

Journal of Medical Internet Research

Impact Factor (2018): 4.945 - ranked #1 medical informatics journal by Impact Factor
Volume 22 (2020), Issue 7 ISSN: 1438-8871 Editor in Chief: Gunther Eysenbach, MD, MPH

Contents

Reviews

Technology Acceptance in Mobile Health: Scoping Review of Definitions, Models, and Measurement (e17256) Camille Nadal, Corina Sas, Gavin Doherty.	13
The Acceptability and Usability of Digital Health Interventions for Adults With Depression, Anxiety, and Somatoform Disorders: Qualitative Systematic Review and Meta-Synthesis (e16228) Shireen Patel, Athfah Akhtar, Sam Malins, Nicola Wright, Emma Rowley, Emma Young, Stephanie Sampson, Richard Morriss.	30
Methods and Evaluation Criteria for Apps and Digital Interventions for Diabetes Self-Management: Systematic Review (e18480) Dillys Larbi, Pietro Randine, Eirik Årsand, Konstantinos Antypas, Meghan Bradway, Elia Gabarron.	45
Technology-Based Interventions in Oral Anticoagulation Management: Meta-Analysis of Randomized Controlled Trials (e18386) Hengfen Dai, Caiyun Zheng, Chun Lin, Yan Zhang, Hong Zhang, Fan Chen, Yunchun Liu, Jingwen Xiao, Chaoxin Chen.	58
Digital Self-Management Interventions for People With Osteoarthritis: Systematic Review With Meta-Analysis (e15365) Reza Safari, Jessica Jackson, David Sheffield.	71
Reinforcement Learning for Clinical Decision Support in Critical Care: Comprehensive Review (e18477) Siqi Liu, Kay See, Kee Ngiam, Leo Celi, Xingzhi Sun, Mengling Feng.	95
Implementing Web-Based Therapy in Routine Mental Health Care: Systematic Review of Health Professionals' Perspectives (e17362) Fiona Davies, Heather Shepherd, Lisa Beatty, Brodie Clark, Phyllis Butow, Joanne Shaw.	111
Information Needs of Breast Cancer Patients: Theory-Generating Meta-Synthesis (e17907) Hongru Lu, Juan Xie, Lynette Gerido, Ying Cheng, Ya Chen, Lizhu Sun.	144
Evidence Regarding Automatic Processing Computerized Tasks Designed For Health Interventions in Real-World Settings Among Adults: Systematic Scoping Review (e17915) Harshani Jayasinghe, Camille Short, Annette Braunack-Mayer, Ashley Merkin, Clare Hume.	162
Design, Use, and Effects of Sex Dolls and Sex Robots: Scoping Review (e18551) Nicola Döring, M Mohseni, Roberto Walter.	174

Computer-Controlled Virtual Humans in Patient-Facing Systems: Systematic Review and Meta-Analysis (e18839)	
Debeleena Chattopadhyay, Tengting Ma, Hasti Sharifi, Pamela Martyn-Nemeth.	202
Effectiveness of Technology-Enabled Knowledge Translation Strategies in Improving the Use of Research in Public Health: Systematic Review (e17274)	
Alison Brown, Courtney Barnes, Judith Byaruhanga, Matthew McLaughlin, Rebecca Hodder, Debbie Booth, Nicole Nathan, Rachel Sutherland, Luke Wolfenden.	223
Digital Behavior Change Interventions for Younger Children With Chronic Health Conditions: Systematic Review (e16924)	
Amberly Brigden, Emma Anderson, Catherine Linney, Richard Morris, Roxanne Parslow, Teona Serafimova, Lucie Smith, Emily Briggs, Maria Loades, Esther Crawley.	239
Implementation Strategies for Web-Based Apps for Screening: Scoping Review (e15591)	
Chor Ooi, Chirk Ng, Anne Sales, Hooi Lim.	468
Assessing the Credibility and Authenticity of Social Media Content for Applications in Health Communication: Scoping Review (e17296)	
Eva Jenkins, Jasmina Ilicic, Amy Barklamb, Tracy McCaffrey.	756
Requirements of Health Data Management Systems for Biomedical Care and Research: Scoping Review (e17508)	
Leila Ismail, Huned Materwala, Achim Karduck, Abdu Adem.	1621
The Use of Social Media to Increase the Impact of Health Research: Systematic Review (e15607)	
Marco Bardus, Rola El Rassi, Mohamad Chahrour, Elie Akl, Abdul Raslan, Lokman Meho, Elie Akl.	1882

Original Papers

Using Digital Communication Technology to Increase HIV Testing Among Men Who Have Sex With Men and Transgender Women: Systematic Review and Meta-Analysis (e14230)	
Vanessa Veronese, Kathleen Ryan, Chad Hughes, Megan Lim, Alisa Pedrana, Mark Stooové.	123
Predictors of Self-Determined Module Choice in a Web-Based Computer-Tailored Diet and Physical Activity Intervention: Secondary Analysis of Data From a Randomized Controlled Trial (e15024)	
Juul Coumans, Catherine Bolman, Anke Oenema, Lilian Lechner.	391
Use of an Unguided, Web-Based Distress Self-Management Program After Breast Cancer Diagnosis: Sub-Analysis of CaringGuidance Pilot Study (e19734)	
Robin Lally, Kevin Kupzyk, Steve Gallo, Donna Berry.	406
Adherence to Established Treatment Guidelines Among Unguided Digital Interventions for Depression: Quality Evaluation of 28 Web-Based Programs and Mobile Apps (e16136)	
Stefan Bubolz, Gwendolyn Mayer, Nadine Gronewold, Thomas Hilbel, Jobst-Hendrik Schultz.	419
Effects of the e-Motivate4Change Program on Metabolic Syndrome in Young Adults Using Health Apps and Wearable Devices: Quasi-Experimental Study (e17031)	
Ji-Soo Lee, Min-Ah Kang, Soo-Kyoung Lee.	436

Dose-Response Relationship of a Web-Based Tailored Intervention Promoting Human Papillomavirus Vaccination: Process Evaluation of a Randomized Controlled Trial (e14822)	
Mirjam Pot, Theo Paulussen, Robert Ruiter, Liesbeth Mollema, Miranda Hofstra, Hilde Van Keulen.	450
Internet-Based Self-Management Support After High-Altitude Climate Treatment for Severe Asthma: Randomized Controlled Trial (e13145)	
Thijs Beerthuizen, Lucia Rijssenbeek-Nouwens, Sophia van Koppen, Rishi Khusial, Jiska Snoeck-Stroband, Jacob Sont.	479
Novel Stepped Care Approach to Provide Education and Exercise Therapy for Patellofemoral Pain: Feasibility Study (e18584)	
Danilo De Oliveira Silva, Marcella Pazzinatto, Kay Crossley, Fabio Azevedo, Christian Barton.	494
Scheduled Telephone Support for Internet Cognitive Behavioral Therapy for Depression in Patients at Risk for Dropout: Pragmatic Randomized Controlled Trial (e15732)	
Satu Pihlaja, Jari Lahti, Jari Lipsanen, Ville Ritola, Eero-Matti Gummerus, Jan-Henry Stenberg, Grigori Joffe.	507
Evaluation of a Blended Physical Activity Intervention for Older Adults: Mixed Methods Study (e16380)	
Sumit Mehra, Jantine van den Helder, Bart Visser, Raoul Engelbert, Peter Weijs, Ben Kröse.	519
Evaluation of a Web-Based Self-Management Program for Patients With Cardiovascular Disease: Explorative Randomized Controlled Trial (e17422)	
Marscha Engelen, Sandra van Dulmen, Saskia Puijk-Hekman, Hester Vermeulen, Maria Nijhuis-van der Sanden, Sebastian Bredie, Betsie van Gaal.	532
An mHealth Intervention (ReZone) to Help Young People Self-Manage Overwhelming Feelings: Cluster-Randomized Controlled Trial (e14223)	
Chloe Edridge, Miranda Wolpert, Jessica Deighton, Julian Edbrooke-Childs.	546
Impact of an Electronic Health Service on Child Participation in Pediatric Oncology Care: Quasiexperimental Study (e17673)	
Britt-Mari Gilljam, Jens Nygren, Petra Svedberg, Susann Arvidsson.	552
Teens Taking Charge: A Randomized Controlled Trial of a Web-Based Self-Management Program With Telephone Support for Adolescents With Juvenile Idiopathic Arthritis (e16234)	
Jennifer Stinson, Chitra Laloo, Amos Hundert, Sarah Campillo, Tania Cellucci, Paul Dancey, Ciaran Duffy, Janet Ellsworth, Brian Feldman, Adam Huber, Nicole Johnson, Geert't Jong, Kiem Oen, Alan Rosenberg, Natalie Shiff, Lynn Spiegel, Shirley Tse, Lori Tucker, Joseph Victor.	568
Designing a Personalized Digital Patient Support Program for Patients Treated With Growth Hormone: Key Design Considerations (e18157)	
Sumaira Malik, Clare Moloney, Ekaterina Koledova, Jonathan Reston, John Weinman.	584
A Mobile Health Approach for Improving Outcomes in Suicide Prevention (SafePlan) (e17481)	
Conor O'Grady, Ruth Melia, John Bogue, Mary O'Sullivan, Karen Young, Jim Duggan.	593
Participatory Interventions for Sexual Health Promotion for Adolescents and Young Adults on the Internet: Systematic Review (e15378)	
Philippe Martin, Lorraine Cousin, Serge Gottot, Aurelie Bourmaud, Elise de La Rochebrochard, Corinne Alberti.	607
Perceived Effectiveness and Motivations for the Use of Web-Based Mental Health Programs: Qualitative Study (e16961)	
Heidi Eccles, Molly Nannarone, Bonnie Lashewicz, Mark Attridge, Alain Marchand, Alice Aiken, Kendall Ho, Jianli Wang.	624
A Virtual Reality-Supported Intervention for Pulmonary Rehabilitation of Patients With Chronic Obstructive Pulmonary Disease: Mixed Methods Study (e14178)	
Timothy Jung, Natasha Moorhouse, Xin Shi, Muhammad Amin.	637

A Dietary Mobile App for Patients Undergoing Hemodialysis: Prospective Pilot Study to Improve Dietary Intakes (e17817)	
Cosette Fakih El Khoury, Rik Crutzen, Jos Schols, Ruud Halfens, Mirey Karavetian.	650
Experiences With Wearable Activity Data During Self-Care by Chronic Heart Patients: Qualitative Study (e15873)	
Tariq Andersen, Henriette Langstrup, Stine Lomborg.	661
Perceptions and Acceptability of Digital Interventions Among Tuberculosis Patients in Cambodia: Qualitative Study of Video-Based Directly Observed Therapy (e16856)	
Lila Rabinovich, James Molton, Wei Ooi, Nicholas Paton, Shelly Batra, Joanne Yoong.	675
Detection of Suicidal Ideation on Social Media: Multimodal, Relational, and Behavioral Analysis (e17758)	
Diana Ramírez-Cifuentes, Ana Freire, Ricardo Baeza-Yates, Joaquim Puntí, Pilar Medina-Bravo, Diego Velazquez, Josep Gonfaus, Jordi González.	685
An Instagram-Based Study to Understand Betel Nut Use Culture in Micronesia: Exploratory Content Analysis (e13954)	
Wayne Buente, Francis Dalisay, Pallav Pokhrel, Hanae Kramer, Ian Pagano.	701
Characterizing Social Media Messages Related to Underage JUUL E-Cigarette Buying and Selling: Cross-Sectional Analysis of Reddit Subreddits (e16962)	
Hejing Liu, Qiudan Li, Yongcheng Zhan, Zhu Zhang, Daniel Zeng, Scott Leischow.	714
The Development of a Smart Health Awareness Message Framework Based on the Use of Social Media: Quantitative Study (e16212)	
Elaf Alsisi, Ahmed Al-Ashaab, Wadhah Abualfaraa.	727
Sudden Infant Death Syndrome on Facebook: Qualitative Descriptive Content Analysis to Guide Prevention Efforts (e18474)	
Kelly Pretorius, Eunju Choi, Sookja Kang, Michael Mackert.	744
Influence of Social Media on Sexualized Drug Use and Chemsex Among Chinese Men Who Have Sex With Men: Observational Prospective Cohort Study (e17894)	
Zixin Wang, Xue Yang, Phoenix Mo, Yuan Fang, Tsun Ip, Joseph Lau.	771
Blended Care-Cognitive Behavioral Therapy for Depression and Anxiety in Real-World Settings: Pragmatic Retrospective Study (e18723)	
Anita Lungu, Janie Jun, Okhtay Azarmanesh, Yan Leykin, Connie Chen.	790
Effectiveness of a Transdiagnostic Guided Internet-Delivered Protocol for Emotional Disorders Versus Treatment as Usual in Specialized Care: Randomized Controlled Trial (e18220)	
Alberto González-Robles, Amanda Díaz-García, Azucena García-Palacios, Pablo Roca, Josep Ramos-Quiroga, Cristina Botella.	802
Habits and Attitudes of Video Gaming and Information Technology Use in People with Schizophrenia: Cross-Sectional Survey (e14865)	
William Choi, Dan Yu, Terry Wong, Tella Lantta, Min Yang, Maritta Välimäki.	825
Mobile Mental Health Apps in China: Systematic App Store Search (e14915)	
Huifang Yin, Klaas Wardenaar, Yuhao Wang, Nan Wang, Wenjin Chen, Yan Zhang, Guangming Xu, Robert Schoevers.	843

Surveilling Influenza Incidence With Centers for Disease Control and Prevention Web Traffic Data: Demonstration Using a Novel Dataset (e14337)	
Wendy Caldwell, Geoffrey Fairchild, Sara Del Valle.	856
Evaluation of Volume of News Reporting and Opioid-Related Deaths in the United States: Comparative Analysis Study of Geographic and Socioeconomic Differences (e17693)	
Yulin Hswen, Amanda Zhang, Clark Freifeld, John Brownstein.	871
Eating Disorder Awareness Campaigns: Thematic and Quantitative Analysis Using Twitter (e17626)	
Iranzu Viguria, Miguel Alvarez-Mon, Maria Llaverio-Valero, Angel Asunsolo del Barco, Felipe Ortuño, Melchor Alvarez-Mon.	879
Conversations and Misconceptions About Chemotherapy in Arabic Tweets: Content Analysis (e13979)	
Abdulrahman Alghamdi, Khalid Abumelha, Jawad Allarakia, Ahmed Al-Shehri.	890
Causality Analysis of Google Trends and Dengue Incidence in Bandung, Indonesia With Linkage of Digital Data Modeling: Longitudinal Observational Study (e17633)	
Muhammad Syamsuddin, Muhammad Fakhruddin, Jane Sahetapy-Engel, Edy Soewono.	899
Investigation of Geographic and Macrolevel Variations in LGBTQ Patient Experiences: Longitudinal Social Media Analysis (e17087)	
Yulin Hswen, Amanda Zhang, Kara Sewalk, Gaurav Tuli, John Brownstein, Jared Hawkins.	909
The Effects of Telemonitoring on Patient Compliance With Self-Management Recommendations and Outcomes of the Innovative Telemonitoring Enhanced Care Program for Chronic Heart Failure: Randomized Controlled Trial (e17559)	
Hang Ding, Rajiv Jayasena, Sheau Chen, Andrew Maiorana, Alison Dowling, Jamie Layland, Norm Good, Mohanraj Karunanithi, Iain Edwards.	909
Wearable Motion Sensor Device to Facilitate Rehabilitation in Patients With Shoulder Adhesive Capsulitis: Pilot Study to Assess Feasibility (e17032)	
Yu-Pin Chen, Chung-Ying Lin, Ming-Jr Tsai, Tai-Yuan Chuang, Oscar Lee.	930
Health Care Professionals' Views on Using Remote Measurement Technology in Managing Central Nervous System Disorders: Qualitative Interview Study (e17414)	
Jacob Andrews, Michael Craven, Jennifer Jamnadas-Khoda, Alexandra Lang, Richard Morriss, Chris Hollis, The RADAR-CNS Consortium.	930
Comprehensive Telestroke Network to Optimize Health Care Delivery for Cerebrovascular Diseases: Algorithm Development (e18058)	
Hernán Bayona, Brenda Ropero, Antonio Salazar, Juan Pérez, Manuel Granja, Carlos Martínez, Juan Useche.	957
The Internet Hospital as a Telehealth Model in China: Systematic Search and Content Analysis (e17995)	
Yangyang Han, Reidar Lie, Rui Guo.	976
Technology-Enabled Self-Management of Chronic Obstructive Pulmonary Disease With or Without Asynchronous Remote Monitoring: Randomized Controlled Trial (e18598)	
Vess Stamenova, Kyle Liang, Rebecca Yang, Katrina Engel, Florence van Lieshout, Elizabeth Lalingo, Angelica Cheung, Adam Erwood, Maria Radina, Allen Greenwald, Payal Agarwal, Aman Sidhu, R Bhatia, James Shaw, Roshan Shafai, Onil Bhattacharyya.	985
Clinical Characteristics of an Internet-Based Cohort of Patient-Reported Diagnosis of Granulomatosis With Polyangiitis and Microscopic Polyangiitis: Observational Study (e17231)	
Jason Springer, Tanaz Kermani, Antoine Sreih, Dianne Shaw, Kalen Young, Cristina Burroughs, Peter Merkel.	999
Worldwide Prevalence of Hearing Loss Among Smartphone Users: Cross-Sectional Study Using a Mobile-Based App (e17238)	
Marcin Masalski, Krzysztof Morawski.	1008

Digital Divide in Perceived Benefits of Online Health Care and Social Welfare Services: National Cross-Sectional Survey Study (e17616)	
Tarja Heponiemi, Vesa Jormanainen, Lars Leemann, Kristiina Manderbacka, Anna-Mari Aalto, Hannele Hyppönen.	1021
Relationships Between the Usage of Televisions, Computers, and Mobile Phones and the Quality of Sleep in a Chinese Population: Community-Based Cross-Sectional Study (e18095)	
Yao Xie, Daphne Cheung, Alice Loke, Bernice Nogueira, Karry Liu, Angela Leung, Alice Tsang, Cindy Leong, Alex Molassiotis.	1033
Exploring the Relationship Between Internet Use and Mental Health Among Older Adults in England: Longitudinal Observational Study (e15683)	
Sabrina Lam, Stephen Jivraj, Shaun Scholes.	1046
Understanding the Dimensions of Medical Crowdfunding: A Visual Analytics Approach (e18813)	
Jie Ren, Viju Raghupathi, Wullianallur Raghupathi.	1059
The Potential of Smartphone Apps in Informing Protobacco and Antitobacco Messaging Efforts Among Underserved Communities: Longitudinal Observational Study (e17451)	
Edmund Lee, Mesfin Bekalu, Rachel McCloud, Donna Vallone, Monisha Arya, Nathaniel Osgood, Xiaoyan Li, Sara Minsky, Kasisomayajula Viswanath.	1078
Diagnosing Parkinson Disease Through Facial Expression Recognition: Video Analysis (e18697)	
Bo Jin, Yue Qu, Liang Zhang, Zhan Gao.	1090
Characterization and Correction of Bias Due to Nonparticipation and the Degree of Loyalty in Large-Scale Finnish Loyalty Card Data on Grocery Purchases: Cohort Study (e18059)	
Anna-Leena Vuorinen, Maijaliisa Erkkola, Mikael Fogelholm, Satu Kinnunen, Hannu Saarijärvi, Liisa Uusitalo, Turkka Näppilä, Jaakko Nevalainen.	1102
Ontological Organization and Bioinformatic Analysis of Adverse Drug Reactions From Package Inserts: Development and Usability Study (e20443)	
Xiaoying Li, Xin Lin, Huiling Ren, Jinjing Guo.	1117
QardioArm Blood Pressure Monitoring in a Population With Type 2 Diabetes: Validation Study (e19781)	
Victoria Mazoteras-Pardo, Ricardo Becerro-De-Bengoa-Vallejo, Marta Losa-Iglesias, Eva Martínez-Jiménez, César Calvo-Lobo, Carlos Romero-Morales, Daniel López-López, Patricia Palomo-López.	1129
Understanding the Acceptability of Subdermal Implants as a Possible New HIV Prevention Method: Multi-Stage Mixed Methods Study (e16904)	
Christine Rael, Cody Lentz, Alex Carballo-Diéguez, Rebecca Giguere, Curtis Dolezal, Daniel Feller, Richard D'Aquila, Thomas Hope.	1139
A Precision Medicine Tool for Patients With Multiple Sclerosis (the Open MS BioScreen): Human-Centered Design and Development (e15605)	
Erica Schleimer, Jennifer Pearce, Andrew Barnecut, William Rowles, Antoine Lizée, Arno Klein, Valerie Block, Adam Santaniello, Adam Renschen, Refujia Gomez, Anisha Keshavan, Jeffrey Gelfand, Roland Henry, Stephen Hauser, Riley Bove.	1153
The Promise of Patient Portals for Individuals Living With Chronic Illness: Qualitative Study Identifying Pathways of Patient Engagement (e17744)	
Maureen Stewart, Timothy Hogan, Jeff Nicklas, Stephanie Robinson, Carolyn Purington, Christopher Miller, Varsha Vimalananda, Samantha Connolly, Hill Wolfe, Kim Nazi, Dane Netherton, Stephanie Shimada.	1171
Features of a Patient Portal for Blood Test Results and Patient Health Engagement: Web-Based Pre-Post Experiment (e15798)	
Bas Struikman, Nadine Bol, Annelijn Goedhart, Julia van Weert, Esther Talboom-Kamp, Sanne van Delft, Anne Brabers, Liset van Dijk.	1181

An Untapped Potential in Primary Care: Semi-Structured Interviews with Clinicians on How Patient Portals Will Work for Caregivers in the Safety Net (e18466)	
Alejandra Casillas, Anupama Cemballi, Anshu Abhat, Miya Lemberg, Jennifer Portz, Shobha Sadasivaiah, Neda Ratanawongsa, Wagahta Semere, Arleen Brown, Courtney Lyles.	1191
Patient Portal Implementation and Uptake: Qualitative Comparative Case Study (e18973)	
Melita Avdagovska, Mark Ballermann, Karin Olson, Timothy Graham, Devidas Menon, Tania Stafinski.	1202
The Assessment of Supportive Accountability in Adults Seeking Obesity Treatment: Psychometric Validation Study (e17967)	
Karishma Chhabria, Kathryn Ross, Shane Sacco, Tricia Leahey.	1219
Benefits of Massive Open Online Course Participation: Deductive Thematic Analysis (e17318)	
Elizabeth Blum, Terese Stenfors, Per Palmgren.	1231
Use of a Low-Cost Portable 3D Virtual Reality Gesture-Mediated Simulator for Training and Learning Basic Psychomotor Skills in Minimally Invasive Surgery: Development and Content Validity Study (e17491)	
Fernando Alvarez-Lopez, Marcelo Maina, Francesc Saigí-Rubió.	1242
Evaluation of Adaptive Feedback in a Smartphone-Based Game on Health Care Providers' Learning Gain: Randomized Controlled Trial (e17100)	
Timothy Tuti, Niall Winters, Hilary Edgcombe, Naomi Muinga, Conrad Wanyama, Mike English, Chris Paton.	1279
An Internet-Based Psychological Intervention With a Serious Game to Improve Vitality, Psychological and Physical Condition, and Immune Function in Healthy Male Adults: Randomized Controlled Trial (e14861)	
Lemmy Schakel, Dieuwke Veldhuijzen, Henriët van Middendorp, Corine Prins, Anne Driittij, Frank Vrieling, Leo Visser, Tom Ottenhoff, Simone Joosten, Andrea Evers.	1295
Diabetes-Related Topics in an Online Forum for Caregivers of Individuals Living With Alzheimer Disease and Related Dementias: Qualitative Inquiry (e17851)	
Yan Du, Kristi Paiva, Adrian Cebula, Seon Kim, Katrina Lopez, Chengdong Li, Carole White, Sahiti Myneni, Sudha Seshadri, Jing Wang.	1
Assessment of Adaptive Engagement and Support Model for People With Chronic Health Conditions in Online Health Communities: Combined Content Analysis (e17338)	
Brian Green, Katelyn Van Horn, Ketki Gupte, Megan Evans, Sara Hayes, Amrita Bhowmick.	1325
Characteristics, Symptom Severity, and Experiences of Patients Reporting Chronic Kidney Disease in the PatientsLikeMe Online Health Community: Retrospective and Qualitative Study (e18548)	
Glen James, Elisabeth Nyman, Marcy Fitz-Randolph, Anna Niklasson, Katarina Hedman, Jonatan Hedberg, Eric Wittbrodt, Jennie Medin, Carol Moreno Quinn, Alaster Allum, Cathy Emmas.	1340
Evaluating the Impact of the Grading and Assessment of Predictive Tools Framework on Clinicians and Health Care Professionals' Decisions in Selecting Clinical Predictive Tools: Randomized Controlled Trial (e15770)	
Mohamed Khalifa, Farah Magrabi, Blanca Gallego Luxan.	1356
Paving the Way for the Implementation of a Decision Support System for Antibiotic Prescribing in Primary Care in West Africa: Preimplementation and Co-Design Workshop With Physicians (e17940)	
Nathan Peiffer-Smadja, Armel Poda, Abdoul-Salam Ouedraogo, Jean-Baptiste Guiard-Schmid, Tristan Delory, Josselin Le Bel, Elisabeth Bouvet, Sylvie Lariven, Pauline Jeanmougin, Raheelah Ahmad, François-Xavier Lescure.	1375
Asthma Exacerbation Prediction and Risk Factor Analysis Based on a Time-Sensitive, Attentive Neural Network: Retrospective Cohort Study (e16981)	
Yang Xiang, Hangyu Ji, Yujia Zhou, Fang Li, Jingcheng Du, Laila Rasmy, Stephen Wu, W Zheng, Hua Xu, Degui Zhi, Yaoyun Zhang, Cui Tao.	1

Development and Usability Evaluation of a Facebook-Based Intervention Program for Childhood Cancer Patients: Mixed Methods Study (e18779)	
Bu Park, Ji Kim, Valerie Rogers.	1408
Enabling Better Use of Person-Generated Health Data in Stroke Rehabilitation Systems: Systematic Development of Design Heuristics (e17132)	
Gerardo Dimaguila, Kathleen Gray, Mark Merolli.	1422
Recruiting and Retaining Youth and Young Adults in the Policy and Communication Evaluation (PACE) Vermont Study: Randomized Controlled Trial of Participant Compensation (e18446)	
Andrea Villanti, Christie Vallencourt, Julia West, Catherine Peasley-Miklus, S LePine, Caitlin McCluskey, Elias Klemperer, Jeffrey Priest, Alison Logan, Bill Patton, Nancy Erickson, Jennifer Hicks, Kathleen Horton, Shayla Livingston, Maria Roemhildt, Erin Singer, Megan Trutor, Rhonda Williams.	1440
Effectiveness of Social Media Approaches to Recruiting Young Adult Cigarillo Smokers: Cross-Sectional Study (e12619)	
David Cavallo, Rock Lim, Karen Ishler, Maria Pagano, Rachel Perovsek, Elizabeth Albert, Sarah Koopman Gonzalez, Erika Trapl, Susan Flocke.	1453
Exploring the Privacy-Preserving Properties of Word Embeddings: Algorithmic Validation Study (e18055)	
Mohamed Abdalla, Moustafa Abdalla, Graeme Hirst, Frank Rudzicz.	1463
Surveillance of Noncommunicable Disease Epidemic Through the Integrated Noncommunicable Disease Collaborative Management System: Feasibility Pilot Study Conducted in the City of Ningbo, China (e17340)	
Sixuan Li, Liang Zhang, Shiwei Liu, Richard Hubbard, Hui Li.	1475
Considerations for Health Researchers Using Social Media for Knowledge Translation: Multiple Case Study (e15121)	
Sarah Elliott, Michele Dyson, Gilbert Wilkes, Gabrielle Zimmermann, Christine Chambers, Kristy Wittmeier, Dianne Russell, Shannon Scott, Denise Thomson, Lisa Hartling.	1486
Adherence to Blended or Face-to-Face Smoking Cessation Treatment and Predictors of Adherence: Randomized Controlled Trial (e17207)	
Lutz Siemer, Marjolein Brusse-Keizer, Marloes Postel, Somaya Ben Allouch, Robbert Sanderman, Marcel Pieterse.	1501
Effects of Incentives on Adherence to a Web-Based Intervention Promoting Physical Activity: Naturalistic Study (e18338)	
Ramona Wurst, Anja Maliezefski, Christina Ramsenthaler, Judith Brame, Reinhard Fuchs.	1519
Synthesizing Multiple Stakeholder Perspectives on Using Virtual Reality to Improve the Periprocedural Experience in Children and Adolescents: Survey Study (e19752)	
Naseem Ahmadpour, Andrew Weatherall, Minal Menezes, Soojeong Yoo, Hanyang Hong, Gail Wong.	1530
Combination of 3-Dimensional Virtual Reality and Hands-On Aromatherapy in Improving Institutionalized Older Adults' Psychological Health: Quasi-Experimental Study (e17096)	
Vivian Cheng, Chiu-Mieh Huang, Jung-Yu Liao, Hsiao-Pei Hsu, Shih-Wen Wang, Su-Fei Huang, Jong-Long Guo.	1542
Virtual Reality Smartphone-Based Intervention for Smoking Cessation: Pilot Randomized Controlled Trial on Initial Clinical Efficacy and Adherence (e17571)	
Emilio Goldenhersch, Johannes Thrul, Joaquín Ungaretti, Nicolas Rosencovich, Cristian Waitman, Marcelo Ceberio.	1554
Biased Sampling and Causal Estimation of Health-Related Information: Laboratory-Based Experimental Research (e17502)	
María Moreno-Fernández, Helena Matute.	1569

Crawling the German Health Web: Exploratory Study and Graph Analysis (e17853)	
Richard Zowalla, Thomas Wetter, Daniel Pfeifer.	1583
Psychometric Properties of the Norwegian Version of the Electronic Health Literacy Scale (eHEALS) Among Patients After Percutaneous Coronary Intervention: Cross-Sectional Validation Study (e17312)	
Gunhild Brørs, Tore Wentzel-Larsen, Håvard Dalen, Tina Hansen, Cameron Norman, Astrid Wahl, Tone Norekvål, The CONCARD Investigators.	1605
The Influence of Electronic Health Record Use on Physician Burnout: Cross-Sectional Survey (e19274)	
Tania Tajirian, Vicky Stergiopoulos, Gillian Strudwick, Lydia Sequeira, Marcos Sanches, Jessica Kemp, Karishini Ramamoorthi, Timothy Zhang, Damian Jankowicz.	1637
Adoption and Performance of Complementary Clinical Information Technologies: Analysis of a Survey of General Practitioners (e16300)	
Placide Poba-Nzaou, Sylvestre Uwizemungu, Xuecheng Liu.	1650
Information Overload in Emergency Medicine Physicians: A Multisite Case Study Exploring the Causes, Impact, and Solutions in Four North England National Health Service Trusts (e19126)	
Laura Sbaffi, James Walton, John Blenkinsopp, Graham Walton.	1663
Assessing Patient Experience and Healthcare Quality of Dental Care Using Patient Online Reviews in the United States: Mixed Methods Study (e18652)	
Ye Lin, Y Hong, Bradley Henson, Robert Stevenson, Simon Hong, Tianchu Lyu, Chen Liang.	1681
Causal Effect of Honorary Titles on Physicians' Service Volumes in Online Health Communities: Retrospective Study (e18527)	
Haiyan Yu, Yali Wang, Jying-Nan Wang, Ya-Ling Chiu, Hang Qiu, Mingyue Gao.	1694
Gender, Soft Skills, and Patient Experience in Online Physician Reviews: A Large-Scale Text Analysis (e14455)	
Zackary Dunivin, Lindsay Zadunayski, Ujjwal Baskota, Katie Siek, Jennifer Mankoff.	1708
Changing the Health Behavior of Patients With Cardiovascular Disease Through an Electronic Health Intervention in Three Different Countries: Cost-Effectiveness Study in the Do Cardiac Health: Advanced New Generation Ecosystem (Do CHANGE) 2 Randomized Controlled Trial (e17351)	
Jordi Piera-Jiménez, Marjolein Winters, Eva Broers, Damià Valero-Bover, Mirela Habibovic, Jos Widdershoven, Frans Folkvord, Francisco Lupiáñez-Villanueva.	1724
The Cyclic Value-Context Reinforcement Model of Problematic Internet Use: Empirical Validation Using a Thematic Analysis of Children's Counseling Data (e17996)	
Young Doh, Bugeun Kim, Seul Lee, Gahgene Gweon.	1742
Public Perception of Artificial Intelligence in Medical Care: Content Analysis of Social Media (e16649)	
Shuqing Gao, Lingnan He, Yue Chen, Dan Li, Kaisheng Lai.	1755
Automatic Recognition, Segmentation, and Sex Assignment of Nocturnal Asthmatic Coughs and Cough Epochs in Smartphone Audio Recordings: Observational Field Study (e18082)	
Filipe Barata, Peter Tinschert, Frank Rassouli, Claudia Steurer-Stey, Elgar Fleisch, Milo Puhan, Martin Brutsche, David Kotz, Tobias Kowatsch.	1766
Artificial Intelligence in Health Care: Bibliometric Analysis (e18228)	
Yuqi Guo, Zhichao Hao, Shichong Zhao, Jiaqi Gong, Fan Yang.	1781
Effectiveness and Safety of Using Chatbots to Improve Mental Health: Systematic Review and Meta-Analysis (e16021)	
Alaa Abd-Alrazaq, Asma Rababeh, Mohannad Alajlani, Bridgette Bewick, Mowafa Househ.	1793

Acceptance and Commitment Therapy Delivered via a Mobile Phone Messaging Robot to Decrease Postoperative Opioid Use in Patients With Orthopedic Trauma: Randomized Controlled Trial (e17750)	
Chris Anthony, Edward Rojas, Valerie Keffala, Natalie Glass, Apurva Shah, Benjamin Miller, Matthew Hogue, Michael Willey, Matthew Karam, John Marsh.	1810
Reactions to an Online Demonstration of the Effect of Increased Fruit and Vegetable Consumption on Appearance: Survey Study (e15726)	
Patrick Cairns, Gozde Ozakinci, David Perrett.	1823
The Current State of Research, Challenges, and Future Research Directions of Blockchain Technology in Patient Care: Systematic Review (e18619)	
Polina Durneva, Karlene Cousins, Min Chen.	1832
Integrating Health Technologies in Health Services for Syrian Refugees in Lebanon: Qualitative Study (e14283)	
Reem Talhouk, Chaza Akik, Vera Araujo-Soares, Balsam Ahmad, Sandra Mesmar, Patrick Olivier, Madeline Balaam, Kyle Montague, Andrew Garbett, Hala Ghattas.	1848
Internet-Based Sharing Nurse Program and Nurses' Perceptions in China: Cross-Sectional Survey (e16644)	
Rendong Huang, Mei Xu, Xiuting Li, Yinping Wang, Bin Wang, Naixue Cui.	1856
Consequences of Gift Giving in Online Health Communities on Physician Service Quality: Empirical Text Mining Study (e18569)	
Li Peng, Yanan Wang, Jing Chen.	1866
Information Loss in Harmonizing Granular Race and Ethnicity Data: Descriptive Study of Standards (e14591)	
Karen Wang, Holly Grossetta Nardini, Lori Post, Todd Edwards, Marcella Nunez-Smith, Cynthia Brandt.	1902

Abstract

Background: Designing technologies that users will be interested in, start using, and keep using has long been a challenge. In the health domain, the question of technology acceptance is even more important, as the possible intrusiveness of technologies could lead to patients refusing to even try them. Developers and researchers must address this question not only in the design and evaluation of new health care technologies but also across the different stages of the user's journey. Although a range of definitions for these stages exists, many researchers conflate related terms, and the field would benefit from a coherent set of definitions and associated measurement approaches.

Objective: This review aims to explore how technology acceptance is interpreted and measured in mobile health (mHealth) literature. We seek to compare the treatment of acceptance in mHealth research with existing definitions and models, identify potential gaps, and contribute to the clarification of the process of technology acceptance.

Methods: We searched the PubMed database for publications indexed under the Medical Subject Headings terms "Patient Acceptance of Health Care" and "Mobile Applications." We included publications that (1) contained at least one of the terms "acceptability," "acceptance," "adoption," "accept," or "adopt"; and (2) defined the term. The final corpus included 68 relevant studies.

Results: Several interpretations are associated with technology acceptance, few consistent with existing definitions. Although the literature has influenced the interpretation of the concept, usage is not homogeneous, and models are not adapted to populations with particular needs. The prevalence of measurement by custom surveys suggests a lack of standardized measurement tools.

Conclusions: Definitions from the literature were published separately, which may contribute to inconsistent usage. A definition framework would bring coherence to the reporting of results, facilitating the replication and comparison of studies. We propose the Technology Acceptance Lifecycle, consolidating existing definitions, articulating the different stages of technology acceptance, and providing an explicit terminology. Our findings illustrate the need for a common definition and measurement framework and the importance of viewing technology acceptance as a staged process, with adapted measurement methods for each stage.

KEYWORDS

Technology Acceptance Lifecycle; patient acceptance; mobile applications; mHealth; mobile phone

Introduction

Background

Technology acceptance is a major challenge faced by designers of new technologies. In health care, patients are a vulnerable

population, and their data are considered sensitive, especially in the case of stigmatized conditions such as those concerning mental health [1,2]. As mobile technology becomes increasingly pervasive in health care [3], the expanding use of potentially invasive technologies such as sensing and machine learning is

likely to lead to greater concerns among users, exacerbating existing problems with attrition, and willingness to use new technologies. In addition, health care providers' perception of a technology is likely to affect treatment delivery, especially if it is not considered sufficiently acceptable [4].

The last decade has seen an increasing number of studies addressing this issue in the mobile health (mHealth) domain. A recent systematic review by Wozney et al [5] revealed that acceptability was the most frequently measured outcome in studies on mental health technologies for anxiety and depression. Designing for acceptance is not straightforward, as the user journey is complex and often nonlinear. Patients who decide to try an application will not necessarily use it in the long run, and similarly, someone who has stopped using a system might go back to it later [6,7]. Conditions such as depression might also impact patients' perception of their experience with technology [8] and thus affect their acceptance. Different stages punctuate the users' journey with technology where they, consciously or not, repeatedly make the decision to keep using or to abandon it [9]. In addition, the extent to which users have appropriated and integrated technology into their lives may impact their decision to maintain use.

Terminology and Definitions

An evolving terminology and range of definitions can be found in the literature discussing technology acceptance. Terms such as acceptability, acceptance, and adoption are often employed, sometimes interchangeably. For instance, Al-Youssef [10] refers to acceptability as users' willingness to use a system while citing the definition of acceptance given in Dillon and Morris [11]. These terms are sometimes equated to other human-computer interaction (HCI) concepts such as user satisfaction [12]. Yet, a part of the literature tries to differentiate the process of technology acceptance from existing concepts. For instance, Schade and Schlag [13] describe acceptability as "a prospective judgement of measures to be introduced in the future," which they detail as "the target group will not yet have experienced the new measures." Close to this interpretation, Adell [14] equates acceptance to "the degree to which an individual intends to use a system and, when available, incorporates the system in his/her [driving]."

The Cambridge Dictionary defines acceptability as "the quality of being satisfactory and able to be agreed to or approved of" [15] and acceptance as a "general agreement that something is satisfactory or right" [16]. This suggests that acceptability is a *quality* of an object from the perspective of a stakeholder, whereas acceptance is more of a process relating to a stakeholder's *interaction* with this object. In the context of HCI, it translates into a user-system dyad.

In the same line, Proctor et al [17] define acceptability as "the perception among implementation stakeholders that a given treatment, service, practice, or innovation is agreeable, palatable, or satisfactory."

With the literature highlighting the importance of temporality in user experience research [18,19], some authors attempt to integrate a temporal dimension into the process of technology acceptance. In that respect, a group of authors supported the

idea of a multistage process. Martin et al [20] and Distler et al [21] define technology acceptability as one's perception of a system before use. They distinguish acceptability from acceptance by equating acceptance to the users' perception of the system after use. Terrade et al [22] and Garces et al [23] go a step further, stating that acceptance refers to the initial use of a system in controlled settings. Reerink-Boulanger [24] introduces the continuum acceptability-acceptance-appropriation, describing acceptability as the subjective perception of the use of a system, acceptance as the first interactions with the system and appropriation as the use of the system by an individual in interaction with other individuals (translated from the original paper in French). Other definitions of appropriation include "a process of social construction in which the actions and thoughts of the user are shaped by the technology, while the meaning and effects of the technology are shaped through the users' actions" [25] and "the process through which technology users go beyond mere adoption to make technology their own and to embed it within their social, economic, and political practices" [26].

Whereas a consistent framework seems to emerge from these definitions, another term, adoption, comes into the picture. Some authors such as Carroll et al [27] equate the process of adoption with the entire user journey: "a multi-phase process starting with deciding to adopt (selecting, purchasing, or committing to use it) and then achieving persistent use." In contrast, Karahanna et al [28] describe "preadoption" and "postadoption (continued use)" stages and present adoption as an event allowing progress from one stage to the other. Similarly, Rogers [29] defines adoption as the user's decision to "make full use of an innovation as the best course of action available."

Models

Another strand of work has attempted to identify the factors influencing technology acceptance, the most well-known of which is the technology acceptance model (TAM) of Davis [30]. In the health domain, Kim and Park [31] have proposed a health information technology acceptance model (HITAM). This model integrates the TAM by Davis, along with antecedents and health-related constructs (health status, health beliefs and concerns, behavioral beliefs, and perceived health threat). Other models, such as the pervasive technology acceptance model [32], integrate the influence of demographics and trust on user acceptance. Dou et al [33] introduced the constructs *relationship with doctor* and *resistance to change*. Finally, Cheung et al [34] introduced constructs related to privacy and consumer innovativeness.

However, the temporal dimension is missing from these models. This raises the question of whether acceptance is motivated by the same factors and in the same manner, regardless of how long the system has been used. As stated in a review on user engagement, describing a concept as a process, rather than a discrete state, "enables the analysis of change over time" [35]. In line with this, some authors propose models that incorporate temporality. Karapanos et al [36] showed that, in their study, qualities that satisfied participants at initial use did not necessarily motivate prolonged use. Building on this, Karapanos et al [37] explored factors influencing user experience over

time; they proposed a temporal framework that identifies 4 stages: anticipation (formation of expectations before any experience of use), orientation (users' initial experiences), incorporation (how the product becomes meaningful in the user's life), and identification (how the product participates in users' social interactions). Although the work addresses user experience rather than acceptance, the authors claim that different qualities contribute to user experience over time, and thus, time alters the way users experience technology. As the extent to which users accept a technology is undeniably linked to their usage experience—or lack of—it is relevant to ask how user acceptance evolves over time and how the influencing factors vary accordingly.

Further exploring the temporal dimension of acceptance, Greenhalgh et al [38] proposed a framework for nonadoption, abandonment, scale-up, spread, and sustainability (NASSS). Directed at health care technologies, the NASSS framework describes different domains influencing technology adoption. It adds a temporal dimension targeting technology's "continuous embedding and adaptation over time." The framework is designed to be used at different points in time (at early design, after deployment, and after abandonment), which distinguishes it from the other models.

Measurement

Both definitions and more detailed models of acceptance may find expression in the form of approaches to measurement. Examples of acceptance studies at different stages of the technology lifecycle can be found in the literature, in some cases employing measurement tools based on theoretical models. This includes gathering of qualitative data via focus groups and interviews based on the TAM [39], a survey based on the unified theory of acceptance and use of technology [40], and interviews based on the fast form TAM [12].

Proctor et al [17] defined eight outcomes for the measurement of implementation of health interventions, two of which were acceptability and adoption. In a recent paper, Hermes et al [41] proposed to adapt the characterization of these outcomes for behavioral intervention technologies. The authors explicitly link the adoption outcome to the use (or intention to use) of a system. In addition, they state that "usability clearly overlaps with acceptability", and thus, usability measurement tools (such as the system usability scale) could be used to assess acceptability. It would be interesting to see whether researchers chose to measure a system's usability to make inferences regarding its acceptability.

Although there seems to be an effort in the research community to ground assessment methods in existing theoretical frameworks, custom measurement tools such as ad hoc surveys are also used to investigate technology acceptance (eg, Allen and Seaman [42]). The use of ad hoc tools allows explorations of acceptance to be tailored to a particular context but makes it more difficult to compare results across projects.

Objective

A number of definitions and models of technology acceptance are available in the literature, several of which make important distinctions between the different stages of the process. Omitting

that distinction in the terminology, and using the terms acceptability, acceptance, and adoption interchangeably can create ambiguities about what is actually being measured, making the replication of interventions and comparison of results difficult. Such ambiguity is highlighted in a review [4] that showed the confusion around the concept of technology acceptability in the health care literature. Furthermore, a review of definitions for electronic health [43] stressed the importance of common terminology for interdisciplinary collaboration. Technology acceptance is a particularly significant challenge for the design of mHealth care technologies; hence we focus on that particular context. In this paper, we present the results of a scoping review of the mHealth literature addressing the following questions:

- How do researchers define technology acceptance?
- What terminology is used to refer to technology acceptance?
- How do researchers measure technology acceptance?
- How do researchers make use of existing models of acceptance?

In addition to outlining research practices to evaluate acceptance, this review reveals the potential limitations and areas for improvement of existing models. A better understanding of these elements contributes toward the development (or improvement) of methodologies and measurement tools for addressing technology acceptance within the development of mHealth applications. Informed by this analysis, a further contribution is made by integrating and disambiguating existing definitions. To this end, we present a lifecycle of the process of acceptance, providing researchers with a common terminology to report results, and help them to measure the evolution of user acceptance over time.

Methods

We performed a scoping review to map relevant literature in the field of mHealth. In contrast to systematic and narrative reviews [44], scoping reviews allow for a broad but structured exploration that permitted us to examine the range of definitions and measurements of technology acceptance, and to identify gaps and inconsistencies in the existing literature. We followed the framework developed by Arksey and O'Malley [45], which consists of the stages outlined below.

Identifying the Research Question

We were interested in how technology acceptance was understood, measured, and reported in mHealth studies.

Searching for Relevant Studies

We searched the PubMed database for papers addressing technology acceptance. Following preliminary searches to assess the relevance of search criteria, a search of the Medical Subject Headings (MeSH) terms "Patient Acceptance of Health Care" and "Mobile Applications," without time restriction, resulted in a corpus of 287 articles starting from 2013.

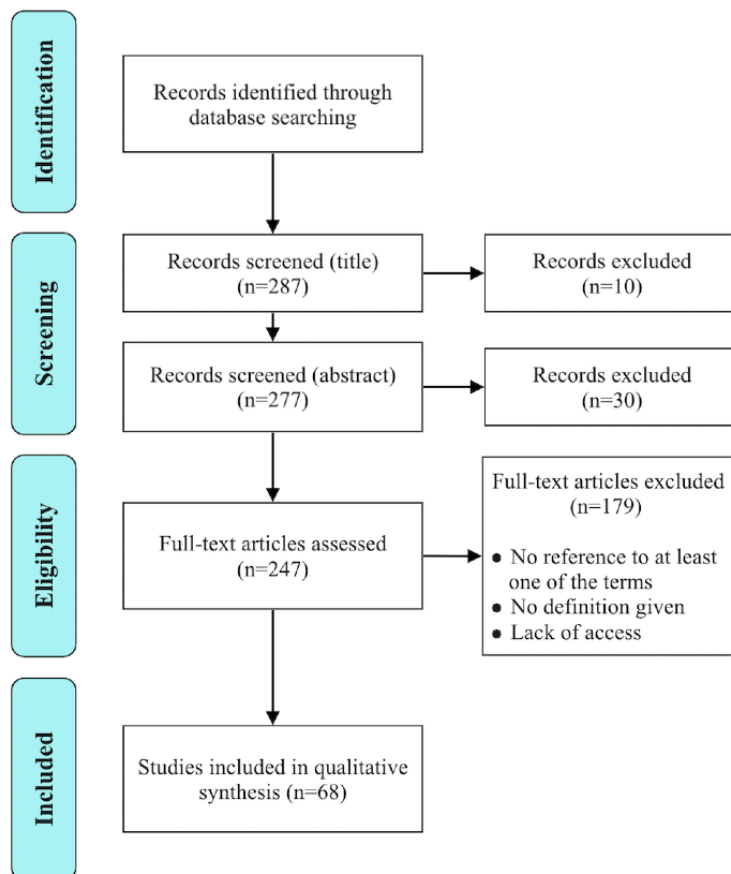

Selecting Studies to Include

Inclusion criteria were subject to discussion between the 3 authors; 2 random samples of 10 papers were independently assessed for inclusion by 2 pairs of authors (first and second,

first and third). Disagreements concerning the definitions of inclusion criteria were resolved by explicitly stating these criteria as following: a publication was considered relevant if (1) it contained at least one of the terms “acceptability,” “acceptance,” “adoption,” “accept,” or “adopt”; and (2) defined the concept in question with (1) a full definition; (2) a synonym; or (3) an operationalized definition (ie, means used to measure the concept). Some articles were associated with the specified

MeSH terms but did not directly discuss technology acceptance. Articles were excluded if they did not contain any of the 5 terms above, did not provide a definition, or if their web version was not accessible. Among those, 40 were excluded at the screening stage (Figure 1) because they did not address acceptance in the sense of technology acceptance (eg, Acceptance and Commitment Therapy). A total of 68 relevant publications were included in the review.

Figure 1. Flow diagram.

Charting the Data

The codes used for analysis aimed to expose how technology acceptance was referred to, defined, and measured, depending

on the context (Table 1). Each pair of authors coded 2 samples of 10 papers independently. This resulted in no disagreement, the codes were straightforward to interpret.

Table 1. Distribution of the main codes (some studies performed multiple measurements).

Themes and codes	Studies, n (%)
Given definition	68 (100)
Nature of given definition	
Operationalized	39 (58)
Synonym	22 (32)
Full definition	7 (10)

Unclear	1 (1)
No measurement	6 (9)

Collating, Summarizing, and Reporting the Findings

Definitions from the literature mentioned earlier distinguish between the different stages of the process of acceptance. We assessed whether the definitions found in our corpus also differentiate between the stages of acceptance and the different terms *acceptability*, *acceptance*, and *adoption*. We carried out 2 classifications of the papers, one with respect to the terminology used (ie, *acceptability*, *acceptance*, or *adoption*) and one following the measurement stage (ie, preuse, initial use, and sustained use). We then grouped papers with similar interpretations of technology acceptance and extracted the measurements used. Finally, we identified possible gaps and suggested ways to improve the exploration of acceptance in mHealth.

Results

All 3 terms (acceptance, acceptability, and adoption) were used in the mHealth literature sample and were associated with various meanings and measurements.

Definitions

Classification of the papers reveals that one-fifth of them cited definitions from the literature. Two-third of the articles reported on a mental health intervention, which shows that the question of technology acceptance is particularly studied in this context. [Figure 2](#) compares the terminology used in the papers with a classification following the measurement stage. A significant difference can be seen between the 2 distributions, marking the

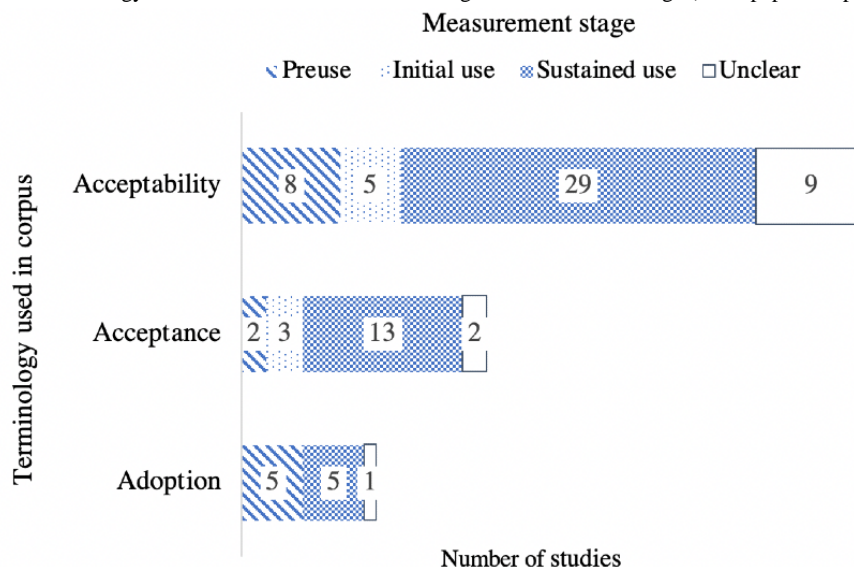

distinction between the 3 terms, but also their use in relation to the measurement timeline.

The majority of publications (n=51) referred to technology acceptability. Among these, a small number (n=8) addressed the preuse stage, sometimes equating acceptability to users' interest or willingness to use a system [46-50]. The other 34

papers referred to acceptability in the context of initial or sustained use.

Papers in the second group (n=20) referred to technology acceptance. Among these, 2 papers refer to it at preuse, and 13 in the context of sustained use.

Figure 2. Comparison of the terminology used with a classification following the measurement stage (some papers employed multiple terms).

The last part of the corpus (n=11) refers to technology adoption. Half of these papers focused on the sustained use stage and the other half on the preuse stage. Papers reported as unclear were those for which classification was not possible as the context of the study was ambiguous. Although the terminology used showed a focus on acceptability, looking at the corpus through the lens of the measurement timeline highlighted that more than

two-third of the papers (n=47) explored the sustained use stage. This distribution suggested a trend in the corpus to employ the term *acceptability*, regardless of the context and stage of the user journey. Table 2 presents the range of interpretations for acceptability, acceptance, and adoption extracted from the corpus.

Table 2. Meanings associated with terminology (some studies referred to several concepts).

Terms and associated meanings	Occurrences [references], n
Acceptability	
Perceived usefulness	14 [51-64]
User satisfaction	11 [54,55,57,60,65-71]
System usability	8 [48,57,67,72-76]
User feedback	8 [52,53,61,73,75,77-79]
Rate of recommendation	8 [51,53,54,61,62,73,79,80]
Actual usage	8 [64,79,81-86]
Perceived efficiency	6 [51,59,66,73,79,86]
Perceived ease of use	5 [52,53,63,64,73]
Intention to use	5 [46,47,50,64,87]
User engagement	4 [58,79,81,88]
User enjoyment	4 [51,58,64,79]
Attitude toward using	2 [49,64]
Quality of the system	1 [64]
Acceptance	
Perceived usefulness	5 [64,89-92]
Intention to use	5 [64,87,90,91,93]
Actual usage	5 [64,85,90,91,94]
User satisfaction	4 [71,89,93,95]
Perceived ease of use	3 [64,90,91]
Attitude toward using	3 [64,90,91]
Perceived efficiency	2 [89,93]
System usability	2 [76,96]
Quality of the system	2 [64,93]
User feedback	1 [97]
User enjoyment	1 [64]
Adoption	
Actual usage	7 [84-86,91,98-100]
Intention to use	3 [91,101,102]
Perceived usefulness	2 [63,91]
Perceived ease of use	2 [63,91]
Perceived efficiency	1 [86]
Attitude toward using	1 [91]

The distribution shown in Table 2 reveals that acceptability was mainly understood as perceived usefulness (a concept from TAM) or user satisfaction. System usability, user feedback, and the other TAM constructs (perceived ease of use, attitude toward using, intention to use, and actual usage) were often mentioned. It also emerged that researchers may consider a perceived reduced stigma [49] and high similarity between the behavior of the technology and traditional health care [61] as markers for acceptability. Furthermore, one study explored sociocultural aspects of technology acceptability in developing regions, explaining that a system needs to take into account “the

preferences and aspirations of individual service users and the cultures of their communities” [103]. A striking finding was that, out of 6 years of research, only 2 works explored mHealth for children [87,104], with Farooqui et al [104] alone studying children’s acceptance.

Fewer studies employed the term acceptance, associating it with constructs from the TAM—perhaps because the model itself uses the term acceptance.

TAM constructs were also found in the interpretations of adoption. Some of this work seeks to adapt or extend the TAM,

such as Khatun et al [105], who developed the concept of *readiness to adopt* mHealth in developing countries. The authors argued that the TAM “does not consider the influence of human factors, the internal resources of the user or the external environmental and ecological factors” and proposed a model integrating TAM constructs and others more specific to rural and developing areas (access, sociodemographics, awareness of mHealth services, and trust).

Among the literature reviews present in the corpus, some associated acceptability or acceptance with feasibility [97,106]. Feasibility, as defined by the National Institute for Health Research glossary, relates to whether a study can be carried out. A feasibility study explores not only technical parameters but also human factors likely to be important for the conduct of the main study. Although a feasibility study may include the assessment of participants’ acceptance, it is not the case that all feasibility studies will do so.

A small number of studies (n=13) cited conceptual definitions from the literature. The TAM was cited in reference to the 3 concepts: acceptability [64,65], acceptance [64,90,91], and adoption [91,102,105].

However, some studies have highlighted the limitations of existing models. Zhu et al [102] argue that conceptual models should not regard mobile services as a generic concept but specifically address particular use cases (eg, mobile services for health monitoring). They present their own model for

technology acceptance, combining TAM constructs with health-related concepts from the health belief model [107].

In the same vein, Povey et al [108] stated that existing models were not suitable for their study. The authors attempted to build a model for the acceptability of e-mental health for an indigenous population and acknowledged that the resulting model is similar to the HITAM [31].

Ammenwerth et al [109] argued that existing models such as the TAM and task technology fit failed to address the interaction between user and task. To bridge this gap, the authors developed and validated the fit between individuals, task, and technology (FITT) framework for information technology adoption in clinical environments. Only one study [85] then employed FITT to measure acceptance of the use of mobile apps among physical therapists. Finally, another study [98] cited Agarwal and Prasad [110], supporting the idea of 2 stages: initial adoption and long-term engagement.

These references to models and definitions within the literature show researchers’ willingness to reuse existing theories. However, the adaptations of these models and their inconsistent interpretation also reveal their limitations and the lack of a common framework to study technology acceptance.

Measurement

We extracted measurements employed in the corpus to assess technology acceptance and classified them by type and temporality (Table 3).

Table 3. Measurements performed (some studies performed several measurements).

Measurement	Occurrences per stage		
	Preuse (11 studies), n	Initial use (7 studies), n	Sustained use (40 studies), n
Customized survey	7	2	28
Standardized survey	2	2	8
Focus groups (qualitative)	2	1	1
Interviews (qualitative)	1	1	4
Completion of task	0	1	1
Usage	0	0	6

Table 3 illustrates a strong preference for the use of surveys (73.0%, 49/67), independently of the timeline, with a prevalence of custom questionnaires (55.0%, 37/67). Almost all studies assessing system usability (which is a frequent interpretation of acceptability, see Table 2), made use of standardized surveys, which reflects the range of reliable tools available to evaluate this concept [72,74].

Other studies used existing surveys incorporating TAM constructs [64,91] or developed their own with elements from different models to fit their research better [102]. Owing to the need to assess technology acceptance in developing countries and remote areas, Chen et al [64] suggested that models found

in the literature may need to be validated on a larger variety of populations.

The rest of the corpus measured technology acceptance through participant feedback (via custom surveys, focus groups, and interviews), adherence, usage, and rate of completion of tasks. Although this wide set of metrics contributes to expanding the number of assessment tools, it also impedes consistency within technology acceptance research.

The low number of measures applied at the pre and initial use stages also reveals that technology acceptance was rarely investigated at the design stage (Table 4).

Table 4. Measurement timeline of constructs (some studies measured several constructs).

Constructs (occurrences)	Measurement stage [references]		
	Preuse (n=13)	Initial use (n=7)	Sustained use (n=87)
Perceived usefulness (n=18)	[61]	[57,58]	[52-56,58-60,62-64,89-92]
User satisfaction (n=15)	— ^a	[57,65]	[54,55,60,62,66-71,89,93,95]
Intention to use (n=11)	[46,47,50,101,102,105]	—	[64,87,90,91,93]
System usability (n=10)	[48]	[57]	[55,67,72-76,96]
Rate of recommendation (n=10)	[61]	—	[53-55,62,73,79,80,104,111]
Actual usage (n=9)	—	—	[64,79,81,83,84,86,90,91,94]
User feedback (n=8)	[61,77]	[78]	[52,53,73,75,79]
Perceived ease of use (n=7)	—	—	[52,53,63,64,73,90,91]
Perceived efficiency (n=6)	—	—	[59,66,73,79,86,89,96]
Attitude toward use (n=4)	[49]		[64,90,91]
User enjoyment (n=4)	[58]	[58]	[64,79]
User engagement (n=3)	—	—	[79,81,88]
Quality of the system (n=2)	—	—	[64,93]

^aNo study measured the construct at that specific measurement stage.

Interestingly, although existing acceptance models provide sets of measurable constructs, researchers' efforts have focused on perceived usefulness. Only the studies in Table 5 measured the

full set of constructs contained in the technology acceptance models which they cite.

Table 5. Use of existing technology acceptance models.

Acceptance models used in the corpus	Measurement stage			Additional constructs
	Preuse	Initial use	Sustained use	
TAM ^a	[102]	— ^b	—	Perceived disease threat, perceived risk, initial trust, and technology anxiety
	—	—	[64]	System quality, social influence, perceived enjoyment, and smartphone experience
	—	—	[90]	Demographics (age, position at work, usage time of PDA ^c , and skill level of using a PDA)
	—	—	[91]	None
Information system success model	—	—	[93]	None

^aTAM: technology acceptance model (Davis [30]).

^bModel was not used at that measurement stage.

^cPDA: personal digital assistant.

Table 5 shows that almost all studies that relied on the TAM added constructs to capture the influence of context-related factors on acceptance. Indeed, Zhu et al [102] followed the added variables approach described by Holden and Karsh [112] to evaluate the acceptance of their technology within the specific Chinese health care context. In addition to the TAM constructs, they used 4 context-related constructs taken from other studies. Similarly, Chen et al [64] used a questionnaire based on the TAM with additional constructs from other studies to fit the context of their application. Finally, Wang et al [90] showed the influence of certain demographic factors (age, position at work, usage time of the personal digital assistant [PDA], and skill level of using a PDA) on the TAM constructs (perceived usefulness and ease of use).

On the other hand, Ammenwerth et al [93] used a survey based on the information system success model [113] to evaluate acceptance postuse at 2 different points in time. The first survey assessed the 7 constructs from the model, whereas the second only assessed intention to use and net benefit. This could suggest that these constructs are seen as more stable or important, or that the existing constructs are not suitable for all study designs.

As expected from the analysis of definitions, these studies measured a wide variety of constructs. New questionnaires were developed, and researchers stressed the limitations of existing measurement frameworks. Without the validation of these new surveys, the comparison and replication of studies may be difficult. Thus, we argue that standardized ways to measure

technology acceptance are needed to support objective and coherent assessments at the different stages of the user journey.

Discussion

This scoping review analyzed the terminology used to refer to technology acceptance and extracted the different interpretations given and measurement methods employed.

Terminology

The findings reveal that technology acceptance was mostly referred to as acceptability and, to a lesser extent, acceptance or adoption. A small part of the corpus converges toward the differentiation of these terms as distinct concepts, corresponding to stages (ie, preuse acceptability, initial and sustained use acceptance) or events (ie, point of adoption) in the user journey of technology acceptance. However, the rest of the corpus does not distinguish between these terms. One reason could be that the existing definitions arguing for that distinction were published separately; hence, providing a coherent and more precise terminology and set of definitions can aid researchers in communicating which concepts they are referring to.

Definitions

The corpus provided a variety of interpretations of the concept of technology acceptance. Among these, some were based on constructs present in literature models such as the TAM [30], indicating that existing models do influence acceptance studies. Other definitions should be associated with the appropriate model constructs; for example, user satisfaction and feedback should refer to the TAM's construct *attitude toward use*. Similarly, factors related to the sensitive nature of health care technologies (such as perceived stigma) should be linked to the appropriate constructs' *subjective norm* (in the HITAM), *social influence* (in the pervasive technology acceptance model), or *sharing* (in the model by Cheung et al [34]). Thus, it is likely that the extent to which an individual is concerned by these risks will impact their acceptance of the technology. Following previous research [102,108], we argue that acceptance models should take into account the cultural and health context of end users.

Models and Measurement

Although part of the corpus employed standardized tools, the majority of the studies used custom surveys. This aligns with

the findings of Wozney et al [5] that the major part of their corpus used nonvalidated measures of acceptability. This could be because of a lack of validated tools to assess technology acceptance in the context of mHealth. Many researchers felt the need to design their own survey to have a measurement instrument adapted to the specific issues of their target population (eg, technology access and cost). Similarly, researchers who used existing acceptance models felt the need to add context-specific constructs. It would be interesting to see a community effort to validate new tools, create adapted tools for important contexts such as mHealth, and adapt existing models and questionnaires so that they embrace the changes in users' acceptance as they use the technology. Finally, technology acceptance was rarely investigated at the design stage. This is unexpected as exploring acceptance issues could greatly inform design work [114] and reduce risks that an implemented technology is rejected or abandoned. On the use of machine learning in clinical contexts, Thieme et al [115] argue that collaborating with health care users at the design stage may increase the chances of acceptance of the technology. Existing acceptance models were only used once to measure acceptance at the preuse stage (Table 5). A reason for this might be that existing models do not target the design stage and are not adapted to measurement at the preuse stage.

Technology Acceptance Lifecycle

In line with the existing literature definitions and informed by our analysis of the corpus, we argue for clearly distinguishing between the different stages of technology acceptance. We have seen in our analysis both a wide variety of interpretations of these concepts, and a range of measurement approaches applied across the lifecycle, mostly based on ad hoc tools. This variety creates ambiguities in the reporting and understanding of results and makes it difficult to draw conclusions on the acceptance of the systems studied. We believe that a better understanding of the process of technology acceptance would greatly benefit the community in terms of researchers articulating their findings with regard to the entire process. To contribute toward clarification of the measurement of technology acceptance, we propose the Technology Acceptance Lifecycle (TAL). The TAL consists of a timeline to anchor the definitions of technology acceptance within the overall process (Figure 3).

Figure 3. Proposed terminology for technology acceptance lifecycle.

Our motivation is to highlight the evolving nature of technology acceptance across the different stages of the user journey with a technology. The two main stages of the TAL follow Karahanna et al [28] and Roger's interpretations [29] in favor of a distinction between the pre- and postadoption stages. With regard to the definitions of Distler et al [21], Martin et al [20], Garces et al [23], and Terrade et al [22], we argue for a distinction between

the stages of acceptability (preuse) and acceptance (initial use) and propose the continuum acceptability-acceptance-sustained use. The TAL proposes a more explicit terminology, embedding temporality in the name of the different stages. The continuum then becomes preuse acceptability—initial use acceptance—sustained use acceptance. Finally, sometime during the sustained use stage, the user would reach the point of

adoption of the technology. According to Rogers [29], a system can be considered adopted when users make full use of it. However, the literature does not specify the conditions for full use to be achieved. On the basis of the existing literature definitions, the TAL articulates the process of technology acceptance and its different stages across the user journey. We argue that acceptance at the initial and sustained use stages is likely to be impacted by factors related to the actual use of the technology and user engagement. Therefore, we suggest that the research community considers acceptance as a process (rather than a discrete measure) and adopts assessment approaches that take into account the temporal dimension and possible evolution of acceptance. We believe that the proposed TAL could help align the research field and provide researchers with a timeline that they can follow to assess technology acceptance and terminology to communicate their research clearly. Further research is needed to establish the influencing factors at the different stages of the process and to develop and validate measurement methods adapted to these stages.

Limitations

Our search focused on the PubMed database and relied on the MeSH classification. We did not apply any time restriction and obtained a reasonably sized and highly relevant sample. However, a more exhaustive sample could be obtained by expanding the search to other terms.

Conclusions

This review has identified the common interpretations and measurement approaches that have been used to assess the

acceptance of mHealth technologies. To our knowledge, this is the first study to look at the terminology employed and examine the basis and consistency of the definitions employed in mHealth research. In addition, this review has described how researchers made use of existing models to measure mHealth acceptance and the lack of readily available assessment tools that are appropriate for specific study contexts and use at the design stage. This paper has uncovered the need for a common definition and measurement framework to address technology acceptance, particularly in the domains of health and mental health. A common set of definitions and more consistent approaches to measurement would support both developers of mHealth applications in addressing user acceptance of their systems and the communication and reporting of results in interdisciplinary studies of mHealth interventions. With the TAL, we propose a more explicit terminology and a representation of the process of technology acceptance throughout the user journey.

Our findings highlight the importance of better articulating the specific concepts highlighted in the TAL and developing appropriate measurement tools, ideally standardized, for each of these concepts. This perspective encourages developers to consider acceptance across the user journey and allows researchers to be more explicit about what they are investigating. Finally, efforts from the mHealth community are needed to adapt existing acceptance models for use in sensitive contexts such as mental health interventions.

Abstract

Background: The prevalence of mental health disorders continues to rise, with almost 4% of the world population having an anxiety disorder and almost 3.5% having depression in 2017. Despite the high prevalence, only one-third of people with depression or anxiety receive treatment. Over the last decade, the use of digital health interventions (DHIs) has risen rapidly as a means of accessing mental health care and continues to increase. Although there is evidence supporting the effectiveness of DHIs for the treatment of mental health conditions, little is known about what aspects are valued by users and how they might be improved.

Objective: This systematic review aimed to identify, appraise, and synthesize the qualitative literature available on service users' views and experiences regarding the acceptability and usability of DHIs for depression, anxiety, and somatoform disorders.

Methods: A systematic search strategy was developed, and searches were run in 7 electronic databases. Qualitative and mixed methods studies published in English were included. A meta-synthesis was used to interpret and synthesize the findings from the included studies.

Results: A total of 24 studies were included in the meta-synthesis, and 3 key themes emerged with descriptive subthemes. The 3 key themes were initial motivations and approaches to DHIs, personalization of treatment, and the value of receiving personal support in DHIs. The meta-synthesis suggests that participants' initial beliefs about DHIs can have an important effect on their engagement with these types of interventions. Personal support was valued very highly as a major component of the success of DHIs. The main reason for this was the way it enabled individual personalization of care.

Conclusions: Findings from the systematic review have implications for the design of future DHIs to improve uptake, retention, and outcomes in DHIs for depression, anxiety, and somatoform disorders. DHIs need to be personalized to the specific needs of the individual. Future research should explore whether the findings could be generalized to other health conditions.

KEYWORDS

digital health interventions; depression; anxiety; somatoform disorders; smartphone; mobile phone

Introduction

Background

The prevalence of mental health disorders continues to rise [1]. It is estimated that globally in 2017, 264 million people (3.4%) experienced depression, and 284 million (3.7%) of the population experienced an anxiety disorder. This included phobias, obsessive-compulsive disorder (OCD), posttraumatic stress disorder (PTSD), or generalized anxiety disorder (GAD) [2]. The worldwide prevalence of somatoform disorders or Medically Unexplained Symptoms in Primary Care is 25%-50% [3]. From an economic and social perspective, the costs of mental health disorders are high. The total costs of mental ill health are estimated at more than 4% of the gross domestic product, or over €600 (US \$650.31 million), across the 28 EU countries [4]. More than two-third of individuals with depressive disorders also have anxiety symptoms, and 40%-70% simultaneously meet the criteria for at least one type of anxiety disorder [5,6]. Depression, anxiety, and somatoform disorders are often comorbid, and treatment can reduce symptomology in all 3 areas [7], implying that treatments could be effective across comorbid mental health conditions. Furthermore, where large-scale mental health interventions have been implemented, there is evidence of coaction—where a change in one disorder is achieved, it is more likely that change will be achieved with other health disorders [8].

Despite the high prevalence, only 33% of adults with depression and anxiety receive treatment in England [9], indicating that few people who need treatment receive it. The barriers to accessing psychological therapy include a shortage of therapists, long waiting times, and the stigma of accessing psychological treatment [10]. A recent authoritative review identified the use of digital health interventions (DHIs) as central to addressing population-level mental health. The absence of widely disseminated, accessible mental health interventions has also been identified as a key reason for the lack of improvement in mental health treatment [8]. DHIs have the potential to improve accessibility and meet the requirements expected from mental health services [10].

DHIs can be defined as interventions that provide information, therapy, and support (emotional, decisional, or behavioral) for physical or mental health disorders via a technological or digital platform (website, computer, mobile phone app, SMS text message, email, videoconferencing, wearable device, patient portals, or personal health records or virtual reality [VR]) [11,12]. The variety and functionality of digital health technologies continue to evolve. The forms of DHIs include computerized cognitive behavioral therapy (cCBT) but can also include telehealth or telemedicine utilizing telecommunications processes such as SMS text messaging, email, and videoconferencing for remote delivery of therapy. Recently, there has also been the emergence of *mHealth* or mobile health, which incorporates smartphone apps, remote monitoring, and wearables. DHIs can be standalone interventions, used as a stepped care model, provided in addition to face-to-face treatment or mediated by a health care professional such as a therapist [13,14].

Numerous systematic reviews have found that for people with depression and anxiety disorders, DHIs can be just as effective as face-to-face therapy [15,16]. However, dropout rates for completion of computerized psychological therapy are high [17,18]. Waller and Gilbody [17] conducted a systematic review of the quantitative and qualitative evidence identifying the barriers to the uptake of cCBT. They concluded that, a median of, 38% (range 4%-84%) of participants who were recruited started cCBT, and a median of only 56% (range 12%-100%) of starters completed it. They concluded that these low figures were influenced more by personal circumstances than technological aspects. Waller and Gilbody [17] acknowledged that more data was needed to explore why so few started or discontinued therapy. The inclusion of therapist support and guidance has been found to improve treatment completion rates and increase treatment effect sizes [19-21], implying that therapist-supported DHIs rather than self-guided DHIs may lead to more positive experiences for participants. The concept of blending face-to-face therapy with computer-delivered therapy or via videoconferencing has recently begun to emerge, which attempts to address some of the barriers to engaging with DHIs [22-24]. Furthermore, a recent article [25] identified that the top 10 priorities for DHIs in mental health include considering how DHIs could be combined with human support to improve its effectiveness.

Existing qualitative systematic reviews provide insight into the potential barriers and facilitators of recruiting and retaining participants in DHI research trials. O'Connor et al [26] investigated the factors affecting patient and public engagement and recruitment to DHIs. They identified that there was a need for greater awareness and understanding about DHIs to improve public understanding of DHIs [26]. They also recommended that DHIs need to incorporate some kind of social interaction to improve recruitment. DHIs also need to be tailored to individual needs. Knowles et al [27] explored user experience of digital technologies as a low-intensity intervention delivered with minimal or no professional support for depression and anxiety, concluding that personalization and tailoring content toward users' needs improved the experience of computerized therapy. Furthermore, they recommended for future research to explore if these findings could be extrapolated to other delivery formats and treatment modalities.

Given the rise in prevalence of depression, anxiety, and somatoform disorders and advances in the development of DHIs, but low uptake and completion rates, it is important to conduct a systematic review exploring perceived barriers and facilitators to the acceptability and usability of a range of DHIs. This systematic review aimed to build on previous literature to explore the diverse nature of DHIs and whether potential facilitators and barriers are consistent across different types and formats of DHIs. We wanted to investigate whether there were specific issues relevant to the integration of support compared with self-guided DHIs and whether varying levels of support, intensity, and delivery formats influenced patient experience.

This is the first meta-synthesis to our knowledge that will look at the acceptability and usability of DHIs across different types and formats and across a range of depression and anxiety disorders. This systematic review includes all DHIs regardless

of the delivery method (ie, text-based, automated, blended therapy). It compares very different experiences to consider whether therapies involving digital aspects share common issues and if consistent themes are found across different formats and modes of delivery. A systematic review of the qualitative literature may provide further explanation and synthesis of factors that may facilitate adherence and outcome of DHIs for comorbid mental health conditions. The key findings of this systematic review will inform the design of mental health digital interventions. This will support the development of digital mental health interventions tailored to service users' needs and thus improve uptake, adherence, and experience, which will have a positive impact on service users and providers.

Objectives of the Systematic Review

This systematic review aimed to understand the experiences of service users with regard to DHIs for depression, anxiety, and somatoform disorders. Specific objectives were to systematically identify, appraise, and meta-synthesize available qualitative literature that explored the following:

1. Service user's perceptions of DHIs regarding their acceptability and usability.
2. Aspects of DHIs that are valued and work well and those that could be improved or altered.
3. Why service users chose to use, continue with, or stop using DHIs.

Methods

The protocol for the systematic review was published on the International Prospective Register of Systematic Reviews (ID: CRD42018104016) before completion of the systematic review. The systematic review is reported in accordance with the

Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) [28] statement checklist and Transparency in Reporting the Synthesis of Qualitative Research [29] guidelines ([Multimedia Appendices 1 and 2](#)).

Search Strategy

A comprehensive search strategy was developed with an expert health information specialist (EY). A scoping search was conducted to identify key papers and associated search terms to inform the design of the search strategy. A systematic search was conducted for published papers that contained qualitative information about service user experiences of participating in a DHI trial for depression, anxiety, or somatoform disorders. A combination of free terms and controlled vocabulary terms was used to ensure that all relevant studies were identified. Search terms were split into 2 categories: DHIs and mental health conditions (depression, anxiety, and or somatoform disorders). Qualitative search filters identified by the InterTASC Information Specialists Sub-Group were also applied [30]. The search strategy was developed for MEDLINE ([Multimedia Appendix 3](#)) and then adapted and applied to PsycINFO, Cumulative Index for Nursing and Allied Health Literature (CINAHL), EMBASE, ISI Web of Science, Scopus, and the Cochrane Library. We searched the electronic databases for eligible studies from database inception to July 17, 2018. The search was conducted by EY. From the search results, papers that were published in the same study but in different publications were not removed to determine more closely if they reported different data aspects of the research. Search results were uploaded and stored using EndNote version X8.

Inclusion and Exclusion Criteria

[Textbox 1](#) describes the inclusion and exclusion criteria.

Textbox 1. Inclusion criteria and exclusion criteria.**Inclusion criteria**

- English language
- Community, primary, and secondary care
- Original qualitative studies, studies involving secondary analysis of qualitative data, or qualitative studies that were part of a mixed methods study (eg, the study also had a quantitative component, but the major component was qualitative, and a qualitative methodology was described). Studies should include a substantial amount of qualitative methods, including interviews, observations, and open-ended evaluation forms. Free textboxes on evaluation forms were included if there was richness in the data provided (ie, sufficient quotes to support the analysis)
- Papers should include some form of qualitative data analysis such as thematic or inductive analysis
- Papers reporting on participants who had experienced the use of digital health interventions (DHIs, also called *internet interventions* or *electronic health interventions*), where the DHI was primarily used to treat depression, anxiety, and/or somatoform disorders. This included interventions that provided information and support (emotional, decisional, and/or behavioral) via a technological or digital platform (website, computer, mobile phone app, SMS text message, email, videoconferencing, wearable device, patient portals or personal health records, or virtual reality)

Exclusion criteria

- Gray literature or literature not published in a peer reviewed journal
- Dissertation or theses
- Published abstracts or conference proceedings
- Any type of literature review, systematic review, and meta-synthesis
- Experiences of health care professionals or parents or carers
- Studies where the primary digital health interventions (DHIs) were telephone-based with no additional technological function (eg, telephone counseling or triaging service), internet-based health tools that were not defined as interventions (eg, internet health searching), or an implantable device that was remotely monitored
- Interventions to improve adherence to medication, improve assessment or diagnosis, or where digital interventions were not the major constituent of the intervention
- Peer-to-peer networks and DHIs of social support via the internet, use of social media, online support groups, or DHIs consisting of group therapy
- Data collected during the testing of the usability and design of DHIs
- Males and females aged <18 years; studies were included if ≥50% of the sample were aged ≥18 years

Screening and Data Extraction**Data Screening**

Duplicated studies were removed in EndNote, and the remaining articles were exported into a Microsoft Excel document for screening. Qualitative results from the same overall study that were split across different publications were not removed until the full-text screening. Papers were removed if they reported the same qualitative findings; otherwise, they were included. In addition, we carried out backward citation by hand searching the references of all included studies and key papers. Forward citation searching of the included studies was carried out in Scopus. Initial screening of titles and abstracts was conducted by 1 reviewer (SP), with a second reviewer (AA) screening a random 10% sample to confirm congruence. Interrater agreement for full-text screening was 99.4%, and disagreements were resolved through discussion.

Data Extraction

Data were extracted by SP from papers included in the systematic review using a data extraction form developed by SP and AA. The primary focus of data extraction was the identification of specific qualitative findings—reported themes and subthemes related to the phenomena of interest, which were subsequently synthesized as described below. All text from the

papers labeled as results or findings were entered into a Microsoft Word document. Additionally, descriptive data, including details about DHIs, study aims, methods and analysis, country of research, and demographics of participants, were extracted. The form was initially piloted on 3 papers by both reviewers. AA completed data extraction for 30% of the articles to confirm congruence. Data extraction forms were compared to ensure data accuracy and comprehensiveness. Any disagreements were resolved through discussion until a consensus was reached.

Quality Appraisal

Quality assessment of papers included in the meta-synthesis was undertaken by SP and AA using the Critical Appraisal Skills Programme (CASP) criteria [31]. Studies were not excluded on the basis of quality because we were more concerned about including papers that contained depth in data collection and analysis, which might provide valuable information regarding participant experience of DHIs. We included papers that collected data through semistructured interviews. We included papers that collected data through open response text if there was richness in the data provided.

Meta-Synthesis

A meta-synthesis approach was used to organize and interpret the data. The findings of the included studies were synthesized

using methods proposed by Noblit and Hare [32]. Papers were read and re-read by SP and AA, and first- and second-order constructs were extracted using a Microsoft Word template form. First-order constructs were defined as direct participant quotes reported in the papers. Second-order constructs were defined as the authors' interpretations of participants' quotes expressed as themes extracted from both the results and findings sections of papers. SP and AA independently sifted the second-order constructs, compiling new third-order constructs that summarized and encompassed the various themes across studies. Third-order constructs refer to synthesized constructs that emerge from the analysis of first- and second-order constructs. Constructs were reviewed to see how the themes were similar when compared across papers to make sense of the variability in participant experience of DHIs. A draft summary of the analytical themes was written by SP and AA and shared with the review team consisting of service providers and service user representatives. Themes were refined until consensus was reached.

Results

Summary of Search Results

The initial search yielded 9030 records. After duplicate records were removed, there were a total of 8936 records. Following title and abstract screening, 8836 articles were excluded, resulting in a total of 100 papers being reviewed in full; 1 paper that was not identified in our search but included in a key systematic review paper [27] was included [33], and 1 paper was identified and included through hand searching [34]. A total of 26 papers met the eligibility criteria and were included in the meta-synthesis. These were amalgamated into 24 studies because 2 of the included studies reported data in 2 papers. One study that was included was reported in a qualitative paper as part of a Health Technology Assessment report, the themes highlighted in the 2 papers differed, and both findings were included [35,36]. For another study that was reported in 2 papers, 1 paper specifically focused on motivation to persist with the DHI, while another paper focused on patient experience and the implementation of digitally delivered cognitive behavioral therapy (CBT) [37,38].

The majority of the studies were nested within a randomized controlled trial (RCT; $n=15$). All the included studies were deemed to be of sufficient quality to contribute to the meta-synthesis. All papers reported a clear statement of the aims of the research and were deemed to be valuable in their contribution to the themes. Question 6 of the CASP referring

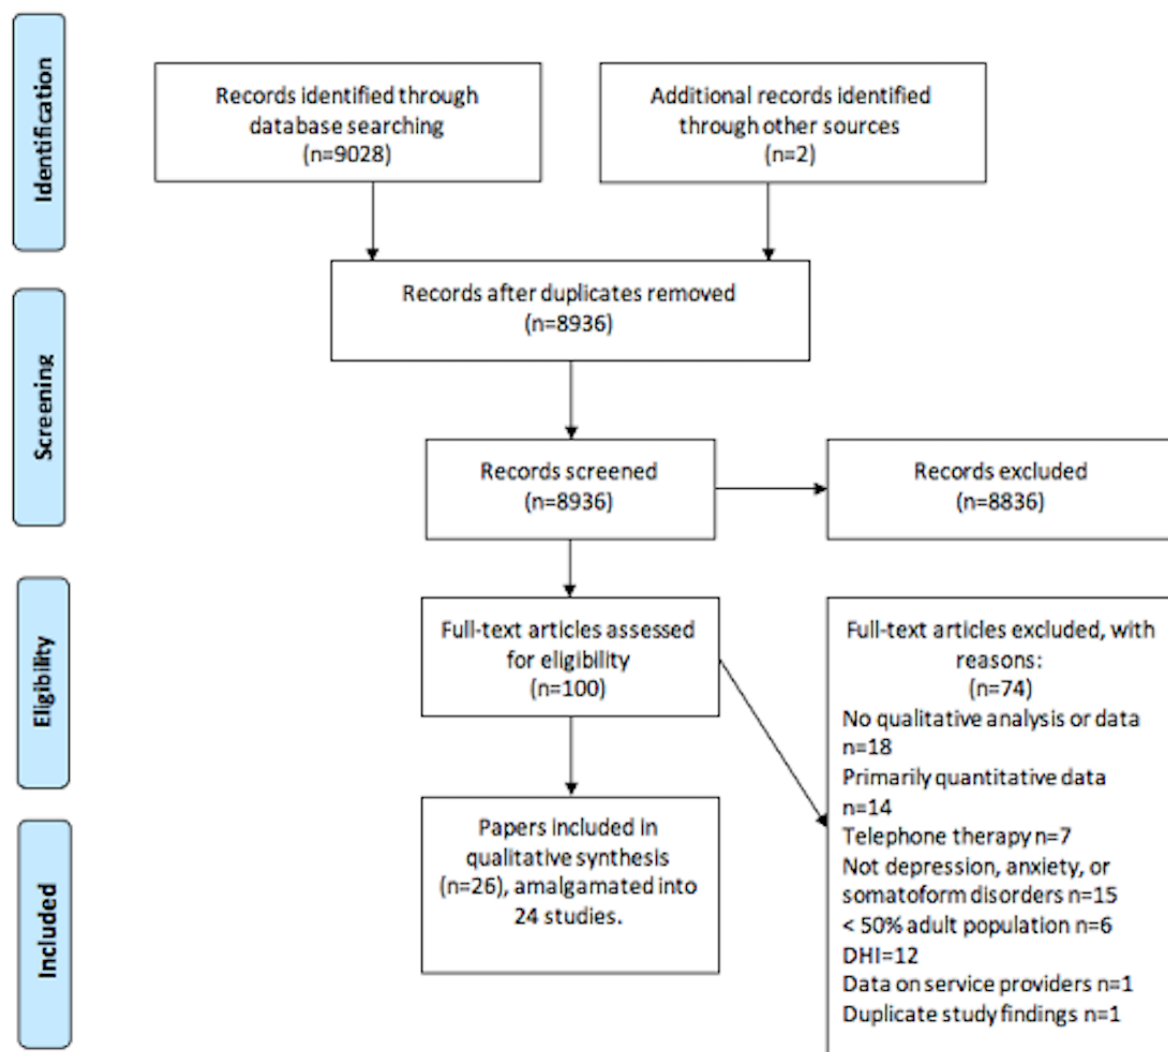

to the relationship between the researcher and participants was acknowledged in only 13 papers. Kuhn et al [39] contributed the least to the meta-synthesis because the paper provided minimal information regarding the data analysis method and how themes were derived (Multimedia Appendix 4).

The PRISMA diagram (Figure 1) illustrates the flow of study identification and selection. The main reasons for exclusion included no qualitative analysis or data, primarily quantitative data, primary focus not being depression, anxiety, or somatoform disorders, and lack of data on the experience of using a DHI. Multimedia Appendix 5 summarizes the included studies. The sample characteristics of the included studies are described in Multimedia Appendix 6.

The included studies were published between 2007 and 2018. The majority of the studies were carried out in European countries, primarily England and Sweden ($n=11$). A total of 13 studies looked at all types of depressive disorders, including major depression and dysthymic disorder, postpartum depression, and studies where depression was comorbid with cardiovascular disease and multiple sclerosis; 6 studies examined anxiety disorders, including panic disorder, PTSD, OCD, GAD, and postpartum anxiety; and 4 studies examined depression and/or anxiety. No qualitative studies have been conducted on the use of a DHI for the treatment of somatoform disorders. The majority of the participants were recruited from the community, and 1 study recruited participants from a multiple sclerosis outpatient clinic. Only 11 papers reported the ethnicity of participants. The participants in the studies were primarily of a white ethnic background and younger or middle-aged. The majority of the studies collected data via interviews, and 2 studies collected data via open-ended questionnaires. Of the total, 18 studies were purely qualitative studies, and 6 studies were mixed methods studies.

The studies varied in types and formats of DHIs. Of the 24 studies, the majority provided additional support via email, telephone calls, or SMS text messages ($n=13$); 6 studies included some form of face-to-face support, whereas 5 studies were purely self-guided DHIs with no support provided. In relation to platforms, the majority of the studies were DHIs accessible on desk-based computers ($n=19$). Only 1 study used a blended approach consisting of video-based therapy. Of the eligible studies, 2 studies consisted of smartphone apps, and 1 study consisted of web- and smartphone-based monitoring. Only 1 study included the use of a computer telephony system designed to monitor and support self-care. In terms of treatment approach, the majority of studies were based on CBT principles ($n=19$).

Figure 1. Flow diagram of study identification and selection adapted from Preferred Reporting Items for Systematic Review and Meta-Analyses (PRISMA).

Results of Meta-Synthesis

The meta-synthesis revealed 3 major themes and 9 subthemes related to the 3 objectives of the systematic review:

1. Service user perceptions of DHIs regarding their acceptability and usability.
2. Aspects of DHIs that are valued and work well and those that could be improved or altered.
3. Why service users chose to use, continue with, or stop using DHIs.
4. Selected supporting quotations from across the studies is provided in [Multimedia Appendix 7](#) to illustrate this meta-synthesis. It shows first-, second-, and third-order constructs and synthesized subthemes with contrasting positive and negative participant experiences of DHIs.

The first theme, *initial motivations and approaches to DHIs*, had 2 subthemes:

1. Initial motivations: hope, accessibility, and cynicism.
2. Participant approaches to engaging with a DHI: active versus passive.

The second theme, *personalization of treatment*, had 3 subthemes:

1. Flexibility and autonomy.
2. Stigma and privacy.
3. Functionality, content, and interface.

The third theme, *the value of receiving personal support in DHIs*, had 4 subthemes:

1. Support for understanding DHIs.
2. Support to enhance commitment and motivation.
3. Suitability and desire for additional support.

4. Support to develop a virtual therapeutic relationship.

Theme 1: Initial Motivations and Approaches to Digital Health Interventions

Participants' initial motivations and approaches to engaging with DHIs had a significant impact on the perceived helpfulness of the intervention. Those who approached the DHI with a sense of hope that it might be helpful and had an active, committed approach to see the treatment through had more positive experiences of treatment and reported greater benefits than those who were initially more cynical and utilized a passive approach in their engagement with DHIs. Thus, the participant approach to DHIs impacted the recruitment and therapeutic process. This began when participants contemplated participating in the study and continued throughout their engagement with the DHI. This is explored further in the following subthemes.

Initial Motivations: Hope, Accessibility, and Cynicism

A total of 15 papers reported on participant expectations of participating in a DHI trial [34-48]. Participants initially decided to engage with a DHI for several reasons. These included hope for recovery and the desire to improve health and reduce symptoms through self-management. The prospect of using DHIs encouraged participants to feel empowered and manage their health by taking responsibility. Participants highlighted that participating in a DHI would enable them to develop coping strategies to manage their difficulties and increase their self-efficacy. DHIs provided a sense of agency to move from a passive to an active role in managing their condition.

DHIs were also viewed as novel approaches to treatment, which provided an alternative opportunity to receive help. DHIs were perceived to be more easily available because they increased accessibility, flexibility, and choice in accessing therapy:

I think it's an easy way to access help without having to like – you know it's easy, it fits into your lifestyle, it's convenient. [48]

There were some negative expectations about DHIs, including skepticism about its helpfulness and concerns about whether a therapeutic relationship could be established remotely. However, in some cases, the ambivalence was overturned once participants commenced treatment, and there was surprise at how quickly a relationship could be established remotely.

Participant Approaches to Engaging With a Digital Health Intervention: Active Versus Passive

Participants' approach to DHIs and technology in general affected motivation to continue engaging with DHIs. This was reported in 17 papers [24,34,37-39,41,44-46,48-55]. Participants who took a more active approach could see the unique benefits of DHIs over medication or face-to-face therapy:

Rather than just saying well here's your pills or sit there and talk to somebody for 35 minutes...actually felt like I was doing something to help myself. [54]

Participants with an active approach embraced independent work. This involved actively processing information received (eg, taking time to reflect on the sessions), educating themselves

about their condition, and applying the learning to their daily living.

Engaging with the DHI gave participants a sense of empowerment, understanding, and awareness about their condition and its triggers, which encouraged them to utilize the tools for self-management. It gave participants a sense of accomplishment and provided greater understanding, and participants felt "inspired to take more control" [38].

This theme was strongly represented in Bendelin et al [49], who identified that an active, self-reliant approach to treatment was related to outcomes that were more positive. However, participants who had a passive style of working struggled to apply the treatment and were more likely to discontinue treatment.

With regard to completing therapy, participants with an active approach felt a sense of obligation or personal commitment to complete the therapy because they had agreed to participate in the DHI and owed it to the researcher or research team to complete the treatment. Others reported that they completed sessions because they valued the importance of research.

Participants with a more passive approach, however, struggled to maintain motivation. They found the nature of DHIs to be "quite difficult," "quite stressful" [52], and isolating. They preferred face-to-face sessions and felt that this was an essential component of personalized practical and emotional support.

Theme 2: Personalization of Treatment

The degree and ways in which DHIs were personalized to participants' situations and health status were deemed to impact the value of the treatment. The flexibility and convenience of DHIs had differential effects. For some participants, this made it more accessible and possible for them to engage in treatment in a way that traditional approaches could not. However, for others, the lack of structure, protected time, and accountability, present in more formal face-to-face therapy, meant that they forgot to complete sessions or disengaged from DHIs. Stigma and privacy were also a double-edged sword: for some, the anonymity of DHIs helped them to trust the process and engage; for others, the lack of a separate, private space to engage with difficult issues felt unsafe. There was broad agreement that DHIs with a simple interface and succinct content were preferred. There was also consensus that reminders, feedback on progress, and acknowledgment of achievements helped to support engagement.

Flexibility and Autonomy of the Digital Health Interventions

Flexibility and autonomy were emphasized in the majority of papers, with 19 papers reporting the flexible and autonomous nature of DHIs [24,35-42,45-49,52-56]. Some participants perceived DHIs to be more accessible and flexible. This led participants to feel that they had more autonomy and choice over their treatment. They used DHIs more responsively when they needed it, and this positively impacted treatment completion:

I like the fact that I could do it in my own time at home...cause I have three children so it wasn't like I

would have to try to have to make appointments and get child care so I could do it when they were in bed or you know whenever it sort of seemed to fit in with my lifestyle I suppose. [56]

Conversely, for some participants, DHIs lacked the structure and protected the treatment time they wanted, which subsequently impacted the motivation to complete treatment. Where interventions were self-guided and did not include monitoring, participants felt less obligated to complete sessions, particularly if they had competing priorities.

Stigma and Privacy

DHIs appealed to some participants because they were perceived to reduce the stigma and anxiety associated with seeking psychological help for mental health conditions. This was reported in 13 papers [35,36,41,42,44,48,49,51-53,55-57]. For participants who had not accepted their condition or felt afraid to express their thoughts, DHIs provided a safe platform to access support from the comfort of their own home. Participants felt more comfortable expressing their feelings on a computer rather than face-to-face because the DHI felt more private. Participants felt less judged and were able to be more honest and open in expressing their feelings to a computer rather than a person. They liked that they “didn’t have to tell anybody else face to face,” and found the DHI to be “a way of coping privately but in a structured way” [36]. However, some participants had concerns about the security and privacy of data [51]. Some believed that a trusting and therapeutic relationship could only be formed face-to-face.

Functionality, Content, and Interface

There was great variability in the DHIs used, consisting of different interventions and varying levels and forms of support. Themes related to DHI functionality, content and interface were highlighted in 21 papers [24,34-39,41-48,50-52,55-57]. Participants reported that content simplicity, reminders, and progress monitoring were very important aspects of functionality, the absence of which impacted treatment completion and satisfaction. This is because it influenced user identification with the material and provided feedback. Accessibility on a range of platforms, content relevance, and ease of navigation, readability, and inclusion of interactive elements impacted user acceptability and engagement with DHIs.

Theme 3: The Value of Responsive Personal Support

This theme was identified in 24 of 25 papers. Only Kuhn et al [39] did not report this. Participants were able to seek treatment to help them self-manage their symptoms via the use of DHIs, but they still valued some form of human, responsive, personal support even if this support was not provided face-to-face. The key elements of additional support valued by participants were support that was personal and human and support that was rapidly responsive to their emotional state, personal difficulties, and achievements. Participants identified that additional support in DHIs helped them better understand DHIs, increased commitment and motivation, and helped form a more therapeutic engagement with DHIs. The rapidly responsive contact with a supporting person or therapist seemed to be missing from those

who had poorer experiences of DHI. The presence and value of the provision of some form of personal support were identified to be integral in the majority of studies and forms the most influential theme.

Support for Understanding Digital Health Interventions and Treatment

Incorporating some form of support in DHIs aided participants’ understanding of the purpose of the intervention. This was particularly pertinent where participants were ambivalent about participating in a DHI or were unsure about the need or value of receiving psychological support. This was emphasized in 16 papers [24,35-38,40,44-48,51,52,54,55,57]. Where support was not provided, participants misunderstood the difference between a research trial and the DHI and would often assume that trial participation was part of therapy. Guided support provided participants with direction about the interpretation of the treatment session content and made therapy more personally relevant.

Support for Enhancing Commitment and Motivation

Incorporating some form of support to enhance commitment and motivation was highlighted in 17 papers [35,37,38,41,43-51,53-55,57]. Owing to the autonomous nature of DHIs, participants reported forgetting or feeling less obligated to engage in treatment compared with face-to-face therapy, as highlighted in the previous theme. Without additional support, they struggled to relate to and apply the therapy content to their own condition, leading to disengagement from the DHI. Receiving feedback from a therapist or others allowed participants to monitor their progress, prevented forgetfulness, and encouraged participants to continue with therapy. Some form of communication was helpful and was achieved via a number of mediums, including face-to-face and remotely via emails, phone calls, and SMS text messages. Thus, receiving support facilitated understanding of symptoms, prevented forgetfulness to complete modules, and provided encouragement to overcome challenges and reduced isolation. Disengagement from a DHI was more likely in the absence of support as it reduced commitment and motivation to complete therapy.

From my point of view, the contact with the therapist was an essential aspect of therapy. Therefore, I lost all my interest in the therapy and didn’t want to continue. [43]

Suitability and Desire for Additional Support

Questions regarding the suitability of DHIs for some problems were raised in 12 papers, alongside some patients’ desire for additional responsive support when DHIs became challenging or unsuitable [24,34,43,45,46,50-56]. DHI therapy sessions could be physically and mentally exhausting, and for some participants, it exacerbated symptoms of low mood and anxiety. Therefore, some participants wanted additional support to manage these negative feelings. The absence of support made module completion overwhelming for some participants, leading them to prioritize other commitments or discontinue the treatment.

Hind et al [52], focusing on DHIs for people with depression and physical comorbidities, found that completion of DHI sessions placed physical demands on participants. Where support was not provided, some form of support was recommended to overcome feelings of isolation and enable emotional expression [34,51,52]. This subtheme was not highlighted by any of the papers that included face-to-face support [24,33,35-38,44,57].

Support for Developing a Virtual Therapeutic Relationship

The interpersonal and relational aspects remained an essential ingredient of therapy, even if it was delivered as a DHI. This subtheme was reported in 18 papers [24,33-35,37,38,41,43-48,50,51,53-55]. Participants who engaged in DHIs reported feeling surprised at how quickly a relationship could be formed remotely with a person. They valued expressing feelings in written form because it enabled self-reflection and communication of emotion without interruptions. Attributes associated with developing a therapeutic relationship face-to-face were also identified in the DHIs. This included building a positive relationship between trust and feeling understood. Participants referred to the therapist as “a real friend” and likened the DHI to a “face-to-face session” [24].

Participants who disengaged from DHIs found them to be impersonal and expressed a preference for face-to-face therapy. The absence of visual cues such as eye contact and gestures was perceived to reduce emotional closeness, and made participants question whether the therapist was giving them their undivided attention. The use of written communication methods and the associated time delay between responses were seen as barriers to developing a therapeutic relationship. The absence of face-to-face contact was perceived to lack empathy, be machine-like “cold, not very friendly” [35], and this negatively impacted the therapeutic relationship.

Summary of Meta-Synthesis

The themes emerging from the meta-synthesis acknowledge the variability within individuals' experiences of DHIs for depression, anxiety, and somatoform disorders. DHIs were perceived both positively and negatively by participants, and this was influenced by the participants' expectations and needs. Personalization was an overarching theme; participants who had a preference for flexibility and autonomy perceived these to be the benefits of DHIs. In addition, the functionality of the DHIs was also important to participants. The key means of personalizing treatment identified as helpful by participants was the addition of rapid, responsive personal or human support. Thus, DHIs need to be responsive to participant preferences and experiences.

Discussion

Principal Findings

This systematic review aimed to meta-synthesize qualitative studies exploring the views of people who had been invited to participate in DHIs for depression, anxiety, and somatoform disorders. The first aim of the review was to examine service user perceptions of DHIs concerning their acceptability and

usability. Findings from the meta-synthesis indicate that the acceptability and usability of DHIs differ on the basis of initial personal perceptions of DHIs, associated motivations, and the degree of responsive support offered. Participants' perceptions of DHIs can be positive or negative depending on expectations, preferences, and approaches to DHIs. Some participants felt more comfortable expressing their feelings on a computer rather than sharing it with somebody face-to-face because the DHI felt more private. Other participants found the nature of DHIs to be impersonal and preferred face-to-face therapy. This did not differ by DHI type or format, suggesting that the acceptability and usability of DHIs is influenced by individual perceptions and preferences. This study highlights that therapeutic work in DHIs is a dynamic process and is perceived positively or negatively depending on how well the DHI is adapted to the participants' preferences. The personalization of DHIs was an overarching theme, implying that DHIs need to consider individual preferences, circumstances, and needs to improve therapy completion rates for DHIs.

The second objective of the review was to examine aspects of DHIs that are valued and work well and those that could be improved or altered. The third aim of the review was to explore why service users chose to use, continue with, or stop using DHIs. This meta-synthesis emphasizes the significance of receiving personal support in DHIs and is consistent with the findings of O'Connor et al [26] and Knowles et al [27], both highlighted the need for personalization and availability of support in DHIs. The meta-synthesis also informs some of the research priorities identified by Hollis et al [25]. This study highlights that the suitability of DHIs is based on differing needs and that DHIs could be optimized by incorporating additional support. This systematic review extends on previous findings of Knowles et al [27] by demonstrating that personalized support was valued across studies irrespective of DHI type, format, or disorder. Participants who received self-guided DHIs expressed dissatisfaction with the lack of human interaction and expressed that it was required to increase commitment as it enabled personal support and feedback. Participants who received face-to-face contact as part of the DHI expressed that incorporating interpersonal features such as the provision of support was central because it personalized therapy. Personalized support facilitated an understanding of therapy, increased commitment and motivation to continue treatment, and helped form a more therapeutic engagement with DHIs. Similarly, participants in DHIs consisting of email or phone support reiterated that the presence of a supporter personalized therapy. However, they also expressed a desire for more contact with a supporter. Participants in the 2 studies that provided no therapy and only technical support or reminders [50,54] expressed a need for personalization in the form of feedback and emotional support. The functionality of DHIs was perceived to facilitate or hinder engagement. DHIs that were easily accessible and interactive were viewed as more beneficial than DHIs that were harder to navigate and inaccessible on a range of platforms. DHIs consisting of smartphone apps were perceived to be easily accessible. A simple interface and succinct content with reminders, feedback on progress, and acknowledgment of achievements also helped to support the completion of therapy.

This review also highlights that the flexible and autonomous nature of DHIs and the desire to gain greater awareness to self-manage conditions can affect participants' choice of whether to engage with a DHI or not. These aspects are consistent with a previous systematic review on DHIs [26], which also emphasized the significance of personal agency and motivation to improve awareness and self-management of health when considering recruitment to DHIs. The current meta-synthesis enhanced these findings by highlighting how individual expectations and perceptions influenced participant engagement and approaches to DHIs. Participants with an active approach perceived DHIs to be more favorable compared with face-to-face therapy and were more likely to actively engage with DHIs by reflecting on and applying session content to their daily lives. Subsequently, these participants were more likely to complete treatment compared with participants who found DHIs isolating. DHIs attracted participation when they were perceived to be accessible and tailored to individual needs. Participants could access treatment from their own homes, which was more convenient and appropriate for those who would otherwise not access treatment. DHIs were also perceived to be more appealing because they reduced the stigma of accessing treatment. However, for some participants, the autonomous nature of DHIs made it easier to prioritize other tasks and disengage from treatment because the sense of commitment to treatment was reduced.

The meta-synthesis illustrates the different requirements of support that can potentially be provided in a number of ways. Thus, on the basis of participant preferences and needs, DHIs could be tailored to meet individual presentations. DHI functions and level of support likely to be required could be determined by initially assessing participant expectations and needs, as opposed to uniformly offering DHIs as an all-or-nothing option.

Strengths and Limitations

This is the first meta-synthesis to our knowledge that has looked at the acceptability and usability of DHIs across different types and formats and across a range of depression and anxiety disorders. This systematic review included all DHIs regardless of the delivery method (ie, text-based, automated, blended therapy), so it compared very different experiences. The themes emerging from the meta-synthesis highlight that personalized support was valued across studies irrespective of DHI type, format, or health condition. In particular, some form of human interaction was valued because it personalized therapy and increased motivation to complete therapy. This supports the generalizability of this finding, given that participants reported similar themes from a range of DHIs.

A limitation of including a range of different interventions is that some comparisons may have been incompatible or inappropriate across these rather different technologies. However, given the broad inclusion criteria, it is particularly important that personal support was still highlighted as a theme across studies and gives greater weight to its importance. We excluded peer-to-peer networks and DHIs of social support via the internet, use of social media, online support groups, or DHIs consisting of group therapy. Future research could explore whether participants' experiences of these delivery formats

differ or are similar to our findings. It is worth highlighting that technological competence was only identified in 3 studies [24,41,51] as a potential barrier to engaging with a DHI. This could be because the views captured in the papers are mainly of participants who chose to engage in a DHI and do not capture the experiences of participants who decided not to participate in a DHI. The majority of the DHIs were CBT-based despite including a broad range of mental health conditions, treatment settings, and types of DHIs. Recommended therapies, such as interpersonal therapy for depression, were notably absent from studies included [58]. In terms of DHI variability, the use of videoconferencing to provide therapy was only included in 1 study [24] and could be investigated further in the future. Videoconferencing has the potential to provide real-time face-to-face therapy remotely, thus improving accessibility but also increasing the level of personalized support. A recent RCT investigating the clinical and cost-effectiveness of videoconferencing CBT delivered to repeat unscheduled care users with health anxiety found completion rates to be substantially higher than other DHI studies [7]. Recent years have also seen an increase in the use of smartphone apps for the treatment of depression and anxiety and the use of VR and interactive games for the treatment of anxiety and phobias. Therefore, it will be useful to update this systematic review to incorporate research regarding the acceptability and usability of smartphone apps to ascertain whether similar themes emerge.

This systematic review was not carried out using double screening, with only 30% of data being extracted by both reviewers. However, the high level of congruence found for the subset sample implied that the screening methods were rigorous. The systematic review only included papers published in English, which may reflect the fact that the majority of the studies were conducted in European and American countries. However, major sources of technology production are found in non-English speaking countries, for example, China, Japan, and India. The majority of studies were for the treatment of depression, and there were no studies on the use of DHIs for the treatment of somatoform disorders; therefore, the conclusions might not apply to somatoform disorders. We excluded participants with bipolar disorder despite depression being a characteristic feature of bipolar disorder; hence, we were unable to see whether the findings could translate to this condition.

Implications and Recommendations

On the basis of our findings from the meta-synthesis, we propose the following implications and recommendations to policy makers and commissioners:

1. Expectations and pre-existing beliefs about DHIs and their effectiveness can have an impact on patient experience and engagement. Therefore, addressing these expectations before beginning a DHI or building this into the initial stages of DHIs would help manage any misconceptions and address early barriers. This might also explain the high dropout rate from DHIs if people perceive them to be less effective than traditional approaches. An initial assessment should also include addressing patient preferences in terms of autonomy, level of support, and medium of

communication. This would help identify whether additional support is needed, and if so, the level required. Responsiveness to these kinds of unnecessary barriers could aid engagement and retention in DHIs.

2. Personalization of DHIs and personalized support was an overarching element that ran throughout all themes. Communication of some form was valued by the majority of the participants. It clarifies the intervention's purpose, personalizes therapy, and increases self-discipline and motivation to engage with DHIs. Thus, engagement with DHIs can be enhanced by including personal reminders for therapeutic activities and giving participants' individualized feedback on their progress with therapeutic tasks. Ensuring that the interface and content is succinct and easy to navigate around would also likely reduce dropout from DHIs. Thus, future DHIs need to consider how feedback and reminders can be incorporated and presented.
3. Both the previous recommendations and many other individual problems described by participants in this study would be addressed by making additional support available to those using DHIs. There is a clear and consistent theme of preferred qualities for this additional support, particularly

where the person is passive or indifferent in their willingness to engage with a DHI. Additional support should be personalized, incorporate some form of human interaction, and be rapidly responsive. This kind of support was especially desirable when participants met significant barriers to DHIs. Therefore, treatment engagement, experience, and response should be monitored throughout DHIs, so those who do not respond or have a poor experience can receive an appropriate level of additional support quickly.

Conclusions

This review indicates that addressing patients' initial expectations of DHIs could help improve uptake, therapy completion, and effectiveness. Furthermore, the addition of rapid, responsive personal and human support, albeit offered remotely, could improve patient experience of DHIs, particularly when patients find DHIs challenging. The recommendations offered by this review have the potential to improve recruitment and retention rates to participation in DHIs and guide the design of DHIs so that they are personalized and improve overall patient experience.

Acknowledgments

Authors' Contributions

SP, AA, and EY designed the search strings. EY conducted the search. AA and SP screened the papers for inclusion. AA and SP extracted data and appraised the quality of the papers. SP and AA coded the results section of each included paper and developed descriptive themes through inductive analysis. SP, AA, SM, SS, ER, NW, and RM reflected on and interpreted the descriptive themes to develop analytical themes. All authors contributed to the writing and refinement of the paper.

Abstract

Background: There is growing evidence that apps and digital interventions have a positive impact on diabetes self-management. Standard self-management for patients with diabetes could therefore be supplemented by apps and digital interventions to increase patients' skills. Several initiatives, models, and frameworks suggest how health apps and digital interventions could be evaluated, but there are few standards for this. And although there are many methods for evaluating apps and digital interventions, a more specific approach might be needed for assessing digital diabetes self-management interventions.

Objective: This review aims to identify which methods and criteria are used to evaluate apps and digital interventions for diabetes self-management, and to describe how patients were involved in these evaluations.

Methods: We searched CINAHL, EMBASE, MEDLINE, and Web of Science for articles published from 2015 that referred to the evaluation of apps and digital interventions for diabetes self-management and involved patients in the evaluation. We then conducted a narrative qualitative synthesis of the findings, structured around the included studies' quality, methods of evaluation, and evaluation criteria.

Results: Of 1681 articles identified, 31 fulfilled the inclusion criteria. A total of 7 articles were considered of high confidence in the evidence. Apps were the most commonly used platform for diabetes self-management (18/31, 58%), and type 2 diabetes (T2D) was the targeted health condition most studies focused on (12/31, 38%). Questionnaires, interviews, and user-group meetings were the most common methods of evaluation. Furthermore, the most evaluated criteria for apps and digital diabetes self-management interventions were cognitive impact, clinical impact, and usability. Feasibility and security and privacy were not evaluated by studies considered of high confidence in the evidence.

Conclusions: There were few studies with high confidence in the evidence that involved patients in the evaluation of apps and digital interventions for diabetes self-management. Additional evaluation criteria, such as sustainability and interoperability, should be focused on more in future studies to provide a better understanding of the effects and potential of apps and digital interventions for diabetes self-management.

Introduction

As the number of people with diabetes continues to rise worldwide [1], the need to increase patients' self-management skills is crucial to improve clinical outcomes and reduce health-related costs [2,3]. There is growing evidence that apps and digital interventions such as websites (web), social media, and other online services have a positive impact on diabetes self-management [4-12], suggesting that standard self-management could be supplemented by digital interventions to aid and improve patients' skills [4-12]. While some apps and digital interventions have benefited patients, not all of them seem to be based on research, and some of these digital interventions could even compromise the safety of patients with diabetes [13].

To improve diabetes self-management with apps and digital interventions, the World Health Organization and the European Commission [14,15] deem it necessary that the available apps and digital interventions are accurate and reliable. Several initiatives, models, and frameworks suggest how some of these apps and digital interventions could be evaluated [16-19]. These approaches commonly name background information, privacy and security, evidence on the provided information, ease of use, or interoperability as issues that need to be addressed [16-18]. Regarding how to evaluate these criteria, several methods of different complexity have been proposed. These include simple questions to be answered by health care professionals (HCPs) and patients, whereas more complex methodology approaches, such as laboratory-based testing, field testing, and N-of-1 design, are used by researchers [18,20]. Although the aforementioned issues are relevant for diabetes self-management apps and digital interventions, a more specific approach is needed for assessing the growing number and rapidly changing functionalities of these digital diabetes self-management interventions.

Another relevant issue is who should be involved in these evaluations. As patients are often required to make critical decisions based on their own generated health information [21], people with diabetes should be involved in these evaluations. However, a previous assessment of digital health interventions demonstrated limited consideration of user perceptions, and also that of health care personnel [22].

In this systematic review, we identify the specific methods and evaluation criteria that were used to assess apps and digital interventions for diabetes self-management. We also report how patients were involved in these assessments.

Methods

This review followed the PRISMA approach [23], and its systematic review protocol is registered in PROSPERO (Registration number: CRD42018115246).

Data Sources and Search Strategy

We performed a single data search in June 2018. The search strategy covered all studies that assessed diabetes self-management apps and digital interventions, involved patients, and were published in English after 2015. We chose a short search period to get a rapid overview of the most recent

methods and evaluation criteria. The search strategy covered the following databases: CINAHL, EMBASE, MEDLINE, and Web of Science. The full search strategy is available in [Multimedia Appendix 1](#).

Inclusion and Exclusion Criteria

We included articles for review if they were (1) primary studies referring to the evaluation of apps or digital interventions for diabetes self-management; and (2) involved patients in the evaluation.

Article were excluded if (1) the evaluation only measured medical values (ie, weight, glycated hemoglobin [HbA_{1c}], blood glucose); (2) it was not a primary study; (3) it did not focus on apps or digital interventions for diabetes self-management; (4) the full-text was not available; (5) it was not a peer-reviewed publication; (6) it was not in English; or (7) it was published before 2015.

Eligibility and Data Collection Procedure

We uploaded all references captured by the search strategy to Rayyan and EndNote and removed duplicates. The eligibility of the articles was assessed in two stages. In the first stage, 2 independent reviewers (PR and EG) examined all titles and abstracts. Eligibility doubts were discussed and agreed with a third and fourth reviewer (KA and EÅ). In the second stage, the full texts of the selected articles were carefully examined by 2 independent reviewers (PR and EG) to confirm their eligibility.

Two reviewers (PR and MB) independently extracted and recorded the data from these articles on an Excel spreadsheet (Microsoft). We extracted the following information from each article: type of platform, targeted health condition, study population, methods of evaluation, and evaluation criteria. Incongruences with the data extraction were discussed among the research group.

Confidence in the Evidence and Risk of Bias Assessment

Two reviewers (EG and KA) assessed the confidence in the evidence and risk of bias of the articles. We used an approach based on the CERQual guidelines [24] to assess the confidence in the evidence of the qualitative primary studies, by evaluating their methodological limitations, relevance, and adequacy. We followed the GRADE guidelines [25] to assess mixed-methods studies, quantitative studies, and randomized trials.

Strategy for Data Synthesis

We provide a narrative qualitative synthesis of the findings from the included articles, structured around confidence in the evidence and risk of bias; type of platform (apps, web, or multiplatform [ie, ≥2 types of platform delivering the same intervention in a study]); targeted health condition (type 1 diabetes [T1D], T2D, gestational diabetes mellitus, both T1D and T2D, and unspecified diabetes type); methods of evaluation (questionnaires, interviews, user-group meetings, health measures, system usage analysis, or other); and evaluation criteria (usability, clinical impact, cognitive impact, behavioral impact, feasibility, engagement, acceptability and acceptance, or security and privacy).

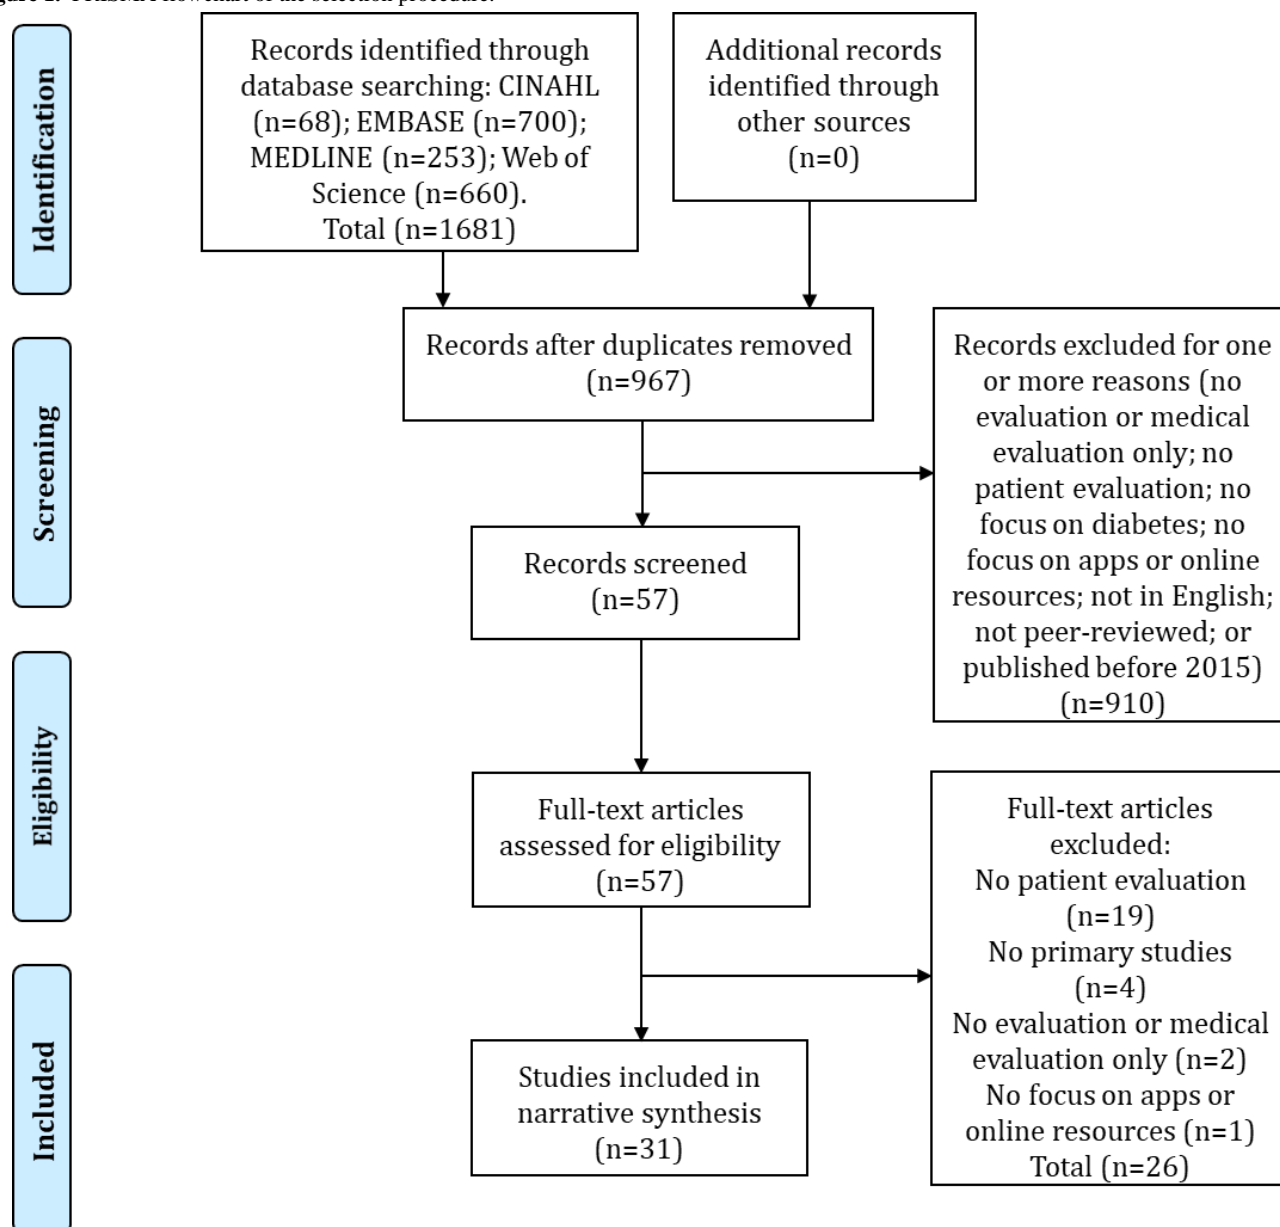

Results

Identified and Included Studies

The search strategy resulted in 1681 articles. After removing duplicates, 967 articles remained. In the abstract screening, we excluded 910 articles in accordance with one or more of the exclusion criteria. A total of 57 articles were eligible for full-text

screening, 26 of which were excluded (see [Multimedia Appendix 2](#)). A total of 31 articles were eventually included in the review [26–56] (see [Multimedia Appendix 3](#)). The PRISMA diagram in [Figure 1](#) summarizes the selection process. The confidence in the evidence was considered high in 7 articles [27,33,36,43,51,52,54]; moderate to high in 1 [56]; moderate in 17 [26,28–32,35,37,39,41,42,45,46,48,49,53,55], and low in 6 [34,38,40,44,47,50].

Figure 1. PRISMA flowchart of the selection procedure.

Study Population

The 31 articles in this review included evaluations from 3689 participants. The number of participants in each study ranged from 7 [41,50] to 1041 [43]. In addition to including patients with diabetes in their evaluations, some of the studies expanded the participant group to include HCPs (8/31, 26%) [26,27,29,37,42,48,53,56], developers (4/31, 13%) [26,44,51,56], researchers (3/31, 10%) [29,38,44], informal caregivers (eg, parents, family members) (4/31, 13%)

[29,44,53,56], and others (including experts and other unspecified individuals) (8/31, 26%) [26,29,32,37,38,48,55,56].

Type of Platform and Targeted Health Condition

Most of the 31 included studies evaluated interventions delivered via apps (18/31, 58%) [29–34,36–39,41,46–49,52,54,56], followed by web (9/31, 29%) [27,28,35,43,45,50,51,53,55] and multiplatform (4/31, 13%) [26,40,42,44]. In the studies that conducted a randomized controlled trial, the self-management platform was the main mode of intervention compared with a standard paper diary [33], the intervention plus counseling via

telephone call [54], and a plain text version of the web intervention [43] as opposed to an interactive version. In addition, the same intervention was referred to by some of the studies: Young with Diabetes app [29,36], My Diabetes My Way [30,55], and WellDoc [31,50]. The evaluated digital self-management interventions targeted mostly T2D (12/31,

38%) [27,31,32,34,43,46-51,54], followed by T1D (7/31, 23%) [29,33,36,40,41,44,56], unspecified diabetes type (5/31, 16%) [26,37,39,53,55], gestational diabetes mellitus (4/31, 13%) [35,38,45,52], and T1D and T2D (3/31, 10%) [28,30,42] (Figure 2).

Figure 2. Distribution of types of platform and targeted health conditions among included articles (n=31).

Identified Evaluation Methods

The methods of evaluation were grouped into 6 categories: questionnaires, interviews, user-group meetings, health-related measures, system usage analysis, and other measurements. We also identified 20 specific methods that were either used once or multiple times by the studies during the evaluation process.

The interrater agreement for the methods of evaluation was found to be $\kappa=0.550$, which represents a moderate agreement [57]. A summary of the specific methods of evaluation and studies that used them is presented in Table 1.

Questionnaires were the most common method used to evaluate diabetes self-management apps and digital interventions (21/31 studies, 68%) [29-40,42,43,45,46,50,51,54-56]. Standardized questionnaires were the most frequently used: 16 in total, each used one or multiple times among 13 studies [31,33-36,38,40,42,43,45,50,51,54]. The second most common method of evaluation was interviews (13/31 studies, 42%) [28,29,31,32,35,36,38,45,48,49,52,53,56], mainly semistructured

interviews, which were used 14 times in 11 studies [28,31,32,35,36,45,48,49,52,53,56]. Other methods of evaluation that were identified in the included studies were user-group meetings (11/31, 35%) [26,27,29,37,40-42,45,47,48,56], health-related measures (9/31, 29%) [31,33,36,42,45,49,51,54,55], system usage analysis (8/31, 26%) [29,34,35,42,43,45,51,54], and other measurements (7/31, 23%) [26,37,38,44,48,51,55]. Table 1 summarizes the specific methods of evaluation, the number of times these methods were used, and the number of studies that employed these methods.

Among the 7 studies considered of high confidence in the evidence, the evaluations of the apps and digital diabetes self-management interventions were based mostly on standardized questionnaires [33,36,43,51,54], medical tests [33,36,51,54], and usage log analysis [43,51,54], followed by author-created questionnaires [43,51], semistructured interviews [36,52], focus groups [27], self-reported health measures [33], self-reported usage [43], alpha testing [51], and other oral and written feedback [51].

Identified Evaluation Criteria

The evaluated criteria were grouped into 8 categories: usability, clinical impact, cognitive impact, behavioral impact, feasibility, engagement, acceptability and acceptance, and security and privacy. The included studies evaluated one or several of these identified criteria. The interrater agreement (κ) for the evaluation criteria was found to be 0.563, which represents a moderate agreement [57].

Among the 7 studies considered of high confidence in the evidence, the most commonly evaluated criteria were clinical impact [33,36,51,54], cognitive impact [33,36,43,54], and engagement [43,51,54], followed by usability [33,51], behavioral impact [33,51], and acceptability and acceptance [51,54]. None of these studies considered of high confidence evaluated feasibility or security and privacy.

Qualitative and mixed-method studies that used thematic analysis in their evaluation focused mostly on usability as an evaluation criterion. Three of the studies considered of high confidence in evidence were qualitative and mixed-method studies. Of these, 2 evaluated cognitive impact [36,52] and usability [27,52], and 1 evaluated engagement [36].

Figure 3 shows the number of studies that used each of the specific methods to evaluate the identified criteria. It illustrates that several methods were used to evaluate one criterion in a single study. Likewise, some studies evaluated several criteria using one or more of the identified methods of evaluation. For example, of the 31 included studies, 9 [31,33,36,40,42,43,45,50,54] evaluated cognitive impact using standardized questionnaires.

Discussion

Summary of the Findings

This review aimed to identify the existing methods and criteria used to assess apps and digital diabetes self-management interventions that involved patients in their evaluations. A total of 31 articles were included in the review, 7 of which were considered of high confidence in the evidence [27,33,36,43,51,52,54]. More than half of the studies (18/31, 58%) focused on the evaluation of apps for diabetes self-management, and 12 of the 31 studies addressed T2D. The most commonly used methods of evaluation were questionnaires, interviews, and user-group meetings. The most used evaluation criteria to assess apps and digital interventions for diabetes self-management were cognitive impact, clinical impact, and usability.

Specific Evaluation Criteria and Diabetes Patients' Assessment

In our review, we have found that studies dealing specifically with apps and digital interventions for diabetes self-management focus on the evaluation of more technology-related and users' interaction aspects (ie, acceptability and acceptance, and engagement). In addition, these studies focus on the impact that these digital self-management interventions have on the individual. Behavioral impact, cognitive impact, and clinical impact were used as relevant criteria for assessing all types of digital interventions for diabetes self-management. It is vital to measure the interventions' impact on their users because those that have shown benefits related to behavioral, cognitive, and clinical impact could reduce health-related costs [2,3].

Evidence shows that involving individuals in the assessment of different health interventions has a positive impact on health

[58]. We found few articles (n=31) in this review that involved patients in the evaluation of apps and digital interventions for diabetes self-management. The evaluations in which patients were involved in mostly focused on usability and cognitive impact. Evaluation criteria that could measure patients' continuous use of these apps and digital interventions for self-management could supplement both their qualitative responses and the more static traditional and clinical criteria. This is an opportunity for improvement, as none of the studies in this review evaluated the same criterion using both qualitative results from patients and quantitative measures.

Involving patients with diabetes in assessing apps and digital self-management interventions, and obtaining their feedback regarding additional evaluation criteria could also increase our knowledge about the features that support engagement with these technologies. This could also help create better digital health interventions that encourage more continuous and effective use [59]. The most common methods of evaluation with the patients were questionnaires, interviews, and user-group meetings. Simple methods such as these elicit the opinion and perceptions of users, as well as encourage them to critically analyze self-management apps and digital interventions. Therefore, such methods should be used in conjunction with complex methods used by researchers and developers [18,20], especially to measure the same criterion.

Improving Reported Evaluations of Digital Interventions for Diabetes Self-Management

Apps and digital health interventions have evolved quickly. Yet, compared with other sectors, the health industry seems to be behind with regard to digitalization [60]. Currently, most apps and digital interventions for self-management are not recommended as part of the treatment plan, maybe because their design and development do not take into consideration sustainability [61]. In fact, digital health interventions rarely advance beyond a pilot phase [62,63], or the duration of an intervention study.

In 2016, the mobile health (mHealth) evidence reporting and assessment checklist was developed by the World Health Organization to help with reporting evidence of the effectiveness of mHealth interventions [64]. The checklist recommended reporting on items that touch on sustainability, scalability, and transparency, such as infrastructure, interoperability, contextual adaptability, and replicability, which we still see are not much focused on in today's studies. Future studies should also consider these evaluation criteria in addition to gender and equity issues associated with the use of apps and digital interventions for diabetes self-management.

Evaluation reports for apps and digital interventions for diabetes self-management must be standardized, as recommended by the CONSORT-EHEALTH guidelines for reporting digital health interventions [65]. The lack of standardization made it challenging to compare studies as different authors used different terminologies to describe the same evaluation criterion. For example, one study [37] used the term *heuristics evaluation*, which was grouped under usability because it evaluated measures such as the visibility of app status, ease of input, and readability. Likewise, another study [32] evaluated *satisfaction*,

which falls under usability because it evaluated among others, visual attractiveness and ease of use.

As electronic health (eHealth) research is a multidisciplinary field, we assume that the authors chose these terms based on the various educational or professional backgrounds and the corresponding target audiences. By following the World Health Organization classification of digital health interventions [66], terminologies related to the evaluation of apps and digital interventions for diabetes self-management could be standardized to facilitate straightforward interpretation and aggregation of research evidence.

Association Between Methods Used and Criteria Evaluated

In our review we have found that there was an almost even split of studies that used standardized questionnaires, author-created questionnaires, and semistructured interviews to evaluate usability. Our results are to some extent in line with the findings of a previous review that found that usability was mainly assessed through polls and questionnaires [67]. The usability of a digital self-management intervention is crucial to its successful adoption, its acceptance, and the individual's engagement with it. In addition, we found that cognitive impact was often assessed not only through standardized questionnaires, but also through semistructured interviews.

Comparing the methods for the evaluation of usability with those for the evaluation of cognitive impact, we identified that it was more common to use author-created questionnaire for usability. A possible explanation might be the wide variety of intervention delivery platforms (eg, different types of apps and online resources) that might create different evaluation needs not captured in existing standardized usability questionnaires. Another explanation might be the different research traditions in different disciplines. Usability might be more often a concern of computer science researchers, whereas cognitive impact a concern of health researchers and professionals.

Finally, health outcomes were almost exclusively evaluated by medical tests, showing the preference of health researchers and professionals in using standardized tests to determine the impact of digital interventions. Several other methods can be used to evaluate multiple criteria; however, depending on the aim and the type of study, researchers must endeavor to exhaust all available methods to ensure consistency of results.

Feasibility of Using Digital Self-Management Interventions in Clinical Workflow

Although most apps and digital health interventions are intended for self-management, some of them also provide access to the health care system, such as communication with HCPs and electronic health journals. The reviewed studies consistently reported that this is in response to patients' interest in being able to contact their HCPs or share results (eg, their blood glucose results with their health care team). This was the case not only within our review [35,36,42,44,47,48,56] but also by industry research groups [68,69]. This implies the potential and expectation for further involvement of HCPs in patients' use of apps and digital interventions for diabetes self-management.

Several studies, including many in this review, have shown that involving HCPs in digital interventions is associated with improved self-management of diabetes and the success of these interventions [31,48,49,52,70-72]. Therefore, studies focusing on apps and digital interventions for diabetes self-management should evaluate the possibilities of effortlessly integrating these interventions in the workflow of HCPs—the connection and interaction with electronic health journals and other existing health information systems. Such an integration can be achieved by evaluating the infrastructure needed for digital self-management interventions [64].

Limitations and Strengths

The search for articles covered a short period (2015-2018) and focused on articles published in the English language. Therefore, we may have missed relevant studies that reported additional evaluation methods or evaluation criteria. Our interrater agreement of the data extraction was only moderate; however, all incongruences were discussed among the research group. Our findings have provided a useful overview of the recent evaluation methods and criteria that researchers are using to assess current apps and digital interventions for diabetes self-management. Furthermore, our review included both quantitative and qualitative studies which provided a better characterization of different evaluation methods and criteria that are being used to assess digital diabetes self-management interventions.

Conclusions

There are only few studies that involved patients in the evaluation of apps and digital interventions for diabetes self-management, and even fewer still considered of high confidence in the evidence. The most common evaluation methods were questionnaires, interviews, and user-group meetings, whereas evaluation criteria were cognitive impact, clinical impact, and usability. Studies with high confidence in the evidence did not evaluate feasibility or security and privacy, neither were patients involved in evaluating the latter criterion which was evaluated in only 2 [29,44] of the included studies.

It is important to the successful implementation and continuous use of apps and digital interventions for diabetes self-management that patients are involved in evaluating every criteria. In that way, they can contribute to the development and modification of these digital interventions to better meet their specific self-management needs. Furthermore, the methods and criteria evaluated in digital diabetes self-management interventions should be expanded to assess and ensure sustainability and interoperability. In addition, studies should evaluate the association between cognitive, clinical, and behavioral impact of these apps and digital interventions, and health-related costs for individuals with diabetes. This could help improve health care associated with the management of diabetes and promote the incorporation of apps and digital interventions for self-management in the services provided at health care facilities.

Acknowledgments

This project is funded by Helse Nord (HNF1425-18). The coauthors acknowledge the advice of the project's Advisory board: Professor Gunnar Hartvigsen, Anne Grethe Olsen MD, and Dr. Med. Anne Helen Hansen, and also the support and contributions of Per Erlend Hasvold in his role as an "internal reviewer." Furthermore, we thank Dr. Steven Bradway for his assistance with the coarse data extraction and organization at the start of this review. The publication charges for this article have been funded by a grant from the publication fund of UiT The Arctic University of Norway.

Authors' Contributions

KA was responsible for database searching; EG, EÅ, KA, and PR were responsible for title, abstract, and full-text screening; MB and PR performed independent data extraction; EG and KA evaluated risk of bias; and DL, EG, EÅ, MB, KA, and PR performed data analysis and interpretation. All the coauthors contributed to drafting and revising the review. All coauthors approved the final version of the manuscript.

Abstract

Background: An increasing number of patients have received prophylactic or therapeutic oral anticoagulants (OACs) for thromboembolic complications of diseases. The use of OACs is associated with both clinical benefits and risks. Considering the challenges imposed by this class of drugs, as well as the enormous progress made in portable device technology, it is possible that technology-based interventions may improve clinical benefits for patients and optimize anticoagulation management.

Objective: This study was designed to comprehensively evaluate the role of technology-based interventions in the management of OACs.

Methods: We searched 6 databases—PubMed, EMBASE, Cochrane, Cumulative Index to Nursing and Allied Health Literature, Scopus, and PsycINFO—to retrieve relevant studies published as of November 1, 2019, to evaluate the effect of technology-based interventions on oral anticoagulation management. RevMan (version 5.3; Cochrane) software was used to evaluate and analyze clinical outcomes. The methodological quality of studies was assessed by the Cochrane risk of bias tool.

Results: A total of 15 randomized controlled trials (RCTs) were selected for analysis. They reported data for 2218 patients (1110 patients in the intervention groups and 1108 patients in the control groups). A meta-analysis was performed on the effectiveness and safety data reported in the RCTs. Technology-based interventions significantly improved the effectiveness of oral anticoagulation management (mean difference [MD]=6.07; 95% CI 0.84-11.30; $I^2=72\%$; $P=.02$). The safety of oral anticoagulation management was also improved, but the results were not statistically significant. Bleeding events were reduced (major bleeding events MD=1.02; 95% CI 0.78-1.32; $I^2=0\%$; $P=.90$; minor bleeding events MD=1.06, 95% CI 0.77-1.44; $I^2=41\%$; $P=.73$) and thromboembolism events were reduced (MD=0.71; 95% CI 0.49-1.01; $I^2=0\%$; $P=.06$). In general, patients were more satisfied with technology-based interventions, which could also improve their knowledge of anticoagulation management, improve their quality of life, and reduce mortality and hospitalization events.

Conclusions: Using technology to manage OACs can improve the effectiveness and safety of oral anticoagulation management, result in higher patient satisfaction, and allow greater understanding of anticoagulation.

Introduction

Oral Anticoagulation Management

Oral anticoagulants (OACs) have been used for decades, especially warfarin, which has been in use since the 1950s. Until recently warfarin has been a fundamental drug in clinical anticoagulant therapy, and although the results of two previously published meta-analyses of atrial fibrillation suggested that novel OACs are not inferior to warfarin in terms of safety and efficacy [1,2], warfarin has the advantage of being inexpensive and having a wide range of indications. Warfarin is widely used in conditions that are prone to thrombosis, such as atrial fibrillation, irregular heartbeat, myocardial infarction, artificial heart valve replacement, recurrent stroke, deep vein thrombosis, and pulmonary embolism [3]. However, it remains challenging to balance effectiveness and safety in treatment [4]. Statistical data from relevant literature estimated that over 6 million patients in the United States have received anticoagulant therapy [5], leading to increased risks of bleeding, thromboembolism, hospitalization, and mortality. Currently, rough statistics indicate that about 1 in 10 surgical patients in the United States receive OACs [6], and approximately 2 million people start warfarin therapy in the United States every year [7]. Therefore, effective anticoagulation management measures are urgently needed.

Technology-Based Interventions for Oral Anticoagulation Management

With the continuous development of telemedicine health service technology, more and more technological devices have been applied to help in the management of patients with chronic diseases, including those with diabetes, hypertension, heart failure, and others [8]. Telemedicine is defined as a long-distance medical practice that can be characterized by health services through a wide range of technical applications and services [9]. It is a new way of providing high-quality resources to primary medical institutions through remote consultation on the basis of internet convenience. Through this approach, medical services and medical activities are mainly carried out through computers, various remote communications, medical technology, and medical equipment. These remote forms of communication enable contact between patients and medical personnel, medical institutions, and medical equipment. This process, in turn, can assist in diagnoses, treatment, monitoring, and follow-up [10]. As a result, telemedicine has become an increasingly popular model for providing accurate international normalized ratio (INR) monitoring for patients taking warfarin. Other terms used to describe telemedicine include connected health [11], mobile health (mHealth) [12], and electronic health (eHealth) [13], which are collectively called technology-based interventions [14]. There is interest in learning whether these interventions can assist medication management and enhance patient compliance, with results suggesting some benefit [15].

Aim of the Study

Telemedicine technology has the potential to enhance multiple aspects of anticoagulant therapy management [16], including patient education, symptom monitoring, follow-up, and encouragement and tracking of medication adherence, given its accessibility by telephone, internet, voicemail messaging, and apps. However, no systematic review or meta-analysis has been published to summarize what is currently known on this topic. Thus, we aimed to evaluate the effectiveness and safety of technology-based interventions in OAC management by performing a meta-analysis.

Methods

Literature Search

Eligible studies were identified by searching PubMed, EMBASE, Cochrane, Cumulative Index to Nursing and Allied Health Literature, PsycINFO, Scopus, and other relevant databases, and the results were combined using literature traceability methods. Searches were conducted on November 1, 2019. Search keywords included *warfarin therapy+*, *oral anticoagulation management+*, *telephone*, *eHealth*, *apps*, and *telemedicine+*. Search strategies are detailed in [Multimedia Appendix 1](#). Only papers written in English were considered. No restriction regarding publication date was applied.

Inclusion and Exclusion Criteria

Inclusion Criteria

The studies included in the analysis met the following criteria: (1) the study was a randomized controlled trial (RCT); (2) the subjects were taking warfarin; (3) technology-based interventions were used to manage OACs; (4) results included the time in therapeutic range (TTR), bleeding, and thromboembolism events; and (5) the results were reported in English.

Exclusion Criteria

Exclusion criteria included: (1) studies that were retrospective, observational, reviews, model research, literature reviews, or conference summaries; (2) the results of the study did not involve the TTR, bleeding, and thromboembolism events; (3) the study was a duplicate report; and (4) technical intervention was only used as a means to collect data.

Document Screening and Data Extraction

All references were initially screened by title and abstract by 2 reviewers for relevance. Finally, full-text analysis for eligibility was performed independently by 2 authors, HD and CL. Disagreements were discussed and resolved by consensus or third-party arbitration.

The required data were extracted by a researcher using a literature data extraction table, and another researcher confirmed the accuracy and authenticity of the data. The extracted content

included (1) basic information of study, such as research topic, author, and date; (2) baseline characteristics of the study subjects, such as sample size, median age, and sex; (3) follow-up time for interventions; (4) efficacy and safety information after interventions, such as TTR, bleeding, and thromboembolism events; and (5) other outcome indicators, including time within expanded target INR range, mortality, and hospitalization events.

Literature Quality Evaluation

Risk of bias assessment of the included RCTs was performed using the Cochrane risk of bias tool based on the *Cochrane Handbook for Systematic Reviews of Interventions* literature evaluation criteria [17].

Statistical Analysis

The meta-analysis of RCTs was performed using RevMan (version 5.3; Cochrane) software. Heterogeneity was assessed using a chi-square test, and quantitative analysis was performed

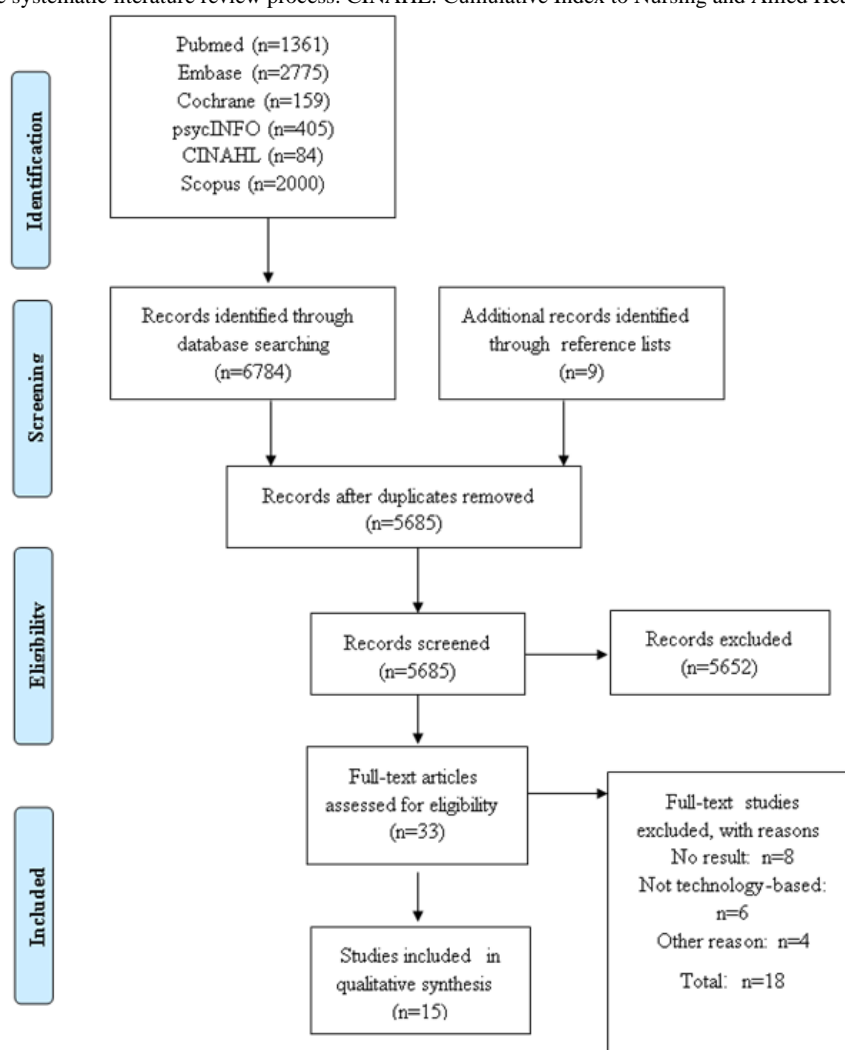

using I^2 . Values of $P \geq .05$ and $I^2 \leq 50\%$ were considered to represent no heterogeneity, in which case a fixed-effect model was used. If $P < .05$ and $I^2 > 50\%$, a random-effects model was used [18].

Results

Search Results

A total of 6784 papers were retrieved from the systematic literature search, and 9 papers were retrieved by other means, totaling 6793 papers. After removing duplicate studies, 2 authors independently reviewed and excluded another 5652 studies that did not meet predetermined selection criteria, based on the title and abstract of each paper. After reading 33 eligible full-text studies, 18 were excluded and 15 were selected for inclusion in the analysis [12,19-31]. The systematic search results are shown in Figure 1.

Figure 1. Flow chart of the systematic literature review process. CINAHL: Cumulative Index to Nursing and Allied Health Literature.

Basic Characteristics and Quality Evaluation of the Literature

The 15 RCTs included a total of 2218 patients: 1110 patients in the technology-based intervention group and 1108 patients in the traditional intervention group. General information (such

as sample size, median age, sex, and specific intervention measures) from the studies is shown in Table 1. The Cochrane systematic evaluation method was used for quality evaluation, and overall, the included studies had low risk of bias and were high quality, as shown in Figure 2.

Meta-Analysis

Time Within Target INR Range

Of the 15 included studies, 9 included TTR values, for a total of 1043 patients. A random-effects analysis was used for the

meta-analysis of these 9 RCTs. As shown in Figure 3, the TTR of the technology-based intervention group was significantly higher than that of the control group (mean difference [MD]=6.07; 95% CI 0.84-11.30; $I^2=72\%$; $P=.02$).

Figure 3. Results of a meta-analysis of the effects of technology-based interventions on time within target international normalized ratio range in oral anticoagulation management. IV: independent variable. Random: random effect model.

Bleeding Events

Of the 15 included studies, 14 included major bleeding values, for a total of 2139 patients. A random-effects model was used for the meta-analysis of these 14 RCTs. There were fewer major bleeding events in the technology-based intervention group than in the control group, but the difference was not statistically significant ($MD=1.02$; 95% CI 0.78-1.32; $I^2=0\%$; $P=.90$). There

were 5 papers that included minor bleeding values, for a total of 519 patients. A random-effects analysis model was used for the meta-analysis of these 5 RCTs. There were fewer minor bleeding events in the technology-based intervention group than in the control group, but the difference was not statistically significant ($MD=1.06$; 95% CI 0.77-1.44; $I^2=41\%$; $P=.73$). Major and minor bleeding event analyses are shown in Figure 4.

Figure 4. Results of a meta-analysis of the effects of technology-based interventions on major bleeding and minor bleeding events in oral anticoagulation management. M-H: Mantel-Haenszel method. Random: random effect model.

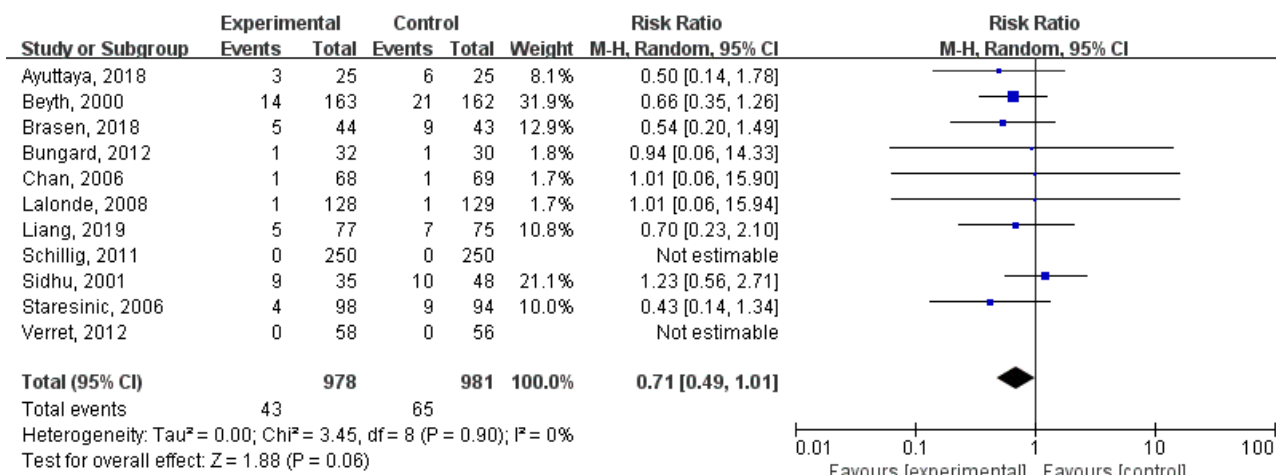

Thromboembolism Events

Of the 15 included papers, 11 had thromboembolism values, for a total of 1959 patients. A random-effects model was used for the meta-analysis of these 11 RCTs. As shown in Figure 5,

there were fewer thromboembolism events in the technology-based intervention group than in the control group, but the difference was not statistically significant (MD=0.71; 95% CI 0.49-1.01; $I^2=0\%$; $P=.06$).

Figure 5. Results of a meta-analysis of the effects of technology-based interventions on thromboembolism events in oral anticoagulation management. M-H: Mantel-Haenszel method. Random: random effect model.

Sensitivity Analysis Results

The data were analyzed with fixed- and random-effects models, and the consistency of these results reflects the reliability of the combined results to some extent. The two effect models were used to analyze the combined effect of each risk factor and calculate 95% CIs. The results were similar, indicating that the results of this study are stable.

Other Results

The time within expanded target INR range of the technology-based intervention group was higher than that of the control group, but the difference was not statistically significant (MD=2.13; 95% CI -1.22 to 5.49; $I^2=35\%$; $P=.21$; Figure 6). There were fewer mortalities and hospitalization events in the technology-based intervention group than in the control group, but the difference was not statistically significant

(mortality MD=0.61; 95% CI 0.26 to 1.41; $I^2=0\%$; $P=.25$; hospitalization MD=1.02; 95% CI 0.85 to 1.23; $I^2=23\%$; $P=.84$; Figure 7). There were 3 papers [28,30,32] that mentioned that patients' knowledge of anticoagulation was significantly improved through telemedicine intervention. There were 4 studies [22,25,26,28] that involved quality-of-life assessments; quality of life was higher in the intervention group than in the control group and it improved from baseline. There were 2 papers [21,25] that mentioned the higher costs in the technical intervention group than in the control group, and 1 paper [24] found that the costs for the nontechnical intervention group were higher. Patient satisfaction surveys were conducted in 5 studies [24,25,28-30], all of which indicated that the technical intervention group had higher satisfaction. There were 4 papers [25,26,28,32] that included data on INR tests, and the technical intervention group tended to have larger numbers of INR tests performed.

Figure 6. Results of a meta-analysis of the effects of technology-based interventions on time within extended target international normalized ratio range events in oral anticoagulation management. IV: independent variable. Random: random effect model.

Figure 7. Results of a meta-analysis of the effects of technology-based interventions on mortality and hospitalization events in oral anticoagulation management. M-H: Mantel-Haenszel method. Random: random effect model.

Discussion

Principal Findings

We performed a meta-analysis of 15 RCTs to determine whether technology-based interventions were beneficial for patients compared with traditional interventions in oral anticoagulation management. TTR reflects the quality and effectiveness of warfarin and is an important determinant of bleeding and thromboembolism in anticoagulation management. A total of 9 studies were involved in the TTR analysis, and almost all studies reported that technology-based interventions were effective. The number of bleeding (including major and minor) events in the technology-based intervention groups was lower than that in the control groups, but the difference was not statistically significant. Outcomes were similar for the thromboembolism events. Time within expanded target INR range, mortality, and hospitalization were not significantly different between the technology-based management model and traditional management model. However, patients' anticoagulation knowledge, patient satisfaction, quality of life, and number of INR tests performed were positively affected by technology-based management.

Oral anticoagulation management can be challenging when ensuring safety of the patient; as long as warfarin is used, regular monitoring is necessary [33]. The technology-based interventions used to manage oral anticoagulation typically include multiple methods, including telephone, internet, voicemail messaging, and apps. These tools are readily available in this era of technological advancement, and they reduce requirements for capacity and waiting time in outpatient clinics. Through this process, mHealth technologies have systematically

demonstrated that they can help improve early diagnosis and treatment of atrial fibrillation and significantly reduce the cost of illness associated with atrial fibrillation [34]. One such example of mHealth technology is SintromacWeb, a management system of internet-based telecontrol tools that has been recognized to have better effectiveness and safety at oral anticoagulation therapy management than a conventional approach does [35]. Technology-based interventions can effectively and professionally teach patients about anticoagulation, provide interpretation of indicators, and provide a timely dose adjustment program.

Comment on Results

It is worth mentioning that the mean age of the patients included in each study was over 60 years, so these patients may have had a relatively poor grasp on learning how to use novel websites and apps. The telephone is an ultra-portable electronic device, and it was chosen as the intervention tool in most of the 15 RCT studies included. Telephone intervention is especially suitable for older patients who are not accustomed to using computers or online services, or who may have difficulties in vision, finger dexterity, and mental state.

Our overall results showed that technology-based interventions significantly improved the effectiveness of oral anticoagulation management but did not significantly increase the safety or other results of oral anticoagulation management. These results may be because of the different follow-up times, which ranged from 1 month to 36 months. The greatest difference between the intervention and control groups in the frequency of major bleeding events occurred in the first week (when anticoagulation therapy was started in the hospital) and after the first month of therapy (when outpatient therapy was presumably stabilized).

The 2 groups differed little during the second through fourth weeks of therapy, when patients were generally discharged and warfarin was first monitored in the outpatient setting [19]. That is to say, most patients might attach great importance to any type of intervention early on and then slowly relax later.

Limitations

We acknowledge that our research has some limitations. The included studies had relatively small sample sizes and varying follow-up times, with some as short as 1 month. Warfarin is the oldest and best known OAC, and as long as warfarin is used, monitoring is necessary. Therefore, in order to more comprehensively assess the safety of OACs, longer follow-up times are needed. Furthermore, patients' adherence to technology-based interventions may be lacking. It would be ideal if intervention compliance studies were added during follow-up. Despite these limitations, this study is the first to comprehensively analyze the effect of technology-based interventions on anticoagulation management. Therefore, larger sample sizes and longer clinical RCTs are needed to further evaluate the impact of technology-based interventions on anticoagulation management.

Comparison With Prior Work

To the best of our knowledge, this is the first meta-analysis of RCTs that evaluates the effectiveness and safety of technology-based interventions for oral anticoagulation management. In published systematic meta-analyses and reviews, most of the literature evaluating the effects of technology-based interventions has focused on atrial fibrillation [34] and cancer [36]. Most studies regarding the administration of OACs have focused on the effects of managers on the effectiveness and safety of anticoagulation management, such as the differences between pharmacist management and physician management or between patient self-management and anticoagulation clinic management [37-41]. The intervention method we chose is a technology-based approach that might have also been included in other studies, such as pharmacist-managed or self-managed interventions [37,41].

Although the study of telemedicine is not specific to OACs and is primarily qualitative, previous studies have highlighted similar challenges [42-44]. Clinical pharmaceutical care provided by Niznik et al [43] through telemedicine (mainly by telephone)

in inpatient or outpatient settings was found to have an overall positive impact on outcomes related to clinical disease management, patient self-management, and adherence to the management of various chronic diseases. The common ground in the studies that had a positive impact on outcomes was the use of continuous or regular patterns of care, including telephone interaction and frequent monitoring and intervention [43]. Xia et al's [44] study was conducted to explore the effects of online and offline management of anticoagulants on therapeutic efficacy and adverse reactions. Considering the convenience and economy of technology-based interventions, online anticoagulation management is more suitable for patients with stable conditions and for whom transportation may be difficult, such as those with disabilities or who live far from the hospital. Lee et al's study [42] suggested that most outcomes for telemedicine were similar to those for conventional medical care, but the incidence of major thromboembolism events was significantly lower in the telemedicine group. However, the papers they included had a higher risk of bias and were of a lower quality study design, and the level of evidence supporting this conclusion was very low.

Conclusions

This meta-analysis explored the effects of technology-based interventions on oral anticoagulation management. The results demonstrate that the technology-based intervention group had significantly improved TTR compared with the traditional intervention group and that there were no significant differences between the 2 intervention models in terms of time within expanded target INR range and the incidence of major bleeding events, minor bleeding events, thromboembolic events, mortality, and hospitalization. Of the different management options, telephone intervention was found to be the most widely used and most convenient means of technology-based interventions; it enables patients to get a professional reply quickly and is not restricted by the patient's ability to use the internet. OAC management through technology-based intervention appears to be superior to OAC management through traditional intervention and may provide more convenient and higher quality anticoagulation services for patients. Further research is needed to explore more optimal technology-based interventions in oral anticoagulation management in a wider array of health care settings.

Abstract

Background: Osteoarthritis (OA) is not curable, but the symptoms can be managed through self-management programs (SMPs). Owing to the growing burden of OA on the health system and the need to ensure high-quality integrated services, delivering SMPs through digital technologies could be an economic and effective community-based approach.

Objective: This study aims to analyze the effectiveness of digital-based structured SMPs on patient outcomes in people with OA.

Methods: A total of 7 web-based and 3 gray literature databases were searched for randomized controlled trials assessing digital-based structured SMPs on self-reported outcomes including pain, physical function, disability, and health-related quality of life (QoL) in people with OA. Two reviewers independently screened the search results and reference lists of the identified papers and related reviews. Data on the intervention components and delivery and behavioral change techniques used were extracted. A meta-analysis, risk of bias sensitivity analysis, and subgroup analysis were performed where appropriate. The Grading of Recommendations, Assessment, Development, and Evaluations (GRADE) approach was used to assess the quality of evidence.

Results: A total of 8 studies were included in this review involving 2687 patients with knee (n=2); knee, hip, or both (n=5); and unspecified joint (n=1) OA. SMPs were delivered via telephone plus audio and video, internet, or mobile apps. Studies reported that digital-based structured SMPs compared with the treatment as usual control group (n=7) resulted in a significant, homogeneous, medium reduction in pain and improvement in physical function (standardized mean difference [SMD] -0.28, 95% CI -0.38 to -0.18 and SMD -0.26, 95% CI -0.35 to -0.16, respectively) at posttreatment. The digital-based structured SMP effect on pain and function reduced slightly at the 12-month follow-up but remained to be medium and significant. The posttreatment effect of digital-based structured SMPs was small and significant for disability, but nonsignificant for QoL (SMD -0.10, 95% CI -0.17 to 0.03 and SMD -0.17, 95% CI -0.47 to 0.14, respectively; each reported in 1 study only). The 12-month follow-up effect of the intervention was very small for disability and QoL. The quality of evidence was rated as *moderate* for pain and physical function and *low* and *very low* for disability and QoL, respectively, using the GRADE approach.

Conclusions: Digital-based structured SMPs may result in improvement in pain and physical function that is largely sustained at the 12-month follow-up in people with knee and hip OA. The effects on disability and QoL are smaller and less clear. The quality of evidence is moderate to low, and further research is required to confirm the findings of the review and assess the effects of digital-based structured SMPs on other health-related outcomes.

Introduction

Osteoarthritis (OA) is a major burden for individuals, the health system, and the economy. The common symptoms of OA (ie, pain and subsequent physical inactivity) are risk factors in other chronic conditions, including cardiovascular problems, depression, stroke, cancers, and, consequently, premature mortality [1-6]. People with OA also experience fatigue, emotional distress, poor sleep, decreased productivity, social isolation, and poor quality of life (QoL) [7-9]. OA is not curable, but the pace of progression and symptoms can be managed. In a systematic review of guidelines for the management of OA [10], 12 of the 15 included guidelines made a strong recommendation for self-management and education. Evidence-based practice guidelines suggest that patients should be provided with tailored information to enhance understanding of the conditions and their progressive nature, tailored self-management programs (SMPs), information sharing, and regular contact with a multidisciplinary team to promote self-care and joint protection strategies [10-12].

SMPs are the structured and coordinated delivery of education and health behavior change interventions to empower people with OA to take care of their own condition [13,14]. Previous meta-analytic reviews show that SMPs and/or exercise interventions have small to medium benefits on health outcomes such as pain, function, and aspects of QoL [15-18]. A recent Cochrane review [19] revealed that, compared with usual care control groups, SMPs resulted in a significant but clinically unimportant reduction in pain up to 1 month postintervention (standardized mean difference [SMD] -0.26; 95% CI -0.41 to -0.10) and at 3- and 12-month follow-ups (SMD -0.17; 95% CI -0.26 to -0.08) [19]. No significant difference in patient-reported function was reported up to 1-month postintervention (SMD -0.01; 95% CI -0.19 to 0.18), but, at the 3- and 12-month follow-ups, function improved significantly in the SMP group (SMD -0.16; 95% CI -0.25 to -0.01). No effect of SMPs on QoL was reported in the review [19].

Due to the growing burden of arthritis on the health system, the increasing need to ensure high-quality integrated services; and the rapid advances in communication technology, health information, and services, delivering SMPs through digital technologies (eg, telephone, internet, mobile apps, and virtual reality equipment) could be an economical and effective community-based model of care [13,14]. Many people with OA continue to be in the workforce and have limited time to attend treatment sessions. In addition, people may live at a distance from physical health services [20,21]. Digital-based structured programs have the potential to be an important component in models of care for enhancing delivery to support self-management, offering a sustainable opportunity to improve patient outcomes, monitoring patients' symptoms for intervention adaptation, and increasing access to best practice [21]. It could also address the lack of continuity of care, lack of self-management support, and difficulty in accessing allied health professionals and pain management specialists [22]. A World Health Organization (WHO) guideline recommends the use of digital interventions in an interlinked manner, among others, to improve individuals' access to health services and

information, and health workers can provide appropriate and high-quality care and can follow-up to ensure that individuals receive appropriate services [23].

There is a growing number of trials relating to digital-based structured interventions in OA conditions. A recent systematic review indicated that electronic health (eHealth; ie, internet, mobile, and telephone) exercise interventions, compared with no or other interventions, resulted in small effects in pain reduction, improved physical function, and improved health-related QoL [24]. Furthermore, moderate quality evidence indicates that telephone-based interventions (with educational material) reduce pain intensity and disability in people with OA of the knee or hip and spinal pain (back or neck pain) [25]. However, no review has focused explicitly on the effect of digital-based structured SMPs in people with OA. Therefore, this review aimed to determine the effectiveness of digital-based structured SMPs with controlled comparators on patient outcomes (pain, physical function, disability, and health-related QoL) in people with OA.

Methods

Systematic Literature Review

Guidance published in Preferred Reporting Items for Systematic reviews and Meta-Analyses [26] and the Cochrane Handbook of Systematic Reviews [27] was adhered to. The a priori protocol for the review is published in the International Prospective Register of Systematic Reviews (PROSPERO): CRD42018089322.

Search Strategy

Studies were identified by searching web-based databases with support and consultation provided by an institutional librarian. The search included the Medical Literature Analysis and Retrieval System Online (MEDLINE), Excerpta Medica Database (EMBASE), Cochrane Central Register of Controlled Trials (CENTRAL), Cumulative Index to Nursing and Allied Health Literature (CINAHL), PsycINFO, Physiotherapy Evidence Database (PEDro), and PubMed and gray literature databases (Dissertation Abstracts International WorldCat, The Grey Literature Report, and Open Grey) using both Medical Subject Headings and free-text keywords relating to OA, digital-based structured self-management interventions, and outcomes stated below from inception to May 2018. Search strategies for the first 3 databases above and dates on which searches were conducted are listed in [Multimedia Appendix 1](#). Searches of the reference list of the previous review papers and included studies were also conducted.

Eligibility Criteria

Type of Studies

Randomized controlled trials (RCTs) of any design, including parallel-group, crossover, and cluster RCTs published in the English language were included in this review.

Participants

Adults (≥ 18 years of age) with a confirmed diagnosis of OA, either radiologically or by a health practitioner. All types of OA

at any stage of the disease were considered. We included studies recruiting patients with OA with other conditions only if outcome data for OA patients were provided.

Intervention

The intervention considered structured and coordinated SMPs as defined by Lorig [14] and Osborne [13] in isolation or in combination with other interventions delivered fully or partially via digital technologies (eg, websites, mobile apps, social networking tools, web-based games, animation, and telephone). Self-management is defined as an engagement in activities that promote health and prevent adverse events; interacting with a health care professional; improving self-monitoring; coping with disease; and developing skills in problem-solving, decision making, resource utilization, forming of a patient and health care provider partnership, and taking action.

Control Condition

Any type of control group (ie, waitlist, treatment as usual or minimal interventions, alternative treatment, or other digital-based interventions) was considered.

Outcome

We included any psychometrically sound unidimensional or multidimensional measure as well as the relevant subscales relating to the following outcomes:

Primary Outcomes

1. Pain: Visual Analog Scale, Numerical Rating Scale, and Brief Pain Inventory.
2. Function: patient-specific physical function, physical function subscale of Arthritis Impact Measurement Scale, or Short Form-36.
3. Disability: Oswestry Disability Questionnaire and Roland-Morris Disability Questionnaire.

Secondary Outcomes

1. QoL: European Quality of Life-5 Dimensions, Short Form-36, or WHO Quality of Life–Brief scale.
2. Cost and resource use: We extracted the results of economics reported alongside the effectiveness studies, either full or partial economic evaluation or estimates of resource use and costs associated with interventions and comparators. Change from baseline data relating to any follow-up time points were considered.

Study Selection and Data Extraction

Two reviewers (RS and JJ) independently screened abstracts and full text of the search results. Any disagreements were resolved through discussion. Data were extracted by 2 researchers (JJ and EH; mentioned in Acknowledgments) and cross-checked by a third researcher (RS) using a data extraction tool developed a priori based on the Cochrane Handbook recommendations. Data items included participants' characteristics, guiding theory or rationale, mechanism of effect, the digital medium, method of delivery, who delivered, where it was delivered, adherence, and fidelity. Additional data relating to describing components of the interventions were extracted based on the Template for Intervention Description and Replication (TiDieR) guidance [28] and SMP components

[13,14]. The behavior change techniques used were also extracted based on the hierarchical taxonomy by Michie et al [29] to examine if certain techniques were favored or, if there were sufficient data, whether particular techniques yielded bigger effects. The data extraction form was piloted on 2 included papers before full data extraction.

Meta-Analysis

Outcome data were expressed as SMD and were pooled in a pair-wise fixed effects model stratified based on the outcome and type of digital medium. We used the mean (SD) of within-group change from baseline to calculate the SMDs. Per Cohen [30], SMDs <0.2 were classified as small, those between 0.2 and 0.8 were classified as medium, and those >0.8 were classified as large. We converted the SMD to the percentage change in the outcome measure by multiplying the SMD with the SD of the control group of the sufficiently powered study (ie, the trial with the largest sample size).

A sensitivity analysis was conducted for the risk of bias assessment. A subgroup analysis was performed to assess the effect of SMPs on the different digital media used, control conditions, and presence of active exercise component in the intervention. Heterogeneity across pooled studies was examined using the chi-squared test and I^2 statistics. As there were <10 studies, we did not use a funnel plot or Egger test to assess publication bias. Furthermore, a narrative synthesis of the studies was conducted where there were insufficient data to pool studies in a meta-analysis. We did not conduct additional exploratory analyses to explore potential moderators because of an insufficient number of studies. The common study characteristics tables were supplemented by additional summary tables including the TiDieR process information; risk of bias assessment; effect estimates; Grading of Recommendations, Assessment, Development, and Evaluations (GRADE) analysis; and behavior change taxonomy groupings. We used Review Manager (RevMan, version 5.3; Cochrane Collaboration) for all analyses.

Dealing With Missing Data

We contacted the authors of included studies for missing data. Aggregated data were provided by authors for 6 studies. We used the RevMan calculator to impute missing SDs from the test statistics reported for 2 studies.

Risk of Bias and Grading of Recommendations, Assessment, Development, and Evaluations Assessment

Risk of bias was assessed using the risk of bias tool of the Cochrane Handbook for Systematic Reviews [27]. Quality of evidence for outcomes was assessed according to the 5 GRADE domains, including study limitation (risk of bias), inconsistency, indirectness, imprecision, and publication bias [31,32].

Results

Study Selection and Characteristics

A total of 2001 titles and abstracts were screened after excluding duplicates, of which 1950 records did not meet the inclusion criteria (Figure 1). Full texts of 51 potential eligible records were read, and 8 studies published between 2008 and 2018 were

included. These studies included 2256 (range 113-352) individuals with OA. A total of 8 digital-based structured SMPs were compared with 10 control conditions. Two studies were cluster RCTs and 6 were RCTs. A list of studies excluded at

the full text screening stage with reasons for exclusion is presented in [Multimedia Appendix 2](#) [33-75]. A summary of the study characteristics and participants' demographics are presented in [Tables 1](#) and [2](#).

Participants

A total of 6 studies were conducted in the United States, and 2 were performed in the Netherlands.

The number of participants in the studies ranged from 113 to 855. The median (IQR) age was 63 (3.55) years. Most of the participants in the 6 studies were female (median 74.7%, IQR

6.9%), whereas in the remaining 2 studies, most participants were men (93.0% and 90.7%).

Two studies recorded participants with knee OA only; 5 studies recorded a mixture of knee (median 71.55%, IQR 15.77%), hip (median 16%, IQR 5.75%), or both (median 6%, IQR 10.5%); and 1 study did not record the area affected. No studies recorded OA in the hand or any other type of OA. Five of the studies

recorded the time since diagnosis, with a median of 15 (IQR 2) years.

Intervention Groups

Intervention Delivery Mechanisms

Out of the studies reviewed, 2 used telephone, audio and video, and written materials to deliver an SMP derived from social cognitive theory and 5 studies delivered an internet-based

exercise training: 1 study was delivered by a physical therapist, 2 studies were delivered in a combination of face-to-face time with a physical therapist, 1 study had a virtual coach, and 1 study was self-administered only. The remaining study used a mobile app with a wearable monitor in combination with a physician face-to-face. Three studies delivered interventions over 52 weeks, 2 studies had 12-week interventions, and 1 study each had interventions lasting 6, 8, and 9 weeks ([Table 3](#)).

Table 3. Detailed intervention delivery mechanisms.

^gLogged at least once into the program.

Self-Management Components

All studies used health education as a component of self-management. For 5 studies, this was the main component. Additional self-management components included goal setting (n=6); action planning (n=4); and exercise components such as physical activity (n=6), aerobic (n=5), resistive (n=4), flexibility (n=3), and balance (n=1) were recorded.

Additional self-management components included diet and/or weight management (n=5); pain management (n=6); medication

(n=3); motivation (n=6); peer support (n=2); patient-therapist communication (n=2); and stress management, relaxation, or sleep (n=4; [Tables 4](#) and [5](#)).

A range of theories were used to inform the intervention, including Social Cognition Theory (n=3), Self-Efficacy Theory (n=2), and behavioral graded activity theory (n=2). One study stated that they used a combination of Social Cognition Theory, adult learning theory, and principles of multimedia instruction ([Tables 4](#) and [5](#)).

Behavior Change Components

A variety of behavior change techniques have been used. The most common techniques involved goal setting and planning (n=8), feedback and monitoring (n=7), and shaping knowledge

(n=7). All studies used at least four different groups of techniques, with Rini et al [83] using 10 group techniques [29] (Table 6; Multimedia Appendix 3). Owing to the heterogeneity in the approaches used, a meta-analysis was not appropriate.

Comparison

Digital self-management interventions were compared with treatment as usual (n=4), wait list control (n=2), in-person physical therapy (n=2), attention group (health education; n=1), and no intervention (n=1).

Risk of Bias

The risk of bias was assessed as unclear for random sequence generation (n=3), allocation concealment (n=1), and incomplete outcome data (n=1). There was a high risk of bias for incomplete outcome data in 1 study (Figure 2). The detection bias and performance bias were rated high in all studies because of the nature of the interventions and patient-reported outcome tools.

Figure 2. Summary of risk of bias assessment.

Effects of Interventions

A summary of findings for the main comparisons of the study with GRADE ratings is presented in Table 7. Detailed

meta-analytic forest plots are also presented in Multimedia Appendix 4.

Table 7. Summary of findings and Grading of Recommendations, Assessment, Development, and Evaluations ratings for the main comparisons.

Main Outcomes

Pain

Seven studies involving 1614 participants reported the effect of digital-based structured SMPs compared with usual care control condition on pain outcome at the postintervention time point (range 9-52 weeks). Overall, a significant and medium effect in favor of the intervention was observed on pain reduction (SMD -0.28 ; 95% CI -0.38 to -0.18); heterogeneity ($X^2_6=5.1$; $P=.53$; $I^2=0\%$). Three studies with 716 participants reported a long-term (≥ 12 months) effect of digital-based structured self-management program compared with usual care conditions, indicating a significant and small overall effect (SMD -0.20 ; 95% CI -0.35 to -0.05); heterogeneity ($X^2_2=0.4$; $P=.83$; $I^2=0\%$). Using the GRADE approach, the quality of evidence was rated *moderate* for both postintervention and long-term follow-up comparisons because of the high risk of bias in most studies (ie, study limitations).

Two studies with 456 participants comparing digital-based structured SMPs (internet) and physical therapy did not show a difference in pain reduction between the 2 intervention conditions (SMD -0.07 ; 95% CI -0.25 to 0.11); heterogeneity ($X^2_1=0.2$; $P=.64$; $I^2=0\%$). The effect of the digital-based structured SMP slightly increased at the 12-month follow-up time point but was not significant (SMD -0.12 ; 95% CI -0.31 to 0.07 ; heterogeneity $X^2_1=0.1$; $P=.94$; $I^2=0\%$). The quality of evidence for both time points was rated as *low* because of the high risk of bias (ie, study limitation) and total small sample size (ie, imprecision).

The only study comparing digital-based structured SMPs with attention control (health education) condition [76] ($n=306$ participants) showed a medium and significant effect on pain reduction in favor of digital-based structured SMPs (SMD -0.26 ; 95% CI -0.49 to -0.04). The quality of evidence was rated as *low* because of unknown consistency and/or publication bias.

Physical Function

A total of 7 studies involving 1625 people with OA reported the effect of digital-based structured SMPs compared with usual care control conditions on patient-reported physical function outcomes at the postintervention time point (range 9-52 weeks). Overall effect size indicates a medium and significant improvement in function in favor of the SMP (SMD -0.26 ; 95% CI -0.35 to -0.16 ; heterogeneity $X^2_6=5.2$; $P=.52$; $I^2=0\%$). Studies reporting the 12-month follow-up data ($n=3$ studies;

$n=707$ participants) showed medium and significant overall effect of the digital-based structured SMP compared with usual care control condition (SMD -0.23 ; 95% CI -0.38 to -0.08 ; heterogeneity $X^2_2=0.1$; $P=.96$; $I^2=0\%$). The quality of evidence was rated as *moderate* for both comparisons because of the high risk of bias in most studies (ie, study limitation).

The 2 studies comparing digital-based structured SMPs (internet) with physical activity did not show a significant difference between the 2 interventions neither at postintervention nor at longer follow-up time points (SMD 0.05 ; 95% CI -0.13 to 0.23 ; heterogeneity $X^2_1=0.1$; $P=.77$; $I^2=0\%$; and SMD -0.03 ; 95% CI -0.22 to 0.16 ; heterogeneity $X^2_1=0.01$; $P=.90$; $I^2=0\%$, respectively). The quality of evidence was rated *low* for both time points due to *limitation* and *imprecision*.

The digital-based structured SMP versus attention control group (health education), compared in 1 study [76], resulted in a small and nonsignificant ($P=.15$) improvement in physical function (SMD -0.17 ; 95% CI -0.39 to 0.06). The quality of evidence for this intervention was rated *very low* because of *imprecision* (ie, small sample size) and unknown consistency and/or publication bias.

Disability

One study [82] reported disability measures in 352 participants. The results show a minimal effect size in favor of internet-based SMPs compared with the usual care condition (SMD -0.10 ; 95% CI -0.17 to -0.03). However, the effect of intervention did not persist after 12 months of follow-up (SMD -0.00 ; 95% CI -0.21 to 0.20). The quality of evidence for this outcome at postintervention was rated as *very low* because of the high risk of bias in the study and unknown consistency and/or publication bias. The quality of evidence for the outcome at the 12-month follow-up was rated *very low* because of *imprecision* (ie, small sample size) and unknown consistency and/or publication bias for the follow-up time point.

Quality of Life

Only 1 study [79] reported the QoL outcome measure in 165 people with OA, indicating that the internet-based SMP did not make a significant improvement in QoL neither at 4 months postintervention nor at the 12-month follow-up (SMD -0.17 ; 95% CI -0.47 to 0.14 and SMD -0.07 ; 95% CI -0.39 to 0.26 , respectively). The quality of evidence for this intervention at both time points was rated *very low* because of *imprecision* (ie, small sample size) and unknown consistency and/or publication bias.

Cost and Resource Use

Data reported on the cost of these interventions and resources used are limited. Allen et al [76] calculated cost by excluding nonrecurring labor costs, such as time for training a health educator at salary cost and the making of the intervention. The cost calculated included labor intervention delivery costs and indirect nonlabor costs, such as printing educational materials and creating compact discs. It was reported that the per-participant costs were US \$107 (range US \$100-US \$121) for OA self-management and US \$51 (range US \$47-US \$60) for health education. This cost was not compared with that of usual care. In the study by Lorig et al [82], no significant difference was reported between digital-based structured SMPs and usual care in terms of health care utilization (ie, physician, emergency, chiropractic or physical therapists visits or days in hospital).

Subgroup Analysis

The planned subgroup analysis based on the digital medium used to deliver the intervention revealed that the mobile app (n=1 study, n=197 participants) resulted in the largest effect size in pain reduction (SMD -0.38; 95% CI -0.67 to -0.10), followed by the internet medium (n=4 studies, n=841 participants; SMD -0.33; 95% CI -0.46 to -0.19; $I^2=0\%$). The telephone as a medium of intervention delivery resulted in the smallest effect size in pain reduction (n=2 studies, n=576 participants; SMD -0.18; 95% CI -0.35 to -0.02; $I^2=0\%$). However, the difference between the 2 groups was not significant ($X^2_2=2.3$; $P=.32$; $I^2=13.4\%$). Subgroup differences for physical function outcome were not significant ($X^2_2=0.1$; $P=.97$; $I^2=0\%$) between telephone, internet, and mobile apps, and resulted in similar small effect sizes (SMD -0.23; 95% CI -0.40 to -0.07, SMD -0.27; 95% CI -0.41 to -0.14, and SMD -0.24; 95% CI -0.51 to 0.03, respectively).

The intervention in most studies had exercise and/or physical activity components, and, in a few studies, it was the main component of the intervention. Therefore, we conducted a subgroup analysis accordingly. The pain reduction in studies with exercise and/or physical activity as the main component of the intervention was greater than the pain reduction in those studies without exercise and/or physical activity as the main component of the intervention (SMD -0.37; 95% CI -0.54 to -0.20 and SMD -0.23; 95% CI -0.36 to -0.11, respectively). However, the difference was not statistically significant ($X^2_1=1.7$; $P=.19$; $I^2=40.6\%$). The improvement in physical function was comparable in both groups—(SMD -0.27; 95% CI -0.44 to -0.11) in studies with exercise and/or physical function as the main component and (SMD -0.24; 95% CI -0.38 to -0.11) in studies without exercise as the main component ($X^2_1=0.1$; $P=.76$; $I^2=0\%$).

No subgroup analysis could be conducted for the follow-up time points as all 3 studies reporting the 12-month follow-up data used the internet as the intervention delivery medium. Similarly, no subgroup analysis could be conducted on the studies with high rates of completion because intervention was delivered via the telephone in 2 studies that did not report completion rate, or there was no measure of adherence.

Risk of Bias Sensitivity Analysis

Risk of bias sensitivity analysis, excluding studies with no or unclear random allocation, inadequate treatment allocation concealment, and/or incomplete outcome data, reduced the effect size in both pain reduction and improvement in physical function (SMD -0.19; 95% CI -0.32 to -0.05 and SMD -0.19; 95% CI -0.32 to -0.06, respectively).

Discussion

Principal Findings

The findings of this review indicate that digital-based structured SMPs compared with the treatment as usual or no intervention control groups resulted in a significant, homogeneous, and medium reduction in pain (SMD -0.28; 95% CI -0.38 to -0.18) and improvement in physical function (SMD -0.26; 95% CI -0.35 to -0.16). The SMDs reduced slightly at longer follow-up time points but remained significant with medium effect sizes. However, the findings should be interpreted with caution as the overall quality of the body of evidence is moderate because of the risk of bias in the included studies. Using SD from the control group of the largest (most adequately powered) study by Lorig et al [82], the SMDs translate to 5.70% reduction in pain and 5.07% improvement in physical function at postintervention time points. In accordance with Tubach et al [84] and Angst et al [85], we determined a minimal clinically important difference (MCID) of 15% in pain and 8% in physical function. Therefore, these effects are unlikely to be clinically significant. The findings on disability and QoL are less clear, as these outcomes were reported in 1 study with very small effect sizes.

Both immediate and longer-term effects of digital-based structured SMPs on pain in our review (SMD -0.28; 95% CI -0.38 to -0.18 and SMD -0.20; 95% CI -0.35 to -0.5, respectively) were slightly greater than those reported in a Cochrane review comparing standard OA SMPs with usual care (SMD -0.26; 95% CI -0.41 to -0.10 and SMD -0.17; 95% CI -0.26 to -0.08, respectively) [19]. However, the immediate and longer-term effect of digital-based structured SMPs on physical function was greater in our review compared with the immediate effect of SMPs reported in the Cochrane review by Kroon et al (SMD 0.01; 95% CI -0.19 to 0.18 and SMD -0.16; 95% CI -0.25 to -0.01, respectively) [19]. Despite the moderate quality of evidence reported in both reviews and a lack of direct comparison between the digital-based structured SMP and the SMP intervention, it could be postulated that the digital-based structured SMPs may have similar or greater effects than conventional SMPs on pain and physical function. Considering the potential cost-effectiveness of digital interventions, digital-based structured SMPs have the potential to reach populations reluctant or unable to attend face-to-face appointments. This could have a considerable benefit from a public health perspective despite the modest size of the effect.

Previous reviews indicate that eHealth interventions have the potential to reduce treatment costs [21,86]. We could not assess intervention costs because none of the included studies compared intervention costs across groups. In the study by Kloek et al [80], participants in the intervention group

(internet-based exercise) had 5 in-person physical therapy sessions, whereas those in the control group visited a physical therapist an average of 12 times. Nevertheless, both groups showed a significant improvement in most health outcomes. Reduced numbers of physical therapy visits would likely result in a reduction in health care costs. Future RCTs of digital-based structured SMPs are encouraged to assess the cost-effectiveness of digital interventions in isolation or combination with face-to-face sessions. It should be noted that smartphones and/or internet devices are now owned by the majority of the population; therefore, these interventions are accessible and can be delivered conveniently and easily to the target audience. However, it should be noted that digital-based structured SMPs may not be suitable for all patients, potentially because of age, preference, comorbidities, and/or severity of illness; therefore, the intervention must be tailored to the needs, preferences, and conditions of patients and include face-to-face, group, and digital modes in the intervention package.

The result of the subgroup analysis indicates that there is no significant difference among the different digital modes of SMP delivery. However, mobile app (1 study) and internet SMPs (4 studies) resulted in medium effects on pain outcome, whereas telephone SMPs (2 studies) showed a small effect. Potential reasons for this observation could be that the majority of participants in the telephone studies were male veterans (>90%) who had more comorbidities and/or severe OA symptoms. In addition, the interventions were low intensity, and telephone call sessions were short (average 16.6 min). However, the small number of studies and the fact that the 2 telephone trials had a low risk of bias cautions against this interpretation; inflated effect size in studies with a high risk of bias is expected. The results of further subgroup analysis indicate that studies with exercise or physical activity as the main component of the intervention resulted in a greater improvement in pain but not in perceived physical function. A possible explanation for the reduced pain in this group of studies could be because of the change in pain tolerance and decreased perception of pain after exercise [87,88]. Four studies (n=2 telephone and n=2 internet) were included in the risk of bias sensitivity analysis. The analysis resulted in a reduction in the effect size compared with the main meta-analysis for both pain and physical function outcomes. Notably, the 2 combined telephone and video studies contributed most to the SMD (weight >65%) in the sensitivity analysis.

Attrition at postintervention was modest; median 10% (IQR 7%) in the intervention groups and median 8% (IQR 4%) in the control conditions. Despite common concerns with high dropout rates in digital interventions [89], the reported attrition rates in the included studies appear reasonable compared with behavioral studies. In a recent study, Bennell et al [90] reported that a web-based exercise program improved home exercise adherence and confidence in the ability to undertake exercise compared with a home-based exercise program prescribed by a physical therapist's usual methods [90]. In our review, treatment adherence in 6 studies reporting treatment completers was 46% in 1 study [79], >80% in 3 studies [78,80,81], and >90% in 2 studies (Table 1) [82,83]. There are a few possible reasons for the relatively low dropout and nonadherence rates. First,

interventions in all studies were tailored to participants' needs and conditions. Second, researchers used features in web-based or mobile apps to develop reminder and monitoring systems and created higher interactivity of the intervention delivery. Third, in some studies, health professionals maintained contact with the study participants during the study through either face-to-face meetings or telephone calls. However, it should be noted that the participants were highly educated in most studies and, in some studies, self-selected (ie, responded to the study participants' recruitment advertisement). Thus, they may have been enthusiastic about the new intervention. In future research and development, the advanced features of mobile apps and internet interventions could be employed to deliver even more effective and tailored monitoring and/or motivational interventions. Digital interventions can also be used to show patients' symptom improvement, which is a useful and effective way not only to improve retention and compliance but also to increase their effect through self-efficacy [91,92].

There are a few limitations to the current review. First, only studies published in English were considered. Second, blinding of intervention and outcome assessment is not possible; therefore, all studies suffer from performance and detection biases. Moreover, some of the most powered studies have a high risk of bias, lowering the overall quality of evidence. Third, disability and QoL outcomes were only reported in 1 study each. Fourth, this review has limited generalizability because participants in most studies were highly educated and self-selected; thus, they may have been highly motivated. Finally, interventions in some studies were targeted to exercise and/or physical activity as the main component of the program, and behavior change techniques were used to improve exercise adherence [78-81]; the multiplicity and heterogeneity of techniques prohibited meta-analysis of the effects of particular techniques. However, almost all studies employed theoretically driven interventions incorporating important components of the SMPs (ie, education, goal setting, action planning, problem solving, skills acquisition, self-monitoring, understanding illness, and managing emotions).

In conclusion, digital-based structured SMPs resulted in medium improvements in pain and physical function postintervention. However, the effects are below the MCID and may, therefore, not be clinically significant. The quality of the evidence for pain and function was graded as *medium* because of the high risk of bias in the studies; therefore, the true effect is likely to be close to our estimate of the effect, but there is a possibility that it is substantially different. The effect of digital-based structured SMP intervention on pain and physical function was slightly reduced at the 12-month follow-up, but remained at the medium threshold. One study reporting results on disability and one study reporting results on health-related QoL indicated small improvements in both outcomes. We rated the quality of the evidence as *low* and *very low* for disability and health-related QoL, respectively, indicating that the true effects are likely to be substantially different from our estimate of effect.

Conclusions

This review of digital-based structured SMPs on self-reported outcomes including pain, physical function, disability, and

health-related QoL in patients with OA revealed 6 RCTs and 2 cluster RCTs. digital-based structured SMPs resulted in medium improvements in pain and physical function postintervention, but these may not be clinically significant. These effects were slightly reduced at the 12-month follow-up, but remained at the

medium threshold. The quality of the evidence for pain and function was graded as *medium* because of a high risk of bias in some studies. More high-quality studies are needed, and the routine assessment of QoL and disability would be useful.

Abstract

Background: Decision support systems based on reinforcement learning (RL) have been implemented to facilitate the delivery of personalized care. This paper aimed to provide a comprehensive review of RL applications in the critical care setting.

Objective: This review aimed to survey the literature on RL applications for clinical decision support in critical care and to provide insight into the challenges of applying various RL models.

Methods: We performed an extensive search of the following databases: PubMed, Google Scholar, Institute of Electrical and Electronics Engineers (IEEE), ScienceDirect, Web of Science, Medical Literature Analysis and Retrieval System Online (MEDLINE), and Excerpta Medica Database (EMBASE). Studies published over the past 10 years (2010-2019) that have applied RL for critical care were included.

Results: We included 21 papers and found that RL has been used to optimize the choice of medications, drug dosing, and timing of interventions and to target personalized laboratory values. We further compared and contrasted the design of the RL models and the evaluation metrics for each application.

Conclusions: RL has great potential for enhancing decision making in critical care. Challenges regarding RL system design, evaluation metrics, and model choice exist. More importantly, further work is required to validate RL in authentic clinical environments.

artificial intelligence; reinforcement learning; critical care; decision support systems, clinical; intensive care unit; machine learning

Introduction

Background

In the health care domain, clinical processes are dynamic because of the high prevalence of complex diseases and dynamic

changes in the clinical conditions of patients. Existing treatment recommendation systems are mainly implemented using rule-based protocols defined by physicians based on evidence-based clinical guidelines or best practices [1-3]. In addition, these protocols and guidelines may not consider multiple comorbid conditions [4]. In an intensive care unit

(ICU), critically ill patients may benefit from deviation from established treatment protocols and from personalizing patient care using means not based on rules [5,6].

When physicians need to adapt treatment for individual patients, they may take reference from randomized controlled trials (RCTs), systemic reviews, and meta-analyses. However, RCTs may not be available or definitive for many ICU conditions. Many patients admitted to ICUs might also be too ill for inclusion in clinical trials [6]. Furthermore, only 9% of treatment recommendations in the ICU are based on RCTs [7], and the vast majority of RCTs in critical care have negative findings [8]. To aid clinical decisions in ICUs, we need other methods, including the use of large observational data sets. ICU data can be useful for learning about patients as they were collected in a data-rich environment. A large amount of data can then be fed into artificial intelligence (AI) systems (using computers to mimic human cognitive functions) and machine learning methods (using computer algorithms to perform clinical tasks without the need for explicit instructions). AI and machine learning can then help with diagnosis [9,10], treatment [11,12], and resource management [13,14] in the ICU. Given the dynamic nature of critically ill patients, one machine learning method called reinforcement learning (RL) is particularly suitable for ICU settings.

Fundamentals of Reinforcement Learning

RL is a goal-oriented learning tool where a computer *agent*, acting as a decision maker, analyzes available data within its defined environment [15], derives a rule for taking actions, and optimizes long-term rewards. The agent is the RL model that we wish to develop. In general, an RL agent receives evaluative feedback about the performance of its action in each time step, allowing it to improve the performance of subsequent actions by trial and error [16]. Mathematically, this sequential decision-making process is called the Markov decision process (MDP) [17]. An MDP is defined by 4 major components: (1) a state that represents the environment at each time; (2) an action the agent takes at each time that influences the next state; (3) a transition probability that provides an estimate for reaching different subsequent states, which reflects the environment for an agent to interact with; (4) a reward function is the observed feedback given a state-action pair. The solution of the MDP is an optimized set of rules and is termed the policy.

RL has already emerged as an effective tool to solve complicated control problems with large-scale, high-dimensional data in some application domains, including video games, board games, and autonomous control [18-20]. In these domains, RL has been

proven to achieve human-level capacity for learning complex sequential decisions. For instance, Alpha Go is an RL agent for playing the strategy board game Go. On the basis of Alpha Go's learned policy, and given the current position of the Go stones, it is possible to decide where the next white/black stone should be placed on the board to maximize its chance of winning.

Analogies to Critical Care

For critical care, given the large amount and granular nature of recorded data, RL is well suited for providing sequential treatment suggestions, optimizing treatments, and improving outcomes for new ICU patients. RL also has the potential to expand our understanding of existing clinical protocols by automatically exploring various treatment options. The RL agent analyzes the patient trajectories, and through trial and error, derives a policy, a personalized treatment protocol that optimizes the probability of favorable clinical outcomes (eg, survival). As this computerized process is an attempt to mimic the human clinician's thought process, RL has also been called the AI clinician [21].

We can consider the state as the well-being/condition of a patient. The state of the patients could depend on static traits (eg, patient demographics including age, gender, ethnicity, pre-existing comorbidity) and longitudinal measurements (eg, vital signs, laboratory test results). An action is a treatment or an intervention that physicians do for patients (eg, prescription of medications and ordering of laboratory tests). The transition probability is the likelihood of state transitions, and it is viewed as a prognosis. If the well-being in the new state is improved, we assign a reward to the RL agent, but we penalize the agent if the patient's condition worsens or stays stagnant after the intervention.

As illustrated in Figure 1, if we take a snapshot of the current well-being of a patient as his/her state, the physician would provide a treatment or an intervention (an action) to the patient. This action would lead the patient to the next state depending on his/her current state and the action performed on him/her. While knowing the next state of the patient, the physician would need to take another action according to the new state. These state-action pairs would continue to rollout over time, and the resultant trajectory of state-action pairs could represent the changes in the patients' conditions and the sequential treatment decisions that were performed by the physicians. We can define the length of the trajectory for each patient as fixed (eg, during the first 24 hours of the ICUs stay) or as dynamic (eg, different patients could be discharged from the ICUs at different times).

Figure 1. Illustration of reinforcement learning in critical care.

The main objective of the RL algorithm is to train an agent that can maximize the cumulative future reward from the state-action pairs given the patients' state-action trajectories. When a new state is observed, the agent is able to perform an action, which could choose the action for the greatest long-term outcome (eg, survival). When the RL agent is well-trained, it is possible to pick the best action given the state of a patient, and we describe this process as acting according to an optimal policy.

A policy is analogous to a clinical protocol. Nonetheless, a policy has advantages over a clinical protocol because it is capable of capturing more personalized details of individual patients. A policy can be represented by a table where it maps all possible states with actions. Alternatively, a policy could also be represented by a deep neural network (DNN) where given the input of a patient's state, the DNN model outputs the highest probability of an action. An optimal policy can be trained using various RL algorithms. Some widely applied RL algorithms include the fitted-Q-iteration (FQI) [22], deep Q network (DQN) [23], actor-critic network [24], and model-based RL [25]. More technical details about various RL models have been explained [26,27].

As RL in critical care is a relatively nascent field, we therefore aimed to review all the existing clinical applications that applied RL in the ICU setting for decision support over the past 10 years (2010-2019). Specifically, we aimed to categorize RL applications and summarize and compare different RL designs. We hope that our overview of RL applications in critical care can help reveal both the advances and gaps for future clinical development of RL. A detailed explanation of the concept of RL and its algorithms is available in [Multimedia Appendix 1](#) [28].

Methods

Search Strategy

A review of the literature was conducted using the following 7 databases: PubMed, Institute of Electrical and Electronics Engineers (IEEE), Google Scholar, Medical Literature Analysis and Retrieval System Online (MEDLINE), Excerpta Medica Database (EMBASE), ScienceDirect, and Web of Science. The search terms *reinforcement learning*, *critical care*, *intensive care*, *intensive care units*, and *ICUs* were combined. The search phrases listed in [Textbox 1](#) were used to identify articles in each database.

Textbox 1. Queries used to retrieve records.

Inclusion Criteria

To be eligible for inclusion in this review, the primary requirement was that the article needed to focus on the implementation, evaluation, or use of an RL algorithm to process or analyze patient information (including simulated data) in an ICU setting. Papers published from January 1, 2010, to October 19, 2019 were selected. General review articles and articles not published in English were excluded. Only papers that discussed sufficient details on the data, method, and results were included in this review.

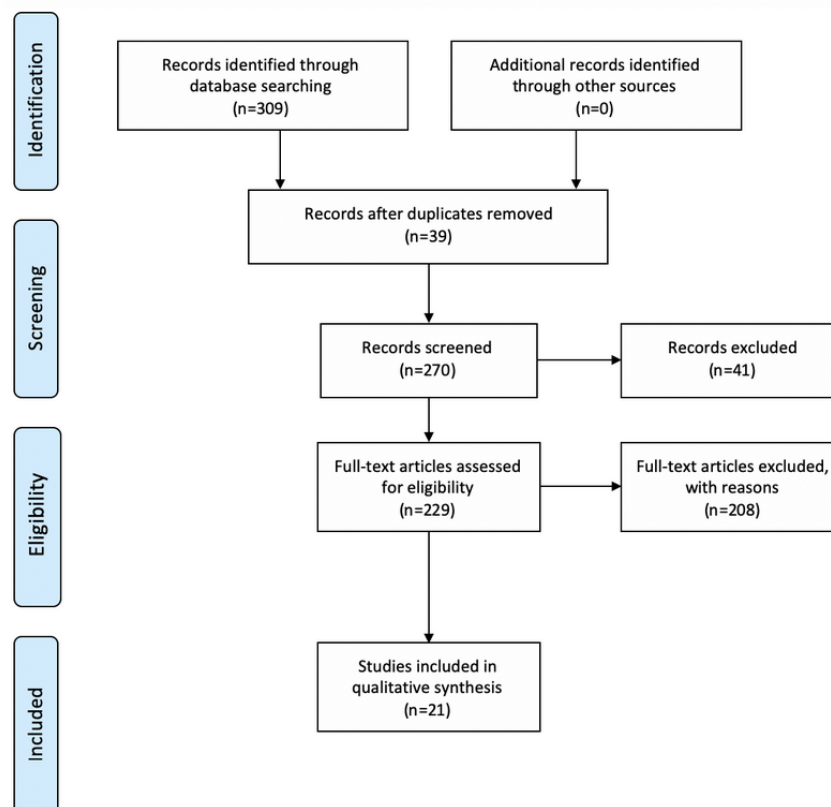

Data Synthesis

Data were manually extracted from the articles included in the review. A formal quality assessment was not conducted, as relevant reporting standards have not been established for articles on RL. Instead, we extracted the following characteristics from each study: the purpose of the study, data

source, number of patients included, main method, evaluation metrics, and related outcomes. The final collection of articles was divided into categories to assist reading according to their application type in the ICUs.

Results**Selection Process and Results Overview**

The selection process of this review was demonstrated using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses flow diagram (Figure 2). From the full text of 269 distinct articles, an independent assessment for eligibility was performed by 2 authors (SL and MF). Disagreements were discussed to reach consensus. During the full-text review, 249 articles were excluded, and 21 articles were eventually included. The reasons for exclusion during the review process are outlined in Table 1.

Figure 2. Preferred Reporting Items for Systematic Reviews and Meta-Analyses flow diagram of the search strategy.**Table 1.** Exclusion criteria used to exclude papers.

Criterion number	Exclusion criteria	Justification	Excluded articles, n
1	Duplicates	The papers have duplicate titles	39
2	Not a research article	The papers were blog articles, reports, comments, or views	23
3	Not written in English	The papers were not written in English	6
4	Review	The papers were review articles regarding general methods on big data, deep learning, and clinical applications	12
5	Not applied in the field of critical care	The papers did not focus on applications in critical care or intensive care	92
6	Not using RL ^a as the approach in critical care	The papers discussed issues in the critical care setting, but not using RL as an approach	115
7	No clear description of the method and result	The methods and results were not clearly described and thus not qualified for this review	1

^aRL: reinforcement learning.

In this section, we organized the reviewed articles into 4 categories, which reflect clinically relevant domains: (1) optimal individualized target laboratory value; (2) optimal choice of medication; (3) optimal timing of an intervention; and (4) optimal dosing of medication.

We plotted the number of articles reviewed by their category and year of publication in Figure 3. We found that the majority of the papers were published in the past 3 years (n=17),

indicating an increasing trend of applying RL-based approaches to assist physicians in decision making in critical care. In each of the 4 categories, we further organized the articles into subgroups based on their clinical questions (Figure 3). The figure shows that most of the applications used RL to find optimal drug dosing (n=16) [6,21,29-42], followed by the timing of an intervention (n=3) [43-45]. Only a few applications were looking at the individualized laboratory value (n=1) [46] and the optimal choice of medication (n=1) [47].

Figure 3. Mapping of reinforcement learning studies in critical care by application type.

Next, we discuss the details for each category with the methods and outcomes for each application. In particular, we further grouped the studies based on specific medication or treatment type in categories 3 and 4 to assist readers. A summary of all study details is found in [Multimedia Appendix 2](#).

Optimal Individualized Target Laboratory Value

Even after decades of routine use of laboratory value ranges, reference standards may need to be reconsidered, especially for individual patients [48]. Personalized targets for laboratory values in ICU patients could account for disease severity, comorbidities, and other patient-specific differences. Weng et al [46] tried to identify individualized targeted blood glucose levels as a reference for physicians. They applied an RL-based approach, *policy iteration*, to learn the target glycemic range at an hourly interval for severely ill patients with sepsis using real ICU data. Their approach was tested using the Medical Information Mart for Intensive Care III (MIMIC III), a large, publicly available ICU database [49]. MIMIC III contains information for hospital admissions of 43,000 patients in critical care units during 2001 and 2012, from which the authors extracted hourly data for 5565 patients with sepsis.

Weng et al [46] constructed their RL model as follows: First, they represented the patients' states from 128 variables. These variables included patient demographics, comorbid conditions, vital sign changes, and laboratory value changes. They used a sparse autoencoder [50] to reduce the high dimensionality of the raw features (128 dimensions) to only 32 dimensions so that

the RL model could be trained more efficiently with limited observational data. Second, they chose to act upon 1 of 11 discrete ranges of serum glucose at each time step. Third, they designed the reward function so that the RL agent could recommend an hourly target glucose level to optimize long-term survival. A positive 100 was assigned to the end state if patients survived 90 days after admission, and a negative 100 was assigned if the patients died. For each state-action pair, the *value* of the pair was iteratively estimated using the reward from the training data.

To understand how the reward value was related to mortality, the authors assigned values to discrete buckets using separate test data. In each value bucket, if the state-action pair is part of a trajectory where a patient died, a label of 1 was assigned to that bucket; otherwise, a label of 0 was assigned. After assigning all the state-action pairs from the test data with the labels in the corresponding value bucket, the mortality rate could be estimated for each value bucket. The authors plotted the estimated mortality rate with respect to the value-buckets and found an inverse relationship between them, where the highest value was associated with the lowest mortality. This result suggested that the learnt value represented the relationship between the state-action pair and mortality and that the learnt value of the state-action pairs from training data was validated on the test data.

To validate the RL policy, the author calculated the frequency of state transitions from the training data and generated new

trajectories. Starting from the observed state in the test data, the RL policy would recommend an action with the highest value, and the subsequent state was estimated with the transition probability. By averaging the value for all state-action pairs in the simulated trajectory, the mortality for simulated trajectories could be estimated by mapping this value in the mortality-value plot. Compared with the actual mortality rate in the test data, the author claimed that if physicians could control patients' hourly blood glucose levels within the range recommended by the RL model, the estimated 90-day mortality would be lowered by 6.3% (from 31% to 24.7%).

Optimal Choice of Medications

Apart from some clinical decision support systems, commonly used systems such as computerized prescriber order entry and bar-coded medication administration lack personalized recommendations to optimize medication effectiveness and minimize side effects [51]. Wang et al [47] applied a deep learning network based on RL to exploit medication recommendations with a data-driven strategy. Their approach accounted for individual patient demographics, laboratory values, vital signs, and diagnoses from the MIMIC III database. They selected the top 1000 out of 4127 medications and the top 2000 out of 6695 diseases (represented by the International Classification of Diseases, Ninth Revision codes), which covered 85.4% of all medication records and 95.3% of all diagnosis records, respectively. To reduce the problem complexity, the authors further categorized the 1000 medications into 180 drug categories using anatomical therapeutic chemical codes and aggregated patients' drug prescriptions into 24-hour windows.

The authors defined RL action as the medication combinations from the 180 drug categories. They adopted an actor-critic RL agent that suggested a daily medication prescription set, and aimed to improve patients' hospital survival. The details of the actor-critic RL algorithm are explained in [Multimedia Appendix 1](#) [28]. For each patient's ICU day, the *actor* network would recommend one medication combination by considering state variables such as demographics, laboratory results, and vital signs. A reward value of positive 15 would be given to the end state if a patient survived until hospital discharge and negative 15 if the patient died. The reward was designated as 0 for all other time steps. To counterbalance the *actor* network, the *critic* network was applied to evaluate the consistency of actual physician prescriptions and the RL agent's recommendations. The net effect of the actor-critic RL agent was to optimize the long-term outcomes of patients (hospital mortality) while minimizing deviations of RL-recommended actions from actual prescription patterns. In addition to the actor-critic network, the authors also applied long short-term memory [52] to represent a patient's current state by incorporating the long sequence of all historical states. Wang et al [47] suggested that hospital mortality would be reduced by 4.4% if clinicians adhered to the RL agent's recommendations.

Optimal Timing of Intervention

Weaning of Mechanical Ventilation

Mechanical ventilation (MV) is a life-saving treatment applied in approximately a third of all critically ill patients [53].

Prematurely discontinuing MV (premature weaning) and excessively prolonged MV (late weaning) are both associated with higher mortality [54]. The best time to wean may be uncertain [55].

To optimize the timing of ventilation discontinuation, Prasad et al [43] applied the RL-based FQI (the details of the FQI algorithm are explained in [Multimedia Appendix 1](#) [28]) on the MIMIC III database for all patients who were kept under ventilator support for more than 24 hours and extracted their records every 10 min from ICU admission to discharge. Patient states included a number of factors that could affect extubation, such as demographics, pre-existing conditions, comorbidities, and time-varying vital signs. The action for the ventilation setting was binary, that is, for each 10-min time step, the RL agent needed to decide whether the ventilation should be set on (continued MV) or off (weaned from MV). For reward design, Prasad et al [43] followed an existing weaning protocol from the Hospital of University of Pennsylvania. They assigned reward values to the RL agent at each time step according to 3 major considerations: (1) the RL agent should penalize each additional hour spent on the ventilator, (2) the RL agent should be assigned a positive reward value to a weaning action if the patient's vital signs and laboratory results were steady and within normal ranges after extubation, and (3) there was no reward value for failed spontaneous breathing trial or for reintubation after the first extubation. For RL policy evaluation, the authors calculated the proportion of weaning actions from the RL policy, referencing the total number of weaning actions from the clinician's policy at each time step, and calculated the overall consistency of weaning transitions. The recommended actions from the RL agent could match 85% of those from clinicians. The authors categorized the degree of consistency into 5 bins, and plotted the distribution of the number of reintubations with respect to the discrete consistency levels. Their results showed that when the consistency was high, vital sign fluctuations were fewer, laboratory results were more in-range, and reintubations were minimized.

Yu et al [45] studied the same clinical issue as Prasad et al [43] and used the same data set, but designed a different reward function using inverse RL. The inverse RL model directly learnt reward mapping from data for each state-action pair and inferred what clinicians would wish to achieve as a reward. Similar to Prasad et al [43], the RL recommendations by Yu et al [45] were associated with shorter weaning times and fewer reintubations compared with clinician decision making.

Timing to Order Laboratory Tests

The timing of ordering a laboratory test can be challenging. Delayed testing would lead to continued uncertainty over the patient's condition and possible late treatment [56]. However, excessively early ordering of laboratory tests can cause unnecessary discomfort to the patient, increase the risk of anemia, and increase health care cost.

Cheng et al [44] applied the FQI method to find the optimal timing for ordering laboratory tests among patients with sepsis in the MIMIC III data set. They examined the timing of 4 types of laboratory tests: white blood cell count (WBC), creatinine, blood urea nitrogen (BUN), and lactate. They sampled the

patients' data at hourly intervals and constructed the state of a patient by considering the predictive variables of severe sepsis or acute kidney failure, including respiratory rate, heart rate, mean blood pressure, temperature, creatinine, BUN, WBC, and lactate. The missing values were predicted by a multioutput Gaussian process [57,58]. In their RL model, they chose to design the reward function with the combination of 4 factors: (1) a positive reward should be given only if the ordering of test was necessary, while penalizing over or under ordering; (2) the RL agent should be encouraged to order laboratory tests when there was a sudden change in laboratory results or vital signs; (3) negative reward should be given if the laboratory results were similar to the last measurements (no information gain); (4) a penalty would be added to a reward whenever a test was ordered, to reflect the testing cost. Their RL agent, compared with clinicians, was able to reduce the number of laboratory tests by 27% for lactate and 44% for WBC, while maintaining high information gain.

Optimal Dosing of a Drug

Recommendations for dosing regimens in ICU patients are often extrapolated from clinical trials in healthy volunteers or noncritically ill patients. This extrapolation assumes similar drug behavior (pharmacokinetics and pharmacodynamics) in the ICU and other patients or healthy volunteers. However, it is well known that many drugs used in critically ill patients may have alterations in pharmacokinetic and pharmacodynamic properties because of pathophysiological changes or drug interactions [59]. Therefore, critically ill patients bring unique challenges in drug dosing.

Dosing of Propofol

Critically ill patients in ICUs often require sedation to facilitate various clinical procedures and to comfort patients during treatment. Propofol is a widely used sedative medication [60], but titration of propofol is challenging, and both over sedation and under sedation can have adverse effects [32]. Of the studies reviewed, 6 studies have focused on applying RL to determine the optimal dosage for propofol while maintaining the physiological stability of the patient. The bispectral index (BIS) was used to monitor sedation level and to determine the effect of propofol.

Borera et al [29] was the first to apply RL to a pharmacokinetic model [61] to describe the time-dependent distribution of propofol in human surgical patients. The RL agent was a neural network aimed at optimizing the propofol dose to achieve the target BIS value. The patient's state and state transition were modeled using a mathematical pharmacokinetic model with predefined parameters such as the concentration at half maximal effect of BIS, degree of nonlinearity of BIS, and time-lag coefficient to estimate the BIS value for simulated patients. The action was a discrete range of propofol infusion rate. The reward function was the error rate between the target BIS value and the current simulated BIS value, where a larger negative reward was given when the current simulated BIS value was further away from the predefined target value. They measured the performance of the RL agent by looking at the time to reach the target BIS value (steady time). The evaluation was conducted

on 1000 simulated patients. On average, the steady time was 3.25 min for the BIS value to reach target.

To ensure patient safety, propofol dosing should consider the concurrent stability of vital parameters. For instance, Padmanabhan et al [30] chose mean arterial pressure (MAP) as the secondary control variable. The authors combined the error rates for both BIS and MAP when designing the reward. The target for the RL agent was to infuse propofol so that the target BIS would be reached in a short time, whereas MAP was kept within a desired range. In subsequent studies, Padmanabhan et al [31,32] modified their methods with different RL training algorithms (Q-learning and policy iteration). In all their studies, the RL agent was able to suggest accurate propofol doses and achieve target BIS values within a few minutes.

In contrast to fixed pharmacokinetic models in the RL model environment, Yu et al [45] applied FQI and Bayesian inverse RL on the MIMIC III database. They considered patients' demographic characteristics, pre-existing conditions, comorbidities, and time-varying vital signs to construct the state of the patient. Their inverse RL model interpreted clinician preference as a reward for different patient states. The learned reward function from the inverse RL model suggested that clinicians may pay more attention to patients' cardiorespiratory stability rather than oxygenation when making decisions about propofol dosage.

Dosing of Intravenous Heparin

Anticoagulant agents are often used to prevent and treat a wide range of cardiovascular diseases. Heparin is commonly used in critical care [62], yet its precise dosing is complicated by a narrow therapeutic window. Overdosing of heparin results in bleeding whereas under dosing risks clotting. To guide heparin dosing, activated partial thromboplastin time (aPTT) is often used as a measure of the anticoagulant effect of heparin.

Nemati et al [6] applied FQI with a neural network to optimize and individualize heparin dosing. Their study was conducted on the MIMIC II database, with the reward function based on aPTT levels following heparin dosing [63]. The reward to the RL agent will be high if the aPTT value is between 60 and 100 seconds. After training, they plot the state-action value with respect to the level of consistency between the RL policy and clinician practice. Their results showed that, on average, following the recommendations of the RL agent resulted in higher state-action values.

Ghassemi et al [33] and Lin et al [34] focused on a personalized optimal heparin dosing using different RL algorithms. In addition to the MIMIC III data set, Lin et al [34] applied an actor-critic network on the Emory Healthcare data set from Emory University. For RL policy evaluation, Lin et al [34] regressed the discordance between RL policy and physician practice over the number of clotting and bleeding complications, adjusting for covariates such as history of clot or bleed, weight, age, and sequential organ failure assessment score. The regression coefficient suggested that following the RL agent's recommendations would have likely resulted in improved clinical outcomes with a reduced number of clotting and bleeding complications.

Intravenous Fluids, Vasopressors, and Cytokine Therapy for Treating Sepsis

Sepsis is the third leading cause of death and is expensive to treat [64]. Besides antibiotics and source control, challenges remain with the use of intravenous (IV) fluids to correct hypovolemia and administration of vasopressors to counteract sepsis-induced vasodilation. Raghu et al [36] suggested a data-driven RL approach to recommend personalized optimal dosage for IV fluids and vasopressors to improve hospital mortality. Their RL model was double DQN with dueling, which can minimize the overestimation problem of previous Q-learning models. The details of the Q-learning and double DQN algorithms are explained in [Multimedia Appendix 1](#) [28]. The authors considered patients' demographics, laboratory values, vital signs, and intake/output events as state features in the RL model. Action was designed as a combination of 5 discrete bins for IV fluid dosing and 5 bins for vasopressor dosing to treat patients with sepsis. The reward was issued at the terminal time step of the patient's trajectory, with a positive reward if the patient survived. Data were extracted from the MIMIC III database for all patients who fulfilled sepsis-3 criteria [65]. For policy evaluation, Raghu et al [36] plotted the estimated hospital mortality with respect to the difference between dosages recommended by the RL agent and by clinicians. The plot showed that the mortality was lowest when there was no discrepancy between RL policy and physician decision making. Six other groups of researchers also focused on the same research question and applied various RL algorithms with slightly different designs of the state space, reward function, and evaluation metrics [21,35,37-40]. The findings from these studies all suggest that the RL agent would be able to learn from the data and if physicians followed the RL policy, the estimated hospital mortality could be improved.

Among the aforementioned studies, Komorowski et al [21] were the pioneers of applying RL in the ICU, using data from patients with sepsis in the MIMIC III database. They inferred a patient's health status using an array of inputs, which included demographics, vital signs, laboratory tests, illness severity scores, medications, procedures, fluid intake and output, physician notes, and diagnostic coding. Patient data were aggregated and averaged every 4 hours to represent patient states. Using a k-means algorithm, these patient states were then simplified into 750 discrete mutually exclusive clusters. A sequence of these clustered states would describe a particular patient's trajectory. The authors estimated the state transition probability by counting how many times each transition was observed and converted the counts to a stochastic matrix. This transition matrix contained the probability for each patient going to a new state, given a previous action taken in the current state. The entire trajectory of a patient's state can be estimated using the transition matrix. The authors applied a policy iteration RL algorithm that learnt the optimal dosing policy for IV fluids and vasopressors to maximize the probability of 90-day survival.

Nevertheless, the study by Komorowski et al [21] had several limitations. First, their study only considered fluid and vasopressor management, ignoring other important treatments such as source control, correction of hypovolemia, and management of secondary organ failures [21]. Second, 90-day

mortality is affected by factors outside of the ICU, which the study did not take into account. Third, clinical decision making considers both short-term outcomes (eg, physiological stability) and long-term outcomes (eg, kidney failure or mortality), but the study only considered mortality as the single goal for training the RL algorithm [66]. Fourth, discretizing patient health status into discrete clusters loses data granularity and may limit the ability to detect changes in patient status. These limitations also occur in other studies, which we will elaborate in the Discussion section.

Other than using IV fluids and vasopressors for treating sepsis. Petersen et al [42] investigated cytokine therapy using the deep deterministic policy gradient [67] method. The details of the policy gradient RL algorithm are explained in [Multimedia Appendix 1](#) [28]. They evaluated the RL model by using an agent-based model, the innate immune response agent-based model [68], that simulated the immune response to infection. The RL policy was able to achieve a very low mortality rate of 0.8% over 500 simulated patients, and suggested that personalized multicytokine treatment could be promising for patients with sepsis.

Dosing of Morphine

Critically ill patients may experience pain as a result of disease or certain invasive interventions. Morphine is one of the most commonly used opioids for analgesia [69]. Similar to sedation, the dosing of analgesia is subject to uncertainty. Lopez-Martinez et al [41] collected data for patients who had at least one pain intensity score and at least one dose of IV morphine in the MIMIC III database. They applied double DQN with dueling as their RL model and constructed the state space to be continuous with features including the patient's self-reported pain intensity and their measured physiological status. The action was a choice of 14 discrete dosing ranges of IV morphine. The reward was determined by considering both the patients' cardiorespiratory stability and their pain intensity. The highest reward was given when pain was absent and both heart rate and respiration rate were within the acceptable range. By comparing the RL policy with physicians' choices, Lopez-Martinez et al [41] found that RL policy tended to prescribe higher doses of morphine. This result was consistent with previous studies: continuous dosing provided similar or even better pain relief with no increase in acute adverse effects [70,71].

Discussion

Principal Findings

Our comprehensive review of the literature demonstrates that RL has the potential to be a clinical decision support tool in the ICU. As the RL algorithm is well aligned with sequential decision making in ICUs, RL consistently outperformed physicians in simulated studies. Nonetheless, challenges regarding RL system design, evaluation metrics, and model choice exist. In addition, all current applications have focused on using retrospective data sets to derive treatment algorithms and require prospective validation in authentic clinical settings.

RL System Design

The majority of applications were similar in their formulation of the RL system design. The state space is usually constructed by features including patient demographics, laboratory test values, and vital signs, whereas some studies applied encoding methods to represent the state of the patients instead of using raw features. The action space was very specific to each application. For instance, in terms of the dosing category, the action space would be discretized ranges of medication dosage. For other categories, such as timing of an intervention, the action space would be the binary indicator of an intervention for each time step. The number of action levels differed among the studies. For some studies, the action levels could be as many as a dozen or a hundred (eg, optimal medication combination), whereas for other studies, the action levels were limited to only 2 (eg, on/off MV). The design of the reward function is central to successful RL learning. Most of the reward functions were designed a priori with guidance from clinical practice and protocols, but 2 studies [40,45] managed to directly learn the reward function from the data using inverse RL.

Evaluation Metrics

The only metric that matters is if the adoption of an RL algorithm leads to improvement in some clinical outcomes. Most studies calculated the estimated mortality as the long-term outcome and drew plots to show the relationship between the estimated mortality versus the learnt value of patients' state-action trajectories, where the higher value function was associated with lower mortality. The RL agent would provide treatment suggestions for those actions with higher values, thus leading to a lower estimated mortality. Estimated mortality is a popular metric for RL policy evaluation. However, the problem with the estimated mortality is that it is calculated from simulated trajectories with observational data, and may not be the actual mortality.

Mortality is not always the most relevant and appropriate outcome measure. For instance, in the study by Weng et al [46], they tried to identify individualized targeted blood glucose levels as a reference for physicians. In their study, 90-day mortality was used to evaluate the RL policy. However, a more relevant measure could be considered, such as short-term changes in the blood glucose level, physiological stability, and development of complications.

Several studies that focused on propofol titration have considered BIS as the evaluation metric to monitor the sedation level and hence to determine the effect of propofol. Although BIS monitoring is fairly objective, assessing sedation is usually performed by health care providers with clinically validated behavioral assessment scales such as the Richmond Agitation-Sedation Scale score [72]. In addition, EEG-based technologies, such as BIS and M-entropy, have been validated more in the operating room than in the ICU [73]. Furthermore, BIS cannot be used as the sole monitoring parameter for sedation, as it is affected by several other factors, including the anesthetic drugs used, muscle movement, or artifacts from surgical equipments [74].

To date, there has been no prospective evaluation of an RL algorithm. Moreover, the observational data itself may not truly reflect the underlying condition of patients. This is known as the partially observable MDP [75] problem, where we are only able to represent a patient's state by the observed physiological features, which are solved by mathematical approximation.

Model Choice

FQI and DQN seem to be the top RL approaches among the reviewed studies. FQI is not a deep learning-based RL model, which guarantees convergence for many commonly used regressors, including kernel-based methods and decision trees. On the other hand, DQN leverages the representational power of DNNs to learn optimal treatment recommendations, mapping the patient state-action pair to the value function. Neural networks hold an advantage over tree-based methods in iterative settings in that it is possible to simply update the network weights at each iteration, rather than rebuilding the trees entirely.

Both FQI and DQN are off-policy RL models. Off-policy refers to learning about one way of behaving from the data generated by another way of selecting actions [76]. For instance, an off-policy RL model tries to train a policy X to select actions in each step, but it estimates the Q-values from state-action pairs where the action was chosen by following another policy Y. In contrast to off-policy learning, on-policy learning uses the same policy X to choose actions and to evaluate the returns in each step during training. Most of the included studies adopted off-policy RL models because the RL models aim to learn policy X from the data, which was generated by following real actions of physicians (policy Y). The data generated by policy Y is the actual physicians' policy, where the RL models try to learn and improve from. This is the fundamental idea of applying off-policy RL models.

In addition, both FQI and DQN are value-based RL models that aim to learn the value functions. In value-based RL, a policy can be derived by following the action with the highest value at each time step. Another type of RL is called policy-based RL, which aims to learn the policy directly without worrying about the value function. Policy-based methods are more useful in continuous space. When the data volume is insufficient to train a DQN model, the DQN is not guaranteed to achieve a stable RL policy. As there is an infinite number of actions or states to estimate the values for, value-based RL models are too computationally expensive in the continuous space. However, policy-based RL models demand more data samples for training. Otherwise, the learned policy is not guaranteed to converge to an optimal one. Both value-based and policy-based RL models can be grouped in a more general way as *model-free* RL. Here the word *model-free* means the environment is unknown to an agent. The RL agent makes use of the trajectories generated from the environment, rather than explicitly knowing the rule or the transition probability. In contrast to model-free RL, *model-based* RL requires the agent to know the transition probability for all the state-action combinations explicitly and hence impractical as the state space and action space grow. In the critical care context, patients' conditions and prognosis are very complex to apply model-based RL because we are not exactly sure about the probability of all state transitions. In

addition, most studies in critical care could only use limited retrospective data to train the model offline. Therefore, we found that most of the studies have applied a value-based RL model to utilize the available observational data.

Common Data Sets

We found that 71% (15/21) of applications utilized the MIMIC II or MIMIC III database to conduct their experiments. We conjecture that such popularity might be due to public availability and high quality of MIMIC data. However, data collected from a single source may introduce potential bias to the research findings. There are inherent biases in the medical data sets obtained at various institutions due to multiple factors, including operation strategy, hospital protocol, instrument difference, and patient preference. Therefore, the RL models trained on a single data set, regardless of the data volume, cannot be confidently applied to another data set. The findings from the reviewed articles may not be generalizable to other institutions and populations. In addition to the MIMIC database, one of the studies also utilized the eICU Research Institute (eRI) database to test their RL model [77]. The eRI database has a larger volume of data compared with the MIMIC database, and it is also publicly available. We suggest that future applications could cross-validate their models on both the MIMIC and eRI databases. In addition, all current applications have focused on using retrospective data sets to derive treatment algorithms and require prospective validation in authentic clinical settings.

Strengths and Limitations of This Study

The strengths of this paper include the comprehensive and extensive search for all available publications that applied RL as an approach in the critical care context. Nonetheless, we acknowledge the limitations. We included papers (eg, those on arXiv) that have not been peer-reviewed *before* publication but these papers have undergone a postpublication peer review. According to the search phrases applied in this review, we may miss out certain papers that applied RL in critical care, but did not specify the phrase *intensive care* nor *ICU* in their full text papers.

Challenges and Future Directions

A number of challenges must be overcome before RL can be implemented in a clinical setting. First, it is important to have a meaningful reward design. The RL agent would be vulnerable in case of reward misspecification, and might not be able to produce any meaningful treatment suggestion. Inverse RL can be an alternative to a priori-specified reward functions. However, inverse RL assumes that the given data represent the experts' demonstrations and the recommendations from the data were already optimal; these may not be true.

Second, medical domains present special challenges with respect to data acquisition, analysis, interpretation, and presentation of these data in a clinically relevant and usable format. Addressing the question of censoring in suboptimal historical data and explicitly correcting for the bias that arises from the timing of interventions or dosing of medication is crucial to fair evaluation of learnt policies.

Third, another challenge for applying the RL model in the clinical setting is exploration. Unlike other domains such as game playing, where one can repeat the experiments as many times, in the clinical setting, the RL agent has to learn from a limited set of data and intervention variations that were collected offline. Using trial and error to explore all possible scenarios may conflict with medical ethics, thereby limiting the ability of the RL agent to attempt new behaviors to discover ones with higher rewards and better long-term outcomes.

In comparison with other machine learning approaches, there is an absence of acceptable performance standards in RL. This problem is not unique to RL but seems harder to address in RL compared with other machine learning approaches, such as prediction and classification algorithms, where accuracy and precision recall are more straightforward to implement. However, it is worth noting that RL has a distinct advantage over other machine learning approaches, that one can choose which outcome to optimize by specifying the reward function. This provides an opportunity to involve patient preferences and shared decision making. This becomes more relevant when learned policies change depending on the reward function. For example, an RL algorithm that optimizes survival may recommend a different set of treatments versus an RL algorithm that optimizes neurologic outcome. In such situations, patient preference is elicited to guide the choice of the RL algorithm.

RL has the potential to offer considerable advantages in supporting the decision making of physicians. However, certain key issues need to be addressed, such as clinical implementation, ethics, and medico-legal limitations in health care delivery [78]. In fact, any machine learning model would need to address these limitations carefully to serve as truly effective tools. In clinical practice, the RL models need to be refined iteratively throughout the time to include newly generated data from electronic health systems in hospitals, and the model must produce robust results for physicians to interpret and understand. Besides, patients' understanding and willingness to use the RL model as a supporting tool in their care would be another important consideration. Another important ethical consideration would be the liability in case of medical error when the RL model recommendation differs from the physician. It has an impact on the autonomy of both the physician and patient. The problem of medical error works in both ways when there is a poor outcome: (1) if the physician follows the RL model recommendation, can the clinician then blame the model and the personnel who maintain the model; (2) if the clinician does not follow the RL model recommendation, can the clinician then be said to have made the wrong decision and be penalized.

Possible directions for future work include (1) modeling the RL environment as a partially observable MDP, in which observations from the data are mapped to some state space that truly represents patients' underlying well-being; (2) extending the action space to be continuous, suggesting more precise and practical treatment recommendations to physicians; and (3) improving the interpretability of the RL models so that physicians can have more confidence in accepting the model results. With further efforts to tackle these challenges, RL methods could play a crucial role in helping to inform patient-specific decisions in critical care.

Conclusions

In this comprehensive review, we synthesized data from 21 articles on the use of RL to process or analyze retrospective

data from ICU patients. With the improvement of data collection and advancement in reinforcement learning technologies, we see great potential in RL-based decision support systems to optimize treatment recommendations for critical care.

Abstract

Background: Web-based therapies hold great promise to increase accessibility and reduce costs of delivering mental health care; however, uptake in routine settings has been low.

Objective: Our objective in this review was to summarize what is known about health care professionals' perceptions of the barriers to and facilitators of the implementation of web-based psychological treatments in routine care of adults in health care settings.

Methods: We searched 5 major databases (MEDLINE, EMBASE, PsycINFO, CINAHL, and the Cochrane Library) for qualitative, quantitative, or mixed-methods studies exploring health professionals' views on computer- or internet-based psychological treatment programs. We coded included articles for risk of bias and extracted data using a prepiloted extraction sheet.

Results: We identified 29 eligible articles: 14 qualitative, 11 quantitative, and 4 mixed methods. We identified the following themes: patient factors, health professional factors, the therapeutic relationship, therapy factors, organizational and system factors, and models of care. Health professionals supported web-based therapies only for patients with relatively straightforward, low-risk diagnoses, strong motivation and engagement, high computer literacy and access, and low need for tailored content. They perceived flexibility with timing and location as advantages of web-based therapy, but preferred blended therapy to facilitate rapport and allow active monitoring and follow-up of patients. They emphasized the need for targeted training and organizational support to manage changed workflows. Health professionals were concerned about the confidentiality and security of client data for web-based programs, suggesting that clear and transparent protocols need to be in place to reassure health professionals before they will be willing to refer.

Conclusions: Without health professionals' support, many people will not access web-based therapies. To increase uptake, it is important to ensure that health professionals receive education, familiarization, and training to support them in incorporating web-based therapies into their practice, and to design systems that support health professionals in this new way of working with patients and addressing their concerns.

KEYWORDS

health professional views; implementation; online psychological therapy; online CBT; barriers; facilitators; models of care; cognitive behavioral therapy; internet-based intervention

Introduction

Background

Internationally there is a move toward using digital technologies in mental health care, including the development of an increasing number of Web-based therapy programs [1,2]. The reasons for this interest in electronic mental health commonly include accessibility, flexibility (in terms of when and where they can be accessed), lack of mental health care professionals to cover need, and cost considerations [3,4]. Randomized controlled trials of web-based therapies show promise, with efficacy reported to be similar to that of face-to-face interventions [5]. A systematic review of internet-based cognitive behavioral therapy [6], for example, found that this therapy has been tested for 25 different clinical disorders, with large effect sizes meeting the highest level of criteria for evidence for disorders such as depression, anxiety, and severe health anxiety.

Despite this interest, research on referral and uptake of web-based therapies in routine care is limited [7]. In a rapid review of literature on this topic, we found no studies set in hospital-based medical clinics and only 1 study in primary care, which reported extremely low rates of referral (14% of the expected number) and uptake (1% of those referred) [8]. A major implementation project in Europe, known as MasterMind, is studying web-based therapies in routine mental health care [9,10], but no data are published at this stage.

Nor is there a large body of evidence on effective processes for implementation of web-based therapies in routine clinical care [7]. A recent review of staff-reported barriers to and facilitators of hospital-based interventions of any kind (web-based or face-to-face) [11] identified 3 key domains that may affect implementation success—system (eg, workload and workflow, physical structure and resources, culture, communication, and external pressures), staff (eg, attitudes, understanding and awareness, role identity, skills, and confidence), and intervention (eg, ease of integration, validity and evidence base, safety and ethics, supporting resources)—with similar barriers likely in community settings [12]. Several conceptual frameworks have been developed to further explicate and guide health care implementation, including the Consolidated Framework for Implementation Research (CFIR) [13]. CFIR is composed of 5 major domains: intervention characteristics, the inner setting, the outer setting, characteristics of individuals involved in implementation, and the implementation process. As health professionals often act as gatekeepers to web-based programs, they are key stakeholders and may be very influential in determining whether web-based programs are disseminated widely. Thus, in this systematic review, we decided to focus on health professionals' perspectives of web-based therapies, which falls within the fourth CFIR domain.

Objective

Several individual studies reported data on health professionals' perceptions of web-based therapy programs, which revealed concerns about therapeutic alliance and the quality and effectiveness of programs [14,15], patient commitment and compliance [15,16], patient barriers such as internet literacy

and access [16,17], and suicide risk [16]. However, we found no synthesis of these studies to provide an overall picture of health professionals' perspectives to date. Thus, we sought to fill this gap by conducting a systematic review. Our research question was what are health professionals' perceptions of the barriers to and facilitators of the implementation of web-based psychological treatments in routine care in health settings?

Methods

Review Registration

We registered the review with the International Prospective Register of Systematic Reviews (PROSPERO CRD42018100869).

Searches

We searched 5 bibliographic databases: MEDLINE, EMBASE, PsycINFO, CINAHL, and the Cochrane Library (Cochrane Database of Systematic Reviews, Cochrane Central Register of Controlled Trials, Cochrane Methodology Register). The search strategy included terms relating to web-based approaches, psychological therapies, and views of barriers to and facilitators of dissemination.

Qualitative, quantitative, or mixed-methods studies exploring health professionals' views on computer- or internet-based psychological treatment programs were eligible if the treatment contained a component designed to change psychological symptoms or behaviors either associated with a diagnosable mental health condition (using *International Classification of Diseases, Tenth Revision*, Diagnostic and Statistical Manual of Mental Disorders [Fifth Edition], or equivalent) or secondary to a physical health condition such as cancer. This could include anxiety, depression, substance misuse, suicidality, insomnia, complex pain, fatigue (eg, chronic fatigue syndrome or cancer-related fatigue), or medication adherence. Studies of views on all models of web-based therapy, from entirely self-directed to blended with face-to-face care, were eligible. Additionally, the patients targeted (and the health professionals) could be situated either in a hospital or clinic setting or in the general community.

We included only studies investigating views on web-based programs for adults (>18 years of age); we excluded programs targeting adults who were completing the program on behalf of someone else, for example, parents completing a program to help their children with anxiety or behavioral problems.

We included studies of the views of all health professionals involved in referring, triaging, or providing psychosocial care to patients with the above conditions (eg, doctors, nurses, psychosocial health professionals, allied health practitioners). We excluded nonclinical professional groups who do the above (eg, schoolteachers, religious advisers).

We limited included studies to peer-reviewed articles, excluding conference abstracts. We searched studies published from 1986 (when the first known digital mental health site, Ask Uncle Ezra, at Cornell University was launched) to the end of October 2019.

Titles or abstracts, or both, of articles retrieved during the search strategy or from reference lists were screened by 1 reviewer to identify studies that met the inclusion criteria described above. As an initial step, 10% of the titles or abstracts and full-text articles were independently reviewed by a second reviewer to confirm inclusion and exclusion decisions. Following this, any titles or abstracts or full-text articles where the reviewer had any uncertainty about the decision was put aside and discussed with a second reviewer. Any continuing uncertainty was resolved through retrieving the full text of the study or discussion with other members of the authorship team. We hand searched reference lists of included articles for relevant articles.

Data Extraction

We extracted information from articles meeting the inclusion criteria, with 2 team members completing extraction for each article. Any uncertainty was resolved through discussion with additional members of the review team. Data extracted were author, country, study design, sample characteristics, web-based therapy characteristics, measures, results, and limitations.

Risk-of-Bias (Quality) Assessment

We assessed the selected articles for risk of bias using checklists appropriate to quantitative and qualitative studies from Kmet et al [18] and to mixed-methods studies from Pluye et al [19]. All articles were graded by 2 team members and discussed with the author team if there was any ambiguity in grading.

Strategy for Data Synthesis

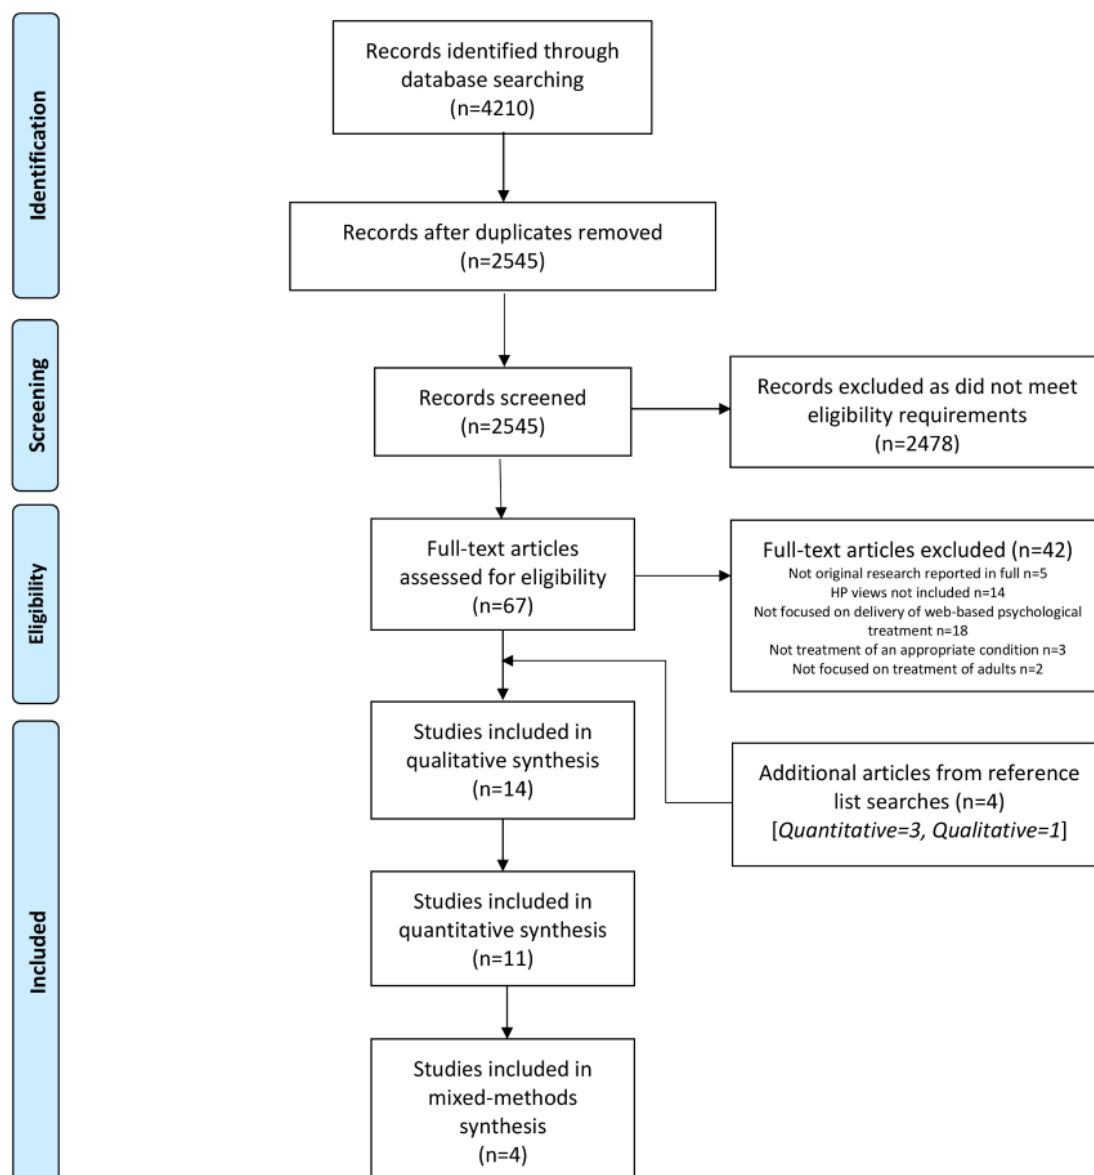

We analyzed the articles using a 3-stage synthesis process that combined qualitative, quantitative, and mixed-methods studies comprehensively and rigorously to answer the review question, following the methods of Thomas et al [20]. First, we summarized quantitative data using descriptive statistics. Second, we synthesized qualitative data by themes [21]. All authors coded 2 qualitative studies line by line to develop a

draft coding tree and themes, which we then refined after coding 2 additional studies. We then applied this coding structure to the remaining qualitative studies, with emerging themes created and discussed by all authors. Similarities and differences between codes and their content were examined to develop higher-order themes. (See [Multimedia Appendix 1](#) for the final coding tree.) Third, we used a matrix to compare the qualitative, quantitative, and mixed-methods findings from the first 2 stages to answer the review research question.

Results

Search Results

We initially identified 4210 potentially eligible articles from the search, with 2545 remaining after deduplication. [Figure 1](#) shows the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow diagram, with 29 articles meeting full inclusion criteria: 14 qualitative, 11 quantitative, and 4 mixed methods. Most articles were published since 2009 and reported results from the United Kingdom (n=5), the United States (n=6), Australia (n=4), Canada (n=4), Europe (n=10), and Israel (n=1). A total of 16 studies specified the professional background of the included health professionals (psychologists, n=12 studies; social workers, n=9 studies; general practitioners, n=4 studies; nurses, n=3 studies; and psychiatrists, n=2 studies), and the remaining 13 studies used general terms (eg, “psychotherapist” or “counsellor” or “practitioner”). Where studies included both health professionals and patients, we included only data from the health professionals in the review. See [Multimedia Appendix 2](#) for study characteristics. All included articles were of acceptable quality, with reflexivity and use of verification procedures to establish credibility the most poorly done (see [Multimedia Appendix 3](#) for quantitative studies, [Multimedia Appendix 4](#) for qualitative studies, and [Multimedia Appendix 5](#) for mixed-methods studies).

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow diagram. HP: health professional.

Thematic Synthesis

We identified 6 themes, which mapped well to the CFIR: therapy factors, organizational (or inner setting) and system (or outer setting) factors, patient factors, health professional factors, the therapeutic relationship, and models of care.

Therapy Factors

In total, 3 of 11 quantitative studies ($n=677$) [22-24], 5 of 14 qualitative studies ($n=78$) [14,25-28], and 3 of 4 mixed-methods studies ($n=111$) [17,29,30] explored the impact of therapy factors on the uptake of web-based therapies. Findings suggested that health professionals believed there was evidence [29,30] supporting the utility of web-based therapies but were generally more comfortable using web technologies as an *adjunct* to therapy, rather than as a *stand-alone* intervention [17,24,26] (see Models of Care subsection below for more detail). Overall, health professionals were neutral to positive toward web-based programs and identified the following consistent therapeutic factors that facilitate or hinder web-based therapy uptake.

The therapeutic content and approach of therapies were frequently raised by study participants as being more or less appropriate for a web-based format, with therapists more likely to refer patients for web-based psychoeducation, monitoring, and skills practice [17,23,26] within a positive psychology, mindfulness, acceptance and commitment therapy, or cognitive behavioral therapy (CBT) framework [17,23]. They were less likely to consider web-based therapy appropriate for psychoanalytic, interpersonal psychotherapy, or schema therapies. Nor were they comfortable with serious gaming [17,22], chat, or video components [17,24]. Concerns were raised regarding privacy of data, ethical considerations for suicidal patients, and levels of evidence available for intervention effectiveness [22,23].

The structured nature of web-based programs, the most commonly raised theme, was extensively discussed as both a facilitator of and barrier to uptake or recommendation. Whereas structure provided focus and aided navigation of programs [27,28], other studies noted that this needs to be balanced with flexible tailoring of content [29,30], a challenge that is

inadequately addressed [14,27]. Some health professionals in the qualitative studies reported wanting to see more transdiagnostic options [25]. Hadjistavropoulos and colleagues partially addressed this recommendation in their mixed-methods study of a transdiagnostic web-based CBT intervention, with feedback specifically citing the transdiagnostic nature as a strength of the program [29].

Organizational and System Factors

A total of 6 of 11 quantitative studies (n=4171) [23,24,31-34], 10 of 14 qualitative studies (n=158) [14,25-28,35-39], and 2 of 4 mixed-methods studies (n=99) [17,29] reported organizational and system concerns, which fall within the second and third domains of the CFIR.

Training

Training was highlighted as driving confidence in recommending web-based therapy options to patients [28]. Health professionals wanted more information, training, clear guidelines, and information on liability to be comfortable with web-based approaches [34].

Training to improve computer skills and stay up to date [23] and the need for better information technology support were also identified [17]. Qualitative studies [14,25,28] highlighted training needs in email or electronic communication skills in a therapeutic context [14,25] and, from an organizational perspective, the time required to obtain skills and to respond to patients in this format. Notably, 1 study suggested that the opportunity to pause and reflect before responding to emails was a strength of web-based therapy [37].

Time Saver or Time Changer

Health professionals reported varying views regarding whether web-based approaches made therapy delivery harder or easier. In the study by Bengtsson et al [27], therapists who were experienced in delivering both web-based and face-to-face therapy noted that work time was more flexible with web-based CBT, enabling work during cancellations, and flexibility in appointment times and place of work. Other advantages included therapy being unaffected by illness, emergencies, or other work; allowing colleagues to take over each other's work if needed; and the potential to work with more clients at once [27]. In contrast, another study noted that web-based therapy was time consuming for both patients and therapists, with experienced web-based therapists spending more time overall on web-based treatment than with face-to-face treatment [25].

Managerial and Organizational Support

In 2 studies, support and leadership from organization staff and local management was noted as valuable in encouraging use of web-based CBT [17,25]. In another quantitative study [31], perceived supportiveness of the organizational environment predicted intention to use web-based CBT. A large study found small effects of workplace factors, such that working in a community treatment center (rather than private practice) and having good access to technology at work increased perceptions of the efficacy of blended treatment [32].

Accessibility and Integration

Some studies reported that health professionals found it easier to integrate written materials into care, rather than referring to web-based programs where specific content is difficult to access easily [38,39]. In the study by Batka and colleagues, health professionals expressed mixed views regarding the ability of web-based therapy to bridge the gap between primary care and behavioral health [36]. One study supported the idea of web-based therapies identifying those in need of additional support [35]. Several studies noted the need to supplement patient self-referral and management with health professional monitoring and follow-up, to ensure the program matched the patient's needs [14,28] and to encourage adherence. Rural health professionals in 1 study [26] expressed concern that an increase in web-based treatment may further isolate rural patients without internet access:

Often online services have been looked at as, you know, the great hope for areas where there aren't real services for people, but where there isn't adequate internet access, you are further marginalizing people who live in remote areas who now don't have access to two different services... [pg 5]

Data Security and Privacy

In 1 study, confidentiality of patient information was listed as the primary concern by 48% of health professionals, with 81% stating they had some concern [33]. Two quantitative studies highlighted health professionals' concerns about information security [17,23], ethical or clinical guidelines [17,23], and legal issues or liability [17], before supporting use of web-based therapies. Concern about confidentiality was raised in 1 study, where health professionals expressed preferences for using secure email or an app over chat or video formats [24]. Qualitative studies identified protocols to address privacy and ethical practice in an information technology context [37,38].

Patient Factors

A total of 4 of 11 quantitative studies [22,23,33,34] incorporating data from 3144 health professionals, 9 of 14 qualitative studies (n=158) [25,26,35-38,40-42], and 3 of 4 mixed-methods studies (n=374) [29,30,43] raised issues related to patient factors. Most health professionals in a quantitative study [22] believed that web-based therapies would be appropriate for 20% of patients; health professionals in another study perceived barriers in 22% to 48% of patients [23]. One study argued that web-based therapies allowed patients to become active participants in their own recovery [40].

Nature and Severity of Symptoms

Patient factors identified in both quantitative and qualitative studies included the nature and severity of symptoms, with anxiety disorders commonly cited as a good fit for web-based therapy [26,34,43], and more complex or severe disorders viewed as a poor fit [26,37,40]. As anxiety and depression symptom severity increased from mild to severe, the disorders were seen as having decreasing fit for web-based therapy [34].

Individual Characteristics

Health professionals were concerned that comorbidity [25] or suicidal ideation required risk management [35]. It was also noted [30] that web-based therapy cannot easily take into account patient characteristics including comorbidity, needs and motivation, written expression, skills, and personality (including self-management). For example [37]:

I found for my anxiety clients, it worked quite well. For the depression clients, who are more severe, I found that they tend to take much longer...there's less motivation...those clients, maybe it would be better for them to like see somebody in person because there's a lot of other issues. [pg 44]

Accessibility

Health professionals identified access to face-to-face treatments as a factor, with several studies noting that web-based therapies were particularly attractive and useful to patients who could not readily access therapy [30] (eg, those with limited mobility, time, or access to local services [37,38], with perceived stigma [29], or in rural or remote locations [33]).

Practical Barriers

Health professionals expressed concern about practical barriers such as access to technology [23] or the internet [35,41]. Additional barriers included having poor literacy, not being “psychologically minded,” or having difficulties with vision or hearing [41]. Health professionals commented that their patients often had grade 6 to 8 reading levels and could not cope with the reading required [36]. This could also impact ability to complete written tasks [37]:

If they don't provide the information or if they're having trouble expressing exactly what the problem was, then it's obviously going to be more difficult. [pg 46]

Health Professional Factors

Health professional factors relevant to the uptake of web-based therapies were raised in 9 of 11 quantitative studies (n=4536) [22,23,31-33,44-47], 6 of 14 qualitative studies (n=96) [25-28,38,48], and 3 of 4 mixed-methods studies (n=407) [17,30,43]. Quantitative studies raised few health professional issues. A total of 3 studies suggested that psychodynamic therapists are less positive toward web-based therapy [22,32,46], but another found no difference [44]. One study found that openness to evidence-based practice predicted more favorable attitudes [32], whereas another found that expectations of ease of use predicted intentions to use web-based CBT [31]. The main issue raised was lack of familiarity with web-based therapy, consistent with the low uptake of these approaches generally [17,23,31,45,47].

Several barriers related to health professionals were raised in the qualitative studies. There were concerns about the technological skills and comfort level of health professionals [26,48]. Significant concerns were raised about workload issues: finding time to incorporate web-based treatment [28] and managing the different demands of electronic work [25]. A final factor raised by therapists was that they saw web-based

treatment as both less engaging and less taxing than face-to-face treatment. For example [27,38]:

I just felt like I was in a call centre rather than being a clinician working with patients who had difficulties. [pg 8]

You feel very much less burdened by [internet-based CBT] than in regular outpatient care. [pg 473]

The mixed-methods studies raised concerns related to health professionals' knowledge and training in web-based therapy. Motivation and use of web-based therapy were low, with reported rates of 2% [33] and 2.4% [43], in part reflecting misunderstandings about confidentiality and liability [33]. For example [30]:

My concern is not to get patients motivated to use the online modules, but to get therapists to use them. That is a much larger bump. Everything that is new is seen as more work, and everybody is already loaded with work and doesn't want more work. I'm afraid that pressure from management is the only way to get therapists to work with it. [pg 7]

The Therapeutic Relationship

A total of 4 of 11 quantitative studies (n=3755) [22,23,32,33], 6 of 14 qualitative studies (n=751) [25,27,28,38,39,48], and no mixed-methods studies explored the impact of web-based therapy on the quality of the health professional-patient therapeutic relationship. Across studies, health professionals who were experienced in web-based therapy held more positive views of the potential for a therapeutic relationship in web-based therapy [33,38,39].

Quantitative findings highlighted minimal concern among health professionals about establishing and maintaining a therapeutic relationship through mobile apps [23] or blended face-to-face and web-based therapy, although concerns were raised in 1 study that including serious games may lead to neglect of relationships and communication during therapy [22]. Health professionals in another large quantitative study indicated that they believed integrating web-based approaches in therapy would interfere with rapport [32].

Among qualitative studies, health professionals perceived the therapeutic relationship as *different from that in face-to-face therapy but not necessarily worse*, and some reported being surprised by their ability to develop relationships online [25]. Bengtsson et al [27] highlighted that the web context may extend the time needed to develop a therapeutic relationship but, as it is less confronting, may be particularly helpful in building relationships with patients with social anxiety.

Two studies reported the views of primary care physicians [28,48], who were ambivalent about the impact of web-based therapy on therapeutic relationships, noting that psychodynamic approaches relied on *open and active dialogue* between health professional and patient.

Models of Care

A total of 3 of 11 quantitative studies (n=677) [22-24], 8 of 14 qualitative studies (n=129) [14,25,28,35,36,38,39,42], and all

4 mixed-methods studies (n=440) [17,29,30,45] explored health professionals' views and preferences regarding models of care delivery incorporating web-based components. In addition, 9 studies [14,25,28,29,35,38,39,42,43] investigated use of web-based therapies as a stand-alone treatment, 2 studies [22,23] discussed preferences for serious gaming and mobile apps as an adjunct to therapy, and 3 studies [17,24,30] explored blending face-to-face and web-based components as part of an integrated approach to therapy. One study [36] included the views of mental health and primary care providers as 1 model of care delivery in a suite of telehealth options.

Among web-based therapy studies, views differed based on whether the therapy was guided or self-directed (low intensity). Although it was acknowledged that self-referral to self-help modules increased ease of access for patients [39] and made it more likely that patients were motivated to engage with treatment [14], there were concerns that this model of care did not provide sufficient health professional support, especially for challenging tasks [29,38]. Health professionals were more comfortable with guided self-help, as they perceived this as fitting more within the therapeutic role [38]. General practitioners trained to administer guided web-based CBT highlighted the challenges in integrating web-based therapy process issues into consultations [28]. Overall, there was a preference to use web-based therapy flexibly, possibly as an adjunct to face-to-face treatment, [38,42,43], as an option to support those on a waiting list for treatment [29] or as part of a stepped-care model [25].

Blended therapy was perceived as a viable alternative to a web-based model, as compatible with current clinical practice, and as raising few concerns about treatment efficacy with the inclusion of web-based components as part of a wider face-to-face model [17,24]. Models of care that incorporated serious gaming and use of mobile apps were perceived as potentially useful adjuncts to traditional therapy approaches to support skills development both during and after therapy [23,30].

Discussion

Principal Findings

Despite good evidence of efficacy in randomized controlled trials [5], the potential of web-based psychological therapies to increase access to mental health care has not been well realized in nontrial settings to date [49]. This is, to our knowledge, the first synthesis of quantitative and qualitative data on health professionals' perceptions of web-based therapy for mental health conditions (both primary and secondary to physical disorders). We found that health professionals perceived many barriers to routine use of web-based therapy and had strong views about appropriate models of care. While health professionals' concerns may not all be evidence based, health professionals are in many cases the gatekeepers to referral. Therefore, addressing their concerns is a key strategy to improve implementation, alongside ongoing education of health professionals so that they are familiar with the content, processes, and evidence base of web-based therapies and are comfortable with incorporating them into their model of care. The importance of thinking carefully about models of care

specifically in the context of web-based therapies has not been addressed adequately in the literature to date.

Health professionals' concerns corresponded closely with the 5 domains of the CFIR [13], with issues raised pertaining to intervention characteristics (eg, flexibility), the inner setting (eg, managerial support), the outer setting (eg, data security and privacy), characteristics of individuals (eg, their health and internet literacy), and the implementation process (eg, health professional education). Furthermore, they also accord with the much broader findings of a systematic review of reviews concerning factors that influence implementation of electronic health [50]. We found, as did the review of reviews, that the factors influencing implementation are multilevel and complex, with no single factor acting as a key barrier or facilitator.

This review suggests that for web-based treatments to maximize their acceptability to health professionals, they should incorporate the following features.

Consider Tailoring

Health professionals noted that the highly structured nature of many web-based therapies, while easier to navigate [27], may contribute to patients' sense of being funnelled through a preset and rigid program [25,27]. This accords well with surveys of patients regarding reasons for dropout from web-based programs. For example, in a qualitative study of patients who had dropped out of a transdiagnostic web-based therapy program, they noted the lack of specificity of content to their own particular problems [51]. Indeed, dropout rates for web-based compared with face-to-face programs are reported to be 10% to 15% higher, reinforcing the need for careful consideration of tailoring, as well as treatment credibility and engaging content, which also predict dropout [52].

Target a Subset of Patients

Even successful online clinics do not see web-based therapy as suitable for all individuals [49], and patients also report a preference for face-to-face treatment over web based [53]. This was reflected in our findings, as health professionals supported the potential utility of web-based therapies for a subset of patients only [22,23]. The findings suggest that, to increase referrals and uptake, web-based treatments should be targeted toward individuals with mild to moderate anxiety and depression, with limited comorbidity and low risk. Further patient factors that may lead to more referrals include sufficient computer literacy and access, good motivation, good health literacy, needing more flexible access to treatment, and concerns about stigma.

Use an Approach That Blends Web-Based Therapy With Face-to-Face Therapist Contact

Health professionals reported concern about wholly self-directed treatments, with a clear preference for blended treatments including some therapist face-to-face contact, as it affords a better opportunity to establish rapport and allows active monitoring and follow-up of patients as they move through online tasks [29,38]. This is in line with patient research, which showed a preference for face-to-face treatment over web based [53], and that adherence increased with therapist support [54].

Whereas health professionals who have no experience with web-based treatments are concerned about the therapeutic alliance, those who were experienced in supported web-based treatment were much less concerned. This suggests that models of care that incorporate some level of therapist support are likely to become more acceptable over time as health professionals become accustomed to the model.

Select Therapeutic Approaches and Content That Are Appropriate for a Web-Based Format

Prioritizing psychoeducation, monitoring, and skills practice, with more complex or interpersonal interventions reserved for face-to-face treatment, may make health professionals more confident in web-based treatments. Considering the balance between providing a clear structure and yet allowing content to be tailored to individual needs may also be important, although our review does not offer any clear guidance on how to optimally achieve that.

Educate Health Professionals in Web-Based Treatment

The vast majority of health professionals are unfamiliar with web-based therapies [17,23,31,45,47], and this needs to be addressed in order to increase rates of referral and use. Implementation of any model of care would need to consider how to educate health professionals about web-based therapy, including how to make appropriate referral decisions, find high-quality evidence-based resources, and incorporate web-based treatment as part of routine care.

Design a Supportive System

The review suggests that the broader setting for health professionals is important in successful implementation. This has 4 aspects.

First, the effect of web-based therapy on the work of frontline mental health care workers would need to be carefully considered to ensure that therapists have adequately engaging work and appropriate supervision in skills specific to web-based therapy such as written communication. Providing web-based therapy requires a different workflow from face-to-face treatment, and this would need to be managed. Web-based therapy was seen as both less rewarding and less draining than face-to-face work; the former was a strong disincentive to some health professionals, who felt that their engagement in, and sense of reward from, delivering expert and successful care was being taken from them [27,38]. A sense of reward is a key dimension of stress and burnout in occupational health [55], and work would need to be designed in a way that is satisfying for health professionals.

Second, the provision of adequate technological resources and support is important, as well as good data security.

Third, clear policies and procedures are needed regarding confidentiality, risk management, and liability issues.

Fourth, clear support and expectations from management regarding the use of web-based therapy are required, including impact on workflow and referral pathways for face-to-face therapy.

Limitations

This review identified only 29 articles examining health professionals' perspectives on web-based therapy. These articles varied considerably in terms of the population of health professionals included as participants, as well as the model of care that was being examined (eg, blended, self-directed), and are unlikely to give a complete picture. The main limitation in the literature so far is the inclusion of a very small proportion of health professionals who are experienced in web-based therapy, with most health professionals responding to questions in the absence of direct experience.

Comparison With Prior Work

This is, to our knowledge, the first systematic review of health professionals' perspectives on web-based therapy and provides a synthesis of the research to date.

Conclusions

The findings of this review echo the factors found in a recent article documenting the experiences of 2 successful online clinics [49], which identified the importance of considering the patient, therapists and their training, comprehensive organizational and systemic support, and the place of web-based therapies in models of care. These results have important implications for the implementation of web-based therapy, emphasizing that important preparatory work is required if implementation is to be successful, in the way the intervention is designed, the training and support health professionals receive, and the engagement of senior management in supporting the transition to a different model of care.

Further research is needed to examine the acceptability of specific models of care [2], which may vary in level of therapist support, timing of the intervention (waitlist, posttherapy, etc), positioning in stepped care, or the way it is incorporated in routine care. As health professionals gain experience with web-based therapies, it will be important for their perspectives to be sought again, to elicit perspectives grounded in real interactions and patient feedback. Interventions to educate and support health professionals in using web-based methods will need to be developed and evaluated. Finally, large-scale implementation studies that document the implementation strategies employed, uptake and retention rates, and effectiveness outcomes will be needed to provide a solid evidence base for this therapeutic approach moving forward.

Abstract

Background: HIV continues to disproportionately affect men who have sex with men (MSM) and transgender women (TW). Undiagnosed HIV is a major driver of HIV transmission rates, and increasing the uptake of regular HIV testing and facilitating timely initiation of HIV treatment is a global HIV prevention priority. However, MSM and TW experience a range of barriers that limit their access to testing and other prevention services. Given their growing ubiquity, digital communication technologies are increasingly being used to support HIV prevention efforts, and a growing number of studies have trialed the use of digital technology to promote HIV testing among MSM and TW.

Objective: We undertook a systematic review and meta-analysis to assess the impact of digital communication technology on HIV testing uptake among MSM and TW. Subanalyses aimed to identify the features and characteristics of digital interventions associated with greater impact.

Methods: A systematic literature review was undertaken using select databases and conference repositories. Studies describing the use of a digital technology—internet-enabled devices, including phones, tablets, and computers—to increase HIV testing uptake among MSM or TW using either randomized or observational cohort design with measurement of HIV testing rates measured pre- and postintervention, and published in English between 2010 and 2018 were included. Pooled effect estimates were calculated using a random effects meta-analysis. Subanalyses calculated effect estimates grouped by selected features of digital interventions.

Results: A total of 13 randomized or observational studies were included in the final review. Digital interventions most commonly used mainstream, existing social media platforms (n=7) or promotion through online peer educators (n=5). Most interventions (n=8) were categorized as interactive and allowed user engagement and most directly facilitated testing (n=7) either by providing self-testing kits or referral to testing services. A total of 1930 participants were included across the 13 studies. HIV testing uptake among MSM and TW exposed to digital interventions was 1.5 times higher than that of unexposed MSM and TW (risk ratio [RR] 1.5; 95% CI 1.3-1.7). Subanalyses suggested an increased impact on HIV testing uptake among interventions that were delivered through mainstream social media-based platforms (RR 1.7; 95% CI 1.3-2.1), included direct facilitation of HIV testing (RR 1.6; 95% CI 1.4-1.9), were interactive (RR 1.6; 95% CI 1.4-1.8), and involved end users in the design process (RR 1.6; 95% CI 1.3-2.0).

Conclusions: These findings provide broad support for the integration of technology with existing approaches to promote and facilitate HIV testing among MSM and TW. Our findings identified key features that may be associated with greater impact on HIV testing uptake and can be used to inform future development efforts given the growing interest and application of digital technologies in HIV prevention.

KEYWORDS

digital technology; men who have sex with men; transgender women; HIV testing; HIV prevention

Introduction

Globally, men who have sex with men (MSM) and transgender women (TW) are disproportionately affected by HIV [1-4]. Evidence of expanding epidemics among MSM have been noted, with new infections among this group comprising up to half of all incident cases in some regions, including North America [5-9], and up to approximately 70% in specific countries, such as the Philippines [7]. This burden of HIV occurs against a background of expanded access to HIV testing and treatment and the emergence and growing coverage of biomedical HIV prevention strategies [5].

The timely diagnosis of HIV plays an important role in preventing transmission, both by prompting reductions in risk behaviors to prevent onward transmission [10,11] and by facilitating early access to treatment and viral suppression. It is now known that people with suppressed HIV cannot transmit the virus to others [12-15]; promoting regular HIV testing is therefore a key global prevention strategy [16]. However, a range of barriers faced by MSM and TW limits their access to HIV testing and other preventive services. Stigma and discrimination remains a key deterrent to HIV service utilization in many parts of the world, particularly in settings where legislation prohibits same-sex relationships and legitimizes discriminatory behavior toward sexual minorities [17-19]. Other structural barriers, such as accessibility of services, costs, waiting time, and confidentiality concerns [20-24], also limit access to HIV testing among MSM and TW and prevent levels of testing coverage required to impact HIV incidence [25].

The use of digital communication technology—internet-enabled technology such as mobile phones, computers, and tablets that allow access to digital platforms and apps—to promote HIV testing among MSM and TW is an area of growing interest. Digital technology has assumed a prominent role in contemporary gay culture [26], and to a lesser extent in TW communities [27], as a tool to meet sex partners [28-30]. Evidence pointing to higher rates of condomless sex [31-33] and diagnoses of sexually transmitted infections (STI) [27,28,34,35] among MSM and TW who use online platforms to find sex partners suggests that online platforms may be appropriate targets for sexual health promotion. It has been suggested that internet-enabled technology can provide a discrete means for HIV health promotion in locations where same-sex behaviors are highly stigmatized or illegal [36], while the acceptability of HIV prevention interventions delivered through digital communication technologies has been noted among MSM and TW [37-43]. Together, these findings enhance the potential of using digital technology to reach those at high risk of HIV and serve as an important platform for health promotion outreach.

We performed a systematic review and meta-analysis to describe the impact of digital communication technology interventions

on the uptake of HIV testing among MSM and TW. Subanalyses were undertaken to identify intervention characteristics associated with increased impact.

Methods

Overview

We systematically searched for current literature that describes the impact of digital communication technology interventions on the uptake of HIV testing among MSM and TW. We defined digital communication technology as technologies that were internet-enabled (through devices such as computers, mobile phones, or tablets) and which provided access to digital platforms such as social media sites, websites, apps, and email. The systematic review was conducted in accordance with the Preferred Reporting for Systematic Reviews and Meta-Analyses guidelines [44] and was registered on PROSPERO (registration number CRD42017070055).

Eligible studies were defined as those that:

1. Utilized at least one digital communication platform to deliver an intervention to promote HIV testing
2. Reported uptake of HIV testing as a result of a digital communication intervention for MSM and TW participants
3. Measured impact either by prospectively comparing testing rates pre- and postintervention exposure within a single cohort or through a randomized study design.

Studies that measured HIV testing outcomes but utilized digital communication technologies primarily for a purpose not directly related to improving HIV testing uptake (eg, to facilitate data collection or recruitment) and those reporting intention to test outcomes only were excluded.

Uptake of HIV testing was defined as any quantitative count of HIV testing events among MSM and TW measured using either self-report or clinic records.

For randomized controlled studies, we report on HIV testing uptake among participants in the intervention and control groups at the study endpoint. For nonrandomized studies, we report on HIV testing uptake at pre-intervention baseline and postintervention study endpoints.

Search Strategy

We conducted a systematic search of the literature published in English using the Medical Literature Analysis and Retrieval System Online, or MEDLARS Online (MEDLINE), Cumulative Index of Nursing and Allied Health Literature (CINHAL), EMBASE, PubMed, and PsychInfo databases. We limited our search to studies published between January 1, 2010, and May 1, 2018, to account for the redundancy of older platforms and technologies. Our search strategy comprised key terms; Medical Subject Headings (MeSH) terms; and subject headings related to participant (eg, *MSM*), intervention (eg, *internet*), and outcome (eg, *HIV testing and counseling*) variables ([Multimedia](#)

Appendix 1 shows the illustration of search strategy and MeSH terms). Electronic repositories of the International AIDS Society and the International AIDS Conferences were manually searched for abstracts from January 2010 onward. Reference sections of the identified papers were also searched for additional papers. No restrictions were placed on participant age or other demographic characteristics of the study population or geographical location or setting of the intervention.

Data Extraction

Following the literature search, the first author (VV) removed duplicate records and assessed the remaining abstracts on the basis of the eligibility criteria. The second author (KR) reviewed a random sample (equivalent to 10%) of discarded abstracts to ensure accuracy. Both authors then conducted a full-text review of the remaining abstracts to determine their inclusion in the final analysis.

The following domains were extracted for final analysis by two authors (VV and KR) using a standardized, Excel-based tool: study identification, study design (data collection period, recruitment, and sampling method), intervention characteristics (aim of intervention, mode of intervention delivery, and duration), study population (inclusion and exclusion criteria, sample size, primary HIV testing outcome used and time frame for the outcome, the mean age of sample, proportion reporting previous testing), and results and analysis (number of testing outcomes, effect size measurement, and reported effect size).

Any discrepancies identified between the two authors during the review and data extraction process were discussed with a third author (MS).

Analysis

Qualitative Synthesis of Study Aims, Intervention Characteristics, and Study Outcomes

A qualitative synthesis was undertaken to characterize included studies by their study participants, location of study, study design, digital communication intervention platform, intervention features, length and frequency of exposure, sample size, and rated study quality. For each study, we then described the proportion of MSM and TW reporting previous HIV testing at baseline, how testing uptake was defined and measured during the study period, whether testing was provided or offered as part of the intervention, and the proportion of MSM and TW reporting or receiving HIV testing at the end of the study period.

The primary outcome of this study was uptake of HIV testing among MSM and TW participants, which we defined as the number of individual MSM and TW reporting or receiving an HIV test divided by the total number of MSM and TW exposed to a digital intervention. Intervention effectiveness was determined by manually calculating risk ratios (RRs) comparing testing uptake between exposed groups and unexposed groups for randomized controlled trials (RCTs) or between pre- and postintervention commencement for nonrandomized studies. HIV testing uptake among controls or at preintervention time point was used as the reference group so that an RR greater than one demonstrates a higher chance of HIV testing uptake following exposure to a digital communication intervention.

Meta-Analysis

We performed a meta-analysis of intervention effectiveness to generate pooled RR using a DerSimonian and Laird random effects model to account for the anticipated heterogeneity between studies. We identified a range of characteristics common to digital communication interventions or regarded as features that potentially enhance the intervention effectiveness and performed submeta-analyses to generate pooled RR to examine the impact of these characteristics on overall intervention effectiveness:

1. Intervention interactivity (yes/no): interventions that permitted end users to interact or engage, for example, by chatting with peer educators or other participants, as opposed to passive viewing of an online video
2. End-user involvement in the design process (yes, no, or not reported): any reported involvement of the intended end users in the intervention design process (eg, consultation and pilot testing)
3. HIV testing facilitated as part of the intervention (yes/no): interventions that directly provided (eg, provided self-tests) or facilitated (eg, direct referral) HIV testing to participants, as opposed to simply promoting HIV testing
4. Social media platform (yes/no): interventions implemented through an established social media platform (eg, Facebook) that facilitates social networking among the general population or specifically among gay and other MSM, as opposed to nonsocial media platforms
5. Single dose exposure (yes/no): interventions that delivered a single, time-bound exposure as opposed to multiple exposures over time.

The presence and magnitude of heterogeneity were assessed in meta-analyses using the χ^2 and I^2 tests, respectively. All statistical analyses were performed using Stata version 14 (StataCorp LP).

Assessing Study Quality

Study quality was assessed by two authors (VV and KR) using the quality assessment tool for quantitative studies [45]. This tool critiqued studies on the basis of selection bias, study design, confounders, blinding, data collection methods, and withdrawal and dropouts. Each criterion was rated as strong, moderate, or weak. On the basis of the combined scores, studies were given a final, global rating of strong (no weak ratings), moderate (one weak rating), or weak (two or more weak ratings). As the final global rating was determined by the number of subcategories scored as *weak*, the tool was modified to include an *N/A* option for blinding and withdrawal and dropout fields to account for nonrandomized studies. The first and second authors (VV and KR) met after completing the first two quality assessments to ensure consistency in the use of the tools. After consistency was confirmed, the two authors completed the remaining quality assessments, and the final results were compared and discussed. Similar to the process for data extraction, any disagreements between the assessments of the first and second author were discussed with a third senior author (MS).

Results

Search Results

The systematic literature search resulted in 1436 identified records, including 8 conference abstracts and 6 papers identified

in the references of the included studies. 37.30% (541/1436) were removed as duplicates. The remaining 909 records were reviewed at the abstract level, 4.4% (40/909) of which were retained for full-text review. Thirteen papers were included in the final analysis [46-58] (Figure 1).

Figure 1. The Preferred Reporting Items for Systematic Review and Meta-Analyses (PRISMA) flow diagram depicting study screening and selection.

Study and Sample Characteristics

Table 1 presents the characteristics of the included studies. All included studies specifically targeted men who identified as gay or self-reported anal sex with a male partner. Two studies included TW [53,54]. Study participants were typically aged in their midtwenties, and the overall level of educational attainment varied substantially across studies. On the basis of the World Bank classifications [59], the majority of studies took place in high-income countries (Hong Kong, n=1; Taiwan, n=1; and United States, n=6), 4 occurred in upper-middle-income countries (China, n=1 and Peru, n=3), and 1 in a low-middle-income country (India). The studies collectively included 8875 participants, 64 (0.70%) of whom were reported as TW, with a mean sample size of 682 participants (SD 808; range 56-3092 participants). Two studies excluded participants with a history of HIV testing, and two studies did not report on participants' previous testing history. Among the 9 remaining studies, the mean proportion of participants reporting a history of HIV testing was 44.1% (SD 19.0; range 21.3%-73.8%). The recall period for these studies varied, with one study reporting lifetime HIV testing history and the remaining studies using recall periods that ranged from 3 months to 3 years. A total of

10 studies used an RCT design [46-49,51,54-58]. The specific study design used by the remaining 3 studies was a prospective cross-sectional study with nonequivalent control group [50], a prospective single-group cross-sectional study [52], and a prospective cross-sectional matched-pair randomized trial design [53]. Due to the lack of individual-level randomization and nonequivalence of control groups, we calculated relative risk for these 3 studies using reported HIV testing uptake at preintervention baseline and postintervention endpoints in the intervention arm only. One RCT described two intervention arms and did not present disaggregated findings; therefore, this study was treated as a single cohort, and relative risk was calculated based on HIV testing uptake at baseline and endpoint [51].

Aims of Included Studies

Promoting HIV testing uptake was identified as the primary aim of all 13 studies. Five studies had multiple primary aims: mutual disclosure of HIV status with sexual partners (ie, asking and disclosing HIV serostatus [49]), STI testing [46], intention to test [47,51], and reduction of unprotected anal intercourse [49,50] (data not reported).

Table 1. Overview of included studies.

Reference	Description of study participants	Location (country of income classification ^a)	Total sample size	TW ^b participants, n (%)	Percentage of participants reporting previous HIV testing preintervention (time frame for testing history)	Study design
Bauermeister et al (2015) [46]	Inclusion criteria: Young MSM ^c aged 15-24 years, self-identified cis male, reported sex with a male partner in the past 6 months; sample characteristics: mean age 21 years, 92.3% educated to high school or GED ^e level	Michigan, United States (high)	130	0 (0)	73.8 (lifetime)	RCT ^d
Blas et al (2010) [47]	Inclusion criteria: MSM aged 18 years and above, reporting lifetime sex with another man, and not reporting testing within the past 12 months; sample characteristics: mean age 26.1 years (range 18-61), 42% educated to university or technical graduate level	Lima, Peru (upper middle)	459	0 (0)	21.3 (more than 1 year ago)	RCT
Blas et al (2014) [48]	NR ^f	Peru (upper middle)	400	0 (0)	NR	RCT
Hirshfield et al (2012) [49]	Inclusion criteria: male aged 18 years or above, reporting oral or anal sex with a current male partner and oral, anal, or vaginal sex with at least one new partner (male or female) in the past 6 months; sample characteristics: median age 39 years (range 18-81), 55% educated to college degree or higher level	United States (high)	3092	0 (0)	69.0 (past 3 years)	RCT

Intervention Characteristics of the Included Studies

Table 2 presents the characteristics of the digital interventions among the included studies. Studies utilized a variety of digital communication platforms to deliver interventions. Six used only social media platforms, 3 used only online videos, and 1 delivered a tailored online HIV/STI testing intervention through a customized website. The remaining 3 studies used multiple platforms: 1 used online videos in conjunction with motivational messages sent via email or instant messaging, 1 used social media and live chat apps, and 1 used online videos in conjunction with live chat apps.

Of the 7 studies that used social media, 5 delivered interventions using Facebook [50,51,55,57,58]. All of these studies used closed or private Facebook groups to promote HIV testing, using a range of accompanying features and modalities using internet popular opinion leaders to disseminate HIV-related information and engage in conversations about HIV testing, prevention, and risk behavior [50]; using trained peer educators to deliver HIV prevention and testing information and promote HIV testing uptake [55,58], including through the provision of HIV self-tests [57]; delivering weekly videos promoting HIV testing alongside moderated group discussion [47]; and sending

HIV prevention and HIV testing promotion messages (in conjunction with messages sent by WhatsApp and email) [51].

Two social-media-based interventions were delivered through sites specifically targeting the gay community [52,53]. Both reported on the Cyber-Based Education and Referral/testing (CyBER/testing) intervention, which utilized trained peers to promote HIV testing through existing social and sexual networking sites popular among the gay community. CyBER/testing was implemented through an existing chat room used by MSM [52] and later through four geographically focused social media sites used by MSM and TW [53], both in the United States.

Only one intervention was delivered through a custom-built website (Get Connected!), which aimed to promote and connect HIV and STI testing to young MSM [46]. The website delivered customized content to participants based on sociodemographic, sexual identity, and behavior and previous engagement with HIV testing data provided during a baseline assessment, so that messaging and content were personalized to mirror participant profiles, and experiences with testing, including motivations and perceived barriers.

Four studies used online videos to promote HIV testing [47-49,54]. One used single-session online videos focusing on HIV prevention to motivate HIV testing among MSM in the United States, in which participants received either dramatic- or documentary-style videos, or both [49]. A 2010 intervention delivered one 5 min video promoting HIV testing customized based on self-reported sexual identity (gay or nongay identified) to MSM in Peru [47]. In 2014, this intervention was repeated with the addition of motivational messages sent by email or instant messaging to encourage HIV testing to MSM in Peru [48]. Finally, online videos developed with crowdsourced content depicted two Chinese men falling in love and getting tested together to target MSM and TW naïve testers in China [54]. One study used online videos in combination with live chat apps to deliver a home-based HIV self-testing service to MSM in Hong Kong [56]. In this study, all participants were exposed to an online video promoting HIV testing, and then, the participants in the intervention group were offered a home-based self-testing kit and online, real-time HIV pre- and posttest counseling and instruction through Line, WhatsApp, or Skype.

Regarding the length of intervention and the frequency of exposure, interventions that used online videos were typically shorter in duration and involved a single exposure to a video [47,54,56]. Two studies sent multiple videos [49,55] and one combined videos and motivational messages via text, email, or instant messaging but did not report on the length or number of

videos and frequency of motivational messages [48]. The customized website-based intervention [46] also provided a single exposure to the website content, but data on the length of time spent on the website were not reported.

Most interventions (n=8) were categorized as interactive for their ability to allow user engagement, for example, through social media platforms, responses on messaging platforms or through email, or via a website. Interventions involving online peer educators interacting with participants through social media platforms were typically longer in duration, ranging from 12 weeks [51,57,58] to 12 months [53]. The frequency of exposure to online peer educators was user-determined, that is, participants were free to choose how often, if at all, they interacted with online peer educators. The exception involved participants receiving twice weekly messages through Facebook, email, or instant messaging, over a 12-week period [51].

Seven studies directly facilitated HIV testing, through the provision of HIV home or self-testing kits [56,57]; referrals to specific, local HIV testing clinics [47,48,58]; or providing location details of free, local HIV testing sites [51,55]. The remaining six studies provided general promotion of HIV testing only.

Five studies specifically mentioned the involvement of intended end users in the implementation design process [46,47,52,55,56]. Theoretical underpinning to intervention development was described by 9 studies [46,47,49,51-53,55,56,58] (Table 2).

Table 2. Characteristics of digital interventions of included studies.

Reference	Platform	Description	Interactive	Intervention length (frequency of exposure)	HIV testing provided or facilitated	Measurement of HIV testing uptake used	Length of follow-up period for outcome	Comparator	Involvement of end users in intervention design	Theoretical framework
Bauermeister et al (2015) [46]	Website	Interactive, customized website (Get Connected!) that delivered HIV/STI ^a testing and prevention content tailored to specific participant profiles of based on psychosocial data and previous engagement with HIV testing	Yes	One time	No	Self-reported	30 days	Control group: test-location website	Yes	Self-determination theory principles and integrated behavioral model
Blas et al (2010) [47]	Online video	One 5-min video delivered through existing gay and commercial websites promoting HIV testing customized based on self-identification of participant as either gay or nongay	No	One time (5 min)	Yes—facilitated (referral)	Attendance based	125 days ^b	Control group: standard public health text	Yes	Health belief model
Blas et al (2014) [48]	Multiple: online videos, email/instant messaging	Motivational videos and messages about HIV testing sent through email and instant messaging, respectively	No	NR ^c	Yes—facilitated (referral)	Attendance based	184 days ^b	Control group: health promotion message with invitation for free HIV testing	No or not reported	None reported
Hirshfield et al (2012) [49]	Online video	HIV prevention videos in either dramatic or documentary style (or both), accessed via banner ads on gay-oriented sexual networking sites, and designed to promote critical thinking about HIV disclosure, testing, and condom use	No	One time (9 and 5 min)	No	Self-reported	60 days	Control group: no content	No or not reported	Social learning theory
Ko et al (2013) [50]	Social media (Facebook)	Trained internet popular opinion leaders promoting HIV testing and prevention to members of a closed Facebook group	Yes	6 months (user-dependent)	No	Self-reported	6 months	Baseline	No or not reported	None reported

Reference	Platform	Description	Interac- tive	Interven- tion length (frequen- cy of ex- posure)	HIV test- ing provid- ed or facili- tated	Measure- ment of HIV test- ing uptake used	Length of fol- low-up period for out- come	Compara- tor	Involve- ment of end users in inter- vention design	Theoretical framework
Patel (2016) [51]	Multiple: social media (Facebook); on-line live chat apps (WhatsApp); email	16 health promotion messages promoting HIV testing framed in either approach or avoidance style of messaging sent by trained peers via their preferred modality (private Facebook group, individual WhatsApp messaging, or email)	No	12 weeks (twice weekly)	Yes—facilitated (test locator)	Self-report- ed	12 weeks	Baseline	No or not reported	Informa- tion motiva- tion behav- ioral skills model
Rhodes et al (2011) [52]	Social media (MSM ^d -specific sites)	Trained peer posting regular triggers about HIV and HIV testing in existing chat room used by gay and other MSM and engaging in direct communication about testing services, processes, and locations with chat room users	Yes	6 months (daily)	No	Self-report- ed	6 months	Baseline	Yes	Natural helping
Rhodes et al (2016) [53]	Social media (MSM-specific sites)	Trained peer posting regular triggers in four existing social media sites used by gay and other MSM about HIV and HIV testing and engaging in direct communication with users about testing services, processes, and locations	Yes	12 months (daily)	No	Self-report- ed	12 months	Baseline	No or not reported	Empower- ment educa- tion, social cognitive theory, and natural helping
Tang et al (2016) [54]	Online video	Online video promoting HIV testing based on a crowdsourced design accessed via banner ads placed on gay-oriented social networking platforms	No	4 weeks (one time)	No	Self-report- ed	3 weeks	Control group: noncrowd sourced online video (standard public health text)	Yes	None re- ported
Washington et al (2017) [55]	Social media (Facebook)	Five, 1-min long videos promoting HIV testing sent through a private Facebook group to black or African American MSM, with moderated group discussion	Yes	6 weeks (weekly)	Yes—facilitated (test locator)	Self-report- ed	6 weeks	Control group: closed Facebook group receiving generic health information	Yes	Integrative model of behavior change

Outcomes of the Included Studies

Table 3 presents the reported outcomes of studies using the RCT study design. Most RCT studies measured testing uptake through self-reports [46,49,54,55]. The length of follow-up over which testing was measured varied greatly from 3 weeks [54] to 6 months [56].

On the basis of the calculated RRs, 3 of 9 RCTs demonstrated a significant improvement in HIV testing uptake [55,56,58], whereas 4 demonstrated nonsignificant improvements [46,47,49,54]. The two remaining RCTs did not demonstrate any impact; in one RCT, testing uptake was extremely low in both intervention and control arms [48], and in another, no members of the control group tested for HIV during follow-up [57].

^aN/A: not applicable.

Table 4 presents the outcomes from nonrandomized studies. All of the 4 nonrandomized studies relied on self-reported HIV testing uptake. The length of follow-up ranged from 12 weeks [51] to 12 months [53], and all 4 studies demonstrated significant improvements in testing uptake based on calculated RRs (**Table 4**).

Across all 13 studies included in this review, 21.75% participants (1930/8875) received an HIV test during a cumulative 3.6 years of study follow-up. Three studies reported on HIV diagnoses (all RCTs) [47,54,56], with 75 new HIV infections detected across these studies (56% in the intervention arm; data not reported).

Table 4. Reported HIV testing outcomes in included quasi-experimental studies.

Reference	Baseline		End line		Risk ratio (95% CI)
	Total number of participants	Participants tested, n (%)	Total number of participants	Participants tested, n (%)	
Ko et al (2013) [50]	501	150 (29.9)	499	219 (43.9)	1.5 (1.2-1.7)
Patel (2016) [51]	130	42 (32.3)	130	57 (43.8)	1.4 (1.0-1.9)

Meta-Analysis

Primary Outcome

The pooled RR across 12 studies (RR could not be calculated for one study because no tests were recorded in the control arm)

[57] indicated a significant increase in the uptake of HIV testing following exposure to digital interventions (RR 1.5; 95% CI 1.3-1.7). Statistical heterogeneity was high ($\chi^2_{11}=31.7$; $I^2=65.2\%$; **Figure 2**).

Figure 2. Forest plot of relative risk of HIV testing uptake among MSM and TW following digital intervention exposure.

Subanalysis of the Study Characteristics

A positive impact was seen on the HIV testing uptake across all intervention type subanalyses. The highest pooled RR was seen for interventions that were delivered through the mainstream social media-based platforms (RR 1.7; 95% CI

1.3-2.1), interventions that included direct facilitation of HIV testing (RR 1.6; 95% CI 1.4-1.9), interventions that were interactive (RR 1.6; 95% CI 1.4-1.8), and interventions that involved end users in the design process (RR 1.6; 95% CI 1.3-2.0; [Table 5](#)).

Table 5. Subanalyses by selected study and intervention characteristics.

Intervention characteristic	k ^a	Risk ratio (95% CI)	χ^2 (df)	I ²

^ak: number of studies included in the subcategory.

Study Quality

The majority of studies (n=8) were classified as *moderate* quality [46,47,52-56,58], 4 were classified as *weak* [48-51], and 1 was classified as *strong* [57]. The most common limitation across studies was insufficient description of blinding procedures (rated as *weak* in 9 studies), whereas controlling for confounding in

either study design or analyses was a common strength (rated as *strong* in 9 studies; [Multimedia Appendix 2](#)).

The observed asymmetry in the study funnel plot ([Figure 3](#)) may be explained by the heterogeneity between studies, given the variability in the intervention design. The attribution of asymmetry to heterogeneity is also supported by the high level of variance between studies (I²=65.2%).

Figure 3. Funnel plot for estimating publication bias and precision of estimate.

Discussion

In this systematic review, exposure to digital communication interventions was associated with greater HIV testing uptake among MSM and TW compared with those unexposed to digital communication interventions. Our findings provide broad support for the integration of technology into existing tools and approaches to HIV prevention among MSM and TW. We extend the current state of evidence regarding the impact of digital interventions on HIV testing by examining the role of key intervention features on effectiveness. Our findings identified key features that were associated with greater uptake for HIV testing for MSM and TW—specifically, interventions that facilitate HIV testing through provision or direct referral to HIV testing services, the use of mainstream social media platforms to engage the target population, interactivity, and involvement of end users in design processes.

Global guidance has recommended the integration of digital technology as a strategy to enhance the reach and effectiveness of HIV prevention efforts among MSM and TW [36,60]. Numerous acceptability studies have identified that MSM would be willing to use phone- and web-based technologies for HIV prevention [39,40,61,62]. Recent systematic reviews have explored the potential of digital technology to advance various HIV priorities among MSM and other key populations [63,64]. One systematic review to date has attempted to quantify the role of digital communication technologies in increasing engagement among key populations across the care continuum through meta-analysis [65]; this study specifically looked at randomized and observational studies describing the impact of social media-based interventions on HIV testing uptake among key populations. All 9 studies included in this meta-analysis targeted MSM and were collectively associated with an approximately 50% increase in HIV testing uptake. Compared with this review, our study adopted a broader definition of digital interventions that encompassed websites, online videos, instant messaging, and live chat apps, resulting in the inclusion of 6

additional studies. Overall, we found that exposure to digital interventions was associated with an approximately 50% increase in HIV testing uptake, in line with the previous study's estimates, supporting the conclusion that digital communication technologies are effective in promoting HIV testing among MSM and TW. Interventions included in this review invariably took advantage of various online engagement tools such as videos, digital messages tailored to participant profiles, and online social networking and compared the outcomes with more generic and less interactive online messaging. The impact of digital communication technology to increase testing uptake may be even greater when compared with more traditional health promotion mediums such as messaging through public media (such as posters and billboards). In addition, our study identified specific features of digital interventions associated with greater impact on HIV testing uptake among MSM and TW.

First, interventions that went beyond creating general demand for testing, either through health promotion or providing educational content, and instead directly facilitated HIV testing through service referrals or the provision of self-tests demonstrated greater impact on HIV testing uptake compared with the overall estimate. Direct facilitation of HIV testing may potentially address some of the more structural barriers MSM and TW face to HIV testing [17,66,67]. In particular, HIV self-testing has emerged as a strategy to mitigate barriers related to HIV service access [68,69]; however, some MSM and TW populations have expressed concerns about the limited availability of support during the testing process [70,71]. The study by Wang et al [56] included in this review suggests that digital interventions can play a role in promoting HIV self-testing by mitigating user concerns through the provision of real-time, online counseling. It should also be noted that the majority of studies included in this review recruited participants with generally high levels of previous HIV testing behaviors, which may be critical to the success of this approach. Past research has shown that a history of testing is a strong predictor of future testing behaviors among MSM [72-74], suggesting

that the direct facilitation of testing through digital communication interventions may work best for those who are experienced in HIV testing and may enable participants to access more frequent testing.

Second, interactive interventions—those that allowed participants to engage directly with online content or other users—demonstrated greater impact on HIV testing uptake compared with the overall pooled estimate. Interactivity in digital interventions has been associated with achieving a greater impact on behavior change across a range of health areas [75-77] and has been identified as a desired feature of digital HIV prevention interventions among MSM and TW [43,78]. Third, our subanalysis also identified that interventions that used mainstream social media platforms, such as Facebook, were also associated with greater uptake of HIV testing. However, all interventions that utilized social media platforms were also categorized as interactive, making it difficult to isolate the source of the enhanced effect. Social networking-based interventions are commonly used for sexual health promotion [79], and the use of existing social media platforms has been identified as a way to enhance retention among young MSM and TW in online HIV prevention activities [43]. Using existing and well-utilized social media platforms may also enhance the reach of digital HIV prevention interventions [80] compared with those that are delivered through new or separate platforms. Interestingly, interventions that used social media sites specifically for gay and other MSM were less effective in increasing HIV testing uptake than interventions delivered through general social media. Others have noted the reluctance of users of gay social networking sites to receive health promotion messages, which are often seen as an intrusion or surveillance and may limit user engagement [81].

Fourth, evidence of enhanced impact was found among digital interventions that reported involvement of end users in the design process. This involvement is a key component of user-centered design, an approach that prioritizes user needs and experiences to maximize functionality and increase engagement and relevance to the target population [82-84]. User involvement is particularly important when developing digital interventions tailored to specific target populations to ensure that such interventions appropriately reflect group priorities, preferences, and culture [83]. Although the literature confirms the value of user-centered design, our review only assessed studies on whether any involvement of end users in the design process was reported; however, it is probable that the quality and depth of this involvement may be a stronger determinant of overall effectiveness. In addition, grounding in theoretical frameworks may also be another indicator of effectiveness, as suggested by the greater uptake of HIV testing reported by theoretically based interventions included in this review. Although the majority of studies in this review reported a

theoretical basis for their intervention, the limited number of theory-based, HIV-focused digital interventions have been noted by others [85,86]; this may be attributed to the speed of development and proliferation of digital approaches to improving HIV outcomes. The findings presented here suggest that theoretical grounding is an important component of effective interventions and should be prioritized in future development.

The findings of this review should be considered with the following limitations. First, due to the restrictions we placed on study design, the interventions included in this review reflect only those conducted as research projects and may not reflect the real-world application of digital technology, including interventions that were not formally evaluated or represented in the published literature. Second, despite our finding that the digital interventions included in this review had a positive overall effect on HIV testing uptake among MSM and TW, the findings do not necessarily reflect the actual quality of the content delivered or levels of end-user acceptability, which are likely to interact in important ways with intervention impact. Third, TW participants were underrepresented in the included studies. TW may use social and sexual networking apps less frequently than MSM, which may reflect the limited number of social and sexual networking sites specifically catering to TW relative to MSM [87]. However, factors such as TW's reported reliance on online sources of sexual health information [88], perceived acceptability of digital approaches to HIV prevention [43], and examples of real-world applications of digital communication technologies to HIV prevention among TW [87] suggest that TW also stand to benefit from digital approaches to HIV prevention and their inclusion in future trials should be prioritized. Finally, the majority of studies were conducted in high- or middle-income settings. Although the use of digital technology to advance HIV prevention priorities in low-resource settings has been both recommended and applied [64,89], further research is warranted to assess the impact of digital interventions of HIV testing among MSM and TW in these settings.

HIV testing is a key focus of global HIV prevention efforts among MSM and TW, yet multiple barriers continue to prevent levels and frequency of testing required to facilitate the early detection of undiagnosed HIV and initiation of treatment. Digital communication technologies are now an accepted medium for HIV prevention efforts; this review provides further evidence of the role of such technologies in increasing HIV testing uptake among MSM and TW. The inclusion of intervention features such as direct facilitation of HIV testing, involvement of end users in the design process, interactivity, and delivery through the existing mainstream social media platforms may enhance the overall impact and maximize the contribution of digital communication technologies to advancing HIV prevention priorities among MSM and TW.

Acknowledgments

This study formed part of the PhD of VV, who was funded through an National Health and Medical Research Council post graduate scholarship.

Authors' Contributions

VV, MS, ML, and MP were responsible for study design; VV and KR conducted the literature review and data extraction; and VV analyzed data and developed the manuscript. KR, ML, AP, CH, and MS provided input into manuscript development. All authors have read and approved the final manuscript before submission.

Abstract

Background: Breast cancer has become one of the most frequently diagnosed carcinomas and the leading cause of cancer deaths. The substantial growth in the number of breast cancer patients has put great pressure on health services. Meanwhile, the information patients need has increased and become more complicated. Therefore, a comprehensive and in-depth understanding of their information needs is urgently needed to improve the quality of health care. However, previous studies related to the information needs of breast cancer patients have focused on different perspectives and have only contributed to individual results. A systematic review and synthesis of breast cancer patients' information needs is critical.

Objective: This paper aims to systematically identify, evaluate, and synthesize existing primary qualitative research on the information needs of breast cancer patients.

Methods: Web of Science, EBSCO, Scopus, ProQuest, PubMed, PsycINFO, The Cochrane Library, the Cumulative Index to Nursing and Allied Health Literature were searched on February 12 and July 9, 2019, to collect relevant studies. A Google Scholar search, interpersonal network recommendations, and reference chaining were also conducted. Eligible studies included qualitative or mixed-methods studies focusing on the information needs (across the cancer continuum) of breast cancer patients or their social networks. Subsequently, a Critical Appraisals Skills Programme checklist was used to assess the quality of included research. The results, findings, and discussions were extracted. Data analysis was guided by the theory-generating meta-synthesis and grounded theory approach.

Results: Three themes, 19 categories, and 55 concepts emerged: (1) incentives (physical abnormality, inquiry from others, subjective norm, and problems during appointments); (2) types of information needs (prevention, etiology, diagnosis, clinical manifestation, treatment, prognosis, impact and resumption of normal life, scientific research, and social assistance); (3) moderating variables (attitudes, health literacy, demographic characteristics, disease status, as well as political and cultural environment). The studies revealed that the information needs of breast cancer patients were triggered by different incentives. Subsequently, the patients sought a variety of information among different stages of the cancer journey. Five types of variables were also found to moderate the formation of information needs.

Conclusions: This study contributes to a thorough model of information needs among breast cancer patients and provides practical suggestions for health and information professionals.

KEYWORDS

breast cancer patients; information needs; incentives; moderating variables; meta-synthesis

Introduction

Breast cancer is one of the most commonly diagnosed malignant tumors worldwide [1]. In 2018, around 2.1 million new female breast cancer cases were diagnosed worldwide, accounting for almost 25% of the cancer cases among women [1]. In the United States, an estimated 42,260 breast cancer deaths were predicted in 2019 [2]. The dramatic growth in the number of breast cancer patients has led to an increasing need for information to manage symptoms [3], make decisions, control lives, and prepare for the future [4]. However, information needs have not been thoroughly examined. For example, a lack of targeted education materials has been reported in clinical practice [3]. Several large-scale patient investigations have identified inadequate and inaccessible patient information [5]. Therefore, it is crucial and challenging for health service providers to systematically investigate patients' information needs and offer relevant information.

We identify two existing reviews on breast cancer patients' information needs. A review of relevant literature published between 1988 and 1998 classified individual studies to examine information needs and source preferences of breast cancer patients and their family members at different points in their cancer journey [6]. They found that essential information needs changed over time, and family members also needed information to support the patients. A recent protocol for a scoping review has been put forward that aims to summarize studies exploring information needs, source preferences, and engagement behaviors of women with a specific breast cancer type (metastatic) [5]. However, it does not address the specific information needs of general breast cancer patients, and no further findings have been published. Therefore, there is no updated review and synthesis of breast cancer patients' information needs.

There is a large body of qualitative studies that have mainly collected data through interviewing and nonparticipatory observation on this topic. These studies contribute to an insightful understanding of patients' information needs and characteristics [7], but they have mostly focused on particular topics with limited samples and produced mixed results. For example, different results have identified the information needs of patients in specific age groups [8,9]. Therefore, a qualitative meta-synthesis will help to address the mixed results and establish a general model of the information needs of breast cancer patients.

To narrow these gaps, this study aims to identify, evaluate, and synthesize existing primary qualitative research on the information needs of breast cancer patients and generate an integrated model to articulate their information needs (ie, incentives, types and moderating variables) across the cancer care continuum. The findings can inform health professionals and information service providers to help breast cancer patients receive appropriate information and be well equipped to cope with the disease.

Methods

This study follows the processes of theory-generating meta-synthesis [10] and grounded theory [11].

Search Strategy

The search strategy was first developed for Web of Science (Clarivate Analytics) and then adjusted to search EBSCO, Scopus, ProQuest, PubMed, PsycINFO, The Cochrane Library, and the Cumulative Index to Nursing and Allied Health Literature. These databases were chosen based on related studies [12,13]. In addition, a Google Scholar search, interpersonal network recommendations, and reference chaining of the included articles were applied. The literature search was conducted on February 12, 2019, and updated on July 9, 2019. Duplicate articles were removed.

Search terms were chosen from two categories: breast cancer patients and information needs. The search terms were chosen according to MeSH vocabulary [14] and related research on information behavior [15-20] (see [Multimedia Appendix 1](#) for the detailed search strategies). "Behavio*," "seek*," "source*," and other words were added so all related studies could be identified since findings on information needs may have also been covered in information behavior research (eg, what information did the patients search?). Limits on research methods were not initially placed on the search terms since it was difficult to accurately identify all qualitative studies when searching for the literature on this topic in the databases [21]. Therefore, qualitative studies were selected in the screening process.

Selection Criteria

Articles were selected according to inclusion and exclusion criteria [12,13] ([Textbox 1](#)).

Textbox 1. Selection criteria for the study.

Inclusion criteria:

- Empirical studies using qualitative or mixed research methods
- Studies focusing on breast cancer patients or support groups encompassing breast cancer patients (can include other types of patients)
- Studies related to information needs

Exclusion criteria:

- Reviews or patents
- Mixed-method studies from which no qualitative findings can be extracted
- Studies focusing on participants with the risk of breast cancer (family history)
- Studies concerning breast cancer patients' relatives, friends, or spouses
- Studies concentrating on doctors of breast cancer patients
- Studies related to breast cancer patients and other kinds of participants that fail to distinguish breast cancer patients from other groups

Screening

The first author and three members of the research team (Juan Xie, Ying Cheng, and Ya Chen) browsed the titles and abstracts to identify possible studies. The full texts of these studies were then retrieved for further screening based on the inclusion and

exclusion criteria. The screening was conducted separately by the four authors, and disagreements were addressed through discussion. An additional 5 articles were found through a snowballing literature track. Finally, 47 full-text articles were included after removing one duplicate. The literature search process is illustrated in [Figure 1](#).

Figure 1. Flowchart of searched, excluded, and included items.

Quality Appraisal

The quality of the included studies was appraised using the Critical Appraisals Skills Programme [22] (see [Multimedia Appendix 2](#) for scores). As shown, all 47 studies received a score indicating high quality (ie, over 8). Therefore, no paper was excluded through this appraisal. A total of 38 articles received a score of 10, which indicated that they fully reported their research objectives, qualitative research methods, research design, recruitment strategy, data collection methods, relationship between researchers and participants, ethical issues, data analysis, statement of findings, and value of the research [22]. Nine articles scored 9 indicating that they did not clearly

describe the research objectives, method of data analysis, or ethics statement.

Data Extraction and Synthesis

All six researchers independently read and extracted the results, findings, and discussions of the included qualitative studies. To extract as many relevant findings as possible, researchers discussed, reached consensus, and adopted the same codes to analyze the articles.

The extracted data were iteratively synthesized in three stages. First, four authors (HL, JX, Y Cheng, and LS) identified the concepts that best fit the extracted raw texts. Categories were

then formed by gathering concepts with the same properties and dimensions through continuous comparison. Second, the relationships among categories were also examined. Themes emerged after an in-depth analysis and classification of categories. Third, concerning the evidence found in the extracted data, all themes were integrated according to their logical relationship. Finally, a model clarifying the information needs of breast cancer patients was built.

Results

Overview of the Literature

In all, 47 journal articles were included. The characteristics of the included studies are shown in [Multimedia Appendix 2](#). The data collection methods used in these studies were semistructured interviews, focus groups, observations, an online survey, and/or an open-ended questionnaire. Most studies applied thematic analysis, content analysis, and grounded theory to analyze the data. The recruitment strategies were generally convenience sampling and purposive sampling. These studies were conducted in the United States (13), Australia (12), United Kingdom (7), Canada (10), Turkey (1), Japan (1), Iran (1), Poland (1), and Switzerland (1). As for the populations, 26 studies reported the race of the participants, among which 18 studies focused mainly on white participants (over 60%), and 6 studies recruited all Asian participants (eg, Japanese and Chinese-Australian). Participants of one study were all African American. In addition, one study recruited mixed participants such as Asian, white, and Filipino. In terms of the types of information patients sought, the studies revealed that participants wanted information from various sources, encompassing information from health care providers (47); peers/support teams (24); the internet (18); books (14); cancer organizations (13); families (13); friends/coworkers (13); brochures and pamphlets

(12); magazines (9); audio/videos (7); complementary, alternative, or unconventional practitioners (6); newspapers (4); libraries (3); television (3); telephone hotlines (3); medical records (2); and broadcasts (1). In addition, 10 studies used theoretical frameworks, such as planned behavior theory and social learning theory, in their research.

Synthesized Findings

Summary

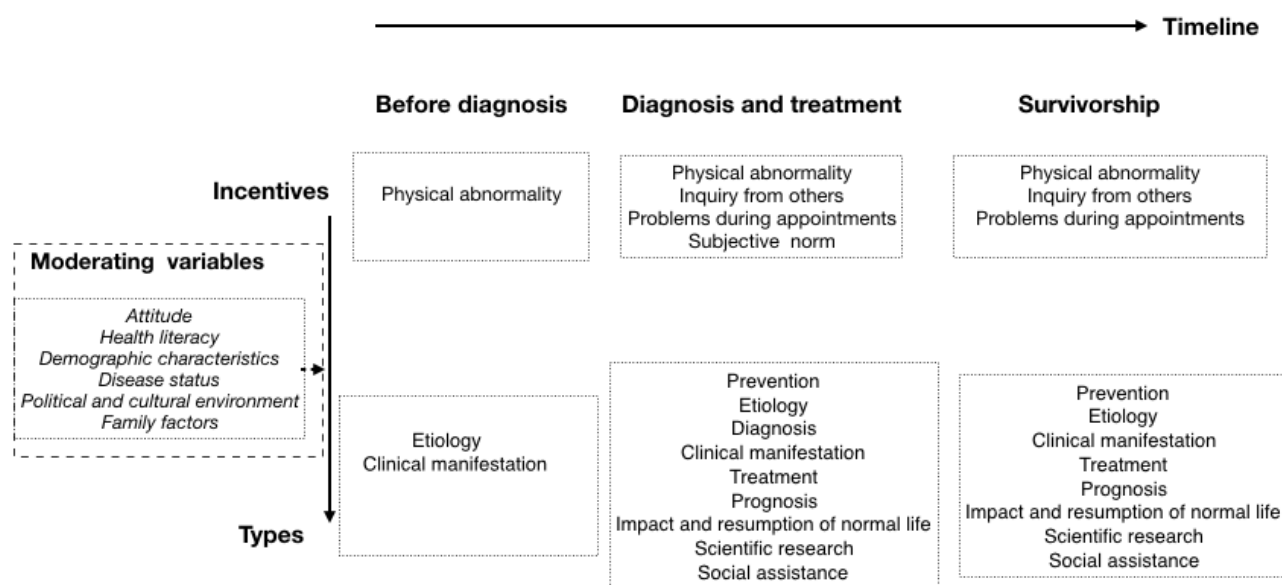

Three themes emerged to articulate the developing process of information needs of breast cancer patients, with 19 categories and 55 concepts underpinning the themes ([Table 1](#)). This study also explored the logical relations between themes and built an integration model ([Figure 2](#)) guided by incentive theory [23]. According to the theory, individual activities are not only derived from internal motivation but are also stimulated by external factors, including positive and negative incentives [23]. The process of diagnosis and treatment in breast cancer patients' journeys is sequential [24] and often accompanied by various diagnostic approaches and treatment regimens in a clinical context [24]. Therefore, diagnosis and treatment were synthesized as one stage in this study (phase 2). Consequently, we identified another two phases. Phase 1 is the stage before diagnosis: before going to the hospital for medical advice or examination in allusion to physical abnormalities. Phase 3 is conceptualized as survivorship. Incentives and content of patients' information needs vary in each of the phases. In particular, 7 studies reported the content and incentives of information needs before diagnosis (phase 1), while 44 studies focused on diagnosis and treatment (phase 2) and 29 studies presented information needs during survivorship (phase 3). Variables moderating the formation of information needs are also shown in the model.

Table 1. Synthesized results of the studies.

Themes, categories, and concepts		Examples of quotations	References
Incentives			
Physical abnormality	Appearance of symptoms of the primary tumor; appearance of symptoms of side effects	"Information needs also became more prevalent when patients experienced side effects..." [25].	[9,25-38]
Inquiry from others	Inquiry from doctors; inquiry from patients around them; inquiry from general people around them	"I was being asked so many questions from those around me, and I wished if I have asked the physicians these questions and knew its answers" [36].	[26,31,32,36,39]
Subjective norm	Advice from support group member	"Leigh followed the advice of another medically savvy support group member and requested copies of 'everything' regarding her diagnosis" [40].	[40]
Problems during appointments	Time span; perfunctory doctors; changes in health care staff; inconsistent information	"When this time frame was more than 4 weeks, patients found it hard to remember everything that had been discussed. They therefore had additional information needs that required attention during their planning appointment" [25].	[25,30,37,41]
Types of information needs			
Prevention	Effectiveness of breast self-examination; prevention for family members	"Themes related to important content issues include:...prevention for daughters" [30].	[30,40,42,43]
Etiology	Internal factors; external factors	"The exchange of misinformation also led many of the women interviewed...to hold misconceptions about breast cancer including misconceptions about risk factors...of the disease" [36].	[36,40,42,44]
Diagnosis	Specific biopsy procedures; pathologic results; precision and applicability of examination tools; explanations of technical terms related to diagnosis; clinical stage; waiting time of diagnostic tests and its impact on prognosis	"Faced with having to go for a mammogram, the women were concerned that this imaging tool lacked the precision needed to detect a tumor through dense breast tissue...the mammograms don't work with young women" [9].	[9,36,40,43,45-47]
Clinical manifestation	Symptoms of the primary tumor; symptoms of side effects; meaning of corresponding symptoms	"Participants reported a preference for a list of signs and symptoms of breast cancer recurrence as a means to reduce unnecessary anxiety" [48].	[30,33,36,37,43-45, 48-50]
Treatment	Treatment options; side effects of treatment; management of side effects; treatment preparation; treatment procedures; treatment evaluation summaries; prevention of recurrence	"A small number of women also reported asking the health care provider which treatment option they would recommend" [28].	[8,9,25,26,28-66]
Prognosis	Survival rates; risk of complications; survival statistics of treatment regimens; risk of recurrence	"The search for survival statistics proved fruitless, though, since such information cannot simply be applied to an individual case to determine prognosis" [26].	[26,27,30-32,42,46,47, 51,54,55,59,66]
Impact and resumption of normal life	Ways to communicate the diagnosis results with family members; impact of treatment on quality of life; strategies to improve quality of life	"Patients had information needs relating to...whether they can return to work and other health services" [25].	[8,9,25-30,32-36,38, 39,41-44,47,48,51-53, 56,60-64,67-69]
Scientific research	Recent research findings; clinical trials	"...every week there's another breakthrough. And you go to your doctor with the clipping" [30].	[30,40,44,47,65]
Social assistance	Insurance; financial support	"Women's careers were often affected by the illness yet information about financial support was extremely difficult to come by" [52].	[9,26,30,43,46,52,60]
Moderating variables			
Attitudes	Affect; behavior; cognition	"Some women talked of being shocked, frightened, and worried when discovering a breast lump and immediately sought medical advice. Other women appeared less concerned and mentioned breast symptoms only when attending their general practitioner for other reasons" [28].	[8,9,25,26,28,33,35, 36,46,48,57]

Themes, categories, and concepts		Examples of quotations	References
Health literacy	Health beliefs; health knowledge; health styles	"The possibility of symptoms being breast cancer was the first thought of some women and most were fatalistic about this. 'I just thought I have cancer and I wasn't bothered about it because let sleeping dogs lie. The less you know the less you bother about it'" [28].	[9,26,28,33,34,40]
Demographic characteristics	Age; education level; economic status	"Ongoing information needs...younger women also discussed the use of complementary therapies...more than their older counterparts" [44].	[8,25,28,40,42,44,57,64]
Disease status	Comorbidity; clinical stage	"Experiences of some participants with special disease showed they needed information regarding secondary prevention" [42].	[41,42,60]
Political and cultural environment	Cultural background; health care policy	"Given that food therapy plays a significant role in Chinese culture, many participants expressed a strong desire for information on diet" [49].	[30,32,33,35,38,49]
Family factors	Age of children	"At diagnosis, women wanted age-appropriate information about how to communicate with their children about cancer" [9].	[9]

Figure 2. Model of information needs of breast cancer patients.

Theme 1. Incentives

This theme illustrates how breast cancer patients formed a cognitive state of information gaps, which led to their information needs. These needs were triggered by various factors.

Physical Abnormalities

Breast cancer patients might experience physical abnormalities anytime during the cancer continuum. Their information needs were often triggered by the appearance of symptoms of the primary tumor (eg, lumps, pain, or discharge) [9,26,28,31-33,36] because patients' panic and uncertainty increased before diagnosis. Nine studies also reported side effects caused by the treatment (eg, irregular menstruation, arm complications, fatigue, sexual dysfunction, lymphedema, and pain) [25,27,29,30,32,34,35,37,38] that would last from the treatment to the survivorship stages and could lead to specific information needs.

Inquiry From Others

Three studies suggested that doctors provided patients with several surgery choices and asked patients to quickly make treatment decisions (in phase 2), resulting in information needs about treatment [26,32,39]. During treatment (in phase 2), a patient wished that she had asked doctors more questions because she could not answer the queries of patients around her, indicating that other patients' questions helped form information needs that some patients themselves were not aware of [36]. In the survivorship stage, a patient was asked questions by general people around her, which reminded her of the risk of a recurrence, leading her to go back to the clinic for a follow-up appointment [31].

Subjective Norm

Patients' information needs were also triggered by subjective norms ("the belief that an important person or group of people will approve and support a particular behavior" [70]). For example, in phase 2, one patient reportedly requested copies of

all her diagnostic results from the hospital [40], following the advice from a support group member.

Problems During Appointments

Similar to the inquiries from others, problems could occur during appointments. For example, during the process of treatment decision making, the long waiting period between diagnosis and making a final treatment decision made it difficult for patients to remember all the information discussed, thus generating more information needs [25]. In addition, the doctors sometimes did not provide patients with enough information about breast cancer treatment options and simply made the treatment decision without discussion with the patient, which left the patient with more uncertainty [41]. The patients also had many questions (eg, who and how often should they see the doctor) as they transitioned from the cancer care group to the primary care physician shortly after treatment (in phase 3) [30,37]. Patients were also confused when health care professionals provided them with inconsistent information (eg, tamoxifen discontinuation) in the survivorship stage [30], triggering the need for more exact information. In a follow-up appointment (in phase 3), it was reported that the doctor's indifferent attitude also led to patients' anxiety and uncertainty when doing a routine examination [30].

Theme 2. Information Needs

This theme refers to specific information patients needed. The included studies suggested that breast cancer patients generally had 9 types of information needs at different stages of cancer care including information on prevention, etiology, diagnosis, clinical manifestation, treatment, prognosis, impact on normal life and coping, research progress, and social assistance. The types of information needs can be divided into several concepts.

Prevention

Three studies reported that patients were concerned about information on prevention, including effectiveness of breast self-examination [40] in phase 2. Patients reported that they also needed information about prevention for family members [30,42,43] during the survivorship stage.

Etiology

Etiology information was needed throughout the whole cancer journey. Four studies reflected on this type of information need. For example, patients wanted to know about internal and external factors (risk factors) before diagnosis in phase 1 [36] and phase 2 [40]. Patients also needed information on internal (genetic) [42,44] and external factors (possible carcinogens and environmental triggers) [44] in the survivorship stage in phase 3.

Diagnosis

In the diagnosis and treatment phase (in phase 2), patients were concerned about specific biopsy procedures (arrangement, temporal sequence, and actual procedure) [45], pathologic results (results of the biopsy) [45], and precision and applicability of the examination tools [9]. They also wanted an explanation of technical terms related to the diagnosis (used to describe tumor types) [46], pathologic results (pathological stage or the type of breast cancer) [36,43,46], clinical stage [36,40], waiting time

of diagnostic tests, and the corresponding impact on prognosis [47].

Clinical Manifestation

Patients wanted to know about the signs of breast cancer (symptoms of the primary tumor) [36] before diagnosis (phase 1). Information about the meaning of the corresponding symptoms was needed by patients who were undergoing a breast biopsy (in phase 2) [45]. They also needed to be informed of the symptoms of the side effects caused by the treatment [30,37] during phases 2 and 3. Eight studies also reported that patients were concerned about symptoms of a recurrence (symptoms of the primary tumor) [30,33,37,43,44,48-50] during phase 3.

Treatment

Patients needing treatment information during the cancer continuum was commonly reported across studies (n=44): 23 studies found that patients needed treatment options while waiting for diagnosis results [45], shortly after receiving diagnosis results [36,40,51], and during the treatment decision process [8,9,26,28,31,32,34,39,40,42,46-48,52-59] such as popularity, advantages and disadvantages, risks, applicability, recovery time, comparison, cost, and optimal time of different treatment options in phase 2. Twelve articles also mentioned that patients wanted to be educated about the side effects of treatment [8,9,25,28,31,36,40,46,56,60] when considering the treatment decision. The information needs of patients during treatment preparation included details about treatment preparation [33,42,48,52] and treatment procedures [9,25,28,30,42,46,61,62].

During treatment, patients' information needs focused on the side effects of treatment [25,47] and management of the side effects [8,25,38,40,46,49,50,53,60,63,64]. The studies also reported that patients needed details on the treatment options (alternative and complementary medicines and treatment) [25,65] and treatment procedures (eg, location of the pharmacy) during treatment [28,40,42,46,53,57,61]. In the survivorship stage, patients also paid attention to information on side effects [8,29,30,32,33,36-38,41,42,48] and management of side effects [25,30,35,37,43,48,49]. In phase 3, patients needed information about treatment options (eg, complementary and alternative therapies) [42,44,64,65] and treatment evaluation summaries [43,48]. In addition, patients wanted information about preventing a recurrence (eg, prevention-related policies, signs and symptoms of a recurrence, natural remedies to prevent recurrence, preventive health actions to minimize the risk of a recurrence) [30,33,37,41-43,49,52,61,66] in the survivorship stage.

Prognosis

Patients' need for prognosis information included general survival rates [26,47,51,54] and the risk of a recurrence [27] in phase 2. Studies also found that patients desired information about the risk of complications [42], risk of a recurrence [31,46], and survival statistics of treatment regimens [55,59] when they made treatment decisions. In particular, patients needed to know the risk of a recurrence in phases 2 [47] and 3 [30,32,66].

Impact and Resumption of Normal Life

Patients wanted to know how to communicate about the cancer with their family members in phase 2 [9,26,52,67,68]. Patients also needed information about the impact of treatment on their own body image [28,32,33,35,42,62,69], fertility (or menopause) [8,35], work [25,26], and psychology [8,26,64] in phase 2. In the survivorship stage, patients were concerned about the impact of treatment on work [44,52], intimate relationships [44,69], fertility (or menopause) [9,30,44], psychology [42,44,69], and body image [9,27,34,35,69]. In 26 studies, strategies to improve patients' quality of life (eg, fertility preservation options, sex advice, instructions about diet and exercise, stress management, reconstruction) were important for patients in both phase 2 [9,26,27,35,38,39,47,51,53,56,60-62] and phase 3 [29,30,32,36,41-44,48,63,64,69].

Scientific Research

Some patients needed information about recent breast cancer research findings [40] and clinical trials [47,65] in phase 2. In

addition, medical breakthroughs (recent research findings), corresponding clinical trials [30], new treatment, and research developments [44] were requested in phase 3.

Social Assistance

Patients generally needed information about insurance (eg, health insurance) in phases 2 [46] and 3 [30]. Five studies reported that patients sought information on financial support (eg, employment benefits, where to get help) during the survivorship stage [9,26,43,52,60].

Theme 3. Moderating Variables

A prominent theme reported in the included studies was variables that moderated the development of information needs of breast cancer patients. Differences among particular subgroups and their forms of information needs are shown in Table 2. No major inconsistencies were detected in the studies.

Table 2. Synthesized results of the moderating variables.

Categories, concepts, and dimension	Effect on information needs	References
Attitudes		
Cognition		
Correct cognition	Facilitated development of information needs	[9,26,28]
Misunderstanding	Inhibited development of information needs	[33,36]
Affect		
Shocked and worried	Facilitated development of information needs	[28,57]
Not worried	Inhibited development of information needs	[28]
Behavior		
Ready	Facilitated development of information needs	[8,35,46,48]
Not ready	Inhibited development of information needs	[25]
Health literacy		
Health knowledge		
Rich in health knowledge	Facilitated development of information needs	[33,40]
Lacking health knowledge	Inhibited development of information needs	[33]
Health style		
Positive coping strategies	Facilitated development of information needs	[33]
Negative coping strategies	Inhibited development of information needs	[34]
Health beliefs		
No fatalism	Facilitated development of information needs	[9,26,34]
Fatalism	Inhibited development of information needs	[28,33]
Demographic characteristics		
Age		
Younger	Paid more attention to information on new treatments, research advances, and effects of treatment on fertility and career, complementary therapies, dietary changes and exercise, possible carcinogens, and environmental factors	[8,25,44]
Older	Expressed less need for reconstructive surgery	[28,40,42]
Education level		
Higher	Paid more attention to information on medical terminology and medical information systems	[40]
Lower	Inhibited the development of information needs	[40]
Economic status		
Higher	Paid more attention to information on natural health products and healthy dietary changes	[57,64]
Lower	Expressed less need for healthy diet information and reconstructive surgery	[42]
Disease status		
Comorbidity		
With comorbidity	Paid more attention to information on secondary prevention; obese patients needed survival guidelines targeting their physical condition	[41,42]
Clinical stage		
Advanced breast cancer	Paid more attention to the experience of other advanced breast patients; information or support related to last will and testament and final arrangements	[60]
Political and cultural environment		
Cultural background		

Categories, concepts, and dimension	Effect on information needs	References
Chinese	Paid more attention to diet and exercise guidelines, less information on postoperative body changes	[33,38,49]
Turkish	Paid more attention to postoperative body changes and contraceptive information	[35]
Japanese	Paid more attention to information on postoperative body changes	[32]
Health care policy		
Policy changes	Paid more attention to information on changes in health care policy and practice (eg, frequency of routine examination)	[30]
Family factors		
Age of children		
Younger	Paid more attention to age-appropriate information on how to guide communication with children about the disease	[9]

Attitudes

Attitudes refer to the amount of affection for or against some object [71]. In this study, attitudes included affect, behavior, and cognition. Affect represented the strong feelings of breast cancer patients, such as being shocked and worried [28,57], while behavior described their readiness to receive information [25]. Cognition was the product of knowledge acquisition or application, such as an understanding of breast cancer.

Six studies showed that patients' cognition and affect influenced the development of information needs. For example, some patients misunderstood the causes and risks of breast cancer, believing that they would not have breast cancer after a certain age [33] or after breastfeeding [36], and thus they did not seek information. Correct cognition of patients facilitated the development of their need for information. For example, patients went to see their physicians after discovering a lump or feeling pain [9,26,28]. Two studies showed that affect also influenced their information needs. For instance, some participants who found a lump and felt shocked immediately went to the hospital to seek medical advice [28,57], while those who were not worried about the lump only described the symptoms when they went to see their general practitioner for other diseases or they chose to completely ignore the lump [28].

In addition, some patients who believed that they were still in the process of receiving diagnosis results were not willing to process a large amount of information [25]. Patients who lacked behavior intention chose to avoid information [25], while other patients asked for various types of information [8,35,46,48].

Health Literacy

Health literacy is defined as individuals' ability to obtain, understand, evaluate, and apply health information, which can affect individual judgments and decisions on health care and disease prevention [72]. In the study, this category included health beliefs, health knowledge, and health styles, respectively, representing patients' values toward breast cancer, awareness of cancer-related information in order to seek appropriate health services [73], and their coping strategies for breast cancer.

For example, one patient did not go to see a doctor after discovering a lump in her breast because she lacked health knowledge about the effect of screening tools (mistakenly

believing that routine mammographic screening had a preventive effect), which inhibited the development of her information needs [33]. Relatively abundant health knowledge could promote the articulation of the need for information [33,40]. While one woman who had a different health style also ignored the discovery of lump until she found that the lump was getting bigger 3 month later, other patients went to see a doctor immediately after feeling breast pain [33]. In terms of health beliefs, some of the patients suspected breast cancer immediately after finding the lump, but they were not worried or did not ask about it because of fatalism [28,33] whereas other patients sought further examination [9,26,34].

Demographic Characteristics

Eight studies reported that the patients' age, education level, and financial situation moderated the formation process of their information needs. For example, young patients cared more about new treatments, research advances, and effects of treatment on fertility and career compared to older patients [8,25,44]. Younger patients also expressed a greater need for information about complementary therapies, dietary changes and exercise, possible carcinogens, and environmental factors of breast cancer because of their interest or a sense of control and comfort [44]. In contrast, some older patients had less need for information and considered that the less they knew, the less they were bothered about it [28]. In general, patients with a lower education level were more likely to trust doctors and be satisfied with the information provided by their doctors [40]. These patients believed that they did not need more information and had fewer information needs than other groups [40]. In terms of education levels, having a high education level had a beneficial effect on information needs and they independently researched areas such as medical terminology and medical information systems [40]. Furthermore, patients with lower economic status showed no concern about healthy diet information due to the high costs as well as the conflicts between a special diet and their family's diet [42]. In contrast, others cared about natural health products and healthy dietary changes [57,64]. It was also found that worse economic status and older age inhibited their need for information on reconstructive surgery [42].

Disease Status

Disease status involved comorbidity and the clinical stage of patients. For patients with comorbidity, information on secondary prevention was needed to avoid complications [42]. For example, obese patients faced a higher risk of recurrence, and they needed targeted survival guidelines based on their physical condition [41]. Patients with advanced breast cancer also wanted to know about the experiences of other patients in the same clinical stage [60]. They also sought information or support related to the last will and testament and final arrangements [60].

Political and Cultural Environment

The political and cultural environment refers to the social and cultural context characterized by a community's values and beliefs [74]. Of the included studies, 6 suggested a moderating effect of cultural background and health care policy. Patients who were influenced by Chinese culture developed more information needs regarding specific recommendations on diet and exercise related to symptom management, promotion of rehabilitation, and prevention of recurrence [38,49] because of the traditional food therapy culture. Some Chinese patients reported no feeling about postoperative body changes because body image was not as important to them as returning home to take care of their families in the context of Chinese culture [33]. In contrast, patients in some other countries like Turkey [35] and Japan [32] attached great importance to the aesthetic needs of the female body image. In addition, for patients from some countries with religious beliefs like Turkey with strong opposition to abortion, the cultural beliefs directly affected the patients' need for contraceptive information [35]. Patients in countries that had experienced changes in the national health care policy (eg, national cost curtailment policy) and corresponding adjustments in practice (eg, frequency of routine examinations) needed more targeted information on these changes [30].

Family Factors

In addition to the moderating variables described above, one study found that patients who had younger children often talked about the lack of personalized information for their kids [9]. They particularly needed targeted information on how to guide their communication about breast cancer with their children because they had difficulty finding age-appropriate information [9].

Discussion

Principal Findings

This meta-synthesis strengthens our understanding of the formation and types of information needs of breast cancer patients. It also highlights the variables moderating the development of information needs.

Information Service Targeted on General Breast Cancer Patients

Figure 2 shows that breast cancer patients' information needs change over the three stages. Patients are often given substantial resources (eg, brochures, books, and nursing plans) but the

information has disadvantages in both content and form. Targeted messages are often embedded in a large amount of irrelevant information. Breast cancer patients are also often given overwhelming information during hospitalization, putting extra pressure on them [75]. In addition, the information is not always delivered in expected, easy-to-digest forms, but is often filled with medical jargon, for instance [3]. This study provides some practical recommendations based on synthesized findings to guide medical professionals attempting to provide better information for breast cancer patients.

In this synthesis, breast cancer patients' information needs were systematically examined and classified into three cancer phases. This can help us understand the changing process of the specific information needed by patients at different phases. The synthesized findings also inform recommendations for health care staff to offer relevant and timely education materials at the appropriate stage of the cancer journey. A total of 94% (44/47) of the studies reported that patients were concerned about treatment information such as treatment procedures, side effects, and preoperative preparation. This type of universal information should be incorporated into education materials to help patients make proper treatment decisions. The synthesis also revealed that it is difficult for patients to obtain information about financial assistance [9,26,30,52,60], as well as complementary and alternative therapies [34,64]. More attention should be given to meet these information needs.

Easy-to-understand materials are also recommended since much the existing information and oral communication seems to contain complex medical language [76]. Education programs using virtual reality technology could also increase the knowledge and positive experience of patients [77]. Graphics and tables can also help patients understand the cancer care information.

Information Services Targeting Specific Groups of Breast Cancer Patients

Attitudes of Patients

The synthesis revealed that patients' attitudes greatly affected their information needs [9,25,28,46]. Numerous other studies have also verified this view. For instance, individual cultural beliefs, views on health and disease, and other factors could affect women's dealing of early diagnosis [78,79], which is an essential strategy for preventing breast cancer [80,81]. Emotional distress may also affect patients' ability to cope with the symptoms and treatment of cancer [82].

To date, doctors have not paid enough attention to the emotional pressure patients feel when confronted with a diagnosis and treatment of breast cancer [83]. Thus, social support (eg, support groups, online health communities, and eHealth mobile apps) can play an active role in assisting patients with stress management and providing high-quality care [84,85]. Health care staff can also provide psychological support for breast cancer patients [86] by providing more mental health information. They can also encourage patients to express their genuine emotions and be willing to listen [87]. Finally, it is necessary for medical staff to give full respect to patients and protect their privacy [61].

Health Literacy of Patients

This study found that breast cancer patients' information needs can be influenced by health literacy [28,33,34]. Patients with limited health literacy commonly had more unsatisfied information needs [88]. Health literacy could also influence patients' cancer screening knowledge, attitudes, and behavior [89]. Inaccurate health beliefs or lack of health knowledge could lead to patients overlooking physical abnormalities, which could affect early detection and treatment of diseases.

People can often detect and treat breast cancer early by improving their health literacy. A higher level of health literacy can also promote effective communication with medical staff and increase patients' engagement in medical decisions [90]. For patients, limited literacy is associated with a low education level and socioeconomic status [91]. For medical practitioners, the knowledge of prevention, causes, early symptoms, and self-examination methods could be communicated better through mass media to improve patients' awareness [92]. Furthermore, educational materials on breast cancer prevention should be sensitive to health beliefs [93] to reduce women's fears of breast cancer screening and fatalism toward the disease. Physicians and other health care providers should continue to give priority to patients' quality of life when determining treatment plans as patients' decisions may be influenced by health knowledge. Additional training would help doctors communicate more effectively with patients with low health literacy and reduce medical inequalities.

Demographic Characteristics, Disease Status, and Political and Cultural Environment of Patients

The significant increase in the number of breast cancer patients has resulted in diverse and complex information needs. For example, there were more unmet information needs among breast cancer patients who had a foreign native language background (eg, immigrants) [94]. Moreover, the age-specific information needs of younger breast cancer survivors is still far from satisfactory [95]. Therefore, tailored information is recommended to help subgroups of breast cancer patients cope with cancer and improve satisfaction levels [96].

As shown in Table 2, this synthesis reveals suggestions and implications for tailored information services. First, some studies suggested that information provided to younger patients could focus more on the impact of treatment on fertility [8,9,35,44],

lifestyle, and career as well as corresponding coping strategies [25,44,52]. More detailed advice on diet could also be provided for patients including many Asian patients. Patients who have young children can also be educated on how to communicate with their children. If patients are adequately informed about body changes before treatment, those who care a lot about body image [32,35] might have more time to consider and prepare for the changes. Policy information should also be given to patients who live in a country with changing medical policies. For patients with comorbidities and other physical conditions, specific prevention and survival guidelines are vital. Since different treatment options have corresponding side effects, health prescriptions that are targeted to each type of treatment can be distributed to patients separately to help them improve symptom management.

Limitations

Whereas the findings of this study offer significant insights, the limitations can lead to recommendations for further study. Some of the included studies did not clearly report cancer stages, making it difficult to analyze the findings according to the timeline of the disease journey. In addition, this theory-generating meta-synthesis only focused on qualitative studies, which could lead to the omission of valuable findings in quantitative research. Further research is needed to fully understand the unique information needs of breast cancer patients at all stages of their journey.

Conclusions

This synthesis has identified different information needs at various stages of the cancer continuum. Among the information needs, patients generally pay more attention to information about treatment and prognosis, as well as impact and resumption of normal life. Moderating variables were also identified. The generated model describes a complete pattern of the formation of information needs. Thus, this study contributes to a deeper understanding of breast cancer patients' information needs and provides practical suggestions for health professionals and information service providers. In particular, health care providers can offer educational materials according to the information needs identified in this study. More personalized information can also be developed to tailor patients' needs with reference to the moderating variables that influence their information needs.

Acknowledgments

HL designed the search strings and conducted the search. HL, JX, YC, and Y Cheng screened the papers for inclusion and appraised the quality of the papers. All researchers read and extracted the results, findings, and discussion of the studies independently. HL, JX, Y Cheng, and LS coded and synthesized the studies through an inductive analysis. All of the authors contributed to the writing and refinement of the paper. The authors would also like to express appreciation for the reviewers' valuable suggestions.

Conflicts of Interest

Abstract

Background: Dual process theories propose that the brain uses 2 types of thinking to influence behavior: automatic processing and reflective processing. Automatic processing is fast, immediate, nonconscious, and unintentional, whereas reflective processing focuses on logical reasoning, and it is slow, step by step, and intentional. Most digital psychological health interventions tend to solely target the reflective system, although the automatic processing pathway can have strong influences on behavior. Laboratory-based research has highlighted that automatic processing tasks can create behavior change; however, there are substantial gaps in the field on the design, implementation, and delivery of automatic processing tasks in real-world settings. It is important to identify and summarize the existing literature in this area to inform the translation of laboratory-based research to real-world settings.

Objective: This scoping review aims to explore the effectiveness of automatic training tasks, types of training tasks commonly used, mode of delivery, and impacts of gamification on automatic processing tasks designed for digital psychological health interventions in real-world settings among adults.

Methods: The scoping review methodology proposed by Arskey and O'Malley and Colquhoun was applied. A scoping review was chosen because of the novelty of the digital automatic processing field and to encompass a broad review of the existing evidence base. Electronic databases and gray literature databases were searched with the search terms “automatic processing,” “computerised technologies,” “health intervention,” “real-world,” and “adults” and synonyms of these words. The search was up to date until September 2018. A manual search was also completed on the reference lists of the included studies.

Results: A total of 14 studies met all inclusion criteria. There was a wide variety of health conditions targeted, with the most prevalent being alcohol abuse followed by social anxiety. Attention bias modification tasks were the most prevalent type of automatic processing task, and the majority of tasks were most commonly delivered over the web via a personal computer. Of the 14 studies included in the review, 8 demonstrated significant changes to automatic processes and 4 demonstrated significant behavioral changes as a result of changed automatic processes.

Conclusions: This is the first review to synthesize the evidence on automatic processing tasks in real-world settings targeting adults. This review has highlighted promising, albeit limited, research demonstrating that automatic processing tasks may be used effectively in a real-world setting to influence behavior change.

KEYWORDS

automatic processing; computerized tasks; health interventions; real-world; adult; behavior change, mobile phone

Introduction

Background

Digital psychological health interventions, which encompass both behavior change and mental health interventions, are increasingly being adopted to prevent and manage chronic health conditions. This includes stroke [1], dementia [2], obesity [3], addiction [4], and mood disorder [5]. The effectiveness of these interventions may be increased by the adoption of dual process theories that propose that the brain uses 2 types of processes to influence behavior [6-8]: automatic processing and reflective processing.

Automatic processing is fast, immediate, unconscious, and unintentional [9,10]. It involves an appraisal of a stimulus (eg, a basketball) in terms of its affective and conditioned properties. A mental representation of the stimulus and the network of associated concepts is automatically activated. By activating these mental networks, stimuli can capture or repel attention (attentional bias), lead to an automatic judgment of the stimulus as good or bad (automatic evaluations), and elicit a tendency to approach or avoid the stimulus (approach or avoidance bias). Cognitive biases are mostly automatic processes that result in individuals giving increased attention to threatening stimuli, with the difficulties in disengaging from these stimuli [11]. In contrast, reflective processing focuses on logical reasoning; it is slow, step by step, voluntary, and intentional, such as self-regulatory processes [9,10]. These 2 types of processes can occur simultaneously and can have concordant or opposing influences on behavior [10]. For example, when a person sees a basketball, this will trigger a network of concepts in the procedural memory, such as *fun* and *good* or *hard* and *bad*, which can lead to an automatic response from the individual to either approach or avoid the basketball (approach-avoidance bias). If the stimuli are automatically perceived as positive, it will result in an approach response, whereas if the stimuli are automatically perceived as negative, it will result in an avoidance response [12,13]. In this instance, these automatic associations could influence the formation of intentions to play basketball in the first place or may contribute to an intention-behavior gap if the conscious, logical intention is at odds with the automatic association.

Given that both types of processes can occur simultaneously and that behavior change may be most likely when they are congruent, the dual process theory suggests that both the reflective and automatic processing pathways should be targeted to create and sustain behavior change [8,14]. However, most digital behavior change and mental health interventions tend to target the reflective system only, aiming to improve self-regulatory processes, for example, processes such as self-monitoring behavior, goal-setting, or cognitive behavioral therapy [10,15]. Although these strategies are useful for supporting intention or goal-directed behavior, there is also clear evidence of an intention-behavior gap [16].

Laboratory-based evidence suggests that digital interventions delivered via computerized tasks can change people's automatic processes to specific stimuli [14,17-19]. Automatic processes can be retrained using cognitive bias modifications (CBM) tasks, attentional bias modification tasks, and evaluative conditioning tasks [14,18,20-22]. CBM tasks have been extensively tested in the field of anxiety and depression in laboratory settings [14,18,20-22] and work by targeting attentional and interpretative biases away from threats [14]. The dot-probe test is often used to assess attentional biases [23] and involves the presentation of pairs of stimuli, one of which is threatening and one that is neutral. Participants are shown the stimuli simultaneously, one stimulus on either end of a computer screen, for a small amount of time (eg, 500 ms); a dot then appears in the place of one former stimulus, and participants are asked to indicate the location of this dot as quickly as possible. The computer automatically measures the speed of this reaction. The test is then repeated several times. Quicker response times to the dot when it appears in the location of threatening stimuli are interpreted as attentiveness to threat [23]. Dot-probe tasks can also be used to retrain attentional biases by replacing a targeted probe (designed to change attentional biases) with neutral or salient stimuli during all cycles of the task [19,20,24-26]. A commonly used task shows participants a smiling or neutral face alongside an unhappy or angry face; participants are then asked to select the positive image as fast as possible [14]. Through the repetitive nature of the task, a person's automatic processes can be reconditioned toward a particular stimulus [14].

Common criticisms of automatic processing tasks are that they are repetitive and boring [18,27]. Recently, the field has attempted to make these tasks more enjoyable and accessible by delivering these tasks on digitally ubiquitous technology such as smartphone apps and drawing on the developing realm of gamification. Gamification seeks to motivate and engage users by using gaming style elements often seen in games (rewards, points, and leader boards). A review by Boendermaker et al [19] into gamified CBM highlighted that there were many projects currently in progress; however, there still remained a lack of evidence to draw any firm conclusions regarding the effectiveness of gamification on increasing engagement. Similarly, Zhang et al [11] highlighted that understanding gamification approaches is crucial in future conceptualization and codesign of attention bias modification interventions.

Objectives

Despite the evidence of the importance of the automatic processing pathway for regulating behavior, the majority of reviews on automatic processing tasks have been limited, focusing mainly on mental health conditions delivered in laboratory settings [17,18,28-30]. In addition, existing reviews have routinely included studies with children whose brain development differs from that of adults [31-33]; thus, a need to map the existing literature examining automatic processing

pathways in digital health interventions in real-world settings among adult populations was identified [16,27,34,35]. This scoping review aimed to explore the effectiveness of automatic training tasks, types of training tasks commonly used, mode of delivery, and impacts of gamification on automatic processing tasks designed for digital psychological health interventions in real-world settings among adults.

Methods

Scoping Review Methodology

Scoping reviews aim to “map rapidly the key concepts underpinning a research area and the main sources and types of evidence available” [36]. This scoping review sought to address the question: “what is the current evidence base around design and effectiveness of automatic processing computerized tasks designed for health interventions in real-world settings among adults?” A scoping review was chosen because of the novelty of the digital automatic processing field and to encompass a broad review of the evidence. Scoping reviews allow the development of inclusion and exclusion criteria during the study selection, the inclusion of all types of studies, and extraction of data regarding key issues and themes, in contrast to systematic reviews that are much more stringent with synthesis [37,38].

This scoping review followed the framework described by Arksey and O'Malley [38], who provided a detailed description of how to conduct a methodologically rigorous scoping review. In addition, the current best practices of Colquhoun et al [37] for the conduct of scoping reviews' guidelines were also applied. Arksey and O'Malley's methodology [38] comprised the following steps: (1) identifying the research question; (2) identifying relevant studies; (3) study selection; (4) charting the data; and (5) collating, summarizing, and reporting the results. A number of additional recommendations from a study by Colquhoun et al [37] were also integrated: development of a protocol before the initial scoping study began, using Preferred Reporting Items for Systematic Review and Meta-Analysis (PRISMA) Protocols, the use of 2 independent reviewers, use of same inclusion criteria during initial data screening, and full-text screening and pilot testing of the data extraction template.

Identifying Relevant Studies

Search Strategy

A systematic literature search was created with the assistance of an academic librarian from the University of Adelaide. It was applied to all databases by HJ. The search was completed using the electronic databases PubMed, Scopus, Excerpta Medica Database (EMBASE), Psychological Information Database (PsycINFO), Web of Science, Cumulative Index to Nursing and Allied Health Literature (CINAHL), Cochrane Database of Systematic Reviews, and Google Scholar. The search was performed in September 2018. A gray literature search was also conducted to identify any published or unpublished data not found through the initial search. This included electronically searching the repositories holding theses and research papers: Trove, The Gray Literature Report, ProQuest, OpenGrey, and Grey Literature Network Service (GreyNet International).

Reference lists of all included studies were manually screened to identify possible relevant citations. The search strategy created was based on 5 main components: (1) automatic processing, (2) computerized tasks, (3) health interventions, (4) real world, and (5) adult. Relevant keywords were identified using Medical Subjects Headings (MeSH) and Emtree terms, synonyms, and keywords from relevant articles ([Multimedia Appendix 1](#)).

The results of the search were uploaded into EndNote X 7.3.1 (Clarivate Analytics), and duplicates were then removed and exported into Rayyan. Rayyan is a web-based tool that assists in the completion of systematic reviews. Rayyan was initially used by HJ to screen titles search and determine eligibility. This was followed by an abstract screen using the inclusion and exclusion criteria. If eligibility was ambiguous, criteria were discussed with other coauthors until consensus was reached. An eligibility proforma was also used during this process. Articles matching the inclusion criteria were then selected for full-text analysis.

Inclusion and Exclusion Criteria

Inclusion criteria for the study were adults aged older than 18 years, designed to be a health intervention (defined as aiming to improve physical or mental health), delivered via a computerized (digital) task, and delivered in a real-world setting (a free-living environment, excluding a laboratory-based environment). Only studies published in English between the years 2000 and 2018 were included. Articles not published in English were excluded. Articles were also excluded if they were published before the year 2000 because of digital expansion in the field of automatic processing predominately occurring after the year 2000.

Charting the Data

Data extraction was performed using a standardized data extraction template with the following fields: author, year, country, aims of the study, setting and population, participant demographics, details of the intervention and comparators, study methodology, sampling and recruitment, completion rates, and intervention details ([Multimedia Appendix 2](#)). HJ, CES, CH, and AB all conducted data extraction for the first 2 publications using the original data extraction template. All reviewers then discussed any iterations, and the template was changed appropriately to reflect any inconsistencies. Data for all remaining studies were extracted by HJ, with 10% being verified by AM. Conflicts or concerns during this period were resolved through discussion with CES and CH.

Collating, Summarizing, and Reporting the Results

The data extraction forms were used to form quick overview summaries of the included studies. A descriptive numerical summary was used to create a numerical overview of general study characteristics, and then a narrative overview was conducted on the type of automatic processing task used and effectiveness.

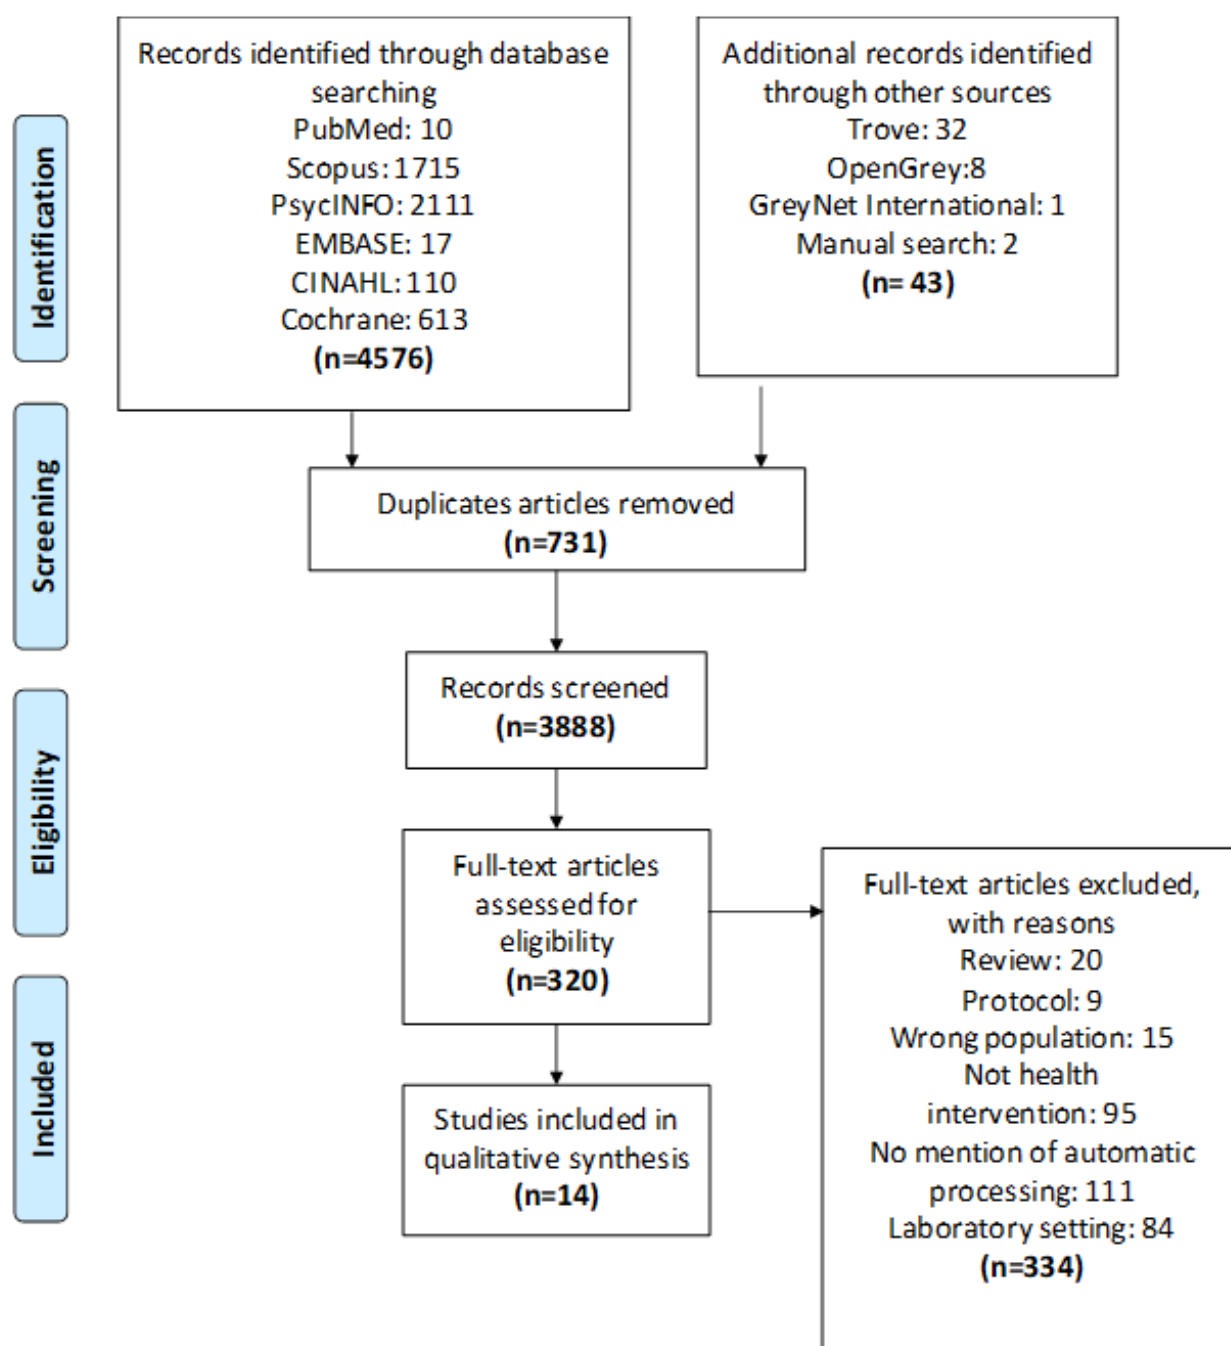

Results

PRISMA Results

The PRISMA flow chart for the results of the search is presented in [Figure 1](#). The flowchart contains results from the initial search, how many studies were removed because of duplications,

study selection, and amount selected for full-text analysis ([Figure 1](#)). The search is up to date until September 2018; 4576 studies were found to be eligible for inclusion ([Figure 1](#)). Of these, 320 were assessed for full-text inclusion, of which 14 studies met all inclusion criteria. The reasons for study exclusion included being a review paper, irrelevant to the topic, and not being set in a real-world setting.

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses for the results of the search. CINAHL: Cumulative Index of Nursing and Allied Health Literature; EMBASE: Excerpta Medica Database; GreyNet: Grey Literature Network Service; PsycINFO: Psychological Information Database.

General Characteristics

Characteristics including the type of study, sample size, country, and follow-up are reported in [Table 1](#). Most of the included studies were conducted in Europe and the United States, with

6 in Europe and 5 in the United States. One study was conducted in China [39] and another in Australia [34]. All studies were randomized controlled trials, except one that was a cross-sectional study. Sample sizes ranged from 21 to 672 participants. Five of the studies targeted automatic processes

regarding alcoholism [19,20,31,32,35]. Two studies targeted smoking attitudes and behavior [35,40]. Two studies targeted automatic processes toward anxiety [21,39], and one study targeted automatic processing toward both anxiety and depression [20]. In addition, one study was found for insomnia

[34], self-injurious thoughts and behaviors [41], attitudes toward homosexuality and self-esteem in gay men [42], and relationship satisfaction in marriages [43]. Follow-up periods also varied and ranged from no follow-up (n=4 studies [39,42,44,45]) to the longest follow-up period of 6 months [35].

Table 1. General demographics of included studies (n=14).

Reference	Type of study	Population size (N)	Country	Follow-up
Robinson et al (2017) [40]	RCT ^a	64	The United States	Two weekly follow-ups
Clarke et al (2016) [34]	RCT	36	Australia	8 days
Yang et al (2017) [39]	RCT	76	China	No follow-up
Fleming and Burns (2017) [42]	RCT	274	The United States	No follow-up
van Deursen et al (2015) [45]	Cross-sectional	437	Germany	No follow-up
de Voogd et al (2016) [20]	RCT	340	The Netherlands	Baseline measures were taken before training and then 3, 6, and 12 months after training
Enock et al (2016) [21]	RCT	429	The United States	Pretest, posttest, and 1- and 2-month follow-ups
Monk et al (2017) [44]	RCT	62	The United Kingdom	No follow-up
Wiers et al (2015) [26]	RCT	615	The Netherlands	The first follow-up was 1 month after the posttest (N=109, 35.0%) and the second 2 months later (N=87, 28.0%)
Boendermaker et al (2016) [25]	RCT	96	The Netherlands	Four sessions conducted at least one day apart and 2-week follow-up after session 4
Crane et al (2018) [46]	RCT	672	The United Kingdom	The follow-up questionnaire was sent to participants 28 days after downloading the app
Elfeddali et al (2016) [35]	RCT	475	Amsterdam	A posttraining assessment (ie, manikin and visual probe tasks) followed the intervention sessions. An assessment of continued smoking abstinence followed 6 months after baseline
Franklin et al (2016) [41]	RCT	114, 131, and 163	The United States	1-month follow-up
McNulty et al (2017) [43]	RCT	288	The United States	2 weeks

^aRCT: randomized controlled trial.

Intervention Characteristics

Types of Digital Technology

Table 2 reports the intervention characteristics of the included studies. The type of digital technology most often used to

execute the intervention was a personal computer or laptop via a website (n=8) [20,25,26,35,42-45], followed by the use of a smartphone app (n=5) [21,34,39,41,46]. One study was delivered on a personal digital assistant device [40].

Table 2. Intervention characteristics of included studies (n=14).

Reference	Type of digital technology	Real-world setting
Robinson et al (2017) [40]	Hewlett-Packard iPAQ Personal Digital Assistant	Laboratory and home
Clarke et al (2016) [34]	Smartphone	Laboratory and home
Yang et al (2017) [39]	Smartphone	Home
Fleming and Burns (2017) [42]	Functioned only on desktop or laptop personal computers	Web-based
van Deursen et al (2015) [45]	Personal computer or laptop	Web-based
de Voogd et al (2016) [20]	Computer	Web-based at school and home
Enock et al (2014) [21]	Smartphone	Web-based
Monk et al (2017) [44]	Computer, mobile prohibited	Web-based
Wiers et al (2015) [26]	Computer	Web-based
Boendermaker et al (2016) [25]	Computer	Laboratory and home
Crane et al (2016) [46]	Smartphone app	Web-based
Elfeddali et al (2016) [35]	Computer	Web-based
Franklin et al (2016) [41]	Mobile app but can be used on phones, tablets, laptops, and desktops	Web-based
McNulty et al (2017) [43]	Computer	Laboratory and home

Use of Dual Process Theory

A total of 5 of the 14 included studies referred to dual process theory when explaining the theory behind the use of bias modification tasks [25,26,35,45,46]. Moreover, 7 studies did not mention any theories guiding their research [20,21,34,39-41,44]. Furthermore, 2 studies did not mention dual process theories but referred to other theories as a guide to their research [42,43].

Only 2 of the included studies [45,46] focused their interventions on targeting both parts of the dual process theory, targeting both automatic processing and reflective processing pathways. Crane et al [46] evaluated module components of an alcohol reduction app called *Drink Less* to change participants' drinking behavior in a factorial trial. Of the 5 modules tested, 1 (cognitive bias retraining module) targeted automatic processes regarding the impulse to drink alcohol. There was a significant two-way interaction between this module on weekly alcohol consumption ($P=.03$), indicating that enhanced normative feedback (targeting misperceptions via reflective processes) led to a significant reduction in weekly alcohol consumption only when combined with enhanced cognitive bias retraining. van Deursen et al [45] examined the relationship among problem drinkers seeking web-based help to change their alcohol use, hypothesizing that executive functions would moderate the relationship between automatic associations and drinking and that this effect would be stronger in individuals with strong motivation to change. A brief *Implicit Association Test* was used to test valence and approach associations, whereas executive (reflective) pathways were assessed via a number of smaller tests. The study results provided partial support for the moderating role of motivation in the interplay between automatic processes and executive functions.

Types of Automatic Processing Tasks

Three types of automatic processing tasks were used in the included studies: attentional bias modification tasks, CBM tasks, and evaluative conditioning tasks. Attentional bias modification tasks were the most commonly delivered intervention through the use of dot-probe, visual probe, and visual search tasks. CBM tasks were delivered via dot-probe test [39], word sentence association paradigms [39], attentional control training, approach bias retraining [26], and cognitive bias retraining [46]. Evaluative conditioning was delivered via evaluative conditioning tasks [42,43], a stop-signal task, and a game-like therapeutic evaluative conditioning task.

Usage

Intervention durations varied considerably between the studies that reported on how long the intervention was delivered for, ranging from the shortest intervention period of 75 min to the longest intervention period of 6 weeks. All studies delivered at least some of their interventions in a real-world setting (as per inclusion criteria), with 4 studies delivering interventions in a mixed setting (both laboratory and home environments). Some studies have reported problems with usage. This included the number of training trials used over sessions being too low, preventing the training from potentially changing attentional biases [25]; low training compliance, with some participants dropping out of the study midway effecting overall results and limiting generalizability of findings [20,26,40,46]; and having self-selected use and dosage during the intervention, making it hard to determine the optimal dosage needed for intervention [41].

Gamification Strategies

Three of the included studies incorporated elements of gamification to enhance engagement of their intervention [25,41,46]. Boendermaker et al gamified [25] an existing automatic processing task, which aimed to train attention away from pictures of alcoholic beverages via a visual probe task.

They found that the gamified automatic processing task did not improve participant motivation to train as compared with the usual ungamified task. In fact, some aspects of motivation appeared to deteriorate rather than improve. Crane et al [46] and Franklin et al [41] saw positive effects with the use of gamified elements in their interventions. However, the effect that gamification had on influencing study outcomes was not investigated, making it difficult to deduce which aspects of gamification produced different effects and overall how effective gamification was.

Outcome Assessments

Two studies reported that it was possible that the option to train at home had a negative effect on the final results, as it may have made participants take the training less seriously. It was also noted that the web-based nature of web-based assessments resulted in issues with standardization of interventions, making it hard to control how measures were completed [45]. The large number of measures included in some studies may have also resulted in participant fatigue [45], and the use of similar types of tasks testing different outcomes may have resulted in practice effects that may have affected the overall findings.

Effectiveness of Interventions

A detailed description of the aims, measures, and effectiveness of included studies can be found in [Multimedia Appendix 3](#) [14,15,19,20,29-34,36-39]. A total of 14 studies assessed changes in automatic processes, whereas 11 studies assessed how changes in automatic processing contributed to changes in behavior. Of the 14 studies that assessed changes in automatic processes, 8 reported a statistically significant effect in the direction expected [21,25,26,34,40,43,44,46]. Of the remaining 6 studies evaluating automatic processes, 4 reported no significant effects on changes in automatic processes [20,35,42,45].

Of the 11 studies that assessed behavioral or mental health outcomes, 4 reported a significant intervention effect [21,26,34,43] and 3 of these included automatic processing intervention strategies only. Five others reported on behavioral or mental outcomes but saw no significant results on changes to outcomes [20,25,35,42,46].

Three studies reported mixed findings [39-41] on changes to automatic processes, with 2 of the studies also further detailing changes to behavior. Robinson et al [40] found that a mobile-delivered attentional bias intervention could reduce attentional bias toward thoughts about smoking but had mixed effects on changing smoking behavior. It was thought that these findings may have been impacted by participant attrition affecting overall results and the sample being nontreatment seeking participants [40]. Yang et al found [39] that 1 of the 3 CBM tools assessed could be used effectively to reduce anxiety and mood problems. However, the other 2 methods assessed yielded limited effectiveness. The authors reported that a low sample size and a lack of engagement elements to make the tasks *fun* may have impacted the results [39]. Franklin et al [41] conducted 3 evaluative conditioning studies designed to reduce self-injurious thoughts and behaviors, finding that 2 of the studies successfully reduced self-injurious thoughts and

behaviors. It was suggested that identifying additional treatment targets, such as other self-injurious thoughts and behaviors not covered by the study, and increasing digital engagement strategies for users may yield better results across all 3 studies in the future [41].

Some of the authors of the studies that showed no significant effects on changes in automatic processes to behaviors outlined possible reasons within their manuscripts. Boendermaker et al [25] attributed these findings to small attentional biases at baseline and low numbers of training trials as compared with other trials in the areas affecting dose-response relationships and having a web-based intervention in a real-world setting, which may have impacted participants' motivation by making them take the training less seriously. Fleming and Burns [42] attributed the null findings to having biased unrepresentative sample populations and the web-based nature of the intervention being available only via a personal computer or laptop limiting those who had an affinity for mobile use. de Voogd et al [20] inferred that the negative findings may have been because of participant dropout, as most adolescents did not complete all 8 intended training sessions. Elfeddali et al [35], Boendermaker et al [25], and de Voogd et al [20] also highlighted that motivation for web-based training appeared low, which they partly attributed to the repetitive nature of the training tasks and the web-based nature of the training tasks, which were completed at home and resulted in a lack of supervision or standardization of training circumstances.

Discussion

Principal Findings

This scoping review aimed to explore the effectiveness of automatic training tasks, types of training tasks commonly used, mode of delivery, and impacts of gamification on automatic processing tasks designed for digital psychological health interventions in real-world settings among adults. A small but developing evidence base was found. Of the 14 studies reviewed, only under half of the interventions resulted in positive changes to automatic processes. The positive trials provide some evidence that this approach may be possible in the real world, although many trials produced mixed results and issues with compliance and engagement were commonly described.

Types of Training Tasks

The review identified 2 main types of tasks commonly used in the field to change automatic processing: attentional bias modification tasks and CBM tasks. These tasks can be delivered via a variety of methods, but the most popular in the health domain are dot-probe, visual probe, and visual search tasks. All 3 tasks have been extensively used and reviewed in the literature [19,47,48]; however, historically, these tasks have been used in a laboratory setting, particularly in mental health interventions seeking to change anxiety and depression. This review revealed an expansion in the field, both in a real-world setting and in other health fields such as problem drinking, smoking, and suicide.

Usability

In the last few years, there has been a shift toward the use of smartphone apps for the delivery of automatic processing interventions. All automatic processing tasks contained within this review were deployed over the web, which made them easily accessible for use in the real world. They were most commonly delivered via a computer or laptop, with over half of the studies using this as the mode of delivery. This aligns with other reviews in the field, such as a recent review of attention and CBM apps by Zhang et al [11], which found 24 CBM apps that were commercially available. Although app usage is increasing, Zhang et al [11] found that most apps ($n=8$) were not rigorously evaluated, whereas the other 17 were all commercial apps, of which only one was evaluated in published literature. This review has been able to add to the work by Zhang et al [11], who found that 5 smartphone-based CBM task studies have been scientifically evaluated.

Digital advancements are increasingly facilitating pathways into real-world investigations in this field. Although digital platforms do increase participant accessibility in real-world environments, there are limitations to this approach. Three studies noted that the web-based nature of tasks, the lack of supervision, and standardization from external distractors may have negatively impacted the results [20,25,35]. Wiers et al [26] highlighted that this may have been because of large dropout rates commonly seen in web-based experiments and suggested making interventions more engaging to combat this. Boendermaker et al [25] and Elfeddali et al [35] suggested that allowing participants to do the training part of the intervention at home may have affected their motivation levels by them taking the task less seriously. de Voogd et al [20] proposed that the mixed results in that study may have been because of the lack of *stress* imposed by the laboratory environment, where most studies in this area have been conducted traditionally. Indeed, the stress of laboratory environments may, in fact, be beneficial to study outcomes, as participants may have taken the training task less seriously in their home environment, thereby negatively affecting conditioning effects. A review by Santarossa et al [49] in the field of health behavior change also shows that digital interventions are more effective when they have a human support element.

Effectiveness of Changing Automatic Processes

Similar to other reviews in the area [32,33], this review also found mixed findings on the effectiveness of automatic processing tasks in real-world conditions. Of the effective interventions, over half of the studies targeted changing automatic processes toward alcohol. The successful characteristics of these interventions included the use of evaluative conditioning or CBM tasks for intervention delivery, the use of personal computers for mode of delivery, and the use of both elements of the dual process theory.

Mixed results on effectiveness were found for smoking, social anxiety, and self-injurious thoughts and behaviors. This may have been because of participant attrition affecting overall results, and Franklin et al [41] suggested that mixed findings in that study may have been because of issues with a lack of engagement elements. This is a common criticism of bias

modification tasks, as they are often reported to be quite boring and repetitive by participants. There has been development in the field to make these tasks more engaging by adding elements of gamification that use visuals, sound effects, point systems, and rewards to make the tasks more engaging [19,24-27,50]. Three of the included studies incorporated elements of gamification to enhance engagement of their interventions [25,41,46]. Boendermaker et al [25] gamified an existing automatic processing task that aimed to train attention away from pictures of alcoholic beverages via a visual probe task. They found that the gamified automatic processing task did not improve participants' motivation to train as compared with the usual nongamified task. In fact, some aspects of motivation appeared to deteriorate rather than improve, suggesting that gamification could have drawbacks if not done optimally.

Crane et al [46] and Franklin et al [41] observed positive effects of study outcomes with the use of games and gamified elements in their interventions. However, the effect that gamification had on influencing outcomes was not investigated. Other reviews have similarly found mixed findings with the use of gamification in automatic and reflective processing interventions [11,19,26,51].

Strengths and Limitations

To our knowledge, this is the first study in the field to review automatic processing studies that specifically focus on real-world settings and adults. The expansive search that included both database and gray literature searching was a strength of this study. This allowed an extensive gathering of evidence to map key concepts and ideas in the field currently.

The eligibility criteria may have limited findings from key studies that did not meet the eligibility requirements, for example, many papers in the field that focus on evaluating automatic processing tasks in real-world settings among children, which may collectively hold key insights into the field at large [24,31,52]. In addition, following the best practice recommendations of conducting scoping reviews from Colquhoun et al [37] and Arksey and O'Malley [38], included studies were not assessed for quality in relation to areas of bias such as randomization. Scoping reviews provide a breadth of information rather than the assessment of quality. The disadvantage of this is that it makes it difficult to gain an insight into the robustness and generalizability of the findings. However, the benefit of this method is that it allows the mapping of a wider range of available resources, painting an overall picture of the field at large, as the guidelines for inclusion are not as stringent as a systematic review. The results of a scoping review can, however, sometimes inform the development of a systematic review, which is better placed to deliver an assessment of quality. Finally, only primary studies published in English were included, resulting in a small number of studies for inclusion, which is a common limitation in scoping review [53].

Future Directions

The increasing use of digital platforms to deliver automatic processing tasks, while increasing population reach and accessibility, does have drawbacks. Although monitoring and

standardization levels are relatively achievable in laboratory-based environments, it is often difficult to monitor compliance and ensure adherence in real-world studies. Future studies could experiment with different instructions or persuasion techniques for completing the training as well as different training paradigms to increase compliance. Furthermore, there may be concerns about privacy and confidentiality issues and require further research [54]. Engagement of automatic processing tasks remains a prominent issue because of their inherent boring nature. Gamification offers promising capabilities, and future research should further investigate how its incorporation can enhance enjoyment in the field. Although research into gamification is mixed, studies contained within this review have highlighted gamification as an important engagement strategy [20,26,35], which if implemented correctly could enhance the enjoyment of traditionally mundane tasks. Finally, it was unfortunate that

there were few studies in the field that targeted both processes during their interventions; both processes alone have shown significant ability to change behavior, and combining these processes could improve the design and effectiveness of future health interventions and could be a crucial missing link.

Conclusions

This is the first review to synthesize the evidence for published and gray literature on automatic processing tasks set in real-world settings targeting adults. This review has highlighted promising, albeit limited, research demonstrating that automatic processing tasks may be used effectively in a real-world setting to influence behavior change. Given that several trials with negative findings were also identified, future research is needed to understand why significant effects are observed in some contexts and not others and how to optimize delivery for optimal engagement and efficacy.

Abstract

Background: Although sex toys representing human body parts are widely accepted and normalized, human-like full-body sex dolls and sex robots have elicited highly controversial debates.

Objective: This systematic scoping review of the academic literature on sex dolls and sex robots, the first of its kind, aimed to examine the extent and type of existing academic knowledge and to identify research gaps against this backdrop.

Methods: A comprehensive multidisciplinary, multidatabase search strategy was used. All steps of literature search and selection, data charting, and synthesis followed the leading methodological guideline, the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) checklist. A total of 29 (17 peer reviewed) and 98 publications (32 peer reviewed) for sex dolls and sex robots, respectively, from 1993 to 2019 were included.

Results: According to the topics and methodologies, the sex doll and sex robot publications were divided into 5 and 6 groups, respectively. The majority of publications were theoretical papers. Thus far, no observational or experimental research exists that uses actual sex dolls or sex robots as stimulus material.

Conclusions: There is a need to improve the theoretical elaboration and the scope and depth of empirical research examining the sexual uses of human-like full-body material artifacts, particularly concerning not only risks but also opportunities for sexual and social well-being.

Introduction

Background

In 2050, it will be perfectly normal for women and men to experience love and sex with robots. This bold prediction from roboticist David Levy [1] started a debate, now more than a decade after, on the ethics, design, use, and effects of human-like, anatomically correct sex robots and of sex dolls, their noninteractive, immobile precursors. Futurologist Ian Pearson [2] went further by predicting that by 2050, women and men will have more sex with robots than with their

conspecifics. One may question the validity of these predictions, but there is no doubt that technological change affecting all areas of life will not leave human sexualities unaffected. Significant changes in sexual behavior because of digital media and technologies are already well established [3,4]. Embodied technologies such as sex dolls and sex robots should not be overlooked in this context, especially as the popularization of the sexual uses of human-like material artifacts has long since begun.

So-called *sex toys* representing human body parts (eg, penis-shaped dildos and vibrators) are widely used and

normalized. The lifetime prevalence of vibrator use, for example, is approximately 50% for heterosexual-identified women and men in the United States and Germany [5,6]. Sex toys are also popular in noncisgender and nonheterosexual populations [7]. Through web-based retailers, the sex toy market has expanded and diversified in recent decades, successfully targeting female customers in particular [8]. In the digital age, sex toys are becoming increasingly technologically advanced. Vibrators having integrated cameras are now available that can be remotely controlled by a partner in a long-distance relationship or that can synchronize with the user's digital music playlist or preferred virtual reality porn. The development of innovative sex toys is, at least in part, pushed by customer demand. This is demonstrated by crowdfunding projects in which future customers grant investment money to entrepreneurs who bring new sex toys to the market (eg, the *Ambrosia Vibe*, a so-called *bionic dildo* providing haptic biofeedback while strapped on). There is also growing interest in the development of sex toys for aging populations and for people with disabilities, for instance, sex toys that are mind-controlled and therefore do not require hand function [9,10].

Despite the broad acceptance of sex toys representing human body parts, the development and marketing of human-like full-body sex dolls and of interactive and moving full-body sex robots have elicited great controversy in both public and academic discourses [11,12]. The discrepancies begin with the clarification of the central concepts. Should sex dolls and sex robots simply be regarded as next-level, high-end sex toys? Do they play a different and more important role in the sexual and social lives of their owners and users? Are they treated as surrogates for real partners or even accepted as fully adequate posthuman synthetic partners? This would raise questions not only about their impact on sexual and overall health but also about the future of intimate relationships.

Domestic Use of Sex Dolls and Sex Robots

A typical usage scenario for sex dolls and sex robots is the domestic context in which the artifacts—after purchase—are available for recreational and long-term use at home. Some authors predict strong positive effects of sex dolls and sex robots, including social companionship, sexual exploration, pleasure, and increased satisfaction for individuals and couples [1]. Others, focusing on male users, predict strong negative effects in terms of objectification of and violence against women [13]. They assume that the men using women-like sex dolls or sex robots will be trained to sexually objectify real women and to disregard sexual consent. Furthermore, they predict that women and adolescent girls, already harmed by ubiquitous exposure to unrealistic beauty standards in the media, will feel even more inadequate when exposed to a consumer culture marketing perfectly beautiful, eternally youthful, and completely submissive female-gendered sex dolls and sex robots. Are we looking into an even more gender-unequal future?

Or are we just creating it with one-sided, male-centered, and sex-negative predictions? Why do we not ask different questions [11], such as: What do women want from innovative sex technologies? How could we design and market women- and couple-friendly, feminist, queer, empowering, and inclusive

sexual health—and well-being—promoting sex dolls and robots? Most of the claims about current and future effects of sex dolls and sex robots are purely speculative so far because design studies and empirical use and effect studies are scarce.

Commercial Use of Sex Dolls and Sex Robots

The same holds true for the commercial use of sex dolls and sex robots. The first so-called *sex doll brothels* have already opened in Asia, North America, and Europe, accompanied by strong media publicity (HJ Nast, unpublished data, 2019) [14]. In *sex doll brothels*, customers pay an hourly fee to be in a room with a human-like sex doll of their choice. Some authors argue that dolls and robots used as *surrogate prostitutes* are a good thing as they relieve women from prostitution and could reduce sexual violence [15]. However, we have not yet seen data collected from sex workers' perspectives on the issue. Do they want to be relieved of their jobs or are they more afraid of dolls and robots as new competition? Furthermore, anecdotal evidence shows that some customers are now booking both a sex worker and a sex doll. This points to possible commercial use scenarios marked by neither substitution nor competition but collaboration between human sex workers and sex dolls or robots.

Again, the conceptualization is unclear here. What are the practical, legal, and ethical implications of framing short-term commercial use options as a *brothel* or *escort* instead of a *rental* business? Who are the customers—that is, will regular customers switch to dolls, or will we see new *technophilic* customers specifically requesting dolls or robots? Will demand for short-term commercial use of sex dolls and sex robots persist, increase, or wane? Budget restrictions (life-like sex dolls and robots are very expensive), need for discretion (hiding a full-body sex doll or robot from other household members is nearly impossible), and media-induced curiosity (seeing sex dolls and robots represented in pornography and fictional and nonfictional media can be intriguing) might be factors motivating a trip to the *sex doll brothel* today. Will these factors still play a role tomorrow when markets, media representations, and attitudes change?

Commercial short-term use of sex dolls and sex robots is barely understood, but is so highly controversial that some of the first *sex doll brothels* in Europe, North America, and Asia had to close shortly after opening because of community protests and police raids, as reported in numerous news media.

Therapeutic Use of Sex Dolls and Sex Robots

The perspectives of clinicians are also divided. Some therapists, based on first case studies, explain how living with a *love doll* (as doll owners often prefer to call them) can be a helpful and healing transitional process after traumatic experiences, especially when accompanied by professional therapeutic care [16]. Other clinical authors warn their colleagues that products from the *sex robot industry* are marketed with health claims that are *rather specious* [17]. Even more heated are debates about childlike sex dolls produced in Asia and shipped worldwide. Some ethicists and clinicians argue that people with pedophilic preferences could use such dolls or robots as substitutes to prevent them from committing actual child sexual abuse and that therapeutic use might be promising [18]. Other

ethicists and therapists completely reject this idea and warn that childlike sex dolls or robots are very harmful as they normalize and foster child sexual abuse in both pedophilic individuals and the society at large [19]. Legal bans against child sex dolls and robots are not only campaigned for (*Campaign against sex robots*) but, in some countries, also already in preparation or in effect (eg, the *Curbing Realistic Exploitative Electronic Pedophilic Robots Act of 2017—CREEPER Act of 2017* for short—in the United States) [20].

Again, conflicting approaches are visible in clinical, ethical, and legal debates. Should sex dolls and sex robots of all kinds be explored as possible therapeutic tools in the context of different paraphilic disorders and other sexual pathologies? Or should at least some of them be criminalized immediately, with the implication that new forms of doll- and robot-related sexual deviance have been introduced and must be prosecuted?

Objectives, Questions, and Purpose of the Scoping Review

Against this backdrop of highly polarized debates, this scoping review study aimed to examine the extent and type of existing academic knowledge on sex dolls and sex robots and to identify gaps in theory and evidence as well as areas for further inquiry. In accordance with the leading methodological guideline for scoping reviews, the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) checklist [21,22], we will proceed to explain, separately and in detail, the review objectives, questions, and purpose.

Review Objectives

To comprehensively map the state of research on sex dolls and robots, it is necessary to cover academic literature from different disciplines and address various dimensions of the issue. Often, debates firstly and primarily focus on the negative or positive *effects* of sex dolls and sex robots. Effects are an important dimension of this issue. However, it is crucial to be aware that effects always depend on the users and *use* in different settings (eg, domestic, commercial, and therapeutic) as well as on the selected sex doll's or sex robot's *design* (eg, gender, age, race, body type, and sexual and nonsexual functionalities). Hence, this review, as indicated by its title, addresses the design, use, and effects of both sex dolls and sex robots.

Definition of Sex Dolls

Sex dolls are defined as human-like, full-body, anatomically correct anthropomorphic dolls of different materials (eg, rubber, plush, silicone, and thermoplastic elastomer) and price ranges that are designed for sexual use [11]. Sex dolls have at least one penetrable orifice (mouth, vagina, or anus) and/or one body part that can be inserted by the user (tongue or penis). The doll parts for sexual penetration or insertion are usually designed to be removable for cleaning. The special thing about sex dolls is their sexual functions, but this does not mean that they are used exclusively for sexual purposes. They can also serve as artificial love partners, social companions, or photo models, which is why their owners often call them *love dolls* or simply *dolls*. The term is also used by most scientists and parts of the media.

Sex dolls come in different genders (female, male, or trans), races (eg, white, Asian, or African), ages (adult, adolescent, or child), body types, skin, hair, and eye colors. High-end sex doll manufacturers (eg, RealDoll Abyss Creations, Sinthetics, and Orient Industry) offer ample options for selection and customization and also produce custom-made sex dolls. Therefore, *abstract sex dolls* with no resemblance to a specific real person need to be differentiated from *portrait sex dolls* designed in the likeness of a real person (eg, porn star, celebrity, or ex-partner). True-to-life sex dolls like RealDolls from Abyss Creations are delicate, need care and repair, and are not easy to handle because of their weight of approximately 65-70 lbs for female dolls and 85-105 lbs for male dolls.

Thus far, the sex doll market—determined by customer demand—offers mainly female sex dolls with highly sexualized looks that meet traditional feminine beauty standards (young, slim, pretty face, long hair, and large breasts). However, customization already allows for more body diversity (eg, androgynous or gender-queer looks), including the deliberate design of so-called bodily flaws (eg, moles, scars, stretch marks, belly fat, or body hair). Hence, the sex doll industry caters to different appearance-related customer demands (eg, the illusion of perfect supernatural beauty, resemblance to a real person, specific body-related preferences, or fetishes).

Definition of Sex Robots

Sex robots (sexbots) are defined as human-like, full-body, anatomically correct humanoid service robots of different materials, technologies, and price ranges that are designed for sexual use [11]. Sex robots look like sex dolls but are equipped with sensors, actuators, and artificial intelligence (AI). Sometimes, they are called AI sex dolls or robotic sex dolls to characterize them as upgrades of their noninteractive, immobile precursors. For gender sex robots, the binary terms fembot and malebot or gynoid and android are used. Sex robots come with all the attributes and functionalities of sex dolls and, in addition, can display conversation skills, emotions, and preprogrammed personalities. Furthermore, they can perform partially autonomous behaviors such as sexual movement (eg, hand movement for masturbation) or simulation of orgasm. However, the range of behaviors of existing sex robots is very limited. It can be assumed that the handling and maintenance of sex robots as large, heavy, and technically advanced products is demanding. Like sex dolls, sex robots are defined by their sexual functions but are also suitable for other functions in addition to sex (eg, social companionship).

Sex robots marketed today should not be confused with *concepts of future advanced sex robots* that are envisioned as having sentience, consciousness, free will, morality, and possibly even the legal status of citizens. There are also visions of future multifunctional assistance robots for domestic use that will do housework and errands, look after children, provide elderly care services, and offer sexual services. These imagined advanced sex robots or multifunctional robots with sexual functions appear in science fiction (eg, the Swedish television series *Real Humans* or the US movie *Ex Machina*) and in recent philosophical and legal sex robot debates [23,24], but are far away from the current state of technological development.

The Relevance of Sex Dolls and Sex Robots

Although high-end, true-to-life sex dolls have been on the market for more than 20 years (the leading US manufacturer Abyss Creations, creator of RealDoll, was founded in 1997), sex robots are still in a very early stage of development. The manufacturer TrueCompanion claims to have brought the world's very first sex robots to the market. It presented its female-gendered sex robot *Roxy* to the public in 2010 and later announced the male-gendered sex robot *Rocky*, stirring a media frenzy [25]. However, it is assumed today, for good reasons, that *Roxy* and *Rocky* have never been more than overhyped prototypes [14,26]. Thus far, not a single customer has surfaced, and the TrueCompanion webshop has not changed over the years. The established RealDoll manufacturer Abyss Creations launched its first sex robot *Harmony* in 2018, followed by *Solana* and *Henry*. Sex robot *Samantha* by the Spanish manufacturer Synthesia Amatus and sex robot *Emma* by the British-Chinese manufacturer AI Tech UK have likewise been sold since 2018. All these sex robots are sex dolls enhanced with some very limited AI and interactive features. Hence, although supposedly thousands of experienced sex doll owners exist worldwide, who have built their own distinct doll owner communities with online forums and offline meet-ups, there is, by comparison, only a very small number of pioneer users of sex robots. This limits the options for empirical research on long-term sex robot users, use, and effects.

However, as we are transitioning into the age of the robot, and sex robots provide interactivity, AI, and partly autonomous behavior, sex robots have been attracting much more public and scholarly attention than sex dolls. After all, they have been an integral part of science fiction literature for decades [27]. Considering the history of and relation between sex dolls and sex robots, it seems reasonable to address them collectively in this research review concerned with the sexual uses of human-like full-body material artifacts.

Review Questions

In mapping the current state of academic knowledge on sex dolls and sex robots, the scoping review aimed to answer the following 4 review questions (RQ):

RQ1: What is the state of sex doll and sex robot research in terms of the overall amount and type of research?

RQ2: What is (not) known about the design of sex dolls and sex robots?

RQ3: What is (not) known about the users and uses of sex dolls and sex robots?

RQ4: What is (not) known about the effects of sex doll and sex robot use?

These 4 RQs will be addressed separately for sex dolls and sex robots based on the respective literature searches.

Review Purpose

By systematically mapping the current state of academic knowledge on sex dolls and sex robots, this scoping review aimed to advance the understanding of sex researchers and practitioners and foster their professional involvement in the

field of sexual uses of human-like material artifacts. Technicization and digitalization are fundamental societal processes that affect all areas of life, including human sexualities. Sex researchers and practitioners must be prepared to deal with these transformations in an informed and professional way, reflecting their own knowledge gaps, prejudices, and projections. Sex dolls and sex robots seem to be a particularly fruitful field of inquiry and professional development, as they often elicit very strong emotions that need to be recognized, worked through, and questioned with the help of clear conceptualizations, sound theories, and solid empirical evidence.

Methods

A scoping review is “a form of knowledge synthesis that addresses an exploratory research question aimed at mapping key concepts, types of evidence, and gaps in research related to a defined area or field by systematically searching, selecting and synthesizing existing knowledge” [28]. As the body of academic literature on sex dolls and sex robots has not yet been comprehensively reviewed and exhibits a broad and heterogeneous nature that is not amenable to a more precise systematic review, a scoping review is of particular use [29]. Our procedure follows current methodological guidelines for conducting systematic scoping reviews [29], particularly the PRISMA-ScR checklist [21,22].

Literature Search

To search for relevant academic publications on sex dolls and sex robots, the following 5 scientific literature databases covering different disciplines were used to ensure a multidisciplinary, multidatabase search strategy:

1. *Scopus* (largest academic literature database, approximately 57 million references, covering different disciplines, 1960-current),
2. *Medical Literature Analysis and Retrieval System Online (MEDLINE)*; approximately 28 million references, focus on medicine, 1950-current),
3. *PsycINFO* (approximately 4 million references, focus on psychology, 1806-current),
4. *Institute of Electrical and Electronics Engineers (IEEE) Xplore* (approximately 4.5 million references, focus on technology, 1872-current), and
5. *Association for Computing Machinery (ACM) Digital Library—Guide to Computing Literature* (approximately 3 million references, focus on computing, 1950-current).

For sex dolls, the search terms “sex doll,” “sex dolls,” “doll sex,” “love doll,” “love dolls,” and “doll love” were used. For sex robots, the search terms “sex robot,” “sex robots,” “sexbot,” “sex bot,” “robot sex,” “love robot,” “love robots,” “lovebot,” “love bot,” and “robot love” were used. Search terms were applied to publication titles, abstracts, and keywords. Searches were limited to the English language, without publication date, publication type, or study type restrictions.

The search strategy was validated through the retrieval of a key set of relevant publications in Scopus, where 24 citations for sex dolls and 73 citations for sex robots were identified. The

Scopus search strategy was then translated to the other 4 databases and executed between August 6, 2019, and August 9, 2019 ([Multimedia Appendix 1](#) shows the full documentation of the electronic search strategy). Bibliographic information for all search results was exported from the databases into the citation management software Citavi 5.7.1 (Swiss Academic Software GmbH).

Literature Selection

The literature selection included 3 steps: (1) the removal of duplicates among identified records; (2) the scanning of citations, titles, and abstracts for eligibility; and (3) the retrieval of full texts and assessment of eligibility. As we are reviewing an innovative emerging research field, we included all study and publication types from all available publication years. The only 2 exclusion criteria applied were lack of topical relevance

(irrelevant were all publications that did not provide substantial knowledge about sex dolls or sex robots, that is, publications that only mentioned but did not investigate the topic or only referred to relevant publications) and nonaccessibility of published full text. We used the reference lists of all eligible full texts found through the databases to systematically search for further publications. Screening, assessing, and inclusion were performed in duplicate.

As can be seen in [Figure 1](#), for sex dolls, we identified 16 eligible publications through the databases and 13 additional publications through their reference lists, resulting in 29 included sex doll publications ([Figure 1](#)).

The same procedure was used for sex robot publications, resulting in 98 included publications ([Figure 2](#)).

Figure 1. Flowchart of the scoping review procedure for literature identification and selection of sex dolls. ACM: Association for Computing Machinery. IEEE: Institute of Electrical and Electronics Engineers; MEDLINE: Medical Literature Analysis and Retrieval System Online.

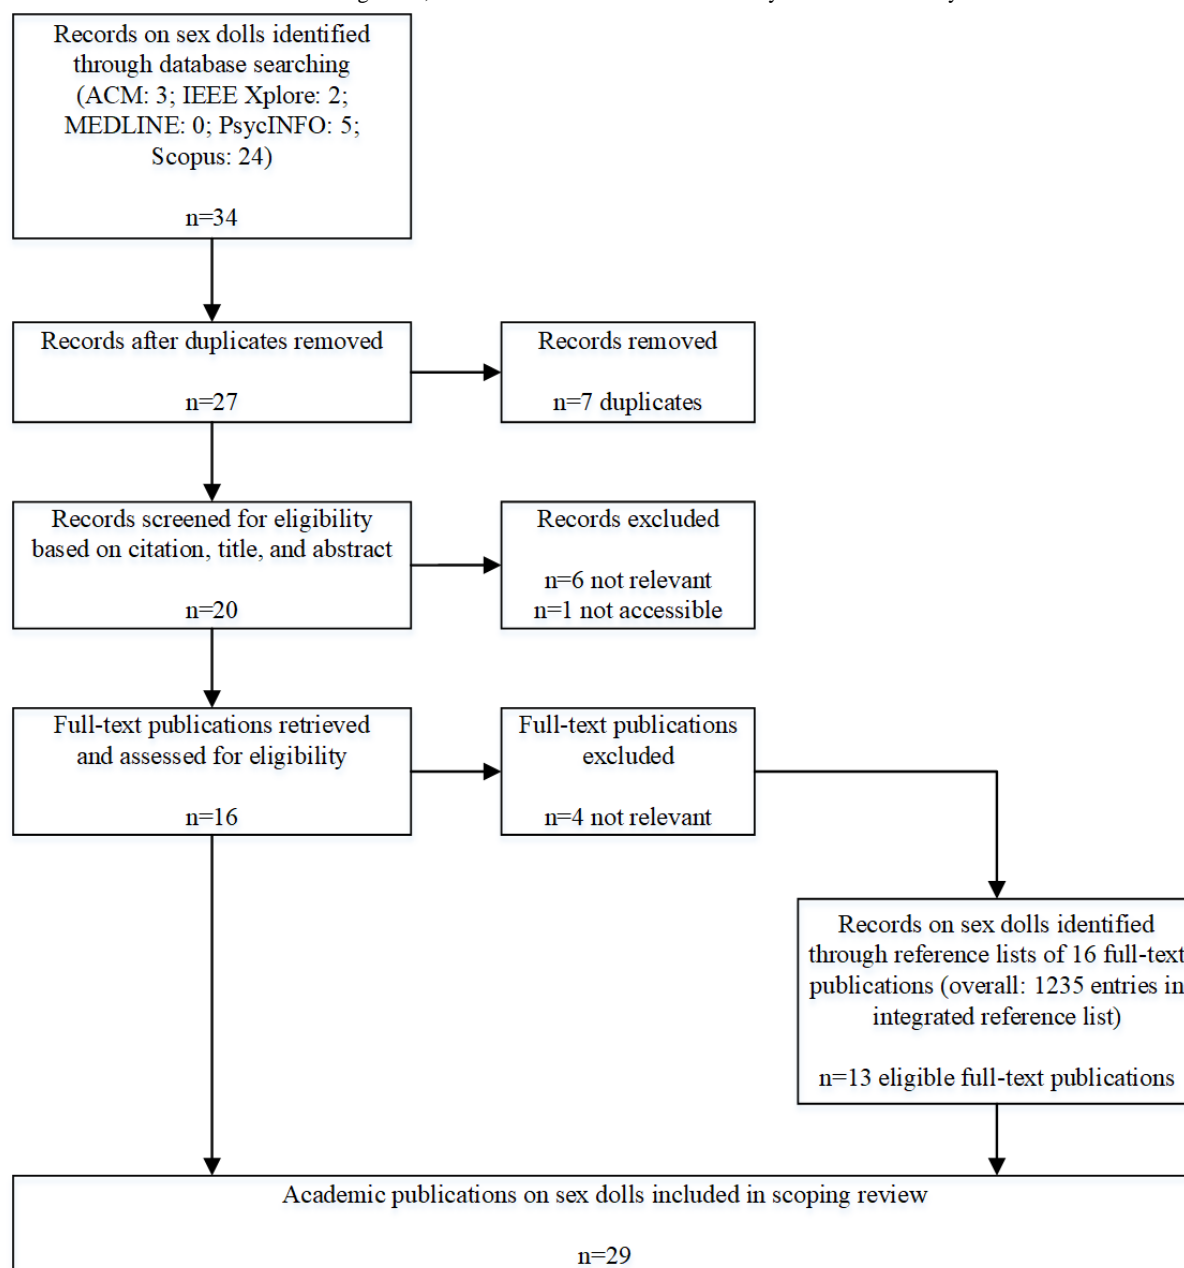

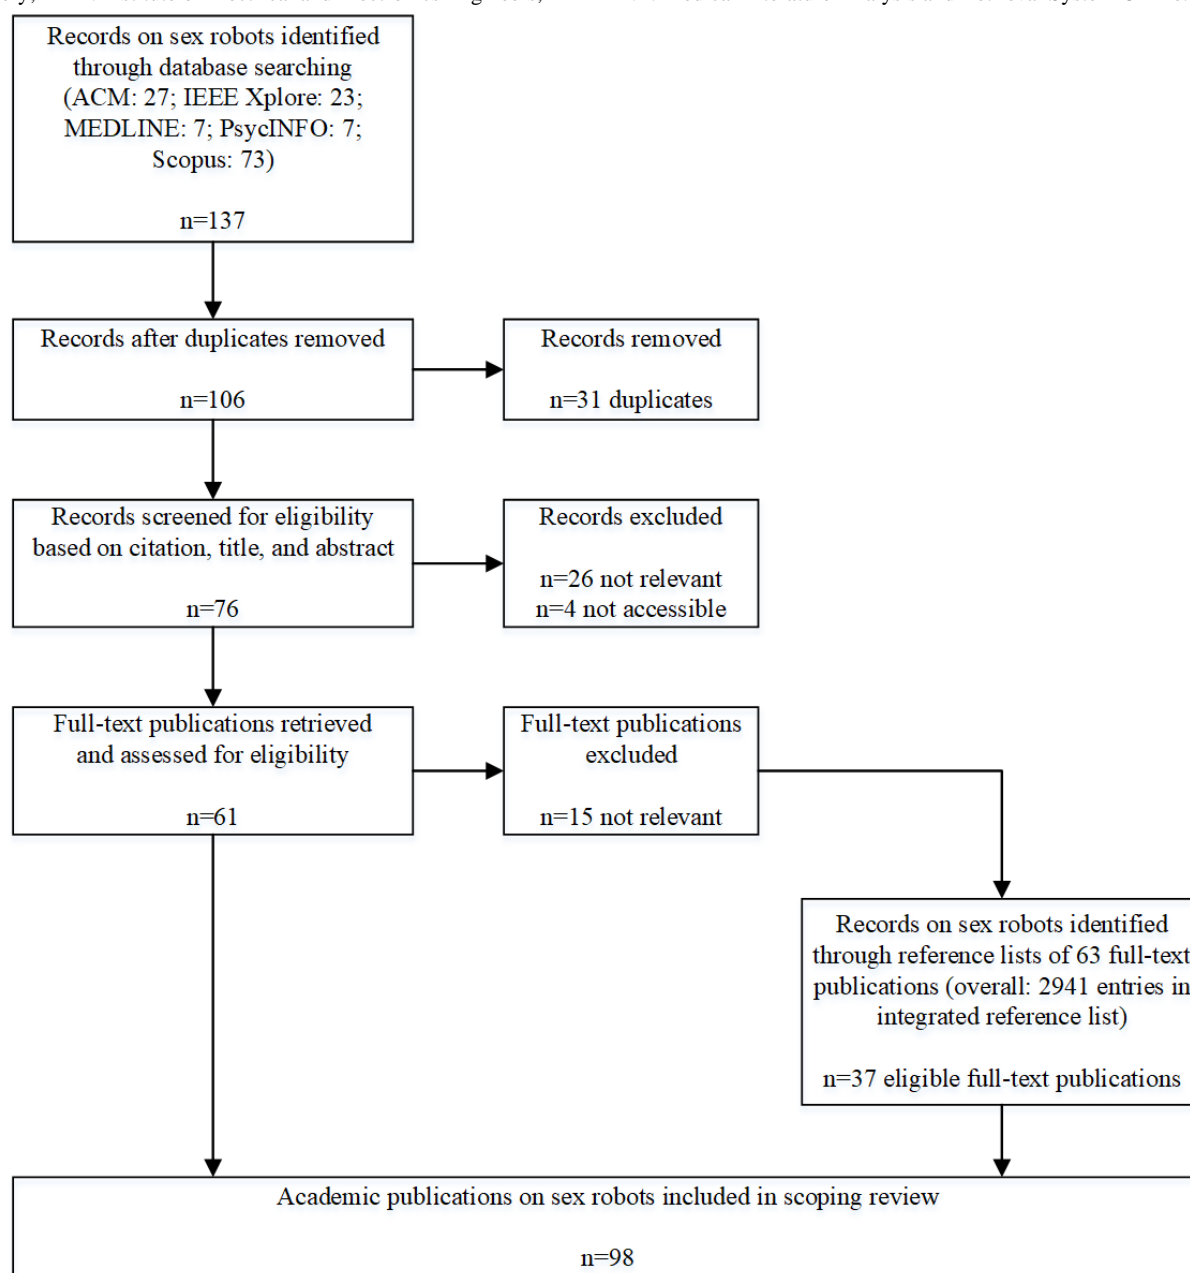

Figure 2. Flowchart of the scoping review procedure for literature identification and selection of sex robots. ACM: Association for Computing Machinery; IEEE: Institute of Electrical and Electronics Engineers; MEDLINE: Medical Literature Analysis and Retrieval System Online.

Data Charting

During the data charting phase, all included publications were reviewed and charted using a data charting form that was pilot tested for all 29 included sex doll publications, discussed within the team, and revised 3 times. The final charting form has a sex doll and a sex robot version, each including 10 variables: (1) citation (author and year), (2) citation count (derived from Google Scholar), (3) publication type, (4) peer review, (5) academic discipline (derived from the first author's academic position and/or education), (6) study type (derived from topic and methodology and used for grouping of sex doll/sex robot publications), (7) key findings regarding the study's research question, (8) key findings—if applicable—regarding sex doll/robot design, (9) key findings—if applicable—regarding sex doll/robot use, and (10) key findings—if

applicable—regarding sex doll/robot effects. Variables 1 to 7 were used to answer RQ1 in the overall state of the research, variable 8 addressed RQ2, variable 9 addressed RQ3, and variable 10 addressed RQ4. The data were charted in duplicate.

Synthesis and Reporting of Results

First, a numeric overview of the number, type, and distribution of included publications was created using 2 summary tables and a chart of the timeline of publication activity. Second, a narrative synthesis of the results of the previous studies was created, focusing particularly on their insights regarding design, use, and effects of sex dolls and sex robots. Third, to fully answer the RQs on “what is (not) known” about sex dolls and sex robots, the state of research was critically assessed for research gaps, and recommendations for future research were included. To avoid vagueness and to achieve maximum

usefulness, recommendations for future research with specific references to applicable theories, relevant methods, and related research fields were backed up. All steps of data synthesis and reporting were discussed within the team and performed in duplicate.

Results

State of Research on Sex Dolls

To summarize the state of research on sex dolls, we first map the number and type of publications and then report their main results regarding the design, use, and effects of sex dolls before coming to the research gaps and recommendations on how to fill them.

Amount and Type of Research on Sex Dolls

During the scoping review literature identification process, we included 29 academic publications on sex dolls ([Figure 1](#)). This

body of literature consists of 5 distinct groups of studies according to both their topics and methodologies, which are closely linked ([Table 1](#)).

The body of academic literature contains 2 published monographs that exclusively focus on sex dolls [[33,43](#)]. Approximately 50% (17/29) of the included sex doll publications were peer reviewed. The Google Scholar citation count reveals a range from 0 to 46 citations; the most cited publication was the monograph *The Sex Doll: A History* by Anthony Ferguson [[33](#)]. It is noteworthy that all of the most cited publications within each of the 5 groups of sex doll publications were not peer reviewed. Regarding the timeline, the oldest sex doll publication identified in the databases and included in our review is a 1993 clinical case study from medicine [[50](#)] that deals with the shared use of an inflatable sex doll. However, this is an outlier, with >85% (25/29) of the sex doll publications having been published within the past 10 years (2010-2019; [Figure 3](#)).

Table 1. Amount and type of research on sex dolls (N=29 included academic publications, based on literature search in August 2019).

Research Findings on Sex Dolls

We have summarized the main findings of previous sex doll research separately for the 5 groups of sex doll publications (Table 1).

Sex Doll Conceptualization and Theory

The largest group of sex doll publications (11/29, 38%) consists of theoretical studies that aim to conceptualize the human–sex doll relationship. Half of them (6/11) promoted a critical feminist conceptualization of the female sex doll as an expression and affirmation of patriarchal gender power relations and women’s sexual objectification by men (ie, by male sex doll producers, owners, users, and observers). The publications deal with the production and use of female sex dolls in Western [30,32,33,36] and Asian (HJ Nast, unpublished data, 2019) [35] countries and sometimes discuss gender issues of female sex doll use in relation to economic, cultural, and racial issues as well as in relation to recent crises of masculinity. Their overall assessment of female sex dolls and their effects is very negative. A typical example of the critical feminist conceptualization of female sex dolls is as follows [33]:

The female sex doll is man’s ultimate sexually idealized woman. It is never more than the sum of its fully functional parts. A woman rendered harmless, it is immobile, compliant, and perhaps most importantly, silent. What the user of the sex doll seeks is the negation of change and the comfort of always retaining control of the relationship.

The other half of the theoretical papers (5/11) conceptualize human–sex doll relations, mainly in a positive way [11,14,31,34,37]. These papers do not limit their focus to female dolls or (supposedly heterosexual, sexist, and misogynist) male

doll users only, but they address the already observable and potentially growing diversity of both dolls and doll users (eg, including women, queers, older people, and people with disabilities). Furthermore, they reject the 2 key assumptions of the critical feminist conceptualizations that dolls are inanimate objects for mere (and questionable forms of) male sexual gratification (eg, acting out sexual fantasies of subjugation and violence against women) and that they are surrogates for real women. Instead, dolls are conceptualized as *new types of social actors*, neither inanimate objects nor surrogate humans but as *posthuman partners* or as *interanimated beings* [31,34,37].

What dolls *are* and what human–doll relationships *mean* is, therefore, not predefined by attributes of the doll, but is the result of the *connections* between the human beings and the *doll beings*. It is up to the users if they *abuse* or *take care of* their dolls if they act out hatred or love. The anthropomorphic, anatomically correct full-body doll in this context might appear passive. The papers, however, argue that in its passivity lies agency and even power [34]: The *doll being*, although vulnerable to abuse just as the human being, is easily able to elicit attention, care, love, and long-term relationships. The conceptualization of dolls as interanimated beings covers rather than denies situations of doll objectification and abuse. However, it also covers situations of doll appreciation, care, and love. Most importantly, such a conceptualization covers complex situations of mixed and ambivalent connections between dolls and their users.

Sex Doll Representations in Art and Media

The second largest group of sex doll publications (7 out of 29; Table 1) analyzes sex doll representations in art and media. Several studies explain that men creating idealized and sexualized female statues, mannequins, or dolls is a *common*

trope in the history of art and culture that can be understood as an expression of patriarchal gender relations, objectification, and fetishization of women [39,42,43]. One notorious example is Ovid's poem about the sculpturer and ancient Greek mythical king of Cyprus, *Pygmalion*. Mythical Pygmalion, appalled by female sexual permissiveness, turned away from real women and created an ivory sculpture of his ideal woman. He physically loved the sculpture, and it later came to life.

A very famous example from modern cultural history is the Austrian artist *Oskar Kokoschka*, who in 1919 commissioned an anatomically correct sex doll in the likeness of his former lover Alma Mahler after she had ended both the relationship with him and her pregnancy. The *Alma Mahler doll* is an example of a portrait sex doll produced without the consent of the person portrayed. Kokoschka lived with the Alma Mahler doll, hired a maid for her, brought her to public spaces like the opera, and created numerous drawings and paintings of her before he destroyed the doll [42,53]. Kokoschka's strange and scandalous actions were often dismissed as a private matter of grief, trauma, or insanity. However, they can also be read as an expression of male entitlement and an attempt to exercise revenge by publicly shaming Alma Mahler. Last but not least, according to the literature, there is also good reason to consider this case as some sort of performance art [42]. Within the sex doll literature, the Alma Mahler portrait sex doll is addressed the most in papers interested in sex doll representations in art and media (4 out of 7) [39,41-43] but is also mentioned in theoretical [33,37], empirical [49], and case study [16,51] sex doll publications.

Although the feminist critique of sex dolls plays a role, most publications in this group provide more complex interpretations. They point to the fact that in creating sexualized female dolls, male artists deal with more than gender relations, also dealing, for example, with their own fear of death [39] or with their own object status [42]. Furthermore, some authors in their cultural analyses point to sex doll-related artwork that reveals additional and potentially emancipatory dimensions of sex doll use. An artist in the United States, Amber Hawk Swanson, who identifies as a lesbian commissioned a RealDoll sex doll in her own likeness from Abyss Creations, married her, and lived and collaborated with her in video and performance artwork. Amber Swanson's *Amber Doll Project* (2006-2011) triggered and disrupted the audience's clichéd (heterosexual) fantasies about lesbian desire, twin sexuality, and the role of females as sexual objects [40].

Another cultural analysis stresses the 2 main functions of dolls: they are made to be looked at and to be played with [41]. Although a feminist critique often assumes a rigid misogynist meaning and use of female sex dolls, art projects demonstrate more complex, creative games to be played with dolls. An artist in the United States Laurie Simmons brought back a female sex doll from Japan and created a series of photographs of her. *The Love Doll* (2009-2011) project goes beyond affirmation and deconstruction of sexual objectification as the female artist casts a loving, *maternal gaze* on her doll, thus inventing "a novel game to play with the doll" [41].

The last 2 publications deal with the representation of sex dolls in movies and television. The first one, the US movie *Lars and the Real Girl* (2007), is interpreted from a psychoanalytic perspective as an "inspiring tale of healing" [44]. The movie tells the story of withdrawn single 28-year old *Lars* who starts living with sex doll *Bianca* to end his loneliness. His family and the whole town play along by treating the doll as his legitimate partner and welcoming her as a new community member. This magically transforms everyone for the better. Ultimately, *Lars* can let go of the doll and turns toward a real woman. The movie deals with the contested topic of men's relations with sex dolls in a very empathetic and romantic way. Interestingly, fictional *Lars* never has sex with his doll because *Bianca* is very religious, and thus, premarital sex is unthinkable. Tellingly, the acceptance of the *Bianca* doll by both the fictional community in which *Lars* lived and by the mainstream cinema audience required her to be a sexually abstinent sex doll [44].

The British Broadcasting Corporation (BBC) documentary *Guys and Dolls* (2007) portrays 4 men (*Davecat*, *Everard*, *Gordon*, and *Mike*) living with their female sex dolls. As media analysis reveals [38], the documentary explains the doll owners' unusual lifestyle as a result of their *heteronormative shortcomings*. The heterosexual men were not able to create relationships with real women and hence settled with dolls. However, a queer reading of the documentary is also possible, as the lifestyle of a doll lover allows men to express their sexualities differently. In the context of doll care, a variety of feminine connotated sensual activities are legitimized and carried out (eg, washing, drying, powdering, dressing, and putting make-up on the doll). Thus, the documentary unintentionally illustrates that the doll owner identity can also be read as a *queer sexual identity* [38].

Empirical Studies on Sex Doll Use and Effects

The third group of sex doll publications (5 out of 29; Table 1) contains empirical studies on sex doll use based on potential future or on current doll users' subjective accounts. We could not find empirical papers dealing with the prevalence of sex doll use. As reported in one of the above-cited theoretical papers [11], in a national web-based survey conducted in 2016 in Germany (N=2000; 50% female, 18-69 years), the lifetime prevalence of sex doll use was 9% for men and 2% for women. A web-based survey of 345 (81% female) undergraduate students in sexuality courses at a university in the United States revealed that 8% of the respondents would use a sex doll and 17% could understand a sex doll user [46]. The authors interpret the result as an indicator of the widespread stigmatization of sex doll use as opposed to the widespread acceptance of sex toy use.

To survey doll owners on their first-hand, long-term experiences with sex dolls, some researchers successfully turned to sex doll owner online community forums for recruitment. A psychological survey with 52 doll owners (6 female) of an English language international online doll owner forum showed that respondents used their dolls for solo and partnered sexual activities and evaluated the sexual experiences with their dolls as enjoyable [49]. Contrary to common belief, the surveyed doll owners (mean age, 43 years) did not show below-average mental health or life satisfaction on standardized scales; however, they

reported possibly above-average problems with sexual functioning. Human-doll relationships are not always monogamous. A considerable number of surveyed male doll owners were in a relationship with a human partner (21%) and/or had more than one doll (39%). The author calls for more research on the psychologically adaptive and maladaptive uses of sex dolls.

An anthropological survey with 83 members (3 female, 2 gender fluid, 2 trans, and 1 other gender) of 2 English language international online sex doll forums revealed that most respondents characterize the relationship with their doll as a *sexual relationship* (50/83, 77%). At the same time, many respondents also describe their relationship with the doll as “companionship” (47/83, 57%) and as a “loving relationship” (39/83, 47%). The researchers conclude that so-called sex dolls not only provide sexual gratification but also serve as multifunctional dolls (they suggest the label *alldolls*) that can provide *posthuman kinship* and alleviation of loneliness.

Instead of using survey methodology, 2 other studies chose a nonreactive approach and collected sex doll owners’ publicly available web-based content. One study qualitatively analyzed 68 customer testimonials (4 written by females) published between 2006 and 2016 on the website of the RealDoll manufacturer Abyss Creations [45]. The researchers found that dolls foster the commodification of female bodies because (1) the manufacturer offers many options for customization that are in line with stereotypical beauty standards, and consequently, (2) the users write a lot and in great detail about their preferences regarding the bodily appearance of their female dolls. Apart from the physical beauty of the doll, emotional closeness to the doll also plays an important role in doll owners’ testimonials. They write extensively about the comforting effect of the doll’s mere presence [45]:

My doll arrived four days ago and my home has a new, warm feeling to it.

They also stress how much they enjoy taking care of the doll (doll maintenance includes regular washing, drying, powdering, and dressing) and, thus, feeling needed [45]:

She’s coming to life for me, I want to take care for [sic] her all the time. Yes, my life has become much fuller.”

The authors’ assessment of men’s attachments to sex dolls is ambivalent—concern about objectification of women’s bodies is mixed with acknowledgment of the creation of supportive emotional intimacy.

The same main result is reported by a qualitative content analysis of 316 discussion threads with 7775 posts from the Abyss Creations RealDoll online forum [48]. Sex doll owners create *embodied intimate fictions* with the dolls. They often praise their idealized bodily attributes and supernatural feminine beauty. However, they do not reduce the dolls to mere sex toys but create rich narratives (in both text and photographs) about their dolls’ personalities, backstories, and experiences, integrating domestic life, outdoor trips, and sexual encounters. Furthermore, the lively discussions in the online forum illustrate that doll owners not only bond with their dolls but also with

other members of the doll owner community. As hobbyists, not unlike pet owners, they share tips and tricks around doll purchase, doll care, and doll photography.

Clinical Case Studies on Sex Doll Use and Effects

The fourth group of sex doll publications involves 3 clinical case studies, 2 from psychology, and 1 from medicine (3 out of 29; Table 1). The clinical-psychological case study of psychoanalyst Danielle Knafo [16] deals with a *48-year-old psychotherapy patient Jack*, an actuary by profession. He had suffered a problematic childhood with a derogatory mother, and his 2 marriages had failed. Deeply hurt by the most important women in his life and inspired by an online forum, he had bought RealDoll *Maya* for over US \$10,000. Reluctantly, he shares with his psychoanalyst that *Maya* has now been his *girlfriend* for 2 years and that she is “beautiful” and “super in bed”. He adds how much he enjoys her company, how harmonious their relationship is (“we never fight”), and that he thinks he might be in love with her. However, he is also conflicted about his unusual lifestyle and therefore seeks therapeutic help. The feminist identified psychoanalyst reports how she was initially repulsed at the idea of a man choosing a sexist object as his girlfriend [16]. However, her “own perversity kicked in” along with a kind of “voyeuristic curiosity,” as she describes it [16]. She manages not to judge Jack but to understand him. She concludes that RealDoll *Maya* is more than a “perversion” and that she is an “invention” and a “lifesaver for Jack” [16]. During psychoanalysis with an accepting female therapist, Jack gains enough self-confidence and optimism to retire *Maya* and return to relationships with real women. In this case study, the sex/love doll served as a soothing and healing *transitional object* in the sense of Donald Winnicott’s [54] theory of transitional objects.

The second case study from the sex doll literature comes again from Danielle Knafo [51] and is based on 7 hours of personal interviews that she led with *Davecat*, a *42-year-old African American self-proclaimed doll lover* in his Michigan home. Davecat has lived with RealDoll *Sidore Kuroneko* (nickname *Shi-chan*) since 1998 and regards her as his wife. They wear matching wedding rings inscribed with the words “Synthetic love lasts forever” [51]. In 2012, Davecat ordered a second doll, this time from the Russian manufacturer *Anatomical Dolls* and named her *Elena Vostrikova* (nickname *Lenka*). *Elena* has the status of a “mistress, plaything and companion” for both Davecat and his bisexual synthetic wife *Sidore*. *Elena* is built lighter with looser joints. “Elena is more built for sex whereas Sidore is built for love” as Davecat puts it [51]. *Muriel Noonan* (nickname *Mew-Mew*), his third doll, is made of wood, leather, Lycra skin, and cotton batting. She is least used for sex and mostly serves as a *flatmate*. Davecat has given all of his dolls complex backstories and personalities and lives with them in what he describes as a harmonious polyamorous *family* to which, at the time of the interview, he plans to add 2 more dolls in the future. Davecat explains how he experiences sex with a doll (for him a “synthetik [sic] partner”) in comparison to sex with a human (for him an “organik [sic] partner”) [51]:

Dolls overall are simultaneously robustly made and fragile. They’re ostensibly made for sex, but they’re

also sculpture pieces. With an organik partner, obviously you can be a bit rougher, but I take care to be gentle with Shi-can and Lenka when we're in bed. Another remarkable difference between organik and synthetik women is that when you're inside a doll's vagina or anus, there's a vacuum effect that's pretty... breathtaking. I'd say sex flows a little better with an organik, as she's able to move herself, whereas changing positions with a doll requires you to pause and rearrange everything. Overall, though, personally, I'd rate sex with a synthetik woman to be as good, if not better, than with an organik woman. Mainly as a doll's artificiality is a huge draw with me....

The psychoanalyst characterizes Davecat as a man who has been struggling all his life with intimacy issues and has found dolls as a viable alternative to having a human partner. At the same time, she acknowledges that Davecat feels sexually and emotionally attracted to the artificial aspects of dolls [51]. He self-identifies as an *iDollator*, a doll lover who prefers dolls to humans. This identity is so meaningful to Davecat that he serves as an activist and spokesperson for the doll lover community. He has participated in numerous press interviews, photoshoots, and television documentaries (eg, the earlier mentioned BBC documentary *Guys and Dolls*). The psychoanalyst, dissecting Davecat's biography, neither stigmatizes nor pathologizes him. Although she assumes that his unconventional lifestyle is rooted in anxieties and conflicts [51], in her evaluation, it appears to be a viable solution. After all, Davecat is not harming anybody, is able to work, well-integrated socially, and satisfied with his life.

The third and last case study is a medical one. It proves that the shared use of an inflatable sex doll can lead to the transmission of a sexually transmitted disease (ie, gonorrhea) if the doll is not cleaned or no protection is used [50]. In this case, a male sailor had found the sex doll of a colleague on board by chance and used it secretly.

Legal Regulation of Child Sex Dolls

The fifth and final group of sex doll publications covers 3 publications on child sex dolls (3 out of 29; Table 1). All 3 call unanimously for a legal ban and explore the implementation of such a ban in different legal systems, namely, in Australia [19], the United Kingdom [52], and the United States [20]. They reject the idea of possible therapeutic value and stress that the production, marketing, and use of child sex dolls would normalize and foster child sexual abuse. The publications point to different harmful uses of child sex dolls (eg, the use of child sex dolls during grooming or during the abuse of children or the exploitation of individual children by producing portrait sex dolls in their likeness). The most important reason given for banning child sex dolls is the assumption that acting out child sexual abuse with a doll would rehearse, train, and trigger real child sexual abuse. Abstract child sex dolls are compared with computer-generated or so-called *fantasy child pornography* [52]. In both cases, no children are directly harmed in the process of production, but the dissemination and marketing of two-dimensional or three-dimensional depictions of sexualized

children is still considered harmful and exploitative and should therefore be criminalized according to all three studies.

Research Gaps in Sex Dolls

There is a considerable discrepancy between the great media interest in the topic of sex dolls and sex robots mentioned in the introduction and the limited amount of scientific knowledge. Overall, the interdisciplinary field of sex doll research is fairly small (RQ1). *Empirical and clinical* studies on doll use, in particular, are scarce (5 peer-reviewed papers in total) and often have limited generalizability due to small convenience samples or single case studies. Accordingly, it is not surprising that many research gaps exist.

Research Gaps in Sex Doll Design

Regarding *sex doll design* (RQ2), many publications agree that the sexualized and idealized looks of female sex dolls pose a problem in terms of further sexual objectification of women within a patriarchal consumer culture already saturated with unrealistic beauty standards for women's bodies. However, previous research falls short on conceptualizing the *sexual fantasy dimension of sex dolls*. Understanding dolls as embodied sexual fantasies, it is neither surprising nor questionable that dolls do not mirror reality as it is, or as it ethically ideally should be, but unapologetically express unrealistic, exaggerated, clichéd, and thus exciting and satisfying fantasies. Research on sexual fantasies has revealed that humans of all genders are usually not particularly turned on by morality or normality but often by the direct opposite [55,56]. What technological change brings about is ample new possibilities to express and materialize sexual fantasies formerly enjoyed purely privately so that they now become readable, audible, visible, and—with dolls and robots—even tangible in the public realm.

Although a sex-positive perspective usually acknowledges the value of fantasy, creativity, play, provocation, and pleasure, a critical perspective usually warns against the expression and dissemination of fantasies whose content is not in line with the ethical standards applied to real life. Obviously, child sex dolls are regarded as a hard limit in the academic sex doll literature. However, for other types of fantasies that dolls can and could embody, there is no consensus and not even a rational debate.

If the breast size of female sex dolls poses a problem (many authors complain about the female dolls' *pornographic looks*), what range of breast sizes would be ethically correct and/or harmless enough regarding the prevailing beauty norms for female bodies? Do we need size norms for ethical dildos and vibrators as well? Questions like these are both banal and profound at the same time: meaningful critical evaluations of sex doll design should go beyond the trivial observation that sex dolls look like sexual clichés because that is exactly the point of sexual fantasy products. Young-looking sex dolls and related products like full-body cushions depicting sexualized young women (so-called *dakimura*) are often criticized, but, in Japan, for example, their main target group is young men and adolescent boys [35]. Is it inappropriate that they desire same-age dolls? Do we want older-looking dolls to be marketed to them? Racial issues are also very confusing. Regarding racial prejudices and privileges, one might problematize that in Japan,

for example, exclusively Japanese-looking sex dolls that emphasize skin whiteness are marketed [35], whereas one may also problematize the marketing of Japanese-looking sex dolls to non-Japanese customers. Is there any way to criticize (and improve) sexual fantasy product designs and marketing strategies that take into consideration both the concern about social inequalities and vulnerabilities and the concern for sexual rights and freedom of sexual fantasy and expression?

The same issues have been discussed for decades regarding pornography [57]. Although some authors still claim that all pornography is inherently inhumane and sexist, just as some authors and activists claim that all sex dolls are inherently inhumane and sexist, other authors and activists accept that sexual explicitness and lack of realism are necessary ingredients of sexual fantasy products. However, they push for a greater variety of fantasies to be represented in the products. This is why female-friendly, couple-friendly, feminist, and queer pornographies have been produced and investigated since the 1980s [58]. The sex doll market could also be diversified. Exploring directions for diverse sex doll designs and their implications could be a task for future research. Design studies could bring together sex researchers, current and future customers with different gender and sexual identities and lifestyles (including older people and people with disabilities), sexual health experts, designers, and/or industry representatives. Collaborations with the sex doll industry promise new insights and, against common belief, do not imply the abandonment of critical analysis. Indeed, critical analysis is often much sharper and more to the point if researchers are closely familiar with the research subject and its context instead of only looking at it from a distance.

Research Gaps in Sex Doll Use

Although pornography use has become mainstream among men and women, it is unclear how large the sex doll user population is and whether it will grow or stay a niche market. Systematic analyses of market data and representative surveys of national populations regarding the prevalence and acceptance of sex doll use are widely lacking. In China, for example, due to the former one-child policy, there is a demographic surplus of millions of men—will they become a target group for sex dolls (HJ Nast, unpublished data, 2019)? With aging societies and a persistent gender gap in life expectancy, we will see a surplus of millions of widows and single older females in developed countries—perhaps another target group for sex dolls and further innovative sexual technologies.

Previous studies on sex doll owners' experiences have demonstrated that men create complex, multi-dimensional relationships with their dolls that include, but are not limited to, the search for sexual gratification. To further explore the *psychology and sexuality of doll play and human-doll relationships*, theories, methods, and results from related research fields should be considered.

Although sex doll conceptualization struggles with the passivity and object status of dolls and the one-sidedness of human-doll relationships, in the field of media research, the concept of one-sided “parasocial relationships” between humans and media figures has been well developed for more than half a century

[59]. It is also established that parasocial interactions and relationships are linked to well-being [60]. Romantic and erotic relationships between humans and media figures are common (eg, adolescent girls falling in love with members of boy groups from the music industry) and psychologically meaningful and helpful [61]. Established measures for parasocial interactions and relationships between humans and media personas could be adapted to investigate human–sex doll interactions and relationships.

Surprisingly, research on men's play with female sex dolls has widely ignored the research on children's play with childlike dolls and research on women's play with babylike dolls. Children love, kiss, cuddle, talk to, and sleep with their dolls, and sometimes, they poke their dolls' eyes, cut their hair without consent, or open their stomachs during questionable operations [62–64]. However, nobody assumes that children's use of childlike dolls makes them antisocial or encourages them to treat other children like objects. The same holds true for the female adult doll owner community that uses realistic baby dolls (so-called *Reborn Dolls*,). Here, women use doll play to express sexuality-related fantasies of procreation and motherhood without being accused of antisocial inclinations or objectification of babies, although their behavior is criticized and scandalized in the media [51,65]. Last but not least, research on sex doll use could learn from research on so-called *doll therapy* [66]. Doll therapy addresses dementia patients and encourages holding, kissing, cuddling, talking to, feeding, or dressing an anthropomorphic doll because interactions and relationships with dolls provide comfort, control, and peace as well as feelings of pride, purpose, and bonding that can alleviate agitation and other symptoms [66]. Such soothing and healing effects of dolls have also been reported by sex doll owners. Theoretical elaboration is needed to link and/or differentiate the various user groups and uses of different types of dolls. Why is men's play with sex dolls so outstanding in its assumed connections with antisocial tendencies and an unhealthy confusion of play and reality? Are male gender and sexual fantasy dolls such a dangerous coupling and/or are we dealing with sex-negative and gendered projections?

The previous literature points to different types of sex doll owners like the passionate, possibly paraphilic, lifelong *iDollator*; the misogynist doll owner, the possibly sadistic doll owner striving for complete dominance; the pedophilic doll owner; the transient doll user working through hurt and heartbreak or through teenage angst; the unattractive, old, or disabled user with very limited prospects of success in the real partner market; the doll photographer and hobbyist; or the sexually experimental female user and couple. However, a definitive typology is missing. According to the literature, approximately 20% of the sex doll owner community are couples and females [67], and thus far, we do not know much about them.

Research Gaps in Sex Doll Effects

Sex doll effects of both long-term and short-term sex doll use are under-researched. Long-term domestic use by doll owners has only been explored with small convenience samples and mostly without the use of established and validated measures

for predictors and outcomes of sex doll use, for example, measures of sexual and mental health, personality, sociability, sexism, doll-related paraphilias (eg, objectophilia and doll fetishism), and new sexual identities (eg, digisexuality) [68]. Short-term commercial uses of sex dolls and their effects are completely unexplored. Interviews with customers of *sex doll brothels* and expert interviews with sex doll brothel staff could be helpful. The therapeutic uses and effects of sex dolls have also been under-researched. More clinical case studies are necessary.

What is special about sex dolls as sexual fantasy products is their materiality: they are embodied sexual fantasies, and their use demands specific sexual skills—fantasy skills to enrich the parasocial interaction and practical skills in positioning and moving the heavy doll to create an enjoyable and satisfying sexual experience. Thus far, no observational or experimental studies of social or sexual interactions between humans and sex dolls and their outcomes have been conducted.

State of Research on Sex Robots

We have summarized the state of research on sex robots by mapping the number and type of publications, reporting their main results and indicating the research gaps.

Amount and Type of Research on Sex Robots

During the scoping review literature identification process, we included 98 academic publications on sex robots (Figure 2). This body of literature consists of 6 distinct groups of publications according to both their topics and their methodologies (Table 2). The groups of sex robot publications are similar to those of sex doll publications, the main difference being unavailability of clinical case studies for sex robot, but the availability of many ethical studies and some design studies.

The largest group of sex robot publications (40/98, 41%) deals with sex robot conceptualization and theory, written by authors from social and life sciences, humanities, philosophy, and engineering. The second largest group of publications (28/98, 29%) addresses the ethics of sex robots and is mainly rooted in philosophy. The third group of publications contains empirical studies on sex robot use and effects (12/98, 12%), mainly from the fields of psychology and human-computer interaction. The fourth group of publications addresses sex robot representations in art and media (8/98, 8%), the fifth group of publications looks at child sex robots and their legal regulation (6/98, 6%), and the sixth and final group of publications involves sex robot design studies (4/98, 4%).

The body of academic literature contains 3 published monographs focusing exclusively on sex robots [1,69,70]. Approximately one-third of the included sex robot publications are peer reviewed (32 out of 98). Many sex robot publications are papers from the international conference series LSR (*Love and Sex with Robots*), initiated by David Levy (LSR1 2014 in Funchal, Portugal; LSR2 2016 in London, United Kingdom; LSR3 2017 in London, United Kingdom; and LSR4 2019 in Brussels, Belgium). The Google Scholar citation count reveals a range from 0 to more than 500 citations, the latter for David Levy's [1] seminal book *Love and Sex with Robots*. Heavily cited sex robot publications are often not peer reviewed. Regarding the timeline, the oldest sex robot publication identified in the databases and included in our review is a 1997 comment of a sociologist on the impact of future sex robots [71] that raises questions still discussed today. However, it is an outlier, with approximately 85% (83/98) of the sex robot publications having been published in the last 5 years (2015-2019; Figure 3).

Table 2. Amount and type of research on sex robots (N=98 included academic publications, based on literature search in August 2019).

Research Findings on Sex Robots

In the following sections, the main findings of previous sex robot research will be reported separately for the 6 groups of sex robot publications (Table 2).

Sex Robot Conceptualization and Theory

The largest group of sex robot publications (40/98, 41%) deals with the conceptualization of sex robots and of human–sex robot relationships. Within this group, 2 issues are predominant: the (non)inherent sexism of sex robots and the (non)humanness of sex robots.

Echoing the critical feminist conceptualization of female sex dolls, several publications on sex robots characterize the female sex robot as an *inherently sexist object*. The most cited author of this position is Kathleen Richardson [13], who conceptualizes the female sex robot as a representative or surrogate of a sexually objectified woman, a female (forced) porn actor, a female (forced) prostitute, or a female sex slave. Following this conceptualization, the production and use of female sex robots is regarded as harmful for individual male users, their female partners, and society at large, as female sex robots symbolically reinvent and reaffirm the status of women as sex slaves [85]. However, this conceptualization operates more with metaphorical equations than established theories and is challenged by other publications as vague and unconvincing [79,80,89]. Although existing sex robots might appear sexist,

different designs are possible; therefore, sex robots are not inherently sexist, according to other authors [11,69,76,78,98].

Further theoretical publications deal with the question of the humanness of the sex robot. Several publications stress that, by their definition, sexual interactions and intimate relationships are bidirectional and require a consenting human partner. Humanness—by the definition of these publications—implies sentience, first-person consciousness, and free will; none of these attributes can be ascribed to current sex robots. Consequently, the authors conclude that current sex robots are *nonhuman pseudo persons*. Accordingly, relations with robots are only *pseudorelationships* that inherently lack mutual concern for the welfare of each other [74] and do not lead to personal or spiritual growth [88]. Following this conceptualization, there is no sexual interaction possible *with* a robot or *between* a human and a robot, only robot-enhanced solipsistic masturbation [83].

There are also publications that focus on *future advanced sex robots* and their humanness. Several authors assume that, in the foreseeable future, sex robots could be produced that are sentient, self-conscious, and have a free will [24]. They might even have the legal status of citizens so that humans can legally marry them [72,84,91]. Such advanced humanoid robots will be so human-like that they must be conceptualized as persons and relations with them as interpersonal relationships. Advanced sex robots with excellent social and sexual skills and perfect looks who enter relationships with humans out of their own free

will could be very attractive for many people [82]. Advanced sex and love robots could bring more love to the world [94], but they could, at the same time, devalue real humans [93]. However, the concept of an advanced sex robot that is almost indistinguishable from a real human paradoxically makes it seem pointless to build sex robots. If the advanced sex robot acts like a self-determined, willful human, if it consequently lies, cheats, criticizes, disregards, rejects, and leaves the human, what is the merit of creating it in the first place [87,92,95,96]?

Obviously, there is an inherent tension in the conceptualization of the degree and quality of humanness of interactive humanoid robots. A dumb robot is easy to control but lacks autonomous capabilities and sociability; hence, it cannot bring much additional value to traditional sex dolls. An intelligent advanced robot provides true sociability but lacks the manageability and obedience that we expect from a service technology.

A third conceptualization overcomes the divide between a sex robot as a mere masturbation aid and a sex robot as a quasihuman and stresses that successful sex robots can easily be imagined as purposefully designed to be nonhuman like regarding appearance, functionalities, and social role. Possibilities might be sex robots as synthetic animals [77], as fantasy creatures, or as interfaces to other types of sexual entertainment technology (*fantasy hardware*) [86]. Sex robots could be cherished and desired by humans, particularly by *digisexuals* or *technophilics*, precisely because of their *fundamental otherness* [68,99]. As humans can bond with sex dolls, it is even easier for them to form meaningful emotional attachments with interactive sex robots [26,73,75]. Instead of insisting that advanced sex robots be as human-like as possible to legitimize sexual interactions and emotional attachments with them, robots could also be accepted as nonhuman social agents, for example, to provide safe sex work [15], alleviate social and sexual deprivation [81], or allow for safe explorations of sexual fantasies [2].

The different implications of a wider use of sex robots are addressed by many theoretical publications as unanswered questions [71,97], for example, regarding health [17], social norms [70], and religious beliefs [90].

Ethics of Sex Robots

What is the *right thing* to do in view of the emergence of sex robots? The second largest group of sex robot publications (28/98, 29%; Table 2) attempts to tackle this core question of sex robot ethics. Although some authors stick to metareflection and debate which ethical approach to use [104], other authors provide answers of 3 different types:

- *Sex robots should not be built and used at all.* Starting from the assumption that human-human sexual and romantic relationships are most healthy and ethically superior to all human-robot pseudorelations and to the use of sexualized and sexist robotic objects, authors with different political [109], philosophical [119], feminist [114,115], theological [100,120], engineering [122], and legal [118] academic backgrounds reject further developments in this field. They call for bans and boycotts, stigmatization of, and abstinence from sex robots. Quite popular and often quoted in the

media are the arguments of the earlier mentioned Kathleen Richardson, founder of the *Campaign against sex robots*, who compares sex robots with killer robots and with female sex slaves [114,115].

- *Sex robots should be built in an ethical way to avoid harm to humans, especially vulnerable humans.* Starting from the assumption that sex robots can be a good thing if they alleviate loneliness and/or sexual deprivation and contribute to the sexual and social well-being of individuals and couples, authors with different backgrounds encourage ethical design [105]. Publications are very diverse and often vague as to what exactly they expect from ethical sex robot design. One author explains that she wants sex robots designed in such a way that they do not get involved in acts of infidelity because they have learned the concept of heartbreak [125]. Other authors explicitly do not want sex robots to be *love robots* because they fear humans could be too easily manipulated by robots that fake romantic attachment [121,123]. Others want sex robots designed in a women-friendly [110] and disability-inclusive [106,107] way or demand design that is more focused on consumer safety [117]. Some authors point out the many different questions for ethical design ranging from “Should the robot become active on its own and entice the partner to have sex?” to “How should the robot collect and evaluate patient data to better satisfy its partner’s sexual needs?” [101,102]. As some authors assume that the development of sex robots is driven by a profit-oriented *uncaring industry* [124], there is a need for more involvement of ethically responsible entrepreneurs and designers from different backgrounds who aim to develop and market sex robots for sexual well-being, pleasure, fun, and play while taking into consideration the concerns and desires of diverse user and stakeholder groups. Some authors are very optimistic that sex robots will bring a lot of pleasure and happiness and are, therefore, ethically a good thing [112], although some ethical issues are unresolved (eg, regarding *robot prostitutes*) [14]. Other authors stress that robots are a good thing only for a very small group of people who absolutely cannot find a human sex partner [124].
- *Sex robots should be built in an ethical way to avoid harm to robots, especially for advanced sentient robots.* Starting from the assumption that future humanoid robots will be advanced to a very high degree of human likeness, according to several authors, their sexual and other citizen’s rights must be protected with a *nonanthropocentric* but *robocentric* ethic [23,24,103,111,116]. For example, sex with an advanced sex robot should only be acceptable if the robot has given explicit consent [108]. Although some authors stress the relevance of a robocentric ethic for sex robots to protect them from anticipated harm and exploitation, other authors argue that sentient robots designed as sex robots could have a “good life” and experience pleasure and satisfaction from fulfilling their tasks [113].

Empirical Studies on Sex Robot Use and Effects

The third group of sex robot publications contains empirical studies (12/98, 12%; Table 2). Thus far, not a single empirical

study has been published that deals with the small but presumably growing number of pioneer users of sex robots. All existing studies address nonusers and investigate their attitudes toward sex robots and their reactions to sex robot-related stimuli.

Most empirical studies (8/12, 67%) are small web-based surveys on sex robot acceptance using convenience samples from the United States (N=261: [126], N=133: [130], N=100: [131], and N=198: [132]), Germany (N=263: [133]), Indonesia (N=380: [136]), and Malaysia (N=32: [127]). Their results show diverse rates of sex robot acceptance. For example, 40% of male and 17% of female respondents in the United States (mean age, 33 years) reported willingness to try out a sex robot [131] in comparison with 16% of Indonesian respondents [136] and 9% of Malaysian respondents [127]. Cultural background, male gender, positive attitudes toward robots in general, interest in manga and games, sensation seeking, and shyness appeared to be predictors of sex robot acceptance. Interestingly, sexual and relationship satisfaction did not predict sex robot acceptance [130,133]. However, because of the small nonrepresentative samples, the generalizability of existing sex robot acceptance data is very limited. Another problem is the varying operational definitions of sex robots given to respondents in the surveys. A Delphi survey explored the predictions of 20 social robot experts who were reluctant regarding sexual apps [129], whereas 1 expert interview explored the sex robot predictions of the founder of sex doll and sex robot manufacturer Abyss Creations, Matthew McMullen [67].

In addition to the survey and interview studies, 3 experimental studies were found (3/12, 25%). They investigated how heterosexual women experience their male partner's imagined infidelity with a female robot vs a real woman [134], at which body parts of female robots vs female humans, both represented in pictures, male and female gaze [135], and how humans physically react when they touch different, including private, body parts of a robot that is not a sex robot [128]. Overall, these experiments show differences and similarities in humans' sexuality-related reactions to humanoid robots and fellow humans. So far, no experimental study exists that uses an actual sex robot as the stimulus material.

Sex Robot Representations in Art and Media

The fourth group of sex robot publications concerns sex robot representations in art and media (8/98, 8%; Table 2). In their selected and analyzed examples from the science fiction literature, some studies from humanities focus on fictional female sexbots that seem to embody male fantasies of the ideal woman but who, in the course of the action, become *feminist robots* striving for independence from their male human partner or creator by leaving or even killing him, for example, the robot *Ava* in the 2015 UK movie *Ex Machina* [141,143], the virtual *Samantha* in the 2013 US movie *Her* [143], or the robotic wife in the 1981 Chinese story *Conjugal Happiness in the Arms of Morpheus* [139]. The famous US television series *Star Trek Voyager* presented the character *Seven of Nine*, a cybernetic organism and former Borg drone, who—although embodying traditional feminine beauty—challenged traditional ideas of gender and sexuality [137]. Other dystopian science fiction

representations, selected and analyzed by the academic literature, illustrate the female sex robots' sexual exploitation and victimization, for example, as porn actors in the 2009 US movie *2040* [138] or as rape victims in the US television series *Westworld* [143]. One monograph critically analyzes posthuman utopias in sex robot representations [142], and one editorial volume documents the *Robot Love 2018 International Expo* of the *Niet Normaal Foundation* in the Netherlands that brought together researchers and artists [140].

A quantitative media content analysis examined the representation of human–sex robot relationships in 370 fictional and 340 nonfictional media examples [27]. The results of this study indicate that media representations of intimate human-robot relationships tend to portray the human partner as a man who is disadvantaged in interpersonal relationships. At the same time, media often portray the involved robot partner as a humanoid female sex robot. Although nonfictional media describe intimate human-robot relationships more often in sexual terms, fictional media focus more on emotional aspects, cohabitation, and even procreation between humans and robots. Overall, media representations of intimate human-robot relationships reveal stereotypical gender roles, heteronormativity, and a focus on sexual vs emotional intimacy [27].

Legal Regulation of Child Sex Robots

The fifth group of sex robot publications covers child sex robots (6/98, 6%; Table 2). All the 6 publications [18,20,52,144–146] characterize child sex robots as harmful and unethical and call for a legal ban that is already in preparation or in effect in several countries (eg, the aforementioned *CREEPER Act of 2017* in the US) [20]. In all, 2 publications speculate on the possible therapeutic uses of child sex robots. Although one of them assumes that their exploration would be too risky [145], the other encourages their exploration only in certain, controlled circumstances under strict medical supervision and in accordance with guidelines issued by an ethics committee [18].

Design of Sex Robots

Only 4 publications in the sex robot literature focus mainly on design (4/98, 4%; Table 2): 1 on erotic voice output [147], 1 on a mind-controlled neurodildo to be used separately or implemented in robots [9], 1 on general design aspects based on results about sex doll use [48], and 1 on feminist sex robot design in an analogy of initiatives for feminist pornography [148].

Research Gaps in Sex Robots

Although the body of sex robot publications is 3 times as large as that of sex doll publications, *empirical* studies on sex robot use and effects are equally scarce (4 peer-reviewed papers in total). Fundamental questions regarding the sexual use of human-like full-body material artifacts that remained unanswered for sex dolls also remain unanswered for sex robots.

Research Gaps in Sex Robot Design

Just as with sex dolls, the question of how much fantasy, and which and whose fantasies should legitimately be implemented in sexual fantasy products to make them socially acceptable,

harmless, and still sexually desirable and exciting, remains unanswered with sex robots as well. Although there is a lot of speculation on the possible therapeutic uses of sex robots to be found in public and academic debates, the literature fails to provide design guidelines for therapeutic sex robots informed by evidence from sex and relationship therapy and focused on specific problems (eg, on sexual shyness and anxiety, sexual dysfunctions, sexual trauma, paraphilias, and paraphilic disorders). Design studies for current sex robots hardly exist, and the literature predominantly speculates about imagined future sex robots. Instead of researchers, it was journalists who first dealt with the question, “What would sex robots for women look like?” [149] and who let women and men draw and explain their *ideal sex robots* [150].

Research Gaps in Sex Robot Use

Thus far, no empirical study has investigated experienced sex robot users or interactions of unexperienced participants with actual sex robots. Results from research on sex doll use are, therefore, the best available proxy for sex robot use. Regarding the potential market size and user population, there are also no data available that allow for sound predictions. One might speculate that sex robots could overcome some of the stigmatization of sex dolls as sex robots can be framed as cutting edge, high-tech products. Thus, their users might appear more modern, future oriented, and competent in comparison with traditional sex doll owners. Against this backdrop, one would expect more growth for the sex robot market than for the sex doll market, but data are needed. To further explore the sexual appeal of robots, insights from research on objectophilia [151,152] and technofetishism [153] could be helpful.

Surprisingly, the sex robot literature falls short in conceptualizing and investigating interactions and relationships between humans and current sex robots in a psychologically nuanced way. Whereas the sex doll literature has already established that dolls easily trigger humans to build meaningful, caring, loving, long-term relationships with them, the sex robot literature often falls back on binary thinking. It categorizes the current sex robot as an inanimate object and mere masturbation aid without any sociability and is only willing to ascribe sociability to future imagined sex robots that are advanced to the point of indistinguishability from humans. Hence, the literature on sex robots often misses the key point that robots are more than mere masturbation aids due to anthropomorphization and that they are meaningful and possibly helpful precisely because they are not substitutes for real humans but are sociotechnical entities for parasocial use and play. Parasocial interactions and play with sexual fantasy products grant more degrees of freedom in sexual expression and allow to take a break from all of the norms, ethics, expectations, and responsibilities of human-human interactions.

Research Gaps in Sex Robot Effects

As sex robot users and use are completely unknown thus far, any claims about positive and/or negative effects are mere speculation. Although some authors are so convinced of their speculations on strong to catastrophic negative effects that they demand immediate boycotts and bans of sex robots, others urgently call for empirical research on sex robot effects. The

idea that sex robots allow humans to indulge in interactive embodied sexual fantasies elicits strong projections of lust and fear. Most likely, empirical research will help us overcome exaggerated projections and understand the diversity and ambivalence of effects on different types of sex robot users.

Discussion

Main Results of the Review

In conclusion, the main results of the whole review are summarized, its limitations are indicated, and a roadmap for future research is drawn. The body of sex robot literature, with approximately 100 academic publications in total, is more than 3 times larger than that on sex doll literature, with approximately 30 publications (RQ1). However, only a handful of peer-reviewed empirical papers on both sex doll use and sex robot use are available thus far. No sex robot study exists that investigates people experienced in sex robot use and/or introduces actual sex dolls or sex robots as stimulus material. Regarding the first RQ, one must concede that sex dolls and sex robots, although attracting growing public and scholarly attention, are heavily under-researched. Both sex doll and sex robot research are fields characterized by disciplinary diversity, with notable participation from philosophy, humanities, and engineering, and a conspicuous lack of participation from sex researchers.

Sex doll and sex robot designs (RQ2) are often critically assessed in the literature, mainly because the bodies of women-like dolls and robots are usually designed in sexualized ways following and exaggerating traditional feminine beauty ideals. However, when understanding sex dolls and sex robots as sexual fantasy products, it makes sense that they do not imitate reality but cater to sexual fantasy. Often, it is exactly the point of sexual fantasies to be unrealistic. Thus far, the literature has not addressed the core question of how we could and should assess designs of sexual fantasy products such as sex dolls and sex robots, considering both social inequalities and vulnerabilities and the freedom of sexual fantasy and expression. Regarding future advanced sex robots, the literature presents various requirements for ethical design, which—at the current state of robot development—are very speculative. Systematic design studies that work with current and future users (eg, private sex doll owners, sex workers, and sex therapists) and address different use scenarios (eg, domestic, commercial, or therapeutic) are lacking.

Although previous research has provided some insights into the domestic long-term use of sex dolls (with or without parallel psychotherapy), no data have been collected thus far on the short-term interactions or long-term relationships between humans and sex robots. Thus, the best proxy for sex robot use and users today is the limited data on sex doll use and users (RQ3).

Considering the lack of empirical knowledge about sex doll users and sex robot users and use, it is obvious that the predictions of positive and negative effects found in the literature can only be speculative (RQ4). It is striking that authors still provide very strong and contradictory effect claims ranging

from utopian visions of improved sexual satisfaction and overall happiness to dystopian visions of dehumanization, objectification, and isolation. Predictions of small and/or ambivalent effects might be more realistic but are seldom discussed in the academic literature thus far, which seems to mirror some of the hype and scandalization observable in public media discourses.

Limitations

This scoping review addressed sex doll and sex robot research as far as it is represented in the accessible literature published before August 2019. We were particularly careful to retrieve publications not only from the databases but also, in a systematic way, from all the included publications' reference lists. Nevertheless, it must be taken into consideration that further studies that have not (yet) been published and/or were not (yet) accessible (eg, conference presentations, qualifications theses, and journal articles under peer review) could exist. However, we are confident that our systematic literature identification strategy covered previous research thoroughly enough, especially as this is the very first systematic review of the field.

To map previous research in a comprehensible and useful manner, we organized the body of literature by building distinct groups of publications according to their key topics and methodologies. We discussed data charting and synthesis within the team and checked everything in duplicate. However, some decisions might be questionable. There is an inherent tension between the aim of providing a clear and comprehensible structure, which requires a reduction in complexity, and the aim of doing justice to the individual publications, which requires a representation of their complexities. Due to space constraints, we were forced to reduce the complexity much more than we would have wished. Therefore, we encourage readers to consult the original publications whenever in doubt and apologize to fellow researchers in case they feel our review misrepresents their work.

Another inherent problem of a multidisciplinary review lies in the tension between the aim of doing justice to discipline-specific styles of knowledge production and communication and the aim of presenting existing knowledge in a consistent, readable, and generally understandable way. We deliberately simplified concepts and streamlined discipline-specific jargon to improve consistency. We provide a broad overview spanning from ancient Greek myths to contemporary web-based surveys, and spanning from the psychoanalyst's office to the robotics lab. We agree with many authors we cite in this review that a deeper understanding of sex dolls and sex robots and their meanings for human sexuality can only be achieved through more interdisciplinary collaboration. We hope that our prioritization of disciplinary width over depth will inspire this collaboration. However, we are aware of the risks and limitations of simplification.

Roadmap for Future Research

Hopefully, the many and diverse research gaps pointed out in this review can serve as starting points for future research projects on sex dolls and sex robots, their design, use, and

effects. To conclude, we suggest 4 selected, particularly urgent research strands:

1. *Public debates* about and *media representations* of sex dolls and sex robots, polarized and scandalizing as they are, attract much attention, shape public opinions, and influence research activity. They deserve more scholarly analysis and participation by the sex research community. This includes traditional mass media and social media. Mass media tend to assume dramatic positive or negative effects, while often completely ignoring the fact that sex dolls and sex robots, overall, could have only small and/or ambivalent effects. Social media, sometimes, offer more nuanced views, but expert statements and documentaries about sex robots on YouTube, for instance, are met by a noteworthy amount of misogynist comments that welcome female sex robots as substitutes for women. On Twitter and Instagram, we see sex dolls communicating to the public, their accounts steered by doll owners (eg, the earlier mentioned *Davecat*) and by doll manufacturers. These examples illustrate that we need to know more about media representations as they are an important element of the cultural context in which sex dolls and sex robots are developed, marketed, discussed, used, and investigated today.
2. Research on the sexual uses of human-like *material artifacts* such as sex dolls and sex robots needs to be advanced and connected to research on human-like *digital artifacts* such as chat bots, avatars, holograms, or immersive virtual reality pornography. After all, a sexual AI system trained by a particular user could be used on different technological and media platforms such as a full-body sex robot, an immersive virtual reality system, or a smartphone. Although the materiality of dolls and robots offers new possibilities in terms of embodied sexual fantasies (eg, physical presence, physical care, physical touch, and physical stimulation), it also creates boundaries (eg, through the body weight and difficult handling of the dolls and robots at home, limited mobility outdoors, high visibility, and risk of social stigmatization). For sexual fantasy products that aim to enhance their users' sexual and social experiences, the right degree and mixture of materiality and virtuality is an open question for research and design.
3. Although sex robots have triggered the publication of many theoretical and ethical papers, we urgently need *empirical data* on actual sex doll and sex robot users and uses. Different study designs (nonexperimental and experimental, cross-sectional, and longitudinal) and data collection methods (qualitative interviews, focus group discussions, surveys, psychological tests, and physiological measurements) are suitable for research with actual sex doll and sex robot users. Instead of using only imagined or visually depicted artifacts as stimulus material, some of the real sex dolls and sex robots should be incorporated in empirical studies.
4. Despite the relatively large number of theoretical papers, the degree of *theoretical elaboration* of human–sex doll/sex robot relations and their consequences is not yet very high [12]. Commonly used theoretical concepts are objectification, gratification, and pseudorelationships. For a more thorough understanding, we suggest including

theoretical concepts from the field of doll play and doll therapy and from the field of human interaction with media personas (parasocial interactions and relationships), with digital technologies (computers as social actors and media equation theory) and with social robots (uncanny valley concept and anthropomorphization) as well as from social psychology (social cognitive learning theory), clinical and developmental psychology (transitional objects,

objectophilia, and robophilia), and sexuality research (sexual scripts theory and theories on sexual fantasies). It is not yet clear which theories from the different related research fields on dolls, robots, sexuality, gender relations, well-being, and health are best applicable to human–sex doll/robot relationships and if and how they can be combined to best explain the complex intimate engagements of humans with artifacts.

Conflicts of Interest

None declared.

Abstract

Background: Virtual humans (VH) are computer-generated characters that appear humanlike and simulate face-to-face conversations using verbal and nonverbal cues. Unlike formless conversational agents, like smart speakers or chatbots, VH bring together the capabilities of both a conversational agent and an interactive avatar (computer-represented digital characters). Although their use in patient-facing systems has garnered substantial interest, it is unknown to what extent VH are effective in health applications.

Objective: The purpose of this review was to examine the effectiveness of VH in patient-facing systems. The design and implementation characteristics of these systems were also examined.

Methods: Electronic bibliographic databases were searched for peer-reviewed articles with relevant key terms. Studies were included in the systematic review if they designed or evaluated VH in patient-facing systems. Of the included studies, studies that used a randomized controlled trial to evaluate VH were included in the meta-analysis; they were then summarized using the PICOTS framework (population, intervention, comparison group, outcomes, time frame, setting). Summary effect sizes, using random-effects models, were calculated, and the risk of bias was assessed.

Results: Among the 8,125 unique records identified, 53 articles describing 33 unique systems, were qualitatively, systematically reviewed. Two distinct design categories emerged — simple VH and VH augmented with health sensors and trackers. Of the 53 articles, 16 (26 studies) with 44 primary and 22 secondary outcomes were included in the meta-analysis. Meta-analysis of the 44 primary outcome measures revealed a significant difference between intervention and control conditions, favoring the VH intervention (SMD = .166, 95% CI .039-.292, $P=.012$), but with evidence of some heterogeneity, $I^2=49.3\%$. There were more cross-sectional ($k=15$) than longitudinal studies ($k=11$). The intervention was delivered using a personal computer in most studies ($k=18$), followed by a tablet ($k=4$), mobile kiosk ($k=2$), head-mounted display ($k=1$), and a desktop computer in a community center ($k=1$).

Conclusions: We offer evidence for the efficacy of VH in patient-facing systems. Considering that studies included different population and outcome types, more focused analysis is needed in the future. Future studies also need to identify what features of virtual human interventions contribute toward their effectiveness.

KEYWORDS

virtual humans; avatars; patient-facing systems; meta-analysis; conversational agents; chatbot; digital interlocutors

Introduction

Patient-facing systems are digital technologies that offer health services and engage people in their health and wellbeing [1]. These systems promote and facilitate both patient engagement with the health care system and patient empowerment in self-care [2]. Globally, one in three adults suffers from multiple chronic conditions [3]; self-management of chronic conditions has become increasingly complex, requiring sophisticated knowledge, motivation, and skill by patients and their families [4]. Engaging in self-management reduces hospitalization and improves health outcomes and quality of life [5]. Patient-facing systems can facilitate self-management of chronic conditions and fill the gap of time and distance to meet with health care providers. Data increasingly support the value of these patient-facing systems, in the form of mobile health (mHealth) applications [6-9] or sensors to monitor physiological parameters (eg, blood glucose) and behaviors (eg, activity) [10-14]. The latest technological addition to patient-facing systems is computer-controlled virtual humans (VH).

Unlike formless conversational agents, like smart speakers or chatbots, VH bring together the capabilities of both a conversational agent and an interactive avatar (computer-represented digital characters). While their humanlike physical appearance is computer-generated (ie, animated), VH are not human-controlled [15-20] nor cartoonlike [21,22]. They are controlled algorithmically, based on active or passive user input during an interaction. These algorithms can simulate key properties of human face-to-face conversation — both verbal and nonverbal (eg, gaze, emotions, head movements, and metaphoric gestures). While humanlike appearance, movements, and nonverbal behavior offer VH the added advantage of communicating empathy and building rapport, they can also bring psychological and social concerns that may not arise when interacting with formless conversational agents [23-26].

Attempts to make computer interfaces anthropomorphic are not new [27,28]. The sophistication of current digital interlocutors, however, can largely be attributed to the recent advancements in artificial intelligence and computer graphics. Recent variants of anthropomorphic interfaces include relational agents, which are agents designed to build and maintain long-term relationships with users [29], including voice-based, intelligent virtual assistants (eg, Amazon's Alexa, Microsoft's Cortana, or Apple's Siri) and text-based chatbots that run on instant messaging applications [30]. Intricate taxonomies capturing different aspects of conversational agents can be found elsewhere [26,31-33].

While intelligent virtual assistants and chatbots have gained mainstream popularity, VH applications are still in their infancy. As graphic rendering capacities progress and ubiquitous computing peripherals such as virtual reality (VR) and

augmented reality head-mounted displays (HMDs) become inexpensive, VH will be increasingly adopted for everyday use. Indeed, similar to education and training [34,35], health care researchers and practitioners have already begun to explore the use of VH in health-related assessments and interventions. As VH come of age and stakeholders in health care deliberate whether to adopt this new computing technology, it is crucial that we examine how prior applications have fared in affecting health outcomes.

To our knowledge, VH in patient-facing systems have not been surveyed before. Only recently, other types of conversational agents in health have been reviewed [31,36-40]. Provoost et al [36] reported a scoping review of 54 articles (49 studies) on low-tech embodied conversational agents in clinical psychology. Laranjo et al [37] surveyed conversational agents with unconstrained natural language input capabilities in health care and included 17 articles, of which only 2 were randomized controlled trials (RCTs). Within mental health, both chatbots ([39]; 10 studies) and relational agents ([38]; 13 studies) have been reviewed. Furthermore, the current state of chatbots and embodied conversational agents as expert systems was recently surveyed ([31]; 40 articles). Kocaballi et al [40] reported a systematic review of how conversational agents can be personalized. It included 13 studies and found that personalization features were assessed for user satisfaction, not in improving health outcomes. None of these reviews included a meta-analysis nor focused on VH. The purpose of this study was to conduct a systematic review and meta-analysis of VH in patient-facing systems.

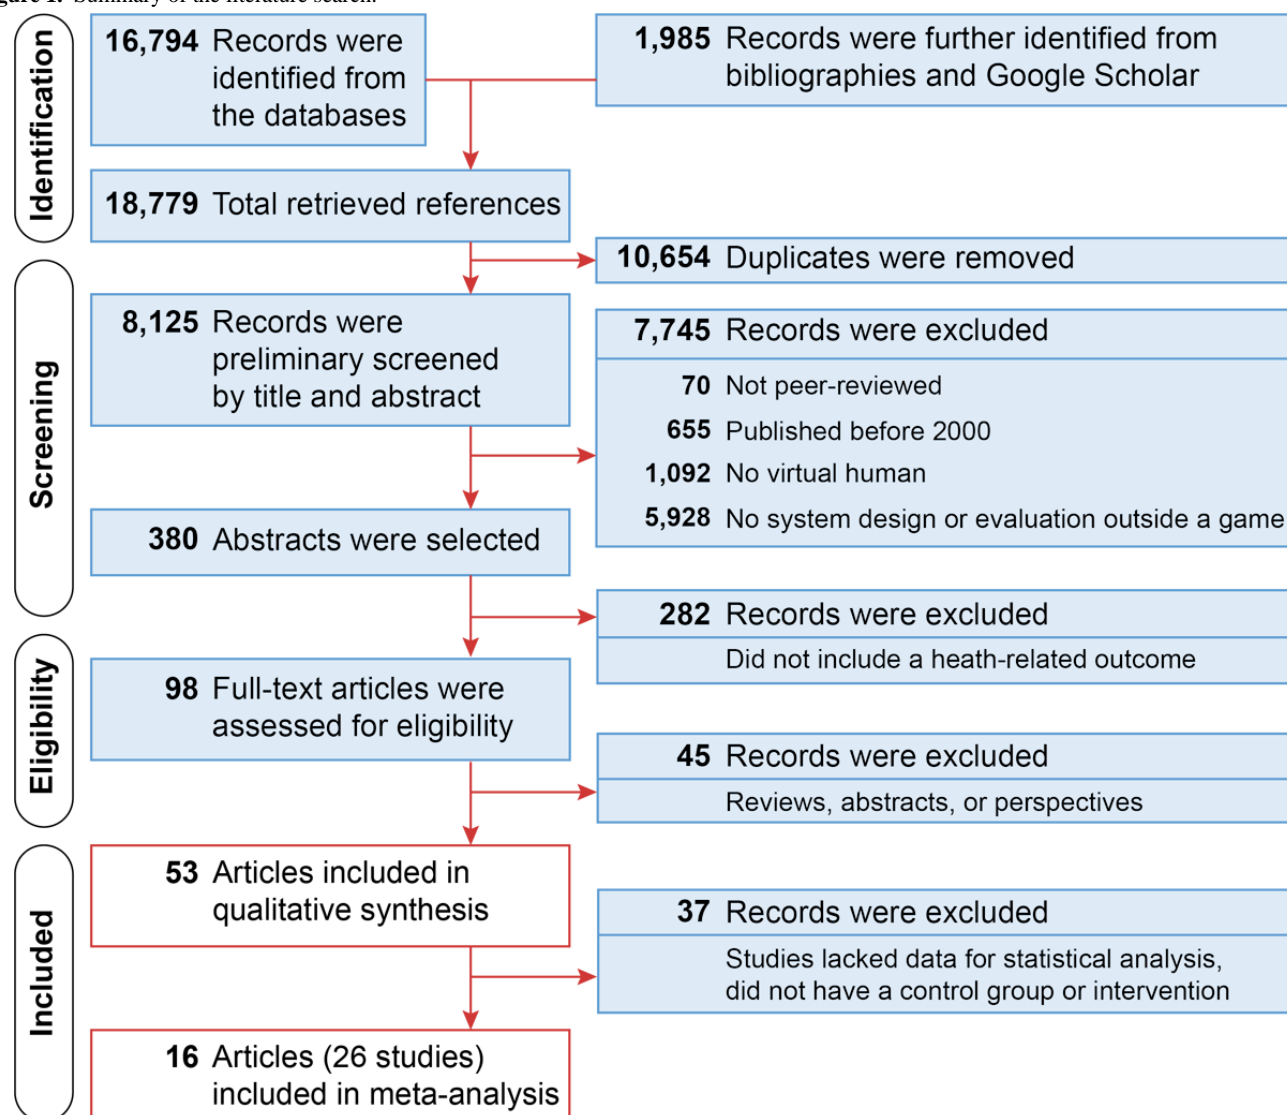

Methods

Overview

This systematic review of the English-language scholarly literature followed standard guidelines for conducting and reporting systematic reviews, including Preferred Reporting Items for Systematic Reviews and Meta-analyses [41] and guidelines from the Cochrane Diagnostic Test Accuracy Working Group [42,43].

Search Strategy

Literature searches were performed from inception to December 31, 2019 in Google Scholar and 7 online databases: MEDLINE, EMBASE, PsycINFO, CINAHL, Cochrane Central Register of Controlled Trials, PubMed, and ACM Digital Library. Search queries covered 3 domains: (1) avatars, (2) (digital) narratives, and (3) virtual assistants (for details, see [Multimedia Appendix 1](#)). Our search was limited to peer-reviewed articles published in English. Manual searches were extended to bibliographies of review articles. [Figure 1](#) shows a summary of the literature search.

Figure 1. Summary of the literature search.

Inclusion and Exclusion Criteria

The topic of our review crosscuts two disciplines — health care and computer science — and their disciplinary priorities are divergent if not orthogonal. On the one hand, health care research prioritizes reporting and replicating empirical evidence of efficacy. On the other hand, driving innovation is a key mission of computer science research. Thus, empirical investigation of these innovative designs — particularly replication of such studies — often takes a back seat. To offer a comprehensive review of the topic at hand, we first present a qualitative, systematic review of VH in patient-facing systems. Some of those articles were then included in a quantitative meta-analysis (Figure 1).

Qualitative Systematic Review

Studies were included in the qualitative review if they met the following criterion: designed or evaluated VH for health-related outcomes in a patient-facing system. Studies were excluded if they used VH for the training and education of health care professionals or students.

Meta-Analysis

Some of the articles included in the qualitative synthesis were further included in a meta-analysis if they met the following criteria: (1) compared the effectiveness of VH in a health-related outcome in a target population against a control group with no VH; (2) studied humans of any age; and (3) reported the sample size and mean and variance of the outcome measure in control and experimental groups. Studies were excluded if they did not use a comparator that was equivalent but different from VH (eg, [44]).

Data Extraction

All records were first downloaded into an EndNote X8.2 library [45], and duplicates were removed. Titles and abstracts were then screened for inclusion and exclusion criteria. To accelerate screening, records were first collated into topics using keyword searches in the EndNote library and then reviewed for inclusion. Two investigators (the first and second authors) independently assessed the relevancy of search results and selected full text articles for further review. The second and third authors independently abstracted the key study factors into a data extraction form and then came to a consensus on which studies

met the inclusion criteria; the first author made the definitive decision when discrepancies would arise.

Data from eligible articles were extracted into a spreadsheet. For the qualitative review, data included target population, design objective, type of evaluation, principal findings, and VH characteristics. For the meta-analysis, studies were summarized using the PICOTS (population, intervention, comparison group, outcomes, time frame, setting) framework [46].

Risk of Bias and Quality Assessment

Articles included in the meta-analysis were assessed for quality and risk of bias using the latest criteria from the Cochrane Consumers and Communication Review Group [47]. Studies were categorized as low risk, unclear, or high risk for each Cochrane bias domain: selection, performance, detection, attrition, reporting, and other [47]. Publication bias was assessed using Egger's test [48] and a *P*-curve analysis [49] and graphically examined using funnel plots [50].

Statistical Analysis

All statistical analyses were performed in R using the meta [51] and metafor packages [52,53]. Standardized mean differences (SMD) were used as the effect size to quantify the effectiveness of VH. The overall effectiveness was estimated using a random-effects model, and forest plots were used to graphically present the combined effectiveness. Statistical heterogeneity among the studies was assessed by I^2 , which estimates the percentage of total variation across studies due to heterogeneity rather than chance alone. We considered heterogeneity statistically significant at $P < .05$ and used random-effects models to take into account the heterogeneity among the included studies. Subgroup analysis was conducted across studies by the type of health outcome — health and wellbeing as well as attitudes toward health and wellbeing.

Results

Qualitative Systematic Review

A total of 16,794 search records were retrieved from the databases, and 1,985 additional records were identified from the bibliographies and Google Scholar. After removing duplicates, we screened the titles and abstracts of 8,125 articles; 380 articles involved a functioning VH system outside a game. Because the computing technology for creating VH did not exist prior to circa 2000, all studies published before 2000 were excluded. These 380 abstracts were further reviewed for their relevance to health, and 282 articles were excluded because the VH was involved in contexts like training, education, or demonstration. The remaining 98 articles underwent full-text review, and 53 articles met the inclusion and exclusion criteria for the qualitative systematic review.

A total of 30 health-related outcomes were identified in the 53 eligible articles, targeting 25 types of populations (Table 1) and 6 modalities of technology delivery apart from a personal computer, desktop, or laptop (Table 2). Unconstrained speech input was sparsely used in VH systems [54,55]. While most systems allowed constrained user input via a touchscreen or keyboard, some systems reacted to nonverbal conversational inputs, such as gaze [56] or proximity [57].

In the 53 eligible articles, 33 unique systems were identified. Of these, 9 systems were used for health assessments and the rest for health interventions (Table 3). Two broad design categories emerged — simple VH and VH with health sensors or trackers (Table 3). These additional trackers did not augment the interaction capabilities of VH, but provided additional data about users (eg, via a heart rhythm monitor, respiration sensor, or eye tracker).

Table 1. In the 53 eligible articles, 30 health-related outcomes and 25 target populations were identified.

Health outcome	Target population	Studies
Improve quality of life	Women with overactive bladder (OAB) symptoms	[58] ^a
Self-manage chronic conditions	Individuals with chronic atrial fibrillation (heart condition)	[59-61]
	Individuals with spinal cord injury	[62]
Engage in physical activity	Older adults	[63] ^a [64,65]
	Individuals with Parkinson's disease	[66]
	Inactive older adults with low socioeconomic status	[67] ^a
	Healthy adults (no reported health conditions)	[68,69] ^a [70]
	Individuals with schizophrenia	[71]
Improve mood	Individuals with depression	[72] ^a [73]
Assess auditory verbal hallucinations (AVH)	Individuals with schizophrenia	[74]
Stress management	Women	[75]
	Individuals with chronic pain and depression	[76] ^a [77]
Healthy eating	Women	[75]
	Healthy adults (no reported health conditions)	[69] ^a
Improve social skills	Children with autism spectrum disorders (ASD)	[44]
	Individuals with schizophrenia	[78] ^a
Assess PTSD ^b symptoms	US military service members	[54] ^a [55]
Assess body image disturbance (BID)	Women on diet (nonclinical)	[79]
Anxiety toward death	Older adults	[80]
Find health-related information online	Individuals with low health and computer literacy	[81] ^a [82]
Explain health documents	Individuals with low health literacy	[83] ^a [65,84-86]
Attitude toward regular physical activity	Healthy adults (no reported health conditions)	[87] ^a
Attitude toward breastfeeding	Pregnant women in their third semester	[88] ^a [89,90]
Attitude toward weight loss	Healthy adults (no reported health conditions)	[91] ^a
Retention of medication knowledge	Individuals with type 2 diabetes mellitus	[92] ^a
Attitudes toward prenatal testing for Down syndrome	Nulliparous women	[93]
Improve medication adherence	Individuals with schizophrenia	[71]
Assess emotion recognition	Adults with ASD	[94]
	Individuals with schizophrenia	[95] ^a
	Children with ASD	[96]
Preconception risk assessment	Women	[97]
Assess the effects of social rejection	Individuals with psychotic disorder	[98]
Assess social attention	Children with ASD	[99]
Assist in deep breathing	Healthy adults (no reported health conditions)	[100]
Substance use counseling	Individuals with alcohol use disorder	[56]
	Individuals with opioid use disorder	[101]
Patient trust	Healthy adults (no reported health conditions)	[102]
Assess social anxiety disorder	Women with high social anxiety	[103]

Health outcome	Target population	Studies
Alleviate social isolation	Older adults	[57]
Understand the distinction between connective and fatty tissue in the breast	Mammography-eligible middle-aged women (40-74 years old)	[104]
Pill count adherence >80%	HIV-positive African American men who have sex with men	[105]

^aStudies included in the meta-analysis.

^bPTSD: post-traumatic stress disorder.

Table 2. Technology characteristics identified in the eligible studies.

Technology characteristics	Studies
Unconstrained speech input	[54,55]
Computer at a community center or school	[44,67]
Smartphone	[59-61]
Head-mounted display (HMD)	[74,78,79,98,99,103]
Virtual reality (VR) in a PC or HMD	[74,78,79,96,98,99,103]
Mobile kiosk with a computer	[63,65,84-86,88]
Tablet	[63,65,66,70,76,77,80,88]

Table 3. Two broad categories of virtual humans emerged from the 53 articles included in the qualitative review.

Type of use	Number of simple virtual humans	Number of virtual humans with health trackers
Intervention	34 [44,57,58,62-64,67-69,71,72,75-78,80-93,97,101,102,104,105]	9 [56,59-61,65,66,70,73,100]
Assessment	7 [54,74,79,94-96,98]	3 [55,99,103]

Virtual Humans for Health Interventions

Of the 34 articles that described simple VH in health-related interventions (Table 3), 27 were based on the same core technology for generating speech [106] and nonverbal behavior [107]. The typical system included a knowledge base of domain-specific top-level dialog fragments (Figure 2). These subdialogs were scripted and then reused to generate natural language speech using a hierarchical transition network, based on augmented transition networks. Augmented transition networks are mathematical structures that can model the grammar of relatively complex natural languages [108]. The generated text was then converted to synthetic speech by the Behavior Expression Animation Toolkit [107]. The Behavior Expression Animation Toolkit also generated appropriate and contextualized nonverbal behavior for the VH. The front end consisted of 3 components: (1) an animated image of the VH communicating with users using speech and gestures, (2) a dynamically updated but constrained multiple-choice menu for user input (via touch or keyboard), and (3) other content supporting the conversation as necessary, like text and images. VH in such a system talked to users with synthetic speech and presented synchronized nonverbal behavior, such as hand

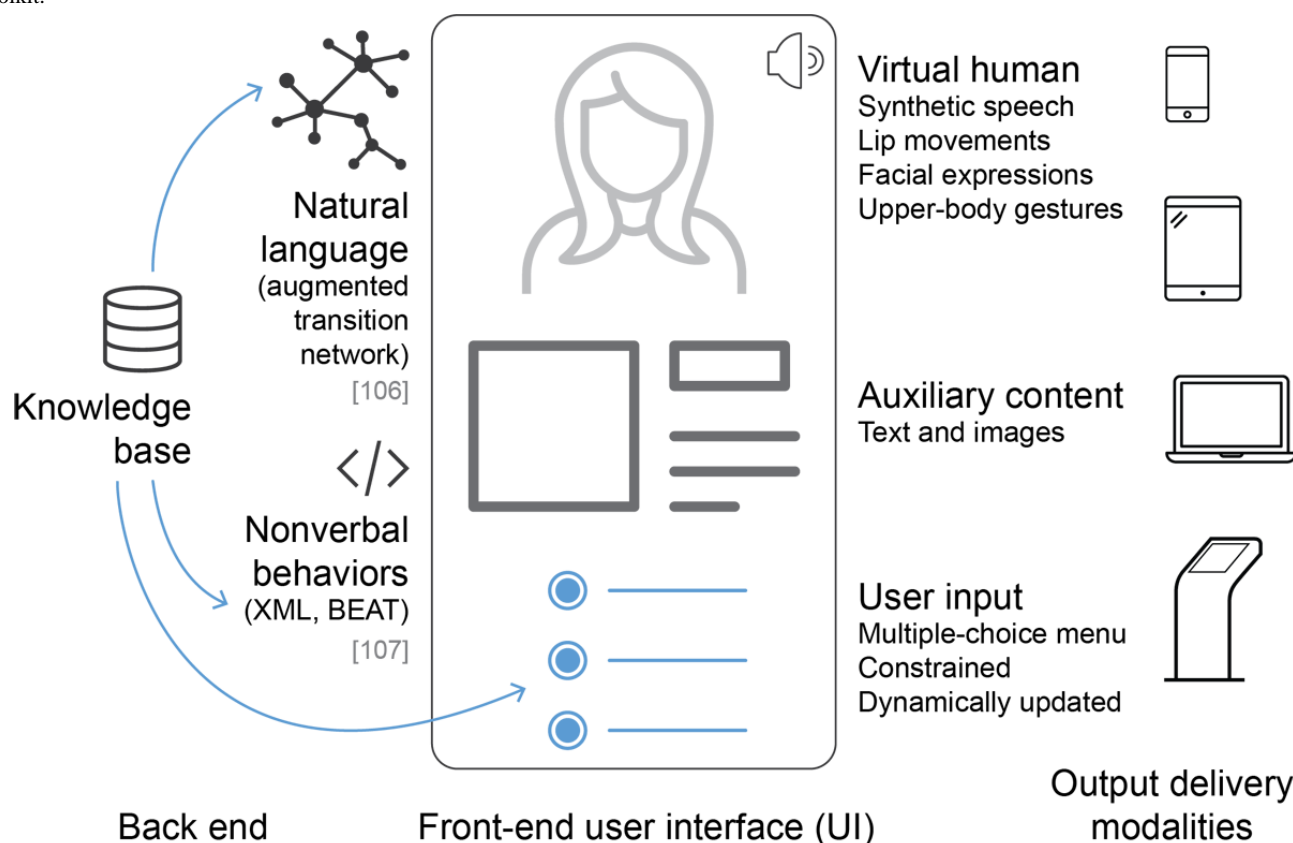

gestures and eyebrow raises for emphasis, looking away to signal turn-taking, and posture shifts to mark topic boundaries.

The VH interface in Figure 2 was mostly delivered via smartphones or personal computers. By tailoring the knowledge base, VH were designed for a range of domains, from managing depression [77], through end-of-life planning [80], stress management [75], and educating about breastfeeding [89], to preconception care [97].

Design approaches were varied in the rest of the studies. Dworkin et al [105] followed the same concepts as in Figure 2 but did not discuss implementation details. Two studies used a third-party system [44,72]. Another used VR and an HMD to deliver the VH intervention [78]. Some studies did not detail exactly how the conversations between humans and VH were automated [58,68,78,92], other than mentioning that nonverbal behaviors were programmed to align with verbal utterances. Two studies modeled their intervention after tutorials, with functionality, such as play, pause, repeat, and answering multiple-choice questions [58,92].

Some designs augmented VH with sensor-based tracking (Table 3), such as heart rhythm monitors for managing chronic heart failure [59-61], a pedometer for promoting walking [65,66], and a breathing monitor for assisting in meditation [100].

Figure 2. The most common structure of a simple virtual human system designed for health-related interventions. BEAT: Behavior Expression Animation Toolkit.

Virtual Humans for Health Assessments

Compared with interventions, fewer studies were found for health-related assessments (Tables 1 and 3); most of these were for people with autism spectrum disorder [94,96,99] and psychotic disorders [74,98,103]. Other studies used VH to assess PTSD symptoms [54,55], emotion recognition [95], and body image disorder [79]. Six studies used VH in a VR environment; 5 used HMDs [74,79,98,99,103], while 1 used a computer [96]. Two studies used advanced tracking systems; these tracking modules were more sophisticated than those used in health interventions. To assess social attention in high-functioning children with autism spectrum disorder, researchers used a sensor to measure head orientation and rotational motion [99]. The MultiSense framework was used for the SimSensei Kiosk [55], which tracks an array of perceptual signals, like smile intensity, gaze direction, and lack of facial expressions, and allows unconstrained speech input [54].

Virtual Human Characteristics

Overall, the physical appearances of VH were primarily created using 3-dimensional (3D) character modeling and animation software, such as the Unity3D game engine. They were designed to be racially ambiguous [64] or accordant with target users [86]. But Marcos-Pablos et al [95] generated dynamic expressions for VH (eg, anger, happiness, sadness) by first using a laser scanner to obtain a 3D face model and then using animation software. The speech of VH was either synthetically produced [76] or lip-synced to audio-recorded voice narrations [58,92]. Synthetic speech was generated using commercially available software.

Characteristics, personalities, and mannerisms of VH were manipulated to build rapport with end users [102]. Schulman et al [87] explored the use of social dialog (small talk) and persuasive arguments (about 30 turns) to change attitude toward exercise. VH argued about the advantages of regular exercise and against statements that emphasized disadvantages. Friederichs et al [68] used social dialog at the beginning of an intervention and during transitions between different parts. To persuade users, Andrade et al [58] developed a peer avatar — based on the front-face view of the participant — who delivered a tutorial about self-managing overactive bladder symptoms. Motivational interviewing techniques were used by Friederichs et al [68] to promote physical activity in adults.

Another study explored the use of personal stories available on the internet to personalize the VH's message and change health behavior [91]. These stories were indexed based on participants' personal state of change during weight loss. To promote breastfeeding, lactation education was framed from a feminist perspective [90]; a VH was designed to motivate women in their third semester to follow breastfeeding recommendations by the US Centers for Disease Control and Prevention. This was realized by introducing a feminist introductory and closing script (eg, "I like to think of myself as a fairly progressive woman, and I hope I do not offend you by some of my opinions" or "A lot of people think that breastfeeding represents a dilemma for feminism.") [90]. Participants who did not self-identify as feminists were significantly less satisfied with the feminist agent than the controls.

Middle-aged Caucasian and African American VH were designed to achieve racial concordance with users [92], but racial concordance did not significantly affect perceived similarity [86]. Researchers also investigated the effects of attire, background image, and alignment on trust. Study participants found a patient-aligned VH explaining an informed consent document more trustworthy than a medical-aligned or federal-aligned VH. Deictic gestures, such as pointing to a document with a finger or open hand, were designed to aid in document explanation [85]. When explaining a medical document, study participants with low literacy were more satisfied with such a VH than a human. Finally, a common theme across many VH designed for health-related interventions was continuity of care, or longitudinal engagement with end users.

Design Process

Of the 53 articles, 23 explicitly described their VH design process [55,58,59,68,71,73,75,78,80,82-87,89-93,95,97,104]. The most common design approaches were collaboration with domain experts, qualitative observation of similar human-human interactions, and adoption of public health and governmental guidelines. Some studies conducted focus groups and one-to-one interviews with target users [59,68,90,92,97,104]. Others informed their design decisions from prior literature or theoretical frameworks [58,59,68,71,90,91,93]. Qualitative observations were often videotaped and coded to generate conversation content [55,71,84]. VH for health-related assessments were always designed in collaboration with health care providers but not end users (Table 3).

Theory

Only a few papers explicitly mentioned adopting theoretical frameworks to ground their design of VH [56,60,68,70,91,93,100]. The chronic care model was used to design VH for people with chronic illnesses [109]; the following 3 guidelines were adopted: facilitate communication between patients and providers, make patients aware of the latest care guidelines consistent with scientific evidence, and motivate patients to manage their health [60].

Two frameworks of behavior change were used widely — the transtheoretical model (TTM) of health behavior change [110] and motivational interviewing (MI) counseling style [111]. The transtheoretical model operationalizes intentional behavior change with 3 core constructs — stages of change (precontemplation, contemplation, preparation, action, and maintenance), processes of change, and levels of change — and recommends stage-matched interventions. VH could ask questions to determine these stages and offer matched interventions, such as therapeutic alliance [56,70,91]. MI was developed to elicit people's readiness to change, explore their attitudes toward change, and transition ambivalence toward reducing resistance to behavior change. The conversation style of VH was sometimes designed based on the MI technique [56,68]. One study designed VH to mirror basic user actions [112], like inhaling and exhaling, to promote behavior change [100]. In another study [93], VH played the role of a decision coach to facilitate shared decision making [113,114]. They informed users of all available options, provided detailed

information about those options, and finally assisted in choosing one of them.

Design Guidelines

Four papers explicitly offered design guidelines for VH [57,60,64,71]. To design VH that can maintain long-term social relationships with end users (ie, relational agents), Bickmore et al [64] recommended developing a model of user-agent relationship; using relational behavior like social dialog, empathy, and humor; maintaining a memory of past interactions; and providing some variability in agent behavior and overall variability in the dialog structure. When designing VH for mental health interventions that are also relational agents, special design considerations may be needed. For patients with schizophrenia, Bickmore et al [71] recommended prolonging the introduction and conclusion phases of the conversation, using clear and concrete language that focuses on real events to reinforce reality, and not relying solely on nonverbal behaviors like a gaze-away gesture. Specific populations, health outcomes, and device modalities may need additional design considerations. When addressing loneliness in older adults, Ring et al [57] recommended VH engage in social interactions, such as small talk and games, help older adults stay connected with friends and family via contemporary technologies, and alleviate mood disorders or loneliness through different types of talk therapy. When designing for smartphones, Bickmore et al [60] recommended keeping interactions short, allowing interruptions during interactions, and using constrained user input.

Meta-Analysis

A total of 26 studies (16 articles) published between 2000 and December 31, 2019 were eligible for the meta-analysis, targeting 11 types of populations and including 10 studies with healthy adults [68,69,81,83,87], 3 studies with older adults [63,67], 3 studies with women [58,88], 2 studies with individuals with schizophrenia [78,95], and 3 studies with individuals with depression [72,76].

Study Characteristics

The included studies comprised approximately 1400 participants across 13 health and wellbeing objectives. The PICOTS information [46] from the 26 studies is available in [Multimedia Appendix 2](#). Outcomes included 44 primary outcomes and 22 secondary outcomes. Of the 26 studies, 9 focused on attitudes toward health and wellbeing [81,83,87,88,91]. There were more cross-sectional ($k=15$) [54,68,81,83,87,88,91,92,95] than longitudinal studies ($k=11$) [58,63,67,69,72,76,78,88]. Longitudinal studies ranged from 1 month to 6 months (see [Multimedia Appendix 2](#)). The VH intervention was delivered using a personal computer in most studies ($k=18$), followed by a tablet ($k=4$), mobile kiosk ($k=2$), HMD ($k=1$), and a desktop computer in a community center ($k=1$).

Evidence of Intervention Efficacy

As evident from Table 2 and [Multimedia Appendix 2](#), the 26 studies eligible for meta-analysis varied in terms of outcomes, target population, timing, and intervention design. Hence, a random-effects model was used. A random-effects model does not assume that the estimated effects come from a single homogeneous population, but that true effect sizes vary from

study to study. Hedges' g was calculated for each reported outcome, and SMD were used as the effect size to quantify the overall evidence for VH interventions. Next, we report the meta-analysis of the 44 primary outcomes across 26 studies. A meta-analysis of all 66 outcomes (including 22 secondary outcomes) is available in [Multimedia Appendix 2](#).

The meta-analysis of data from 26 studies (44 outcomes) revealed a significant difference between intervention and control conditions, favoring the VH intervention (SMD .166, 95% CI .039-.292, 95% prediction interval -.548 to .879, $P=.012$) but with evidence of some heterogeneity: $I^2 = 49.3\%$, 95% CI 28.1%-64.3% ([Figure 3](#)).

A 3-level model (level 2: different outcome measures; level 3: different studies) did not capture a significant amount of variability in the data ($P>.05$). Thus, a 2-level model was used. The between-study heterogeneity of the data was moderate: $\tau^2=.12$, $I^2=49.3\%$. We examined whether this heterogeneity was caused by outliers or influential cases [[115,116](#)]. No influential cases were detected, but we spotted 3 outliers [[67,76,95](#)]. While

2 of these outlier studies found extremely positive evidence about VH efficacy [[67,76](#)], 1 study found extremely negative evidence for one of its outcome measures: happiness emotion recognition by patients with schizophrenia [[95](#)]. However, the meta-analysis after removing these outliers ($k=41$, SMD .144, 95% CI .028-.260, $P=.016$; $I^2=33.7\%$, 95% CI 2.6%-54.8%) was similar to the original analysis ([Figure 3](#)). Because these 3 studies were interesting outliers, but neither error nor influential outliers [[117](#)], we chose to retain them.

A subgroup analysis for health-related outcomes and health-related attitudes was conducted, but no significant difference was found in the overall effect between outcome types ($P=.762$). The number of studies was insufficient to conduct subgroup analyses for different population or outcome types.

To explore publication bias, a funnel plot was generated. Egger's test was not significant ($P=.70$), indicating no substantial asymmetry in the funnel plot. Furthermore, the P -curve analysis did not indicate publication bias ([Figure 4](#)).

Figure 3. Forest plot of the meta-analysis of health-related virtual human interventions from 26 studies (44 primary outcomes). a-PDHA: anonymized post-deployment health assessment; ACT: physical activity; BDI-2: Beck Depression Inventory-II; BICEP: brief informed consent evaluation protocol; DAS-SF2: Dysfunctional Attitude Scale-Short Form 2; DIET: fruit and vegetable consumption; EQ-5D-5L VAS: 5-level version of the EuroQol 5D visual analogue scale; FVS: NIH/NCI Fruit and Vegetable Scan; HRQOL: health-related quality of life; OABq: overactive bladder questionnaire; PDHA: post-deployment health assessment; PTSD: post-traumatic stress disorder; QIDS-SR: Quality of Life Enjoyment and Satisfaction Questionnaire-Short Form; SBS: social behavior scales; SMD: standardized mean difference; SVH: social virtual human.

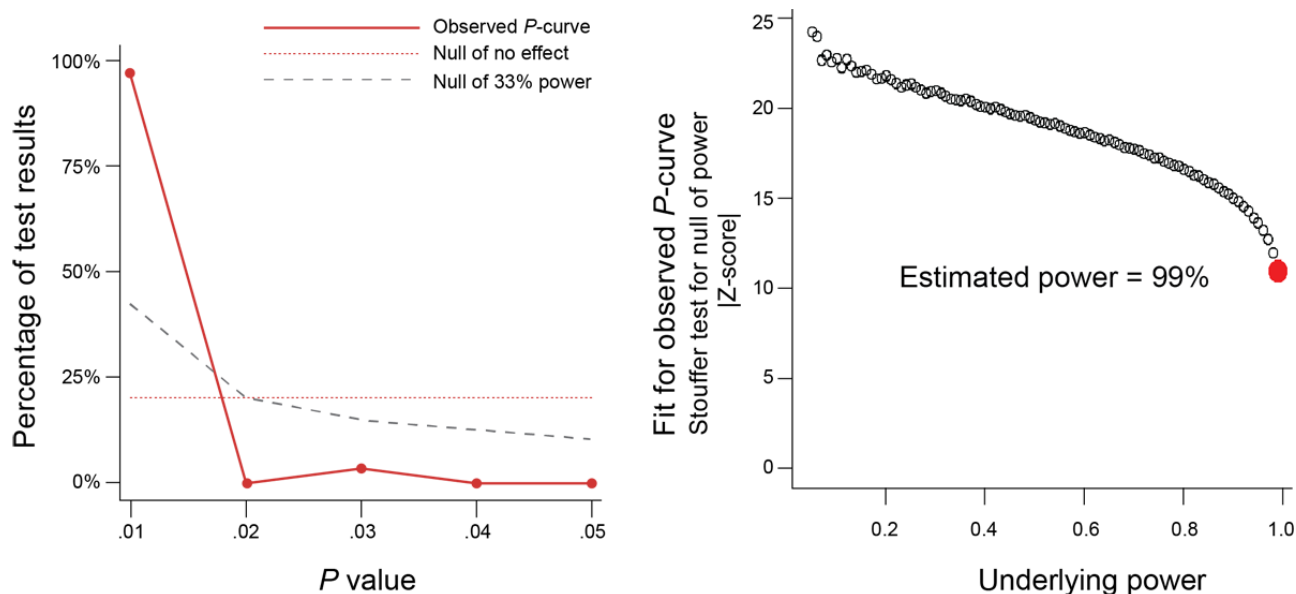

Figure 4. The observed P -curve has an estimated power of 99% (left and right), significant right skewness, $P_{full} < .0001$, $P_{half} < .0001$ (left), and no significant flatness, $P_{full} > .9999$, $P_{half} > .9999$.

Risk of Bias in Included Studies

The quality of studies included in the meta-analysis was evaluated for risk of bias (Figures 5 and 6). Randomization was adequate in 19 studies [58,63,67-69,72,78,87,88,91,92,95] but unclear in 7 others [54,76,81,83]. Allocation was reported to be concealed in 11 studies [58,63,67,72,88,92,95], but other studies did not provide enough information to assess allocation bias. It was unclear in 15 studies whether participants and research personnel were blinded to the allocated interventions [54,68,69,76,78,81,83,87,91].

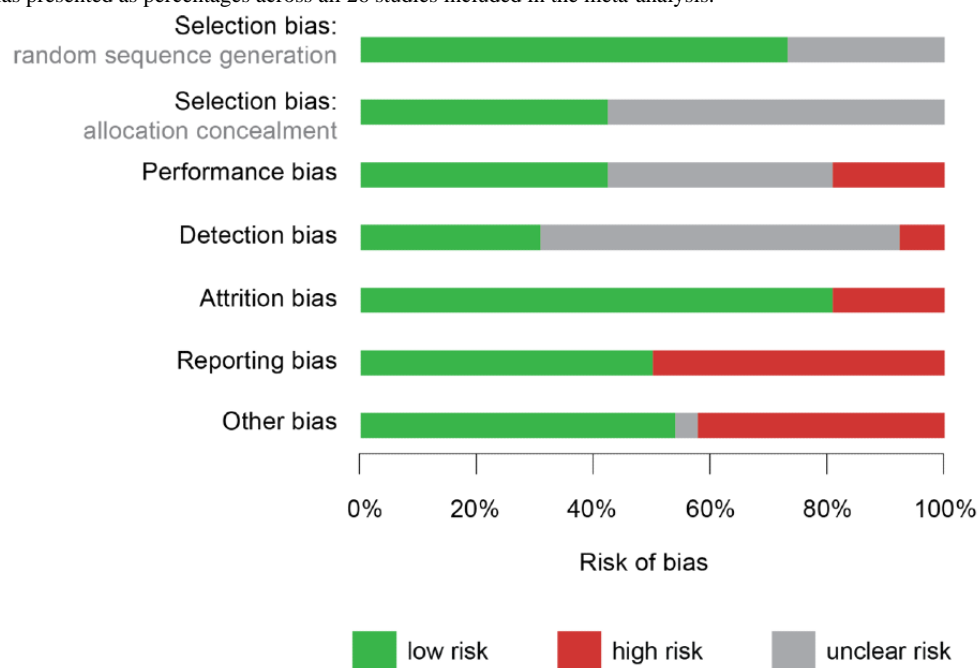

Eleven studies were successful in blinding participants and research personnel to the allocated interventions

[58,63,72,81,87,92,95], while 5 studies were not [54,78,88]; the remaining studies were unclear. Blinding the assessors of outcomes was achieved in 8 studies [58,63,78,92,95], 2 studies did not blind research personnel [67,72], and 16 did not clearly report this [54,68,69,76,81,83,87,88,91]. Attrition was high (>20%) in 5 studies [63,68,72,78]. With respect to selective reporting, we identified 13 studies that did not report either descriptive statistics for nonsignificant outcomes or participant demographics [54,67-69,76,88,92]. In assessing other potential sources of bias, we identified 11 studies at a risk of bias due to a small sample size [87,88] or self-selection from provider invitations [72] and websites like Craigslist or Amazon Mechanical Turk [54,69,87,91].

Figure 5. Summary of the authors' consensus judgment about the risk of bias for each study included in the meta-analysis, by various sources of potential bias.

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding of participants and personnel (performance bias)	Blinding of outcome assessment (detection bias)	Incomplete outcome data (attrition bias)	Selective reporting (reporting bias)	Other bias

Discussion

Primary Findings

This meta-analysis found VH interventions significantly more effective than other types of traditional interventions that did not include conversational agents (SMD .166, 95% CI=.039-.292, $P=.012$). This is an important finding because effective interaction modalities are needed to promote improved consumer or patient engagement in health, thereby promoting behavior change and the management of chronic conditions. The effect size may have been small because the studies involved many different population and outcome types. As more studies become available in the future, some populations and outcome types may show stronger effect sizes than others.

The efficacy of VH may also depend on the type of intervention for which they are used, such as delivering cognitive behavioral therapy vs delivering education. However, the number of current studies was insufficient to conduct such subgroup analyses. Nevertheless, the effectiveness of VH did not significantly differ between health-related outcomes and health-related attitudes.

Like prior reports [37], we found considerable heterogeneity in evaluation methods and outcome measures and a predominance of quasiexperimental study designs or usability studies over RCTs. But unlike previous reviews [36], we found most applications were fully developed, and many of them were either evaluated or soon to be evaluated in RCTs. Our findings cannot be compared directly with the previous reviews because each of the reviews used a different definition of conversational agents or avatars. Typically, earlier reviews did not discriminate between conversational agents with and without a humanlike physical appearance; therefore, they did not discriminate between whether they were able or unable to engage in nonverbal conversation. Only 5 of the 26 studies that were included in the meta-analysis compared the efficacy of VH interventions with text-based chatbots or any other type of

conversational agents (Multimedia Appendix 2) [58,68,87,91,92]. Other studies compared interventions against treatment as usual, such as a therapist visit or standard educational materials. Voice-based and text-based conversational agents, without a physical humanlike appearance, were used as comparators in 2 studies [58,92] and 4 studies [68,87,91,92], respectively. Thus, it is too early to tell how much the efficacy of VH in health-related interventions can be attributed to their humanlike physical appearance.

Of course, some health applications, especially some mental health assessments, would only work with VH and could not be replaced with a voice-based or text-based conversational agent. For example, VH were used to assess the influence of unusual voices on daily activities of hallucinating patients [74] and the effect of social rejection in individuals with psychotic disorder [98]. But apart from these, when should a VH intervention be more desirable than other types of conversational agents? Engineering health-related VH interventions is far from trivial and may further cause unintended effects, such as a lack of empathy or a sense of complacency among users [23,24]. When is it worth investing in designing VH over chatbots or smart speakers? This question kept resurfacing in our analysis but remained unanswered. As more studies become available, subgroup analyses of specific interventions could answer this question.

Currently, the prevalence of VH in health applications appears to lag behind that in other areas, such as education and training [118,119] or serious games [120], which is not surprising given the concerns about patient safety [121], ethical and legal issues [122], and perception of professional counselors [123]. Technological advancements will continue to augment VH capabilities; equally important is identifying the design tradeoffs associated with those capabilities in patient-facing systems. When should a conversational agent have a humanlike appearance or any physical embodiment? Would allowing for unconstrained speech and gesture input improve intervention

effectiveness or reduce patient safety and privacy? When are nonverbal cues significant in designing a conversational agent? Does age, gender, socioeconomic status, literacy levels, or certain characteristics of target users mediate the effectiveness of VH interventions?

Finally, we found that the input and output of VH systems have evolved significantly over the last 2 decades, drawing on the most recent technological advancements. While systems in the 2000s extensively used desktops, kiosks, 2-dimensional graphics, and constrained text input [64], more recent systems were developed in 3D, were delivered in VR, sometimes used HMDs, and allowed for unconstrained input, such as speech, gestures, and facial emotions. Two key design trends were identified: (1) multimodal sensing of the user's state using computer vision algorithms and ubiquitous computing technologies, ranging from upper-body gestures to heart rate (input), and (2) striving toward high fidelity, humanlike appearance and behavior of the VH to improve presence and immersion (output).

Limitations and Future Research

The limitations of this review should be noted and can be addressed by future studies. First, not all studies on VH in patient-facing systems were included in our work. This is because they did not present sufficient quantitative information, only reported usability metrics, or did not clarify whether their avatar technology was computer-controlled or human-controlled. Including additional studies and VH designs could allow reinforcing the results reported here or provide different results. Second, some of the studies included in our meta-analysis had relatively small sample sizes (<20 participants); thus, additional caution is recommended when generalizing these results. Third, there was moderate heterogeneity among trials in the meta-analysis ($\tau^2=.12$, $I^2=49.3\%$). This can be attributed to the different health outcome measures, population types, and health objectives. For example, health objectives ranged from increasing physical activity and improving mood to improving social skills. When more studies become available with the same or similar health objectives, it would be worth updating this study with new results.

Although research on conversational agents began circa 2000, their design and capabilities have changed and diverged

substantially as new technologies and sensors have emerged. This change is expected to continue. Future studies are suggested to consider the difference between different types of conversational agents when synthesizing or generalizing the agents. For example, does a physical appearance or nonverbal behavior increase the effectiveness of a conversational agent? In what kind of tasks? Furthermore, there is rich literature on behavior change and health behavior change theories. However, theoretical frameworks explicating how different features of VH work together in building (or disrupting) rapport with patients is lacking. As such models emerge, future studies will need to examine those relationships between model constructs with methods such as meta-analytic structural equation models.

Conclusion

VH are conversational agents with a humanlike physical appearance; autonomy in verbal and nonverbal behavior; and speech, gaze, or gesture interaction capabilities. In patient-facing systems, they can demonstrate listening and empathy, as well as tailor to various sociocultural backgrounds, languages, and literacy levels. We surveyed the existing literature on VH in patient-facing systems — from inception to December 2019. Of the 53 articles reviewed, a meta-analysis of 26 studies with more than 1400 participants showed that VH interventions significantly improve health outcomes compared with other traditional intervention methods. But whether a physical embodiment is crucial for a conversational agent to significantly improve health-related outcomes remains to be explored, as does any effect of the VH's physical appearance, type of voice, or quality of movements.

Although not yet comparable to computer-animated films or high-end video games, the appearance and behavior of VH in health care are increasingly becoming sophisticated, with studies finding that users prefer more humanlike VHs in health care [124,125]. Elsewhere, studies continue to report the possibility of unintended negative user reactions (ie, the uncanny valley effect) when interacting with VH, owing to a mismatch in the levels of realism, either physical, behavioral, or both [23,24,126]. However, the literature on VH in patient-facing systems has not yet examined whether the uncanny valley effect affects patient perception and, in turn, health outcomes.

Abstract

Background: Knowledge translation (KT) aims to facilitate the use of research evidence in decision making. Changes in technology have provided considerable opportunities for KT strategies to improve access and use of evidence in decision making by public health policy makers and practitioners. Despite this opportunity, there have been no reviews that have assessed the effects of digital technology-enabled KT (TEKT) in the field of public health.

Objective: This study aims to examine the effectiveness of digital TEKT strategies in (1) improving the capacity for evidence-based decision making by public health policy makers and practitioners, (2) changing public health policy or practice, and (3) changes in individual or population health outcomes.

Methods: A search strategy was developed to identify randomized trials assessing the effectiveness of digital TEKT strategies in public health. Any primary research study with a randomized trial design was eligible. Searches for eligible studies were undertaken in multiple electronic bibliographic databases (Medical Literature Analysis and Retrieval System Online [MEDLINE], Excerpta Medica dataBASE [EMBASE], PsycINFO, Cumulative Index to Nursing and Allied Health Literature [CINAHL], and Scopus) and the reference lists of included studies. A hand search of 2 journals (Implementation Science and Journal of Medical Internet Research) and a gray literature search were also conducted. Pairs of independent review authors screened studies, assessed the risk of bias, and extracted data from relevant studies.

Results: Of the 6819 citations screened, 8 eligible randomized trials were included in the review. The studies examined the impact of digital TEKT strategies on health professionals, including nurses, child care health consultants, physiotherapists, primary health care workers, and public health practitioners. Overall, 5 of the interventions were web-training programs. The remaining 3 interventions included simulation games, access to digital resource materials and the use of tailored messaging, and a web-based registry. The findings suggest that digital TEKT interventions may be effective in improving the knowledge of public health professionals, relative to control, and may be as effective as a face-to-face KT approach. The effectiveness of digital TEKT strategies relative to a control or other digital KT interventions on measures of health professional self-efficacy to use evidence to enhance practice behavior or behavioral intention outcomes was mixed. The evidence regarding the effects on changes to health policy or practice following exposure to digital TEKT was mixed. No trials assessed the effects on individual or population-level health outcomes.

Conclusions: This review is the first to synthesize the effectiveness of digital TEKT interventions in a public health setting. Despite its potential, relatively few trials have been undertaken to investigate the impacts of digital TEKT interventions. The findings suggest that although a digital TEKT intervention may improve knowledge, the effects of such interventions on other outcomes are equivocal.

KEYWORDS

knowledge translation; public health

Introduction

Background

Investment in public health research is intended to improve public health policy, practice, and decision making [1]. To enhance the impact of public health services, public health care decision making based on high-quality research evidence is recommended [1]. Currently, research evidence is often not utilized optimally in public health decision making [2-4], increasing the risk that public health policies or practices may be enacted that are inferior to alternative interventions, that have little evidence of benefit, or that may be harmful [2,3].

Knowledge translation (KT) is “the synthesis, dissemination, exchange, and application of knowledge in an effort to improve health services and products and strengthen the health care system” [5]. The process of KT aims to bridge the gap between research evidence generated by researchers and the use of this evidence by health professionals in their decision making regarding the adoption of health policies, practices, or programs [3,6]. Conceptual frameworks suggest that KT is a dynamic process that is inherently linked to the engagement of end users, including patients, policy makers, and health care professionals, to enhance the uptake of research via the creation, dissemination, and use of knowledge (research) [3]. An important part of the KT processes is the development of knowledge tools, products, or other strategies (*interventions*) that are accessible and interactive and meet the needs of stakeholders for informed decision making [3,4,7].

A variety of factors impede KT in public health. A 2018 critical interpretive synthesis for KT in public health in low- and middle-income countries highlighted the complex nature of creating and accessing evidence for the end user and the contextual factors, including cultural, political, and economic factors that influence the ability to inform evidence-based decision making [8]. A number of KT strategies have previously been applied to address some of these barriers. A systematic review of 5 randomized and non-randomized studies evaluating the effectiveness of public health KT [9] found that single KT strategies, such as disseminating materials to health professionals, were as effective as complex, multicomponent interventions, such as interventions with multiple face-to-face contacts, in changing the practice behavior of public health professionals [9]. However, some KT strategies, such as access to web-based registries to find evidence, did not significantly impact decision making in public health professionals [9].

Changes in technology over recent decades have provided considerable opportunities to improve access and use of

evidence in decision making [4]. Technology-enabled KT (TEKT) is the incorporation of digital technology in the application of KT [10]. Digital TEKT does this by using digital technologies, for example, via the use of social media, email, internet, electronic databases, electronic prompts or reminders, web-based webinars, and training or interactive websites. Such strategies may include *push* strategies, whereby research is disseminated (eg, via social media) to target end-user audiences to increase its awareness and use of *pull* strategies that aim to increase the target end user’s demand and use for research (eg, webinars to improve research literacy) [2,11].

Despite the opportunity that digital TEKT presents in facilitating KT, there are few reviews assessing the impact of digital TEKT on decision making in health. To the best of our knowledge, there have been no reviews that have assessed the effects of digital TEKT in the field of public health. This is important given the contextual differences in public health and clinical practice decision making. Nonetheless, reviews of their impact in clinical settings suggest that they can be beneficial. For example, a 2016 systematic review by De Angelis et al [12] examined the impact of information and communication technologies in the dissemination of clinical practice guidelines to health professionals. The review included 21 studies in which dissemination occurred via a variety of communication technologies, including computer software, web-based workshops, educational games, and email and assessed the skills, knowledge, intention of the health professionals, or perceived usefulness of the intervention [12]. The review found that website and computer software dissemination of practice guidelines showed little evidence in improving practice behavior [12]. Conversely, web-based workshops and emails were found to improve practice behavior by improving the skills and knowledge of clinical practice guidelines [12]. Similarly, a 2019 systematic review highlighted that the most effective KT strategies for health professionals in child health settings were those relating to web-based education and computerized prompts and reminders [13]. The existing literature highlights the promise of the use of digital TEKT; however, the effectiveness of digital TEKT in the public health setting is not known.

Objectives

In the context of existing evidence synthesis gaps for public health digital TEKT, this review aimed to examine the effectiveness of digital TEKT strategies in improving the following measures:

1. Public health policy makers or practitioners’ capacity to make evidence-based health policy and practice decisions such as changes in knowledge acquisition, knowledge

- retention, change in reasoning, judgment, or decision making [14].
2. Evidence-based public health policy and practice such as changes in behavior, public health policy, or practice.
 3. Individual- or population-level health outcomes from the use of research in public health.

Methods

Registration

This review was prospectively registered with the International Prospective Register of Systematic Reviews (PROSPERO; CRD42018112715) and is reported per the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines [15].

Eligibility Criteria

Types of Studies

Any primary research study with a randomized trial design, including cluster randomized, was eligible.

Studies published in peer-reviewed journals, as well as gray literature publications, were included in this review. There was no restriction on the length of the study follow-up period, the language of publication, or country of origin.

Types of Participants

Studies were eligible for inclusion if they included public health end users, such as health care policy makers, health care managers, and health professionals employed by public health services. For this review, public health services were defined as aiming to promote health and well-being and prevent illness and disease [16]. Such services may be delivered by government or nongovernment organizations. Examples of public health services include health protection and health promotion of preventable diseases and illnesses such as childhood obesity, injury prevention, vaccinations, and immunizations [9,16].

Health professionals who are involved in public health may have included, but was not limited to, health practitioners; allied health professionals such as dietitians, occupational therapists, physiotherapists, speech pathologists; pharmacists; nurses; physicians; and social workers with a focus on preventative care. Studies targeting clinicians were only included if they were engaging in preventative health services. Studies that assessed the impact on researchers embedded within public health services were excluded from this review.

Types of Interventions

Any study that reported on the effectiveness of digital TEKT strategies targeting public health policy makers or practitioners was eligible for inclusion that compared the following:

1. Digital TEKT strategies targeting public health policy makers and practitioners with no intervention.
2. Two or more alternative KT strategies targeting public health policy makers and practitioners, where at least one alternative included a digital TEKT strategy only.

Digital TEKT could make use of social media, email, internet, electronic databases, electronic prompts or reminders, web-based

webinars, or training or interactive websites to facilitate research use by end users. Digital TEKT strategies could employ either or both *push* and *pull* strategies. Examples of digital TEKT strategies included in this review form part of the knowledge creation component (knowledge tools and products) of the knowledge to action framework [3].

Studies in which digital TEKT was not the exclusive component of a study were excluded.

Comparison

Groups may have received any alternative KT strategy, usual care, no intervention, or a waitlist control.

Types of Outcome Measures

We included any trial that included the assessment of the effects of digital TEKT strategies on the following:

1. Measures of public health end users' capacity to make evidence-informed health policy and practice decisions. Any cognitive measures of end users' capacity for evidence-informed decisions were included, such as measures of knowledge acquisition, knowledge retention, change in reasoning, judgment, or decision making [14]. In addition, measures of change in intention, attitude, and self-efficacy were included. Such data could be collected via surveys of policy makers and practitioners, completion of performance tasks, observations, or other measures.
2. Measures of evidence-based public health policy and practice, including changes in the behavior of policy makers or practitioners in decision making, in actual public health policy, or practice. Measures could include surveys of policy makers and practitioners, practice reviews, and assessment of core competencies or observations.
3. Measures of individual-, community-, or population-level health outcomes. These could include measures of the presence or absence of disease, health condition, or behavioral risk factors (eg, tobacco use) at the level of an individual, collected via patient surveys, use of medical records, objective measures of behavior or disease, or any other method to determine health outcomes; or at a population level, for example, the use of population-level surveys or disease surveillance systems or change in health service use [14].

Information Sources and Search Methods

A comprehensive search was developed in consultation with an information specialist (DB) conducted for peer-reviewed articles in electronic databases.

Electronic Searches

The following electronic databases were searched from inception to October 5, 2018: Medical Literature Analysis and Retrieval System Online (MEDLINE), Excerpta Medica dataBASE (EMBASE), PsycINFO, Cumulative Index of Nursing and Allied Health Literature (CINAHL), and SCOPUS.

We developed the search strategy in MEDLINE and adapted the search for each database (Multimedia Appendix 1). Search filters used in other systematic reviews for KT strategies [9,17,18] and digital dissemination or intervention [12] were

adapted for use in this review. Additional search filters were developed to capture the outcomes included in the review [14].

Searching for Other Resources

The reference lists of all included studies were searched for additional relevant studies. A hand search of studies published between December 2016 and October 2018 was conducted in the *Implementation Science* and *Journal of Medical Internet Research (JMIR)* journals due to their relevance to the aims of the systematic review. Hand searches were conducted for 2 years, consistent with the practices of other Cochrane Reviews [19,20].

We also conducted a gray literature search using Google, with the search terms “knowledge translation” AND (“digital dissemination OR digital intervention”) AND “public health” and reviewed the first 200 results against the eligibility criteria.

Selection of Studies

All studies obtained in the literature search were deduplicated. The titles and abstracts of the identified studies were independently screened for eligibility by 2 reviewers (from a pool of 4 reviewers: AB, CB, JB, and MM) and full texts of all relevant or unclear studies were obtained and reviewed against the inclusion criteria using Covidence. Any ambiguity in the inclusion of a study was resolved by discussion or by a third reviewer to reach consensus. Review authors were not blinded to author or journal information.

Data Collection and Analysis

Data Extraction and Management

Two review authors (AB and LW) independently extracted information from the included studies using a data extraction form developed and piloted by the research team. Any discrepancies regarding data extraction between the review authors were resolved via discussion. An attempt to contact study authors occurred if there was insufficient data in the included studies. The following information was extracted: general information (author name, title, date of publication, and country) methods (study design, setting, duration, sample size, and number of experimental conditions), participants (total number and participant characteristics), types of intervention (characteristics of the digital TEKT intervention and comparison components including the type of strategy and modality [website, web-based training, and emails]), type of outcome measures and results (outcomes aligned to the review inclusion criteria, data collection procedure, effect size, and summary data for each intervention group), and information to allow assessment of risk of study bias. Additionally, we extracted information regarding the intervention for each element recommended by the Template for Intervention Description and Replication (TIDieR) checklist. The TIDieR checklist is a 12-item checklist used to report characteristics of interventions in a structured manner. It includes information on why the study was conducted, how the study was conducted, materials used, where it was conducted, frequency of the intervention, and any tailoring or modifications [21]. Such information was not planned in the review protocol and was not used in formal study

synthesis but has been included to enhance characterization of the trials.

Assessment of Risk of Bias

Two reviewers (AB and RH) independently assessed the risk of bias using the *Cochrane Handbook for Systematic Review of Interventions Risk of bias 2.0* tool [22]. Each included study was assessed for the following risks of bias (and rated as *high*, *low*, or *some concerns*): randomization, deviations from the intended intervention, missing outcome data, measurement of the outcome, and free of selective outcome reporting. The overall risk of bias for each study was determined using guidance from the *Cochrane Handbook for Systematic Review of Interventions Risk of bias 2.0* tool [22]. Discrepancies in rating the risk of bias between reviewers were resolved by discussion.

Data Synthesis

A random effects meta-analysis was planned in the protocol to provide a quantitative assessment of the effects of interventions. However, meta-analysis could not be conducted as outcomes reported were not able to be pooled due to considerable heterogeneity across the included studies. As such, the results are described narratively by synthesizing study findings by outcome. Within the outcome category, synthesis was then undertaken by first synthesizing the findings of studies comparing digital TEKT versus the control group and then by synthesizing the effects of studies comparing digital TEKT strategies versus an alternative intervention.

Results

Description of the Included Studies

A total of 6819 citations were screened for eligibility (Multimedia Appendix 2). The full text of 46 studies was obtained to determine eligibility against the review criteria. Of these 46 studies, 8 were included in the review [23-30]. The primary reasons for exclusion of ineligible studies were as follows: non-randomized controlled trials (non-RCTs; n=17), nondigital studies (n=6), not specifically KT (n=6), protocol only (n=4), based on the clinical setting (n=4), or had no digital TEKT outcome (n=1).

A summary of the study characteristics and outcomes of the 8 included studies is provided in Table 1. All 8 studies were RCTs, of which 4 were cluster RCTs [25,27,29,30]. A total of 3 studies were conducted in the United States [23-25], 2 in the Netherlands [26,28], 2 in Canada [27,30], and the remaining study was conducted in China [29].

Health professionals recruited in the included studies comprised nurses [23,26,30], nurse practitioners [23], physicians [23], child care health consultants [24], physiotherapists [30], primary health care workers [29], and public health practitioners [30]. A further study recruited program managers or coordinators of public health departments [27] and the remaining study recruited professionals employed in schools, community agencies, and policy-making bodies [25].

There was variability in the digital TEKT interventions tested. Overall, 5 of the interventions were web-based training programs

aimed at improving nutrition and physical activity knowledge in children [24], utilizing smoking cessation guidelines [26], body positivity in children and adolescents [30], physical activity levels in patients with cardiovascular risk factors [28], and improving basic public health services knowledge [29]. The remaining 3 interventions included simulation games to improve communication with patients with mental health disorders [23], access to digital resource materials on substance abuse prevention programs [25], and the use of tailored messaging in comparison with knowledge brokering or a web-based registry concerning healthy body weight promotion in children [27]. Of the 8 included studies, 6 reported using evidence-based information to develop the intervention or as part of the program [23-27,30], including the use of systematic reviews [27], and previous programs and studies [23-26,30]. A full description of the intervention consistent with the TIDieR checklist is provided in [Multimedia Appendix 3](#) [23-30].

The majority of comparison groups for the included studies were control groups that had no access to the digital TEKT strategies (n=3) [23,24,26] or waitlist control group (n=2) [28,30]. A study that aimed at providing information on substance abuse prevention programs compared groups accessing information via CD-ROM or the internet to those who accessed information via printed materials [25]. A further study in public health department personnel compared its most interactive KT strategy (access to knowledge broker, web-based registry, and tailored messages) and its moderate interactive KT strategy (web-based registry and tailored messages) with the least interactive KT strategy of access to a web-based registry only [27]. The study in primary health care workers compared its face-to-face education group with its comparison group that

accessed information via websites only, in an effort to improve cardiovascular risk management [29].

The majority of studies reported on fidelity with the intervention to some extent; however, studies were inconsistent in how fidelity was measured, which included time to complete intervention and percent use of program [23,24,27,28,30]. Of the 2 studies that reported on time to complete, the mean time ranged from 124 to 4998 min [23,24] and the percent usage of the program ranged from 45% to 100% in the 3 studies that reported this [27,28,30].

The most commonly reported KT outcome measure was a change in knowledge, as reported in 4 of the included studies [23,24,26,29,30]. Of the 8 included studies, 3 reported the outcome measure of intention to change behavior [23,25,28] and 2 reported self-efficacy for identifying evidence and confidence to improve the health professional's practice behavior [25,30]. Only 1 study reported the impact of digital TEKT strategies on measures of attitude regarding health professional practice behavior to improve physical activity in cardiovascular patients and on the health professional's perceived behavior control [28]. Changes to health policy, practice, or decision making were reported by 3 studies [26-28]. No study reported outcomes relating to individual-, community-, or population-level health outcomes.

The majority of outcome measures within the included studies (n=7) were evaluated using telephone, written, or web surveys [23,25-30], with the remaining study using a knowledge test to measure its outcome [24]. Of the 8 included studies, 2 studies reported using validated measures of trial outcomes [23,30].

Table 1. Study characteristics and key findings.

Study (reference, country, study design)	Population: type of participant, sample size, mean age and gender of participants, industry experience	Intervention description; duration of intervention; comparator	Outcomes and measures	Key findings
Albright et al [23]; United States; RCT ^a	227 nurses, nurse practitioners, and physicians; 81.9% female; 65.6% nurses; Industry experience: mean 10.89 (SD 11.01) years; Age not reported	<i>Description:</i> At risk in primary care web-based simulation <i>role-playing</i> game. Provides learners opportunities to practice role playing with emotionally responsive virtual patients that are experiencing mental health disorders; <i>Duration:</i> Simulation takes 1-1.5 hours to complete. <i>Comparator:</i> control	<i>Outcome:</i> knowledge and skills; <i>Measure:</i> 6-item Gatekeeper Behavior Scale web-based questionnaire; <i>Outcome:</i> likelihood to screen and manage mental health issues; <i>Measure:</i> single item, 4-point Likert-type scale web-based questionnaire	The score for the treatment group, postsimulation (mean 3.40, SD 0.89) was significantly higher than the control group at presimulation (mean 2.91, SD 0.69), $P<.001$; Likelihood of engaging in screening behavior for the treatment group (mean 3.27, SD 0.74) was significantly higher than the control group (mean 2.90, SD 0.87), $P<.01$
Benjamin et al [24]; United States; RCT	51 CCHCs ^b ; Control (n=17): 6.9 years old; 94% female; 88% nursing degree. Web-based (n=17): 41.9 years old; 100% female; 94% nursing degree. In-person (n=16): 39.8 years old; 100% female; 87% nursing degree. Industry experience not reported	<i>Description:</i> web-based (group 1) and in-person trained (group 2) CCHCs. Each training included 4 modules: intervention overview, introduction to childhood overweight, nutrition and physical activity, and providing consultation to child care centers. In-person training and web-based training were designed to be similar in both content and structure. <i>Duration:</i> training took 3 hours; <i>Comparator:</i> control	<i>Outcome:</i> nutrition knowledge related to childhood overweight. <i>Measure:</i> 28 multiple choice questions (childhood overweight=4, nutrition for children=10, physical activity for children=8, and nutrition and physical activity for adults=6) with 2-5 possible response options	Participants from the web-based trained group (difference in pre/post score=16.18) did not perform better than the in-person trained group (difference in pre/post score=16.53). Both training groups improved significantly more than controls (difference in pre/post score=1.89; $P<.001$ for each group)
de Ruijter et al [26]; the Netherlands; RCT	269 PNs ^c across the Netherlands. Mean 47.3 years old; 97.8% female. PN counseling experience was mean 5.6 years	<i>Description:</i> Guideline adherence to smoking cessation counseling. Computer-tailored, web-based program relating to smoking cessation. Consisted of web-based modules, tailored advice, forum, and smoking cessation counseling materials. <i>Duration:</i> 6 months to access and use the program. <i>Comparator:</i> control group engaged in normal smoking cessation counseling practices	<i>Outcome:</i> adherence to STIMEDIC ^d guidelines. <i>Measure:</i> questions on guideline adherence concerned the 9 evidence-based counseling steps, as described in the STIMEDIC guideline. PNs adherence at baseline was assessed by asking PNs to self-report their adherence to each guideline step during complete smoking cessation trajectories of their last 10 patients (range 0-10). Additionally, during the trial period, guideline adherence was assessed by asking PNs to self-report their adherence to each guideline step after every consultation with a smoking patient using the counseling checklist	Overall intervention effect not reported. Significant interaction between groups based on the average years of counseling experience ($P=.045$)

Study (reference, country, study design)	Population: type of participant, sample size, mean age and gender of participants, industry experience	Intervention description; duration of intervention; comparator	Outcomes and measures	Key findings
Di Noia et al [25]; United States; RCT	188 school, community agency, and policy-making professionals; 68.6% females; 25% 30-39 years, 23% 40-49 years, 19% 50-59 years (mean age not reported); 48% some graduate school, 22.3% college, 10.6% some college. Industry experience not reported	<i>Description:</i> illustrative dissemination materials for 3 youth-oriented substance abuse prevention programs. Materials for each program were tailored for each setting (school, community agencies, and policy makers) and disseminated by: Group 1: accessed resource materials via CD-ROM (n=64); Group 2: accessed resource materials via the internet (n=69). <i>Duration:</i> 2 years. <i>Comparator:</i> resource materials accessed via printed pamphlets (n=55)	<i>Outcome:</i> self-efficacy. <i>Measure^e:</i> via survey assessing professionals' self-efficacy for identifying and obtaining prevention programs to serve the needs of youth; confidence in ability to recommend programs to their constituents. <i>Outcome:</i> intention to apply prevention program materials; likelihood of their future applications of materials disseminated in the trial; likelihood of request program materials, implementing a prevention program and recommending programs to their constituents. <i>Measure:</i> via survey	No significant differences between groups for self-efficacy for the ability to identifying programs or recommend programs. Significant between channel effects in ability to obtain programs for pamphlet (mean 1.37, SD 0.93) versus internet (mean 0.87, SD 0.79) and pamphlet versus CD-ROM (mean 0.94, SD 0.84) at $P<.05$ at follow-up; No significant differences between groups for likelihood of requesting program or likelihood of implementing program. Significant difference between CD-ROM (mean 1.41, SD 1.13) and pamphlet (mean 1.55, SD 1.13) for likelihood of recommending program at $P<.05$ and significant difference between CD-ROM and internet (mean 1.06, SD 1.05) for likelihood of recommending program at $P<.05$ at follow-up
Dobbins et al [27]; Canada; RCT	108 public health departments with program managers and/or coordinators and/or program directors responsible for making program decisions related to healthy body weight promotion in children; 35% frontline staff; 26% manager; 47% nursing discipline; Mean 5 years in current position; Mean years in a public health role=13. Age and gender not reported	<i>Description:</i> the 3 interventions included access to a web-based registry of research evidence, tailored messaging, and a knowledge broker. Moderate interactive intervention (digital TEKT ^f strategy): tailored targeted messages plus access to a health evidence repository (TM). Most interactive intervention: access to a knowledge broker, tailored targeted messages plus access to health evidence repository (KB). Least interactive intervention: access to health evidence repository (HE). <i>Duration:</i> program implemented over 1 year	<i>Outcome:</i> public health policies and programs; <i>Measure:</i> This measure was derived as the sum of actual strategies, policies, and/or interventions for health body weight promotion in children being implemented by the health department. Participants were asked whether the public health policies and programs were being implemented by their health department (yes/no); <i>Outcome:</i> global evidence-based decision making. <i>Measure:</i> in a telephone-administered survey, participants were asked to report on the extent to which research evidence was considered in a recent program planning decision (previous 12 months) related to healthy body weight promotion	TM group improved significantly from baseline to follow-up in comparison to the HE and KB groups that showed no significant change ($P<.01$); Intervention had no significant effect on global evidence-based decision making ($P<.45$), although all groups improved to some extent (HE group: 0.74; TM group: -0.42; KB group: -0.09)

Study (reference, country, study design)	Population: type of participant, sample size, mean age and gender of participants, industry experience	Intervention description; duration of intervention; comparator	Outcomes and measures	Key findings
McVey et al [30]; Canada; RCT	89 public health practitioners (100% female) from 2 Canadian provinces; Public health participants: public health nurses (n=62) and nutritionists (n=27), with average number of years 12.72; 84.4% identified as white. Age not reported	<i>Description:</i> the student body Promoting Health at Any Size web-based program; 6 learning modules: (1) media and peer pressure (2) healthy eating, (3) active living, (4) teasing, (5) adult role models, and (6) school climate including case studies, background information, additional resources, and classroom activities. <i>Duration:</i> the intervention group had 60-day access to the web-based intervention. <i>Comparator:</i> waitlist control	<i>Outcome:</i> knowledge of the physical changes associated with puberty, facts concerning restrictive dieting, peer and adult influences, and the influence of the media on weight loss. <i>Measure:</i> assessed via a survey using true-false questions and Likert scales; <i>Outcome:</i> efficacy to fight weight bias. <i>Measure:</i> 6-item subscale used to assess self-efficacy expectations for fighting weight bias in their schools. On the basis of a 4-point Likert scale (Cronbach $\alpha=.44$)	Physical changes associated with puberty: there was no significant interaction effect, $F_{1,77}=.486$, $P=.488$. Facts concerning restrictive dieting: there were no significant interactions or time effects found for any of the items that tapped knowledge about dieting. Peer or adult influences: there were no significant interactions or time effects. Influence of the media on weight loss: there were no significant interactions or time effects; There was a significant interaction effect found for the variable efficacy to fight weight bias, $F_{1,77}=10.81$, $P=.002$. Participants in the intervention group only reported significant improvements in efficacy scores between baseline and the postintervention periods, $P<.001$
Sassen et al [28]; the Netherlands; RCT	69 health care professionals with at least a bachelor's degree in nursing or physiotherapy and who had regular consultations with patients with CV ^g risk factors and low levels of PA. Control group: 78% female, mean 39.7 years old; 68% bachelor's degree, mean 9.58 years professional experience. Intervention group: 69% female, mean 38.6 years old; 79% bachelor's degree, mean 9.76 years professional experience	<i>Description:</i> web-based intervention to increase health care professionals' intention and encouraging behavior toward patient self-management, following CV risk management guidelines. Website contained modules to help the health professionals improve their professional behavior, support the health professional, improve patients' intention, and risk reduction. The website also included a forum directed at health professionals to share experiences with other professionals. <i>Duration:</i> not reported. <i>Comparator:</i> waitlist control	<i>Outcome:</i> intention to encourage CV patients to become physically active. <i>Measure:</i> self-assessed through a questionnaire (3 items on intention); <i>Outcome:</i> attitude to encourage PA ^h in CV patients. <i>Measure:</i> self-assessed through a questionnaire of a series of 8 questions regarding the usefulness of assessing patients' motivation, pros and cons of PA, teaching patients: resisting social pressure, teaching specific PA skills, teaching patients how to handle barriers, formulating PA goals, teaching patients to handle relapses, and helping patients understand the relationship between health problems and PA; <i>Outcome:</i> perceived behavior control. <i>Measure:</i> self-assessed through a questionnaire (23 items on behavior outcomes); <i>Outcome:</i> behavior change in encouraging CV patients to PA. <i>Measure:</i> assess via 2 items by asking whether professionals encourage CV patients to increase PA and how often do they encourage CV patients to become physically active	No significant differences in both the intervention and the control groups between baseline (mean: 6.25, SD: 1.00 and mean: 5.87, SD: 1.15) and follow-up (mean: 6.06, SD: 1.11 and mean: 6.02, SD: .091) for intention No significant differences in both the intervention and the control groups between baseline (mean: 6.30SD: 0.44 and men: 6.23, SD: 0.69) and follow-up for attitude (mean: 6.30 SD:0.56 and mean: 6.31SD: 0.68); Significant difference in perceived behavior control between baseline and follow-up for the intervention group ($t_{26}=-2.954$, $P<.001$, effect size=0.50) and a significant increase for the control group ($t_{19}=-2.651$, $P=.02$, effect size=0.54). No significant difference between intervention and control group; No significant differences in both the intervention and the control groups between baseline (mean 4.54, SD: 1.02 and mean: 4.83 SD: 0.69) and follow-up for behavior (mean: 4.63, SD: 0.85 and mean:4.79, SD: 0.82)

Study (reference, country, study design)	Population: type of participant, sample size, mean age and gender of participants, industry experience	Intervention description; duration of intervention; comparator	Outcomes and measures	Key findings
Zhan et al [29]; China; RCT	1237 primary health care workers. Blended learning group (n=569): Mean 41.67 years old, 48.9% female, 9.6% technical secondary school or below; Pure web-based learning group (n=563): mean 41.98 years old, 43.2% female, 77.3% technical secondary school or below	<i>Description:</i> the blended learning (intervention) and pure web-based learning (control) groups had the same course materials to improve basic public health services knowledge. Participants in the blended learning group studied PowerPoint-based theoretical materials, received the handouts of case study materials for self-studying and attended 1-day (8 hour) face-to-face case study training. <i>Duration:</i> overall study period was 5 weeks. <i>Comparator:</i> control (pure web-based learning group—digital TEKT strategy); received via a web-based platform: Microsoft PowerPoint; case studies consisted of 3 video sessions, and 2 discussion forums were developed on the training platform	<i>Outcome:</i> knowledge for course module components. <i>Measure:</i> a total of 3 knowledge MCQ ⁱ tests were developed, consisting of a 10-item MCQ test in course module 1, a 15-item MCQ test in course module 2, and a 20-item MCQ test in course module 3	Baseline knowledge scores of the 3 course modules between experimental and control group were similar. Higher gains in the experimental group than in the control group; module 1: adjusted mean difference=4.92, $P<.001$; module 2: adjusted mean difference=3.67, $P=.004$; module 3: adjusted mean difference=4.63, $P<.001$

^aRCT: randomized controlled trial.

^bCCHC: child care health consultants.

^cPN: practice nurses.

^dSTIMEDIC: A registered trademark that stands for smoking cessation (SMR) in health care.

^eLower scores indicate more favorable ratings.

^fTEKT: technology-enabled knowledge translation.

^gCV: cardiovascular.

^hPA: physical activity.

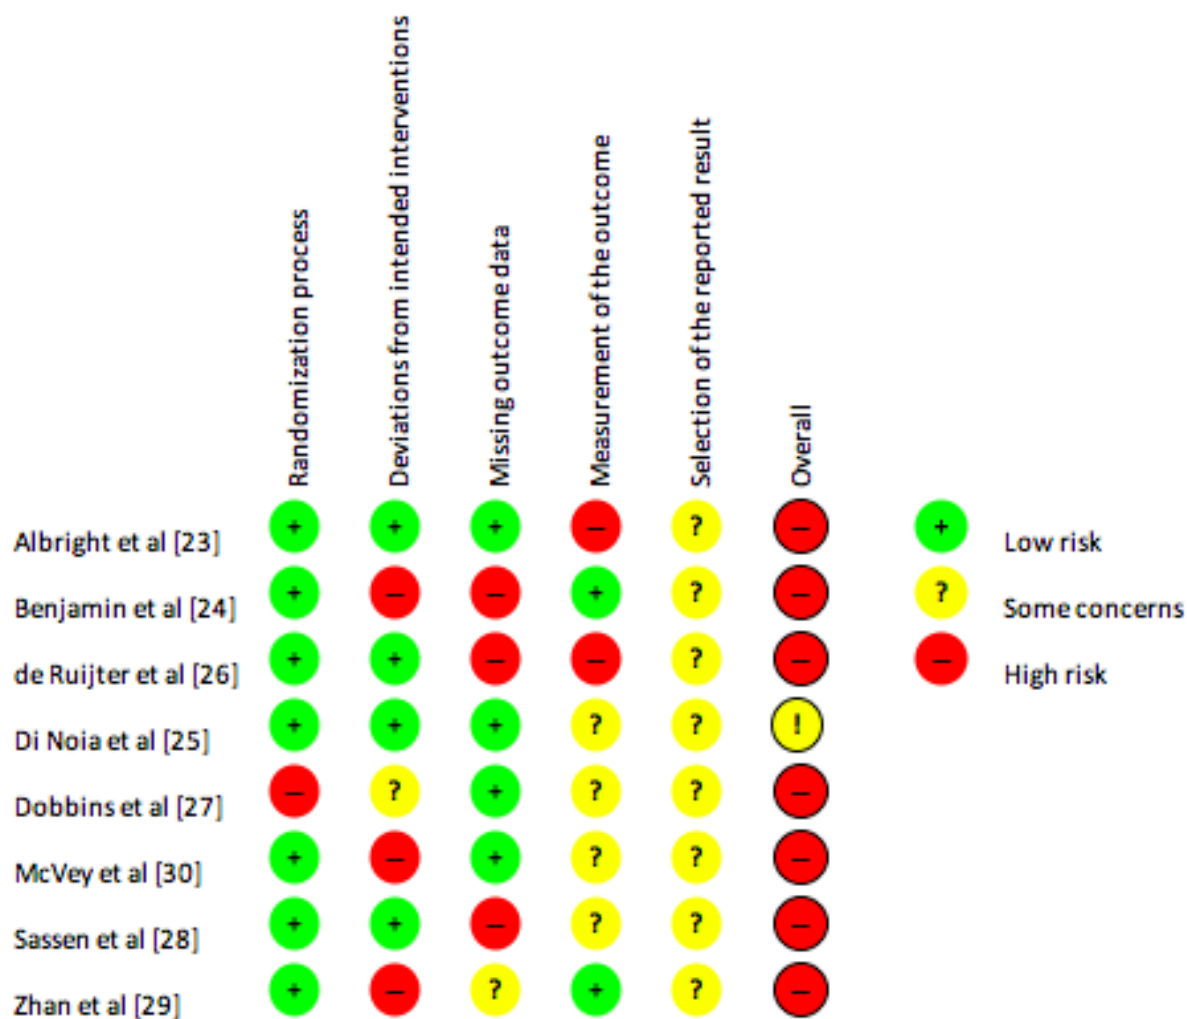

ⁱMCQ: multiple choice questions.

Risk of Bias

Figures 1 and 2 summarize the risk of bias for each of the studies.

Of the 8 studies, 7 were assessed as having an overall high risk of bias [23,24,26-30]. Only 1 study was considered to have a high risk of bias for the randomization process [27]. For

deviations from intended interventions, 3 studies were assessed as having a high risk of bias [24,29,30], with 1 study having some concerns [27]. Missing outcome data resulted in 3 studies having a high risk of bias [24,26,28], with measurement of the outcome highlighting 2 studies with a high risk of bias [23,26]. All 8 studies were classified as having some concerns in relation to the selection of the reported results.

Figure 1. Risk of bias summary.**Figure 2.** Risk of bias graph.

Key Findings

A summary of the outcomes and key findings is provided in [Table 1](#).

Measures of Public Health End Users' Capacity to Make Evidence-Informed Decisions

Knowledge Change

A total of 4 trials examined the effects of digital TEKT strategies on knowledge outcomes [23,24,29,30]. Of these, 3 compared the effects of digital TEKT interventions with a control, each of which reported significant improvements in knowledge favoring the intervention [23,24,29]. A study using a web-based simulation game reported significant improvements in knowledge and skill scores postintervention to enhance the assessment of mental health disorders ($P<.001$) [23]. Similarly, a study in child care health consultants reported significant improvement in nutrition and physical activity knowledge among those receiving web-based training relative to those in a control that did not provide training ($P<.001$) [24]. A study in primary health care workers in rural China compared the provision of web-based learning only to improve knowledge regarding basic public health services in rural China with a blended learning group provided with a combination of digital and face-to-face training. The study found greater improvements in knowledge of public health services in the blended learning group ($P<.001$) [29]. Finally, a study allocating public health professionals to receive a web-based program to prevent eating disorder behavior in children or a waitlist control reported no significant differences across any knowledge outcomes [30].

Only 1 trial compared the effects of a digital TEKT intervention with an alternate KT intervention [24]. The study of child care health consultants compared nutrition knowledge among those receiving face-to-face training versus those receiving web-based training [24]. The study found no differences between groups in terms of knowledge outcomes.

Self-Efficacy

Overall, 2 trials assessed self-efficacy for identifying evidence and confidence to improve the health professional's practice behavior as a digital TEKT outcome, the findings of which were mixed [25,30]. The first, a study by Mcvey et al [30], found that public health professionals who had accessed the web-based program had significant improvements in self-efficacy scores compared with controls ($P=.002$). The second study compared alternate KT interventions and found no difference in professionals from schools, community agencies, and policy-making bodies, confidence to recommend suitable programs, or self-efficacy for identifying and recommending relevant programs between those allocated to receive substance abuse prevention program resources via CD-ROM or websites compared with those receiving such information via pamphlets [25]. However, there were between-group differences in self-efficacy to obtain youth prevention programs, with those in the internet group and the CD-ROM group reporting significant improvement when compared with the pamphlet group ($P<.05$) [25]. Bonferroni post hoc analyses highlighted favorable differences for the internet group ($P<.05$).

Intention

In all 3 studies that measured behavioral intentions reported mixed effects of digital TEKT interventions on these outcomes [23,25,28] and 2 studies compared digital TEKT interventions

versus no intervention control. The first, a study by Albright et al [23], found that participants allocated to the web-based simulation game reported a higher likelihood of assessing and screening patients for mental health disorders relative to the control group ($P<.01$). However, Sassen et al [28] reported no significant differences between the website-trained group and the control group in the intention of health professionals to encourage cardiovascular patients to become physically active [28].

The study by Di Noia et al [25] compared the effects of different KT interventions for a substance abuse prevention program. The study found that participants receiving dissemination materials via the internet had significant improvements in their likelihood of recommending programs compared with the CD-ROM group ($P<.05$). The CD-ROM group, however, showed significant improvements compared with the pamphlet group ($P<.05$) [25]. There were no differences between any of the 3 groups in their likelihood of requesting programs or the likelihood of implementing the program [25].

Attitude

Only 1 study reported attitude as an outcome measure and reported that there were no differences between the website-trained group and the control group in their attitude to encourage cardiovascular patients to become physically active [28].

Perceived Behavior Control

Perceived behavior control to assess health professionals' perceived skills and knowledge in encouraging physical activity in cardiovascular patients was reported by Sassen et al [28], who found no significant difference between the website-trained group and the control group [28].

Measures of Evidence-Based Public Health Policy and Practice

Changes to Health Policy, Practice or Decision Making

Of the 8 included studies, 3 reported changes to health policy, practice, or decision making as an outcome measure [26-28]. A web-based study to improve the behavior of health professionals who were nurses or physiotherapists in following cardiovascular risk management guidelines reported no significant differences between groups in encouraging cardiovascular patients to increase physical activity levels ($P=.68$) [28].

A study by de Ruijter et al [26] in practice nurses reported on the outcome of smoking cessation guideline adherence and found that there was a significant difference between groups as counseling experience increased guideline adherence; however, the overall intervention effect was not reported.

The study by Dobbins et al [27] in public health departments reported outcome measures relating to a change in public health policies and programs and a change in global evidence-informed decision making. In relation to public health policies and programs, the group that received tailored messages via email plus access to a health repository improved significantly in the number of public health policies and programs implemented in comparison with both the group that received only access to the

health repository and the group that received access to the health repository, tailored messages, and a knowledge broker ($P<.01$) [27]. The study reported no significant differences between groups in relation to global evidence-informed decision making [27].

Measures of Individual-, Community-, or Population-Level Health Outcomes

No included studies reported on individual-, community-, or population-level health outcomes.

Discussion

Principal Findings

To the best of our knowledge, this review is the first to report on the effectiveness of digital TEKT strategies in improving public health end users' capacity to make evidence-informed health policy and practice decisions. Overall, the findings from the 8 included studies suggest that digital TEKT interventions may be effective at improving public health professionals' knowledge, and may be as effective at improving knowledge as a face-to-face KT approach. The effectiveness of digital TEKT strategies relative to control or other KT interventions for self-efficacy or behavioral intention outcomes and changes to health policy or practice were mixed. Such findings offer little guidance for those interested in utilizing digital TEKT strategies to promote the transfer of knowledge to improve public health and demonstrate a considerable need for further research in this field.

The small number of trials identified in this review examined the impact of the digital TEKT intervention on a narrow range of potential outcomes, namely knowledge, self-efficacy, and behavioral intentions. Other outcomes suggested by evaluation frameworks are important in assessing digital TEKT interventions, including behavioral and population-level health outcomes; however, these were rarely reported [14]. These findings are consistent with other systematic reviews of KT and digital dissemination strategies. For example, a systematic review published in 2012 on the effects of KT on public health identified only 5 included studies and reported outcomes relating to knowledge change and change in practice only [9]. Similarly, a systematic review in 2016 including 21 studies on the effectiveness of digital dissemination of clinical practice guidelines included outcomes such as usability of the technology (perceived usefulness and perceived ease of use) and practice behavior (using the theoretical domains framework including knowledge, skills, beliefs, and motivations), with knowledge and skills being the most frequently reported outcome and limited studies reporting other behavior change outcomes [12].

A 2019 systematic review on KT strategies in the clinical child health setting included 48 studies and reported outcomes relating to health care professionals or patient-reported outcomes [13]. Although the review included some digital TEKT studies, only 9 RCTs had a positive effect on clinician-related or patient outcomes [13]. This recent systematic review highlights the continued paucity of research on digital TEKT broadly. The limited reporting of behavioral and population-level health outcomes and the differences in measures used to report other

outcomes highlight the challenges of conducting and synthesizing the effects of KT research. Although a variety of tools have been suggested to be useful in assessing the impact of digital KT strategies, including altmetric scores, measures of engagement and process indicators, and use of consistent evaluation metrics in reporting KT outcomes, would assist in appropriately assessing the effectiveness of digital TEKT and comparing these across trials. Core outcome sets are currently being used in several specific health areas to determine a standardized set of outcomes that should be measured and reported [31]. However, there are currently no core outcome sets developed for KT [32]. To address the issue of inconsistent evaluation outcomes in KT research, it may be necessary to develop KT-specific core outcome sets.

For knowledge outcomes, the findings of this review are broadly comparable with other systematic reviews of the effects of KT interventions in other health professions. For example, a 2012 review of public health KT strategies suggested that KT strategies were effective in improving knowledge outcomes, with 2 of 3 included studies reporting significant improvements in measures of knowledge acquisition [9]. Similarly, a 2016 systematic review found improvements in knowledge following web-based workshops, emails, educational web-based games, and multifaceted KT interventions, but not interventions using websites or computer software [12]. Consistent with the findings of this review, other systematic reviews have also reported mixed effects of KT on measures of behavioral intentions [12]. The findings of the review on other outcomes are difficult to contextualize, given the limited number of trials reporting these outcomes. Collectively these findings suggest that digital TEKT strategies may influence precursors for behavior change, such as knowledge and intention, but are yet to demonstrate impacts on public health policy and community outcomes. This is an important evidence gap for researchers to remedy, as public health policy and community impacts represent the ultimate goal of TEKT interventions. Indeed, such outcomes are required for TEKT strategies to yield improvements in public health decision making. The conduct of rigorous trials of digital TEKT strategies that include policy or community health outcomes, however, may represent a considerable challenge for researchers given the limited resources available to conduct such large trials with long periods of follow-up required for KT to occur [3]. Embedding such trials into public health services, which have an interest in KT for health service improvement, and have existing infrastructure and access to routinely collected data on community health improvement may represent a means of addressing the logistical challenges of undertaking such trials [33].

Strengths and Limitations

There are a number of strengths to this review. A comprehensive search strategy was used in consultation with an information specialist, using multiple electronic databases, hand search of reference lists, and gray literature searches. A systematic approach was utilized to review the current literature on digital TEKT in public health, including the use of pairs of reviewers to double-screen studies for inclusion, extract data, and determine the quality of the studies included. However, there were some limitations that must be considered when interpreting

the findings of the review. All but 1 study was assessed as having an overall high risk of bias, particularly due to the measurement of the outcome and selection of the reported results. As most studies had follow-up periods <12 months, it is difficult to determine the effects of the intervention over a longer period of time, which is particularly important when considering behavior and policy change. There was also a high level of heterogeneity due to differing health professional populations, interventions, and outcome measures, making it difficult to draw comparisons between studies and limiting the ability to conduct a meta-analysis. The KT search terms used in this review may have missed relevant KT studies, given the high variability of terms that are used in health to describe KT, a common limitation described in the literature [2,3].

Conclusions

This review addresses an important knowledge gap for digital TEKT in the public health setting and is the first to synthesize

the effectiveness of digital TEKT interventions. Although the review has highlighted potential improvements in knowledge using digital TEKT strategies, it remains unclear whether digital TEKT strategies improve other behavioral and population health outcomes. Currently, there are limited studies assessing digital TEKT in the public health setting, with a limited range of outcomes to assess their effectiveness appropriately. As such, the findings of the review provide limited guidance to assist in the development of effective digital TEKT strategies. A recent scoping review conducted in 2020 summarized the most relevant KT frameworks for use by researchers, policy makers, and clinicians in the health care setting [34]. In the absence of sufficient evidence on the effectiveness of TEKT, the use of relevant KT frameworks is suggested to appropriately disseminate research findings to influence evidence-informed health policy and practice decisions.

Acknowledgments

This work was supported by infrastructure support from Hunter New England Population Health. RH was supported by a National Health and Medical Research Council (NHMRC) Early Career Fellowship and a Prevention Research Support Program Fellowship funded by the New South Wales Ministry of Health. NN was supported by an NHMRC Translating Research Into Practice (TRIP) Fellowship and a Hunter New England Clinical Research Fellowship. RS was supported by an NHMRC TRIP Fellowship. LW was supported by an NHMRC Career Development Fellowship and a Heart Foundation Future Leader Fellowship and a Hunter New England Clinical Research Fellowship.

Authors' Contributions

AB, RS, NN, and LW conceived and designed the systematic review. DB, AB, and LW developed the search strategy and DB conducted the search. AB, CB, JB, and MM screened studies for inclusion. AB and RH completed the risk of bias assessment. AB and LW completed the data extraction. AB drafted the manuscript, with all coauthors contributing to drafts of the paper. All authors approved the final manuscript.

Abstract

Background: The prevalence of chronic health conditions in childhood is increasing, and behavioral interventions can support the management of these conditions. Compared with face-to-face treatment, the use of digital interventions may be more cost-effective, appealing, and accessible, but there has been inadequate attention to their use with younger populations (children aged 5-12 years).

Objective: This systematic review aims to (1) identify effective digital interventions, (2) report the characteristics of promising interventions, and (3) describe the user's experience of the digital intervention.

Methods: A total of 4 databases were searched (Excerpta Medica Database [EMBASE], PsycINFO, Medical Literature Analysis and Retrieval System Online [MEDLINE], and the Cochrane Library) between January 2014 and January 2019. The inclusion criteria for studies were as follows: (1) children aged between 5 and 12 years, (2) interventions for behavior change, (3) randomized controlled trials, (4) digital interventions, and (5) chronic health conditions. Two researchers independently double reviewed papers to assess eligibility, extract data, and assess quality.

Results: Searches run in the databases identified 2643 papers. We identified 17 eligible interventions. The most promising interventions (having a beneficial effect and low risk of bias) were 3 targeting overweight or obesity, using exergaming or social media, and 2 for anxiety, using web-based cognitive behavioral therapy (CBT). Characteristics of promising interventions included gaming features, therapist support, and parental involvement. Most were purely behavioral interventions (rather than CBT or third wave), typically using the behavior change techniques (BCTs) *feedback and monitoring*, *shaping knowledge*, *repetition and substitution*, and *reward*. Three papers included qualitative data on the user's experience. We developed the following themes: *parental involvement*, *connection with a health professional is important for engagement*, *technological affordances and barriers*, and *child-centered design*.

Conclusions: Of the 17 eligible interventions, digital interventions for anxiety and overweight or obesity had the greatest promise. Using qualitative methods during digital intervention development and evaluation may lead to more meaningful, usable, feasible, and engaging interventions, especially for this underresearched younger population. The following characteristics could be considered when developing digital interventions for younger children: involvement of parents, gaming features, additional therapist support, behavioral (rather than cognitive) approaches, and particular BCTs (*feedback and monitoring*, *shaping knowledge*, *repetition and substitution*, and *reward*). This review suggests a model for improving the conceptualization and reporting of behavioral interventions involving children and parents.

Introduction

Background

The prevalence of chronic health conditions in childhood is increasing [1,2]. Chronic health conditions are defined as “any physical, emotional, or mental condition that prevented him or her from attending school regularly, doing regular school work, or doing usual childhood activities or that required frequent attention or treatment from a doctor or other health professional, regular use of any medication, or use of special equipment” [3].

Behavioral interventions can support the treatment and management of chronic health conditions and can be effective in improving symptom management, reducing physical disability, and improving mental health [4-6]. These outcomes are particularly important in childhood because they have implications for children across their lifespan [7-13]. Behavioral or behavior change interventions are sets of techniques that aim to change health behaviors [14]. For children with long-term health conditions, these interventions typically focus on adherence to medical treatment, education about the medical condition, and improving aspects of medical care [15]. A specific example is the management of diabetes via behavioral intervention; glycemic control can be improved by encouraging behaviors of blood glucose monitoring, selection of healthy food choices, attendance at routine clinical appointments, and adherence to insulin therapy or other medications [16]. Improving the management of chronic health conditions at an early age can lead to immediate health improvements, but it also lays the foundations for health across the lifespan of the patient [7]. As such, it is important that younger children (and their families) are supported to improve understanding of their condition and develop self-management skills [17].

Digital interventions can deliver behavior change interventions using mobile phones, smartphones, portable computers, desktop computers, the internet, wearable technology, and television [18]. This is an emerging and rapidly developing field of research, and the potential advantages include increased cost-effectiveness, anonymity for users, appeal to younger people, and the ability for recipients to access interventions anywhere and at their own pace [19-22]. There is a growing body of evidence to suggest that digital interventions are potentially effective for adults and adolescents with chronic health conditions; they have beneficial effects on improving knowledge, self-management, self-care, quality of life, medication use, symptom control, and health service utilization [23-30]. However, there are some potential disadvantages that may affect the uptake, attrition, and efficacy of interventions. Some individuals may not be able to access the intervention because of technical issues, illiteracy, or the cost involved in obtaining the devices. Negative attitudes toward technology may also create barriers to use, and this includes concerns about data security. A lack of strong therapeutic relationships may discourage users and reduce engagement and efficacy of

interventions. These potential disadvantages [31,32] should be carefully considered when planning and designing digital interventions. Furthermore, there are limitations with the evidence base for digital interventions, with systematic reviews highlighting the need for clearer reporting and higher quality research [23-29].

Despite the increasing availability of digital interventions and a growing body of evidence for adults and adolescents, there has been inadequate attention to designing and delivering these interventions to children. Children have different developmental characteristics and needs, and the developmental stage of children should be considered when designing interventions [33,34]. To the best of our knowledge, there are no systematic reviews that specifically investigate digital interventions for the management of chronic health conditions in children (aged <13 years). Furthermore, reviews investigating digital interventions for young people with chronic health conditions typically do not include children aged below 10 years [35], or, if they do, only a minority of the interventions included in the reviews include children aged below 13 years [15,36-38], recognizing that there are “fewer interventions targeting...the extreme pediatric age ranges of early childhood and emerging adulthood” [16]. The reviews spanning childhood and adolescence note important differences between these age groups. Three separate reviews of internet and computer-based cognitive behavioral therapy (CBT) for mental health problems found different treatment effects for older and younger children. The reviews found some positive effects for adolescents, but concluded that treatment effects were smaller or more uncertain for younger children [36,37,39]. Similarly, a review of electronic health interventions for young people with long-term physical conditions concluded that effectiveness was uncertain at this time, especially in children aged <10 years [15]. One review acknowledged, “we could not take the developmental stage of the patients...into account. As evidence is mounting, this issue should be addressed in future trials” [17].

Therefore, this review aimed to explore digital interventions for the management of chronic health conditions in children aged between 5 and 12 years.

Behavior change interventions are often complex [40], which can pose a challenge when synthesizing the effects of these interventions [41]. Advances in behavioral science have provided taxonomies and coding systems that help identify specific characteristics or *active ingredients* associated with effective interventions [42]. This includes the behavior change techniques (BCTs) taxonomy [43], which presents 93 discrete BCTs, “observable, replicable and irreducible component of an intervention designed to alter or redirect causal processes that regulate behavior” [43]. In addition to understanding what is being delivered (BCTs), it is important to understand how the content is delivered; this can be categorized using the mode of delivery taxonomy [18]. Identifying the theoretical underpinnings is possible with a coding frame [44]. Using these

BCTs, mode of delivery and theory taxonomies in systematic reviews may result in more optimal evidence syntheses and health care practice recommendations [41].

Objectives

This systematic review aimed to investigate digital interventions for the management of chronic health conditions in children aged between 5 and 12 years. We used an inclusive definition of chronic health conditions that included both physical and mental health. Conceptually, behavioral interventions for physical and mental health conditions are the same; they are designed to change the child's behavior to improve the clinical outcome. Furthermore, there is a strong overlap between physical and mental conditions; comorbidity of physical and mental health conditions is common [45], and many conditions involve both mental and physical health issues (eg, chronic fatigue syndrome or myalgic encephalomyelitis, pain, and obesity), thus developing integrated approaches toward mental and physical health is increasingly becoming a priority [46]. In this review, we aimed to answer the following questions: (1) Which of these interventions are effective in promoting behavior change for the management of the chronic health condition? (2) What are the characteristics of effective interventions, considering the following: recipients, what is being delivered (BCTs), how this content is being delivered (the mode of delivery), the theoretical basis, and the modality of the intervention? and (3) What are the users' experiences of the digital intervention?

Methods

Registration

The review was prospectively registered in the Prospective Register of Systematic Reviews (PROSPERO) database.

Search Strategy

We carried out a systematic search of relevant databases: Excerpta Medica Database (EMBASE), PsycINFO, Medical Literature Analysis and Retrieval System Online (MEDLINE), and the Cochrane Library (January 2019). The search strategy included keywords and Medical Subject Headings (MeSH) for (1) children aged between 5 and 12 years, (2) behavior change, (3) randomized controlled trials (RCTs), (4) digital interventions, and (5) chronic health conditions (we used a mixture of generic terms, ie, "Chronic disease," and also search-specific terms, informed by the most common chronic illness in childhood; Multimedia Appendix 1) [47].

Screening

To be included in this review, studies had to fulfill the following criteria:

1. Include children aged between 5 and 12 years (this review aimed to examine digital interventions for children in the developmental stages of middle childhood).
2. Include children with a chronic health condition, excluding those with developmental delays.
3. Investigate a digital intervention to promote behavior change. Digital interventions included those delivered via internet (static or interactive websites, automated emails, or web-based apps), personal computers (PCs; eg, PC videogames), social media, mobile phones (automated phone calls or short text messages), or smartphones (mobile websites or smartphone apps). These may be stand-alone interventions or guided (eg, therapist supported).
4. Compare the digital intervention with any comparator.
5. Have an RCT study design (RCTs are considered the gold standard for judging the benefits of treatments [48], and including RCTs only allowed us to focus on the interventions most likely to be adopted into clinical care).
6. Published in peer-reviewed journals and available in English.
7. Published between 2014 and January 2019. We chose a 5-year time frame because of the rapid pace of digital interventions [49], indicating that older interventions were not likely to be relevant.

Titles and abstracts (stage 1) and full-text papers (stage 2) were independently double screened against the inclusion and exclusion criteria using the data management platform Rayyan (stage 1) and Covidence (stage 2). AB screened all papers, and CL, LS, and EB were responsible for the independent second screening. Reasons for exclusion were recorded at stage 2. Discrepancies at both stages were discussed and resolved in meetings by the reviewers. Papers were tracked using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow diagram [50].

Data Extraction and Synthesis

For data extraction, papers were reviewed independently by 2 researchers and conflicts were resolved in regular meetings (AB reviewed all papers, and CL, LS, and EB were responsible for an independent second review). Two researchers independently coded BCTs (EA and AB, a health psychologist and health psychology trainee, respectively). We extracted information that allowed us to answer the 2 primary research questions, as described in Table 1. If the full text did not contain the information needed, we made 2 attempts to contact the authors by email.

Due to the clinical and methodological heterogeneity, we synthesized data using narrative synthesis [51,52] to answer our research questions. We reported effectiveness based on whether interventions were deemed as *very promising*, *quite promising*, *possibly promising*, *nonpromising*, or *unable to assess effectiveness*, determined by change in the outcomes and the quality of the science (Table 1 defines these categories).

Table 1. Data extraction.

Data extraction category	Details extracted
Population	<ul style="list-style-type: none"> Age: the age range of the population, at the time of entry into the study. Ages were then grouped by UK school <i>key stage</i> categories [53]: <ul style="list-style-type: none"> 5-7 years, corresponding to key stage 1. 8-11 years, corresponding to key stage 2. 12 years, corresponding to key stage 3. Chronic health condition: the chronic health condition that the intervention was designed to target.
Overview of intervention	<ul style="list-style-type: none"> Overview of aims: the overview of the aims of the RCT^a. Overview of intervention: an overview of the digital component of the intervention and, if applicable, other key components. Overview of comparator: an overview of the comparator arm or arms.
Aim 1: effectiveness	<ul style="list-style-type: none"> Overview of <i>promise</i>: <i>promise</i> was based on the beneficial effects of the intervention and the quality of the study (risk of bias). To determine the beneficial effects of the intervention, we looked at the CIs of the mean difference from baseline to follow-up between the intervention and control group, considering the behavioral outcomes and the primary outcome (or outcomes). We developed 5 categories: <ul style="list-style-type: none"> Interventions were deemed <i>very promising</i> where there were beneficial effects of the intervention on both the primary outcome <i>and</i> at least one behavior change outcome, and the evidence was judged as having a low risk of bias. Interventions were deemed <i>quite promising</i> where there were beneficial effects of the intervention on the primary outcome <i>or</i> at least one behavior change outcome (but not both), and the evidence was judged as having a low risk of bias, or some concerns. Interventions were deemed <i>possibly promising</i> where there were beneficial effects of the intervention on the primary outcome and or behavior change outcome (or outcomes), <i>but</i> the study was deemed to have a high risk of bias. Interventions were deemed <i>nonpromising</i> where there were <i>no</i> beneficial effects of the interventions on either the primary outcome or behavior change outcomes. Interventions were put in the category <i>unable to assess effectiveness</i> where there were <i>no</i> effectiveness data available for the primary outcome or behavior change outcomes, for example, if the paper was a pilot or feasibility RCT. The direction and size of the effect [51] was extracted for behavioral and primary outcomes, and the following was reported: <ul style="list-style-type: none"> Summary of the effect of the intervention compared with the control. Statistic comparing the change in the intervention group and control group from baseline to final follow-up. Where sufficient information was available comprising either SDs and numbers of participants, or SEs, we calculated the net mean difference (difference in mean changes), with 95% CI and <i>P</i> value. Where possible, this was interpreted in the context of the authors' judgment of clinically significant effects. If available, we reported the adjusted mean difference (adjusted for baseline measures) as this is the accepted best method. Outcome measure: all behavioral outcomes were extracted, as exploring the effect of the intervention on behavior change was the primary aim of this review. The primary outcome was also extracted as this is the main determinant of whether the study is considered a <i>success</i> or a <i>failure</i> [54]. For each outcome we extracted: <ul style="list-style-type: none"> the behavior and or primary outcome how this was measured the final time point. Adverse events: health interventions carry some risk of harm. Systematic reviews should minimize bias toward favoring an intervention by assessing adverse effects alongside beneficial effects [55]. Data on adverse events associated with the intervention were extracted.

Data extraction category	Details extracted
Aim 2: characteristics of promising interventions	<ul style="list-style-type: none"> The following data were extracted from very promising, quite promising, and possibly promising interventions: <ul style="list-style-type: none"> Recipients: whether the intervention was delivered directly to the child, via a parent-proxy or both. Intervention techniques: intervention techniques refer to what is being delivered, the content or <i>active ingredients</i> of an intervention. The behavior change techniques taxonomy provides a standardized method of classifying intervention content [43]. This taxonomy consists of 93 behavior change techniques, in 16 groupings. We coded interventions using the 16 groupings. We coded whether each BCT identified was delivered to the parent or the child and whether it featured in the digital or human component. Digital mode of delivery: intervention mode of delivery refers to how the content is delivered. We categorized mode of delivery, based on elements of the mode of delivery Taxonomy [18]: <ul style="list-style-type: none"> <i>Tailored or generic</i>: tailored interventions change the content of the text, images, recommendation, messages, etc based on the individual needs of the user. <i>Guided or stand-alone</i>: guided interventions are delivered with some form of support by a professional or coach, either with human contact or electronic means (eg, email or telephone calls). <i>Interactive techniques</i>: these include play, arts, story, and or game-based techniques. Theoretical basis: whether a named theory of behavior or behavior change was explicitly mentioned in the Abstract, Introduction, or Methods section [44]. Modality: the intervention modality, coded as either a first, second, or third wave intervention. <i>First wave</i> interventions are purely behavioral, based on the theory that all behaviors are learned (through classical and operant conditioning) [56], and that maladaptive behaviors can be changed using principles such as reinforcement, modeling, graded tasks and habit formation [43]. <i>Second wave</i> refers to cognitive behavioral interventions, based on the principle that thoughts, feelings, physical sensations and actions are interconnected; individuals are supported to identify negative or unhelpful patterns in their cognitions, emotions, behaviors, physical sensations and supported to adopt more adaptive patterns [57]. <i>Third wave</i> interventions are characterized by techniques such as metacognition, acceptance, mindfulness, compassion and spirituality [56].
Aim 3: The users' experience of the digital intervention	<ul style="list-style-type: none"> Qualitative analysis: two researchers independently reviewed all eligible papers and identified those that included qualitative data about the users' experience of the digital intervention. Qualitative data were extracted, compared, and summarized into themes.

^aRCT: randomized controlled trial.

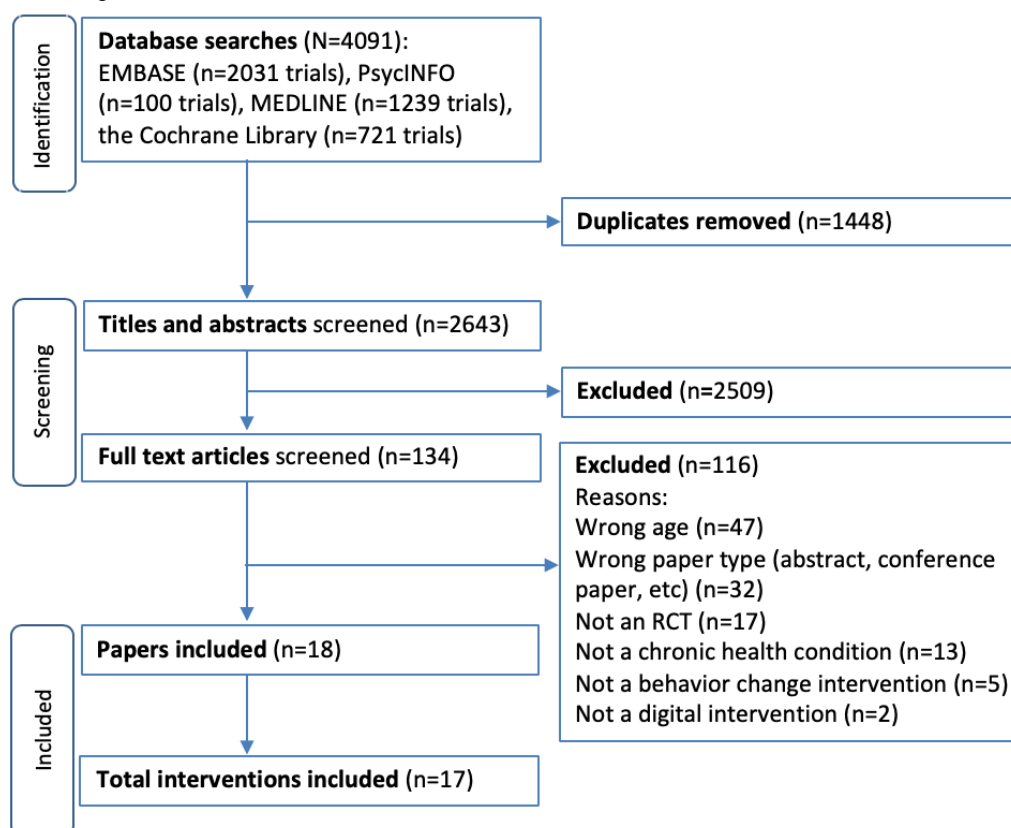

Quality Assessments

As all studies in this review were RCTs, the Cochrane risk of bias tool for randomized trials (RoB 2.0) [58] was used to assess the scientific quality of each study. Two researchers reviewed each paper, and the researchers then compared their quality assessment and resolved conflicts (AB reviewed all papers, and ML, LS, and EB were responsible for an independent second review). Following this, each paper was given a score of either low risk of bias, some concerns, or high risk of bias. Where available, we reviewed trial registries and published protocols. If needed, we also requested further information from the authors, including statistical analysis plans.

Results

Literature Search and Selection of Studies

After deduplication, 2643 papers were identified from the database searches, of which 18 papers were identified as eligible for inclusion. Two of these papers reported on the same intervention; therefore, we identified 17 digital interventions for the management of chronic health conditions in children aged between 5 and 12 years. Figure 1 displays the PRISMA diagram.

Figure 1. PRISMA flow diagram. RCT: randomized controlled trial.

Population Characteristics

The digital interventions targeted a range of chronic health conditions, including overweight or obesity ($n=7$), anxiety and preoperative anxiety ($n=3$), cerebral palsy ($n=3$), attention-deficit/hyperactivity disorder (ADHD; $n=1$), type 1 diabetes ($n=1$), asthma ($n=1$), and social-emotional problems ($n=1$). All the interventions included children of key stage 2 age (8–11 years), 13 included children of key stage 3 age (12 years), and 9 included children of key stage 1 age (5–7 years).

Aim 1: Which Digital Interventions Are Effective in Promoting Behavior Change for the Management of the Chronic Health Condition?

Table 2 details the characteristics of the population, intervention, and outcome data (Multimedia Appendix 2). This is presented by their potential effectiveness, based on outcomes and quality assessment (Multimedia Appendix 3).

No interventions were identified as *very promising*.

A total of 5 interventions were identified as *quite promising*; 3 of these were interventions targeting overweight or obesity. An intervention involving exergaming used Kinect and Xbox with additional components of Fitbit step count monitoring and parent-child telehealth sessions with a fitness coach. Compared

with the control group, the intervention group showed an increase of 11.4 min of moderate-to-vigorous physical activity (MVPA) per day (95% CI 2.25–20.55) at 6 months. However, there was no clear evidence of effect on the primary outcome; the reduction in BMI Z-scores was -0.08 (95% CI -0.16 to 0.003) at 6 months, which did not reliably meet the authors' threshold for change (-0.09). An exergaming plus a family-based pediatric weight management program led to an increase of 8.0 (95% CI 0.5–15.4) min of MVPA per day at 4 months, with the trial powered to detect a change of 4.0 to 4.6 min of MVPA per day (MVPA was the primary and behavior change outcome) [54]. A further trial involved 4 training units (2 face-to-face and 2 via Facebook) plus weekly support through a parental WhatsApp group for 12 weeks. This led to a decrease in BMI Z-scores of 0.14 (95% CI -0.28 to -0.003) at 6 months, with the trial powered to detect a decrease of 0.24 (no behavior change outcome was available). The third and fourth *quite promising* interventions were both internet-delivered CBT for children with anxiety disorders, both offering completely web-based modules for parents and children in conjunction with web-based therapist contact [60,63,64]. Both led to an improvement in anxiety as assessed by the clinician severity rating, equating to an estimated change of -0.77 (95% CI -1.15 to -0.40) at 3 months [60] and -1.16 (95% CI -1.55 to -0.77) at 10 weeks [63].

Table 2. Data on population, interventions, and effectiveness of behavior change outcomes and primary outcomes, grouped by intervention promise.

Categories and reference	Condition; age	Overview of intervention/recipients	Recipients	Behavior change outcome	Primary outcome (if different)
Quite promising					
Ahmad et al (2018) [59]	Overweight or obesity; 8-11 years	Digital component: 2 training units delivered weekly via Facebook. Weekly 1-hour sessions using a parents' WhatsApp group that lasted for 12 weeks. In the WhatsApp group, the researchers posted key information and skills, responded to parent queries, and provided feedback on the adiposity progress of the children. Parents were encouraged to interact with the group WhatsApp group; additional component: 2 half-day face-to-face training sessions	Digital component: parent only; face-to-face component: parent and child	Healthy lifestyle behaviors, children's eating, physical activity, and screen time: effectiveness data not reported	BMI Z-score: the intervention group had a reduced BMI Z-score compared with the control. Net mean difference ^a =−0.14 (95% CI −0.278 to −0.003; <i>P</i> =.05)
Jolstedt et al (2018) [60]	Anxiety; 8-12 years	Digital component: ICBT ^b . A web-based program with 12 modules delivered over 12 weeks, consisting of texts, films, illustrations, and exercises and focused mainly on exposure therapy. Limited weekly asynchronous support from a clinician to encourage families to engage in the program. Twelve parent-directed modules, covering parental behaviors, which can maintain anxiety and how to best support their child. Parents helped children with the child-directed modules	Digital component: parent and child; face-to-face component: parent and child	None reported	Anxiety (CSR) ^c : Participants allocated to ICBT showed improvements on the CSR compared with the control. Net mean difference=0.79 (95% CI 0.42-1.16; <i>P</i> =.002); the estimated between-group effect size at 12-weeks post-treatment 0.77 (95% CI 0.40-1.15)
Staiano et al (2018) [61]	Overweight or obesity; 10-12 years	Digital component: participants were provided a Kinect and Xbox 360 gaming console, 4 exergames, and a Fitbit Zip to wear during the 24-week period. Steps per day were wirelessly uploaded and reviewed by the fitness coach; additional component: telehealth, consisting of the child and parent meeting with a fitness coach over video chat, on a weekly basis for the first 6 weeks and biweekly thereafter	Digital component: child only; face-to-face component: parent and child	Physical activity: the intervention showed an increase in MVPA ^d compared with the control group; estimated mean difference 11.4 min of MVPA per day (95% CI 2.25-20.55); Dietary habits: there was no evidence of effect	BMI Z-score: there was no clear evidence of effect
Trost et al (2018) [62]	Overweight or obesity; 8-12 years	Digital component: participants were provided a game console and motion capture device (Xbox and Kinect; Microsoft Corporation) and 2 active sports games. No explicit advice or goals were given to any study participant regarding the use of their active gaming tool; additional component: a comprehensive family-based pediatric weight management program	Digital component: child only; face-to-face component: parent and child	Physical activity: the intervention group exhibited a greater increase in MVPA compared with the control group. Net mean difference=8 min of MVPA per day (SE 3.8; 95% CI 0.5-15.4; <i>P</i> =.04)	The primary outcome was physical activity (see the behavioral outcomes column)

Categories and reference	Condition; age	Overview of intervention/recipients	Recipients	Behavior change outcome	Primary outcome (if different)
Vigerland et al (2016) [63] and Vigerland et al (2017) [64]	Anxiety; 8-12 years	Digital component: a treatment platform with 11 modules, including reading material, films, animations, illustrations, and exercises. A combined parent-child intervention. Seven parent-directed modules containing information and instructions on how to help their child. Four child-directed modules. Participants had web-based contact with an assigned psychologist or CBT therapist through written messages and written feedback. Three scheduled telephone calls plus additional telephone calls if needed (to increase motivation or problem solve)	Digital component: parent and child; face-to-face component: parent and child	None reported	Anxiety (CSR): the intervention group had a larger improvement on the CSR. Net mean difference=-1.16 (95% CI -0.77 to -1.55)
Possibly promising					
Bul et al (2016) [65]	ADHD; 8-12 years	Digital component: a serious web-based adventure game (Plan-It Commander) developed by health care professionals, researchers, and game experts in collaboration with parents and children with ADHD. A web-based mission-guided game in which principles of behavior therapy and game-based learning were combined. The missions addressed specific skills addressing time management, planning and organizing, and prosocial behavior. Players could access a closed social community (<i>Space Club</i>) to stimulate prosocial behavior (eg, helping other players and giving compliments); additional component: treatment as usual	Digital component: child only; face-to-face component: N/A ^e	Time management: the intervention arm showed greater improvements in parent-reported time management skills compared with the control arm. Estimated net mean difference of parent-reported time management=5.98 (95% CI 1.32-10.64) and teacher time management=5.46 (95% CI 1.71-9.20); planning and organizing skills, social skills: no clear evidence of effect	The 3 primary outcomes were: parent-reported time management, parent-reported planning and organization, and parent-reported social skills (see the behavioral outcomes column)
Hsieh et al (2018) [66]	Cerebral palsy; 5-10 years	Digital component: a PC ^f gaming platform. The participants stood in front of the platform and viewed a monitor that displayed 1 of a series of simulated tasks, such as hitting ground rats. The gaming platform handle was loaded, 0.5 to 2.5 lb. This PC gaming platform provided trunk movements in 3 directions: horizontal, vertical, and multidirectional trunk movements	Digital component: child only; face-to-face component: child only	None reported	Measures of postural balance: there was clear evidence of effect of the intervention for 2 of the 7 measures

Categories and reference	Condition; age	Overview of intervention/recipients	Recipients	Behavior change outcome	Primary outcome (if different)
Wantanakorn et al (2018) [67]	Preoperative anxiety; 5-12 years	Digital component: <i>Children-Friendly Hospital</i> , a tablet app for pediatric patients who need bone marrow aspiration procedures. It was used to provide medical information; participants started with the cartoon about the procedure then played matching games and practiced the breathing exercise game to reduce anxiety; additional component: usual bone marrow aspiration procedures	Digital component: child only; face-to-face component: N/A	N/A	Preoperative anxiety: anxiety was lower in the intervention group versus the control group. Estimated difference means=-7.71 (95% CI -14.27 to -1.15)

Nonpromising

Armstrong et al (2017) [68]	Overweight or obesity; 5-12 years	Digital component: daily mobile text messages, based on motivational interviewing, for 12 weeks. Initial texts encouraged parents to set a health behavior goal. In a reply text, the investigators reinforced the most evidence-based goals for BMI reduction (sugar-sweetened beverage reduction, increased physical activity, eating meals at home, and increased vegetable consumption). Subsequent daily texts prompted parents to self-monitor adherence to the goal. Each week for 12 weeks, parents can choose a new goal or continue working on the present goal; additional component: standard care, including monthly lifestyle counseling visits by a physician and dietician	Digital component: parent only; face-to-face component: parent only	Child nutrition habits, activity habits and screen time: no clear evidence of effect of intervention	BMI Z-score: no clear evidence of effect of intervention
Christison et al (2016) [69]	Overweight or obesity; 8-12 years	Digital component: The Exergaming for Health Program is a community-based, multifaceted pediatric weight management program including 1 hour of weekly group exergaming; additional component: classroom curriculum	Digital component: child only; face-to-face component: parent and child	Activity levels, sedentary screen time, and diet: no clear evidence of effect of intervention	BMI Z-score: no clear evidence of effect of intervention
Sanchez et al (2017) [70]	Social-emotional problems; 7-11 years	Digital component: a single-player story-based digital game that requires children to apply specific social-emotional skills to solve social problems encountered in the game. For example, approaching an individual that appears easy to talk to, joining a group at a game in progress, and approaching small groups that appear less easy to talk to. Within each scenario, the player had to make behavioral choices and individualized feedback to choices was given	Digital component: child only; face-to-face component: N/A	Bullying perpetration: no clear evidence of effect of intervention	No primary outcome specified

Unable to assess effectiveness

Categories and reference	Condition; age	Overview of intervention/recipients	Recipients	Behavior change outcome	Primary outcome (if different)
Burckhardt et al (2018) [71]	Type 1 diabetes; 8-12 years	Digital component: the Dexcom G5O [®] Mobile continuous glucose monitoring system transmitted glucose levels via Bluetooth to a mobile device that generated alerts. This information could be shared via the <i>cloud</i> with up to 5 individuals who could remotely monitor the continuous glucose reading in real time along with the possibility to use individualized alerts. Participants were able to see their sensor glucose levels in real time	Digital component: child only; face-to-face component: N/A	Pilot study (n=14)	No primary outcome specified
Fiks et al (2015) [72]	Asthma; 6-12 years	Digital component: the features of MyAsthma include identification of parents' concerns and goals for asthma treatment; monthly tracking of symptoms, medication side effects, and progress toward goals; educational content; and access to the child's asthma care plan. Parents were encouraged with email reminders to complete monthly portal surveys with input from their affected child. In response to these surveys, families and clinicians received guideline-based decision support that directed them to speak to one another if asthma was not well controlled or if there were side effects, or to continue current therapy	Digital component: parent only; face-to-face component: parent only	Only acceptability or feasibility data	Only acceptability or feasibility data
Hamilton-Shield et al (2014) [73]	Overweight or obesity; 5-11 years	Digital component: Mandolean teaches patients how to eat and recognize satiety. The patient puts a measured portion of food determined by a therapist on the Mandolean (scales and computer), which records and displays, in real-time graphics, the removal of food from the plate as the patient eats. This is compared with a preset eating line and deviation from the training line by eating too quickly or slowly elicits a spoken request from Mandolean to slow down or eat faster. The patient rates their level of satiety, which appears as a dot on screen yielding a <i>development of satiety</i> curve allowing comparison of the development of fullness with a <i>normal</i> fullness curve again preset on screen. Additional component: standard care comprising of dietary and activity advice by trained practice nurses	Digital component: child only; face-to-face component: parent and child	None of the pilot trial's objectives were met; thus there were no full trial effectiveness results	BMI Z-score: none of the pilot trial's objectives were met; thus there were no full trial results

Categories and reference	Condition; age	Overview of intervention/recipients	Recipients	Behavior change outcome	Primary outcome (if different)
Kassee et al (2017) [74]	Cerebral palsy; 7-12 years	Digital component: a Nintendo Wii U system, 1 Wii MotionPlus remote controller, 1 Wii Nunchuck, and the Wii Sports Resort game to be played at home. Games were designed to promote higher upper-limb activity. Participants were instructed to play games using their affected hand for at least 40 min each day, 5 days a week for 6 weeks (30 days); additional component: parents supervised and recorded sessions and were asked to encourage the child to use their spastic hand as much as possible	Digital component: child only; face-to-face component: parent and child	Pilot study (n=6)	Pilot study (n=6)
Preston et al (2016) [75]	Cerebral palsy; 5-12 years	Digital component: computer-assisted arm rehabilitation gaming used at the child's home. Parents were asked to encourage their children to use the gaming technology for 30 min a day; additional component: a visit at week 3 to offer encouragement and to check the gaming technology system. Usual follow-up treatment	Digital component: child only; face-to-face component: parent and child	None reported	Pilot study (n=15)
Price et al (2015) [76]	Overweight or obesity; 6-12 years	Digital component: text messages to parents to reinforce telephone health behavior coaching. Text messages to promote behavioral self-monitoring and skills training, focused on behaviors, including limiting fast food and eating fruits and vegetables in place of high-calorie snacks. At the time of a well child care visit, digital alerts were sent to pediatricians designed to identify children with a BMI ≥ 95 th percentile. These contained information on how to monitor and support the child; additional component: Well child visit	Digital component: parent only; face-to-face component: parent only	Only acceptability or feasibility data	Only acceptability or feasibility data

^eN/A: not applicable.

^fPC: personal computer.

In all, 3 interventions were identified as *possibly promising*. A PC game led to improved balance control in children with cerebral palsy on 2 of the 7 measures of balance at 3 months [66]. An internet-based serious game for ADHD led to an improvement in parent- and teacher-rated time management skills at 5 months, but no evidence of improvement on parent- and teacher-rated planning and organization skills or social skills. A tablet app that included an educational animated video, along with games for distraction and to encourage relaxation

or breathing exercises for preoperative anxiety [67], led to reduced anxiety scores on the modified Yale Preoperative Anxiety Scale of -7.71 (95% CI -14.27 to -1.15) immediately after the intervention. Although there was evidence of an effect, these studies were limited in scientific quality. There was a lack of transparency around randomization processes, a combination of nonblinded participants, and the use of self-report measures, and none of these trials were prospectively registered.

Three interventions showed no promise; 2 of these were targeting overweight and obesity, 1 was the exergaming plus classroom curriculum, and the other was motivational interviewing delivered via one-way text messaging [68,69]. Neither lead to improvements in behavioral outcomes (screen time, physical activity, and diet) or the primary outcome (BMI Z-scores) at 6 and 3 months, respectively. The other intervention was a video game for social-emotional problems [70], which did not lead to changes in bullying perpetration behavior at 9 weeks.

Six interventions were pilot studies, and they only reported acceptability or feasibility data [72,73,76] or involved small

sample sizes (6, 15, and 14) that were not powered to determine effectiveness [71,74,75]. Of these studies, 3 reported that there were no further plans for investigation [72-74] and 1 reported that a larger, fully powered trial was planned for the future [75]. Information on the remaining 2 studies is unknown [71,76].

Adverse events for each study are reported in Table 3. Three studies reported adverse events; these were not severe and or there were similar numbers in the intervention and control arms. Four studies monitored adverse events and reported that no adverse events occurred during the trial. Most studies (n=10) failed to capture adverse events.

Table 3. Summary of adverse events.

References	Details of adverse events
Ahmad et al (2018) [59]	"No adverse events or unintended adverse consequences of the intervention were reported by the participants."
Armstrong et al (2017) [68]	"We observed no adverse events associated with participation in the text message intervention."
Bul et al (2016) [65]	"There were 10 adverse events that could be related to the intervention... All adverse events were of mild (n=5) or moderate (n=5) severity... Examples of adverse events were pain in the fingers, irritability, and headache. An adverse event was a reason to discontinue the study for only one known participant. This participant did not want to play the game anymore because he could not concentrate during his school activities. Sounds reminded him of the game and this consequently distracted and frustrated him. No serious adverse events were reported."

^aICBT: internet-delivered cognitive behavioral therapy.

Aim 2: What Are the Characteristics (Active Ingredients) of Effective Interventions?

We considered the 8 interventions that were classified as promising, quite promising, and possibly promising to represent *promising interventions*.

Recipients

A total of 7 of the 8 interventions had a digital component for the child, and all the interventions involved the child in some capacity (either digital or human component). In all, 5 of the 8

interventions involved the parent in some capacity (either digital or human component).

What Is Being Delivered: BCTs

Table 4 provides the definitions of the BCTs, and Table 5 provides a summary of the BCTs used in promising interventions.

All the promising interventions used more than one BCT. Digital components for the child typically included techniques coded into the following BCT categories: *feedback and monitoring*,

shaping knowledge, repetition and substitution, and reward and threat (we note that none used *threat*, but this is the overarching BCT taxonomy category label). Digital components for the parent typically included *goals and planning, social support, and natural consequences*.

The most promising interventions were for overweight or obesity (3 studies) and anxiety (2 studies). All 3 of the promising overweight or obesity interventions included a face-to-face component for both the parent and the child. Two interventions included a digital component for the child, both using the BCT repetition and substitution. Only 1 intervention had a digital component for the parent.

Both promising anxiety interventions included digital and face-face elements, all of which involved both the child and the

parent. Both interventions used the following BCTs in the digital component: goals and planning (child and parent components), shaping knowledge (child and parent components), feedback and monitoring (parent component), and associations (child component).

We acknowledge that there may have been more BCTs included in the intervention; however, we were unable to code these as they were not explicitly reported in the paper. Furthermore, it was often unclear as to whether the BCT was delivered to the parent or the child and by what means it was planned to take effect. In some cases, we believe that the BCTs were directed at the parent, with the parent then eliciting behavior change in the child. However, none of the papers addressed this level of complexity; they did not describe this mechanism of change nor did they include a parent behavior change outcome measure.

Table 4. Definitions of behavior change techniques.

BCT ^a categories ^b	Definitions
Goals and planning	Includes setting and reviewing goals defined in terms of the behavior (eg, physical activity) or the outcome (eg, weight loss); problem-solving to overcome barriers and or increase facilitators; and detailed action planning of the behavior, considering the context, frequency, duration, and intensity of the behavior
Feedback and monitoring	Includes observing or recording the behavior or the outcome either by the recipient (self-monitoring) or by others; feedback on the performance of the behavior or the outcome
Shaping knowledge	Includes advising how to perform the behavior, the factors that reliably predict performance of the behavior, alternatives to unhealthy behaviors, and how to carry out behavioral experiments
Repetition and substitution	Includes practicing the behavior in a context or at a time when the performance may not be necessary to increase habit and skill; setting easy-to-perform tasks, making them increasingly difficult, but achievable, until the behavior is performed
Reward and threat	Includes using material (eg, money and vouchers) or social (eg, praise) incentives and rewards for the behavior or outcome; informing that future punishment or removal of reward will be a consequence of performance of an unwanted behavior
Social support	Includes advising, arranging, or providing social support (eg, from friends, relatives, colleagues, “buddies,” or staff) for practical and or emotional reasons
Natural consequences	Includes providing information (eg, written, verbal, visual) about the health, social, emotional, or environmental consequences of performing the behavior; using methods to emphasize the consequences
Associations	Includes introducing environmental or social stimulus to prompt or cue behavior; reducing situations in which unwanted behavior can be rewarded; systematic confrontation with a feared stimulus to reduce the response to a later encounter; and presenting a neutral stimulus jointly with a stimulus that already elicits the behavior repeatedly until the neutral stimulus elicits that behavior

^aBCT: behavioral change techniques.

^bThe study by Michie et al [43] provides a full description of all BCTs.

^aN/A: not applicable.^b≥50% of interventions using the characteristic.

How Is the Content Delivered: Mode of Delivery

A total of 5 of the 7 interventions with child digital components used gaming features. All the parent digital components and 5 of the child digital components were guided. In all, 3 digital interventions involving parents and 1 digital intervention for the child were tailored.

Theoretical Basis

Half of these papers reported the use of theory in the intervention: social cognitive (n=2) and CBT (n=2).

Modality

A total of 6 of the 8 interventions were first wave (purely behavioral) interventions, and 2 were second wave (cognitive-behavioral) interventions. There were no third wave interventions.

Aim 3: What Are the Users' Experience of the Digital Intervention?

Only 3 of the studies included qualitative data on users' experiences and views of the intervention [68,72,73]. One study evaluated the family experience in a preceding pilot study [77]. A table of the raw qualitative data and themes are available (Multimedia Appendix 4).

Themes

Parental Involvement

Parents talked about the interventions improving their knowledge ("made me more aware") and shaping their behavior, which in turn led to the child's behavior change ("it does make me stop him and sit him down and make him eat the breakfast"). Some commented on the problems of parent-led interventions and how a health professional, who is external to the parent-child relationship, is important to encourage the child's behavior

change (“I think some kids will listen to their doctor better than their parents”).

Connection With a Health Professional Is Important for Engagement

Digital interventions were seen to facilitate *convenient* communication with a health care professional. There was a desire to share information between parents and clinicians (“It should go back somehow to the paediatrician”) to increase families’ motivation to engage with interventions. The involvement of a health professional was also viewed as important in engaging the child (“I think some kids will listen to their doctor better than their parents”).

Technological Affordances and Barriers

Parents commented on the technologies being quick, easy, and possible to integrate into everyday life. However, others commented on practical challenges such as the cost, lack of familiarity, and difficulty to use. Users commented on the fixed nature of the technology, which meant that it was not personalized to their individual preferences or needs (“but I really want to focus on these”) and did not deliver content with ongoing relevance that would maintain engagement over time (“I think enthusiasm’s gone off”).

Child-Centered Design

Children commented on some of the interventions being enjoyable (“I like the electronic stuff”). However, in other cases, the material was not understood by the child (“It’s really confusing” and “I don’t know how much [child] actually understands”), it was not acceptable to children (“boring” and “annoying”), and they expressed a wish for features such as personalization in the design.

Discussion

Principal Findings

To the best of our knowledge, this is the first review to identify effective digital interventions for younger children, report the characteristics of promising interventions, and describe the user’s experience of digital interventions. Of the 17 eligible interventions, we only identified 5 that had a beneficial effect and had a low risk of bias; 3 targeted overweight or obesity, using exergaming or social media with additional human support, and 2 targeted anxiety, using web-based CBT with therapist support.

Characteristics of promising digital interventions included gaming features in the child digital component and having additional therapist support (guided digital interventions). Digital components for the child typically used the BCTs [43] *feedback and monitoring, shaping knowledge, repetition and substitution, and reward*. Most were purely behavioral interventions (first wave), with only a quarter using CBT (second wave) and none using third wave approaches; half of the interventions had a theoretical basis (social cognitive theory and CBT). Over 60% involved the parents in the intervention.

Only 3 papers used qualitative methods to explore the users’ experience of digital intervention. These studies reported the

affordances of digital interventions, including ease of use, integration into daily life, and the ability to enhance communication with a health professional. However, a lack of personalization, technical problems, and cost issues posed challenges to families. The qualitative data indicated how the content (eg, language and concepts) and design could be improved for younger users.

Strengths and Limitations

We included a range of chronic health conditions, which enabled us to review a larger number of interventions and identify patterns or commonalities of promising interventions. Spanning health conditions makes these findings relevant to a wide audience of researchers working in the field of digital interventions. We focused on RCTs because they have the strongest study design and are most likely to be adopted in clinical care [78]. This review focused on the outcomes that were most important to our research question (behavioral outcomes) and most important for that particular study (the primary outcome). It was outside the scope of this paper to review all the possible outcomes, such as health status or symptoms of the disease, quality of life, and knowledge.

Guidance was followed on how to report effectiveness in narrative reviews [51]. We extracted a common statistic to show the size and direction of effect, and where possible, we placed results in the context of clinically meaningful change [79]. Strengths of narrative synthesis include richer exploration of more complex questions, exploring both effectiveness (aim 1) and what “might explain differences in direction and size of effect... how and why interventions have or do not have an effect” (aim 2) [51]. We increased the rigor of presenting characteristics of interventions by using established coding systems and taxonomies for BCTs [43], modality [56], mode of delivery [18], ages [53], and population type [80]. We also considered parental and child components separately, which is important for this younger population.

A limitation of this review is that we only included RCTs. Although observational studies and nonrandomized trials could have provided additional information on the characteristics and effectiveness of digital interventions for this population, we excluded these study designs as they have a greater potential for risk of bias [81]. Although we believe that our search strategy (which included the terms “Randomized Controlled Trial,” “Trial,” and “Clinical Study”) was broad enough to identify different RCT designs, it is possible that we may not have identified some designs specifically used in the evaluation of digital interventions, such as micro randomized trials. We also restricted our search to papers published after 2015. We chose this strategy as digital health is a rapidly changing field, and recently conducted studies are likely to be the most relevant. We excluded studies that included our target age group (5-12 years) but also included older and younger children (eg, 5-18 years). Although it is possible that these studies could have been stratified by age, it was not feasible to contact authors to request these stratified data. As expected, the broad scope of this review led to heterogeneity across studies (in terms of population, intervention, and outcome), meaning formal meta-analysis was not possible; therefore, we selected the most appropriate method,

narrative synthesis. Although potential limitations to narrative synthesis include a lack of transparency and reproducibility and being subject to author interpretation [52], we mitigated this by prospectively registering our protocol, with specified outcomes, and following narrative synthesis guidelines [51]. To identify the characteristics of effective interventions, we reviewed both *quite promising* and *possibly promising* interventions and acknowledged that the *possible promising* interventions were of poorer scientific quality. Due to the small number of qualitative studies, we did not conduct full meta-ethnography [82] to synthesize qualitative data, and we did not undertake critical appraisal. However, to increase the transparency of our qualitative summary, we reported the raw data from the papers along with the themes developed by us.

Implications for Developing, Evaluating, and Implementing Digital Interventions for Children With a Chronic Health Condition

Clinical Implications

This review identified promising exergaming and social media interventions for children with obesity or overweight and web-based CBT for children with anxiety. There is potential for these to be implemented in clinical practice with further surveillance, monitoring, and long-term follow-up [40]. These findings are consistent with a previous systematic review that concluded that digital game-based interventions should be considered as methods to promote physical activity among children, but that there is a need for further, high - quality research that provides more sound evidence about clinical practice and health promotion [83]. This study extends a previous meta-analyses investigating digital interventions for children with anxiety, which concluded that the quality of studies was low (lack of blinding, use of subjective outcome measures, waiting list comparison groups, and relatively small samples) and that the effect is uncertain for younger children [36]. Our review updates this work, identifying 2 interventions with promise. These trials had sample sizes of 131 and 93, and both were prospectively registered trials with prespecified primary outcomes; 1 trial used a blinded outcome assessor for the primary outcome and an active control.

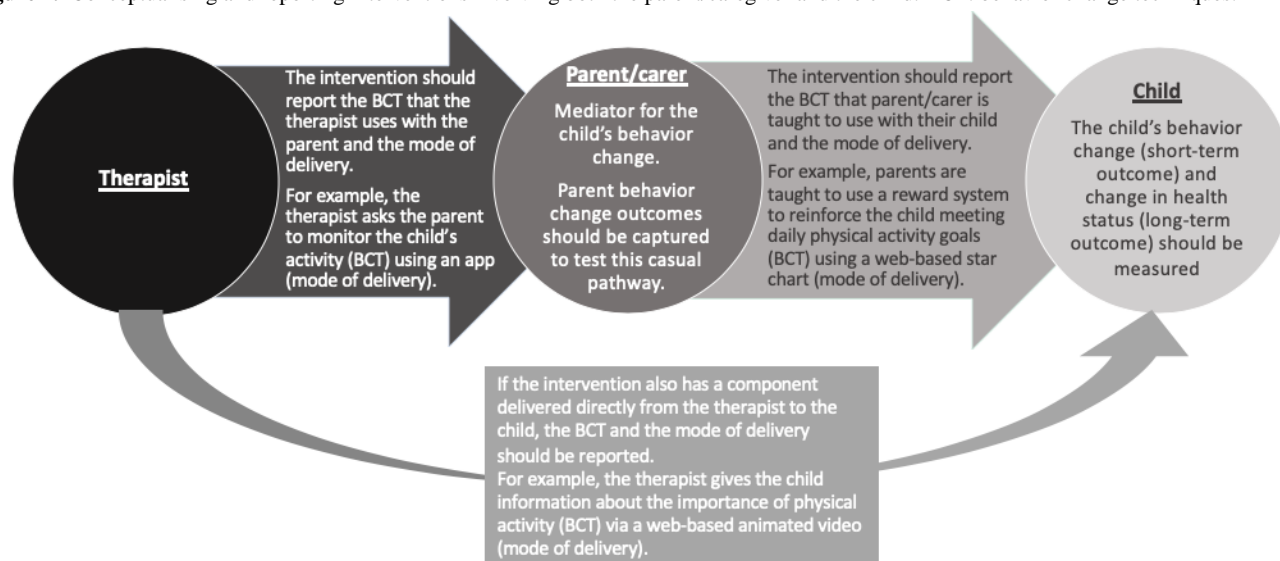

Implications for Developing and Evaluating Interventions

This work highlights characteristics that may be beneficial when developing digital interventions for younger populations. The finding that purely behavioral interventions (first wave, not including cognitive components) are common in promising interventions is consistent with developmental theory; children tend to be limited to concrete thought [57]. There were fewer CBT (second wave) interventions, possibly because elements

of CBT require abstract thinking, which may be beyond the cognitive abilities of children aged <8 years [57]. Similarly, third wave interventions also include abstract concepts such as metacognition. The lack of third wave approaches may also be explained by the fact that this is a relatively new approach for children. As such, concrete interventions focused on behavioral recommendations may be more appropriate [84]. Caregivers are commonly involved in promising interventions. This is also consistent with developmental theory, which highlights the important role of caregivers in structuring the child's environment and shaping the child's behavior [84,85]. Gaming features have been used in many promising interventions. Digital games can be adapted to the developmental level and can effectively engage younger users in medical education and treatment, as they are typically more visually oriented, involve appealing exploration, and are perceived as fun [17]. Consistent with the literature, guided interventions were common in promising interventions and have been identified as a moderating factor that can influence therapeutic outcomes and engagement [86,87].

Guidelines encourage standardized reporting of interventions to ensure transparency and reproducibility [43,88]. On the basis of our findings, we have developed recommendations for increasing the clarity of interventions with parental involvement. Interventions with both a child and a parent recipient have a complex model of behavior change; it is likely that the therapist aims to shape the behavior of the parent, with the expectation that the parent will change the behavior of the child. Studies in this review failed to explicitly differentiate the BCTs used by the therapist for parental behavior change and the behavior techniques used by the parent for child behavior change. Furthermore, none of the studies in this review captured a parental behavior change outcome measure, when this may be on the causal pathway to the child's behavior change. This recommendation is consistent with guidelines on process evaluation; outcome measures should be used to test the causal mechanism of the intervention. Figure 2 illustrates the relationship between therapist, parent, and child, detailing our recommendations for how these interventions could be conceptualized and reported.

The low number of promising interventions demonstrates the need to better understand the perspective of those receiving interventions. Few studies have conducted qualitative research to explore the user's experiences. Qualitative methods, such as the person-based approach [89], base the development and evaluation of digital interventions on an in-depth understanding of the perspectives of the people who will use the intervention. This can lead to interventions that are more meaningful, usable, feasible, and engaging in improving uptake and adherence and maximizing effectiveness [89].

Figure 2. Conceptualising and reporting interventions involving both the parent/caregiver and the child. BCT: behavior change techniques.

Conclusions

Of the 17 interventions, we only identified 5 with promise (those with a beneficial effect and low risk of bias). Using qualitative methods during digital intervention development and evaluation may lead to more meaningful, usable, feasible, and engaging interventions, especially for this under-researched younger population. Promising interventions were exergaming and social media for obesity or overweight and a web-based CBT platform

for anxiety. We identified characteristics that could be considered when developing digital interventions for younger children: involvement of parents, gaming features, additional therapist support, behavioral (rather than cognitive) approaches, and particular BCTs (*feedback and monitoring, shaping knowledge, repetition and substitution, and reward*). We suggest a model for improving the conceptualization and reporting of behavioral interventions involving children and parents.

Abstract

Artificial intelligence (AI) is seen as a strategic lever to improve access, quality, and efficiency of care and services and to build learning and value-based health systems. Many studies have examined the technical performance of AI within an experimental context. These studies provide limited insights into the issues that its use in a real-world context of care and services raises. To help decision makers address these issues in a systemic and holistic manner, this viewpoint paper relies on the health technology assessment core model to contrast the expectations of the health sector toward the use of AI with the risks that should be mitigated for its responsible deployment. The analysis adopts the perspective of payers (ie, health system organizations and agencies) because of their central role in regulating, financing, and reimbursing novel technologies. This paper suggests that AI-based systems should be seen as a health system transformation lever, rather than a discrete set of technological devices. Their use could bring significant changes and impacts at several levels: technological, clinical, human and cognitive (patient and clinician), professional and organizational, economic, legal, and ethical. The assessment of AI's value proposition should thus go beyond technical performance and cost logic by performing a holistic analysis of its value in a real-world context of care and services. To guide AI development, generate knowledge, and draw lessons that can be translated into action, the right political, regulatory, organizational, clinical, and technological conditions for innovation should be created as a first step.

KEYWORDS

artificial intelligence; health technology assessment; eHealth; health care; medical device; patient; health services

Introduction

Artificial intelligence (AI) raises many expectations in all sectors of society. There is no universally agreed upon definition of what AI encompasses. Generically, it refers to a branch of informatics that develops systems that—through their ability to *learn*—imitate the characteristics associated with human intelligence: reasoning, learning, adaptation, self-correction, sensory comprehension, and interaction [1,2].

AI is seen as a strategic lever to improve access, quality, and efficiency of health care and services [3]. For example, by exploiting exhaustive data sets from complex systems, it could contribute to improving clinical decision making (eg, diagnosis, screening, and treatment), service organization (eg, flow optimization, triage, and resource allocation), and patient management and follow-up (eg, drug administration and compliance) [4].

However, research on the application of AI in health focuses primarily on technological performance in experimental contexts or on ethical issues. Although relevant, these studies do not fully address the broader systemic policy questions surrounding their use in a real-world context of care and services. In a recent meta-analysis, Lieu et al [5] concluded that despite a diagnostic performance equivalent to that of health care professionals, the diagnostic applications of AI have not been externally validated in a real-world context of care and services. Poor reporting is also prevalent in studies on AI, which limits the reliable interpretation of results. Thus, before being integrated into clinical routine, AI applications should overcome what is called the *AI chasm*, that is, the gap between reported performance in laboratory conditions and its performance and impacts in a real-world context of care and services [6]. AI raises issues of different types, but they are, in practice, closely interconnected: economic, professional, organizational, clinical, human,

cognitive, legal, ethical, and technological. To date, few scholars have examined these issues in a systemic and holistic manner [7].

In this viewpoint paper, relying on the *health technology assessment (HTA) core model* [8], which is a methodological framework used to facilitate production and sharing of HTA information [9], we examine, based on our own experience as HTA academics and practitioners and in light of the emerging literature on the subject, issues raised by the use of AI. More specifically, we contrast the expectations specific to the health sector and the risks that should be mitigated for AI to be deployed responsibly. We limit our analysis to AI-based applications for clinical use (eg, diagnostic), some of which would be classified by the US Food and Drug Administration (FDA) as *software as a medical device*: “software intended to be used for one or more medical purposes that perform these purposes without being part of a hardware medical device” [10]. They are subject to formal regulatory approval [6,11].

In this paper, we offer critical observations and reflections that are informed by our various roles in HTA as health technology governance experts, researchers-evaluators, and/or decision makers. The analysis primarily adopts the perspective of payers (ie, health system organizations and agencies) because of their central role in regulating, funding, and reimbursing technologies [12].

On the basis of the *HTA core model*, we summarize key challenges posed by AI in a real-world context of care and services, which include (1) technological, (2) clinical, (3) human and cognitive (patient and clinician), (4) professional and organizational, (5) economic, and (6) legal and ethical dimensions (Textbox 1). We provide examples for each of these dimensions and underline how decision makers could approach them in a more systemic and holistic manner.

Textbox 1. Synthesis of some key challenges posed by artificial intelligence.

Technological

- Laboratory performance versus a real-world context of care and services
- Data quality and representativeness of the general population or other contexts
- Black box: how and why the decision is made?
- Is artificial intelligence (AI) reliable and free of biases or technical failures?
- How AI would react in situations where input data deviate from initial data?
- Cybersecurity: data and model (algorithm)
- Interoperability: fragmented systems and unstructured data

Clinical

- Reproduction of tropism of practice models
- Actual clinical added value in a real-world context of care and services: difficult to distinguish the effect of the AI's decision from the rest of the preventive and/or therapeutic strategy
- The level of accuracy of AI in diagnosis and recommendations (reference standard) in a real-world context of care and services

Human and cognitive (patients)

- Evolution of the nature and quality of the clinician-patient relationship
- Loss of human contact: isolation of some people
- Unrealistic expectations in some patients regarding clinical outcomes
- Black box: could be perceived as a restriction on the patient's right to make a free and informed decision
- AI could be beneficial for one part of the population and not be for others: what is the good target population?

Human and cognitive (clinicians)

- How to integrate AI into the electronic health record (EHR) and clinical routine with minimal effort and disruption for clinicians?
- Nonintuitive technologies: weigh-down workflows and burden for clinicians and cognitive overload
- Disruption of interpersonal communication styles (eg, clinician-clinician and clinician-patient)
- AI as clinical mind: challenge of clinician's decision-making autonomy
- Absolute confidence in AI: technical dependence

Professional and organizational

- How will it fit into the patient care and services trajectory?
- How will it be integrated into the clinical-administrative processes and workflows of organizations and health system?
- What changes will result in terms of service organization (eg, waiting time, primary care and specialized services relationships)?
- How will it impact on professional jurisdictions (eg, reserved activities, responsibility, training, new skills, and expertise)?

Economic

- Investments required: continuous performance tests, software and data quality tests, infrastructure and equipment upgrades, human expertise, and training
- Clinical tropism and reimbursement/billing biases: costs for patients, clinicians, organizations, and health system
- Need of new financing mechanisms, appropriate remuneration and/or reimbursement models, and insurance models

Legal and ethical

- When is AI considered as a decision-making support tool? When is it considered as a decision-making tool?
- What are the limits of technology and their potential legal implications?
- If the AI makes a mistake (eg, black box), who will be held responsible? If the patient is harmed, who will pay for the repairs?
- What would be the consequence if the clinician does not comply with the recommendations of an AI and this leads to an error?
- AI needs access to data from different sources: consent is becoming more complex, as patients will be asked to authorize the use of diversified amounts of data

- Protection and confidentiality: origin of the data, how consent was obtained, and authorization to use and/or reuse the data
- Who owns the data? Who is responsible for it? Who can use (or reuse) it and under what conditions?

Technological Dimension

Generalizability and Reproducibility

Studies that focus on technological issues indicate that AI should provide the same level of performance in a real-world context of care and services as that obtained in laboratory conditions. However, this requirement is difficult to achieve [13-16]. The majority of AI applications reported in the literature are not exploitable in clinical practice [17]. AI is often trained with so-called *clean* (exclusion of poor-quality images) and complete data sets (elimination of imperfect data) [18]. It may not be operational in other contexts where data are incomplete or of poor quality (electronic health record [EHR] with missing data and/or erroneously entered data) [19-21]. This applies to some categories of the patient population (eg, low economic status and psychosocial problems) who receive care and services in a fragmented way in several organizations (institutional wandering) [21-24]. In addition, AI is usually trained on data specific to certain sites (hospital) and patients who are not necessarily representative of the general population. This includes decontextualized data (lack of psychosocial and organizational indicators) and data about disproportionately sick individuals (data enriched by metastases cases), men, and those from a European origin (ethnodiversity) [23,25-28].

Health organizations and systems produce and manage data in different ways. Variations may exist in clinical protocols (eg, diagnosis, procedures, and vital parameters) and devices (eg, different types of scanners, EHRs, and laboratory devices) on which AI applications are trained and those on which they are expected to operate [29,30]. These variations could affect the AI performance in a real-world context of care and services [31]. For example, an AI application trained on data from 2 hospitals in the United States performed poorly in a third hospital [13,32]. In its decision, the AI application had as predictors the image characteristics (magnetic resonance imaging machines specifications), imperceptible to humans, specific to the technological systems of the hospitals where it was trained. The AI solution had adapted to *noise* rather than to the signal of clinical interest [33]. When used in the third hospital, it was *deprived* of these expected predictors (*noise*), which affected its anticipated performance [32]. In the same vein, the use of data from the *Framingham Heart Study* to predict the risk of cardiovascular events produced biased results, which both overestimated and underestimated risk when AI was used in non-white populations [34,35]. The ability of AI to operate without bias or confounding factors on different devices and protocols remains a major challenge [36,37]. Thus, the fact that an algorithm was trained on large data sets does not mean that its results are generalizable.

Interpretability and Transparency

The interpretability and transparency of AI are important issues. The *black box* logic makes some AI applications vulnerable and at risk to false discoveries via spurious associations: how

is the decision made and on what basis (justification and process description) [24,38,39]. This issue is central because these technologies will be diffused on a large scale. The error of a defective AI could have a greater impact (several patients) than a clinician's error on a single patient [20,31,40].

Interpretability and transparency are also necessary to identify the origin of errors, biases, or failures that should be prevented and/or avoided in the future [3,21,41]. For example, an AI application could lead to many undesirable impacts related to: (1) poor-quality training data, which could lead to erroneous or biased knowledge (*garbage in, garbage out*), whereas technology may further amplify how poor data produce poor results (noisy data and missing values); (2) the presence of a technical flaw in the algorithm (code), which could lead to erroneous inferences, even if good-quality data are used; (3) decision-making criteria that may not be universally acceptable; and (4) the emergence of new situations for which AI could not adapt, even with good-quality data and code [21,30,42-45]. For example, the emergence of new treatments or practices may require changes in clinical protocols; however, at present, AI applications are not developed to manage temporal data naturally in a real-world context of care and services. However, diseases and treatments evolve in a nonlinear manner [18,45]. The question thus remains regarding how AI would react, with observable indicators, in situations where input data deviate from initial data (EHRs and real-time monitoring devices), in the medium and long term [45,46].

The risk of cyberattacks is also a major concern. The data could be modified and/or fed by other false or biased data in a way that is difficult to detect [1]. For example, a slight intentional modification of laboratory results in a patient's EHR resulted in significant changes in the estimates of a *well-trained* AI of the same patient's risk of mortality [24]. For AI, the issue is two-fold because it is necessary to ensure the security of the data and that of the model (the algorithm). Interoperability is also a significant issue. The integration of AI in fragmented and noninteroperable information technology systems and organizations could create more problems than it will solve; to deliver its full potential, AI needs integrated and interoperable systems with fluent and optimal data circulation and exchange [17].

Finally, addressing interpretability and transparency in AI could be compromised by intellectual property issues, competitive strategy, and financial advantages that make companies reluctant to disclose their source codes [3].

Clinical Dimension

AI can entrench and disseminate practice models specific to particular contexts (organizations or health systems) and not necessarily accepted or used in others (tropism) [38]. For example, clinicians in some countries stopped using *IBM Watson for Oncology* because it reflected US specificity in cancer treatment [1,47].

To use AI in their decision making, clinicians should understand how it makes decisions in the first place [38,45,48]. They need the evidence to support a given conclusion to be able to carry out the necessary verifications or even corrections [14]: Why this decision (what information or image—or part of the image—tipped the final decision of the AI)? Why not another option (or choice)? When may I consider that the decision is correct? When should I accept this decision? How can I correct the error when it occurs?

AI should provide clinically added value for the patient. In a real-world context of care and services, much information, decisions, and diagnoses could intersect (eg, symptom assessment, laboratory tests, and radiology). At present, it is difficult to distinguish the effect of an AI-based decision from the overall preventive and/or therapeutic strategy of patient care [49,50].

Another clinical issue is determining the level of accuracy of AI for diagnosis and recommendations. In practice, decisions physicians make could diverge or even contradict each other in many situations. The *gold standard* is not always easy to define in a process that involves complex judgments [38,51,52]. In this case, should the standard reflect that of the lead clinician (or clinicians) in the organization? Or the one accepted by the majority of clinicians? Or the one reported in similar contexts? Some authors believe that for technologies that aim to provide pragmatic solutions under suboptimal conditions, AI performance should correspond to clinically acceptable practice in a given context and not necessarily to recommended practices [32]. This last point is likely to be problematic, particularly in a context where health systems are trying to overcome the challenge of practice variations to be able to provide equitable and quality services for all citizens.

Human and Cognitive Dimensions

AI could affect the nature and quality of the clinician-patient relationship and their expectations for care and follow-up [53,54]. The loss of human contact could lead to increased isolation of some people (replacement of health care providers) [1]. Some patients may feel able to control and manage their disease, with passive surveillance and/or less contact with the clinician, whereas others may feel overwhelmed by additional responsibilities [55]. AI may also create unrealistic expectations in some patients regarding clinical outcomes, which could have a negative impact on their care and service experience [56]. In addition, some AI-based decisions could be perceived as a restriction on the patient's right to make a free and informed decision [1,53]. Cultural and social aspects could play an important role in how patients will respond to AI and therefore how effective it can prove in practice [57]. Hence, it is important to know on which basis one may define the target population that can benefit from it [58]. In this regard, the question of social acceptability (acceptable risk and public confidence) also needs to be considered, which goes beyond the simple question of the effectiveness and usability of AI [59].

For clinicians, the challenge is to integrate AI into the EHR and clinical routine with minimal effort while respecting their decision-making autonomy [24]. Nonintuitive technologies could encumber workflows and become a burden for clinicians

without improving service delivery [30,60]. Otherwise, the ability of AI to combine data from the scientific literature with learning from practice data could generate a repository of clinical practices (*clinical mind*), which could give AI an *unwanted* power or authority [35]. In some situations, AI may reduce the clinician's ability to take into account patient values and preferences. In contrast, some clinicians may develop absolute confidence and become dependent on AI, thus relinquishing their responsibility to verify or double-check its decisions [1].

In short, if clinicians feel overloaded and workflows become more complex, AI may be rejected because of self-perceived inefficacy and performance, alert fatigue, cognitive overload, and disruption of interpersonal communication routines [54,61-63].

Professional and Organizational Dimensions

Global appreciation of the added value of AI should take into account the nature and magnitude of the professional and organizational changes required for its use [6]. For example, the FDA has approved an AI application used for diabetic retinopathy screening, which may be used in primary care clinics [11]. As in some countries, the screening procedure is performed by an ophthalmologist (specialist), some questions arise: How will this technology fit into patient care and services trajectory? How will it be integrated into the clinical-administrative processes of organizations and the health system? If used at the primary care level, will general practitioners, nurses, or optometrists be allowed to supervise the AI? If so, under what conditions? What will be the impact on professional jurisdictions (regulated activities, remuneration, and training)? What changes will result in terms of service organization and clinical-administrative workflows (waiting time at primary care level, primary care, and specialized services relationships)?

Thus, AI could lead to a redistribution of work between different professional scopes of practice and highlight the need for other clinical, administrative, and technical skills and expertise. This will require clarifying new rules and processes (clinical and administrative), negotiating and reframing professional jurisdictions, responsibilities, and privileges associated with them and reassessing the number of positions needed and the new skills required to work (with) and/or perform other tasks that accompany its use. This will have to take into consideration how new roles in terms of skills in informatics and data science and the ability to liaise may be introduced within clinical teams [64].

Finally, today, most AI applications are developed to perform a single task or a set of very specific tasks (eg, diagnosing only diabetic retinopathy and macular edema) [65]. They are unusable for other diagnoses for which they are not trained (eg, nondiabetic retinopathy lesions and eye melanoma) and are unable, at least for the moment, to replace a complete clinical examination [66]. Payers will thus be tasked to determine whether AI provides sufficient added value in relation to the nature and magnitude of the clinical, cognitive, professional, and organizational changes it could generate.

Economic Dimension

To adapt an AI to a local environment, considerable investments and expenditures may be necessary. The evolution of AI in a real-world context of care and services, by integrating large amounts of data of various types and sources, requires additional resources to ensure its proper functioning and stability: continuous performance tests, software and data quality tests, infrastructure and equipment upgrades, human expertise, and training [3,67]. However, many health organizations do not have a secure and scalable technological and data infrastructure as well as adequate human resources to ensure proper collection of the data necessary for the training and adaptation of AI to their local population and clinical environment [17]. The literature on AI's promises as well as innovation policies that support its development downplays the capital-intensive requirements that are required to properly deploy AI, compared with the day-to-day work of managers in organizations.

In health systems where activity-based financing is the basis for funding health organizations, some clinicians tend to enter the *highest paying* codes for each clinical activity (ie, the most complex case of an intervention) to increase performance and maximize revenue. An AI application trained on data from these organizations (EHR with invoicing or reimbursement data) could amplify biases inherent in such practices that do not necessarily reflect the actual clinical condition [23,44,68]. The replication and entrenchment at a large scale of these biases could result in significant costs for patients, clinicians, organizations, and the health systems [35].

Similarly, some AI applications may be *too cautious*, resulting in an increase in requests for unnecessary testing and treatment, leading to overdiagnosis or overprescription [69]. Their recommendations, which are not necessarily associated with improved patient outcomes, could lead to increased costs and expenses for patients and the health system.

Legal and Ethical Dimensions

Many AI technologies are still considered today as *decision-making support tools* for clinicians. It could then be argued that the legal responsibility for the decision still rests with the clinician. However, with the growing performance of AI, clinicians may be increasingly influenced and may more easily accept AI decisions, even when there is clinical ambiguity. Determining the clinician's degree of responsibility becomes more complex [30]. The challenge here is to distinguish between several situations: When is it considered a decision-making support tool? When is it considered a decision-making tool? This distinction is key in defining who is legally responsible in the event of an error or a malfunction (professional misconduct) [30,51,70].

For example, if the clinical decision is based on an erroneous clinical recommendation from the AI (delayed or erroneous treatment), who will be held responsible? Is it the technology developer, technology provider, clinician, organization, or do they all share responsibility (and how)? In some jurisdictions, to confirm professional misconduct, it is necessary to prove that the *standard of care* was not followed. This standard is blurred when AI comes into play [2]. In addition, the likely consequence

if the clinician does not comply with the recommendations of an AI and if this leads to an error must be anticipated [2]. It could be argued that the responsibility should rest with the human controller of AI, but such a responsibility becomes difficult to clarify when autonomous technologies are used [57]. In this regard, standards may shift over time: "What happens if medical practice reaches a point where AI becomes part of the standard of care?" Medical insurers and regulators will have to be able to distinguish errors inherent in the tool from those resulting from misuse by the clinician, the organization, or even the patient, an issue exacerbated by the *black box* of AI [51,71].

To generate a complete picture of the patient, AI will need access to data from different organizations (hospitals and insurers) [45]. The risk of disclosing sensitive information about patients or certain populations is real [45]. For example, some AI applications can reidentify an individual from only three different data sources [25,38,72]. In the same vein, the issue of consent is becoming more complex, as patients will be asked to authorize the use of increasingly large and diversified amounts of data about them: medical records, audio, videos, and socioeconomic data [58]. Problems could arise if the patient only consents to sharing parts of his or her data. Usually, confidentiality means that the clinician can withhold certain information—at the patient's request (or not)—and avoid entering it into the EHR. Incomplete data make AI less efficient and does not allow patients to benefit from the best possible services. AI may not be fully operational in a real-world context of care and services if specific restrictions on data access and use are applied [38].

Protection and confidentiality requirements imply the obligation to know several things: the origin of the data, how consent was obtained, and authorization to use and/or reuse the data for training and in a real-world context of care and services. As the data may come from different sources and contexts, different conditions and precautions will need to be considered [73]. Regulators will need to determine who owns the data and, in the context of public-private partnerships, who is responsible for its collection, use, transmission to third parties, and under what conditions [17]. As the answers will vary according to the nature of the data, the jurisdictions, and the purpose of use, the task at hand is sizable [73]. Finally, payers will have to recognize that the ethical implications of AI affect, directly or indirectly, all the other dimensions discussed earlier.

Conclusions

The purpose of this viewpoint paper is to provide a structured roadmap of the issues surrounding the integration of AI into health care organizations and systems. To the best of our knowledge, this is one of the few papers that offers a multidimensional and holistic analysis on the subject [7]. It contributes to current knowledge by providing a necessary basis for reflections, exchanges, and knowledge sharing among the various stakeholders concerned with AI in health care.

In light of the issues we identified, it becomes clear that regulatory and decision-making organizations as well as HTA agencies are facing unprecedented complexity: evaluating and approving so-called disruptive technologies, especially AI, requires taking several issues into consideration altogether.

Many studies have reported significant technical performance of AI technologies, but very few have adopted a holistic standpoint that can situate their impacts and associated changes and transformations in health systems. Technical studies are rarely adapted to the complexity surrounding AI applications, as they overlook the context-dependent changes or adjustments the implementation and use of technology requires (variations, clinical and organizational interactions, and interdependencies) [74]. According to *the frame problem* [62,75], which highlights the difficulty for AI, beyond the specific tasks it masters, to update its set of axioms to capture the context in which it is implemented and used (eg, patient preferences, environment and social support, clinical history, personality/cultural characteristics and values that influence clinical outcomes, and empathy in medicine), the complexity inherent in the use of AI applications in the real-world context of care and services may seem difficult to overcome [62].

For informed decision making, there is a real need for evaluations that address AI as a lever of health system transformation. Given the magnitude of the implications it could have at all levels, the evaluation of AI's value proposition should go beyond its technical performance and cost logic to incorporate its global value based on a holistic analysis in a real-world context of care and services. In this vein, technology brings value when its use in a real-world context of care and services contributes to the aims of the health system and aligns with the values of society. Global value appreciation could be based on the *quintuple aim*: (1) better quality and experience of care and services for patients; (2) a better state of health and well-being for the entire population; (3) reducing costs for responsible and sustainable resource management; (4) a better quality of work and satisfaction of health care providers; and (5) equity and inclusion to avoid exacerbating health disparities in the population [76]. From this perspective, further research on the evaluation of AI should no longer be limited to a technological approach, which only demonstrates quality from an engineering point of view and costs—motivated mainly by a logic of short-term savings—but should broaden its horizons to include the dimensions this paper underscored [77,78].

Real-world evaluations could be a major asset in informing AI decision making. In the context of uncertainty, iterative and reflective evaluation approaches should be developed to encourage dialog and collaboration among all relevant

stakeholders (eg, payers, health care providers, technology providers, regulators, citizens/patients, academic researchers, and evaluation agencies) [63,78,79]. In addition, an early dialog between these stakeholders is needed to identify the evidence required to inform decision making [63,78]. This approach would also help AI providers to better understand the expectations of the health system [78]. This change implies that HTA should play an active role as a mediator and facilitator of transparent dialog between different stakeholders who are implicated throughout the technology's life cycle [78,80].

Decision making for innovative technologies is inherently complex, in particular because of visions, perceptions, and objectives that may differ between the stakeholders involved: *risk sharing* is essential to strive to find a balance between uncertainty and added value [81]. In this regard, “major radical innovations never bring new technologies into the world in a fully developed form” but “appear in a crude and embryonic state with only a few specific uses” [81]. It is their use in a real-world context of care and services, through a process of *learning by doing* (improving users' skills) and *learning by using* (improving users' knowledge), which makes it possible to appreciate their global value [81]. With the complexity associated with AI, value appreciation becomes even more complex, challenging the traditional methodological foundations that are the basis for decision making about innovative technologies [82]. This also presents a unique opportunity for HTA to evolve and adapt (evaluative framework and contextualized data), particularly in view of the importance of contexts in the appreciation of the value of innovative technologies [83,84]. It is necessary for HTA scholars and practitioners to explore and exploit other avenues, complementary to traditional methods, to collect data and information that can better inform AI-related decisions [85].

Finally, this new context implies mechanisms for continuous collective learning and sharing of lessons. To do so, there is a need for learning and flexible health organizations and systems that are able to adjust and operate under uncertainty. In this regard, creating the political, regulatory, organizational, clinical, and technological conditions necessary for proper innovation is the first step. This requires building trust to ensure stakeholder engagement to guide AI developments, rapidly generate knowledge in a real-world context of care and services, and draw lessons to translate them into action.

Acknowledgments

HA was supported by the Canadian Institutes of Health Research (CIHR)'s Health System Impact Fellowship. This program is led by CIHR's Institute of Health Services and Policy Research, in partnership with the Fonds de recherche du Québec—Santé and the Institut national d'excellence en santé et services sociaux. The authors would like to thank the reviewers and the editorial team for their insightful comments and suggestions, as these comments and suggestions led to an improvement of the manuscript.

Authors' Contributions

HA and PL produced the first draft of this manuscript and received input from YA, MG, MG, JS, DR, RF, MA, and JF. All authors have read and approved the final manuscript.

Abstract

There has been an increasing interest in blockchain technology from the health care sector in the last couple of years. The value proposition for using blockchain technology in the health care sector is to share sensitive patient data among health care entities securely and to empower patients. Blockchain technology allows patients to have an active role in developing and updating their own patient data. However, is blockchain technology really the silver bullet it seems to be? With this paper, we aim to understand the benefits and challenges of blockchain technology in the health care sector. We discuss innovation and security implications concerning blockchain technology in health care. Furthermore, we show that there is a need for more use cases to ensure the secure sharing of data within the health care sector. In our opinion, blockchain technology will not solve the issues encountered by the health care sector; in fact, it may raise more issues than it will solve.

KEYWORDS

blockchain; health care; innovation; security; implications

Introduction

Beyond its first application as the peer-to-peer payment system Bitcoin, blockchain technology is anticipated to revolutionize industries and sectors [1,2]. The implementation of blockchain technology has been clearly dominant in the financial industry [3], the supply chain industry [4], the payments industry [5,6], and e-commerce [7]. The health care sector can potentially benefit from blockchain technology by making health care information systems patient-centric and facilitating health data-sharing securely and efficiently [8]. A plethora of studies have proposed various potential use cases for using blockchain in health care [8-10]; however, the vast majority of those proposed use cases were not implemented [10]. In their recent literature review, Hasselgren et al [8] analyzed 39 studies on blockchain in health care that proposed solutions that were implemented as proof of concept.

The common use cases that benefit from blockchain-based solutions for a patient-centric health care information system include patient-managed health records, enhanced insurance claim processes, enhanced health care research, and advanced medical records shared among patients and health care providers [11]. Despite the suitability of blockchain solutions for problems

and innovation needs in health care information systems, the feasibility of fully implementing those solutions is scarce to moderate [8]. Even if some solutions have proven feasible to implement into practice, they require reductions in data size and operating costs, as well as better protection of personal information to maintain privacy and security [12].

Further, barriers to the feasibility of fully implementing blockchain-enabled patient-centric electronic medical records include interoperability and scalability issues [9]. Interoperability issues manifest in the lack of standards among various blockchain-based solutions [9]. However, proposals have been introduced to address those issues [8]. Due to the high volume of clinical data, scalability issues arise, as blockchain-based solutions have data size limitations [9,13]. Patient engagement seems to be a benefit of blockchain-based solutions in health care; however, it is likely not the case for all types of patients, as not all patients are enthusiastic about managing their own data [9].

Blockchain-based solutions have not been adequately assessed for their compliance to individuals' rights protected by the General Data Protection Regulation (GDPR) [8,14]. The abovementioned opportunities, barriers, and concerns have implications for patients, health care providers, and researchers.

Furthermore, the legal, security, and privacy implications deserve further exploration. This may lead to some workarounds to make the blockchain architecture GDPR compliant, which have not yet resulted in something concrete [14-16].

Through this viewpoint article, we aim to discuss innovation and security implications that blockchain brings to the health care sector. We did not attempt to conduct a thorough literature review on the topic, as there are already comprehensive literature reviews on blockchain in health care [8-10,14]. Rather, we discuss our viewpoint on the implications of blockchain for the health care sector, with support from the current body of literature.

Thus, we aim to answer our research question: What implications may blockchain technology bring to the health care sector?

First, we present a background on blockchain technology. Second, we discuss implications of innovating with blockchain in health care. Third, we discuss the security implications of blockchain in the health care sector. Fourth, we summarize our discussion, and finally, conclude this paper.

Background of Blockchain Technology

Blockchain technology is described as a disruptive innovation that brings opportunities and challenges to various industries and sectors, and it deserves further exploration [17-19]. There is an ongoing debate as to which came first, blockchain or Bitcoin [1,2,20]. Blockchain is the underlying technology with broader capabilities and characteristics. Bitcoin is just an application area for trading that inherits blockchain characteristics [21]. Stuart Haber and W Scott Stornetta invented the notion behind blockchain first, when they proposed a framework for a “timestamping digital document” to calculate hash values that uniquely identify documents and save them in certificates with a timestamp [22]. These documents are linked by a data structure with the hashes of previous records. Nakamoto [2] adopted the framework proposed by Haber and Stornetta, creating the first Bitcoin peer-to-peer payment system based on timestamped blocks of transactions, which are chained using the hash values of previous blocks. Bitcoin then became commonly known as a means for trading with cryptocurrency [23].

Swan [13] defined blockchain as a decentralized transparent ledger with transaction records. Blockchain contains a set of data blocks, each of which contains data on multiple transactions (ie, transactions list, timestamp, nonce, hashes of the transactions and their root hash or block hash, and the hash of the previous block). As more blocks are added to the chain, the distributed ledger becomes a complete transaction history book [24]. Before adding the new transactions to the ledger, the consensus mechanism is applied by multiple participants to validate the transaction and the block. Transactions reside in the block for a specified time until the consensus process is done. Then, the block of transactions is stored in the ledger, where the information cannot be changed [24]. If the hash of a block is modified, the block is no longer valid [25], which makes subsequent blocks invalid as well, and this will require verifying

the block after recalculating its hash and the hashes of subsequent blocks [26].

There are two basic deployment forms of blockchain; these are public permissionless and private permissioned blockchains [1,27]. Public permissionless blockchains are open and decentralized, where anyone can join and leave the network as reader and writer at any time (eg, Bitcoin). The network has no central authority to monitor it and no one owns and controls the network. Private permissioned blockchains only authorize a limited set of readers and writers (eg, Hyperledger). The network has a central authority that assigns the right to individuals to read and write operations.

Several definitions of blockchain mainly refer to the characteristics of public permissionless blockchains, such as absolute immutability, anonymity, decentralization in running the consensus mechanism, and openness [1,21,26]. The definitions do not provide a description of private permissioned blockchains, which are managed by a central trusted authority that controls the consensus process, in which the identities of participants are predefined and access permissions are restricted [28].

Blockchain technology is claimed to be an “accelerating force of innovation” that promises a wide range of benefits [17]. However, the claims about blockchains being tamperproof and offering strong security are challenged by a long list of security threats [29]. Blockchains are claimed to be immutable and unable to be hacked, but this has been proven invalid [30,31]. Furthermore, blockchains are energy-consuming, which entails considerable costs (eg, network performance problems) [25,32]. This poses a concern about whether the benefits and promises brought by blockchain can be taken for granted or whether they will become a threat to the ambitions for innovation and better security. Consequently, practice and academia still have questions to address regarding benefits and risks that arise from blockchains, including whether blockchain is a radical or incremental innovation in nature [17].

Innovation and Security Implications of Blockchain in Health Care

Innovation and Security Needs

Whether blockchain is a blessing or a curse, in terms of innovation and security, it is a matter of what it adds to a no-blockchain situation. It can add information technology (IT) or business costs or complexity [33]. An ever-present challenge for any industry or sector is the balance between implementing modern IT solutions and keeping information assets safe from security threats. Blockchain technology emerged with the promise to address this challenge; it enables innovation by implementing a modern decentralized information infrastructure [17,19,34].

The health care sector has a long history of heavy regulation and bureaucratic inefficiency that has decelerated its innovation [35-37], and an increasing number of data breaches have been reported in recent years [38]. It is claimed that innovating with blockchain ensures the privacy and security of highly vulnerable

and sensitive patient data in the cyber world [35]. However, there are more experiments of proposed blockchain solutions than full implementations in the health care sector [36,39,40].

Implications of Innovating With Blockchain in Health Care

Blockchain is a disruptive innovation that can leverage health care information systems' abilities to improve patient care; however, this has considerable regulatory, financial, and operational implications [41,42]. Private permissioned blockchains are a proper option for the health care sector to deal with sensitive patient data [8,27]. This type of blockchain deployment has beneficial implications for the use of blockchain in health care. The use cases suggested by researchers for blockchain in health care include patient-managed medical records, improved insurance claim processes, accelerated medical research with the use of shared anonymous patient data, and an advanced health data ledger maintaining clinical transaction logs, pharmaceutical supply chains, and consent recording [8,11,43,44].

The exploration of blockchain's compliance with GDPR is scarce despite its importance [8]. Private permissioned blockchains have implications for GDPR due to the central authority controlling the network and access to personal data [45]. In the case of using patient data to support health care researchers [11], a pseudonymization technique is required to protect patients' sensitive data [16], which may pose a risk of reidentification (ie, linking the pseudonym code or metadata to the patient's health data), raising a conflict with GDPR [45]. This requires a careful consideration of the use case and the design of the blockchain-based health information system [46].

Blockchains are immutable; therefore, it is not possible to delete a block. Thus, blockchain does not comply with the requirement under GDPR that stipulates that data subjects have the right to request for their data to be erased, including health sensitive data [9,47]. A proposed workaround is to store the patient data off-chain and have the pseudonym codes stored on-chain [16,47]. However, this implies that the pseudonym code and any transaction records on the patient data that are stored on-chain would still be existent even after deleting the patient data that were stored off-chain [47]. To reverse the immutability of blockchain, a proof-of-concept prototype for a "forgetting blockchain" was proposed to delete old data from private permissioned blockchains; however, the prototype still has limitations to address [15].

Beck and Müller-Bloch [19] argued that blockchain is a radical innovation that outdates the conventional distributed systems approach with a different architecture and characteristics [19,48]. Thus, radical innovations are difficult to implement and they bring more complex challenges, which require organizational readiness and the updating of old organizational knowledge and IT infrastructure [49]. This has financial implications for using blockchain technology in the health care sector; despite the fact that it has the potential to improve the quality of medical services, it may create financial uncertainties [41]. The top challenges facing the adoption of blockchain in health care include computational overhead, lack of interoperability and standardization, privacy concerns, and the uncertainty about

who is responsible for the cost of technology implementation and who profits from it [14,50]. Barriers to adopting blockchain in the health care sector include immaturity of the technology itself, insufficient skills to understand and implement it, lack of buy-in, and lack of clear return on investment [51]. The lack of buy-in goes back to the unfamiliarity of blockchain, the negative attitudes of medical doctors toward the use of blockchain [52], and the fact that not all the patients are interested in managing their health records [9].

Beck and Müller-Bloch [19] suggested that in order to manage a radical innovation with blockchain, 3 competencies are needed to realize its benefits: discovery, incubation, and acceleration. Discovery refers to recognizing and articulating the blockchain opportunities and building research communities. Incubation involves designing blockchain use cases and experimenting with them (ie, proof of concept). Acceleration involves proposing the blockchain implementation and investing in the implementation of a full-functioning blockchain logic and infrastructure. The proof of concept of blockchain technologies strives to replicate real-world conditions in order to evaluate the feasibility of blockchain in health care and address its challenges [8,12]. Even though the required improvements are tested and have provided successful results, they come at the expense of other important aspects in the health information system. A proof of concept for a blockchain-based patient-centric information exchange between patients and providers has provided promising results; however, the real-world implementation is expected to provide different results [53]. Using blockchain to improve health data exchange and patient engagement can come at the expense of performance due to the dynamic regeneration of smart contracts. Additionally, the experimentation files will never be at the same size as the actual patient data [53]. Data size is considered to be one of the important considerations for the feasibility of blockchain solutions for health care [12].

Approaches to implement blockchain in the health care sector can be evolutionary or revolutionary. The evolutionary approach involves integrating blockchain with legacy electronic health records systems, which can compromise the availability of patient information and cause the relaxing of security countermeasures [14]. The revolutionary approach is a bottom-up approach that aims at building the entire health care information system as a blockchain-enabled system and then migrating to it [14]. Both approaches create uncertainties around the cost of implementing or integrating blockchain-based solutions for health care and provide unclear returns on investment. It has been claimed that implementing blockchain-based solutions negatively affects the financial metrics in the short term but pays off in the long term [41]. Reducing operating costs is an important consideration to test the feasibility of blockchain solutions [12].

With blockchain technology, transactions are processed and verified by an automated programmable logic with predefined rules, which reduces transaction costs (ie, effort and time spent on bureaucracy) [17,54]. The consensus mechanism of blockchain ensures the integrity of the data, but calculating the hashes for a single block in the chain is time-consuming and energy-consuming [13,25,32]. Consequently, complex or

computation-intense systems are not the best use cases for blockchain [18]. For health care information systems, performance, real-time communication, coordination, data sharing, and medical service availability are critical in life-threatening situations [55].

Some of the major challenges with the current health information systems are interoperability, integration complexities, and the inability of current legacy systems to communicate directly and share health records [40,56,57]. However, the use of blockchain in health care is found to have interoperability challenges, and blockchain, as a radical innovation, brings integration and implementation complexities [9,10,19]. Even though there are proof-of-concept suggestions and experiments to improve the interoperability, the challenges still exist [8]. This implies an unclear difference between no-blockchain and blockchain situations.

Security Implications of Blockchain in Health Care

It is claimed that private permissioned blockchain deployment brings the most benefits for health care applications [8,9]; however, it brings security risks at the same time [11,41]. Private permissioned blockchains are limited to trusted and predefined participants, and a central authority manages the rights to read and write operations of the blockchain [27]. This feature provides more control by assuring that only authorized participants can perform read or write operations on the patient data [9]. This has positive implications for the confidentiality and integrity of the data. Additionally, the immutability enables tracking of patient-generated data for medical research purposes, transactions on insurance claim processes to detect fraud, and pharmaceutical supply chains for quality assurance [11,41]. Private permissioned blockchain can also enable the availability of audit trails and progress traceability.

In the case of using patient-generated health data for research purposes, smart contracts enable patients to give consent and permission for researchers to access their health data [58]. However, data integrity can be compromised, as the patient data entry point, which is the patient's device, can be used to impersonate the patient [59]. Sharing patient health data with researchers poses a threat to the privacy of the patient; even if the data are pseudonymized, there is a risk of reidentification [60]. However, the attempts to enhance patient privacy in blockchain environments and design blockchain features for privacy are still in the pilot phase, and there is no guarantee they will preserve privacy [60,61].

Private permissioned blockchains are most prone to a 51% attack [21]. This happens when the central trustworthy node is compromised by the attacker; since the validation of the transactions is centralized, the attacker gains the authority to control the computational power of the network, causing a transaction to happen twice. Hence, the integrity of the transaction data is affected and the resources of the network are exhausted. This has negative implications on the integrity of the data and service availability, which are critical for health care applications [11].

Private permissioned blockchains have limitations in saving patient data with transaction data for the purpose of preventing

distributed denial-of-service (DDoS) attacks [12]. This represents an obstacle, as the volume of patient health data is growing over time [12]. Addressing the data size limitation in private blockchain would need to accommodate the increasing volume of patient data, exposing the network to DDoS attacks [12]. Additionally, validating a block of a large data size consumes much power and entails further operational costs [12]. In either case, the service availability, which is critical for health care services, would be compromised.

The security of patient health data with blockchain technology is still in its proof-of-concept phase, and security and privacy are not fully guaranteed so far. The attempts to address security and privacy of blockchain in health care appear to be at the expense of other important features of blockchain technology itself or the needs of the health care sector [62].

Discussion of the Implications

In this viewpoint paper, we have examined the various innovation and security implications of using blockchain technology in the health care sector. Based on that, we revisit our research question: What implications may blockchain technology bring to the health care sector?

Blockchain technology is not new; however, exploring the feasibility of blockchain applications for the health care sector is in its infancy. The current state of innovating with blockchain in health care is in the proof-of-concept phase [8,58]. Blockchain is a technological innovation that brings benefits and challenges [42]. The health care sector is expected to benefit from blockchain in terms of empowering patients and increasing immutability and traceability [11,41,58]. The needs of the health care sector include sharing vast amounts of patient health data across involved entities (ie, interoperability), regulatory compliance (eg, GDPR), data confidentiality, data integrity, privacy, and data and service availability. The feasibility of using blockchain in health care is dependent on the capability of storing and processing vast amounts of patient health data, ensuring privacy, and reducing operating costs [12,46]. Customizing private permissioned blockchain solutions to fit the needs of the health care sector may result in manipulating the characteristics of blockchain technology [15] or manipulating the needs of the health care sector [12,46]. This is a known trade-off approach happening in the proof-of-concept attempts to apply blockchain solutions in health care [62]. This trade-off involves compromising between two desirable but incompatible features. For instance, complying with GDPR requirements involves manipulating the immutability of blockchain. Additionally, the block size limitation in blockchain is intended to reduce performance overhead and prevent DDoS attacks. However, this compromises the scalability needed to accommodate the vast amount of patient health data [12], and manipulating the size of patient health data is difficult. On the other hand, if the blockchain is designed to process large data, it will cause extra operating costs due to the performance overhead, and it will expose the network to DDoS attacks.

We see the need to distinguish between the benefits and challenges that are unique to blockchain and those that are common across other technological innovations. For example,

interoperability is not a challenge specific to blockchain per se; rather, it is a common challenge when adopting any technological innovation.

Based on the topics and views debated in this paper, we summarize the implications of blockchain for health care in terms of both the patients and the health care providers (see [Table 1](#)).

Table 1. Blockchain implications for the health care sector.

Group	Benefits	Challenges
Patients	<ul style="list-style-type: none"> Patients are empowered with self-sovereignty through self-managing personal patient-generated health data The identity of the patients is anonymized 	<ul style="list-style-type: none"> Some patients may not be interested in self-managing their health data
Health care providers	<ul style="list-style-type: none"> Providing a decentralized database with identical copies of the same complete health information, which is made accessible to all parties in the health care chain Facilitating collaboration and data sharing Claimed immutability of a transaction's history 	<ul style="list-style-type: none"> Interoperability is a challenge, and complex systems are not the best use cases for blockchain DDoS^a attacks are likely to happen and affect the availability of the patient health data A 51% attack, specific to blockchain, affects the integrity of transactions' data and consumes the network resources Compliance issues with GDPR^b Blockchain can be resource consuming when all entities in the chain have to approve a large-sized data block

^aDDoS: distributed denial-of-service.

^bGDPR: General Data Protection Regulation.

We argue that blockchain technology is surrounded by a controversy between marketing hype and realistic criticism. The marketing hype has manifested in the claim that blockchain is immune to common security attacks that threaten data confidentiality, integrity, and availability. Meanwhile, there are realistic criticisms that show that blockchains are hackable in many ways [21]. A comprehensive list of security threats in blockchain and their causes has already been rendered [29]. This serves as an incentive for research on security improvements for blockchain in general as well as in health care [14,21].

In terms of medical research, there is potential for using blockchain technology. It is possible to store participants' informed consent to ensure a more transparent, traceable, and tamperproof research method for medical research [63].

This work has implications for further research. Health care researchers can benefit from anonymized health data, which can be shared and aggregated to generate new insights into improving patient health or health care services while maintaining the privacy of patients. Further research is needed to increase awareness about blockchain and to clear the misconceptions and the hype around it. More context-specific use cases need to be designed to avoid generic arguments about blockchain's applicability across sectors. Future research efforts can aid health care providers in developing the required

competencies to innovate with blockchain (ie, discovery, incubation, and acceleration) [19].

Conclusion

Throughout this paper, we have presented and discussed various views on blockchain technology and the positive and negative issues related to it. Blockchain technology is regarded as a promising technology for securely sharing health data. However, it is not clear if blockchain is really the solution to all the issues regarding highly sensitive data.

Throughout this work, we have highlighted the myths and important challenges concerning blockchain technology. Further, we have questioned the applicability of blockchain technology to the health care sector. Governments may want to examine feasible scenarios in which to use blockchain in the health care sector as well as the challenges associated with the traditionalism of such a sector and the immaturity of blockchain. This requires a careful consideration of the trade-offs that may be made when designing and implementing blockchain solutions for health care.

In this paper, we identified blockchain technology's positive and negative implications for patients and health care providers, which opens up unlimited opportunities for future research to delve into.

Abstract

This paper reports on the reflection of the lead researcher, a 48-year-old patient with cystic fibrosis (CF), and aims to portray his real-life experience of a 10-month action design research (ADR) project. Playing a dual role, as both a patient and researcher, the lead researcher reflects deeply on his ADR experience with particular emphasis on the problem formulation stage of creating a simple yet impactful checklist to aid memory recall of CF patients or caregivers during a medical appointment. Using Driscoll's model of reflection, a real-life unsanitized ADR experience is carefully imparted via a series of 4 vignettes, including 4 key learnings, which highlight the connection between a meticulous considered approach to problem formulation and truly effective outcomes. By providing this rich account of problem formulation within ADR, it is hoped that this reflection will help researchers to better understand the complexity of problem formulation in design-oriented research; to avoid making assumptions and becoming fixated on solutions; and to move instead to an end point where several possible ways of examining a problem have been considered, explored, and understood—an end point where successful end results are reached through grit and determination. This paper advocates for the inclusion and portrayal of the actual realities or ups and downs of this dynamic and evolving stage of ADR, capturing the often-tacit knowledge of problem formulation and begetting a sense of realism and humanity to ADR serving as knowledge contributions in their own right. The lead researcher is the patient and researcher in this ADR project. This is my story!

KEYWORDS

action design research; patient; reflection; problem formulation; checklist; cystic fibrosis

Introduction

It is a windy Saturday afternoon in February 2020, and I am busy packing up a box of checklist booklets that I designed to aid the memory recall or information retrieval of patients with cystic fibrosis (CF) and their caregivers during their medical appointments. The box is on its way to the Royal London Children's Hospital, Whitechapel, London, for distribution to caregivers of patients with CF. Caregivers know the reality of having a sick child in a medical appointment, the stress of trying to remember medical history, and the difficulty of trying to recall afterward what took place within a medical appointment. I tape up the box carefully, making sure it is secure for its journey ahead.

A journey that would not have come to pass had I not been invited to present my action design research (ADR) study at the International CF Clinical Conference held in Killarney, Ireland, on January 30, 2020. Out of that, came the dispatching of the checklist booklet to Spain, Sweden, Israel, and Australia. There is no doubt that the checklist booklet is beginning to travel far and wide. Earlier, in January 2019, the booklet was distributed by Cystic Fibrosis Ireland to every patient or caregiver within the Republic of Ireland (1300 patients with CF). Afterward, in April 2019, it was shipped to the Czech Cystic Fibrosis Association and Austria for review.

Moreover, in October 2019, I was invited to present my research on the booklet to over 100 clinicians at a *Hot Topics in CF* conference held in Birmingham, England. Nevertheless, the real

impact of the checklist booklet is best depicted by the mother of a 7-year-old child with CF:

We just wanted to say we received our medical appointment check list today, and we just wanted to say THANK YOU so much, we love it and it's going to be incredibly handy for us, although it's just a book to our little boy now, in a few years he'll know how great and simple it is as well.

As I contemplate the same, a warm feeling envelops me, I feel I am beginning to make a difference, a difference to people like me.

The box is ready to go, a thought enters my mind, *So was my ADR journey easy*, the answer is definitely no. *Did it take determination and patience?* Yes, for sure! *And did I sometimes think of giving up? Did it test me to my limits?* I would have to say yes on both accounts. So how do I account for the success of the checklist booklet? Earlier I mentioned determination; I was unyielding in my quest to understand the problem, the problem that I and others like me experience every time we are in a medical appointment. To help you understand, however, I need to take you on a voyage, a voyage of reflection. It is only by coming on this journey that you will come to comprehend the end point, where through grit and determination, success can be achieved.

"Humans have always reflected on experiences and feelings" [1]. According to Boud et al [2] reflection is "an important human activity in which people recapture their experience, think about it, mull it over and evaluate it." As a researcher, I felt an obligation to share my unsanitized lived experience of *problem formulation* in ADR, not only as a practitioner but also through the eyes of a patient researcher living with a chronic illness.

To this end, I found that a reflection would be the most appropriate instrument to aid me with the *mental process of trying to structure or restructure* [3] my real-life experience of *problem formulation*, to put together or capture the *existing knowledge or insights* [3] from the project that I lived through over a 10-month period. I hope that the insights imparted herein may serve not only as insightful to ADR practitioners in their *problem formulation* endeavors but also to highlight the importance of this stage of ADR in achieving successful outcomes. Moreover, I hope that any patients reading my reflection may be inspired to enter the stimulating world of research, making real-world impacts within their own patient communities, as I have strived to do in mine.

The paper is structured as follows. First, I present a very brief background on ADR, the methodology that I used in my research exploration, going somewhat deeper on the *problem formulation* stage of the methodology (the focus of my reflection). Next, I endeavor to set the scene, giving the reader a deep candid sense of the patient researcher behind the reflection, followed by a very brief section on why a reflection was the correct tool for my deliberations, and the rationale behind the model of reflection I selected. I subsequently organize my reflection through a series of 4 vignettes, which are used to explain the lessons that I learned from my experience of *problem*

formulation within ADR and how crucial this was to the effects my research is having now. Finally, I bring my musings to a close in the concluding remarks section of the paper.

Background

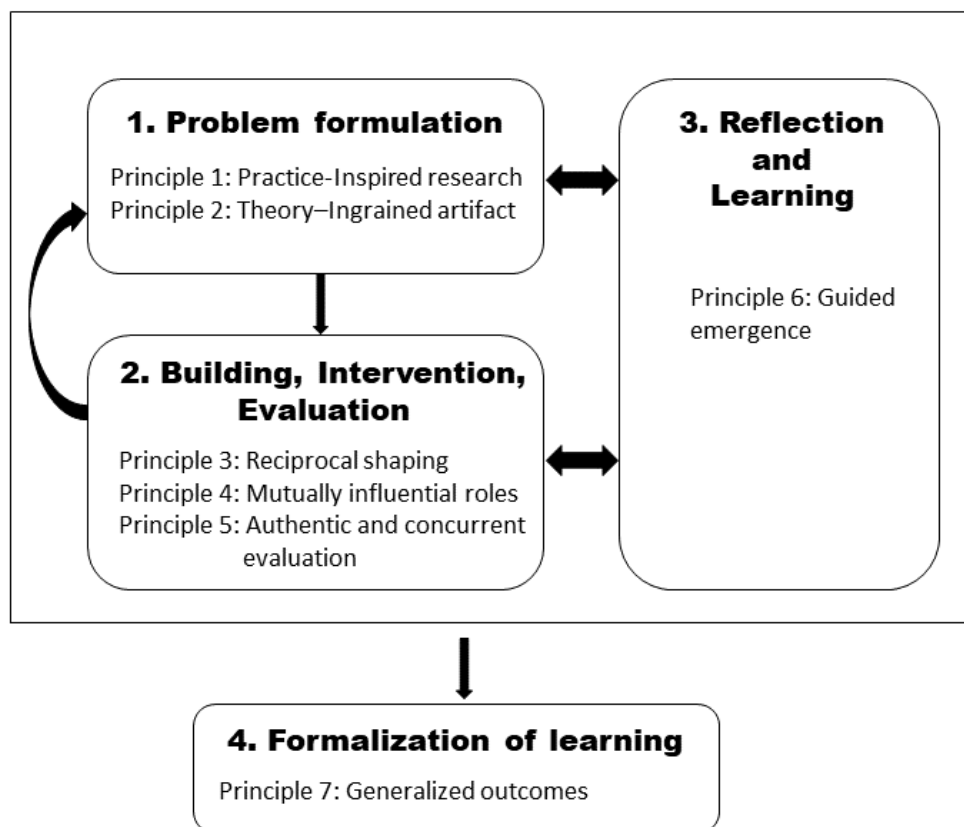

Action Design Research

Design science research (DSR) accentuates a *construction-oriented* interpretation of information systems (IS) research, which at its core lies the design and build of innovative information technology (IT) artifacts and which is deemed appropriate when research aims to produce artifacts that address so called *wicked problems* or ill-structured problems [4]. Although this approach provides IS researchers with the ability to go beyond mere elucidation, toward research that spawns design knowledge relevant to practitioners [4], it still fails to "fully recognize the role of organizational context in shaping the design as well as shaping the deployed artefact" [5].

In their seminal paper, Sein et al [5] proposed a variant of DSR (Figure 1), which is called action design research (ADR), and clearly acknowledged IT artifacts as "shaped by the interests, values, and assumptions of a wide variety" [6] of stakeholders at the same time retaining the essence of design research. ADR targets the creation of innovative artifacts in an *organizational context* but at the same time produces knowledge contributions from the intervention while tackling a problematic situation [4,7]. Sein and Rossi [8] argue that the "embedding of the context in the design through intervention in an organisation, a single-entry point (problem-centered), and, inductive epistemology, is the characteristics of ADR that validate knowledge claims of emergent knowledge co-produced with practice."

ADR differs from other design approaches in so far as it draws on DSR, which centers on the utility of an artifact, and action research, which primarily focuses on learning from an environment, believing that "[t]he only way to produce conditions of practice is to move to practice" [9]. Moreover, at the core of ADR is an inquiry with rigorous evaluation, which is highly iterative in nature, consisting of nested loops [8], where each iteration concludes with a consideration of the artifact. This evaluation acts as the impetus for thorough *reflection and learning*, which then feeds back into *problem formulation*, thereby challenging "organizational participants' existing ideas and assumptions about the artefact's specific use context in order to create and improve the design" [5]. It is these very characteristics that make ADR so successful as a methodology.

It comes as no surprise, therefore, that ADR has been used very effectively in a wide array of research projects, and "because of its ever-expanding applications, the ADR concepts and process model continue to grow and evolve to meet the demands of new and challenging environments" [10], including those within the health domain. For example, the successful solution by Bretschneider et al [11] helps to leverage the innovative idea potential of patients better than traditional communication forums.

Figure 1. Action design research method: stages and principles.

As a pragmatist who is “more interested in utility and usefulness than in an abstract notion of truth” [12], I deemed ADR as a suitable methodology for my research endeavors as it is grounded in and grounds research from practice, academia, and empirical data. Its primary focus is on learning from designing an artifact or intervention within an environment. This is important as it was imperative that the solution that I created worked within the complex environment of the medical appointment. My reflections later on in this paper reveal my experience of ADR as a patient and researcher and serve to contribute to the recent open and engaging discussions regarding *problem formulation* in ADR, consistent with the original authors’ contention, who contend that ADR “is still an open endeavor” [13]. First, let us delve into the *problem formulation* stage of ADR in greater depth.

Problem Formulation

In 1998, Berthon et al [14] stated that *problem formulation* was the least researched of problem-solving activities. In 2018, Mullarkey and Hevner [10] reported on the challenges they had regarding the *problem formulation* stage of ADR. More specifically, they discovered that they “needed to better understand the problem space” [10] and maintained that the ADR model by Sein et al [5] required an explicit *diagnosis* stage (with a clear separation from design) model “to analyse the importance of the problem domain and the relevance of the IT solution class to research and practice” [10].

What Is Problem Formulation?

Simply put, *problem formulation* is the sum of problem ID (perception), problem definition (conceptualization), and problem structuring (instrumental reasoning). “The first requirement with any complex problem is to try and understand it as a totality. How has it arisen, and why? Where is it going and what route is it taking? Is it changing its nature or structure as it develops?” [15]. The *problem formulation* stage in ADR (Textbox 1 presents the tasks in the stage) identifies and conceptualizes (using both divergent and convergent metacognitive processes) a research opportunity based on existing theories and technologies [4], where the research activity is said to be problem inspired [16,17].

How important is the *problem formulation* stage of ADR? The value of a suitable definition has been established empirically [18]: “The more of the context of a problem that a scientist can comprehend, the greater are his chances of finding a truly adequate solution” [19]. Mintzberg et al [20] argue that *problem formulation* is “probably the single most important routine, since it determines in large part, however implicitly, the subsequent course of action.” However, Mitroff et al [21] maintained that problem forming and defining are as critical, if not more so than, problem solving. This is probably not surprising as our understanding of a problem greatly influences our selection of solutions [22] and helps avoid type III errors, solving the wrong problem [23].

Textbox 1. Tasks in the problem formulation stage of action design research [5].

- Identify and conceptualize the research opportunity
- Formulate initial research questions
- Cast the problem as an instance of a class of problems
- Identify contributing theoretical bases and prior technology advances
- Secure long-term organizational commitment
- Set up roles and responsibilities

Why Is Problem Formulation So Challenging?

According to Mitroff and Featheringham [24], one of the most important challenges of the problem-solving activity is solving the *wrong* problem by adapting a formulation that is either too narrow or inappropriate. So, one may well ask why *problem formulation* is so challenging? In Textbox 2, I have tried to encapsulate some of the key challenges to *problem formulation* that have been reported in literature.

How Might Problem Formulation Be Done Better?

In their ADR process model, Mullarkey and Hevner [10] argued that every iteration should go through *problem formulation* and

that reflection and learning should also be executed in every cycle—mainly as it informs the *problem formulation* for the next ADR iteration. They also included a fourth ADR stage *evolution*, as a means to address the very temporal and evolving nature of both the artifact and the problem environment.

Sein and Rossi [8] agreed that these modifications were a *valuable* addition to their initial model (which did not go into details) in terms of making it more *transparent* and *accessible to researchers*; they do however point out that this was intentional “because in launching a new method of doing DSR, we wanted to keep it at a broad enough level of abstraction to allow the actual application of the method to emerge in use.”

Textbox 2. The challenges of problem formulation.

- Problems, by their very nature, are complex and ill-structured [25-27].
- “In real life there is not a single, static, well-defined problem, but a constantly changing problem.” [28]
- “The capacity of the human mind for formulating and solving complex problems is very small compared with the size of the problems whose solution is required.” [29]
- Stakeholders may have conflicting interpretations of a problem resulting from different life experiences, competencies, goals, and values [23].
- Human biases: “fixated on these unwarranted assumptions, and this fixation interferes with the insight needed to solve the problem” [30].
- People often are too quick to move on to evaluative stages of problem solving rather than gaining a complete understanding of the problem [31].
- “We may be too ready to re-use features of known existing designs, rather than to explore the problem and generate new design features.” [32]
- People often only identify the most obvious symptoms, or those to which they are most sensitive, resulting in the problem being described inappropriately [24,27].
- Most companies are not adequately thorough in actually defining the problems they are trying to solve [33].
- “Problem formulation” has been shown to be highly dependent on the mode of problem presentation [34-36].
- Changing problem presentation modes has considerable effects on mental model formation [34], where Simon and Hayes found that “innocent changes in language had major effects on problem formulation.” [37]

When several stakeholders are affected by a problem, all viewpoints must be taken into consideration for a solution to be deemed successful [23]. After declaring the problematic gap, it is advisable to specify evidence supporting the presence of that gap. Indeed, Brody [38] raises the question, should problem statements include an “as evidenced by” clause? Moreover, Mitroff et al [21] advocated the use of assumptional analysis to question any assumptions, projections, and explanations lying beneath the problematic statement, whereas Lyles and Mitroff [25] also proposed that alternative views of the problem be sought to improve *problem formulation*.

The use of conceptual processing and mental models is also encouraged in DSR literature [39,40] to assist the *problem formulation* stage. Interestingly, Lesgold [41] discovered that

experts expended additional time deciding an appropriate mental model of a problem than did novices. This may be explained because “what we understand and how we understand a situation depends on the information we bring to a given situation, and the longer we think about the situation the more its cognitive representation changes. It may be assumed that cognitive elaboration activates more schemata” [42] and hence enriched *problem formulation*.

Like any good story, it is important to first set the scene, facilitating an appreciation for key contextual elements of the story that I feel are important to comprehend, and so, we now move to the next section, that is, the research setting.

Research Setting

It is 11:27 AM, it is a pleasant day outside, the sun is shining, summer shows visible signs of its arrival in the garden outside, with many perfumes and aromas creating an exciting olfactory feast. It seems appropriate that I start this paper on this date, May 25, 2019, as it is my sister Jane's 50th birthday, and she was one of the key motivators and sources of inspiration for my research journey. Unfortunately, I cannot celebrate this special occasion with her as she passed away with CF on July 29, 1997. I feel an intense sense of sadness mixed with emotions of happiness as the memories of her sail across the horizon of my memory.

I have witnessed the effect that her passing has had on my family. I have seen the agony and the physical effects that the death of my sister has had on my dear parents. I will never forget that day. I will never forget the life-support machine flat-lining, the tears, the pain in that intensive care unit; it will live with me forever. The experience of her end has left an indelible mark on me not only because of the pain of her passing but also as I have CF myself. I have also lived through the hardship that one endures with CF. I have faced the dark shadows that come into a room when gasping for breath, where one's mortality becomes all too real.

After my sister's death, I had a choice; to let this disease define me and become a bitter, negative person who craved self-pity or to embrace the positive aspects that the disease had carved out or sculpted into my heart and mind. You might ask what do I mean by positive? I mean the appreciation for life, for family, for fun, and for being able to breathe. I mean the ability to empathize with others and to be compassionate to another person's suffering. I wanted to make a difference, to give something back, as others have given to me, which has resulted in my own good health. I wanted to help others with CF who are going on their own difficult journey, a passage that has many dark and difficult days.

Although I admit that living with CF is not always easy, I have always been a fighter, I had to be! I would not give into myself or my condition, I love life too much. Life has so much to offer, alas many take their lives for granted. Moreover, I think when you are faced with the very serious question of your mortality at a young age, you learn to be truly grateful for the gift of life. That is the real reward of a chronic condition, and it became the match that ignited the fight and passions within me.

My appetite for learning and wanting to help other patients with CF and their caregivers was really kindled in October 2014 when I returned to postgraduate executive education, and it continues to burn brightly. For those who know me best, it probably comes as no surprise that I have become a researcher. Even at an early age, I was quite inquisitive and sought to explore and understand the world around me. However, it may surprise you to know that my first attempt at research failed miserably. I was just 7 years old, and I was trying to make sense of how one could get a liquid (in this case, petrol) to rise in a tube. I thought it fascinating until I imbibed or inhaled a gulp of it and also flooded the neighbor's driveway. I was the talk of the neighborhood for about a week. Thankfully, it did not

end in complete disaster, nor did it quell my inquiring mind, but I am sure I scared my poor parents half to death. This event became known as the *petrol episode* (Figure 2, in yellow).

It is a day that we at home do not speak of too often, except to remind me that I am capable of some awful blunders and that research does not always go according to plan. However, I like to think that that day in May 1979 gives you the reader a little glimpse of the character that I am, spirited, curious, and not afraid to explore!

Many would contend that, as a patient with CF with over 47 years of experience living with CF, I was the perfect candidate to research or explore and understand the associated problems of memory recall within the medical appointment. And yes, there is no doubt that I had the ability to impart rich CF-related information to the project; however, quite quickly, I became very cognizant of the fact that my illness journey (although sharing similarities with others) was my own unique voyage, with all the biases of any individual. Recognizing this and taking advantage once again of the robust ties that I had within the CF community, I enrolled 2 caregivers of patients with CF into a design team and a clinician specializing in CF to reduce the bias that I brought to the ADR project and to enrich the knowledge of the collective.

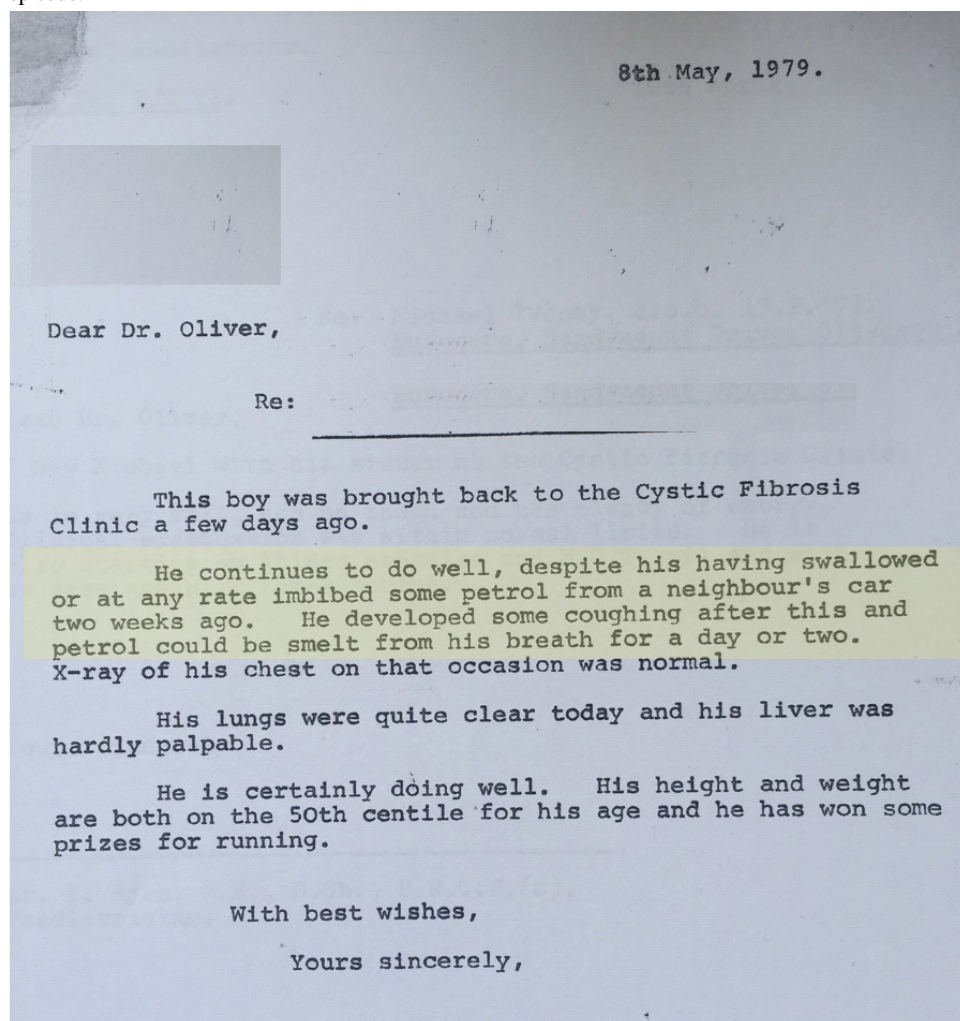

My patient-inspired investigation was driven by what eventually became the following motivation: how might I augment the memory recall or information retrieval of patients with CF and their caregivers within the elicitation and elucidation phases of the medical appointment?

Having attained ethical approval from the University College Cork Social Research and Ethics Committee, my primary focus eventually (discussed later) became the design of a checklist artifact over a 10-month period (September 2016 to April 2017). A checklist that would not only ameliorate the challenges of memory recall within the CF medical appointment but also augment our actual comprehension of these same challenges.

My research activity occurred in 3 iterative ADR cycles. Each iteration comprised rigorous naturalistic evaluation, involving subjective ex post interviews between myself and the evaluation team (7 adult patients with CF and 11 caregivers of children with CF), regarding their use of the artifact within their real-life medical appointments. In these evaluation interviews, I used qualitative metrics evaluating completeness, usability, robustness, and impact (Multimedia Appendix 1) [43], which helped shape our sensemaking process.

In tandem with this, I also sought expert opinions from clinicians on their appraisal of the checklist design and its subsequent use by patients with CF and their caregivers. These activities were followed up with learnings, reflections, and frequently additional consultation with the literature, followed by conformity by the design team on the design enhancements to be executed in any subsequent iteration, incorporating the intervention strategy of the same.

I now visit the next section of the paper, starting with the model of reflection I opted for, and the reflection (through 4 vignettes) on *problem formulation* within my ADR journey and its significance to efficacious outcomes.

Figure 2. The petrol episode.

Reflection on My Action Design Research Journey

Model of Reflection

In 1988, Gibbs [44] argued that it was “not sufficient simply to have an experience in order to learn; without reflecting upon this experience it may quickly be forgotten, or its learning potential lost. It is from the feelings and thoughts emerging from this reflection that generalisations or concepts can be generated. And it is generalisations that allow new situations

to be tackled effectively.” After all, “we learn from reflection on experience. Reliving of an experience leads to making connections between information and feelings produced by the experience” [45].

Many of the seminal works on reflections or reflecting served as the initial stepping stone of my reflection in this paper. Although many models exist as possible viewpoints from which one might reflect, I opted to use Driscoll's What? Model of reflection [46] (Figure 3), as I felt it resonated with me the most as an instrument to steer my reflection through the often-murky waters of my inner self.

Figure 3. The What? Model of reflection - adapted from Driscoll.

Furthermore, as a reflection can be very personal and tacit in nature, it can be quite a challenging exercise or experience in and of itself. For example, it can take considerable time and may be painful and may even create a crisis of confidence [47]. That being said, it “offers distinctively grounded opportunities to pursue the connections between biography and social structure” [48]. Moreover, “reflection allows us to draw conclusions about our past experiences and develop new insights that we can apply to our future activities” [49].

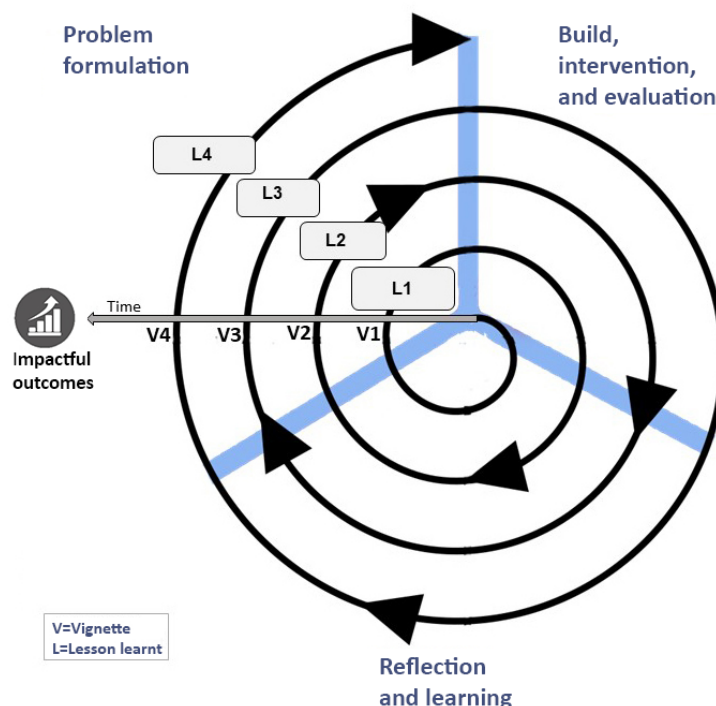

Therefore, I felt it important to select the correct lens for me, one that would facilitate the recapture of my real-world experience rather than curtail or hinder the narration of my ADR journey as a patient and researcher. I reflect (using a series of 4 vignettes and Driscoll’s model) on an aspect of my ADR journey that I feel quite passionate about, that of the *problem formulation* stage of ADR, and of course its value to the fruitful outcomes of my study. I have also added a lesson learned in each vignette; this is merely to reinforce the key message I wish you, the reader, to take away from my meanderings.

Although my ADR journey is still ongoing, the paper-based checklist aspect of the project, the majority of which took place over a 10-month period (from September 2016 to April 2017), culminating in the creation of a checklist booklet in January

2019, is for now complete. It is this period that I wish to reflect upon, a *reflection on action* or a reflection through review as described by Schon [50], the process of review to inform learning [50].

However, it is also important at this juncture to accentuate how and where these vignettes and learnings arose in the context of the overall ADR project. To this end, I include a simple diagram (Figure 4) that depicts the vignettes and learning in the context of the emergent, cyclical nature of the ADR project and its eventual outcomes. Although this reflection focuses on the *problem formulation* stage of ADR, it is critical to never lose sight of the fact that this stage moved in tandem with the other key stages of ADR.

These stages of ADR are akin to dancers performing the Tango, moving together in a closed embrace, individually and yet as one, influencing each other, each receptive to the other’s movements, shaping and being shaped by each other, all to a combination of an on-and-off-beat rhythm. It is in this spirit that I wish the reader to embark with me on my ADR journey. Although I try to minimize the use of any references, where I have used them, it is merely to enforce or enrich the musing of my ADR journey. And so, we move to my first vignette.

Figure 4. Visualisation of reflection within the context of the ADR project, where V=vignette and L=lesson learnt.

Vignette 1: Tragic Thursday—September 2016

What Happened?

It was September 8, 2016. I was giving a presentation to my class on my efforts to date. I stood there like a proud peacock, chest out, boldly claiming the problem statement to be as follows:

There is currently no Patient Electronic Medical Records (PEMR) System that caters for the needs of CF patients or caregivers.

Therefore, patients with CF and their caregivers needed an app to manage their medical data. What is more, my design team and I were going to deliver it. We had created a number of wire-frames for each screen of the app, and here I was presenting them, “at long last CF patients and caregivers would no longer struggle in their medical appointments when asked by physicians about their medical histories” I said. Moreover, “when they leave the medical appointment, they will not struggle to remember the information imparted to them by the physician, it will sit on their phones and tablets and eventually in the cloud.”

And then it came, “I’m not convinced, I don’t think they will use it, I don’t think you have a handle on this yet” my innovation lecturer said. It was like he had pulled the rug from under me; I stood there shocked! The conversation that ensued between me and the lecturer (I am embarrassed to say) got somewhat heated, and what made the whole situation worse was it all happened in front of the entire class!

I returned home; the day had not gone as planned; I was very frustrated and quite upset; I had been publicly challenged regarding my solution and indeed the problem I thought I was trying to solve. I was now sitting in the kitchen with my head

in my hands; I was not in a good place. Why was I having such difficulties with the *problem formulation* stage of ADR? My wife and child came into the kitchen and knew by my demeanor that all was not well. “What happened, did the presentation not go well?” she asked. “No, it was awful” I replied. “Let’s talk later” she said with a quick glance at our little boy.

Later on, that evening, I proceeded to give her all the gory details of what had happened. However, I did not realize my little boy (of 7.5 years) was listening as he had left the kitchen and had gone upstairs to his bedroom before the regurgitation of my day. However, as you know, children occasionally have a happy knack of overhearing or eavesdropping on discussions that they should not be privy to. This, despite our best efforts to protect them from the trivialities of adult conversations, and so, after ascertaining the gist of what had happened to me, he enters the kitchen with the swagger of a man who was going to expound some wonderful insight, and says “Daddy wouldn’t you think that after all the trips to the doctor that you have had, that you would understand what happens at a medical appointment?” I was left dumbstruck. I now refer back to that particular day as *tragic Thursday*, and yet on reflection, there was nothing tragic about it, in fact, the complete opposite is true; from that day onward, my eyes were going to be opened! I was going to realize the importance of this day as a turning point in my research.

So What?

I refer to the earlier event merely to illustrate my toil within the *problem formulation* stage of ADR. Although Sein et al [5] outline this as the first stage in ADR, they, unfortunately, do not refer to *how* one might or should go about *problem formulation*. I, probably like many others before me, ran into the solution space, convinced that I understood *the problem* that needed to be solved. I really thought after the presentation on

tragic Thursday that I was the issue and that I may not be the patient or researcher for the job in hand. So, was it just me?

Well, yes and no. Let me clarify; as the earlier background section on *problem formulation* exemplifies, there is a lot more to *problem formulation* than one might initially think. Unsurprisingly, as we saw, we humans are not always logical in how we approach problems. We hold many biases and repeatedly make suppositions becoming fixated on unjustifiable assumptions [30]. These faults within humans often run counter to the successes that we strive to achieve and to the challenges that we strive to overcome.

Furthermore, solution fixation often results, leading to adverse consequences, precluding or hindering in-depth questioning or interrogation of problems, and prematurely freezing a problem space before it can fully form. I think the most unfortunate negative effect of poor *problem formulation* is on the divergent exploration of the creative possibility in design. I was an exemplar of this behavior, as a patient living with CF for 48 years, with countless visits to physicians, I thought I knew the problem *inside out*. As far as I was concerned, I had conducted an initial survey of 305 patients with respiratory illnesses and their parents back in 2015, and 77.9% (280/359) said they had difficulty in remembering their medical history. Furthermore, over 95% of them said they would use a secure app if one existed. I had taken offense to being challenged. I remember thinking, *what the hell does he know?* My ego had thwarted my ability to hear and appreciate the very sound advice that was actually being imparted to me.

Thankfully, I am not a stubborn fellow, and sense prevailed. I have since become a lot humbler and more open to criticism. I suppose, as a patient who has faced the question of my mortality at a very young age, I have become somewhat resilient, accustomed to picking myself up, dusting myself down (this often involves giving myself a good telling off, including the words—“*stop feeling sorry for yourself, remember why and who you are doing this for*”) and getting on with it. After all, someone had to resolve the issue, and if not me, then who?

Moreover, had *tragic Thursday* not happened, I would be sitting here on this Saturday afternoon in February 2020 (like many others before me) with a failed app. I most definitely would not be boxing up a solution for departure to the Royal London Children's Hospital, London. A solution that, in the coming weeks ahead, will grace the laps of caregivers all over southeast England, within their real-world medical appointments.

Now What?

As we established earlier, I was not alone in my thoughts and tribulations regarding *problem formulation*. Mullarkey and Hevner [10] and others had also reported complications with this stage of ADR. My challenge then was to be mindful of the real need for an in-depth implicit problem analysis and to understand and define the information problem that patients with CF and their caregivers face during their medical appointment in tandem with a solution/s to ameliorate the same. My next design workshop was calling.

My first lesson learnt (L1) was as follows: If we wish to achieve successful outcomes, *problem formulation* requires a

conscientious focus on problem comprehension, avoiding *solution fixation* and other assumptions.

Vignette 2: So, What Is the Problem Again? —September 2016

What Happened?

I was sitting in the car in mid-September 2016. I was on my way to a workshop, looking forward to working with my design team, I was excited but also extremely nervous, it was only a week ago that my ship (I call the patient innovator) had taken a flurry of shots across the bow and nearly sunk, joining all the other vessels who had failed to survive on the wicked high seas in the world of innovation.

Many thoughts had been incubating in my head since *tragic Thursday*. My metacognitive processes were working furiously; my thoughts were a mix of emotions and ideas; to anyone brave enough to look inside my head, it would look *really messy*, like my room when I was a kid. I replayed the many medical appointments that I had attended in my mind, in tandem with all the literature that I had read in the area since autumn 2014. Although I had identified a problem or anomaly in the medical appointment, the issue that I now endeavored to solve was to understand and define the problem that patients with CF and their caregivers face during their medical appointment and delineate it in a way that made sense to me and others. Suddenly, a memory popped into my mind, vis-à-vis the time I endeavored to explain the issue to my darling wife for ≥10 min, after which she turned around and said, *so*, “what’s the problem again?” Moreover, I needed to be able to classify and represent the problem in a way/s that would assist my design team and I to see how we might best deal with it.

I was struggling; my experiences as a patient with CF alone were not sufficient to articulate and solve the problem. I felt as if my mind was constantly being polluted by irrelevant details and assumptions. I could feel my heart beating faster; questions flooded my mind; how was I going to structure or represent the problem? How broad was the problem? What were the constraints? What knowledge was needed to understand and solve it, and what gaps existed in my or our current knowledge base? What external and social factors would come into play? What strategy would we adapt? What did success look like? It was going to be a thought-provoking, challenging workshop!

So What?

Let us be honest; we all face problems of one kind or another every day of our lives. A 1-year-old may face the problem of how to stand unaided, or how to escape from their cot, the Alcatraz of their world. On the other hand, teenagers face the challenge of living in the evolving world of social media, acceptance, bullying, and so on. Problems come in all forms, some are simple, some are quite complex in nature, and others have an undeniably *wicked* composition.

Although there is a myriad of difficulties within the medical appointment, I needed clarity regarding the specific enigma (or part thereof) that I was going to focus on. I needed to avoid or at least be aware of the symptoms that were polluting and confusing the situation I was trying to remedy. Those related

to other problems and yet overlapped with mine; otherwise, my ability to make sense of the issue with my design team was going to be a long, arduous process, one which would most likely end in failure. My design team and I needed to find an appropriate representation of the problem we had identified within the medical appointment, one that would give us insight/s to an appropriate solution pathway. Although my experience was beneficial and useful, it was only one CF patients' voyage and nothing more; there were many more patients with CF and their caregivers that also had their story to tell, stories that would enrich our comprehension of the problem space. However, how should I go about gathering such insights?

The problem I found with the ADR methodology is twofold; first, it appears to hold a rather technocentric view of innovation; by this, I mean it does not seem to take into account the often-idiosyncratic nature of humans. This is evident in the lack of guidance on *how* we might or should come to truly understand the people behind a problem. For example, Who has the problem? Why is it a problem? What do they think? What really matters to them? What do they feel as they toil within a problem space? and so on. The ability to garner such fundamental human insights is crucial to disentangling, understanding, and defining a problem. Second, not enough emphasis seems to be placed on the *problem formulation* stage of ADR. It is almost portrayed as if *problem formulation* is a straightforward process, when in reality, the opposite is often true; it is frequently wicked and ill-defined.

Now What?

Arlin [51] argues that for a problem to be real, there needs to be a *felt need* to eradicate any impediments to an objective. Considering these words further, they conjure or evoke thoughts of sentiment, of emotions, the very essence of what makes us human. Therefore, to pursue ADR within the context of the social environment of the medical appointment, I also needed a deeply human-centered mindset, an approach that was profoundly human in and of itself. Unfortunately, I found ADR wanting in this regard.

In contrast, design thinking focuses on a user's experiences and the emotions that are encapsulated in such events. Design thinking is a human-centered design methodology that "relies on our ability to be intuitive, to recognize patterns, to construct ideas that have emotional meaning as well as functionality, to express ourselves in media other than words or symbols" [52]. As one might imagine, some of the core principles of design thinking are empathy with users and discipline of prototyping.

Emotions are an integral part of what makes us human. Therefore, my design team and I began a series of design thinking workshops, beginning with a number of design thinking tools, from personas (Multimedia Appendix 2) to empathy maps (Multimedia Appendix 3) and journey maps (Multimedia Appendices 4 and 5). This meant spending a great deal of time with fellow patients with CF and their caregivers discussing the many facets of living with CF, their experiences (building on mine) within the medical appointment, and capturing their reality of being a patient with CF or having a child with CF, which are unique perspectives that were both profound and deeply

insightful and often times quite moving. Empathy became the key to helping define the problem, but why empathy?

Many different interpretations of empathy exist from sharing the feelings of others and comprehending the emotions of others [53-56] to feeling what another experiences and the ability to appreciate the views of others [57]. Although we shared a medical condition, our life journeys are our own, unique, molding us, and shaping us into individuals. I came to understand the experiences of other patients with CF and their caregivers, assisting me to feel what they felt, I came to comprehend the stress they experienced living with CF, something that they (and I) have learned to manage daily. I heard of their experiences of holding a conversation with physicians while being short of breath, described by an adult patient with CF:

I was gasping for air, and trying to remember stuff for the doctor.

A young mother of a child with CF explained to me what it was like trying to list the medications that her child was on at a particular medical appointment:

My 5-year-old child was really sick with a chest infection, she was crying due to the pain in her lungs, it was impossible to concentrate, it felt like I had 500 things going through my head, I was so stressed. I remember thinking, what if I make a mistake? What if I leave something out? I felt so guilty and helpless at that moment.

Although insightful, I confess that, at times, I found this aspect of the project very difficult from a personal perspective. However, I learned to manage my own feeling quite quickly, forcing myself to compartmentalize my thoughts and feelings when and as required. I knew that this was critical if I wished to succeed and avoid floundering on the rocks in the sea of my own internal thoughts and emotions.

Nevertheless, it is important to note that it was through this appreciation of the problem through the senses and experiences reported by other patients and caregivers that we (my design team and I) would come to realize that a technocentric approach to the problem was not an appropriate starting point. It was only by really listening to what the patients and caregivers were telling us that we came to grasp what we were really dealing with. They were not, in fact, talking about apps or technology at all; they were complaining about their needs regarding their information and their frustrations regarding access to their medical history when and as required. A patient explained:

If I'm away traveling, I need to have my medical information at hand in case I get sick. I can't walk into a doctor who knows nothing about me or my condition. This happened to me before and I was put on the wrong treatment. It was very upsetting; I could have died.

My design team and I eventually settled on the following new problem statement: "CF patients and caregivers are not having their information needs adequately addressed within their medical appointments."

Interestingly, renowned cardiologist Eric Topol [58] argued that “patients exist in a world of insufficient data, insufficient time, insufficient context.” In line with the principles of design thinking, we decided to engage in prototyping (paper-based prototyping) in the form of a checklist to aid in our comprehension of initial interest and actual usage by users of our solution. The prototype was designed for patients with CF and their caregivers to fill out before and during the physician’s appointment. Prototyping (conceived by Alberto Savoia [59]) also made sense as it enabled the smallest investment of time and money possible, while still facilitating the capture of distinctive insights from users of the checklist within the context of the medical appointment. The checklist prototype was also prudent as a precursor to any digital solution that we may eventually embark on. It also steered me clear of *falling in love* with any early solutions. I wished to avoid another tragic Thursday. Checklist iteration 1 was designed and released at the end of September 2016 (Multimedia Appendix 6) [43] with evaluations conducted at the end of October and through November 2016 (Multimedia Appendix 1) [43]. Interestingly, even at this early stage, the checklist demonstrated positive outcomes, with 81% of participants reporting better memory recall as a result of using the checklist.

My second lesson learnt (L2) was as follows: *Problem formulation* requires in-depth human-centric exploration—scrutinizing a problem thoroughly through the senses of those who experience it, understanding how it affects them, and culminating in the articulation of an accurate problem definition and more positive solution outcomes.

Vignette 3: Teaching an Old Dog New Tricks—May 2017

What Happened?

It was a beautiful morning in May 2017 and I was out walking my dog, *Suzy*, down in the local forest not far from home. There was a very light breeze, the trees gently swayed to the dawn chorus of bird acoustics, a melody of song and calls. I had recently completed iteration 3 [43] (Figures 5 and 6) of the checklist, and thankfully, the evaluations were very positive (Multimedia Appendix 1) [43], with the artifact having major impacts within the CF community. Here, patients and caregivers reported reduced stress and increased empowerment as a result of having their medical information with them during their medical appointments and, of course, afterward. The checklist really appeared to work, but why was it working so well?

What had we done that seemed to be tipping the results in our favor? Our enhanced understanding of the problem definitely seemed to be manifesting itself in the delivery of an improved solution? However, I had this innate feeling that I was missing something, that we still had not achieved an absolute sense of why the checklist was so impactful? I was bothered.

I proceeded down the forest path toward this small brook in which my dog was playing. She was play acting with a stick, when much to her dismay she dropped it, and it disappeared into some sort of small drain. I watched her with as much a sense of curiosity as amusement, as she endeavored to retrieve her prized possession. She approached the drain from one angle, then another, and then back again. This all went on for a number of minutes, it was clear from her expression that she was engaging the very limits of her cognitive abilities, as she tried to make sense of the predicament. Eventually, she managed to work it out, after several failed attempts doing it one way, she suddenly approached the problem differently, in a simpler fashion, she had her stick again!

My mind wandered back to my own thoughts, was there other ways that I should be tackling or viewing the information challenges that patients with CF and their caregivers were experiencing as well? Surely there were additional ways from which I could view the problem and solution, possibilities yet to be considered, ways that may come to enlighten me as to why the checklist was begetting such light into the often dark setting of the medical appointment with regard to memory recall. I was convinced that there was more to learn and more to understand, and yet, every time I tried to think about it, I found myself back where I started. It was like a neural impasse, as if the mental pathways in my mind were predetermined, immovable objects, defeating my abilities to explore new possibilities and new ways of thinking. I grew frustrated; my mind was tiring. I kicked a stone into the brook, “if only we had a more advanced memory, akin to some sort of futuristic form of Artificial Intelligence then there wouldn’t be this stupid problem” I thought. And then just like my dog a few moments earlier, a new thought entered my mind, “If we had perfect memories, we would not need a solution.”

The problem I thought was not really *information needs* as much as the limitations of human memory, arguably defective, often resulting in an inability to remember, a failure to recall memories on demand, and a malfunction of our biological information retrieval system. Inadequate *memory recall* was the real problem, it had been there under my nose all the time, and yet I failed to see it, until now, months later.

So What?

The abovementioned vignette reminds me of the American inventor and engineer Charles Kettering when he declared that “a problem well stated is a problem half-solved” [60]. So, what exactly did Kettering mean here? Do we take from his statement that once a problem is stated, we are halfway to a solution? Or does he infer something more arcane, that even with a well-stated problem, there is abundant knowledge yet to be

unearthed, comprehended, and considered, regarding how and why solutions perform as they do within their intended environments? Having traveled through my ADR experience, I think he may well have intended for us to appreciate both in combination and individually.

In May 2017, I really realized and appreciated the richness of looking at a problem through multiple lenses. I was also amazed at how static my cognitive frameworks or schemas were. Moreover, I was amazed at how long I had stayed in these

cognitive states, unable to move, paralyzed if you will, this despite numerous evaluation interviews with patients and caregivers and workshops with my design team. Why had it taken so long for the older mental model to be replaced and augmented with a new one that would enhance my explanatory power? Was it the assumptions I was making while trying to make sense of the complex environment of the medical appointment? Had I become locked in on a particular mental representation of what I perceived was the *sweet spot* of the issue?

I mentioned earlier that “what we understand and how we understand a situation depends on the information we bring to a given situation, and the longer we think about the situation the more its cognitive representation changes. It may be assumed that cognitive elaboration activates more schemata” [42]. I was fascinated by this and yet cautious, what other points of view had I not considered? In spite of these contemplations, I decided that I would refrain from tormenting myself and spoiling this moment in the process.

I had no doubt that as I continued on my voyage, I would discover new ways of thinking of framing my understanding. However, a sense of balance and perspective is required; one must avoid entering a state of *analysis paralysis*. As the esteemed English writer Samuel Johnson once said, “nothing will ever be attempted if all possible objections must first be overcome.” I would take each enlightenment as it came, relishing the cognitive challenge that each schema would bring.

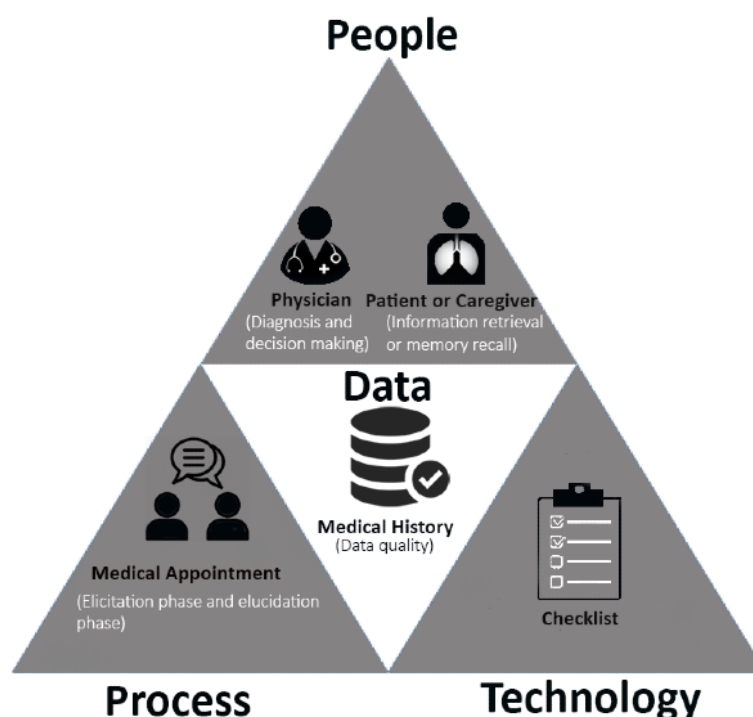

More than one account of a complex system is achievable, where altered portrayals will break the system down in diverse forms, and changed descriptions may also have altered levels of intricacy. I was both relieved and excited that I had discovered a new viewpoint from which to perch my telescope of inquiry. Moreover, I felt an augmented confidence ignite within me, the cause of which was twofold; first, I now felt more assured regarding my grasp of the actual problem, and second, I sensed more confidence in my appreciation as to why the checklist was functioning so well for patients with CF and their caregivers.

Now What?

I relayed my thoughts to my design team, and we came up with a new problem statement: *The challenges of memory recall or information retrieval that CF patients and caregivers have or experience within the medical appointment are not well understood or solved.*

This made a lot more sense to all of us, and so taking a people, process, technology, and data view, we created a model (Figure 7) to depict our new representation or understanding of the problem, including the roles of memory recall or information retrieval within 2 key information stages of the medical appointment. I have also expanded on each of these people, process, technology, and data concepts as they pertain to the medical appointment in Table 1. The usefulness of Figure 7 and Table 1 is twofold: first, to depict my interpretation of the problem, and second, to highlight the advancement of my comprehension of the various interacting or moving components within the problem space.

Figure 7. People, process, technology, and data.

Moreover, I came to realize why the checklist was so effective, it was in effect acting as a tool aiding the long-term declarative memory of the patient and caregiver during their medical appointments. From another perspective, one could say that it achieved this by actually relying less on the patients or

caregivers' own memory and more on the checklist within the appointment. Patients and caregivers now came prepared with the information required within the elicitation phase of the medical appointment already written down in front of them.

Moreover, they had a placeholder to capture key information within the appointment as well.

Table 1. People, process, technology, and data model concepts.

Concept	Reference
People	
Physician	
The purpose of the medical appointment is to “make the diagnosis.”	[61]
The consequences of poor memory recall or information retrieval are: On the quality of information imparted to a physician, the ability to make an effective diagnosis and treatment decisions, and impacts on patient outcomes.	[62]
Clinician satisfaction	[63]
Patient or caregiver	
Research shows “that memory for medical history, like other forms of autobiographical memory, is likely to be flawed, incomplete and erroneous.”	[62]
Process	
The elicitation phase	
Physician and patient or caregiver participate in a bidirectional conversation regarding the patient’s medical history, current well-being, current medication, and so on.	[64]
Furnishes the physician with 60%-80% of the data required to make a diagnosis.	[65-67]
The elucidation phase	
Physicians communicate diagnoses, clinical options, and self-care plans, in tandem with overall advice regarding the management of a medical condition/s.	[68]
This phase directly impacts patient adherence and other self-managing activities, such as regime change.	[69]
Technology	
Checklist	
Defined as “a formal list used to identify, schedule, compare, or verify a group of elements or...used as a visual or oral aid that enables the user to overcome the limitations of human memory.”	[70]
Data	
Medical history data includes the following: medical appointments, symptoms, illness episodes, encounters with other clinicians, medical therapies and medications.	[62]

Hence, they would not need to rely on memory when they left the medical encounter either. They had it all in the checklist and could refer back to it as required, even when traveling, if they happened to get ill. It probably comes as no surprise then why patients or caregivers were reporting such impacts on stress and empowerment. Additionally, I really came to fathom the potency of precise *problem formulation* vis-à-vis its impacts on actual outcomes. However, as one might expect, as I delved deeper into the area of memory recall during the medical appointment, I realized there was a lot more to this puzzle than I first envisaged or ever imagined on that beautiful summer morning in May 2017.

My third lesson learnt (L3) was as follows: In the *problem formulation* stage of ADR, we must challenge ourselves to look at a problem from different perspectives and from alternative disciplines. If we have not found or considered alternative viewpoints, we may fail to understand a problem well enough, affecting the most appropriate articulation of the problem definition, and the successful design of a solution or comprehension of why a solution functions as it does.

Vignette 4: Breaking It Down—May 2018

What Happened?

It was a warm, humid day on May 25, 2018; the sky was cloud-flecked; and the various bird songs bestowed a pleasing accompaniment to the day. I was on my way to a symposium in my university to give a presentation on my research. I was nervous; my stomach was making noises, clamoring’s that I hoped were inaudible to the various scholars gathered in the room. I imagined that none would be too fond of hearing such clamoring ascend from my abdomen.

I hoped they would, however, be very interested in hearing how the checklist we had designed, built, and evaluated, functioned so well within the environment of the CF medical appointment. Moreover, following a 9-month rigorous systematic literature review of memory recall within medical appointments, I sought to impart where my comprehension of the problem had advanced to and why carrying out such an activity was fundamental to unlocking the additional knowledge I required in the *problem formulation* stage of our ADR project.

So What?

I had decided to conduct a meticulous literature review for 2 reasons. First, I wanted to understand why the checklist was functioning so well in the medical appointment. Second, I wanted to see if I was overlooking anything, for example, was defining the problem as memory recall or information retrieval of patients with CF and their caregivers within the medical appointment comprehensive or deep enough? I found that the answers to both questions were, in fact, deeply intertwined.

In the first instance, I came to understand that human declarative long-term memory was analogous to many complex systems consisting of components, in this case different memory types: episodic memory, autobiographical memory, and prospective memory ([Multimedia Appendix 7 \[71-77\]](#)). The components themselves are often simple (or can at least in this instance can be viewed as such) and interact with each other through various routes possible among components, mediated in distinct circumstances.

So why was the checklist functioning so well in medical appointments? Henry Ford is noted for saying, “Nothing is particularly hard if you divide it into small jobs.” Breaking down memory recall or information retrieval into its components, studying the physician and patient narratives (supplied by consenting patients and caregivers from real medical appointments), and assigning declarative memory components to each sentence or group of sentences allowed me to unearth a more profound comprehension of the complexities of dialogues within the medical appointment and the variety of long-term declarative memory components used therein. I also came to truly appreciate the pressures that memory recall places on the patient and caregiver, such as recalling a particular episode (episodic memory), time period/s (autobiographical memory), or remembering to report symptoms at an appointment (prospective memory) or a combination of declarative memory types. In addition, I found that the checklist design actually maps to *aid* the declarative long-term memory component drawn upon by the patient or caregiver during the medical appointment. This deeper, more comprehensive level of understanding of memory recall or information retrieval, breaking it down into its components, afforded me far deeper knowledge from which to view, examine, and indeed make sense of the problem I endeavored to solve, and of course as already put forward, why the checklist functioned so well for patients with CF and their caregivers within the complexities of the medical appointment.

Second, although a single checklist simplifies the capture of information at a particular medical appointment and, thus, aids the episodic memory of the patient or caregiver regarding that specific event, I came to understand that from an autobiographical memory perspective, the checklist was still somewhat inadequate. I wanted to support the autobiographical memory of patients and their caregivers in the best way possible, and, although theoretically, one could file away a single printed checklist in a folder after each medical appointment, I decided that this would not suffice. Patients and caregivers have enough

going on in their lives without trying to find another workaround. Being a patient myself, I was sick to death of always having to settle for second rate solutions, solutions that I would later try and adapt to my own needs. On several occasions, I remember thinking, why is it that no one can get this stuff right? Are we (patients) that hard to understand, are our needs that difficult? Or is it that no one really gives genuine thought when designing products for us? I could not be a hypocrite; I had to improve the checklist, no workarounds!

Now What?

First, my design team and I came up with a new problem statement: *The challenges of memory recall information retrieval (and its components) that CF patients and caregivers have or experience within the medical appointment are not well understood or solved.*

Second, after iteration 3, and my comprehension of long-term declarative memory components, we decided to create a professional, physically robust booklet ([Figure 8](#)), with a little help from a professional graphic designer (a friend of mine; [Multimedia Appendix 8](#) shows the final checklist). A booklet containing 28 checklist items, unshackles the patient or caregiver from having to do any workarounds, including any printing. At once, a repository of medical discourse is created, where 28 medical appointments checklists are held together, not only facilitating the episodic and prospective memory of patients and their caregivers but also acting as an autobiographical memory of a specific time span. Searching for a previous appointment/s was now simple and straightforward.

Many may argue that this further exploration was a step too far, unnecessary, and indeed prohibitive for many researchers and organizations in terms of cost, and so on. Although I appreciate these sentiments, I would not agree. If you really care about the user's experience (and you should) and you want to deliver quality impactful solutions, you must be willing to *go the whole nine yards*. In fact, I believe this is the only way to accomplish truly successful outcomes. To do anything else is to cheat yourself, your organization, and, most importantly, the user from what might have been.

Had I not gone deeper, the checklist as a booklet would never have come to pass. Granted, I would have a checklist (as a single page); however, I cannot say I would be confident that a patient or caregiver would continue to go to the trouble of printing a checklist before every appointment, and then file it away afterward. One must appreciate that patients with chronic diseases and their caregivers are busy trying to lead as normal a life as possible, and they often have very complex and time-consuming treatment schedules. Hence, asking what may seem a simple task can, unfortunately, often be the *straw that breaks the camel's back* for a patient or caregiver and hence lead to unused or underused solutions. By having a deeper grasp of the problem, I was able to put this knowledge to good use, advancing to a more robust solution. This, I believe, is why so many are now requesting the checklist booklet.

Figure 8. The checklist booklet.

Additionally, when I explain the rationale behind the workings of the checklist booklet to those with the CF community, including clinicians, I can see that they are really intrigued, and if I may be so bold as to say, excited by the solution. This has of late manifested itself in a large amount of dialogue within the community, much of which I am only now becoming aware of, as it has translated into invitations to various clinical conferences, and international requests to see the checklist booklet, and of course boxes of checklist booklets being taped up on a Saturday afternoon. Checklist booklets that will soon find their way into the hands of patients with CF and their caregivers far and wide.

My final and fourth lesson learnt (L4) was as follows: Going deeper in the *problem formulation* stage of ADR will help to explain observed phenomena, highlight shortcomings in a solution, and enrich problem definitions, resulting in a truly comprehensive understanding of a problem domain and the delivery of truly successful impactful solutions.

Concluding Remarks

Unfortunately, that a small amount is appreciated vis-à-vis how problems are formulated in ADR seems as true today as it was six decades ago. In many of the ADR papers that I have read, there appears to be a very quick shift in focus to the subsequent stages of the methodology, with little mention or focus on the *problem formulation* stage. Moreover, *problem formulation* is seldom mentioned again in manuscripts. This is despite the iterative nature of ADR (Figure 1), where after *reflecting and learning*, the researcher/s refer back to the *problem formation* stage to ascertain whether or not a problem definition has

changed or evolved. This is, of course, not to say that the stages that follow the *problem formulation* stage are not important, quite the contrary, they are also fundamental to an ADR project. Hence, I have included the same again in Figure 9, which, unlike Figure 4 earlier, now includes the lessons learned (as concepts) from each vignette extracted from my ADR journey. You will note in Figure 9 that our impactful outcomes are only attained at the culmination of our journey through iterations of ADR and *problem formulation* exploration and determination.

The question that I still contemplate is, why further regard is not given to this crucial stage of ADR? In my researcher story overlaid on an ADR story, I have sought to bear (through my series of vignettes) how difficult this stage of ADR actually is. I have also tried to portray what can go wrong without a conscientious focus on problem comprehension. Moreover, I have highlighted how beneficial time spent in this stage of ADR is, in terms of research impacts and results. Surely, I am not alone in my struggles as a researcher in *problem formulation*?

As I have already stated, but wish to emphasize once more, it is fundamental to empathize or understand the people behind a problem, what they experience, what they are feeling, and what and how they think, if you wish to deliver truly impactful solutions and sought-after outcomes. Indeed, Southard [78] was the first to articulate the significance of empathy in the physician and patient therapeutic relationship and its role in assisting diagnostic (*problem formulation* within the medical appointment) outcomes. To do otherwise is to deny our humanity, blocking the very comprehension we require to address the often-difficult problems we encounter, as we go about our lives on a daily basis, navigating the many complex systems within which we live.

Figure 9. Visualization of reflection within the context of the action design research project.

In vignette 3, I contended that we challenge ourselves to look at a problem from different perspectives, to be more open to other disciplines, and to be prepared to “repeatedly change our point of view, our way of looking at the problem. We have to shift our position again and again” [79]. This augmented comprehension not only facilitates a more appropriate articulation of a problem but should also liberate insights into why a solution functions the way it does within a particular environment.

However, as illustrated in L4, we must also be willing to probe and dissect these new viewpoints further, atomizing them down into components and concepts, facilitating deeper insights into phenomena, deepening our problem definitions, and thereby enabling a truly inclusive augmented comprehension of a problem. Additionally, such curiosity draws our attention to inadequacies in our solution/s, such as the checklist before it being in booklet form, where it really failed to address autobiographical memory. Through this knowledge, we further enhanced the checklist. Without delving deeper, this would not have happened.

The checklist produced evolved and was shaped, not only by the environment into which it is placed but also by my mind, which also underwent a type of metamorphosis, as empirical findings and knowledge waltzed together to the beat of my heart and the passions and conviction that expounded from within. Time and time again on this ADR project, I felt like I was on a journey of self-discovery, with many twists and turns, good days and bad days, days that taught me some valuable lessons, experiences that sometimes had a real sting to them, but will not be forgotten.

None of it was, of course, in vain; quite the contrary, I know I have made a real difference and continue to change the lives of many patients with CF and their caregivers during their medical appointments. I could not ask for a better outcome in my research endeavors. As pointed out earlier, I put this down to both grit and determination, especially as I have shown, within the *problem formulation* stage of my research. Therefore, fundamental to ADR success is the continuous revisiting of *problem formulation* after each iteration of an artefact, it is only by doing same that we can hope to gain a truly augmented understanding of a problem, and become more confident in designing and in our solution designs. I hope what I have discovered and aimed to impart here proves useful and insightful to those who brave the high seas of *problem formulation* in ADR, helping them to avoid some of the fatuous mistakes that I have made while on this chapter of my ADR voyage. Aiding them reach their intended research destination in one piece, confident that they too, have delivered impactful solutions through an augmentation of problem comprehension.

In tandem with the above viewpoints, I would advocate for the inclusion and portrayal of the actual realities of this stage (as I have endeavored to accomplish in this reflection) to be included and explored by researchers and practitioners. I feel that the insights garnered regarding same would not only bring a sense of realism and humanity to research (a component that I feel is often missing), they would also generate contributions to knowledge in and of themselves, the *how to* or *how I or we* navigated challenges encountered in research.

I miss my dear sister, but I choose to honor her memory by doing something that I know would bring a warm smile to her

face. I will be honest at this moment I have no idea where my researcher voyage will eventually take me, but it feels so right. Like a faint whispering in my ear that gets louder each day, like a fog lifting, giving a clearer aspect to the road ahead. My heart quickens as my quest becomes clearer.

Abstract

Background: Although helping people living with HIV manage their antiretroviral therapy is a core competency of HIV nursing care, no educational intervention has sought to strengthen this competency. Thus, we codeveloped a simulation of a virtual patient (VP) having difficulty adhering to treatment to foster the relational skills that nurses require in such situations.

Objective: This viewpoint paper aims to describe the codevelopment process and the content of VP simulation, as well as the challenges encountered and the strategies used to overcome them.

Methods: We use a collaborative and iterative approach to develop the simulation based on qualitative evidence, theoretical approaches (strengths-based nursing, motivational interviewing [MI], and adult learning theories), and expert recommendations. We carried out 2 main phases: (1) planning the simulation development and (2) designing the simulation content, sequence, and format. We created the script as if we were writing a choose-your-own-adventure book. All relational skills (behavior change counseling techniques derived from MI) were integrated into a nurse-patient dialogue. The logic of the simulation is as follows: if the nurse uses techniques consistent with MI (eg, open-ended questions, summarizing), a dialogue is opened up with the VP. If the nurse uses relational skills inconsistent with MI (eg, providing advice without asking for permission), the VP will react accordingly (eg, defensively). Learners have opportunities to assess and reflect on their interventions with the help of quizzes and feedback loops.

Results: Two main challenges are discussed. The most salient challenge was related to the second phase of the VP simulation development. The first was to start the project with divergent conceptions of how to approach the VP simulation—the simulation company's perspective of a procedural-type approach versus the clinical team's vision of a narrative approach. As a broad strategy, we came to a mutual understanding to develop a narrative-type VP simulation. It meshed with our conception of a nurse-patient relationship, the values of strengths-based nursing (a collaborative nurse-patient relationship), and the MI's counseling style. The

second challenge was the complexity in designing realistic relational skills in preprogrammed and simulated nurse-patient dialogue while preserving an immersive learning experience. As a broad strategy, we created a collaborative and work-in-progress writing template as a shared working tool.

Conclusions: Our experience may be helpful to anyone looking for practical cues and guidance in developing narrative VP simulations. As relational skills are used by all nurses—from novices to experts—and other health care practitioners, focusing on this clinical behavior is a good way to ensure the simulation's adaptability, sustainability, and efficiency.

Introduction

The Role of Simulation in Continuing Professional Development

Professional expectations and social accountability require nurses to pursue continuing professional development (CPD) to reinforce and maintain their competencies, so they can provide evidence-based care and ensure patient safety [1,2]. CPD is typically offered through interactive and/or didactic educational meetings such as conferences, workshops, seminars, lectures, and courses [3]. However, many of these approaches require time, money, and human resources, which are often limited in health care environments [4,5]. There is a need to develop accessible and innovative ways to strengthen nurses' learning and expertise while considering resource availability and workplace realities. The use of virtual patient (VP) simulation, a digital learning modality, is one way to address these challenges and is increasingly used in contemporary nursing education [6].

Virtual Patient Simulation and Education for Health Professionals

VP simulation is an interactive computer simulation that depicts real-world scenarios with the goals of training, education, and assessment [7] for health care professionals. A VP enables learning in a nonjudgmental, ethical, and safe environment [4,8-10] as learners acquire knowledge and develop skills by learning from their mistakes, without harming patients [11]. The use of VP simulation in health professional education is growing exponentially, considering the number of reviews published in the field [6,12-15]. Although the populations included in these reviews are mainly undergraduate and postgraduate students and health care providers in medicine, nursing, and other disciplines, we found only 1 integrative review focusing exclusively on web-based simulation in nursing programs [6]. Thus, it is relevant to explore the use of VP simulation as a means of supporting CPD for nurses.

On the basis of the needs identified by nurses providing HIV care in a qualitative study [16], we developed a VP simulation aimed at improving the nurses' relational skills consistent with motivational interviewing (MI) [17] in situations of antiretroviral therapy nonadherence. MI is a person-centered, collaborative communication style that seeks to elicit people's motivation and commitment to change. A systematic review conducted by Shingleton and Pafai [18], which included 41 studies, aimed to characterize the use of technology-delivered MI interventions

and their efficacy at changing various health-related behaviors among several populations. One of the authors' recommendations was to provide details, for instance, in methodological papers, on how the relational (eg, empathy) and technical (eg, confidence rulers) components of MI are translated into a technology-delivered intervention.

Insufficient Guidance for Developing a Specific Type of Educational Intervention

Several approaches exist to develop interventions aimed at improving health [19] and supporting behavioral change by health care professionals [20]. Relative to a taxonomy of eight approaches to intervention development [19], we locate ours as a specific type of intervention and behavior [21] because of the following elements: its modality (VP simulation), the action to be performed (adoption of relational skills consistent with MI), the actors performing the action (nurses and, more broadly, all health care professionals), the target behavior (medication adherence), and the recipients of this action (patients who are living with HIV or not). Developing such a specific intervention was challenging, given that we faced a scarcity of operational and practical guidelines for doing so, particularly with regard to creating and translating the relational skills into preprogrammed schemes of communication between the virtual nurse and VP. Although we strongly believe in the value of development frameworks [19,20] to broadly inform intervention development, these frameworks are not intended to offer the extensive and practical description needed to guide the creative process of translating relational skills into an intervention-specific VP simulation. Furthermore, while the evaluation of interventions is well known to be a core research activity, the interventions themselves and their methods remain poorly described in the literature. Cheng et al [10,22] supported the importance of providing a detailed description of the development process of simulation.

Relevance of This Viewpoint Paper

This viewpoint paper attempts to fill the gaps cited earlier. In addition, this study may be helpful to VP simulation developers, educators responsible for CPD, and health care professionals wanting to undertake such an endeavor. At the same time, as our paper ensures transparency in reporting the development methods, the components of the VP simulation (including its content), and the lessons learned, it provides insights into an approach to codeveloping a theory-informed VP simulation aimed at improving nurses' relational skills with patients. This viewpoint paper provides practical cues on how to deliver and

translate MI through technology into preprogrammed nurse-patient dialogues.

Scope, Aim, and Objectives

This viewpoint paper is an opportunity to make explicit the tacit knowledge that comes from our personal experience in codeveloping a VP simulation, supported by theoretical approaches and the literature. The specific objectives are to describe (1) the entire codevelopment process of a VP simulation, including its guiding principles, its content, and features and (2) the challenges encountered and the strategies used to overcome them.

Methods

Codeveloping a Virtual Patient Simulation and Its Content

In this section, we describe the methods and processes involved in 2 main phases: (1) planning the VP simulation development and (2) designing the content, sequence, and format of the VP simulation. We also identify the deliverables (or outputs) of each phase and subphase, such as the qualitative evidence of the needs assessment, the composition of an interprofessional team, the clinical content, and the graphical presentation of the VP simulation. We used a collaborative and creative approach to codeveloping the VP simulation. The term *codevelop* is preferred because 2 nurses worked together to produce the clinical content from scratch, along with the project manager of the VP simulation team, and with the support of a larger interprofessional team. Some models [23,24] and standards of best practice in simulation [25] inspired and broadly informed the general codevelopment processes. Although being very useful, especially in the planning phase, these models did not provide operational guidance for the design phase, particularly with regard to creating the full conversational script of the nurse-patient consultation rooted in relational skills. Therefore, describing this process of codevelopment was a retrospective exercise: it was not preplanned but was rather emergent.

The processes are presented in a linear manner to facilitate understanding. However, in reality, they were conducted concurrently, and some in a preordered sequence (the planning phase was done before the design phase). We used field notes, meeting summaries, and debriefing sessions with team members to keep track of important decisions throughout the project. In this paper, sentences or groups of words in *italics* are used to emphasize important guiding principles or key elements surrounding the codevelopment of the VP simulation.

Phase 1: Planning the Virtual Patient Simulation Development

There are 4 subphases related to the planning phase: (1.1) assessing training needs; (1.2) selecting theoretical approaches to inform the VP simulation development; (1.3) negotiating a detailed partnership contract between the research institution, the researcher, and the VP simulation company; and (1.4) assembling an interprofessional team.

1.1. Assessing Training Needs by Understanding HIV Nursing Practice and Its Challenges

To gain insight into HIV nursing practice and the challenges nurses face when providing antiretroviral therapy–related care, a qualitative study [16] was conducted, identifying 3 challenges. The first was performing nursing roles at the interface of social and biomedical boundaries: nurses sometimes felt unequipped to perform their social role. The second challenge was the lack of alignment in the expectations of nurses and patients regarding antiretroviral therapy adherence. The third focused on dealing with the sociopolitical determinants affecting access to health care resources and services.

From these results, *one challenge was chosen and prioritized because it targeted a clinical behavior amenable to change within the nurse-patient relationship and offered room for practice improvement and change*: the misalignment between the expectations of nurses and patients regarding medication adherence. Some nurses had an optimistic attitude toward antiretroviral therapy; they encouraged patients to take their medication while expecting an outcome of adherence that was not achieved. Nurses felt powerless in such situations of nonadherence, as though they had failed in their role. One of the strategies used by nurses to overcome this challenge was to use the MI [17] approach. This challenge was then transformed into a learning opportunity and thus appeared feasible for translation into a simulated clinical situation.

1.2. Selecting Theoretical Approaches to Inform Virtual Patient Simulation Development

We selected 3 theoretical approaches to lay the groundwork for the VP simulation, each serving a different purpose. First, strengths-based nursing (SBN) was chosen as a philosophy and value-driven approach [26] to clarify the goals and mission of nursing overall. *It offers a lens through which to view the roles of nurses and patients, the focus of nursing care, and the nature of the nurse-patient relationship. The assumptions and values underlying SBN guided the conceptualization of the core of the simulation to be a collaborative partnership within the nurse-patient relationship.* Second, while SBN allows for a broad conception of the role of nurses, *MI is the approach used to design the virtual nurse's key actions in the simulation. MI was used to inform the creation of the VP simulation content (ie, the nurse-patient dialogue, quizzes, and feedback).* The use of MI aimed to operationalize content creation. Third, *considering the learner-centered vision of the VP simulation, the principles of adult learning theories were identified to support the learning processes and activities.* SBN and adult learning theories were used for the basic structure of the VP simulation.

Strengths-Based Nursing Approach

SBN is grounded in the principles of person and family-centered care, empowerment, relational care, and innate health and healing. *Collaborative partnership*, one value underlying SBN, meshes with our conception of the nurse-patient relationship. The term *collaborative partnership* refers to power, to the way it is distributed, and how it is shared with the person/family to give them a voice in achieving their goals [26]. In this approach,

goals are set by the nurse and patient together, each bringing their own experience, knowledge, and competencies to the relationship [27]. Under a facilitator role, the nurse provides guidance to help patients find their own solutions. The recognition of the patient's strength is a key element in this collaborative relationship.

In [Textbox 1](#), we present the criteria underlying the collaborative partnership adapted from SBN [28], showing how this form of

the nurse-patient relationship can guide nursing practice based on different assumptions, principles, and values. The purpose here is to raise awareness and reflect on how nursing activities and actions can potentially be influenced or shaped by broad conceptions of the nurse-patient relationship, whether these conceptions are known or unknown, conscious or unconscious, implicit or explicit.

Textbox 1. Collaborative partnership within the nurse-patient relationship; strengths-based care.

Focus
The person's capacity to be well, have a high quality of life, and experience it in a meaningful manner
Role of the nurse
The nurse is a facilitator. Encourages people to share their perspectives and expertise, participate in shared decision-making processes, develop their autonomy, and use their strengths and resources
Role of the person (includes patient/client and the family)
Acts as an active partner who plays an important role in setting goals and in looking for solutions that best match the person
Nature of the relationship
It is reciprocal and mutual, more symmetrical, with continuous negotiation of goals, roles, and responsibilities. Both partners give and receive and gain and grow
Goal setting
Goals are jointly set
Evaluation
Nurse and person share in the joint assessment of progress in reaching mutually determined goals
Expected outcome
The problem may or may not be solved, but the person's skills for managing current or future problems are reinforced. Joint responsibility is accepted for the outcomes

Motivational Interviewing

The SBN approach and MI share common roots and a core value: collaborative partnership. The person-centered communication style characterizing MI [17] can be established only in a relationship where these 4 values are present: partnership, acceptance, evocation, and compassion. In MI,

collaborative partnership is about honoring and respecting the person's autonomy and seeking to understand the person's internal frame of reference.

In addition to these values, the VP simulation is based on a number of elements related to MI. First, the VP simulation is divided into 4 processes: (1) engaging, (2) focusing, (3) evoking, and (4) planning (see definitions given in [Textbox 2](#)).

Textbox 2. Definitions of the 4 motivational interviewing processes that are the building blocks of the virtual patient simulation.

1. *Engaging*: “Engaging is the process of establishing a mutually trusting and respectful helping relationship” [17]. Engaging in the relationship can be very brief at times, as is the case in the consultation between Mr Wilson and the nurse who have known each other for a long time. At other times, engaging can be very long. However, in all cases, it goes beyond stock greetings or courtesy. Engaging must be manifest throughout the therapeutic relationship. It is about the development of a *working alliance* [17]
2. *Focusing*: Focusing serves to pinpoint the goal to be achieved to set and maintain a direction. To this end, nurses clarify the following with patients:
 - Their values and goals
 - The nature of the desired change
 - The importance patients attribute to the change
3. *Evoking*: “Evoking involves eliciting the client’s own motivation for change” [17]. At this stage, nurses guide patients in exploring their motivation, while simultaneously evoking hope and confidence. To this end, nurses:
 - Explore with patients their perceptions (*ambivalence*) about change
 - Mobilize relational skills to elicit *change talk* (a discourse in favor of changing the patient’s health-related behavior such as medication adherence)
 - Mobilize relational skills to respond to *sustain talk* (a patient’s discourse in favor of the status quo)
4. *Planning*: A clear plan drawn up by the patient and guided by the nurse is conducive to engagement toward change and success in effecting change. To this end, nurses:
 - Recognize signs or cues indicating that patients are ready to take action (ie, increased *change talk* or decreased *sustain talk*)
 - Avoid slipping (back) into a *directing counseling style* by drawing up the plan for the patients
 - Make a transition from *evoking* to *planning* (eg, “Where does this get you?” “What do you intend to do about it?” and “Let’s imagine for a moment that you decide to change: How might you go about it?”)
 - Mobilize their relational skills and their practical knowledge to clarify the plan
 - Guide patients in anticipating obstacles and solutions to these

Second, the VP simulation is based on relational skills that are essential to the proficient practice of MI (Multimedia Appendix 1) by creating optimal conditions for relational engagement with patients: asking open-ended questions, using reflective listening, summarizing, affirming the patients’ strengths, providing information and advice, evoking a hypothetical change, eliciting and scaling change talk, setting patient-determined goals, and arriving at a plan. These relational skills are called *behavior change counseling techniques* because they are active ingredients that allow providers to initiate or maintain health behavior changes [29-31]. Third, traps or roadblocks (eg, expert and blame traps, a directing counseling style) are also part of the VP simulation (Multimedia Appendix 2). These are interventions, advice, or relational skills inconsistent with MI that are delivered by nurses with the best of intentions to help their patients but are likely to cause relational disengagement and to shut down dialogue with them.

Several reasons justify the use of MI to inform the VP simulation. First, some nurses from the previous work used it in their current practice and found it effective, whereas others clearly expressed the need for training in it [16]. Second, MI training is promising for improving the relational skills of health care professionals working in HIV care [32] and has proven effective in enhancing medication adherence [33-35]. Third, MI is commonly used as a behavioral change counseling approach in nursing, as highlighted in a systematic review conducted by Fontaine et al [30]. This means that some nurses

may be familiar with it and associate this approach with prior knowledge and experience.

Adult Learning Theories

Simulation is rooted in certain principles of adult learning theories [36] that describe how adults learn and gain an understanding of clinical expertise. In our case, [37,38] is created by the interaction of nurses with the VP simulation environment. The learners, or nurses (these terms will be used interchangeably), will be actively involved in the simulated experience by practicing and testing relational skills with the VP. They will have opportunities to assess their interventions and reflect on them with the help of quizzes and feedback loops (these will be explained later on). We sought to create a *transformative learning experience* [39]. *Transformative learning* capitalizes on the learners’ prior experiences and their interpretation of a situation to build a new way of thinking and then act differently by using critical reflection [36,40]. Feedback is a powerful and effective mechanism to support adult learning and was integrated throughout the VP simulation [41].

In sum, SBN and adult learning theories contributed structuring elements with regard to the goal of the nurse-patient relationship and learning processes. MI informed the integration of concrete communication techniques in the fine content of the VP simulation.

1.3. Negotiating a Detailed Partnership Contract Between the Research Institution, the Researcher, and the Virtual Patient Simulation Company

The coming together of the research team and a representative of the VP simulation company (SimforHealth) was an important aspect of this project. The research team was composed of experts in clinical content, and the company had expertise in digital training for health care providers [42]. A person with extensive experience at the research institution was in charge of negotiating the terms of the contract between the researcher (JC) and the company. These terms were financial considerations, accountability and commitments, mandate duration and timeline, confidentiality duties, intellectual property, and platform use licenses.

1.4. Assembling an Interprofessional Team

An interprofessional team was formed, comprising experts from a VP simulation team and clinical, research, and community-based settings. The VP simulation team was composed of a project manager, a pedagogical engineer, two-dimensional (2D) design professional, 3D graphic designers, and a software engineer. The clinical, research, and community team members included nurses (clinical nurse specialists, a head nurse, researchers, and student researchers, including one with experience using MI with people living with HIV), an infectious disease specialist, the director of an HIV community-based organization, a woman living with HIV, and researchers with experience in developing and evaluating web-based interventions to improve antiretroviral therapy adherence and in health technology assessment.

Furthermore, 2 members of the team (GR and JP) cocreated the clinical content of the VP simulation and worked in close collaboration with the project manager of the VP simulation team. These 3 people made up the working committee. The other team members played a consultative role, providing input on the clinical content and graphical components (eg, the VP, the nurse's office).

Phase 2: Designing the Content, Sequence, and Format of the Virtual Patient Simulation

This second phase includes the following subphases: (2.1) setting the learning objectives and cocreating the clinical content; (2.2) recording the nurse and patient voice-overs; (2.3) designing and validating the 2D learning environment; and (2.4) integrating 3 modes of fidelity to ensure learner engagement and immersion in the VP simulation.

To provide an exhaustive description of the content, sequence, and format of the VP simulation and of how we can translate MI through technology, we have provided detailed information on the following in [Multimedia Appendices 1 to 5](#): the relational skills that are or are not consistent with MI, the key elements of the VP simulation, an excerpt of the writing template, and the table of contents of the glossary. In [Multimedia Appendix 3](#), we offer a comprehensive description of all the key elements (eg, simulation designs such as quizzes and feedback points, learner orientation, exposure, participant groups) constituting

the VP simulation, which was adapted from Cheng et al [10,22] and Peddle et al [43].

2.1. Setting the Learning Objective and Cocreating Clinical Content

The learning objectives evolved throughout the clinical codevelopment of the VP simulation and are listed in [Multimedia Appendix 3](#). Cocreating the clinical content involved more than just the wording of the script for the nurse-patient dialogue. It was a creative process that took into account the assumptions, nursing philosophy, and values embedded in the simulated situation (ie, SBN)—the active ingredients of MI and the learners' roles (adult learning theories).

The clinical content as a whole was made up of the following: a prebriefing video featuring the nursing student-researcher and its corresponding text; the simulated clinical situation, also referred to as the "virtual nurse-patient consultation," which includes the patient's electronic record (also named patient's file); a glossary; quizzes and feedback loops; and labels (green and red visual cues).

Key simulation design elements and features, including prebriefing, repetitive practice, MI techniques, quizzes, feedback, labels, and fidelity, were included to optimize interactivity, foster nurses' engagement with and immersion in the training, and to promote their active and transformative learning.

Prebriefing

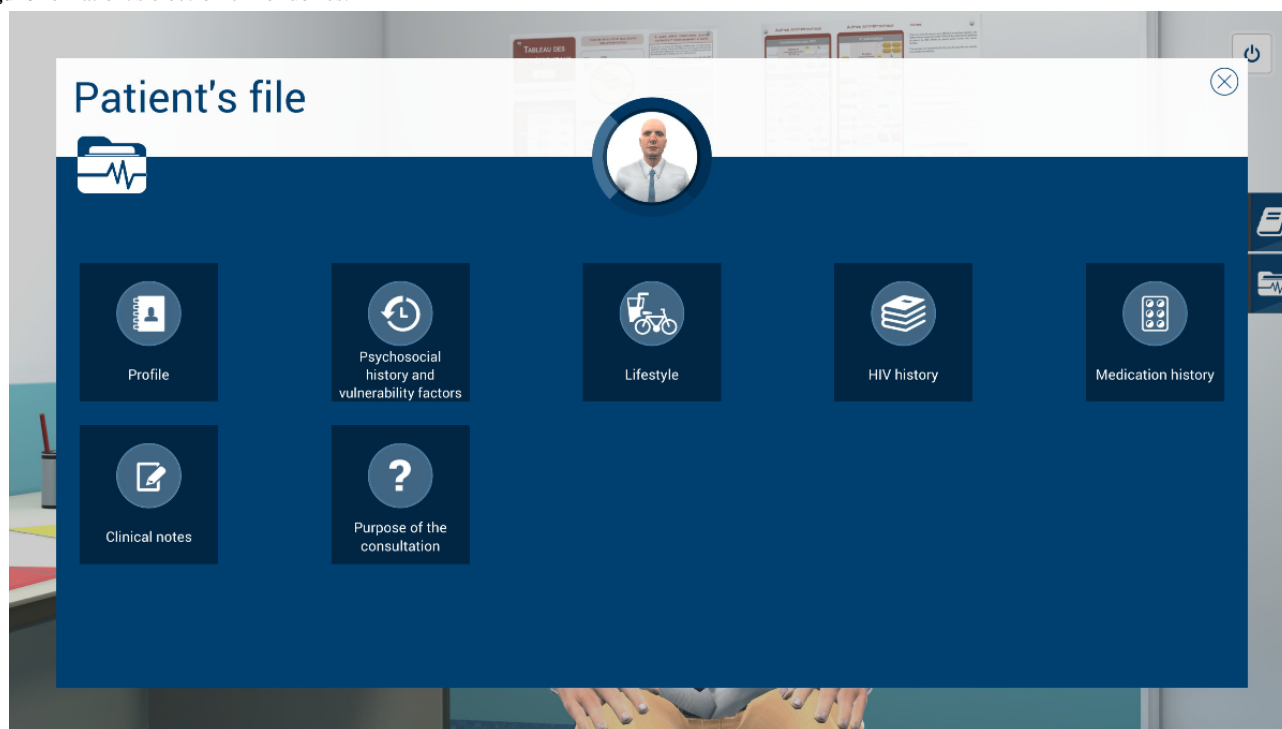

The simulation-based experience with a prebriefing is considered the best practice in simulation [25]. In our case, the goal of the prebriefing, provided via video and text, was to offer basic information about MI so that all learners could begin the simulated nurse-patient consultation with the same standardized information. It also aimed to set boundaries about the scope of the simulation to help nurses manage their expectations. For instance, some nurses might otherwise have thought that the simulation's goals were to acquire or deepen knowledge of antiretroviral therapy, or that prior experience with people living with HIV was needed (neither of which were the case). The prebriefing was also an opportunity to establish a fiction contract, which refers to a kind of commitment in which nurses are invited to act as though the simulation is real, although acknowledging its limitations [44,45]. [Multimedia Appendices 6 and 7](#) show excerpts of the prebriefing video and a demonstration of the VP simulation.

Patient Electronic Record

The content of the patient's electronic record was cocreated with the interprofessional team members for 2 reasons: (1) to ensure the credibility and validity of the patient's medical history and (2) to ensure the fidelity with real patient record rubrics in HIV outpatient clinics. The purpose of the patient's consultation is presented in the patient's record and is summarized in [Textbox 3](#). The different rubrics of the patient's electronic record (eg, clinical notes, HIV, and medication history) are illustrated in [Figure 1](#).

Textbox 3. Purpose of consultation.

The story is about Mr Wilson, a 50-year-old man living with HIV since 2011. He generally takes his medication regularly. His viral load was undetectable for 6 years (which is a sign of antiretroviral therapy adherence). Mr Wilson changed his treatment 1 year ago. He was very busy at work, and his routine changed, so it was difficult to take the medication as prescribed. Now, his viral load is over 1000 copies/ml, indicating that the antiretroviral therapy is not as effective (the target is to achieve an undetectable viral load, that is, below 40 copies/ml). What is going on?

Figure 1. Patient's electronic file rubrics.**Full Script of Nurse-Patient Consultation**

We created the script as if we were writing a *choose-your-own-adventure* book. We started by writing the *green pathway*, that is, the whole storyline in which the script is based on relational skills that are consistent with MI. Afterward, we identified strategic places in the script to incorporate traps or roadblocks—the *red pathways*. These crossroads between the green and red pathways are introduced by quizzes in which learners must select an intervention. When a red pathway is chosen, a short interaction inconsistent with MI shows learners how some types of communicational traps used by nurses generate negative reactions in the patient's speech. At the end of the interaction, the red pathway stops, written feedback is given to the learners, and they can go back to the crossroads to make a different choice. When the green pathway is chosen, the script (ie, nurse-patient dialogue) becomes automated until the next crossroads. We had to carefully select the strategic places within the script to insert the crossroads. Thus, the arborescence that supports the whole script is made up of the green and red pathways, including quizzes and feedback loops.

All these relational skills, whether they are consistent with MI (eg, open-ended questions) or not (eg, providing advice without asking for permission), were integrated into a nurse-patient dialogue in which learners had to choose between the interventions that generate openness in the patient's speech and those that can shut down communication. This scenario

provides learners with safe, constructive, positive, and nonjudgmental spaces that allow for transformative learning and self-reflective practice [36].

The main stages in writing, validating, and producing (ie, filming, voice-over recording) the overall content and testing it on the platform are summarized in [Textbox 4](#). Steps 1 to 4 are more general and account for how we created a script for nurse-patient consultation.

In our various attempts to write the script, we developed multiple versions of a writing template. This was a work in progress throughout. The final template ([Multimedia Appendix 4](#)) includes the nurse-patient dialogue (script), quizzes, feedback, labels, guidelines for the VP simulation team regarding the branching, and notes for the actors who would record the voice-overs. This template was a tool that allowed us to write the script in the manner of a *choose-your-own-adventure* book.

A total of 14 quizzes, including multiple-choice and open-ended questions, are part of the VP simulation. Most were formulated to allow learners to select the most appropriate intervention, depending on the script's progress and the patient's speech. Each quiz is supported by synchronous written feedback focusing on the rationale for the good or bad answer selected based on their consistency with or without MI ([Multimedia Appendices 1 and 2](#)).

Visual cues, called *green* and *red labels*, were introduced during the nurse-patient consultation to qualify their speech (eg,

open-ended questions, defensive attitude) and in the written feedback. These labels correspond to theoretical MI techniques and provide feedback. The introduction of visual cues into the automated dialogue allows learners to grasp the rationale for

the virtual nurse's communication skills and to observe the patient's reaction while limiting the number of pathways (green and red) to be scripted.

Textbox 4. Main stages in writing, producing, and validating the overall content and making it accessible as a virtual patient simulation platform.

1. Writing the green pathways, meaning the overall storyline between the nurse and patient that is consistent with motivational interviewing, by using behavior change counseling techniques ([Multimedia Appendix 1](#)), and structured according to its 4 processes: (1) engaging, (2) focusing, (3) evoking, and (4) planning ([Textbox 2](#)). *Note:* The script of the nurse-patient dialogue was first written in a linear way to open up onto the patient's experience. At this stage, no crossroads (red pathways) were part of the script
2. Validating the green pathway with the interprofessional team
3. Identifying strategic places along the green pathway where traps or roadblocks could be integrated and then writing the *red pathways* ([Multimedia Appendix 2](#)). This step included the creation of quizzes and feedback
4. Creating visual cues that we called *green* and *red labels* to engage the learner observing the preprogrammed dialogue. These labels were integrated into strategic places in the script (eg, when the nurse uses a directing counseling style)
5. Producing the content of the patient's electronic record, the glossary, and the prebriefing (video and text)
6. Validating the whole clinical content with members of the interprofessional team
7. Culturally adapting the script (nurse-patient dialogue). Originally, it was written in French from Quebec (Canada). The text was adapted to *international French*
8. Recording of the nurse's and the patient's speech by professional actors and filming the prebriefing video
9. Integrating all the content in the MedicActiV platform [[42](#)]
10. Performing functionality tests and validating the content within the platform
11. Validating the virtual patient simulation with a small group of nurses
12. Launching the French version
13. Translating the virtual patient simulation to English and revising the content in close collaboration with an anglophone nurse who was an expert in motivational interviewing and a member of the Motivational Interviewing Network of Trainers.

Note: Steps 9 to 13 were repeated for the English version.

Glossary

A web-based glossary is available within the VP simulation as supplementary educational material to complement the content of the nurse-patient consultation. It covers theoretical concepts, definitions, and applications. The main topics covered in the glossary are presented in [Multimedia Appendix 5](#).

2.2. Recording the Nurse and Patient Voice-Overs With French- and English-Speaking Actors

The project manager of the VP simulation team was responsible for preselecting French- and English-speaking actors and assisting them during the recording of the nurse and patient voice-overs.

It is important to add stage directions in the writing template, alongside the speech of the nurse and patient, so that the actors can respect the tone of voice and the ambience/vibe in the virtual nurse-patient relationship, consistent with MI.

The nurse's mode of communication had to be respectful, calm, warm, and welcoming, without becoming caricatured, especially in the red pathways. That way, the learners could not guess or deduce the right answer merely from the character's tone of voice or an intervention that is obviously inadequate. As for the patient, if he was feeling worried, the actor had to convey this in his performance.

2.3. Designing and Validating the 2D Learning Environment

At the same time, as the clinical content was being written, the VP simulation team was working on designing the graphical elements of the 2D learning environment. [Figure 2](#) shows a mock-up of the virtual office, including both nurse and patient, and [Figure 3](#) shows the patient only.

These mock-ups allowed us to obtain the team members' opinions of the graphical designs before selecting the final 2D learning environment. It was important to display a chart of antiretroviral therapy on the wall to represent a real-life artifact. Decisions about the virtual nurse and patient had to then be made. For example, would we see the nurse on-screen (third-person view) or not (first-person)? What would the HIV-positive man look like? How would the desk be positioned in the virtual office (ie, between the nurse and patient or on the side)? Ultimately, the first-person view was preferred, where the nurse is not visible on-screen, but we hear her voice and see her speech. In this way, only the VP is visible. The desk was placed on the side to avoid creating distance between the nurse and patient. [Figure 4](#) shows the final design of the virtual nurse's office and the patient (Mr Wilson).

Some features were created to fit with this project, such as the green and red labels, and the interfaces to support synchronous feedback. Furthermore, SimforHealth developed a specific content and dialogue management module (questions/answers)

to meet the clinical team's needs. This module made it possible to speed up the content creation (full script of the nurse-patient consultation) and facilitated content integration into the VP simulation.

All the regular 3D content was created using 3Ds Studio Max (Autodesk), the leading 3D digital content creation solution

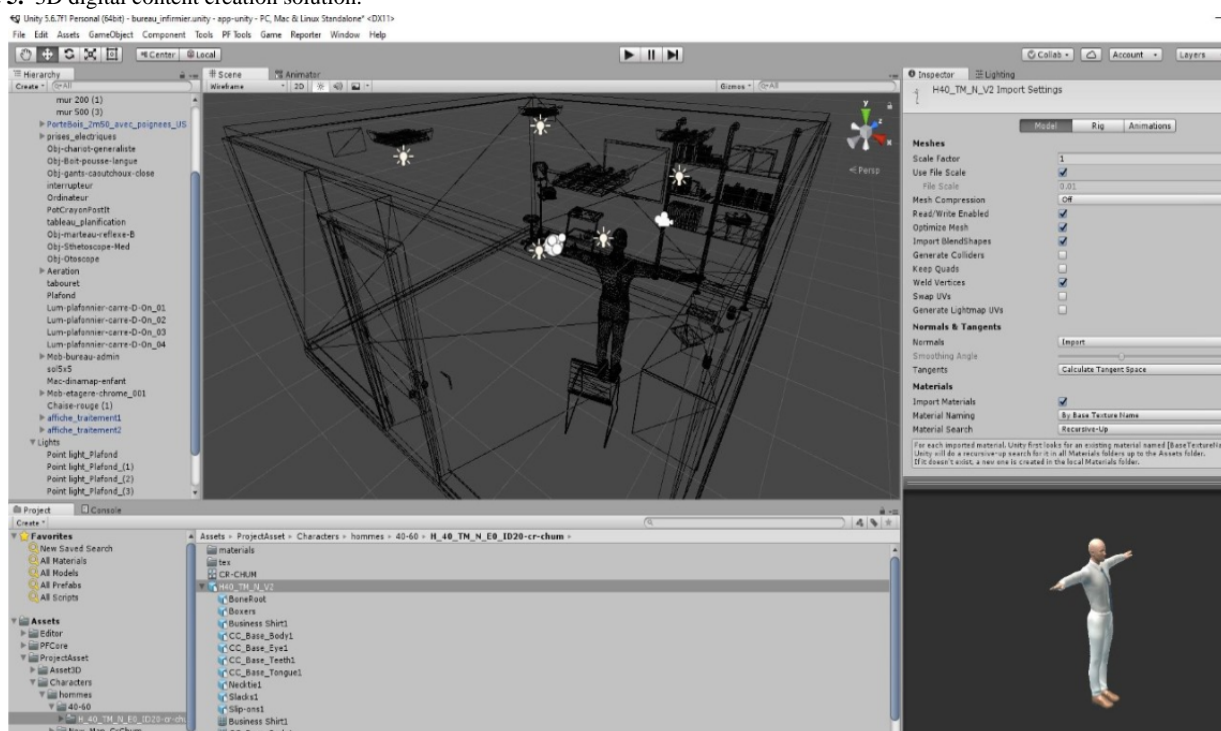

(Figure 5). Figure 6 shows examples of the wireframes used in the creation of the 3D content. Wireframes are illustrations of the proposed VP simulation components and "assist in visual communication and design of the structure, functionality, learner interface, and positioning of an application" [24].

Figure 2. Mock-up of the virtual office including nurse and patient.

Figure 3. Mock-up of the virtual patient.

Figure 4. Final design of the virtual patient simulation.**Figure 5.** 3D digital content creation solution.

MedicActiV Platform

The MedicActiV platform [42] was designed to support digital training for health care providers and was used to host the simulated nursing scenario. The simulated scenario is a self-directed learning approach that is accessible via a computer or tablet. It is a 2D visual interface (Figure 4) with 3D content and is considered nonimmersive virtual reality [46]. The 2D elements include a graphical user interface, such as colors, icons, and text-based interfaces. The 3D elements are the dynamic

objects created to have volume, such as the VP and the nurse's office (Figure 6). MedicActiV is a software as a service solution that provides a library of virtual clinical cases. Thanks to the authoring tool, developers (eg, researchers, educators, health care providers) can easily create their own clinical case to share it with other users on the platform. The trainer can set up the training sessions' parameters (eg, date, time, duration) and, immediately after any session, is able to retrieve several key performance indicators (eg, time, errors). Most of the clinical cases are available on multiple devices and operating systems

(eg, Windows, macOS, iOS, Android). However, our clinical case with the HIV-positive VP was not available to everyone because it was embedded in a research process, and thus, was

available only to a small sample of research participants, namely, the nurses.

Figure 6. 3D Virtual patient.

2.4. Ensuring Fidelity to Ensure Learner Engagement and Immersion Throughout the VP Simulation

One important feature to include in any simulation, be it virtual or not, is the concept of fidelity, also known as realism or authenticity [47]. Fidelity is about the learner's perceptions of how well a simulation represents or reproduces reality [44] and offers them a realistic learning opportunity [15]. In this context, 3 modes of fidelity represent the ways humans think about reality: (1) physical; (2) conceptual (or semantic); and (3) emotional and experiential (or phenomenal) [44,45,48]. These modes can influence the learner's engagement with and immersion into the simulation as well as their learning process [15,44,48].

The *physical mode* can be described by the *physical* properties of the VP (eg, movements, appearance) and of the nurse's office,

including objects and artifacts in that environment. The voice-over acting for the nurse and patient (eg, voice tone, vocabulary) are other elements of fidelity that were taken into account. The *conceptual* or *semantic mode* relates to concepts and their relationships, for example, theories, meaning, or information that are presented via various means (eg, text, voice-overs). It also involves the *if/then* relationship. In our simulated situation, it is globally represented by the following logic: if the nurse uses behavior change counseling techniques (communication skills) consistent with MI, this will open up a dialogue with the VP. If the nurse uses relational skills inconsistent with MI, then the VP will react accordingly (eg, defensively). Finally, the *emotional* and *experiential mode* refers to the learner's emotions, feelings, and beliefs relating to their holistic experience of participating in the simulation. In Table 1, we present strategies used to ensure that the VP simulation had the characteristic of fidelity.

Table 1. Strategies used to ensure 3 modes of fidelity throughout the virtual patient simulation.

Modes of fidelity	Strategies used
Physical fidelity	<p>Giving cues to the VP^a simulation team for their design of the VP:</p> <ul style="list-style-type: none"> • Taking a picture of a real nurse's office for the representation of the virtual nurse's office • Adding objects that represent reality (eg, chart of antiretroviral therapy on the wall) <p>Getting charts from real patient records to use the same vocabulary in the VP's electronic record</p> <p>Designing the VP with human features (eg, facial expression and body movements) based on past experiences of the VP simulation team</p> <p>Using real voice-overs for both patient and nurse:</p> <ul style="list-style-type: none"> • Preselecting some French- and English-speaking actors, listening to their audio tracks and choosing the ones that best fit the spirit of the simulation • Providing descriptive cues in the script besides the nurse's and patient's speech, so that the actors can respect the tone of voice and ambiance and vibe in the nurse-patient <i>virtual</i> relationship, consistent with SBN^b and MI^c <p>Getting written approval for each step of the graphical design before undertaking the subsequent one</p>
Conceptual fidelity	<p>Co-designing the clinical content with a nurse having expertise in HIV care and MI to ensure that the simulation reflects the nursing practice and the validity of the theory injected in preprogrammed interactions</p> <p>Meeting a clinical nurse specialist who is an expert in HIV care to discuss real-life situations of people living with HIV having difficulty taking their medication to identify nursing actions, in partnership with physicians and pharmacists, in nonadherence situations</p> <p>Validating the content with health care professionals</p> <p>Working with pedagogical engineering to make sure that good educational practices are met</p>
Emotional and experiential fidelity	<p>Promoting a positive learning experience and relatedness by creating messages that value and respect nurses' competencies and current practice. In doing so, clinical content inventors must themselves be consistent with the MI values in their way of translating the educational content to the simulation</p> <p>Creating opportunities for reflection on action (virtual practice) by incorporating quizzes and feedback that represent what nurses do in their current practice</p> <p>Establishing a fiction contract with nurses [44,48]. The following message in the prebriefing video is intended to create such a contract: "The relational aspect of the practice of caring cannot be simulated to perfection. Needless to say, human beings are not preprogrammed to respond to a nurse this way or that. I invite you, then, to immerse yourself in this virtual simulation as if it were real and to pay attention to the interactions between Mr. Wilson and the nurse".</p>

^aVP: virtual patient.^bSBN: strengths-based nursing.^cMI: motivational interviewing.

Discussion

Challenges and Strategies

Thus far, we have described VP simulation development methods and the deliverables of each phase and subphase, including the theory-informed content. We now discuss the main challenges and strategies used to overcome them.

The most salient challenges and strategies are discussed in this section. The second phase (ie, designing the content, sequence, and format of the VP simulation) was the most challenging because of the difficulty in determining realistic clinical content in a virtual learning environment. We had to preserve the philosophy and values of SBN and the collaborative partnership that shaped the nurse-patient relationship. We were also concerned with translating relational skills informed by MI within the simulated nurse-patient dialogue while ensuring that the functionalities of the VP platform could support the content. *We also had to find a balance between a nursing-driven approach and a technology-driven approach while optimizing the learning experience.*

Challenge 1: Starting the Project With Divergent Conceptions of Virtual Patient Simulation Approaches

At the beginning of the project, the VP simulation team suggested a generic template that could help structure and organize the clinical content into pre-established *categories* consistent with virtual simulators already developed by the company. However, the 2 clinical inventors (GR and JP) felt that such a template would not be helpful because it reflected a problem-solving [47,49] or procedural [6] simulation approach. This is appropriate for teaching, for instance, clinical reasoning and diagnosis. To perform these tasks, learners must, for example, collect data and make diagnoses and treatment decisions based on their anamneses. In such simulations, learners are given a set of information from which they must draw conclusions (eg, in patient-facing problems with adherence to antiretroviral therapy, the nurse's identification of solutions drives the direction of the VP simulation script). However, this approach did not mesh with a collaborative partnership as a form of the nurse-patient relationship, and thus with the nature of relational skills that are consistent with a narrative approach to simulation [47,49]. The ways of seeing the approach to the

VP simulation diverged between the simulation team (who perceived it as a procedural one) and the clinical team (who perceived it as a narrative one).

The narrative approach, also called *situational simulation*, [6] is generally found in a personal storyline that progresses over time around a logic of cause and effect and that involves a decision-making process that yields different *outcomes* (or effects). The script is anchored in a strengths-based approach, consistent with MI, in which the virtual nurse's role is that of a facilitator, using relational skills to open up the dialogue with the patient (eg, where a patient is facing problems with adherence to antiretroviral therapy, the identification of solutions *by the patient* drives the direction of the VP simulation script). At the time we started the VP simulation project, it would have been helpful to rely on the paper of Peddle et al [43] because it describes the development of VP to support undergraduate nursing students in learning nontechnical skills such as communication. The authors give an overview of the narrative approach and the *choose-your-own-adventure* game structure used to design the VP simulation.

Strategies: Getting a Mutual Understanding of the VP Simulation Approach That is Aligned With the Philosophy and Values of a Collaborative Nurse-Patient Relationship

We first consulted some virtual clinical cases on the MedicActiV platform to familiarize ourselves with the possibilities and limitations of the virtual learning environment and to understand how it works. It helped to understand how the VP simulation team perceived the simulated clinical situations and then pinpointed the differences between our different VP simulation approaches (procedural vs narrative). We collaborated closely with the project manager of the VP simulation team from the outset of the project. It was essential to make sure that the narrative approach, the SBN, the relational skills informed by MI, the principles of adult learning theories, and the functionalities of the simulation platform all meshed together. Holding regular meetings with the working committee allowed us to gain a better understanding of each other's roles, responsibilities, and evolving perspectives on the VP simulation.

Challenge 2: Struggling With the Complexity of Designing Realistic Relational Skills Into Preprogrammed and Simulated Nurse-Patient Dialogue While Preserving an Immersive Learning Experience

This challenge was three-fold: (1) translating complex actions (uptake of relational skills) within fully automated and preprogrammed nurse-patient dialogue, (2) having insufficient guidance in integrating such skills in this form of virtual simulation, and (3) designing the proper immersive and realistic 2D learning environment.

Writing the scripts with high-quality motivational responses is not just about wording. It is about creating a natural flow of interactions that involves great sensitivity and attention to verbal and nonverbal aspects of communication while respecting values such as empathy, collaborative partnership, acceptance, affirmation, and so on. Such an endeavor is easier to put into action spontaneously in real-time interactions. This challenge

is well summarized by Villaume et al [50]: “While the processes and skills of MI are theoretically understandable, using them in individual utterances requires a considerable adjustment of vocabulary, grammar, emotional tone, and rhetorical strategy. Trying to work through these adjustments in real time with a standardized patient is difficult.”

Adding to the complexity of the actions to be performed is the lack of guidance on how to create and translate preprogrammed interpersonal nurse-patient interactions. It is easy to become quickly overwhelmed by the multiplicity of alternative scenarios and the growing decision tree (arborescence) if we do not limit the number of points at which learners can make choices and the number of options they have.

At the same time, as we were writing the script, SimforHealth had to design immersive and realistic nurse-patient interactions in a virtual learning environment, which was challenging. The decision tree is a kind of backbone for the nursing content, but it needs to be enhanced with graphic design, such as representing the *real appearance* of the VP's digital facial expression and behavior. This is key to achieving a better commitment from the learners.

Strategies: Creating a Collaborative and Work-in-Progress Writing Template

It is certain that we cannot make the nature of relational skills less complex, be they consistent with MI or not. However, the VP simulation's clinical inventors, as educators, were accountable for being skilled with using MI to be able to transfer theoretical knowledge in an understandable way within the VP simulation and allow for an optimal learning experience. The quality of the VP simulation depends partly on the inventors' expertise. In the working committee, the *codevelopment* involved knowledge transfer and an opportunity for discussion between these 2 members, given that one (JP) has expertise in MI whereas the other (GR) was new to this theory.

We had to build up our own method and find our own guidance to develop the VP simulation. The writing journey required a high level of creativity and inductivism. The flow of the storyline evolved over time, with a concern for making connections with theory and practice, so that nurses would benefit from a constructive and positive learning experience. In doing so, teamwork was the most important success element. To begin with, the 2 members of the working committee (GR and JP) worked in close collaboration to write the content for the nurse-patient consultation. We created a *writing template* (Multimedia Appendix 4) that evolved over time and represented a guide for both the clinical and the VP team. We wrote the script as a *choose-your-own-adventure* book, that is, by starting to write the green pathway, and then adding the red pathways. In addition, the role of learners' emotions and feelings was taken into account. *From our perspective, the conception of the clinical content (scenario) had to depict the nursing practice (ie, what nurses actually do) without falling into stereotypes or judgments. The clinical content inventors themselves had to be consistent with MI principles and values in their way of translating the educational content to the simulation. Learners had to recognize themselves in the whole scenario (including traps and roadblocks) to be engaged with and immersed in the*

learning experience (fidelity). This principle is comparable to what Yardley et al [51] call “promotion of a learner’s positive experience and relatedness.”

Strengths of VP Simulation

We believe our VP simulation has a long life span because the action of adopting relational skills consistent with MI is *stable*, and does not need regular updates, as it would if the simulation focused on pharmacological treatment, where scientific breakthroughs occur frequently. Behavioral change counseling techniques (eg, asking open-ended questions, summarizing) are timeless. Another strength is that communication is a transversal skill used by all nurses, from novice to expert, and by all other health care professionals. Relational skills are then applicable independently of the health care professionals’ roles, the context of practice or level of experience, and of the population they care for. Focusing on this clinical behavior is a good avenue to ensure the adaptability, sustainability, and efficiency of this VP simulation. We ensured the integrity and quality control [52] of the MI intervention by relying on original work by the authors on MI [17] and by involving nurses who are experts in this approach: one nurse was involved in the design of the French content and a certified trainer in MI revised the English version. Furthermore, the involvement of a patient-partner added value at the early stage of the project, adding insight into the credibility and fidelity of the storyline and the graphic design of the VP simulation. It is a theory-informed intervention, and thus, we are confident in the quality of the clinical content and its potential to induce a practice change.

Conclusions

The knowledge gained from our experience of VP simulation codevelopment has the potential to optimize the development process of other VP simulations, particularly those using a narrative approach. VP simulation is the only means to support learning; it is not the technology per se that generates learning [53]. Many elements were put together to create favorable conditions for generating a positive learning experience. We strongly believe that the duration of the codevelopment process can be shorter if developers have a clear idea of the theories to use to structure the VP simulation (eg, SBN, MI, adult learning theories) and if they know which approach fits (eg, narrative, problem-based) with their perspective of the clinical behavior or action to address. This paper offers concrete examples of how to translate behavior change counseling techniques derived from MI into an asynchronous and preprogrammed nurse-patient dialogue. The inductive approach used in codeveloping the content of the VP simulation was a transformative learning experience for the working committee.

With a view to professional development, nurses will have the opportunity to try this VP simulation, informed by experiential, theoretical, and empirical knowledge, and thereby help evaluate it. The standardized nature of the intervention is a strength of this approach that could be helpful for evaluation purposes. If the nurses’ relational competencies are enhanced, then the quality of the therapeutic relationship between nurse and patient may benefit and, ultimately, this can have positive repercussions on the health of people living with HIV.

Acknowledgments

The authors would like to thank the following people for their contributions at various stages of the project: Dominique Debay, Hélène Morin, Alexandra de Kiewit, Catherine Dufault, Kenneth Monteith, Julien Bouix-Picasso, John Kayser, and Production Multimédia du Centre hospitalier de l’Université de Montréal. The authors are grateful to Zozita Translation and Editing for their participation in editing this manuscript.

GR is funded by doctoral fellowships from the partnership between Fonds de recherche du Québec Santé (FRQS) and the Quebec Strategy for Patient-Oriented Research Support Unit, the Canadian Institutes of Health Research (CIHR), Quebec Network on Nursing Intervention Research, and Quebec’s Ministry of Higher Education. JC holds the research chair in innovative nursing practices. MPG holds the Tier 2 Canadian Research Chair on Technologies and Practices in Health. VML is funded by Clinical Research Scholars–Junior 1 from the FRQS. The authors thank the Quebec Population Health Research Network for its contribution to financing this publication. GF was supported by the Vanier Canada Graduate Scholarship (CIHR), a doctoral fellowship from the FRQS, multiple scholarships from the Canadian Nurses Foundation, a doctoral scholarship from the Montreal Heart Institute Foundation, a doctoral scholarship from Quebec’s Ministry of Higher Education, and multiple scholarships from the Faculty of Nursing at Université de Montréal.

The development of this VP simulation was funded by a student project grant from Quebec Network on Nursing Intervention Research, by a planning and dissemination grant from CIHR (144030) and by a doctoral scholarship allocated to GR from CIHR (337439). The collaborators of SimForHealth at Bordeaux, France, are Clémentine Dupouy, Olivier Gardinetti, Nathalie Piérard, Stéphane Petit, Eric Méresse, Anne-Sophie Milcent, Xavier Abadie, and Jérôme Leleu.

Conflicts of Interest

JC, the University of Montréal Hospital Research Centre, and SimforHealth are linked by a partnership contract. SimforHealth is the owner of the MedicActiV platform that supported the VP simulation and was involved throughout the codevelopment process. GR and JP codeveloped the clinical content of the VP simulation and JC validated it.

Abstract

Due to the coronavirus disease (COVID-19) pandemic, medical schools have paused traditional clerkships, eliminating direct patient encounters from medical students' education for the immediate future. Telemedicine offers opportunities in a variety of specialties that can augment student education during this time. The projected growth of telemedicine necessitates that students learn new skills to be effective providers. In this viewpoint, we delineate specific telehealth opportunities that teach core competencies for patient care, while also teaching telemedicine-specific skills. Schools can further augment student education through a variety of telemedicine initiatives across multiple medical fields. The explosion of telemedicine programs due to the pandemic can be a catalyst for schools to integrate telemedicine into their current curricula. The depth and variety of telemedicine opportunities allow schools to continue providing high-quality medical education while maintaining social distancing policies.

Medical Education on Hold

On March 23, 2020, the Association of American Medical Colleges (AAMC) issued guidance on medical student involvement during the coronavirus disease (COVID-19) pandemic, recommending that medical students not participate in direct patient care, unless there is a critical workforce need, and only on a voluntary basis [1]. The COVID-19 pandemic has generated unprecedented stress for our national health care system. Consequently, it has created practical and logistical challenges for the learning environment that can have a lasting impact on medical education [2]. The widely varying predictions, regarding how long the pandemic will continue, raise questions as to when and how traditional clerkships will resume. In light of this, academic centers must consider new measures to continue their mission of training future physicians. There are potential technological solutions to the current challenge of clinical education during a time of social distancing.

The cornerstone of medical education is patient care. While direct patient care has been appropriately limited at most schools, the lessons learned from these critical patient interactions cannot be fully replaced by readings, lectures, case studies, or online modules. Certainly, direct in-person care has important educational value to the medical student. Although not an exact replacement for in-person care, institutions have a unique opportunity to bridge this current gap in clinical education with telemedicine. This viewpoint contributes to the ongoing discussion by offering specific guidance on how schools can incorporate medical students into the massive expansion of telehealth initiatives during and beyond the COVID-19 pandemic.

The Expansion of Telemedicine

In recent years, telemedicine has grown exponentially. Telemedicine applications have expanded from phone triage and ambulatory electronic visits (e-visits) to include mental

health, postsurgical operation follow-ups, and specialty consults [3]. In support of the efforts to socially distance medical care during the COVID-19 crisis, health systems across the United States are ramping up their telehealth programs [4]. As both patients and providers grow more accustomed to these virtual interfaces during the pandemic, many will likely choose to continue using telemedicine going forward [5]. Even before the pandemic, the telemedicine market was predicted to grow from \$38.3 billion in 2018 to \$130.5 billion by 2025 [3]. Therefore, while telemedicine has seen an acute spike in response to the pandemic, it is anticipated that it will continue to be an important vehicle for health care.

A Unique Skillset for the Telemedicine Provider

With the imminent growth of telemedicine, teaching providers this unique skillset is essential for the success of future telemedicine programs. Practitioners who have not used telemedicine may find it difficult to translate their traditional interview and physical exam skills to the virtual sphere [6]. Furthermore, technical challenges are cited as one of the most common reasons for failure to implement telemedicine by providers [7]. These barriers are compounded by patient discomfort, possible technological illiteracy, and the stress associated with adapting to a new environment or system [6]. Additionally, a computer screen or phone makes for more detached patient interactions and distant provider-patient relationships [6]. When providers do not have the relevant skills, it becomes harder to concurrently adopt new technologies and maintain high-quality patient care. One study has found that trainees inexperienced with telemedicine struggled with gaining detailed histories or providing appropriate next steps—jumping straight to requesting unnecessary in-person visits [8]. A systematic review has found that courses have been successful in teaching telemedicine skills through dedicated curricula [9]. With the proper resources, these skills can be taught and therefore should become a key component of contemporary medical school curricula.

Telemedicine Curriculum Considerations

Education is critical to the future success of telemedicine implementation. Integration of telemedicine into undergraduate medical education allows for all future physicians to have access to this type of training. The American Medical Association (AMA) has similarly articulated the value of telemedicine curricula in medical schools and residency programs [10]. In addition, the United States Medical Licensing Exam incorporates telephone encounters into its Step 2 Clinical Skills exam [11]. Multiple curricular resources already exist that have identified core competencies for telemedicine for physicians [6,12]. Other health professions have even initiated discussions around establishing competencies associated with virtual care [13].

There are a number of suggested skills associated with optimal telemedicine care. These include but are not limited to the following: communication, physical examination, professionalism, and technological literacy. Communication

skills include clear enunciation and the minimization of body motions, gestures, and colloquial speech [12]. These measures help to account for clarity that may otherwise be lost through online platforms [6]. Unique physical exam techniques that can be learned involve functional physical exams [6], application of remote monitoring devices [12], and collaboration with on-site providers. Virtual evaluations can extend to include home assessments, such as in-home mobility barriers [6]. Training for professionalism in a virtual domain can cover education on privacy concerns, electronic prescribing (e-prescribing), and reporting of practices [6,12]. Trainees should also learn technological skills such as screen sharing to discuss diagnostic findings [6], assessing for technological literacy [6], and coaching patients through the use of virtual health platforms [12].

Some programs have already started to institute courses to teach these telemedicine communication and evaluation skills. Among the most common curricular elements includes standardized patients [8,9]. However, creating simulations, training standardized patients, and implementing new technology may prove to be insurmountable barriers for medical schools in the current setting. Instead of recreating new technology solely for medical students, schools can engage students in clinical care through the same telemedicine technology that hospital systems are currently employing. Already, a select number of schools successfully expose students to telemedicine during traditional clinical rotations [9]. With the acute expansion of telemedicine, more schools could provide enriching telemedicine opportunities for their students.

Envisioning Remote Clinical Education During COVID-19

Telemedicine curricula could mimic traditional curricula that medical educators already employ with minimal adjustments, allowing for the continuation of clinical education during the pandemic. Students can easily access and get involved with telemedicine initiatives through technological platforms. For example, some electronic health record (EHR) platforms already integrate third-party platforms that would allow three-person calls [14]. Other options could be to implement Health Insurance Portability and Accountability Act (HIPAA)-compliant group-video options [15], or a three-way call led by the student. Third-party platforms often require institution licenses; however, with the dramatic growth in the last month, many of these platforms have become more readily available and have expanded their services [15]. Future access may require advocacy from medical schools for student licenses, or for clinician educators to share licenses with their students.

Educating students through telehealth initiatives could parallel a majority of the 13 Core Entrustable Professional Activities for entering residency (EPAs) (Table 1). These EPAs were created by the AAMC to provide medical schools with curricular guidelines to ensure a uniform set of skills for all medical school graduates [16]. We identified several curricular activities for schools to integrate now and during the transition back to regular clerkships.

Table 1. Telemedicine curricular activities that align with each of the Association of American Medical Colleges' Core Entrustable Professional Activities (EPAs) [16].

EPA	Telemedicine curricular activity
EPA 1: Gather a history and perform a physical exam	<ul style="list-style-type: none"> • Clinical e-visit^a • Virtual consult
EPA 2: Prioritize a differential diagnosis	<ul style="list-style-type: none"> • Clinical e-visit • Virtual consult • Pathology/radiology cases
EPA 3: Diagnostic and screening tests	<ul style="list-style-type: none"> • Clinical e-visit • Virtual consult • Pathology/radiology cases
EPA 4: Enter and discuss orders and prescriptions	<ul style="list-style-type: none"> • Clinical e-visit • Virtual consult
EPA 5: Document a clinical encounter	<ul style="list-style-type: none"> • Clinical e-visit • Virtual consult • Pathology/radiology cases
EPA 6: Provide an oral presentation of a clinical encounter	<ul style="list-style-type: none"> • Clinical e-visit • Virtual consult • Pathology/radiology cases • Student-led patient education project
EPA 7: Clinical questions to advance patient care	<ul style="list-style-type: none"> • Post e-visit reflection • Virtual journal clubs • Student-led inquiry projects
EPA 8: Give or receive a patient hand-off	<ul style="list-style-type: none"> • Virtual standardized patients and Objective Structured Clinical Examinations [8,9]
EPA 9: Collaborates as a member of an interprofessional team	<ul style="list-style-type: none"> • Interdisciplinary rounds • Teleconsults [4] • Tumor board [17] • Group discussions with other health-professional schools
EPA 10: Recognize urgent or emergent situations	<ul style="list-style-type: none"> • Clinical e-visit • Telestroke team [18] • Teletrauma team [19] • COVID-19 call centers, forward triage response team [4]
EPA 11: Obtain informed consent for tests and/or procedures	<ul style="list-style-type: none"> • Clinical e-visits in surgery, surgical subspecialties, obstetrics and gynecology, etc [20]
EPA 12: General procedures of a physician	<ul style="list-style-type: none"> • Online procedure courses, augmented and virtual reality simulations, including CPR^b training and ultrasound techniques [20] • Participation in live-streamed surgical theaters [20]
EPA 13: Identify system failures and contribute to culture of safety and improvement	<ul style="list-style-type: none"> • Post e-visit reflection • Quality improvement training • Student reflections

^ae-visit: electronic visit.^bCPR: cardiopulmonary resuscitation.

By integrating multiple EPAs, a single e-visit could provide students exposure to skills that they will employ throughout their careers. A telemedicine student visit could be similar to most other ambulatory student clinic visits. To ease patient burden and reduce confusion, ideally the patient, the medical student, and the physician would all be present concurrently at the e-visit. The attending could observe the student lead as much

of the visit as possible, with a seamless transition when the attending takes lead of the conversation. Using telehealth technology, students could gather a history and perform a virtual physical exam (EPA 1), focusing on communication skills, rapport building, and functional physical exam maneuvers. Students could summarize their findings (EPA 6) to both the patient and attending in patient-friendly language. Depending

on the comfort level of the patient, the physician could lead the student through a discussion of the possible diagnoses (EPA 2), potential diagnostic tests (EPA 3), or orders (EPA 4). This style would mimic “family-centered rounds,” providing the student the opportunity to think through an assessment and plan with direct patient input. Alternatively, the physician and student could discuss the clinical reasoning and key academic concepts after the patient’s call. Following the visit, the medical student would then document the encounter (EPA 5). To augment these visits, medical students could research topics inspired by patient cases (EPA 7) and discuss the impacts of telemedicine on health care (EPA 13). These examples show how the e-visit can provide in-depth, high-quality education. A single e-visit can provide the opportunity to teach medical students invaluable skills that they would otherwise not be able to obtain from reading case studies.

With the expansion of novel telemedicine applications into more fields, including procedural fields, students can continue to learn foundational knowledge through engagement in telemedicine even beyond the stereotypical telemedicine visit. In fact, involvement in virtual opportunities exist for all EPAs (Table 1), thus making telemedicine a powerful supplement to the traditional inpatient and outpatient clinical curriculum. In surgery and obstetrics and gynecology, students could assist with pre- and postoperative e-visits (EPA 11) [20]. Students can become educators for patients, by researching a topic such as diabetes nutrition strategies (EPA 7) and then leading a group virtual session with patients (EPA 6). Within the context of inpatient encounters, the aforementioned outpatient recommendations can be further adapted to the inpatient setting. For example, students could participate in virtual consults by talking to admitted patients via a tablet or other similar equipment following the above format (EPAs 1-6). In pathology and radiology, screen-sharing technologies could allow students to become involved in review of slides and imaging remotely (EPAs 2 and 3). Unique experiences such as opportunities to triage urgent cases may exist for hospitals that have telestroke

[18] or teletrauma teams (EPA 10) [19,20], or to participate in virtual interdisciplinary rounds (EPA 9) [17]. Students could benefit from participating in as few as one opportunity to augment their online learning. Furthermore, with so many clinicians going online, the use of telemedicine in education is not dependent on a single department. With telemedicine opportunities now available in almost every field, students have the opportunity to learn a variety of skills in multiple specialties.

Even if students are to return to the clinical setting soon, traditional clerkships may look different for them. For example, some students may have continued needs for self-quarantining while others may return to the hospital. For students in hospitals, there will likely still be patients admitted for COVID-19. In this context, telemedicine may provide a way to resume medical student education while maintaining a safe environment. For example, students can participate in consults or rounds without stepping into patient rooms through the use of tablets [4,5]. In fact, this is already a strategy for our institution’s burn center during multidisciplinary rounds. As previously stated, even as clerkships return and social distancing measures are relaxed, the high use of telemedicine will likely persist. Therefore, students could continue to participate in these e-visits during their clerkships. The vast array of telemedicine initiatives can be utilized to augment traditional clerkships, providing students with broader access to diverse learning opportunities.

Concluding Thoughts

As telemedicine is further implemented, clinical skills unique to remote care have become necessary. The rapid adoption of telemedicine due to the COVID-19 outbreak can serve as an opportunity to augment medical education curricula and to continue to provide medical students with critical educational opportunities when in-person encounters are limited. If hospital systems are already building and expanding videoconferencing and e-visit tools for providers, why not include students as well?

Abstract

Physicians, nurses, and other health care providers initiated the #GetMePPE movement on Twitter to spread awareness of the shortage of personal protective equipment (PPE) during the coronavirus disease (COVID-19) pandemic. Dwindling supplies, such as face masks, gowns and goggles, and inadequate production to meet increasing demand have placed health care workers and patients at risk. The momentum of the #GetMePPE Twitter hashtag resulted in the creation of a petition to urge public officials to address the PPE shortage through increased funding and production. Simultaneously, the GetUsPPE.org website was launched through the collaboration of physicians and software engineers to develop a digital platform for the donation, request, and distribution of multi-modal sources of PPE. GetUsPPE.org and #GetMePPE were merged in an attempt to combine public engagement and advocacy on social media with the coordination of PPE donation and distribution. Within 10 days, over 1800 hospitals and PPE suppliers were registered in a database that enabled the rapid coordination and distribution of scarce and in-demand materials. One month after its launch, the organization had distributed hundreds of thousands of PPE items and had built a database of over 6000 PPE requesters. The call for action on social media and the rapid development of this digital tool created a productive channel for the public to contribute to the health care response to COVID-19 in meaningful ways. #GetMePPE and GetUsPPE.org were able to mobilize individuals and organizations outside of the health care system to address the unmet needs of the medical community. The success of GetUsPPE.org demonstrates the potential of digital tools as a platform for larger health care institutions to rapidly address urgent issues in health care. In this paper, we outline this process and discuss key factors determining success.

KEYWORDS

digital health; getusppe; getmeppe; COVID-19; personal protective equipment; protection; Twitter; pandemic; health care worker

Introduction

On March 17, 2020, the Twitter hashtag #GetMePPE went viral [1-3] as thousands of nurses, physicians, and other health care providers posted pictures of themselves with personal protective equipment (PPE). The pictures were accompanied by attestations of dwindling—or in some cases completely absent—stocks of

face masks, N95 respirators, and other supplies, even as providers began to evaluate and treat patients with coronavirus disease (COVID-19). The hashtag drew an outpouring of public support and media attention [4] amplifying the PPE shortage (Figure 1); a website, GetMePPE.org, obtained over 62,000 signatures for its online petition for increased government support of, and funding for, PPE [5].

Figure 1. Example tweet from an individual who increased the viewership of #GetMePPE [4].

Simultaneously, a separate group launched GetUsPPE.org [6] with the goal of connecting people who needed PPE with individuals or organizations who had some available. The two groups came together on March 21, with the GetUsPPE.org webpage taking on the #GetMePPE petition as well as the coordination of PPE donation delivery. Only 10 days later, the site had over 120,000 views, the petition had over 10,000 signatures, and over 1800 hospitals and PPE suppliers had entered their information into the continuously updated database.

Currently, one month after the merger, a web application with automated attribution and a last-mile system has facilitated the delivery of hundreds of thousands of items of PPE in three trial cities (getusppe.org/data), and partnerships have been formed with the American Medical Association, the American Hospital Association, and a number of specialty societies [7]. The GetUsPPE.org website was rapidly launched to collect available supply and demand requests. Textbox 1 shows a list of the types of facilities that can request PPE on the website.

Textbox 1. Types of health care facility designations for the Request Donations page on the GetUsPPE.org website.

- Acute care hospital
- Freestanding emergency room
- Field hospital
- Hospital overflow facility
- Emergency medical services
- Urgent care clinic
- Nonacute care hospital
- Inpatient psychiatric facility
- Inpatient rehabilitation facility
- Residential substance treatment facility
- Nursing home or skilled nursing facility
- Assisted living facility or group home
- Homeless shelter
- Correctional facility or detention center
- Hospice
- Dialysis center
- Outpatient clinic (primary care or specialist)
- Public health clinic or community health center
- Indian or Tribal healthcare facility (any kind)
- Outpatient rehabilitation facility
- Dental or oral surgery clinic (providing urgent/emergency care)
- Home health agency
- COVID-19 test site
- Ophthalmic provider
- Clinical laboratory
- Pharmacy
- Mortuary or coroner's office
- Social services organization
- Other

Much like just-in-time manufacturing [8], we propose that this type of rapid website deployment will be a solution in the future when urgent health care scenarios arise.

Needs

At the time of writing, 56/60 US jurisdictions (93.3%) have reported cases of COVID-19 infection [9]; most states are experiencing sustained community spread. While analysis of US statistics is ongoing, in analyses from Wuhan, China, 26% of patients received ICU care, and the mortality rate was 4.3% [10]. PPE is critical to protect health care workers at the front lines of caring for these patients. According to US Centers for Disease Control guidelines for use of PPE in US hospitals [11], both N-95 filtering facemask respirators and powered air-purifying respirators should be accompanied by the use of a full-face shield, helmet, or headpiece. Prior experience with

the Ebola virus and severe acute respiratory syndrome (SARS) affirm that PPE provides “the last physical barrier” between health care workers and infectious body fluids [12,13].

Despite this, health care providers across the United States are lacking basic PPE, including gowns and masks, as they care for sick patients with COVID-19 [14]. Evidence from past epidemics suggests that clinical workers are at much higher risk than the general population of being infected [15,16]. PPE shortages not only compromise the safety of health care workers but also put patients at risk. As health care providers fall sick, fewer of us are available to care for patients. The lack of PPE also results in higher infection rates within hospitals as staff move from patient to patient without proper protection. In the Wuhan case analysis, hospital-related COVID-19 transmission occurred in 41% of patients [10].

Application of Digital Tools

In less than 12 hours over the course of a weekend, a group of medical students, doctors, software engineers, and volunteers from around the US built and launched a web-based platform, GetUsPPE.org, to enable the public to answer the call for help. On the website, organizations requesting PPE report their name, organization type, and address, followed by their PPE needs (such as PPE types and conditions of acceptance). People or organizations interested in donating PPE provide their contact details and information about their supplies, and they indicate if they are available to deliver or ship them. We were immediately flooded with heartwarming support and offers to help, not only from a variety of existing sources of PPE but also from novel additive manufacturing facilities and homemade makers. More importantly, the site enabled us to collect signatures to push for government action, process PPE donations from a public now keenly aware of the problem, and facilitate distribution of the PPE to health care workers in need. The website now supports global affiliates, including India as a prominent partner [17].

We attribute the success of our digital platform to three key components. First, there was unity around a clear and common cause. Importantly, the effort was not limited to physicians but was extended to all staff impacted by the shortage of PPE. Through firsthand stories of paramedics facing exposure in the field, nurses treating patients who were coughing in their faces, housekeeping staff cleaning rooms without adequate protection, pharmacists assisting with intensive care unit medication dosing without masks, and concerned friends and family, it was clear that our platform was needed for health care workers of all types.

Second, as health care providers in the “trenches,” we leveraged social media to share what we were witnessing and give all stakeholders a voice. Using the #GetUsPPE hashtag, physicians shared photographs of themselves without proper PPE, video tutorials teaching each other how to create homemade PPE [18], and images of store shelves fully stocked with boxes of N95 masks [19] while hospitals had none [20]. Stories circulated quickly on Twitter and on other social media platforms, including stories of emergency physicians hospitalized after contracting COVID-19 on the job [21]. Later, the stories became more uplifting, with updates of community members coming together to support health care workers and donate PPE to hospitals and other health care organizations.

Finally, the digital platform itself is intuitive and easy for users to negotiate, and it was not difficult to develop. The website, while initially primitive, was created literally overnight with

the aid of the increasingly large number of tools that facilitate building and maintaining websites for the uninitiated; after its quick launch, the site experienced rapid growth. The live launch and traffic catalyzed further development and collaboration with subject matter experts to quickly iterate multimodal technological solutions, including databases (eg, to store information regarding which hospitals are most in need of PPE), matching algorithms (eg, to match PPE donations with the closest hospital in need), and logistics capabilities (eg, to coordinate the manufacturing of PPE and delivery to hospitals).

Lessons

Our experience with #GetMePPE and GetUsPPE.org exemplifies the untapped potential of digital platforms to mobilize and enable a ready and willing public to alleviate some of the largest barriers faced by health care workers. The COVID-19 pandemic has illuminated the deficiencies of our health care supply chain, rendering traditional sources of support inadequate. Fortunately, digital literacy is increasing rapidly worldwide, and the general public is increasingly embracing digital media. However, the medical field has yet to take full advantage of this opportunity.

Social media is just one example of a digital opportunity for health care providers to help increase the quality and efficiency of health care [22]. Current use of social media by physicians is mostly one-way rather than interactive [23]. However, it is critical for health care providers and organizations to create and participate in websites. While social media is essential for raising public awareness and excitement, a website enables health care providers to action this momentum to manifest tangible benefits for themselves and their patients.

Conclusion

GetUsPPE.org is just one example of the successful use of digital tools not only to voice needs, such as those of people working on the front lines of a pandemic, but to mobilize available resources at a speed we have rarely seen before. This initiative has demonstrated the efficacy, reach, and speed of digital platforms; however, it by no means represents the potential the medical community could achieve with full support and buy-in from larger national organizations or the federal government. To date, we have taken a bottom-up, grassroots approach, operating in entrepreneurial fashion, often donating our personal time and resources. It is interesting to imagine what we could accomplish with formal support. In this time of unprecedented crisis and need, we health care professionals have a responsibility to do everything we can to offer the best possible care, including ensuring that we can continue serving our patients without sacrificing either our safety or theirs.

Abstract

People across the world have been greatly affected by the ongoing coronavirus disease (COVID-19) pandemic. The high infection risk of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) in hospitals is particularly problematic for recently delivered mothers and currently pregnant women who require professional antenatal care. Online antenatal care would be a preferable alternative for these women since it can provide pregnancy-related information and remote clinic consultations. In addition, online antenatal care may help to provide relatively economical medical services and diminish health care inequality due to its convenience and cost-effectiveness, especially in developing countries or regions. However, some pregnant women will doubt the reliability of such online information. Therefore, it is important to ensure the quality and safety of online services and establish a stable, mutual trust between the pregnant women, the obstetric care providers and the technology vis-a-vis the online programs. Here, we report how the COVID-19 pandemic brings not only opportunities for the development and popularization of online antenatal care programs but also challenges.

Introduction

The coronavirus disease (COVID-19) outbreak has spread globally and caused a pandemic that has led to almost 10,000,000 diagnosed cases and 500,000 deaths as of June 28, 2020 [1]. The impact of COVID-19 can be greater in vulnerable

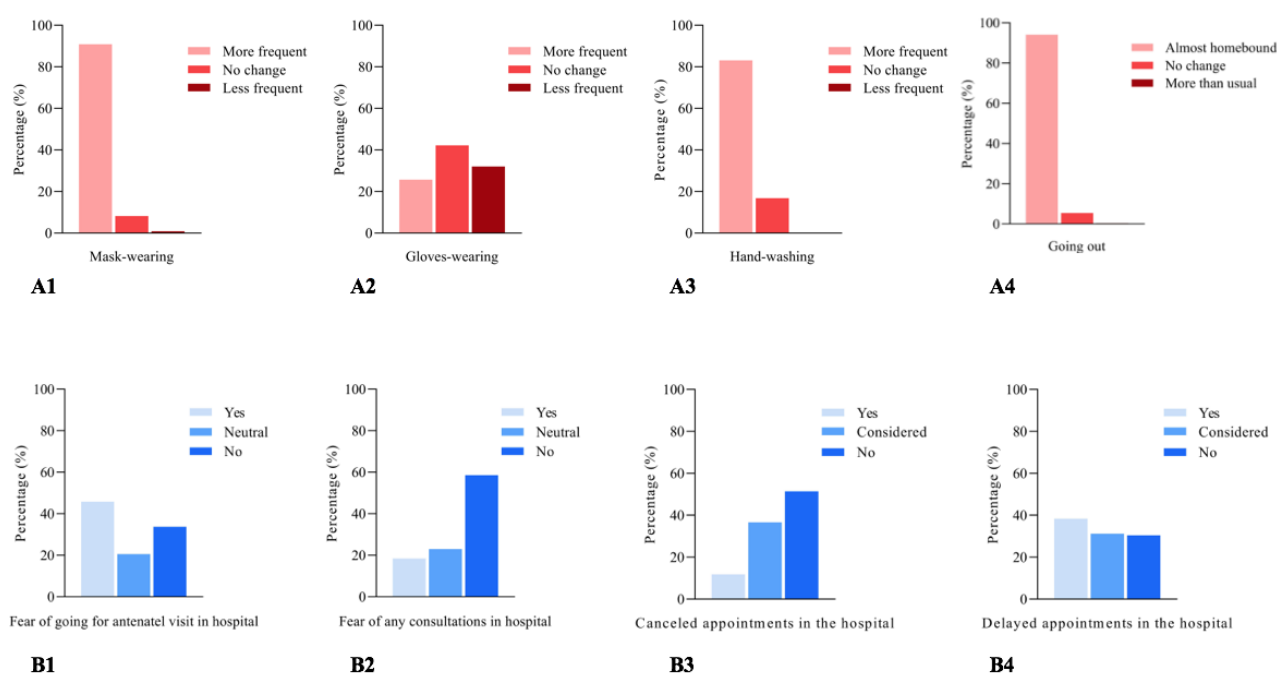

populations. Pregnant women, for example, tend to be more physiologically and psychologically susceptible to infectious diseases, putting them at higher risk of maternal complications such as preterm birth, gestational hypertension, gestational diabetes, and miscarriage [2-4]. Appropriate antenatal education can be beneficial to them in many ways including reducing cesarean section rates, maternal and infant mortality, and anxiety

problems as well as improve their general reproductive health outcomes [5]. In the context of the pandemic, pregnant women face an additional dilemma—they need professional antenatal care, there is a potential risk for cross-infection if they choose to visit a hospital to receive this service [6].

Recently, we performed a web-based survey among Chinese pregnant women via a national online platform (Banmi National Online Maternity School) to investigate their self-protection behaviors and attitudes toward antenatal care during the pandemic. A total of 983 Chinese pregnant women completed the questionnaire, and it was found that more than 80% had taken self-protection actions, such as wearing a face mask,

handwashing, and home quarantine, to avoid being infected with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) (Figure 1). Our findings indicate that about 20% of respondents were afraid of any type of consultation at a hospital, while over 40% feared in-hospital antenatal visits. Moreover, more than half considered or decided to cancel their in-hospital antenatal care visits and postponed their appointments. These behaviors and attitudes indicate that pregnant women were anxious and worried about potential infection in the hospital environment. Considering the dilemma mentioned above and the fear of some other unknowns from hospital visits, online antenatal care might be a preferable choice for pregnant women during this pandemic [7].

Figure 1. Pregnant women's self-protection behaviors and attitudes toward antenatal care in hospitals.

Online Antenatal Care Programs Before the COVID-19 Pandemic

Online antenatal care programs can take various forms: online courses to deliver pregnancy-related information, mobile phone apps to motivate healthy behaviors during pregnancy, and mobile health (mHealth) apps to provide mental consultations [8,9]. Numerous studies have reported that a great majority of pregnant women search for pregnancy-related information on the internet [10,11]. However, the popularity of online antenatal care programs remains low.

Opportunities for Online Antenatal Care During the Pandemic

In the midst of the COVID-19 pandemic, it is advisable that pregnant women should stay at home and receive necessary antenatal care via online antenatal care programs. For example, online antenatal care programs may guide pregnant women to

perform blood and urine glucose tests at regular intervals, especially for those with or at high risk of gestational diabetes mellitus (GDM). The obstetric doctor can then closely monitor patients' glucose levels and provide appropriate dietary suggestions and medications. This would be helpful in decreasing the incidence and negative impact of GDM. Moreover, women can upload their daily blood pressure and simple home urine dipsticks results to an online system. This would allow monitoring for serious pregnancy complications such as preeclampsia. General gestational education and mental health consultation can be done through an online education program via voice or video calls. Pregnant women can also be guided to study pregnancy and labor instructions through books, and receive antenatal care education by online conferencing. All of these approaches would likely contribute to better labor preparedness, maternal experience, postpartum adjustment and outcomes, fewer infection risks, and more economic benefits to the health system and the women themselves. Therefore, pregnant women without any serious issues should use online antenatal care programs as an alternative to routine antenatal

care in a hospital at least to some extent. Learning to self-monitor while in lockdown or home quarantine is essential to prevent viral infection or spread [12]; this is especially important to pregnant women as they are more likely to have severe complications if infected with SARS-CoV-2 [13-15].

During the pandemic, daily necessities were scarce and the cost of medical appointments was substantially higher than usual. Many families lost employment and suffered a heavy economic burden. People who were unable to obtain or pay for sufficient medical resources were most vulnerable [16]. Online antenatal care can provide relatively less expensive medical services and diminish inequalities in health care due to its convenience and cost-effectiveness, especially in developing countries or regions. This could contribute to a reduction in medical resources inequality and help pregnant women resolve various health problems during the pandemic. Medical experts and institutions should strengthen the quality of online antenatal care in terms of skilled professional services, technology, and availability.

Challenges of Online Antenatal Care During the Pandemic

There are some challenges and areas for improvement associated with online antenatal care. A study in China found that many pregnant women had concerns about the reliability of online gestational information [17]. Therefore, it is important to establish close collaboration between hospitals and professional institutes to improve the quality of online programs, ensuring the reliability of their information. In the meantime, this can be combined with information technology products, such as using electronic devices with remote monitoring functions to monitor basic indicators such as fetal heart rate and movement, to serve as a proxy for some routine obstetric examinations. However, in certain circumstances, antenatal care in hospitals is irreplaceable (eg, high-risk pregnant women with or at risk of vaginal bleeding, abdominal pain, or other serious discomforts) [18]. In such cases, further obstetric examinations and consultations in a hospital are essential. Moreover, some specific antenatal examinations such as the Nuchal Translucency test,

Down syndrome screening, and the Oral Glucose Tolerance Test should be completed in a hospital. The future of maternal care is likely to include technological innovations to address the above challenges. Due to this, more extensive, optimized maternal care services should be applied to reduce overall maternal morbidity and mortality if online antenatal care are to be further developed, popularized, and adopted as an alternative path to health care services for pregnant women.

Furthermore, it has been mentioned that less than one-third of the population in Africa and the Middle East use the internet, with a global usage rate of 51% in 2018 [19]. Therefore, in addition to improving online antenatal care, the popularization of both the use of the internet and mobile electronic devices is crucial to allow more pregnant women to receive online education and care. Network operators need to be improved to guarantee the widespread use of internet services during the COVID-19 outbreak. Governments should use their financial budget to support the popularization of modern electronic devices and internet service, which are essential for online antenatal care programs. Additionally, governments need to legislate relevant laws to regulate and protect the privacy of pregnant women when using online antenatal care services.

Conclusion

In summary, online antenatal care can be a useful, alternative option for pregnant women in need of basic antenatal care and mental health consultation. It can reduce unnecessary hospital visits and limit potential risks of infection among this vulnerable group during the COVID-19 pandemic. Efforts to implement online care is likely to result in multiple innovations and revolutionize antenatal care services both in China and globally. This will contribute to reducing maternal morbidity and mortality by providing opportunities for wider coverage. The popularization of online antenatal care programs is likely to have an economic benefit to both the health care system and to women in terms of cost, time, and manpower. This can improve overall maternal and reproductive health services and family life.

Authors' Contributions

HW, WS, and XH contributed equally to this work. HW, WS, and XH contributed to the conception and design of this viewpoint, drafted the primary version of manuscript, edited the manuscript, and reviewed the final version. SY, HW, XB, JS, SC, BA, and CJPZ edited and reviewed the final version of manuscript. WM contributed to the conception and design of this viewpoint, edited the manuscript, and reviewed the final version. All authors discussed and agreed on the implications of the study findings and approved the final version to be published.

Abstract

Biofeedback has shown to be a promising tool for the treatment of anxiety; however, several theoretical as well as practical limitations have prevented widespread adaptation until now. With current technological advances and the increasing interest in the use of self-monitoring technology to improve mental health, we argue that this is an ideal time to launch a new wave of biofeedback training. In this viewpoint paper, we reflect on the current state of biofeedback training, including the more traditional techniques and mechanisms that have been thought to explain the effectiveness of biofeedback such as the integration of operant learning and meditation techniques, and the changes in interoceptive awareness and physiology. Subsequently, we propose an integrative model that includes a set of cognitive appraisals as potential determinants of adaptive trajectories within biofeedback training such as growth mindset, self-efficacy, locus of control, and threat-challenge appraisals. Finally, we present a set of detailed guidelines based on the integration of our model with the mechanics and mechanisms offered by emerging interactive technology to encourage a new phase of research and implementation using biofeedback. There is a great deal of promise for future biofeedback interventions that harness the power of wearables and video games, and that adopt a user-centered approach to help people regulate their anxiety in a way that feels engaging, personal, and meaningful.

Introduction

Background

The era of the quantified self is upon us [1]. Anywhere and at any time, we have access to an abundance of information about how our bodies are adapting to the world around us, be it through the internet, apps on our smartphones, or wearable devices. With these current technological advances, we are able to track, monitor, and regulate various aspects of our physiological and behavioral activation, ranging from heart rate to sleep patterns, to number of steps taken, and calories burned. The popularity of these devices and apps is increasing, and they are becoming increasingly simple to integrate into our daily

lives, providing us with the means to take on a more active role in the management of our health and well-being [2-9].

Monitoring our physiological state informs us about not only our physical health but also our psychological well-being, as our physiology is intimately linked with our psychology [10-12]. In particular, our ability to monitor and modulate our emotional arousal, feelings, and expressions—our capacity for emotion regulation—is an integral part of mental health [13,14]. One fundamental aspect of emotion regulation is interoceptive awareness, which is the ability to sense and interpret internal physiological signals [15-18]. Furthermore, physiological dysregulation underpins breakdowns in mental health and psychopathology (eg, anxiety disorders) [19-24]. For some diagnoses such as generalized anxiety disorder and posttraumatic

stress disorder, physiological symptoms and dysregulation also serve as important inclusion criteria for diagnosis [19]. However, the majority of current interventions for anxiety and related disorders mainly focus on cognition and behavior, with physiology being seemingly undervalued.

The Promise of Biofeedback

Together with psychopharmacology, cognitive behavioral therapy (CBT) is currently viewed as the gold standard for the treatment of anxiety [25-27]. Although some components of CBT involve attending to the physiological signals of anxiety, such as self-monitoring and relaxation training, the core of CBT programs is aimed at modifying the maladaptive cognitive and behavioral components of anxiety instead [28-30]. This is an important limitation, as somatic symptoms are strongly related to the severity and level of impairment associated with anxiety [22,31,32]. Therefore, integrating training that facilitates the awareness, monitoring, and regulation of physiological signals might strengthen the effectiveness of anxiety treatment.

In recent years, there has been a rising interest in incorporating self-monitoring technology in the field of medicine and treatment of mental health [7,9,33,34]. In addition to fostering self-regulation, this type of technology also aligns with the current treatment needs as individuals seem to increasingly gravitate toward holistic forms of therapy that emphasize the mind-body connection and allow them to take on an active role in managing their health [7,35]. One promising form of self-monitoring technology is biofeedback. Biofeedback is the process of measuring an individual's physiological states and feeding that information back to them so that they can learn how to change their physiological activity for the purpose of health improvement [35]. Biofeedback has an extensive history in science [36] and has been shown to be efficacious as a treatment for a large variety of physical [37-39] as well as mental health issues, including stress and anxiety [40-43]. Surprisingly, however, biofeedback has not yet been widely implemented in standard anxiety treatment. Instead, it is generally regarded as an alternative form of treatment [25]. The reported use of alternative treatment is fairly high among people with anxiety, with the most recent numbers indicating that 1 out of 6 (16%) patients with anxiety received alternative care in addition to conventional care [44]. Earlier studies reported numbers ranging between 110 out of 193 (56.7%) [45] and 430 out of 1004 (43%) [26]. However, the available estimate for the specific use of biofeedback among people with anxiety seems fairly small, specifically 3 out of 193 (1.6%) [45].

Part of the reason why biofeedback has not yet been incorporated in standard treatment programs is our general lack of understanding of the mechanisms by which biofeedback training actually works. Although some factors that can explain the effectiveness of biofeedback have been proposed, there is no existing model that encompasses the possible mediating or moderating factors that contribute to positive outcomes of biofeedback training and what should be implemented to strengthen its effects. Understanding the processes that lead to improvement is essential in intervention research, even though they are often overlooked [46]. In addition, practical limitations including hardware requirements, costs, time commitment, and

lack of engagement may have prevented wide adaptation [47,48]. However, there have been some promising advancements in recent years that may address some of these limitations, such as the development of biofeedback-based video games, which may increase accessibility and engagement, especially for youth [49-57]. With these current technological advancements in biofeedback training and the accompanying surge in self-monitoring apps, we propose that biofeedback could have a second run in the treatment of anxiety.

Objective

This viewpoint paper reflects on the current state of biofeedback training for the treatment of anxiety. The theoretical and scientific background regarding the working mechanisms of biofeedback are reviewed. In addition, several key gaps in the empirical literature are highlighted, and reasons for these oversights are addressed. Subsequently, we propose an integrative theoretical model that combines factors that have been traditionally linked to the effectiveness of biofeedback with cognitive appraisals as determinants of the effectiveness of biofeedback training. Finally, a set of guidelines will be presented for future research and the design and implementation of a new wave of biofeedback training. These guidelines will be based on the integration of our theoretical model with the mechanics and mechanisms offered by emerging interactive technologies such as video games and wearables. Using these guidelines, we aim to encourage a new phase of research and implementation using biofeedback.

Techniques Used in Biofeedback Training

Operant Learning

One core technique that is integrated in biofeedback training is operant learning. In biofeedback training, feedback is given about physiological changes that occur. The complexity of biofeedback can vary from presenting raw signals of physiological activity (eg, heart rate variability [HRV], respiration, and electroencephalography [EEG] signals) to a moving frequency analysis [58]. In clinical and educational settings, additional aids are often provided by presenting feedback in the form of graphs, images, or sounds [59]. However, simply showing individuals their activity is insufficient. Instead, it is vital that individuals are actively taught, using operant (or instrumental) learning, how to change their physiological state, specifically by providing real-time feedback and reinforcement while regulation attempts are made [60-64].

In operant learning, positive reinforcement is used to shape an individual's behavior by strengthening adaptive behavior through the use of rewards, which makes the original behavior more likely to occur [65]. In a typical biofeedback paradigm, an individual is placed in front of a computer screen on which feedback regarding their physiological state is presented. When the appropriate activity increases or inappropriate activity decreases, this change is followed by a pleasant response (eg, a pleasant tone). As sessions are repeated, the thresholds for receiving a reward are gradually modified, thereby stimulating the display of healthy physiological activity [66,67].

Meditation Techniques

In addition to operant learning techniques, biofeedback training often incorporates self-regulation techniques that are similar to meditation and mindfulness practices. Meditation is a practice consisting of various exercises that are meant to shift one's attention primarily to internal stimuli to achieve better well-being and emotional balance [31,68]. Mindfulness meditation likewise aims to shift one's attention to present experiences, but puts an additional emphasis on regarding experiences in a nonjudgmental and accepting manner [69,70].

Furthermore, similar mechanisms of change can be identified in both biofeedback and meditation. For instance, similar physiological patterns of change are found in response to biofeedback as well as meditation [71], such as a coherent cardiac rhythm [72,73]. Another similarity is that both practices encourage individuals to shift their attention to internal experiences. In biofeedback, this is achieved by using biosensors to provide individuals with feedback on changes in their physiological activity, whereas in mindfulness training, this is achieved by guided meditation exercises where individuals are prompted to shift their attention to the present moment and present experiences [69,70,74]. Both approaches also often train individuals to use slow, diaphragmatic breathing [58,75-79]. However, although both approaches try to enhance individuals' internal attention, biofeedback specifically focuses on changes in physiological activity, whereas meditation aims for a broader focus on the present moment, including all present experiences. Furthermore, mindfulness meditation explicitly encourages individuals to regard observed sensations in a nonjudgmental manner [69,70], whereas biofeedback training does not. The core difference between meditation and biofeedback, however, is that meditation training does not provide feedback on how the person is doing in terms of regulating their stress. In contrast, biofeedback training gives participants continuous feedback on how they are doing in terms of physiologically regulating their stress. Thus, although there are various similarities between meditation practices and biofeedback, we argue that the feedback provided in biofeedback training is crucial to help people gauge their progress and to keep them engaged in the training.

Working Mechanisms in Biofeedback Training

Interoceptive Awareness

Various mechanisms have been proposed to explain the effectiveness of biofeedback (Figure 1). One of the core

assumptions is that biofeedback leads to increases in interoceptive awareness, which in turn helps individuals to better regulate their physiology (Figure 1, paths A and B) [80-82]. Interoceptive awareness is our ability to sense and interpret internal and physiological signals, which is an important part of emotion regulation [13,15,36,83,84]. Scientific research on interoceptive awareness started in the field of psychophysiology back in the 70s and 80s, followed by a new wave of interest in the 90s sparked by the introduction of the somatic marker hypothesis [36,83]. According to this hypothesis, the interpretation of bodily sensations is closely associated with emotional processing and decision making [10,85]. These early days of interoceptive awareness research also gave rise to the idea that biofeedback training could help individuals improve their interoceptive awareness [36], and this assumption is still at the core of biofeedback research today [35,38,41,43,47,59,60,86,87]. The support for this claim, however, seems to be mostly theoretical in nature, as there is very little direct empirical evidence showing that biofeedback training systematically improves awareness of physiological states (Figure 1, path A). Equally important is that it is unclear if and when this internal acuity is adaptive [36,88,89].

Interoceptive awareness has been positively related to decision making [90,91] as well as various forms of emotional processing, such as emotional memory [92], emotion recognition [93], and emotion regulation [15-18]. Importantly, it seems that increased interoceptive awareness is not always better. For example, heightened interoceptive awareness has been linked to increases in anxiety [94,95] and has also been linked to various anxiety disorders such as panic disorder and social anxiety disorder [89,96-99]. In individuals with panic disorder, an increased focus on and the subsequent misinterpretation of physiological sensations is the main cause of panic attacks [96,100]. For individuals with social anxiety disorder, this vigilant attention to physiological sensations likewise impairs their ability to process information from their immediate social environment. Socially anxious individuals often interpret bodily sensations of anxiety as a confirmation that they cannot function well in social situations. Furthermore, these anxious individuals believe that their bodily sensations are clearly noticeable by others, which plays into their fear of being humiliated [89,97,101,102]. Thus, whether or not high levels of interoceptive awareness are adaptive seems to, at least in part, rely on how internal sensations are interpreted.

Figure 1. Traditional techniques and mechanisms thought to explain the effectiveness of biofeedback training.

Physiological Changes

Biofeedback training teaches individuals how to regulate their physiological activity [35], and the benefit of biofeedback is often attributed to the acquisition of these self-regulation skills. This belief is rooted in the large body of research dedicated to linking specific emotional states to specific physiological changes [36]. The strong physiological ties of anxiety make it a particularly fitting target for biofeedback, as biofeedback training addresses a wide array of physiological processes. The most prominent forms of biofeedback that are used for anxiety treatment and stress management are HRV biofeedback and neurofeedback.

Heart Rate Variability Biofeedback

The primary aim of HRV biofeedback is to create a balance in the autonomic nervous system (ANS). The ANS is divided into 2 branches: the sympathetic nervous system (SNS) and the parasympathetic nervous system (PNS). The SNS prepares individuals for action by increasing their heart rate, blood pressure, and cardiac output, whereas the PNS slows these processes as part of the restorative process [103,104]. Anxiety has mostly been tied to hyperarousal of the SNS, which is associated with physiological responses such as increases in breathing rate and intensity, heightened blood pressure, increases in electrodermal activity, increases in heart rate, and decreases in HRV [42,105]. However, anxiety can also be tied to disrupted PNS function, as is reflected in the low vagal tone that is exhibited by individuals with anxiety disorders [105-109]. Vagal tone is the inhibitory action exerted by the vagus nerve. Specifically, an increase in vagal tone lowers the heart rate and a decrease in vagal tone elevates the heart rate [108]. Vagal tone is used as a marker for emotion regulation, with a higher vagal tone reflecting effective emotion regulation and a lower vagal tone reflecting emotion regulation deficits [110-112].

As the name indicates, HRV biofeedback targets the variability in time (R-R) intervals between heart beats [113,114]. HRV is an important marker for emotion regulation as it reflects the interplay between the PNS and the SNS [110,114-117]. HRV has shown to be particularly sensitive to changes in emotional state, with positive and negative emotions often being readily distinguishable [72]. During negative emotions such as anxiety, there is less synchronization between the PNS and the SNS [118]. In particular, low HRV has been linked to a lack of emotional flexibility [119,120] and has been found to be present in depression [121,122] and anxiety disorders [105,106,109,123].

The primary aim of HRV biofeedback is to create autonomic balance by enhancing cardiac coherence, which is a heart rhythm oscillating at a frequency of approximately 0.1 Hz [39,58,72]. In common HRV biofeedback paradigms, this rhythm is achieved by training individuals to increase the amplitude of respiratory sinus arrhythmia (RSA) [39,58]. RSA is the cyclical change in heart rate occurring when the heart rate increases during inhalation and decreases during exhalation. RSA is commonly used as an index of vagal control of the heart, particularly parasympathetic control [124]. Low amplitudes of RSA are found in anxious and depressed individuals [125,126], and HRV biofeedback aims to increase these amplitudes [58].

In HRV biofeedback training, participants are often shown raw signals of their HRV or a moving frequency analysis. Participants are then instructed to pace their breathing to around 6 breaths per minute to maximize their RSA amplitude [58,75].

Neurofeedback

In addition to heart function, emotion regulation deficits in anxious individuals have also been linked to irregularities in electrical activity in various brain regions such as the amygdala and the prefrontal cortex [127,128]. Neurofeedback uses a brain-computer interface to provide feedback to an individual about their brain's electrical activity, which is measured by EEG electrodes placed on the scalp. The aim of neurofeedback training is to maintain the level of brain activity within a specified frequency range (eg, Theta 4-8 Hz) [61,129,130]. Effective neurofeedback training protocols for the treatment of anxiety have mostly focused on enhancing alpha, increasing higher theta activity, and inhibiting beta frequencies [66,67,131,132]. However, quantitative EEG is increasingly used to identify additional patterns of brain activity related to anxiety and to improve neurotherapy (for a detailed overview, refer to the study by Price and Budzynski [132]).

Limitations and Gaps in Biofeedback Research

Despite the fact that teaching individuals to change their physiology is central to both HRV biofeedback as well as neurofeedback, there is no convincing evidence as to whether these changes are indeed essential for positive treatment outcomes (Figure 1, path C). In fact, early evidence suggests that physiological changes may only account for a small percentage of variance in clinical outcomes [133,134]. In current efficacy studies, physiological changes are treated as secondary to clinical changes [39], with many studies failing to check whether subjects have been trained to criterion, thus lacking a demonstration that physiological responses have truly been altered [43]. When changes are monitored in neurofeedback, many individuals seem unable to effectively control their physiological activity [135]. However, even in the absence of significant physiological changes, or even when the change was in the wrong direction, significant clinical improvements can still be found [131]. In HRV biofeedback training, similar findings indicated improvements in symptoms of depression and anxiety, although no significant changes in HRV could be established [136]. In addition, improvements in anxiety were found even when sham feedback was given [137]. This could indicate that certain expectations or perceptions of control in relation to biofeedback training may be important determinants for the treatment outcomes of biofeedback [62,135]. However, empirical evidence regarding specific working mechanisms and possible influencing factors related to physiological changes in biofeedback training is lacking.

In the current biofeedback literature, the efficacy of biofeedback is attributed to the implementation of operant learning reinforcement and meditation techniques as well as changes in interoceptive awareness and physiology (Figure 1). Although there is indeed a wealth of theoretical speculation about the importance of these factors, the empirical evidence linking these processes to biofeedback outcomes remains scarce. Equally important is the fact that there are likely important mechanisms

that mediate the effectiveness of biofeedback that have not yet been investigated. Specifically, we propose that there is a set of cognitive appraisals that acts as a mediator between previously identified processes (eg, interoceptive awareness and physiological change) and anxiety reduction from biofeedback training. In the section *Cognitive Mechanisms Underlying Biofeedback Processes*, we introduce this set of cognitive mechanisms and discuss the importance of including them in a more comprehensive framework for understanding biofeedback training.

Cognitive Mechanisms Underlying Biofeedback Processes

Regulating physiology (such as heart rate) is only one aspect of emotion regulation. Emotion regulation also includes changing subjective experience (affective states) as well as cognitions [13]. Cognitive processes, including how we interpret and evaluate certain situations or feelings, play a major role in the onset and regulation of emotion as well as how we respond to and interact with our environment [11,13,138,139]. Evaluations and interpretations of certain events or situations are commonly referred to as appraisals, which are central to our current understanding of emotion [104,140]. Appraisals drive our entire emotional experience, including how our body reacts (eg, sweating or heart racing), how we feel (eg, anxious or calm), and how we take action (eg, avoid or approach) [139,141-144]. Furthermore, dysfunctional interpretations and attributions mediate recovery from mental health problems [145,146]. Appraisals may, therefore, be an important factor explaining or contributing to the effectiveness of biofeedback interventions that aim to help individuals with stress and anxiety.

The broad categories of appraisals include valence (eg, whether something is viewed as positive or negative); causal agency; evaluations regarding one's potential to cope with or control a situation; and compatibility and relevance with regard to one's goals, norms, and expectations. Different appraisals of the same situation or stressor can therefore lead to an array of emotional responses [140]. We suggest that there are varying levels of appraisals that are relevant to understanding the mechanisms by which biofeedback works: appraisals of the self, such as self-efficacy and locus of control, and situational appraisals, such as threat-challenge appraisals.

Self-Efficacy

When considering appraisal mechanisms by which biofeedback may work to regulate anxiety, appraisals about the self are particularly relevant [140,147]. For example, someone's uncertainty regarding their ability to cope with a situation is highly predictive of anxiety [148]. Whether someone succeeds in self-regulation may therefore strongly depend on their self-efficacy, in other words, the belief that they can do it. Various meta-analyses have shown that self-efficacy is important for self-development, adaptation, and change [149]. Moreover, high self-efficacy is linked with better emotion regulation skills and general psychosocial functioning [150]. In contrast, low levels of self-efficacy are accompanied by high levels of anxiety [151-153]. In youth, self-efficacy has been found to be predictive of the development and maintenance of affective disorders [154,155]. Furthermore, self-efficacy is an important predictor

of treatment outcomes for panic disorder [156]. Given the importance of self-efficacy in anxiety regulation, it is likely a key mechanism for effective biofeedback training.

Locus of Control

An additional way in which self-efficacy may be tied to biofeedback is by changing the locus of control. Locus of control refers to the degree to which individuals believe that they themselves have control over the outcome of events in their lives (internal locus) as opposed to forces outside of their control (external locus) [157,158]. People with high self-efficacy generally have an internal locus of control, believing that their own actions and decisions shape outcomes. In contrast, people with low self-efficacy have an external locus of control, often viewing their lives as being beyond their control [149]. Control is an important factor that determines distress and anxiety in a given situation. Specifically, the less someone feels like they are in control, the more anxious they become [159-163]. Moreover, perceived control has been shown to predict outcomes of mental health therapy, with stronger feelings of control being linked to better outcomes [164]. The amount of control someone feels in biofeedback paradigms may therefore influence the success of the training [60,162,164].

Over the course of biofeedback training, with repeated practice and continued feedback on physiological changes, participants in training may increasingly believe that they themselves can influence the outcome of the intervention, in turn leading to a decrease in distress and anxiety. If biofeedback training indeed leads to an increased internal locus of control and locus of control directly influences anxiety, this may also explain why positive therapeutic outcomes of biofeedback can still be present even in the absence of significant physiological changes or when sham feedback is given.

Threat and Challenge

Appraisals of the self often interact with more specific appraisals regarding the situation at hand to determine how anxious someone is and whether they are able to regulate their anxiety. For instance, when personal resources are perceived as greater than the situational demands posed by a stressor, the situation is likely to be appraised as a *challenge*. However, when situational demands are perceived as exceeding personal resources, the situation is more likely to be appraised as a *threat* [36,165-167]. Therefore, someone with high self-efficacy is more likely to view difficult tasks as something to be mastered (ie, a challenge) rather than something that should be avoided (ie, a threat) [168].

Challenge and threat appraisals are both related to activation in the SNS. However, they differ in how they prepare the body for action. When individuals enter a threat state, the body responds by activating the hypothalamic-pituitary-adrenal axis, leading to increases in cortisol production. In addition, downstream vascular resistance increases and cardiac efficiency decreases. These changes prepare the body for damage of a physical or social nature. In contrast, when individuals are in a challenge state, there is an increased activation of the sympathetic-adrenal-medullary axis, which results in increased oxygenation of the bloodstream to the brain and peripheral sites

and vasodilation, leading to increased cardiac efficiency. These changes prepare the body for approach-oriented behavior [166].

In biofeedback training, the goal is to change a person's physiological activity from an erratic state to one where there is increased cardiac efficiency and synchrony between the parasympathetic and sympathetic branches of the ANS, that is, a state of autonomic balance or homeostasis [39,58,72,118]. However, the extent to which homeostasis is maintained may not solely depend on practice and feedback but may also be determined or moderated by how physiological activity is appraised over the course of biofeedback training. According to the threat-challenge model, these appraisals are key to changing physiology, cognition, and behavior in stressful situations [166,169]. Indeed, reappraising stress arousal as helpful rather than harmful has been shown to effectively reduce attention bias to threat cues and improve physiological functioning, resulting in decreased vasoconstriction and increased cardiac efficiency [170]. Thus, another way in which biofeedback may work is by helping individuals to shift from interpreting their physiological arousal as being indicative of a challenge rather than a threat.

An Integrative Model of Biofeedback Training

We began by reviewing the main factors to which the effectiveness of biofeedback has conventionally been attributed, including the implementation of operant learning and meditation techniques and changes in interoceptive awareness and physiology (Figure 1). We suggested that cognitive processes have been largely neglected in biofeedback research even though they play an important role in emotion regulation and adaptive trajectories of anxiety treatment [11,13,138,139,145,146]. Several cognitive appraisal dimensions were identified that may be important determinants of adaptive trajectories within biofeedback training. Specifically, we identified appraisals varying from appraisals of the self to situation-specific appraisals. In the section Real Time Change we propose an integrative model that combines and causally links these appraisals with previously identified mechanisms to explain the effectiveness of biofeedback. In this model, we pay particular

attention to both the real-time changes that occur within single biofeedback sessions and the developmental changes that may happen as a result of repeated exposure and training.

Real Time Change

Figure 2 summarizes our integrative model of biofeedback effectiveness on a real-time scale. We propose that the relationship between interoceptive awareness and anxiety regulation could be mediated by changes in a person's moment-to-moment appraisals (Figure 2). Focusing on these real-time processes could potentially address conflicting results in past research on biofeedback. On the one hand, increasing interoceptive awareness through biofeedback is thought to facilitate anxiety regulation. On the other hand, we also know that an increase in physiological awareness can lead to an increase in anxiety [94,95]. Examining how cognitive appraisals may interact in a feedback process in real time with interoceptive awareness helps us make sense of these contradictory findings.

At the start of biofeedback training, participants with heightened anxiety symptoms may begin with low interoceptive awareness, and they may not yet be able to effectively self-regulate. However, as biofeedback training continues, awareness of physiological signals may increase as participants begin to detect changes in their physiology. Importantly, however, this increase in awareness may only have a positive effect on self-regulation when certain appraisals are elicited. For instance, when a person becomes aware of physiological sensations and changes related to their anxiety but they have low self-efficacy, their ability to effectively self-regulate may be impeded and give rise to further anxiety. Alternatively, a person with higher self-efficacy who becomes increasingly aware of changes in their physiology may feel more competent to focus on the training and regulate that physiology. Thus, appraisals such as self-efficacy and locus of control may influence the real-time effects of biofeedback training within individual sessions. However, we argue that for lasting improvements in anxiety to be realized through biofeedback, repeated sessions are needed for locus of control, self-efficacy, and threat-challenge appraisals to change and stabilize into more resilient patterns.

Figure 2. Integrative model of changes in real time including appraisal mechanisms.

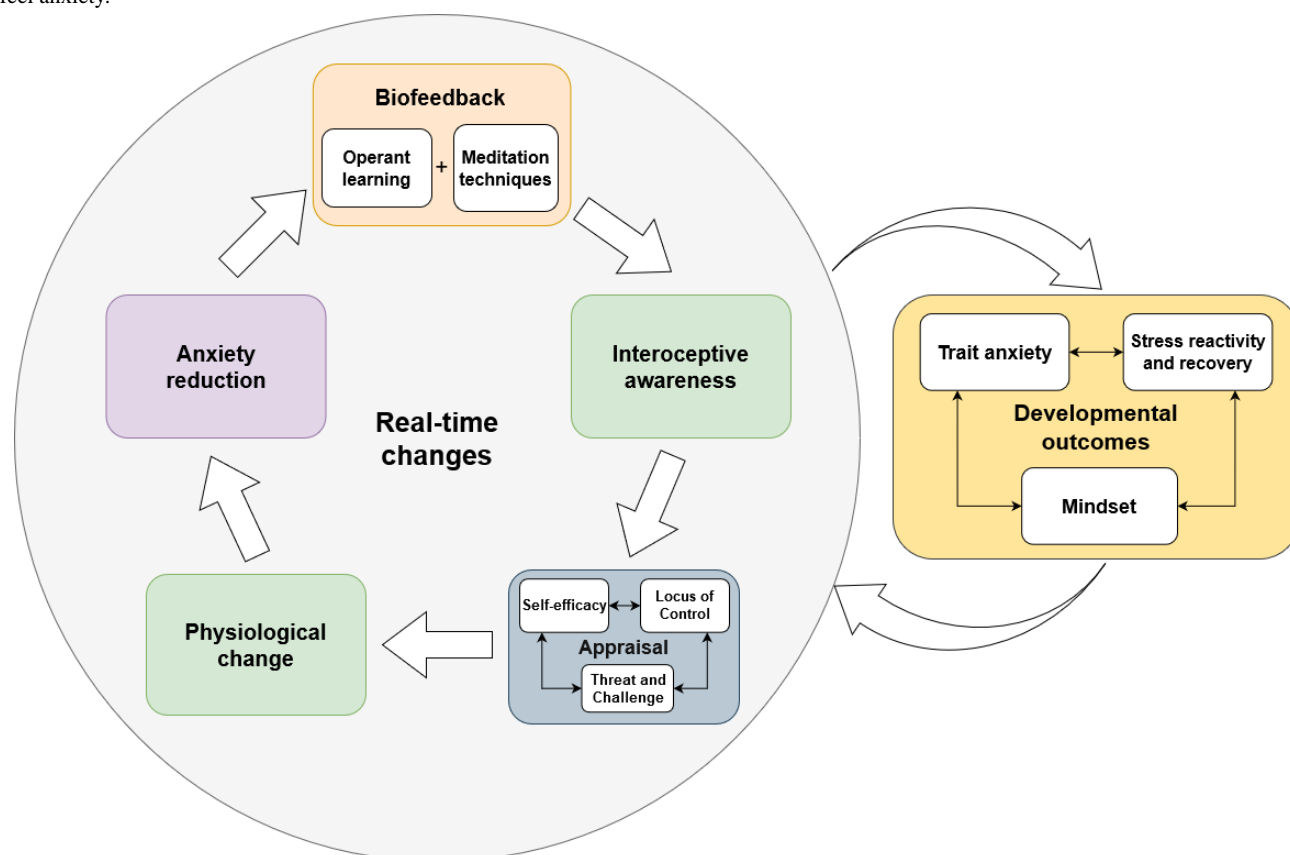

Developmental Change

Some mechanisms of change may already occur within a single biofeedback session, but it is likely that repeated exposure is essential for changes to become automated and internalized.

Specifically, we suggest that only when practice is provided in such a way that the proposed changes are optimized will changes generalize to outside the context of the training and influence developmental outcomes such as mindset, stress reactivity and recovery, and trait anxiety (Figure 3).

Figure 3. Model of developmental change showing repeated practice leading to changes in mindset, stress reactivity and recovery, and a trait proclivity to feel anxiety.

Mindset

Before someone engages in a biofeedback training, they already have certain expectations regarding the efficacy of the training and their ability to change. These expectations are tied to a general belief system regarding the malleability of traits. Someone with a growth mindset believes that traits are malleable and change as a result of circumstances and situations. In contrast, someone with a fixed mindset assumes that traits are stable across time and situations [171,172]. Having a fixed mindset compared with a growth mindset has been found to predict psychopathology [173,174]. Furthermore, a recent study found that students who received a growth mindset intervention viewed stressors as less threatening and showed more adaptive physiological responses, which resulted in better performance outcomes, such as better grades [175]. Differences in individual performance and improvement in biofeedback paradigms may likewise be influenced by someone's initial mindset with regard to the malleability of self-regulation skills.

Someone with a growth mindset may have a stronger belief that, through practice, they will be able to effectively exert control over their physiology and will regard the training as a positive challenge. This is because individuals with a growth mindset believe change can be obtained through effortful engagement and they regard failure as a sign to remain engaged and bolster one's efforts [176]. Training as a positive challenge may improve not only someone's performance in the training but also their physiological functioning [170]. Furthermore, we argue that biofeedback training may lead to changes in people's mindset. In initial training sessions, participants may start out

with a fixed mindset, low self-efficacy, and a low internal locus of control. However, as participants practice repeatedly and observe their progress in terms of self-regulation, they begin to learn that they are indeed able to effectively change their physiology; this awareness, in turn, may influence their mindset. Specifically, someone who previously had a more fixed mindset with regard to their ability to self-regulate could shift toward a more growth-oriented mindset as the training continues.

Stress Reactivity and Recovery

Over the course of biofeedback training, participants are also likely to change how they physiologically and psychologically respond to stressful situations (ie, their *stress reactivity*) [177] as well as the speed at which they are able to recover after the stressor has ended (ie, their *stress recovery*) [177]. In particular, anxious individuals exhibit increased stress reactivity and slower stress recovery [177-179], but with repeated practice, they may be able to change their reactivity and increase the speed at which they recover. Specifically, as participants receive practice in changing their physiological activity, they are likely to increase the speed at which they are able to do so. Furthermore, as they receive feedback on their progress, they may change the way they perceive changes in physiological activity and their ability to control this change. For instance, instead of being hypervigilant toward bodily cues and changes in physiology, which often results in increases in anxiety, they may tune their attention to a more balanced, optimal level of engagement. It is likely that *riding* this more balanced form of attention to physiology feels more like a *flow* state [180,181] and results in more positive, agentic, and challenge-based appraisals of the

situation. In turn, these challenge-based appraisals will improve stress reactivity and may help individuals to recover more quickly from being exposed to stressors [166,169,170].

Trait Anxiety

With repeated practice, as the self-regulation techniques and changes in cognitive mechanisms become more internalized, people may become more adept at appraising and regulating their physiological and psychological responses to stressful situations. Over development and repeated training sessions, we propose that an increased growth mindset and more adaptive stress reactivity and recovery will develop in concert with lower day-to-day levels of anxiety (ie, their trait anxiety).

Implications for Research

Studies testing the effectiveness of biofeedback training have primarily focused on outcome measures. However, to update theoretical models that link physiology to emotional states, and to improve outcomes from biofeedback interventions, it is vital to study how individuals change with repeated practice and exposure and how outcomes may be tied to certain mediators and moderators. In particular, there seems to be a great deal of promise in studying the appraisal processes outlined in [Figures 2 and 3](#) as mediators within individual sessions as well as across sessions to determine how they influence developmental outcomes.

To capture the mechanisms of change, experimental studies need to be set up in such a way that measurements of interest are repeated within and across multiple training sessions. For instance, training at the very beginning may make individuals feel like they do not have a lot of control over their physiology and the way that they feel, but this perceived control may increase over the course of the training. By assessing locus of control at multiple times during the training, the extent to which changes in these appraisals, in real time, predict or perhaps mediate the effect of the training on anxiety symptoms can be examined. Subsequently, by examining at what point in the training and which particular circumstances these changes occur, future training programs can be designed to amplify these changes and subsequently maximize positive outcomes.

Although it is important to capture change, it is also important to examine how certain beliefs or characteristics present before starting the training (ie, cognitive moderators) may influence performance or how quickly someone learns to self-regulate. For example, someone with a growth mindset who believes that they are able to change their ability to self-regulate through practice may be more receptive to feedback about their physiology, viewing the training as an opportunity to better themselves. In contrast, a fixed mindset may initially inhibit progress in the training, as physiological sensations of anxiety and feedback on physiology may be interpreted as threatening. Thus, in studies focused on evaluating the effect of a biofeedback training, it seems important to include mindset as a moderator in the analyses. Alternatively, participants can be divided into groups using a particular cutoff of the characteristic of interest. The extent to which individuals with one particular trait (such as growth mindset) improve more than those with a fixed mindset can be examined. It would also be interesting to

track the trajectories of change over the course of the various training sessions to determine whether they differ between groups. Information about the influence of certain traits and characteristics can inform us about who is an ideal participant for biofeedback training and why, such that future interventions can be improved and better targeted. For instance, if the results indicate that individuals with a growth mindset respond better to biofeedback training, then it may be more effective if the training is adapted in such a way that expectations related to this type of mindset are primed early on in the intervention.

Implications for Designing New Biofeedback Interventions

Thus far, we have proposed a new integrative model that presents several cognitive appraisals as possible moderators or mediators of adaptive outcomes in biofeedback training and have suggested ways in which these appraisals can be assessed in future experimental studies. Furthermore, we emphasized that adaptive and lasting developmental changes can only be achieved by repeated practice. Our design recommendations follow from these points, emphasizing 2 main sets of suggestions. First, biofeedback interventions should work optimally if they enforce all factors in our model, including interoceptive awareness and physiological change as well as the newly proposed cognitive mechanisms. Second, these interventions need to be designed to keep individuals intrinsically motivated and engaged enough to keep practicing over several repeated training sessions. In the following sections, we describe how specific design aspects of interactive technology, such as video games and wearables, could be integrated with biofeedback training to optimize the factors described in our integrative model.

Interoceptive Awareness

Even if someone may become increasingly aware of their internal state while engaging in biofeedback training, it may still be difficult to notice changes in physiology in someone's daily life. Although continued practice may increase the likelihood that changes and skills transfer to outside the training context, this process may be further enhanced by using wearable self-monitoring technology. *Wearable* technology is becoming increasingly easy to integrate in our daily lives [9]. There are already a large number of mobile phone apps available that are either linked to internal sensors (eg, global positioning system or pedometer) or external sensors (eg, heart rate sensors), which can generate real-time information or provide daily, weekly, or even yearly overviews of a person's activities, mood, and physiology. Using these wearables may not only increase someone's interoceptive awareness but may also provide information regarding the contexts in which certain internal changes are most likely to occur. Furthermore, providing an overview of how someone has changed over a certain period may foster a growth mindset as it emphasizes their malleability. Finally, reports provided by wearables may also be valuable for clinicians as they can more closely monitor their clients' improvement or deterioration and identify contexts in which certain exercises or interventions may be most effective.

At this point, it is important to emphasize that although interoceptive awareness is an important aspect of emotion

regulation, merely increasing this awareness may actually result in an increase in anxiety [94,95]. Continuously providing feedback on whether a desired level of physiological activity is reached may lead to extreme attention vigilance and be counterproductive for those anxious people who already focus too much on their internal states. Therefore, fostering a balanced awareness may be a better approach for biofeedback training for anxiety reduction. To achieve this balance, the training should be designed in such a way that other elements in the environment provide opportunities to disengage from attending to physiological activity. For instance, in the biofeedback video game Dojo [49-51], there is a figure of a seated human with a heart displayed in the corner of the computer screen that changes color based on the player's HRV. Specifically, the heart changes in color from red to orange to green, with green being the most optimal level of HRV. Using this type of stimulus clearly communicates changes in the physiology of the player; however, having it continuously present may result in a singular focus on their internal state. Thus, making the training context more engaging in different parts of the game and leading participants' attention away from the heart representation for short periods is likely a more optimal strategy. It may actually be most effective to move away from explicit representations of heart rate, pulse, and other bodily representations of stress and arousal.

If the digital context where self-regulation is practiced is engaging enough (eg, by offering thrilling or beautiful environments to explore where stimuli respond to changes in physiology), these design features may craft a more balanced attention landscape. Practicing in this type of landscape may change from a vigilant form of interoceptive awareness to a state of concentrated relaxation in which participants are aware of their arousal, but instead of fighting it or losing themselves in it, they are in control and move along with it. Gamers have described this state of *concentrated relaxation* as feeling completely focused and concentrated but at the same time feeling like they are able to let go of both [182,183]. For example, the game Nevermind [52], in addition to using explicit representations of HRV (a heart changing in color), also uses atmospheric changes that reflect the player's level of arousal. Players find themselves in an eerie environment that becomes more or less unsettling depending on how well the player is able to self-regulate their arousal. The screen becomes more distorted or ominous noises become even more pronounced as the person feels more anxious. Moreover, specific scenic elements are used, such as the kitchen that floods with milk, the more anxious the player becomes. In addition, the game also includes challenging puzzles that require the player's attention, which means they cannot singularly focus on changes in their HRV [53]. Another exemplary biofeedback app is DEEP, which integrates atmospheric forms of biofeedback [54]. In DEEP, players receive feedback on their breathing by means of a circle that enlarges and shrinks in accordance with the player's breath. Although this circle is always directly in the player's line of sight, the game environment is designed in such a way that it grabs the attention and invites players to explore the beautiful underwater world with its vibrant flora and fauna that respond to players' breath. For example, some of the plants mirror players' in and out breath by growing and shrinking or becoming more or less bright [55,56]. As these examples

demonstrate, there is a great deal of promise in integrating biofeedback into engaging environments where participants are made aware of their internal states but feel competent and able to focus on the task at hand.

Self-Efficacy and Locus of Control

One of the foremost sources of information from which we derive our sense of self-efficacy is the genuine experience of mastery [184]. Specifically, our feelings of competence and confidence are largely based on earned failures and successes [184,185]. A sense of mastery can be felt when a task's level of challenge is aligned with our perceived level of competence. In the developmental literature, this ideal balance between challenge and guidance is known as the zone of proximal development [186]. Putting players in this sweet spot of challenge to keep them motivated and engaged is something that video game designers excel at, as is demonstrated by the large number of individuals that play games and by the number of hours that they play them [187-189].

This balance of challenge and difficulty experienced in games is also referred to as a state of flow. Flow is experienced when individuals are immersed in a task, with energized focus, full involvement, and enjoyment in the process of the activity. This flow state coincides with a high sense of control and a loss of self-consciousness [181]. Notably, flow has also been linked to increased self-esteem and decreased anxiety [190]. To achieve a flow state, clear goals must be set beforehand and there must be a possibility to monitor progress. In addition, clear and immediate feedback needs to be given with the aim of balancing the perceived challenge and one's perceived skills [180]. Some of these conditions are already an inherent part of biofeedback, such as immediate feedback and the ability to monitor progress. However, most biofeedback training programs are not specifically designed with flow states in mind. Video games are designed in such a way that flow states are likely to occur as the difficulty level dynamically adapts to the player's current level of mastery, ramping up whenever the skill of the player increases [191]. Although some biofeedback programs do in fact dynamically adjust the level of difficulty, participants may still not experience mastery. To accomplish a true sense of mastery, it is not only important to balance the level of challenge but also to balance rewards and acknowledgments of success. Providing rewards when appropriate instills a sense of accomplishment and pride. However, if challenges are too easily overcome and rewards are disproportionately doled out, the same sense of accomplishment is not felt due to ill-gotten gains [192]. When designing biofeedback interventions, it may therefore be beneficial to focus on facilitating flow and genuine mastery experiences, thereby creating experiences where participants feel competent, in control, and focused on the goals in the training but are still aware of their physiological arousal.

Threat and Challenge

Clinical interventions often focus on decreasing physiological arousal as increases in arousal (eg, quickening of the breath and an increase in heart rate) are often associated with negative emotional states such as anxiety. Interventions that focus on changing appraisals of stress from a threat to a challenge do not focus on reducing arousal or inducing relaxation per se, but

instead aim to change the way the arousal is interpreted and experienced [169,170,193]. Interventions aimed at changing threat-challenge appraisals either directly target arousal interpretations or target higher-level belief systems such as growth mindset. When directly targeting threat-challenge appraisals, participants are often provided with information in a written, oral, and sometimes video form, which demonstrates that arousal is not harmful but rather a functional response of the body that aids performance in challenging and stressful situations. Interventions focused on fostering growth mindset use similar strategies but have an additional emphasis on people's ability to change (for a complete review of threat-challenge manipulation strategies, refer to the study by Jamieson et al [193]). Appraising arousal in a positive manner has been shown to lead to more adaptive stress responses [166] and even better academic performance [169,175].

To encourage challenge appraisals, feedback messages could be implemented in biofeedback training before and throughout biofeedback training, which frames arousal as adaptive. However, a downside to integrating these types of messages is that they are fairly explicit, which may clash with the more implicit, bottom-up type of feedback that is delivered through biofeedback. Therefore, if feedback messages are integrated, they should nicely blend into the environment. One successful example of this type of integration can be found in the phone-based companion app called #SelfCare [194]. In this app, which aims to provide relaxation and mindfulness training, users are invited to stay inside their virtual bedroom where they can interact with objects in the environment and play some minigames. When interacting with the app, messages pop up on screen that encourage the user to observe how they feel, such as "Is there tension somewhere?," "Where does this tension come from?," and "What can we learn from it?." These types of messages frame bodily sensations and arousal as informative, similar to threat-challenge manipulation strategies [193]. Furthermore, the user is addressed in a comforting and encouraging way, such as "There's no hurry, we can stay as long as we'd like." However, the messages do not feel patronizing or forced because they are phrased in a personal and relational way and because they blend in with the soothing and safe atmosphere of the environment. Thus, although biofeedback training may benefit from integrating feedback messages that frame arousal as functional and encourage a growth mindset, we argue that caution must be given so that it is well balanced with the design.

In previous sections, we posited that merely interacting with biofeedback could already help individuals to appraise increasing arousal from a perspective of challenge as they witness that arousal as something they can control. However, the environments in which participants train are often fairly neutral, and participants are rarely given the opportunity to practice in situations that increase their arousal [57]. We argue that especially when it comes to anxiety, it is important that individuals practice in contexts where feelings of anxiety are actually triggered, similar to exposure exercises in anxiety treatment [195]. When practicing self-regulation within contexts that evoke arousal, the likelihood increases that skills are transferred outside of the training to stressful situations where

these skills are needed most. Moreover, when practicing within these contexts, reappraisals of arousal are more likely to occur than practicing in a neutral or relaxing setting [196,197]. Some biofeedback-based games such as Nevermind [53] and Mindlight [198] have already adopted the use of anxiety-inducing settings. The latter game, Mindlight, has also been shown to be as effective in relieving anxiety as CBT [199]. Ideally, stressful training environments are designed to increase arousal, but they also allow individuals to directly interact with and exert control over the environment so that they feel immersed, in control, and motivated to continue.

Mindset

Although biofeedback training may already implicitly change participants' mindset as feedback with regard to change and progress is constantly provided, incorporating design elements that explicitly facilitate a growth mindset may further strengthen the training's effects. Various approaches have been used in previous interventions to foster a growth mindset, such as providing individuals with excerpts from scientific texts, showing them educational videos, or giving them writing exercises. All these strategies focus on priming individuals with or explicitly displaying information that emphasizes people's ability to change [175,200]. These mindset interventions have shown positive results in improving physiological responses, work performance, affective responses, and health outcomes (for overview, refer to the study by Jamieson et al [193]).

Although biofeedback training may already foster a growth mindset by providing feedback with regard to physiological change, the training may further benefit from including elements that are explicitly designed to emphasize a person's malleability. For instance, feedback messages in initial biofeedback sessions could be adapted so that they not only indicate how someone is currently doing but also highlight their rate of improvement and that they have the potential to further improve. Furthermore, participants can be provided with regular opportunities to check their progress throughout the course of the training. For instance, they could be shown a visual representation of all changes that they went through from the first session onward. Specifically, feedback messages in the initial session can be used to demonstrate the possibility of change, and showing explicit evidence of a person's progress can serve as a more concrete representation of improvement. Furthermore, for these growth mindset microinterventions, it is essential to structure the specific feedback messages such that they reinforce and focus on the participant's efforts instead of emphasizing that the participant is a competent person [176]. For instance, messages should not focus on personal traits such as "You're awesome!" or "You're so smart!" Instead, these messages should highlight progress and effort such as "You're doing great, it's clear that you are improving!" or "Keep at it, you'll figure it out!" Adding these types of feedback messages could result in someone adopting a growth mindset regarding their ability to self-regulate.

Engagement as a Prerequisite for Change

In the previous section, we have shown how future biofeedback interventions can be designed in such a way that they optimize all factors in our integrative model (Figure 3). Several of these

suggestions focused on harnessing the power of new technologies such as video games and wearables. These forms of technology can directly target some of the suggested mechanisms and are also more likely to keep users engaged and motivated. However, although we have proposed that using these forms of technology is promising in terms of accessibility and engagement, we also suggest that merely integrating game elements or wearables into a biofeedback intervention is not sufficient to guarantee user engagement. For instance, the use of wearables has increased in recent years, and one-third of all adopters stop using their devices after a couple months [201]. A similar lack of adherence and uptake has been observed for the use of digital mental health apps, including game-based interventions [202-205]. For wearables, the observed drop in usage is attributed to the fact that many of these apps suffer from poor user research (or none at all), which results in unsatisfactory user experiences [7,206]. A similar lack of user-centered approaches and design principles has been posited for digital mental health interventions [202,204].

One possible solution to avoid the same pitfalls in the design of the next generation of biofeedback interventions may be to adopt design thinking principles and practices. A recent paper by Scholten and Granic [204] outlined how design thinking could be used to improve digital mental health interventions. Design thinking focuses on empathy, multidisciplinary ideation, and experimentation. The design thinking approach puts the needs of the user at the center of the development process. Furthermore, there is cross-disciplinary teamwork and collaboration, and the development process consists of rapid prototyping and iterative testing of services [204]. Although this is just one suggested approach, its emphasis on user engagement integrated with a strong design foundation that

tailors the intervention or app to the user's needs seems particularly promising.

Conclusions

With current technological advances and the increasing interest in the use of self-monitoring technology to improve mental health, we argue that this is an ideal time to launch a new wave of biofeedback training. Our hope for this paper was to inspire a new phase of research and implementation of biofeedback training. We reviewed the more traditional techniques and mechanisms thought to explain the effectiveness of biofeedback: operant learning and meditation techniques, interoceptive awareness, and physiological change. We then identified several cognitive appraisal dimensions as potential determinants of adaptive trajectories within biofeedback training, including self-efficacy, locus of control, and threat-challenge appraisals. Subsequently, we proposed a new comprehensive model addressing real-time as well as developmental processes of change. Specifically, we posited that the relationship between changes in interoceptive awareness and anxiety regulation in individual sessions may be mediated by changes in a person's moment-to-moment appraisals such as self-efficacy and locus of control. Furthermore, we highlighted the importance of repeated exposure and practice to achieve adaptive and lasting developmental changes in growth mindset, stress reactivity and recovery, and trait levels of anxiety. Finally, we presented guidelines for the design of future experimental studies as well as new biofeedback training programs and apps that are in line with our integrative model. In summary, there is a great deal of promise for future biofeedback interventions that harness the power of wearables and video games and that adopt a user-centered approach to help people regulate their anxiety in a way that feels engaging, personal, and meaningful.

Acknowledgments

This work was supported by the Netherlands Organisation of Scientific Research Creative Industry grant (314-99-115). In addition, the authors would like to acknowledge Owen Harris, Niki Smit (Monobanda), Andy Mooney (Paradoxical Recordings), and Bryan Duggan (Dublin Institute of Technology School of Computing) for developing the game DEEP, which inspired this work.

Abstract

Digital technology, which includes the collection, analysis, and use of data from a variety of digital devices, has the potential to reduce the prevalence of disorders and improve mental health in populations. Among the many advantages of digital technology is that it allows preventive and clinical interventions, both of which are needed to reduce the prevalence of mental health disorders, to be feasibly integrated into health care and community delivery systems and delivered at scale. However, the use of digital technology also presents several challenges, including how systems can manage and implement interventions in a rapidly changing digital environment and handle critical issues that affect population-wide outcomes, including reaching the targeted population, obtaining meaningful levels of uptake and use of interventions, and achieving significant outcomes. We describe a possible solution, which is to have an outcome optimization team that focuses on the dynamic use of data to adapt interventions for populations, while at the same time, addressing the complex relationships among reach, uptake, use, and outcome. We use the example of eating disorders in young people to illustrate how this solution could be implemented at scale. We also discuss system, practitioner-related, and other issues related to the adaptation of such an approach. Digital technology has great potential for facilitating the reduction of mental illness rates in populations. However, achieving this goal will require the implementation of new approaches. As a solution, we argue for the need to create outcome optimization teams, tasked with integrating data from various sources and using advanced data analytics and new designs to develop interventions/strategies to increase reach, uptake, use/engagement, and outcomes for both preventive and treatment interventions.

Introduction

Digital technology, which includes the collection, analysis, and use of data from a variety of digital devices and other sources, has the potential to reduce the prevalence of mental health disorders and improve mental health in populations by integrating preventive interventions to reduce incidence with clinical interventions to reduce existing cases, both of which are needed to reduce the prevalence of mental health disorders, into health care and community delivery systems. Furthermore, digital technology has the advantage of collecting large amounts of information that can inform preventive and intervention processes. Such data need to be analyzed and, even more importantly, used to adapt and improve a variety of interventions, including digital ones, toward optimizing outcomes. The process of optimizing outcomes needs to be dynamic and responsive to the rapid changes in the use of digital technology, consumer interests and preferences, and regulations among other factors as well as to enable rapid changes in the content and process of intervention delivery (a study by Michie et al [1] provides an excellent overview of challenges in developing and evaluating digital interventions targeting behavior change as well as methods for doing so). At the same time, interventions need to be designed in partnership with stakeholders and consumers to increase the likelihood of subsequent implementation and dissemination [2-6].

The need to find novel solutions for improving mental health outcomes in populations is based on extensive data, showing that mental health disorders are very common and severely undertreated. In the United States, for instance, approximately 25% of the population experiences a mental health disorder during a given year and 50% in their lifetimes [7]; however, fewer than 30% of individuals with mental health disorders receive any treatment [8,9]. Thus, solutions for reducing prevalence in populations will require approaches that can be applied on a large scale [10].

To meet the need for outcome optimization at a population level, new approaches are required. Digital interventions have been developed to increase access and reduce costs, but engagement with these interventions is suboptimal, with many individuals engaging in only 1 or 2 sessions and fewer than half completing more than half of the treatment [11]. A recent study, for instance, of 93 mental health apps found that the medians of app 15-day and 30-day retention rates were 3.9% (IQR 10.3%) and 3.3% (IQR 6.2%), respectively [12]. To improve population-level outcomes, we have recently argued for the need for outcome optimization at the population level—an approach that simultaneously attempts to improve reach, uptake, engagement, and outcomes [1,13,14]. In this paper, we discuss how prevalence reduction in whole populations might be achieved through outcome optimization applied to both preventive and clinical interventions and suggest ways to address potential issues raised by this approach. Of note, outcome optimization applies to the entire population rather than the individual, and as we are focusing on prevalence, a reduction in caseness. However, as discussed later, the approach applies as well to any mental health or behavioral outcomes. We will argue that outcome optimization needs to be directed by a group of

individuals with a diverse set of skills, which we refer to as an outcome optimization team, tasked with both reducing prevalence and incidence of a disorder in a population. Such teams would integrate data from various sources to increase reach, uptake, use/engagement, and outcomes for both preventive and clinical interventions and consider interactions/trade-offs among the variables. In a population model, focusing on incremental improvements in effect size may have much less impact on prevalence than focusing on increasing reach. For instance, Moessner and Bauer [15] noted that an increase of 10% from 10% in treatment utilization would decrease the number of cases by an additional 5%, whereas an improvement in treatment efficacy of 10% (from 10%) would only reduce the number of cases by approximately 2%. However, if the intervention used is not effective whatsoever or of very limited effectiveness, there would not be any population health benefits, irrespective of reach, uptake, and use, and there may also be harm associated with the intervention. Therefore, when considering how to optimize an intervention effect on a population, the aim should be to focus on reach while also considering how to improve efficacy.

The Overall Approach

Prevalence Reduction

The prevalence of a disorder in a population is measured by two primary factors: the number of individuals who are identified with the disorder and the number of individuals who develop the disorder during a defined period. To reduce prevalence, there are two necessary components: preventive interventions that reduce disorder onset (the incidence of new cases) and clinical interventions that are effective enough so that the individual already affected with the disorder no longer meets the clinical criteria for that condition.

A core premise of the approach we are suggesting is the recognition that interventions evaluated under carefully controlled circumstances in selected, often convenience populations may not be as feasible or effective when applied more broadly [5,16,17]. Therefore, to reduce the burden of mental health disorders in populations by delivering interventions at scale, interventions need to be carefully and systematically adapted to the needs, requirements, and interests of different defined populations in a dynamic way. In the following sections, we discuss the necessary components to achieve prevalence reduction through an outcome optimization model and use the example of eating disorders in young people to illustrate what we are proposing. The general model we follow is described in detail in a paper by Wilfley et al [18]. In this model, individuals in various populations are identified via an evidence-based screening [19] that sorts respondents into the following categories: possible anorexia, possible other eating disorder, risk of an eating disorder, and low risk of an eating disorder. The screening tool then provides appropriate prevention or treatment recommendations.

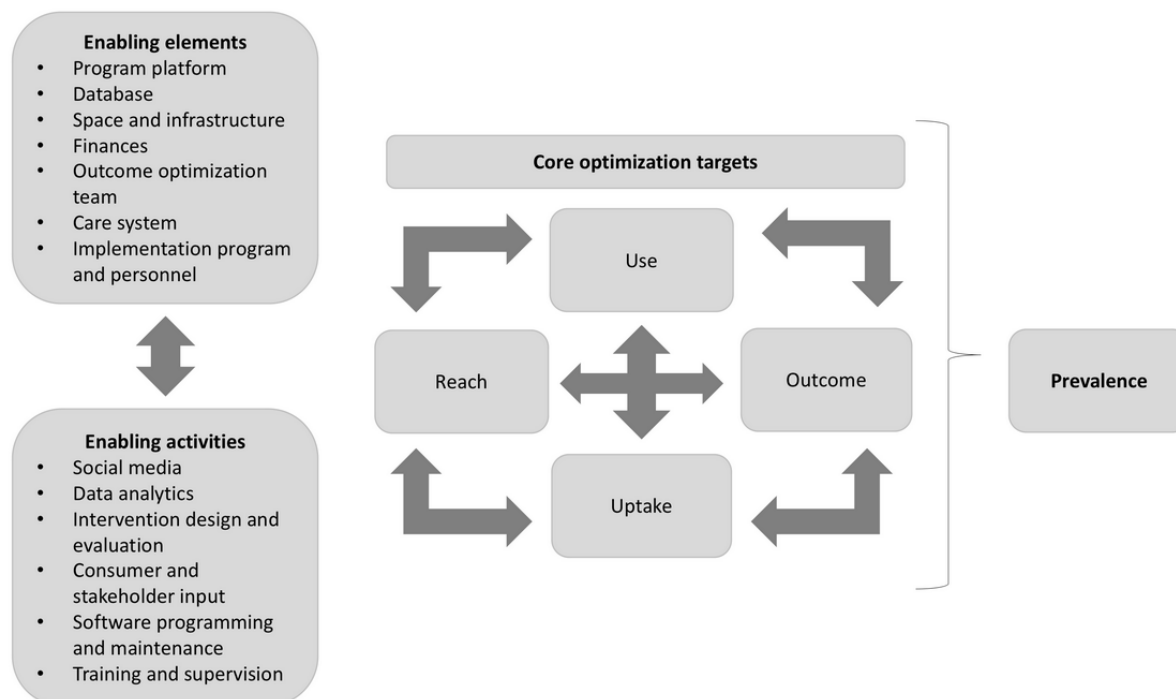

Outcome Optimization Teams

Affecting the key variables for optimizing outcomes is both a management and scientific process. As already mentioned, we have previously described the need for organizations to create

outcome optimization teams or similar groups, tasked with monitoring the key variables mentioned in Figure 1 and developing and implementing strategies to improve the various targets and key outcomes. These teams must possess a set of specific skills to enable effective use of the data to improve the key outcomes, use novel trial designs to conduct rapid evaluations, and iteratively adapt available interventions to improve the effects of the interventions on all critical variables (ie, from reach to outcome). The outcome optimization team needs to include individuals who are able to address administrative issues, manage complex problems, design social

media and intervention strategies, and analyze and interpret data, as well technology partners and oversight members (including consumers), brought together with adequate resources for the task. There are now many examples of applications of technology (eg, e-commerce) in areas not related to health and companies that now employ the equivalent of outcome optimization teams to one extent or another, with diverse skills and competencies, focusing on data science to help optimize the outcomes of interest. These approaches are equally relevant to population-level mental health interventions.

Figure 1. Outcome optimization model enabling elements, activities, and targets.

Outcome Optimization Targets

In the optimization outcome approach, the primary components subject to intervention and evaluation (any of which could be targeted separately) are (1) *prevalence* of the disorder, the number of individuals in the population who are appropriate for a clinical intervention; (2) *risk* for the disorder, the number of individuals in the population who are appropriate for a preventive intervention (thus reducing incidence); (3) *reach*, the number of individuals in a population who are offered a relevant prevention or clinical intervention; and (4) *outcome*, the number of individuals who begin a program and achieve the desired outcome within a set time frame. The individual-level outcome would be categorical (case/no case), and the population-level outcome would be prevalence (defined as new cases and existing cases). In addition, two other variables are important for optimizing individual- and population-level outcomes: (5) *uptake*, how many of those individuals offered an intervention actually begin it (eg, create a user account for a web-based, guided self-help program and see a therapist); and (6) *engagement/use* (eg, how much of the intervention is used). To improve overall outcomes, we will argue that each of these parameters can be targeted individually and, yet, should be

targeted and measured simultaneously, given that changes in one variable can have a downstream impact on another variable. For example, increased reach can reduce uptake rates, as less motivated individuals may be screened/included, or delivery of more effective treatments characterized by greater demands on client participation might be associated with reduced engagement.

We illustrate the different elements of our proposed approach by drawing from our research with eating disorders. Eating disorders are common and disabling problems with the highest mortality rates of any psychiatric illness. The risk factors for eating disorders are well known and have been shown to reduce incidence when addressed [20], and a variety of effective and cost-effective clinical interventions are available [21-23]. Furthermore, we have already developed and implemented an evidence-based screening on the web to categorize college students as being at risk for or with an eating disorder. Following completion of the web-based screening completion, we have provided appropriate and effective digital interventions or referrals to in-person intervention when appropriate at scale [24].

Reach

In this paper, reach represents the percentage of the population who are at risk for or who have a clinical disorder who complete a web-based screening and who are offered a preventive or clinical intervention appropriate to their needs and interests. We focus on reach via a web-based screening, but individuals at risk for or with clinical disorders could also be identified in other ways, including clinical interviews, algorithms, and, of course, through self-identification.

In the example of eating disorders, the goal of a prevalence reduction program should be to reach most individuals at risk for or with eating disorders. The prevalence of eating disorders in female college students has been estimated to be approximately 13.5% [25]; the rates for those at risk of eating disorders are even higher. For instance, Lipson et al [26] found that approximately 17.29% (1163/6723) of women in their survey had high weight and shape concerns, and many others had binge eating and/or weight and shape concerns without meeting clinical criteria. Conservatively, at least 25% of college-aged women are at risk for but do not have eating disorders. Unfortunately, reach in most populations is often very low. For instance, in our recent study, which used screening in college and universities to recruit women to use an eating disorder intervention, 1.42% (4284/300,613) of undergraduate women completed the web-based screening [27]. Thus, increasing reach is a high priority. An outcome optimization team might use three strategies to increase reach in the population. Hypothetically, the initial focus might be to provide screening through customary channels (eg, student listservs and flyers). In this model, approximately 5.00% (50/1000) of those with eating disorders completed the screening. To increase reach, the next optimization strategy might be to add the use of targeted Facebook advertisements, followed by using both targeted Facebook and Google advertisements. In the example, we assumed that adding Facebook advertisements increased the reach to 7.50% (75/1000), and by adding Google advertisements (strategy 3), the reach increased to 10.00% (100/1000). We realize that these examples are hypothetical, but there is very sparse literature on the use of different digital techniques (eg, social marketing) for increasing reach in targeted populations.

Ten percent is still far below the goal of reaching most of the population, and targeted Facebook and Google advertisements can be expensive. Other, perhaps more effective and less expensive approaches could be used. For instance, web-based screening for an entire student population for a variety of problems, including eating disorders, could be routinely required, or a web-based screening sent directly to individual student emails could be offered. The Healthy Minds Network routinely reaches approximately 16% of students using the latter approach [28]. The outcome optimization team should continuously experiment with new approaches for increasing overall reach and reach for subpopulations of interest.

Uptake

Once individuals have completed screening and have been offered feedback that directs them to a tailored intervention, the next critical variable is the uptake of the intervention, defined as having at least *begun* an intervention, such as engaging with

at least some of a digital intervention or attending at least one individual or group therapy session. The uptake of interventions can be quite low. However, in our recent study of college women, 75.5% (690/914) of female students who were eligible for the clinical trial agreed to be randomized; of those randomized to the intervention, 79.2% (305/385) began it [27]. Data from another study that provides prevention and clinical interventions to students in public universities in the state of Missouri found that uptake rates of the digital programs offered for both the high-risk population and clinical population were about 44.2% (420/955) and 49.3% (187/379), respectively [24]. In another study, 26% (16/61) of students with possible anorexia nervosa who were recommended to seek treatment reported doing so at follow-up [29], and Lipson et al [26] found that 18.0% (345/1916) of students at risk of an eating disorder referred to an indicated preventive program began it. Overall, available data on the uptake of interventions have varied quite widely and may be impacted by such features as the population screened and the accessibility and perceived helpfulness of the interventions offered.

In our example, we assumed that for the clinical population, 50% of individuals provided with a referral recommendation will at least go on the web once, see a provider, or in some other way, engage in an intervention. A strategy that lends itself to digital technology is to provide a set of interventions that can be adapted to different needs and interests, with different resources to subpopulations within the larger targeted population. In our hypothetical example, the outcome optimization team found that the baseline uptake rate (number of individuals who were offered an intervention who began it) was 50%. The outcome optimization team explored and enacted a number of options to increase uptake. First, 25% of the sample was eligible but expressed little intention of acting on the recommendation and was provided a brief motivational intervention. Second, approximately 5% of the sample was found to favor Spanish as a primary language. A Spanish language version was authored and offered to interested individuals. A consumer survey found that approximately 25% of the reached population would choose in-person therapy but reported not being able to afford it. As a way to address this issue, the outcome optimization team created an option where therapists trained in evidence-based treatments for eating disorder (eg, cognitive behavioral therapy-guided self-help) would be reimbursed for treating individuals sponsored by a nonprofit organization, and this was offered, randomly, to half the individuals who might want to it. Another issue revealed by the outcome optimization team through consumer needs assessments was that many individuals with eating disorders live in areas with no available treatment expertise for eating disorders and/or preferred teletherapy to face-to-face therapy. The outcome optimization team, thus, developed a teletherapy eating disorder program based on previous work. To increase motivation in future users who met the characteristics identified through a moderator analysis, a postscreen feedback message was then designed to inform them that previous users with characteristics similar to theirs had achieved positive outcomes as a result of the program. Of course, the issues affecting uptake are not mutually exclusive, and variables such as cost, language, and expectation of success may have different impacts on

different individuals depending on their needs and interests. All subpopulations are part of the larger population, and the needs and relative importance of subpopulations will continue to change, reflecting, for instance, changing demographics in the targeted population. Uptake will also change depending on consumer needs and interests, available resources, cost, and other factors.

One of the challenges of population-based interventions is that little is actually known about what users may want. A general strategy is to first consider the interests/resources of the users/stakeholders, followed by using user-centered design [30] approaches to build out interventions designed with ultimate implementation in mind [5]. In building out the interventions, modern designs would be used (eg, the multiphase optimization strategy and others [1,2,31,32] to engineer optimized interventions, before evaluation in randomized controlled trials). Depending on the size of the targeted population, other general approaches could be examined in subsamples. For instance, futility studies of stepped-care approaches, which might appeal to organizations as a way of reducing costs, could be examined [18,33].

Use/Engagement

Program use, often defined as engagement, is the next key variable to consider. Use includes several factors, such as the amount of the prescribed intervention used (eg, sessions of therapy attended and web-based sessions opened); application of the skills outside of the program; and/or sufficient use to lead to reductions in clinical targets, clinical status, risk factor reduction, or other indicators of significant improvement [11]. For example, the results might indicate that individuals who complete a specific amount of intervention might show clinically significant improvements. This amount might refer to the number of sessions attended in face-to-face therapy or pages opened in web-based interventions. Important to determining sufficient engagement is to examine progression within an intervention both for symptom improvement and successful adaptation of behaviors, skills, and other targets considered necessary for a meaningful outcome. Digital technology and analytic methods offer the potential to passively assess a number of variables that might affect engagement and outcome (eg, activity, sleep, and search history). This offers advantages over other types of intervention in the availability of extensive data related to program use and, therefore, easier determination of use cutoffs.

Perhaps the most important use problem is that of early dropout. Early dropout has been defined in various ways, but it is defined, for the purpose of this discussion, as individuals who begin an intervention but complete an insufficient amount of a program to have a positive outcome (however, even this definition is problematic as many individuals seem to benefit from simply beginning an intervention or using it for only a short time) [1]. Recent meta-analyses of web-based studies report high rates of early dropout, partly depending on the amount of support offered [34]. Individuals may drop out of an intervention for a variety of reasons. A major goal of the outcome optimization team would be to understand why people are dropping out (particularly before they achieve a meaningful outcome) and to

enact strategies to reduce dropout rates. Furthermore, the outcome optimization team would monitor use/dropout rates as they relate to clinical or preventive outcomes to help determine when a problem exists.

As with other components of the intervention, strategies to reduce early dropout and increase rates of sufficient engagement could be developed and tested. For instance, in a substudy of our recently completed trial [12], we examined the relationship between early and later session completion ($n=47$): individuals who completed at least three sessions were likely to complete at least 50% of the total program. In another analysis, we found that a very high score on a measure of thin body ideal (TBI) internalization predicted students likely to drop out of the intervention early. We then examined the components of the first three sessions to see what might have negatively impacted 21 individuals with a high TBI. One component tasked users to write a letter to their body. Of these 21 individuals, 10 rated it as not useful at all, 10 as somewhat useful, and only one as very useful. Therefore, we dropped this technique from the program and added a motivational interviewing piece. A subsequent sample of the first 59 users of the motivational interviewing piece was reviewed. The component was rated as not helpful by 10% (6/10) of individuals, a bit helpful by 44% (26/60), helpful by 42% (25/60), and very helpful by 5% (3/60). A number of other small changes were made over the course of a year, and we found that completion rates for the first two sessions increased from 69.5% (105/131) to 78% (70/89) following implementation of all the changes.

Within a dynamic, monitored population, there are innumerable approaches to improving engagement, and methods to do so have been well described [1,5]. However, it is worth noting that as reach is successful in subpopulations, each of these subpopulations is likely to generate new issues of uptake, engagement, and outcome.

Outcome

As with engagement, much has been written about how to improve outcomes using many of the strategies already discussed. The outcome optimization being discussed aligns with movements toward outcome-based care and measurement-based care [34], in which the delivery of interventions provided to clinical populations should focus on the use of outcomes to guide clinical decision making. We briefly mentioned what constitutes a positive outcome (eg, a clinically significant change) measured by loss of clinical status or even abstinence from eating disorder behavior. However, from a population-based prevalence reduction standpoint, there are some important considerations, as illustrated by the eating disorder program we are discussing. First, most of the studies on new models to improve outcome focus on digital interventions. Given some individuals' preference for face-to-face interventions, other treatment modalities and methods should be considered—we mentioned teletherapy above, for instance, as one obvious example. Second, as mentioned previously, focusing on incremental improvements in effect size may have less impact on prevalence than focusing on increasing reach. Third, interventions should be selected and designed with implementation in mind [5]. Mohr et al [33] noted

that when digital interventions that are shown to be efficacious in laboratory-based studies move to real-world settings, individuals do not engage with the tools and implementation often fails. Fourth, the complex issue of the ordering of interventions needs to be considered in population-based models. We, and others, have proposed stepped-care models as a *cost-effective* approach and also as a way to identify subpopulations that may need alternative approaches [14]. Thus, randomized controlled trials remain an important component of digital interventions. At the same time, our central thesis is that researchers must consider issues related to dissemination and implementation from the beginning [5]. This will lead to interventions that maximize public health impact.

Refining the Public Health Model

The model overlaps with other public health models, such as the highly influential Reach, Effectiveness, Adoption, Implementation and Maintenance model [35]. Similar to other public health models [36], we stressed the importance of offering both prevention and intervention approaches to reduce the prevalence. The model proposed here differs from existing models in terms of focusing on the use of digital databases and digital health interventions and innovations in reducing the prevalence of targeted populations. These data and analytics need to be monitored and interpreted by a multidisciplinary team involved in program codesign and delivery so that the digital health solution and its delivery can be quickly refined and improved, an approach consistent with Mohr et al's [5,17] recommendation that program evaluation should be more rapid and agile with iterative improvements. In the model we propose, the key innovation is that the key outcomes (reach, uptake, engagement, and outcome) are being simultaneously and continuously monitored, with ongoing testing and refining of strategies to improve these various indices. Fortunately, some emerging studies deal with at least several components of our proposed model. For instance, the Quit Sequential Multiple Assignment Randomization Trial Utah trial uses a cluster-randomized, multilevel sequential multiple assignment randomized model to examine strategies to increase reach and efficacy in community health centers [37].

System-Level Issues

Our proposed approach has focused on identifying the key elements for reducing symptoms in individuals, to reduce the prevalence of eating disorders in a population. However, program delivery and access and uptake of interventions are affected by a variety of system-level issues, including regulations/policies (eg, reimbursement), service delivery (eg, availability of trained providers), social environment (eg, support of family/friends), infrastructure (eg, availability of exercise equipment for those who may want to use it), accessibility (eg, availability of reliable transportation), and, of course, funding and reimbursement. For example, building out a teletherapy option may be limited by professional practice guidelines and issues of practicing across state lines, reimbursement, access to privacy-protected systems, and/or professional attitudes and training. The outcome optimization team needs to take these

factors into consideration so that possible strategies are considered in the context of what can be achieved within the system responsible for prevalence reduction. Another issue is that there may be divergent agendas across different levels of the organization. Providers, supervisors, division leaders, and organizational leadership may have different ideas about what a service should be doing or offering.

Another major challenge for the outcome optimization model is for the outcome optimization team to have access to platforms in which interventions can be easily offered and adapted for use in various formats (eg, mobile apps and web browser access). Furthermore, the delivery system needs to be integrated with a broader health care delivery system. An example of a system designed to integrate digital practice into a common health care record is now being implemented in Australia [38]. Such a system allows feedback between outcome optimization teams and health care practitioners.

Putting It All Together: Prevalence Reduction Through Outcome Optimization

Using this approach at the population level has the potential not only to reduce population prevalence but also to provide important information about intervention and prevention mechanisms, subpopulation needs, and even how to provide personalized and customized interventions to individuals in a population. The model is based on data and data analyses, but most importantly, on having an expert and technically proficient team that is tasked with using data and novel trial designs to conduct ongoing redesign, implementation, and rapid evaluation of evolving interventions that adapt/provide for individuals' needs and address the effects of interventions on all critical variables (ie, from reach to outcome) that can potentially result in greater overall reductions in prevalence. *The creation of outcome optimization teams within organizations tasked with reducing prevalence would be the single most important step toward optimizing outcomes.*

Our approach also assumes that there is agreed-upon access to users' data and their willingness to provide information about their progress. The use of such data will need to be transparent, and the user will need to agree. Thorough and repeated efforts will need to be made to ensure that such information follows Health Insurance Portability and Accountability Act guidelines and remains confidential. The concerns of individuals about sharing data need to be taken seriously, and it is likely that many will opt out of data sharing, given the many examples of how personal data are being misused. However, there is also an increasing movement—sometimes referred to as the *quantified self* movement—toward health consumers having access to their own data and making this information available to their health providers and others to access.

Limitations of Dichotomous Measures as Outcomes

Before discussing how an outcome optimization team model might be enacted, it is important to note that prevalence rates determined by caseness have a number of limitations.

Psychopathology exists on a continuum, and individuals, over time, may fall in and out of risk and/or caseness. Continuous measures are much more likely to be informative than categorical measures. However, for the foreseeable future, prevalence reduction will be measured in terms of reduction/prevention of caseness; thus, the reduction of prevalence remains the most important goal of a population-based approach.

More broadly, digital technologies will need to and are able to address a number of other important issues besides any specific psychopathology or risk that is being addressed. First, dissemination and implementation research have tended to focus on single disorders. However, nearly all mental health problems presenting in practice have substantial comorbidities. In theory, one could reduce the prevalence of one disorder in an individual while having little effect on several other important problems. A number of studies are examining transdiagnostic approaches and considering outcomes across multiple categories and dimensions [12]. Second, being a case may be less important to the individual identified as such than other issues, such as quality of life and well-being. The inclusion of variables relevant to the individual should be part of an intervention system. Third, health behaviors and risk factors (eg, obesity) are intrinsically related to many disorders and should also be addressed. Unfortunately, few models of multicomponent, multidimensional interventions assessed over time have been reported. Fourth, individual-level data obtained through ecological momentary assessment and other techniques can be used as part of a population reduction strategy, and an outcome optimization team will need to consider both general and personalized interventions as part of an array of opportunities provided to individuals at risk for or with clinical disorders. The model we describe is applicable to multidimensional personalized interventions once models for doing so have been developed.

A Note on Prevention

A major strength of digital technology and the use of an outcome optimization team is that screenings and other methods can be used to identify both individuals at risk for and/or with clinical disorders [39] and to address issues of reach, uptake, use, and outcome in at-risk populations using the methods discussed earlier. In most settings, we know of where screenings are used that could identify both risk and caseness; only the latter group is addressed. Not providing preventive interventions is a lost opportunity. We realize that there are many issues with doing so: the burden of adding prevention onto the responsibilities of clinical services, the challenge of providing prevention at a low cost given the large number of individuals who might need to be provided with interventions, and issues of reimbursement, to name a few. However, scalable interventions shown to reduce onset for common problems such as depression [39] and eating disorders [20] are available. Implementing, altering, and adapting them to optimize reach, uptake, use, and outcome (reduction in risk) using the methods we have described may be one of the most important challenges we face.

How Reduction of Population-Wide Prevalence Could Happen

Efforts to reduce the population-wide prevalence of disorders will require considerable resources, and any effort to achieve such reductions will need to be aligned with government/institutional/provider/community perspectives and/or other values and goals. There are many health care systems (eg, Kaiser Permanente, the United States Department of Veteran Affairs) that consider prevalence reduction of disorders (eg, suicide, posttraumatic stress disorder [PTSD], and depression) within their populations to be of importance and routinely screen their populations for problems such as depression and PTSD. Reducing prevalence across populations is similarly critical to many governments and other institutions with missions to serve specific groups. For example, colleges and universities have a strong interest in reducing the prevalence of mental health disorders and ultimately reducing the number of individuals who drop out from college with the result that many could create outcome optimization teams focused on reducing these outcomes in their populations. Another option in health care systems is that groups of collaborative care teams could take responsibility for the outcome optimization of preventive and clinical interventions in their panels, sharing findings among the teams. However, deploying digital technologies focused on reach and uptake may create a major problem for the provider systems: it is likely to create a major increase in demand for services. As we go forward, considerations of the cost-effectiveness and creative design of service delivery models, including stepped-care approaches, will need to be layered into the models.

A population-wide prevalence reduction program also has implications for the health care system, where cost/benefits and trade-offs of combined prevention and intervention need to be considered and may compete with interests, where, for instance, might be more interested in the short-term benefits of treating cases rather than preventing new cases and considering needs to be given to who directs the outcome optimization team goals.

An alternative approach to a total population-based approach is to focus first on outcome optimization within defined segments of the total population, for instance, individuals identified through screening. This approach does not focus on reductions in overall prevalence but only the reduction of risk and caseness within a subset of the entire population of interest. Working with the National Eating Disorders Association, we created a virtual outcome optimization team (comprising information scientists, statisticians, data managers, psychologists, psychiatrists, program designers, software providers, and others) to focus on both prevention and intervention for eating disorders for individuals identified through the National Eating Disorders Association screening tool. As an example of the need to enact new models of care delivery, over a 6-month period, 71,362 individuals completed the screening and most individuals (61,585/71,362, 86.30%) screened positive for an eating disorder. In addition, 10.20% (6602/71,362) were screened as being at high risk for the

development of an eating disorder. Of those who screened positive for an eating disorder, 85.90% (52,902/61,585) had never received treatment and only 3.00% (1847/61,585) were currently in treatment [40].

As another step forward, funding agencies should actively support innovative population-based interventions that use *newer* designs, including just-in-time adaptive interventions and other ways of thinking about and using digital technology and data to improve outcomes. As noted previously, we remain advocates of traditional randomized controlled trials, when implemented following intervention optimization, and we see them as being most meaningful when instituted within populations where they might eventually be deployed. Funding agencies might initially focus not on a comprehensive population prevalence reduction model but initially examine issues that would be relevant to the model. The investigators would be required to focus on defined,

large populations, reach, uptake, engagement, and outcomes using modern data analytics and methods—and many such studies are now underway—with a demonstration as to how, where, and when they would be implemented in real-world situations.

Implementing prevalence reduction in populations is a challenge, but given the large number of people in any population at risk for or with a clinical disorder, scalable, innovative models of service delivery are urgently required [16]. Digital technologies can enable scalability, but new systems and models need to be developed to take advantage of this capability. We have argued that the implementation of outcome optimization teams represents an important possible approach to enable the delivery of technology-facilitated mental health interventions in a way that can optimize outcomes for the entire population.

Abstract

The rapid growth of online health communities and the increasing availability of relational data from social media provide invaluable opportunities for using network science and big data analytics to better understand how patients and caregivers can benefit from online conversations. Here, we outline a new network-based theory of social medical capital that will open up new avenues for conducting large-scale network studies of online health communities and devising effective policy interventions aimed at improving patients' self-care and health.

online health communities; self-care; social networks; social capital; open and closed structures; social cohesion; brokerage

Recent years have witnessed the rapid growth of online health communities targeted at patients with long-term conditions [1-3]. Patients and caregivers have increasingly used forums and social networks as alternative or complementary sources of support to more traditional forms of health care provision. Recent advances in network science and data-intensive analytics, combined with the growing advent of big data from social media, promise to yield new insights into how patients can tap the full potential of health communities to improve disease self-care and find the support and information they need [4,5].

Ongoing initiatives such as the Values in Action Champions [6], the Health Service Executive Quit Smoking Programme [7] and its Facebook community [8], the Public Health England Stoptober smoking cessation campaign [9], and NHS Digital [10] show how harnessing the power of social networks can help people to spread behaviors, affect cultural changes in the health service, and improve health and well-being outcomes. Similarly, our recent work on communities targeted at patients with respiratory conditions [11] and stroke survivors [3] has provided evidence regarding how certain patients can fare better than others simply by leveraging their communication patterns.

What these studies suggest is the idea that some patients can be at an advantage simply because they are somehow better connected than others. In other words, a patient's distinctive pattern of social engagement and communication in a community is an asset in its own right. That asset is what we call social medical capital.

As suggested by previous work on social capital and health care access, there is still controversy over the definition and measurement of social capital and its association with various types of health-related outcomes [12]. In this paper, we endorse a network-based perspective and describe a new conceptual framework for theorizing about the emergence of social medical capital as a function of communication patterns within online health communities. Previous studies of social capital in the health literature have also identified a variety of health-related outcomes that might be affected by social capital [12-15]. These include individuals' health (eg, health status, mortality), health-related behavior (eg, health care-seeking behavior, illness self-management), access to local health services (eg, to community health clinics), and psychological well-being (eg, self-esteem, mutual respect). Here we focus only on two broad

categories of outcomes (informational benefits and social support) and associate each of them with distinct network mechanisms viewed as structural sources of social capital.

We broadly define social medical capital as the advantages that any user (patient or caregiver) can gain from participation in the social networks provided by online health communities, where communication takes place at virtually no cost and across spatial and temporal boundaries. Like other forms of capital (eg, human or financial), social medical capital enables the achievement of certain ends (eg, emotional support); however, unlike other forms, it is based on the idea that social structure serves as a wellspring of advantages to users. That is, social medical capital is contingent on resources socially embedded in connections between users and accessible through these connections. This means not only that users can benefit from one another, but also that whether they can extract value from one another depends on how they interact [16,17]. This idea can be further articulated into four networking principles: (1) defragmentation, (2) bonding, (3) bridging, and (4) multiple-group membership.

Defragmentation and Superusers

The value of participating in a community lies in the users' ability to gain prompt access to a range of people. As more users join a community, a catalyst of social medical capital is structural defragmentation; that is, social interaction becomes

more valuable as more pairs of users become mutually reachable along some path. Recent work has suggested that communities undergo defragmentation by self-organizing into hub-dominated structures [11]. The emergence of a small number of "superusers" (ie, the hubs engaging in conversations with a disproportionately large number of other users) engenders normative control and safeguards the communities from splitting into disjoint components [18].

Bonding and Closed Structures

In a socially cohesive closed network, links are forged locally, and pairs of connected individuals tend to be tied to at least one third party that they have in common (Figure 1A). Previous studies have suggested that closed structures, rich in third-party relationships, engender a shared identity and a sense of belonging, foster trust and cooperation, and sustain emotional support [16,17,19]. Evidence from two communities where patients primarily seek social support has shed light on the role of social cohesion in eliciting social medical capital [11]. Two empirical regularities have been uncovered: (1) highly connected support-giving superusers preferentially communicate with poorly connected support-seeking users; and (2) pairs of support-seeking users who communicate with the same support-giving superuser tend to communicate with each other as well, thus creating closed connected triangles centered on superusers. Local redundancy is therefore the structural engine of a support-oriented community.

Figure 1. Three network structures associated with three distinct forms of social medical capital. The nodes represent the users, and each link refers to communication between users. The type of benefits that a focal user (the red node) can accrue from communication depends on whether the structure is: (A) closed, ie, the user's partners also communicate with each other; (B) open, ie, the user acts as the intermediary between other users; or (C) mixed, ie, the user belongs to multiple densely connected groups and acts as the only intermediary between members of different groups.

Bridging and Open Structures

An open network is rich in structural gaps and opportunities of intermediation between individuals (Figure 1B). Open structures, where connections tend to be weak and constitute "local bridges" between otherwise disconnected parts, have long been associated with informational benefits [16,17,20]. In an openly structured community, communication is likely to take users closer to complementary sources of information they do not already possess [21]. Brokerage opportunities between distinct social circles expose users to greater variance and novelty of resources, and eventually help them to satisfy their informational needs [20,21]. Paucity of local redundancy is therefore the structural engine of an information-oriented community.

Multiple-Group Membership and Mixed Structures

In cases where the community aims to provide both emotional and informational support, social medical capital lies at the interface between bonding and bridging [17,22]. In such cases, the community will be most beneficial to the users if they can combine local redundancy with brokerage opportunities (Figure 1C). In a limiting case, this can be achieved when the following conditions are met: (1) a given user is a member of multiple clusters of users; (2) these clusters do not have any other users in common except the focal one (who therefore is the only intermediary between otherwise disconnected clusters); and (3)

each cluster has an underlying closed cohesive structure (ie, all members are connected with one another).

Research and Policy Roadmap

Empirically testing our theoretical framework will require the construction of large-scale longitudinal network data sets with information on users and their time-stamped messages. To comparatively assess the efficacy of network mechanisms of social capital, content analysis of messages would be needed so as to uncover how users' psychological well-being and access to information vary as social connections also change over time.

To help policy makers to realize our vision of social medical capital as a crucial enabler of large-scale health care

interventions in resource-constrained systems, we propose four targets: (1) promote patients' and caregivers' participation in online health communities to ensure continuous provision of socially embedded resources (eg, information, advice, support) that users can access through their (direct and indirect) social connections [14]; (2) support superusers' role in online health communities through appropriate training programs [1]; (3) enhance the quality of peer support and patients' self-care through robust evaluation systems; and (4) develop governance modes for maintaining privacy and confidentiality, cultivating trust and a participatory culture, and promptly detecting and preventing the spreading of misleading information and malicious behavior.

Acknowledgments

We thank Mr Yifan Qian for his help in the preparation of the figure. Nishanth Sastry was partially supported by grant number ES/M00354X/1 (A Shared Space and a Space for Sharing: A Transdisciplinary Exploration of Online Trust and Empathy).

Conflicts of Interest

Pietro Panzarasa and Anna De Simoni were invited by Values in Action, Health Service Executive, and the Chalfont Project to deliver a presentation at the "Network Sciences and Large-Scale Behavioural Change in Healthcare" workshop held in Dublin on February 20, 2019. All other authors declare no conflicts of interest.

Abstract

Developing or independently evaluating algorithms in biomedical research is difficult because of restrictions on access to clinical data. Access is restricted because of privacy concerns, the proprietary treatment of data by institutions (fueled in part by the cost of data hosting, curation, and distribution), concerns over misuse, and the complexities of applicable regulatory frameworks. The use of cloud technology and services can address many of the barriers to data sharing. For example, researchers can access data in high performance, secure, and auditable cloud computing environments without the need for copying or downloading. An alternative path to accessing data sets requiring additional protection is the model-to-data approach. In model-to-data, researchers submit algorithms to run on secure data sets that remain hidden. Model-to-data is designed to enhance security and local control while enabling communities of researchers to generate new knowledge from sequestered data. Model-to-data has not yet been widely implemented, but pilots have demonstrated its utility when technical or legal constraints preclude other methods of sharing. We argue that model-to-data can make a valuable addition to our data sharing arsenal, with 2 caveats. First, model-to-data should only be adopted where necessary to supplement rather than replace existing data-sharing approaches given that it requires significant resource commitments from data stewards and limits scientific freedom, reproducibility, and scalability. Second, although model-to-data reduces concerns over data privacy and loss of local control when sharing clinical data, it is not an ethical panacea. Data stewards will remain hesitant to adopt model-to-data approaches without guidance on how to do so responsibly. To address this gap, we explored how commitments to open science, reproducibility, security, respect for data subjects, and research ethics oversight must be re-evaluated in a model-to-data context.

data management; privacy; ethics, research; data science; machine learning

Introduction

Sharing health data is essential to accelerate knowledge and discovery through opportunities for replication, validation, meta-analysis, and creative reuse [1]. Indeed, many research funding agencies, institutions, and scientific journals encourage or even require the disclosure of research data to the broader scientific community as a means to foster collaborations and to increase scientific accountability, transparency, and reproducibility [2]. Traditionally, data generated as part of research projects or routine clinical care are shared with the scientific community by means of direct download, with the

data recipients analyzing data in their local computing environments. However, it is impractical to share some data sets in this manner because of their large size or because of legal restrictions on transfer between institutions or across sovereign borders. One common category of legal restriction is the confidentiality requirement applicable to health information, such as those required in the United States by the *Health Insurance Portability and Accountability Act* [3]. Another category of legal restriction is the limitations on cross-border transfers of certain data. For example, the European Union restricts the transfer of personal data to external countries under its *General Data Protection Regulation* 2016/679 (GDPR) [4].

Finland's *Secondary Use Act* requires health care data, including nonidentifiable data, to be processed in a secure data center based in Finland [5]. For more examples internationally, see International Compilation of Human Research Standards [6]. Furthermore, researchers and health care institutions who generate data may be concerned over relinquishing data assets given their perceived commercial or academic value, the costs of organizing and annotating data, the confidentiality and security of individual-level data, and loss of oversight of future data use.

The traditional data sharing governance role of health care institutions has been as custodians of data, whose primary responsibility was to keep data secure and confidential. This was achieved through silos, as illustrated by the patchwork of distinct health and accounting records one accumulates when navigating health care systems from hospitals to specialty clinics. The move to open data governance for broadening data sharing practices since 2000 represents a shift of that philosophy, one in which the community of data recipients is collectively responsible for protecting and maintaining the integrity of the data [7]. Open data is attractive in some ways, precisely because it externalizes the very real financial and logistical costs of data governance while providing opportunities for new research perspectives. However, open data governance may be insufficient for many holders of clinical data sets with individual-level privacy or intellectual property concerns.

In between data custodianship and open data governance, data stewardship is an institutional commitment to maximizing the organizational, scientific, and societal benefits of data sharing when also protecting data against privacy and security breaches and misuse [8]. Data stewards may be data generators themselves (eg, hospitals or research institutions) or an honest broker who acts as an independent mediator and trusted partner on behalf of one or more data generators and data users. An honest broker is generally mandated contractually or otherwise to protect and manage secure access to data under the ultimate legal control of another organization.

Data stewards (whether data generators or honest brokers) can now adopt different technical models for making data accessible to users. Typically, a data steward provides access by transferring copies of data to users. This copy-and-download model, however, raises concerns about unaccountable data management and use. Two alternative models promise greater security. In a researcher-to-data approach, a steward makes data available to users within a secure and auditable (cloud) computing environment. In a model-to-data approach, users can submit queries or algorithms to run on secure, hidden data. Each data access model involves different divisions of costs between stewards and users as well as tradeoffs between data use and data protection.

The first part of our paper compares these models primarily in the context of a single health data resource, controlled by a single entity (although this could be a pooled or centralized resource). We highlight the challenges that arise when attempting to scale each data access model beyond single health data resources to networks of multiple resources. The second part of our article focuses on the model-to-data approach.

Admittedly, there are only a few existing implementations of model-to-data, and all these essentially involve single resources. Scaling model-to-data to connect multiple resources requires the establishment of a federated data system and, at this time, these systems remain to be largely theoretical. We argued that model-to-data can be a valuable addition to our data sharing arsenal, but it should only be adopted where truly necessary. This approach should supplement rather than replace existing data sharing approaches for the following reasons. First, model-to-data tends to limit scientific freedom and reproducibility. Second, although model-to-data reduces concerns over data privacy and loss of local control when sharing clinical data, it is not an ethical panacea. Model-to-data approaches require just as much, if not more, attention to matters of ethical and legal governance as other data sharing approaches. Third, furnishing the appropriate infrastructure and expertise for a model-to-data approach requires a significant and sustained investment of resources. Misaligned incentives remain to be a major barrier to data sharing, generally [1]. The challenges of aligning incentives are likely to be exacerbated for model-to-data, given the associated expenses of hosting both data and analyses. Finally, all the aforementioned scientific, legal-ethical, and resource challenges also threaten the scalability of model-to-data from single data resources to networks of multiple resources (federated data systems).

Technical Data Access Models

Data sharing has long been synonymous with a copy-and-download approach, where data stewards transfer copies of data sets to researchers. The resulting loss of control over data raises a range of privacy, credit, and proprietary concerns. Access governance mechanisms, such as due diligence review of access requests by a data access committee and data access agreements, can mitigate these concerns to some degree, but may limit access by researchers who do not have a recognized institutional affiliation. Data recipients must also have the expertise and means to provide data hosting, management, and analysis environment. Emerging technical data sharing models aim to further alleviate tradeoffs between data use and data protection (Figure 1). In a researcher-to-data approach, instead of transferring a copy of the data to data recipients, researchers programmatically access data sets that are maintained in a secure computing environment. This approach arose from the development of cloud computing. Cloud cyberinfrastructure has successfully expanded programmatic access to data and analysis tools to a global community of researchers, in many cases cheaply and efficiently, without the cost and logistical challenges of data transfer [9]. These secure computing environments are sometimes characterized as virtual data enclaves or data safe havens [10,11]. A data safe haven implies a collective resource kept in a secure computing environment and managed with appropriate ethical and legal governance for the mutual benefit of individuals, communities, and the society. Data safe havens can enable investigators to conduct exploratory research or can limit investigators to conduct a preapproved analysis, but only results, not individual data, are permitted to leave [11]. An example is the Centers for Medicare & Medicaid Services

Virtual Research Data Center, which allows research on Medicare and some Medicaid claims [12].

Data safe havens address the costs, risks, and logistical challenges of sharing large, sensitive data sets by obviating the need for copying and distributing the data. Additionally, the cloud platform may allow researchers without intensive local computing resources to run complex analytical models in rented cloud computing infrastructures. Nonetheless, data safe havens do not fully resolve concerns over privacy leaks and misuse because data users must still be trusted to some degree to keep the data within the secure environment and to use the data appropriately. However, these risks can be reduced through access oversight, data use agreements, and active monitoring. Finally, because users can directly interact with data in secure environments, data stewards can share at least some of the costs of data hosting and curation with them.

A comparison of the technical data access models has been provided in Table 1.

A more secure approach has been piloted to allow researchers to extract knowledge from sensitive data sets that remain sequestered. In a model-to-data approach, researchers submit their analytic code or model to a data steward, who maintains the restricted data set in a secure computing environment. The data steward runs the code and returns outputs (eg, summary or performance statistics) to researchers. Data are not moved or even made directly accessible to data users. Model-to-data is made possible by container technologies (eg, Docker) that simplify the bundling and transfer of software models and their

dependencies across computing platforms [13]. The utility of model-to-data has been successfully demonstrated in crowdsourced research competitions involving confidential medical data [14,15]. For example, the Digital Mammography DREAM Challenge enabled the analysis of >640,000 deidentified digital mammography images from >86,000 individuals, without transferring or providing direct access to the images [13]. Lisa Austin and David Lie incorporate a version of model-to-data as part of a safe sharing sites proposal, where “computations may be performed on the data in a secure and privacy-protective manner without releasing the raw data, and all data sharing is transparent and auditable” [16]. It may be important depending on the context that the safe sharing site is an independent, honest broker. More recently, the Korean OpenData4Covid19 initiative used a model-to-data approach to share novel coronavirus disease–related health care data with researchers worldwide to fight the pandemic. Researchers must submit their analyses to be run by the Korean Data Centre. Only aggregate results are returned [17]. This example demonstrates how model-to-data can allow data to be rapidly shared with a broad community of users than would otherwise be possible.

We discussed the 4 categories of challenges confronting the model-to-data technical data access approach: (1) scalability to multiple resources, (2) scientific governance, (3) legal-ethical governance, and (4) incentives and sustainability. Data stewards must consider each of these challenges to determine if and how a model-to-data approach should be adopted in a particular context.

Figure 1. Common Data Sharing Models.

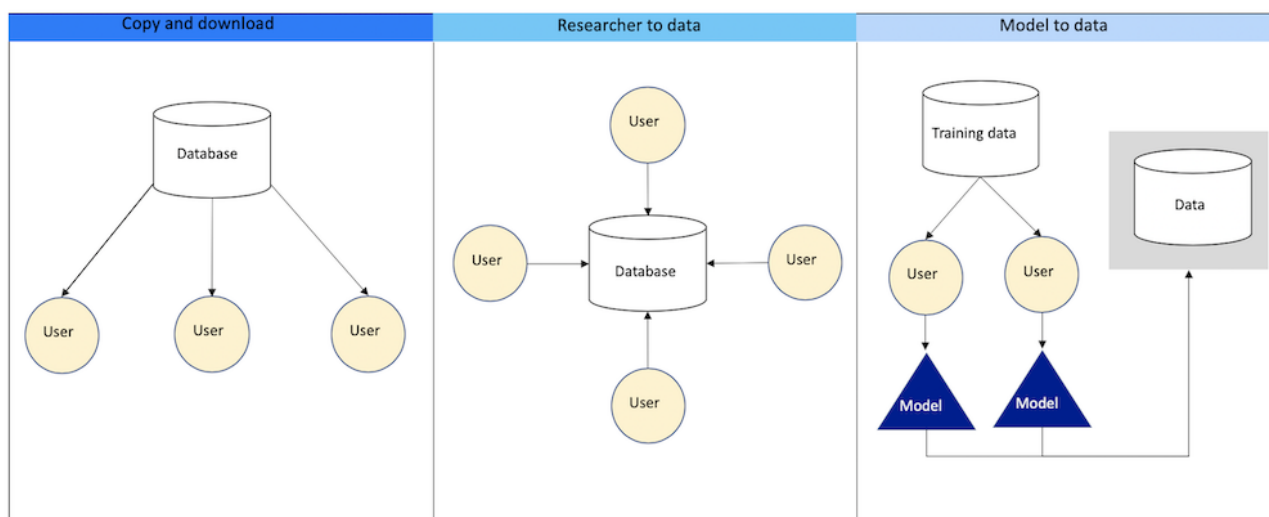

Table 1. Comparison of technical data access models.

Characteristics	Copy-and-download	Researcher-to-data	Model-to-data
Costs of data curation	Shared between data steward and data user	Primarily borne by data steward	Completely borne by data steward
Cost of computing infrastructure	Borne by data user	Borne by data steward (users may be charged for compute)	Borne by data steward (users may be charged for compute)
Researcher freedom (eg, methods and tools)	Greatest degree of freedom. Limited by terms of use	Limited freedom. Limited by computing infrastructure and terms of use	Least freedom. Limited by API ^a structure and computing infrastructure
Security and confidentiality of <i>individual-level data</i>	Weak. Many copies of data shared with many users, possibly in many countries, subject only to data access agreements. Difficult to audit. Difficult to withdraw data once shared	Strong. Data shared with third party users within a secure and auditable computing environment. Data can be easily withdrawn	Very strong. Data remains hidden from users. Data can be withdrawn at any time
Data privacy protection	Weak. Deidentification and data access agreement limiting reidentification	Strong. Individual-level data may be viewable but not downloadable. Only results are released. Outputs may need to be deidentified	Very strong. Individual-level data are not downloadable or viewable. Only results are released
Security and confidentiality of <i>Researchers' Ideas or Code</i>	Very strong. Researchers submit proposals but maintain control over methods	Medium. Researchers' activities are supervised/audited	Weak. Researchers must share query/workflow with data steward
Informed consent	Consent may be needed for research use, sharing, and cross-border transfer	Consent may be needed for research use only	Consent may be needed for research use only
Research ethics oversight	Data user may need research ethics approval	Data steward may need to provide research ethics approval	Data steward may need to provide research ethics approval
Scalability to multiple resources	Straightforward through a distributed data commons, with some shared infrastructure (eg, access portal)	Can only be done indirectly through an individual-level meta-analysis	Difficult but theoretically possible through a federated data system
Legal agreements	Data access/transfer agreement and data use agreement	Data use agreement and computing environment terms of use	Data use agreement only

^aAPI: application programming interface.

Scalability of Model-to-Data to a Network of Multiple Resources

Thus far, we have only considered the case of providing access to a single data resource held by a single data steward. Much of the value of data sharing occurs, however, where multiple data resources are connected into a network. Researchers often seek to achieve greater statistical power or refine an algorithm by aggregating multiple data sets. This is particularly relevant to research requiring a comprehensive analysis of data sets at scale. For instance, efforts in achieving precision medicine rely on the ability to combine a vast amount of diverse data types to investigate health and wellness [18]. There is also a strong interest in combining data across sectors to improve knowledge. For example, AllIn partners are looking for solutions to intersect data from diverse community resources to improve community health outcomes [19]. However, combining data from diverse sources is challenging because of the lack of interoperable standards between various data models (eg, OMOP, PCORnet, and TrinetX) [20].

In addition, data sharing networks or consortia must agree on a shared technical solution, raising additional complexity [21]. Consortia of data stewards can agree to centralize or pool their data into a single repository governed by common ethical and legal governance rules and processes (eg, the *All of Us* Research

Program [22]). Once the data are centralized, the data stewards must still decide on a technical data sharing model (ie, copy-and-download, researcher-to-data, or model-to-data). Where data distribution is problematic, a researcher-to-data approach may naturally align with a centralized consortium model. The aggregated data can be hosted in a single, secure computing environment. The stewards of the repository can then grant qualified researchers access to data and tools within the secure environment. Admittedly, centralization still involves relinquishing local control and trusting a third party to govern the data. However, these concerns can still be mitigated by adopting a researcher-to-data or a model-to-data approach as copies of data would not be further distributed to researchers.

Where data cannot be shared or centralized, model-to-data can still theoretically enable a virtual form of data aggregation through a federated data system (ie, distributed data system). A federated data system is composed of a network of autonomous data repositories or nodes that share a common data structure/schema and governance principles, but the data remains localized. Users can run an identical query or analysis at each data repository [23]. The results of the queries or analyses are aggregated and returned to the researcher who submitted the query. A federated data system enabling linkage and analysis of sensitive health care data in multiple repositories is proposed by the European Personal Health Train, where *analytical tasks visit data sources* [24]. Data sets are likened to

stations, algorithms are likened to the payload delivered by a *train*, and the network is likened to the train *track*. However, because of the variety of challenges explored below, federated data systems remain to be largely theoretical at this time.

Federated data systems potentially provide high levels of local security, control, and sovereignty as data remain hidden at each node in the network. They also potentially allow for the scalability of some analyses across multiple nodes into large, virtual cohorts. In addition, federated data systems can share ethical and legal governance standards (eg, access and use policies) and associated technical infrastructure like user authentication and authorization, such as the researcher passports infrastructure proposed by the Global Alliance for Genomics and Health [25]. Federated data systems can, in theory, also allow for virtual analysis of international cohorts without sacrificing compliance with data localization requirements, such as the cross-border transfer restrictions imposed by the European GDPR [26,27]. With model-to-data, only the results of algorithmic queries, and not the underlying individual-level data, need to leave a particular territory.

Challenges hampering the implementation of federated data systems include reaching and maintaining “agreement and commitment from federation members on the shared goals, operating principles, metrics for success and apportionment of the benefits and commercial value” [23]. Negotiation is also needed to determine what aspects of the data sharing architecture will be common versus what parts will be decentralized, and who will pay for building and maintaining the common aspects. Given that finding consensus solutions about these aspects in large groups can be difficult, large federated data systems may need to appoint a governing body to facilitate decisions among the federated members and designate data stewards at each node to implement the federation’s resolutions. In a federated data system, each node is accountable to all other nodes. Thus, the effectiveness of governance may be inversely proportional to the number of nodes. In short, although complicated, large virtual cohorts can still theoretically be achieved through federated analyses, where algorithms run across multiple secure databases, with aggregation of results.

Many projects are piloting this federated data system approach. For example, the World Economic Forum aims to connect genomic databases from Canada, Australia, the United States, and the United Kingdom to enable queries of rare disease patients. Two European-funded Horizon 2020 projects implementing the federated data system approach include (1) the Research on European Children study and the Adults Born Preterm study, which connects multiple European cohort studies and aims to improve health, development, and quality of life for preterm and low-birth weight individuals [28,29] and (2) EUCAN-Connect, which aims to connect genomic databases to advance precision medicine [30].

Although an attractive alternative to the copy-and-download and researcher-to-data approaches, model-to-data, including federated model-to-data, highlights key scientific, ethical, and legal governance issues that must be addressed as we balance scientific innovation and discovery with data protection.

The current lack of guidance may discourage the real-world implementation of model-to-data solutions. We aim to address this gap by identifying key points to consider for data stewards, focusing on a single data resource model-to-data approach. We conclude that model-to-data should only be adopted in limited circumstances, as a complement to rather than as a substitute for existing data sharing models. This argument applies by extension to the more complicated case of federated data systems involving a network of multiple resources made available through model-to-data.

Scientific Governance of Model-to-Data

The effectiveness of any data sharing model is a function of the type, quality, and richness of the data; the number of problem solvers who can access the data; the diversity of questions and analysis methods that can be applied; and the ability to validate and compare outputs. Modern data sharing governance philosophy has been popularly articulated according to the *FAIR guiding principles* that data be findable, accessible, interoperable, and reusable [31]. The FAIRness of data is always heavily dependent on the actions and abilities of the data steward. FAIRness is all the more dependent on stewards in the case of model-to-data as the data user has no ability to curate or conduct quality assurance on the data. In this paper, we focus on the case of a single data resource. Many of these issues will be challenging in the case of a federated data system involving multiple resources, as participating resources will all have to agree on standards and cost-sharing arrangements.

Findable

To be findable, data resources must be associated with rich, accurate, and standardized metadata. Metadata must generally be openly accessible for researchers to discover relevant data sets through data search engines. New technologies such as genomic Beacons and clinical Beacons allow researchers to search for individual-level traits, outcomes, or genetic variants without revealing detailed individual-level data [32]. Beacon technology works through an application programming interface (API), allowing researchers to query a data set (“do you have any patients with genetic variant ABC?”) and receive a simple *Yes* or *No* in response (or some slightly more detailed demographic or clinical information about the individual). Individual-level search may be equally possible across different data sharing models, with appropriate protections in place to ensure that searches do not leak excessive information about individuals. In model-to-data, enabling meaningful discovery may also call on data stewards to provide sufficient metadata or, better, an unbiased, representative training (testbed or sandbox) data set to help users understand the characteristics of the sequestered data set or to develop, train, and test their workflows and machine learning algorithms. The selection, composition, curation, and annotation of the representative training data sets is critical to the success of model-to-data as the training data set is used to *fit* models. Curation of the training (visible) and validation (sequestered) data sets must match perfectly for the data to be truly *findable*.

Accessible

Model-to-data enables analyses of sequestered data that cannot be directly accessed by researchers. At least superficially, the model-to-data approach is one way to resolve tensions between openness and confidentiality. In model-to-data, the data steward does not focus on securely transferring data to trustworthy and qualified users or on controlling access to a cloud computing environment, yet the data steward may still play an important governance and scientific oversight role. Determinations may still need to be made about who is authorized to analyze the data (ie, who can submit code to run on the data), and these determinations would need to be enforced through defined user authentication and authorization processes. In this manner, the model-to-data data steward will need to play a role akin to traditional data access committees in the review of data user access requests. Data stewards may also need to take on a more hands-on scientific advisory role, reviewing the appropriateness and scientific validity of the submitted analysis codes, providing feedback on model performance, and troubleshooting. Further complicating the responsibilities of the model-to-data data steward is the reality of finite computing and advisory resources. Because data are not directly accessible, model-to-data may enable data stewards to expand access to a wider group of data users than would otherwise be allowed because of reduced concerns over security and privacy. However, broadening access would need to be balanced with the need to be parsimonious against limited resources.

Interoperable

The responsibility for making data interoperable in model-to-data rests primarily with the data stewards, as data users cannot access the data directly. Furthermore, data stewards must ensure that their computing environment is interoperable to enable the third-party code to run accurately. This need for interoperable platforms is encouraging harmonization of not only data collection approaches but also technology architectures, data ontologies, formats, and governance structures. Indeed, the Global Alliance for Genomics and Health [33] has proposed a federated international ecosystem of genomic databases for which it is developing technical standards and policy frames to make the data available to authorized data users under relevant conditions [34]. The GA4GH Cloud Work Stream developed standardized computing routines, protocols, and tools (APIs) to enable the portability of algorithms, tools, and workflows across cloud environments in large-scale distributed projects [35]. These standards are being piloted in GA4GH Driver Projects, including the National Cancer Institute Genomic Data Commons [33,36] and the Canadian Distributed Infrastructure for Genomics [37]. These ongoing efforts to harmonize data ontologies, formats, and workflows support the interoperability of data sets both in the cloud as well as in the model-to-data research.

Reusable

The goal of data reuse is to enable the generation of new knowledge from data and to enable validation of previous findings to promote scientific consensus. In order for data to be reusable through model-to-data, data stewards must ensure that the data are high quality, rich, and fit-for-purpose. Preparing

data for analysis is often the most taxing part of data science [38]. Regardless of the data sharing model, data generators and stewards bear a significant degree of responsibility for data curation. There are also efforts to harmonize clinical assays as evidenced by the proposed *Diagnostic Accuracy and Innovation Act* [39]. Where copies of data are distributed, researchers can participate to various degrees in curating data to render it usable for specific purposes. In model-to-data, however, the responsibility for curation and annotation of the sequestered data set is entirely the responsibility of data stewards.

Ensuring the Quality of Research Outputs

A concern for data sharing generally is not only ensuring the quality of data but also the quality of research outputs. These results are usually in the form of summary statistics, but increasingly data science outputs also include trained algorithms. Usually, the quality of research outputs is left to quality control by journals and peer review. Owing to their intensive role in data curation and algorithmic facilitation, in some cases, model-to-data data stewards may insist on coauthorship or may reserve the right to review abstracts or manuscripts before publication, although these approaches can raise concerns about scientific freedom.

Ethical and Legal Governance of Model-to-Data

Considerations for ethical data sharing go beyond scientific concerns. Data stewards adopting a model-to-data approach must also address issues of privacy, confidentiality, security, ownership, research ethics oversight, and sustainability.

Privacy, Confidentiality, and Security of Patients' Data

Concerns about risks to privacy are at the core of resistance to data sharing. Data sharing models involving the distribution of data to researchers rely heavily on deidentification (the process of removing direct identifiers). However, the residual reidentification risk of even limited genetic or demographic data sets has been clearly demonstrated [40]. Data access governance mechanisms (eg, due diligence review of access requestors, data access agreements) may mitigate risks, but ultimately depend on trust [41]. There are few means available to monitor obligations to keep data confidential and secure and, even if a breach is detected, it is not clear if and how a breach could be sanctioned. In model-to-data, by contrast, no copies of data are distributed, reducing privacy risks. Data stewards do not have to predict all possible future reidentification scenarios or assess the trustworthiness of data requestors to keep data secure when they enable model-to-data research.

However, there remain some limited privacy concerns regarding model-to-data. First, to make model-to-data data sets usable, limited training sets of data may need to be distributed. It may be possible to distribute synthetic or *noisy* training data sets as a way to preserve the data subject's privacy and data confidentiality. Second, privacy risks may differ depending on whether model-to-data access is provided for algorithm training, validation, or application. Unintended memorization of data has been shown to occur during the training of algorithms [42]. Outputs from applying a model could contain identifiable

information, or such information may be reverse engineered or inferred. Privacy leaks can be reduced by adding safeguards such as auditing of outputs and limiting what kinds of outputs may be returned to researchers. Even when the release is limited to outputs or knowledge, there may still be a need for careful risk assessment and calibration between openness and privacy protection.

Informed Consent and Research Ethics Oversight

Whereas model-to-data may allow data stewards to meet data confidentiality and localization requirements, *ethical* concerns remain related to the principles of informed consent and research ethics oversight. Ethically, patients have an interest in knowing who is being provided access to their data and what their data are being used for, even if those parties never directly access their individual-level data. Data privacy laws, particularly the European GDPR [4], require a legal basis, such as consent or public interest, to be able to analyze personal data for certain research purposes. The US National Institutes of Health's dbGAP genomic data repository imposes ethical data use limitations on data based on the scope of the participant's consent [43]. With model-to-data, *legal* constraints on use may appear to be diminished or inapplicable as individual-level data are not disclosed to third parties. Nevertheless, data use may raise ethical and social license concerns if data were used by controversial parties or for controversial purposes without patients' knowledge. Data stewards are responsible for ensuring appropriate oversight of data use. This responsibility overlaps with the scientific oversight mechanisms discussed above.

A traditional mechanism to ensure the ethical conduct of health research is to subject project proposals to approval and oversight by an independent research ethics oversight body (eg, Institutional Review Board, Research Ethics Committee). In a model-to-data context, however, the locus of research ethics oversight may need to shift from the data user's institution to the data steward, where the actual analysis of data is performed. This shift may in fact allow access to a wider range of data users from outside academic or health care institutions—who would not necessarily be subject to human subject research regulations—to analyze data (eg, commercial researchers and citizen scientists). The data steward would essentially provide a research ethics review as a service to these users. In the case of a federated data system involving multiple data stewards, some level of coordinated research ethics oversight between stewards would need to be developed. For example, a data user could receive approval from one data steward in a network and the other stewards could mutually recognize that approval. Fortunately, models for coordinated oversight of data-intensive research have already been developed and could be adapted to the model-to-data context [41,44].

Confidentiality and Security of Researchers' Ideas and Software

A central strength of model-to-data is that it improves data security. However, the trust patterns required to enable security in model-to-data research are novel. In traditional data sharing models, data subjects and data generators must trust data users to secure individual-level data. In model-to-data, by contrast, data users must trust that data stewards will keep their queries

and code secure from unauthorized access and that data stewards will not appropriate the ideas or internet protocols of data users for themselves. This issue becomes more problematic when scaling model-to-data to multiple resources. From this perspective, allowing an honest broker to act as the data steward in model-to-data may be desirable (although this would require data generators to transfer control over their sensitive data to the honest broker). Involving an independent trusted third party can reduce real or perceived conflicts of interest. Another potential solution analogous to privacy-preserving record linkage is to enable secure computation without the data steward being able to directly inspect the query or code [45,46]. The query or code is encrypted and sent to a trusted third party to unencrypt at runtime. However, this may be technically complex and data stewards may insist on inspecting the nature of the submitted algorithm. Model-to-data stewards must also consider the security risks associated with allowing outside code to be run inside their protected computing environment (eg, tampering). Providing read-only access to data directories limits the risks that input data may be altered. Preventing network access while executing the analysis code reduces the risk that users may accidentally download data.

Data Sharing Incentives and Sustainability

The FAIRness of data in model-to-data contexts is heavily dependent on the role of the data steward. The FAIRness of analysis workflows is also increasingly key for the reproducibility of data-intensive health research. In the context of model-to-data, this FAIRness may additionally be essential for trust between data users and data stewards [24,47]. Data stewards need to possess not only *traditional* data governance expertise but also significant computational and analysis skills, a rare combination, and one without formally recognized qualifications at this time. These issues of oversight may hamper the adoption of model-to-data. Ultimately, by shifting more responsibility for data curation and infrastructure costs to data stewards, model-to-data represents a fundamental recalibration of the tripartite responsibilities of data generators, data users, and funders envisaged by the Toronto Statement on Pre-publication Data Sharing, a policy promoting rapid data sharing by large-scale community resource projects in biology [48]. Although model-to-data may seem like a technical decision, it significantly exacerbates the incentive problem already plaguing data sharing [49]. To succeed, model-to-data requires dedicated support from funders as well as from the highest level of leadership within organizations seeking to share data.

Similarly, all databases face sustainability challenges [50]. Who pays for the development, management, and maintenance of data sets, especially over time? For model-to-data, similar questions must also be asked about the sustainability of maintaining computing environments and security infrastructure. Open data distribution models promise a cheap solution to the preservation of data sets in part through the existence of numerous copies of the data set. In model-to-data, a data steward is trusted with preserving the data set and providing access to

it over time. Different sustainability models may need to be explored, from fee-for-access to sustained public funding. The choice of model may be influenced by the source of investment in data generation, curation, and infrastructure. Private investors may want to commercialize data access, whereas public funders may insist on an open science approach. One solution could be a commitment by funders to pay for stewardship as a utility contract, one that simultaneously sustains infrastructure and explicitly requires strict platform neutrality. Good contracting practices that guarantee the portability of data sets from steward to steward in the event of bankruptcy or bad faith would also be essential. Furthermore, data stewards must be careful to avoid conflicts of interest toward either the data generators who entrust them with the data or data users who entrust their hypothesis and analysis methods to them. Ultimately, the question for model-to-data approaches and, by extension, federated data systems, is whether the benefits to science and society are worth the cost. The first-of-its-kind economic evaluation of federated data systems concluded that their return on investment was unclear [51].

The major concerns related to sustainability in model-to-data are the evaluation and reproducibility of model-to-data research, the key to research quality, and transparency. If a data steward were to refuse or discontinue algorithmic access services, this would imperil research reproducibility. This issue becomes greater at scale. In a federated data system, all it takes is for one data steward in a network to withdraw algorithmic access to undermine reproducibility. The reproducibility of model-to-data research may be vulnerable to the caprices of funders, scientific priorities, politics, or even individual data subjects. Indeed, because there is only one copy of a data subject's data in model-to-data, it may also be easier for subjects to withdraw their data. On the one hand, model-to-data supports individual autonomy, allowing individuals to control how their data are (or are not) shared and used over time, which may bolster public trust and willingness to share. On the other hand, this may make reproducibility of research more susceptible to the caprices of individuals.

Conclusions

Model-to-data promises to unlock health data currently stuck behind institutional (fire)walls and country borders, providing access to researchers without sacrificing security, confidentiality, or local control. Model-to-data can improve the quality of research outputs by providing access to more data.

For algorithms, model-to-data access can serve as a means of rapid, continuous quality control. The accuracy of algorithms can be determined or compared through benchmarking, where the algorithm is run on a standard data set. For traditional research findings, model-to-data may allow peers to reach consensus about insights if running different models generates similar findings. In practice, however, this technical access model involves significant costs and drawbacks. It falls short

of its utopian promise of technology, overcoming legal and human constraints on data sharing. We have argued that model-to-data should only be adopted where necessary to supplement rather than to replace existing data sharing approaches for scientific, legal-ethical, and resource reasons. By segregating researchers from data, model-to-data tends to limit scientific freedom, integrity, and reproducibility. Although model-to-data scores high on security and confidentiality, ethical concerns persist about individual control over who uses their data and for what purposes. Model-to-data also presents a coordination puzzle for research ethics oversight systems, with the research analysis occurring in an institution different from that of the researcher.

Model-to-data intensifies the incentive issues already plaguing open science [49]. Data stewards must provide expertise and resources to curate data, maintain technical infrastructure, and conduct scientific activities on behalf of users. Meanwhile, direct benefits tend to accrue to data users. Scalability is another concern for model-to-data. Scalability from a single resource to multiple resources is possible with a federated data system. However, as these systems scale, the challenges of maintaining scientific data harmonization, technical standardization, and agreements about cost and benefit sharing scale as well. The scale of federated data systems may therefore be naturally limited to a smaller number of trusted parties.

We predict that the model-to-data approach will become an increasingly attractive option for particular use cases as the scale, diversity, and regulatory complexity of international data sharing continue to rapidly increase. This assumes that the scientific, legal-ethical, incentives, and network issues described above are addressed. Model-to-data will be most useful for large-scale stand-alone resources or small networks of resources when scientific data standards are well established, where the inquiry is clearly defined in advance (eg, in a hackathon challenge), and when providing access to a specific community of users who would not otherwise be authorized. Ultimately, the success of model-to-data may require the migration of expertise in data curation, data science, and technical interoperability from institutions hosting researchers to those hosting data. It may further depend on the willingness of funders to support the creation and sustainability of data centers and their networks. Although expensive for single data stewards, model-to-data may be more efficient overall by reducing the need for redundant, secure computing environments.

We are cautiously optimistic that model-to-data can unlock at least some data sets for broader sharing, for at least some uses, but we remain skeptical that it can fully square the circle. To successfully adopt an model-to-data approach, the concept of data stewardship needs to be reconfigured, with implications that reach the organization's core business model. At least for now, responsible scientific, ethical, and legal data governance remains a reliably human endeavor.

Abstract

Digital health solutions, in particular information communication technologies, often experience implementation failures leading to slower adoption than expected. This implementation challenge has spurred the development of frameworks to help navigate this uncertain and messy process. These frameworks point to environmental, organizational, individual, and technological factors that can drive or hinder implementation, with some in the field suggesting that perceived value may play a pivotal role. However, the concept of value can have varying meanings and be challenging to operationalize as a means to support implementation. Attending to philosophical and psychological meaningfulness for users and organizations in which technologies are adopted may offer a useful lens, by linking perceived value to individual behavior changes often required as part of implementing digital health technologies. Lessons learned from developing, evaluating, and implementing the electronic Patient-Reported Outcome (ePRO) tool demonstrate how qualitative methods can be used to uncover meaningfulness. By drawing from this example and other similar studies, this viewpoint offers suggestions on how future inquiry could deepen an understanding of meaningful innovation to help drive the implementation of digital health technologies.

KEYWORDS

digital health; implementation; meaningfulness

The Implementation Challenge Facing Digital Health

While digital technologies have transformed many industries worldwide, health systems remain laggards in adopting innovative and disruptive technology. In a recent reflection, Jadad and Jadad Garcia lament the glacial crawl of innovation adoption in health systems, stating that “sadly, the promises of information and communication technologies to transform healthcare services remain unfulfilled” [1]. Global health leaders have recognized this gap and are establishing strategies to support wider adoption of technologies that are viewed as foundational for robust health systems [2,3]. Included in these

strategies is attention to overcoming implementation challenges that have slowed adoption. Implementation factors such as adaptability of the innovation, the implementation climate, the policy and system environment, and user characteristics are key hindrances [4,5]. In her viewpoint paper in the 20th anniversary issue of the *Journal of Medical Internet Research*, Buis argues that to achieve the vision of digital health, the next decade of inquiry requires greater attention to these implementation challenges [6].

Several theoretical frameworks and models of implementation have emerged and been applied to digital health. Two promising models include the Value-Proposition Design (VPD) [7], and the Non-adoption, Abandonment, Scale-up, Spread, and

Sustainability (NASSS) framework [8]. These frameworks represent an important step forward in implementation science, offering applied and practical approaches that build on heuristic models like the Consolidated Framework for Implementation Research (CFIR) [9]. VPD and NASSS include attention to multiple implementation factors, and both suggest that the value proposition of a given technology is a critical driver of its implementation, an idea also reflected within the World Health Organization guidelines on adopting digital health solutions [10]. The importance of the perceived and evidenced value of these technologies has spurred calls for better evaluation standards of digital health products to drive adoption [11].

Although perceived value is one of several factors to consider, the above frameworks suggest it to be a central concern as it can *drive behavior change* in the individuals and organizations needed to implement a technology. However, the concept of value can be understood in many ways and through multiple disciplinary lenses. This viewpoint suggests *meaningfulness* as one potentially useful approach to uncover how perceived value can drive implementation.

What is the Meaning of Meaning?

The notion of “meaning” in thinking of technology adoption in healthcare is not a new idea. The concept of “meaningful use” of electronic health records (EHRs) emerged in 2010 in an attempt to establish rules for how EHRs are to be used in order to improve quality and efficiency [12]. While this functionally focused notion of meaning has an important place, it may be too narrow to encompass different interpretations of meaning held by users. A broader understanding is offered through philosophical approaches exploring how individuals perceive that they are living meaningful lives. Some philosophers have argued that we see our lives and actions as being meaningful when we feel we are promoting good in the world, experiencing subjective satisfaction, and/or achieving our aims and life goals [13]. While the intention of this commentary is not to dive into the deep and rich philosophical literature on meaning, this approach to meaning can offer a lens to help explore and perhaps overcome some of the challenges experienced when implementing technology in health care.

Perceived meaningfulness is related to the implementation of digital health solutions in two ways. First, meaningfulness drives behavior, and behavior change is needed when adopting new technology. Social and cognitive psychology theories have shown how group interactional processes and individual cognitive and emotional processes motivate behavior change needed when implementing new practices [14], like when adopting a new electronic medical record or including telemonitoring as part of clinical care. Social determination theory, which suggests individuals’ goals and aspirations (one of the components of meaningfulness mentioned earlier), are key drivers of behavior [15]. Social determination theory has also been used to understand patient adherence to digital health interventions [16].

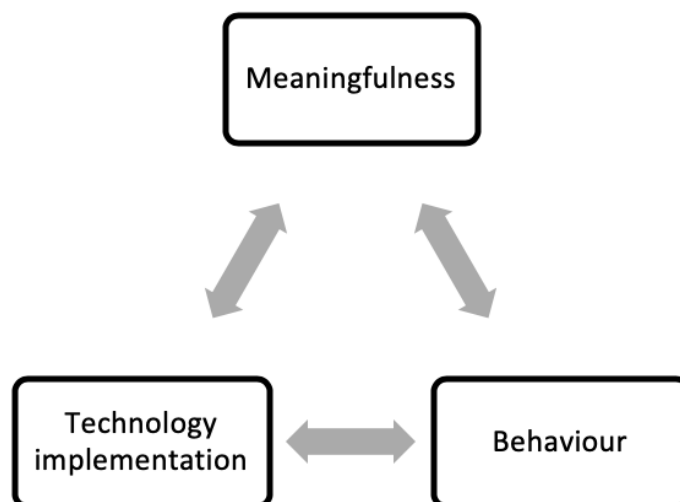

For providers, psychological meaningfulness associated with work has been shown to incent better engagement with that work. As Kahn [17] describes in his foundational paper on the subject, psychological meaningfulness in work is “*the harnessing of organization members’ selves to their work roles; in engagement, people employ and express themselves physically, cognitively, and emotionally during role performances.*”

Here Kahn connects meaning in work to a broader sense of self, which can, in turn, act as a powerful motivator to drive behavior. Classic motivation theorist Maslow viewed meaningfulness as one of several higher-order needs which humans strive for through the ongoing process of self-actualization [18]. Meaningfulness in work is argued to help individuals reach a level of self-actualization where individuals are driven by the work itself, rather than completing a task. Building on Maslow’s theory, Chalofsky and Krishna suggest meaning *in* work occurs when work speaks to an individual’s whole self and is perceived to be *good work*. When perceived meaning *in* work is paired with meaning *at* work, where individuals feel emotionally committed to their organizational environment, they will be subsequently more engaged and willing to go “above and beyond” [19]. This feeling of *meaningfulness* in work represents a “deeper level of intrinsic motivation” [19]. Tapping into that level of motivation to change can be crucial in technology implementation, where resistance to change is a significant barrier to implementing digital health solutions [4].

Second, while individuals’ sense of meaning in their lives can drive their behavior, it can also be influenced by the technologies they use. Technology itself represents an artifact in the social and work environment that can influence meaningfulness to individuals. There may be a risk in assuming the technology is simply a tool to manipulate, having little to do with what is important to people and their identities. Another perspective, grounded in a sociological approach, suggests technology plays an important role in how we understand ourselves, our work, and our environment. As Lupton so eloquently argues, health technologies are “*sociocultural products located within pre-established circuits of discourse and meaning. [Technologies] are active participants that shape human bodies and selves as part of heterogeneous networks, creating new practices and knowledge*” [20].

As such, when seeking to drive implementation of technology, we not only need to determine what value this brings to the individuals interacting with the technology as suggested by VPD and NASSS, but we also need to unpack how using the technology may change perceptions of value and meaning over time.

Figure 1 offers a simple visualization of this proposed interrelationship between meaningfulness, behavior, and technology implementation.

Figure 1. Meaningfulness in digital health.

Seeking Meaningful Innovation

If meaningfulness is a key driver to implementation, then it is essential to uncover what is meaningful to users of systems within their organizations and system contexts. VPD and NASSS offer a set of questions to guide the implementation process iteratively. These questions are not only useful in uncovering objective opportunities and challenges in implementation (eg, whether there are necessary resources and regulations needed to adopt a particular technology) but can be used to uncover meaningfulness as well (eg, how individuals perceive a shared problem to be solved).

In adopting this approach, however, two challenges can arise. First, those asking the questions may struggle to pick up on meaningfulness because users will have different abilities and willingness to express what is meaningful. Simply put, you may ask the right question, but the answers may not be articulated in a way that meaningfulness can be easily understood. Second, it can be challenging to attend to what is important and meaningful to the many different users of a system which can include providers, administrators, patients, and families involved in health service delivery; all of whom have different professional and personal backgrounds, aims and goals, and personal perceptions of meaning.

Drawing on multiple *qualitative methods* can help not only ask the right questions at the right times but unpack and interpret the answers with an ear for meaningfulness. To demonstrate how this approach could be put into practice, the remaining sections draw on experiences implementing the electronic Patient-Reported Outcome (ePRO) tool, a mobile app and web-based platform designed to support goal-oriented care in primary care settings. Qualitative methods used to develop, evaluate, and implement ePRO across multiple settings offer lessons on how what was meaningful to patients, providers, and their organizations influenced the adoption of technology. Experiences with this technology are compared to other literature emphasizing meaningfulness to drive the implementation of digital health technologies.

Developing for Meaningfulness

A focus on meaningfulness suggests a shift from merely seeing technology as a tool to support a process toward a deeper understanding of a user's experience of receiving or delivering care in a particular context. User-centered co-design is a popular approach to employ the experiences and views of users to guide development [21]. It is essential to recognize that the process requires analytic work and iterative dialogue to link articulated desires for functionality, to why that function is important to users.

In the first rounds of developing the ePRO tool [22-24], interpretive description was used to understand user experiences. This method allows for situated and contextualized analysis with a view toward practical application of findings [25], which supported an iterative building of the interpretation of meaningfulness and drove the development of the technology. After undergoing multiple rounds of co-design, usability analysis found that although the technology had many shortcomings, it was highly used by patients, because they perceived it as meaningful [24].

The ARCHIE framework similarly suggests that the development of telehealth and telecare products must be “anchored in what matters to users” through iterative co-creation driven by a phenomenological lens [26]. The framework aligns with philosophical and sociological traditions that emphasize meaningfulness to users, in this case, patients, suggesting the use of phenomenological and ethnographic approaches to uncover meaningfulness and guide development.

Evaluating for Meaningfulness

As the development of the ePRO tool moved from design into the iterative evaluation of usability testing and pilot trial, the focus on meaningfulness to both patient and provider users became even more important. This phase required the next step of linking meaningfulness to other components of the intervention beyond just the technology, looking at contexts, processes, and mechanisms that drive any change in patient

outcomes. A narrative analysis of patient and provider interview data was used to identify dominant themes in the stories they told of using the technology [27].

Critical to both patient and provider stories was how the technology linked to what was important in their lives and work. For patients, this meant it supported their care goals (achieving personal aims) and reinforced a sense of shared accountability to those aims with their provider. Providers recounted that they were willing to put in more time and energy to learn and use the new technology, adapting workflows and processes, when the technology was perceived as important to their patients (linked to a sense of doing *good work*). When they viewed the technology as meaningful, patients and providers changed their behavior to support the regular use of the tool.

Other evaluation methods that have been applied to similar complex technology interventions have viewed meaningfulness as a central component. For example, Gomersall and colleagues suggest adopting network-based evaluation approaches, like social networking or realist approaches, to pick up on social and individual values and meaningfulness in evaluations of ambient assistive living technologies [28].

Using Meaningfulness to Drive Implementation

The ePRO example and other studies indicate that meaningfulness may play an important role in the implementation of technologies. In these examples, meaningfulness is linked to personally held values and beliefs of individuals interacting with technologies, demonstrating that when technology aligns with those beliefs, it may be more likely to be used. However, meaningfulness is only one factor among other implementation drivers occurring at organizational and system levels. Uncovering meaningfulness for organizations and systems may also be required to support implementation. One approach is to consider how a given technology aligns to the *why*, or the vision, of an organization or care model. The critical point is to not just attend to that vision but also think about the guiding principles and values that drive organizations toward their goal. The disconnect between technology and what providers perceive as being foundational to their work and organization is a significant barrier to implementation [29].

Ideally, technologies would fit the aims and activities of the model of care as well as the guiding principles and values of the organizations and individuals delivering and seeking care. The ePRO tool was co-designed with those engaging in goal-oriented, person-centered care models. When spreading the tool to new environments as part of the pragmatic trial (see protocol [30]), it was most successful in primary care clinics

that also had a strong vision of person-centered care delivery along with processes they could adapt to meet that aim. Although we are still analyzing findings from this study, observationally we found that where there was alignment, the ePRO tool was more likely to be perceived as valuable to providers and patients leading to changes in how patients engaged in their care, and how providers managed patients and communicated with each other around supporting patient goals. Preliminary analysis of trial data suggests alignment between technology and the organization's vision and guiding principles can play an important role in implementation. A deep dive into the ethnographic data planned for this year will provide additional insight into this relationship.

Future Work

The experience of developing, evaluating, and implementing the ePRO tool, and the emerging literature in this space suggests that meaningfulness matters. In particular, philosophical and psychological meaningfulness may be playing an important role in the process of implementation. The ideas presented are based on just a few examples and require more empirical testing. While meaningfulness to users was explored as part of the ePRO study, the importance of meaning as related to implementation emerged throughout the study; as such we did not start explicitly looking for connections between meaningfulness and other implementation constructs until we got to later stages and had an opportunity to reflect on what was learned.

This viewpoint is intended to start a conversation about the role of meaningfulness in implementation. Many questions are yet to be explored, including: is there a unique understanding of meaningfulness that pertains to technology? How does meaningfulness interact with other components of implementation? Can strong empirical evidence of the value of a technology overrule intrinsic perceptions of meaning held by users? How does meaningfulness relate to other socially grounded concepts like ethics and equity when implementing technologies?

Perhaps the more important takeaway from this viewpoint is that philosophical and psychological meaningfulness for those who engage with technologies in their work and lives plays a role that deserves attention. Adopting qualitative methods can serve to uncover meaningfulness for diverse users and organizations, and could help to drive implementation decisions. Future work can help to uncover how we can adapt and build research methods to place meaningfulness at the center of our implementation efforts so that perhaps our reflections on the state of digital health a decade from now are much less grim than those we see today.

Acknowledgments

I would like to thank the dozens of wonderful colleagues, volunteer participants, trainees, and mentors with whom I have worked over the past 7 years as part of the ePRO project. It is through this work that the ideas shared in the commentary originated. A particular acknowledgment and deeply felt thank you to Drs Laura Desveaux and James Shaw, who invited me to speak on this topic at the Women's College Hospital Institute for Health System Solutions and Virtual Care (WIHV) Innovations Rounds in

Toronto in October 2019, and later provided thoughtful feedback on this viewpoint. It was in preparing for the talk that the ideas presented in this commentary were first brought together, presented, and then discussed with a terrific and engaged audience. I would also like to acknowledge Drs Ross Upshur and Kerry Kuluski, who offered support as I put thoughts together for this viewpoint. While this specific commentary was not explicitly funded, the ePRO project has been funded through the Canadian Institute for Health Research (FN-143559; FN-137200) and the Ontario Ministry of Health and Long-term Care Health Research Fund (#06034).

Abstract

Background: Tailoring an online intervention to participant preferences (eg, by giving participants a choice which modules to follow) may increase engagement in the intervention, motivation for behavioral change, and possibly intervention effects. So far, little is known about what characteristics predict these module choices. Filling this knowledge gap is useful for optimizing program engagement.

Objective: We investigated participant choice for a dietary and/or physical activity (PA) promotion module in our web-based computer-tailored intervention based on self-determination theory (SDT) and motivational interviewing (MI). Furthermore, we investigated which demographic characteristics, current behavior, psychosocial constructs and constructs from SDT and MI, and program-related variables such as advice on which module to follow were associated with these choices.

Methods: Observational data were used from the randomized controlled trial MyLifestyleCoach of participants who were randomized into the intervention condition, completed the baseline questionnaire, and made a module choice in the opening session of the intervention. Here, they received advice on their own dietary and PA behavior. At the session's end, they chose which lifestyle modules they would like to follow (both, diet, PA, or no module). Measurements included demographic information; self-reported diet and PA; and several psychosocial, SDT, and MI constructs. In total, data from 619 Dutch adults (59.6% women; mean age was 51.9 [SD 13.5] years) were analyzed. A stepwise multinomial logistic regression analysis was conducted to investigate which characteristics are related to module choice; the diet module served as reference category as almost everyone was advised to follow this module.

Results: Of this sample, 54.8% (339/619) chose to do both the diet and PA module, 25.4% (157/619) chose to follow the diet module, 17.8% (110/619) preferred to follow no module, and 2.1% (13/619) chose to do the PA module only. Furthermore, it was found that older people, those who consumed more fruit, and those who scored lower on importance to change their current diet were more likely to choose no module compared to the diet module. People who had more motivation to change their current PA and those who received strong advice compared with slight advice to follow the diet module were more likely to choose both modules compared with the diet module only.

Conclusions: The results show that more than half of the sample was interested in following both the diet and PA module in this online lifestyle intervention. Several characteristics were found to be related to module choice. A future challenge is to examine how this knowledge can be used to improve future interventions, such as tailoring (messages or content) on specific groups or examining where and how MI could be used to motivate people to make a certain module choice.

KEYWORDS

eHealth; computer-tailoring; self-determination theory; multiple health behaviors; lifestyle promotion; module choice

Introduction

Health risk behaviors such as unhealthy dietary intake and insufficient physical activity (PA) are widespread among adults, making the prevention of these behaviors a public health priority [1-3]. The small effect sizes, limited sustainability of effects, and high dropout rates usually found with existing online diet and PA interventions suggest that there is room for improvement in this field [4,5]. In this regard, there is more and more evidence showing the importance of autonomous motivation in sustained behavioral change [6,7], and this might therefore be a potential strategy for improving diet and PA interventions. Self-determination theory (SDT) postulates that providing conditions that support autonomy and choice are important basic psychological needs to improve more autonomous forms of motivation [8-11]. This autonomy support may be relevant during participation in intervention programs but also necessary at the start of an intervention, allowing participants the option to choose for themselves what parts of the intervention program they want to participate in. For interventions targeting multiple behaviors, this means people should have the option to choose which behavior they want to work on, preferably from separate modules so they can focus on a behavior in which they are really interested. Until now, research about the choices people make in such interventions (ie, which modules people choose) has been limited. But research that focuses on which factors and determinants are related to these choices is even more scarce.

To date, research has mainly investigated predictors of participation, use, and revisits of eHealth interventions instead of why people choose certain topics in these interventions [12-19]. In general, these studies have shown that women, older people, people with more education, people with a higher income, and people with a healthier BMI and a healthier lifestyle are more likely to visit, start, use, and revisit web-based interventions. In addition, insufficient time, no personalized content, dissatisfaction with the content, and computer difficulties were linked to a decrease in adherence [20]. Giving participants a choice of which modules to follow may improve user engagement and favorably affect compliance and long-term success [21]. One study found that a majority of patients showed improvements in anxiety and depressive symptoms when they could decide what modules to use in a tailored web-based treatment, and only one participant (of out 27) dropped out [22].

Yet only a few studies have described which behaviors (modules) individuals choose to start with in multiple health behaviors interventions [21]. Two studies in the general adult population found that people prefer to select the PA module over dietary modules [19,23]. In a study with cancer survivors, a reversed pattern was present: the diet module was preferred over the PA module [24]. Another study found no favorable effects of messages tailored to a participant-selected topic over an expert-determined topic on PA levels [25]. Based on these mixed findings, the role of module choice should be further explored in tailored web-based interventions.

So far, two studies have identified factors that relate to module choice in online interventions [23,24]. These studies have demonstrated that age, marital status, advice (both content and number of referrals), and healthier lifestyle have been related to module choice. Research to date has not yet determined whether psychosocial factors also relate to module choice. According to the SDT, individuals experience more autonomous forms of motivation when the needs for relatedness, autonomy, and competence are met [10,26]. Thus, feeling a higher degree of autonomy and perceived competence in changing or maintaining improved dietary intake or PA may lead to more intrinsic motivation to change behavior, which could subsequently lead to engagement in actions to achieve the intended behavior change [8-11]. The client-centered counseling style and techniques from motivational interviewing (MI) can create a facilitating environment in which these needs are promoted [27]. However, (intrinsic) motivation alone is often not sufficient for initiating and maintaining improved nutrition or PA levels. Other psychosocial characteristics closely linked to motivation may also play a role in this process and possibly in module choice. It may be that people who have a higher commitment to change certain behaviors are more likely to choose a certain module. However, to our knowledge, no study has examined to what extent these factors relate to module choice [28].

With eHealth interventions becoming more and more popular in recent years, there is now a general idea concerning elements that make an intervention effective and increase its use. However, a detailed understanding of what actually occurs within an intervention is still lacking. Our main aim is to elucidate factors related to module choice. Identifying and understanding which characteristics relate to the choice of a specific module or the choice not to follow any module can inform intervention improvement. This knowledge can be used to optimally tailor the intervention to the specific characteristics and needs of the participants and prevent nonuse. This may result in increasing intervention exposure and relevance that could result in increased effectiveness of the intervention.

In this study, participant choice of a dietary and/or PA promotion module is investigated in our web-based computer-tailored intervention based on SDT/MI. The main aim of this study is to examine which factors are related to these module choices (diet, PA, both, or no module) in the intervention. For these factors, we will look at demographic characteristics, psychosocial constructs related to SDT and MI, current behavior, and program-related variables (advice on which module to follow and the importance of changing behavior after feedback). Several hypotheses have been formulated based on previously mentioned literature. Regarding demographic characteristics, it is expected that women, older people, and people with more education are more inclined to choose a module (both, diet, PA) compared with no module. Furthermore, it is expected that a higher intrinsic motivation to perform a certain healthy behavior is related to choosing that particular module (ie, a higher motivation to engage in sufficient PA is related to choosing the

PA or PA and diet module compared with the diet or no module). In addition, a healthier lifestyle is likely to affect module choice as well (eg, people with a healthier diet should be more inclined to choose the diet module compared with no module). Last, advice to follow a particular module and importance of the targeted change behavior is also expected to relate to choosing that particular module (both, diet, PA) compared with no module.

Methods

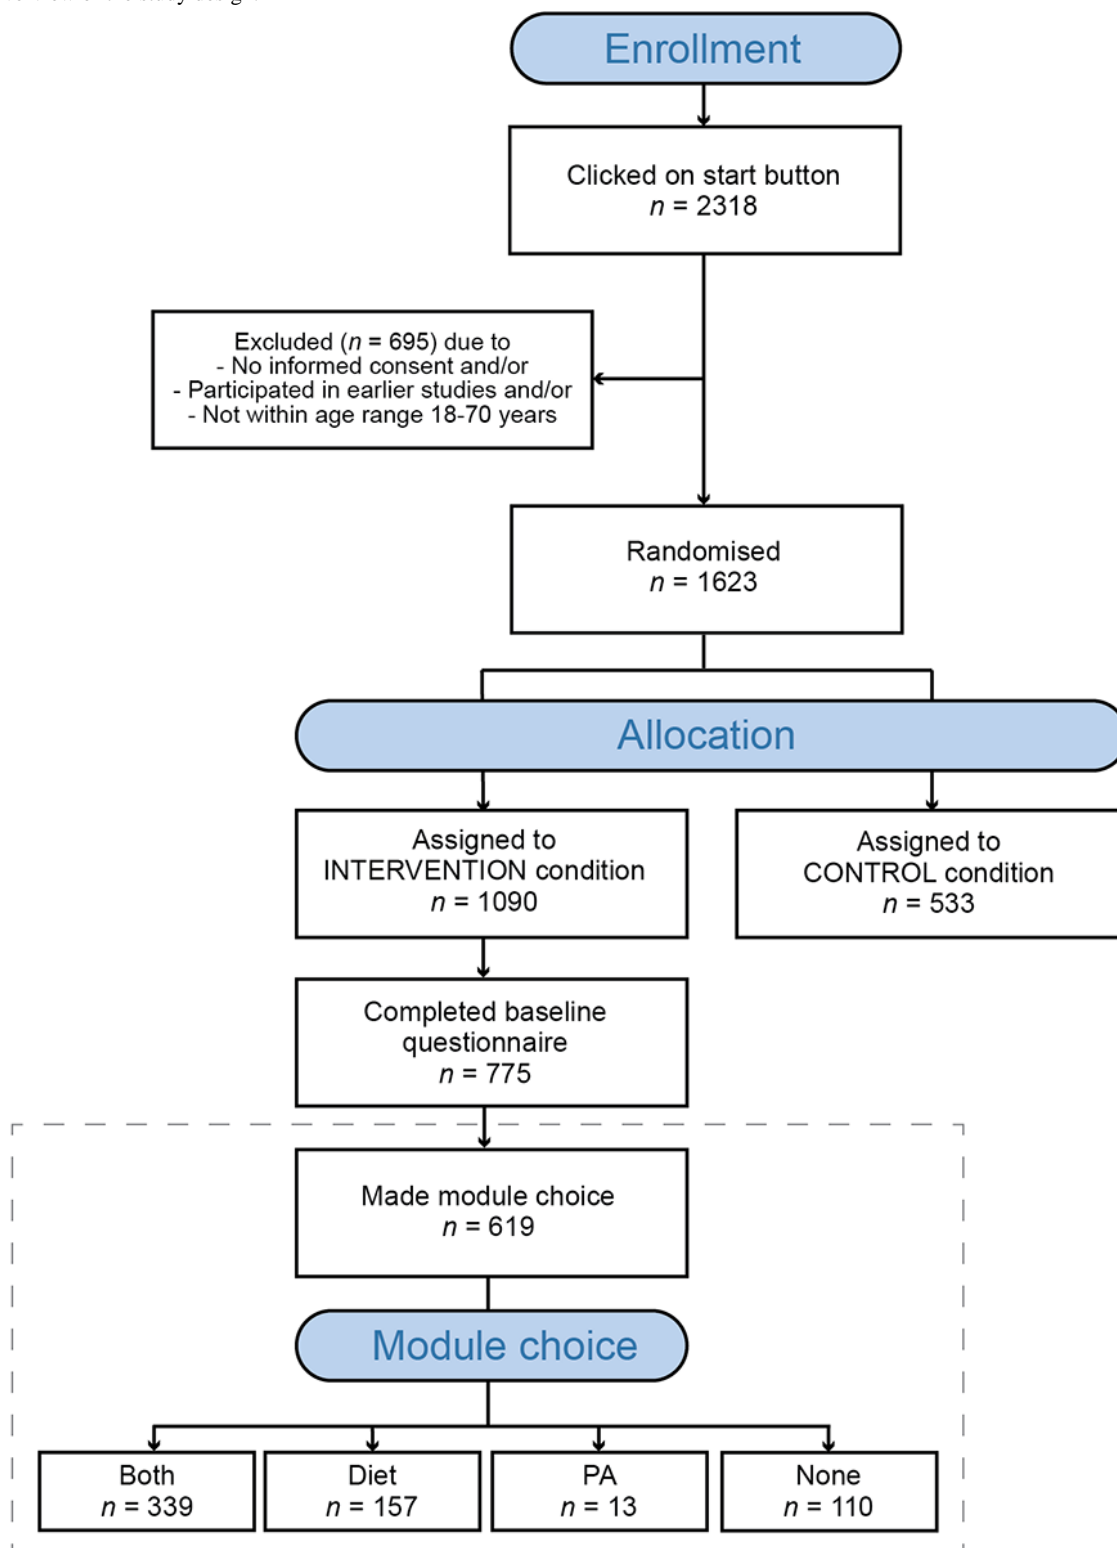

Design

This observational study was conducted as part of a 2-armed randomized controlled trial, MyLifestyleCoach. Data were collected in the period from mid-October 2018 until mid-May 2019. A comprehensive description of the intervention and the underlying theoretical frameworks, details of the trial design, and sample size calculations have been published elsewhere [29,30]. This web-based computer-tailored dietary and PA promotion intervention was developed using the intervention mapping protocol, and it is based on principles from SDT and

MI. MyLifestyleCoach consists of two modules: I Move, an existing effective computer-tailored intervention to promote PA (PA module), and I Eat, which is aimed at promoting healthy eating (diet module), using similar behavior strategies as the I Move module [31]. The I Eat module is new, however, and its effectiveness has not been evaluated yet [29]. This study has been reviewed and approved by the Committee for Ethics and Consent in Research of the Open University of the Netherlands (reference number: U2018/07266/SVW) and was registered with the Netherlands Trial Register [NL7333].

Participants

Participants for this study were recruited via an internet research panel of Dutch inhabitants who occasionally volunteer in web-based research. They were eligible to participate if they were aged 18 to 70 years. A total of 1090 participants were randomized into the intervention condition of this study, of which 71.10% (775/1090) of participants completed the baseline questionnaire and 79.9% (619/775) of participants made a module choice in the opening session of MyLifestyleCoach. See Figure 1 for an overview of the study design and flow of participants. The dashed line represents the focus of this study.

Figure 1. Overview of the study design.

Measurements

All the following constructs were measured in the online self-reported baseline questionnaire except for perceived importance; this was measured at the end part of the opening session, after feedback regarding current behavior had been provided. Researchers had no influence on how participants reported the outcomes. Participants had to complete each

question to be able to proceed to the next section of the online questionnaire.

Demographics

The baseline questionnaire assessed gender, age, educational level, marital status (with or without a partner), health status (on a scale from 0 to 100), and height and body weight to calculate BMI. Educational level (ie, the highest level of education completed) was recoded into three categories: low

(primary or basic vocational school), medium (secondary vocational school or high school), and high (higher vocational school or university). Work was recoded into two categories: employed (full-time or part-time work) and unemployed (volunteering, having no job, incapacitated to work, retired, household chores, or studying). Furthermore, we asked whether participants had an impairment that would prevent them from being physically active (yes/no).

Psychosocial Constructs Including Self-Determination Theory/Motivational Interviewing–Related Constructs

Competence

Two Perceived Competence Scales were used to assess perceived competence (basic psychological need, SDT) for a healthy diet and PA [32]. This is a 4-item questionnaire on which participants indicated the extent to which each statement is true for them on a 7-point Likert scale (1 = not at all, 7 = very true). An example item is: “I feel confident in my ability to maintain a healthy diet/exercise regularly.” The perceived competence scores were determined by calculating a mean score for the 4 items, separately for diet and PA. The internal consistency of these scales in this study was excellent (Cronbach α = .95 for diet and .96 for PA).

Self-Regulation and Motivation

The Treatment Self-Regulation Questionnaire concerns why people would engage in health-relevant behavior [33,34]. It was used to assess the degree to which a person’s motivation for a healthy diet and PA is relatively driven by autonomous or self-determined reasons (SDT). Participants indicated the extent to which each of the 15 items was true for them on a 7-point Likert scale (1 = not at all, 7 = very true) for healthy eating and PA. Six items measure an autonomous regulatory style (Cronbach α = .92 for diet and .93 for PA), 6 items measure a controlled regulatory style (Cronbach α = .86 for diet and .89 for PA), and 3 items assess amotivation (Cronbach α = .70 for diet and .76 for PA). Responses to the respective items for each regulatory style were averaged to obtain a score for each of the three self-regulatory styles.

Intrinsic Motivation

According to the SDT, autonomous motivation consists of identified, integrated, and intrinsic regulation. However, the Treatment Self-Regulation Questionnaire does not differentiate between these autonomous forms of motivation. Therefore, the subscale intrinsic regulation from the Dutch Behavioral Regulation in Exercise Questionnaire was administered to determine intrinsic motivation, as this is the only fully self-determined form of motivation [35]. Participants rated on a 5-point Likert scale to what extent each of the 4 items was true for them with values of 1 = not true for me to 5 = very true to me. An example item was: “I exercise because it’s fun” (translated to engage in PA in Dutch). To compare intrinsic motivation for exercise with a healthy diet as closely as possible, we replaced exercise in all items by eating healthily. The scores of the 4 items were averaged into one intrinsic motivation score, both for a healthy diet and PA. The internal consistency of these scales in this study was excellent (Cronbach α = .93 for diet and .98 for PA).

Importance

In the opening session, participants were asked to rate their perceived importance of eating (more) healthily and becoming more physically active using an importance ruler after they received feedback on their current behavior. This is a 1 to 10 scale, a tool to support the use of MI [36]. Including this factor next to the baseline importance scale was necessary because importance could have been changed as a result of the content (eg, feedback on current behavior) of the opening session.

Intention

Three items were used to measure intention for eating healthier and being physically active [37]. Participants rated on a 10-point scale to what extent, how strong, and how probably they intended to eat (more) healthily and become physically more active (or stay sufficiently active). A mean score was calculated for diet and PA based on these 3 items. The internal consistency of these scales in this study was excellent (Cronbach α = .91 for diet and .95 for PA).

Commitment

Three items were used to measure commitment to eating healthier and being physically active [38]. Participants rated on a 5-point Likert scale how important eating (more) healthily/PA is for them, how involved they were in eating (more) healthily/PA, and how committed they are toward eating (more) healthily/PA. A mean score was calculated for diet and PA based on these items. The internal consistency of these scales in this study was good (Cronbach α = .89 for diet and .92 for PA).

Diet

Diet was assessed with a validated Food Frequency Questionnaire [39,40]. It assesses the frequency and quantity of a variety of food items eaten in a typical week in the last month. Participants reported on how many days they typically consumed fruit, vegetables, and fish (ranging from 0 to 7 days per week). We added questions assessing the size of vegetables and fruit portions based on Willems et al [41]. The intake of pieces of fruit per day was calculated by multiplying the frequency by the number of pieces with the reported number of consumption days, divided by 7 (days a week). When participants reported eating fruit or vegetables on at least one day but did not fill in the portion size, the portion size was replaced by the median. Furthermore, participants reported the consumption frequency of a particular snack food in a typical week in the last month on a 7-point Likert scale: 1 = never/less than once a week, 2 = 1 to 3 times a week, 3 = 4 to 6 times a week, 4 = 1 time per day, 5 = 2 times per day, 6 = 3 times per day, or 7 = 4 or more times per day. Eight types of snacks were assessed, namely unsalted nuts, dried fruits, chocolate, candy, cookies, chips, ice cream, and savory pastries. The consumption frequency of unhealthy snacks per day was determined by summing the recoded frequencies for last 6 snacks (chocolate to savory pastries) and dividing by the numbers of days in a week.

Physical Activity Level

PA behavior was assessed using the validated self-administered Dutch Short Questionnaire to Assess Health [42]. This

questionnaire has been adapted to an online format. Participants were asked on how many days of in a typical week (0-7) during the past month they engaged in (1) walking to work/school, (2) cycling to work/school, (3) work, (4) household activities, (5) walking, (6) cycling, (7) gardening, and (8) odd jobs. If participants engaged at least once a week in the before mentioned activities, they reported how many hours and how many minutes they engaged in this activity. Work and household activities were separated for light/moderate and vigorous activity (examples were provided for light/moderate and vigorous activities). For sports, participants were asked which sports they engaged in the last month (they could choose up to 4 sports). Then they provided the number of days per week and duration for these sports. For walking, cycling, gardening, and sports, participants rated whether they considered it to be light, moderate, or vigorous. PA behavior was operationalized as the total number of minutes of moderate to vigorous physical activity per week (MVPA). This was calculated by multiplying the frequency (how many days per week), and duration (how many hours and minutes per day) of leisure and transport walking, leisure and transport cycling, gardening, household activities, odd jobs, and sports performed with moderate or vigorous intensity. Values were inspected using frequency tables, and extreme values (eg, 16 hours of heavy household activities) were replaced by the median of the sample. This self-report was used as this was the most feasible method (ie, convenience, low costs, and proven as a reliable and valid tool) in assessing PA compared with objective observations [43].

Procedure

Members of the research panel received an email advertising the study about lifestyle containing information regarding the study (background, providing personal advice regarding dietary and PA behavior, that the program could help to improve their dietary and PA behavior, and information about prizes they could win for fully completing the intervention) and a link to the study website. Participation was free. When they clicked on the link, they could read further extensive information regarding the project, target population, expectations, data protection regulations, benefits (such as insight in current dietary and PA behavior and having a chance to win prizes), and contact details. If they were interested, they could click on the start button.

All eligible participants who agreed to participate answered some questions relevant to the inclusion and exclusion criteria and signed an online consent form. They were then computer randomized into the intervention condition or waiting list control condition (2:1) using a computer-determined sequence and completed the baseline questionnaire. In this paper, only respondents of the intervention condition were included in the analysis. After completing the baseline questionnaire, participants in the intervention condition continued directly to the opening session. Here, they were introduced to the structure of the program by text and by video coach. The video coach did not go into detail about the content of the modules or give advice on which module to follow. Participants were also asked to rate their perceived importance of eating (more) healthily and becoming more physically active on a 10-point scale. They

received advice on which module to follow using a traffic light system based on the responses to the baseline questionnaire on where there was room for improvement, separately for diet and PA (see more information about this in the advice section). Participants were given a feedback message consisting of a summary of the extent to which they adhered to the diet and PA guidelines, in which domains there was room for improvement, and how important a healthy diet and sufficient PA was to them. They also received a brief reminder about the structure of the program.

Subsequently, participants were invited to choose which module they wanted to follow: diet, PA, both, or no module. The ones who chose no module received an email 2 weeks later with a link to the program where they could again make a module choice. Within the program, participants who had chosen to follow either the diet or the PA module were given the option to follow the other module once they had completed a session. Participants who did not immediately enter the opening session after completing the baseline questionnaire got a friendly reminder to do so 1 week after they completed the baseline questionnaire.

Advice

Participants received traffic light–based advice presented on two separate pages, one each for diet and PA. The color of the traffic light displayed in the advice indicated how closely their current PA level and diet corresponded to health recommendations. The corresponding text advised which modules were most relevant for them to use. For diet, the targeted behaviors (based on a pilot study) were to consume at least 200 grams of fruit (2 portions) and 250 grams of vegetables daily, eat fish at least once a week, and consume no unhealthy (ie, energy-dense) snacks [44]. For PA, the advice recommended accumulating at least 2.5 hours of MVPA every week [45]. A green light was shown when participants met the guideline. We then praised the positive scores and advised that it was not of high priority to follow the corresponding module but participants were still free to have a look at the module. An orange light was shown when the participants were close to meeting the guidelines (ie, the recommendations for at least one of the targeted behaviors for diet but not all were unmet or participant had 120 to 150 minutes of MVPA per week). Here, we also praised the reasonable positive score but advised following the module because there was room for improvement. Last, a red light was displayed when the participant failed to meet the guideline (ie, less than 120 minutes of MVPA per week). We strongly advised the participant to follow the corresponding module because the module could help them improve their behavior and health. If participants did not meet a certain guideline, they got detailed results about their current activity toward that particular behavior (fruit, vegetables, fish, unhealthy snacks, or PA) in relation to the guidelines. See Figure 2 for an example of the traffic light–based advice. The traffic lights were meant to provide participants with insight into their behavior and what they could change; they were not necessarily intended to induce compliance with dietary recommendations and PA guidelines.

Figure 2. Screenshot of the page where people get advice in the opening session.

Statistical Analyses

Descriptive statistics were used to depict demographic and psychosocial characteristics of the participants included in this study. To investigate the predictors of module choice, we performed Spearman correlations between all predictors to determine the intercorrelation of predictors. In case of high intercorrelation, predictors could be removed beforehand. A stepwise multinomial logistic regression analysis was conducted to identify which demographic (step 1), psychosocial including SDT and MI constructs (step 2), dietary behavior (step 3), and program-related variables such as advice and changed importance (step 4) were related to module choice. Significance was set at $P < .05$. Multicollinearity was assessed using variance inflation factors (VIF). Furthermore, the fits of the models were compared with likelihood ratio tests. If $P < .05$, the more complex model was significantly better than the simpler model, and thus the more complex model was favored. All statistical analyses were performed with the statistical software R version 3.4.4 (R Foundation for Statistical Computing).

Results

Participants

The study population was slightly overrepresented by women (369/619, 59.6%; men: 250/619, 40.4%). The mean age was

51.9 years, and about two-thirds of the participants were in a relationship. Furthermore, the majority of the participants had a high level of education. Of this sample, more than half of the participants had a paid job (full-time or part-time). Of those who did not have a paid job, 8.9% (20/225) were volunteering, 7.1% (16/225) were unemployed, 16.4% (37/225) were incapacitated to work, 44.0% (99/225) were retired, 16.4% (37/225) were studying, and 7.1% (16/225) did household chores as their main activity. In total, 4.8% (30/619) of participants had a physical impairment that prevented them from being physically active. The mean BMI was 26.6 kg/m²; 1.8% (11/619) were classified as underweight, 42.2% (261/619) had a healthy weight, 35.2% (218/619) were classified as having nonobese overweight, and 20.8% (129/619) were classified as obese. About one in three participants complied with the fruit guideline of 2 portions of fruit per day, 11.8% (73/619) adhered to the vegetable guideline of 250 grams of vegetables per day, 62.5% (387/619) of this sample consumed fish at least once a week, and 7.8% (48/619) never consumed unhealthy snacks. More than 90% of this sample engaged in 150 minutes or more MVPA per week (Table 1).

^aPA: physical activity.

^bSDT: self-determination theory.

^cMI: motivational interviewing.

^dVegetables: corrected values were used. Portion sizes of 75 grams or larger were divided by 50, as one portion equals 50 grams.

^eMVPA: moderate to vigorous physical activity.

^fCorrected values were used according to the Short Questionnaire to Assess Health manual; extreme values were furthermore replaced by the median. As a consequence, 7 participants were excluded as they reported to be physically active over 6720 minutes per week.

Module Advice and Module Choice

Table 2 displays the provided module advice and subsequent module choice. In total, 24.6% (152/619) of participants were strongly advised to follow the diet module (red traffic light), 75.0% (459/619) of participants were slightly advised to follow the diet module (orange traffic light), and only 0.5% (3/619) of participants were not advised to follow the diet module (green traffic light). Regarding the PA advice, 3.6% (22/619) of participants were strongly advised to follow the PA module (red traffic light), 1.9% (12/619) of participants were slightly advised

to follow the PA module (orange traffic light), and 94.5% (585/619) of participants were not advised to follow the PA module (green traffic light). Of the participants who made a module choice in the opening session of the intervention, 54.8% (339/619) of participants chose to follow both modules, 25.4% (157/619) of participants only chose the diet module, 2.1% (13/619) of participants chose only the PA module, and 17.8% (110/619) of participants chose no module. Thus, more than 80% of the participants were interested in following at least one module, and more than half of the participants were interested in following both modules.

Table 2. Overview of advice and module choice.

Traffic light ^a		Module choice				Total
Diet	PA ^b	Both, n (%)	Diet, n (%)	PA, n (%)	None, n (%)	N (%)
Red	Red	5 (1.5)	1 (0.6)	0 (0.0)	1 (0.9)	7 (1.1)
Red	Orange	2 (0.6)	0 (0.0)	1 (7.7)	0 (0.0)	3 (0.5)
Red	Green	86 (25.4)	39 (24.8)	1 (7.7)	16 (14.5)	142 (22.9)
Orange	Red	9 (2.7)	1 (0.6)	3 (23.1)	2 (1.8)	15 (2.4)
Orange	Orange	5 (1.5)	2 (1.3)	1 (7.7)	1 (0.9)	9 (1.5)
Orange	Green	229 (67.6)	114 (72.6)	7 (53.8)	90 (81.8)	440 (71.1)
Green	Red	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)
Green	Orange	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)
Green	Green	3 (0.9)	0 (0.0)	0 (0.0)	0 (0.0)	3 (0.5)
Total	— ^c	339 (54.8)	157 (25.4)	13 (2.1)	110 (17.8)	619 (100.0)

^aTraffic light advice was based on self-reported (uncorrected) values. A red traffic light indicates that the module was strongly advised, an orange traffic light indicates that the module was slightly advised, and a green traffic light indicates that the module was not advised but that participants could have a look at the module.

^bPA: physical activity.

^cNot applicable

Which Factors Are Related to Module Choice?

First, it was investigated using Spearman correlations whether there was collinearity between the continuous predictors. There were several predictors that were highly intercorrelated ($r \geq .60$) with the other predictors. See [Multimedia Appendix 1](#) for the correlation table. Based on these results, it was decided to remove the psychosocial constructs of intention, as the correlation coefficients were approaching a correlation coefficient of .80 with perceived competence (intention diet with perceived competence of diet, $r_s = .78$, $P < .001$, and intention PA with perceived competence of PA, $r_s = .76$, $P < .001$) and because perceived competence was of more theoretical relevance in this study (basic psychological need in the SDT).

Since only 13 participants chose the PA module only, the frequency was too low to enable group comparisons and coefficients could not be reliably estimated. We, therefore, removed those cases from the analyses. Then the stepwise multinomial logistic regression analysis was conducted with module choice as the outcome (both modules, diet, or no module). The diet module served as the reference category, because everyone was advised to follow the diet module, except for 3 participants who were excluded here. [Multimedia Appendix 2](#) presents the results of this analysis. The means each predictor presented in [Table 1](#), stratified for module choice, may aid understanding.

Model 1 shows that people with a higher age were more likely to choose both modules as well as no module compared with the diet module; however, the effect that older adults were more likely to choose both modules became nonsignificant. When the psychosocial and SDT/MI predictors were added to the previous (model 2), it was found that people who had higher levels of amotivation to change their current PA levels were less likely to choose both modules compared with the diet

module. Model 3 additionally shows that people who consumed more fruit per day were more likely to choose no module compared with the diet module. When the program-related variables (model 4) were added to model 3, it could be seen that people who were strongly advised to follow the diet module were more likely to choose both modules than those who were slightly advised compared with the diet module. Last, people who found it more important to change their current diet were less likely to choose no module compared with the diet module.

Model Comparisons

Adding the predictors to each subsequent model led to an increased Nagelkerke R^2 . Models 2 and 3 did not have a significantly improved fit compared with model 1 (see [Multimedia Appendix 3](#)). However, model 4 had a significantly better fit than models 2 and 3, whereas compared with model 1 there was found a marginal statistically significant effect. Therefore, model 4 seems to explain our data best, as this model had a significantly better fit than the other models (except for model 1) and also was indicated by the highest Nagelkerke explained variance (see [Multimedia Appendix 2](#)).

Additional Information Regarding the Regression Analysis

A VIF larger than 10 is an indication of multicollinearity (see [Multimedia Appendix 4](#)). We removed autonomous motivation and commitment for diet and PA from the analysis. Importance was nevertheless included in the analysis, as this turned out to be an important factor in relation to module choice. The results of the full model, including those predictors that were excluded because of a too large VIF, can be seen in [Multimedia Appendix 5](#). Although minor differences in the results were found, our main findings seem to hold.

Discussion

Principal Findings

This study investigated participant choice for a dietary and/or PA promotion module in a web-based computer-tailored intervention based on SDT/MI. The main aim was to examine which factors were associated with these module choices. The results showed that more than half of the sample (55%) chose to follow both the diet and the PA module. About a quarter of the sample chose to follow the diet module only, 18% of the participants did not want to follow any module, and 2% chose the PA module only.

Our findings are in line with a previous study in which more participants used the diet module (58%) than the PA module (22%) [24]. But our findings are not consistent with several other studies in which the PA module was preferred over dietary modules that focused on limiting fat intake and increasing fruit and vegetable consumption [19,23,25]. Several explanations could be offered for this discrepancy. First, improvements in diet seemed to be far more necessary in our sample than improvements in PA levels. In our study, almost no one completely adhered to the dietary guidelines, whereas most participants already adhered to the MVPA guideline, which may be an overestimation of findings in the general Dutch population [46]. Second, people were completely free to decide for themselves which behavior they wanted to work on (ie, improving or maintaining current behavior) rather than simply trying to achieve or maintain the recommended levels as in line with Kanera and colleagues [41]. This may also be evident for a large proportion of the participants who chose both modules even though they were not advised to do so, indicating that for them it is important to maintain a healthy lifestyle. In other studies, there were restrictions in making a choice, such as only choosing modules when participants received orange or red traffic light advice [23]. Third, in our study, as well as in the study by Kanera and colleagues [41], the diet module was rather broad targeting multiple dietary behaviors; in other studies, individuals could choose more specific topics (eg, fat) which might be more relevant for some participants. Still, there were 110 participants in our study who were not interested in following either the diet or PA module, even though all participants were advised to choose at least the diet module. This is interesting since most studies did not investigate the explicit option of following no module, even though it is an important choice that might be common in the intervention practice and research.

The main aim of this study was to examine why some people are likely to make a particular module choice. Our results showed that age was the only demographic factor related to module choice. Older people were more likely to choose no module compared with the diet module. This is somewhat in contrast to our expectations and previous findings in which older people generally participated more in eHealth interventions in terms of start and (re)visit [14,15,17,19].

Surprisingly, amotivation was the only motivational construct found to be related to module choice, while we expected that especially intrinsic motivation was related to module choice.

People who lacked motivation to become more physically active were less likely to choose both modules compared with the diet module alone, possibly because many already adhered to the MVPA guidelines and only those who were more motivated (ie, having lower amotivation scores for PA) were interested in the PA module. Next to these findings, it could still be that there are other motivational constructs that are more important in explaining module use, adherence/dropout, and behavioral change [6]; these will be investigated in a future study.

Previous research found that an already healthier lifestyle was related to module choice [23,24]. In our study, we only found that people who consumed more fruit per day were more likely to choose no module compared with the diet module. Almost half of the people who preferred no module already ate enough fruit according to the fruit consumption guideline of two servings per day. Sufficient fruit intake might be a reason why they were less interested in following the diet module. Eating behavior is very complex, and when people estimate how healthy their current diet is, they might use various indicators and fruit consumption may be an important one.

As expected, dietary advice did affect the modules people in our study chose. Participants who were strongly advised compared with those who were slightly advised to choose the diet module were more likely to choose both modules. It could be that these participants felt more need to change their lifestyle at a broader level. PA advice, on the other hand, did not affect module choice. These findings somehow validate our nondirectional goal of advice; many participants already adhered to the PA guideline but still preferred to choose the PA module in addition to the diet module. With regard to participant perceptions of how important they find eating healthy and getting sufficient PA, we found that people who considered it more important to eat more healthily during the opening session were less likely to choose no module compared with the diet module. To note, importance was measured after advice including feedback about their current behavior was given. It is conceivable that in this basic opening session awareness about their own unhealthy behavior was increased. As a result, people might have changed their perceptions on the importance of their dietary behavior. So in terms of the transtheoretical model of behavioral change, people who were in the precontemplation stage (ie, having no intention to change behavior) could have moved toward the contemplation stage (ie, intending to start the healthy behavior) as a result of the opening session [47]. It should further be noted that this model (including the program-related variables) had the highest explained variance and the best fit, meaning that compared with all other models we tested, this model explained our observed data the best.

By giving individuals the opportunity to not follow any of the offered modules—in accordance with SDT and MI principles [48,49]—we definitely lost people before the more specific parts of the intervention started. It is possible these participants were mainly interested in completing the questionnaires (eg, for the possibility of winning rewards). This may have resulted in additional dropout. However, participants received reminders in a later stage that they could still begin using the modules if they wanted, which has not been accounted for in this study. It would be interesting to see if the option of choosing no module

would lead to less dropout during the actual modules, as it is expected that only motivated participants are actually participating. It could also be that for those who chose to follow no module, the opening session provided sufficient information to fulfill their needs (for example, by receiving feedback on their PA and dietary behavior) and possibly even change their health behavior.

The findings of this study are preliminary, making it difficult to provide concrete recommendations for intervention development. Several factors were identified that were linked to choosing no module instead of the advised diet module: an older age, eating more fruit, and finding eating healthily less important. More research is needed to find out why those individuals are more likely to choose no module compared with the diet module, thus examining what could be improved (ie, more relevant content, better tailoring to specific groups, using MI to improve importance as early as possible) to make them more likely to choose the diet module. Future research is also necessary to investigate how and when MI could be applied to target those individuals who are more likely to choose no module and for whom the opening session is not sufficient to get them engaged in intervention activities and behavioral change.

Strengths and Limitations

To our knowledge, this is the first study to investigate to what extent the combined demographic characteristics, SDT/MI constructs, psychosocial factors, diet-related behavioral outcomes, and program-related variables (eg, advice) are related to participant module choice in a web-based tailored eHealth lifestyle intervention that is directed to more than one behavior. The findings of this study should be interpreted in the light of several limitations. First, we only used self-report to gather data. For example, even though the Dutch Short Questionnaire to Assess Health was the most feasible method to measure PA levels in our study, it may be subject to recall bias. In our study, a larger proportion of the people adhered to the PA guidelines compared with the general Dutch population, which could also be an overestimation of their actual PA level [46]. Second, our findings may not be fully generalizable to the entire Dutch adult population. A large part of our sample was highly educated. Even though our results showed that education did not affect module choice, generalizability may be questioned as a large proportion of the sample also adhered to the PA guideline, which may also concern overrepresentation [50]. Furthermore, women

and people who are classified as obese were overrepresented as well, but age seems to be in line with the Dutch population. Third, attrition bias could play a role in several phases of the intervention period, such as between completing the baseline questionnaire but not completing the opening session (ie, making a module choice); this may threaten external and internal validity. This study did not provide insight into this matter; however, the process evaluation and effectiveness study will. Fourth, it may be that a combination of predictors and/or other predictors that are not measured in this study are also relevant in predicting module choice. No interaction effects were tested in this study since our sample size was not sufficient to test these effects on top of the already numerous predictors in our current analysis. Interactions between advice and the different types of motivation would be an interesting avenue to explore—for example, one can expect that people who score higher on controlled motivation might be more likely to follow advice within the intervention. Future research is necessary to examine additional relevant combinations of factors that could provide further insight into what predicts module choice.

Conclusions

Most participants chose to follow both the diet and PA modules in our web-based tailored lifestyle intervention. Our study has provided new insights into which characteristics are related to module choice in a lifestyle intervention. Additional research is necessary to examine how to target those individuals who are likely to choose no module and thereby who are at risk of dropping out in studies where this option is not explicitly offered. Most of the SDT/MI-related concepts did not affect module choice, suggesting that for initial module choice constructs from the SDT were less relevant than expected. These factors may, nevertheless, be relevant at a later stage of the intervention, and they could be related to participation or behavioral change. This will be examined in a follow-up study. A stepped approach to develop and pilot an intervention may be of relevance as various factors may be related to different aspects of an intervention (ie, module choice, participation, and behavioral change). To conclude, the findings in this study have important implications for developing eHealth interventions containing multiple health behaviors, as they can provide input for intervention improvement by providing insights that could help to optimally tailoring to the needs and characteristics of participants, such as making it more interesting for older adults, increase its effectiveness, and prevent dropout in a later stage.

Abstract

Background: Unguided, web-based psychoeducational interventions are gaining interest as a way to reach patients while reducing pressure on clinical resources. However, there has been little research on how patients with cancer use these interventions.

Objective: The objective of this analysis was to evaluate how women newly diagnosed with breast cancer used the unguided web-based, psychoeducational distress self-management program CaringGuidance After Breast Cancer Diagnosis while enrolled in a pilot feasibility study.

Methods: Women with stage 0 to II breast cancer diagnosed within the prior three months were recruited from clinics primarily in the Northeastern United States for participation in a 12-week pilot study of CaringGuidance plus usual care versus usual care alone. Usage prompts included sets of emails sent weekly for 12 weeks; standardized congratulatory emails after every two hours of program use, and informative emails for each cognitive-behavioral exercise. Individual user activity on the site was automatically tracked by an analytics system and recorded directly in the CaringGuidance database.

Results: Complete usage data were available for 54 subjects. Ninety-eight percent of the intervention group logged into CaringGuidance independently at least once. Thirty-eight (70%) logged in during all three months, 15 (28%) were intermittent users, and one (2%) was a non-user. Users (n=53) averaged 15.6 (SD 9.85) logins. Mean logins were greatest in month 1 (7.26, SD 4.02) and declined in months 2 (4.32, SD 3.66) and month 3 (4.02, SD 3.82). Eleven (21%) used CaringGuidance with both the frequency and activity level intended at study outset, 9 (17%) exceeded intended frequency and activity (high-high users), and 10 (19%) were below expected usage on both login frequency and activity (low-low users). Low-low users and high-high users differed significantly ($P<.001$) in the total number of views and unique views of all program components. Change in depressive symptoms and the number of sessions ($r=.351$) and logins ($r=.348$) between study months 1 and 2 were significantly correlated ($P=.018$, $.019$). Higher baseline distress was associated with more unique views of program resources ($r=.281$, $P=.043$). Change in intrusive/avoidant thoughts from baseline to month 3, and the number of users' unique exercise views were negatively correlated ($r=-.319$, $P=.035$) so that more unique exercise views, equated with greater decline in intrusive/avoidant thoughts from baseline to month 3.

Conclusions: These findings favor the hypothesis that the key ingredient is not the amount of program use, but each user's self-selected activity within the program. More research is needed on the ideal ways to maintain use, and capture and define engagement and enactment of behaviors by people with cancer accessing unguided, self-management web-based programs.

Introduction

Background

Interest in unguided, web-based psychoeducational and behavioral interventions is growing due to ease of delivery and need for few clinical resources. The outcomes of such interventions, however, rely on patients accessing and using these programs independently [1]. Identifying how populations of patients use web-based programs and the best way to support individuals in meaningful program use and engagement is an emerging science [2]. Perceived program quality and usability [3] and supporting potential users' intent to and persistence in program use, are crucial to reducing use-attrition and increasing the likelihood that patients receive health benefits [4]. Duration of use may also be insufficient to describe the dose of web-based intervention necessary to achieve the intended benefit due to the inability to monitor off-line processing of program content, difficulty capturing the depth of online engagement [5,6], and not all users need to use the full program to attain their personal goals [7,8].

Moment-to-moment use of a website is one part of program users' engagement and has been coined, "microlevel engagement" [6]. Together with measures of the depth of user interaction with the program, which results in the enactment of behavior change (ie, macrolevel engagement), micro- and macro-level engagement result in "effective engagement" [6]. At least some amount of program use, measurable through the program's analytic system, must occur for there to be engagement and intervention effect. Analyses presented are focused upon the moment-to-moment use of a new unguided, web-based program for women with breast cancer.

Published reports on completely unguided, web-based psychosocial distress self-management interventions for adults with cancer are limited [9-13]. To the best of our knowledge, CaringGuidance After Breast Cancer Diagnosis [13-16] is one of only two such interventions specifically designed to address the psychosocial needs of women with breast cancer. The primary differences between CaringGuidance and the other program (BREATHE) [11] are that CaringGuidance is presented in English; was developed with input from, and includes vignettes of, Black as well as White American breast cancer survivors [16]; and is intended for initial use by women as soon as possible after diagnosis as opposed to after treatment has ended. While it is best to initiate cancer-related distress reduction to alleviate anxiety and depressive symptoms early after diagnosis [17], the initial post-diagnosis period is also busy with pre-treatment examinations, physician appointments, surgery, and chemotherapy. Therefore, it was expected that program use statistics for CaringGuidance might differ from

unguided programs in which users access the program when treatment has been ongoing or is complete.

Objective

The objective of this analysis was to evaluate how women newly diagnosed with breast cancer used the unguided web-based, psychoeducational distress self-management program CaringGuidance while enrolled in its first pilot study [13-15]. The overall goal is to further inform the science of unguided web-based interventions by describing the (1) frequency, duration, and activity of CaringGuidance use by women newly diagnosed with breast cancer in total and by the month of study participation; (2) baseline characteristics of women who demonstrated high, moderate, low, and no program use; and (3) to evaluate high, moderate, and low program users' study completion, program satisfaction, enactment of distress management skills, and distress outcomes.

Methods

Participants

Women with stage 0 to II breast cancer diagnosed within the prior three months were recruited from clinics primarily in the Northeastern United States for participation in a 12-week pilot feasibility study of CaringGuidance plus usual care versus usual care alone. Enrollment was limited to stage 0-II breast cancer to reduce variation in the treatment experience among subjects. Details of recruitment and eligibility for this study of 100 women have been previously reported [13,14]. Institutional Review Board approval was received, and written consent obtained from all participants before study assessments. This feasibility pilot study, not involving drugs or devices, was not deemed eligible in 2013 for clinical trial registration by the university research administration.

Intervention

Baseline demographic and psychosocial measures of distress (ie, Distress Thermometer, Center for Epidemiologic Studies Depression Scale, and Impact of Events Scale), as well as Social Constraints Scale on spouse/partner and family/friends, were completed following written consent. These measures were repeated at months 1-3. Participants randomized to the CaringGuidance user condition received individual usernames and passwords. Usernames and passwords cannot be changed by users, thus permitting tracking use by assigned usernames.

CaringGuidance After Breast Cancer Diagnosis (version 1) is an unguided, web-based, psychoeducational program based on theories of stress and coping [18], and adjustment to illness through cognitive processing of life-threatening events [19-22]. The program's topical outline was guided by findings of the

PI's grounded theory describing women's thought processes following diagnosis [23,24]. Interventional components of CaringGuidance are based on cognitive-behavioral, problem-solving, and supportive oncology techniques, which have demonstrated efficacy in both in-person and web-based delivery for the breast cancer population [25,26]. From 2011-2013, the program was developed in an iterative process of review and revision by a team of oncology professionals, including psychologists, breast cancer survivors, web developers/programmers, and software engineers [16].

CaringGuidance program components include 5 learning modules divided into 17 topical sections (Textbox 1). Resources include 90 video vignettes filmed with 6 breast cancer survivors (ages 30-70, stage 0-III breast cancer, equal representation of Black and White American women) and 20 self-management "cognitive-behavioral homework" exercises (eg, visualization, cognitive reframing). There are also 13 resource modules consisting of a glossary, links to the program exercises, a library of full-length videos from which the vignettes were derived, breast cancer risk factors, signs of depression and anxiety, links to cancer resources, and myths and facts about breast cancer. The five modules are listed in tabs at the top of each page. Pages include a list of topical sections within each module to provide quick access (Multimedia Appendix 1). Users can orient and navigate using breadcrumb navigation at the top of each page and the titles of the next and previous sections appearing at the bottom of each page. Additional descriptions of CaringGuidance may be found elsewhere [14,15].

At login, first-time users are directed by the program through three introductory pages, including a welcome video from the program creator/PI, instructions for use, and a 12-statement tailoring exercise that guides users to program modules based on their self-selected greatest concern. The purpose of tailoring in this program is to help match the content to each user's needs with the expectation that this will increase content relevance [27] and contribute to users achieving their health goals [28]. Upon subsequent logins, users are directed to a personalized homepage but may access the introduction and tailoring exercise at any time. The 140 program components may be accessed by users at will in a flexible manner to direct their distress self-management. There is no required order in which to use

the components nor requirements for completion before moving on to a different component.

Study participants were instructed that the suggested usage frequency and duration were 20-30 minutes for 2 to 3 times per week (range 40-90 minutes/week) for 12 weeks (480-1080 total minutes, 8-18 hours), but that they were permitted to access the program as much or as little as desired to create their own experience. The frequency/duration suggested was based on the traditional 12-week program of 1-hour counseling sessions. It was not expected that all users would access all components as everything within the program was not relevant to every user. Participants were informed during the consent process that program use would be tracked by the program's analytic system in a manner invisible to them.

At enrollment, research staff showed participants the login page and the first page containing the welcome video but did not go further into the program. When enrollment was completed by email, an explanation of the first three program pages was provided in the email containing the user's login information. All participants received a hard copy pictorial guide on basic website use (eg, how to enlarge the font and adjust the volume).

During the study, usage prompts included standard emails sent weekly for 12 weeks supporting continued use or encouraging use; standard congratulatory emails after every two hours of program use, and pre-written informative emails for each cognitive-behavioral exercise sent following two or more minutes of a user accessing that component (these emails also directed users to relevant program components for self-reflection). All emails were automated or sent by staff using a CaringGuidance Gmail account to simulate an automated message, thus avoiding personal interaction. To assess safety and review of the daily symptom/support log maintained by all participants, one research assistant phoned monthly for a scripted conversation. These calls averaged 18.8 minutes (SD 7.73) in month 1, down to a mean 13.5 minutes (SD 4.64) in month 3. The script directed the research assistant to suggest portions of the program not yet accessed during the call. Calls were recorded and 10% reviewed by the principal investigator to assure script adherence. Emails and calls placed by participants to the research office for technical support (n=6) were tracked [14].

Textbox 1. CaringGuidance modules and topical sections

- Are my reactions normal?
 - Fears and anger
 - Exploring other emotions
 - Why might I think about cancer differently than other women?
- What does this diagnosis mean?
 - Why me? or Why not me?
 - Questions and misconceptions
- Who am I now?
 - Self-concept
 - Accepting support
 - Is a support group right for me?
 - The meaning of survivor
 - Body image and sexuality
 - How will people act toward me now?
- What are strategies to care for myself?
 - Coping with cancer
 - Talking with people around you
 - Personal control strategies
- Moving forward
 - Personal growth from this experience
 - How much will cancer be a part of my life?
 - Setting healthy goals

Usage Data Storage and Retrieval

The CaringGuidance web analytics system was developed by our team to collect user activity information that would facilitate the analysis of various usage modalities. The activity of

individual users on the site was automatically tracked by the system and recorded directly in the CaringGuidance database. Each time a user visited an individual page on the site (referred to as a “page visit”), the analytics system collected the information specified in [Textbox 2](#).

Textbox 2. Information collected by the analytics system.

- The name and internal identifier of the user,
- Whether or not the activity is a login event (eg, the user logged into the site using their username and password),
- A session identifier that facilitates the tracking of a user’s activity during a particular visit,
- Whether or not the user viewed a resource, article, exercise, or video and which of these items were viewed
- A timestamp with second resolution

Usage Definitions and Measures

Page visits and login information stored in the database were used to construct a set of sessions that provided details as to how each user utilized the site during that time. We defined a session as a set of consecutive page visits, starting with a login event and ending with a logout or a period of inactivity. The amount of time that a user spent on any given page visit was calculated using the difference between the timestamps of the

current page visit and the next page visit within the session. Because users may simply close their web browser, turn off their computer, or leave their computer for some time in addition to clicking the “logout” button, we did not have a reliable method for calculating the time spent on the final page visit in a session ([Figure 1](#)). To overcome this limitation, we used a configurable period of inactivity to infer a logout event and expired the session—currently set to 30 minutes. In the case where a user’s session expired, and they later returned to the

site, this activity was treated as a new login event and initiated a new session for that user (Figure 2). The activity/inactivity rules provided a lower bound for the time that a user visited CaringGuidance during any given session.

Figure 1. User session comprised of 4-page visits where clocks represent page view timestamps. The user visited for at least 20 minutes; however total time is underestimated as it is not known how long the user spent on the site during page visit 4.

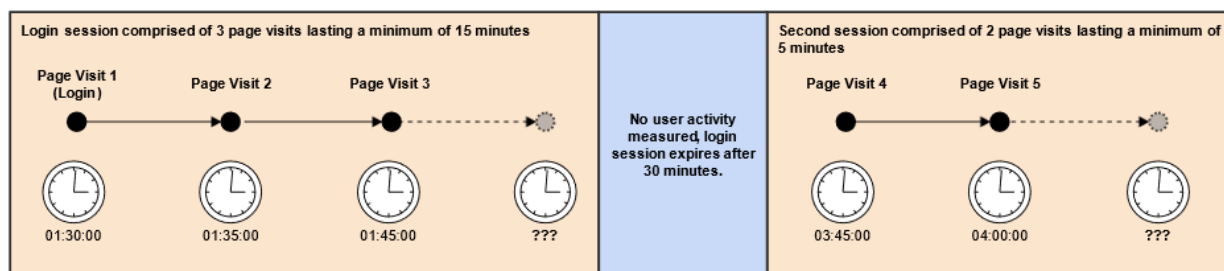

Figure 2. User session wherein a period of inactivity triggers use to be treated as two individual sessions.

Usage

In this current micro-level engagement analysis, usage was defined as frequency, duration, and user program activity. This definition is consistent with definitions of usage applied in prior research [29]. The *frequency* was defined as the number of logins to CaringGuidance per participant per study month over the 3-month study enrollment. Frequency also was characterized by the number of sessions in which users engaged per month and over the study enrollment period, since more than one session may have been engaged in during a single login (Figure 2). The *duration* was defined as the total number of minutes logged in each month and over the 3-month study period. The *activity* was defined as the number of total page views and the number of unique page views per participant per month and overall for each of the CaringGuidance program components (ie, module, exercise, videos, and resource pages). Finally, activity was examined for which components appeared to be preferred based on use and repeated access.

Users and Non-Users

It was expected that participants would access CaringGuidance with varying frequency and duration for multiple reasons, including the recency of their cancer diagnosis, levels of distress, and ongoing treatment. *Non-users* were defined as study participants who received a username and password but who registered ≤ 1 log-ins/sessions and for whom zero minutes were recorded. Consistent with definitions described by van den Berg

et al [29], *continuous users* were defined as registering at least one login/session per month for each of the 3 study months. *Intermittent users* were defined as those who logged in initially and registered at least one login/session in study month 1 but then registered <1 session in study month 2 or 3, or both study months 2 and 3.

Macrolevel Engagement

For this pilot study, macro-level engagement [6] was measured with three questions rated from 1 (strongly disagree) to 5 (strongly agree) on the self-report satisfaction survey at the conclusion of month 3 [14]. These questions were, “I used things I learned from CaringGuidance to change (a) my thoughts about breast cancer; (b) how I talked or acted around people; and (c) my self-care behaviors.

Participant Usage Groups

In order to characterize CaringGuidance usage concerning baseline and monthly psychological outcomes, user patterns were divided into three usage groups designated as low, moderate, and high. In so doing, we were inspired by definitions used by van den Berg et al [29]. For our usage analysis, *low frequency* was defined as 1-12 logins total throughout the 12 weeks; in other words, 50% or less of the minimum number of logins suggested to participants (ie, 24 logins) at enrollment. *Moderate frequency* was defined as 13-24 logins throughout the study, and *high frequency* was defined as ≥ 25 logins over the 12 weeks. Activity was likewise defined as *low activity*

equal to opening 0-25% of the program's 140 components (ie, unique views), *moderate activity* equal to opening 26-50%, and *high activity* equal to opening 51-100% of the program components. High activity was defined as viewing >50% of the components because not all components applied to all study participants. Logins and activity were cross-tabulated to characterize use as *low-low*, *moderate-moderate*, or *high-high*.

Total duration logged into the program was not used in the usage group calculation because of varying speeds of Internet connections, differing participants' reading speed, differing times needed to use various program components, and the analytics systems' inability to measure the duration of the last session, thus underestimating total time on the program.

Results

Demographics

Study participants were women diagnosed with stage 0 to II breast cancer within the prior three months at baseline. Ability to read English and access a computer with Internet service and

email were required since the program at that time was not mobile accessible. Fifty-seven participants were randomized to the CaringGuidance condition; however, one participant did not receive a password until week 5, and two participants withdrew after randomization due to feeling too busy to participate. Thus, CaringGuidance analytic data were available for 54 participants.

These 54 participants ranged in age from 36 to 78 years (mean 55.02, SD 9.4). They reported prior experience using the Internet, with a median of 1-hour Internet use (range 10 to 600 minutes) per day at baseline. Of these 54 participants, the majority were White (n=50, 93%) and married/partnered (n=32, 59.3%), while 22 (40.7%) were single/divorced/widowed. Forty-nine of the 54 (91%) had attended at least some college. Most were employed full-time (n=33, 61.1%) while 10 (18.5%) reported part-time employment at baseline, and of those reporting income (n=47), 53.2% had a household annual income of \$75,000 or above. See [Textbox 3](#) for clinical characteristics. Full demographic data on the 100 participants enrolled in the pilot study have been previously reported [13].

Textbox 3. Clinical characteristics and treatment during the study (N=54).

- Cancer stage at baseline
 - 0 (n=13)
 - I (n=24)
 - II (n=16)
 - "early" (n=1)
- Time since diagnosis at baseline
 - <4 weeks (n=20)
 - 1-2 months (n=28)
 - 2-3 months (n=6)
- Breast surgery procedure during the study (n=29)
- Chemotherapy received during the study (n=33)
- Radiation therapy received during the study (n=43)

Attrition

Eight participants assigned to the CaringGuidance condition withdrew or were lost to follow up, meaning that they did not complete all study psychosocial measures [14]. These include the 3 participants noted above who did not receive their login information or withdrew after randomization. The other 5 participants continued to use CaringGuidance despite not completing all psychosocial measures. Four of these were intermittent users (ie, logged in only in month 1) while one was a continuous user (ie, logged in in all three study months). These five participants did not differ demographically at baseline from others assigned to the CaringGuidance condition.

Of the 54 CaringGuidance participants for whom usage data are available, 38 (70%) were continuous users, 15 (28%) were intermittent users, and one (2%) was a non-user. The non-user was age 62, Black, unemployed and widowed, with Stage 0

breast cancer. She completed the psychosocial surveys and monthly calls with the research assistant, during which she indicated her intention to use a library computer to access CaringGuidance, but transportation barriers prevented her from doing so. The "non-user" was eliminated from this analysis and findings for the 53 "users" (continuous or intermittent) with mean age 54.9 years (SD 9.4), and 94% White are reported here.

Frequency

Users (n=53) logged in an average of 15.6 (SD 9.85) times during their 12-week access period. The mean number of logins was highest in month 1 (mean 7.26; SD 4.02) and declined after that such that the mean logins in month 2 were 4.32 (SD 3.66) and 4.02 (SD 3.82) in month 3. Overall, login attrition was significant across all three study months ($F_{2,104}=28.9$, $P<.001$) with the sharpest decline in logins occurring between study months 1 and 2 ($F_{1,52}=38.8$, $P<.001$) ([Figure 3](#)).

Users averaged 16.94 sessions (SD 10.42) over 12 weeks. Session attrition mimicked login attrition, as would be expected, with the most considerable decline in sessions between months 1 (mean 7.85, SD 4.34) and 2 (mean 4.83, SD 4.28; $F_{1,52}=27.4$, $P<.001$) and remaining stable from month 2 to month 3 (mean 4.26, SD 3.84; $F_{1,52}=17.0$, $P=.217$).

With one exception, no significant correlations were identified between use frequency (number of logins or sessions) and change in psychological outcomes; the one exception being a significant positive correlation between change in depressive-symptoms and the number of sessions ($r=.351$) and logins ($r=.348$) between study months 1 and 2 ($P=.018$ and $.019$ respectively), but not between any other study months.

Figure 3. Change in login frequency and duration of program use over 3 months.

Duration

Time spent on CaringGuidance by users during their 12 weeks of access ranged from 9.27 to 1265.3 minutes (21.1 hours; mean 4.98 hours, SD 3.61). The mean duration of use declined significantly over the 3 study months from 169.38 minutes (SD 120.08) in month 1 to 49.06 minutes (SD 45.06) in month 3 ($F_{2,104}=40.2$, $P<.001$). The decline in duration of use was also significant when examined by month; from month 1 to month 2 ($F_{1,52}=33.7$, $P<.001$) and month 2 to month 3 ($F_{1,52}=7.9$, $P=.007$).

The total duration of CaringGuidance use was found to have a significant positive relationship ($r=.291$, $P=.036$) with users' baseline intrusive/avoidant thinking such that users with more initial intrusive/avoidant thinking used CaringGuidance for more total minutes over the 3 study months [14,15]. This was also true for baseline spouse/partner derived social constraints and the total duration of CaringGuidance use ($r=.370$, $P=.031$) and minutes of use in study month 2 ($r=.422$, $P=.013$) and month 3 ($r=.345$, $P=.045$) [15]. No additional statistically significant correlations were found between duration and baseline or month 3 psychological outcomes.

Activity

Modules

The 17 written learning component pages (modules) were accessed 1 to 103 times per user (mean 41.11, SD 26.57). All 53 users accessed at least one module. There were between 1 and 17 unique module page views per user (mean 12.06, SD 4.65), meaning that all module pages were accessed at least once. Eleven users (21%) accessed all 17 module pages. The five most viewed modules were: "Fears and Anger" (211 views), "Why me? Why not me?" (218 views), "Self-concept" (242 views), "Personal growth from this experience" (243 views),

and "Coping with cancer" (290 views). Least accessed modules were: "Is a support group right for me?" (51 views), and "How will people act toward me now?" (59 views).

Exercises

Each of the 20 cognitive-behavioral exercises was accessed from 33 to 199 times [14]. Fifty-two of the 53 users (98%) viewed exercises yielding between 0 and 162 exercise views per user (mean 38.91, SD 34.69). Of these, there were between 0 and 20 unique exercise views (mean 12.06, SD 5.61), meaning that some users viewed the same exercises multiple times. Repeat viewing was encouraged by several exercises that directed users to review prior exercises as a means to self-monitor changes in thinking over time. Six of 53 users (11%) viewed all 20 exercises.

Videos

Fifty users (94%) accessed videos resulting in between 0 and 119 video views per user (mean 29.7, SD 28.29). Unique video views ranged from 0-80 (mean 23.91, SD 21.17). Eighty-nine of the 90 videos (99%) were viewed. The 10 most viewed videos were viewed between 29 to 42 times and featured four of the six survivors (two Black and two White American survivors). An overall theme of these most viewed videos was self-concept as a newly diagnosed survivor.

Resources

Each of the 13 resource components was accessed from 30 to 252 times by program users. Fifty-one of 53 users (96%) accessed at least one resource page. Three users (6%) accessed all resource pages. Resource pages were accessed between 0 and 67 times per user (mean 20.91, SD 14.93). On average, 7.62 (SD 3.62) of the resource page views were unique, indicating that some users returned to the same resource pages multiple times to review the content. The five most accessed pages were:

breast cancer risk factors (96 times), cancer information resources (98 times), common questions about breast cancer (99 times), mindfulness-based stress reduction (109 times) and all program exercises list (252 times). Least accessed were questions to ask your doctor (30 times) and first appointments—talking with your doctors (40 times).

Figure 4. Program component views over 3 study months.

Psychosocial Associations

Baseline overall distress correlated positively with activity such that higher baseline distress was associated with more unique views of program resources by users ($r=.281$, $P=.043$). Additionally, at study month 3, the number of unique module views was negatively associated with spouse/partner derived social constraints ($r=-.418$, $P=.021$). In other words, more unique modules were viewed by subjects when perceived social constraints were lower.

When the *change* in overall distress, depressive-symptoms, and intrusive/avoidant thinking was examined, no correlations were found with user activity, with one exception. A significant negative correlation ($r=-.319$, $P=.035$) was identified between the change in intrusive/avoidant thoughts from baseline to month 3 and the number of users' unique exercise views. In other words, the higher number of unique exercise views, the more significant the decline in intrusive/avoidant thoughts from baseline to month 3.

Use Groups

Eleven of 53 (21%) users were defined as moderate program users. In other words, they used CaringGuidance in the range that approached the intended usage told to them at study entry for *both* frequency and activity (*mod-mod*). Nine users (17%) exceeded intended usage for *both* login frequency and activity (*high-high*), while 10 users (19%) were below expected usage on *both* login frequency and activity (*low-low*). In total, 39

Overall, the most significant program activity occurred in month 1 for all components and significantly decreased between months 1 and 2 ($P<.001$). Views of program modules and videos continued to decrease between study months 2 and 3 ($P=.004$ and $.003$) (Figure 4).

(74%) users were in the moderate to high activity range during the period they were logged in the program, and 30 (57%) logged-in with moderate to high frequency. Overall frequency and activity were highly associated ($r=.565$, $P<.001$). Low-low users and high-high users differed significantly ($P<.001$) on the total number of views and unique views of all program components.

Low Frequency/Low Activity (Low-Low)

Three of the 10 low-low users were also part of the group who did not complete any of the study's monthly mailed psychological assessments, and one of these subjects formally withdrew due to feeling too busy to participate. The low-low use group's number of logins ranged from 2 to 10 (mean 5.2, SD 3.26). This group consisted of the one subject of all 53 users who viewed no exercises, the two subjects who viewed no resources, and the three subjects who viewed no videos. Low/low user activity involved 0 to 13 unique exercise views per subject (mean 5.3, SD 3.62) of the possible 20, 1 to 14 unique module views per subject of a possible 17 (mean 5.9, SD 3.87), 0 to 10 unique views of resource pages per subject of a possible 13 (mean 3.7, SD 3.62), and 0-18 unique video views per subject of a possible 90 (mean 4.0, SD 5.44). Low-low users returned to view individual study components, on average, 3.8 (resources) to 6.6 (modules) times, exclusive of videos. No videos were viewed a second time by these users (Figure 5). Despite being low on frequency and activity, 30% of subjects in the low-low group were "continuous" users, logging-in 8 to 10 times each over the 12-week study.

Figure 5. Repeat views by user group. An asterisk indicates significant differences between adjacent groups (left to right): Resources $P=.002$; Exercises $P<.001$ and $.012$; Modules $P<.001$; Videos $P=.001$ and $.016$.

High Frequency/High Activity (High-High)

In contrast to the low-low user group, the 9 high-high users returned all monthly psychosocial assessments and completed the study. All 9 were “continuous” users logging-in from 25 to 30 times (range) throughout the study (mean 27.3, SD 2.0). Their activity involved 15 to 20 unique exercise views per subject of a possible 20 (mean 18.56, SD 1.67; 33% accessed all 20 exercises), 10 to 17 unique module views per subject of a possible 17 (mean 15.56, SD 2.35; 56% accessed all of the modules), 8 to 13 unique views of resource pages out of a possible 13 (mean 10.56, SD 1.74; 1 subject accessed all resource pages), and 34 to 74 unique video views per subject of a possible 90 unique video views (mean 51.0, SD 14.76). High-high users returned to view program components an average of 17.7 (videos) to 64.1 (exercises) times. The most return views were to exercises and modules (mean 54.8 views). This behavior resulted in significant differences in repeat viewing behavior between usage groups (Figure 5).

Demographic Characteristics of User Groups

There were no significant differences identified in the demographic characteristics (age, race, education, employment status, income, breast cancer stage, pre/post-op status, and self-rated knowledge about breast cancer at baseline) of low, moderate, and high login frequency users nor users with varying amounts of activity. Additionally, no significant difference was found between pre-study self-reported daily Internet minutes across low, moderate, or high CaringGuidance login frequency or activity. This remained true when low-low and high-high groups’ demographic characteristics were compared.

Psychosocial Outcomes by User Group

Study outcomes on psychological distress indicated that access to CaringGuidance versus not was favorable for the intervention group as evidenced by significant differences in the reduction of distress and depressive symptoms between study months 2 and 3 [13]. When low, moderate, and high number of logins and low, moderate and high activity groups were examined individually, or combined low-low, mod-mod, or high-high, no significant differences in change for overall distress, depressive-symptoms, intrusive/avoidant thinking, or reports of social constraints from family/friends or spouse/partners were found from baseline to month 3 or between study months. In

other words, no usage group was superior to another regarding the change in distress over the study period as represented by these variables.

User Satisfaction Survey Completion

The CaringGuidance user satisfaction survey was completed by 60% ($n=6$) of the low-low users and 100% of high-high users. Low-low and high-high users did not differ significantly in CaringGuidance satisfaction except that the high-high users perceived that using CaringGuidance increased their knowledge about their breast cancer (mean 4.56, SD 0.73) versus mean 3.50 (SD 0.84) of possible 5 points among low-low users, ($P=.049$). Forty-nine percent of survey respondents reported that CaringGuidance use changed their thoughts about breast cancer, 44% indicated that program content led them to change self-care behavior, and 40% reported that what they learned from CaringGuidance changed how they talked or behaved with people [14].

Discussion

Principal Findings

This analysis explored the unguided use of a web-based psychoeducational distress self-management program by women recently diagnosed with breast cancer. We described the characteristics of users and non-users, the frequency and duration of use, users’ activity within the program, and outcomes associated with different use patterns.

Ninety-eight percent of the women who proceeded in the study logged into the CaringGuidance program independently at least once after randomization, a very positive result given reports of other studies in which rates of initial login were less than 50% [30]. Our data closely approximates that of similar unguided programs tested in a research environment where 90% of those assigned to the intervention logged in [29]. Those who volunteer for research are likely a motivated population and, of course, are aware that they have committed to study participation. On the other hand, the usage results from this study are notable because subjects not only voluntarily logged into a website on their own time, they did so after recently receiving likely the worst news of their lives—a cancer diagnosis, and while making hospital and clinics visits to undergo tests, surgery, chemotherapy and radiation treatments.

Of course, use attrition was significant after month 1, but this is also typical of web-based interventions [30-33]. We did not collect information on users' reasons for waning use, which could represent that some users achieved their goal for using the program sooner than others (e-attainers) [8]. Research continues to be needed to understand better how people recently diagnosed with cancer may be motivated to use and engage with unguided programs.

We also found that, consistent with prior research, total duration users spent on CaringGuidance did not correlate with psychological outcomes. Neither did the sheer number of logins nor the number of program components viewed correspond with distress as measured in this study. In other words, simply more use was not better. Researchers have argued that it is the depth of engagement with the program and the ability to glean what the user desires to support their needs that matters [5,6]. Evidence varies, however, among studies concerning the effect of higher amounts of intervention use on psychological outcomes, with some finding more logins and time spent reduces distress [34]. In contrast, other studies found the number of logins and duration not to affect depression or anxiety [35]. The variability in findings is likely related to the uniqueness of interventions' targeted populations, behaviors targeted by the intervention, and how program use is defined, supporting the need to evaluate micro and macro-engagement for specific interventions [6].

Based on our findings, we hypothesize that given at least a minimal amount of program use, it is the content that viewers access and whether that content engages and satisfies the user that holds the most significant import to psychological outcomes. While this hypothesis requires additional testing, support is provided by our finding that the higher number of unique exercise views made by users, the more significant their decline in intrusive/avoidant thoughts. This finding supports the mechanism of action of the cognitive-behavioral influenced program exercises, which are intended to assist users to reframe their thinking and process the cancer experience, in turn reducing intrusive/avoidant thoughts over time.

Additionally, our findings demonstrated that women who reported higher depressive symptom scores logged in with greater frequency over months 1 to 2; in turn, significant differences between months 2 and 3 in depressive symptoms favored the intervention over control [13]. Although it is acknowledged that correlation does not inform us whether depressive symptoms led to more frequent logins or visa-versa, it is logical to presume that if logging in increased women's feelings of depression, they would have stopped this voluntary activity.

Repeated views of program components favor the hypothesis that women found value in using CaringGuidance. If users found no value, they would not have returned dozens of times to multiple components, as we saw in this study. Similar conclusions have been drawn in prior studies [29]. Not only did we note repeated viewing of program components, but a greater propensity among high frequency/high activity users compared to other users to return to all components while showing repeat interest, particularly in program exercises and written content.

This finding is promising because these components convey the program's cognitive-behavioral ingredients, and thus, further development of these types of components is supported. Also promising is that the most accessed program modules focused on coping, personal growth from the cancer experience, and supporting survivors' self-concept. The most viewed videos also dealt with self-concept, indicating that CaringGuidance users independently focused on program components that were meaningful for distress reduction through confronting and re-evaluating how cancer reshaped their identity and world view which are vital to cognitively processing the cancer experience [19-24].

Finally, we were surprised to find that there was no relationship between high distress and greater use of program videos. At the time of design, it was anticipated that women with more considerable distress at baseline would gravitate toward the program videos as an activity that took less focused attention. At the same time, those further in their ability to cognitively process the diagnosis would attend to program exercises. Breast cancer survivors involved in program development expressed concern over overwhelming distressed women, which in turn inspired our addition of more videos, the glossary of terms, and "Questions for your doctor" resource components. The hypothesis seemed to be somewhat supported in that women distressed at baseline gravitated to the program resources component, however women with intrusive/avoidant thoughts and experiencing spouse/partner social constraints used the overall program with greater duration and women with depressive symptoms used the program with greater frequency.

Limitations

A limitation of this usage analysis was the potential underestimation of the total time users spent on the program because of the tracking system's inability to define the time users spent on their last page visit of a session. This underestimation may be balanced somewhat by the fact that all participants in this pilot study received scripted monthly calls from the research assistant about which the primary purpose was to assess for adverse study events but included questions about users' ability to login and find the information they sought in the program. Although it was not found that users viewed program components that were discussed during the calls, the contact may have prompted more program use than if users had only received the email prompts [36,37]. Other researchers have also found phone calls to be less effective than email prompts [38]. Data were not collected on whether email prompts were opened, although the sender (CaringGuidance program) likely acted as a weekly reminder. Additional limitations include the small, educated, and racially homogenous sample of women whom all had prior Internet experience and computer access, thus limiting generalizability. Lastly, although data were collected on user satisfaction and enactment of behaviors gleaned from the program, data were not systematically collected that would allow for analysis regarding reasons for use attrition.

Conclusions

In conclusion, distressed women recently diagnosed with breast cancer self-selected the CaringGuidance program components that satisfied their needs and used these components with

considerable variability in frequency, duration, and activity. These findings favor the hypothesis that the key ingredient is not the amount of use, but rather the self-selected activity of each user within the program. Given the ease of accessibility and low resource utilization associated with CaringGuidance as well as the safety, satisfaction, and preliminary efficacy findings [13-15], CaringGuidance offers a potential clinically implementable option for distress management in this population. Future work should focus on implementation such

as encouraging women's acceptance of mental health online support, helping users to find the components within the program that they desire, increase users' motivation to continue using to their maximum benefit and to explore the depth of engagement and cognitive processing in which users engage off-line. Overall, more information is needed on the ideal ways to capture and define engagement and enactment of behaviors by people with cancer accessing unguided, self-management web-based programs.

Abstract

Background: Web-based interventions for depression have been widely tested for usability and functioning. However, the few studies that have addressed the therapeutic quality of these interventions have mainly focused on general aspects without consideration of specific quality factors related to particular treatment components. Clinicians and scientists are calling for standardized assessment criteria for web-based interventions to enable effective and trustworthy patient care. Therefore, an extensive evaluation of web-based interventions at the level of individual treatment components based on therapeutic guidelines and manuals is needed.

Objective: The objective of this study was to evaluate the quality of unguided web-based interventions for depression at the level of individual treatment components based on their adherence to current gold-standard treatment guidelines and manuals.

Methods: A comprehensive online search of popular app stores and search engines in January 2018 revealed 11 desktop programs and 17 smartphone apps that met the inclusion criteria. Programs and apps were included if they were available for German users, interactive, unguided, and targeted toward depression. All programs and apps were tested by three independent researchers following a standardized procedure with a predefined symptom trajectory. During the testing, all web-based interventions were rated with a standardized list of criteria based on treatment guidelines and manuals for depression.

Results: Overall interrater reliability for all raters was substantial with an intraclass correlation coefficient of 0.73 and Gwet AC1 value of 0.80. The main features of web-based interventions included mood tracking (24/28, 86%), psychoeducation (21/28, 75%), cognitive restructuring (21/28, 75%), crisis management (20/28, 71%), behavioral activation (19/29, 68%), and relaxation training (18/28, 64%). Overall, therapeutic meaningfulness was rated higher for desktop programs (mean 4.13, SD 1.17) than for smartphone apps (mean 2.92, SD 1.46).

Conclusions: Although many exercises from manuals are included in web-based interventions, the necessary therapeutic depth of the interventions is often not reached, and risk management is frequently lacking. There is a need for further research targeting general principles for the development and evaluation of therapeutically sound web-based interventions for depression.

Introduction

Background

Major depression is the leading cause of disability and affects more than 300 million people worldwide [1], with a lifetime prevalence up to 20.6% for different populations [2-4]. Even minor forms of depression are associated with reduced quality of life [5], increased mortality [6], and functional impairments [7]. Additionally, the economic consequences of depression are extensive, and the treatment costs are increasing [8]. Although psychotherapy is an established, evidence-based treatment for depression [9-12], many individuals in need of mental health services do not receive adequate treatment [13,14]. Access barriers to treatment that are often associated with mental illness include limited availability of psychotherapists, long waiting lists, high costs of treatment, and fear of stigmatization [15-19]. Web-based interventions are considered a promising model to address this treatment gap [13,14]. They provide immediate support at any time and place, are cost-effective, and can easily be administered to a vast majority of people, thus reducing barriers and enabling high accessibility to treatment [20-22].

The number of concepts for web-based interventions has been gradually increasing, including telemedicine, electronic health apps, smartphone health apps, or mobile health apps. Furthermore, web-based interventions can be classified according to various criteria, ranging from smartphone apps for mere self-management to guided programs that include the support of a therapist through either asynchronous communication (such as email) or synchronous communication (such as videoconferencing). In many cases, a clear and distinctive assignment of a web-based intervention to a single type is not possible [23]. In this study, we followed the definition of a web-based intervention as an intervention program that is (1) available via the internet, (2) provides interactive components, (3) comprises health-related material, (4) aims to create positive change, and (5) aims to improve knowledge and understanding of a disease [24]. Following this definition, we included interventions that provide initial access via the internet, whereas it was not mandatory for the intervention to remain connected to the internet throughout its course. Additionally, we distinguished between smartphone apps and desktop programs because of their differences in technological features (eg, use of push notifications in smartphones and better readability of text on desktop screens).

The increase of innovative technologies in the field of web-based interventions shows great promise for potential in improving quality of life for people suffering from depression. Web-based treatment for depression has proven to be effective in reducing symptoms [25-29], reducing stigma [30-32], and improving depression literacy [31,32]. Furthermore, web-based interventions can deliver therapy to users independent of location with 24-hour accessibility [33].

Consumers searching for mental health apps most likely use social media, online search engines, or web forums [34]. A recent study identified more than 380,000 health apps worldwide, 28% of which are targeted toward mental health and behavioral disorders [35]. For users in the United States,

more than 500 apps for depression are currently available [36]. Nevertheless, only a small proportion of the web-based interventions available for depression are supported by evidence-based studies [37], and research on web-based interventions has thus far focused mainly on validating single products [38]. Criticisms of web-based interventions include poor methodological quality of effectiveness studies such as by comparing interventions with wait-list control groups or by showing evidence only through analysis of short-term effects [23,39].

When web-based interventions lack evidence or disregard standards and guidelines for psychotherapeutic treatment, they may offer ineffective care or cause direct harm to users, such as by providing adverse advice or diverting users from accessing effective treatment [40-42]. Another problem that many web-based interventions face is a high attrition rate because many users drop out after a few days or weeks of using the intervention [43,44]. Reasons for low user engagement, especially with smartphone-based mental health apps, were recently summarized in a review by Torous et al [45]. Low usability, lack of user-centric design, concerns about privacy, lack of trust by users and by clinicians, and concerns about unhelpfulness in emergencies were the most relevant issues identified. Thus, "building trust through standards" [45] is considered to be the most important, yet challenging, goal for developers of high-quality web-based interventions.

Clinicians and scientists are calling for standardized assessment criteria for web-based interventions to enable effective and trustworthy patient care [23,46]. As a result, professional associations such as the Anxiety and Depression Association of America have started to develop their own criteria [47], but further research is necessary.

Previous Research on Quality Measures for Web-Based Interventions

There are several approaches adopted in previous research to develop appropriate assessment tools for ensuring the therapeutic quality of web-based interventions for depression.

Renton et al [48] provided a scoping review and evaluated web-based interventions for depression on a 28-point rating system, covering aspects such as usability, accessibility, and type of tools used (eg, worksheets and assessments). They found high variability among the web-based interventions, and that most of these interventions used cognitive behavioral therapy (CBT) as the therapeutic approach with mood assessments and homework sheets implemented as the primary interactive tools. These results are supported by another recent review showing that 85% of the web-based interventions for depression implemented CBT techniques [49].

One prominent and often used scale is the Mobile App Rating Scale (MARS) [50], a multidimensional measure that includes 19 items on 4 objective quality indicators for apps: engagement, functionality, esthetics, and information quality. Additionally, 4 items measure the subjective quality of an app [50]. MARS has been validated with well-being apps and the instrument showed high internal consistency (Cronbach $\alpha=.90$) [50]. The MARS has been used for a broad scope of apps, including

smoking cessation apps [51], fitness apps for cancer patients [52], and German depression apps [53].

However, Baumel et al [54] noted that current criteria-based rating scales such as MARS lack an assessment of therapeutic alliance principles. Therefore, the authors developed a detailed evaluation tool for mobile and web-based health interventions termed “Enlight,” which includes a quality assessment section with 6 constructs: usability, visual design, user engagement, content, therapeutic persuasiveness, and therapeutic alliance (ie, basic acceptance and support). The instrument was validated with mobile apps and web-based programs for behavioral change in the case of medical illness or mental health, and showed high internal consistency (Cronbach α = .83 to .90). Although Enlight recognizes the therapeutic content of web-based interventions, only 4 items are dedicated to this issue.

Previous studies have measured the therapeutic quality of web-based interventions only at a general level, reflecting the overall impression of raters, without specific analysis of particular treatment components (eg, behavioral activation, cognitive restructuring) or therapeutic approaches. Although the majority of web-based interventions implement CBT as the therapeutic approach [48,49], we found only one study that examined the realization of a specific component of CBT in web-based interventions in detail (ie, behavioral activation) [55]. The authors found that the utility of these interventions is questionable, because only a few adhere to the core principles of CBT.

Qu et al [56] systematically examined the functionalities of depression apps and found that 31% of the apps evaluated offer depression screening, 66% offer tracking functionalities (eg, mood tracking), and 83% offer some form of therapeutic intervention (eg, psychoeducation or thought diaries). However, the therapeutic quality of these interventions was not the focus of their study.

To our knowledge, no studies published to date have aimed at specifically evaluating the therapeutic quality of web-based interventions at the level of several individual treatment components. As clinicians and scientists are calling for standardized assessment criteria, and previous measures did not examine the individual treatment components of web-based interventions for depression at an in-depth level, in the present study, we evaluated the therapeutic quality of currently available web-based interventions for depression.

Study Aim

The aim of this study was to evaluate the quality of unguided web-based interventions for depression at the level of individual treatment components based on their adherence to gold-standard treatment guidelines and manuals. Our primary research question was: How extensively do web-based interventions for depression adhere to established treatment standards? This includes (1) which core treatment components of established guidelines were realized in the web-based intervention, (2) how close did the treatment components follow the recommendations of the guidelines regarding their delivery mode and instruction, and (3) how potential risks in the treatment process are managed. We did not aim to provide recommendations for or against

individual programs or apps. As a means to achieve the study aims, we examined current treatment guidelines and manuals for depression, and developed a questionnaire that comprises standardized testing criteria.

Methods

Search Strategy and Inclusion Criteria

In January 2018, three researchers independently searched for online treatment programs targeted at depression. Since we aimed at searching for web-based interventions from a patient perspective, the searches were carried out in three major app stores (Google Play, iTunes, Windows Store) and four broadly popular search engines (Google, Yahoo, Bing, Duckduckgo). Additionally, we investigated the Beacon website [57] (an Australian platform for health apps) and HealthOn [58] (a German platform for health apps) for web-based interventions meeting our inclusion criteria. We did not search published evidence in the scientific literature because it is not clear when a web-based intervention reported in the literature becomes available on the market. Further, we excluded web-based interventions that required participation in a study. We found that it is more likely for patients to participate in a noncommittal web-based intervention with easy access when they are looking for online treatment options, which is not the case in a clinical study. The search terms used were “depression” or the wildcard search term “depress*” either by itself or in combination with one or more of the following terms: “online,” “web-based,” “treatment,” and “program.”

Apps or desktop programs were included in our analysis based on the following criteria: (1) claimed to provide treatment or support for depression, (2) were accessible to the public via the internet (with or without fee), (3) had an interactive component (ie, were not purely educational) and required user participation or input (eg, homework, worksheets, mood assessments), (4) were available in English or German (because these were the fluently spoken languages by all raters), (5) provided a scientific basis for their treatment (eg, based on CBT), and (6) were targeted to adults (older than 18 years). We adapted inclusion criteria that can be found in previous scoping reviews on web-based interventions for depression in the scientific literature [48] to fit the purpose of this study (criteria 1-4), and added further criteria that we considered necessary to fulfill the particular objective of this study (criteria 5-6).

Apps or desktop programs were excluded from this study if they (1) only provided information regarding depression (ie, psychoeducation) and offered no further intervention, (2) did not claim to be based on a scientific background, (3) did not specifically target depression (ie, were targeted at other or multiple disorders), (4) were not accessible to the public (ie, programs for patients of a specific clinic), (5) targeted health care professionals for training purposes, (6) offered only mood tracking, (7) were only available for research purposes (ie, user must be enrolled in a study to access the program), (8) offered no treatment program, (9) could not be completed within the home or private setting (ie, must attend classes), (10) required the participant to get in touch with a counselor (ie, webcam

counseling, therapy sessions, chatroom counseling), and (11) refused participation in this study.

Programs were screened for relevance based on the title, description, and available further information given on the respective webpages (eg, frequently asked questions, videos, or screenshots).

In line with previous work that identified web-based intervention programs for depression [48], we ceased the search when no new programs could be identified within five consecutive pages of search results.

Testing Criteria

The original questionnaire used in this study was developed in German. A translated version of the complete questionnaire can be found in [Multimedia Appendix 1](#).

To obtain objective testing criteria, we examined current guidelines and manuals that are established in the treatment of depression, including the S3 and National Health Care guideline on unipolar depression [59,60], Beck's manual for CBT [61], and the "Coping with Depression" course [62].

The treatment guidelines were examined by three researchers who each extracted treatment components and developed a set of objectively ratable criteria that could possibly be implemented by a web-based intervention. Subsequently, the researchers compared their criteria and solved discrepancies by consensus. The criteria were then reviewed by medical experts of the psychosomatic and psychosocial field, who provided comments and compared the criteria to the guidelines once more. The researchers used this information to revise the criteria conclusively, and any discrepancies were solved by consensus.

Following this process, we chose CBT components as superordinate categories in our questionnaire because CBT was identified as the most frequent approach in web-based interventions for depression [48,49]. Based on the guidelines and manuals, we expected the following components to occur in web-based interventions that claim to be evidence-based: behavioral activation, cognitive restructuring, psychoeducation, mood tracking, journal keeping, relaxation training, social skills training, resource activation, and crisis management.

The questionnaire includes a general and a specific part for each component, except for resource activation and crisis management. The general part comprises the same items for each component and aims to address basic principles such as transparency, understandability, or therapeutic potential. Example items for the general part are: "The therapeutic background for the intervention is presented," "The instruction can easily be understood," and "Possible difficulties regarding the intervention are addressed."

The specific part comprises items unique to the therapeutic tools or the theoretical rationale of each component. For example, in case of cognitive restructuring, items for the specific part were: "The principle of automatic thoughts is explained clearly," "The program suggests alternative thoughts for negative thoughts," and "The program offers the option to create a daily record of negative thoughts."

The questionnaire closes with crisis management and resource activation. For crisis management, items concerning the instruction, therapeutic background, digital implementation, and therapeutic meaningfulness were included from the general part. Further items asked for emergency contacts, relapse prevention, contact to support groups, and behavior in case of suicidality. Resource activation comprises 4 items concerning the identification of resources and their reflection in the course of the intervention.

The developed criteria do not claim to be exhaustive. Rather, we tried to find as many objectively ratable aspects as possible that can characterize a good and CBT-conforming psychotherapy. The absence of a treatment component or a particular criterion does not necessarily imply poor quality of the intervention. However, the presence of many criteria can indicate high quality.

Testing Procedure

The three independent researchers who conducted the search also rated the included web-based interventions following a standardized testing procedure. Raters followed the recommendations for usage given by each web-based intervention regarding the time and duration of usage (eg, daily usage for several minutes or weekly completion of session). When programs consisted of sessions, the programs were tested until all sessions relevant to the identified treatment components were completed. When provided, we followed the suggested order and instructions of each web-based intervention (eg, completing 12 sessions over 12 weeks). When a web-based intervention was designed to be used at will and no clear point of completion of the treatment could be identified, it was tested in an intuitive manner (ie, interventions were completed in the order in which they appeared to the user) until each intervention was completed at least once.

When symptom questionnaires, mood tracking, or progress tracking were included in a web-based intervention, raters responded with a set of previously defined symptoms. At the beginning of the web-based intervention, raters responded with a moderate symptom severity and changed the occurrence and severity of symptoms during the course of the intervention. Symptoms were chosen following a moderate depression score according to Beck's depression inventory II [63]. When repeated assessments were included during the progression of a web-based intervention, each researcher submitted a deterioration of symptoms, characterized by increased severity of core symptoms and the addition of suicidal thoughts, to test how the web-based intervention responded to suicidal tendencies and how it provided risk management. At later stages, each rater submitted an improvement of symptoms, characterized by mild degrees of core symptoms and loss of additional symptoms, to test how the program responded to treatment progress.

All raters have a degree in psychology and backgrounds in psychotherapy (CBT, psychodynamic therapy, and systemic therapy). Web-based interventions were randomly allocated to the raters and each intervention was independently tested by two raters.

No ethical approval was required because no human participants outside the researchers took part in this study.

Statistical Analysis

Descriptive statistical analysis (including means, SDs, and frequencies) and intraclass correlation coefficient (ICC) estimates were calculated using SPSS statistical package version 24 (IBM Corp Released 2016, IBM SPSS Statistics for Windows, Armonk, NY, USA).

To assess the interrater reliability for all reported metric items, ICC estimates and their 95% CIs were calculated for each rater pair based on a one-way random-effects model with absolute agreement.

To assess the interrater reliability for all reported dichotomous items, Gwet AC1 statistic was calculated using formula 4.1 of Gwet [64] through the WINPEPI software developed by Abramson [65]. Gwet AC1 statistic is a chance-corrected measure of the extent of agreement between raters but has been

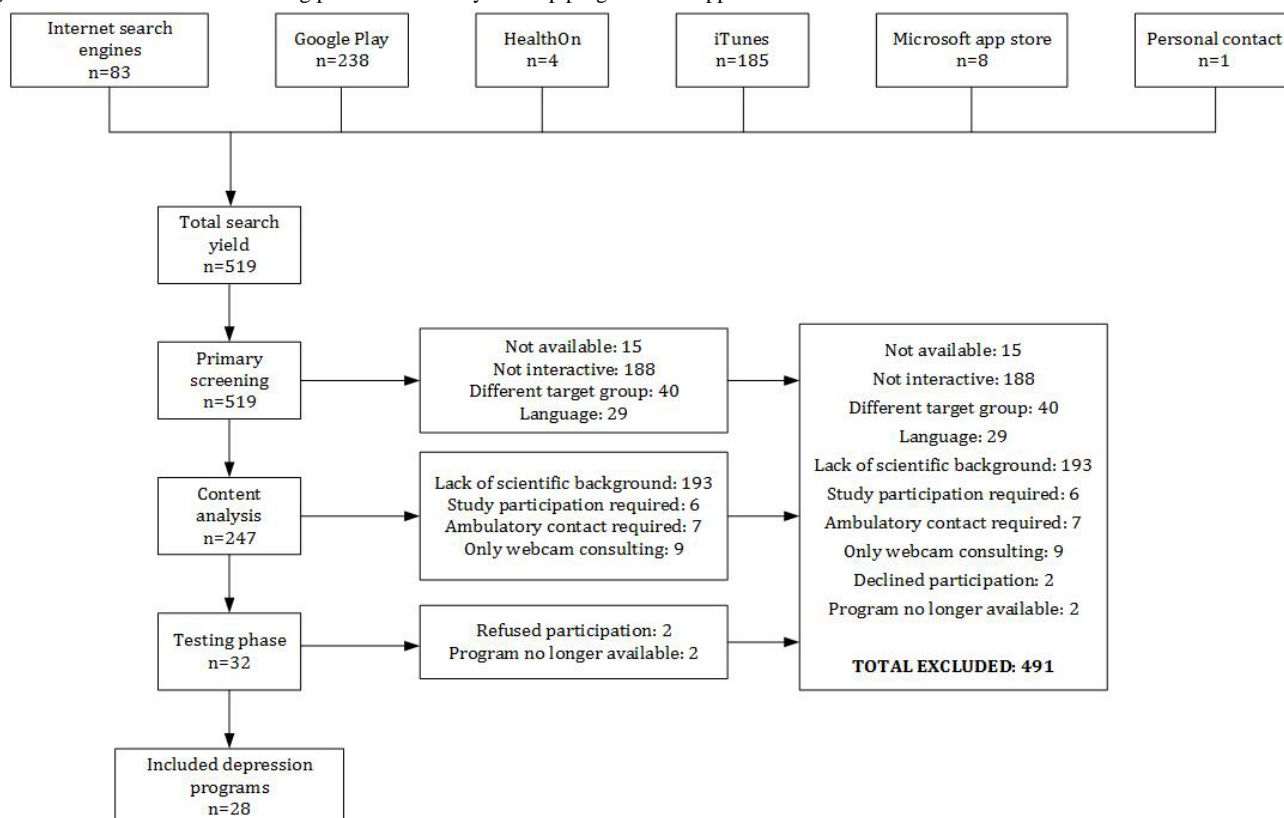

recommended for use because it is less influenced by differences in individual rater tendencies to give positive ratings and by differences in the prevalence of the response categories, thus making it more robust and less biased compared to other metrics [66-68].

Results

Search Results

The initial search yielded 519 web-based interventions. Thirty-two of these were identified to meet our inclusion criteria. Discrepancies regarding the identified programs were resolved by consensus. During our testing period, 2 programs withdrew their participation from the study and 2 programs were no longer publicly available, leaving 28 programs that were ultimately tested (see Figure 1 for a flowchart of the screening and inclusion process). The 28 programs included 11 desktop programs and 17 smartphone apps. A list of the tested web-based interventions can be found in Multimedia Appendix 2.

Figure 1. Flowchart of the screening process to identify desktop programs and apps.

Interrater Reliability

Mean ICC estimates and Gwet AC1 statistics for all reported metric items are shown in Table 1. The overall range for ICC estimates was 0.66 to 0.79. According to the guideline developed by Koo and Li [69], mean ICC estimates in this study were

indicative of moderate to good interrater reliability for all rating pairs. The overall range for the Gwet AC1 statistic was 0.75 to 0.84. Concordance for Gwet AC1 statistic is measured on the same scale as used for Landis and Koch's κ criteria [70,71]; therefore, interrater reliability for the dichotomous items in this study can be considered to be substantial.

Table 1. Intraclass correlation (ICC) estimates and Gwet AC1 statistics for all rating pairs.

Rating pair	ICC (95% CI)	Gwet AC1 (95% CI)
Rating pair 1 and 2	0.79 (0.72-0.87)	0.84 (0.79-0.89)
Rating pair 1 and 3	0.70 (0.58-0.83)	0.75 (0.68-0.83)
Rating pair 2 and 3	0.66 (0.51-0.81)	0.80 (0.74-0.87)
Overall	0.73 (0.67-0.79)	0.80 (0.76-0.84)

General Results

An overview of the identified treatment components for each web-based intervention can be found in [Multimedia Appendix 3](#). [Table 2](#) depicts the relative number of treatment components

for each web-based intervention. We did not include resource activation in this summary because no web-based intervention assigned a specific module to resource activation, but rather implemented resource activation in several treatment components.

Table 2. Absolute numbers and respective availability of treatment components for desktop programs (N=11) and apps (N=17).

Treatment component	Desktop programs, n (%)	Apps, n (%)
Behavioral activation	9 (82)	10 (59)
Cognitive restructuring	8 (73)	13 (76)
Psychoeducation	10 (91)	11 (65)
Mood tracking	11 (100)	13 (76)
Journal keeping	4 (36)	8 (47)
Relaxation training	8 (73)	10 (59)
Social skills training	6 (55)	2 (12)
Crisis management	9 (82)	11 (65)

Taken together, the presentation of the therapeutic background of interventions received higher ratings in desktop programs (mean 4.13, SD 1.17) than in apps (mean 2.92, SD 1.46) and moderate ratings overall (mean 3.47, SD 1.46). Regarding the understandability of instructions, desktop programs received higher ratings than apps, and high ratings were given desktop programs and apps overall (mean 4.18, SD 1.15). The digital implementation of interventions was rated as moderate for both

desktop programs and apps (mean 2.90, SD 1.17). Overall, interventions received moderate ratings for their therapeutic meaningfulness for desktop programs and apps (mean 3.54, SD 1.15). However, discrepancies regarding the therapeutic quality were identified between single interventions, with desktop programs receiving higher scores for behavioral activation, cognitive restructuring, and psychoeducation than apps, and similar scores for mood tracking and relaxation training (see [Table 3](#) and [Table 4](#) for detailed results).

Behavioral Activation

Interventions aimed at behavioral activation were included in 9 desktop programs and 10 apps. All behavioral activation interventions suggested activities, including activating activities and relaxing activities, whereas fewer interventions suggested social activities (16/19, 84%).

The suggested activities were rated to be easy to realize (mean 4.47, SD 0.89) and pleasant (mean 4.26, SD 0.89). Complex activities were rated as not divided into achievable intermediate steps (mean 1.74, SD 1.33). Difficulties that can occur in the realization of suggested activities were rated as not sufficiently addressed (mean 2.24, SD 1.52).

The relative share of web-based interventions realizing further features of behavioral activation can be found in [Table 5](#).

Table 5. Absolute numbers and relative share of web-based interventions addressing specific features of behavioral activation in desktop programs (N=9) and apps (N=10).

Features of behavioral activation	Desktop programs, n (%)	Apps, n (%)
Difficulty levels for activities	1 (11)	1 (10)
Push notifications	9 (100)	2 (20)
Add individual activities	9 (100)	9 (90)
Schedule activities	9 (100)	5 (50)
Reminders for activities	9 (100)	4 (40)
Check completed activities	1 (11)	1 (10)
Reference to past activities	2 (22)	3 (30)

Cognitive Restructuring

Cognitive restructuring was included in 8 desktop programs and 13 apps. The explanation of the principle of automatic thoughts was rated to be more clear in desktop programs (mean 4.44, SD 1.15) than in apps (mean 2.92, SD 1.57). Beck's cognitive triad was addressed in desktop programs (mean 3.00, SD 1.41), but less often in apps (mean 1.50, SD 1.14).

Desktop programs and apps presented typical negative thoughts (8/8, 100% and 10/13, 77%, respectively), suggested alternative thoughts (8/8, 100% and 8/13, 62%, respectively), and suggested that the user write down individual negative thoughts (8/8, 100%

and 13/13, 100%, respectively) as well as alternative thoughts (8/8, 100% and 10/13, 77%, respectively).

All cognitive restructuring interventions offered the option of keeping a daily thought protocol (21/21, 100%), which included the situation (19/21, 90%), feelings (17/21, 81%), negative thoughts (19/21, 90%), alternative positive thoughts (15/21, 71%), and the result of positive thoughts (16/21, 76%).

Cognitive distortions were addressed in both desktop programs and apps. An overview of the relative share of web-based interventions addressing cognitive distortions can be found in [Table 6](#).

Table 6. Absolute numbers and relative share of web-based interventions addressing cognitive distortions for desktop programs (N=8) and apps (N=13).

Type of cognitive distortion	Desktop programs, n (%)	Apps, n (%)
Should statements	7 (88)	10 (77)
Focus on the negative	7 (88)	10 (77)
Disqualifying the positive	7 (88)	8 (62)
Personalization	3 (38)	11 (85)
Labeling and mislabeling	6 (75)	9 (69)
Catastrophizing	7 (88)	9 (69)
Magnification and minimization	6 (75)	8 (62)
Emotional reasoning	6 (75)	10 (77)
Jumping to conclusions	7 (88)	11 (85)
Polarized thinking	7 (88)	10 (77)
Overgeneralization	8 (100)	10 (77)

Psychoeducation

Psychoeducation was implemented in 10 desktop programs and 11 apps, which included explanations of depressive symptoms in both desktop programs (mean 3.90, SD 1.29) and apps (mean 3.35, SD 1.53). An explanatory model for the development of depression was provided in desktop programs (mean 3.95, SD 1.40) and apps (mean 3.48, SD 1.59). Low ratings were found for whether the user received support in the development of an

individual explanatory model for desktop programs (mean 1.80, SD 1.24) and apps (mean 1.22, SD 0.52).

Both desktop programs and apps conveyed that depression is well treatable (mean 4.25, SD 1.12 and mean 3.30, SD 1.40, respectively) and that the user can overcome depression (mean 4.60, SD 0.75 and mean 3.30, SD 1.40, respectively).

Further evaluations regarding psychoeducation can be found in [Table 7](#).

Table 7. Mean (SD) scores for evaluation of psychoeducation features in web-based interventions.

Item	Overall	Desktop programs	Apps
“The program appropriately conveys that there may be fluctuations in the course of treatment.”	2.45 (1.35)	2.89 (1.49)	2.09 (1.13)
“The possible relationship between depression and anxiety is adequately conveyed.”	2.16 (1.29)	2.45 (1.36)	1.91 (1.20)
“The role of avoidance behavior is explained clearly.”	2.62 (1.58)	3.21 (1.40)	2.65 (1.58)
“The role of social isolation is explained clearly.”	2.91 (1.44)	3.20 (1.24)	2.65 (1.58)
“The possibly increased perception of physical symptoms associated with depression is explained clearly.”	1.84 (1.31)	1.75 (1.16)	1.91 (1.44)
“Possible somatic causes of physical symptoms are adequately addressed.”	1.91 (1.49)	1.85 (1.63)	1.96 (1.40)

Mood Tracking

Mood tracking was implemented in 24 web-based interventions, including 11 desktop programs and 13 apps. When a web-based intervention reminded the user to report his or her mood on a regular basis, the reminders occurred less than every 6 hours in most cases (19/24, 79%). The queries of the mood were visualized in desktop programs (mean 3.41, SD 1.37) and apps (mean 3.85, SD 1.32), and took into account common diagnostic criteria for depression (desktop programs mean 3.45, SD 1.50; apps mean 2.50, SD 1.56). The mood queries fulfilled our criteria for scaling (ie, offering at least 5 options) in some desktop programs (8/11, 73%) and apps (11/13, 85%).

Low ratings were given for the explanation of why it can be important to track small periods of time (to detect triggers for specific moods; overall mean 1.27, SD 0.79) or large periods of time (to detect trends in the mood progression; overall mean 1.08, SD 0.35). When mood progression was visualized (eg, as a curve), small periods of time (eg, the last few hours) could be chosen in 10 web-based interventions, including 3/11 (27%) of desktop programs and 7/13 (54%) of apps, and longer periods of time (eg, more than 1 week) could be chosen in 12 web-based interventions, including 5/11 (45%) desktop programs and 7/13 (54%) apps. When mood improvements were given, 4 web-based interventions highlighted improvements (3/11, 27% of desktop programs and 1/13, 8% of apps) and 8 web-based interventions suggested possible relations between mood and current events (2/11, 18% of desktop programs and 6/13, 46% of apps).

Overall, 11 web-based interventions asked the user about anxiety symptoms (6/11, 55% of desktop programs and 5/13, 38% of apps) and 15 web-based interventions asked the user about physical ailments (8/11, 73% of desktop programs and 7/13, 54% of apps). When physical ailments were assessed, 7 web-based interventions advised the user to consult a physician (5/11, 45% of desktop programs and 2/13, 15% of apps).

Journal Keeping

Interventions that provided journal keeping were included in 4 desktop programs and 8 apps. Overall, the web-based interventions received low ratings for their explanation of which

components the journal entries might contain (mean 1.96, SD 1.43) or for their explanation of how it can be helpful to note the positive aspects of the day (mean 2.38, SD 1.70). In most cases, journal entries could be entered through blank text boxes, although some web-based interventions suggested preset phrasings for particular aspects of the journal (7/12, 58%). Some web-based interventions took up journal entries in the progression of the program (2/12, 17%) or provided feedback on the content of journal entries (2/12, 17%).

Relaxation Training

Overall, relaxation trainings were realized in 8 desktop programs and 10 apps. In both types of web-based interventions, mindfulness was suggested as a relaxation technique and the concept of mindfulness was explained in desktop programs (mean 3.00, SD 1.63) and apps (mean 2.85, SD 1.63). Other relaxation techniques that were suggested in the web-based interventions are summarized in Table 8.

When mindfulness was discussed in an intervention, 12 web-based interventions suggested to accept perceptions without judging them (5/8, 63% of desktop programs and 7/10, 70% of apps). Overall, 12 web-based interventions suggested to distance oneself from thoughts (5/8, 63% of desktop programs and 7/10, 70% of apps) and 7 web-based interventions suggested to perform mindfulness exercises as part of a daily routine (2/8, 25% of desktop programs and 5/10, 50% of apps). Additionally, 14 web-based interventions offered audio- or video-based mindfulness exercises (6/8, 75% of desktop programs and 8/10, 80% of apps).

The explanation of typical stressors received low ratings in desktop programs (mean 2.00, SD 1.14) and apps (mean 1.45, SD 0.76). One desktop program and one app offered the user to add personal stressors. The explanation of possible risks in performing mindfulness exercises (eg, the occurrence of unpleasant feelings) received low ratings for desktop programs (mean 1.81, SD 1.17) and apps (mean 1.30, SD 0.57). Similar results were found for the explanation of possible difficulties in performing mindfulness exercises (eg, boredom or falling asleep) in desktop programs (mean 2.00, SD 1.10) and apps (mean 1.80, SD 1.15).

Table 8. Absolute numbers and relative share of relaxation techniques suggested in web-based interventions for desktop programs (N=8) and apps (N=10).

Relaxation technique	Desktop programs, n (%)	Apps, n (%)
Mindfulness	8 (100)	8 (80)
Progressive muscle relaxation	7 (88)	5 (50)
Meditation	4 (50)	8 (80)
Guided imagery journeys	1 (13)	3 (30)
Imagination exercises	2 (25)	5 (50)

Social Skills Training

Social skills training was included in 6 desktop programs and 2 apps. When social skills training was included, users were encouraged to perform a change of perspective in desktop programs (mean 4.25, SD 1.22) and apps (mean 4.50, SD 0.58).

When nonverbal or verbal components of social interaction were discussed (eg, maintaining eye contact or paying attention to voice modulation), desktop programs received higher ratings for their explanations (mean 3.08, SD 1.38 for nonverbal components and mean 3.42, SD 1.44 for verbal components) than apps (mean 1.50, SD 0.58 and mean 1.25, SD 0.50, respectively).

Six desktop programs and one app encouraged the user to perform exercises of social interaction (eg, paying somebody a compliment). The perception of social cues was rated higher in desktop programs (mean 2.92, SD 1.38) than in apps (mean 1.75, SD 0.96).

Both desktop programs and apps addressed the establishment and maintenance of social contacts (mean 3.17, SD 1.33 and mean 3.00, SD 1.42, respectively) and the assertion of one's own wishes in social situations (mean 3.50, SD 1.62 and mean 3.25, SD 1.71, respectively).

Crisis Management

Crisis management was included in 9 desktop programs and 11 apps. Nine desktop programs and 9 apps provided an emergency contact to the user (eg, phone numbers or contact details that

are accessible at any time; 9/9, 100% and 9/11, 82%, respectively). One desktop program and one app required the user to provide an emergency contact in order to use the program (1/9, 11% and 1/11, 9%, respectively). To prevent relapses, 3/9 (33%) desktop programs and 3/11 (27%) apps suggested creating an individual list of warning signs. Contact to support groups was offered by 2/9 (22%) desktop programs and 3/11 (27%) apps.

When the mood in the mood tracking dropped immensely, 7/9 (78%) desktop programs and 4/11 (36%) apps suggested contacting the emergency contact. Three desktop programs and 5 apps suggested creating an emergency plan with individual measures (3/9, 33% and 5/11, 45%, respectively). When the mood dropped, 1/9 (11%) desktop program and 1/11 (9%) app suggested resorting to the emergency plan.

Resource Activation

Although no web-based intervention evaluated in our study implemented a specific module for resource activation, this aspect was indirectly included within several other treatment components. A summary of evaluations regarding resource activation can be found in Table 9, including encouragement to identify individual resources, assistance in identifying resources, encouragement to reflect resources in their context, and uptake of resources in the progression of the web-based intervention. Among all web-based interventions included in this study, 3 desktop programs and 3 apps took up identified resources as the intervention progressed.

Table 9. Mean (SD) scores in the evaluation of resource activation features of web-based interventions.

Item	Overall	Desktop programs	Apps
"The user is encouraged to identify his/her own resources."	2.76 (1.56)	3.45 (1.36)	2.30 (1.54)
"The program provides adequate assistance in identifying individual resources (eg, thinking about past successes)."	2.32 (1.60)	3.20 (1.51)	1.73 (1.39)
"The user is encouraged to reflect resources in their context (eg, origin story, typical situations, promoting or inhibiting factors)."	2.02 (1.39)	2.75 (1.41)	1.53 (1.17)

Discussion

Principal Results

The aim of this study was to evaluate the quality of unguided web-based interventions for depression at the level of individual treatment components based on their adherence to established treatment guidelines. We tested 28 web-based interventions with a self-developed, standardized list of criteria, which were

based on gold-standard treatment guidelines and manuals for depression. Despite the high number of programs and apps for depression available through the commercial market that claim to follow a scientifically sound methodology, we found varying degrees of adherence to established treatment guidelines and manuals.

All web-based interventions included some of the interventions we expected in a CBT-based treatment, indicating conformance

to treatment guidelines to some extent. As a result, our criteria were applicable, and we could gather insights about how the interventions were digitally realized. Overall, there is an evident trend for desktop programs to be rated as more adherent to treatment manuals than apps, which is in line with previous research. In a systematic review, Huguet et al [55] found that only 10% of depression apps seem to be consistent with evidence-based methods of CBT. However, their study focused on behavioral activation, which was only one part of our approach. In our study, cognitive restructuring, psychoeducation, and mood tracking were the most frequently realized components, which were included in more than 70% of the web-based interventions that we tested.

Our key findings reveal substantial variation regarding the therapeutic utility of these interventions, and interventions were diversely realized. For example, in treatment components targeting cognitive restructuring, the explanation of the principle of automatic thoughts was rated high in desktop programs, yet had a lower rating in apps. In contrast, Beck's cognitive triad was addressed less often, although it can provide therapeutic background as an explanatory model for depression. Nevertheless, all cognitive restructuring interventions offered the option to keep a protocol of negative thoughts, as recommended in the manuals, and most of them included details such as the situation, feelings, negative thoughts, alternative positive thoughts, and result of positive thoughts.

When considering the use of mood tracking, we found that 79% of the web-based interventions that implemented mood tracking in our study inquired the mood only once every 6 hours or less frequently. Since retrospective recall of mood in people with depression is biased toward the negative [72,73], web-based interventions could be improved by adding more frequent mood inquiries. Additionally, frequent mood tracking throughout the day can help patients identify triggers for negative moods. However, it may be difficult for patients to track their mood frequently throughout the day on a desktop program. This could be complemented by using worksheets or combining desktop programs with app features. In particular, apps that have the opportunity to make ideal use of ecological momentary assessment could tap into their full potential by suggesting multiple mood inquiries throughout the day [74].

Out of all of the web-based interventions that we tested, 61% did not provide sufficient risk and crisis management when the mood dropped immensely. The most common reaction to a sudden mood drop was the recommendation to call emergency contacts or a crisis line. Yet, some web-based interventions did not react at all to severe mood drops. Although all of the web-based interventions self-identified as not suitable for suicidal patients, strong mood changes and suicidality are common symptoms in depression [75] that should not be completely excluded.

Another aspect that we noted is that the majority of web-based interventions asked the user about physical ailments, but not about anxiety symptoms. Web-based interventions should pay attention to and educate the user about anxiety symptoms and somatic diseases related to depression because there are high rates of comorbidity among depression, anxiety, and physical

illness [76-78]. It would be beneficial if a web-based intervention asked the user about anxiety symptoms and provided information about treatment opportunities for anxiety so that users can reach out to professional help when they need it. Additionally, web-based interventions should recommend that users receive a proper somatic examination when somatic symptoms are present because some symptoms of depression can also be caused by physical illnesses (eg, lack of energy, difficulty in concentrating).

Some web-based interventions did not mention possible difficulties regarding the interventions they suggested. This can result in feelings of failure or disappointment when the user does not manage to complete the intervention. As an example, we found that 19 web-based interventions included behavioral activation and suggested the uptake of specific activities, but the raters evaluated that complex activities were not sufficiently divided into achievable intermediate steps, difficulties for the realization of suggested activities were not sufficiently addressed, and difficulty levels for the suggested activities were not sufficiently provided. Additionally, only 2 out of these 19 web-based interventions asked if an activity was completed. Altogether, this may result in the user feeling invalidated.

As some components of web-based interventions can be text-intensive and do not achieve proper risk management, ongoing engagement and motivation may be required for the user to follow the intervention, which may be very challenging for a depressed individual. Previous research found dissatisfaction and a lack of motivation to be a possible explanation when no benefits of a web-based intervention could be found [79]. Additionally, lack of a user-centric design and concerns about unhelpfulness in emergencies were identified as reasons for low user engagement in smartphone-based mental health apps [45].

Taken all together, we suggest that lack of adherence to treatment guidelines might be a reason why some users find no sufficient benefit in web-based interventions and discontinue the use after a short time, a phenomenon that was identified in previous research [43,44]. The quality of reviewed interventions is variable and the lack of risk management and appropriate adherence to treatment guidelines make it questionable as to whether these products can be recommended to patients suffering from depression without professional oversight. However, many developers are aware of this issue and most web-based interventions do not claim to be a sole therapy tool, but rather a supplement to professional treatment. One reason for this is that high-quality web-based interventions require a wide range of psychotherapeutic, financial, legal, and technological support that cannot always be provided by the developers.

Given the rising demand for web-based treatment options, further research should aim to find principles for the development and evaluation of therapeutically sound web-based interventions for depression, to make it easier for both clinicians and patients to find a suitable product.

Limitations

This is the first study that investigated the quality of unguided web-based interventions for depression at the level of individual treatment components based on established treatment guidelines. However, some limitations should be regarded when interpreting our findings.

Although we used a standardized questionnaire and trained psychologists to achieve systematic and thorough evaluations, the questionnaire in this study has not yet been externally validated and all ratings are subjective to a certain degree. Further, some beneficial interventions might not be included in this questionnaire. For example, some web-based interventions offered interventions based on problem-solving therapy or systemic therapy, which we did not examine in this study. We consider this questionnaire to be an important first step, but there is room for improvement in the future. A future direction is the external verification of this questionnaire. Additionally, future research should aim to examine a wider range of interventions beyond those based on CBT. As we only used three psychologists to rate the web-based intervention in this study, future research should aim to include more raters with different areas of expertise.

Another limitation is that our raters had no depression diagnosis. Therefore, our raters were not the selected target group of the examined interventions and no conclusion on the effectiveness of web-based interventions for patients can be made. Although the criteria used in this study can be an indicator of high-quality interventions, they do not necessarily have a causal relation to symptom reduction or quality of life improvement, and they cannot be compared to randomized controlled trials involving patients. However, since the aim of this study was not to evaluate effectiveness or symptom reduction, but rather to evaluate the quality of interventions based on their adherence to psychotherapeutic guidelines, we considered the use of expert ratings to be suitable for the purpose of our study. Nevertheless, future research could compare the ratings of patients with the ratings of experts to determine if end users hold different opinions toward the quality of an intervention.

A further limitation of this study is that web-based interventions that required the user to get in touch with a counselor or psychotherapist were not included. Therefore, we can make no

claim about how elaborated these interventions are. Additionally, we only evaluated interventions that were available in English or German, as these were the only languages that are fluently spoken by the researchers.

Finally, as we searched for web-based interventions in January 2018 and all our evaluations were performed in 2018, some interventions might no longer be available or may have changed through updates in the meantime.

As a side note, we did not evaluate web-based interventions that used sensor data (eg, through a smartwatch), because we could only identify one such app, which was not available in Germany. As the usage of sensor data is rising in research and practice and promises many advantages to patients, practitioners, and researchers, future research should aim to develop and evaluate web-based interventions that include sensor data.

Conclusion

Many unguided web-based interventions for depression claim to deliver therapeutic content of high quality, but there is high variability in their adherence to established treatment guidelines and manuals. Although many interventions from manuals are included in web-based interventions and developers offer a wide range of treatment components, the necessary level of therapeutic depth is seldom reached. Mental health professionals and developers should work together to implement current treatment guidelines in their interventions to close this gap, especially concerning the lack of risk management that we identified in our study. This could improve user experience and prevent adverse side effects such as users feeling overwhelmed, frustrated, or leaving the intervention altogether. When developers implement quality criteria of established treatment guidelines in their products, web-based interventions can be a valuable tool to supplement professional treatment. The use of web-based interventions in the treatment of depression enables patients and professionals to gather important information from the patients' everyday lives and to save financial and time resources because treatment components can be completed at home. There is a need for further research targeting general principles for the development and evaluation of therapeutically sound web-based interventions for depression, which includes treatment interventions beyond CBT.

Acknowledgments

This study was part of the project Self-administered PsychoTherapy SystemS (SELPASS) funded by the Federal Ministry of Education and Research (FKZ 13GW0157B). We thank Dr. Simone Alvarez for providing linguistic support in translating the questionnaire for this publication.

Abstract

Background: The health behaviors of young adults lag behind those of other age groups, and active health management is needed to improve health behaviors and prevent chronic diseases. In addition, developing good lifestyle habits earlier in life could reduce the risk of metabolic syndrome (MetS) later on.

Objective: The aim of this study is to investigate the effects of the e-Motivate4Change program, for which health apps and wearable devices were selected based on user needs. The program was developed for the prevention and management of MetS in young adults.

Methods: This experimental study used a nonequivalent control group. In total, 59 students from 2 universities in Daegu, Korea participated in the study (experimental group $n=30$; control group $n=29$). Data were collected over 4 months, from June 1 to September 30, 2018. The experimental group received a 12-week e-Motivate4Change program intervention, and the control group received MetS education and booklets without the e-Motivate4Change program intervention.

Results: After the program, the experimental group had significantly higher scores for health-related lifestyle ($t=3.86$; $P<.001$) and self-efficacy ($t=6.00$; $P<.001$) than did the control group. Concerning BMI, there were significant effects by group ($F=1.01$; $P<.001$) and for the group \times time interaction ($F=4.71$; $P=.034$). Concerning cholesterol, there were significant main effects for group ($F=4.32$; $P=.042$) and time ($F=9.73$; $P<.001$).

Conclusions: The e-Motivate4Change program effectively improved participants' health-related lifestyle scores and self-efficacy, and significantly reduced their BMI and cholesterol levels. The program can be used to identify and prevent MetS among young adults.

Introduction

Background

Chronic disease is a significant factor of disability as well as a major cause of death for nearly 60% of the global population [1]. Metabolic syndrome (MetS) is a serious risk factor for heart disease, stroke, and type 2 diabetes. There are numerous

indicators of MetS, including hypertriglyceridemia, high blood sugar, and abdominal obesity; the incidence rate of MetS is steadily increasing [2]. Concurrently, MetS significantly lowers individuals' quality of life (QOL) [3-6], which is defined as one's level of acceptance in relation to the ideals, interests, expectations, and norms of one's culture and value system [7]. Health-related QOL, in particular, is a personal evaluation of the physical and psychological impact of a disorder [8].

Although patients use this indicator to demonstrate their satisfaction level with their own functionality, scholars use it to analyze the average health level and the impact of health care among a wide range of populations [6].

The World Health Organization (WHO) reported that the incidence rate of chronic disease is not only related to social and economic factors but also to individuals' eating habits and physical activities such as drinking and smoking [9]. Sedentary lifestyle, high-calorie diet, sweetened drinks, low economic status, and saturated fats are key risk factors that increase the risk of obesity; however, regular physical activity is known to lower individuals' risk [10,11]. People who are habitually active, less sedentary, and have better cardio-pulmonary functions are less obese and thus have lower incidence rates of MetS [12]. Further, one exemplary study reported that better knowledge of one's own disease increases medical accessibility and has a positive impact on the treatment process and self-care, thus improving individuals' lifestyles [13].

The incidence rate of MetS is notably high among children and adolescents in the United States [14]. Further, the morbidity rate is associated with the obesity rate among young adults, which is also highly related to numerous adult diseases including arteriosclerosis, cardiovascular disease, cancer, and diabetes. Thus, appropriate prevention and intervention is needed in all related fields [14]. One can significantly lower the risk of and prevent MetS by controlling diet habits, physical activity, smoking, drinking, and stress levels [10,15,16]. In particular, men aged 30 to 39 years and women aged 20 to 29 years have worse health activity compared to other age categories, and thus require more active and focused health management to improve their health habits and prevent chronic diseases [17]. Since most health habits become more solidified in mid to older age, it is important to develop a MetS prevention program and prepare the foundation for appropriate health habits among young adults.

Several studies have analyzed the relationship between the incidence rate of MetS and its risk factors such as smoking, drinking, physical activity, depression, and environmental and demographic factors [18]. Moreover, one study revealed that an unhealthy daily lifestyle increases the risk of cardiocerebrovascular diseases and that improved habits act as preventive measures [19]. Further, the Third Report of the National Cholesterol Education Program Expert Panel in Europe reported that it is important to identify patients with MetS and treat them to prevent cardiocerebrovascular diseases [20].

Previous studies on MetS intervention programs examined ubiquitous health (uHealth) nutrition education that focused on increasing fruit and vegetable intake [21] and community-based health education, both of which appeared effective [22]. The uHealth nutrition education initiative is an online self-monitoring program, and data are collected during each session, and are then analyzed cumulatively [21]. A previous cross-sectional study in rural Taiwan successfully reduced the mortality rate from MetS by applying an appropriate Health City plan [23]. The Health City plan for Miaoli County, Taiwan integrated public and civil departments, nongovernmental organizations, and community resources to develop a model of "must move" and "healthy diet" as part of a sustainable development strategy.

Thus, an appropriate health promotion project may effectively reduce the threat of death by MetS [23]. However, most previous studies on MetS and its interventions focused on adults aged >30 years; consequently, more studies about young adults are needed.

With the rapid development of information and smart technology, the demand for mobile health (mHealth), which uses mobile technology such as health apps to prevent disease and improve health, has increased [24,25]. Currently, there are numerous apps that support users' health management. However, users report an unsatisfactory experience when they download the desired app and do not find the content of the app useful or relevant, making it difficult to use the app in the long run [26]. According to a user experience survey, 25.3% of users delete an app once they stop using it [27].

Wearable devices are a key subfield of mHealth. Wearable devices can constantly and easily monitor one's physical activity, and they can provide tailored feedback through synchronized apps [28]. According to previous international studies, wearable devices can improve the lifestyle of patients with chronic diseases [24,26,28]. Numerous companies including Fitbit, Xiaomi, and Samsung produce wearable devices, and the market for devices that primarily manage health is steadily increasing [29]. According to Wijsman and colleagues [30], health interventions using wearable devices increase the daily physical activities of older adults and improve their metabolism.

However, there are some problems with mHealth. First, there is a lack of entertaining aspects that can motivate sustained use. Second, the system that directly delivers the information and professional health care guidelines is incomplete [27]. Other reported problems include a lack of visual information, inconvenient data entry, and one-sided feedback [26]. Therefore, to motivate users and foster active participation, it is important to increase users' self-efficacy, which provides significant intrinsic motivation [31].

Self-efficacy is closely related to how well a person can control and perform specific activities under certain situations. Based on previous studies, health-related self-efficacy is a key motivator for one to continue physical activity; [32] thus, it serves as an important determinant of healthy lifestyle promotion [33]. Previous studies also reported a significant correlation between young adults' health activity and self-efficacy [34,35].

Therefore, this study aims to improve on existing intervention programs by actively using wearable devices and mobile apps and increasing entertaining factors and motivation. To support sustained health activity, we developed a tailored program based on the specific needs of young adults to increase their self-efficacy and general health-related QOL.

Objectives

The specific goal of our study is to develop a program (e-Motivate4Change) using health apps and wearable devices selected based on user's needs, and analyze its impact on MetS prevention among young people. In addition, we sought to determine the program's effect on participants' health-related lifestyle, self-efficacy, and QOL.

Methods

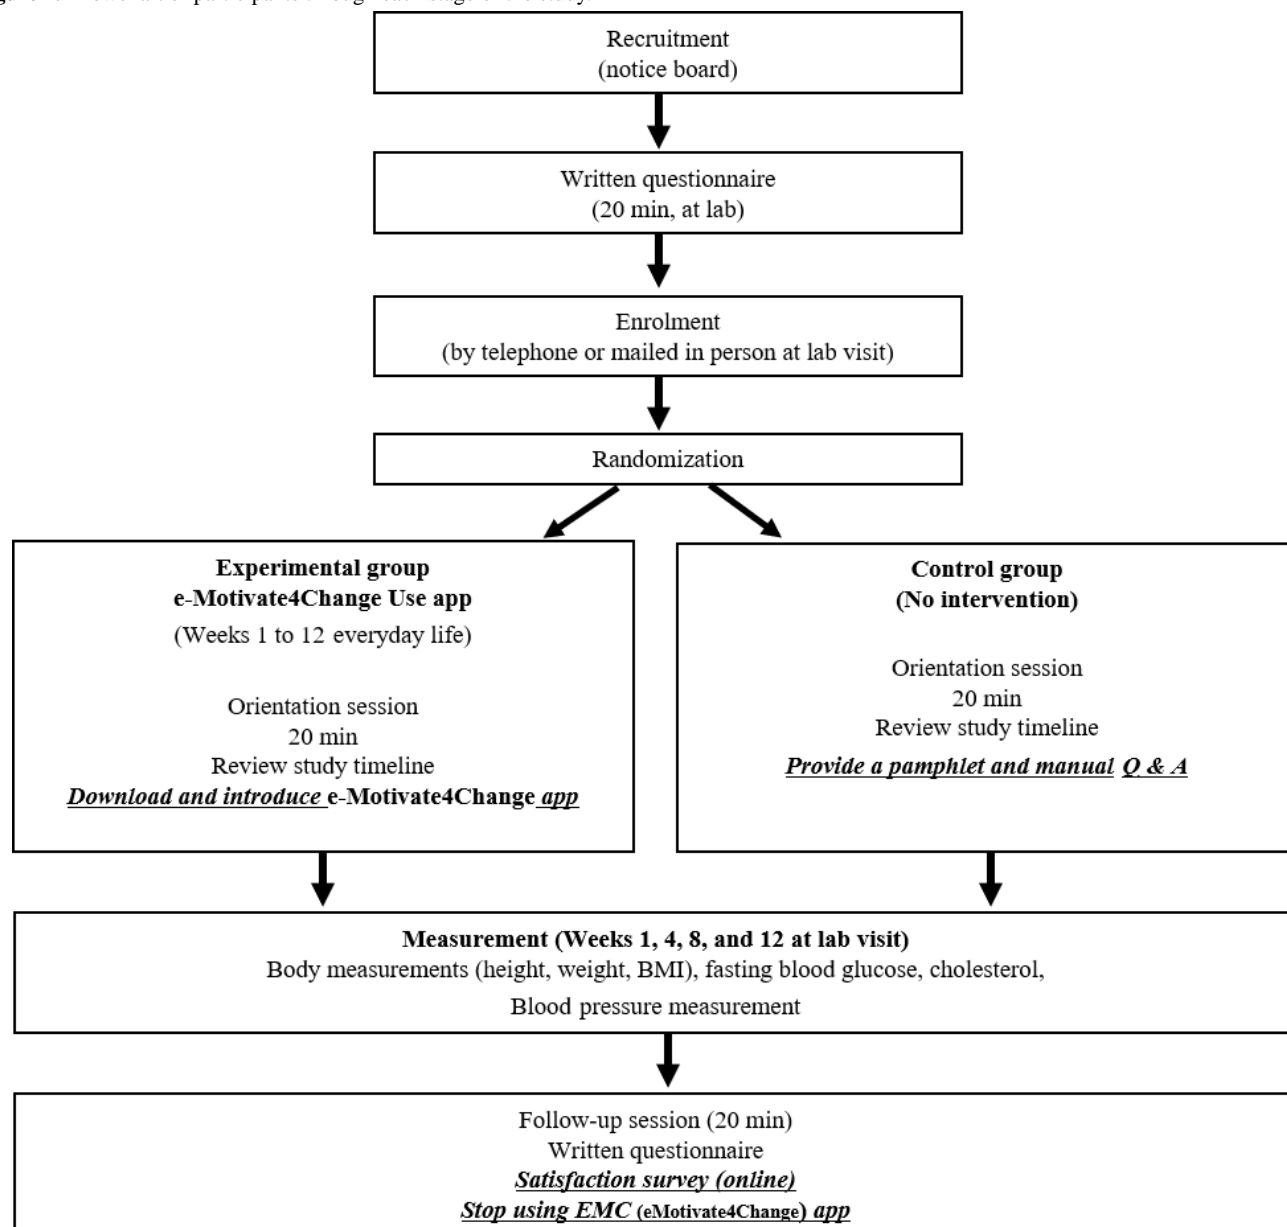

Study Design

This experimental study used a nonequivalent control group and pre- and post-test design. The experimental group completed a presurvey, the e-Motivate4Change program intervention, and three postsurveys. The control group received a pamphlet on

MetS and completed three postsurveys. Data were collected over 4 months, from June 1 to September 30, 2018.

The questionnaire consisted of general characteristics, healthy lifestyle promotion, self-efficacy, and QOL. To collect physiological indicators, we measured participants' BMI, blood pressure, blood sugar, and cholesterol level. The general flow of the study is shown in Figure 1.

Figure 1. Flowchart of participants through each stage of the study.

Participants

Nursing students from Daegu University and Keimyung University who volunteered to participate and met the criteria were recruited. G*power (Version 3.1.7) was used to calculate the appropriate sample size with an effect size of 0.50, a significance level of .05, and a qualification level of 80%. The program indicated that at least 27 participants were required.

Anticipating a dropout rate of 20%, we recruited 60 participants (30 for each group) [36]. During the study period, one student

from the control group opted out owing to a leave of absence; therefore, the data from 59 students were analyzed.

Research Procedure

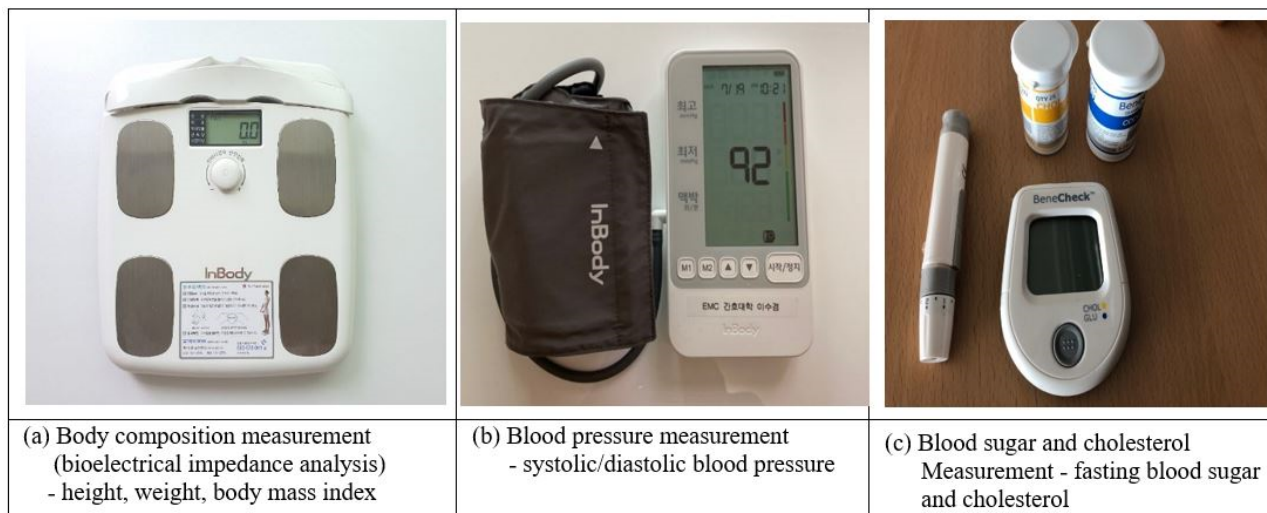

Participants were allocated to either the experimental or control group and the questionnaires were distributed. To measure healthy lifestyle promotion, we used Kang's modified version [31] of Walker's health-promoting lifestyle profile [37]. We used a self-efficacy measurement tool developed by Sherer and colleagues [38] to measure self-efficacy. We also used the translated version of the WHO's QOL instrument (short version;

WHOQOL-BREF) to measure QOL. It took approximately 10 minutes to complete the questionnaire.

After completion, participants' height, weight, body composition, blood pressure, blood sugar level, and cholesterol level were measured (Figure 2). BMI was measured using a body composition analyzer (InBody 3.0; Biospace), which uses

bioelectrical impedance analysis. According to the categorization of Asian adults' BMI, as reported by the Korean Society for the Study of Obesity, participants with a BMI from 18.5 to 24.9 kg/m² are "normal," while a BMI from 25.0 to 29.9 kg/m² indicates "slightly overweight," and a BMI over 30.0 kg/m² indicates "obese" [39].

Figure 2. Physical and physiological assessment tools.

Participants were not provided with any written results of their body measurements since participants could freely check their status through the program. Additionally, the case report form, which is the electronic document of individuals' information as stated in the research design, provided the necessary data to the team. All participants were thoroughly educated on how to complete the case report form.

The e-Motivate4Change program was implemented for 10 minutes with the experimental group to increase their knowledge about MetS and promote health-related activities. Participants could also ask questions. In addition, 5 minutes were allowed for questions and answers. The control group was not provided with the e-Motivate4Change program; they only received a pamphlet. After the e-Motivate4Change program, the experimental group were asked to complete the questionnaire on healthy lifestyle promotion, QOL, and self-efficacy. We then measured their BMI, blood sugar level, cholesterol, and blood pressure again. Participants also completed an online satisfaction survey using a separate site on the e-Motivate4Change app. The control group completed the same surveys and health measurements.

Intervention Design

When participants entered their personal information, the e-Motivate4Change program generated and delivered tailored

information and feedback. Such an interaction aimed to increase users' interest and self-efficacy. The e-Motivate4Change program framework is shown in Figure 3. The entity-relation of the e-Motivate4Change system is shown in Figure 4.

To develop an effective intervention program for young adults with a risk of MetS, we surveyed and analyzed users' demands, which could be used as foundational data for the development of further prevention and intervention programs that use mobile health. According to the needs analysis of professional program developers (N=40), nearly half had previously used health apps. The need for tailored prescription for individual users was rated the highest. Furthermore, 13.9% of the sample had used smart health bands. The most requested functions included a record of calorie consumption (88.9%), followed by a pedometer function, analysis of sleeping patterns, and a waterproof device [40].

We required a mobile app for data collection, a back-end server for storage, a server for real-time data analysis, a prediction server, and a message push server for a long-run comprehensive platform. To make exercise an entertaining factor, gamification was necessary. Therefore, we motivated users through the most foundational flow of gamification: mission, point, rewards [41]. After unifying all necessary factors, we developed a customized program for individual users [42].

Figure 3. E-Motivate4Change system architecture.

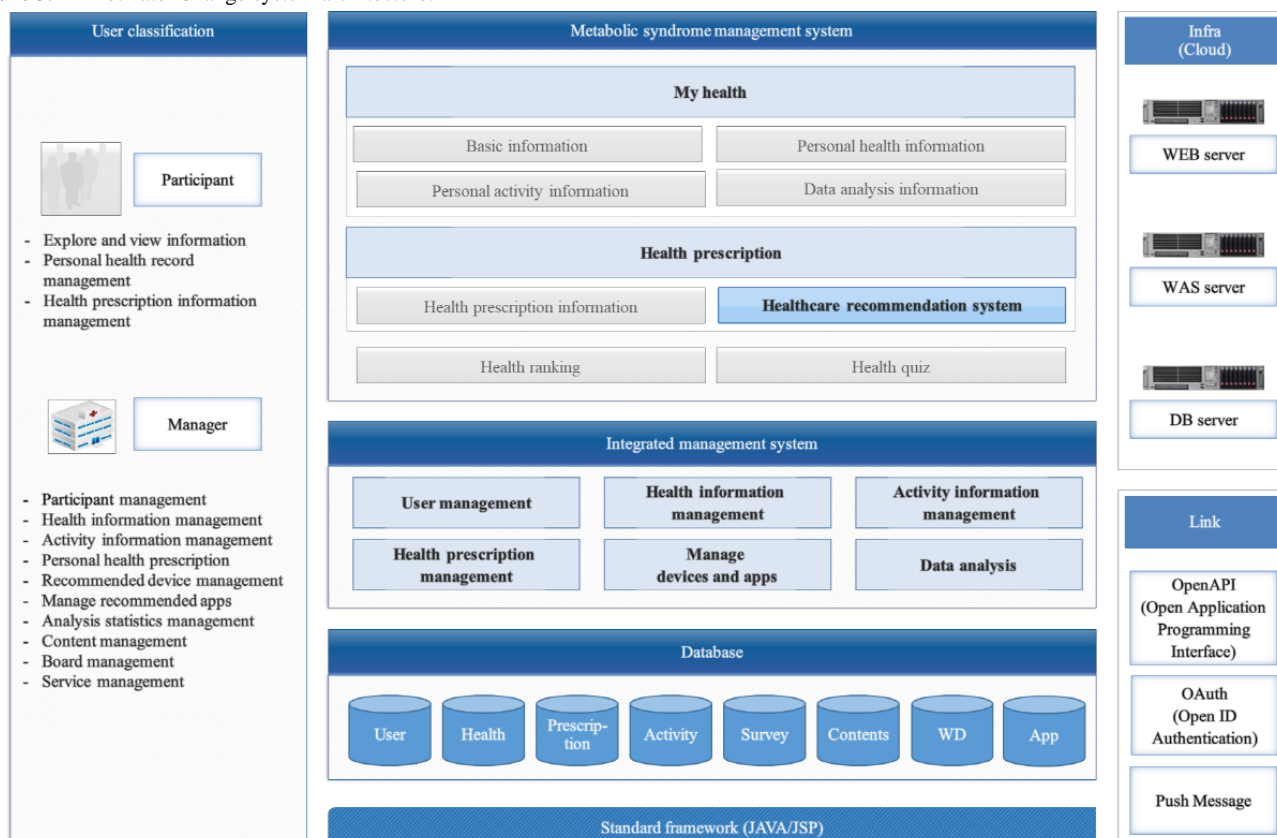

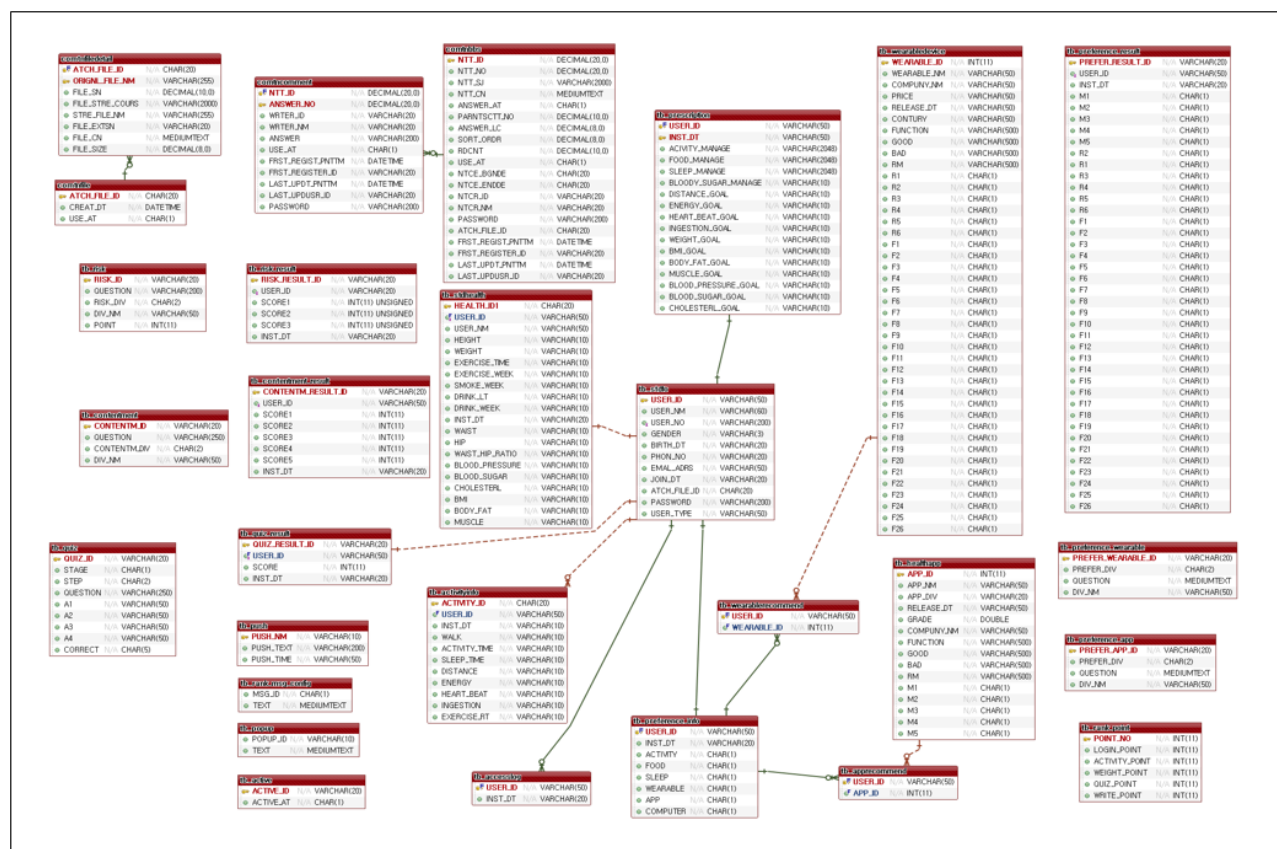

Figure 4. Entity-relation diagram of e-Motivate4Change system.

The e-Motivate4Change program was developed based on three modules (Figure 5). The first is a health behavior prediction

and planning module that notified users of their current risk of MetS when they input their current health status, life habits,
