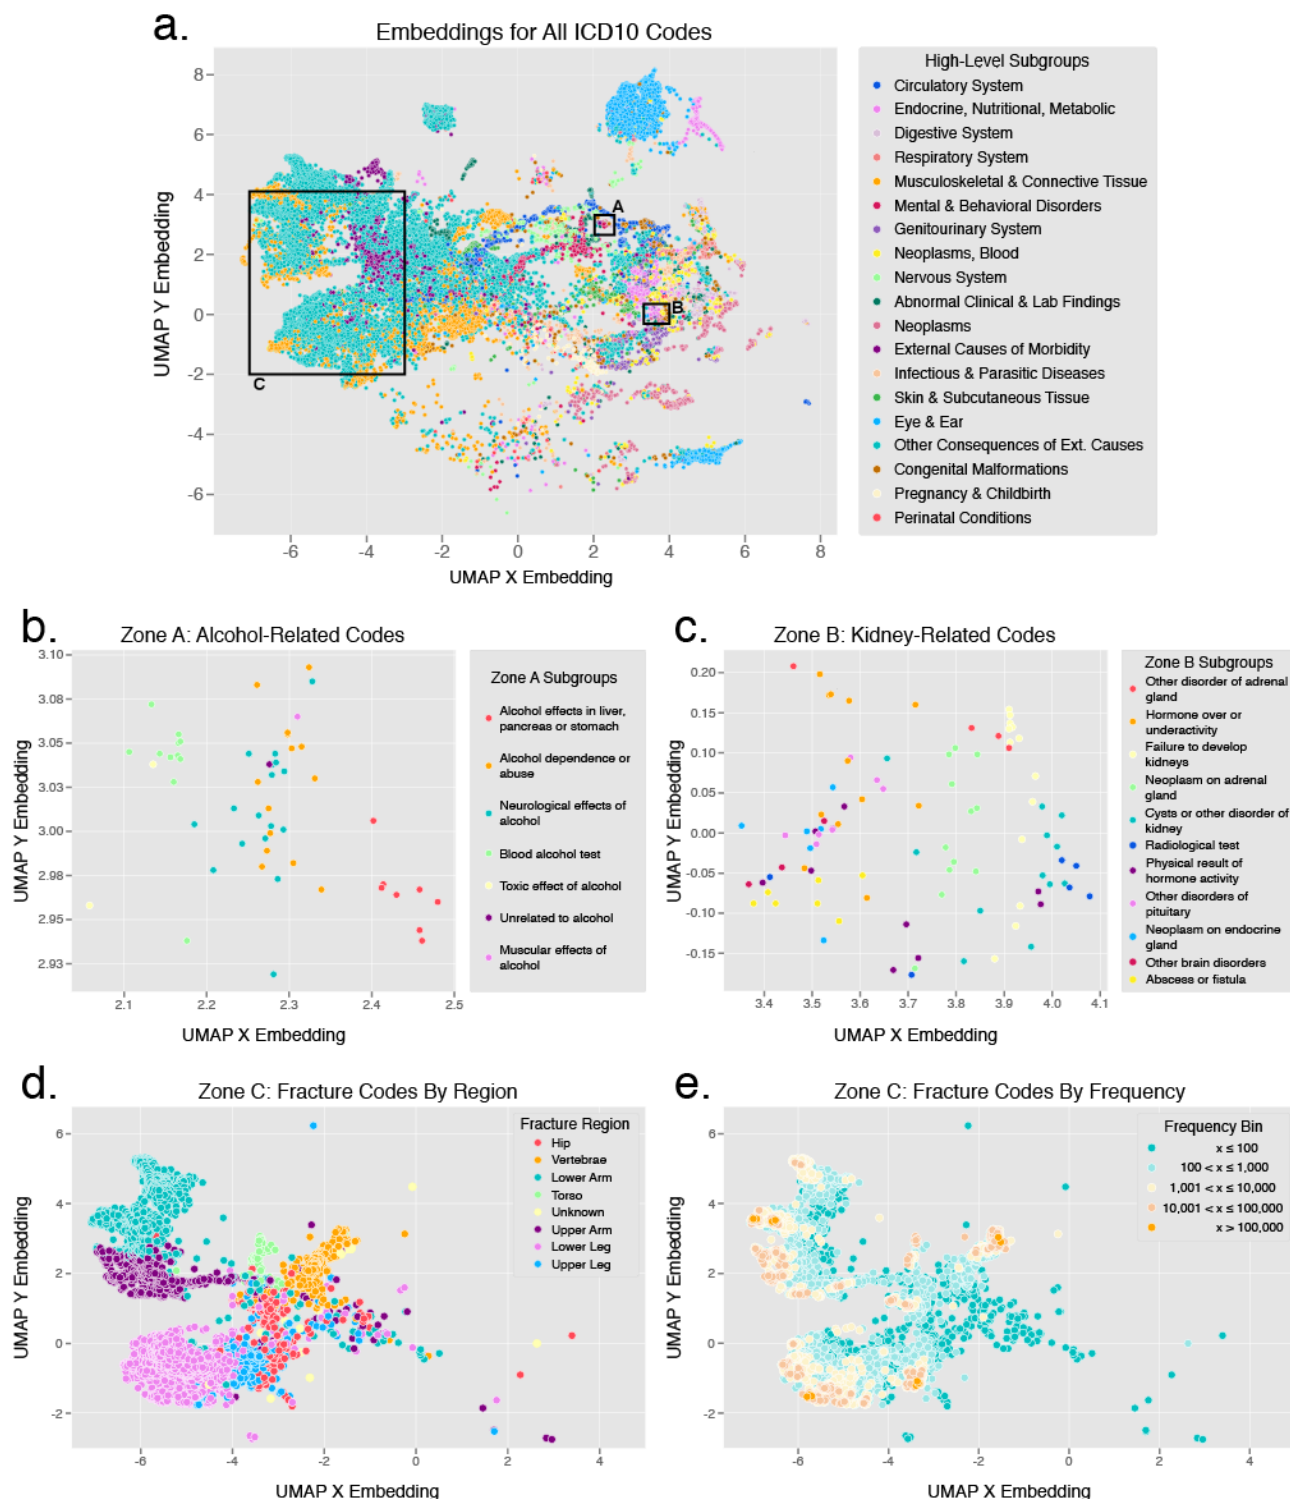

The first framework consisted of 2 primary components. The ICD code vectorization component was responsible for learning a “definition” for each ICD code based on skip-gram architecture word embedding (word2vec) [55], an unsupervised learning approach that mapped each code in the vocabulary to a 100-dimensional vector. To generate these embeddings, we utilized sequences from the pan-therapeutic training set alone (without oversampling), to avoid bias toward bone-health related codes. In our implementation, the vocabulary consisted of all diagnosis codes that occurred at least 5 times in this data set, amounting to more than 40,000 unique codes. The method generated a vector for each code based on the context in which it appeared; in electronic health records, similar ICD codes

appear in similar contexts, and as a result have similar vector representations. These embeddings reduced the dimensionality and sparsity of the feature space, and helped the neural network recognize related ICD codes. [Figure 2](#) illustrates the encoded vectors projected onto a 2D space using uniform manifold approximation and projection (UMAP) for dimension reduction [56]. The collocation of related diagnosis codes in this coordinate space provided qualitative evidence that the ICD code vectorization had encoded meaningful latent information.

The long short-term memory component consisted of a neural network with long short-term memory layers, a deep learning architecture that enables the evaluation of recurrent data, such as sequences of embedded ICD codes. We trained this network with the complete training set (including oversampling from the bone health data set). The long short-term memory network predicted the likelihood of a fracture event within 2 years as a classification problem. Long short-term memory networks are a common approach for solving such problems [57].

Additionally, given the ubiquitous use of nonsequential features such as age and sex for predicting fracture risk, we supplied age and sex to the neural network as static features through concatenation of long short-term memory and dense layers. Furthermore, because the long short-term memory framework required all input sequences to have uniform length, we also included total diagnosis count as a static feature to account for the effects of truncating or padding the sequences. The schematic in [Figure 3](#) provides an overview of the model architecture and inputs to the algorithm, namely age, sex, diagnosis count, and the patient’s unique sequence of ICD codes.

**Figure 2.** 2D projection of ICD-10 code embeddings from the ICD code vectorization model: (a) All ICD-10 codes by the first letter (high-level category) of the code, (b) a cluster of codes related to alcohol near coordinates (2.3, 3) by code subgroups, (c) a cluster of codes related to kidney function near coordinates (3.75, 0.025) by code subgroups, and all ICD-10 fracture codes in region C (d) by region of the body, and (e) by frequency of occurrence. ICD: International Classification of Diseases; UMAP: uniform manifold approximation and projection.

**Figure 3.** High-level architecture of the long short-term memory neural network including the dimensionality of the inputs, as well as the number of nodes in each layer. Dx: diagnosis; Icd2vec: ICD code vectorization; LSTM: long short-term memory.

### Framework 2: Patient-Level Vectorization and Extreme Gradient Boosting

Similar to the ICD code vectorization + long short-term memory modeling framework, the patient-level vectorization and extreme gradient boosting decision trees framework consists of 2 components. First, the patient-level vectorization embeds entire ICD code sequences to a 128-dimensional semantic space using the distributed bag of words framework [58]. Much as the ICD code vectorization learned definitions of individual ICD codes, the patient-level vectorization instead learned summaries of patient sequences. The method for doing so is the same; patients with similar sequential contexts will have similar summary vectors. We trained the patient-level vectorization with the sliding window ICD code sequences, again only utilizing the pan-therapeutic data to avoid bias toward the bone health therapeutic area. This created embeddings that represented 2-year episodes of patient histories; a detailed exploration of these embeddings is in [Multimedia Appendix 1](#).

The extreme gradient boosting decision trees component utilized the embeddings from the patient-level vectorization, as well as the static features of age, sex, and total diagnosis count that were incorporated in Framework 1, to predict fracture risk. This type of algorithm, also referred to as XGBoost, is a scalable tree-based modeling approach that improves the generalizability, speed, and efficacy of prediction [59]. We trained this algorithm with the full training set (including bone health data set oversampling) to learn a classification model that predicted the likelihood of fracture within 2 years.

### Ensemble Model

An ensemble model was also evaluated. This algorithm combined the outputs of both the aforementioned frameworks with a logistic regression metaclassifier.

### Baseline Models

We compared these modeling frameworks to 2 baseline models. The first baseline model utilized the age and sex of each patient at each window. These were 2 of the only features shared by the FRAX tool and the GIH-BFRC models. The other shared feature is prior fracture; however, because neither the FRAX tool nor GIH-BFRC's method of measuring this value was possible for our data set without censoring, we did not include it in the model. The second baseline incorporated age, sex, and total diagnosis count (number of ICD codes) in each sample; these represent all of the static features used by both modelling frameworks, enabling evaluation of the relative benefit of including sequential ICD code data. Both baseline models utilized extreme gradient boosting decision tree algorithms, the same classification approach that was used in Framework 2.

### Human-Level Performance Approximation

In addition to these baselines, we approximated human-level performance by isolating a set of retrospective physician-prescribed interventions that were identifiable in the electronic health record data set. These interventions consisted of diagnostic tests as well as pharmacologic treatments. The list of interventions was based on treatment guidelines provided by the National Osteoporosis Foundation [60] and the Journal of Clinical Endocrinology and Metabolism [61] and was further validated by the physician coauthors of this manuscript, who confirmed that the interventions aligned with their understanding of osteoporosis treatment guidelines ([Table 1](#)). If a patient received one of these interventions in a 2-year historical window, that window was flagged as "physician-identified risk, worthy of intervention." A full description of the limitations of this approach is described in [Multimedia Appendix 1](#).

**Table 1.** List of physician interventions for human-level performance analysis.

Type and name	Pharmacologic
<b>Procedure</b>	
Dual-energy x-ray absorptiometry	No
Vertebral fracture assessment	No
Quantitative computed tomography	No
Other bone density measurements (single energy x-ray absorptiometry, radiographic absorptiometry, ultrasound, single-photon absorptiometry)	No
Bone turnover markers	No
Administration of any medications referenced below	Yes
<b>Treatment</b>	
Bisphosphonates (alendronate, alendronate-cholecalciferol, ibandronate, risedronate, zoledronic acid)	Yes
Abaloparatide	Yes
Denosumab	Yes
Raloxifene	Yes
Bazedoxifene	Yes
Romosozumab	Yes
Teriparatide	Yes
Calcitonin	Yes
<b>Diagnosis</b>	
Osteoporosis (M80, M81, 733.0)	No

We defined the cohort of patients who did not receive any form of intervention (diagnoses, tests, or treatments) as *no intervention* and assessed how well the algorithm was able to correctly identify which patients had a fracture within 2 years, as well as how frequently the algorithm mistakenly flagged patients with no imminent fracture. We also evaluated the patients who received interventions (the *intervention cohort*) with this method, referred to as the *cohort analysis*. However, since an intervention can directly modulate fracture risk, we performed a separate analysis in order to mitigate some of the uncertainty due to the effects of interventions. For this analysis, we identified each patient's first pharmacologic intervention and used the diagnosis history leading up to this date as input. This analysis allowed us to gauge the extent to which the algorithm flags agreed with human-level performance interventions (without needing to adjust for their effects). We termed this the *overlap analysis*. The cohort analysis utilized

the full list of interventions, while the overlap analysis utilized the pharmacological subset of the list of interventions.

### Model Performance

We report model performance on a set of 5 primary metrics: AUROC, recall (sensitivity), specificity, precision, and area under the precision-recall curve (AUPRC).

## Results

### Model Performance

The overall performance of the algorithms is shown through comparison of the 2 frameworks with the 2 baseline models to demonstrate the quality of each algorithm's predictions. [Table 2](#) shows a summary of key model performance metrics on the same holdout data set. The Crystal Bone models, including the ensemble model that combined the 2 approaches, outperformed the baseline models for nearly all performance metrics.

**Table 2.** Comparison of model performance metrics.

Model	AUROC <sup>a</sup>	Recall	Specificity	Precision	AUPRC <sup>b</sup>
ICD code vectorization + LSTM <sup>c</sup>	0.812	0.646	0.812	0.192	0.462
Patient level vectorization + XGBoost <sup>d</sup>	0.790	0.670	0.758	0.161	0.358
Ensemble	0.818	0.693	0.777	0.177	0.463
Baseline (age, sex)	0.667	0.787	0.416	0.0855	0.119
Baseline (age, sex, diagnosis count)	0.668	0.547	0.707	0.114	0.130

<sup>a</sup>AUROC: area under the receiver operating characteristics curve.

<sup>b</sup>AUPRC: area under the precision-recall curve.

<sup>c</sup>LSTM: long short-term memory.

<sup>d</sup>XGBoost: extreme gradient boosting.

### ICD Code Vectorization + Long Short-Term Memory Model

To further characterize this performance, we evaluated the ICD code vectorization and long short-term memory model on primary and subsequent fracture events. While the model performs best on subsequent fractures, both primary and subsequent fracture analyses (AUROC 0.742 and 0.910, respectively) show a marked improvement against corresponding baseline models (AUROC 0.591 and 0.747, respectively). We report detailed results of this experiment and additional evaluations of sensitivity and robustness of this model in [Multimedia Appendix 1](#).

### Human-Level Performance Comparison

[Table 3](#) contains the results of the cohort analysis. For windows with no interventions, Crystal Bone Framework 1 correctly flagged 16,127 of the 28,626 windows that resulted in fracture

(56.3%); this corresponds to 9649 out of 13,765 (70.1%) of the unique fracture events. Crystal Bone Framework 1 incorrectly flagged 91,717 of the 532,621 windows with no fractures as at-risk (17.2%); however, 1053 of the windows in this cohort (3%) sustained a fracture in >2 years.

For windows with interventions, only 11,833 of 69,198 (17.1%) of the detected interventions included treatments; thus, the remaining 57,365 (82.9%) interventions were either diagnoses or diagnostic tests. In the intervention cohort, Crystal Bone Framework 1 correctly captured 10,277 out of 12,244 windows for which fracture occurred within 2 years (83.9%). For the windows with interventions and no fracture event, 19,235 out of 56,954 (33.8%) are incorrectly flagged by our algorithm as at risk. These results suggest Crystal Bone's ability to recognize interventions through their associated ICD codes and adjust the predicted fracture risk accordingly. However, a deeper exploration of specific interventions is required to verify this.

**Table 3.** Human-level performance results.

Cohort	Windows, n (%)	Flag, n (%)	No flag, n (%)
<b>Total</b>	630,445 (100)	— <sup>a</sup>	—
<b>No intervention</b>	561,247 (89.0)	—	—
Fracture	28,626 (5.1)	16,127 (56.3)	12,449 (43.7)
Nonfracture	532,621 (94.9)	91,717 (17.2)	440,904 (82.8)
<b>Intervention</b>	69,198 (11.0)	—	—
Fracture	12,244 (17.7)	10,277 (83.9)	1967 (16.1)
Nonfracture	56,954 (82.3)	19,235 (33.8)	37,719 (66.2)

<sup>a</sup>Not reported.

The overlap analysis enabled us to better understand how well Crystal Bone Framework 1 correlated with observed physician interventions through exploration of the first pharmacological treatment in the holdout set. Of the 7127 patients who received treatment, 6071 had enough medical history leading up to this treatment for Crystal Bone Framework 1. When evaluating these patients, 3017 out of those 6071 (49.7%) were considered at risk of fracture in 2 years.

We evaluated the incidence of fracture within 2 years for this subgroup. Of the cohort deemed at risk by the algorithm, 684 out of 3017 (22.7%) experienced a fracture within 2 years of

the first intervention date. This precision is a slight improvement over that of the algorithm on the overall holdout set, at 19.2%. Furthermore, of all 570 patients in this pharmacological intervention cohort who ultimately suffered from a fracture within 2 years, Crystal Bone Framework 1 correctly flagged 469 (82.3%).

## Discussion

### General

In this study, we evaluated the performance of 2 natural language processing–inspired fracture prediction models: (1) ICD code vectorization and long short-term memory (AUROC 0.812) and (2) patient-level vectorization and extreme gradient boosting (AUROC 0.790). The performance of these models reflected a substantial improvement over 2 baseline models: (1) with age and sex (AUROC 0.670) and (2) with age, sex, total diagnosis count (AUROC 0.670). Furthermore, these short-term prediction metrics were an improvement over cross-sectional tools for long-term time frames, such as FRAX and GIH-BFRC, which have been widely clinically accepted [41]. Although fundamental differences in study design make it impossible to compare these metrics directly, sensitivity analyses of Crystal Bone across fracture types, prediction time frames, and fracture definitions suggest robust predictive performance and generalizability. To our knowledge, this is the first study that has experimented with separate models for primary and subsequent fracture types; further discussion of this analysis, as well as the additional sensitivity analyses, is in [Multimedia Appendix 1](#).

The human-level performance comparison provides deeper insight to the benefits of Crystal Bone. The retrospective labeling utilized in both the cohort and overlap analyses enabled a scalable, data-driven comparison of physician action and Crystal Bone and avoided bias that may occur through alternative methods of human-level performance evaluation [62]. To our knowledge, this is the first fracture risk prediction study which includes such a human-level performance comparison in the analysis.

Through the cohort analysis we learned that only a small proportion of patients received preventative interventions, including basic diagnostic tests, showcasing the extent of unmet need in the health care system [1,2,4,12]. In the subset of patient windows with no interventions, Crystal Bone was able to flag 70.1% of the unique fracture events. Given the existence of rapid-acting preventative therapeutics [8,46,47], as well as the demonstrated efficacy of bone-forming agents in reduction of 1- to 2-year fracture risk [63–69], these results suggest that, had appropriate preventative measures been taken, the risk of these fractures may have been reduced, thus mitigating a significant burden to both the patient and the health care system.

The findings of the overlap analysis further support the merits of Crystal Bone, through demonstration of alignment with observable interventions made by physicians. Because it is impossible to confirm whether these treatment interventions were taken in response to a perceived short-term risk of fracture, we cannot expect 100% overlap between Crystal Bone and these observed interventions. We saw that Crystal Bone was aligned with these physician interventions 49.7% of the time. While this overlap is not complete, it captured 82.3% of the patients who ultimately experienced a fracture, reflecting the algorithm's increased sensitivity for the cohort deemed at-risk by physicians.

This suggests a meaningful alignment with both physician evaluation and actual observed fracture risk. Ultimately, these human-level performance comparisons, coupled with performance against baseline models and alternative risk prediction methods, suggest that Crystal Bone can fulfill a critical unmet need through identification of patients at high risk of fracture.

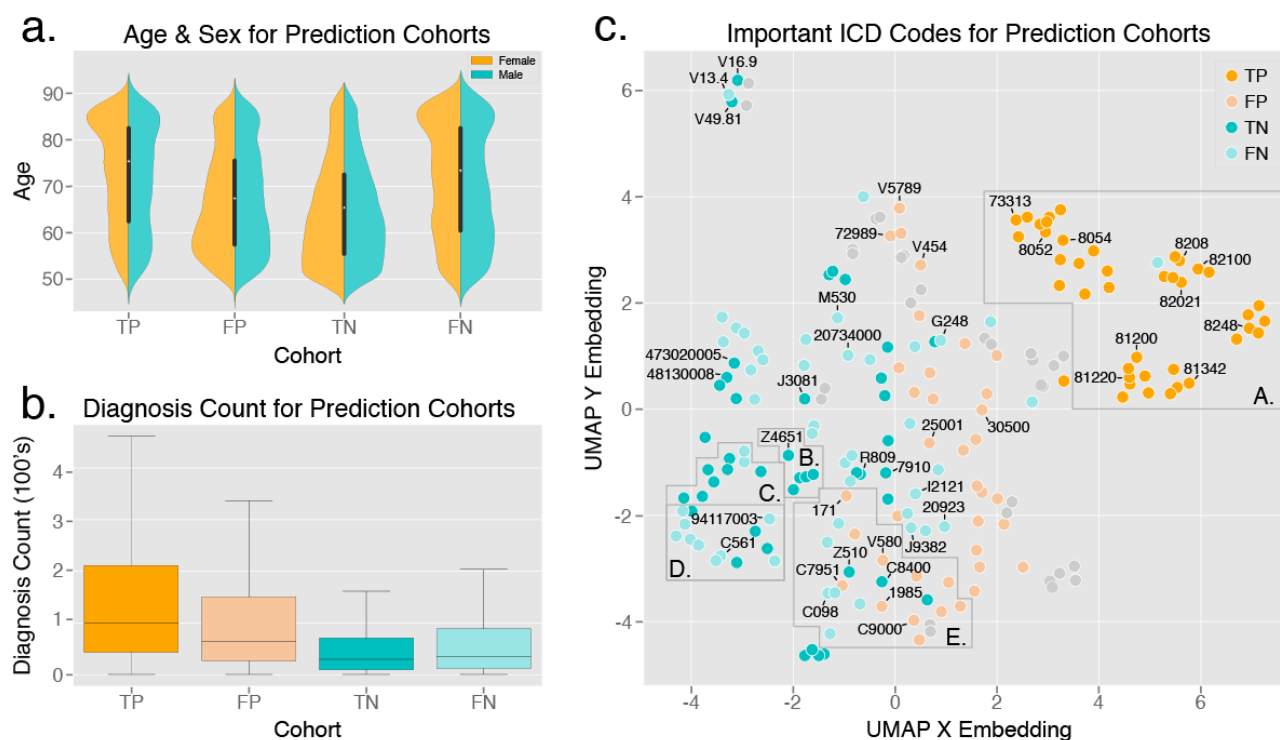

### Limitations of the Current Approach

Various limitations exist for the approaches described, particularly from the inherent complications of using real-world data. The techniques described rely upon ICD codes recorded in electronic health record systems, which will impact the performance and validity of the models if diagnoses are not detected, incorrectly recorded, or missed due to patient dropout. Indeed, most vertebral fragility fractures are clinically silent and hence not captured in electronic health records [70]. While an approach utilizing only ICD codes is potentially more comprehensive and straightforward for real-world implementation due to the quality of coverage and descriptive nature of diagnosis codes, we may miss salient clinical features captured elsewhere in the electronic health record. For example, there exist ICD codes associated with obesity, osteopenia, and osteoporosis, which represent measurements of BMI and bone mineral density on a categorical level. However, these do not reflect exact clinical measurements; the exclusion of these quantitative measurements may limit the performance and clinical impact of the algorithm. Nevertheless, it may be advantageous to utilize these ICD codes rather than the quantitative measures, as such measures in an electronic health record frequently contain human error and may not always be readily available.

In addition to data set challenges, there exist limitations inherent to assumptions of the modeling approach. The suppositions of constant time between diagnosis codes and uniform sequence length may affect performance. Exploration of more advanced methods that do not require such assumptions could improve the model and is an area of future work.

Perhaps the greatest limitation of the described approaches is that they are generally considered black box approaches and lack significant interpretability. Developing methods for improved interpretation of deep learning models is an active area of research. We have performed an initial exploration of this for the ICD code vectorization and long short-term memory model in [Figure 4](#), which compares various characteristics of the four prediction cohorts of the confusion matrix for the test set (true positive [TP], false positive [FP], true negative [TN], false negative [FN]). Within each of these groups, we performed exploratory analysis on the associated samples for each of the input features in the model: age, sex, total diagnosis count, and ICD codes. Results of this analysis are described in detail in [Multimedia Appendix 1](#). While this serves as an initial evaluation of model interpretability, a deeper exploration of interpretability techniques is an area for future work in these algorithms.

**Figure 4.** Exploration of model interpretability by comparison of various characteristics of the input data for the 4 prediction cohorts of the confusion matrix. FN: false negative; FP: false positive; ICD: International Classification of Diseases; TN: true negative; TP: true positive; UMAP: uniform manifold approximation and projection.

Another limitation of this study is the inability to perform direct comparisons with established risk calculators such as FRAX. Additionally, this approach has yet to be validated with external data, which is the subject of future work.

### Potential Applications

We foresee numerous applications of this work in the health care system, with benefits for patients, providers, and payers alike. For payers, Crystal Bone provides a unique opportunity to explore population health, enabling insurers to identify and address patients in need of evaluation or intervention, and preventing the large expenses associated with fracture events. For providers, direct electronic health record integration would facilitate patient care, and help identify at-risk patients who are not currently identified as such. That being said, effective implementation requires additional understanding on the impact of interventions on short-term fracture risk; while there is evidence to suggest that rapid acting treatments and bone-forming agents can significantly decrease fracture risk on a shortened time frame [8,46,47,63-69], a more detailed exploration of the optimal care pathways for various Crystal Bone risk scores would likely be required to facilitate real-world use of the algorithm.

Crystal Bone addresses the need for an automated and largely physician-independent tool that is effective at predicting

short-term fracture risk. It is the first such approach that takes longitudinal patient trajectories into account, rather than focusing primarily on cross-sectional information, enabling a more personalized assessment of fracture risk. Furthermore, with automated aggregation of patient histories in an electronic health record system, the prediction of fracture risk could be entirely hands-off, without requiring a doctor or patient to manually enter any information into the software. This unique approach may facilitate broader adoption of the algorithm. Still, the lack of clinical guidelines for 1- and 2-year risk may limit adoption in the near future.

Such a tool, if widely applied, could facilitate early patient identification, and help reduce the morbidity and mortality associated with fractures. The retrospective human-level performance comparison suggests that Crystal Bone would identify patients who are currently missed in the health care system, potentially minimizing the burden on patients and the health care system overall. Given the prevalence and anticipated increase of fractures due to osteoporosis and low bone mass as the population ages, as well as the enormous personal, clinical, and economic costs associated with such fractures, Crystal Bone could provide a meaningful positive impact through reduced burden and improved outcomes.

### Acknowledgments

This study was funded by Amgen Inc. The costs covered by Amgen Inc were licensing of the Optum data set, access to the computational resources required to develop the model, and compensation for listed Amgen Inc employees. No additional funding was provided for this study.

Thank you to Optum for providing access to and assistance with the data. We would like to additionally thank the following individuals for their guidance and support in conducting this study and creating this manuscript: Inbal Lapid, Tammy Lindberg, Howard Chen, Mandy Suggitt, Lisa Humphries, Marc Doble, Nkem Ogbechie, John Page, Michi He, Akhila Balasubramanian, and Erle Davis.

### Authors' Contributions

YA is the first author. Technical conception, design and direction: YA, AR, PZ, and KW. Medical direction and interpretation: CH, MO, EM, and SRC. Data analysis and interpretation: YA, PZ, AWM, RP and AM. Writing of the manuscript: YA, AR, PZ, KW, CH, MO, EM, and SRC. Authors EM and SR contributed equally. All authors contributed to critical revisions of the draft and approved the final manuscript.

### Conflicts of Interest

YA, PZ, RP, AM, KW, and MO are employees and stock owners at Amgen Inc, the funders of this study. AR, AWM, and CH are former employees and stock owners at Amgen Inc. EM is a consulting fee recipient, grant recipient, and speaker on behalf of Amgen Inc, as well as a member of the International Osteoporosis Foundation. SRC is a consulting fee recipient and grant recipient from Amgen Inc.

## Abstract

**Background:** Clinical decision support (CDS) design best practices are intended to provide a narrative representation of factors that influence the success of CDS tools. However, they provide incomplete direction on evidence-based implementation principles.

**Objective:** This study aims to describe an integrated approach toward applying an existing implementation science (IS) framework with CDS design best practices to improve the effectiveness, sustainability, and reproducibility of CDS implementations.

**Methods:** We selected the Practical Robust Implementation and Sustainability Model (PRISM) IS framework. We identified areas where PRISM and CDS design best practices complemented each other and defined methods to address each. Lessons learned from applying these methods were then used to further refine the integrated approach.

**Results:** Our integrated approach to applying PRISM with CDS design best practices consists of 5 key phases that iteratively interact and inform each other: multilevel stakeholder engagement, designing the CDS, design and usability testing, thoughtful deployment, and performance evaluation and maintenance. The approach is led by a dedicated implementation team that includes clinical informatics and analyst builder expertise.

**Conclusions:** Integrating PRISM with CDS design best practices extends user-centered design and accounts for the multilevel, interacting, and dynamic factors that influence CDS implementation in health care. Integrating PRISM with CDS design best practices synthesizes the many known contextual factors that can influence the success of CDS tools, thereby enhancing the reproducibility and sustainability of CDS implementations. Others can adapt this approach to their situation to maximize and sustain CDS implementation success.

clinical decision support; PRISM; implementation science

## Introduction

### Background

Clinical decision support (CDS) tools within electronic health records (EHRs) have led to some improvements in patient care [1-4]. However, there are also numerous examples of CDS tools leading to low adoption or negative impact on outcomes. Up to 95% of CDS tools are dismissed [5], 52%-66% improve process outcomes such as appropriate drug selection, and only 21%-43%

lead to improvements in clinical outcomes [6-9]. CDS design best practices may be a way to improve the impact of CDS tools [10,11]. As a framework, CDS design best practices are intended to provide a narrative representation of the key determinants that influence the success of CDS tools [12-18]. [Textbox 1](#) provides a high-level summary of the best practices that include a user-centered design process. Initially established by experts in the field, retrospective studies support the potential benefit of applying CDS design best practices [13-16,19,20].

**Textbox 1.** Overview of clinical decision support design best practices and examples of how to address the best practice.

#### Minimize alert fatigue

- Ensure accuracy and completeness of data and information recommended and used to formulate recommendation. Continual performance evaluation and end user feedback throughout implementation. Evaluations and feedback should be used to iteratively update the clinical decision support (CDS). CDS customization to fit the end user and institutional needs, including type (interruptive or passive), presence of a dismiss option, and frequency and timing of alert. Consideration of whether the CDS can support agenda setting

#### Support team-based care

- Comprehensive inclusion of care team members in which the CDS is tailored to the workflows and roles of each member

#### Fit within the end user's workflow when considering other internal and external drivers

- Presentation of the CDS in such a way that it is available when needed, supports (versus impedes) end users, and human factors principles that makes it easy for them to synthesize and apply the information displayed (eg, visual cues such as size, position or color; prioritization; standardization). Flexibility to delay or defer CDS to another time or person can optimize workflow integration. Response options that reflect all possible patient situations (eg, other). Obtaining end user input on the design (user-centered design) with consideration of other internal and external factors such as national guidelines or value-based performance measures

#### Present pertinent and transparent information that supports and does not impair autonomy of decision-making

- Provide the rationale and supporting information (eg, references) on why the CDS is displayed so as to allow the end user to evaluate whether to apply the recommendation. Avoid giving a perception of shaming or use of insulting language

#### Make it easy, and incentivize users to follow the recommendation

- Provide actionable recommendations and functionality to save the end user time (eg, ability to place orders within display; links to review or update patient data). Provide a relative advantage to using the CDS (eg, peer or patient recognition for actions taken; save time).

CDS design best practices acknowledge the importance of implementation but do not provide a comprehensive framework or direction on evidence-based implementation principles. Some implementation science (IS) frameworks are available for health information technologies (health IT) [21-24]. However, there are no published reports that are comprehensive in providing direction for all stages of health IT or CDS implementation. A comprehensive IS framework could provide direction on how to account for field-specific nuances and contextual factors that influence the success of CDS tools [25]. Such an IS framework can allow health systems to proactively address the areas where things often break down in the process of adoption, implementation, and maintenance.

### Objectives

Here, we describe how to apply an existing IS framework to CDS to improve effectiveness, sustainability, and reproducibility. The specific objectives of this report are: (1) discuss how an IS framework can be integrated with CDS design best practices, (2) describe how to apply this integrated approach using illustrative case studies, and (3) discuss directions for future research and application of this integrated approach to CDS implementation.

## Methods

### Selection of an IS Framework

Although there are many IS frameworks [26], we selected the Practical Robust Implementation and Sustainability Model (PRISM) because it: (1) is a process, evaluation and

determinants framework, (2) comprehensively addresses the interactions between the intervention and stakeholders and both organizational and external factors, (3) is directly tied to real-world, pragmatic implementation outcomes, and (4) is easy to use, thereby maximizing scalability [26-30]. As a process model, PRISM provides direction on how to address factors that influence implementation. As a determinant framework, PRISM makes it possible to reproduce the process for considering key factors that may influence implementation success [26]. As a comprehensive framework, PRISM considers all stages of implementation (preimplementation planning and

design, implementation operations, postimplementation evaluation) and all groups or levels of influences within and external to the organization. As illustrated below, it is also compatible with CDS design best practices. Finally, PRISM builds on the Reach, Effectiveness, Adoption, Implementation, and Maintenance (RE-AIM) framework [31] for key implementation outcome measures. [Textbox 2](#) describes the domains of PRISM and how they apply to CDS. [Figure 1](#) depicts the domains of PRISM, their interactions, and how they influence CDS.

**Textbox 2.** PRISM domains and application to clinical decision support.

**Intervention: organizational perspective includes leadership, management, clinicians, and frontline staff**

An intervention is more likely to be successful if:

- It is aligned with the organization's mission and readiness for change
- The strength of evidence supporting the intervention is strong
- It addresses a barrier to or gap in health care
- It has been observed to be beneficial before a long-term commitment (observability, trialability, reversibility)
- It is simple and inexpensive

**Intervention: patient perspective**

An intervention is more likely to be successful if it is:

- Patient centered
- Simple and inexpensive
- Accessible to and understood by a wide variety of patients (cultural backgrounds, literacy, or numeracy levels)
- Addresses key patient concerns, not limited to clinical issues

**Recipients: organizational characteristics includes leadership, management, clinicians, and frontline staff**

Characteristics of the organization can impact the success of an intervention, such as financial health, tendency to take risks or deviate from the norm, and morale.

An intervention is more likely to be successful when:

- Management is supportive
- Goals are cohesive and clearly communicated across the organization
- Input is provided across all levels of the organization, including senior leadership, midlevel management, and pertinent frontline clinicians and staff

**Recipients: patient characteristics**

- Characteristics of patients can impact the success of an intervention, including socioeconomic factors such as affordability and access or transportation barriers to the intervention

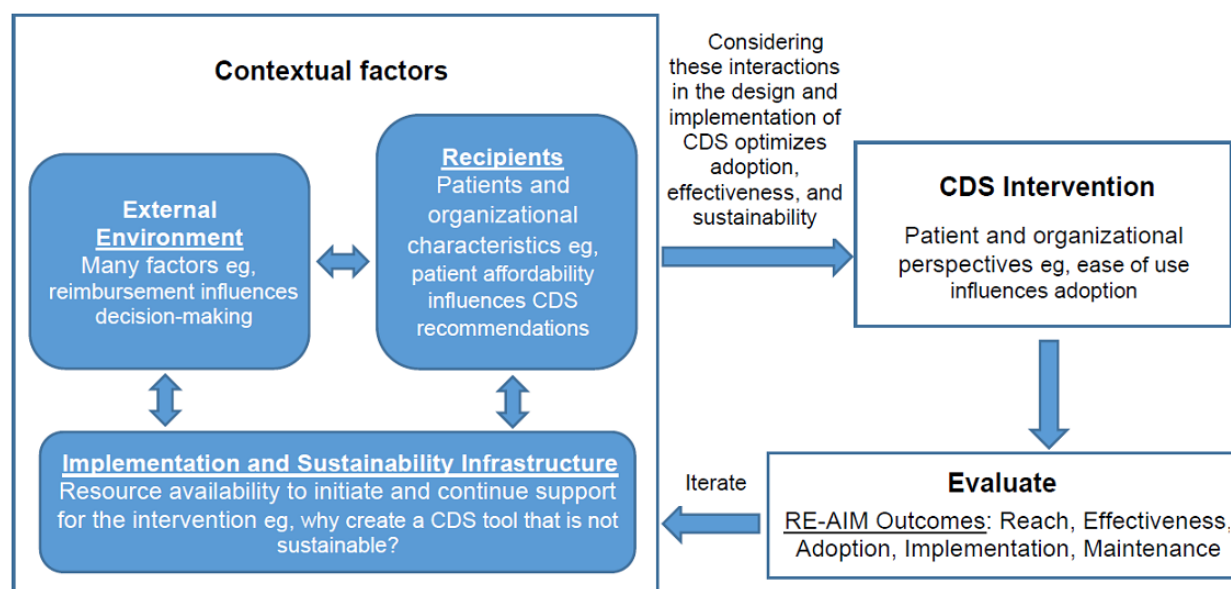

**External environment**

- Factors outside of the organization can influence the organization, such as reporting on performance metrics (public face), policy, guidelines, and reimbursement issues

**Implementation and sustainability infrastructure**

- The implementation plan should be carefully crafted with a dedicated team for implementation, input from management and other stakeholders, and consideration of sustainability and dissemination from the beginning.
- Adequate resources and ongoing assessment or audit and feedback system should be in place

**Figure 1.** Domains of Practical Robust Implementation and Sustainability Model, their interactions, and how they influence clinical decision support. CDS: clinical decision support.

### Integration of the PRISM With Clinical Decision Support Design Best Practices

To account for the specific contextual factors of CDS in health care, we integrated PRISM with CDS design best practices, which we hereafter refer to as the PRISM/CDS best practice approach. Table 1 highlights areas where PRISM and CDS design best practices complement each other and the corresponding methods to address each. For example, clinician focus groups address both the PRISM domain of the *intervention* from the organizational perspective and CDS design best practice principle of *support team-based care*. Therefore, the focus group should include questions to understand who is involved in the specific care process, organizational barriers to prescribing, and whether the subject matter experts (SMEs) feel

the strength of evidence is strong and clinically relevant. When performing the cross-walk between the 2 frameworks, there are situations where the individual principles and domains do not complement each other (empty cell in Table 1), which is appropriate. For example, when designing a CDS for clinicians to use, methods to address the best practice principle of *fit within end users workflow* would generally be unrelated to methods used to address the PRISM domain of *intervention* from the patient perspective. In general, instances in which cells are empty are because 1 framework focuses on the clinician's perspective, the other focuses on the patient perspective, and there is no common area or overlap that integrates the 2 perspectives. Lessons learned from applying the methods outlined in Table 1 were then used to further refine the PRISM/CDS best practice approach.

**Table 1.** Practical Robust Implementation and Sustainability Model and clinical decision support design best practices: complementary areas and corresponding methods to address.

PRISM <sup>a</sup> domains		Overarching CDS <sup>b</sup> design best practice principles

## Case Study

Throughout this paper, we will refer to a CDS tool to improve the prescription of evidence-based beta blockers for patients with heart failure and reduced ejection fraction. CDS was deployed within the EHR of primary care practices across a large regional health system. The PRISM/CDS best practice approach was applied to the design and implementation of the CDS, as described in the 5 phases below. We note that the methods and results of a randomized controlled trial (RCT) evaluating the PRISM/CDS best practices approach are under review separately, but our focus here is on the application and integration of the approach, not outcome results.

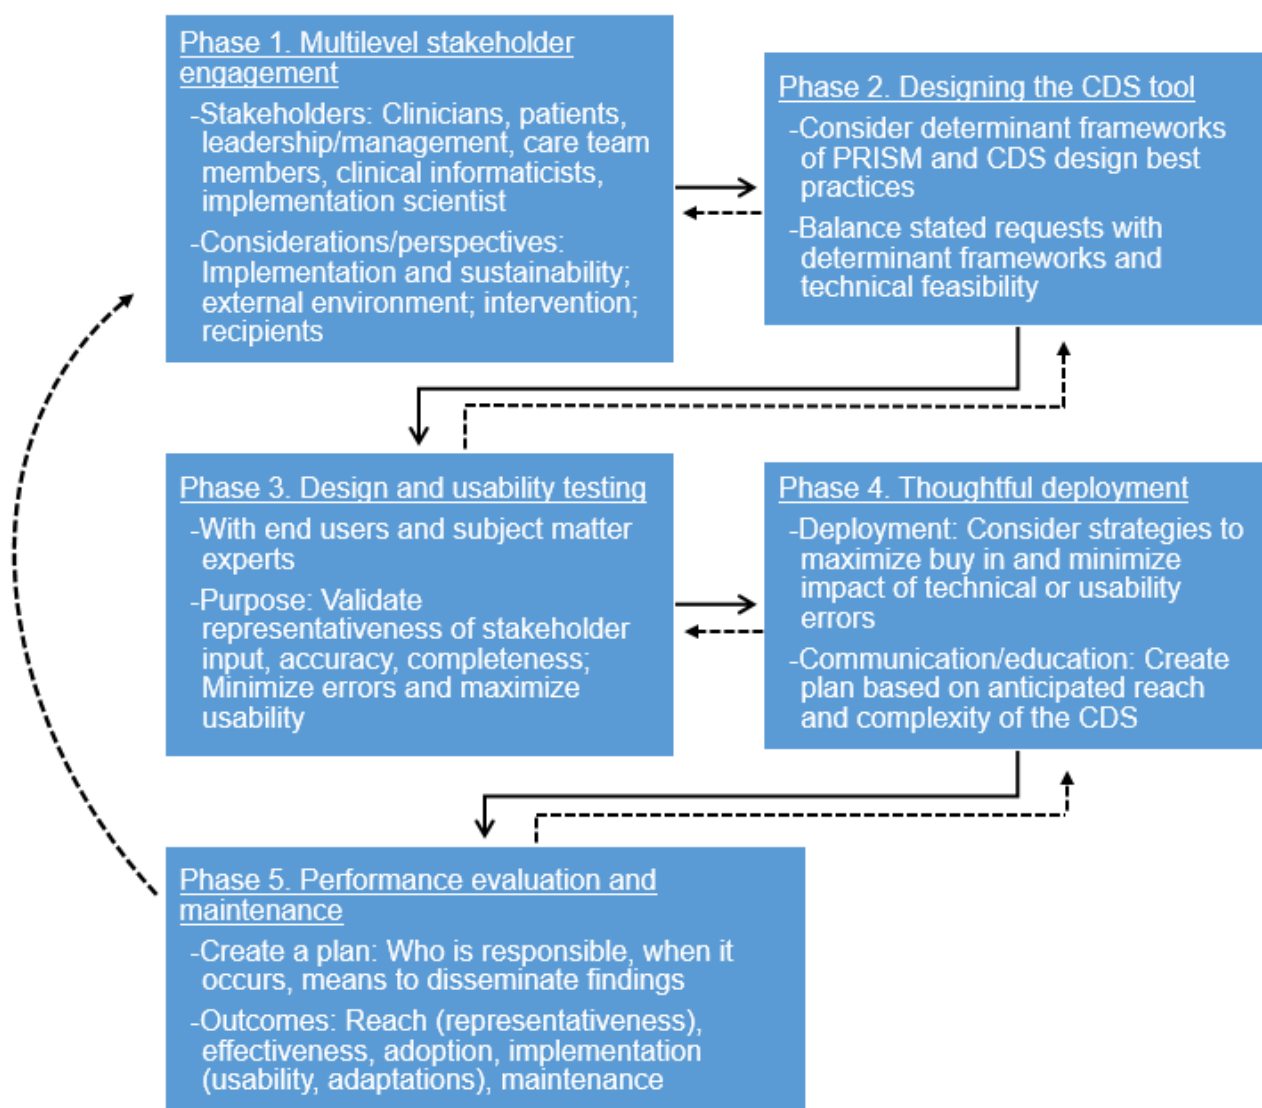

## Results

### Overview

Our integrated approach to applying PRISM to CDS consists of 5 phases: (1) multilevel stakeholder engagement, (2) designing the CDS tool, (3) design and usability testing, (4) thoughtful deployment, and (5) performance evaluation and maintenance. Although there is some logical sequence to these phases, the process is not linear. The phases interact and iteratively inform each other. [Figure 2](#) provides an overview of the phases, which emphasizes that the process is iterative and agile. Here, we describe each of the phases and the key determinants of implementation success from PRISM and CDS design best practices. These phases are intended to be adapted for each unique health system and CDS implementation.

**Figure 2.** Phases of applying the Practical Robust Implementation and Sustainability Model to clinical decision support implementation. CDS: clinical decision support.

### Phase 1. Multilevel Stakeholder Engagement

Multilevel stakeholder engagement is central to PRISM and extends the concept of user-centered design by incorporating stakeholders beyond the end user. PRISM emphasizes factors that can influence implementation success: perspectives of the patient and organization as well as characteristics of the recipients. Patient and organizational beliefs, technology support, and patient ability to afford medical care are some of the characteristics that can influence CDS implementation (Textbox 2 and Figure 1). Following PRISM, it is important to cultivate positive stakeholder perspectives of the CDS tool and identify recipient characteristics that can influence implementation success.

The types of stakeholders will vary for each CDS implementation and can range from a small homogenous group to large groups representing diverse disciplines and specialties. To build CDS tools that are trusted by end users, engaging the right stakeholders with the necessary skills is critical [32]. Stakeholders unique to health IT and CDS include health IT

leadership or governance, clinical informaticists, and analyst builders. Of these stakeholders, a clinical informaticist and analyst builder should be part of a dedicated implementation team, whereas the role of health IT leadership or governance is generally to provide support and approval for implementation. The dedicated implementation team is a key component of the PRISM's implementation and sustainability infrastructure. Often overlooked, clinical informaticists span across disciplines and are uniquely trained to empathize with clinicians, apply the determinants of effective CDS implementation, and balance what is asked for with what is technically possible [33-37]. Clinical informaticists should ideally have experience in IS or an IS expert should be engaged.

Gaining early support from health IT leadership is generally the first step, followed by input from SMEs and end users, and then formal governance approval. When patients are not the end users, their engagement is likely best reserved until after formal governance approval, just in case approval is not granted. The system's health IT leadership assists in determining whether a particular CDS tool is generally aligned with the system's

priorities and whether resources are available to build the CDS tool. Health IT leadership can also provide direction regarding steps needed to secure necessary approval from the health system's formal governance process. Although not all health systems have a formal health IT governance approval process, an increasing number do [38,39]. The organization and process for securing governance approval can vary greatly across health systems and can be complex; thus, early understanding is important. The formal governance approval process includes a review of CDS appropriateness from a workflow and safety perspective and considers potential overlapping or competing system-level initiatives.

SME and end user engagement is a dynamic process that often requires the clinical informaticist, leading the effort to iteratively engage each party until consensus on the design of the CDS tool is established. Obtaining input from SMEs is key to validating the clinical evidence, whereas input from end users is key to ensuring acceptance and practicality of the CDS tool. End user engagement is key to optimizing the workflow

integration. The workflow and preferences of clinician end users can vary greatly across disciplines (eg, respiratory therapists, physicians) and practice settings (eg, acute care, dialysis center). The type of information elicited from patients or caregivers will depend on the type of CDS, notably whether the patient will be an end user or whether the CDS tool makes recommendations that might impact patient treatment decisions. Although patient-facing CDS tools are becoming more common, the majority are still clinician facing. When clinician facing, the line of questioning directed at patients or caregivers is on treatment priorities and values to ensure alignment with the CDS tool's recommendations. When conducting focus groups or interviews with stakeholders, questions should be tailored to the situation [40] and informed by the determinants of effective implementation, which include CDS design best practices. The objectives of SMEs and end user engagement are to garner their support and define the general scope of the CDS tool. Such a written CDS scope can be used to facilitate the formal governance approval process. [Textbox 3](#) describes our approach to engaging stakeholders.

### Textbox 3. Phase 1 case study.

#### Case study:

- For the beta-blocker CDS tool, the Chief Medical Information Officer (CMIO) was contacted at the start of the project. The CMIO provided support contingent on approval from other stakeholders and the formal governance process. To engage patient and clinician stakeholders in preimplementation design activities, we conducted focus groups rather than individual interviews to maximize the efficiency of resources and to facilitate idea generation among participants. However, we also sought to elicit individual patient and clinician thoughts.
- Clinicians, after the open-ended group discussion regarding needs and preferences for a CDS tool, were asked to individually design on paper their ideal CDS [41], which provided valuable insights. For example, most clinicians expressed strong dislike for interruptive CDS during group discussion, but many individually described their ideal CDS as being interruptive. The discordance may be the result of peer influence or reflect differences between their preferences and their perceptions of what is most effective. These findings led to an interruptive CDS tool [41].
- In our case, the CDS tool was clinician facing; thus, the goal of the patient focus groups was to evaluate the factors that influence patients' decisions to take heart failure medications. The focus groups occurred early in the design process to ensure that the prototypes were driven by patient-centered factors. We found that patient values and preferences for heart failure medications aligned with clinical guideline recommendations that prioritize benefits over risks, cost, and the inconvenience of taking medications. These findings provided reassurance that we were designing a CDS tool that reflected patient priorities.

## Phase 2. Designing the CDS Tool

Following PRISM, stakeholder input is used to design the intervention to maximize the recipient's perceived value and ensure sufficient support infrastructure ([Textbox 2](#)). Such interventions are more likely to be successful and sustained over time. PRISM emphasizes the importance of designing interventions with sustainability in mind.

Once there is general agreement or saturation of ideas [42] from the stakeholders, this information is used to draft the build scope of the CDS tool. The CDS scope includes an idea of the user interface (UI) content, workflow integration, and format (eg, interruptive alert versus passive, mobile app) for interfacing with end users. The clinical informaticist drafts the build scope based on what is clinically relevant, the stated workflow needs and preferences of the stakeholders, organizational priorities, and patient-centered considerations. Aligned with the learning health care system and agile design principles, the first CDS build scope is not intended to be perfect, rather a first iteration [43]. However, every iteration must be vetted to *do no harm*.

Stakeholders suggest many ideas. If they are all followed, the CDS UI may not be intuitive because too much information is presented. It is the role of the clinical informaticist to identify the most salient stakeholder requests and determine the appropriate balance between user-centered design and other determinants of implementation success outlined by PRISM and CDS design best practices. Finding this balance is challenging and varies for each situation. [Textbox 4](#) provides an example of a situation in which stakeholder requests were balanced with CDS design best practices. CDS in health care is fraught with nuances, and design decisions require thoughtful consideration of multiple dynamic and interacting contextual factors. The clinical informaticist also liaises between the stakeholders and build analysts (or they may be the builder), advocating for the stakeholders as appropriate and creatively adapting to the constraints of the EHR technical infrastructure, standards, and local resources to ultimately fit within the clinical workflows. Standards can include norms around the appearance and presentation of CDS tools within the organization or external technical standards to promote interoperability, such as Health Level 7 and use of standardized vocabularies such as SNOMED (Systematized Nomenclature of Medicine) to classify diagnoses.

An important consideration is the most appropriate technical integration format for the CDS tool, which could include the use of native EHR software, web services, or Substitutable Medical Apps Reusable Technology on Fast Healthcare Interoperability Resources applications. Each institution's EHR

offers a unique set of options to integrate CDS tools natively or interface them with external software. A clinical informaticist will be abreast of what technical integration options each institution has available and guides the design accordingly.

**Textbox 4.** Phase 2 case study.

Case study:

When designing the beta-blocker CDS tool, some stakeholders requested that a complete list of patient medications be included in the UI. However, most patients with heart failure are on many medications. Compliance with that request would have significantly decreased intuitiveness of the CDS tool. Balancing this request with CDS design best practices, it was decided not to include a complete medication list within the UI. However, this decision was difficult, given that this was a consistent request from stakeholders and the information influenced their decision-making. Without inclusion of this information in the UI, clinicians who did not recall concurrent medications would have to leave the CDS tool and search elsewhere in the EHR for the information, which decreases the relative advantage of the CDS tool. Later iterations of the CDS tool will consider creative ways to integrate medications with the CDS tool (eg, info button functionality).

### Phase 3. Design and Usability Testing

Following PRISM, at each stage of stakeholder engagement, new insights are learned. As CDS development activities evolve to testing, the format and nature of stakeholder engagement changes, but patient safety issues are always considered. Aligned with PRISM, design and usability testing aim to ensure that the CDS tool is designed well and simple to use. Design testing includes both SMEs and end users, whereas SMEs may be conditionally included in usability testing if their inclusion optimizes general buy-in. Design testing does not necessarily require build completion. However, before usability testing begins, the build should be complete within EHR testing environments and thoroughly tested to ensure that there are no errors. The resolution of build errors maximizes the focus during usability testing on optimizing the end user experience. When possible, the use of >1 UI during design and usability testing can enrich preimplementation design activities [44].

Testing can be completed in a variety of ways. Exemplars of design and usability testing can be found outside of health care [45], but for a variety of reasons have proven difficult to apply in health care. Therefore, here we describe an approach that can be practically applied in health care. Testing in actual clinical scenarios is not always possible in health care; thus, we propose design testing in which static screenshots of the CDS UI are shared with stakeholders, and usability testing with simulated patient scenarios followed by open-ended discussion. Design testing serves to validate whether the stated needs and preferences of stakeholders are accurately represented in the

UI. During design testing, the UI is iteratively updated before commencement of the more resource-intensive usability testing.

During usability testing, proctored simulation coupled with the *think aloud* protocol [46] and open-ended discussion can serve to inform educational materials, identify usability issues before going live, and identify additional areas for improvement, such as unintended consequences. Using the *think aloud* protocol during usability testing simulations can help identify barriers to following the CDS tool. Such barriers can be elaborated on during the open-ended discussion and, when actionable, the CDS tool can be redesigned to address the barrier. Proctored, simulated patient scenarios may not always be feasible given time or other resource constraints. Less resource-intensive usability testing methods could consist of asking end users to test the CDS tool remotely in EHR testing environments at their convenience and reporting back electronically with any feedback.

During design and usability testing, it is important to get end users in the mindset of their clinical workflow and consider (1) all members of team-based care, (2) factors that would impede or aid their workflow (cause alert fatigue versus fit into workflow), (3) whether the CDS tool supports their ability to make an informed decision, (4) whether it makes it easy to take (or incentivize) action, and (5) potential barriers to following the CDS tool's recommendation, especially over time. The determinants of effective implementation and sustainability from PRISM (Textbox 2) and CDS design best practices (Textbox 1) should inform specific questions to be asked during testing. Textbox 5 describes our approach to design and usability testing.

**Textbox 5.** Phase 3 case study.

Case study:

For our beta-blocker CDS tool, design testing occurred via email. Stakeholders were asked for input with specific questions, which we found to be effective and efficient. During usability testing, we incorporated our educational handout as part of the simulations, which resulted in substantial revisions to the handout as a result of end user feedback. Furthermore, during usability testing, we discovered that many clinicians were unaware that respiratory disease was not a contraindication to beta blockers; thus, a statement to address this misconception was added to the UI. Multimedia Appendix 1 provides examples of feedback from stakeholders during design and usability testing and reasons for or not incorporating into the CDS design.

#### Phase 4. Thoughtful Deployment

The implementation and sustainability infrastructure domain of PRISM considers practical measures to facilitate the ease of workflow integration. Adoption is improved when the necessary support to use the intervention is provided, and there is a means to quickly resolve any unintended consequences. Thoughtful introduction into clinical workflows is imperative for the adoption of CDS tools. Deployment should consider how to move the CDS tool into actual clinical workflows and how to communicate the change with end users. Re-engagement with clinical leadership before deployment is also key, especially in situations in which the preimplementation process occurred over a long period of time or for health systems undergoing certain changes.

The decision to implement the CDS tool in a pilot cohort or begin with widespread deployment is an important consideration to resolve any remaining usability or technical errors and to facilitate buy-in. In some instances, it is prudent to begin with a pilot group of users, which may include one clinical department or group of users across departments. The decision to deploy the CDS tool on a large or small scale initially should be informed by the anticipated frequency of exposure, acuity of the clinical situation, and workflow disruption of the CDS tool. In the case of a CDS tool with infrequent end user exposure, widespread dissemination can serve as a natural pilot

when appropriately monitored. Implementing CDS in a pilot fashion can help to bolster buy-in and to discover unintended issues before widespread roll-out.

With every CDS go-live, some communication with end users is needed but the extent should vary based on the complexity of the CDS tool and the anticipated frequency of end user exposure. When exposure to a CDS tool is infrequent or highly intuitive, end user education may not be necessary. However, an interruptive CDS tool that recommends discontinuation of nonsteroidal anti-inflammatory drugs in patients with cardiovascular disease would likely require some education of end users because of its alert frequency and obtrusiveness. In the latter example, end user education may provide a more detailed explanation of why this new tool is being implemented and what the response options provided within the UI mean. For example, the response options may include *never appropriate* without space to explain within the CDS UI that selecting this option will suppress the CDS tool forever for all clinicians. It would be helpful to share such information in the educational material. Many clinicians wish to know the consequences of their actions in response to a CDS tool. Communication plans should be informed by the given health system's standard processes and adapted based on the type of CDS and anticipated impact on the end user. [Textbox 6](#) describes key experiences from our deployment.

#### Textbox 6. Phase 4 case study.

##### Case study:

- For the beta-blocker CDS tool, re-engagement with the leadership of the clinical practices before deployment was pivotal. During our preimplementation planning process, the health system acquired several outpatient practice groups, which resulted in changes in priorities and approaches to decision support. At the beginning of the preimplementation planning stage, we secured leadership approval to deploy the CDS tool across all practices; however, given the changes that occurred, this approval was no longer applicable. Therefore, we needed to solicit approval for deployment from individual practices. Our experience emphasizes the need to maintain frequent engagement with leadership and a nonlinear approach to CDS implementation.
- When soliciting approval from individual practices, we piloted the CDS tool in 2 of the largest practices. These 2 pilot practices expressed early support for the CDS tool. When soliciting approval from other practices, they found it reassuring to know the tool was already accepted by their peers and being tested.

#### Phase 5. Performance Evaluation and Maintenance

PRISM includes the RE-AIM evaluation framework and outcomes. RE-AIM captures a broad and balanced evaluation of the nuances and pragmatic nature of implementation in clinical workflows [31]. Such a multilevel IS framework assesses the representativeness of participants, the extent to which the intervention needs to be adapted, and its sustainability [27-30]. Adaptions to interventions should be anticipated and evaluated. RE-AIM also encourages continuous evaluation and

dissemination of findings to promote observability and thereby optimize implementation and sustainability. [Table 2](#) provides an example of how RE-AIM can be applied to CDS. For example, changes in clinical outcomes are difficult to associate with CDS tools; thus, effectiveness is often measured as a change in behavior. Other instruments and tools can also be used to evaluate CDS tools. The usability of CDS tools can be evaluated using the validated System Usability Scale (SUS) [47].

**Table 2.** Reach, Effectiveness, Adoption, Implementation, and Maintenance evaluation framework applied to clinical decision support.

RE-AIM <sup>a</sup> domain	Described	Potential CDS <sup>b</sup> outcome measures
Reach (individual level)	Proportion and representativeness of those impacted by the intervention (and reasons for these results)	<ul style="list-style-type: none"> <li>• Number of patients the CDS tool fired for divided by the number of patients the CDS tool should have fired for</li> <li>• Characteristics of each group in numerator and denominator</li> <li>• Investigation of reasons not fired</li> </ul>
Effectiveness (individual level)	Impact of the intervention, including heterogeneity across subgroups and any negative outcomes (and reasons for these results)	<ul style="list-style-type: none"> <li>• Number of patients the CDS tool changed care for divided by the number of patients the CDS tool fired for</li> <li>• Characteristics of each group in numerator and denominator</li> <li>• Reasons care did or did not change</li> <li>• Number and type of unintended or negative outcomes</li> </ul>
Adoption (setting and staff at multiple levels)	<ul style="list-style-type: none"> <li>• Proportion and representativeness of those accepting or using the intervention</li> <li>• At levels of health systems, departments, and individuals (and reasons for these results)</li> </ul>	<ul style="list-style-type: none"> <li>• Number of clinicians who responded<sup>c</sup> to the CDS tool (did not outright dismiss) divided by the number of clinicians the CDS tool fired for</li> <li>• Number of patients who the CDS fired for that were not outright dismissed divided by the number of patients the CDS tool fired for</li> <li>• Number of practices, setting or clinicians participating divided by the number invited</li> <li>• Characteristics of each group in the numerators and denominators above</li> <li>• Reasons for or not to participate or dismiss</li> </ul>
Implementation (setting and staff at multiple levels)	<ul style="list-style-type: none"> <li>• Fidelity of the intervention and implementation strategy</li> <li>• Adaptations</li> <li>• Burden of delivery, including costs</li> </ul>	<ul style="list-style-type: none"> <li>• Adaptation: number and type of changes to the CDS build or workflow integration after deployment</li> <li>• Usability of the CDS tool (eg, SUS<sup>d</sup>)</li> <li>• Interviews on experience and adaptations</li> <li>• Cost of implementing (eg, time, resources)</li> </ul>
Maintenance (individual level and setting and staff at multiple levels)	Long-term effects of the intervention and extent the intervention becomes a routine part of care	<ul style="list-style-type: none"> <li>• Long-term outcomes (eg, change in mortality)</li> <li>• Sustained workflow integration and effectiveness</li> <li>• Interviews on intended or actual sustainment or further modification</li> </ul>

<sup>a</sup>RE-AIM: Reach, Effectiveness, Adoption, Implementation, and Maintenance framework.

<sup>b</sup>CDS: clinical decision support.

<sup>c</sup>Technically in PRISM or RE-AIM, adoption is defined as only initial agreement to participate in (or be trained in) a program. In this paper, it will be defined as above to be consistent with how this term is used in informatics and to reflect the fact that end users do not always have the choice to interface with a CDS tool.

<sup>d</sup>SUS: System Usability Scale.

CDS tools are critical components of the learning health care system and should be regularly evaluated for performance and safety. Performance and safety evaluations are necessary for CDS maintenance and assist in minimizing alert fatigue. Evaluations should be scheduled with defined procedures of who is responsible, what the evaluation entails, and when it occurs. What is evaluated should be informed by operational leadership and influenced by external drivers, such as regulatory requirements and pay for performance metrics. The evaluation can also be informed by input from stakeholders regarding unintended consequences. For example, stakeholders might express concern that a CDS tool may lead to an increased risk

of bradycardia; thus, this is an outcome that should be monitored.

Evaluations should not be limited to 1 instance and should lead to action when appropriate. CDS implementation should be an iterative, thoughtful, and continuous improvement process. Proactively seeking end user input during and post exposure also demonstrates commitment to improvement. Findings from evaluations should be disseminated to stakeholders, including appropriate levels of leadership, SMEs, and end users. Appropriate levels of leadership should vary based on the specific CDS tool and do not necessarily require notification at the chief executive level. Communication with individual SMEs

and end users may be at the discretion of and via their direct leaders but should be offered at a minimum. This level of transparent communication can promote trust, improve adoption,

and reduce the culture of negativity that currently exists around CDS and EHRs [48]. [Textbox 7](#) describes key findings from our evaluation approach.

#### Textbox 7. Phase 5 case study.

##### Case study:

- We monitored clinician responses and feedback to the beta-blocker CDS tool weekly to screen for unintended consequences and errors. After 1 month of deployment, a clinician alerted us to an error in the build of our CDS tool, which we were able to resolve quickly. Had our CDS tool fired more frequently, we would likely have identified this error during our 2-week pilot. Such errors are common when a CDS tool is deployed, reinforcing the importance of ongoing monitoring and clear lines of communication between the informatics team and the end user.
- We also conducted brief structured interviews with clinicians exposed to the CDS tool. Together with completion of the SUS survey, the interviews provided valuable open-ended feedback that was used to refine both the CDS tool and our PRISM/CDS best practices approach. Key discoveries made during the interviews were the importance of carefully considering whether to include a dismiss button and avoiding a sense of shaming or disrespect. These discoveries were explicitly added as determinants of implementation success within CDS design best practices in [Textbox 1](#).

## Discussion

### Principal Findings

The PRISM/CDS best practices approach accounts for the multilevel interactions and dynamic factors that influence CDS implementation in health care. IS frameworks make social science more replicable and, by adding the context of CDS to PRISM, the reproducibility and sustainability of CDS implementations should be enhanced. *Integrating PRISM with CDS design best practices synthesizes the many known contextual factors that can influence the success of CDS implementation*, thereby elevating the experience from implementation to IS. This approach can be adapted for other health systems and CDS tools and used to guide resource allocation in a manner that optimizes CDS implementation success.

However, an effective approach may not be optimally efficient. When applying PRISM to CDS, resources include the time and availability of skilled personnel. Especially during the preimplementation period, this approach can require resources that may not be available at every health system or be appropriate allocation to every CDS instance. It may not be appropriate to allocate extensive resources to implementation efforts for CDS tools that are minimally invasive (eg, infobuttons) or address infrequent care gaps or low severity clinical situations. When resources are limited or the situation does not justify the allocation of full resources, stakeholder engagement may be abbreviated. Abbreviated stakeholder engagement may be limited to a smaller sample, representing a few representatives from each stakeholder group. Irrespective of resource availability, stakeholders should include representation from SMEs and end users. If allowed by resources, greater representation reaching saturation and general agreement from SMEs and end users is ideal.

The results of an RCT demonstrating the positive effect of the PRISM/CDS best practice approach on prescribing for heart failure in primary care is currently under review for publication. However, there are several limitations of the PRISM/CDS best practice approach. Although our study team represents diverse expertise, including informatics and IS, the approach was created based on our knowledge and experiences. Inclusion of additional

expertise and experiences across other clinical contexts and situations would likely refine the PRISM/CDS best practices approach. Our approach also relies on one of many IS frameworks and existing CDS design best practices. Other frameworks may have different advantages or disadvantages when applied to CDS. As CDS design best practices and technical capabilities evolve, the PRISM/CDS best practices approach will need to adapt. Further, the PRISM/CDS best practices need to be adapted based on a given institution's available resources and skilled personnel. Despite these limitations, the PRISM/CDS best practices approach provides a basis for advancing the science of CDS implementation.

Future research is needed to apply PRISM to additional real-world CDS implementations to capture all contextual factors and understand its impact on CDS adoption and effectiveness. Although the PRISM/CDS best practices approach was created for adaptation across any health care setting, it was refined within primary care settings across a large health care system. Future research should explore the application of PRISM to diverse CDS formats (eg, mobile apps) in a variety of patient care situations and practice settings of different sizes and identify means to refine the model to maximize effectiveness and efficiency. Use of the PRISM/CDS best practices approach should be documented in terms of its costs and benefits relative to other approaches. A key issue for both PRISM and CDS design best practices is the degree of iteration and number of cycles required for a given implementation. Efforts to improve the efficiency of the PRISM/CDS best practices approach are needed and may include integration with principles of rapid prototyping or tailoring the approach based on the severity of the clinical situation or the anticipated reach or workflow interruption of a given CDS tool. This tradeoff between resource allocation and benefits will have to be evaluated for every setting and clinical situation. Further, given that many of the contextual issues related to CDS are applicable to other types of health IT solutions, the applicability of this integrated approach to health IT beyond CDS should also be explored. Although the PRISM/CDS best practices approach provides guidance on evaluation, future research should consider how the approach can be expanded to include a systematic and standardized knowledge management process to evaluate and update CDS tools.

## Conclusions

We described an approach for applying PRISM to design, implement, and evaluate CDS tools that are integrated with CDS design best practices. Others are encouraged to adapt this approach to their situation to maximize CDS implementation success. This approach considers the many dynamic and interacting contextual factors that influence CDS implementation

success and sustainability in health care and suggests specific methods for designing and implementing CDS. Informed by an evidence-based IS framework, such an approach is foundational to maximizing the success of CDS implementation and the necessary platform from which cutting-edge innovations in CDS can be created to significantly improve and sustain health care outcomes.

## Abstract

**Background:** Epidemiologic cohort studies have begun to leverage electronic research participant portals to facilitate data collection, integrate wearable technologies, lower costs, and engage participants. However, little is known about the acceptability of portal use by research participants.

**Objective:** The aim of this study is to conduct focus groups among a sample of Cancer Prevention Study-3 (CPS-3) participants to better understand their preferences and concerns about research portals.

**Methods:** CPS-3 participants were stratified based on sex, race and ethnicity, age, and cancer status, and randomly invited to participate. Focus groups used an exploratory case design with semistructured guides to prompt discussion. Using a constant comparison technique, transcripts were assigned codes to identify themes.

**Results:** Participants (31/59, 52% women; 52/59, 88% White/non-Latinx) were favorably disposed toward using a research participant portal to take surveys, communicate with the study staff, and upload data. Most participants indicated that a portal would be beneficial and convenient but expressed concerns over data safety. Participants stressed the importance of an easy-to-use and trustworthy portal that is compatible with mobile devices.

**Conclusions:** In addition to being beneficial to researchers, portals may also benefit participants as long as the portals are secure and simple. Participants believe that portals can provide convenient ways to report data and remain connected to the study.

## Introduction

**Background**

A common, contemporary application of health information technology is the electronic patient portal [1]. Electronic patient portals are secure web-based systems that provide patients 24-hour access to their personal health information, enable two-way communication with health care providers, and potentially decrease costs through patient self-service [2,3]. Currently, less than half of US adults use patient portals

annually, although use is more common among younger (younger than 65 years), more educated people with broadband internet access [4,5]. Patient portals also have the potential to facilitate the integration of new technologies for remote monitoring, such as home blood pressure monitors, ecological momentary assessment apps, and other wearable devices (eg, activity trackers and heart rate monitors) at a lower cost [6]. Collectively, patient portals can simplify the collection of patient-generated health data (PGHD), including vital signs (eg, temperature, blood pressure, and blood glucose), lifestyle data

(eg, caloric intake, diet, exercise, and medication adherence), and patient-reported outcomes data (eg, mood, sleep quality, and pain) [7].

The use of electronic health portals has spread beyond the clinical setting. The adoption of commercial products such as Apple HealthKit [8], 23andme [9], and PatientsLikeMe [10] illustrates that an increasingly large number of people are willing to exchange medical and health behavior information with professionals other than their health care providers. Electronic portals have also been leveraged to survey and engage participants in research studies. Similar to the various benefits of patient portals, research participant portals could facilitate the collection of PGHD and data from wearable technologies, provide a way to administer targeted surveys to different subsets of the study population, collect electronic health data, and save costs and time associated with printing and mailing logistics [11]. Portals may be useful for frequently engaging participants in long-term studies, potentially reducing attrition. In addition to the aforementioned researcher benefits, participants may find portals convenient for storage and anytime access to study materials such as copies of consent forms, surveys, and study newsletters or updates.

Despite the potential benefits, very little is known about the feasibility and acceptability of electronic portal use by research participants in longitudinal cohort studies. Participant portals have been adopted by a few prospective cohorts thus far, including the University of California-San Francisco's PRIDE study [12] and the National Institutes of Health All of Us study [13]; however, none of them have published details regarding their portal development and testing. A better understanding of research participants' preferences and concerns about research portals could inform portal design and maximize the benefits to and engagement of participants and researchers.

## Objectives

In this study, focus groups were implemented among a sample of Cancer Prevention Study-3 (CPS-3) participants to facilitate the open sharing of insights largely unavailable through pre-existing surveys, especially (1) research participants' perceptions of the facilitators and barriers to utilizing an electronic research portal; (2) participants' views about using an interactive research portal to submit health records, complete lifestyle and medical surveys, and communicate with study staff; and (3) participants' recommendations for electronic research portals.

## Methods

### Sample Recruitment

CPS-3 is a contemporary prospective epidemiologic cohort study initiated by the American Cancer Society (ACS) [14]. In total, 303,682 participants aged 30-65 years across the United States, including Puerto Rico, were enrolled in CPS-3 between 2006 and 2013. Participants are sent surveys approximately every 3 years to update exposure and medical information and will be followed to identify incident cancers and cause-specific mortality through linkages with state cancer registries and the

National Death Index, respectively. The Emory University Institutional Review Board approved all aspects of CPS-3.

In 2017, plans to develop a CPS-3 participant portal began as a way to increase participant engagement and facilitate survey administration. This effort launched with a series of virtual and on-site focus groups conducted to gain insight into participant perspectives and willingness to share data through a participant portal. Virtual focus groups, offered via conference calls, enabled the inclusion of a broader geographic distribution of CPS-3 participants. To be eligible for virtual focus groups, participants must have been involved with CPS-3 since enrollment (2006-2013) and must have (1) a valid email address and (2) completed the 2018 triennial CPS-3 survey online. On-site focus groups took place in Atlanta, Georgia, and Albany, New York, and allowed participants who had not previously engaged with CPS-3 online to be included. To be eligible for on-site focus groups, participants must have (1) completed the 2018 survey (online or paper) and (2) resided in one of the predefined zip codes near the on-site locations.

Eligible CPS-3 participants were stratified based on sex, race and ethnicity, age group, and cancer status and invited to participate in the portal feasibility focus groups. We used this purposive sampling strategy to ensure adequate representations in focus groups by race and ethnicity, sex, age, and cancer history. Overall, 608 participants were invited, 78 registered to participate, and 59 participated in the focus groups.

### Study Design

The focus groups used an exploratory case design, which is used when there are no clear or predictable outcomes [15,16]. To guide the focus group discussion, semistructured guides were developed before conducting focus groups and were used to prompt group discussions regarding perceived portal benefits, barriers, and preferences (Multimedia Appendix 1). All focus group participants were assigned a pseudonym for anonymity and were asked to introduce themselves using their pseudonym before sharing opinions to ease transcription.

### Qualitative Analysis

All focus groups were audio recorded and transcribed verbatim, excluding phrases like *um* and *uh*. A ground-up or grounded theory approach was used to analyze the data [17]. Open coding was initially performed to code each line of the text. During this process, in vivo codes were generated based on the participants' words. Following the open coding process, the data were coded using axial coding. The open-coded data were iteratively and systematically compared and then linked together using one or more codes. Finally, selective coding was used to identify the core categories that emerged from the data. Selective coding was completed by re-reading the data and coding data that related to these categories.

Coding consensus was used to validate the data. One researcher coded all data, and two additional researchers reviewed all codes and their assignment to the text; any differences in coding assignments were adjudicated until consensus was reached. NVivo 12 (QSR International) was used to store, code, query, and organize all data [18].

## Results

### Sample Characteristics

A total of 11 focus groups were conducted in November 2018, with 7 virtual focus groups (2-8 participants each) and 4 on-site (6-8 participants each). Of the 11 focus groups, 5 consisted entirely of participants sharing an underrepresented demographic

characteristic (1 focus group of all African Americans, 1 virtual and 1 on-site focus group of all older adults [60 years and older], and 1 virtual and 1 on-site focus group of all cancer survivors). The focus group participant (n=59) demographics are presented in [Table 1](#). About half of the participants were women (31/59, 52%) and most were non-Latinx White (52/59, 88%). The age range of participants was 41 to 72 years (mean 59, SD 6 years), with about half over the age of 60 years (32/59, 54%).

**Table 1.** Individual-level demographics (n=608 invited, n=59 participants).

Characteristic	Participants invited (n=608)	Participants registered (n=78)	Focus group participants (n=59)
Women, n (%)	314 (51.6)	41 (52)	31 (52)
<b>Race and ethnicity, n (%)</b>			
Non-Latinx White	458 (75.3)	65 (83)	52 (88)
Black	50 (8)	5 (6)	3 (5)
Latinx	50 (8)	6 (7)	2 (3)
Other	50 (8)	2 (2)	2 (3)
<b>Age group, n (%)</b>			
59 years and under	507 (83.4)	62 (80)	27 (46)
60 years and older	101 (16.6)	16 (21)	32 (54)
Cancer survivor, n (%)	100 (16.4)	11 (14)	8 (15)
<b>Focus group location, n (%)</b>			
Virtual	406 (67)	46 (59)	31 (52)
On-site	202 (33)	32 (41)	28 (48)

As an introduction to the topic of electronic portals, participants were asked about their current portal use. Most, although not all, of the participants were familiar with the concept of online portals, and many already use them with their health care providers and/or banks. On the other hand, there were 3 on-site and 2 online focus group participants who stated they “have no experience with online portals,” “don’t know” if they have access to one or have ever used one, or “have not set up” a portal. Most participants described the benefits and barriers to general portal participation, including improved communication with health care providers, appreciation for 24-hour access to health care records, and concerns about private health information remaining secure. These benefits and barriers were also consistent with the existing literature on patient portals [19-23].

### Benefits of Research Portals

The majority of participants indicated that a research participant portal would be beneficial. Participants cited convenience as the main benefit of portal use. For example, one participant described the convenience of the all-hours access:

*...being able to access 24/7 is very helpful. It's the convenience, and then also you get two-way feedback. It's more interactive.*

Other benefits ([Textbox 1](#), theme 1) include appreciation for having all their study material at one place:

*...I would say convenience, being able to access [the portal] on my phone...all my data is in one place. I don't have to keep a lot of paper that I'm worried about getting in the wrong hands.*

**Textbox 1.** Additional quotes by theme.**Theme 1: Perceived portal benefits**

## Subtheme: convenience

1. "Same thing with the [CPS-3 study] newsletters, you can go back and access, but a lot of us read them and then we possibly throw it out or it ends up in a pile somewhere. We don't remember where it is. I think that's going to be a great advantage of having the portal."
2. "I would like having it all in that one portal. It's there, it's handy. You can go back. If I travel, I have the app on my phone. I can pull it up, it's there"

**Theme 2: Portal use concerns**

## Subtheme: worried about data privacy

1. "I volunteered to do this study for discovery of treatment or diagnoses to better peoples' health. I think that should be limited to that only. ... it's not happening in health data yet, but the selling of stuff to other people. That kind of thing should not happen."
2. "...what nags me about the online portals is, how much information am I giving out? Who is actually seeing this? And how do I know it's secure, whether it's coming or going?"

## Subtheme: not concerned about data privacy

1. "I'm okay with my information being used for educational purposes and by colleges and by universities and students and professors for purposes of figuring out what's going on to heal cancer patients and stuff like that."

**Theme 3: Information accessed or shared through the portal**

## Subtheme: comfortable sharing information

1. "I don't mind sharing all that information with the American Cancer Society in relation to this study, and I wouldn't mind my doctor sharing it directly with them. I have no qualms with any of that."
2. "...the whole point like somebody said, we chose to be participants in this study to gain information, so I would think you would want, and need said information. I'm fine. If I wasn't fine, I wouldn't participate in the study in the first place, so I'm fine sharing that information with them. Again, presuming it's all confidential..."

## Subtheme: not comfortable sharing certain information

1. "I'm okay with sharing most information, especially regarding research. The one piece of information I probably would not be as comfortable with is anything that relates to sex."
2. "I think it's hard for people to share any kinds of mental health or certain diagnoses, and I think cancer, or any kind of chronic illness might be that. Because if you need to find health insurance, sometimes I think there is a feeling that it's going to be...people are going to know it, and you're not going to be able to get insurance, or life insurance. If somehow, they can access this information."

**Theme 4: Communication with the American Cancer Society staff**

## Subtheme: comfortable communicating

1. "The ease of both ways communication with using a portal what strikes me if it's on my screen, I get a message, or I'm asked a question, I'm likely to respond. If I get something in the mail or that's going to get lost in the shuffle."
2. "I'm going to look at what the letters are after the name. Does it say RN? Is the person who's answering my question properly trained to have answered my question? That would be my concern, not whether it's John Smith, RN, but whether it's RN or not. In terms of knowing who all the people are who are involved, when would we ever know that? That doesn't seem relevant to me, whereas the qualifications of the person to respond matter a lot."

**Theme 5: Cancer Prevention Study-3 (CPS-3) portal desires**

## Subtheme: CPS-3 study information

1. "...any successes where the researchers have used our data to help point them at some conclusions that are going to have an impact, certainly we've all gotten in to this so that we would have an impact and if we can be rewarded with milestones, it would be wonderful."
2. "I'd like to see how many people participate and how many of these poor people have gotten cancer in the meantime and how long it's been going on and all that."

## Subtheme: security

1. "That two-factor authentication gives me a much more better comfort level."

## Subtheme: portal-based surveys

.

1. "...if I know ahead of time that the survey's gonna take longer then I'm probably gonna be okay with it... but if I start a survey and I don't know how long it's gonna take and it's going on forever, I'll quit it."
2. "I would want to know... can I save it and stop and come back to it? And/or is there any information that I need other than just my memory to take this survey, or to think about before I actually start taking it?"

Subtheme: technical support

1. "I personally find online customer service chats to be way more effective and easier than phone calls. You have a transcript, too, afterwards when you're done."
2. "I don't really perceive needing any assistance, just the basic. Being able to call an 800 number or chat with somebody online if there was a difficulty."
3. "I must have 35 passwords. Between remembering capital, star, or whatever it is, space and all that stuff and if you're not exact then you don't get in. If you're only doing it once every three months, it's difficult. It just needs to be easily you can retrieve a password."

## Research Portal Use Concerns

Participants' concerns were focused largely on data privacy, including data storage and use (Textbox 1, theme 2). For example, many participants felt uninformed about how their data would be used and by whom:

*I would be concerned as to how long that data would be stored. I mean if the study's only going to be 20 years, what happens to the data at the end of that 20 years?*

Several participants also specifically mentioned concerns about their data being accessed by employers or insurance companies, impacting their careers and/or insurability:

*I think that in light of the pre-existing condition kind of controversy out there, I would have the same concerns that my insurance company would get that information and use that somehow against me.*

A few participants shared that they generally do not trust the internet, with one explaining:

*I don't know that much about the internet and the ethernet or whatever they call it, but who knows who could get a hold of... my medical records going across the airwaves, I don't know.*

Conversely, some participants did not feel worried about data privacy. One participant reported the following:

*I don't know that I have concerns. I was assuming the information would be used for research in order to help prevent cancer...I'm trusting.*

## Information Accessed or Shared Through the Research Portal

Many participants expressed willingness to share certain types of information through portals, such as CPS-3 survey responses, medical records, and/or data from electronic devices (eg, wearable physical activity monitors and blood pressure monitors; Textbox 1, theme 3). When prompted, a few participants said they were willing to "share whatever [researchers] want". Another participant stated:

*One of the reasons we signed up for this study was we wanted to give information so that it could be used for future generations... I have no problem sharing everything.*

On the other hand, several participants expressed reluctance to share information they perceived as more sensitive, such as details regarding their mental health or sexual habits (Textbox 1, theme 3, subtheme: not comfortable sharing certain information, quote 1). One participant shared:

*I think anything with mental health, there's still a stigma there. So, if I have [mental health] issues... I would not feel comfortable sharing.*

Participants were also hesitant about providing too many personal identifiers on a portal:

*The things I don't feel comfortable sharing, I guess on health-related sites, would be my social security number, my Medicare number, things that other people can use to really get access to information about me and use in other harmful ways.*

Several participants drew a clear distinction between patient and research participant portals. They expressed a willingness to share details on patient portals but set limits on the amount of information they would share on research participant portals. One participant described the conditions required for sharing medical information with researchers:

*I'm a little concerned about keeping a clear distinction between researchers and medical providers...I'm willing to provide some of my medical records to researchers as long as I'm clear as to what they're doing with that and how they're asking that I transfer any kind of medical information aside from just surveys.*

In contrast, other participants clearly understood the distinction between patient and research participant portals and felt equally willing to share their information through both:

*I think the portal for our personal physician is a different situation. There it helps the patient/physician interaction and helps save time for both parties. As far as a portal for this study or studies like this, I think it's very important to assist research. I'm a big fan of sharing information in an anonymous fashion to help the research parties involved.*

## Communications With Study Staff

When asked, most participants expressed a willingness to receive and respond to messages through the participant portal (Textbox

1, theme 4). Further, participants felt that two-way communication would improve study engagement, as exemplified in this participant's thoughts:

*I would like to feel more connected to the study... I don't even know how often we get the opportunity to participate in answering a survey. And sometimes I don't feel connected to it. I feel like, "Have I missed one because I missed that email?"...more communication with the ACS in regards to the study might help me feel more connected to it.*

These perspectives were echoed by other participants:

*I think the communication piece is really important and even as we take surveys, now I sometimes find certain questions not as clear as I would like them to be, it would give us that avenue to offer good feedback to the team working on it in the first place.*

However, as another participant noted, some understanding of the study staff credentials would ease communication:

*I want to know a little bit about who's responding, so if the responder has some certification or some specialty in whatever the information they're providing, that would be really helpful to know. I don't want to take information on face value unless I know that it's coming from someone who has a background, at least, and experience.*

### Features of a Research Portal

Participants expressed a desire for a "well-designed [portal] that is user-friendly" and "doesn't have a lot of bells and whistles." Participants made several specific recommendations for features and content they would like to see on a research participant portal. For example, several participants hoped to find information regarding participant demographics (Textbox 1, theme 5), study design, and research findings on the portal:

*I'd like to see some updates, some CPS-3, some just in general, regarding the work they're doing. Then, also, maybe a section for comments or questions.*

Participants also spent time discussing their wish for a safe and secure portal, with several participants advocating specifically for two-step verification:

*I like a two-step validation or verification process...while it is a little inconvenient because it requires extra steps is, if I'm going to log onto a portal, the portal will send a message to my cell phone with a code and then to complete the login, I have to use the code. I like that kind of two-step authorization.*

Most participants expressed openness to completing regular surveys through the portal. During these discussions, the topic of preferred survey length frequently arose, with several participants stating that they were willing to commit "as long as it takes" or however much "time [the surveys] require." However, other participants had specific suggestions for maximum survey length and administration frequency:

*I think 15 to 20 minutes for a survey is an appropriate amount of time for me and how often, two or three times a year I think would be okay.*

Other participants suggested providing clear indicators of survey length (Textbox 1) by adding a completion bar or page countdown to help them manage their time while taking more lengthy surveys:

*I'm more likely to finish the survey if during it, it tells you how far you are so that you know if you're getting close to the end or not.*

Finally, many participants discussed the importance of technical support (Textbox 1, theme 5). Participants expressed concerns over having too many passwords and reiterated the importance of some sort of technical support to quickly retrieve a new password:

*I would like just a quick password reset email if necessary. Something quick as opposed to 20 minutes later and perhaps an online video if things get very technical.*

## Discussion

### Principal Findings

In this qualitative study, we investigated epidemiologic cohort research participants' perspectives and expectations of an electronic portal for study engagement and data collection. Through 11 focus groups, we found that most participants were favorably disposed toward the concept of using a portal to participate in the cohort study as long as the portal is secure and easy to use. Many themes that arose in this study were consistent across groups. Importantly, we were able to recruit enough participants to gain an understanding of how research participants in longitudinal cohort studies may view the implementation of an electronic portal. Given that the final focus group did not produce any significant new information, we can assume that we achieved data saturation. This suggests that participants in CPS-3 and other longitudinal cohort studies might be willing to use a research portal that has the potential to benefit both researchers and participants.

Some of the themes that arose in this study regarding research participant portals were similar to those documented in the literature regarding health care patient portals. For example, the most commonly discussed perceived benefit in this study was convenience, especially regarding access to research records anywhere, at any time, with a variety of electronic devices, which also applies to health care portals [19,20]. Similarly, the most commonly cited concern was data privacy and protection, including hacking, data sharing, and password management [20,24]. Although participants were informed of data privacy and protection at the time of CPS-3 enrollment, continuing to educate and inform participants is clearly important, and a participant portal would make it easier to do so. Given the similarities in the themes presented here and in patient portal research, it is possible that some findings regarding the design and implementation of patient portals may be applied to research portals. This is potentially important as there is considerably

more research on the use of portals for health care purposes than on the use of portals for research purposes.

Several novel concepts relating specifically to research participant portals have emerged. Generally, participants were willing to upload medical records, connect wearable devices, and share other PGHD through an electronic portal outside of a health care setting. Although most participants were open to completing surveys on the portal, many wished to be informed of the survey duration before and/or during administration. Similarly, participants expressed their preference to save responses and complete surveys at a time that is convenient for them. Participants' willingness to provide survey data appears to be based primarily on the altruistic belief that the data could benefit others through research findings. Although altruistic motivation for research participation may not be a novel concept [25], it is useful to understand these motivations when considering how to communicate the importance of logging in and participating on the portal. Finally, most participants were willing to communicate with the study staff through the portal, although several participants mentioned the importance of understanding the staff member's credentials.

On the basis of the participant feedback provided through the focus groups, we recommend that research participant portals be easy to use and function on all platforms (eg, mobile phones, tablets, and all commonly used web browsers). Given participant concerns regarding data privacy and protection, it is essential to design a portal with robust security (eg, dual-factor authentication) and easy access to data privacy policies from the signed informed consent form. Research participant portals should also provide timely technical support. Surveys administered through a portal should include progress bars and options to save and return to the survey later. The findings also suggest that a portal would be more appealing to participants if it connects and engages them through information on new study findings and discoveries.

## Strengths and Limitations

This study has some limitations. First, the level of transferability (ie, the degree to which these findings can be applied to other groups or initiatives) of these results is unclear, particularly as the participants in this study have already demonstrated a long-term commitment to a longitudinal cohort study. Additionally, although several underrepresented groups were present in our focus groups, we did not have large enough subgroup sample sizes to consider differences by group. Similarly, only 2 participants were present for one of the online focus groups, although more had initially registered; thus, group discussion may have been affected for that particular group. Although it is beyond the scope of this study, more consideration around the real-world integration of electronic research portals is needed, especially as participants presumably begin to gain access to more electronic patient portals through their health care providers. Future research should identify ways to simplify the implementation and management of research portals for both participants and study staff. Despite these potential limitations, this study is, to our knowledge, the first to systematically investigate the views of research participants regarding online research participant portal use.

## Conclusions

Participant portals may be beneficial to researchers for facilitating new data collection, integrating wearable technologies, administering targeted surveys on special topics to subset populations, saving costs and time compared with mailed surveys, and engaging participants between survey cycles. For participants, portals have the potential to reduce burden by providing convenient ways to report data, review study materials, and remain connected to the study. The rich data from these focus groups provide a rationale for building a research participant portal and information to inform the design of the portal. To achieve these potential benefits, portals should be easy to use, secure, trustworthy, and compatible with a variety of devices.

## Abstract

**Background:** Recruitment of health research participants through social media is becoming more common. In the United States, 80% of adults use at least one social media platform. Social media platforms may allow researchers to reach potential participants efficiently. However, online research methods may be associated with unique threats to sample validity and data integrity. Limited research has described issues of data quality and authenticity associated with the recruitment of health research participants through social media, and sources of low-quality and fraudulent data in this context are poorly understood.

**Objective:** The goal of the research was to describe and explain threats to sample validity and data integrity following recruitment of health research participants through social media and summarize recommended strategies to mitigate these threats. Our experience designing and implementing a research study using social media recruitment and online data collection serves as a case study.

**Methods:** Using published strategies to preserve data integrity, we recruited participants to complete an online survey through the social media platforms Twitter and Facebook. Participants were to receive \$15 upon survey completion. Prior to manually issuing remuneration, we reviewed completed surveys for indicators of fraudulent or low-quality data. Indicators attributable to respondent error were labeled suspicious, while those suggesting misrepresentation were labeled fraudulent. We planned to remove cases with 1 fraudulent indicator or at least 3 suspicious indicators.

**Results:** Within 7 hours of survey activation, we received 271 completed surveys. We classified 94.5% (256/271) of cases as fraudulent and 5.5% (15/271) as suspicious. In total, 86.7% (235/271) provided inconsistent responses to verifiable items and 16.2% (44/271) exhibited evidence of bot automation. Of the fraudulent cases, 53.9% (138/256) provided a duplicate or unusual response to one or more open-ended items and 52.0% (133/256) exhibited evidence of inattention.

**Conclusions:** Research findings from several disciplines suggest studies in which research participants are recruited through social media are susceptible to data quality issues. Opportunistic individuals who use virtual private servers to fraudulently complete research surveys for profit may contribute to low-quality data. Strategies to preserve data integrity following research

participant recruitment through social media are limited. Development and testing of novel strategies to prevent and detect fraud is a research priority.

## KEYWORDS

social media; internet; methods; data accuracy; fraud

## Introduction

Health research participants are increasingly recruited online [1]. Researchers may access potential research participants through a variety of online sources, including classified advertisements, search engine advertisements, survey panels, email listservs, crowdsourced online labor markets, and social media platforms [2-4]. Recruitment of health research participants through social media is particularly popular and has been reported in at least 69 unique papers published between 2011 and 2019 [5-7].

Recruitment of health research participants through social media may appeal to researchers for several reasons. First, 80% of US adults use social media, and rates of social media use exceed 60% in almost every sociodemographic category for which data are available [8]. Although only 40% of US adults aged 65 years and older use social media, this proportion has grown substantially from 12% in 2010 [8]. Second, social media platforms permit researchers to target advertisements to users according to their age, gender, education, location, interests, and behaviors [9]. Targeted social media advertisements enable researchers to direct their recruitment efforts toward individuals who are likely to meet study eligibility criteria. Third, the practical and ethical considerations of recruiting health research participants from social media have been well characterized. Guides to using social media to recruit participants to health research studies are available in the peer-reviewed literature and are increasingly produced by academic institutions [9-14]. Likewise, several authors have proposed approaches to ensure the protection of human research participants who are recruited through social media [11,13,15].

Researchers have sought to describe the extent to which participant recruitment through social media is cost-effective and efficient [2-4,7,16-19]. Although study results vary, some researchers suggest the use of social media may be more efficient and affordable than traditional recruitment methods in clinical settings [5]. Likewise, there is evidence that social media platforms effectively provide researchers with a way to access members of small or difficult-to-reach populations [7,11,12,16,20]. Despite these findings, studies in which research participants are recruited through social media are vulnerable to the same challenges associated with other methods of recruiting research participants online [21,22]. Respondent misrepresentation of eligibility criteria, duplicate enrollment, and automated enrollment by software applications known as

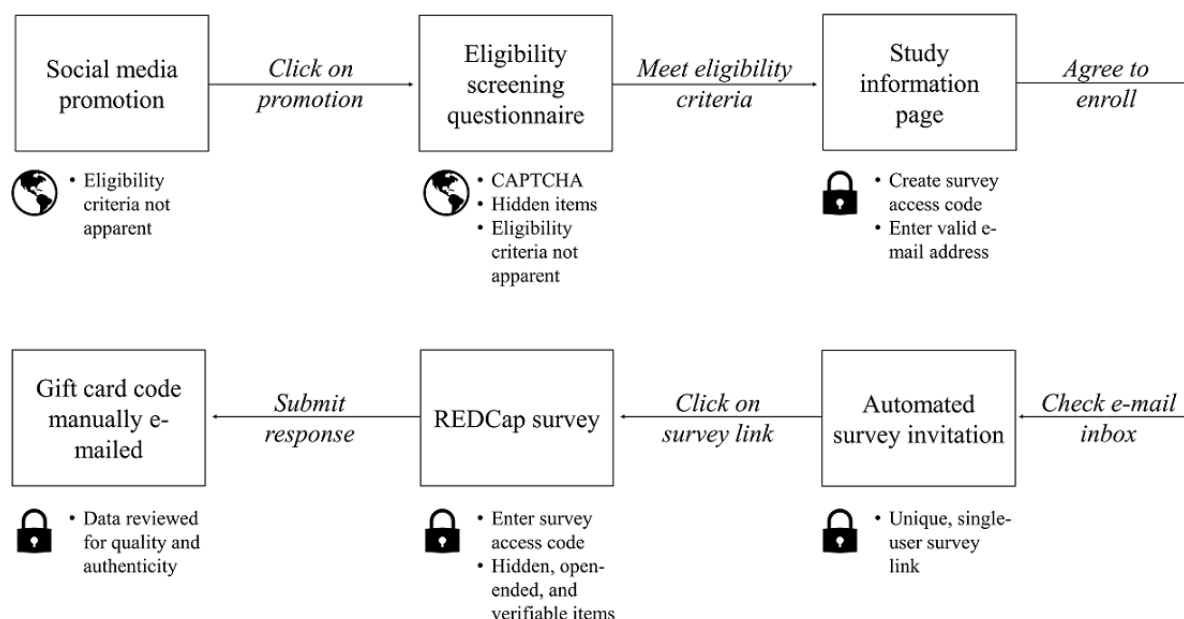

bots pose serious threats to sample validity and data integrity [23]. Nevertheless, these challenges are poorly described in the health sciences literature, particularly as they relate to the recruitment of health research participants through social media.

Ongoing development of best practices for all aspects of online research is necessary to encourage rigor and ensure judicious use of limited resources. The purpose of this paper is to describe and explain potential threats to sample validity and data integrity associated with the recruitment of health research participants through social media. We use our recent experience recruiting health research participants through social media as a case study. Drawing upon this example and from published research within and outside of the health sciences literature, we aim to provide a comprehensive overview of strategies that may be used to mitigate these threats.

## Methods

We designed a cross-sectional descriptive study that elicited patient perceptions of patient-provider communication in the ovarian cancer care setting. At the time of initial recruitment, eligible participants were English-speaking US adults diagnosed with ovarian cancer within the last 12 months. We planned to recruit participants through the Facebook and Twitter social media platforms and collect data online through a Research Electronic Data Capture (REDCap) survey [24]. Upon survey completion, valid participants would be issued a \$15 electronic gift card. The Dana-Farber/Harvard Cancer Center institutional review board (IRB) approved the study protocol.

We developed our study protocol (Figure 1) after reviewing published guides to recruiting health research participants online [9,11,23,25] and seeking advice from our institution's REDCap administrators and survey research core. First, we created a study page on Facebook and study account on Twitter. Next, we developed and planned to disseminate a set of Facebook posts, targeted Facebook advertisements, tweets (Twitter posts), and targeted Twitter advertisements. The Facebook page, Twitter account profile, Facebook posts, tweets, and targeted advertisements each included a brief overview of the study purpose and link to an eligibility screening questionnaire. Promotions described a gynecologic cancer communication study rather than an ovarian cancer communication study to prevent respondent misrepresentation of eligibility criteria [9,11]. No other details related to eligibility criteria were apparent from study promotions.

**Figure 1.** Procedure for participant recruitment and enrollment.

To access the eligibility screening questionnaire, respondents were required to pass a completely automated public Turing test to tell computers and humans apart (CAPTCHA) [23,25]. The eligibility screening questionnaire asked respondents to report how they heard about the study and used branching logic to deny access to ineligible respondents [25]. Respondents who reportedly met eligibility criteria were directed to a study information page that included all elements of informed consent. The study information page informed respondents that remuneration was limited to one gift card per participant and evidence of fraudulent activity may result in study removal [23]. Respondents who agreed to enroll in the study were prompted to provide their email address and create a survey passcode. Enrolled participants received automated emails containing a unique survey link and were required to enter their passcode to access the survey.

The survey included 124 closed- and 14 open-ended items. We pretested the survey and estimated that it would require 15 minutes to complete. We designed the survey to include several elements aimed at identifying low-quality or fraudulent responses. These included (1) a timestamp at the beginning and end of the survey, (2) hidden items, which are visible to bots but invisible to human respondents, and (3) pairs of items that could be used to identify inconsistent or illogical responses (eg, timestamp time zone and self-reported location). Prior to manually distributing participant remuneration, we planned to review completed surveys for evidence of inattention, duplicate or unusual responses to open-ended items, inconsistent responses to verifiable items, and evidence of automation. Specific examples from each of these categories are provided in the Results section.

We initiated recruitment with a single tweet that read “Help researchers learn about communication in gynecologic cancer care. Fill out a research survey from Dana-Farber Cancer

Institute and receive a \$15 Amazon gift card. Visit [link to the eligibility screening questionnaire] to learn more.” We also added the link to the eligibility screening questionnaire to the study Facebook page and Twitter account profile. We scheduled targeted advertisements to be launched at a later date.

## Results

Less than 7 hours after initiating recruitment, 576 respondents had completed the eligibility screening questionnaire. We suspected fraudulent activity after noting that although eligibility was limited to US residents, 82.5% (475/576) of responses to the eligibility screening questionnaire were submitted between the hours of midnight and 4:00 am Eastern Standard Time. In turn, we removed the tweet containing the link to the eligibility screening questionnaire, deleted the link from the Facebook page and Twitter account profile, and temporarily deactivated the survey.

Of the respondents who completed the eligibility screening questionnaire, 47.0% (271/576) reportedly met eligibility criteria, enrolled in the study, and completed the survey. Of the completed surveys, 47.2% (128/271) were submitted between the hours of 1:00 and 5:00 am in the participant’s reported time zone. The mean time to survey completion was 12.8 (SD 14.8) minutes. Three members of the study team (RP, MJH, and DLB) assessed completed surveys for quality and authenticity. We began by highlighting evidence of inattention, duplicate or unusual responses to open-ended items, inconsistent responses to verifiable items, and evidence of automation in each case. Next, we documented the specific indicators of low-quality or fraudulent data that were present in the data set. Indicators that could reasonably be attributed to respondent error or coincidence were labeled as suspicious, while those that strongly suggested automation or respondent misrepresentation were labeled as fraudulent (Table 1). Given the possibility that some legitimate

respondents could have completed the survey between the hours of 1:00 and 5:00 am, we opted not to include hour of survey submission on our list of indicators.

We classified cases with 1 fraudulent indicator or at least 3 suspicious indicators as fraudulent, cases with no fraudulent indicators and 1 to 2 suspicious indicators as suspicious, and cases with no fraudulent or suspicious indicators as legitimate.

In total, we classified 94.5% (256/271) as fraudulent, 5.5% (15/271) as suspicious, and none as legitimate. Most cases (241/271, 88.9%) exhibited more than 1 type of indicator of low-quality or fraudulent data. Of the fraudulent cases, 52.0% (133/256) exhibited evidence of inattention, with survey

completion times under 5 minutes in 24.6% (63/256) of cases and under 10 minutes in 27.3% (70/256) of cases. More than half of the fraudulent cases (138/256, 53.9%) included a duplicate or unusual response to an open-ended item. For example, in response to an item asking if participants wished to share anything else about communicating with doctors and other health professionals, 2 respondents entered “professional and technical personnel carry out film packaging management.” In response to an item asking participants what recommendations their clinicians had made about surgery, 6 respondents entered “the first choice surgery excision treatment, surgery pathology.”

**Table 1.** Indicators of low-quality or fraudulent data.

Indicator	Designation
<b>Evidence of inattention</b>	
Survey completion time <5 minutes	Fraudulent
Survey completion time <10 minutes	Suspicious
Same response provided to every closed-ended item on a survey page (straight lining)	Suspicious
<b>Duplicate or unusual responses to open-ended items</b>	
Exact response (consisting of more than 2-3 words) provided by more than one respondent	Fraudulent
Response is nonsensical or irrelevant to item	Suspicious
Several responses follow the same pattern in terms of phrasing or formatting	Suspicious
Response is an exact duplicate of text found on an existing website	Suspicious
<b>Inconsistent responses to verifiable items</b>	
Reported location and zip code prefix do not match	Suspicious
Reported location and timestamp time zone do not match	Suspicious
Reported treatment facility is not a cancer care facility	Suspicious
Timestamp time zone indicates survey was completed outside of the United States	Fraudulent
Response to “Where did you hear about this survey?” identified an organization that was not involved with recruitment	Suspicious
<b>Evidence of bot automation</b>	
Response provided to one or more hidden items	Fraudulent

In total, 86.7% (235/271) of cases included an inconsistent response to 1 or more verifiable items, and 16.2% (44/271) included a response to a hidden item. Every case that included a response to a hidden item and had valid timestamp data (25/271, 9.2%) exhibited a survey completion time under 2 minutes.

After consulting with our institution’s IRB, we removed fraudulent cases from the study without remuneration. We issued remuneration to the 15 respondents whose cases were classified as suspicious; however, we will exclude these cases from planned data analyses. We reinitiated recruitment by creating a duplicate REDCap project with a new URL. The new URL was not posted publicly; rather, promotions were limited to targeted Facebook advertisements and Facebook posts in private groups. Several months after successfully reinitiating recruitment in this fashion, we received 3 completed surveys in rapid succession. Upon review, we classified these cases as fraudulent. On review of Facebook user engagement with our targeted advertisements, we determined that a Facebook user who met

our targeting criteria had shared one of our advertisements in a public Facebook post. We promptly removed the advertisements from Facebook and reinitiated recruitment using a third REDCap project URL without further issues.

## Discussion

### Principal Findings

Our initial attempt to recruit health research participants through social media resulted in a large volume of low-quality and fraudulent data. Although we implemented strategies to prevent respondent misrepresentation of eligibility criteria and automated enrollment, hundreds of respondents navigated past checkpoints meant to restrict access to eligible human respondents.

Although our study protocol was informed by published guidance on the recruitment of health research participants through social media [9-14], discussions of data quality and

authenticity are largely absent from these works. Likewise, existing discussions of data quality and authenticity may be embedded in articles that discuss the challenges of online research more generally [23,25]. Researchers who consult the literature prior to recruiting health research participants through social media may overlook articles that do not refer to social media explicitly.

Our experience suggests studies in which research participants are recruited through social media are susceptible to many of the same pitfalls as studies in which participants are recruited through other online means [25-28]. In a related example, Dewitt and colleagues [22] conducted a cross-sectional descriptive study in which data were collected via web-based survey. The study team recruited research participants through an electronic mailing list and Facebook. Following data collection, they found that 60.5% (289/478) of completed survey responses were fraudulent. Similarly, Ballard and colleagues recruited research participants through an unspecified social media platform [21]. Following data collection, they determined that of the survey responses, 28.3% (117/414) were fraudulent and 10.1% (42/414) were potentially fraudulent. It is possible that the proportion of fraudulent responses was higher in our study because we shared the link to our eligibility screening questionnaire on both Facebook and Twitter. Nevertheless, these findings highlight the need to address issues of sample validity and data integrity as they pertain to the role of social media in health research.

Although issues of data quality and authenticity are not unique to studies in which research participants are recruited online, individuals who intend to defraud researchers may find that technology permits them to do so on a larger scale than would otherwise be possible. For example, bots can be programmed to rapidly complete online surveys. However, our experience and those of others suggest that the majority of fraudulent data cannot be attributed to bots alone [21,28]. All respondents in our study were able to pass a CAPTCHA, and only 16.2% (44/271) responded to one or more hidden survey items. Although some bots may be capable of passing a CAPTCHA and generating a fraudulent email address [22], access to our survey was restricted to respondents who provided a valid email address and had access to its inbox. Moreover, most respondents successfully identified a cancer treatment facility in the United States and entered a zip code prefix in the same geographic region. These activities require a degree of sophistication characteristic of human respondents [28].

Several authors have observed that *satisficing*, in which eligible respondents expend the minimal amount of cognitive effort needed to complete a survey, contributes to low-quality data

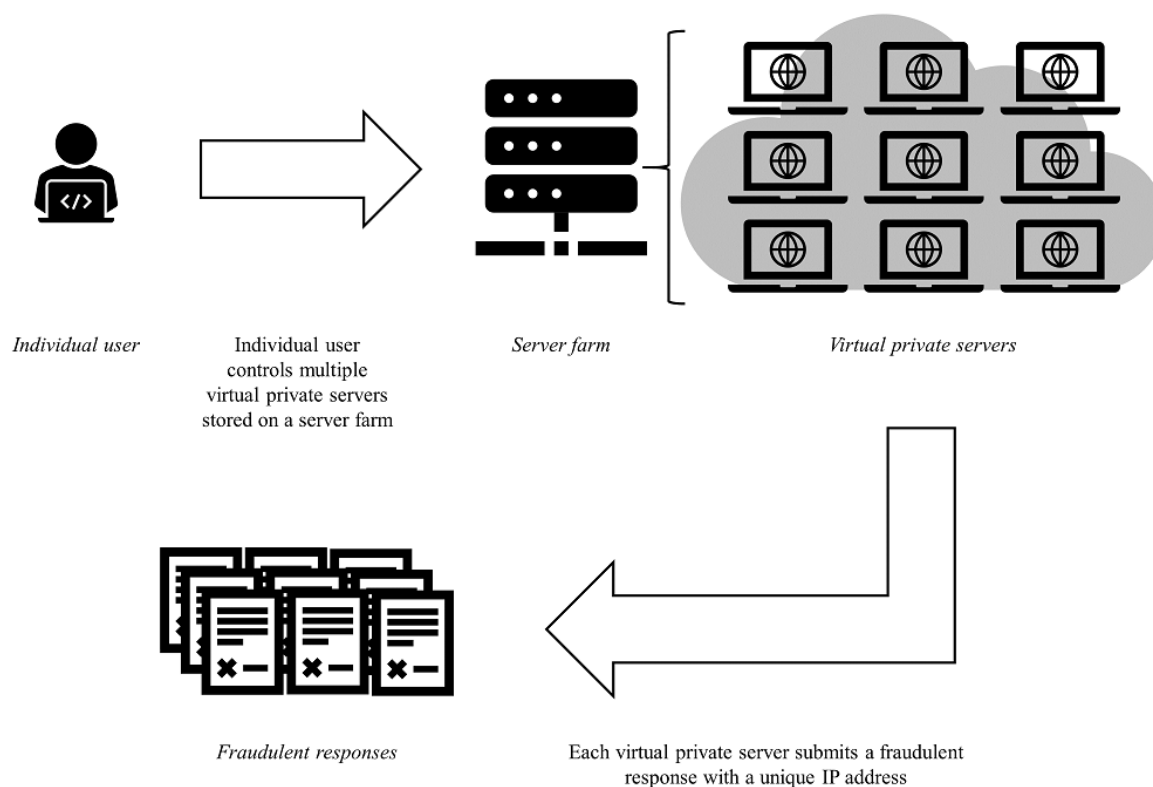

[29,30]. One limitation of our fraud detection protocol is the overlap between indicators of fraud and indicators of satisficing. However, given the speed with which we accumulated low-quality data, it is likely that our results largely reflect a coordinated effort by ineligible respondents to obtain remuneration rather than sample-wide satisficing. Groups of individuals who intend to defraud researchers may exchange information about online research studies that provide financial incentives [23]. Moreover, in a 2019 blog post, the founder of a company specializing in market research identified at least one website dedicated to training individuals to fraudulently complete large volumes of online surveys [31]. Although the phenomenon of respondent misrepresentation has been identified in the health sciences literature [25], the mechanisms by which low-quality and fraudulent survey responses are submitted by human respondents are poorly described. Improved understanding of this phenomenon is necessary to prevent the exploitation of research studies in which participants are recruited through social media and other online means.

### Role of Virtual Private Servers

Research from other disciplines offers insight into strategies used to defraud researchers who recruit research participants online. In the field of behavioral accounting, Dennis and colleagues [28] described 2 studies in which they recruited research participants through Amazon's Mechanical Turk, a crowdsourced online labor market. They received a large volume of responses that exhibited many of the same indicators of low-quality or fraudulent data that were present in our data. The authors used internet protocol (IP) address geolocation to identify the source of these responses and discovered multiple IP addresses with identical global positioning system coordinates. On further investigation, the authors determined that the IP addresses in question were associated with both a server farm and an internet service provider known to provide virtual private servers (VPSs).

Server farms are large collections of computer hardware housed in a single location. Server farms provide users with remote access to hardware with a processing capacity that exceeds that of a single computer. Each server farm can host a nearly unlimited number of VPSs, each of which functions like an individual computer but lacks its own physical hardware [28]. Like a physical computer, a VPS comprises data files, software programs, and an operating system [28]. An individual using more than one VPS would be able to use one physical computer to remotely program multiple VPSs to complete research surveys at the same time (Figure 2).

**Figure 2.** The role of virtual private servers in research participant misrepresentation.

Responses that originate from one individual using more than one VPS may be difficult to identify. Each VPS has a unique IP address associated with the physical location of the server farm rather than that of its user [28]. An individual using more than one VPS may masquerade as multiple respondents, each with a unique IP address. Furthermore, an individual using a VPS hosted on a server farm within the United States may mask his or her true location and circumvent strategies to limit study enrollment to US residents [28,32].

A VPS is not the only way in which an individual can mask his or her location. Virtual private networks, anonymous proxies, and spoofed IP addresses may be used for the same purpose. It is important to note that some individuals conceal their location or IP address out of privacy concerns and may not have malicious intent [32]. However, research suggests VPS use is associated with the collection of low-quality and fraudulent data following online recruitment of research participants.

Dennis and colleagues [28] used respondent IP addresses to compare the data they received from respondents who used a VPS to the data they received from those who did not. In open-ended item responses, respondents who used a VPS exhibited significantly higher proportions of English language misuse, incoherent or nonsensical phrases, duplicate responses, and responses that were copied verbatim from an existing website. The similarities between the responses received by Dennis and colleagues and our study team suggest individuals who use a VPS to defraud researchers are active outside of crowdsourced labor markets and may enroll in research studies that recruit participants through social media. The implications

of this finding for data quality are especially concerning given a recent analysis by Kennedy and colleagues [32], who analyzed 38 studies that recruited research participants through Amazon's Mechanical Turk and found evidence of respondents using a VPS as early as 2015.

### Strategies to Preserve Sample Validity and Data Integrity

Published papers within and outside of the health sciences literature offer suggestions to avoid collecting low-quality and fraudulent data from research participants recruited online. Although most strategies are applicable to studies that recruit research participants through social media, we provide additional suggestions that are specific to this approach. Limited research describes strategies to identify respondents using a VPS. Herein, we summarize the progress that has been made in this area to date and identify topics in need of further development. Strategies to prevent collection of low-quality or fraudulent data are proposed according to project phase below.

Preparation of study protocol and IRB application:

- Develop a written protocol for identifying and responding to low-quality data [22]
- Include language that permits the study team to verify respondent identities if needed (eg, via telephone call) [22,25]
- In consent document, state that participants will be removed from the study without remuneration in cases of fraud and participants will not receive additional remuneration for completing the study more than once [21,23]

- Mail remuneration to a physical address to avoid respondent misrepresentation of location-based eligibility criteria [21,25]
- Lower the value of or eliminate remuneration [23,25]
- Prepare study advertisements that do not explicitly state eligibility criteria [9,11]
- Seek guidance from institutional resources (eg, information systems, research computing, and the IRB)

#### Preparation of data collection instruments:

- Use a data collection platform with fraud prevention and detection features (eg, Qualtrics) [21-23,32]
- Use automated invitations to send each respondent a unique link to the data collection instrument [25]
- Ask respondents to identify where they heard about the study [25]
- Require respondents to pass a CAPTCHA [22,23,25]
- Collect respondent IP addresses (according to the Health Insurance Portability and Accountability Act Privacy Rule, IP address is considered an identifier) [21,23,25,28,32,33]
- Collect verifiable information, such as telephone number or physical address [21,23]
- Include at least one hidden item in each instrument. This can be accomplished by adding the @HIDDEN action tag to an item in REDCap or by adding custom JavaScript code to an item in Qualtrics
- Include a time stamp at the beginning and end of each instrument [21,23,25]
- Include (and consider requiring a response to) open-ended items [28]
- Include items with embedded directives (eg, “select the third option below”) [27]
- Include pairs of items that can be compared for consistency [23,25]
- Include items that require respondents to demonstrate insider knowledge [25]

#### Active recruitment and data collection:

- Avoid posting links to data collection instruments in the public space
- Use targeted advertisements to avoid promoting the study to ineligible respondents [9]
- Limit visibility of study-related social media profiles to audiences in the target geographic regions
- Monitor social media user engagement with study posts and advertisements (eg, for public shares or comments related to eligibility criteria)
- Monitor frequency and content of responses for suspicious patterns
- Identify respondents using a VPS with a tool such as the rIP R package or Shiny [32-34]

Researchers will need to weigh the potential benefits of each strategy against the financial and practical burden it may impose. For example, eliminating participant remuneration may remove the incentive for individuals who aim to defraud researchers [23,25]. However, survey completion and response rates are likely to be higher when remuneration is offered [35]. Entering participants into a raffle drawing for a larger incentive may serve as an acceptable compromise [25]. Alternatively, to verify

that respondents meet location-based eligibility criteria, researchers may elect to mail gift cards to a physical address rather than send them electronically [25]. Some researchers have reported successfully verifying respondent eligibility over the telephone [22,25], but as Teitcher and colleagues [23] observed, respondent eligibility verification is labor-intensive and may increase burden for legitimate participants.

Not every strategy mentioned will be appropriate for every research study. Similarly, no strategy will effectively preserve sample validity and data integrity when used alone. For example, although CAPTCHAs are intended to differentiate human respondents from bots, they are not always effective [22,23]. Likewise, although IP addresses can be used to verify that a respondent meets geographic eligibility criteria, IP-based geolocation is not always accurate [21,25]. Given that each strategy may be associated with one or more shortcomings, we recommend a comprehensive and multifaceted approach.

There is a need for research that develops and tests strategies to limit enrollment of individuals who may be using a VPS to defraud researchers. One approach has been proposed by Waggoner and colleagues [33], who developed a package called rIP for the statistical computing environment R (R Foundation for Statistical Computing). The rIP package provides researchers with the location of respondent IP addresses, information about likely VPS or server farm use, and a recommendation about whether to include the respondent's data in the data set. The team created an online version of the tool called Shiny that allows users to upload comma-separated value files for analysis in lieu of using R [33]. Although the rIP package and Shiny application have the potential to substantially reduce the workload associated with data quality review, prevention of low-quality responses is preferable to retrospective data classification. In a separate paper, Kennedy and colleagues [32] described embedding code in their Qualtrics survey to identify respondents whose IP address is associated with a server farm or VPS. The code used the IP verification website IP Hub [36] to identify these respondents and redirected them to a message informing them that they were ineligible to participate in the study. Additional solutions that capitalize on emerging knowledge of low-quality and fraudulent data sources are needed.

#### Limitations

Our study team did not collect the IP addresses of respondents. As such, we could not use the rIP R package or Shiny app [33] to determine whether a respondent used a VPS to access our survey. Future research that compares information provided by the rIP R package or Shiny app to the indicators of fraudulent or low-quality data that are described in this paper is warranted.

#### Conclusions

The recruitment of health research participants through social media is associated with several potential advantages. Nevertheless, studies in which research participants are recruited through social media are vulnerable to significant threats to sample validity and data integrity. There is a pressing need for best practices to prevent respondent misrepresentation of eligibility criteria and to identify low-quality and fraudulent

data. As health researchers increasingly turn to social media to access potential research participants, development of strategies to ensure rigor remains a priority.

## Abstract

**Background:** Recruiting participants into clinical trials continues to be a challenge, which can result in study delay or termination. Recent studies have used social media to enhance recruitment outcomes. An assessment of the literature on the use of social media for this purpose is required.

**Objective:** This study aims to answer the following questions: (1) How is the use of social media, in combination with traditional approaches to enhance clinical trial recruitment and enrollment, represented in the literature? and (2) Do the data on recruitment and enrollment outcomes presented in the literature allow for comparison across studies?

**Methods:** We conducted a comprehensive literature search across 7 platforms to identify clinical trials that combined social media and traditional methods to recruit patients. Study and participant characteristics, recruitment methods, and recruitment outcomes were evaluated and compared.

**Results:** We identified 2371 titles and abstracts through our systematic search. Of these, we assessed 95 full papers and determined that 33 studies met the inclusion criteria. A total of 17 studies reported enrollment outcomes, of which 9 achieved or exceeded their enrollment target. The proportion of participants enrolled from social media in these studies ranged from 0% to 49%. Across all 33 studies, the proportion of participants recruited and enrolled from social media varied greatly. A total of 9 studies reported higher enrollment rates from social media than any other methods, and 4 studies reported the lowest cost per enrolled participant from social media.

**Conclusions:** While the assessment of the use of social media to improve clinical trial participation is hindered by reporting inconsistencies, preliminary data suggest that social media can increase participation and reduce per-participant cost. The adoption of consistent standards for reporting recruitment and enrollment outcomes is required to advance our understanding and use of social media to support clinical trial success.

## Introduction

Patient recruitment continues to be a major challenge in clinical trials, with 19% of trials being terminated due to poor recruitment and another one-third needing to extend recruitment time [1,2]. Delay and termination of clinical trials has significant scientific, ethical, and financial impact on patients, researchers, and society [3]. Termination of clinical trials due to recruitment issues leads to failure to obtain the necessary evidence to assess efficacy, safety, and effectiveness of an intervention, which could subsequently delay the implementation of a more beneficial therapy or allow an existing suboptimal standard therapy to remain in practice [3,4]. From an ethical perspective, study termination exposes enrolled patients to unnecessary risks and inconvenience due to the impossibility of generating sufficient data [3]. Furthermore, delay and termination also involve human, time, and financial opportunity costs, lower researchers' morale, and may reduce society's trust and subsequent willingness to participate in medical research [3].

Multiple factors contribute to recruitment failure in clinical trials, including lack of funds, complex and unclear trial design, and failure to find and interest eligible participants [5]. The inability to reach potential participants may result from overestimation of prevalence, competing trials, and ineffective advertising strategies [5]. Although researchers employ multiple strategies to improve clinical trials recruitment, evidence on best practices is lacking.

In recent years, researchers have increasingly augmented traditional methods, such as newspaper, radio or television advertisements, flyers, and signs on buses, with social media strategies to help accelerate enrollment and achieve their recruitment targets. Social media may offer distinct benefits compared with traditional methods due to its ability to target specific patient segments using customized messages that may resonate better with the target segments [6]. Additionally, several social media platforms have a higher proportion of users from minority groups (eg, African American use of Twitter), which can facilitate reach and diversity of recruitment for trials [6].

Research evaluating the effectiveness of social media in enhancing clinical trial recruitment in various settings has produced conflicting results [7-10]. Some studies find social media more effective and less costly than traditional methods [7,8], while others do not [9,11]. A scoping review on the use of social media in health research recruitment published in 2016 also yielded inconclusive findings [12]. Differences in the results reported appear to be due to the ways researchers defined social media, the types of studies included in the review, and variation in how studies compared and assessed recruitment and enrollment through social media and traditional methods.

In this study, we define social media as "a group of Internet-based applications that build on the ideological and technological foundations of Web 2.0, and that allow the creation and exchange of User Generated Content" [13]. According to the Organization for Economic Co-operation and Development definition, user-generated content needs to be published on a website that is publicly accessible, show some

creative effort, and not be created in the context of professional work [14]. This definition excludes online media supported by internet-based platforms, such as email, instant messaging, regular websites, replications of existing content, and work created by companies for commercial use. We define traditional methods as offline (non-internet-based) platforms, such as television, print, and in-person recruitment. By using generally accepted definitions of social and traditional media, we address the heterogeneity observed in a prior scoping review and more clearly articulate the basis for including studies in this scoping review.

The prior scoping review included both observational and interventional studies [12], which potentially confounded the results. To avoid potential incommensurability across studies, this review includes only research studies that meet the National Institutes of Health's definition of a clinical trial [15]. Beyond refinements to the inclusion criteria, new studies comparing the use of social media and traditional methods for clinical trial recruitment have been published. As a result, two-thirds of the studies included in this scoping review were not evaluated in the prior scoping review.

Our scoping review examined the literature on the use of social media in conjunction with traditional methods in clinical trials to improve recruitment outcomes (success rate and cost). Specifically, this review addressed the following questions: (1) How is the use of social media, in combination with traditional approaches to enhance clinical trial recruitment and enrollment, represented in the literature? (2) Do the data on recruitment and enrollment outcomes presented in the literature allow for comparison across studies?

## Methods

### Review Method and Search Strategy

A scoping review was performed and reported using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for scoping reviews (PRISMA-ScR) guidelines, and the checklist is provided in [Multimedia Appendix 1](#) [16]. The protocol can be accessed through the Open Science Framework website [17]. Since this study focused on previously published literature and thus did not involve direct contact with human participants, institutional review board approval was not required [18].

We performed a comprehensive search in July 2019 using the following databases: PubMed; MEDLINE, EMBASE, and PsycInfo via Ovid; Cochrane Library via Wiley; Scopus; and Web of Science Core Collection. A combination of natural language and controlled vocabulary was employed in accordance with Methodological Expectations of Cochrane Intervention Reviews guidelines [19]. A complete search strategy is available in [Multimedia Appendix 2](#). To ensure that we did not overlook potentially relevant items, we also reviewed reference lists of related systematic and scoping reviews and included studies. Results were compiled and deduplicated in EndNote (version X.9; Clarivate Analytics).

## Inclusion and Exclusion Criteria

Papers employing strategies according to the stated definitions of social media and traditional methods were included. Papers also needed to be a clinical trial and describe at least one of the following outcomes: number of participants recruited or enrolled, cost of recruitment, or length of recruitment. Papers that contained no original data (editorials, letters to editors, opinions, conference proceedings, comments, systematic reviews), that recruited health care professionals as participants, or that did not report outcomes of interest were excluded.

## Screening

Papers were screened in 2 stages: (1) title and abstract screening and (2) full-text screening using the aforementioned inclusion and exclusion criteria. Two independent screeners reviewed papers at both the title and abstract stage and the full-text stage (ID, CB, and TAB). We resolved discrepancies through discussion and consensus or through the intervention of a third party when necessary. Study screening was facilitated using Rayyan (Qatar Computing Research Institute).

## Data Charting Process

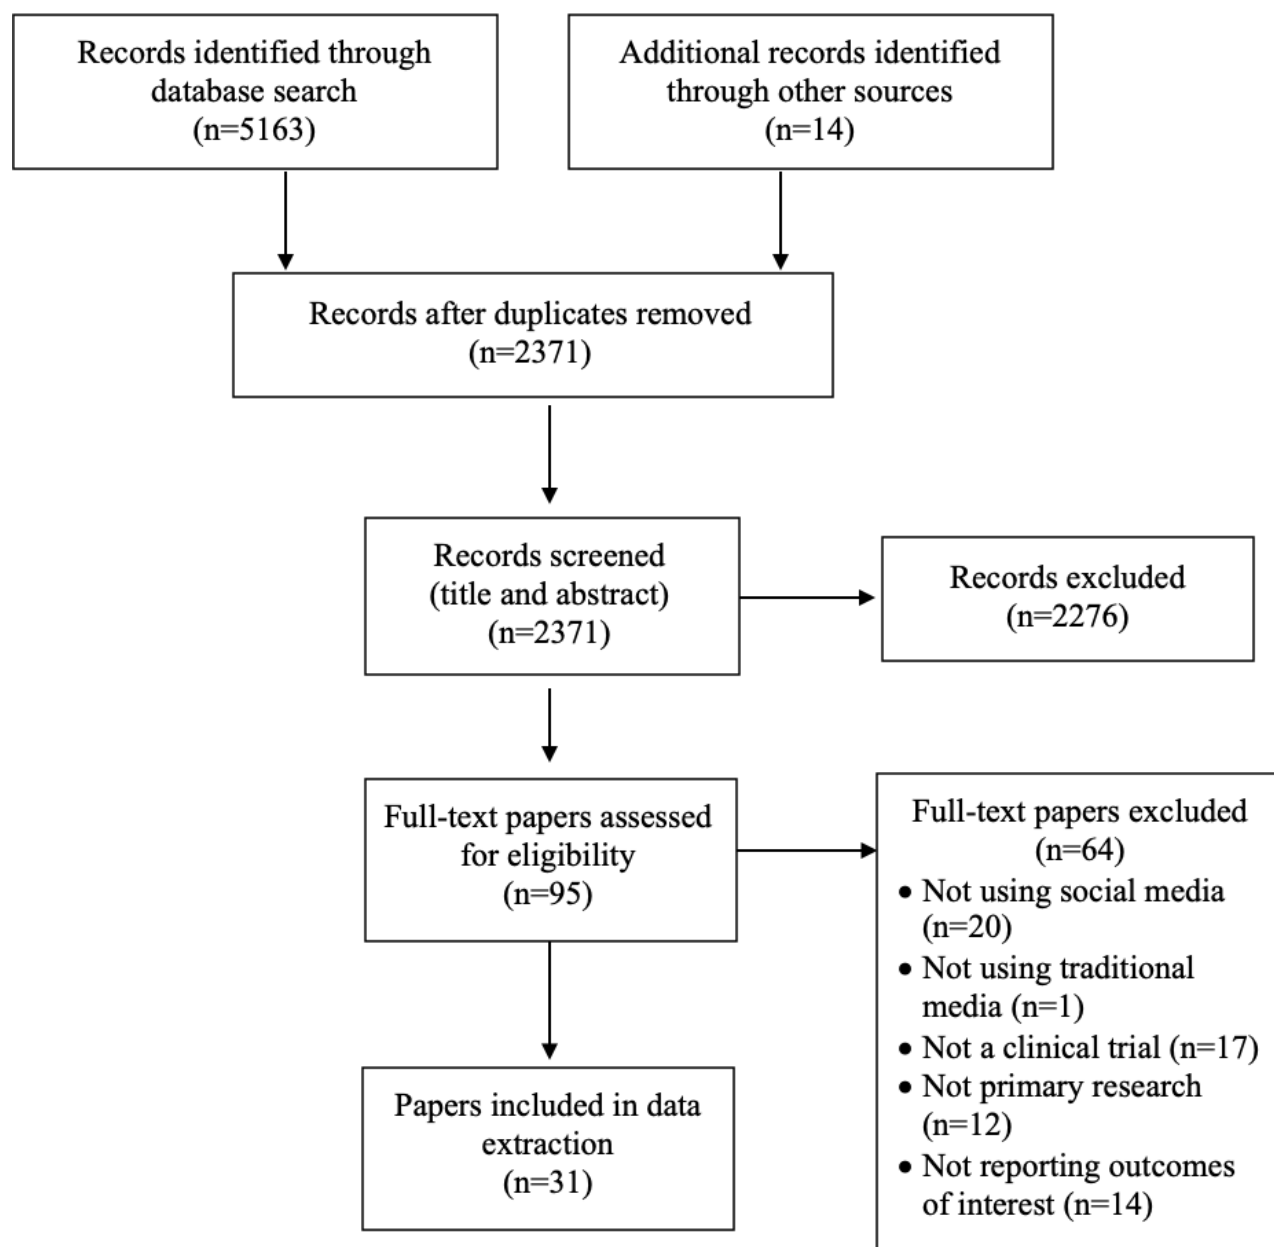

Two independent reviewers charted data using standardized collection forms created in REDCap (Vanderbilt University).

Again, discrepancies were resolved by discussion to achieve consensus. Data charted included study characteristics (goal of intervention, disease, mode of intervention), recruitment methods (social media platforms, traditional methods, other online methods), participant characteristics (age, sex, ethnicity, geographic location, type of residential area), and recruitment outcomes (number of participants recruited via each method, cost of recruitment, length of recruitment). We encountered differences in the way researchers described recruitment versus enrollment outcomes across studies. As a result, we defined recruitment as the first contact between prospective participants and study staff and enrollment as when participants were enrolled in the study after they signed informed consent. We extracted both recruitment and enrollment data when available.

## Results

### Paper Selection

Our search strategy identified a total of 5177 papers. After removing duplicates ( $n=2806$ ), the titles and abstracts of 2371 papers were screened against the exclusion criteria, resulting in 95 papers for full-text screening. From this, 64 papers did not meet inclusion criteria (Figure 1); the remaining 31 papers were included in this review and described in detail below.

**Figure 1.** PRISMA flow diagram.

### Study Characteristics

Of the 31 papers, 29 reported on a single study and 2 included reports on 2 studies each. This review identified a total of 33 studies that reported using social media and traditional methods in recruitment to clinical trials. The 33 studies described interventions for treatment (n=19) and prevention (n=14). A total of 19 studies consisted of in-person visits only, 10 were

online only, and 4 consisted of in-person and online participation. Study diseases or conditions focused on lifestyle and behavior (eg, weight loss, smoking), neurology, obstetrics/gynecology, and HIV. Most studies (32/33) recruited adults (18 years or older), with 5 studies focusing on older adults and seniors; 1 study recruited adolescents. Detailed characteristics of included studies are presented on [Table 1](#).

**Table 1.** Characteristics of included studies.

Study authors (year)	Purpose of intervention	Mode of intervention	Diseases or conditions	Participant's age (years)
Abbate et al (2017) [20]	Treatment	Online	Smoking	18+
Adam et al (2016) [21]	Prevention	In-person	Weight gain and diet	23-40

Watson et al (2018) [48]	Treatment	Online	Smoking	18+

<sup>a</sup>Participants were 11th-grade students. Age range is estimated.

<sup>b</sup>PTSD: posttraumatic stress disorder.

<sup>c</sup>HPV: human papillomavirus.

<sup>d</sup>ARHL: age-related hearing loss.

## Recruitment Methods

Facebook was the most commonly used social media platform (31/33), followed by Twitter (6/33). The majority of studies (21/33) used a single social media platform and the remainder used two or more social media platforms, with one study reporting the use of 4 platforms. Facebook use occurred across all studies reporting the use of more than one social media platform.

Studies that reported using Facebook for their recruitment used a variety of Facebook features: Facebook ads, Facebook pages (including boosted posts on a page) [10,36], or sending a friend invite to prospective participants using a Facebook account [32]. One study used untargeted Facebook ads, then switched to targeted Facebook ads that showed ads only to participants who met the study criteria [22]. Several studies started using social media after other recruitment methods were deployed [28,31,38,44], while others used social media at the beginning of their recruitment period.

The most commonly used traditional method was print (32/33), followed by in-person venues (17/33) and referrals from health care professionals (16/33). A total of 23 studies used other online

media, such as website ads (15/23), emails (11/23), and Craigslist (8/23).

## Recruitment and Enrollment Rates

A total of 17 out of 33 studies reported overall enrollment rates. Of these, 9 studies achieved or exceeded their enrollment target. Of these 9 studies, 8 reported the proportion of participants enrolled through social media, which ranged from 0% to 49%. One study that achieved its enrollment target reported that social media outperformed other recruitment methods [48].

About half of the studies (17/33) reported both recruitment and enrollment rates from social media, 3 studies reported recruitment rates only, 11 studies reported enrollment rates, and 2 did not report either (Table 2). The proportion of participants recruited and enrolled from social media varied greatly from study to study (Table 2) and across study types (Table 3). Studies with a high proportion (50% or greater) of participants enrolled from social media recruited adult participants. Studies recruiting seniors [26,35,43] and the 1 study involving adolescents [32] enrolled the majority of participants from traditional methods (Table 3).

<sup>a</sup>OB/GYN: obstetrics/gynecology.<sup>b</sup>Not available (not reported by original study).

Out of 20 studies that reported recruitment rates by method, 7 reported higher recruitment rates from social media than from any other methods. Similarly, out of 28 studies that reported enrollment rates by method, only 9 reported higher enrollment rates using social media than any other methods (Table 4). Among the 9 studies that reported the highest enrollment rates from social media, 6 studies were for treatment (3

lifestyle-related conditions, 3 neurological) and 3 were for prevention (2 HIV, 1 lifestyle). Of the 9 studies reporting enrollment, 5 involved an online intervention and the remainder used an in-person intervention. A total of 5 of these 9 studies used Facebook only, and the rest used more than one social media platform.

<sup>e</sup>Includes participants enrolled from both traditional and other online media.

## Recruitment and Enrollment Costs

A total of 20 studies reported itemized recruitment and enrollment costs. Of these, almost all studies reported the costs to place the recruitment ads in various media (19/20), and 6 reported the costs to develop these ads. Only 5 studies reported the costs of staff involved in participant recruitment and enrollment.

Of the 19 studies that reported cost per enrolled participant, only 4 [10,21,30,33] reported lower cost per enrolled participant using social media than any other methods. Recruitment methods used in these 4 studies included Facebook, Instagram, print, television, radio, in-person recruitment, and website ads. Detailed costs per enrolled participant by media type can be found in Table 5.

<sup>d</sup>Includes cost using Craigslist.

## Discussion

### Principal Findings

This scoping review examines literature describing the use of social media and traditional methods as well as other online media in clinical trial recruitment. We found that using social media resulted in the highest recruitment rates in 7 of 20 studies and the highest enrollment rate in 9 of 28 studies. We also found that social media resulted in the lowest cost per enrolled participant in 4 of 19 studies. However, the data reported about social media outcomes varied greatly across studies, obscuring our ability to evaluate if particular studies might benefit more from using social media.

Our review discovered a lack of consistency in defining and reporting recruitment and enrollment data across studies. Several studies seemed to use these terms interchangeably, and some failed to specify which data they reported (eg, when consent occurred). Furthermore, we noted inconsistencies resulting from the varied use of social media, even within a platform, and the opportunistic use of social media by several studies that started using social media only after traditional methods failed to achieve sufficient interest and enrollment. We also observed

that some studies did not indicate how many participants were counted as being reached by more than one recruitment or enrollment method. Lastly, we observed inconsistencies in cost reporting, with some studies reporting itemized costs and others reporting aggregated costs. Collectively, these inconsistencies contributed to the variations in describing the outcomes of using social media and traditional methods to support clinical trial recruitment and enrollment. The inconsistencies in reporting also rendered comparison of data across the studies included in this scoping review impossible.

To address these inconsistencies, we recommend that future studies use the terms “recruitment” and “enrollment” in alignment with the definitions used by the Food and Drug Administration’s advisory committee [49]. The term “recruitment” should report on all interactions with potential study participants prior to obtaining informed consent, while the term “enrollment” should report only on the total number of individuals who provide informed consent. Studies should report recruitment using as the denominator the total number of participants reached and as numerators the number of study participants reached through each method. Enrollment rates should be calculated using as the denominator the total number of participants providing informed consent and as numerators

the number of participants enrolled through each recruitment method. Additionally, screening that results in the exclusion of participants after they provide informed consent should be reported separately, enabling a more accurate count and cost of the individuals actively participating in the intervention. Using consistent definitions of key terms across research studies will allow researchers to improve the clarity and comparability of clinical trial management data. Establishing reporting standards will also allow researchers to adopt evidence-based recruitment strategies by choosing optimal recruitment methods to reduce cost and timelines [50].

To facilitate shared learning based on the experience of prior research, we further recommend that future studies report in detail their approaches to using each social media platform (eg, Facebook ad, Facebook page) and specify the number of participants recruited or enrolled from multiple methods, which will allow for more accurate response analyses and cost estimates. As the ability to capitalize on existing social media relationships may influence both the success of recruitment and enrollment as well as their subsequent costs, researchers should consider explicitly stating whether their social media recruitment strategies are related to a larger social media initiative.

When adding social media to existing recruitment methods, researchers should report both the incremental costs of social media and the personnel cost to develop and monitor posted content. Furthermore, researchers are encouraged to report trade-offs between cost and time when analyzing the effectiveness of each recruitment method. For example, social media may result in higher cost per enrolled participant but reduce the time to enroll participants. Although we recognize the complexity in analyzing and comparing cost in different time increments and the potential for historical trends to confound results, such reporting may provide deeper insights on different recruitment methods. Such analyses may help researchers, organizations, and corporations determine whether to build social media expertise directly into their research teams to optimize the full extent of social media capabilities or to engage social media experts as consultants. The costs associated with such arrangements should be identified and, ideally, reported.

### Comparison With Prior Work

The mixed results on the use of social media found in this study are similar to those found in a prior scoping review [12]. While

the prior scoping review attributed the different success rates to the effort researchers put into the use of social media as a recruitment method, we found that the variations in the use of social media and the inconsistencies in the way outcomes were reported prevented comparisons across studies. Having explored the ways researchers used and reported the use of social media in clinical trial recruitment, this study advances recommendations for achieving data consistency in reporting, which would facilitate comparison across results.

Similar to the findings from a systematic mapping study conducted by Frampton et al [51], we found that the use of social media to recruit participants involved a variety of diseases and health conditions. We also failed to find many studies involving minority populations (eg, African American or lesbian, gay, bisexual, transgender, and queer populations). As a result, we are unable to provide any insights on the use of social media to recruit diverse populations when compared with traditional recruitment methods.

### Limitations

Our scoping review is limited in its examination of data from clinical trials that combined social media and traditional methods in their recruitment strategies because we cannot guarantee that the review identified all relevant studies. We also cannot claim this review is comprehensive, as research not organized or reported as a clinical trial may inform reasoning about incorporating social media into the research recruitment armamentarium. The relatively recent use of social media also renders highly speculative any conclusions drawn about its appropriateness in recruitment and enrollment methods for particular diseases and conditions. We also recognize a limitation in our ability to assess the quality of the recruitment strategy, the recruitment materials, or the enrollment process. However, we advance recommendations to improve consistency in reporting on recruitment and enrollment that we believe to be necessary precursors for comparative analysis.

### Conclusions

The use of social media for clinical trial recruitment holds great promise. However, this scoping review identified continued inconsistency in reports on the use of social media for clinical trial recruitment and enrollment. We recommend that future studies incorporate the recommendations for collecting and reporting recruitment and enrollment data advanced here to facilitate comparison of study data and shared learning.

### Acknowledgments

This project was supported by grant number UL1 TR002494 and UL1 TR002377 from the National Center for Advancing Translational Sciences. Its contents are solely the responsibility of the authors and do not necessarily represent the official views of the National Institutes of Health.

### Authors' Contributions

ID developed the project concept, performed database searches, screened papers, extracted data, analyzed social media use and recruitment and enrollment outcomes across studies, and was the lead in writing the manuscript. CB and TAB refined the project concept, screened papers, extracted data, and were major contributors in writing the manuscript. CAP was a major contributor in writing the manuscript. ME developed the project concept, analyzed recruitment and enrollment outcomes across studies, and was a major contributor in writing the manuscript.

## Abstract

**Background:** People use the internet as a primary source for learning about medical procedures and their associated safety profiles and risks. Although abortion is one of the most common procedures worldwide among women in their reproductive years, it is controversial and highly politicized. Substantial scientific evidence demonstrates that abortion is safe and does not increase a woman's future risk for depressive disorders or infertility. The extent to which information found on the internet reflects these medical facts in a trustworthy and unbiased manner is not known.

**Objective:** The purpose of this study was to collate and describe the trustworthiness and political slant or bias of web-based information about abortion safety and risks of depression and infertility following abortion.

**Methods:** We performed a cross-sectional study of internet websites using 3 search topics: (1) is abortion safe?, (2) does abortion cause depression?, and (3) does abortion cause infertility? We used the Google Adwords tool to identify the search terms most associated with those topics and Google's search engine to generate databases of websites related to each topic. We then classified and rated each website in terms of content slant (pro-choice, neutral, anti-choice), clarity of slant (obvious, in-between, or difficult/can't tell), trustworthiness (rating scale of 1-5, 5=most trustworthy), type (forum, feature, scholarly article, resource page, news article, blog, or video), and top-level domain (.com, .net, .org, .edu, .gov, or international domain). We compared website characteristics by search topic (safety, depression, or infertility) using bivariate tests. We summarized trustworthiness using the median and IQR, and we used box-and-whisker plots to visually compare trustworthiness by slant and domain type.

**Results:** Our search methods yielded a total of 111, 120, and 85 unique sites for safety, depression, and infertility, respectively. Of all the sites (n=316), 57.3% (181/316) were neutral, 35.4% (112/316) were anti-choice, and 7.3% (23/316) were pro-choice. The median trustworthiness score was 2.7 (IQR 1.7-3.7), which did not differ significantly across topics ( $P=.409$ ). Anti-choice sites were less trustworthy (median score 1.3, IQR 1.0-1.7) than neutral (median score 3.3, IQR 2.7-4.0) and pro-choice (median score 3.7, IQR 3.3-4.3) sites. Anti-choice sites were also more likely to have slant clarity that was "difficult to tell" (41/112, 36.6%) compared with neutral (25/181, 13.8%) or pro-choice (4/23, 17.4%;  $P<.001$ ) sites. A negative search term used for the topic of safety (eg, "risks") produced sites with lower trustworthiness scores than search terms with the word "safety" (median score 1.7 versus 3.7, respectively;  $P<.001$ ).

**Conclusions:** People seeking information about the safety and potential risks of abortion are likely to encounter a substantial amount of untrustworthy and slanted/biased abortion information. Anti-choice sites are prevalent, often difficult to identify as anti-choice, and less trustworthy than neutral or pro-choice sites. Web searches may lead the public to believe abortion is riskier than it is.

## KEYWORDS

internet; abortion; media; websites; infodemiology; infodemic; quality of health information; bias in patient education

## Introduction

The internet is the first source the public turns to for medical information [1-3]. At least 70% of adults who use the internet use it for health information research, with 43% of them seeking information about specific treatments or procedures [4]. Although the internet is a vast repository of searchable information, there is often incorrect, deliberately misleading, conflicting, and/or hard to understand information [5]. Furthermore, public perception and knowledge is shaped by personalized internet experience, which is delimited by technology company algorithms [6-8]. Abortion is one of the most common medical procedures in the world. According to recent estimates, over 800,000 women in the United States choose an abortion each year [9]; even more consider abortion but do not obtain one [10]. Surgical procedures for abortion are referred to as aspiration, dilation, and curettage (D&C), or dilation and evacuation (D&E) if done later in pregnancy. For abortions in the first trimester of pregnancy (up to 10 weeks), medications are used [11]. The best scientific evidence clearly demonstrates that induced abortion is safe [12,13] and that abortion does not increase a woman's future risk for disorders such as depression, anxiety, or suicidality [14], or secondary infertility [15,16]. Only low-quality and/or discredited studies suggest otherwise [17,18]. The risks of abortion do increase with the gestational age of the pregnancy, but abortion at any gestational age is safer than childbirth [12].

Despite these facts, many antiabortion arguments rest on misinformation regarding the safety and health consequences of abortion [19]. Crisis pregnancy centers (CPCs)—organizations that try to intercept women who are considering an abortion—often describe abortion as dangerous or deadly in order to dissuade women from choosing to obtain an abortion [20]. In addition, false or misleading information on the internet about abortion continues to exert an influence on public debates and policy [21]. Previous studies have examined web-based abortion information, focusing on the quality of information available for self-referral (on CPC websites, specifically) and about D&E procedures [20,22,23]. These studies found frequent inaccuracies and a lack of comprehensive information about abortion on the internet. However, the studies were limited by small data samples [23,24] or narrow inquiries on specific websites [10]. It remains unclear exactly what a search about abortion safety or potential subsequent risks would yield in terms of websites, as well as the trustworthiness and accuracy of information contained on them. The purpose of this study was to collate and describe the web-based ecosystem about abortion in terms of the

trustworthiness and bias about abortion safety and risks. We focused on websites that provided information related to three questions: (1) is abortion safe?, (2) does abortion cause depression?, and (3) does abortion cause infertility? We chose safety, infertility, and depression for our case studies because the existing medical evidence is very clear; the mainstream scientific consensus is that abortion is safe and does not cause subsequent infertility or depression [25]. However, these questions continue to be disputed in public discourse and provide an opportunity to evaluate the quality of website information.

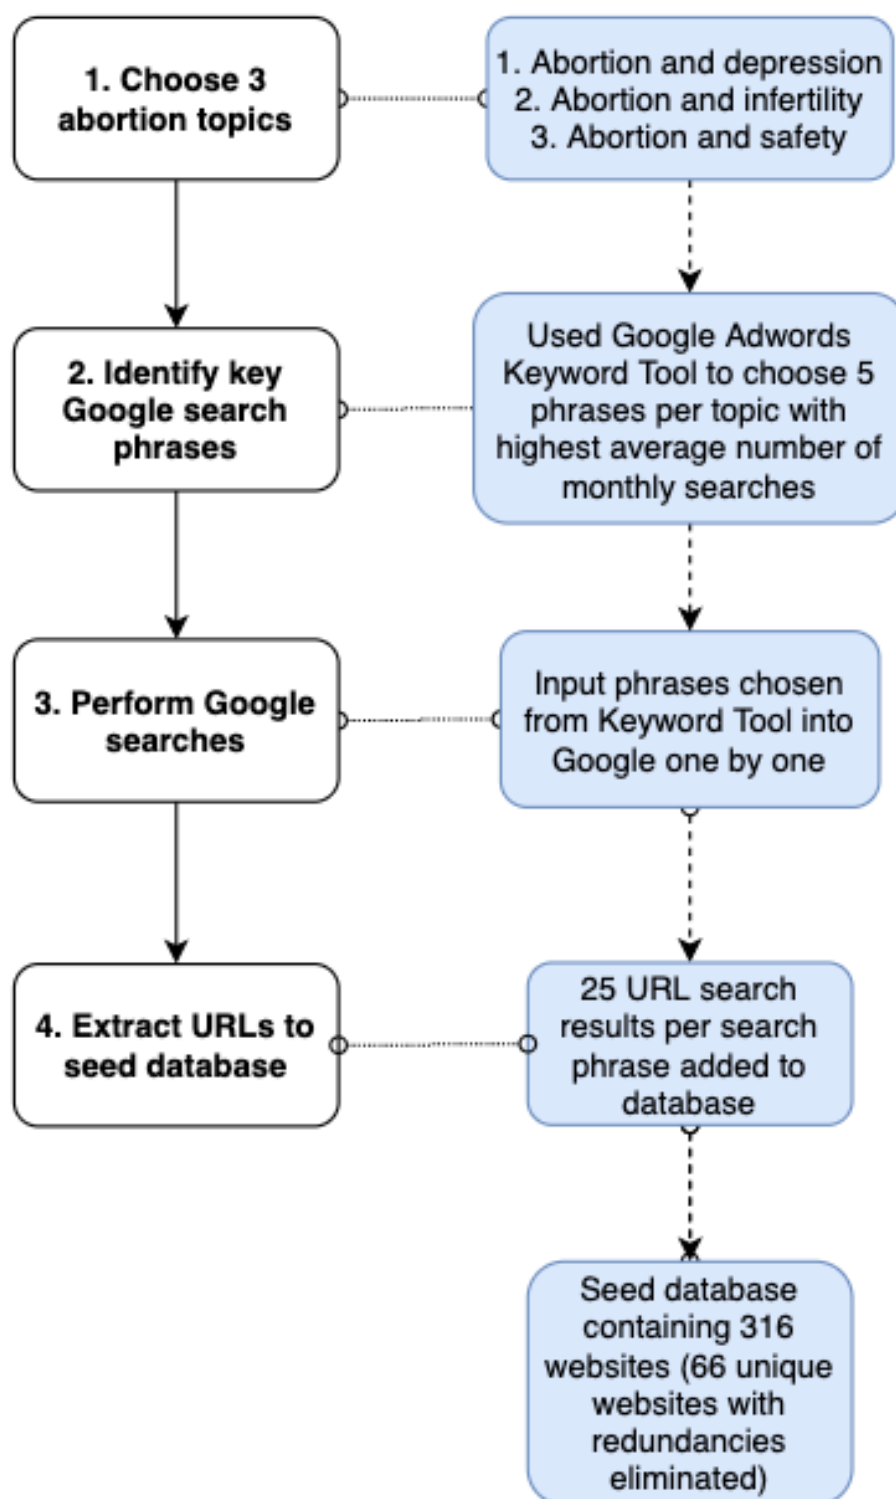

## Methods

This cross-sectional study had two phases: first, we created a database of websites from searches about abortion and safety, depression, and infertility; second, we used the ecosystem database that we created to classify websites in terms of content trustworthiness, political slant on abortion, type of site, and top-level domain.

### Website Database

We utilized several steps to create our website database in order to minimize bias and most broadly capture what the general public would encounter while searching on the web (Figure 1). First, we used Google's Adwords tool, a free Google advertising tool that allows advertisers to associate their ads with search terms based on the popularity of the term. For a given topic, the keyword tool identifies the most commonly used search terms with a topic based on historical search data [26]. We selected 5 search terms for each of our 3 keyword combinations (abortion safety, abortion depression, and abortion infertility) based on their frequency as identified by Google Adwords and relevance (Figure 2). Next, we conducted Google searches using these phrases on August 31, 2018, and compiled website results for each of our search terms. In order to remove search term personalization, each search was performed using a cookie-cleared Google Chrome (version 10.8) browser in incognito mode combined with a free virtual private network called Windscribe (version 1.82) in order to reduce locational bias as well as anonymize our internet protocol addresses. For each search phrase, we extracted the top 25 page-ranked results, noting multiple occurrences. Each link was then imported into a spreadsheet using MozBar (Moz Inc), a Chrome extension that also produced titles, brief excerpts, and a search position number for each link based on its proximity to the top of the Google page. We produced a database for each of our topics (safety, depression, infertility) based on this search methodology.

**Figure 1.** Workflow of website selection for the analysis.

[illegible]

We next classified and rated each website in the database. We rated websites on 5 metrics: (1) slant, (2) slant clarity, (3) trustworthiness, (4) type, and (5) domain. For slant, a website was determined to have a pro-choice or anti-choice bias if either (a) information was given in a biased or dramatic fashion (eg, an anti-choice site describing the procedure as “tearing the baby from the womb”), or (b) the website displayed an opinion regarding the provision of abortion and its legality (eg, a pro-choice site stating that abortion should be free and legal for all women); otherwise, the website was considered neutral. We assigned a slant clarity rating based on how easy it was to discern the website’s slant (obvious, in-between, or difficult/can’t tell). We scored trustworthiness on a rating scale from 1 to 5, with 5 being most trustworthy based on factors

<http://www.jmir.org/2020/10/e20619/>

## Data Analysis

First, we created a visualization of the websites and their parent search terms and topics using RAWGraphs. Next, we compared website characteristics overall and by search topic (safety, depression, or infertility) using Pearson chi-square test or Fisher exact test for all categorical classifications to compare characteristics across topics. We summarized trustworthiness, measured on a 5-point scale, using the median and IQR. For each search topic, we also assessed the distribution of websites based on the content's slant for the 5 query terms, and then compared the trustworthiness of query term results using Kruskal-Wallis and Wilcoxon rank sum tests. We used box-and-whisker plots to visually compare trustworthiness by slant and by domain type. Finally, we tabulated websites according to their slant and slant clarity, comparing distributions using Fisher exact test, and then used a bar graph to examine website counts graphically. The study was reviewed and approved by the Oregon Health and Science University's institutional review board and was deemed not human subjects research.

## Results

After removing duplicates, our search methods yielded a total of 111, 120, and 85 unique sites for safety, depression, and infertility, respectively. [Figure 2](#) provides a visualization of these websites and their parent search terms and topic (see [Multimedia Appendix 1](#) for full list of sites with URLs). While the majority of sites had a neutral slant (181/316, 57.3%) overall, the slant distribution differed by topic, with a higher proportion of sites about safety and depression having an anti-choice slant ([Table 1](#)). Approximately 40% of sites about safety and depression had an anti-choice slant (safety: 44/111, 39.6%;

depression: 51/120, 42.5%), compared with 15.3% (17/111) and 3.3% (4/120) of the safety and depression sites, respectively, being categorized as having a pro-choice slant. Infertility had the highest proportion of neutral sites (66/85, 77.7%). In terms of website type, we categorized the majority of websites as resource pages (158/316, 50.8%). Commercial (.com/.net) (154/316, 48.7%) and organization (.org) (101/316, 32.0%) sites accounted for the majority of domain types. While we did not specifically perform an analysis of slant by web address (URL), we noticed that many of the anti-choice sites came from generic-appearing addresses (eg, americanpregnancy.org, adviceandaid.com). One state health department site (Alaska) was rated by our researchers as being anti-choice.

We found that the median score for trustworthiness of the websites was 2.7 (IQR 1.7-3.7), which did not differ significantly across topics (safety: median score 3.0, IQR 1.7-3.7; depression: median score 2.3, IQR 1.7-3.7; infertility: median score 2.7, IQR 1.7-3.7;  $P=.409$ ). Agreement in trustworthiness scores among our coders was 71.8%, 70.0%, and 80.9% for safety, depression, and infertility, respectively. Of the 316 sites in our sample, only 59 (18.7%) sites received median trustworthiness scores of 4 or more (data not shown). The trustworthiness rating of sites was different by slant and by domain type ([Figure 3](#)). Overall, anti-choice sites had lower trustworthiness scores (median score 1.3, IQR 1.0-1.7) compared with neutral (median score 3.3, IQR 2.7-4.0) and pro-choice (median score 3.7, IQR 3.3-4.3) sites. Sites that came from educational institutions (.edu) were consistently given higher trustworthiness scores (median score 4.3, IQR 3.7-4.3), while other domains received overall lower and more widely distributed trustworthiness scores, with commercial sites (.com/.net) considered to be the least trustworthy (median score 2.3, IQR 1.3-3.3).

**Table 1.** Website characteristics by search topic (n=316).

Characteristic	Overall	Safety (n=111) <sup>a</sup>	Depression (n=120)	Infertility (n=85)	P value
<b>Slant, n (%)</b>					<.001
Pro-choice	23 (7.3)	17 (15.3)	4 (3.3)	2 (2.4)

Difficult/can't tell	70 (22.1)	21 (18.9)	38 (31.7)	11 (12.9)	
<b>Domain, n (%)</b>					.002
Commercial (.com/.net)	154 (48.7)	45 (40.5)	60 (50.0)	49 (57.7)	
International	42 (13.3)	8 (7.2)	17 (14.2)	17 (20.0)	
Education (.edu)	5 (1.6)	2 (1.8)	1 (0.8)	2 (2.4)	
Government (.gov)	14 (4.4)	8 (7.2)	4 (3.3)	2 (2.4)	
Organization (.org)	101 (32.0)	48 (43.2)	38 (31.7)	15 (17.7)	
<b>Page type, n (%)</b>					.007
News article	30 (9.7)	12 (11.3)	13 (10.8)	5 (5.9)	
Forum	17 (5.5)	2 (1.9)	2 (1.7)	13 (15.3)	
Blog	16 (5.1)	5 (4.7)	8 (6.7)	3 (3.5)	
Feature	63 (20.3)	21 (19.8)	20 (16.7)	22 (25.9)	
Scholarly article	25 (8.0)	9 (8.5)	11 (9.2)	5 (5.9)	
Resource page	158 (50.8)	57 (53.8)	64 (53.3)	37 (43.5)	
Video	2 (0.6)	0 (0)	2 (1.7)	0 (0)	
Trustworthiness, median (IQR)	2.7 (1.7-3.7)	3.0 (1.7-3.7)	2.3 (1.7-3.7)	2.7 (1.7-3.7)	.409

<sup>a</sup>Five websites in the safety category were missing data about page type.

**Figure 3.** Box-and-whisker plots comparing trustworthiness of online abortion resources by slant and domain type (n=316). Trustworthiness was scored on a scale of 1 (least trustworthy) to 5 (most trustworthy). The central line in each box marks the median trustworthiness score; upper and lower box edges mark the 75th and 25th percentile, respectively; whiskers indicate 150% of the interquartile range and outliers are shown as individual points. Int'l: international domain (eg, .uk, .nz, .id).

We also examined our results using specific search query terms and noted that for searches on safety and infertility, trustworthiness scores were significantly different across query search terms (Table 2). For searches focused on abortion safety, including the word “safe” resulted in sites with significantly higher trustworthiness scores (median score 3.7, IQR 3.3-4.3) compared with searches that included the more negative word “risks” (median 1.7, IQR 1.0-3.3; Wilcoxon rank sum  $P<.001$ ). Anti-choice sites appeared more frequently with negative search terms, such as “risks of abortion” (17/23, 73.9%), compared with when the word “safe” was included in the search term, such as, “How safe is abortion?” (1/27, 3.7%) (Table 2).

Finally, we found that slant clarity, or how difficult it was to discern the anti-choice, neutral, or pro-choice slant of a website, varied significantly both by topic and by slant. In regard to the topic, there were many more depression websites with a “difficult/can’t tell” slant compared with sites about safety and infertility (31.7% versus 18.9% and 12.9%, respectively;  $P=.002$ ). However, all 3 topic categories contained clarity ratings of “obvious” for fewer than one-half of the sites (Table 1). In terms of slant, anti-choice sites were more likely to have slant clarity that was “difficult/can’t tell” (41/112, 36.6%) compared with neutral (25/181, 13.8%) or pro-choice (4/23, 17.4%) sites ( $P<.001$ ) (Figure 4).

**Table 2.** Search query terms used and associated trustworthiness and website slant for each search topic.

Topic and search query terms	Total, n (%)	Pro-choice, n (%)	Neutral, n (%)	Anti-choice, n (%)	Trustworthiness, median (IQR)	P value
<b>Safety (n=111)</b>						<.001
Abortion health risks	19 (17.1)	1 (5.3)	7 (36.8)	11 (57.9)	2.3 (1.7-3.3)	
Effects of abortion	24 (21.6)	0 (0)	10 (41.7)	14 (58.3)	1.7 (1.0-3.0)	
How safe is abortion?	27 (24.4)	5 (18.5)	21 (77.8)	1 (3.7)	3.7 (3.0-4.3)	
Risks of abortion	23 (20.7)	0 (0)	6 (26.1)	17 (73.9)	1.3 (1.0-2.3)	
Safe abortion	18 (16.2)	11 (61.1)	6 (33.3)	1 (5.6)	3.7 (3.7-4.3)	
<b>Depression (n=120)</b>						.143
Abortion depression	28 (23.3)	0 (0)	17 (60.7)	11 (39.3)	3.2 (1.7-3.7)

Pregnancy after abortion	23 (27.1)	0 (0)	22 (95.7)	1 (4.3)	3.0 (2.3-3.7)	

**Figure 4.** Counts of online abortion resources by slant and slant clarity (n=316).

## Discussion

### Principal Findings

Our study of websites that provide information about safety of abortion or subsequent risks of depression or infertility found that overall, 35.4% (112/316) of sites had an anti-choice slant. Anti-choice sites were less trustworthy, and the clarity of their stance was also more difficult to determine. Our data also show that people seeking information about the safety and potential

risks of abortion are likely to find substantial amounts of untrustworthy abortion information; the overall median trustworthiness score of these sites was 2.7 (on a scale of 1-5), with a wide range (IQR 1.7-3.7).

Our results are consistent with other examples of intentionally disseminated abortion disinformation. CPCs have an antiabortion agenda but use neutral language and advertising to appear as if they are a normal medical clinic [20]. In our study, almost two-thirds (71/112, 63.4%) of anti-choice sites were categorized

as resource pages and many derived from web addresses that appeared generic and neutral. Moreover, one state health department site rated as anti-choice, which demonstrates that even official governmental sites can be biased sources of information. These findings suggest that anti-choice sites may be trying to obscure their biases or appear as neutral information brokers. Based on the high number of “difficult to tell” sites in our data sets, we need more research to understand the characteristics of anti-choice sites that create this effect.

We know that in the case of abortion, false or misleading information continues to play a role in public debates and government legislation. For example, Targeted Regulation of Abortion Providers (TRAP) laws, or costly and burdensome regulations aiming to restrict access to abortions by dictating how, by whom, and when abortions can be provided, are often based on false health claims but framed as protecting patient safety [31]. The internet is one of the most important propagators of false information. Previous research has shown that media is more influential among young people (aged 13 to 29 years) than friends, family, and health care providers when it comes to learning about abortion [32]. However, there is also evidence that exposing the public to more evidence-based information on abortion can change opinions about the provision and regulation of abortion services [33]. Thus, efforts to address the spread of false information and strengthen the presence of evidence-based information on abortion can have real impact. Our results can help inform clinicians and others who work in the abortion field about likely information gaps [34]. Moreover, health organizations that seek to disseminate evidence-based information may want to conduct regular search audits such as this in order to optimize their search positions to reach a broader audience.

### Limitations

Our study results should be interpreted with the following limitations in mind. We used expert ratings to gain insight into the abortion online media ecosystem. All of our experts are engaged in abortion-related research and two-thirds of our

experts are abortion providers. We recognize that non-experts may have rated and classified these same websites differently. However, our expert ratings provide a benchmark for future work that explores how non-experts perceive the information contained in these websites. We also acknowledge that trustworthiness scores could be confounded with slant and that sites with obvious anti-choice slants may have been rated with lower trustworthiness scores based on the impression of bias. However, it is difficult to blind these components from each other and we wanted to provide some kind of measure of quality for the information we encountered. We recognize that our study provides only a cross-sectional snapshot of the internet. While specific site rankings may be driven by news cycles, we believe the overall picture is unlikely to change [35]. We also acknowledge that while we took measures to anonymize the search results, individuals will receive different results based on their previous search history, and the majority will not scroll past the first page. However, our database sizes captured approximately the first 8 to 12 pages of search results for a given topic. Finally, while our focus was on websites, websites alone do not fully address the digital means through which abortion information is shared. In particular, social networking platforms are critical sources [36]. The strengths of our study include the use of a systematic and rigorous approach to create our website database, incorporation of multiple topic areas, and focus on content trustworthiness and bias.

Our results provide insight into the online abortion ecosystem. We find that anti-choice sites are prevalent, often hard to identify as anti-choice (difficult slant clarity), and less trustworthy than neutral and pro-choice sites. Additionally, the search terms a user chooses may play a substantial role in the quality and bias of websites they see. Our results help us understand how the internet may impact public perceptions and knowledge about the safety of abortion and potential risks of depression and infertility. Our findings suggest that web searches may lead people to perceive abortion procedures as more dangerous and riskier than they actually are.

## Abstract

**Background:** Immunizing children throughout their early years prevents the spread of communicable disease and decreases the morbidity and mortality associated with many vaccine-preventable diseases. Searching online allows individuals rapid access to health information.

**Objective:** The purpose of this review was to develop an understanding of the existing literature of parents' online health information-seeking behaviors to inform their vaccination choices for their children and to identify gaps in the literature around parents' use of online health information and their vaccination choices.

**Methods:** A scoping review of peer-reviewed literature from Canada and the United States was performed. The following databases were utilized to perform the search: PubMed, CINAHL, Nursing & Allied Health Database, Scopus, and PsycINFO. The purpose of this review was to examine parents' use of online information seeking related to vaccine information and to understand how parents utilize this information to inform decisions about vaccinating their children. Of the 34 papers included in the review, 4 relevant themes and subthemes were identified: information seeking, online information resources, online vaccine content, and trust in health care providers.

**Results:** Examination of the literature revealed conflicting information regarding parents' use of social media and online resources to inform decisions around vaccinating their children. There is evidence of significant misinformation regarding vaccine risks online. Parents' digital health literacy levels are unknown and may affect their ability to appraise online vaccination information.

**Conclusions:** Parents are seeking vaccine information from online sources. However, the influence of online vaccine information on parental vaccine practices remains uncertain.

**KEYWORDS**

childhood vaccination; parental vaccine decisions; online vaccine information; social media; vaccine hesitancy; digital health literacy

## Introduction

Vaccination programs are a vital contribution to public health practice in North America [1,2]. Immunizing children throughout their early years prevents the spread of communicable disease and decreases the morbidity and mortality associated with many vaccine-preventable diseases. Sustaining

vaccination rates above 95% maintains community immunity and prevents outbreaks of vaccine-preventable diseases [3]. Despite ongoing public health efforts in North America, childhood vaccination rates are not meeting the established goals for effective disease prevention [4,5]. In 2019, outbreaks of measles, a highly contagious, vaccine-preventable disease, occurred in both the United States and Canada [6]. Health Canada has highlighted the importance of understanding factors

associated with under-vaccinated and unvaccinated children, as well as vaccine hesitancy among parents and guardians, as key to improving vaccination rates in Canada [4]. Public health officials in the United States have also identified that parental delay and refusal of vaccinations threaten community immunity and identify this issue as a significant research priority [7]. The health implications for under-vaccinated children are concerning as the prevalence of communicable disease outbreaks become increasingly common. The use of digital information, including the prevalence of social media use among Canadian parents, highlights a need to understand the impact of online information on parents' vaccine choices.

National immunization targets for Canadian children aim for 95% vaccination coverage by a child's seventh birthday for the following diseases: diphtheria, tetanus, pertussis, polio, measles, mumps, and rubella [8]. Recently reported statistics demonstrate that vaccination rates fall short of the established immunization targets across Canada; immunization rates for 7-year-olds are 71% for diphtheria, tetanus, and pertussis; 90% for polio; and 86% for measles, mumps, and rubella [8]. American statistics also demonstrate immunization rates lower than 95%, with 83.2% of children aged 35 months having received at least 4 doses of diphtheria, tetanus, and pertussis vaccine; 92.7% having at least 3 doses of polio vaccine; and 91.5% having at least 1 dose of the measles, mumps, and rubella vaccine [9].

Vaccine hesitancy among parents or guardians is a growing public health issue reflected by the increased number of medical and nonmedical vaccine exemptions in both Canada and the United States [10]. Vaccine hesitancy is defined by the World Health Organization as the reluctance or refusal to vaccinate despite the availability of vaccines [11]. Despite continued efforts to improve childhood vaccination rates, both Canada and the United States are not meeting national goals, and nonmedical exemptions continue to proliferate [4,9].

Accessing information about the benefits and risks of childhood vaccines helps parents make informed decisions regarding vaccinating their children. Searching online via the internet allows individuals rapid access to health information. A 2016 survey of Canadians' online activity demonstrated that 96% of Canadians aged 15-34 years and 93% of those aged 35-44 years use the internet on a daily basis [12], and as many as 79% of American internet users have searched online for health information [13]. While accessing health information online is important, digital health literacy or having the skills to seek, find, understand, and appraise online health information and then apply that knowledge to making an informed decision is critical [14]. While population-based assessments of Canadian digital health literacy levels are unknown, the health literacy of Canadians is concerning. Over 60% of Canadians have low health literacy skills that place them at higher risk of poor health [15,16]. Canadian adults' health literacy skills were measured utilizing the International Adult Literacy and Skills Survey that assesses prose literacy, document literacy, numeracy, and problem-solving skills in different languages and cultures focused on broadly defined health content in the following areas: health promotion, health protection and accident prevention, disease prevention, and health care activities [16].

Vaccination information is available to most Canadians and Americans, although understanding and applying this information to one's individual health can be challenging. Online digital health information has evolved from static information retrievable from online websites to include interactive and collaborative sites where there is no central authority [17]. Within the context of childhood immunization information, parents are able to retrieve information but also contribute their personal knowledge and experience through interactive online social media platforms. Given the high prevalence of online information seeking among parents [18-20], investigating what information exists online related to childhood vaccinations and how parents use this information may provide insight into vaccination decision making. This scoping review examined research regarding parents' use of online resources regarding primary schedule vaccinations, to understand where parents are searching online and how they utilize online information to inform vaccination choices for their infants and children.

A scoping review was undertaken for 2 reasons: to grasp an understanding of the existing literature of parents' online health information-seeking behavior to inform vaccination choices for their children and to identify gaps in the literature around parents' use of online health information resources and their vaccination choices.

The following research questions informed this review: "What are parents' online information-seeking patterns and behaviors related to childhood primary immunization series?" and "How did parents use online resources to inform their decision regarding vaccination of their children?"

## Methods

A scoping review of the research literature was an appropriate method to examine this issue that is inclusive of qualitative, quantitative, and mixed methods literature to achieve a breadth of knowledge in this subject area. Researchers followed the collective guidelines of Colquhoun et al [21], Arksey and O'Malley [22], and Levac et al [23] to conduct this scoping review study. The steps involved in this review were identification of the research question; identification of relevant studies; study selection; charting the data; and collating, summarizing, and reporting the results [22].

### Identification and Study Selection

The following databases were searched: PubMed, CINAHL, Nursing & Allied Health Database, Scopus, and PsycINFO. The following search terms were used: vaccine, vaccines, vaccination, immunization, vaccinated, vaccinate, vaccine hesitancy, parent, parents, mother, mothers, father, fathers, parental, social media, digital health information, facebook, twitter, pinterest, snapchat, tumblr, Instagram, linkedin, google plus, youtube, reddit, flickr, vine, quora, periscope, whatsapp, and internet. Search terms were combined using AND or OR in the database search. A research librarian was consulted to assist with the search strategy. A justification search was completed with the Allied and Alternative Medicine (AMED) database; this search revealed no further articles in the subject area. Grey literature was located by searching Proquest

Dissertations & Theses Global. Reference lists of articles were hand searched to identify any further literature that met the inclusion criteria.

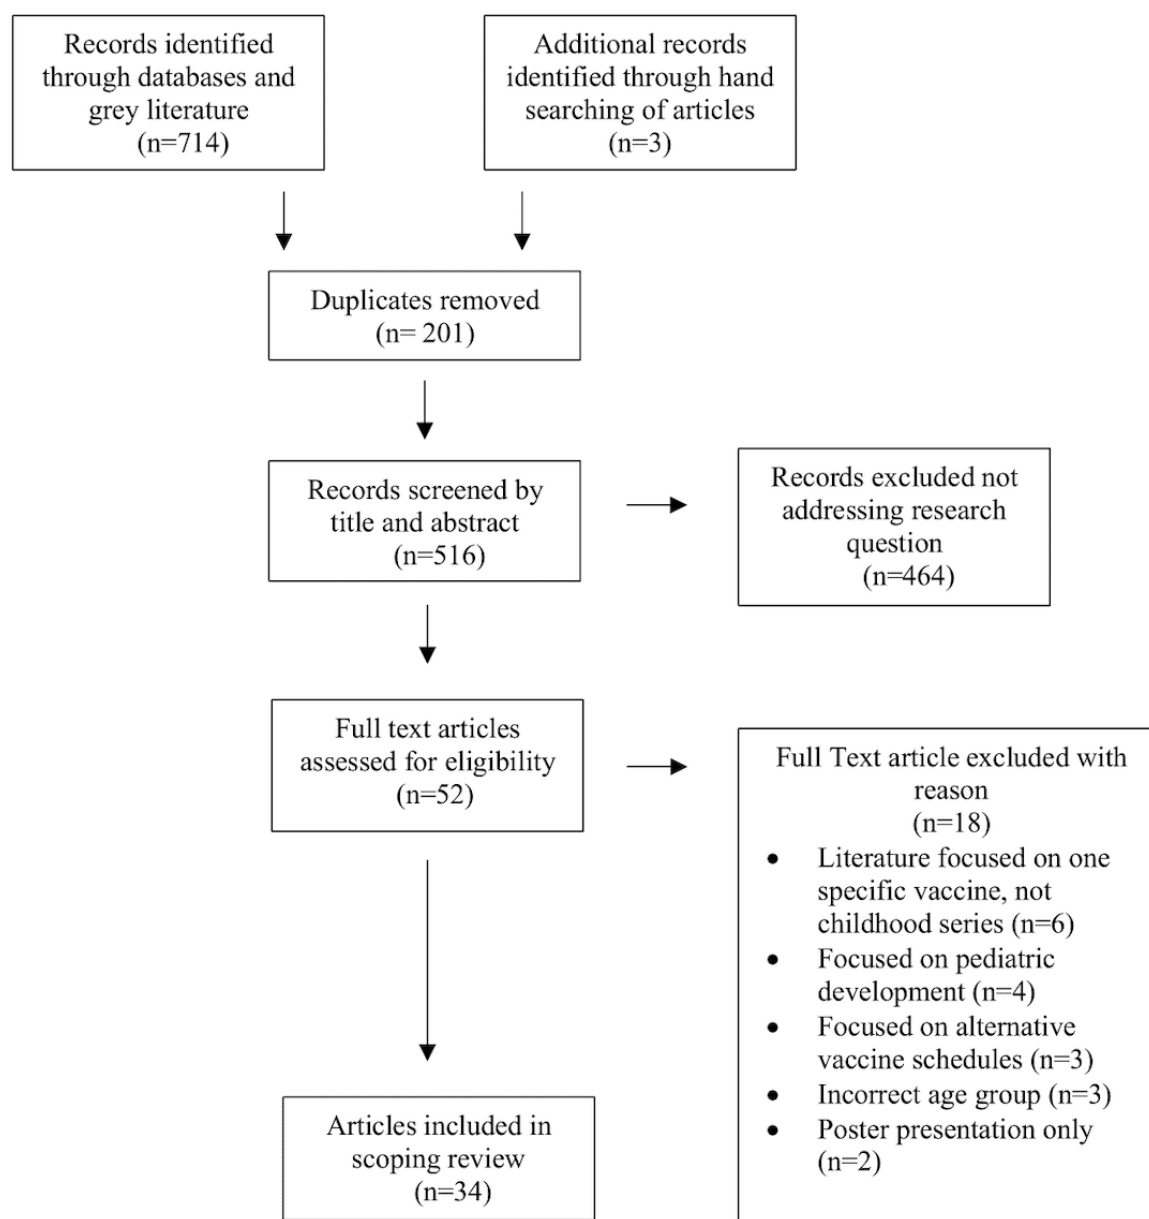

### Inclusion Criteria

Articles published from January 1, 2010 to December 31, 2019 in the English language from Canada and the United States were included. The aim was to focus on the past decade to reflect changes in information seeking that have occurred with widespread internet access in North America. The selected literature focused solely on the primary immunization series of children, parental decision relating to childhood vaccinations, online vaccination information seeking, and social media and childhood vaccinations.

### Exclusion Criteria

Articles published prior to January 1, 2010 were excluded as it is the authors' intent to determine the use of current social media and internet. Articles that focused on vaccination outside of the primary childhood series such as human papillomavirus and influenza and adult and adolescent hepatitis vaccinations were excluded. Any articles that focused on general childhood development and on adolescent vaccination decision making were excluded, as the intention is to focus the topic on parents' choices regarding vaccinations. Literature involving children who were able to consent to their own vaccines was also excluded from this review. Articles published in languages other than English were excluded, and articles where research was conducted outside of North America were excluded. [Figure 1](#) illustrates the PRISMA selection process [24].

**Figure 1.** PRISMA process to select articles.

## Analysis

A title review of all articles was conducted for subject eligibility, followed by an abstract review and finally a full article review. A second reviewer read 15% of the articles to ensure consistency in data analysis to address the research question and purpose [22,23]. Discrepancies between inclusion of articles were discussed between the authors until consensus was reached. After eligible articles were identified, each was read several times for detail and to identify relevant categories and themes. Articles were identified by a numbering system and collated in a spreadsheet identifying country of origin, methodologies, limitations, instruments, methods, and key findings from an iterative and inductive analysis of all articles. Thematic analysis allowed for identification of relevant themes grounded in the data and gaps in the literature. An iterative analysis process was utilized by the authors; themes were identified through discussion and immersion in the literature. Discrepancies were reconciled through discussion until all themes were mutually agreed upon.

## Results

The eligibility criteria for inclusion in the study were met by 34 articles. The majority (28/34, 82%) of the literature is from the United States, and 18% (6/34) is from Canada. The majority (20/34, 58%) of the literature was qualitative in nature, 32% (11/34) was quantitative, and 9% (3/34) used mixed method studies. Of the mixed method studies, 2 studies were concurrent, and 1 was sequential. Literature on social media was focused on the second half of the decade, with all but one article published between 2015 and 2019. The following 4 broad themes were identified: information seeking, online information resources, online vaccination information content, and trust in health care providers. A narrative review of these themes follows.

### Information Seeking

One of the most prevalent themes identified throughout the literature was one of information seeking; 50% (17/34) of articles discussed this theme [18,19,25-39]. Parents are looking online for vaccination information [18,26,27,30,31,39].

Online information seeking may have implications for the way that parents perceive the health and safety consequences of childhood vaccinations [20]. Canadian researchers investigated the impact of parental online information seeking through surveying parents and found that parents who searched the internet for childhood vaccine information (in 2011 and 2014) are more likely to perceive vaccines as less safe than those who did not search on the internet [20]. Yet, in another study also performed in 2011 that surveyed American parents, researchers found that 95% of parents of school-aged children who chose not to have their children vaccinated listed their health care provider as their main source of information, with only 34.5% reporting the internet as a source of information [25].

Mossey et al [34] evaluated Canadian parents' experiences in making vaccination decisions. Parents identified that searching for information was an important part of their decision-making process and that locating and interpreting online information

was difficult at times [34]. Reportedly, some parents looked for information online to confirm information provided by their health care provider; parents expressed concerns about their health care provider's lack of knowledge regarding childhood vaccines [35]. There is some evidence that parents who delayed or declined vaccinating their children specifically sought information through online social media platforms, such as blogs and videos, appreciating the personal experiences from other parents found on these platforms [34]. Jones et al [18] examined the information sources of parents of school-aged children in the United States who refused at least one vaccine for their child(ren). Researchers assessed the impact of diverse information sources on vaccine attitudes, beliefs, and medical exemptions. In this study, 40% of all respondents reported that the internet was a good source of vaccine information; however, only 19.9% of all parents in this study reported using the internet as a source of vaccine information [18]. Those who reported using the internet to obtain information about vaccines were less likely to agree that their children needed or would benefit from vaccines and were more likely to have obtained a nonmedical vaccine exemption for their child [18].

Hwang and Shah [33] examined the associations between health information sources, parental perceptions of vaccine benefits, and maintenance of vaccine schedules. They evaluated magazines, newspapers, television, the internet (search engines, general websites, drug company websites, and other health websites), interpersonal communication (doctors, nurses or physician assistants, pharmacists, and friends), and social media (social networking sites, blogs or vlogs) as health information sources [33]. Parents that valued social media as a source of health information reported fewer perceived benefits (identified as vaccine benefits outweighing vaccine risks) of vaccinations [33]. Positive parental perceptions of vaccine benefits were strongly associated with the maintenance of vaccination schedules [33].

Berthel [25] assessed sources of information among parents of school-aged children in the United States. They found that 95.4% of parents sought vaccine advice from their health care provider, 51.1% from family and friends, 34.5% from the internet, 25.3% from the news, and 15.5% from television and radio. Parents who cited the internet as a source of information listed the sites they most frequently used as webmd.com (34.4%), mayoclinic.com (27.5%), and government or other medically endorsed sites (68.9%) [25]. Researchers compared information sources of parents who vaccinated their child with those who exempted their children from vaccines. While 83.3% of immunizers versus 77.8% of vaccine abstainers identified health care providers as sources of vaccine information, only 25% of parents who immunized their children utilized the internet as a source of information compared to 44.4% of parents who did not immunize [25]. Deas et al [29] interviewed parents of school-aged children in 3 counties in the US state of Oregon with low immunization rates (combined pediatric immunization rate of 65%). Researchers found that all parents, regardless of vaccine acceptance or hesitancy, dismissed social media as they found it an unreliable source of vaccine information [29].

However, when exposed to evidence-informed online information, parental attitudes regarding childhood vaccinations

shifted; researchers found that, after exposure to a vaccine information website developed by experts in the field, vaccine-hesitant parents had a more positive attitude toward vaccines compared to vaccine-hesitant parents with no exposure to the evidence-informed website [28]. Glanz et al [32] evaluated vaccine information-seeking behaviors in parents who accessed information from an online website. The website was developed and mediated by several experts (pediatrician, vaccine safety researcher, and risk communication specialist). Parents in this study preferred to engage with online experts about vaccinations rather than interacting with other parents within this online site [32].

Researchers who focused on the composition of search terms used by parents seeking online vaccine information found that parents who utilized positive search terms (eg, “vaccine benefits”) when looking for childhood vaccine information encountered few myths about vaccine safety and effectiveness [40]. In contrast, parents who used negative search terms (eg, “vaccine risks”) found 4.8 times more misinformation or myths than a person using positive terminology [40]. The nature of the search terms used to find online vaccination information can alter the results and the information made available to parents [40].

### Online Information Resources

Parents searched online for vaccine information using common search engines such as Google and Yahoo, and many used popular social media sites such as Facebook, Instagram, Pinterest, Twitter, and YouTube [27,38,41-43]. One study found that the internet was listed within the top 3 most common sources for vaccine information among those who vaccinated their children, and 46% of parents who used the internet reported using search engines such as Google and Yahoo to search online for vaccine information [27].

The popularity of social media has given rise to prosumers — individuals who not only access online information but produce online content. Researchers found that websites that allow users to post online content without verification of information promoted antivaccination messages through antigovernment views, celebrities, personal stories, and naturalist arguments [43]. A Canadian assessment of online vaccine information websites (identified through searching Google, Facebook, Twitter, and YouTube) targeted to parents found that the majority of websites offered poor-quality information regarding childhood vaccination [42]. Researchers rated the websites with a communication index tool developed by the Centers for Disease Control and reported that 5% of materials (3 websites) met the standards for clear communication [42]. However, websites that monitored user-generated content and required academic references demonstrated a balance between openness and credibility [43].

### Online Vaccination Information Content

Researchers assessed the content of online vaccine information, and there is evidence that content was conflicting and inconsistent [20,41,43-47].

Regarding online websites, American researchers investigating online information content generated from Google searching

found that 59% of the first 100 Google sources were provaccine and 41% were antivaccine [43]. Similarly, Kata [46] sought antivaccination websites to assess their content and accuracy. Researchers utilized neutral vaccine information-seeking search terms (“vaccine,” “vaccination,” and “immunization OR immunisations”) to search American and Canadian versions of Google and found that, within the first 10 results, 24% of American and 13% of Canadian results were antivaccine [46]. A content analysis revealed that all of the assessed antivaccine websites claimed that vaccines are poisonous and cause idiopathic illnesses [46]. As well, 88% of the websites contained information that challenged the evidence about the efficacy of vaccines and whether vaccines conferred immunity, 88% endorsed alternative treatments (homeopathy, chiropractic care, naturopathy, or acupuncture) as superior to vaccination, 75% of the websites made accusations that regulatory bodies have information about vaccines that they are hiding from the public, and 75% of the websites suggested that vaccine promotion is solely motivated by profit seeking [46].

The content developers of websites advocating antivaccine messages used sophisticated strategies to communicate their perspective [48,49]. Researchers examined the content of antivaccine websites and found that these websites used persuasive tactics, attacked the credibility of vaccine advocates, expressed mistrust about scientific evidence, and used pseudoscientific evidence to support claims in favor of antivaccination [49]. Similarly, Getman et al [48] performed a network analysis of over 50,000 websites that contained vaccine-relevant content to determine the structure and influence of the online vaccine-hesitant community. They discovered effective use of hierarchical scientific language by the vaccine-hesitant community to enforce their online authority [48].

Regarding social media vaccine resources, researchers evaluated literature on vaccine information on the following social media platforms: YouTube, Twitter, Pinterest, Facebook, and various blogs. Facebook was identified as a vaccine information resource for parents in several studies [20,38,42,50]. The majority of research literature that focused on social media use among parents was published between 2015 and 2019, reflecting parents’ recent use of social media for seeking vaccine information. Parents also accessed social media sites to understand other parents’ experiences with vaccination processes; peer-to-peer information was a valued source of information accessible on social media sites [50]. Across social media platforms, there was a mix of positive and negative vaccine messaging. Our findings indicate widespread mistrust of government institutions and skepticism towards the vaccine industry across all social media platforms except for pediatrician-authored blogs [37,41,44,45,47,50-53]. Vaccine-hesitant online communities tend to leverage scientific and academic language to enforce their antivaccination narrative [48]. Consistent messaging about the dangers of vaccines was present on Twitter, Facebook, YouTube, parenting blogs, and Pinterest. The dominant message across social media was one of elevated health risks among vaccinated children — perceived as information concealed by government and industry.

## Trust in Health Care Providers

The concept of trusted health care providers was prevalent in many of the reviewed studies [18,20,27,30,31,34,35,45,46,49,50]. Parents often listed their physician or health care provider as a trusted source of vaccination information [18,27,30,31]. Eller et al [30] examined the association between the level of trust a mother had with their pediatrician and vaccine information sources. Mothers who trusted their pediatrician were 2.47 times more likely to list their pediatrician as their main source of vaccine information compared to mothers who had not established a trusting relationship with their pediatrician [30]. Parents who chose to vaccinate their children reported their physician as the biggest influence in their decision to vaccinate [27].

However, parents who identified as vaccine-hesitant or those who did not vaccinate their children were less trusting of information conveyed by their health care provider [27]. Parents who chose to delay or declined vaccinating their children tended to seek information from a diverse group of health disciplines such as cardiologists, health researchers, health care students, and homeopathic practitioners [34]. Kata [46] identified mistrust in the medical system as a strong message on antivaccine websites and on an antivaccination Facebook group [46,50].

## Discussion

This scoping review of 34 articles investigated parents' use of online information to inform vaccination choices for their children. Overall, research studies were broadly focused on understanding the content of online vaccine information and parents' online information seeking to inform their vaccine decisions. Our analysis of the current literature indicates that parents are actively looking online for vaccination information. Vaccination information was found on the social media platforms of YouTube, Twitter, Pinterest, and Facebook as well as various types of blogs. However, there is conflicting information within the published research regarding parental trust in the information found online and utilization of online information. Google was reported as the main online search engine among parents seeking vaccine information in both countries. The search terms that parents used in their online information seeking significantly impacted the disposition of the vaccine information and exposure to the number of vaccine myths retrieved online. Trust in health care providers plays an important role in information seeking. Parents who trust their health care provider tend to value them as an accurate source of vaccine information while those who do not trust their health care provider often seek information online. This is consistent with literature that demonstrates higher quality of life, more beneficial health behaviors, and higher treatment satisfaction when patients trust their health care provider [54].

The challenge for parents seeking vaccine information was the conflicting information found online. The influence of online vaccine information on parental vaccination practices (provaccination vs antivaccination) remains uncertain. A continuum of online information seeking among parents ranged from a complete dismissal of online information to regular online information access to inform their vaccine decision

making. Due to the limited amount of Canadian research available, direct comparison between Canada and the United States was not plausible. Existing Canadian research findings highlight the relationship between online information seeking and parental antivaccination sentiment; parents seeking information online were more likely to perceive vaccines as less safe and be less inclined to adhere to the recommended vaccine schedule [20]. However, a greater number of studies in this area is needed to substantiate these findings. There is a need for further research performed in Canada on parents' use of online vaccine information to determine how it informs their vaccine decisions.

Essentially absent in the published research was an understanding of parents' digital health literacy skills. Only one of the studies in this review considered parents' digital health literacy. The ability to interact with health information becomes more complex within the digital health context. Digital health literacy refers to the knowledge and skills inclusive of the ability to read and understand general information (traditional literacy and numeracy); effectively use digital devices, which includes awareness of data privacy, security, and ownership (computer literacy); critically understand and assess sophisticated media messages (media literacy); discern what is reliable and valid health information (scientific literacy); source information (information literacy); and navigate the health care system (health literacy) [14]. Although parents are looking online for information to inform their decision, the impact of parents' health literacy and digital health literacy skills that support access to credible information sources and an ability to critically assess the vaccination information is a significant gap in the research literature [55,56]. In fact, research exploring parents' information ecosystems is warranted to fully understand their information-seeking practices, preferred resources, and ability to critically evaluate vaccination-related information.

There was no research in this review that focused on parents' use of Instagram as a source for vaccine information. Research focused on parental use of Instagram and other emerging popular social media networks as a source for vaccine information is warranted.

The influence of misinformation on parental vaccine choices is an issue that may have significant implications for maintaining community immunity. Parents encounter inaccurate and false vaccine information, vaccine conspiracy theories, and vaccine myths propagated online, especially on social media sites [42,52]. Parents, in their search for information, may be exposed to persuasive tactics that perpetuate myths and fear mongering. Persuasive tactics combined with misinformation and myths may cause parents to believe that vaccines themselves are a threat to their child's health. Similar findings on the harms of social media rumors and misinformation surrounding COVID-19 also demonstrate the detrimental effects of online myth propagation. Improper use of pharmacological drugs and panic buying have resulted from online COVID-19 myths [57], as well as concern over the disease being spread through meat consumption and Chinese biological military laboratories [58].

Given the diversity of health information sources, health care providers along with public health organizations need to work

together with popular social media platforms to ensure information accuracy. Recently, some social media platforms have implemented measures to prevent the propagation of antivaccine messaging and misinformation. Twitter recently (2019) integrated a search tool into their platform that directs users to a sanctioned US government vaccine website [59]. Pinterest also implemented community guidelines in 2019 that limit misinformation; Pinterest now removes pins that promote antivaccine advice and redirects individuals to reputable vaccine information sources such as the World Health Organization [60]. Facebook and Instagram also implemented similar policies in 2019. Facebook suggests users visit a public health website for vaccine information, and Instagram blocks some false information posts and reports using third-party fact checkers to help reduce false information [61]. However, the prevalence of online vaccination myths including the misconception that vaccination causes autism persists [18,20,53], demonstrating that further work needs to be done to dispel unsubstantiated vaccine myths.

Given the prevalence of online antivaccine information and the use of hierarchical and authoritative language among the online vaccine-hesitant community to promote the antivaccine sentiment, [48] the composition of information-seeking factors has the potential to influence the nature of information that parents are accessing. Algorithms are used by online search engines such as Google to tailor information and influence the outcome of individuals' online information seeking [62]. The algorithms determine the information outcome based on factors such as the search terms used, country, and type of digital device [62]. One of the algorithms used by Google determines if content is reliable and demonstrates "expertise, authoritativeness, and trustworthiness" on a given topic [62]. Ruiz and Bell [40] determined that the character or disposition of a Google search for vaccine information significantly affects the outcome of the search. Parents who are concerned about and search for risk information regarding vaccines will encounter more vaccine myths than parents who use neutral search terms to search for vaccine benefits [48]. Understanding that Google is the most popular online search engine, health care providers may want to consult with parents regarding their search terms for online vaccination-related information. Further research exploring the impact of search algorithms and information-seeking behaviors regarding online vaccination information would be beneficial. It may be that clinicians not only "prescribe" evidence-informed online resources to parents but in addition will need to consider the composition of search strategies (eg, search terms or strings) to mitigate parents' access to vaccine misinformation and myths. The use of information prescriptions has been successful in the past for online searching in the pediatric parent population [63]. Educating parents about the benefits and risks of searching online and prescribing search terms may allow parents to access

evidence-informed information to facilitate informed decision making and also mitigate the potential harms of online vaccine myths. Research on the use of a search term prescription in this population is required.

### Limitations

This review evaluated parental information seeking in those who have internet access; it did not capture parents who have limited or no access to online health information. The online environment is fluid due to its interactive user-driven features with websites and social media evolving and changing from day to day. Findings involving online information should be viewed cautiously as digital information changes rapidly. This review included English-only research reports, and research literature in languages other than English may have findings that are different than reported here.

### Conclusion and Implications
