and hobbies. It also provided customized health activity information (physical activity, diet, education, etc). In addition, it recommends a customized wearable device for users so that they can select one that they prefer. The second is an education module, which aimed to change users' health behavior based on the I-Change 2.0 model [43]. The education module included the definition of MetS and its causes, diagnosis criteria, incidence rate, further symptoms, prevention, and intervention. Such contents were also customized to maintain users' focus. The third module is an interactive communication module. Unlike previous one-sided feedback, the e-Motivate4Change program was designed to provide interactive feedback so that its users can share information and achieve the same goals together.

On the first page, participants could see a brief description about MetS, as well as a description of the program, types of MetS, and its risk factors. We also provided participants with links to websites (including YouTube) that provided information about effective dance moves for preventing MetS. Users could self-diagnose their health status at the login page and check their risk of MetS as well as their body image. Risks of MetS were categorized into diet, disease, and lifestyle factors. Once the users answered a quick survey, the program provided scores on diet, disease, and lifestyle, indicating users' risk of MetS as "fair," "warning," or "danger."

Users were also asked to enter their basic health status, which provided an appropriate avatar with the same body image as the user (based on height and weight). There were five types of male and female avatars based on users' risk of MetS, and the avatar was designed to change as users' health status changed.

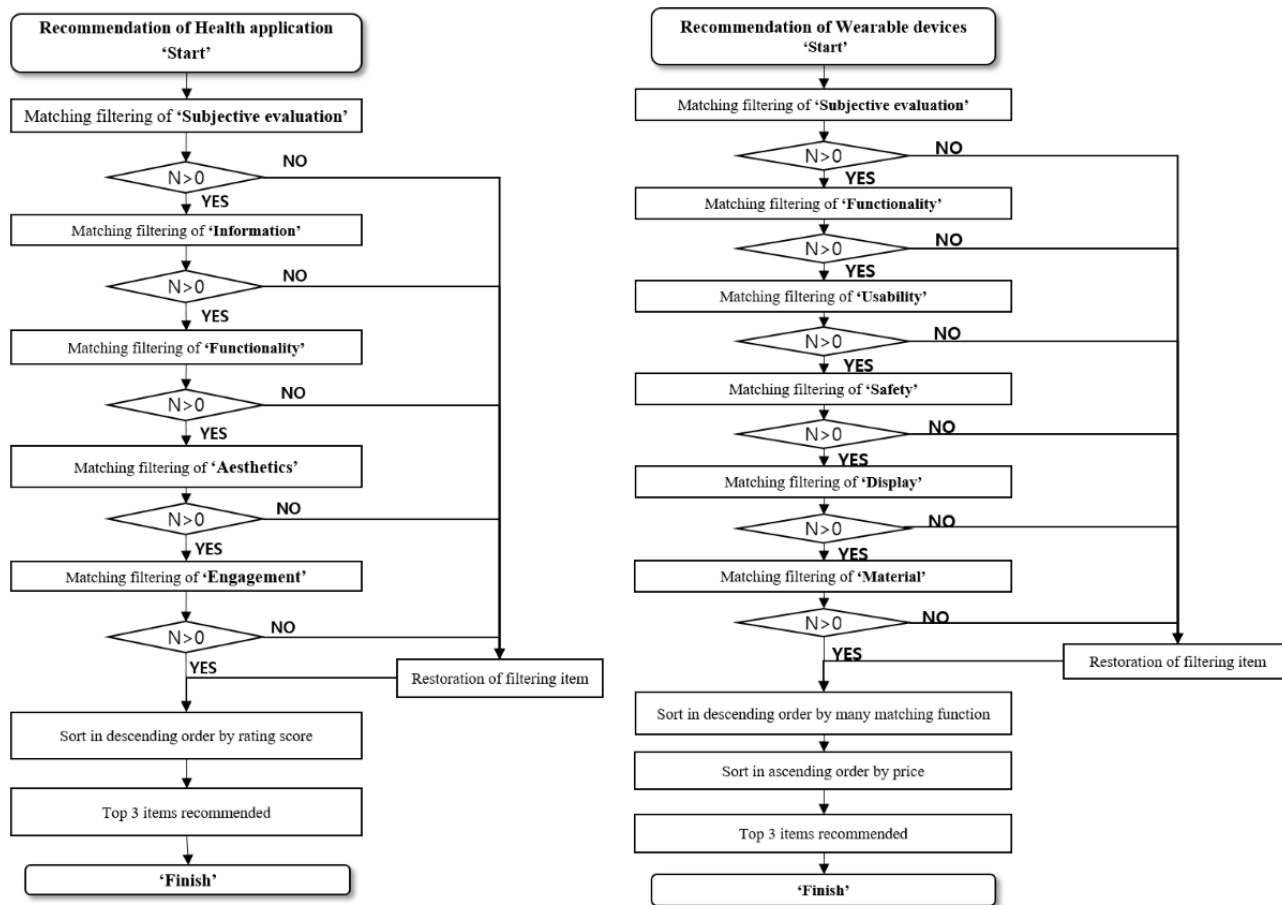

Moreover, users could choose their preferred health management method (app, wearable, diet, or physical activity). The program reflected the needs of the users and recommended customized apps and wearable devices. The recommended algorithm is shown in Figure 6.

Concerning users' health management, we sought the advice of two professional clinical nurses who worked at the national health care company, "Meta Health." We regularly examined users' health information such as weight, obesity rate, body fat, and fasting cholesterol to provide individualized health prescriptions, which included detailed descriptions regarding physical activity, diet, and sleep management.

The community category consisted of a social networking service, questions, and games and quizzes for entertaining factors. Health rankings and a free bulletin board represented the community function. First, users could view their real-time health ranking information, which was determined by points ("mileage") gained from active participation in the program, such as writing on the bulletin or participating in a quiz. Users received mileage for getting the correct answer on a health quiz as well as writing and replying on the bulletin. To encourage participation and motivate the users, the users could check their real-time mileage rankings as well as their rewards. The program also included a "real-life alarm service" so that users could look at their avatars as their risk of MetS changed. Group messaging through a social network was also provided so that the participants could actively engage in information sharing about their health status. Lastly, we included a user preference survey so that we could receive feedback on their experience with the program at the end of the study.

Figure 6. Recommended algorithm of e-Motivate4Change system.

Statistical Analyses

All data collected through the study were analyzed using SPSS Statistics (Version 23.0; IBM Corp). To compare the general characteristics between groups, we used numbers, percentages, means, and standard deviations. We conducted chi-squared tests and Fisher exact tests to analyze the differences between groups, and we used *t* tests to determine if there were original differences in the dependent variable before the study. Subsequently, we used independent *t* tests to identify the effects of the program on participants' healthy lifestyle promotion, self-efficacy, and QOL. A repeated-measures analysis of variance was conducted for participants' physiological measurements (ie, weight, BMI, cholesterol, fasting blood sugar, and blood pressure level).

Ethical Considerations

This study was approved by the heads of two universities in D city and by the Institutional Review Board of Keimyung University (number 40525-201704-HR-020-02). Participants were informed about the research purpose and methods, as well as their rights, including the right to cease participation at any point without penalty. All questionnaires were completed anonymously, and participants were told that the results would not be used for anything other than research purposes. Participation was voluntary, and all respondents provided written informed consent.

Results

Participants' General Characteristics and Homogeneity Test

In total, 59 students (57 females) participated in the study (30 in the experimental group and 29 in the control group). Everyone agreed that lifestyle habits matter for the prevention of MetS. Further, 54.2% (26/48) answered that MetS was "a disease related to obesity and high cholesterol," 75% (36/48) answered that MetS causes "adult disease," 25% (12/48) answered that MetS results in "decreased physical strength and abnormal symptoms," and 52.1% (25/48) answered that exercise matters the most for preventing MetS, followed by a better diet (20/48; 41.7%). No significant differences were found in the homogeneity test conducted between the experimental and control groups regarding general characteristics; thus, the two groups were homogeneous.

Effect of the e-Motivate4Change Program on Psychosocial Indicators

We compared healthy lifestyle promotion, self-efficacy, and QOL between the two groups (Table 1). After the program, there were significant differences in healthy lifestyle promotion and self-efficacy, but not QOL. We also used Cronbach α to measure the reliability of the questionnaire.

Table 1. Comparison of psychosocial indicators between the experimental and control groups.

Variable and group	Prestudy, mean (SD)	Poststudy, mean (SD)	<i>t</i> value	<i>P</i> value
Healthy lifestyle promotion				
Experimental (n=30)	173.13 (21.89)	191.57 (19.19)	3.86	<.001
Control (n=29)	161.66 (26.12)	165.48 (24.76)	N/A ^a	N/A
Quality of life				
Experimental (n=30)	88.73 (9.79)	88.50 (11.23)	.08	.93
Control (n=29)	82.66 (9.28)	83.55 (9.80)	N/A	N/A
Self-efficacy				
Experimental (n=30)	977.97 (185.87)	1140.33 (99.74)	6.00	<.001
Control (n=29)	940.34 (178.11)	957.24 (134.66)	N/A	N/A

^aN/A: not applicable.

Effect of the e-Motivate4Change Program on Physiological Indicators

Table 2 shows participants' change in BMI, cholesterol, blood sugar, and blood pressure based on different measurement periods. First, there were significant differences in BMI between

groups and times; however, the interaction between group and time was nonsignificant. Second, there were significant differences in cholesterol scores per time, group, and the group × time interaction. Lastly, there were no significant differences concerning fasting blood sugar, systolic blood pressure, or diastolic blood pressure between groups.

Table 2. Comparison of physical and physiological indicators between the experimental and control groups.

Variable and group	Baseline, mean (SD)	Week 4, mean (SD)	Week 8, mean (SD)	Week 12, mean (SD)	<i>F</i> value (<i>P</i> value)		
					Group	Time	Group × time
Cholesterol							
Experimental (n=30)	219.47 (66.09)	193.67 (53.84)	183.23 (52.62)	166.30 (43.15)	4.32 (.42)	9.73 (.001)	6.15 (.01)
Control (n=29)	221.48 (61.01)	224.76 (63.41)	212.03 (60.30)	209.86 (58.98)	N/A ^a	N/A	N/A
Body mass index

Discussion

Principal Findings

To the best of our knowledge, this study was the first of its kind in Korea. This study was conducted to investigate the effectiveness of the e-Motivate4Change program using mobile apps and wearable devices developed to prevent and manage MetS in young adults. In total, 59 people from 2 universities in

Korea participated. (experimental group n=30; control group n=29). The experimental group received a 12-week e-Motivate4Change program intervention, and the control group received MetS training and brochures without the e-Motivate4Change intervention. After the intervention, the experimental group scored significantly higher for health-related lifestyle ($t=3.86$; $P<.001$) and self-efficacy ($t=6.00$; $P<.001$) than the control group. With regard to BMI, there was a

significant effect by group ($F=1.01$; $P<.001$) and group \times time interaction ($F=4.71$; $P=.03$). Regarding cholesterol, significant main effects for group ($F=4.32$; $P=.04$) and time ($F=9.73$; $P<.001$) were confirmed.

As the boundaries of traditional industry change owing to the fourth industrial revolution, scholars are anticipating an era of individually tailored services [44]. Such a trend also applies to the national medical policy. The paradigm of worldwide medical policy is gradually shifting from treatment to prevention. Concurrently, considering the rising incidence rate of MetS, the need for appropriate prevention is necessary, especially among young adults who benefit most from lifestyle changes [14,17,45]. Thus, in this study, we developed a MetS prevention program that used mobile apps, wearable devices, and the advice of professional nurses and developers. We then tested its effectiveness on voluntary participants for 12 weeks.

Among both groups, most participants answered that lifestyle was a key preventive factor of MetS, and most defined MetS as a disease related to obesity and cholesterol. Many answered that there was an abnormal physical change when one fails to prevent MetS, and that exercise and diet improvement matter the most. Such answers are consistent with the results of Cornier and colleagues [16] and Clark and colleagues [21].

Participants were asked to record their daily activities in the e-Motivate4Change program for 12 weeks, and the program provided a visual change in the form of their avatars to display their goals and achievements. When we analyzed the risk factors of MetS, there was a significant difference in the mean change in BMI and cholesterol level between the two groups. There was a significant decrease in mean BMI and cholesterol for the experimental group. Such results also showed that, despite their young age, participants had a relatively high BMI and cholesterol level and were at a high risk for MetS [34].

For the experimental group, continued participation in the e-Motivate4Change program decreased their cholesterol and BMI significantly. This result aligns with Aktas and colleagues' [46] study in Turkey, which tracked the lifestyles of participants for 12 weeks. These findings show that people with a chronic disease (including MetS) could lower their blood sugar and cholesterol by continuously improving their lifestyle. However, while fasting blood sugar and blood pressure levels decreased marginally for the experimental group, there was no significant difference between the two groups. One possible explanation is that all participants had average levels at baseline.

Concerning the psychosocial aspects of this study, we must note that the experimental group's self-efficacy and healthy lifestyle promotion scores increased significantly. This result aligns with Khalili and colleagues [22] and Shekari and colleagues [47], who showed that a health education program based on social recognition theory increased young adults' self-efficacy. However, when we look at QOL, the score of the experimental group slightly decreased, and there was no significant difference between the two groups. One potential explanation could be the short duration of the study. The study lasted for 12 weeks, which may have been too short to impact participants' QOL. Therefore, further studies should implement a longer intervention to determine if it could increase young adults' health-related QOL.

Moreover, it is critical to increase young adults' self-efficacy and promote health-related lifestyles. Their needs and preferences should be properly understood so that more customized management programs can be developed. The e-Motivate4Change program is a customized interactive program that provides individualized information (ie, an avatar that reflects personal body shape and recommends health apps and wearable devices) and feedback based on users' input. The program also used big data technology with gamification functions to entertain users, ultimately promoting a healthy lifestyle and educating users about MetS.

Generally, MetS can be prevented through changing diet habits and lifestyle. However, it can be challenging to maintain regular physical activities and good diet habits at an individual level. Thus, by recommending appropriate mobile apps and wearable devices and encouraging their use, this study made it possible for the users to engage in sustained health management. The findings of this study align with those from previous studies that revealed the significance of health trackers and smart apps that are free of time and space limitations for a sustained increase in physical activities [30,48]. Previous recommendation systems were rather one-sided and manager-centered, which made it difficult for users to stay entertained. Consequently, most users stopped using the service.

To find a solution, we developed a needs-based customized recommendation system. Some of the most important features of this program can be summarized as follows. First, the program provides individualized health management prescriptions for the prevention of MetS. Based on the medical paradigm shift from treatment to prevention and management owing to an increasing risk of chronic disease, effective prevention is largely changing the clinical health sectors, as is the fourth industrial revolution [45]. Thus, the combination of data and artificial intelligence will enable individualized medical service. When supported with digital technology, the prevention and management of chronic disease will become much more effective and efficient [45,49]. Furthermore, it is critical for health managers to learn new competencies and skills in rapidly changing medical environments [49]. Thus, health managers for the e-Motivate4Change program analyzed the real-time data of participants and provided customized consulting and health prescriptions, which brought about positive changes in health-related lifestyle and self-care. An efficient system will increase the usability of medical services, decrease the symptoms of chronic disease, and increase cost efficiency, while also improving patients' medical experiences.

Clinical nurses play a critical role in enhancing health; therefore, more effort is needed to expand the role of nurses and support their competency [50]. Clinical nurses will pioneer a new field of expertise by using big data technology and artificial intelligence. Thus, it is necessary to combine the humane and technological aspects of nurse's expertise [45,49,51].

Second, previously one-sided services may not include gamification and entertainment factors. Such improvement provides individualized services for the users, maintaining their high level of interest and their motivation, encouraging them to keep using the program. For sustained management of chronic

diseases, including MetS, more user-centered content is necessary.

Limitations

The personalized service recommendation system proposed in this study provides appropriate dietary and physical activity recommendations to improve youth health to prevent MetS. The ranking system included in the program provides entertainment and motivation to encourage continued use of the program. Moreover, this study can be regarded as different from previous studies as the participants were aged <30 years, whereas the typical age range of MetS study participants is 40 to 60 years. However, this study had limitations. We used a portable body fat measurement device that may not be able to provide accurate and detailed data. At the same time, it was not possible to monitor the type, intensity, or length of physical activity. Subsequent studies should aim to achieve this. In addition, future studies could aim to recruit a participant group with a wider age range than this study. For example, future health intervention programs could include young working women and working mothers.

Conclusions

Despite its limitations, this study is meaningful in that we tried to increase accessibility and usability through smartphone apps while also bringing about changes in the perceptions and health behaviors of young adults by providing individualized recommendations from professional clinical nurses [47]. Moreover, unlike previous group-based education, this program encouraged users' voluntary participation in creating a healthy lifestyle, which allows for better long-term management and operation of the program.

In conclusion, the e-Motivate4Change program was associated with increased physical activity, decreased BMI, lower cholesterol, and increased self-efficacy among experimental group participants, thus effectively promoting a health-related lifestyle. Moreover, by providing programs to prevent and manage MetS, the program informed further studies. Therefore, this study provides foundational data to design further preventive strategies for relevant chronic disorders (eg, diabetes, high blood pressure, hyperlipidemia, cardiovascular disease).

Acknowledgments

The authors gratefully acknowledge Shin-Sil Kim (CEO) and Eun-Kyung Song (manager) of Meta Healthcare for their support and health consultations during this project. This research was supported by the Basic Science Research Program through the National Research Foundation of Korea (NRF) and funded by the Ministry of Education (number NRF-2015R1C1A1A01055753; 2018R1D1A3B07050652).

Authors' Contributions

All authors had full access to all data and take responsibility for the integrity of the data and the accuracy of the data analysis. JSL and SKL contributed to study concept and design. JSL and MAK contributed to the acquisition and statistical analysis of data. JSL and SKL contributed to the interpretation of data and drafting of the manuscript. SKL contributed critical revision of the manuscript for important intellectual content, obtained funding, and supervised the study. SKL provided administrative, technical, and material support.

Abstract

Background: In the Netherlands, human papillomavirus (HPV) vaccination uptake remains low. To improve informed decision making (IDM) and HPV vaccination acceptability, we systematically developed an interactive, web-based tailored intervention to which mothers of Dutch girls were invited to participate.

Objective: The aim of this study was to provide insight into the intervention's working mechanisms by evaluating (1) program use, (2) program acceptability, and (3) the relationship of program use with program acceptability and intervention effects (ie, dose-response relationship).

Methods: Only mothers from the intervention arm of a randomized controlled trial that assessed the effectiveness of the web-based, tailored intervention were included in this study. They were invited to visit the website of the web-based intervention between baseline (January 2015, just before access to the intervention) and follow up (March 2015, prior to the first HPV vaccination). Indicators for program use were time of website use (ie, duration of intervention exposure) and completeness (ie, proportion of all available web pages visited). HPV vaccination uptake registered by Praeventis was used as the primary outcome. Secondary outcomes were IDM, decisional conflict, and social-psychological determinants of HPV vaccination uptake.

Results: Among the 3995 invited mothers, 2509 (62.80%) logged on to the website, 2239 of whom (89.24%) visited at least one page of the intervention components. On average, mothers spent 21.39 minutes (SD 12.41) on the website and completed 50.04% (SD 26.18%) of the website components. Participants rated the website 7.64 (SD 1.39) on a 10-point scale. Program acceptability was significantly associated with completeness ($\beta=4.36$, $P<.001$), but not with time of website use ($\beta=-.07$, $P=.77$). Intention-to-treat analysis ($N=3995$) showed a significant positive effect of completeness on all outcome measures (all $P<.003$; Bonferroni-corrected $\alpha=.05/15$ factors), including on HPV vaccination uptake. Time of website use had a significant positive effect on all outcomes (all $P<.003$), except for uptake ($P=.20$), risk perception when not vaccinated ($P=.14$), subjective norms ($P=.03$), and habit ($P=.01$).

Conclusions: Program use and acceptability of the intervention were adequate. Completeness was positively associated with acceptability. Furthermore, positive effects (ie, dose-response effects) were found for completeness and time of website use on the mothers' IDM, decisional conflict, and almost all of the social-psychological determinants of HPV vaccination acceptability. In addition, the extent to which mothers completed the intervention had a positive impact on their daughters' vaccination uptake. This indicates that the web-based, tailored intervention fits well with the mothers' needs, and that completeness of use is essential for improving HPV vaccination uptake, acceptability, and IDM. Program use should therefore be promoted.

KEYWORDS

HPV vaccination; web-based tailored intervention; process evaluation; intervention use; dose-response relationship; randomized controlled trial; informed decision making

Introduction

Cervical cancer is the fourth most common cancer among women worldwide. Globally, in 2018, there were 569,847 new cases and 311,365 deaths caused by cervical cancer [1]. Persistent infection by human papillomavirus (HPV) appears to be the major cause of cervical cancer; nearly all cases (over 99%) are attributable to an HPV infection [2,3]. There is also an increasing body of evidence that strongly links HPV infection with cancers of the anus, vulva, vagina, penis, and head and neck (eg, [4,5]). In the Netherlands, on an annual basis since 2010, girls are invited by the Dutch National Immunization Program to receive the vaccine against HPV upon reaching 13 years of age. However, HPV vaccination uptake remains low (45.5% in 2017) [6]. The uptake needs to be higher to reduce the incidence of cervical cancer in women. Therefore, we developed an interactive, web-based, tailored intervention promoting HPV vaccination acceptability among Dutch mothers of invited girls for HPV vaccination [7]. Further, to improve vaccine acceptability, important intervention objectives were to improve informed decision making (IDM) and to decrease decisional conflict [7].

To date, only four studies have examined the effectiveness of tailored interventions in promoting HPV vaccination acceptance [8-11]; three of these studies showed positive effects [9-11]. To our knowledge, the only tailored intervention that was web-based turned out to be ineffective [8]. The advantage of web-based interventions is that they have the potential to enable large-scale application at relatively low cost [12] and therefore can have a substantial impact at the population level [13].

Furthermore, only two of the existing studies using tailored interventions to promote HPV vaccination acceptance incorporated a process evaluation [9,11]. Process evaluation provides insight into the extent to which an intervention was used, which is relevant for determining factors that influence the effectiveness of an intervention [14-16]. Specifically, this analysis can provide insight into whether an intervention is ineffective due to implementation failure or to the inferior quality of the intervention method(s), thereby avoiding the so-called type III error [17]. It also provides recommendations for intervention improvement.

For the use of online interventions, three aspects are relevant: a first visit, staying, and revisiting [18,19]. In the context of decision making about HPV vaccination, we consider a first visit and staying as the most relevant aspects. Revisiting seems less relevant, since getting the HPV vaccine is hardly a repetitive behavior (ie, it consists of two injections). Within the electronic health (eHealth) arena, limited intervention use in terms of a first visit and staying is a broadly recognized problem [20]. The extent to which one uses an intervention may positively impact the intervention effects (ie, the so-called “dose-response

relation”). Positive dose-response relationships have been found for eHealth interventions (eg, [21-23]). In the context of promoting HPV vaccination acceptability, none of the studies that incorporated a process evaluation addressed the dose-response relationship (for a review, see [24]). Moreover, data on the use of web-based interventions have been poorly reported [20,25] or not reported at all [26].

Furthermore, assessing program acceptability may shed light on the causes of nonuse or incomplete use [27]. An intervention needs to be considered appropriate by the target group and to suit their needs in order to reach the intended outcomes [28]. Acceptability will improve interaction and the users’ feelings of engagement, and, as a consequence, the likelihood of health-related behavior changes [29].

Results from the effect evaluation showed positive intervention effects on IDM, decisional conflict, and nearly all determinants of HPV vaccination uptake (for more details on the results of the effect evaluation, see [30]). This paper describes the process evaluation of the web-based tailored intervention promoting HPV vaccination acceptance [7]. The aim of this process evaluation was to provide insights into the intervention’s working mechanisms by evaluating (1) program use, (2) program acceptability, and (3) the relationship of program use with program acceptability and intervention effects (ie, dose-response relationships).

Methods

Participants and Study Design

The study was approved by the Ethical Committee of the VU Medical Center in Amsterdam (Netherlands Trial Register: NTR4795). This process evaluation was part of a randomized controlled trial on the effectiveness of the intervention [30]. For the purpose of this study, only participants from the experimental condition (ie, those invited to use the web-based intervention; N=3995) were included in the analyses. Details of the trial design, such as power calculations, participant eligibility, and recruitment procedures, have been published elsewhere [30]. This study was conducted between January 2015 (baseline, just before access to the intervention) and March 2015 (follow up, prior to the first HPV vaccination), in line with the national HPV vaccination round of 2015. Mothers were invited to use the web-based intervention between baseline and follow up (mid-January 2015).

Intervention Components

We developed the web-based tailored intervention with virtual assistants using the 6-step Intervention Mapping protocol for developing theory- and evidence-based health promotion interventions [31]. In short, the web-based intervention provided mothers with tailored feedback about topics on HPV vaccination, delivered by two virtual assistants. [Multimedia Appendix 1](#)

presents a selection of screenshots of the website. The website consisted of 4 menu options: (1) 2-sided, tailored information about HPV vaccination, (2) a decisional balance in which mothers could weigh their perceived pros and cons, (3) practical information, and (4) frequently asked questions. Within menus 1-3, mothers could visit several components. In addition,

mothers were given the opportunity to visit an “in-depth” information page within some of the components (eg, educational movies). Table 1 provides a brief overview of the intervention components. More detailed descriptions of the intervention, including its theoretical basis, are published elsewhere [7].

Table 1. Brief description of intervention components.

Menu and component	Description
Information about HPV^a vaccination	
General information	Mothers are provided with general information about HPV, cervical cancer, and HPV vaccination.
Importance of vaccinating at a young age	Mothers are challenged to consider whether the age of their daughter is appropriate to get vaccinated against HPV. The relationship between sexual activity in relation to the HPV vaccine is also discussed.
HPV-related risks	Mothers are asked to estimate both the risk of their daughter getting infected with HPV and the risk of their daughter developing cervical cancer later in life, and are then provided with tailored feedback accordingly.
Methods to protect against cervical cancer	Mothers are asked to rate the effectiveness of alternative methods for protecting against cervical cancer and are then provided with tailored feedback according to their answers.
From HPV to cervical cancer	Mothers are provided with an explanation of how infection with HPV can lead to cervical cancer (eg, by viewing an educational video).
Facts and stories	Mothers are provided with several statements regarding HPV, cervical cancer, and HPV vaccination, and are asked to indicate whether these are true (a fact) or false (a story). They then receive tailored feedback accordingly.
Side effects	Mothers are presented with a variety of potential side effects of the HPV vaccine and are asked to indicate whether or not they are scientifically proven. They are then provided with tailored feedback, stating the correct responses.
Effectiveness	Mothers are asked about the effectiveness of the HPV vaccine in protecting both against their daughter getting infected with HPV and developing cervical cancer. They are then provided with tailored feedback about the effectiveness of HPV vaccination.
Other mothers	Mothers are asked to indicate what they think most mothers in their direct environment will decide regarding their daughters' HPV vaccination. They are then provided with tailored feedback and are shown the actual HPV vaccination uptake in different regions of the Netherlands in 2014.
Vaccine working mechanisms	Mothers are explained in a generic way how the HPV vaccine works in protecting against HPV and cervical cancer with an educational video.
Weighing the pros and cons	
Decisional balance	Mothers are presented with a list of pros and cons of HPV vaccination. Based on pros and cons mothers marked as most salient, a decisional balance reveals their current position on a scale ranging between wanting and not wanting to get their daughter vaccinated.
Value clarification	Mothers are invited to list their central values for life and link these to HPV vaccination.
Practical information	Practical information provides mothers with information such as how and where to receive the HPV vaccine and provides them with advice on how they discuss HPV vaccination with personal important others (eg, their daughter and partner).
Frequently asked questions	
About HPV vaccination	Frequently asked questions provides answers to known questions about the HPV vaccine (eg, “does my daughter know if she’s infected with HPV?”) or getting the HPV vaccine (eg, “where do I get the HPV vaccine?”).
Problems with the website	Mothers are provided with possible solutions to problems with the website such as not being able to hear or see the virtual assistants.

^aHPV: human papillomavirus.

Measurements

All data were derived from web-based self-report questionnaires and computer logs.

Program Use

Program use was measured according to time of website use and completeness. Both factors were constructed based on computer logs that registered the pages and components the

mothers had visited and the amount of time they spent on the website during their visit(s).

Time of website use represents the total amount of time spent on the website. Each time mothers logged on to the website, a record was created, in which both the date and time of the first and last page the mothers entered were registered. Time per session was calculated by subtracting the time of the last entered page from the time of the earliest entered page. The total time of website use was then calculated by adding up the amount of time spent in each session.

Completeness represents the proportion of all available web pages visited by the mother while she was logged on to the website, ranging from 0% (visited no pages) to 100% (visited all pages).

Program Acceptability

Program acceptability was assessed at the 6-week follow up by asking mothers to rate the intervention and the virtual assistants on a 10-point scale, ranging from 0 (very bad) to 10 (excellent). The grade for the website was used as an indicator for overall program acceptability to examine the association with program use. In addition, mothers evaluated the information provided by the website (eg, credibility, relevance), perceived user control (eg, perceived degree of autonomy), and how they perceived the virtual assistants (eg, reliability) (See [Table 2](#) and [Table 3](#) for an overview). These acceptability measures were assessed on a 7-point scale, and some were averaged into one scale. All composite scores showed sufficient internal consistency (Cronbach $\alpha \geq .71$ for scales with >2 items; Pearson $r \geq 0.84$ for scales with 2 items).

Table 2. Overview of the program acceptability measures for the website.

Measures	Items	Score and scale	Cronbach α or Pearson r	Reference
Rate	On average, how would you rate the website on a scale from 0 to 10?	0=very bad to 10=excellent	N/A ^a	[32]
Interest	In general, what did you think of the website?	1=very uninteresting to 7=very interesting; 1=boring to 7=engaging	0.84 (r)	[33]
Informative	In general, what did you think of the website?	1=very uninformative to 7=very informative; 1=very noneducational to 7=very educational	0.86 (r)	[34]
Perceived user control	I felt that I had a lot of control over my visiting experiences at this website. While I was on the website, I could choose freely what I wanted to see. While surfing the website, I felt in control. While surfing the website, my actions decided the kind of experiences I got.	1=strongly disagree to 7=strongly agree	.71 (α)	[35]
Elaboration	How well did you read the information?	1=not carefully at all to 7=very carefully	N/A	[36]
Support	The website has helped me decide about my daughter's HPV ^b vaccination.	1=strongly disagree to 7=strongly agree	N/A	[37]
Recall	I can recall the information from the website.	1=strongly disagree to 7=strongly agree	N/A	[32]
Personal relevance	I considered the website to be personally relevant.	1=strongly disagree to 7=strongly agree	N/A	[32,37]
Tailoring	I considered the information on the website to be...	1=not tailored to me at all to 7=very tailored to me	N/A	[37]
Comprehensibility	I considered the information on the website to be...	1=not at all understandable to 7=very understandable	N/A	[37]
Reliability	I considered the information on the website to be...	1=very unreliable to 7=very reliable	N/A	[37]
Credibility	I considered the information on the website to be...	1=very incredible to 7=very credible	N/A	[37]
Usefulness	I considered the information on the website to be...	1=very useless to 7=very useful	N/A	[38]
Readability	I considered the information on the website to be...	1=very unreadable to 7=very readable	N/A	[39]
Sidedness	I considered the information on the website to be...	1=focused on the cons to 7=focused on the pros	N/A	[40]
Enjoyment	I considered the information on the website to be...	1=very unenjoyable to 7=very enjoyable	N/A	[41]
Novelty	The website contained new information for me.	1=strongly disagree to 7=strongly agree	N/A	[39]
Attitude toward website	How good or bad did you find... - the possibility to first answer a question and then receive information? - the possibility to weigh the pros and cons? - the speed of the website? - the layout of the website?	1=very bad to 7=very good	.81 (α)	[42]

^aN/A: not applicable.^bHPV: human papillomavirus.

Table 3. Overview of the program acceptability measures for the virtual assistants.

Measures	Items	Score and scale	Pearson <i>r</i>	Reference
Overall rating	On a scale from 0 to 10, how would you rate: - the mother-like assistant - the doctor-like assistant	0=very bad to 10=excellent	0.94	[43]
Enjoyment	I considered the virtual assistants to be...	1=very unenjoyable to 7=very enjoyable	N/A ^a	[41]
Reliability	I considered the virtual assistants to be...	1=very unreliable to 7=very reliable	N/A	[43]
Credibility	I considered the virtual assistants to be...	1=very incredible to 7=very credible	N/A	[37]
Usefulness	I considered the virtual assistants to be...	1=very useless to 7=very useful	N/A	[37]

^aN/A: not applicable.

Outcomes

Primary Outcome: HPV Vaccination Uptake

An objective measure for HPV vaccination uptake was derived from Praeventis, which is the national electronic vaccination register that monitors the vaccination status for all children up to 18 years of age living in the Netherlands [44]. Uptake was dichotomized into having received no HPV injection (0=not vaccinated) and having received 1 or 2 HPV injections (1=vaccinated), as data analyses showed that determinants of HPV vaccination uptake contrasted the most between these groups.

Secondary Outcomes: IDM, Decisional Conflict, and Social-Psychological Determinants of HPV Vaccination Uptake

Multimedia Appendix 2 provides the measurement details of the constructs IDM, decisional conflict, and the social-psychological determinants of HPV vaccination uptake [30,45-54]. Determinants accounted for were intention, attitude, risk perception of having received the HPV vaccine, risk perception without having received the HPV vaccine, anticipated regret about rejecting the HPV vaccine, beliefs, subjective norms, habit strength toward HPV vaccination, self-efficacy, knowledge, and perceived relative effectiveness of HPV vaccination compared to alternative methods.

Sociodemographics

Sociodemographics were included as background variables (ie, age, educational level, country of birth, and religion).

Level of education referred to the mothers' highest completed level of education. It was classified as low (less than secondary or vocational education), intermediate (secondary through preuniversity education), or high (professional or university education) [30,49,50].

Country of birth was dichotomized into "Netherlands" vs "other," because the percentage of mothers born in the latter category (276/3995, 6.91%) was too small for further subdivision in our sample.

Religion was measured by asking mothers about their religious convictions (Protestant, Roman Catholic, Muslim, Jewish,

Buddhist, Hindu, other, or no religion). This was dichotomized into "Protestant" vs "not Protestant" as earlier research and data analyses showed that Protestants more frequently refrain from vaccination compared to other religious groups [30,49,50].

Statistical Analyses

The sample and intervention use data are summarized using descriptive statistics. For determining the dose-response relation, intention-to-treat (ITT) analyses were used, which increases power, while decreasing the risk of possible bias caused by selective dropout [55]. Missing data were imputed for uptake, determinants, and sociodemographics (not for use): we applied multiple imputation by chained equations [55,56]. In total, 15 imputed datasets were generated using the predictive mean matching algorithm in Statistical Package for the Social Sciences (SPSS, IBM Corp). Results from these datasets were pooled together using Rubin's rules [57]. Iteration plots were inspected to check convergence of the imputations.

The relationship between acceptability and use was examined using univariate regression analyses. The dose-response relation between program use and intervention effects was examined by logistic and linear regression analyses (for dichotomous and continuous variables, respectively) using the outcome score at follow up as the dependent variable and the outcome scores at baseline and program use (both completeness and time of website use) as the independent variables [58]. Effects were considered significant when the *P* value was lower than .003 (Bonferroni-corrected $\alpha=.05/15$ factors). For the logistic regressions, the odds ratio (OR) was used as an index of effect sizes. These were interpreted as small (OR=1.5), medium (OR=3.5), or large (OR=9.0) [59]. For the linear regressions, effect sizes were calculated in R software (R Development Core Team, Vienna, Austria) using Cohen f^2 statistic, $(R^2_{AB} - R^2_A)/(1 - R^2_{AB})$, in which *B* is the variable of interest (ie, use), *A* is the set of all other variables (ie, the outcome at baseline), R^2_{AB} is the proportion of variance accounting for *A* and *B* together, and R^2_A is the proportion of variance accounted for by *A* [60]. These were classified as small ($f^2=0.02$), medium ($f^2=0.15$), and large ($f^2=0.35$) [59]. We performed complete case analyses as a sensitivity check for substantial differences with the results from ITT.

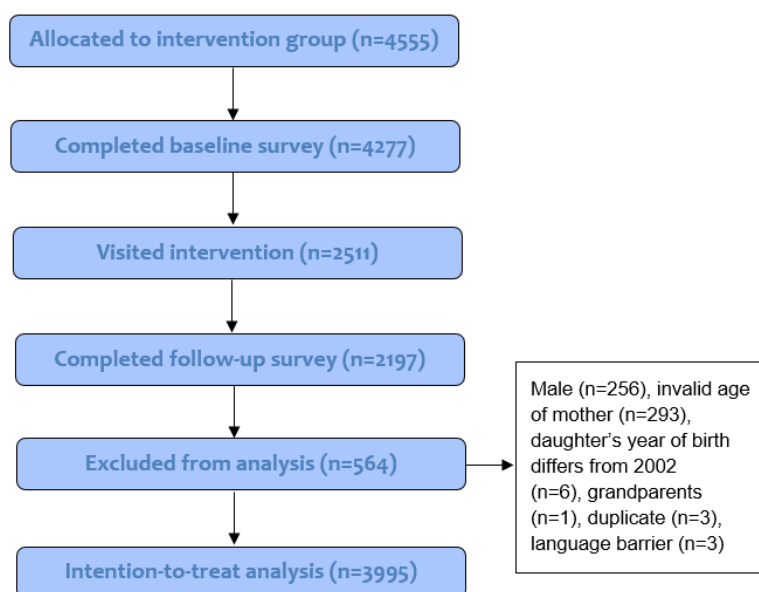

Results

Response Rates and Attrition

A flow diagram of the recruitment and response of participants in the experimental condition, as part of the process evaluation, is shown in Figure 1. From the 4555 participants who were randomized into the experimental condition at baseline (T0), 4277 (93.90%) completed the baseline questionnaire, 2511 (55.13%) visited the intervention, and 2197 (48.23%) completed

the follow-up questionnaire 8 weeks later (T1). Dropout analysis showed that there was significantly more dropout with regard to participants not born in the Netherlands, those with a lower educational level, those having a daughter not being vaccinated, and those with low levels of risk perception. In total, 564 participants were excluded as they (a) did not meet the inclusion criteria (ie, being a mother of a daughter born in 2002 and aged 24-62 years), (b) were found to be duplicates, or (c) encountered a language barrier. The final sample for ITT analysis consisted of 3995 mothers.

Figure 1. Flow diagram of the recruitment and response of study participants from the experimental condition. Participants could be excluded based on multiple criteria (eg, male with an invalid age). Therefore, the total number of participants excluded differed from the sum of separate criteria for exclusion.

Sample Description

Table 4 shows the sample description of participants in the experimental condition. No data were available on sociodemographics of the population from which the sample was derived (ie, Dutch mothers of 12-year-old girls); hence, we were unable to assess whether the study sample was

representative. The mothers' mean age was 43.70 years (range 27.00-62.00 years). On average, mothers had a positive intention toward their daughters' HPV vaccination at baseline (mean score 5.35, SD 1.69). Compared with the national HPV vaccination uptake at the time (ie, 2015), uptake was higher in the study sample (59,866/93,173; 60.98% vs 2923/3995; 73.17%) [61].

Table 4. Sample description of mothers in the intervention group (N=3995).

Variables	N (% missing)	Value ^a
Age in years, mean (SD)	3995 (0)	43.70 (4.27)
Country of birth, n (%)	3991 (0.10)	
The Netherlands		3715 (92.99)
Other		276 (6.91)
Religion, n (%)	3998 (0.18)	
Protestant		753 (18.85)
Not Protestant		3235 (80.98)
Educational level, n (%)	3991 (0.10)	
Low		588 (14.72)

^aBy reporting 2 decimal points for the percentages, summing the percentages for each category may differ from 100%.

^bHPV: human papillomavirus.

Program Use

From the 3995 mothers in the intervention group, a total of 2509 mothers (62.80%) logged in (ie, time of website use >0). Of these, 73.06% (1833/2509) logged in once, 19.89% (499/2509) logged in twice, 5.00% (125/2509) logged in three times, and 2.07% (52/2509) logged in four times or more. On average, mothers spent 21.39 minutes (SD 12.41) on the website.

Of the 2509 mothers that had initially logged in, 2239 (89.24%) visited at least one page of a component of the intervention (ie, completeness >0). Only these 2239 mothers were included for describing use of specific intervention components and program acceptability (see below). On average, the mothers completed 50.04% (SD 26.18%) of the website components (ie, 51/101 pages).

Use of Intervention Components

Table 5 shows the breakdown for the use of intervention components (N=2239). When mothers clicked on one or more links to receive in-depth information, it was marked as “visited.” Mothers visited the page “Ways to Protect Against Cervical Cancer” the most frequently (1971/2239, 88.03%), followed by “Chance” (1945/2239, 86.87%), whereas they visited “Value Clarification” the least (293/2239, 12.53%). “General Information” had the highest completion rate (1622/2239, 72.44%), whereas “Side Effects” and “Effectivity” were completed the least (both 19/2239, 0.85%). Only a small percentage of the mothers (4.20%-13.22%; n=94-298) visited in-depth information (comprising educational movies or extra information).

Table 5. Program use of the various intervention components among those who visited at least one page of the intervention (N=2239).

Intervention component	Completed ^a , n (%) ^b	Partly completed ^c , n (%)	Not visited ^d , n (%)	Visited in-depth information ^e , n (%)
General Information	1622 (72.44)	71 (3.17)	546 (24.39)	N/A ^f
Ways to Protect against Cervical Cancer	130 (5.81)	1841 (82.22)	268 (11.97)	N/A
Chance	135 (6.03)	1810 (80.84)	294 (13.13)	142 (6.34)
From HPV ^g to Cervical Cancer	96 (4.29)	1110 (49.58)	1033 (46.14)	298 (13.22)
Age	154 (6.88)	1568 (70.03)	517 (23.09)	160 (7.15)
Side Effects	19 (0.85)	1686 (75.30)	534 (23.85)	299 (13.35)

Weighing Pros and Cons	615 (27.47)	911 (40.69)	713 (31.84)	N/A
Value Clarification	269 (12.01)	24 (1.07)	1946 (86.91)	N/A
Practical Information	556 (24.83)	1147 (51.23)	536 (23.94)	N/A

^aA component was considered “completed” when mothers visited every page of the component.

^bBy reporting 2 decimal points for the percentages, summing the percentages for each category may differ from 100%.

^c“Partly completed” indicates that the mothers had seen at least one, but not all pages.

^d“Not visited” means that the mothers had not visited any of the component’s pages.

^e“Visited in-depth information” was also part of the total completeness, but is depicted separately here to provide a better overall view of the mothers’ interest in this information. When one or more of the links to more in-depth information had been clicked on, the in-depth information was marked as “visited.”

^fN/A: not applicable as the component did not contain in-depth information.

^gHPV: human papillomavirus.

Program Acceptability

The overall acceptability of the intervention was rated 7.64 (SD 1.39) on a 10-point scale (1513/2239, 67.57%). Acceptability was significantly and positively associated with completeness ($\beta=4.36$, $P<.001$); this did not account for time of website use

($\beta=-.07$, $P=.77$). The virtual assistants were rated 7.41 (SD 1.57) on a 10-point scale (1513/2239, 67.57%). The mean scores on all other program acceptability measures were moderate to high (range 4.34-5.71 on a 7-point Likert scale; see Table 6). As the data were not normally distributed but were positively skewed, the median scores are also included in Table 6.

Table 6. Mean (SD) and median scores on the program acceptability measures among those who visited at least one page of the intervention (N=2239)^a.

Variable	Website (n _{missing} =726-734)		Virtual assistants (n _{missing} =960)	
	Mean (SD)	Median	Mean (SD)	Median
Rate (1-10)	7.64 (1.39)	8.00	7.41 (1.57)	8.00

Personal relevance (1-7)	4.87 (1.41)	5.00	N/A	N/A

^aA higher score represents a higher score on the program acceptability measure.

^bN/A: not applicable.

Dose-Response Relation Between Program Use and Intervention Outcomes

Table 7 provides an overview of the effects of program use (completeness and time of website use) on the primary and secondary outcomes according to the ITT analyses. Significant positive effects were found for completeness on all outcome measures (all $P < .003$). The more mothers had completed the intervention, the more likely they were to have their daughter vaccinated against HPV and make an informed decision, and were less likely to experience decisional conflict at follow up. In addition, positive effects of completeness were found with respect to all social-psychological determinants of HPV vaccination acceptability (eg, HPV vaccination intention, beliefs; see Table 7).

Time of website use had a positive effect on all outcomes (all $P < .003$), except for HPV vaccination uptake, risk perception when not vaccinated, subjective norms, and habit (Table 7). The more time mothers spent on the intervention, the more likely they were to make an informed decision, experience less decisional conflict, have a higher intention to vaccinate their daughter, have a more positive attitude, have more positive beliefs, have a lower risk perception of HPV vaccination, anticipate more feelings of regret about rejecting the HPV vaccine, report a higher relative effectiveness of the HPV vaccine, have higher self-efficacy expectations, and have more knowledge at follow up.

Effect sizes were small overall (see Table 7). Results from the complete case analyses were similar for both completeness and time of website use, except for a lack of effect of time of website use on intention.

Table 7. Effects of use on the outcome measures according to intention-to-treat analyses (N=3995).

Outcome ^a	Pretest, mean (SD)	Posttest, mean (SD)	Completeness		Time of website use

^aA higher score means a higher outcome (eg, more positive attitude) except for decisional conflict in which a higher score means less decisional conflict.

^bOR: odds ratio; OR>1 means the higher the score on a factor, the higher the outcome of IDM and higher chance of the daughter being vaccinated; OR<1 means the higher the score on a factor, the lower outcome of IDM and lower chance of the daughter being vaccinated.

^cHPV: human papillomavirus.

^dHPV vaccination uptake was not assessed at baseline.

^eN/A: not applicable.

^f $P<.003$ (significant; Bonferroni: 0.05/15 factors).

^g $P=.20$.

^hIDM: informed decision making.

ⁱ $P=.14$.

^j $P=.03$.

^k $P=.01$.

Discussion

Principal Findings

The aim of this process evaluation was to examine (1) program use, (2) program acceptability, and (3) the relationship between program use and acceptability and intervention outcomes for the web-based tailored intervention about HPV vaccination.

Program Use

Almost two thirds (62.80%) of the mothers who were invited to visit the intervention logged in to the intervention. This reach is adequate, and is comparable to that reported for other eHealth interventions (eg, [62]). However, it still leaves room for improvement to increase the reach by employing strategies such as arousing interest in this eHealth intervention. Support for this notion comes from Crutzen et al [63], who showed that arousing interest successfully increased the intention to visit a

website about hepatitis A, B, and C virus and the likelihood of clicking on the link to visit the website. Interest was aroused in the invitation by challenging the potential visitor regarding their knowledge about hepatitis and it was emphasized that the website provided this information in a comprehensible manner. Not only could interest be aroused in the invitation for HPV vaccination for girls and their parents but also, for instance, via other channels by which the target group is reached (eg, the internet, social media). In addition, research has shown a positive recommendation by word of mouth to be an important trigger for visiting a web-based intervention for the first time [19]. Word-of-mouth recommendations could be encouraged by providing “tell-a-friend” services at the web-based intervention [19].

Of the mothers that logged in to the intervention, nearly all visited at least one component. However, a small portion of the mothers (10.76%) did not view any of the intervention’s content after having logged in. This is likely due to technical difficulties because at follow up, some mothers (320, 12.75%) indicated that they were not able to see or hear the virtual assistants.

On average, time of website use, indicating the time mothers spent with the intervention, was adequate (21.39 minutes). This is longer than that reported by Brouwer and colleagues [26] in their review of web-based, interactive healthy lifestyle interventions, in which intervention exposure time varied from less than 10 minutes to 10–20 minutes. However, the present exposure time was lower than found by Sanders and colleagues [64] for their interactive, web-based tailored intervention promoting colorectal cancer screening (33 minutes). This difference could be explained by the controlled setting of their study [64], in which participants arrived 60 minutes prior to a medical appointment and viewed the intervention in the waiting room in the presence of a research assistant.

In addition, the mean completeness of the intervention was 50.04%. This indicates that the intervention fits well with the mothers’ needs, which is also supported by the results regarding acceptability (see below). The mean completeness in this study is comparable to that found by Watts and colleagues [65], who reported a completeness of 49.09% for a web-based prostate cancer screening decision aid.

Use of Intervention Components

When looking at exposure to intervention components, we found that mothers were most interested in the effectiveness of (alternative) methods to protect against cervical cancer (88.03% visited) and the risks of their daughter getting infected with HPV and developing cervical cancer (86.87% visited). These appear to be essential components of communication about HPV vaccination.

The “Value Clarification” component was visited the least overall (13.09%). This may be attributed to the fact that it was not easily found by participants: this page was only accessible once mothers completed the component “Weighing Pros and Cons.” Voncken-Brewster and colleagues [66] also found that participants overlooked a certain part of their intervention, and they successfully improved its visibility by repositioning it. In

order to promote exposure to values clarification, we could enhance its visibility.

The “General Information” component was completed the most overall (72.24%). This is likely due to the fact that the mother-like virtual assistant recommended starting with this component when mothers first entered the main menu, and that it was brief (2 pages). “Side Effects” and “Effectivity” were completed the least (both 0.85%). This could be explained by the fact that these two components contained the most links to in-depth information. Only a small proportion of the mothers ($\leq 13.22\%$) visited in-depth information.

Program Acceptability

The mothers evaluated the website as positive, as shown by the overall acceptability (7.64/10) and the scores on all acceptability measures (mean scores ranging from 4.34 to 5.71 on a 7-point Likert scale). The virtual assistants were also well appreciated (7.41/10). This is likely because it matched with the mothers’ preferences for more interactive personalized feedback [40]. This adequate acceptability is similar to the findings of Paiva and colleagues [67] for a web-based tailored intervention to increase HPV vaccination among young adult women (3.27/4.0). We believe the high acceptability in the present study can be attributed to the systematic and user-centered development process of the intervention [7]. The target group was extensively involved throughout the development. Not only did we fine-tune the content of the intervention to the mothers’ preferences and requirements but this also was considered in the design of the website, which was chosen by the mothers.

Furthermore, we found a positive relationship between acceptability and completeness ($P < .001$). This association was also found by others in a web-based intervention for breast cancer [68–70]. This finding underlines the importance of an intervention to be considered appropriate by the target group.

Effects of Program Use on Intervention Outcomes

In line with our expectations, completeness had a significant positive effect on all outcome measures (IDM, decisional conflict, social-psychological determinants of HPV vaccination uptake), including actual HPV vaccination uptake itself. Mothers who had completed more of the intervention were more likely to have their daughter vaccinated against HPV, and had higher levels of IDM and more positive scores on determinants of HPV vaccination acceptance. In particular, the effect on HPV vaccination uptake is an important finding, which was not found when simply contrasting the experimental to the control condition [30]. This stresses the importance of conducting a process analysis alongside such an effect evaluation. These results are very promising, considering the currently low HPV vaccination uptake rates in the Netherlands [6].

We believe that these positive effects can be attributed to the extensive tailoring throughout the intervention. Support for this notion comes from the study results indicating that mothers perceived the intervention to be well-tailored (5.22 on a 7-point scale). Not only did we tailor the content of the intervention to the mothers’ personal interest, it was also used to guide the mothers’ personal route through the intervention. The latter is likely to have improved the usability of the intervention.

Moreover, the intervention accounted for tailoring on a variety of themes. For example, it considered perceived barriers similar to the approach taken by Gerend and colleagues [9] as well as other beliefs, attitudes, subjective norms, habits, relative effectiveness, anticipated regret, risk perception, self-efficacy, and knowledge.

In contrast to our expectations, time of website use had a positive effect on all outcomes ($P < .003$), except for risk perception when not vaccinated ($P = .14$), subjective norms ($P = .03$), habit ($P = .01$), and vaccination uptake ($P = .20$). The latter is also in contrast to findings of a previous study [64]. An explanation for this lack of effects may be the measurement we used for time of website use, which may be less reliable for measuring exposure. We measured the total time spent on the website, but this does not indicate the specific pages the mothers had visited and for how long. In addition, we were unable to determine if there were any timeouts during a session and what the duration of a timeout was, because the intervention was web-based. For instance, they could have been distracted in the home environment during website use, which may have influenced the measured time of website use and may also have caused the lack of effect of acceptability on time of website use. An alternative, more accurate, measure can be found within the domain of education, namely time on task [71]. Future studies are needed to examine whether time on task (instead of total time of website use) has a positive influence on uptake.

Methodological Considerations

There are three methodological considerations. First, as mentioned above, the measurement of total time spent on the website seemed to be not entirely adequate to measure program use. In this study, completeness seemed to be a better indicator of use as it demonstrates the mother's navigation through the website, whereas time of website use did not. In addition, within (almost) every component, mothers were first asked a question about an HPV-related topic. The page was marked as "completed" if they provided an answer, which was necessary to obtain tailored feedback. Within the decisional balance, completeness was calculated based on the mother's answer to each statement. These are more complete indicators of actual use. Nevertheless, it is not an entirely complete indicator for use, since we could not measure whether they read generic information, listened to the tailored feedback from the virtual assistant, or saw a video. This may have influenced the dose-response effects found.

Second, considering the aim of initiating active processing of information, the positive effect found of completeness on habit may seem unwanted. However, at follow up, the mothers had already been exposed to the intervention, and were therefore likely to have actively processed the information. These results may indicate that the more mothers completed the intervention, the less they had to think about getting the HPV vaccine. The intervention may have helped them make a decision rather than inducing perceptions about HPV vaccination as something you take for granted, without thinking. In retrospect, the label "habit" appears to be misleading.

Third, the effect sizes found were small, which is in line with other web-based interventions targeting health behavior

outcomes [72]. Despite this, we believe that even small effects are of relevance in public health as they become substantial at the population level. After all, in the Netherlands, approximately 100,000 girls are invited to receive the HPV vaccine on a yearly basis.

Strengths and Limitations

The most important strength of this study is that we, to our knowledge, are the first within the field of HPV vaccination to conduct an extensive process evaluation. According to a review [24], the process evaluation of an intervention promoting HPV vaccination acceptance by tailoring information to participants' perceived barriers, such as that performed by Gerend and colleagues [9], was limited to the evaluation of intervention information (eg, the extent to which the information was informative and convincing). Other notable strengths are the objective measurement of HPV vaccination uptake, the dose-response effect of completeness on actual HPV vaccination uptake, the broad focus on outcomes (ie, determinants of HPV vaccination acceptance, uptake, IDM, and decisional conflict), and the adequate level of both (objectively assessed) program use and acceptability.

However, some limitations need to be addressed. First, there appeared to be technical difficulties despite our best effort to minimize such issues (eg, by extensively pilot testing the website using various devices). For instance, it turned out that a portion of the mothers were unable to see or hear the virtual assistants and that certain components did not work adequately among some of the mothers. Such technical difficulties are likely to have influenced website usability and therefore may have had a negative impact on program use. Second, this eHealth intervention requires mothers to have eHealth literacy [73]. People with lower eHealth literacy have been shown to have a lower educational level and to spend less time online [74,75]. It could be interesting to examine the extent to which eHealth literacy might have influenced use, acceptability, and effects. Considering the latter, we do not expect substantial differences since we did not find any differences in intervention effects among mothers with a low vs high educational level [30]. Third, it was hard to compare the study results to other studies because data on program use are often very poorly reported or even completely lacking (for a review, see [20]). Furthermore, the study was subject to a considerable amount of attrition. This is a common finding in studies on eHealth interventions [20]. Dropout appeared higher, for example, among mothers with a lower educational level, which has also been reported for other web-based tailored interventions [76]. In this study, missing data and selective dropout were handled by using multiple imputation [55,56]. Fortunately, there were nearly no differences between the results from the complete case analyses and the ITT analyses. Therefore, it seems unlikely that the effects found are spurious or due to selective dropout. Finally, caution is needed when generalizing the results of this study to the general population (ie, Dutch mothers of 12-year-old girls) because we were unable to check the representativeness of the sample. Besides, it should be noted that a very homogenous sample was reached. An undiversified reach is a known phenomenon within web-based interventions aimed at health promotion [20]. In our study, the mothers were predominantly born in the Netherlands,

highly educated, and likely to have a daughter that was vaccinated against HPV. However, results from the effect evaluation showed no differences in intervention effects in specific subgroups of participants, as indicated by moderation analyses with sociodemographic variables [30].

Conclusions and Recommendations

This process evaluation has demonstrated that program use and acceptability of the web-based tailored HPV vaccination intervention were adequate. We found a positive association between completeness and acceptability. Furthermore, dose-response effects were found for completeness and time of website use on (nearly) all social-psychological determinants of the mothers' decision making about vaccination, levels of IDM, and decisional conflict. Importantly, the extent to which mothers completed the intervention positively influenced their daughters' actual HPV vaccination uptake. These results indicate that this web-based, tailored intervention fits well with the mothers' needs and has the potential to increase HPV vaccination uptake. Because of the intervention's adequate (dose-response) effects and acceptability, the intervention has

recently been incorporated into the national HPV vaccination communication alongside the existing communication materials.

We recommend future interventions promoting HPV vaccination acceptance to (1) incorporate a process evaluation alongside the effect evaluation, (2), include strategies to arouse interest so as to expand reach, and to (3) include time on task. In addition, we recommend investigating the influence of different media types (eg, graphic vs nongraphic presentations) on decision making about HPV vaccination. For instance, Cox and colleagues [77] found that parents who viewed a graphic presentation of HPV-related risk information had a higher HPV vaccination intention compared to parents who viewed a nongraphic presentation. Furthermore, we recommend future research to examine differences in use and acceptability in specific subgroups of participants, for example by conducting moderation analyses with sociodemographics (eg, educational level). Finally, we recommend developing similar intervention models for (a) target groups other than mothers (eg, the daughter or sons in case they will become a next target group for HPV vaccination) and (b) other vaccinations (eg, maternal pertussis vaccination).

Acknowledgments

We would like to thank Petra Oomen (RIVM) and the panels (Veldkamp BV, Intromart GFK, and NGO Flycatcher) for their help with data collection. The Netherlands Organization for Health Research and Development (ZonMw) and Netherlands Organization for Scientific Research (NWO) support this study (grant-number: 50-51515-98-259).

Abstract

Background: Screening is an effective primary prevention strategy in health care, as it enables the early detection of diseases. However, the uptake of such screening remains low. Different delivery methods for screening have been developed and found to be effective in increasing the uptake of screening, including the use of web-based apps. Studies have shown that web-based apps for screening are effective in increasing the uptake of health screening among the general population. However, not much is known about the effective implementation of such web-based apps in the real-world setting. Implementation strategies are theory-based methods or techniques used to enhance the adoption, implementation, and sustainability of evidence-based interventions. Implementation strategies are important, as they allow us to understand how to implement an evidence-based intervention. Therefore, a scoping review to identify the various implementation strategies for web-based apps for screening is warranted.

Objective: This scoping review aims to identify (1) strategies used to implement web-based apps for health screening, (2) frameworks used for implementing web-based apps for health screening, (3) outcome measures of implementation strategies, and (4) effective implementation strategies.

Methods: This scoping review was conducted based on Arksey and O'Malley's framework. After identifying the review question, two researchers independently screened and selected relevant literature from PubMed, Embase, Cochrane, Cumulative Index of Nursing and Allied Health Literature, PsycINFO, International Standard Randomised Controlled Trial Number Registry, OpenGrey, ClinicalTrials.gov, World Health Organization International Clinical Trials Registry Platform, and Web of Science. This was followed by charting the data using a standardized form. Finally, we collated, summarized, and reported the results quantitatively and qualitatively based on the review objectives.

Results: A total of 16,476 studies were retrieved, of which 5669 were duplicates. From a total of 10,807 studies, 10,784 studies were excluded based on their titles and abstracts. There were 23 full-text articles reviewed, and 4 articles were included in the final analysis. Many studies were excluded because they focused on the effectiveness and not on the implementation of web-based apps. Facilitation was the most cited implementation strategy used, followed by reminders, clinical champions, and educational meetings and materials. Only 2 studies used implementation frameworks to guide the evaluation of their studies. Common outcome measures for implementation strategies were feasibility, fidelity, and penetration. Implementation strategies reported to be effective were quality improvement meetings, facilitation, educational meetings, and clinical champions.

Conclusions: There is a dearth of literature on the implementation of web-based apps for health screening. Implementation strategies were developed without any reported use of implementation theories or frameworks in most studies. More research on the development and evaluation of web-based screening app implementations is needed.

Introduction

Background

Screening is one strategy for health promotion and disease prevention. Screening is the process of identifying healthy people who may be at an increased risk of a particular disease or health problem [1]. Screening enables early detection of disease so that steps can be taken quickly, when relatively little damage has been done, to prevent the disease from progressing [2].

Prior Research

Many studies have shown screening to be effective in the prevention of diseases. A study in Korea reported that participation in cardiovascular disease (CVD) health screening was associated with lower CVD and all-cause mortality from CVD. There was also an increase in the early detection of CVD and a reduction in health care use and cost [3]. A systematic review of colorectal cancer (CRC) screening using fecal occult blood test showed that it is effective in reducing CRC mortality [4]. However, not all health screening tests are beneficial [5]. Studies have shown, for example, that prostate-specific antigen testing has led to overdiagnosis in up to 40% of the patients screened [6]. Screening tests are not uniformly accurate and are liable to false-positive results and overdiagnosis, which can cause harm to patients [5]. Therefore, care is needed in discussing the pros and cons of screening tests with patients, and to come to shared decision making about screening [5].

Methods of Screening Delivery

However, even when screening is beneficial and effective, its uptake remains suboptimal [7]. One reason is that screening cannot be done using just a single method, a “one size fit all” solution [7]. Different delivery methods must be used to address patient needs. A systematic review looking at improving health screening uptake in men showed that there was a variety of delivery methods for screening, ranging from use of education materials or video decision aids to web-based approaches [8].

Information and communication technology (ICT) has become an important platform to improve health care in the general population [9,10]. ICT use in health is sometimes also known as electronic health (eHealth) [11]. Many forms of eHealth interventions have been developed to improve public health care, in particular, web-based apps [12]; although, the use of electronic health records is another approach using ICT. Our focus in this study was on web-based approaches that do not require the use of an electronic health record, which is often not available, especially in low-resource settings.

A web-based app is defined as a program that is accessed over a network connection using HTTP rather than existing within a device’s memory. Web-based apps often run inside a web browser. However, web-based apps may also be client-based, where a small part of the program is downloaded to a user’s desktop, but processing is done over the internet on an external server [13]. With the proliferation of the internet and the accessibility of Wi-Fi and mobile data, web-based apps have become highly accessible to the general population, even in low-resource settings. The availability of smartphones enables the general population to have easy access to many web-based apps instantaneously from anywhere around the world. Web-based apps addressing different health needs like health screening, health promotion, and health advice have proliferated over the last decade. Many studies have shown that these web-based apps can be effective in changing health behaviors and improving health status [12]. For example, a completed systematic review showed that computer-based interventions are effective in improving sexual health knowledge [14].

Web-based apps for screening use questionnaires to accomplish screening. This screening can include mental and behavioral health as well as risk factor assessment. Examples include screening for depression risk, alcoholic addiction, and smoking. Users (patients) enter their responses based on the questions, and the web app sometimes provides appropriate advice to the patient. Several studies have shown that web-based apps for screening are effective in increasing the uptake of health screening among the population [15-17]. However, how successful implementation of these web-based health apps is accomplished has not yet been studied.

Rationale for Implementation Research

Implementation research involves the study of “the use of strategies to adopt and integrate evidence-based health interventions and change practice patterns within specific settings” [18]. Implementation science approaches use a systematic process of getting an evidence-based intervention (EBI) to reach the target population. Many frameworks, theories, and models are available to guide the implementation process [19]. By using frameworks appropriately to guide the implementation process, including development and design of strategies, *implementation strategies* can be developed to facilitate the uptake of EBIs in a specific health care setting. *Implementation strategies* are activities to enhance the adoption, implementation, and sustainability of EBIs [20]. Explicit implementation increases the likelihood of getting the EBI to the target population compared to leaving it to usual processes. For example, a study done in a clinic found that by attaching a reminder to each patient’s chart about guidelines on the management of dyslipidemia, 94% of patients received the

recommended treatment compared to just 35% in the control group [21].

Nonetheless, studies have shown that many EBIs do not reach their target population [22]. There is an obvious evidence-practice gap. Considerable effort is expended on the discovery of new EBIs but not on examining how these EBIs can be successfully implemented in health care settings [18]. A previous scoping review showed that limited research has been done to implement internet interventions for depression [23]. Therefore, there is a need to increase the amount of implementation to ensure that this evidence-practice gap can be reduced.

Studies show that implementing ICT in health care settings can be complex [23-25]. Systematic reviews demonstrate that organizational factors, setting, integration of the EBI into the workflow, and contextual and societal factors are important influences on the success of implementation [23,24]. However, most studies have focused more on the features of the ICT app and characteristics of end-users than on implementation factors or determinants [24]. Studies of the process of implementation and the factors associated with it are also lacking in the context of ICT in health care [24]. A systematic review demonstrated that studying the implementation process and factors influencing it are important in determining the success of implementation [23]. It is important to evaluate barriers and facilitators to successful implementation of an EBI [24].

Studying *implementation strategies* allows us to understand how to implement a particular EBI [26]. As noted in the literature, developing implementation strategies to overcome barriers to implementation is an important research agenda. Implementation strategies can be critical in bridging the evidence-practice gap when appropriately designed and deployed. Recognizing the importance of implementation strategies, various studies have been done to identify effective implementation strategies for various types of EBI [27]. However, there is a scant of literature on implementation strategies for web-based screening apps. A search of the PROSPERO (International Prospective Register of Systematic Reviews) database of systematic review protocols found no systematic reviews in this area. Therefore, a scoping review to identify the various implementation strategies for web-based screening apps appeared appropriate.

Methods

Overview

This scoping review uses the framework by Arksey and O'Malley [28] and Levac et al [29]. This methodology was selected because our aim is to explore the variation in implementation strategies used to implement web-based health screening apps. The Arksey and O'Malley framework is comprised of six stages: (1) identifying the research question; (2) identifying relevant studies; (3) study selection; (4) charting the data; (5) collating, summarizing, and reporting the results; and (6) consultation exercise.

Stage 1: Identifying the Research Question

Among studies exploring the implementation of web-based screening apps:

1. What implementation strategies were used and proven effective?
2. What studies were informed by implementation theories, models, and frameworks, and which ones in particular?
3. What implementation outcomes were measured?
4. What factors were identified as influencing implementation effectiveness?

Stage 2: Identifying Relevant Studies

The literature search was conducted using PubMed, Embase, Cochrane, CINAHL (Cumulated Index to Nursing and Allied Health Literature) via EBSCOHost, PsycINFO via OvidSP, ISRCTN (International Standard Randomised Controlled Trials Number) registry, OpenGrey, ClinicalTrials.gov, World Health Organization International Clinical Trials Registry Platform, and Web of Science for peer-reviewed scientific literature. The search was conducted in August 2018 for 2 weeks and concluded on August 28, 2018. Other search methods used to supplement the literature include reference or footnote tracking, using the "related articles" function in PubMed, citation tracking, personal knowledge and personal contacts, and contacting experts in the field. The search terms and search strategies are included in [Multimedia Appendix 1](#).

Stage 3: Study Selection

The inclusion criteria were studies that described any implementation strategies used to implement web-based apps for screening. Definition of specific terms are outlined as follows:

- Implementation strategies: methods or techniques used to enhance the adoption, implementation, and sustainability of EBIs [20]
- Web-based app: any program accessed over a network connection using HTTP rather than existing within a device's memory [13]
- Frameworks: A framework is a structure, overview, outline, system, or plan consisting of various descriptive categories (eg, concepts, constructs, or variables) and the relations between them that are presumed to account for a phenomenon [19].

The study must also include all age groups and genders; quantitative, qualitative, and mixed-method study designs will be included, and studies must be in the English language.

The exclusion criteria were as follows:

1. Non-web-based apps such as desktop-based, computer-based, CD-ROM interventions, mobile apps, and electronic health records
2. Nonempirical references such as trial protocols, book reviews, editorials, magazine articles, and theoretical or methodological articles
3. Non-English studies

Two independent reviewers screened the titles and the abstracts. The full texts of relevant articles were retrieved and screened

by the two independent reviewers. Any disagreements were discussed among the two reviewers, and a third reviewer was consulted if the two reviewers were unable to resolve any disagreements.

Stage 4: Charting the Data

Data were extracted using a standardized form. Two reviewers independently extracted the data. Any disagreements were resolved with a third reviewer. Data extracted from individual studies include author(s), year of publication, origin or country of origin (where the study was published or conducted), aims or purpose, frameworks, study population and sample size (if applicable), methodology or methods, intervention type, comparator and details of these (eg, duration of the intervention; if applicable), duration of the intervention (if applicable), outcomes and details of these (eg, measures; if applicable), and how the key findings relate to the scoping review question(s). The two reviewers met after extracting data from two articles to determine if the data extraction process was consistent with the research questions and purpose. Any inconsistencies were discussed until a consensus was reached. A third researcher was consulted when the two researchers were unable to reach a consensus.

Stage 5: Collating, Summarizing, and Reporting the Results

The results of this review were divided into three distinct steps based on recommendations by Levac et al [29]: (1) analysis

(descriptive numerical summary analysis and qualitative thematic analysis); (2) reporting the results according to the research questions; and (3) considering the meaning of the findings as they relate to the overall study purpose and discuss implications for future research, practice, and policy.

Stage 6: Consultation Exercise

The consultation exercise was conducted among experts in primary care, eHealth, and implementation science. The experts discussed the selection of articles and helped troubleshoot the issues that occurred during the review process. This exercise helped to validate and shape the study outcomes of this review.

Quality Assessment

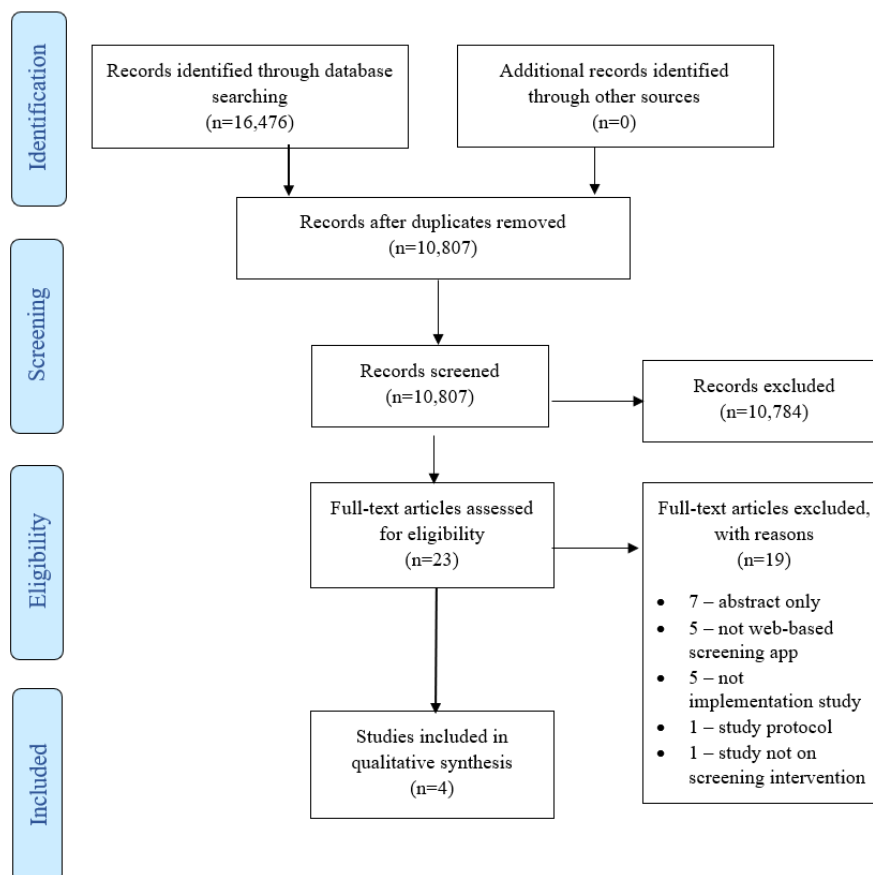

Quality assessment of the studies was done using the Mixed Methods Appraisal Tool (MMAT). MMAT was used as it is a validated tool to quickly assess qualitative, quantitative, and mixed methods studies [30]. This was done to assess the quality of the studies and not used as criteria for the inclusion of studies. The table reporting the quality assessment is included in [Multimedia Appendix 2](#).

Results

Included Studies

The searching databases yielded a total of 16,476 records. After the initial screening and removal of duplicates, 4 studies were included in this review ([Figure 1](#)).

Figure 1. Flow diagram of selection of studies.

Most studies were excluded at the title or abstract screening phase because the aim of this review was to identify implementation strategies for web-based apps. Most studies found through the database search evaluated the effectiveness of the web-based apps rather than focusing on their implementation. Only 4 studies fulfilled the inclusion criteria

[31-34]. Of these studies, 3 were conducted in primary care settings and 1 in an emergency department. All the studies were descriptive in nature, and the study duration ranged from 2 to 15 months. The characteristics of each study are summarized in Table 1.

Table 1. Characteristics of included studies.

Authors	Year	Intervention	Setting	Study population	Methods	Implementation duration
Webb et al [31]	2018	Health and lifestyle screening tool ("app"), Check Up GP ^a for young people in an Australian general practice	<ul style="list-style-type: none"> • Australia • General practice 	<ul style="list-style-type: none"> • Patients: young people 14-25 years of age • HCP^b: GP, practice manager, reception coordinator, and receptionists 	<ul style="list-style-type: none"> • Qualitative: semistructured interviews and focus groups • Quantitative: cross-sectional survey 	2 months
Diez-Canseco et al [32]	2018	A web-based mental health screening app	<ul style="list-style-type: none"> • Peru • Primary care 	<ul style="list-style-type: none"> • Patients: adults ≥18 years of age • HCP: midwives, nurses, and nurse assistants 	<ul style="list-style-type: none"> • Mixed methods • Qualitative: face-to-face structured interviews with HCPs and patients • Quantitative: web-based data collection platform 	9 weeks
Krist et al [33]	2014	MOHR ^c , a web-based health risk assessment tool	<ul style="list-style-type: none"> • United States • Primary care 	<ul style="list-style-type: none"> • Patients: adults • HCP: clinicians, front desk staff, practice rooming staff, and medical assistants 	<ul style="list-style-type: none"> • Cluster-randomized, mixed methods implementation trial • Qualitative: interviews with HCPs • Quantitative: data from research networks and the MOHR tool 	10 months

Quality Assessment

The single randomized controlled trial included in this review was of moderate quality [33]. The 2 arms were not comparable at baseline, and the outcome assessors were not blinded [33]. The other 3 studies contained both qualitative and quantitative components [31,32,34]. For the qualitative component, 2 studies were of good quality [31,32]. As there was no clear descriptions on how the data were collected, analyzed, and interpreted, 1 study was considered to be of poor quality [34]. For the quantitative component, 2 studies were of moderate quality, as the sample population and the risk of nonresponse bias of the studies were not clearly described [32,34]. The other study was of good quality [31].

Implementation Frameworks and Strategies for Web-Based Screening Apps

Only 2 studies used frameworks to guide and evaluate the process and outcomes of the study. However, in both studies, a framework and theory were used to guide the evaluation of the studies and not on the development of the implementation strategies. Table 2 summarizes the implementation strategies and frameworks used in each study. The types of frameworks were categorized based on Nilsen's [19] taxonomy of implementation frameworks. The implementation strategies are categorized based on the Effective Practice and Organisation of Care taxonomy [35].

Table 2. Implementation frameworks and strategies used for web-based apps.

Authors	Frameworks	Types of framework [19]	Implementation strategies [35]	Implementation activities
Webb et al [31]	NPT ^a	Implementation theories	Reminder	Phone call and SMS as reminder to patients to complete the app
			Reminder and facilitation	Receptionist to prompt patient to complete app in the waiting room using tablet
			Continuous quality improvement	Quality improvement meetings with HCPs ^b
			Educational materials	Provision of educational documents to support HCPs
Diez-Canseco et al [32]	None	N/A ^c	Leadership engagement/buy-in	Engaging policy makers for support and buy-in
			Educational meetings	Training for HCPs
			Technical assistance	Telephone and face-to-face support, and supervision for HCPs throughout the implementation period
			Coaching	Regular supervision meetings with HCPs to troubleshoot problems encountered throughout the implementation period
Krist et al [33]	RE-AIM ^d	Evaluation framework	Clinical champions	Appointment of practice champions
			Educational meetings	Training for HCPs
			Facilitation	Mailed invitations to complete the app
			Facilitation	Kiosk provided in the clinic waiting room to complete the app with help from researcher
			Facilitation	Completion of the app via phone call by researcher
			Facilitation	Completion of the app via tablet with help from either researcher, practice rooming staff, or medical assistant in the clinic waiting room
Scribano et al [34]	None	N/A	Patient education and facilitation	Nurses and receptionists provided instruction forms to patients for the screening kiosks
			Environment	Placing screening kiosks in strategic locations
			Clinical champions	Appointment of practice champions

^aNPT: Normalization Process Theory.^bHCP: health care provider.^cN/A: not applicable.^dRE-AIM: Reach, Effectiveness, Adoption, Implementation, Maintenance.

Facilitation was the most cited strategy used. Other strategies that were cited more than once included reminders, clinical champions, and educational meetings.

Outcome Measures

The implementation outcomes for the studies included in this review were categorized based on the taxonomy of

implementation outcomes by Proctor et al [36]. The implementation outcomes can be broadly categorized into acceptability, adoption, appropriateness, feasibility, fidelity, implementation cost, penetration, and sustainability. Table 3 outlines the outcome measures reported in the studies.

Table 3. Outcome measures.

Authors, Outcomes measured	Implementation outcome
Webb et al [31]	
Number of times needed to provide support to staff on the use of the app	Feasibility
Location completed Check Up GP ^a	Feasibility
If patients received an SMS with a link to Check Up GP before attending the practice	Fidelity
If patients felt that they had sufficient privacy when completing the app	Fidelity
Postimplementation staff interviews and focus group discussions based on NPT ^b	Acceptability, adoption, appropriateness, feasibility, fidelity, sustainability
Diez-Canseco et al [32]	
Number of screenings	Penetration
Fidelity to screening	Fidelity
Integration of screening into routine clinical service	Sustainability
Krist et al [33]	
Reach: proportion of eligible patients approached who completed a MOHR ^c assessment	Penetration
Adoption: percentage of practices approached for study participation who agreed to participate	Adoption
Implementation: how practices integrated MOHR into their workflow and the time and staff needed to carry out implementation steps	Fidelity
Maintenance: whether early intervention practices continued to use MOHR after the study	Sustainability
Scribano et al [34]	
Number of screenings completed by patients	Penetration
Computer technology failure rate	Feasibility

Effective Implementation Strategies

Different studies revealed different implementation strategies that were reported to be effective in their settings (Textbox 1).

For Webb et al [31], the quality improvement meetings using the Plan-Do-Act-Study framework were reported to be effective.

Textbox 1. Effective implementation strategies.

<p>Health care providers</p> <ul style="list-style-type: none"> • Quality improvement meetings • Facilitation • Educational meetings • Clinical champions <p>Patients</p> <ul style="list-style-type: none"> • Environment • Facilitation

In the study conducted by Diez-Canseco et al [32], the authors stated that training health care providers was the key to promote use of the web-based app. Supervision was another important strategy to troubleshoot issues when implementing the web-based app.

The study also reported that facilitation by researchers on-site helped in the implementation process. Comparing different sites using the web-based app, the authors found that using the web-based app in the waiting room was the most effective compared to other settings (84%) [31].

For Krist et al [33], the authors compared implementation strategies used in nine different primary care clinics. They found that the strategy with the highest screening completed was to complete the app in the clinic waiting room with facilitation from the researcher (94.4% completion rate). Overall, they found

that facilitation from staff in the clinic to help the patient complete the web-based app was the key to successful implementation. There was a higher completion rate with facilitation from staff compared to no facilitation (71.2% vs 30.3%) [33].

In the study by Scribano et al [34], appointing nurse champions helped to increase the screening rate. Another strategy that improved the screening rate was moving the kiosk to a more strategic location in the emergency department.

Discussion

Principal Findings

This review revealed that there is a very small set of literature reporting on the implementation of web-based apps for screening. Many studies evaluated the effectiveness or application of web-based screening apps, but very few described how to implement them [10,25]. The lack of literature found in this review suggests that there is a need for more implementation studies to be conducted in this area. Many studies have shown that implementation will not happen on its own, and implementation has to be planned to succeed [37].

Integrating an implementation study with an effectiveness study may be one way forward. Hybrid study designs may yield more information, as both the effectiveness of the intervention and the implementation can be assessed in a single study [38]. This may also reduce the time needed to translate an EBI into practice. However, these study designs require more expertise, resources, and manpower to conduct [38]. Therefore, it may not be feasible to conduct a hybrid study in settings with limited resources.

In this review, the most common implementation strategies used in implementing web-based apps were facilitation, education, and clinical champions. Most of these strategies targeted only patients and health care providers. Only 1 study mentioned strategies related to leadership engagement [32]. The strategies found in this review were limited to smaller scales and local contexts.

There was also no clear discussion on how strategies were developed or designed for implementation. Using a systematic process and determinant frameworks to help guide the development of strategies can be important for successful implementation and evaluation [19]. Having a systematic process for developing strategies will also help others replicate the process if the implementation was successful. We found that only 2 of the 4 studies used implementation frameworks or theories. This is consistent with the implementation research literature [19]. Without a solid theoretical foundation, it is challenging to explain why an implementation fails or succeeds [19]. Currently, many theories and frameworks are available for implementation research [19]. By using a combination of these theories or frameworks, researchers may better understand how to plan an implementation study systematically. By testing strategies and frameworks, new knowledge can be gained for future implementation studies.

In this review, different outcome measures were used in each study. However, there was no clear explanation of how the authors of the studies determined which outcome to measure. Which implementation strategies contributed to the outcomes were not clear because several different strategies were used in most studies, and their individual effects could not be evaluated. Therefore, we were unable to conclude which implementation strategies were useful. The lack of implementation frameworks or theories used in the studies may have contributed to this issue. The process of developing implementation strategies should be done systematically, ideally to link each strategy to different outcomes. If this is feasible, it could allow us to assess which strategies work. This may also allow researchers to further explore why a particular strategy works for a specific outcome. Lack of effect may lie with the implementation strategy itself or may be related to how the implementation strategy was implemented. Therefore, it is crucial that researchers give adequate thought to the implementation outcomes they measure and how an implementation strategy might affect each outcome. In addition, the field of implementation research is shifting from an exclusive focus on the effectiveness of implementation strategies to a focus on how strategies achieve their effect, if any, and on the factors that make implementation, across a spectrum of evidence-based practices, including ICT approaches, either more or less likely to be successful. Future studies will hopefully include this broader focus, as the current literature does not go beyond a simplistic examination of the implementation strategies' effectiveness.

Strengths and Limitations

This review may be limited because only English language studies were included. Another limitation could have been related to screening titles and abstracts. This may have limited the inclusion of studies if implementation strategies were not discussed in the abstract. However, based on our review, we found that most of the implementation strategies could be identified from abstracts alone. To this end, this scoping review revealed that only a few studies addressed the implementation of web-based health screening apps, and therefore, more research is needed in this area.

Conclusion

This scoping review shows that the study of implementation of web-based apps for screening is still in its infancy. Many studies have assessed the effectiveness of web-based apps, but only a few have focused on how to implement them. We were able to identify different implementation strategies for implementing web-based apps for screening. However, there is little evidence that the strategies reported were systematically developed using theories or frameworks. The lack of frameworks and theories used in these studies was also evident. There is a need to study not only the effectiveness of implementation strategies but the process of implementation and how this affects outcomes. This review shows that more work is still needed to study implementation of web-based apps for screening in a systematic process based on implementation theories and frameworks.

Abstract

Background: In patients with severe asthma, high-altitude climate treatment has been shown to improve asthma control. However, asthma symptoms and limitations may increase after finishing inpatient rehabilitation programs and returning to sea level.

Objective: We assessed the effectiveness of a patient-tailored, internet-based, self-management strategy in addition to usual care after finishing high-altitude climate treatment.

Methods: We performed a randomized controlled trial with a 1-year follow-up in patients from a high-altitude asthma center in Davos, Switzerland. At the end of a 12-week multidisciplinary rehabilitation program, 62 adults with asthma were randomized to receive either internet-based self-management support in addition to usual care (n=33) or usual care only after discharge (n=29). The endpoints were changes in asthma-related quality of life according to the Asthma Quality of Life Questionnaire (AQLQ) (a higher score is better) and asthma control according to the Asthma Control Questionnaire (ACQ) (a lower score is better), with a minimally important difference of 0.5 points for both.

Results: Asthma-related quality of life and asthma control declined over time in the usual care strategy group, whereas there was a slower decline in the internet-based strategy group. For both endpoints, mixed-model analysis showed a significant positive effect in favor of internet-based self-management during follow-up (mean AQLQ score difference 0.39, 95% CI 0.092-0.69; $P=.01$ and ACQ score difference -0.50 , 95% CI -0.86 to -0.15 ; $P=.006$), which was prominent among patients with uncontrolled asthma at discharge (AQLQ score difference 0.59, 95% CI 0.19-0.99; $P=.003$ and ACQ score difference -0.73 , 95% CI -1.18 to -0.28 ; $P=.002$).

Conclusions: Internet-based self-management support was associated with a smaller decline in quality of life and asthma control as compared with usual care, especially in patients with lower asthma control, after completion of high-altitude climate treatment. Internet-based self-management support in adults with severe asthma seems feasible and effective to maintain quality of life and asthma control.

Trial Registration: The trial is registered in the Netherlands Trial Register (NTR1995).

KEYWORDS

self-management; pulmonary rehabilitation; severe asthma; quality of life; asthma control; internet; monitoring

Introduction

In patients with severe refractory asthma, standard treatment according to international guidelines [1] is often not sufficient for achieving adequate asthma control [2]. Patients with persistent uncontrolled asthma can be referred to specialized asthma high-altitude clinics [3,4]. The population referred for in-patient pulmonary rehabilitation comprises patients with complex somatic and psychosocial problems [5]. The effectiveness of pulmonary in-patient rehabilitation in severe asthma has been established in a previous study that reported relevant improvements in asthma control, quality of life, and clinical outcomes with a 12-week multidisciplinary treatment program involving environmental trigger avoidance in an alpine climate among patients with severe refractory asthma [6]. Pulmonary rehabilitation should be part of an integrated care process and include self-management support. Changing patient behavior and ensuring maintenance are complex processes and require time. Currently, most self-management programs take between 6 and 12 weeks, and a longer duration is associated with greater improvements in physical and psychological functioning [6]. At present, there are sparse data on whether the benefits are sustained beyond the completion of high-altitude climate treatment, and patients are not always amenable to optimal self-management on returning to sea level in their own environment. A recent prospective uncontrolled observational cohort study suggested reduced exacerbation and sustained improvements in asthma control 12 months after high-altitude climate treatment for severe asthma as compared to the findings before admission, with only a slight relapse after discharge [7,8]. To sustain these improvements in long-term outcomes, appropriate self-management behavior during and after discharge is considered essential [9]. In order to achieve a sustained optimal long-term quality of life, we need a dependable system of coordinated health care intervention and communication, and components that include self-management support. Innovative forms of self-management support, including an online community, monitoring, communication, an action plan, and motivational feedback via the internet, have high potential to improve long-term outcomes.

Several recent studies have shown the feasibility and effectiveness of telemonitoring and self-management support [10-14]. Earlier studies of our group have demonstrated that internet-based self-management support improves quality of life, the number of symptom-free days, and clinical outcomes [15,16] in patients with partly controlled asthma.

However, the long-term effectiveness of sustaining self-management support via the internet in patients with severe asthma, who have completed in-patient pulmonary rehabilitation, has not been determined yet.

We hypothesize that self-management support via an internet-based service in addition to usual care will improve health-related quality of life and asthma control in patients with severe asthma who have completed pulmonary rehabilitation in a specialized high-altitude asthma clinic. We conducted a pragmatic randomized controlled trial to assess the effectiveness of an internet-based self-management support app in patients

who completed an in-patient pulmonary rehabilitation program at high altitude. In this trial, the primary outcome was asthma-related quality of life. In addition, we assessed asthma control and evaluated whether the degree of asthma control impacts the changes in quality of life. The process outcomes were engagement with the electronic health (eHealth) intervention and aspects of self-management and health education impact.

Methods

Study and Approval

The PRACTISS (Pulmonary Rehabilitation of Asthma: a Trial of sustained Internet-based Self-management Support) study is a randomized parallel group trial with 12 months of follow-up. The trial was performed from December 2012 through January 2016 in The Netherlands. The study was approved by the Medical Ethics Committee of the Leiden University Medical Center. All participants provided written informed consent upon entering the trial. The trial is registered in the Netherlands Trial Register (NTR1995) and conforms to the Helsinki Declaration.

Patients

Patients with a diagnosis of severe asthma according to the American Thoracic Society criteria were recruited from a specialized asthma clinic. All patients completed pulmonary rehabilitation in the Dutch Asthma Centre Davos (Switzerland). They were referred to the rehabilitation clinic because previous maximal treatment did not lead to adequate asthma control. The exclusion criteria that may interfere with compliance or reliability of the measurements were relevant somatic comorbidity, serious psychological problems, and psychiatric comorbidity assessed by the Hospital Anxiety and Depression Scale [17].

Design

The study was started during a high-altitude treatment program for severe asthma in a specialized asthma clinic. Upon enrolling in the study, approximately 1 week before completing the rehabilitation, patients were randomized via a computer-generated permuted block scheme by an independent researcher to either an internet-based strategy or usual care strategy group, with stratification for age and gender. Patients received explanations about the study procedures during the last days of their rehabilitation program, in addition to the usual preparation prior to discharge. After completing the program and finishing the baseline questionnaires, patients returned home and were treated by their own physicians who had referred them to the rehabilitation program. These physicians were notified about the participation of the patients in the study. Participants were asked to fill out questionnaires at 3, 6, 9, and 12 months.

Intervention

Patients in the internet-based strategy group had access to various tools that supported them to achieve optimal self-management skills. For effective self-management, asthma patients need to understand the condition, the purpose of medication, and the environmental influences. Furthermore, they need to recognize worsening respiratory function and know

when to seek medical attention [18]. The PatientCoach self-management support app was designed to promote attributes attained in the rehabilitation program. The self-management support modules could be customized by the health care professionals, allowing the program to be tailored to the specific needs of each patient. The modules included a written action plan, personalized asthma control questions, a daily asthma control questionnaire with lung function measurement, an actometer (Fitbit Ultra; Fitbit), patient health goals, a calendar, education provided by asthma centers, and a helpdesk. The app did not provide an option to communicate with a care provider.

The individual action plan was written by a physician from the rehabilitation clinic and included patient-tailored alarm signals, physician recommendations, and directives on when to contact health care professionals. Each patient together with the rehabilitation clinic physician formulated a patient-tailored question that served as a red flag for the patient to act upon when answered positively. In the daily asthma control questionnaire, patients could fill out the Asthma Control Questionnaire and the forced expiratory volume in one second (FEV₁) measurement. Patients in the internet-based strategy group were provided with a small personal device (PIKO-1, NSpire Health) to measure the FEV₁. The asthma control cutoff values that patients used to act upon were patient-tailored by the rehabilitation clinic physician. Internet support patients received an actometer (Fitbit) for daily use to measure activity. Each patient had a personal goal for daily steps. Patients formulated personal health goals together with the rehabilitation clinic physician for motivational purposes.

The calendar could be used by patients to list their health-related appointments. Patients received access to the educational material used by the rehabilitation clinic. The helpdesk was accessible for information and communication technology purposes. Several screenshots of the current version of the PatientCoach app are presented in [Multimedia Appendix 1](#). As this was a pragmatic trial, participants were free to use the intervention as often as they liked.

Health-Related Quality of Life

The primary outcome of this trial was health-related quality of life, which was assessed every 3 months using the validated and standardized Asthma Quality of Life Questionnaire (AQLQ) by Juniper et al [19]. A minimally clinically important difference of 0.5 was reported for the overall score [20]. The AQLQ consists of the following four subdomains: activity limitation, symptoms, emotional function, and environmental stimuli, and the overall score is determined. A higher score represents a more favorable outcome.

Clinical Control

Every 3 months, all participants in this study were asked to fill out a questionnaire assessing clinical control (six-question Asthma Control Questionnaire [ACQ6]) as an outcome parameter for study purposes. The ACQ6 questionnaire is a validated questionnaire to measure clinical control in patients with asthma [21]. For the ACQ6, a lower score represents a more favorable outcome.

eHealth User Engagement

User engagement was based on the amount of times a patient logged into the PatientCoach web app, as registered in the log files during the study period of 12 months.

Health Education

The aspects of self-management and impact of health education were measured using the Health Education and Impact Questionnaire (heiQ) [22]. The heiQ is a validated questionnaire consisting of eight independent scales, providing a rich range of information about the value of patient self-management programs. The domains comprise health-directed behavior, positive and active engagement in life, negative affect, self-monitoring and insight, constructive attitudes and approaches, skill and technique acquisition, social integration and support, and health service navigation [23]. Scores range from 1 to 4, with a higher score representing favorable outcomes, except for negative affect, where a lower score represents favorable outcomes.

Statistical Analysis

Power analysis showed that with the use of 36 patients per arm and an SD of changes in the AQLQ score of 0.75, we could expect to detect a minimally important difference of 0.5 points between AQLQ changes in the two arms ($\alpha=.05$, power=0.80). Patients were analyzed according to the intention-to-treat approach. To correct for possible selective nonresponse, missing data were imputed using linear regression modelling. We created 100 sets of imputations using disease severity, age, gender, center, strategy, and available quality of life data as regression variables. Rubin rules were used to congregate the imputations [24]. After imputation, we constructed a linear mixed-effects model assessing the impact of the intervention on quality of life and asthma control. In this mixed model, we used strategy, follow-up, strategy \times follow-up interaction, and a random intercept at the patient level to adjust for repeated measurements, as data from 3, 6, 9, and 12 months were imputed. These mixed models provided estimates for changes in asthma-related quality of life and asthma control during the follow-up period per strategy.

Patients were stratified for clinical asthma control at baseline using the ACQ6. Patients with an ACQ6 score <1.5 at baseline were considered as controlled, whereas those with an ACQ6 score ≥ 1.5 were considered as uncontrolled.

To define user engagement, we established a cutoff point of 12 logins per year. Patients with <12 logins were included in a low user engagement group, and those with ≥ 12 logins were included in a high user engagement group. We assessed whether there were differences in the AQLQ score between the user engagement groups.

To obtain insights into which self-management domains lead to improved quality of life, we used mixed models with the improvement in the AQLQ score with the internet-based strategy during follow-up as a dependent variable and the improvement in separate heiQ domains as the independent variable. All analyses were performed with Stata/IC 11.0 (Stata Corp).

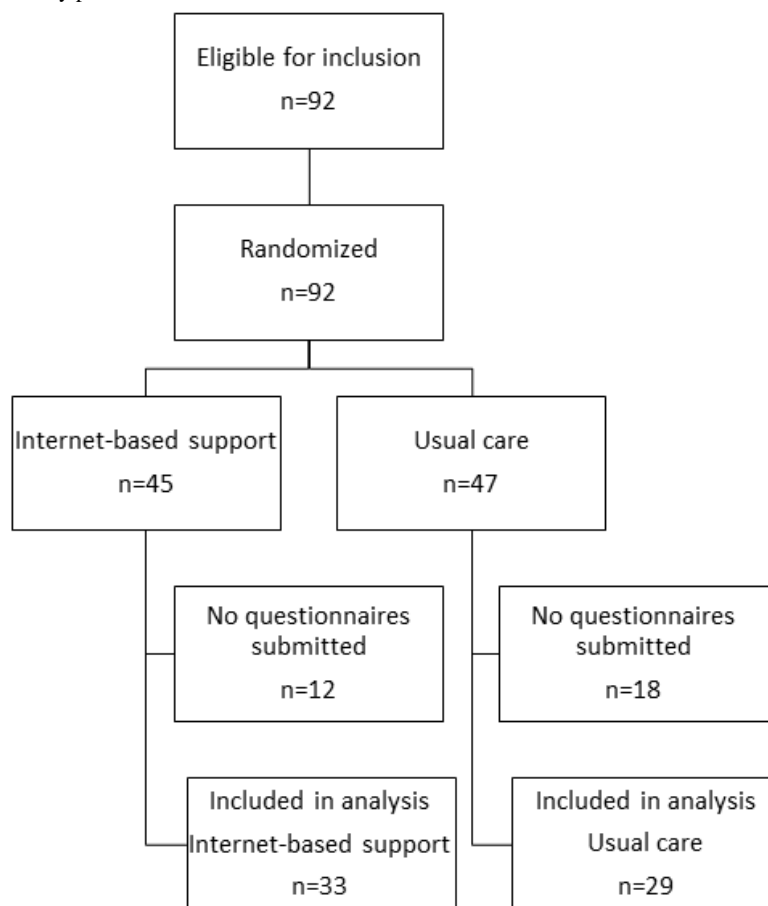

Results

Recruitment and Baseline Characteristics

In total, 92 patients from the Dutch Asthma Centre Davos were eligible for enrollment and were randomized after consent. However, 30 patients did not fill out the baseline questionnaire required to be included in the analysis. In our analysis, the usual

care strategy group included 29 patients and the internet-based strategy group included 33 patients. Figure 1 shows the patient flow diagram. Out of 310 records (five questionnaires for 62 patients), 91 (27%) were missing, with the internet-based strategy group missing 49 questionnaires (29%) and the usual care strategy group missing 34 questionnaires (23%) ($P=.22$). All baseline questionnaires were completed.

Figure 1. Flow diagram for the study patients.

The population characteristics at baseline are shown in Table 1. There were no relevant differences in age, sex, quality of life, and asthma between the two strategy groups. It should however be noted that clinically relevant [20], but statistically insignificant, baseline differences were found in quality of life

($P=.11$) and asthma control ($P=.17$). For both parameters, the usual care strategy group appeared to score slightly better than the internet-based strategy group. In the domain negative affect, the internet-based strategy group scored worse than the usual care strategy group.

Table 1. Baseline characteristics.

Characteristic	Usual care strategy (n=29), n (%) or mean (SD)	Internet-based strategy (n=33), n (%) or mean (SD)	P value
Age, years	44.0 (2.4)	46.7 (2.3)	.47

^aAQLQ: Asthma Quality of Life Questionnaire.

^bACQ6: six-question Asthma Control Questionnaire.

^cheiQ: Health Education and Impact Questionnaire.

Health-Related Quality of Life

The changes in asthma-related quality of life for both strategies are shown in [Figure 2](#). Quality of life declined in both groups during follow-up, showing less decline in the internet-based strategy group. There were no relevant between-group differences in quality of life at 12 months. Analysis by a linear mixed-effects model, with treatment, strategy, follow-up \times strategy interaction, and a random intercept at the patient level to adjust for repeated measurements, showed that the decline in quality of life according to the 3-month AQLQ scores (a higher AQLQ score is better) was significantly smaller during 12 months of follow-up in the internet-based strategy group than in the usual care strategy group (mean between-group AQLQ score difference 0.39, 95% CI 0.092-0.69; $P=.01$).

A similar graph showing quality of life during follow-up using absolute values instead of changes is shown in [Multimedia Appendix 2](#). As the baseline values for the ACQ6 ($P=.17$) and AQLQ ($P=.11$) were slightly different between the groups, but not statistically significant, we analyzed the results separately in strata according to well-established cutoff points for asthma control at baseline. This approach using stratification was also adopted in a previous study [25]. Patients with an ACQ6 score <1.5 were considered as controlled, whereas those with an ACQ6 score ≥ 1.5 were considered as uncontrolled. In the usual care strategy group, 16 patients were considered as controlled and 13 were considered as uncontrolled. In the internet-based strategy group, 12 patients were considered as controlled and 21 were considered as uncontrolled. Among patients with controlled asthma, a comparable decline was observed with

both strategies (mean AQLQ score difference 0.07, 95% CI -0.38 to 0.53 ; $P=.76$) ([Table 2](#)). However, among patients with uncontrolled asthma at baseline, the decline in quality of life was relatively smaller in the internet-based strategy group than in the usual care strategy group (mean between-group AQLQ score difference 0.59, 95% CI 0.19-0.99; $P=.003$) ([Figure 3](#)).

The results of the AQLQ domains are shown in [Table 3](#). Patients in the internet-based strategy group showed less worsening in activity limitation during follow-up as compared with the usual care strategy group (AQLQ score difference 0.44, 95% CI 0.06-0.82; $P=.02$). Overall, patients in the internet-based strategy group reported significantly less impact of asthma symptoms on quality of life during follow-up (AQLQ score difference 0.48, 95% CI 0.12-0.83; $P=.009$). Among patients with controlled asthma at baseline, no differences between the study arms were found. However, among patients with uncontrolled asthma at baseline, patients in the usual care strategy group reported significantly more impact of symptoms on quality of life, whereas those in the internet-based strategy group maintained better levels of symptom-related quality of life throughout the follow-up (AQLQ score difference 0.83, 95% CI 0.34-1.31; $P=.001$).

Similar results were found in the environmental stimuli AQLQ domain in favor of the intervention, specifically among patients with uncontrolled asthma. Overall, no relevant differences were found in the emotional functioning domain, except within the uncontrolled group, which had less impact of emotional functioning on quality of life with the internet-based strategy as compared with the usual care strategy.

Figure 2. Quality of life according to the Asthma Quality of Life Questionnaire (a higher score is better) during follow-up.

Figure 3. Quality of life according to the Asthma Quality of Life Questionnaire (a higher score is better) during follow-up in controlled and uncontrolled asthma patients.

Table 2. Asthma-related quality of life and asthma control between strategies.

Variable	Difference between baseline and follow-up, mean (95% CI)		Difference between strategies ^a , mean (95% CI)	P value

^aAQLQ: Asthma Quality of Life Questionnaire.

^bStatistically significant.

Asthma Control

The favorable findings in quality of life for the internet-based strategy were confirmed by changes in asthma control. A similar mixed model showed a favorable and statistically significant change in asthma control (a lower ACQ6 score is better) in the internet-based strategy group during follow-up as compared

with the usual care strategy group (mean ACQ6 score difference −0.50, 95% CI −0.86 to −0.15; $P=.006$) (Figure 4).

A similar graph showing asthma control during follow-up using absolute values instead of changes is shown in [Multimedia Appendix 3](#). With respect to the stratified analysis, a similar pattern was observed for asthma control. Among controlled patients, both groups showed a comparable trend of declining

asthma control during follow-up (mean ACQ6 score difference 0.04, 95% CI -0.60 to 0.53 , $P=.89$) (Figure 5). However, among uncontrolled patients, a clinically and significantly better asthma control level was sustained with the internet-based strategy

(mean ACQ score difference -0.73 , 95% CI -1.176 to -0.277 ; $P=.002$), and this was most noticeable at 6 and 9 months (Figure 5).

Figure 4. Asthma control according to the Asthma Control Questionnaire (a lower score is better) during follow-up.

Figure 5. Asthma control according to the Asthma Control Questionnaire (a lower score is better) during follow-up in controlled and uncontrolled asthma patients.

eHealth User Engagement

The results with respect to eHealth user engagement are depicted in Figures 6 and 7. There was a decline in login frequency in both the low and high user engagement groups. During the last

6 months of follow-up, asthma-related quality of life was significantly better maintained in the high user engagement group than in the low user engagement group (mean AQLQ score difference -0.39 , 95% CI $0.049-0.73$; $P=.03$).

Figure 6. Login frequency in low (left panel; n=18) and high (right panel; n=13) user engagement groups.**Figure 7.** Asthma-related quality of life in low and high user engagement groups. AQLQ: Asthma Quality of Life Questionnaire.

Health Education Impact

The results of the mixed models for health education impact are shown in Table 4. We assessed whether the improvement in asthma-related quality of life could be explained by the changes in the separate heiQ domains. Improvement in the domain of health care navigation during follow-up was

positively related to improvement in quality of life (AQLQ score difference 0.55, 95% CI 0.06-1.04; $P=.03$) in patients with access to the intervention. Although the domains of health-directed behavior, positive engagement, and monitoring and insight suggested a positive relationship with asthma-related quality of life (effect estimates of 0.28 [$P=.19$], 0.29 [$P=.19$],

and 0.40 [$P=.18$] points, respectively), none of these domains reached statistical significance.

Table 4. Relation between improvement in health education impact domains and improvement in quality of life.

heiQ ^a domains	Mixed model effect sizes ^b (β), mean (95% CI)	<i>P</i> value
Health-directed behavior	0.28 (–0.14 to 0.70)	.19
Positive engagement	0.29 (–0.15 to 0.73)	.19
Negative affect	–0.20 (–0.60 to 0.19)	.31
Monitoring and insight	0.40 (–0.18 to 0.97)	.18
Constructive attitude	0.15 (–0.26 to 0.57)	.47
Skill acquisition	0.03 (–0.58 to 0.64)	.92
Social support	0.13 (–0.24 to 0.49)	.49
Health care navigation	0.55 (0.06 to 1.04)	.03

^aheiQ: Health Education and Impact Questionnaire.

^bIn the domain of negative affect, a negative effect size reflects a favorable outcome, whereas in the other domains, a positive effect size reflects favorable outcomes.

Discussion

In this study, we assessed the effectiveness of internet-based self-management support in addition to usual care in patients with severe asthma after completing high-altitude climate treatment. Both the internet-based strategy and usual care strategy groups showed declines in asthma-related quality of life and asthma control during follow-up. This trend was expected as patients were enrolled upon completing a pulmonary rehabilitation just before returning to their home situation at sea level. However, the declines in both endpoints in the internet-based strategy group were significantly smaller than those in the usual care strategy group. In particular, in the internet-based strategy group, patients who still exhibited uncontrolled asthma at discharge did not show a further decline in quality of life in contrast to their counterparts in the usual care strategy group.

The individual domains of the AQLQ (activity limitation, symptoms, emotional function, and environmental stimuli) showed results similar to those of the AQLQ aggregated score described above. The most prominent results were found within the symptoms domain, where patients with controlled asthma reported an increase in symptoms during follow-up, with comparable effect sizes between the study arms. However, among patients with uncontrolled asthma at baseline, those who received the usual care strategy reported clinically relevant increases in symptoms, whereas those who received the internet-based strategy reported no increase in symptoms.

Asthma control did not decline greatly during follow-up in the internet-based strategy group, whereas asthma control declined in the usual care strategy group. Similar to the findings for quality of life, no significant difference in the decline in asthma control was found between the study groups among patients with controlled asthma at discharge. However, among patients with uncontrolled asthma, no decline in asthma control was observed with the internet-based strategy.

There are sparse data regarding the effectiveness of self-management support strategies in patients with severe

asthma after completion of high-altitude climate treatment. Our results are consistent with the findings of previously published articles regarding interventions in patients with mild asthma [10–12,15]. In addition, our results substantiate the findings of a recently published uncontrolled observational study reporting sustained improvements in asthma control and quality of life after high-altitude climate treatment in the years before this study started [6,7]. To our knowledge, this is the first study to assess the effectiveness of internet-based self-management support in patients with severe asthma after completing high-altitude climate treatment.

Several possible limitations in this study need to be addressed, including possible selection bias, the nonresponse rate, and statistical power. As this was a self-management study and a pragmatic trial, we did not spend large amounts of time in motivating people during follow-up to fill out questionnaires, as this would be an intervention by itself and was not possible in the clinical setting after implementation. Therefore, in our data set, 27% (91/310) of possible entries were missing. However, as the rates of missing data in both groups were comparable, we assumed that there was no impact on the internal validity of the study. In addition, the relatively high drop-out rate is consistent with an earlier study in patients with severe asthma [6]. It is not clear whether this is due to omissions within the studies or the requirement of an alternative approach for the population to adhere to the study protocol. Another explanation might involve patients' initial willingness to cooperate with a study conducted by the rehabilitation center where they stayed for many weeks, resulting in the inclusion of patients without a high intrinsic motivation, who are usually not included in a typical 12-month trial. We imputed missing data using linear regression modelling with 100 sets of imputations, thereby minimizing the impact of missing data.

As we calculated the differences between baseline and follow-up, it could be argued that our results might be explained by selection bias as the usual care population had better, although not statistically significant, asthma-related quality of life and asthma control at baseline. Therefore, there might be more room for a decline in the follow-up period. To correct for

this possible bias, we stratified for asthma control at baseline, showing that quality of life and asthma control did not decrease in patients with uncontrolled asthma. We therefore conclude that this bias does not explain the current results.

Not all differences found in this study reached statistical significance, possibly due to the limited number of patients enrolled. Based on our power analysis, we aimed to enroll 72 patients (36 patients per arm) to have sufficient power for the detection of a minimally important difference. Of the 92 eligible patients, 62 contributed to the study. However, we had sufficient power to detect a minimally important and consistent difference of 0.5 points in the AQLQ and ACQ. Therefore, despite the fact that the number of patients could still be regarded as a limitation, we feel that the number of patients included was sufficient for our conclusions.

A further limitation of this study is that the results were based upon self-reported outcome measures, as we had no access to FEV₁ measurements or other biomarkers. Although such markers would definitely be of additional value, we feel that by using well-validated instruments our self-reported outcomes are sufficiently robust to draw conclusions.

One of the strengths of this study is the pragmatic approach we adopted. Patients were included by members of the rehabilitation center, indicating the feasibility of imbedding a self-management program on completing the rehabilitation program. The patients had access to a helpdesk service for technical support, but no follow-up from the rehabilitation center or the patient's own physician was required for support during the intervention. Certainly, regular visits to their own physicians continued to be applicable. Although this study does not amount to a formal feasibility study, the usability, accessibility, and more than monthly use of the intervention in half of the intervention group suggest that this self-management support intervention might be feasible without investments other than the introduction to the program during follow-up and the costs for technical maintenance of the system.

These findings confirm the presumption that patients with severe asthma who complete a high-altitude climate treatment deteriorate at a group level in terms of asthma control and quality of life after discharge. Partially, this could be attributed to regression to the mean, as patients leave the rehabilitation in

an optimized health status. However, the results suggest that this decline could be reduced by offering an internet-based self-management program specifically in patients who leave rehabilitation with uncontrolled asthma (ACQ score ≥ 1.5). These patients represent the group of patients in which achieving asthma control is most complicated. Additionally, without self-management support intervention, their quality of life and asthma control declined even further, resulting in lower scores than patients who were able to achieve asthma control during rehabilitation. However, with an internet-based self-management program, this group may be able to stabilize their symptoms, which is an important and clinically relevant improvement.

In this study, the results were achieved without any interference by health care professionals in the internet-based self-management program after discharge, suggesting that the intervention is easily feasible for implementation and the approach might be very cost-effective, although this needs to be confirmed in future research.

Other patients with asthma who have not completed rehabilitation might also benefit from such interventions. For instance, patients discharged after asthma-related hospital admission may benefit from the same self-management support tools. The support tools are easily tailored to patients with various degrees of severity, enabling health care providers to provide this intervention to patients with less severe asthma. Access to the internet has become ever more widespread, implying that internet-based self-management tools are already accessible to most patients in developed countries. The large dropout rate emphasizes the importance of motivating people prior to enrollment in postrehabilitation self-management interventions. Future research is needed as evidence of self-management support in patients with severe asthma remains limited. The assessment of lung function and biomarkers may be of additional value to establish the effectiveness of self-management outcomes.

In conclusion, internet-based self-management support is an effective addition to usual care in patients with severe asthma on completion of a pulmonary rehabilitation program. Implementation of such interventions is feasible in clinical practice and may contribute to the stabilization of symptoms in patients with severe asthma.

Acknowledgments

We thank the involved physicians, nurses, and lung function technicians for their help and active guidance throughout the study. This study was funded by Lung Foundation Netherlands, The Netherlands Organization for Health Research and Development (ZonMW), and Chiesi the Netherlands.

Abstract

Background: Patellofemoral pain (PFP) impairs joint- and health-related quality of life and may be associated with knee osteoarthritis. We developed a novel, 2-phase, stepped-care approach for PFP, combining (1) self-directed web-based education and exercise therapy with (2) physiotherapist-supported education and exercise therapy. Physiotherapy sessions can be provided using 2 different modalities: face-to-face and telerehabilitation.

Objective: This study aims to (1) determine the feasibility of our stepped-care approach, (2) explore patient-reported outcomes following self-directed web-based education and exercise therapy in people with PFP (phase 1), and (3) estimate the differences in treatment effects between face-to-face and telerehabilitation to support further education and exercise therapy (phase 2) in those who had not completely recovered following self-directed care.

Methods: Phase 1 involved 6 weeks of self-directed web-based education and exercise therapy. Phase 2 involved random allocation to a further 12 weeks of physiotherapist-led (up to 8 sessions) education and exercise therapy delivered face-to-face or via telerehabilitation to participants who did not rate themselves as completely recovered following phase 1. Feasibility indicators of process, adherence, and participant retention were collected as primary outcomes alongside patient-reported outcomes on Global Rating of Change and knee pain, disability, knee-related quality of life, pain catastrophism, kinesiophobia, and knee self-efficacy. All participants were assessed at baseline, 6 weeks, and 18 weeks.

Results: A total of 71 participants were screened to identify 35 participants with PFP to enter the study. Overall, 100% (35/35) and 88% (31/35) of the participants were followed up with at 6 and 18 weeks, respectively. In phase 1 of the study, participants accessed the My Knee Cap website for an average of 6 (7.5) days and performed the exercises for an average of 2.5 (3.6) times per week. A total of 20% (7/35) of the participants reported that they had completely recovered at 6 weeks. Furthermore, 93% (26/28) of the participants who were followed up and had not completely recovered at 6 weeks agreed to be enrolled in phase 2. No statistically significant differences were found between the face-to-face and telerehabilitation groups for any outcome. The novel stepped-care approach was associated with marked improvement or complete recovery in 40% (14/35) of the participants following phase 1 and 71% (25/35) of the participants following phase 2.

Conclusions: Self-directed web-based education and exercise therapy for people with PFP is feasible, as noted by the high rate of participant retention and home exercise adherence achieved in this study. Furthermore, 20% (7/35) of people reported complete recovery at 6 weeks. Both face-to-face and telerehabilitation physiotherapy should be considered for those continuing to seek care, as there is no difference in outcomes between these delivery modes. Determining the efficacy of the stepped-care model may help guide more efficient health care for PFP.

Introduction

Background

Patellofemoral pain (PFP) is the most common knee condition experienced by young adults, affecting approximately one in four people worldwide [1]. PFP is characterized by diffuse anterior knee pain during activities that load the patellofemoral joint, including stair negotiation, running, and squatting [2,3]. PFP also impairs joint- and health-related quality of life [4]; reduces physical function [2]; results in fear of movement [5]; alters movement patterns [6,7]; and is associated with manifestations of peripheral and central sensitization, including lower pressure pain threshold and facilitated temporal summation of pain [8].

Exercise therapy is considered the cornerstone treatment for PFP [9-11]. When provided with or without other treatments (manual therapy, taping, and bracing), exercise therapy reduces pain, improves function, and leads to greater recovery rates in the short- and long-term compared with a placebo or *wait and see* approach (when participants do not receive any intervention over the study period) [9,12,13]. However, 57% of people with PFP report unfavorable outcomes 5 to 8 years following treatment [14]. Patient education for PFP is considered a key treatment by international experts to optimize self-management and long-term outcomes [9,11,15]. Our recent systematic review indicates that patient education may lead to similar short-term outcomes for pain and function as exercise therapy in PFP, but it is under researched [16]. During the development of an education leaflet for people with PFP, patients consistently requested a dedicated website to facilitate patient education [17]. Web-based interventions might facilitate self-directed education and exercise therapy to reduce health care-related costs at the system and personal levels [18]. Self-directed web-based interventions for low back pain [19,20] and osteoarthritis [21] can lead to improved patient-reported outcomes, including disability and perceived benefit compared with the *wait and see* approach. The impact of self-directed web-based interventions for people with PFP is unknown.

Implementation of a stepped-care model for PFP could benefit both patients and health systems. Stepped care can be defined as a staged evidence-based system comprising hierarchically delivered interventions, from the least to the most intensive, linked to patients' needs [22,23]. The goal is to provide effective care with the least intensive treatment. Self-directed web-based care may reduce the burden of health professional consultations, but it is unlikely to benefit or satisfy all people with PFP. Additional supported education and exercise therapy may provide better outcomes in those continuing to seek care because of persistent pain. Education and exercise therapy can be provided via face-to-face or telerehabilitation delivery. Telerehabilitation produces similar benefits as the face-to-face delivery across several chronic conditions [19,24,25], including reports of no difference in pain and function when compared

with face-to-face rehabilitation following a total knee replacement [26]. No study has compared telerehabilitation with face-to-face delivery of physiotherapy care in people with PFP.

Objectives

This study was designed to (1) evaluate the feasibility of a stepped-care approach for people with PFP, (2) explore the effect of self-directed web-based education and exercise therapy on the perceived recovery and clinical outcomes of people with PFP (phase 1), and (3) estimate the differences in treatment effects between face-to-face and telerehabilitation delivery of physiotherapy to support further education and exercise therapy (phase 2) in those who did not completely recover following initial self-directed care.

Methods

Reporting, Registry, and Ethics Approval

This study was reported in accordance with the Consolidated Standards of Reporting Trials statement [27]. The study was approved by the La Trobe University Human Ethics Committee (process number: HEC17-102), and all participants provided written and verbal informed consent. We used 2 separate consent forms for phases 1 and 2 of our study. The protocol was a priori registered and approved by the Australian New Zealand Clinical Trials Registry (ACTRN12618000224224).

Participants

Participants with PFP aged between 18 and 40 years were recruited using advertisements at La Trobe University and gyms of Melbourne (Australia) and on social media (Facebook, blogs, and Twitter) between February 26 and July 1, 2018.

Eligibility criteria were based on a consensus statement on terminology, definitions, and clinical examination of people with PFP [2]. The following eligibility criteria were assessed by an experienced (>6 years) physiotherapist from the research group. Participants were included if they presented anterior or retropatellar pain (1) corresponding to at least thirty on a 100-mm visual analog scale (VAS) in the previous week; (2) for at least 3 months; or (3) during at least two or more activities from prolonged sitting, squatting, kneeling, running, ascending and descending stairs, jumping, and landing. Exclusion criteria included a history of any lower limb surgery, history of patellar subluxation or dislocation, ligament or meniscus tears assessed clinically, presence of neurological diseases, or individuals who had received oral steroids and opiate treatment in the last month [28].

Procedures

This study was designed to evaluate the feasibility of a stepped-care approach, including a randomized, clinical, single-center trial, comparing physiotherapy delivery modes. The novel stepped-care approach evaluated consists of 2 phases.

Phase 1 involved a pre-post design where all participants received 6 weeks of self-directed web-based education and exercise therapy.

Phase 2 involved a parallel-group randomized clinical trial (RCT). Participants were not informed of the existence of phase 2 when entering phase 1. Participants who were offered inclusion in phase 2 were those who did not rate themselves as *completely recovered* on the Global Rating of Change (GROC) 6-item Likert scale following phase 1. Each patient was offered the option to receive further 12 weeks of physiotherapy, which involved either face-to-face or telerehabilitation delivery, allocated randomly. All participants were reassessed after phase 2 (ie, at 18 weeks). Participants not receiving treatment during phase 2 (ie, those who *completely recovered* after 6 weeks) were also followed up at 18 weeks.

Randomization and Blinding in Phase 2

A member of the research team not involved in data collection generated randomization lists (block randomization; block size of 4-6) using a random number generator on the website (sealedenvelope.com). Group allocations were concealed using sequentially numbered, sealed opaque envelopes, which were opened by one member of the research team not involved in data collection or randomization following baseline assessment.

Assessor

The assessor was blinded to participant group allocation.

Participants

Participants were told that they would be randomly allocated to one of the two different education and exercise therapy treatments. Once randomized, care was taken to ensure that the

participants were unaware of the details of the alternative program (delivery mode). Participants were also instructed not to reveal the details of their allocated intervention to the blinded outcome assessor at the final follow-up (18 weeks).

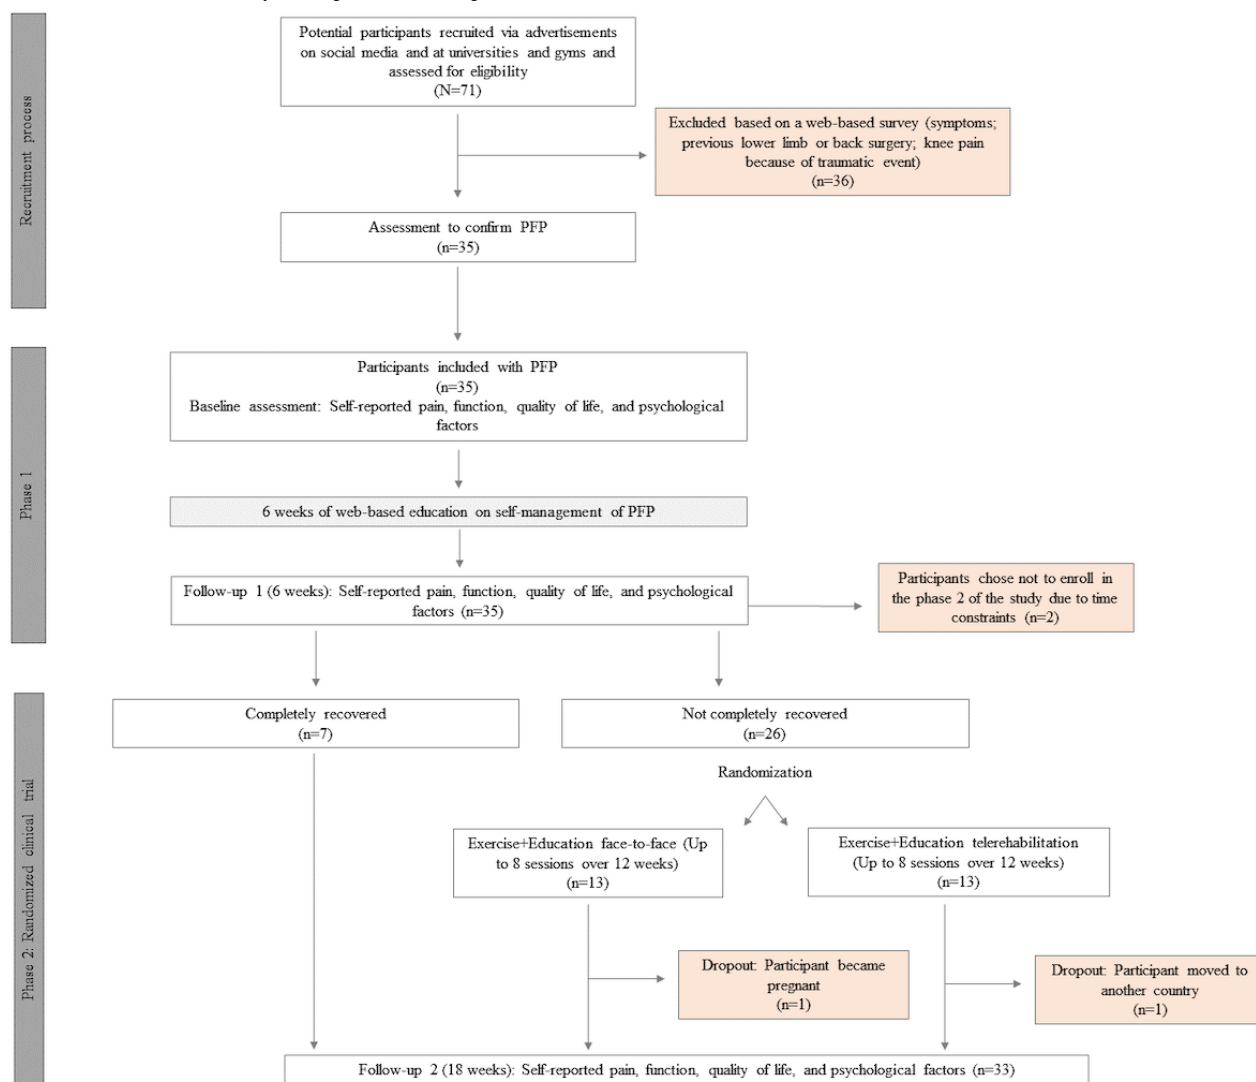

Therapist

A total of 5 registered physiotherapists (>5 years of clinical experience) delivered the physiotherapy treatment—3 physiotherapists delivered the intervention in face-to-face mode and 2 physiotherapists delivered telerehabilitation via Skype. Precautions were taken to ensure that the physiotherapists were unaware of the existence of another intervention group, with physiotherapists believing that they were participating in a case series design to evaluate the feasibility of the respective intervention they delivered.

Outcomes

The baseline, 6-week, and 18-week follow-up face-to-face assessments (Figure 1) were performed by the same blinded assessor at La Trobe Sports and Exercise Medicine Research Centre, La Trobe University, Melbourne, Australia.

All participants were asked to attend one 60-min initial screening and assessment at the university's physiotherapy department. All questionnaires were self-administered, and participants completed the questionnaires independently on paper. Before starting the questionnaires, participants were asked to report their age in years. Body mass and height were measured using a scale and a measuring tape fixed on the wall, respectively. BMI was then calculated as weight in kilograms divided by height in meters squared. Participants also reported their symptom duration (months).

Figure 1. Flow chart of the study. PFP: patellofemoral pain.

Primary Outcome

Recruitment rates were recorded and defined as the number of participants recruited each week. The consent rate was calculated by dividing the number of people who met the inclusion criteria by the number of people who consented to participate in both phases 1 and 2.

Adherence to phase 1 was monitored by assessing the number of accesses to the *My Knee Cap* website, monitored through an algorithm embedded in the website. Participants also completed an exercise log daily for 6 weeks to indicate the days they performed the exercises available on the website. Adherence to phase 2 was monitored through the number of appointments scheduled with the physiotherapist for each group. In addition, all participants received a logbook to add information regarding how many times they accessed the website and performed the exercises each week and to record any adverse events (defined as negative consequences of care that result in unintended injury or illness that may or may not have been preventable).

Primary Estimates of the Treatment Effect

GROC

Participants rated their perceived recovery at 6 weeks (phase 1) and 18 weeks (phase 2) following trial commencement on a 6-item Likert scale: (1) completely recovered, (2) markedly better, (3) moderately better, (4) same, (5) moderately worse, and (6) markedly worse. GROC is highly reliable, easily understandable, sensitive to change, and the preferred measure of pain and disability among people with PFP [29]. It also moderately correlates with pain and disability and strongly correlates with health-related quality of life changes [30].

Pain (VAS)

The worst knee pain intensity during the previous week was assessed on a 100-mm VAS, with 0 indicating *no pain* and 100 indicating *the worst pain possible* [31]. The minimal clinically important difference for people with PFP is 20 mm [32]. The VAS has been validated for people with PFP, and it has been reported to demonstrate high test-retest reliability [32].

Secondary Estimates of the Treatment Effect

Disability

The Anterior Knee Pain Scale (AKPS) is a self-reported 13-item questionnaire, with scores ranging from 0 to 100 and higher values indicating better knee function [33]. The minimal clinically important difference for people with PFP is 10 points [32]. AKPS has been validated for people with PFP and has been reported to demonstrate high test-retest reliability [32].

Knee-Related Quality of Life

The Knee Injury and Osteoarthritis Outcome Score-Quality of Life subscale is a self-reported 4-item subscale with responses ranging from 0 to 4. Responses are transformed to a scale of 0 to 100, with 0 representing extreme knee problems and 100 representing no knee problems at all [34].

Pain Catastrophizing

The Pain Catastrophizing Scale (PCS) is a self-reported 13-item questionnaire to describe the various thoughts and feelings a person might experience when they are in pain. Scores range from 0 to 52, with higher values indicating more severe catastrophic thoughts about pain [35]. PCS has been previously validated for people with musculoskeletal conditions and has high test-retest reliability [36].

Kinesiophobia

The Tampa Scale for Kinesiophobia (TSK) is a self-reported 17-item questionnaire to quantify fear of movement. Scores range from 17 to 68, with higher values indicating greater fear [37,38]. TSK has been previously validated for people with musculoskeletal conditions and has moderate test-retest reliability [37].

Knee Self-Efficacy

The Knee Self-Efficacy Scale (K-SES) is a self-reported 22-item questionnaire where the participant rates the certainty about the capability of performing an activity, despite pain/discomfort, on an 11-point Likert scale, ranging from 0 (not at all certain) to 10 (very certain). The sum of the item scores is calculated and then divided by the number of items, yielding a total K-SES score ranging from 0 to 10. Higher scores indicate greater knee self-efficacy.

Adverse Events

Participants were given a specific form to record any adverse symptoms or events they experienced during the study (eg, pain flares, muscle soreness, and injury unrelated to the trial). No instructions were provided regarding the intensity of pain that would characterize an adverse event.

Intervention

Phase 1 (0 to 6 Weeks)

During this phase, all participants received the same intervention: access to the *My Knee Cap* website for 6 weeks. The website provides education to participants with PFP on self-management of their knee pain based on current evidence [10,11,15], along with a self-directed exercise therapy program. The website was designed by the authors DS and CB, with the

assistance of a web designer, to be both didactic and engaging, with a simple user interface and navigation appropriate for patients with low health literacy. We asked for feedback on the content, language, and functionality of the website from one layperson diagnosed with PFP (end user), one physiotherapist experienced in managing PFP, and one researcher with a strong track record of publications in PFP. Refinements were made to the website based on this feedback before the commencement of the study.

The website provides public access to 4 main sections: (1) understanding your pain, (2) treatment options, (3) exercise program, and (4) patient stories.

The *understanding your pain* section provides information covering a variety of subjects, including diagnosis, prognosis, incidence and prevalence, noisy knees, fear of movement, self-management of exercise load, and self-management of pain.

The *treatment options* section includes treatment options that can be beneficial (taping/bracing, foot orthosis, and exercises) and information about common treatments with inconsistent evidence (knee surgery, ultrasound, and platelet-rich plasma).

The *exercise program* section is focused on 4 types of exercises targeting the trunk, hip, and knee muscles, based primarily on a previously published exercise therapy trial. The participants had access to videos demonstrating the exercises proposed in the *exercise program* section. Explanations about how to progress the exercises were also provided ([Multimedia Appendix 1](#)).

The *patient stories* section presents the stories of 2 patients (1 woman and 1 man), from a private physiotherapy clinic in Melbourne, with knee pain who had successful outcomes after engaging in education and exercise therapy.

All information on the website was provided in plain language, with multimedia resources such as infographics, animated videos, and podcasts, to facilitate engagement and understanding. After the baseline assessment, a physiotherapist introduced the content of the website and gave the password of the exercise videos that were included on the website during a 30-min orientation session. In addition, participants were asked to complete one exercise of each type 3 times a week for a period of 6 weeks and access the website as often as needed.

Phase 2 (6 to 18 Weeks)

Participants who reported themselves to be *completely recovered* did not receive further treatment during phase 2. Participants who reported not being completely recovered were randomized to 12 weeks of face-to-face- or telerehabilitation-delivered education and exercise therapy with a physiotherapist.

Participants were permitted up to 8 sessions with their physiotherapists to receive guidance on education and exercise therapy. The upper limit of physiotherapy sessions was determined through a previous feasibility study [39], high-quality RCTs [13], and discussion with physiotherapists providing our intervention. To reflect clinical practice, we did not specify a minimum number of sessions and at what exact time points physiotherapy sessions should occur. Typically, physiotherapy sessions were closer together in the early stages

(eg, every 1-2 weeks) and spread out toward the end of the 12 weeks (eg, monthly), as participants became more confident with their home exercise programs and knowledgeable about the condition. Education and exercise therapy that were provided were similar to what was available on the website, and the website was used to reinforce educational messages and exercise where relevant. The exercise therapy program and education content can be found on the *My Knee Cap* website and [Multimedia Appendix 1](#). Physiotherapists were permitted to provide additional exercise input, including gym-focused progression, if deemed appropriate. When required, gym memberships were provided.

Statistical Analyses

Statistical analyses were performed using SPSS version 23 (IBM, SPSS Inc). The level of significance was set a priori at $P < .05$. All statistical analyses were conducted by an investigator blinded to the group allocation.

Phase 1

Global perceived recovery after 6 weeks of self-directed web-based education and exercise therapy was reported descriptively (percentages). Within-group changes in primary and secondary estimates of effects were evaluated using paired t tests. Effect sizes (ESs) were calculated to guide the interpretation of the power of the comparison. ES values were defined as small (0.2-0.5), medium (0.51-0.80), or large (≥ 0.81) [40]. Correlations of exercise adherence with changes in patient-reported outcomes were performed using Pearson coefficient correlations.

Phase 2

Demographic data from the 2 groups (face-to-face and telerehabilitation) at 6 weeks were compared using independent t tests. Intention-to-treat analyses were used for all outcomes. We performed a 2×5 chi-square test for independence to investigate whether there was an association between GROCC outcomes and the groups to which the participants were allocated at the end of 18 weeks (face-to-face and telerehabilitation groups). Independent t test and ES were used to compare patient-reported outcomes between the face-to-face and telerehabilitation groups. Using the same criteria as phase 1, ES values were defined as small (0.2-0.5), medium (0.51-0.80), or large (≥ 0.81) [40].

Results

Recruitment and Feasibility

Between February 2018 and July 2018, 35 participants (27 women and 8 men) with PFP were recruited from 71 potential candidates. The recruitment rate was 2 participants per week over an 18-week period, with a consenting rate of 100% (35/35). Overall, 77% (27/35) of the participants included were recruited via advertisements on social media, 11% (4/35) via advertisements at La Trobe University, and 11% (4/35) via advertisements at gyms in the neighborhood of La Trobe University. The trial was completed in December 2018, with 100% (35/35) of the participants followed up at 6 weeks and 88% (31/35) followed up at 18 weeks. For phase 2, the

consenting rate was 93% (26/28), with 2 participants choosing not to enter because of time constraints, despite ongoing symptoms ([Figure 1](#)).

Adherence

Phase 1

All participants accessed the website at least once, with web usage data indicating that the participants accessed the website for an average of 6 (7.5) days over the 6 weeks ([Multimedia Appendix 2](#)). Exercises were reported to be performed on an average of 15 (12.2) days over 6 weeks, equating to an average of 2.5 (3.6) times per week (18/35, 52% of the participants completed the exercises on an average of at least three times per week). Low to moderate correlations were found for exercise adherence (total number of days on which exercise was performed) with self-reported pain ($r=0.33$; $P=.03$), knee-related quality of life ($r=-0.52$; $P=.001$), self-reported function ($r=-0.37$; $P=.01$), pain catastrophizing ($r=0.52$; $P=.001$), kinesiophobia ($r=0.39$; $P=.009$), and knee self-efficacy ($r=-0.51$; $P=.001$).

Phase 2

Participants enrolled in phase 2 ([Multimedia Appendix 3](#)) performed an average of 4.5 (1.5) physiotherapy sessions in the face-to-face group and an average of 5.2 (2.1) physiotherapy sessions in the telerehabilitation group.

Adverse Events

Phase 1

One participant reported an adverse event unrelated to the trial. Furthermore, 11 participants reported knee pain flares or muscle soreness of low intensity while performing the exercises, with most occurring in the first week ([Multimedia Appendix 2](#)) and no impact on participation in future exercise sessions.

Phase 2

Two adverse events unrelated to the trial were reported, one from each group. One participant fell on their knees while running to catch a bus, but this event did not alter the treatment. The other participant fell on a staircase, which led to a few scratches on her knee, delaying physiotherapy treatment for 2 weeks. No adverse event related to the trial was reported because of physiotherapy consultations or exercise therapy during phase 2.

Secondary Outcomes

Phase 1

After 6 weeks of self-directed web-based education and exercise therapy, 20% (7/35) of the participants starting the trial reported that they had *completely recovered*, 20% (7/35) were markedly better, 40% (14/35) were moderately better, 17% (6/35) were same, and 3% (1/35) were moderately worse. Patient-reported outcomes at baseline and after 6 weeks are described in [Table 1](#). Large improvements across the cohort occurred for worst knee pain in the previous week (ES=1.04), knee-related quality of life (ES=-1.13), disability (ES=-0.89), pain catastrophizing (ES=1.21), and knee self-efficacy (ES=-1.01), along with a medium improvement in kinesiophobia (ES=0.78).

Table 1. Comparisons between patient-reported outcomes at baseline and after the 6-week self-directed web-based education and exercise therapy.

Outcomes	At baseline, mean (SD)	At 6 weeks, mean (SD)	Mean difference (95% CI)
Worst knee pain (visual analog scale ^a , range: 0-100)	58.03 (17.54)	29.39 (25.52)	28.64 (18.88-38.39)
Knee-related quality of life (Knee Injury and Osteoarthritis Outcome Score-Quality of Life subscale ^b , range: 0-100)	41.86 (20.28)	66.67 (21.69)	-24.81 (-32.60 to -17.02)
Disability (Anterior Knee Pain Scale ^b , range: 0-100)	69.27 (13.41)	82.36 (13.87)	-13.09 (-18.34 to -7.85)
Pain catastrophizing (Pain Catastrophizing Scale ^a , range: 0-52)	21.73 (11.91)	10.09 (9.14)	11.64 (8.22-15.05)
Kinesiophobia (Tampa Scale for Kinesiophobia ^a , range: 17-68)	38.48 (6.14)	33.03 (6.83)	5.46 (2.99-7.92)
Knee self-efficacy (Knee Self-Efficacy Scale KSE-S ^b , range: 0-10)	5.57 (1.71)	7.28 (1.53)	-1.71 (-2.31 to -1.11)

^aHigher scores indicate worse condition.

^bLower values indicate worse condition.

Phase 2

A total of 26 participants entered phase 2 and were randomly allocated to face-to-face- (n=13) or telerehabilitation-delivered education and exercise therapy (n=13). No between-group differences were found for demographics between these 2 groups (Table 2), and no between-group differences were found for any secondary estimates of treatment effect (Table 3). Both groups had one dropout during the intervention period, with one participant becoming pregnant and another moving to a different country.

The participants' GROC outcomes after 18 weeks are shown in Figure 2. There was no significant difference in the proportion

of GROC outcomes between the face-to-face and telerehabilitation groups ($\chi^2_5=2.03$; $P=.73$).

No significant difference between face-to-face- and telerehabilitation-delivered education and exercise therapy was found for any patient-reported outcomes (Table 3). The between-group differences for the patient-reported outcomes had a moderate effect on worst knee pain in the previous week (ES=0.72) and a small effect on knee-related quality of life (ES=0.22), disability (ES=0.16), pain catastrophizing (ES=0.33), kinesiophobia (ES=0.22), and knee self-efficacy (ES=0.16). Overall, 71% (25/35) of all participants entering the study reported having completely recovered or markedly improved following phase 2.

Table 2. Demographic characteristics of face-to-face and telerehabilitation groups.

Variables	Face-to-face group, mean (SD)	Telerehabilitation group, mean (SD)	P value
Age (years)	32 (6)	31 (6)	.62
BMI (kg/m ²)	27.58 (6.71)	26.46 (8.97)	.59
Symptoms duration (months)	53 (55)	32 (29)	.14

Table 3. Between-group comparisons for patient-reported outcomes at 6 and 18 weeks.

Outcomes	Face-to-face group, mean (SD)	Telerehabilitation group, mean (SD)	Mean difference (95% CI)
Worst knee pain (visual analog scale, range: 0-100)			
6 weeks	32.31 (22.51)	42.31 (23.15)	-10.00 (-26.36 to 6.36)
18 weeks	18.46 (18.46)	33.08 (22.13)	-14.62 (-31.25 to 2.02)
Knee-related quality of life (Knee Injury and Osteoarthritis Outcome Score-Quality of Life subscale, range: 0-100)			
6 weeks	63.94 (16.76)	56.73 (21.87)	7.21 (-7.27 to 21.69)
18 weeks	68.27 (21.57)	73.08 (21.71)	-4.81 (-20.56 to 10.95)
Disability (Anterior Knee Pain Scale, range: 0-100)			
6 weeks	78.54 (12.61)	77.69 (12.94)	0.85 (-8.34 to 10.03)
18 weeks	86.54 (10.59)	84.62 (13.49)	1.92 (-6.99 to 10.84)
Pain catastrophizing (Pain Catastrophizing Scale, range: 0-52)			
6 weeks	8.23 (6.92)	14.46 (10.26)	-6.23 (-13.70 to 0.76)
18 weeks	5.92 (6.02)	8.54 (9.44)	-2.62 (-8.29 to 3.06)
Kinesiophobia (Tampa Scale for Kinesiophobia, range: 17-68)			
6 weeks	34.15 (7.72)	35.31 (5.01)	-1.15 (-6.07 to 3.76)
18 weeks	30.38 (7.12)	31.77 (5.43)	-1.39 (-6.07 to 3.30)
Knee self-efficacy (Knee Self-Efficacy Scale, range: 0-10)			
6 weeks	6.95 (0.93)	6.74 (1.75)	0.21 (-0.84 to 1.25)
18 weeks	7.64 (1.45)	7.36 (1.98)	0.28 (-1.08 to 1.65)

Figure 2. Global Rating of Change outcomes of the face-to-face and telerehabilitation groups.

Discussion

Summary of the Findings

This study confirms the feasibility of evaluating the efficacy of a stepped-care approach, including initial self-directed web-based education and exercise therapy, followed by physiotherapist-led education and exercise therapy. Overall, 35 participants with PFP were recruited from 71 potential candidates, with a recruitment rate of 2 participants per week and all eligible participants consenting to enter the trial. The follow-up rate was high for both phases of the trial, including 100% at 6 weeks and 88% at 18 weeks.

Six weeks of self-directed web-based education and exercise therapy was associated with 1 in 5 participants with PFP rating themselves as *completely recovered*. Self-directed care was associated with moderate to large improvements in pain, disability, kinesiophobia, pain catastrophizing, knee self-efficacy, and knee-related quality of life. Self-reported adherence to exercise (number of days completed) during phase 1 was related to clinical improvements in pain, function, and psychological outcomes. Although not significant, findings reported by Rathleff et al [41] in adolescents with PFP also indicate a link between greater exercise adherence and improved outcomes. In addition, a systematic review evaluating the influence of exercise dose on outcomes in knee osteoarthritis has reported that a greater number of exercise sessions per week is related to greater improvements in pain and function [42]. An interesting finding from our study is that participants reduced the number of exercise sessions they completed and the frequency in which they accessed the website during phase 1. Including consumers in the further development of the website may help to improve website engagement and exercise adherence.

Beneficial outcomes for pain and disability following self-directed web-based education and exercise therapy in this study are consistent with previous RCTs reporting improvements in the same outcomes following web-based interventions for low back pain [19] and hip and knee osteoarthritis [21,43]. Clinical improvements for the 20% (7/35) of participants who reported complete recovery at 6 weeks were sustained at 18 weeks, highlighting the potential for sustained recovery through self-directed care in people with PFP. Further research comparing self-directed web-based education and exercise therapy with a *wait and see* approach will help to determine efficacy and potential to reduce the current burden of overtreatment in health care systems around the world [44].

Overall, 4 out of 5 participants did not report complete recovery following self-directed web-based education and exercise therapy, indicating that some people may require or benefit from additional care. Face-to-face and telerehabilitation delivery of physiotherapy following initial self-directed care produced only small differences for all but one patient-reported outcome. The exception was for pain reduction, which was moderately greater ($ES=0.72$) in the face-to-face group, possibly because of differences exceeding 10 mm between groups at 6 weeks. Similar outcomes between face-to-face and telerehabilitation delivery of physiotherapy in this study are consistent with a

large ($n=201$) high-quality noninferiority RCT in people following total knee joint replacement [26]. Thus, the physiotherapy delivery mode among people with knee pathologies may have minimal influence on patient-reported outcomes. Increasing the availability of physiotherapy care delivered via telerehabilitation is recommended to improve access to people with limited mobility, distressing symptoms, and/or inability to access center-based programs [18]. In addition, telerehabilitation approaches to physiotherapy practice could reduce the need for physiotherapy facilities requiring consultations and work-related travel for physiotherapists themselves.

Our findings indicate that 31% (11/35) of the participants reported low-intensity pain flares or muscle soreness while performing the exercises, with most occurring in the first week. This finding is not surprising, considering that participants need to initially learn new exercise skills, including how to manage and increase exercise loads without increasing knee pain. Reductions in the frequency of pain flares over the 6 weeks of self-directed care found in this study may be the result of participants improving their ability to independently manage exercise loads or ongoing active management leading to improved knee self-efficacy, which is typically impaired in people with PFP [45,46].

The overall proportion of participants reporting marked improvement or complete recovery across the cohort increased from 40% (14/35) at 6 weeks to 71% (25/35) at 18 weeks. High-quality RCTs, including long-term follow-up, are now needed to test this stepped-care approach against usual care or current best care [10] to evaluate efficacy, effectiveness, and cost-effectiveness. Findings from our study can be used to inform larger studies comparing face-to-face mode with telerehabilitation mode or investigating our stepped-care approach for people with PFP, which will allow more definitive conclusions.

Limitations and Future Directions

Before making definitive recommendations regarding its potential value, our novel stepped-care approach requires comparison with a *wait and see* approach in both phases. Specifically, it is unclear whether self-directed care facilitated by our platform is superior to *wait and see* approach or whether any mode of physiotherapy following self-directed care can improve outcomes. Nonetheless, our findings suggest that if a self-directed web-based education and exercise therapy is provided as a first-line treatment, 1 in 5 patients may be able to independently manage their condition without the need for additional health professional referral.

Adherence seems to be related to better patient-reported outcomes. Future trials should develop strategies to optimize adherence to interventions (eg, digital support). In addition, the web-based platform was created with limited co-design processes [47]. Further modifications and improvements are currently being guided by additional qualitative research with consumers and physiotherapists and by using tools such as Health on the Net Foundation Code and DISCERN. Low computer and health literacy have been reported as barriers to improvement following other web-based interventions for

chronic musculoskeletal conditions [48,49]. Our findings may not be applicable for people with low computer literacy skills. Further evaluation of efficacy, barriers, and cost-effectiveness of self-directed use of the website evaluated in this study, compared with usual care, is needed to inform potential implementation.

Although we measured the number of physiotherapy sessions attended during phase 2, we did not measure adherence to exercise, subjectively or objectively. Considering conflicting findings related to the importance of exercise adherence among people with knee pain [42,50], further evaluation of the importance of exercise adherence in PFP is strongly encouraged. In addition, approaches to treatment may have varied across the 5 physiotherapists providing care in our trial. However, all physiotherapists followed the same structure and content for education and exercise, guided by the *My Knee Cap* web-based platform. Each had a minimum of 5 years of clinical experience and received training and ongoing support as required, facilitated by an experienced physiotherapist (15 years) researcher involved in the study. Finally, we only included individuals with PFP aged between 18 and 40 years because of the high prevalence

of PFP in this population [1], limiting the extrapolation of findings to adolescents and older adults with PFP.

Conclusions

This study confirms the feasibility of evaluating the efficacy of a stepped-care approach, including initial self-directed web-based education and exercise therapy, followed by physiotherapist-led education and exercise therapy. Self-directed web-based education and exercise therapy were associated with 1 in 5 participants with PFP rating themselves as completely recovered at 6 weeks and having large improvements in pain. An additional 12 weeks of physiotherapy provided face-to-face or via telerehabilitation to support education and exercise therapy was associated with 71% (25/35) of participants reporting to be completely recovered or markedly improved. The absence of differences in outcomes between face-to-face and telerehabilitation delivery modes indicates that either mode could be considered depending on patient preference and need. Evaluating the efficacy of self-directed web-based education and exercise therapy as a stand-alone intervention and as part of a stepped-care model that includes additional physiotherapy care may help guide more efficient health care for people with PFP.

Abstract

Background: Therapist-supported, internet-delivered cognitive behavioral therapy (iCBT) is efficient in the treatment of depression. However, the optimal mode and intensity of therapist support remain to be identified. Scheduled telephone support (STS) may improve adherence and outcomes but, as it is time- and resource-consuming, should be reserved for patients for whom the usual support may be insufficient.

Objective: This paper aims to reveal whether add-on STS for patients at risk of dropping out improves treatment adherence and symptoms in iCBT for depression.

Methods: Among patients participating in an ongoing large observational routine clinical practice study of iCBT for depression delivered nationwide by Helsinki University Hospital (HUS-iCBT), those demonstrating a ≥ 14 -day delay in initiation of treatment received invitations to this subsidiary STS study. A total of 100 consenting patients were randomly allocated to either HUS-iCBT as usual (control group, $n=50$) or HUS-iCBT plus add-on STS (intervention group, $n=50$). Proportions of those reaching midtreatment and treatment end point served as the primary outcome; secondary outcomes were change in Beck Depression Inventory (BDI)-measured depressive symptoms and time spent in treatment.

Results: Add-on STS raised the proportion of patients reaching midtreatment compared with HUS-iCBT as usual (29/50, 58% vs 18/50, 36%; $P=.045$) and treatment end point (12/50, 24% vs 3/50, 6%; $P=.02$). Change in BDI score also favored add-on STS (3.63 points vs 1.1 points; $P=.049$), whereas duration of treatment did not differ.

Conclusions: Add-on STS enhances adherence and symptom improvement of patients at risk of dropping out of iCBT for depression in routine clinical practice.

KEYWORDS

internet CBT; depression; scheduled telephone support; adherence; routine clinical practice

Introduction

Despite the growing burden of mental health disorders, treatment is available for fewer than half of those in need [1]. Among mental health conditions, depressive disorders are some of the most prevalent [2]. As a leading cause of disability worldwide [3], they represent a major burden for health care systems [4].

For depressive disorders, recommended first-line treatments include psychological interventions, specifically psychotherapies [5]. Although psychotherapies are highly acceptable among clients [6,7], their availability is limited [8]. Some of the main challenges are shortage of professionals, perceived stigma, cost, and long distance to services [9].

Computer-based delivery of psychotherapy improves access to psychological treatments of depression [10]. Internet-delivered cognitive behavioral therapy (iCBT) entails modules or lessons delivering cognitive behavioral therapy (CBT) concepts via the internet [11]. iCBT for depression offers solutions to such challenges as poor treatment availability, fidelity and affordability, and constraints of location and time [10,12]. In randomized controlled trials (RCTs), iCBT for depression demonstrates efficacy equal to that of traditional face-to-face CBT but only if accompanied by therapist support [11,13,14], wherein the program involves therapist guidance, typically via email [15]. Fully automated iCBT treatments, supported by only computerized reminders, tend to be less efficacious than the ones with therapist guidance [16,17].

High variation in attrition rates indicates that in some iCBT studies, a considerable number of patients fail to complete the treatment even in therapist-supported programs [18]. In a review comprising 19 studies on iCBT with therapist support for various mental disorders, the dropout (defined as termination at any point between registering for treatment and completing follow-up questionnaires) ranged from 2% to 83%, with a weighted average of 31% [19]. Two reviews of RCTs for therapist-supported iCBTs have shown a dropout rate of approximately 20% [10,20] and one meta-analysis on iCBT for depression showed a mean dropout rate of 28% [21]. However, in a large routine clinical practice study of a primary care population, 82% of participants failed to finish the program [22].

A meta-analysis of iCBT studies [19] identified several potential predictors of attrition, including age, gender, socioeconomic and relationship status, duration and target of the psychological problem, comorbidity, client-related psychological variables, treatment credibility, computer experience, motivation, the type of support medium, and quality and duration of clinician contact. Research evidence on these variables is, so far, limited. Adding fees, choice, reminders, and clinician support seems to strengthen adherence [23]. The essential elements of the contact are, however, debatable. Eysenbach [18] hypothesized that dropout is more likely the more “virtual” the support is. Synchronous telephone contact may be less virtual than is support in writing. Thus far, to our knowledge, no meta-analysis has yet directly investigated the impact of the contact medium used in iCBT for depression [24].

Telephone calls offering technical assistance facilitated self-monitoring during a web-based intervention versus only automated assistance [25]. Automated but personalized telephone prompts were useful for maintaining adherence in a study on weight control intervention [26]. However, in iCBT for depression, weekly telephone calls by a lay telephone counsellor did not confer additional advantage for callers to a helpline service [27]. The researchers proposed that more benefits might be achieved with support provided by a clinician. Nevertheless, therapist-delivered telephone and email support in iCBT for depression did not yield improvement in outcomes or in dropout rates [24]. Neither did technician-delivered telephone support demonstrate advantages over a clinician-moderated online discussion forum in iCBT for social phobia [28], although in the same program, telephone calls facilitated symptomatic improvement and adherence versus automatic reminders only [29]. In an iCBT aftercare program for bulimia nervosa, telephone prompts by a research assistant improved adherence [30], as did telephone support by a technician in iCBT for depression in primary care compared with text-based support [31]. Furthermore, in a trial of patients with treatment-resistant obsessive-compulsive disorder (OCD), scheduled telephone support (STS) reduced dropout rate compared with optional telephone support [32].

Even though STS has improved adherence, it consumes more resources than iCBT as usual and the target group therefore needs careful defining. Several potential factors predict dropout [19], but to the best of our knowledge, no clear-cut criteria for identification of increased dropout risk exist, and no trials have directly studied the effects of extra support in iCBT for depression to aid patients at such risk.

This RCT investigated whether STS added to iCBT as usual enhanced adherence to and effectiveness of iCBT for depression in a sample of patients at high risk for dropping out, (ie, those demonstrating delayed start of iCBT).

We expected that the add-on STS would enhance adherence to treatment, reduce symptoms of depression, and shorten the duration of treatment in patients at risk for dropping out.

Methods

HUS-iCBT as Usual

The department of psychiatry of Helsinki University Hospital (HUS) has developed and is providing nationwide a range of original Finnish-language iCBT programs (further referred to as HUS-iCBTs) for common psychiatric disorders to which all physicians licensed in Finland can refer patients. To receive HUS-iCBT for depression, patients must be diagnosed with a depressive episode (code F32-F33 in International Classification of Diseases 10) and be aged ≥ 18 years. Exclusion criteria are current alcohol misuse as judged by the referring physician; known diagnosis of schizophrenia or other psychotic disorder, bipolar disorder, serious personality disorder, or neurological or neuropsychiatric disorder that adversely affects the patient's cognitive performance; or demonstrated, reported, or observed suicidal intentions. However, each referring physician holds primary judicial responsibility for overall treatment and, prior

to referral, verifies the diagnosis and checks all of these criteria. No pretreatment interview by the therapy provider is thus necessary.

The HUS-iCBT for depression consists of 7 consecutive modules and is 109 pages in total, including texts, videos, illustrations, and assignments. Contents include information on depression and CBT, goal definition, behavioral activation, cognitive restructuring, advice on a balanced life, relapse prevention, and homework. Patients use a secure online identity system to enter the program. They are required to report possible suicidal thoughts. The time schedule of the treatment is flexible, although patients are prompted to progress at a pace of 1 module per week. Active engagement is required, since progress to the next module is prevented if any of the previous module assignments is not completed.

The program sends email prompts for new messages and login reminders. The same internet therapist follows each patient throughout the treatment, and they communicate asynchronously via text-based message board within the therapy program. The therapist sends messages in the beginning, at midtreatment, at the sixth module, and at the end point; patients receive encouragement to write to the therapist any time with their questions or concerns. The therapist comments on the completed tasks, offering praise and support for the patient. The patients receive automatic messages recapitulating the contents of the modules, which are distinguished from the messages sent by therapists. In addition, the patients receive an email prompt if no login occurs for 2 weeks and when they receive a new message. Automatic prompts notify therapists of new messages or in case of any sign of suicidality. When expected progress fails, the therapist tries to contact the patient by a message within 2 to 4 weeks. If the patient still does not appear in the program, the therapist tries to reach the patient by telephone (therapist-initiated telephone calls are not used for other purposes). If the patient remains unreachable by telephone, a letter on paper is sent to uncover the reason for no show.

Study Patients and Design

Large Simple Observational Study

All patients referred to the HUS-iCBT for depression are invited to participate in an ongoing nationwide, low-threshold, flexible-time schedule, observational, routine clinical care study on the effectiveness of HUS-iCBT in depressive disorders (original report under preparation). The only additional criterion for that study is a signed informed consent. All consenting patients (currently 79% of those accepted for the HUS-iCBT) are eligible to participate and are enrolled into that study.

The STS Study

The current study was a subsidiary RCT branch of the observational study described above. Patients participating in the observational study received invitations to participate in the STS study if they had not proceeded in the HUS-iCBT for ≥ 14 days after their first entry, a delay interpreted as increased risk for dropping out. The patients were enrolled subsequently from September 2015 to October 2016 until the number of participants reached 100. These patients were randomly allocated to either HUS-iCBT as usual plus add-on STS (add-on STS group, $n=50$)

or to HUS-iCBT as usual (control group, $n=50$) when a 14-day delay was detected, either during or after completing the first module of the treatment. The maximum time span allowed for this study participation since initiation was 6 months.

Add-on STS Intervention

In addition to the standard HUS-iCBT, the add-on STS intervention group received 8 weekly 15-minute telephone calls, the first at the beginning of iCBT and the subsequent calls during each of the 7 modules, without any further calls regardless of patient progress. If necessary (eg, if a patient was reached in a bad moment or asked the therapist to call again), new calls were allowed, amounting to more than the intended 8 calls. During the first call, selection of individual goals took place. The tasks and themes of each module were discussed in the calls that followed each module. Support was individually tailored and followed the principles of the model of supportive accountability [33], which combines elements of motivational theory, organizational psychology, and computer-mediated communication to create a framework for supported computerized treatment. According to this model, combining elements of support and accountability with a legitimized and trustworthy relationship increases adherence. If delays occurred, the prescheduled calls were generally not replaced, although therapists had final judgement over this.

Therapists

All 5 therapists involved in this trial were clinical psychologists employed by HUS and had at least 2 years of work experience with depressed patients. They attended a 1-day training session in HUS-iCBT on the study protocol of the above-mentioned observational study and of the current STS study, the STS methodology, and the International Council for Harmonisation Good Clinical Practice (ICH-GCP) guidelines. Their role included providing feedback on assignments and support with any patient issues. Every 2 months, they participated in a group supervision session, discussing any concerns or issues arising. At any time, the therapists could consult a clinical psychologist with advanced iCBT experience.

All 5 STS therapists were at the same time also providing regular HUS-iCBT for other patients, and in this study, each treated both add-on STS intervention and control groups. Study patients were assigned to each therapist randomly, depending on that therapist's current workload, resulting in the 5 therapists having 35, 30, 18, 14, and 3 patients.

Outcome Measures

Primary outcome measures were proportion of patients reaching midtreatment (third module) and end point (seventh module). Secondary outcome measures were change (from start to completion or to dropout, with last observation carried forward) in Beck Depression Inventory (BDI) [34] scores and treatment time (in days) from start to end point (or premature discontinuation). The internet-administered BDI has good psychometric properties [35]. The patients completed it online at the beginning, midtreatment, and end point.

At enrollment, all patients completed 6 demographic questions. The rest of the demographic data were collected from the

referrals. The therapists recorded the number and duration of telephone calls. The experienced usefulness was recorded at the end of each module by visual analog scale, where “not at all useful” equaled 0 and “very useful” equaled 10.

Ethics and Legislation

The study followed the ICH-GCP and Finnish national regulations. The study protocol was approved by the Ethics Committee of HUS and by pertinent institutional authorities. After reading a complete description of the study, the patients provided informed consent electronically. The trial was registered at the International Standard Randomised Controlled Trial Number (ISRCTN) registry (ISRCTN55123131).

Statistical Analyses

Primary analyses, based on the intention-to-treat principle, included all patients. Analysis of variance and chi-square tests served to reveal group differences in baseline characteristics and in dropout rates.

Group comparisons of patients reaching midtreatment and end point employed chi-square tests. Cox regression survival analysis served to determine group differences in survival probabilities (ie, time spent in treatment before dropping out during the 6-month time period). This analysis was adjusted for experienced session usefulness at the end of the first session, measured by visual analog scale. The Mann-Whitney test served for group comparisons of change in depression (BDI scores) from baseline to last observation carried forward and treatment length (in days).

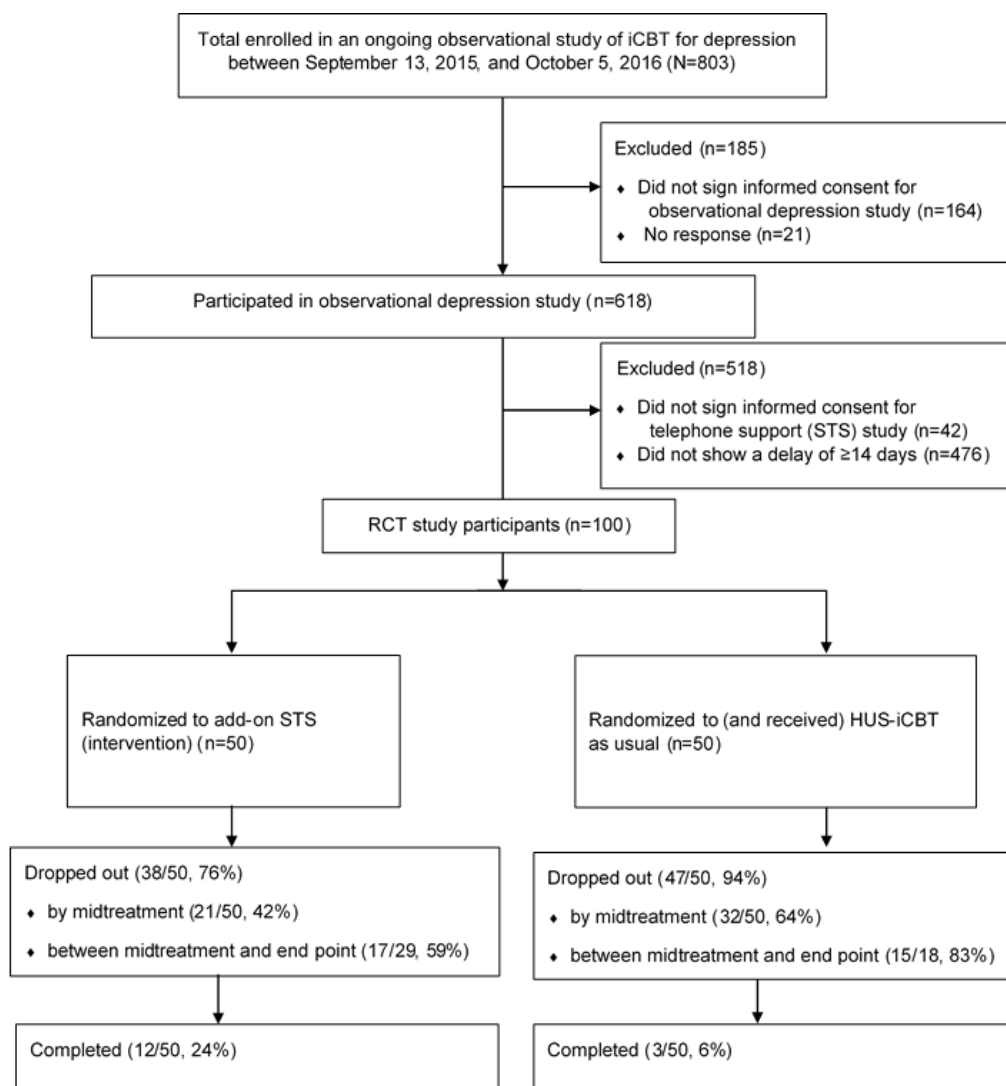

Statistical analyses employed SPSS Statistics (version 25; IBM Corp) for Windows (Microsoft Corp).

Results

Baseline Characteristics

Analyses comprised 50 patients in the add-on STS group and 50 patients in the control group (see Figure 1).

Figure 1. Scheduled telephone support in iCBT for depression: patient flow diagram. HUS-iCBT: Helsinki University Hospital internet-based cognitive behavioral therapy programs; iCBT: internet-delivered cognitive behavioral therapy; RCT: randomized controlled trial; STS: scheduled telephone support.

Of 618 patients of the observational depression study, all 618 (100%) were invited to participate in the STS study, which

amounts to 77.0% of the 803 patients enrolled during the time period between September 13, 2015, and October 5, 2016. Of

the 618 invited, 576 patients (93.2%) agreed to participate. Of these 576 patients, 476 (82.6%) did not show a 14-day delay in beginning the treatment and were excluded on that criterion. A total of 6 patients of the add-on STS group never received any telephone calls (ie, did not receive the STS intervention).

No significant differences between groups emerged at baseline (see Table 1). Some patients did not provide several baseline

demographic data (marital, educational, and employment statuses and use of medication or sick leave within last 6 months). However, there was no association between missing data and group membership. Interpretations of results concerning primary and secondary outcomes remained the same after controlling for an indicator of nonresponse to these demographic questions.

^aSTS: scheduled telephone support.

^b2-tailed *t* test.

^cN/A: not applicable.

^dInformation available for 14 patients in add-on STS intervention group and for 14 control group patients.

^eAnxiolytic or antidepressant.

^fBDI: Beck Depression Inventory.

Since there was a considerable amount of missing data in some of the baseline characteristics, we performed comparisons (using a 2-tailed *t* test) of depression at baseline (BDI score) between patients that filled in (*n*=28) and did not fill in (*n*=72) a separate questionnaire of demographics. There was no difference in depression at baseline between the groups ($t_{96}=0.445$; $P=.66$).

No adverse events, such as hospitalization or serious illness, occurred during the study. Altogether, 44 of the 50 (88%)

patients in the add-on STS intervention group received the previously scheduled telephone calls (versus a total of 5 patients received optional calls in the control group), as seen in [Table 2](#).

Patients in the add-on STS group reached an average of 3.54 modules, while patients in the control group reached an average of 2.46 modules (see [Table 3](#)).

Table 2. Mean number and duration of telephone calls received.

^aSTS: scheduled telephone support.

Outcomes

Adherence (Primary Outcome)

Of the 100 randomized patients, 21 of the 50 patients in the add-on STS group (42%) and 32 of the 50 patients in the control group (64%) dropped out by midtreatment. Corresponding

figures for the end point were 38 of 50 patients (76%) and 47 of 50 patients (94%). The proportion who reached midtreatment and end point favored the add-on STS group significantly ([Table 4](#)). Cox regression survival analysis revealed no difference in the timing of dropout between groups (survival curves $\chi^2_2=2.5$, $P=.48$; hazard ratio=1.29, 95% CI 0.64-2.61, $P=0.48$), as shown in [Figure 2](#).

Figure 2. Cox regression survival curves for staying in treatment for the add-on STS and control groups at 6 months. STS: scheduled telephone support.

Secondary Outcomes

The BDI-measured change from baseline showed a statistically significant difference also favoring the add-on STS group. This result also remained when analyses were carried out using linear

mixed models, which handles missing values more efficiently and without imputing the missing values ($F_{2,30}=3.77$; $P=.04$). No statistically significant differences emerged for days spent on therapy ($P=.67$).

Table 4. Effects of add-on STS on adherence, depression, and time in treatment.

Discussion

Principal Results

In patients at risk of dropout during iCBT for depression, add-on STS yielded an increased proportion of patients reaching midtreatment (29/50, 58% vs 18/50, 36%; $P=.045$) and proportion of patients who completed treatment (12/50, 24% vs 3/50, 6%; $P=.02$) compared with the control group. Moreover, depressive symptoms decreased more for those with add-on STS than with HUS-iCBT alone (mean change 3.63 vs 1.06; $P=.049$), but the survival analysis did not reveal any statistically significant differences in survival probabilities, that is, time spent in treatment before dropping out ($P=.67$).

Comparison With Prior Work

Two other RCTs on STS have reported positive results. Notably, both studies used iCBT with no text-based support, meaning that comparison of our results with these previous reports should be undertaken with caution.

Gilbody and coauthors [31] compared STS to iCBT with no STS in primary care patients with depression, reporting improvement in symptom change and a decrease in dropout rate from 71% to 54% at midtreatment and from 90% to 81% at end point in their STS group patients compared with their control group patients with access only to a support helpline. Despite the at-risk population in the current study, our figures seem comparable (drop from 32/50, 64% to 21/50, 42% at midtreatment and from 48/50, 96% to 38/50, 76% at end point). Kenwright and colleagues [32], in their iCBT trial comparing STS to patient-initiated calls, reported an STS-induced change from 59% to 14% for early dropout rate and from 64% to 50% for late dropout rate. Their patients, however, suffered not from depression but from OCD. OCD is known to often be difficult to treat and, as a group, patients in that study could thus also be counted as being at risk of dropping out. Nevertheless, due to the differences in population and methodology, the results cannot be directly compared with ours.

Of note, completion of the program does not always indicate treatment success in iCBTs. For instance, in iCBT for depression, there seems to exist a subgroup of patients who benefit rapidly and therefore prematurely discontinue the treatment because it is subjectively perceived as unneeded [36]. In our study, in-depth analysis of reasons and exact time point of dropout could not be performed due to having only 3 measurement points of depression.

Not all RCTs on STS showed the desired results, however. In one depression study [24], patients received either email or STS support added to iCBT, but with no differences in dropout rates. Similarly, adherence did not improve with STS added to email in a headache study by Andersson et al [37], nor did STS demonstrate advantages over a clinician-moderated online discussion forum in terms of adherence in an RCT on social phobia from Titov and colleagues [38]. Interestingly enough, all these negative studies included only unselected, self-referred participants. In contrast, we focused only on physician-referred patients (51/100, 51% of them from primary care) whose initiation of iCBT was delayed by ≥ 2 weeks, which was

considered a risk of dropping out. These patients may have experienced a special challenge in terms of adherence, since unlike their counterparts in the majority of previous RCTs, they may not always have originally been motivated to use iCBT; they had no contact with a therapist or other research personnel at screening (a contact that might have improved adherence), and they showed a possible lack of engagement at the beginning of iCBT.

The education level of supporting personnel may also matter, but data on this issue are conflicting. In the negative-result depression study by Lindner and colleagues [24], support providers were psychology students, whereas our positive results were achieved with support personnel being certified, experienced clinical psychologists. Nevertheless, positive results also emerged in the depression study of Gilbody and colleagues [31], in which contact personnel comprised telephone support workers. Moreover, STS personnel involved in other (nondepression) conditions differed. Therapists were the support providers in one positive-result OCD trial [32] and in one negative headache trial [37], whereas technicians took this role in the negative-result social phobia trial of Titov and colleagues [38].

In psychotherapy research, researcher allegiance, a tendency to favor certain preferred treatments, is widely discussed [39]. Treatment developers' trials tend to yield better outcomes than the later research performed by others, probably due to researcher allegiance. One alternative explanation is that developers themselves gain an advantage through their intense clinical and research involvement with the treatment; they become superior in treatment delivery [40]. Gilbody and colleagues [31] attributed their poor outcomes and adherence—results inferior to those demonstrated by treatment developers—to differing means of service provision. Gilbody and his group performed their trial within the Randomised Evaluation of the Effectiveness and Acceptability of Computerised Therapy trial, a large National Health Service-funded program in which treatment provision was decentralized. In contrast, in our setting, the developer of the HUS-iCBT program, which was the Department of Psychiatry of Helsinki University Hospital, was the only nationwide centralized provider of both iCBT and the add-on STS. This may explain our somewhat better-than-expected results.

The mechanism of the desirable effects of STS is uncertain. These effects may result from increased therapist contact time, from the telephone as the medium versus written contact only, or from the proactivity of therapist-initiated scheduled contact.

What has been maintained is that increased therapist contact time in iCBT for mood and anxiety disorders correlates strongly with treatment outcome [41]. This association has not always been detectable in reviews, however [24], and has been considered true only up to a certain threshold [42]. Gilbody and colleagues [31] did not describe their average STS time. The STS time in the iCBT study on OCD [32] was 232 minutes versus 178 minutes for the optional contact, which was markedly more than the typical 90 to 150 minutes per patient in iCBT trials [43]. In our study, average added telephone contact time for the add-on STS intervention group was 73 minutes per

patient (versus 2 minutes for the control group). Given the average 55-minute therapist time per patient for HUS-iCBT, SPS means a 2.4-fold increase in contact time. Neither the study by Kenwright and colleagues [32] or by Gilbody and colleagues [31] nor the present one has been a dose-finding trial. We were unable to locate any dose-finding trials on the effects of contact time in added STS in any iCBT program. It therefore remains unclear whether those 54 additional minutes of STS time for OCD or our 73 additional minutes for depression are optimal in terms of adherence or symptomatic improvement in iCBT. Nevertheless, the 2.4-fold increase in resource allocation when weighted against health benefits achieved may be of interest to administrative decision makers.

The telephone as a medium is one of the synchronous contact modes, in contrast to asynchronous contact via written message (usually referred to as minimal contact) in the majority of iCBT studies. Furthermore, unlike text message, a telephone conversation conveys nonverbal voice signals (such as intonation and pausation). Since in these 2 studies [31,32] the control groups received no text-based support, no conclusions can be drawn on the specific role of the telephone as a medium. Moreover, other RCTs comparing telephone support with email support found no differences in treatment outcomes or dropout rates [24,37,38]. The role of the voice contact in iCBTs and the specific mechanisms of action therein remain poorly understood.

Limitations and Strengths

Our sample size was relatively small. Although between-group differences were statistically significant, statistical power was insufficient for subgroup analyses and hence for identification of a subpopulation for optimal therapist resource allocation.

Due to selection of population (patients at risk for dropout in everyday clinical practice), the dropout rate in our study was expectedly high, with 76% (38/50) in the STS group and 94% (47/50) in the control group dropping out, when dropout is defined as those who did not finish the treatment in 6 months. In addition, the patients did not have a strict deadline of 6 months, even though the measurements were conducted at that point. Studies comparing iCBT programs with unselected populations reported a 62% dropout rate in everyday clinical practice and 15% to 25% in RCTs [29]. Our findings underline the difficulties of maintaining adherence in routine clinical care for digital health products that demonstrate impressive results in clinical trials [44]. Nevertheless, the STS in this study showed results comparable to an 82% dropout rate in earlier observational studies on iCBT for depression with unselected population [22].

Therapist effects in our study could not be ruled out, since 2 of altogether 5 therapists treated 63 of the 100 (63%) patients. This

small number of therapists is, however, too small for reliable assessment of possible therapist effects [45].

The effect of support may depend on the patient group [46]. We defined the ≥ 14 -day delay prior to the beginning of iCBT treatment as a criterion of dropout risk based on clinical experience, since, to the best of our knowledge, no clear-cut criteria for such risk have yet been defined. This criterion might fit only a certain subgroup of our patients, meaning that the add-on STS intervention was applied for no reason also to a not-at-risk subgroup. Understanding the reasons for patient delay could help to sharpen this criterion, but in our study, data as to the reasons were unavailable.

The HUS-iCBT with add-on STS required 77 minutes more therapist time than did the HUS-iCBT as usual. Cost-benefit analysis of STS was not a subject of this study, so our results are insufficient to inform decision makers on whether to use STS for patients at risk for dropout in routine clinical practice, not to mention for patients at no such risk.

Future Research

Future research should explore in depth possible criteria for those at risk for dropping out to discover optimal contact time with larger populations. Add-on STS in other populations, such as depressed patients who demonstrate no delay in initiation of iCBT or patients with disorders other than depression, is worth studying. Reasons for the delayed initiation of iCBT as well as other predictors of poor adherence call for exploration. Cost-benefit analysis could optimize the use of add-on STS. Add-on STS provided by professional groups of a lower educational level than that of our clinical psychologists also demands exploration.

Our study employed STS added to text-based support, but STS alone should also be a focus of research in populations at risk of dropout to reveal the unconfounded effects of STS as such. Comparison of STS with other support media, such as voice messages (asynchronous contact mode but enriched with nonverbal voice modulations) or chat (synchronous contact but devoid of nonverbal voice modulations), can yield new insights into both the mechanism of action of STS and the practical means to optimize cost benefits of support.

Possible therapist effects should be explored in further iCBT studies with a greater number of therapists with equal caseloads providing STS.

Conclusion

STS added to the usual iCBT appears to improve both adherence and clinical symptomatology in patients with depression at risk for dropout from iCBT, but more research is required to optimize its use.

Abstract

Background: Physical activity can prolong the ability of older adults to live independently. Home-based exercises can help achieve the recommended physical activity levels. A blended intervention was developed to support older adults in performing home-based exercises. A tablet and a personal coach were provided to facilitate the self-regulation of exercise behavior.

Objective: In line with the Medical Research Council framework, this study aimed to carry out process evaluation of a blended intervention. The objectives were (1) to assess the long-term usability of the tablet adopted in the blended intervention and (2) to explore how the tablet, in conjunction with a personal coach, supported older adults in performing home-based exercises.

Methods: The process evaluation was conducted with a mixed-methods approach. At baseline, older adults participating in the blended intervention were asked to fill out a questionnaire about their general experience with information and communication technology (ICT) devices and rate their own skill level. After 6 months, participants filled out the Usefulness, Satisfaction, and Ease of use (USE) questionnaire to assess the usefulness, satisfaction, and ease of use of the tablet. With a random selection of participants, in-depth interviews were held to explore how the tablet and coach supported the self-regulation. The interviews were double coded and analyzed with the directed content analysis method.

Results: At baseline, 29% (65/224) of participants who started the intervention (mean age 72 years) filled out the ICT survey and 36% (37/103) of participants who used the tablet for 6 months (mean age 71 years) filled out the USE questionnaire. Furthermore, with 17% (18/103) of participants (mean age 73 years), follow-up interviews were held. The results of the baseline questionnaire showed that the large majority of participants already had experience with a tablet, used it regularly, and reported being skillful in operating ICT devices. After 6 months of use, the participants rated the usefulness, satisfaction, and ease of use of the tablet on average as 3.8, 4.2, and 4.1, respectively, on a 5-point scale. The analysis of the interviews showed that the participants felt that the tablet supported action planning, behavior execution, and self-monitoring. On the other hand, especially during the first few months, the personal coach added value during the goal setting, behavior execution, and evaluation phases of self-regulation.

Conclusions: The results of the process evaluation showed that older adults who participated in the study were positive about the blended intervention that was designed to support them in performing home-based exercises. Participants reported that the

tablet helped them to perform the exercises better, more frequently, and safely. It supported them in various phases of self-regulation. The availability of a personal coach was nevertheless crucial. To support physical activity in older adults, a blended approach is promising.

Introduction

Background

As people age, they face a decline in daily functioning and mobility [1,2]. Physical activity can delay the onset and slow the decline associated with aging [3,4]. Older adults who exercise on a regular basis can prevent impairments and remain self-reliant for a longer period of time [5,6]. Accordingly, various community centers around the world offer senior citizens the opportunity to participate in group-based exercise classes under the guidance of an instructor [7-9]. For instance, in the Netherlands, over 400,000 older adults participate in the weekly activities of “More Exercise for Seniors” (“*Meer Bewegen voor Ouderen*,” which is abbreviated as MBvO in Dutch). Despite the popularity of this program, its effects on physical health are limited. A previous study has shown that older adults who participate once a week in the exercise classes, do not achieve a higher health-related quality of life or an increased ability to perform daily tasks [10]. In order to capitalize on the health benefits of physical activity, the frequency, intensity, and duration of exercises have to be sufficient [9,11].

Older adults can increase the level of physical activity by doing exercises at home, either as an independent program or in conjunction with group-based classes [12-16]. The latter approach combines the motivational aspects of exercising along with peers with the flexibility of a home-based exercise program that is tailored to individual needs. However, in the absence of an instructor, older adults may have adherence and safety concerns about home-based exercises [17]. The use of mobile technology (mobile health [mHealth]) can help overcome these issues by providing detailed instructions, offering tailored programs, and tracking progress [18-23] for individuals, including older adults [24,25].

Development of a Blended Intervention

In order to enhance community-based exercise programs like MBvO, a blended intervention was developed as part of the MOTO-B (Motivating Technology for Older Adults’ Behavior) and VITAMIN (VITal AMsterdam older adults IN the city) research projects. The aim of the intervention was to support older adults in performing home-based exercises. In line with the self-determination theory [26,27], the intervention was conceived to increase competence and stimulate the autonomy of older adults, but at the same time, to maintain relatedness with peers [17]. The intervention consisted of a home-based exercise program that was supported by a tablet and a personal coach, and could be followed alongside community-based exercise programs or other sport activities.

Objective

According to the UK Medical Research Council (MRC), complex interventions need to be evaluated systematically [28]. Three different types of evaluations can be distinguished as follows: (1) assessing the feasibility, (2) assessing the effectiveness, and (3) understanding the underlying change process.

First, prior to assessing effectiveness, feasibility should be investigated thoroughly. For the blended intervention described here, a previous usability study that was conducted in a laboratory showed that older adults (age ranging from 69 to 99 years) who used the app for the first time during a 45-minute session could operate it without any relevant problems [29], suggesting that the blended intervention is feasible. However, a more thorough evaluation is needed to account for the long-term use in a real-world setting. The usability of mHealth apps is often not tested sufficiently, thereby limiting their effectiveness [30,31].

Second, the effectiveness of a complex intervention can be assessed with randomized controlled trials (RCTs). To assess the effectiveness of the blended intervention in terms of health outcomes, a trial study is currently ongoing and will be reported in the future elsewhere [32].

Third, an explorative process evaluation can provide insights into the underlying change process. By exploring the mechanisms of action, a process evaluation is a valuable extension of effectiveness studies. The aim of this study was to conduct such an evaluation. The objectives were as follows: (1) to assess the long-term usability of the tablet in a real-world setting and (2) to explore how the tablet, in conjunction with a personal coach, supported older adults in performing home-based exercises.

Methods

Intervention

The intervention consisted of two components to support older adults in performing exercises at home. The first component was the tablet containing a custom-developed app that was designed to ensure behavior change by facilitating self-regulation. Self-regulation is the process of consciously guiding one’s own behavior in order to achieve goals. In particular, behavior change techniques that support goal setting, action planning, behavior execution, self-monitoring, and evaluation appear to be important for the self-regulation of behavior [33-35]. Figure 1 presents a schematic representation. The app supported self-regulation by allowing older adults to

set goals, tailor a weekly schedule to their individual needs, and watch video instructions. It also tracked their progress and facilitated remote guidance by a personal coach. An elaborate description of the app and its theoretical underpinning have been presented previously [36].

The second component of the intervention was counselling. Each participant was appointed a personal coach. The coach paid house visits, helped the participants to get acquainted with the tablet, and counselled, either remotely or face-to-face, the participants in setting up and following the tailored exercise

schedule. The coaches were third- and fourth-year physical therapy bachelor students. Prior to taking on their responsibilities, the coaches received a 2-week training on functional exercises, good clinical practice, and e-coaching by faculty staff members. Furthermore, during their 6-month internship, they received weekly supervision from faculty staff members. When the responsibilities of a coach ended at the end of a teaching semester, ongoing cases were transferred to a new coach. As a result, participants received in sequence counselling by two personal coaches during a 6-month period. The complete details of the intervention have been reported previously [32].

Figure 1. Behavior change through self-regulation.

Study Design and Participants

An RCT was conducted to assess the effectiveness of the blended intervention in terms of health outcomes. Older adults were recruited from the surroundings of Amsterdam, the Netherlands, through postal mailing and local community-based centers offering weekly exercise programs. Applicants were included in the trial if they met the following criteria: (1) age 55 years or older, (2) ability to understand the Dutch language, and (3) absence of specific cognitive or physical impairments. The protocol that describes the RCT has been published, including detailed methods, inclusion criteria, measurement procedures, and interventions [32].

To increase the fidelity of the trial, an additional nested mixed-methods study was set up (described in this paper) by administering questionnaires to the participants who received a tablet and coaching, as well as conducting follow-up interviews among a random selection of those participants [37].

Measurements

Before commencing the intervention, at baseline, the trial participants filled out a three-item questionnaire about their general experience with information and communication technology (ICT) devices, such as computers, smartphones, and tablets. To assess the long-term usability of a tablet (objective 1), after 6 months, participants who received a tablet were asked to fill out a usability questionnaire that was based on the Usefulness, Satisfaction, and Ease of use (USE) questionnaire [38]. The first part of the questionnaire consists of 23 items (Likert) that measure the following three components of usability: usefulness, satisfaction, and ease of use. Each item

consists of a statement with the following five response options: strongly disagree, disagree, neither agree or disagree, agree, and strongly agree. The second part of the questionnaire contains three general questions about tablet use in the past 6 months, whether participants would recommend the tablet to friends, and an item participants could use for general remarks. All questionnaires were administered by paper and pencil in the Dutch language.

Furthermore, to explore how the tablet, in conjunction with the coach, supported the self-regulation of exercise behavior (objective 2), 18 participants were randomly selected for an in-depth interview. The interview questions were previously piloted among two participants. The interviews were conducted in a home setting, were held in Dutch, and lasted for about 45 minutes. All interviews were recorded.

Analysis

The questionnaires were processed with double-entry verification. For usefulness, satisfaction, and ease of use, separate mean scores were calculated. The mean scores could range from 1 (very low) to 5 (very high). The interviews were transcribed verbatim and subsequently double coded by two researchers. The directed content analysis method was used to explore how the participant's experience related to the five key constructs of self-regulation that the intervention was based upon (goal setting, action planning, behavior execution, self-monitoring, and evaluation). Directed content analysis was deemed more appropriate than conventional content analysis, because of the focus on existing theoretical constructs [39–41]. To minimize differences in interpretation, first calibration sessions were held. Subsequently, both researchers coded all

the transcripts independently with the key constructs of self-regulation and then compared the results. Differences were resolved via discussion. In the rare case no interrater consensus was reached, the first author settled the dispute.

Results

Questionnaire About ICT Experience and Skills

In total, 224 older adults with a mean age of 72 years (SD 7 years; 71% female) participated in the RCT at baseline. The questionnaire about the prior use of ICT devices and

self-reported skill level was filled out by 29% (65/224) of the participants, of which 72% (47/65) were female. Their mean age was 71 years (SD 5.8 years). The tablet was one of the most popular devices among the participants. A large majority of the participants used this device several times a week. See [Table 1](#) for the results.

Most participants rated themselves as somewhat skilled with ICT devices. Specifically, 6% (4/65) of the participants rated themselves as very unskilled, 2% (1/65) as unskilled, 38% (25/65) as somewhat skilled, 40% (26/65) as skilled, and 6% (4/65) as very skilled.

Table 1. Prior use of information and communication technology devices (N=65).

Device ^a	Use, n (%)				
	Never	Rarely ^b	Sometimes ^c	Regularly ^d	Often ^e
Personal computer	17 (26%)	1 (2%)	3 (5%)	8 (12%)	24 (37%)
Laptop	17 (26%)	3 (5%)	3 (5%)	7 (11%)	25 (39%)
Tablet	16 (25%)	2 (3%)	3 (5%)	3 (5%)	35 (59%)

^cFew times a year.

^dFew times a month.

^eFew times a week.

^fDevice without touchscreen.

Usability Questionnaire

The usability questionnaire was filled out by 36% (37/103) of the participants who had used the tablet for 6 months, of which 60% (22/37) were female. The mean age was 71 years (SD 5.1 years). The questionnaire had excellent internal consistency with Cronbach α of .89. The internal consistencies for the subscales were as follows: usefulness, .82; ease of use, .89; and satisfaction, .71.

Participants indicated that they found the tablet very useful (item 1) and it helped them to perform their exercises better (item 3) and safely (item 4). They were, however, neutral about how this affected their daily lives (item 6 and item 7). Overall, they were satisfied with the tablet and found it easy to use. [Table 2](#) presents the results of the USE items. Finally, 68% (25/37) of the participants indicated that they would recommend the tablet to friends. Participants who indicated that they would not recommend the tablet provided varying reasons like “it didn’t work properly,” “I don’t need it to be active,” or “it’s too noncommittal.”

Table 2. Scores of usefulness, ease of use, and satisfaction items (5-point Likert scale) (N=37).

Questionnaire item ^a	Score ^b , mean (SD)
Usefulness	3.8 (0.6)
1. The tablet is useful.	4.5 (0.6)
2. With the tablet, I can follow an individual exercise program that suits me.	4.0 (0.7)
3. The tablet helps me to perform my exercises better.	4.2 (0.7)
4. With the tablet, I can perform exercises safely.	3.9 (0.9)
5. The tablet helps me to perform exercises more often.	3.8 (1.1)
6. Since using the tablet, I have a more active life.	2.9 (1.0)
7. The tablet supports my daily activities.	3.0 (1.1)
8. The tablet has everything I need to be physically active.	3.6 (1.1)
9. The information about the exercises is understandable.	4.4 (0.6)
Ease of use	4.2 (0.6)
10. I learned to use the tablet quickly.	3.9 (1.1)
11. I easily remember how to use the tablet.	4.3 (0.9)
12. I am capable of using the tablet.	4.2 (0.8)
13. I can use the tablet without any help.	4.3 (0.7)
14. I understand how the tablet operates.	4.3 (0.7)
15. I can easily find what I am looking for on the tablet.	4.2 (0.9)
16. The tablet is easy to use.	4.4 (0.7)
17. Using the tablet is effortless.	4.4 (0.5)
Satisfaction	4.1 (0.6)
18. I am satisfied with the tablet.	4.2 (0.7)
19. The tablet is pleasant to use.	4.1 (0.8)
20. The tablet is fun to use.	4.0 (0.7)
21. I am going to keep on using the tablet.	4.0 (1.1)
Miscellaneous	
22. Family and friends believe I should use the tablet.	1.9 (0.9)
23. The trainer/coach believes that I should use the tablet.	3.3 (1.3)

^aTranslated from Dutch.^bThe minimum score is 1, and the maximum score is 5.

Interviews

In total, 17% (18/103) of the participants who used the tablet for 6 months were approached for a follow-up interview. One participant declined without giving a specific reason. The interviews were conducted with the remaining 17 participants, of which 53% (9/17) were female. Their mean age was 73 years (SD 7.0 years). The results of the interviews are described below according to the following five phases of self-regulation: goal setting, action planning, behavior execution, self-monitoring, and evaluation.

Goal Setting

Goal setting involves the process of determining the objective a person aspires. Setting goals was the departure point of the blended intervention. The tablet was designed to support the participants by letting them rank a set of daily activities and

subsequently formulating their goals. It was also the main topic of the first two meetings with the coach.

The participants' goals varied greatly (ie, from decreasing backache to improving balance). For some participants, the goal was not to improve physical health but to maintain it. Occasionally, participants formulated the goals with only the tablet, but most participants first consulted with the coach to explore related issues and translate top-level goals to specific and challenging, but realistic and measurable, goals. The attention the coach paid to the individual situation of the participant was appreciated. For instance, participants commented as follows:

...then we looked what is useful for me, what will help me to improve?... well, this was decided in consultation. [Participant #14]

I believe it is important that the coach kept in mind: what does this person want to achieve? [Participant #6]

well... they asked me about everything... which problems do I face? [Participant #1]

In summary, the tablet, in conjunction with the coach, supported the participants in setting goals. The sensitivity of the coach for the personal circumstances was valued by the participants.

Action Planning

Action planning involves the process of making a plan regarding how the goals will be achieved. After determining the goals, participants could draw up a personal exercise schedule on the tablet. They could select functional exercises that would increase balance, strength, flexibility, and endurance. Each exercise was available in three variations that differed in difficulty.

The choice of different exercises was valued. For instance, participants commented as follows:

... then you always can choose your own exercises. I think it is great you have a lot of choice. [Participant #4]

That's good. Then I can adjust it entirely to my own needs. [Participant #6]

Some participants commented that customizing the exercise schedule was not easy to do, either because of technical limitations of the tablet or because of limited knowledge about the benefits of each exercise. In those cases, the coach was available to help. For instance, participants commented as follows:

...well, which exercise should you choose? ... that I could do this together with my coach was very effective. [Participant #4]

with his help I had in no time an entire exercise program. [Participant #3]

The weekly overview of planned exercises helped the participants to be physically active. The majority of participants exercised daily. They commented that this was due to the intervention as follows:

I am chaotic and have no discipline, this helped me a lot! [Participant #17]

I do the exercises every day at home. I did not do that before. [Participant #13]

now I am consistently doing exercises, every day. Actually, because of this [tablet]. [Participant #10]

When asked about the underlying reason for this, they mentioned different aspects. Several participants indicated that the tablet provided them structure to build a routine. For many, this was doing the exercises at a fixed time of day, generally in the morning. Participants commented as follows:

before taking a shower and getting dressed, first those exercises. A fixed structure, that helped. [Participant #2]

...well, that rhythm is a good feeling. [Participant #15]

Others commented that the exercises were more integrated in their daily activities as follows:

...sometimes I also do the exercises as I go; then I walk step by step back into the living room after a visit to the bathroom. [Participant #11]

...I do the exercises in between times. I stand on one leg when I am brushing my teeth for instance. Well, I kind of integrate it. [Participant #14]

Besides providing structure, some participants mentioned that the tablet also acted as a cue to action as follows:

...when I sit down and see it [tablet] I think 'ah, a reminder!' [Participant #16]

In summary, participants felt that the blended intervention supported them in action planning. It provided them with structure to develop a routine. Several participants indicated that it helped them to do exercises daily, a frequency they previously did not achieve. They valued the possibility to personalize the exercise schedule to their own needs. The help of the coach was essential for some participants.

Behavior Execution

Behavior execution involves performing the actual behavior that should lead to achieving the goals. The tablet was designed to support this by various features like giving an overview of today's exercises, providing background information about each exercise along with video demonstrations, and providing a countdown timer or the ability to modify each exercise with three parameters (duration, number of repetitions, and intensity level).

Participants found the daily overview of exercises to be useful. It provided them in a brief glance which exercise had to be performed today and with what duration, repetition, and intensity level. The countdown timer was used especially in the beginning when participants had to familiarize themselves with the exercise routine. The same applied for the video demonstrations. It helped them to see how the exercises could be performed correctly. For instance, participants remarked as follows:

...but I did need it [video demonstration] to do it [the exercise] in the correct manner. [Participant #6]

...that was nice, I could perform the exercises better this way. [Participant #7]

Additionally, attention to safety was valued, with the following statements:

the exercises are safe. Well, at least a lot safer than riding a bike. Biking is dangerous. [Participant #12]

...yes, attention was paid to this [safety]. That you had to hold on to something, when you stand on one leg, for instance. [Participant #6]

One of the participants stressed the benefit of using a tablet for the instructions as follows:

I can write it down, but it's nice to have visual image of what is meant.... instructions written down are always subject to different interpretations. I think, as

it has been done now, is very instructive. [Participant #4]

Nevertheless, numerous participants mentioned that the additional instructions of the coach were also valuable as follows:

I also asked the coach, "am I doing it right?" He said "yes, that's right" or "you have to do it like this and that". [Participant #11]

...that was nice. Sometimes he would demonstrate the exercise, or I would demonstrate it and ask him if I was doing it correct. [Participant #6]

The coach also helped participants modify exercises if they were struggling with limitations or wanted more of a challenge. The latter was often needed. Many participants stressed that the exercises were too easy, despite the possibility to increase the difficulty level with the tablet. Apparently, this was not sufficient for numerous participants. An illustrative remark was as follows:

...yes, I can say that I wished they were a bit more challenging. [Participant #10]

Some felt very strongly about this. For instance, a participant remarked as follows:

Look, I believe these exercises are meant for people who are in a retirement home and, more or less, don't do anything the entire day. [Participant #15]

Two participants indicated that they stopped doing the exercises because of this reason. Others found creative ways, together with their coach, to increase the intensity level, for instance, by increasing the repetitions, skipping breaks, or adding weight. For instance, a participant commented as follows:

...such as the exercise with shopping bags... I added dumb-bells to it, now it's really challenging. [Participant #10]

Finally, as participants developed a routine, they relied less on the tablet and on the coach for performing the exercises. Some participants kept on having the tablet in sight during the performance of the exercises, while others merely glanced at which exercises had to be performed today and then executed them without the tablet. Watching the video demonstrations or using the countdown timer was not needed anymore. In some cases, participants even did all the exercises by heart, and one participant mentioned the following:

... I can do the exercises when I am at work, in between times. I just count the exercises myself. [Participant #8]

When asked about the necessity of a coach, most of the participants felt that after 2 or 3 months, the coach's help was not needed anymore.

In summary, the video demonstrations and countdown timer helped the participants to perform the exercises safely and correctly, especially during the early stages of the intervention. The coach played an important role in adapting the exercises to meet the capacity of the participants, as many of them sought

a bigger challenge. In time, the participants developed a routine and performed the exercises more autonomously.

Self-Monitoring

Self-monitoring involves the process of keeping track of one's progress. The tablet was designed to support this by letting users tick off exercises that had been completed. In a weekly overview, users could see which exercises had been done and which had not been done. Additionally, a progress bar indicated how many exercises still had to be done today and for the current week. Furthermore, the coach could remotely monitor the progress of the participants.

The moment at which participants ticked off exercises varied. Some did this directly after completing the exercises, whereas others did it at the end of the day. The majority of participants felt that keeping track in this manner gave them insights into their own behavior and was motivating. For instance, one participant made the following statement:

...for me it's very easy...it gives insight and lets me follow what I have done. [Participant #9]

Remarkably, various participants expressed that the mere action of ticking off exercises was not only easy but also rewarding. It left them with a feeling of accomplishment. For instance, one participant made the following statement:

...look, in the end you want to finish off your list. [Participant #8]

However, the progress bar, which indicated how many exercises were completed, was hardly used. Many participants did not seem to have noticed this feature, indicating a usability issue. A couple of participants also expressed the desire for more advance features to investigate their progress, like graphs and tables.

Several participants mentioned that remote monitoring by the coach was an important factor for them to keep doing the exercises. For instance, some participants remarked as follows:

...the tablet motivates me, but...I must say. I think this is also because...that it is being monitored. [Participant #7]

...I think it helps... there is someone keeping an eye on you. [Participant #14]

you are participating in study, you want to show that you are cooperating. [Participant #10]

On the other hand, other participants indicated that this was not the case for them. They would keep doing the exercises if there was no coach involved.

In summary, keeping track of progress with the tablet was easy and motivating. Ticking off completed exercises was experienced as rewarding and gave participants insights into their progress. For some participants, the fact that they were remotely being monitored was motivating, while for others, the social presence of a coach was not important.

Evaluation

Evaluation involves the process of reflecting on the effort and the progress that has been made in relation to the goals that

were set out to be achieved. First, the tablet was designed to support the evaluation process by letting participants rate each exercise on three aspects (effort, complexity, and enjoyment). Second, either via video calls on the tablet or with face-to-face meetings, the participants had the opportunity to reflect on the progress together with their personal coach.

The ability to rate exercises with the tablet was superfluous according to several participants. The need to evaluate each exercise after completion seemed tedious. One participant made the following statement:

Well, look. This bothers me. I think 'come on guys. Everything is so easy and simple. For me there is no difference in it [the effort, complexity or enjoyment of the various exercises]. [Participant #2]

Some participants suggested that it would have been better if they could rate exercises on a weekly basis instead of on a daily basis or only when they felt the need to do so. In contrast, the participants were more positive about the evaluation with the coach. They felt that it helped them to identify issues. Several participants mentioned, however, that toward the end of the 6-month intervention, the coaching was not needed anymore.

Finally, some participants reported that they experienced an improvement in vitality. They found themselves to be in a better shape than before and attributed this to the blended intervention. One participant made the following comment:

...yes, I now really get up without any backache, although this was previously the case. The pain returns in the evening when I am tired, but in the morning it's different. That is a huge benefit. [Participant #5]

Others did not notice an improvement, despite performing exercises, but also expressed more modest expectations. Maintaining their health status was more important than achieving progress for them, as indicated by the following remarks:

Do I notice an improvement in the gym? No. But if I don't do my exercises for a week or two...then I can notice the difference. [Participant #6]

I notice, I am 85, that I am declining... my goal is to stay steady. [Participant #4]

Another participant mentioned the following:

...when you are 18 you can expect to keep on getting better, but for me, after one year I am even more old again... Can I perform some exercises that I couldn't do before? Sure. In that sense there is progress. But it isn't so that I am going to keep on improving. [Participant #16]

When asked if they would like to keep the tablet for exercising, the vast majority of participants expressed the wish to do so, regardless of whether they notice an improvement.

In summary, the blended intervention supported participants in evaluating their progress. Specifically, the conversations with the coach were responsible for this. Overall, the participants evaluated the blended intervention to be useful. Some felt that

their health improved, but others did not have this feeling. Nevertheless, almost all participants indicated that they wanted to continue their exercise routine with support of the tablet.

Discussion

The Value of the Blended Approach

The objectives of this study were to assess the usability of the tablet and how it supported older adults in performing home-based exercises, in conjunction with a personal coach. A previous usability study showed that first-time users (age ranging from 69 to 99 years) could successfully complete various predefined tasks on the tablet during a 45-minute session in a laboratory [29]. This study extends those findings by showing that the tablet can be not only successfully operated in a standardized setting for a short period of time, but also useful, satisfying, and easy to use within the context of exercising at home during daily life for an extensive period of time. The participants indicated that the tablet allowed them to follow a tailored exercise program that suited them. It also helped them to perform the exercises more often, better, and safely. From the perspective of older adults, it can be concluded that the use of the tablet successfully supported them in their exercise behavior.

The interviews revealed a more detailed view on the underlying processes. The tablet was useful in developing an exercise routine. The tablet supported the participants in action planning and behavior execution by providing them with a tailored schedule that gave structure and video instructions demonstrating the appropriate behavior. Furthermore, ticking off exercises as a simple form of self-monitoring appeared to be motivating. On the other hand, the interviews revealed that the personal coach played an essential role. The interactive and social nature of coaching was especially useful during the self-regulation phases of goal setting and evaluation. The ability to interact with users in this manner is yet to be achieved by a virtual coach or avatar [24,42,43]. In addition, although the tablet allowed users to tailor the exercise program to their own needs, the exercises in the app did not sufficiently match the needs of the participants. The expertise of the coach was crucial for adapting the exercises to accommodate preferences. Finally, the presence of the coach in the form of remote monitoring was motivating for some participants. These findings are in line with other research showing that physical activity interventions incorporating access to a remote expert for advice and social support tend to be effective [34,44,45]. This study indicates that the coach might, in particular, be beneficial during the initial period, when participants familiarize themselves with the intervention and develop a routine.

Improvements

Although the participants were overall positive about the blended intervention, the evaluation also revealed several possibilities to improve the intervention. First, fit older adults should be able to add more challenging exercises to their schedule. Taking into account the preferences of some older adults, adding support for outdoor activities to the tablet would be enriching. For instance, a map with walking trails in the vicinity could stimulate older adults in achieving daily physical

activity. Second, the tablet should offer more detailed reports of user progress (eg, graphs that display long-term trends). Some participants requested such a feature. Third, the extent participants relied on a coach varied from person to person. Owing to the protocol of the RCT, coaches contacted the participants with a fixed frequency. When the intervention is implemented in practice, the intensity of counselling should be tuned to the preferences of individuals. Presumably, some older adults will extensively make use of counseling, while others will merely limit it to initial support.

Study Limitations

The aim of the blended intervention was to support older adults in performing home-based exercises. Questionnaires as well as interviews showed that older adults felt that the intervention accomplished this. However, an underlying assumption of the intervention was that regularly performing exercises would support older adults in their daily activities and lead to an active lifestyle and an increase in their vitality. The interviews showed mixed results on this topic, and no support was found for these assumptions from the questionnaires. More challenging exercises or a more comprehensive approach for the vitality of older adults might be needed for such secondary effects; however, the effectiveness of such strategies is also debatable [46-50].

The results of the questionnaires have to be interpreted with caution though. All older adults who participated in the clinical trial were given at the start of the trial a questionnaire about their prior experience with ICT devices. Only 65 of the 224 trial participants completed this baseline questionnaire. Furthermore, the 6-month trial had a 18% drop-out rate. Among the remaining 103 older adults who were part of the group that received a tablet, only 37 filled out the USE questionnaire about the usability of the tablet. The usability results may therefore be biased. Perhaps only participants who had a positive experience with the tablet filled out the usability questionnaire. We do not, however, think this is plausible. First, the baseline questionnaire had a high rate of nonresponses. This fact cannot be explained by a negative experience with tablet use in the blended intervention. The participants were yet to embark on the intervention when filling out the baseline questionnaire. The high nonresponse rate for both the questionnaires might have been caused by the numerous tests that were administered by the researchers as part of the larger clinical trial [32]. The testing procedure, including body measurements, took half a day. This might have led to fatigue, causing participants to skip questionnaires. Second, the positive evaluation based on the

questionnaire is in line with the results from the interviews. Although the sample size of the interviews was small, it was not susceptible to selection bias. The interviews were based on random selection of participants. Only one participant declined to be interviewed. Therefore, the sample that was drawn for the interviews can be considered to be representative of the older adults participating in the intervention. The previous usability study among first-time users and the questionnaires and interviews of this study all point in the same general direction of a favorable evaluation.

The extent to which the findings can be generalized to older adults in general is a different issue. The baseline questionnaire showed that prior use of tablets was high among the participants. Studies have shown that among older adults, tablets are easier to operate than smartphones or personal computers owing to the large touchscreen [51-53]. This was one of the reasons to choose a tablet as the delivery device for the blended intervention [36]. The usability of tablets can also explain the increasing popularity of tablets among older adults. In the United States, tablet ownership among adults aged 65 years or older rose from 1% in 2010 to 32% in 2016 [54]. In the Netherlands, a similar trend has taken place, where tablet ownership among those aged 65 to 75 years grew from 28% in 2012 to 60% in 2016 [55]. In this light, the prior use of tablets among the participants of this study is representative of the larger population. Nevertheless, perhaps only older adults with a positive attitude about ICT in general or a tablet in particular signed up to participate in the blended intervention. More research is needed to assess how a wider range of older adults will experience a physical activity intervention that incorporates the use of tablets.

Conclusion

A mixed-methods process evaluation showed that older adults are positive about a blended intervention designed to support them in performing home-based exercises. Participants rated the adoption of a tablet as useful, satisfying, and easy. They indicated that it helped them to perform exercises better, more frequently, and safely. It supported them in various phases of self-regulation. The interactions with a personal coach strengthened this by offering deeper reflection and more fine-grained tailoring during the earlier stages of the intervention. A blended approach appears to be a promising strategy for delivering physical activity interventions in older adults.

Abstract

Background: Web-based self-management programs have the potential to support patients with cardiovascular disease (CVD) in their self-management (eg, by focusing on behavior change and improving physical activity). The intervention mapping framework was used to develop a web-based program called Vascular View. The Vascular View program contained 6 modules (coping with CVD, setting boundaries, lifestyle, healthy nutrition, being physically active, interaction with health professionals) aiming to increase self-management behavior by tailoring to the perceived problems and (support) needs of patients after CVD.

Objective: The aim was to test the effectiveness of Vascular View before embarking on a full-scale randomized clinical trial (RCT) by evaluating the potential effectiveness and effect sizes of the Vascular View program and identifying outcome measures most likely to capture the potential benefits.

Methods: An explorative RCT was performed. Both control and intervention groups received care as usual and, in addition, the intervention group received 12 months of access to a web-based self-management program. Assessment occurred at baseline, 6 months, and 12 months. Outcome measures included general patient-reported outcome measurements: Illness Perception Questionnaire (IPQ), Rand-36, Patient Activation Measure, and patient self-efficacy. Module-specific patient-reported outcome measurements were Beliefs about Medicines Questionnaire, International Physical Activity Questionnaire, Dutch Healthy Diet Index, Fagerström Test for Nicotine Dependence (FTND), Alcohol Use Disorders Identification Test, and Perceived Efficacy in Patient-Physician Interaction. Linear mixed models for repeated measures using intention-to-treat and per-protocol analysis were applied to study differences between the patients in the intervention and control groups. Floor and ceiling effects were explored to give insight into the outcome measures most likely to capture the potential benefits.

Results: A total of 105 patients in the control group and 103 patients in the intervention group participated in the study. A positive direction of change between baseline and 12 months was shown for most outcome measurements in favor of the intervention group, of which 2 out of 10 outcomes showed a significant effect: attribution of cause of the disease to risk factors and immunity factors (IPQ) and dependency of nicotine (FTND). Floor and ceiling effects were seen in the IPQ, Rand-36, and the self-efficacy questionnaire.

Conclusions: No conclusion for the efficacy of the Vascular View program or selection of outcome measurements can be taken yet. A process evaluation will be conducted to gain thorough insight into the working elements of the program, patient needs in eHealth, and the use of the program by patients. This can determine for whom web-based self-management programs will work and help to adapt the program.

KEYWORDS

explorative randomized controlled trial; cardiovascular diseases; self-management; eHealth support programs; internet; lifestyle; nursing

Introduction

Cardiovascular diseases (CVDs) are the leading cause of death worldwide, and survivors of CVD are at high risk for a secondary CVD event [1]. Prevention of secondary CVD events can be influenced by focusing on the interaction of behavioral risk factors (lifestyle components), metabolic risk factors (hypertension, high blood glucose levels, raised blood lipids, and overweight), and other risk factors (eg, advancing age, sex, stress, and depression) [1]. Managing these factors poses high demands on patient self-management skills. Despite support from health care professionals, patients have trouble managing their CVD and its consequences in daily life themselves [2]; they experience disease-related problems such as dealing with the symptoms, treatment, physical and psychological consequences, and recommended lifestyle changes.

Self-management of chronic illness has been widely recognized as a way to support patients in achieving the best possible quality of life with their chronic condition [3,4]. Secondary prevention programs targeting self-management through risk factors and (lifestyle) behavior change have been associated with reduced mortality, reduction of repeated cardiac events, and improved health-related quality of life [5,6]. However, attendance rate in cardiac rehabilitation programs remains less than 50% worldwide [7,8] due to barriers like lack of transportation, embarrassment of participation, a dislike of group environments, and work or domestic commitments [9,10]. The use of web-based self-management programs could be a remedy to these barriers, since these programs have the potential to reach a large group of patients and diminish barriers because of the possibility of accessing programs anytime and anywhere and providing anonymity. Buys and colleagues [11] found that patients with CVD showed a high interest in support through the internet (77%) and mobile phones (68%).

Recent systematic reviews have shown the high potential of electronic health (eHealth) interventions for CVD prevention [12-15]. Widmer and colleagues [14] demonstrated significant reduction on CVD outcomes due to digital health interventions (relative risk -0.61, 95% CI 0.46-0.80; $P<.001$; $I^2=22\%$). Another systematic review studied behavioral change by using mobile health interventions: studies aiming to improve physical activity ($n=2$) or medication adherence ($n=3$) showed positive effects, but no effects were seen in studies aiming to decrease smoking ($n=1$) or change diets ($n=1$) [12]. Duff and colleagues

[15] investigated the use of behavior change techniques (BCTs) in eHealth interventions for improving physical activity for patients with CVD: 8 of the 15 interventions showed significant improvements, while in 5 of the 15 studies the intervention group scored equal to the control group.

Not all studies recognize the potential of eHealth interventions, and demonstrate more questionable results. Hamine and colleagues [16] evaluated the effectiveness of mobile health (mHealth) interventions in supporting adherence of patients to chronic disease management (including CVD). Out of 41 randomized controlled trials (RCTs) that measured the effects of mHealth interventions on disease-specific clinical outcomes, significant improvements between groups were reported in only 16 studies (39%). Specific for cardiovascular risk factors, another review showed that the use of multiple modifiable internet lifestyle interventions in primary or secondary care is not superior to usual care [17]. Although 4 out of 9 studies demonstrated significant improvement in various risk factors, clinical relevance of these differences is questionable [17]. Inconsistent evidence is often due to limitations in the intervention and research design and a lack of power in the studies [18]. Limitations like small sample sizes, unclear description of intervention characteristics, short duration, and selection bias were noted in review studies [12,13].

To reduce the risk of limitations, we used the intervention mapping (IM) framework to develop a comprehensive, multicomponent web-based self-management program for patients with CVD called Vascular View (Vaar in Zicht in Dutch). IM contains 6 steps to design, implement, and evaluate an intervention based on the foundation of theoretical, empirical, and practical information [19]. The program Vascular View aims to increase self-management behavior tailored to the perceived problems and (support) needs of patients after CVD diagnosis [20]. Each of the 6 modules has a specific goal based on determinants of the I-change model [21]. For each of these selected determinants, BCTs were selected [22]. A detailed description of the development and content of Vascular View has been described elsewhere [20].

The last step of IM (step 6) is evaluation. This paper describes the testing of the effectiveness of Vascular View before embarking on a full-scale RCT. This explorative RCT study in patients with CVD aims to evaluate the potential effectiveness and effect sizes of the Vascular View program on 10 patient outcome measures and identify the outcome measures most

likely to capture the potential benefits of the Vascular View program.

Methods

Design

An explorative RCT was conducted at four outpatient clinics (cardiology, internal medicine, neurology, and vascular surgery) at Radboud University Medical Center in the Netherlands. To explore the efficacy of the web-based self-management program

and identify suitable outcome measures, questionnaire data of patients allocated to the intervention and control groups were compared at 6 and 12 months after baseline on 10 outcome measurements related to the performance objectives of the intervention. Table 1 shows the modules, performance objectives, and related outcomes of the intervention. Since all outcomes are targeted through the intervention, positive effects are expected on all outcomes. The trial is registered in the Dutch Trial Register [NTR5412]. The medical ethics committee of Arnhem-Nijmegen in the Netherlands approved this study (registration number: 2015/1908).

Table 1. Modules, performance objectives, determinants, and related outcomes of the intervention.

Module	Performance objectives	Determinants	Module-specific outcomes
Coping with CVD ^a (3 sessions)	Patients have insight into CVD and accompanying symptoms and consequences. Patients cope with CVD and accompanying symptoms and consequences. Patients cope with (changed) sexuality and intimacy. Patients cope with stress in daily life. Patients cope with fear and emotions related to CVD. Patients cope with pain related to CVD. Patients adhere to medication instructions.	Knowledge, awareness, risk perception, attitude, self-efficacy, subjective norm, intention, action plans	BMQ ^b , Self-efficacy (subscale: acceptance)
Setting boundaries in daily life (4 sessions)	Patients set boundaries. Patients adapt to changed circumstances. Patients ask for support from partner, relatives, and social environment. Patients cope with changed roles in family, job, and/or society. Patients are able to resume activities within their own possibilities.	Knowledge; awareness, attitude, self-efficacy, subjective norm	Self-efficacy (subscale: social environment), Self-efficacy (subscale: setting boundaries)
Lifestyle (4 sessions)	Patients refrain from tobacco use. Patients refrain from (harmful) alcohol use.	Knowledge, awareness, attitude, self-efficacy, subjective norm, intention, habits, skills	FTND ^c , AUDIT ^d , Self-efficacy (subscale: smoking), Self-efficacy (subscale: alcohol)
Healthy nutrition (3 sessions)	Patients eat healthy.	Knowledge, awareness, attitude, self-efficacy, subjective norm, intention, habits, skills	DHD ^e , Self-efficacy (subscale: diet)
Being physically active in a healthy way (3 sessions)	Patients are physically active.	Knowledge, awareness, attitude, self-efficacy, subjective norm, intention, habits, skills	IPAQ ^f , Self-efficacy (subscale: physical activity)
Interaction with health professionals (4 sessions)	Patients interact with health professionals.	Knowledge, awareness, attitude, self-efficacy, subjective norm	PEPPI-5 ^g , Self-efficacy (subscale interaction)

^aCVD: cardiovascular disease.

^cFTND: Fagerstorm Test for Nicotine Dependence.

^dAUDIT: Alcohol Use Disorders Identification Test.

^eDHD: Dutch Health Diet Index.

^fIPAQ: International Physical Activity Questionnaire.

^gPEPPI-5: Perceived Efficacy in Patient-Physician Interactions.

Participants

In the third quarter of 2015, 600 consecutive patients who had visited the outpatient clinic because of an established cardiovascular event were invited by the treating medical specialist to participate in this study. Inclusion criteria were (1) a cardiovascular disease (myocardial infarction, cerebrovascular disease [stroke included], peripheral artery disease, or combination); (2) a CVD event within 2 months to 1 year before start of the study; (3) aged 18 years or older; (4) able to read and understand Dutch; and (5) have access to a computer, internet, and an email account. Patients with a psychiatric disorder were excluded. Patients received information about the content and aim of the study, a short questionnaire to assess the inclusion criteria, and an informed consent form from the medical specialist via postal letter. Patients were asked to sign and return the informed consent form and completed questionnaire to the researcher (ME). When patients agreed to participate and were eligible, they received an invitation to complete the online questionnaire baseline data collection.

Randomization

Randomization took place after the baseline measurement and was stratified for four patient diagnoses: myocardial infarction, cerebrovascular disease (stroke included), peripheral artery disease, and aneurysm. The most recent diagnosis was used in randomization for patients with comorbidity in CVD. A blinded and independent statistician executed the randomization using SAS version 9.4 (SAS Institute Inc), which is an automated randomization program. The researcher (ME) informed patients about their assignment to control or intervention group. All patients in both groups continued with their care as usual: regular visits, treatment at the outpatient clinics, and standardized cardiovascular risk management, which contained an evaluation of cardiovascular risk factors, including feedback to optimize lifestyle. In addition to the care as usual, patients in the intervention group received 12 months access to the intervention (October 2015 until October 2016) directly after randomization.

Intervention

The Vascular View program was systematically developed in collaboration with CVD patients and health care professionals [20]. By defining performance and change objectives in conformity with the IM steps [19], 6 topics were distinguished and incorporated into the modules included in Vascular View: (1) coping with CVD, (2) setting boundaries in daily life, (3) lifestyle in general with specific attention to tobacco and harmful alcohol use, (4) healthy nutrition, (5) being physically active in a healthy way, and (6) interaction with health care professionals. Moreover, patients had access to two diaries (exercise and nutrition) in which patients could register their behavior to get insight into their exercise and nutrition routines. Each module comprised 3 or 4 sessions, which were personalized and supported by written information, tailored feedback, quotes from and videos of patients with CVD, pictures, and exercises. The Vascular View program started with information about the content and objectives of the 6 modules. The program was unguided but patients could complete an assessment and receive

tailored advice about which of the 6 available modules was recommended for them.

Patients could visit the web-based self-management program and different modules as often as they wanted. Three groups were determined to give insight in the use of the program: nonusers, minimal users, or frequent users. Nonusers were patients that never or only once visited the program, minimal users visited the program 2 to 20 times, and frequent users visited more than 20 times. A detailed description of Vascular View, implementation, and the process evaluation is described elsewhere [20], and an overview of the program can be seen in Table 1.

Measurements and Outcomes

Baseline Characteristics

All patients who completed the baseline questionnaire between August 2015 and October 2015 received a questionnaire after 6 months (T1) and after 12 months (T2). At baseline, the following demographic and disease-related characteristics were collected: age, sex, educational level, work participation, cultural background, diagnosis and comorbidity, duration of illness, body weight, height, computer use, and experience with rehabilitation programs. Patient-reported outcome measurements were assessed at baseline and during follow-ups (T1 and T2). These outcomes could be distinguished in generic and module-specific outcomes (Table 1). The great amount of outcomes resulted in a long questionnaire with a great demand of time on participants. Therefore, the questionnaire at T1 was shortened by omitting two questionnaires: the Illness Perception Questionnaire (IPQ) and Rand-36. When patients preferred a paper questionnaire, a version was sent by post.

General Patient-Reported Outcome Measurements

Patient's illness attributions were assessed by the "causes of my illness" section on the IPQ. It contains 18 items measured on a 5-point Likert scale measuring four dimensions: psychological attributions, risk factors, immunity, and accident or chance. A higher score indicates a higher level of attribution to the dimension [23].

The patient's general health status was measured with the Rand-36, consisting of 36 items measuring 8 dimensions: physical functioning, social functioning, physical role limitations, emotional role limitations, mental health, vitality, pain, and general health perception [24]. The subscales physical and emotional role limitations have dichotomous items. The other subscales contained Likert scale items, with a higher score indicating better perceived health-related quality of life. All subscale scores were transformed to a 0-100 point scale.

The Patient Activation Measure (PAM-13), which includes statements about an individual's knowledge, confidence, and skills for self-management of their chronic illness behavior and the level of activation, was used to measure participants' self-management ability. The PAM-13 includes 13 items on a 5-point scale with a higher score indicating a higher level of patient activation [25,26].

No validated questionnaire was available that corresponded to the aims of the intervention; therefore, patient's self-efficacy

was measured with a self-developed questionnaire (see [Multimedia Appendix 1](#) for an overview of the scales and examples of items). The aim of this questionnaire was to measure how confident patients felt about self-managing CVD based on the performance objectives and corresponding determinants (step 2 of the IM framework). Four patients from the expert group, who were involved in the development of the Vascular View-program [20], were asked to participate in the Think Aloud procedure, a technique used to evaluate the questionnaire [27]. The final questionnaire included 26 items measuring 8 subscales. The items were scored on a 4-point scale with a higher score indicating a higher level of confidence about self-managing CVD. For each subscale, Cronbach α was calculated using the baseline, 6-month, and 12-month data of both groups (control and intervention). Each subscale is related to a module in the Vascular View program (see [Table 1](#)): acceptance (Cronbach α =.81), social environment (Cronbach α =.87), interaction with professionals (Cronbach α =.85), physical activity (Cronbach α =.83), diet (Cronbach α =.84), smoking (Cronbach α =.83), alcohol (Cronbach α =.90), and setting boundaries (Cronbach α =.78).

Module-Specific Patient-Reported Outcome Measurements

To measure patient attitudes toward their prescribed medicine, the first scale on the Beliefs about Medicines Questionnaire (BMQ) was used, which contains 10 items on a 5-point Likert scale. Two subscales (concerns and necessity) each contained 5 items that summed up to a scale score. A higher score reflects higher levels of concerns or feelings of necessity concerning the prescribed medicine [28,29].

Patient physical activity was measured with the International Physical Activity Questionnaire (IPAQ, short version) [30]. The IPAQ contains 7 questions divided in 3 subscales: walking, moderate intensity activity, and vigorous intensity activity. These subscales are described in minutes per week.

The Dutch Healthy Diet Index is a 34-item questionnaire to estimate adherence to the 2006 Dutch guidelines for a healthy diet, containing 8 components: vegetables, fruit, dietary fiber, fish, saturated fats, trans fats, sodium, and alcohol. Per component the score ranges between 0 and 10, resulting in a total score between 0 (no adherence) and 80 (complete adherence) [31].

Patient tobacco dependence was measured with the Fagerström Test for Nicotine Dependence. This questionnaire consists of 6 items resulting in a total score between 1 and 10, in which a higher score reflects more dependence of nicotine [32].

Alcohol use was measured by the 3-item Alcohol Use Disorders Identification Test with a total score from 0 to 12. A score of 5 or higher indicates the possibility of increasing risk and higher risk of alcohol drinking [33].

Patient interaction with health care professionals was measured with the Perceived Efficacy in Patient-Physician Interaction, which contains 5 items on a 5-point Likert scale that are summed to determine the total score. A higher score reflects more confidence of the patient in interactions with their physician [34,35].

Biomedical Measurements

Electronic patient dossiers were searched for biomedical data on two time points: April 2015 to December 2015 (baseline measurement) and April 2016 to March 2017 (12-month measurement). The search of biomedical data included weight, BMI, systolic and diastolic blood pressure, total cholesterol, low-density lipoprotein-cholesterol, high-density lipoprotein-cholesterol, triglycerides, and non-high-density lipoprotein-cholesterol.

Statistical Analysis

For explorative RCTs such as this, sample sizes are not calculated based on formal power analyses. Therefore, a sample size of 200 patients was chosen for this trial, which was considered a sufficient size for a representation of the relevant variation in the target group. All quantitative data were analyzed using SPSS Statistics version 25 (IBM Corporation). Descriptive analyses were used to describe the control and intervention groups at baseline. The differences between patient characteristics in the intervention and control group were tested using *t* tests and chi-square tests. A *P* value of <.05 was determined as statistically significant in all analyses.

A linear mixed-model analysis with repeated measures on intention-to-treat (ITT) basis was used to determine the differences in outcome measures between the intervention and control group. In this model, the outcomes were the dependent variables and the patient was the random factor. The fixed factors were group (intervention/control) and time and the interaction between time and group. This method automatically uses the missing at random assumption to handle missing data.

Subsequently, a per-protocol analysis (PPA) was performed to compare the control and intervention group with only those patients who completed the treatment originally allocated. Patients in the control group were included if they completed the questionnaire at baseline and 6 and 12 months. Patients in the intervention group were included if they completed the questionnaire at baseline and 6 and 12 months and used Vascular View at least once. Moreover, the same tests and linear mixed-model analyses were used as described in the ITT section.

Identifying Outcome Measures

To identify outcome measures most likely to capture the potential benefits, floor and ceiling effects were explored for all outcome measurements using Likert scales at baseline. A floor effect indicates that most of the participants score near the minimum score and a ceiling effect indicates that most participants score near the maximum score on a questionnaire.

In this calculation, we considered floor and ceiling effects exceeding 20% to be significant [36]. Thereby, spaghetti plots were used to analyze the changes between T0 and T2 for all individuals.

Results

Participants

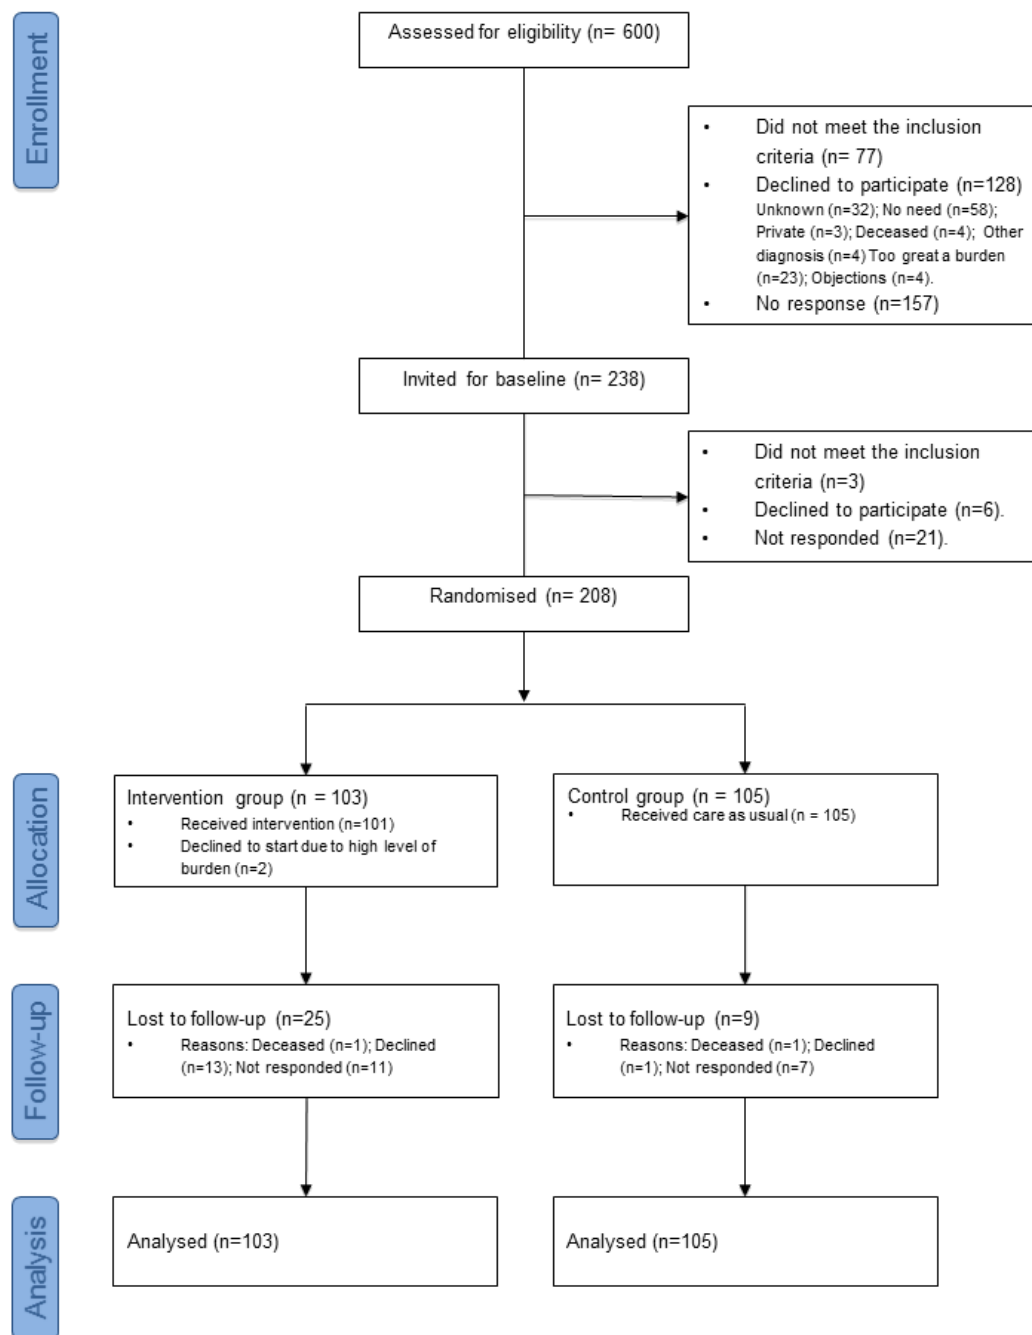

In total, 600 patients were eligible and invited by the medical specialist. Of these, 238 patients expressed interest, and 208

(87.4%) participated in the study (see Figure 1). Of the 30 patients who were not included, 3 did not meet the inclusion criteria, 6 declined, and 21 did not respond to the invitation. The 208 participating patients were randomized to the intervention (n=103) or control group (n=105) and stratified by CVD diagnosis. Two intervention group patients completed the baseline questionnaire but declined to participate in the intervention. At T1, 86 patients in the intervention group and 103 in the control group completed the questionnaire. At T2, 78 patients in the intervention group and 96 in the control group

completed the questionnaire. More intervention group patients (25/103, 24.3%) compared with control group patients (9/105, 8.6%) were lost to follow-up.

All patients in the intervention group (n=101) had access to Vascular View, of which 37.6% (38/101) did not visit the program or only once, 27.7% (28/101) visited the program 2 to 20 times, and 34.7% (35/101) visited the program more than 20 times. The range of visits was between 1 and 43 visits per participant.

Figure 1. Flowchart of Vascular View study.

Outcomes of the Intention-To-Treat Analysis

Baseline Characteristics of Patients

Demographic and disease-related characteristics at baseline were compared for the control and intervention group, as shown in Table 2. The mean age of the patients in the intervention

group was 63.3 (SD 10.0) years and 63.7 (SD 9.8) years in the control group. Both groups had more men than women: 69 men in the control and 73 in the intervention group. There were no statistically significant differences between the control and intervention group.

Table 2. Intention-to-treat analysis: patient characteristics at baseline.

Characteristics	Control (n=105)	Intervention (n=103)
Sex (male), n (%)	69 (66.0)	73 (71.0)

Biomedical Measurements

An overview of the mean scores and standard deviations of patients in the intervention and control group at baseline and after 12 months is presented in Table 3. No statistically

significant differences were found between the control and intervention group.

The biomedical data show a high level of missing values in both the control and intervention group. For example, triglycerides show a large group of missing values: 45% of values are gathered at T2 compared with T0.

Table 3. Biometrics of control and intervention group.

Patient Outcome Measurements at Baseline and Follow-Up

Multimedia Appendix 2 provides an overview of the mean scores and standard deviations of outcome measurements of the patients in the intervention and control group at baseline and after 6 and 12 months. At baseline, the intervention group had more patients who smoked (n=13) compared with the control group (n=5), which was a statistically significant difference (mean difference 0.4; $P=.04$). Thereby, patients in the intervention group scored at baseline significantly higher on self-management behavior (PAM-13) compared with patients in the control group (mean difference 4.4; $P=.03$).

The estimated differences and P values between the intervention and control group after ITT analysis at 6 and 12 months after baseline are presented in Multimedia Appendix 2. Six out of 29 variables in the intervention group and 13 out of 29 in the

control group decreased over time. Two questionnaires showed significant effects in favor of the intervention group. First, the IPQ scores showed that intervention group patients attributed the cause of their disease more to risk factors and immunity factors after 12 months. Patients in the control group showed a decrease on attribution to risk factors and a small increase on immunity factors. Second, the intervention group showed a statistically significant decrease for the dependency of nicotine after 6 months (-1.55 ; $P=.01$) and after 12 months (-1.67 ; $P=.01$) with respect to T0.

Outcomes Per-Protocol Analysis

Baseline Characteristics of Patients

There were no significant between-group differences found in the demographic and disease-related characteristics at baseline for the control and intervention group of the patients following the intervention per protocol (Table 4).

Table 4. Per-protocol analysis: patient characteristics at baseline.

Characteristics	Control (n=95)	Intervention (n=52)
Sex (male), n (%)	62 (65.3)	36 (69.2)

Patient Outcome Measurements at Baseline and Follow-Up

Multimedia Appendix 3 gives an overview of the PPA with mean scores, standard deviations, effect sizes, and *P* values of outcome measurements of the patients in the intervention and control group at baseline and after 6 and 12 months. At baseline, patients in the intervention group scored significantly higher on self-management behavior (PAM-13) compared with patients in the control group (mean difference 5.6; *P*=.03). The subscale social environment showed a significantly higher score on self-efficacy for intervention group patients compared with the control group (mean difference 0.2; *P*=.04) at baseline.

The PPA showed effects on the same outcomes as the ITT analysis. The IPQ scores on risk factors (0.31; *P*=.02) and immunity factors (0.48; *P*<.001) showed a statistically significant difference between intervention and control group: the IPQ scores show that after 12 months, patients in the intervention group attributed the cause of their disease more to risk factors and immunity factors. Patients in the control group showed a decrease on attribution to risk factors and no change on immunity factors. Patients in the intervention group decreased the dependency of nicotine significantly toward the control group after 6 months (−1.87; *P*=.01) and after 12 months (−1.72; *P*=.02).

Suitable Outcome Measures

The percentages of patients scoring 0 (floor effects) or full marks (ceiling effects) on the 10 outcome measures were assessed at baseline. Significant floor effects were seen on the subscales IPQ psychological attributions (22.0%), IPQ immunity (35.3%), and IPQ accident or chance (26.6%). Significant ceiling effects

were noticed on the subscales Rand social functioning (29.3%), Rand bodily pain (29.3%), patient self-efficacy with a self-constructed 26-item questionnaire (SE) interaction (26.9%), SE physical activity (33.8%), SE diet (30.9%), SE alcohol (35.2%), and SE setting boundaries (23.7%).

Discussion

Principal Findings

This explorative RCT aimed to evaluate the potential effectiveness and effect sizes of the Vascular View program on 10 patient outcome measures and identify the outcome measures most likely to capture potential benefits. The evaluation of potential effectiveness of Vascular View showed significant effects for illness attribution and nicotine dependence. At 12 months, patients in the intervention group attributed the cause of their diseases more often to risk factors and immunity factors than patients in the control group. Intervention group patients showed less dependency of nicotine after 6 and 12 months compared with the control group. It should be noted that we are not convinced that this effect was clinically meaningful due to the small number of participants who stopped or decreased smoking and because the effect is partly due to a high dropout of smokers in the intervention group (4 out of 13) compared with no dropout in the control group and one patient in the control group who started smoking after the baseline measure. Although the other outcomes showed no statistically significant differences between the intervention and control group, there seems to be a positive trend in the improvement of outcome measurements in favor of the intervention group. Overall, we did not expect to find a nonconvincing trend regarding the efficacy of Vascular View, since the theory-based intervention

was thoroughly designed with patients and health care professionals on the basis of patient support needs according to the IM steps [19]. Furthermore, the outcome measures were selected carefully and in line with the objectives of the intervention. Randomization was successful, and the number of missing values was limited.

To our knowledge, Vascular View is the first web-based self-management program for secondary care patients with CVD that aims to improve so many components and in which patients can decide which modules they want to use. Other (effective) eHealth interventions for CVD prevention focused primarily on one or two risk factors (eg, physical activity [15] and smoking cessation [37]). Results of web-based self-management programs with multiple components in other diseases show comparable results [38-40]. Vascular View tried to guide patients by using a questionnaire to advise them in choosing courses in the welcome module and lifestyle module [20]. However, the large amount of topics might have resulted in an overload of information and subsequently demotivation and minimal use of the program. The lack of efficacy of the Vascular View program is not in line with studies that show the potential of eHealth interventions for secondary prevention of CVD [12-16]. For example, Vascular View addressed patients' intrinsic processes through the determinants, which is seen as a successful strategy for face-to-face self-management programs [41]. However, it is hard to compare studies on eHealth self-management programs because of the various eHealth approaches and outcome measures available. Review studies show a large diversity in studies, looking at outcome measures, use of eHealth interventions, implementation, etc.

A discrepancy between needed self-management support by patients and provided self-management support by nurses is familiar in health care. Vascular View is an unguided self-management program in which nurses did not discuss the Vascular View program with patients, the program was not part of consultation, and nurses did not encourage patients to continue use of the program. The question should be raised whether use of the intervention should be supported and perhaps even used as a partial replacement of usual care. Providing self-management support is a core task of nurses in outpatient clinics, and patients expect health care professionals to fulfill a comprehensive role [42]. However, nurses seem to experience barriers in discussing all self-management categories (symptom management, treatment, biomedical cardiovascular risk factors, psychosocial consequences, and lifestyle changes). Physical components are often discussed, but psychological components are left behind [43]. Web-based self-management interventions could be a way to improve self-management support by focusing on the patient instead of the health care professional. More research needs to be conducted to determine the balance between support by the nurse and a self-guided self-management program.

Only half of the intervention group ($n=51$) adhered to the intervention: they completed all questionnaires and used Vascular View once or more often. Moreover, 38% did not use the program or used it only once. Although a previous questionnaire study showed that 77% of patients with CVD were interested in support through the internet [11], it seems to

be important to match expectations of patients with the online program [44]. When patient expectations did not line up with the online program, patients refused to complete the measurements and revisit the online program [44]. Three striking differences between patients in the ITT and PPA give insight in the difference between users and nonusers. First, mostly patients with an intermediate education level drop out (difference between ITT and PPA: 9.9%) and a relatively high number of patients with a lower level of education used the program (difference between ITT and PPA: 6.6%). These results are contrary to other research suggesting that lower educational levels are a barrier for eHealth use [45]. Second, the percentage of patients with myocardial infarction is higher in the intervention group of the PPA (65.4%) compared with the ITT (56.3%). This suggests a higher need for self-management support in patients with a myocardial infarction diagnosis. Third, the Vascular View program seems to be more popular in patients scoring higher on patient-related outcomes such as self-management, physical activity, quality of life, diet, nicotine adherence, and alcohol adherence. Improvement is more difficult to achieve in this group.

The second aim was to identify the outcome measures most likely to capture the potential benefits. Most of the chosen outcome measures were likely to capture the potential effect, although floor and ceiling effects were seen in the IPQ, Rand-36, and patient's self-efficacy questionnaire. Patient's illness attributions (IPQ) [23] showed a right-skewed distribution, meaning that more than 20% of the patients attributed their disease not to psychological factors, immunity, accident, or chance at all. However, effects after 12 months were seen on the IPQ since the intervention group increased attribution to psychological factors, immunity, and risk factors. In spite of the floor effects, the IPQ is a valuable measurement to give insight in the efficacy of the Vascular View program. A left-skewed distribution was found in 2 subscales of the Rand-36 [24] (social functioning and bodily pain), indicating that more than 20% of the patients already experienced a high quality of life. Since CVD patients show relatively low pain levels and physical symptoms, for future research we suggest an instrument with a higher sensitivity such as the Seattle Angina Questionnaire [46,47]. The self-efficacy questionnaire also showed a left-skewed distribution, suggesting high self-efficacy on interaction, physical activity, diet, alcohol, and setting boundaries. More research should be conducted to determine the reliability and validity of this self-developed questionnaire. To conclude, a more sensitive instrument for quality of life is suggested for future research. All other questionnaires were sensitive to measure change in this population.

Limitations

We believe this explorative RCT has numerous methodological strengths, although some limitations need to be mentioned. First, more patients in the intervention compared with the control group were lost to follow-up. However, we have not established that patients with specific characteristics dropped out. Second, this research was conducted in the outpatient clinic of a university hospital in which high quality of CVD care is already delivered, and therefore it may be harder to achieve improvement. Last, all patients in the outpatient group were

informed but only the ones who were interested in the study were invited to participate. A limitation is that this might be a biased group because they were probably already interested in self-management.

Recommendations for Clinical Practice and Research

For future studies, we recommend further studying patient self-management needs and the possibilities of tailoring eHealth. Although Vascular View was developed using IM on the basis of the support needs of patients with CVD [20], individual participating patients were not asked for their intentions to improve self-management and change their behavior and what kind of support needs they preferred. In our study, patients with higher starting levels (eg, self-management) were more likely to use the program. So, the readiness to change or phase of the disease might be predictors for using the program (and the needed support type). To conclude, to increase use and efficacy of eHealth programs, more insight into characteristics of patients who could benefit from web-based self-management programs is needed. A process evaluation will be conducted and published using the components of Saunders (fidelity, dose, reach,

recruitment, and context) to get more insight into the low compliance with and noneffectiveness of the intervention and fine-tune the inclusion criteria. Furthermore, we believe that the program should be embedded in treatment and supplement self-management support provided by nurses. More research needs to be conducted to determine the balance between nurse support and self-guided self-management programs.

Conclusions

This study contributes to our understanding of self-management support for patients with CVD using eHealth apps. Although we believe in the potential of the Vascular View program, there is no conclusive evidence for the efficacy. Using an unguided self-management program might not work for everyone, and the program might need to be embedded in health care more firmly. A detailed process evaluation of the program should be conducted to gain thorough insight into the working elements of the program, patient needs in eHealth, and the use of the program by patients. Finally, it should be investigated how Vascular View can be more tailored to the patient needs and become more embedded in treatment.

Acknowledgments

This study is funded by ZonMw, the Netherlands Organization for Health Research and Development (520001001). The authors would like to thank the patients with CVD and health care professionals for their contribution in the expert groups.

Abstract

Background: Mental health difficulties in young people are increasing, and there is a need for evidence on the effectiveness of digital interventions to increase opportunities for supporting mental health in young people. Such studies are complicated due to issues of implementation and adoption, outcome measurement, and appropriate study designs.

Objective: The objective of this study was to examine the effectiveness of an mHealth intervention (ReZone) in reducing mental health difficulties in young people.

Methods: The cluster-randomized controlled trial enrolled 409 participants aged 10-15 years, and classes were allocated to ReZone or management as usual. Self-reported questionnaires were completed at baseline and 3-month follow-up.

Results: There were no significant differences between the ReZone condition and management as usual in the self-reported outcome measures. However, there were 3467 usage sessions, which corresponds to 16.9 times per student (total of 205 students) in classes allocated to ReZone.

Conclusions: It is essential to publish studies that do not show significant differences, as these findings can still contribute to the literature, help in learning, and inform the direction of future work. The results reported in this paper could be due to a range of reasons, including whether ReZone has the scope to impact change or limitations related to the setting, context, and appropriateness of an RCT. The findings of this study suggest that ReZone was implemented and adopted.

KEYWORDS

cluster trial; behavioral difficulties; schools; mHealth; digital; mental health

Introduction

Mental health difficulties are increasing among young people. Emotional disorders are the most prevalent and show the most significant increase over time and with age [1,2]. Recent figures show that 1 in 8 (12.8%) people aged 5-19 years had at least one mental disorder when assessed [3]. Mobile health (or mHealth) interventions have the potential to provide mental health support at scale, and there is a need for evidence as to

the effectiveness of digital interventions for supporting mental health in young people [4]. However, non-adoption and implementation issues present substantial barriers to effectively doing so [5]. Additionally, questions about whether randomized controlled trials are always the most appropriate method of evaluation need to be considered in the context of practicality and feasibility factors [6-8].

The authors have co-designed an mHealth intervention, ReZone, with young people, parents/carers, and teachers, based on

cognitive behavioral therapy (CBT), mindfulness, and attention bias modification training (ABMT). This short paper will report the findings from a cluster randomized controlled trial (RCT) to test the hypothesis that young people in classes receiving ReZone have fewer behavioral difficulties than young people in classes receiving management as usual. Full details on the methods and development are reported in the protocol [9] and implementation paper [10].

Methods

Participants and Procedure

A total of 49 classes were recruited (27 mainstream, 22 alternative provision), resulting in a sample of 409 students (mean age 10.9, SD 1.44 years; 56% male; Table 1). Schools

were recruited via newsletters and events published in our Schools in Mind network. Participants were enrolled from 12 mainstream primary schools (307 students) and 11 secondary alternative provision schools (103 students). A total of 66 people were lost to follow-up, resulting in an attrition rate of 16%. All students (aged 10-15 years) in schools taking part in the project were eligible to participate. Classes were randomized using a true random number generator in blocks of two by an independent trials unit, to management as usual or ReZone stratified by school type (alternative provision vs. mainstream) after classes were recruited and baseline measures assessed. Ethical approval was received from University College London (UCL) Research Ethics Committee (number: 7969/001). The present research is reported in line with CONSORT guidelines [11].

Intervention: ReZone App

Full details of the ReZone intervention are described in the protocol [9]. The intervention primarily aims to reduce behavioral difficulties. It is available as a web-based smartphone and tablet application flexibly designed to be used in groups or individually, with or without adult support depending on the user's capability and confidence. This flexibility also extends

to the order and frequency in which elements of the tool are used. However, it is required to have an initial guided session or tutorial with an adult. This flexible approach to implementation aimed to fit within a variety of schools and their differing student characteristics, priorities, and timetables.

The primary features of ReZone (Textbox 1) are presented below.

Textbox 1. The primary features of ReZone.

Stress bucket. The stress bucket lets the user add any stressors that they are experiencing to a bucket. They are then able to introduce activities that help them cope with each stressor. They can see the water in the bucket rise and fall as they add and relieve stressors. If the bucket reaches 50 stress points, it will overflow.

Timeout. Timeout asks the user to think through a time when they have felt stressed, angry, or upset. The user works through the events leading up to feeling this way and what happened afterward. The user can also think through what they could have done differently, thus guiding them to develop a behavioral plan. The timeout visualization is a rocket, and each thought process creates an exhaust cloud.

Chill out. Chill out uses breathing to help the user calm down and relax. Each chill out activity is based around an object or animal (ie, rabbit, jellyfish, ball, or square), using breathing in different ways.

Art therapy. The user can choose between a castle, dinosaur, fish, goat, heart, helicopter, unicorn, rocket, footballer, sea, or turtle to color in. There is a range of colors and tools to complete the drawing.

Happy faces. The user is given 30 seconds to find as many happy faces as they can, amongst other faces depicting negative emotions.

Game. In the game Balloon Blast, the user taps the screen to move a balloon up, trying to avoid all the obstacles as hitting one will mean the game is over. The game provides a break or reward for the user in between uses of the other features.

Measures

All measures were self-reported by young people and administered in school by researchers or school staff in paper form. Baseline demographic data were collected and are reported in Table 1. Emotional ($\alpha=.78$) and behavioral difficulties ($\alpha=.81$) were measured using the 16-item Me and My School (M&MS) questionnaire [12]. Mental wellbeing was measured using the 7-item Short Warwick-Edinburgh Mental Wellbeing Scale ($\alpha=.83$) [13]. Empowerment was measured using the 6-item “self” subscale of the Youth Empowerment Scale-Mental Health ($\alpha=.73$) [14]. Health-related quality of life was measured using the 6-item (with global health visual analog scale) EQ-5D-Y ($\alpha=.63$) [15].

Intervention Usage

Intervention usage data were collected in ReZone and exported to the data analysis software. There were 3467 usage sessions, which corresponds to 16.9 times per each of the 205 students in classes allocated to ReZone. The game ($n=752$), breathing exercises ($n=811$), and happy faces ($n=1169$) were used the most; stress bucket ($n=404$), art ($n=225$), and time out ($n=106$) were used the least. Based on teacher consultations, which are discussed elsewhere [10], usage methods and frequency varied across schools and students due to a variety of factors, including student characteristics, teacher priorities, and school environment.

Analytic Strategy

Means and standard deviations, for all measures, across conditions at baseline and follow-up, were calculated. Intention-to-treat and per-protocol analyses with four multilevel regressions were tested for each of the outcome variables with time nested within students within classrooms. Per-protocol analyses included only those that had completed follow-up. Model 0 was computed as the null model to examine the change

in outcome over time, without predictors. The intraclass correlation coefficients for each measure were 17% (emotional difficulties), 24% (behavioral difficulties), 7% (empowerment), 9% (wellbeing), and 3% (quality of life). We then entered school type (ie, alternative provision vs mainstream) as a fixed effect predictor to Model 1. In Model 2, patient-level grand mean-centered age, ethnicity, gender, and disability were entered as predictors. Demographics were controlled for in the analyses as there were significant differences in gender between groups at baseline within mainstream primary schools and age between groups within alternative provision schools (Table 1). In the Final Model (Model 3), condition (ReZone vs management as usual) was entered as a predictor. The likelihood ratio test was used to compare the fit of Models 1, 2, and 3. For example, Model 1 was significant for behavioral difficulties and therefore compared to Model 2, which was significant. Models 1 and 2 were therefore retained in the final model, with Model 3 (final model) being compared to Model 2 using the likelihood ratio test. Models 1 and 2 were significant for empowerment and wellbeing and therefore retained in the final model. For emotional difficulties and quality of life, only Model 2 was significant and retained in the final Model.

Results

The means and standard deviations of all study measures at baseline and postintervention are presented in Table 2. The likelihood ratio test for the intention to treat analysis was not significant for any of the final models compared to the previous significant model. There were no significant differences between the ReZone condition and management as usual in emotional difficulties ($\chi^2_1=0$, $P>.05$), behavioural difficulties ($\chi^2_1=0.01$, $P>.05$), empowerment ($\chi^2_1=0.01$, $P>.05$), wellbeing ($\chi^2_1=0.05$, $P>.05$), or quality of life ($\chi^2_1=0.3154$, $P>.05$). The per-protocol results showed similar patterns.

Table 2. Baseline and follow-up mean scores by condition. All values are provided as mean (SD).

Outcome	Mainstream primary				Alternative provision			
	Intervention – T1 ^a	Intervention – T2 ^b	Control – T1	Control – T2	Intervention – T1	Intervention – T2	Control – T1	Control – T2
Emotional difficulties	5.56 (3.38)	5.18 (3.74)	6.27 (3.38)	5.43 (3.27)	6.08 (3.91)	5.61 (4.12)	5.48 (3.77)	6.08 (4.03)
Behavioral difficulties	3.31 (2.27)	3.28 (2.44)	3.32 (2.24)	3.18 (2.04)	5.45 (2.37)	5.11 (2.34)	5.57 (2.35)	5.82 (2.52)
Empowerment	24.53 (4.57)	25.69 (4.25)	24.65 (4.09)	25.13 (4.03)	22.96 (4.96)	23.61 (5.74)	23.35 (4.02)	23.79 (4.25)
Wellbeing	24.11 (4.78)	24.94 (5.41)	24.41 (5.18)	24.94 (5.06)	21.09 (5.90)	23.61 (5.74)	21.76 (3.98)	21.93 (4.65)

Discussion

This cluster randomized controlled trial examined the effectiveness of ReZone in reducing behavioral and mental health difficulties in young people. The study did not show a significant difference between those using ReZone and management as usual in the reduction of behavioral and emotional difficulties and improving empowerment, wellbeing, and quality of life.

Potential limitations of the study, implementation, and adoption barriers to digital interventions within schools have been discussed in depth [10]. Implementation barriers to new digital interventions in schools include the technology itself, the adopter system, and the organization [5]. The process of embedding ReZone into the school system can sometimes leave minimal time to utilize it successfully. Implementation strategies differed, with varying levels of teacher encouragement and consistency of scheduled ReZone use. Competing teacher priorities, opinions, and seniority of the school advocate could have impacted the time and drive to use the tool [10].

ReZone was used a total of 3467 times throughout the 3-month study period, and current usage data show that ReZone is still being used 10 months poststudy (501 sessions over the last 3 months). Aggregated objective usage data is useful to indicate overall acceptability and use. However, teacher consultations (fully reported in [10]) suggested students either used ReZone frequently or not at all. Analysis of a dose-response effect could be improved by gathering further quantifiable individual school usage information related to implementation.

The usage statistics and teacher consultations indicated happy faces and breathing were the most used activities, while the stress bucket, art, and time out were used the least. Happy faces and breathing can be completed in only 1-2 minutes; they are a fun challenge/game type of activity, and most of the time can be completed without teacher assistance. The stress bucket and time out require more time to work through thought processes, requiring the user to be willing to think and talk about their feelings, needing teacher support (which is not always feasible).

The challenges discussed link to the emerging concept of gamification within digital mental health tools [16,17]. There are some basic elements of gamification within the most popular elements of ReZone. Further work on gamification combined

with other crucial processes such as co-design, could help address the broader issue of nonadoption and sustainability, with many users reporting that they stop the use of a health app after only two weeks [18]. This lack of consistency could be particularly applicable when working with young people in such settings as alternative provision schools. Pupil behavior often places higher demands on staff in alternative provision schools than in mainstream schools, and disengagement and loss of concentration are common issues.

Measures used were related to overall mental health, wellbeing, and behavior leading us to question how often a tool such as ReZone would need to be used to effect changes in broad domains and specifically in schools. If tools such as ReZone do not provide large-scale, substantial longer-term changes, we must also ask whether there is any impact on immediate feelings, behavior, and interactions. We did attempt to measure this by asking teachers to complete a few short questions related to how well students refocused and re-engaged after using ReZone. However, due to practical issues such as teacher demand, these were not completed. On reflection, this could have also been something students were asked to complete. It is also possible that effects were delayed, and further long-term data collection, such as one-year post-trial, may have shown differences [19-21].

Due to the complex nature of digital interventions, traditional RCTs may be insufficient to assess efficacy [8]. As this study shows, there are multiple objective and subjective data sources available, including quantitative self-report data, objective usage data, and subjective qualitative data, while digital and school studies present particular challenges in adherence, sustainability, and roll-out [10]. As with psychotherapy research in general and a reliance on self-report measures, participant blinding was not possible, although true and independent randomization was used. Additionally, due to this being a pragmatic trial, there may have been other interventions the school and participants may have been using.

It is essential to publish negative results to avoid publication bias. These studies can still make a substantial contribution to the literature, learning, and informing the direction of future work [22]. The negative results of this study could indicate that ReZone has a limited scope to impact change, that its utility is hampered by issues with implementation and nonadoption, and limitations of mHealth research in a school context. The results

may also suggest the limited applicability of the RCT study design for evaluating tools such as ReZone.

Abstract

Background: For children 6-12 years old, there is a shortage of electronic Health (eHealth) services that promote their participation in health care. Therefore, a digital communication tool, called Sisom, was developed to give children a voice in their health care. Children with long-term diseases want to be more involved in their health care and have the right to receive information, be listened to, express their opinions, and participate in decision making in health care. However, the outcomes of using Sisom in practice at pediatric oncology clinics have not been investigated.

Objective: The aim of this study was to investigate children's participation during appointments with pediatricians at pediatric oncology clinics, with or without the use of the eHealth service Sisom.

Methods: A quasiexperimental design with mixed methods was used. We analyzed 27 filmed appointments with pediatricians for 14 children (8 girls and 6 boys) aged 6-12 years (mean 8.3 years) with a cancer diagnosis. The intervention group consisted of children who used Sisom prior to their appointments with pediatricians at a pediatric oncology clinic, and the control group consisted of children who had appointments with pediatricians at 4 pediatric oncology clinics. Data from observations from the videos were quantitatively and qualitatively analyzed. The quantitative analysis included manual calculations of how many times the pediatricians spoke directly to the children, the proportion of the appointment time that the children were talking, and levels of participation by the children. For the qualitative analysis, we used directed content analysis to analyze the children's levels of participation guided by a framework based on Shier's model of participation.

Results: Pediatricians directed a greater proportion of their discussion toward the child in the intervention group (731 occasions) than in the control group (624 occasions), but the proportion of the appointment time the children talked was almost the same for both the intervention and control groups (mean 17.0 minutes vs 17.6 minutes). The levels of participation corresponded to the first three levels of Shier's participation model: children were listened to, children were supported to express their views, and children's views were taken into account. The results showed an increased level of participation by the children in the intervention group. Several codes that were found did not fit into any of the existing categories, and a new category was thus formed: children received information.

Conclusions: This study shows that the eHealth service Sisom can increase children's participation during appointments with health care professionals. Further studies employing a randomized control design focusing on the effects of eHealth services on children's health outcomes, perceived participation, and cost-effectiveness could make a significant contribution to guiding the implementation of eHealth services in pediatric care.

Introduction

Background

Advancements in electronic Health (eHealth) services to promote health, participation, and communication have been made in recent years [1-4]. These are in the form of mobile health technology (mobile devices) [5], and the majority are aimed at adults and adolescents [6,7], while the range of eHealth advancements for younger children is limited [8]. Most eHealth services for adolescents do not focus on participation, are not validated, and lack proof of effectiveness [6,9-11]. Existing eHealth services instead primarily focus on self-management [6,10-12], symptom assessment [9,12,13], social support, support for self-care [12,13], or medication adherence [11,13,14]. Only one study on an eHealth service promoting participation for young children, 3-5 years old, has been performed [15], while there are no studies that describe an eHealth service that promotes participation for children 6 years old and older [16,17].

Children's Participation in Health Care

Children with long-term diseases such as cancer want to have greater involvement in their own health care [18-21]. They want to receive more information about emerging symptoms, treatment, and prognosis [22] and have the possibility to decide whether and to what extent they want to participate in decision-making processes regarding their own health care [18,23]. It is, however, difficult for children to explain how their long-term disease makes them feel [24] and to accept and manage the consequences and lifestyle related to their long-term disease [17]. It is thus essential to include children in their own health care and support them in their self-management responsibility in order to improve their wellbeing and reduce fear and anxiety [25] as well as to strengthen their self-confidence and independence [17,18,26]. Even if children's participation is considered an essential part in health care, there is still a number of barriers to overcome in relation to health care professionals' attitudes and viewpoints [27]. Furthermore, it is emphasized in the United Nations Convention on the Rights of the Child [28] that children have the right to be involved in all matters affecting them. Despite the knowledge that children want to be more involved in their health care, that their participation has positive effects on treatment and health outcomes, and that laws and regulations emphasize the requirement of patient participation in health care, there is still a lack of knowledge, strategies, and methods for strengthening children's participation in pediatric health care and how to accomplish their participation [29,30].

eHealth Services: Example of Sisom

Sisom is an eHealth service helping children to communicate in health care by engaging them in a playful virtual world

[31,32]. Sisom was developed with a participatory design that included children with cancer in the process [31]. Previous research conducted on Sisom has primarily focused on usability and content validity, resulting in different diagnosis-specific versions and country-specific versions: Norway, Sweden, United States, and Canada [33-36]. In Sisom, the children travel by boat in an archipelago of islands with different subjects where they can express their feelings and symptoms by answering a set of 82 questions (Multimedia Appendix 1) [33]. The 5 islands represent different topics for the questions: (1) to handle things, (2) my body, (3) thoughts and feelings, (4) things you may be afraid of, and (5) in the hospital (Figure 1). The intent is that the children answer the questions in Sisom prior to a health care appointment or when they are hospitalized. A report of the children's responses can be printed. Based on the children's answers, the health care professionals can talk to the children about how they perceive their situation and how they think about different health care-related and social issues. It has been shown that communication between children, their parents, and health care professionals is improved when using Sisom [37,38].

It has been highlighted that participatory approaches where patients have a real influence on the development of eHealth interventions lead to a more user-friendly and effective intervention [39]. This is especially important for interventions aimed at children, since adults lack a child's perspective. However, children's participation in the development of eHealth services is not common [40]. The use of eHealth services to enable and support children's participation in pediatric health care is scarce. We found only one review of eHealth services that was designed to support communication between children with cancer and health care professionals with the purpose of strengthening children's participation in care [12]. The implementation of eHealth services for children with chronic conditions is primarily focused on changing health behavior [7,14,41,42] and medical adherence [14], and most of the eHealth interventions that have been implemented in pediatric oncology clinics target emotional distress, health behaviors, health outcomes, and neurocognitive functioning [7], with insufficient evidence of effects. Furthermore, there is a need for more rigorous research and evaluations to determine eHealth service efficacy [6,7,14,42,43] especially in relation to eHealth services that are directed towards strengthening children's participation in care. There is a lack of evidence to support that eHealth services actually promote children's participation in their health care. It is also unclear to what extent children's participation is supported and promoted in practice in pediatric oncology clinics. Thus, the aim of this study was to investigate children's participation during appointments with pediatricians at pediatric oncology clinics, with or without the use of the eHealth service Sisom.

Figure 1. The 5 islands of Sisom.

Methods

Design

A quasiexperimental design [44] with a convergent parallel mixed method [45,46] was used, where the frequencies and

differences between groups were calculated with descriptive statistics and qualitative content analysis was used to determine how children's participation was manifested [47] (Figure 2).

Figure 2. Processes for quantitative and qualitative analysis.

Participants

Inclusion criteria for participation were children 6-12 years old undergoing cancer treatment at 4 pediatric oncology clinics in

Norway. Exclusion criteria were children who did not speak Norwegian, diagnosis of brain tumors, mental disability, developmental delay, speech disorders, or hearing impairments. The demographic characteristics are provided in [Table 1](#).

Table 1. Demographic characteristics of the participants.

Characteristics	Intervention group, n (%)	Control group, n (%)
Age (years)		
6-8	2 (33)	5 (63)
9-12	4 (67)	3 (37)
Gender		
Girl	2 (67)	6 (75)
Boy	4 (33)	2 (25)
Diagnosis		
Acute lymphoblastic leukemia (ALL)	3 (50)	3 (38)
Lymphoma	1 (17)	2 (25)
Carcinoma	1 (17)	0 (0)
Not defined	1 (16)	3 (37)

Recruitment

The children were successively recruited after receiving a cancer diagnosis and began the treatment. The head nurse identified eligible children and asked them and their parents if they were willing to be contacted about the study. The project assistant then informed the child and the parents, both verbally and in writing, about the content of the study including the voluntary nature of participation and the possibility to withdraw later in the process and asked if they were willing to participate. Families interested in participating signed an informed consent form. Of the 20 children who were asked to participate, 15 chose to opt-in. One child, who had disease-related complications, withdrew, resulting in 14 participants aged 6-12 years, of whom 6 were boys and 8 were girls.

Data Collection

Data were collected through video recordings of the appointments with the 15 pediatricians, who conducted 1-5 recorded appointments each, for a total of 27 video-recorded appointments in outpatient examination rooms. Although an additional 3 pediatrician appointments were planned to be filmed with each child, this was not possible for all the children due to medical complications or relocations to another hospital. All the control group appointments took place prior to Sisom being introduced at the hospitals. The group of children in the intervention then met the pediatricians after Sisom was introduced. The appointments, both for the children in the control group and children in the intervention group, were in the form of routine meetings, which started with a nurse taking standard measurements of length, weight, and pulse oximetry. The pediatrician started by reviewing the children's medication,

reviewing infection status, and explaining the results of blood tests, supplemented by a medical examination. All those participating in the appointments were aware that they would be filmed. The children in the intervention group used Sisom while they were in the waiting room prior to meeting the pediatrician, and the project assistant was available for help. A report of the children's responses was then printed and given to the pediatrician as well as to the parent and child; then, the meeting with the pediatrician took place. It was only during one appointment that the pediatrician revealed (to the researcher analyzing the recording) that Sisom had been used using the words: "I saw in your schedule that one of your feet is hurting; is it?" The word Sisom was not mentioned during any appointment.

Data Analysis

The analysis was performed using a convergent parallel mixed method [46] to combine qualitative and quantitative data to be able to attain a more complete understanding [48] of the children's participation during the appointments with pediatricians, with or without using Sisom. The quantitative and qualitative data were collected concurrently, and the results were combined and compared for convergence and differences [46]. All the video recordings were viewed several times with the aim of trying to gain an overall picture and see and hear everything that occurred during the appointments. The analysis process was carried out by two researchers who had no knowledge about which recordings were from the appointments during which Sisom had been used. The data acquisition consisted of manual counting and observations in accordance with an observation scheme and a categorization matrix ([Table 2](#)).

Table 2. Summary of the research questions, data collection methods, and data analysis.

Research questions	How many times did the pediatricians speak directly to the children?	How long did the children speak?	Which levels of participation were achieved during the appointments?	Which levels of verbatim were achieved in the appointments?	How did the children's participation manifest itself?
Data collection	Manual counting of the number of times the pediatricians spoke to the children.	Manual counting of the amount of times the children spoke.	Observations in accordance with two observation schemes with 4-degree scales were developed, and the children's participation was ranked.	Observations in accordance with two observation schemes with 4-degree scales were developed, and the children's level of verbatim was ranked.	Observations according to a categorization matrix were developed and used for the collection of brief episodes of participation in the films.
Data analysis	Quantitative analysis	Quantitative analysis	Ranking	Ranking	Qualitative analysis

Quantitative Analysis

Frequencies and differences were calculated using quantitative analysis. The number of times the pediatrician spoke directly to the child was counted manually and recounted repeatedly. Frequency calculations were performed to calculate the percent values of the proportion of the total appointment time that the child was talking, the proportion of the time the child spoke to the pediatrician, and the proportion of the total number of times the pediatrician spoke that was addressed to the child [49]. The number of times the children spoke and the number of times the pediatrician spoke to the children were calculated. Descriptive statistics of the results were compiled and divided into the intervention group and control group, after the blinding was revealed.

An observation scheme was used to assess the children's verbatim [50]. The level of the children's verbatim during the appointments was ranked with a 4-degree verbatim scale: (1) verbally inactive, gave <3 answers during the appointment and did not comment on anything or ask any questions; (2) limited verbatim, gave >3 answers but no comments or questions; (3) moderate verbatim, answered questions with ≥4 words but made <3 comments or questions; (4) verbally active, responded extensively to >3 questions, commenting or asking questions >3 times [50].

An observation scheme was developed by the authors to assess the children's level of participation. The observation scheme was based on the levels in Shier's participation model "Pathways to participation," a theoretical model intended to be used in practice when working with children up to 12 years old. The model consists of 5 levels: (1) children are listened to, (2) children are supported in expressing their views, (3) children's views are taken into account, (4) children are involved in decision-making processes, and (5) children share power and responsibility over decision making [51]. The 3 lowest levels present levels of participation that are the limit of what is stated in the children's Convention on the Rights of the Child as the meaning of participation. The 2 highest levels thus represent higher participation and are also consistent with the definition of shared decision making. The aim of the observation scheme was to rank the levels of the children's participation during the pediatrician appointments, in relation to Shier's 5 levels of participation. We defined in the observation scheme that the decision making should consider decisions concerning medication, caring, or procedure. To make the grading clear and understandable at each level, a 4-degree scale was used for

each level in the observation scheme: (0) on a low level or not at all, (1) on a fairly low level, (2) on a high level, and (3) on a very high level (Multimedia Appendix 2). For example, at the first level of participation (children were listened to), "on a low level (0)" was assessed if the health care professionals only spoke to and listened to the parents during the conversation and if the health care professionals only took the initiative to ask the child on a few occasions or not at all. "On a fairly low level (1)" was assessed if the health care professionals spoke to and mostly listened to the parents and took the initiative to ask the child on some occasions but did not listen to what the child had to say. "On a high level (2)" was assessed if health care professionals spoke to and mostly listened to the child and took the initiative to ask the child something on several occasions but did not listen clearly to what the child was saying. "On a very high level (3)" was assessed if the health care professionals spoke to and mostly listened to the child and took the initiative to ask the child something on several occasions and listened clearly to what the child was saying. The grading for all levels is described in detail in Multimedia Appendix 2.

Face validity and content validity were assessed through the training of coders [52] to test the observation scheme and its reliability; two of the researchers analyzed the same video separately. Then all the researchers evaluated and made adjustments to the observation scheme. Interrater reliability was assessed in the next step [44], where a number of video recordings were examined by two of the researchers, who then compared their individual documentation.

Qualitative Analysis

In order to attain a greater understanding of the results, a directed, deductive qualitative content analysis was performed to discern how the children's participation manifested itself during the appointments [47]. A categorization matrix was developed from Shier's participation model [51], with which the data from the videos were reviewed for content, passages of participation, and brief episodes of participation [47]. The analysis process was performed in the following steps: (1) looking at the videos and highlighting all episodes that, on first impression, appeared to represent passages of participation; (2) coding all highlighted passages using the predetermined categories in Shier's model; and (3) giving a new category label that captures the essence of participation to any codes that could not be categorized with the predetermined categories [47]. Brief episodes in the films were found during the analysis of the video recordings where the children were actively excluded from participation. These film episodes were also included in the

results as negative codes in order to more clearly describe the degree of the children's participation. The blinding was released when the categorization process was completed, and the codes in each category were divided into the intervention group and control group. Two researchers completed the analysis, and to enhance the credibility and the dependability of the analysis, the data analysis was discussed continuously with all authors.

Ethical Considerations

The videos were collected between 2006 and 2009 by the Center for Patient Involvement and Collaboration Research, a research group at Oslo University Hospital. This study was approved by the Regional Ethical Review Board in Oslo (2014/1599), with approval for use of the collected videos. The research group at Oslo University Hospital offered the data to the first author to use for this study. The difficulties in doing research on already collected data and to have to depend on the specific setting and design of the data collection were discussed by the authors as a limitation of the study. However, not analyzing already collected data could be considered unethical, which was considered in the decision to conduct this study. The participating children had approved their participation and expected that their contribution to the research would improve care for children with cancer. The funders Region Halland and the Center for Research on Welfare, Health, and Sport at Halmstad University had no access to the study data and have not influenced the way in which the data were analyzed.

Results

Sample

In the intervention group, 13 appointments with pediatricians were performed at 1 pediatric oncology clinic, with 2 girls and

4 boys participating (mean age 9.5 years). In the control group, 14 appointments with pediatricians were performed at 4 pediatric oncology clinics, with 6 girls and 2 boys (mean age 8.1 years) participating who received care as usual.

Quantitative Results

Verbality

The appointments lasted from 6 to 41 minutes. The average times that the children and the parents met the pediatricians were 17.8 minutes for the intervention group (out of 231 minutes and 13 appointments) and 17.6 minutes for the control group (out of 246 minutes and 14 appointments; [Multimedia Appendix 3](#)). The children spoke to the pediatricians, on average, 1.14 minutes in the intervention group and 1.78 minutes in the control group ([Multimedia Appendix 3](#)). Except for answers to specific questions, the children responded by saying "yes," "no," or "hmmm" in most of the appointments. Short and unclear expressions were difficult to record and thus not included. The pediatricians in the intervention group spoke directly to the children on more occasions and for longer total time (average 56.23 minutes from 731 occasions) compared with the control group (average 44.57 minutes from 624 occasions; [Multimedia Appendix 4](#)). The children's verbatim was slightly higher in the control group than in the intervention group ([Multimedia Appendix 4](#)).

Participation

There was a higher score for the children's participation, based on Shier's participation levels [51], when using Sisom compared with the control group. The higher scores are particularly noticeable for the following 3 levels: children were listened to, children were supported in expressing their views, and children's views were taken into account ([Table 3](#)).

^aTo grade the level of children's participation, we used a 4-degree scale: (0) on a low level or not at all, (1) on a fairly low level, (2) on a high level, and (3) on a very high level.

Qualitative Results

The findings from the directed qualitative content analysis showed passages and episodes of participation that were in line with the first 3 levels in the model presented by Shier: (1) children were listened to, (2) children were supported in

expressing their views, and (3) children's views were taken into account. However, the analysis of the videos did not reveal any passages or episodes that could be included in the fourth or fifth level of participation. One new category, which was not included in Shier's model, named "children received information" emerged in the analysis (Table 4).

Table 4. Analysis of the videos: examples and number of codes in each group.

Group	New category	5 levels in Shier's model of participation				
	Children received information	Children were listened to	Children were supported in expressing their views	Children's views were taken into account	Children were involved in decision-making processes	Children shared power and responsibility for decision making
Intervention group						
Examples	The pediatrician informed about what would happen. The pediatrician informed the child about a medicine.	The pediatrician gave the child time and waited for an answer. The pediatrician showed through body language and position that the child was in focus. The parent answered on behalf of the child.	The pediatrician asked the child a medical question in order to get the child's perspective. The pediatrician asked if the child wanted to talk about something special.	The pediatrician followed the child's wishes about the medical examination.	The child was involved in a decision about a blood test.	None
Number of positive codes	84	21	100	2	1	0
Number of negative codes	0	4	4	0	0	0
Control group						
Examples	The pediatrician informed the child about the medical examination. Information was only directed to a parent.	The pediatrician talked over the head of the child. Children asked and said something without receiving attention from health care professionals.	The child expressed a desire on a medical aspect. The pediatrician asked the child about symptoms.	The physician followed the child's wishes about the medical examination.	None	None
Number of positive codes	36	5	32	3	0	0
Number of negative codes	6	34	28	0	0	0

Children Received Information

Receiving information meant that the children were provided with medical information about what the pediatricians were doing and what could be expected to happen. The children also received information in response to their direct questions about, for example, test results, whether they could eat before a specific examination, or whether a peripheral venous catheter was required before an operation. In the intervention group, the pediatricians gave the children information about examinations and medication during the appointments. The disease-related information was often repeated several times during the same appointment, and almost all the children were informed by the pediatrician about the medical examination, what the pediatrician would do, and the result of the examination. The children were also often informed about the disease, symptoms, and side effects. Some children received health advice, such as the importance of eating so that the body gets nutrients. No child from the intervention group asked for further information during the appointments, but in the control group, the children asked for information on a number of occasions, such as "Why did you press there?" (when the pediatrician palpated his stomach; boy, 6 years old, control group).

The information the children in the control group asked for during the appointments was whether the child had to spend

Christmas at the hospital or about examinations, tests, their anatomy, and things they did not understand. One exception to this was one child in the control group who was informed about the course of the disease and the future. The explanation during this appointment was given slowly and in a language adapted to the child's level of development. During another appointment in the control group, the pediatrician had two accompanying medical colleagues. The conversation during this appointment was conducted in English and was thus not understandable to the Norwegian-speaking child and was only directed to the medical colleagues. The pediatrician informed his colleagues about what he did in English during the medical examination but said nothing to the child. The pediatricians informed the children about the results of the medical examination and the medicines and their side effects in only a few of the appointments in the control group, and the information was aimed only at the parents.

Children Were Listened To

The children were listened to when the pediatrician paid full attention to the child and gave the child time to think before answering. The pediatricians often turned to the children during the conversation in the appointments in the intervention group. The pediatricians' body language, sitting close to the child and looking at the child, showed that they were really listening. The

pediatricians sat either squatting or near the child and thus had better eye contact.

The pediatricians waited for and gave the child time to think before answering when talking with the children during the appointments in the intervention group. The pediatricians listened to the children's answers and asked further questions or confirmed that they were listening with an "Hmm." The child's response was followed up by the pediatrician in the cases when parents and children responded differently to the same question. One physician moved closer to the child to get better eye contact and repeated the questions after the parent repeatedly responded on behalf of the child. For example, a pediatrician asked "Doesn't the food taste good anymore?" When there was no answer from the child, the pediatrician squatted twice in order to get better eye contact with the boy, pats him on the blanket, and repeats the question (boy, 7 years old, intervention group).

The children were not listened to when the pediatrician spoke quickly without giving the child time to reflect and answer or when the pediatrician used language that was difficult for a child to understand. These types of communication occurred during many appointments in the control group, although there were also appointments when the pediatrician listened to the child. The pediatricians were more often focused on the parents than on the child during the appointments in the control group. The pediatricians looked quickly at the parent and seemed to expect the parent to respond even though the question was initially addressed to the child. The conversation between the child and pediatrician was performed through a parent, leaving the child ignored during some of the appointments in the control group. On one occasion, the child was playing with the blood pressure equipment and said he would like to take his blood pressure, but none of those present, including the pediatrician, nurse, and parent, responded or reacted. On one occasion, when another pediatrician asked a child what medications the child took, the latter began to respond, but the pediatrician did not listen to the child and turned to the mother instead. The child got upset and went and put on music at a high volume. During other appointments, the pediatrician asked the parents how the child was feeling, even though the child was sitting next to them. One pediatrician even expressed his desire for the child to be quiet. Several children during the appointments in the control group said or asked things without anyone listening and responding. On one occasion, a child started talking to her mother, and the pediatrician drowned the child by telling her mother a story about his private holiday trip. This child protested loudly without any reaction from the pediatrician or support from the mother.

Children Were Supported in Expressing Their Views

The children were supported in expressing their views, which entailed the child being asked and invited into the conversation, but also that the children themselves initiated discussions about for example, how the child wanted the procedure or process to be conducted during a medical examination or that the child wanted to return home. The children often appeared to be tired and silent in both the intervention and control groups; thus, support from the pediatrician was needed. The children were

often invited into the conversation during the intervention group's appointments. The pediatricians were attentive in their interactions with the child and gave the latter time to express themselves, which in some appointments gave the children courage and capability to express their opinions. The pediatrician offered their support and built trust by trying to get the children to talk about their problems, thoughts, and reflections. Some pediatricians asked the children questions about their social life, friends, social exclusion, and mental health, while others only asked questions about the child's disease and treatment. The pediatricians had nearly all their attention directed to the child during some of the appointments in the intervention group. Although some children were mostly silent, they were then invited into the conversation through questions directed at them and being given enough time for answering and expressing their views. The conversations and questions during the various appointments mainly concerned the children's condition and possible symptoms. There were often open questions posed by the pediatricians.

When the parents in the intervention group said, during one appointment, that their child had a stomachache, the pediatrician turned to the child and asked questions about it. During some of the other appointments in the intervention group, the pediatricians asked how the children wanted the medical examination to be carried out, and sometimes the children expressed their views spontaneously. A girl said that she preferred to lie down during the examination. The children in the intervention group were often directly asked questions about medication, such as which medicines they took. The problems the children spoke about were, for example, pain when measuring blood pressure and a medicine that was only available as a tablet that the child had difficulties in swallowing. The children often demonstrated their knowledge about medicines; for example, they could list all the medicines they took and often the doses. Moreover, they spoke about incidents such as infections and blood transfusions since the last appointment, as well as new symptoms, such as bruises. For example, a 9-year-old girl in the intervention group said "The medicine is a bit awkward; we have to crush it and mix it with yoghurt."

The pediatricians offered emotional support to the children during many of the appointments in the intervention group by encouraging them to come to them if problems arose. The pediatricians generally wanted to know if the children had difficult or unpleasant experiences or if they had other questions and concerns. Several of the pediatricians explained to the children that they wanted to understand how the children thought and felt. A pediatrician explained at one appointment that it was sad but normal that the child could no longer ride a bike or ski downhill, but that it would be possible to do it again in the future, while another pediatrician praised the child's strength in showing her baldness despite everyone in school knowing and being able to see. The pediatricians also asked open questions about participation where they offered support to the children by allowing them to express their views: "Is there anything you have forgotten to ask about or anything else you want to say?" (pediatrician to girl, 9 years old, intervention group).

The pediatricians rarely invited the children into the conversation during the control group's appointments; for example, at one appointment, many questions were asked very quickly, not giving the child time to answer. The pediatricians gave instructions rapidly during the medical examination in some of the control group's appointments, not allowing the children to express their opinions.

Talking about private things helped the children relax and feel secure. The pediatrician talked to the children about private things in approximately half of the appointments in the intervention group. They talked about how the children spent the summer, whether they had swum, and whether they would be going away on holiday. Other subjects were also raised, such as being unable to go to school, difficulties in sports activities, and talking about computer games and Christmas presents. The pediatrician only talked to the children about private things, such as pets and school, in a few of the control group's appointments.

Children's Views Were Taken Into Account

The level in Stier's model concerning the children's views being taken into account pertains to the pediatricians' consideration of the children's views. Only a few brief episodes in the videos were found for this level. The children's views were taken into account during the interventions group's appointments. For example, at one appointment when a child asked her parent if she could go out and listen to music, it was noted by the pediatrician who said to the child that she could go out if that was what she preferred, and at another appointment, a child expressed a wish to lie down during the medical examination.

You can do it [the examination] when I'm lying down, that's better. [girl, 9 years old, intervention group]

Jump up and lie down then [on the examination table]. [pediatrician]

A child in the control group was informed during an appointment of the need to stay and have treatment, and the child became very upset. The child's opinion was taken into account in a respectful and supportive way when the child started to scream and cry. The pediatrician, nurse, and parents were completely silent, allowing the child to express her disappointment. The adults showed empathy through eye contact and body language expressing that they were also sad on behalf of the child. A child protested about having to remove clothes during another appointment in the control group. This child's opinion was taken into account by the pediatrician who lifted the clothes up a little instead.

Children Were Involved in Decision Making

The children were not involved in decision making in their health care. The pediatricians made most of the decisions, purely medical, both in the control and intervention groups, and neither the parents nor the children participated in these decisions. The decisions concerned continuation or temporary suspension of treatment, a need for blood transfusion, removal of a subcutaneous venous port, and planning for new blood tests and were expressed as already having been determined. Only one brief episode was found, which was in the intervention group, where a nurse suggested that the child allowed blood samples

to be taken prior to talking to the pediatrician, and the latter then asked the child if this was a good idea. The child participated in the decision by deciding whether blood samples could be taken prior to or after the appointment with the pediatrician.

Children Shared Power and Responsibility for Decision Making

No brief episode was found showing that children shared power and responsibility for decision making.

Discussion

Principal Findings

The overall results showed increased participation for the children in the intervention group using Sisom compared to the control group, especially in relation to the lower levels of participation (levels 1-3) in Shier's model [51]. Levels 4 and 5 concern the child's possibilities for sharing decision making and responsibility with health care professionals. These levels were barely noticeable in any of the appointments in the two groups. These findings confirm previous research that has shown that children's possibilities for participating in decisions that concern them in health care are almost nonexistent [50,53,54]. It has been highlighted both in research and clinical practice that there is a need for guidelines, strategies, and methods to enable a higher level of children's participation in clinical practice. This study showed that the use of the eHealth service Sisom can increase the health care professional's ability to promote children's participation, but there is much more to do to reach a higher level where the children are co-actors and share decisions about issues in their care. To change and restructure the working procedures for children's participation in practice, it is crucial to consider both the individual and contextual factors such as attitudes, values, knowledge, readiness for behavioral change, culture, resources, and priorities [55]. For example, it has been maintained that pediatric care needs guidance and support [56], education [57], training [58], and interventions and methods (for example, eHealth services such as Sisom) [29,53,59,60] to increase children's participation. This entails extensive effort by both the health care services provided for children and the professionals who work there to increase their ability to involve children in decision making. It is also necessary for them to access adapted and person-centered information for children to have the ability to participate in decisions [19,20]. The children in the intervention group received more information from the pediatrician, expressed in a child-centered way and adapted to the needs of the child, in comparison with the control group. However, in the control group, the children asked for more and further information than those in the intervention group. One explanation for these differences between the groups could be that the pediatricians in the intervention group were more focused on and paid greater attention to the child's problems expressed through the use of Sisom. The pediatricians thus provided information based on the children's perspectives. However, information in pediatric health care is a complex aspect. The children's preference for and ability to absorb information could vary depending on different factors such as personality, age, maturity, and disease

state [20]. Another factor could be that the child is afraid of appearing to be stupid or feeling too shy to ask for information [61]. The child's preferences could also vary in different situations and change over time [23,28,62,63]. Previous research has shown that children speak infrequently to health care professionals during pediatric appointments [64]. Information in pediatric health care has also been highlighted by children with different diseases as being important for their possibilities for participating in health care [65,66]. The directed qualitative analysis in our study revealed one further category termed "children received information," which is not included in Shier's model [51]. The health care professionals were giving the children information with the purpose of letting them know and understand what would be happening and to experience control over the situation.

It appears that health care professionals find it more difficult to give children space and opportunity to speak during appointments without having the support from an eHealth service such as Sisom. The children can convey problems and thoughts through Sisom, which can provide the health care professionals with a different way to engage with the children and to facilitate interaction. The compelling ambition, as emphasized in the United Nations Convention on the Rights of the Child [27], is that pediatric care and professionals' interaction with the child should lead to the children being listened to and supported in expressing their views, these views being taken into account, and children being involved in the decision-making processes [51]. The decision-making level was not, however, achieved in this study. Even in care situations where there is a strict treatment protocol that needs to be followed in order to succeed with the care, informing and interacting about the treatment and care plan with the child are important for the child to understand, be able to ask questions [19], and express how they want to be involved in decision making [19,23]. The pediatricians in the intervention group were more focused on the children and seemed to be more aware of their own behavior when interacting with the child, which is important for the children to have positive experiences with care [67,68]. The use of an eHealth service for children has the potential of facilitating transition towards more trustful and supportive behavior from health care professionals [37,38,69,70].

Methodological Considerations

The results in this study would have shown higher levels of participation for the children in the intervention group if based solely on the quantitative methodology, but the reasons for these results and how they came about would have remained unknown. Supplementing the methodology with a qualitative approach helped to gain an understanding of how the eHealth service, Sisom, can influence health care professionals through the visualization of the children's needs and promotion of interactions, thus demonstrating the benefit of a mixed method approach [48].

Video observations are used in studies to observe how people behave towards each other, how they act and interact, to see body language and glances, and to hear what they talk about [71]. A video-recorded observation can be preferred in complex

processes, such as appointments with pediatricians in health care settings, where many different things can happen simultaneously, and the researcher is able to review the videos several times [72]. It was sometimes difficult to see facial expressions and hear who was talking and what they were saying in the analyzed videos, partly due to technical reasons but also due to the participants' location in the room. This led to the videos being reviewed many times to ensure that the content was perceived correctly. The pediatricians' behavior towards the children can vary based not only on the use of Sisom but also on the different personalities and attitudes of the pediatricians and the different clinics' organization and working procedures. However, all pediatricians have specialist expertise and lengthy experience working and interacting with children. The children were between 6 and 12 years old, which means different levels of development and verbality that may have affected their interactions in the appointments. However, this was not obvious in relation to the children's statements to the pediatrician or their verbalities. This may impair the study's credibility as we draw conclusions based on the differences between the control and intervention groups. A strategy was applied to strengthen the credibility and dependability of the study, whereby the coders were trained and the similarity in the analysis of the two researchers was assessed by interrater reliability. Detailed information about the analysis process has been provided, and examples of citations in the qualitative results are presented for confirmation.

Study Limitations

One limitation could be that the data were collected several years ago. The fact that the data were collected by other researchers led to difficulties in obtaining facts about the execution of this data collection. For example, it was unclear if the child had met the current pediatrician before. The sample size was too small to perform significant statistical calculations. It is possible that health care professionals are more child-centered today since the importance of this approach has received greater attention in recent years. However, even if we are aware of some limitations in this study, it is important to investigate the implementation of eHealth services such as Sisom in daily practice since there is still a lack of similar resources to promote children's participation in health care. This study can thus make an important contribution.

Conclusions

eHealth services, such as Sisom, can increase children's participation in health care and influence health care professionals' ways of communicating with children in health care services. The overall results showed increased participation for the children in the intervention group compared to the control group, but a higher level of participation where the child could share decision making and responsibility with health care professionals was not visible in any of the groups. Sisom provides opportunities for enhanced improvement in health care, but its capabilities are far from being fully utilized. Further studies employing a randomized control design focusing on the effects of eHealth services on children's health outcomes, perceived participation, and cost-effectiveness could make a

significant contribution to guiding implementation of eHealth services in pediatric care.

Acknowledgments

Funding for the research for the first authors from Region Halland and the Center for Research on Welfare, Health, and Sport at Halmstad University is gratefully acknowledged. The authors would like to acknowledge Professor Cornelia Ruland and the Center for Shared Decision Making and Collaborative Care Research at Oslo University Hospital for valuable support during the design of the study and for sharing recorded data used for this study.

Abstract

Background: Juvenile idiopathic arthritis (JIA) is a serious and potentially debilitating pediatric illness. Improved disease self-management may help to improve health outcomes.

Objective: This study aimed to evaluate the effectiveness of the *Teens Taking Charge* Web-based self-management intervention in reducing symptoms and improving health-related quality of life (HRQL) in adolescents with JIA compared with a Web-based education control condition.

Methods: Adolescents with JIA aged 12 to 18 years were recruited from 11 Canadian pediatric rheumatology centers. Caregivers were invited to participate along with their child. In addition to standard medical care, participants were randomized to receive either (1) the *Teens Taking Charge* self-management intervention or (2) a Web-based education control condition for a period of 12 weeks. Adolescents in the intervention group completed website modules addressing cognitive behavioral coping skills, stress management, and other self-management topics, while also receiving monthly telephone calls from a trained health coach.

Adolescents in the education control group were instructed to view a series of preselected public JIA educational websites and received monthly calls from a coach who asked about *their own best efforts* at managing JIA. Caregivers in the intervention group completed website modules related to promoting independence and disease self-management in their child. Caregivers in the education control group were instructed to view a series of preselected public JIA educational websites. Outcome assessment occurred at baseline, 12 weeks (posttreatment), and at 6 and 12 months postrandomization. The primary outcomes were pain intensity, pain interference, and HRQL. Secondary outcomes were emotional symptoms, adherence, coping, knowledge, and self-efficacy.

Results: In total, 333 adolescents and 306 caregivers were enrolled. Significant overall reductions in pain intensity ($P=.02$) and pain interference ($P=.007$) were observed for intervention group participants compared with those in the education control group, after adjusting for baseline levels. There was a significant overall improvement in HRQL related to problems with pain ($P=.02$) and problems with daily activities ($P=.01$). There was also a significant difference in the intervention group over time ($P=.008$) for HRQL related to treatment problems, with the intervention group participants demonstrating improved HRQL by 12 months compared with education control group participants. Both groups showed nonsignificant improvements compared with baseline in other primary outcomes. There were no significant differences between the groups in any secondary outcomes or caregiver-reported outcomes.

Conclusions: The results of this randomized trial suggest that the *Teens Taking Charge* Web-based intervention is effective at reducing both pain intensity and pain interference, as well as improving HRQL in adolescents with JIA, compared with education control. These effects are sustained for up to 12 months following program completion. The *Teens Taking Charge* program is now publicly available at no cost.

Trial Registration: ClinicalTrials.gov NCT01572896; <https://clinicaltrials.gov/ct2/show/NCT01572896>

Introduction

Background

Juvenile idiopathic arthritis (JIA) is a serious and potentially debilitating pediatric illness. It is the most common rheumatic disease in childhood, affecting approximately 1 in 1000 children [1]. The disease course can be unpredictable, and children commonly experience both physical (eg, pain, fatigue, stiffness) and emotional (eg, stress, anxiety, depression) symptoms that may restrict day-to-day function [2-7]. Persistent pain is common and can contribute to adverse psychological effects and functional disability [8,9]. As children mature, they are expected to assume increasing responsibility for disease self-management concomitant with their growing independence and autonomy. However, adherence to disease management is typically suboptimal [10,11]. Poor adherence and inappropriate strategies for self-management may reduce the potential benefits of treatment and impact health-related quality of life (HRQL) [10,11].

Improved disease self-management early in the disease trajectory may help to improve health outcomes. Web-based self-management interventions are a promising strategy for improving the accessibility and availability of education, psychosocial interventions, and social support for adolescents with JIA [12,13]. There is preliminary evidence that self-management interventions can improve symptoms and health status in certain childhood illnesses [14-20].

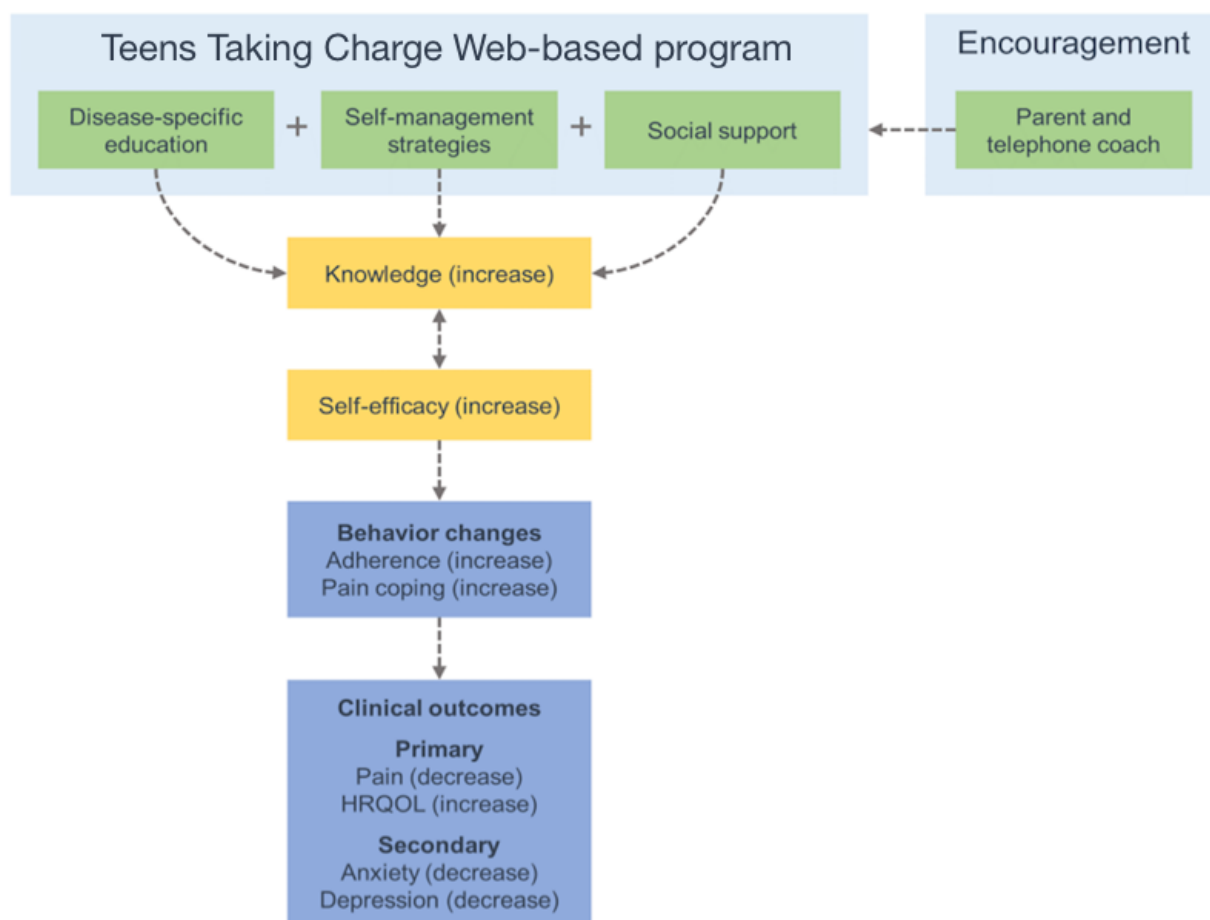

Teens Taking Charge is a Web-based treatment that was developed to meet the need for a high-quality, accessible, empirically grounded, and multilingual self-management

program for adolescents with JIA [21-23]. The program was developed using a sequential phased approach. In phase 1, a qualitative needs assessment was conducted to identify the self-management needs of adolescents with JIA [21]. Adolescents articulated a universal need for more JIA-specific knowledge, self-management strategies, and meaningful social support to better manage their JIA. In phase 2, a prototype website was developed, and it underwent iterative cycles of usability testing to ensure ease of use and understanding of the program [22]. In phase 3, a pilot feasibility randomized controlled trial (RCT) was completed with 46 adolescents with JIA and their caregivers [23]. The pilot RCT supported the feasibility (high acceptability, user satisfaction, and compliance) and initial effectiveness of the program in improving knowledge and decreasing pain in adolescents with JIA compared with an education control condition.

Objective

The objective of this study was to evaluate the effectiveness of the *Teens Taking Charge* Web-based self-management intervention in reducing symptoms and improving HRQL in adolescents with JIA compared with a Web-based education control condition. We hypothesized that adolescents randomized to the intervention group would demonstrate (1) reduced pain and improved HRQL; (1) reduced emotional (anxiety and depression) symptoms; and (3) increased treatment adherence, pain coping, JIA-specific knowledge, and self-efficacy compared with adolescents randomized to the control group. See [Figure 1](#) for a summary of the hypothesized mechanism of action of the *Teens Taking Charge* intervention on health outcomes. This model is based on the published work of Murray et al [24].

Figure 1. Conceptual model outlining the hypothesized mechanism of action of the Teens Taking Charge: Managing JIA Online Web-based intervention. JIA: juvenile idiopathic arthritis. HRQL: health-related quality of life.

Methods

Trial Design

A 2-arm parallel group RCT design was conducted to evaluate the effectiveness of the *Teens Taking Charge* program in comparison with a Web-based education control condition. The allocation ratio was 1:1. The trial was registered on ClinicalTrials.gov with the identifier, NCT01572896. The study was approved by the local research ethics boards at each of the participating institutions.

Participants

Adolescents were recruited in person from 11 Canadian pediatric rheumatology centers. A local research coordinator explained the study to eligible adolescents and obtained written consent.

Parents and caregivers were invited to participate with their child. Adolescents were eligible to participate if they were (1) between 12 and 17.9 years of age, (2) diagnosed with JIA as per their rheumatologist, (3) able to speak and read English or French, and (4) able to complete Web-based outcome measures as per self-report. Adolescents were excluded if they had (1) major comorbid illnesses or cognitive impairments that could affect their ability to use and understand the Web-based program as per their health care provider or (2) were currently participating in other cognitive behavioral therapy interventions.

Parents and caregivers were eligible if they were (1) able to speak and read English or French and (2) able to complete parent modules and outcome measures. Participants received gift cards (total value Can \$100 [US \$75]) in recognition of their time and commitment to the study.

Study Conditions

Intervention Condition

The intervention was based on cognitive behavioral principles of improving pain and HRQL through providing disease education, empowering patients with coping skills to help manage disease symptoms and stress, and providing validation and encouragement through opportunities for social support.

The intervention condition had three components: (1) a 12-module adolescent website consisting of JIA-specific education, self-management strategies, and social support, (2) telephone health coaches for the adolescent only, and (3) a 2-module caregiver website consisting of education about the impact of JIA and strategies to support their adolescent in self-management.

The adolescent and caregiver websites were available in English and French. The module content is summarized in Table 1. All content was developed by a team of experts from across Canada including study investigators, allied health team members, and adolescent medicine health care professionals, and patient

advocates. Modules were written at a grade 6 to grade 7 level, were developmentally appropriate for those aged 12 to 18 years, and were geared to address the needs identified in the phase 1 qualitative study [21]. See Figure 2 for screenshots of the *Teens Taking Charge* adolescent website.

Participants were instructed to work through the modules over a 12-week period at their own pace to allow sufficient flexibility to accommodate for exams, holidays, and illnesses. Participants received automated standard weekly emails to remind them to complete their next module and to congratulate them on module completion.

Adolescents in the intervention group also received monthly telephone calls from a health coach who was a trained non-health care professional [23]. The telephone coach (1) reviewed content from the previous 4 weeks (eg, assignments, knowledge quizzes, and goals); (2) determined whether the participant completed the modules and answered questions regarding the material and or self-management skills; and (3) provided guidance and helped problem-solve any issues with the program content that may have arisen in the previous 4 weeks. If participants asked questions that the coach could not answer, the coach redirected them to their rheumatology health care team. All calls were audio recorded and audited every 3 months to ensure integrity of the intervention delivery.

Table 1. Module breakdown of the Teens Taking Charge intervention for adolescents and caregivers.

Module number and title	Content description
Adolescent modules	
1. About JIA ^a	Clinical features of JIA
2. Understanding diagnosis	How JIA is diagnosed, coping, and health check-ups
3. Managing your symptoms	Understanding and managing pain, fatigue, and stiffness
4. Managing stress	Understanding and managing stress
5. Relaxation	Belly breathing, relaxation with and without tension, mini relaxation, and behavioral reversal
6. JIA medications	Overview of medications for JIA and medication management
7. Distraction	Attention focusing, imagery, mental games, and pleasant activities
8. Other types of care	Physical activity, nutrition, orthotics, occupational therapy, psychological therapy, complementary therapy, surgical procedures, eye care, and dental care
9. Managing your thoughts	Understanding stress and thinking; changing negative thoughts
10. Therapies, self-monitoring, and supports	Getting the most from your treatment, self-monitoring, and communication with the health care team
11. Your lifestyle	Staying active, healthy eating, and lifestyle choices
12. Looking ahead	Transitioning to adult care, preparing for higher education and employment, and maintaining a treatment program
Caregiver modules	
1. Impact of arthritis	Impact of JIA on the family and finances; JIA disease education
2. Letting go	Communicating with your teen and helping your teen to take control of disease management

^aJIA: juvenile idiopathic arthritis.

Figure 2. An example screenshot of the Teens Taking Charge: Managing JIA Online adolescent Web intervention.

Education Control Condition

This condition was designed to control for the potential effects on outcomes of time, attention, and computer use during the intervention and through the follow-up period. In addition to standard medical care, adolescents and caregivers in the education control group were provided with access to a self-guided education study website called the *JIA Resource Centre*. It featured links to 12 publicly available JIA websites (identified from a systematic review) that provided patient education, but did not offer self-management strategies or opportunities for social support [25]. The information in these websites was similar to the materials that are routinely provided at the time of diagnosis in the participating recruitment centers. The educational websites were monitored on a weekly basis to ensure that they did not add any *active ingredients* during the trial. See [Multimedia Appendix 1](#) for a list of websites in the *JIA Resource Centre*. Adolescents and caregivers were encouraged to browse one website per week from the *JIA Resource Centre*. They received automated email reminders each week to access the education content.

Each adolescent in the education control group also received monthly telephone calls from a coach. The coaches were trained non-health care professionals who encouraged participants to view the websites and also discussed adolescents' *own best efforts* at managing their JIA over the 12-week period. The coach used standardized scripts for these calls. They did not

provide any advice or self-management support to participants, and the interaction was minimal. If a participant asked for information related to self-management of their JIA, the coach redirected them to their rheumatology health care team. All calls were recorded and audited to ensure integrity of the control calls. Participants from the education control group were offered the full intervention following their trial completion (at 12-month time point after completion of all outcome measures) for a period of 3 months.

Outcomes

Outcome data included a combination of adolescent self-reports and parent-proxy reports, as outlined in [Multimedia Appendix 2](#) [26-34]. Measures were completed at four different time points: baseline (after consent, before randomization; T_1), condition completion (3 months after randomization; T_2), 6 months after randomization (T_3), and 12 months after randomization (T_4). Measures were completed online by study participants through the Research Electronic Data Capture secure Web-based system hosted at the Hospital for Sick Children. The lead study coordinator contacted participants via telephone, email, and mail to remind them to complete follow-up measures. All measures have evidence of validity and reliability for adolescents with arthritis and were available in English and French.

Sample Size

Sample size was calculated by assuming an effect size (standardized group difference) of 0.31 units on the outcome of average pain intensity over a 12-month follow-up because this magnitude of difference is considered the minimally clinically significant important group difference for pain intensity [35]. It is also congruent with the treatment effect observed during pilot work [23]. Assuming a type I error rate (alpha) of .05 and the maximum correlation between repeated pain measurements to be 0.90, a sample size of 117 participants per group (234 in total) was required to achieve 80% power to detect an effect of this magnitude or larger. To account for the lack of compliance in completing online measures, we assumed a loss to follow-up of 20% based on our pilot RCT (13%) [23] and systematic review [36]. Therefore, we planned to randomize 294 adolescents to one of the two groups.

Randomization

Randomization was centrally controlled, concealed, and balanced by physician-rated disease activity into those with low (<3/10) and moderate-to-severe (>4/10) disease activity [37] and by study center (ie, to control for center-specific education, transitional care programs, and treatment approaches). A secure, Web-based randomization service was used for allocating participants to the trial groups. Following randomization, participants were sent instructions on how to access their assigned program (website link and log-in) and were contacted by their assigned coach.

Blinding

This was a single blind study (adolescent and caregiver only). Both groups received a website and monthly telephone calls. Participants were informed that they would be chosen at random to either receive the *Taking Charge: Managing JIA Online* internet education program or the *JIA Resource Centre* internet education program. They were not explicitly told which program was considered the intervention condition.

Statistical Methods

As per an intent-to-treat approach, all participants were included in the final analysis and according to the arm (intervention or control) to which they were randomized. Only participants who completed at least one follow-up outcome assessment after baseline were included in the analysis. In addition, outcome assessments were required to be completed within 35 days of each time point (ie, 3 months, 6 months, 12 months) to be included in the analysis for that time point. This 35-day window

was used because the *PedsQL Rheumatology Module* asks respondents to describe their function over the previous month [38]. Thus, participants who completed their outcome assessments beyond the assigned time point were reporting their function within a different window of time compared with participants who completed assessments on schedule and the data were considered missing.

Data were analyzed using the SAS software (Version 9.1.3, developed by SAS Institute Inc, Cary, North Carolina, 2006). [39]. Descriptive statistics were used to describe characteristics of the sample. A significance level of .05 was used for the primary question. A Bonferroni-adjusted alpha level of .007 was used to maintain an overall level of .05 for all secondary and other study outcomes. Linear mixed models were used to assess the effects of the intervention on primary, secondary, and other outcomes using the baseline scores as covariates. Models used an autoregressive first order covariance structure, which allows for correlations between measurements to decline as they are further apart in time [40,41]. To assess the effects of disease-related variables (eg, disease activity, duration of illness, and disease subtype) and age on primary and secondary outcomes, separate linear mixed models of each posttreatment measure were constructed using pretreatment disease-related variables and age as covariates [42].

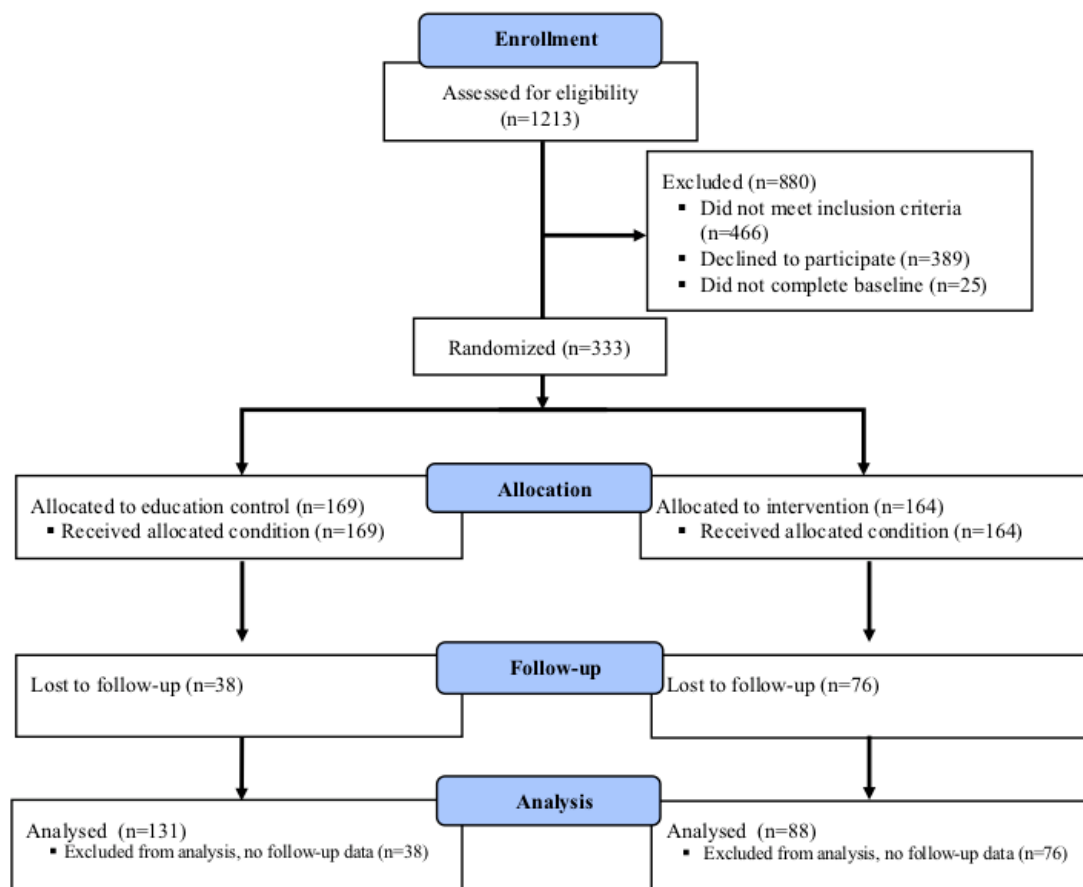

Data Safety and Monitoring

A Data Safety and Monitoring Board (DSMB) was formed to regularly review the safety and treatment-specific efficacy data of the trial. The board included experts in translational research, pediatric rheumatology, chronic pain, cognitive behavioral therapy, RCTs, and biostatistics. The DSMB met via teleconference every 6 months for the duration of the trial.

Results

Participants

The Consolidated Standards of Reporting Trials (CONSORT) [43] flow diagram detailing participant enrolment, allocation, follow-up, and analysis is provided in Figure 3. The randomized study sample consisted of 333 adolescents. As illustrated in the CONSORT diagram, 76/164 (46.3%) participants in the intervention group and 38/169 (22.5%) in the control group were lost to follow-up. Those participants lost to follow-up did not have any significant differences in baseline characteristics with the exception of the PedsQL worry subscale (lost to follow-up=40.0; analytic=45.9; $P=.03$).

Figure 3. Consolidated Standards of Reporting Trials flow diagram.

Across the entire sample, 100/604 (16.6%) outcome assessments were completed beyond the 35-day window for that time point. The breakdown of overdue assessments across time points was as follows: 3 months (24/197, 12.2%); 6 months (38/200, 19.0%); and 12 months (38/207, 18.4%). Comparing the groups, 45/251 (17.9%) intervention outcome assessments and 55/353 (15.6%) control outcome assessments were completed outside the window. Similarly, 101/541 (18.7%) caregiver outcome assessments were completed beyond the 35-day window for that time point. The breakdown of overdue caregiver assessments across time points was: 3 months (26/169, 15.4%);

6 months (35/182, 19.2%); 12 months (40/190, 21.1%). Comparing the caregiver study groups, 46/216 (21.3%) intervention assessments and 55/325 (16.9%) control assessments missed the allowed window.

Characteristics of the analyzed adolescent sample by assigned condition are provided in Table 2. The analyzed caregiver sample consisted of biological mothers (158/197, 80.2%), biological fathers (36/197, 18.3%), and adoptive parents or grandparents (3/197, 1.5%). More than half of the caregiver sample (129/197, 65.5%) had graduated from college or graduate school.

Adherence to Assigned Study Condition

Telephone coach calls were considered *complete* if a participant had reviewed their assigned website module content for that month. Thus, coach calls were used to define participant adherence to their assigned condition. In total, 72.4% (241/333) of participants completed at least two of three coach calls. Across all participants, coach call completion was as follows: 0 calls (75/333, 22.5%); 1 call (17/333, 5.1%); 2 calls (4/333, 1.2%); or 3 calls (237/333, 71.2%). A higher proportion of participants in the control condition met the minimum criteria for being considered adherent compared with the intervention condition (148/169, 87.6% vs 93/164, 56.7%). Overall, 146/169

(86.4%) control participants and 91/164 (55.5%) intervention participants completed all 3 calls.

Primary and Secondary Outcomes: Adolescents

There was a significant effect of condition on pain intensity ($P=.02$) and pain interference ($P=.007$) after adjusting for baseline differences between the groups, with improved scores (lower values) observed in the *Teens Taking Charge* group. The effect of condition was stable over time (from 3 to 12 months), as there were no significant conditions by time interactions. Similar results were seen for the HRQL domains of problems with pain ($P=.02$) and problems with daily activities ($P=.01$). Although there was no overall condition effect, there was a

significant condition by time interaction ($P=.008$) for treatment problems, suggesting that the difference between the groups changed over time. No significant differences were seen on the PedsQL subscales of worry or communication problems. Results

from the linear mixed models are presented in Table 3, and the mean values in both groups over time are depicted in Figures 4 to 6. See Multimedia Appendices 3-5 for additional analytic outputs from the adolescent analyses.

Table 3. Adolescent reported primary outcomes, linear mixed models.

Outcome measure	Linear mixed model					
	Time		Condition		Time by condition	
	<i>F</i> value (<i>ddf</i> ^a =281)	<i>P</i> value	<i>F</i> value (<i>ddf</i> =281)	<i>P</i> value	<i>F</i> value (<i>ddf</i> =281)	<i>P</i> value
Pain

Primary and Secondary Outcomes: Caregivers

The primary and secondary caregiver outcome variables as a function of condition and assessment time point are displayed

in [Multimedia Appendices 6 and 7](#). There were no significant differences between study groups on primary and secondary caregiver outcomes.

Discussion

Principal Findings

This study sought to evaluate the effectiveness of the *Teens Taking Charge* intervention compared with Web-based education in improving symptoms and HRQL in adolescents with JIA. Our results indicate that the *Teens Taking Charge* self-management intervention has evidence of effectiveness at improving pain intensity and pain interference. These improvements were sustained for up to 12 months postrandomization. The intervention group also demonstrated significant improvements in HRQL related to pain and hurt, daily activities, and treatment problems compared with the control. There were improvements, yet no significant group differences in the secondary outcomes of emotional symptoms, treatment adherence, pain coping, JIA knowledge, and self-efficacy. The data trends support the conceptual model for how JIA self-management education could be foundational to promote improvement in health outcomes.

Comparison With Previous Work

As expected, there is concordance between the results of this trial and the *Teens Taking Charge* pilot RCT. The pilot trial demonstrated initial program effectiveness in improving JIA knowledge and decreasing pain intensity compared with education control [23].

Results of this RCT should also be compared with published results by Connelly et al [44], who evaluated an adapted version of *Teens Taking Charge* in English and Spanish-speaking adolescents with JIA in the United States. Data from the Connelly trial indicated that participants in both study groups had comparable and statistically significant improvements in pain intensity, pain interference, and HRQL over the study period, with no significant between-group differences. The effect size estimates associated with outcome improvement were small.

The findings of these two RCTs should be considered in the context of several factors. First, this study was conducted in Canada while the Connelly study was conducted in the United States. Given that the *Teens Taking Charge* program was delivered in addition to usual care, it is possible that regional differences in baseline care affected the relative impact of the supplemental intervention. Although both RCTs demonstrated improvements in primary outcomes in the control and intervention groups, only this study found significant improvements in the intervention participants compared with control participants. Connelly hypothesized that the choice to compare a self-directed Web-based self-management intervention with an *active* control arm (ie, online education) rather than a wait list or standard care condition may have contributed to the lack of between-group differences in his trial. Participants may have engaged differently with the *active control* condition—with participants in the American trial benefiting more from the provided JIA education and/or attention from a telephone coach. This may be a function of the type of education routinely offered as part of usual clinic care and/or how much participants actually viewed and used the *active control* content. Unfortunately, as data about how often

control participants perused the educational websites were not captured, direct comparisons between the trials in this regard is not possible.

This trial's results also concur with two systematic reviews, which found that remotely delivered self-management interventions can be effective in improving painful symptoms in children and adolescents [45,46]. However, a meta-analysis of pediatric chronic pain studies [46], which used an active comparator condition rather than usual care, found that Web-based cognitive behavioral therapy was not significantly better than active control (pooled $g=0.10$; 95% CI -0.32 to 0.52 ; $P=.64$). Although this study did demonstrate significant between-group differences with an active comparator group, our findings should be considered in the context of previous similar studies. Of the three active control studies included in the meta-analysis study [46], the trial by Palermo et al [47] had the largest sample size ($N=273$ vs $N=18$ and $N=48$) and the highest Moncrieff quality rating [48] (37 vs 16 and 26, respectively). The Palermo trial evaluated a program called Web-based Management of Adolescent Pain (Web-MAP2). Their data demonstrated that, from baseline to 6-month follow-up, adolescents with chronic pain who received the Web-MAP2 intervention achieved greater reductions in the primary outcome of daily activity limitations than the education control group. However, while both groups improved, there was no significant difference between groups from baseline to the immediate posttreatment period. Most participants in the Palermo trial reported a baseline pain intensity of moderate-to-severe intensity, while most participants in this trial (181/219, 82.6%) had low disease severity at baseline and low pain intensity (see Table 2). As they started their trial with higher dysfunction, intervention participants in the Palermo trial may have needed more time to consolidate and apply their learned self-management skills, which may have contributed to a lack of differentiation in initial pain outcomes compared with control group participants who received pain education alone.

Overall, this study demonstrates that a Web-delivered cognitive behavioral intervention can significantly improve health outcomes in adolescents with JIA, compared with active control, and that these improvements can be sustained from the immediate posttreatment period for up to 12 months.

Trial Strengths

The extended follow-up period over 1 year allowed for the examination of the maintenance of treatment effects. This is an important aspect of trial quality to address in pediatric Web-based self-management interventions, given that most previous studies have only reported outcomes in the immediate posttreatment period. The use of an education control condition is also an important contribution as most pediatric Web-based RCTs have employed usual care or wait-list control conditions, making it difficult to separate the effects of active treatment from those of increased attention and access to an online program.

Trial Limitation

In this study, telephone coach calls were used as a proxy for program adherence. The website platform, which was built and supported by hospital IT infrastructure, did not support the capture of user-level usage analytics at the time of development. Thus, the impact of program usage level on outcomes could not be examined.

As per the sample size calculation, this trial aimed to analyze a minimum of 117 participants per group. The study analytic sample included 88 intervention and 131 control participants. This loss of participants reduced our statistical power to detect small differences between the study groups. Although we did identify significant group differences on primary outcomes owing to sufficiently large effect sizes, it is possible that smaller effect sizes on other outcomes were missed owing to the underpowered sample.

The higher rate of loss to follow-up in the intervention vs control group may have been the result of increased participant burden (eg, greater time commitment required to review intervention content vs control). Intervention group participants were also less likely to complete all coach telephone calls than those in the control group. In light of the high rate of loss to follow-up and lack of data on program usage, the generalizability of study findings should be interpreted with caution.

Significance

This study shows the beneficial effects of a digital approach to disease self-management for the youth with JIA. This paradigm could have far-reaching implications for self-management of other chronic health conditions experienced by the youth. Given that the *Teens Taking Charge* program has been found effective, we envision that it should be offered as a resource for all youths with JIA to supplement their medical care. We believe that this adjunctive self-guided online program will help to overcome current barriers that prevent adolescents with JIA and their families from receiving adequate support in disease self-management.

Conclusions and Next Steps

The results of this RCT indicate that the *Teens Taking Charge* Web-based intervention is effective at reducing both pain intensity and pain interference and improving HRQL in adolescents with JIA compared with education control. These effects are sustained for up to 12 months following program completion. The *Teens Taking Charge* program is now publicly available at no cost [49]. Efforts are underway to widely disseminate this resource to increase the accessibility of self-management care for adolescents and families living with JIA. Efforts are also underway to culturally adapt the intervention for use in different settings.

Acknowledgments

The authors thank the members of the DSMB: Dr Susmita Kashikar-Zuck (Cincinnati Children's Hospital), Dr Chandima Karunanayake (University of Saskatchewan), and Dr Ilona Szer (Rady Children's Hospital). Research coordination by Stephanie Luca and Carol Chan (the Hospital for Sick Children), Michele Gibbon (Children's Hospital of Eastern Ontario), Angelyne Sarmiento and Audrea Chen (BC Children's Hospital), Aleasha Warner, Cindy Campbell, Victoria Dempsey (IWK Health Centre), Jeannine Schellenberg and Shirley Frederickson (Winnipeg Children's Hospital), Ronda Danchak (Stollery Children's Hospital), Mary Gardner, Karen Murphy, Rana Aslanov (Janeway Children's Health and Rehabilitation Centre), Dorothy McKelvey and Joanna Mazza (Montreal Children's Hospital), Dwaraka Veeramreddy (Alberta Children's Hospital), Lois Saunders (McMaster Children's Hospital), and Joan Dietz (Royal University Hospital). The telephone coaches were Lidia Giosa and Maria Fernanda Frances (The Hospital for Sick Children). Dr Mark A Connelly (Children's Mercy Kansas City) provided a helpful manuscript review. Mallika Makkar (The Hospital for Sick Children) aided with manuscript submission. The authors thank the families who took part in this research.

Abstract

Background: Recombinant human growth hormone treatment can optimize growth potential; however, optimal outcomes are not always achieved for several reasons, including poor adherence. The overall objective of this project was to design a patient support program to maximize the chances of treatment success for people being treated with somatropin injection. An approach known as the behavior change wheel was used to enhance the development of the patient support program. The behavior change wheel provided a comprehensive framework to support the design of interventions.

Objective: The aim of this paper was to describe how the steps of the behavior change wheel were applied to the development of a patient support program for individuals with growth hormone deficiency undergoing treatment with somatropin.

Methods: We followed a series of steps that align to tenets of the behavior change wheel, namely, a narrative literature review to identify which behaviors needed to change and the potential drivers of and barriers to the behaviors, the selection of an intervention strategy and discrete behavior change techniques, and, finally, intervention specification.

Results: A recent systematic review identified a range of potentially modifiable factors found to have an influence on patient adherence to growth hormone treatment. Insights from the systematic review were used to guide the development of a patient support program. The final design of the patient support program consisted of four elements: (1) a personalization questionnaire to tailor support for each individual, (2) tailored reminder and support SMS text messages, (3) nurse-led phone calls, and (4) Easypod connect, an automated electronic autoinjector drug-delivery device with a transmitter and connection platform for Saizen (somatropin) that allows automatic recording, storage, and transmission of drug-usage data, thus providing insight into suboptimal adherence.

Conclusions: The patient support program that was designed is currently being piloted with patients to assess engagement with the program and determine its impact on patient outcomes. Results from the pilot will be used to further refine the program to ensure it meets user needs.

KEYWORDS

growth hormone; behavior change wheel; somatropin; adherence

Introduction

Recombinant human growth hormone (r-hGH; somatropin) treatment is well established for children and adolescents with growth hormone deficiency [1]. The goal of this treatment is to optimize growth potential, so that the expected target height (based on a normal growth curve for each individual) is achieved by adulthood [2]. Evidence has demonstrated the efficacy of growth hormone treatments to improve growth in children with growth hormone deficiency compared to that of children whose growth hormone deficiency is not treated [3].

The impact of growth hormone deficiency goes beyond reduced growth potential. Research has shown that children with growth hormone deficiency may also experience a psychosocial burden as a result of being physically different from their peers [3,4]. This burden can continue into adulthood, particularly if short stature persists, limiting both personal and professional success [3] as well as potentially having an impact on long-term health, since, as adults, they may also have an increased risk of cardiovascular diseases [5]. With prevalence estimates for growth hormone deficiency from 1.8 to 2.9 per 10,000 in Europe and the United States [6-8], the potential of treatment success to benefit the health economy as well as patients and their families is significant [3].

The overall objective of this project was to design a patient support program to maximize the chances of treatment success for people treated with somatropin by injection. An approach known as the behavior change wheel [9] was used to enhance the development of the patient support program. The behavior change wheel provided a comprehensive framework to support the design of the interventions allowing designers to move from behavior analysis to intervention design using evidence-based techniques and behavior change theory. Central to the behavior

change wheel is a framework called the capability, opportunity, motivation, and behavior model (COM-B) [9] (Figure 1). The COM-B model proposes that a person's health behaviors are driven by a range of factors, which can be grouped under three broad headings: *capability*, their physical or psychological ability to engage in the behavior, for example, in the context of adherence to medication, factors such as reduced cognitive functioning, mobility problems, or poor treatment comprehension may affect an individual's ability to understand how to physically administer their treatment; *motivation*, the internal thoughts and emotions that influence individual decision making in relation to the behavior, for example, beliefs about the need for treatment or the seriousness of the illness may affect how motivated an individual is to try a new treatment or depression as a result of their health condition can reduce their motivation to adhere to a treatment regimen; and *opportunity*, the external factors which make it possible to engage in the behavior, for example, having a supportive social network and easy access to healthcare resources. In addition to each component influencing medication-related behavior directly, opportunity and capability may affect motivation, and thus also influence behavior in this manner. Jackson and colleagues [10] successfully applied this model to treatment adherence behaviors. While there are similarities in factors for adherence across a patient population, it is important to note that each patient has their own unique needs and set of beliefs that have an impact on their ability to adhere to treatment [11]. Offering personally tailored self-management or adherence interventions to suit their individual needs is the most effective way to ensure patients understand and adopt targeted behaviors, including adherence to r-hGH treatment [11-13]. Tailored interventions and support have also been shown to be more cost-effective [14], an important consideration in the sustainability of support services.

Figure 1. Capability, opportunity, motivation, and behavior framework.

Another crucial component of the behavior change wheel is the selection of appropriate techniques to change behavior. In this paper, we describe how the steps of the behavior change wheel were applied to the development of a patient support program for individuals with growth hormone deficiency who were prescribed somatropin; the duration of individual treatments

varies depending on age at time of diagnosis (usually early childhood), and in order to reach full height potential, are continued up to the age when bone growth stops (as the individual reaches adult height). The patient support program was designed to incorporate a large digital component, while also maintaining a strong human support element to personalize

and complement the digital aspects of the intervention. Digital interventions that incorporate a wide range of communication channels such as SMS text messaging, interactive websites, apps, and electronic devices are thought to have great potential for this patient population, given the popularity of digital media among young people [15]; however, despite this, maintaining engagement with digital interventions can be difficult with many studies reporting high levels of dropouts or nonusage [16]. Personalized messaging and multicomponent interventions including both digital and nondigital aspects have been shown to be more effective for behavior change than nontailored messaging and single-component interventions [17]. Yardley et al [16] proposed several general principles and considerations for maximizing engagement with digital behavior-change interventions; they stressed that, most importantly, the intervention should be relevant to the user, ie, it should address an unmet need and should be tailored to the specific situation, needs, and motivations of the user [16]. Utilizing the behavior change wheel and the COM-B framework allowed us to identify the drivers that underlie treatment-related behavior in growth

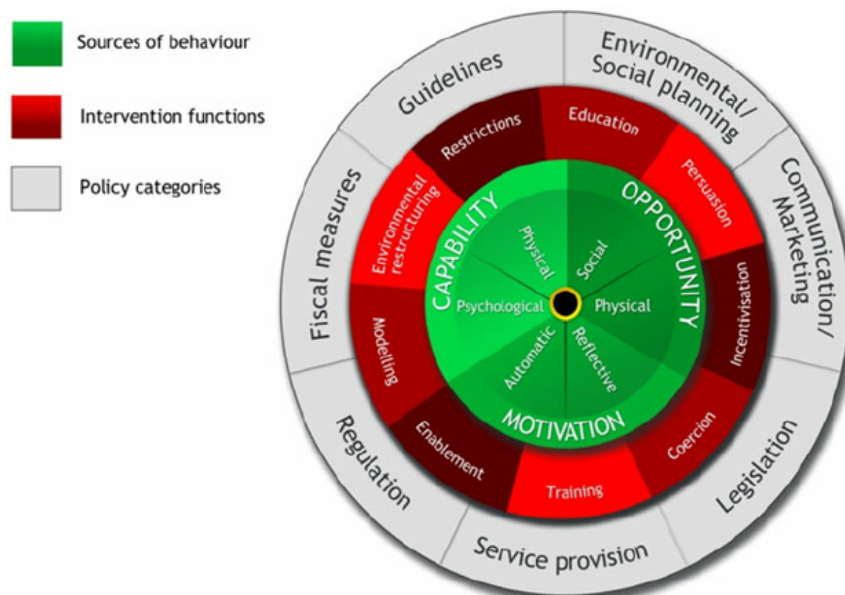

hormone deficiency patients and caregivers, and thus, to create a program with relevant tailored content. Further suggestions [16] included adding a human element to help maintain motivation and ongoing adherence to the digital components of the intervention, ensuring the intervention content was accessible and engaging for people with different levels of health literacy, and taking an iterative approach to intervention development and evaluation to refine the intervention to ensure it would continue to meet user needs. These considerations were also used to guide the design of the patient support program.

Methods

Overview

We followed a series of steps that were aligned to tenets of the behavior change wheel [9], namely, identifying behaviors that needed to change, identifying the potential drivers of and barriers to the behavior, selecting an intervention strategy and discreet behavior change techniques, and specifying an intervention (Figure 2).

Figure 2. Behavior change wheel.

Step 1

A narrative review of the literature was carried out to understand problems associated with treatment management in growth hormone deficiency and to select and specify the target behavior. Literature searches were conducted using CINAHL, Medline, PsychINFO (via EBSCOHost), and the Cochrane Register for Controlled Trials and Systematic Reviews. The following keywords were used: “growth hormone,” “human growth hormone” (MeSH), “child” (MeSH), “adolescent” (MeSH), “patient compliance” (MeSH). Literature was limited to papers written in English and no date restrictions were applied. The reference lists and citations of publications that were identified were also searched for additional papers on the topic.

Step 2

Underlying barriers and drivers were defined using insights from a 2018 systematic review [18] looking at the range of

potentially modifiable factors that have been found to influence levels of adherence to growth hormone treatment; these factors were grouped according to the COM-B framework. The findings from this review provided direction for selecting the types of interventions that would be needed to effectively target these factors in digital interventions.

Step 3

Intervention options were identified using the behavior change wheel, which proposes nine intervention functions: education, persuasion, incentivization, coercion, training, restriction, environmental restructuring, modeling, and enablement. We used APEASE criteria (acceptability, practicability, effectiveness or cost-effectiveness, affordability, safety or side effects, and equity) [19] to guide our selection of the most relevant intervention functions. We also engaged a team of specialists in health psychology with expertise in behavior change.

Step 4

Based on the factors identified by Graham et al [18] and the intervention functions that were selected, a list of relevant behavior change techniques was defined to address each COM-B factor.

Step 5

The full intervention was mapped out, which involved selecting delivery channels (SMS text messages, nurse-led calls, Growlink app), applying the appropriate behavior change techniques to develop content, and designing a personalization questionnaire to tailor the patient experience. In addition, a measurement strategy was designed to evaluate the effectiveness of the intervention.

Table 1. Target behavior description.

Target behavior	Adherence to somatropin injection
Who needs to perform the behavior?	Pediatric patients with growth hormone deficiency or their caregiver
Where will they do it?	At home
How often will they do it?	This will vary depending on individual needs and will be determined by the prescription issued by their health care provider

Step 2: Behavior Diagnosis

In work relevant to this study, Graham et al [18] conducted a systematic review of pediatric nonadherence to r-hGH treatment using the COM-B framework to identify potentially modifiable factors. Key factors were identified in the review: within the scope of capability—knowledge and understanding of the condition, a lack of understanding of the consequences of missed r-hGH doses, forgetting to administer the medication, or poor administration technique; within the scope of opportunity—inadequate contact with health care providers and the quality of the health care provider–patient relationship, as well as the discomfort and pain associated with daily injections; and within the scope of motivation—the long duration of treatment and dissatisfaction with growth response results.

These findings were largely reflective of the insights gained from our narrative review of growth hormone and adherence literature; they suggested a need to address a range of factors related to patients receiving growth hormone therapy, their

Results

Step 1: Defining the Problem

A narrative review of the literature on growth hormone deficiency treatments found that despite the potential of r-hGH treatment to optimize growth potential, optimal outcomes were not always achieved; it was proposed that poor adherence was a key contributor to this [2,20,21]. The levels of nonadherence that were reported varied, particularly since definitions and assessment methods differed between studies, but with the proportion of nonadherent patients ranging from 5% to 82% across several indications for which growth hormone therapy is used [2] and with 7% to 71% of patients with growth hormone deficiency found to be nonadherent to treatment [18], it was clear that there was room to improve adherence in this population [2]. Adherence to somatropin injections was selected as a target behavior and outcome for the design of the patient support program. Table 1 further describes the target behaviors.

caregivers, and growth hormone deficiency and its treatment to ensure optimal adherence.

Steps 3 and 4: Implementation Strategy and Behavior Change Technique Selection

While all nine of the interventions listed in the behavior change wheel were found to be relevant to nonadherence to treatment in growth hormone deficiency, we selected the five intervention functions that we felt were the most relevant and the most appropriate to address within the patient support program; these were education, persuasion, training, modeling, and enablement. This decision was based on a combination of practical considerations such as affordability and cost-effectiveness as well as on behavior change expertise from a team of specialists in health psychology. Table 2 shows the relationship between the factors identified in the COM-B, intervention functions, and selected behavior change techniques. An expanded version of Table 2 including COM-B categories, intervention functions, and intervention content is available in Multimedia Appendix 1.

Table 2. COM-B adherence factors and behavior change techniques.

Adherence factors	Behavior change techniques
Long duration of treatment	<ul style="list-style-type: none"> • Framing or reframing
Dissatisfaction with treatment outcome	<ul style="list-style-type: none"> • Self-monitoring • Framing or reframing • Reduce negative emotion
Knowledge and understanding of condition	<ul style="list-style-type: none"> • Credible source • Information on health consequences
Discomfort or pain from daily injection	<ul style="list-style-type: none"> • Instruction of how to perform the behavior • Problem solving • Verbal persuasion of capability • Reduce negative emotion
Lack of understanding of the consequences of missed doses	<ul style="list-style-type: none"> • Information on health consequence • Salience of consequences
Forgetting	<ul style="list-style-type: none"> • Feedback on behavior • Self-monitoring • Prompts or cues • Problem solving
Health care provider–patient communication	<ul style="list-style-type: none"> • Demonstration of the behavior • Problem solving • Verbal persuasion of capability
Poor injection technique	<ul style="list-style-type: none"> • Instruction on how to perform the behavior • Demonstration of the behavior

Step 5: Mapping the Design of the Patient Support Program

Overview

Based on these findings, as well as on insights from digital behavior change intervention design principles and behavior change theory, a multicomponent digital patient support program was designed for patients receiving treatment with somatropin injection (see [Table 2](#) for example content). The patient support program consists of four components: personalization screening, SMS text messages, nurse-led phone calls, and an eHealth component.

Personalization Screening Questionnaire

A set of personalization questions was created based on the drivers of adherence that were identified in step 2. The design includes different questions for caregivers and patients, allowing for support to be tailored to both or either, depending on who is taking part in the patient support program. Patients and caregivers will be asked to complete the screening questionnaire when they join the patient support program and will be rescreened every 12 weeks. This is to ensure that support can be flexible to changing needs and to allow for review of intervention effectiveness by monitoring changes to beliefs and to support needs. The personalization screening questionnaire will be used to determine topic priority and focus of the SMS text messages and of the nurse-led components of the program.

SMS Text Messages

These include medication reminders as well as tailored intervention messages to address adherence factors that have been identified as important through the personalization screening questionnaire.

Nurse-Led Phone Calls

Patient support program nurses will be trained to deliver brief, evidence-based interventions to address the adherence barriers that were identified. The content and order of these telephone calls will be tailored to the needs of each individual patient or caregiver based on personalization screening questionnaire responses.

eHealth Component

The Easypod is an automated electronic autoinjector drug-delivery device with a transmitter and web-based connection platform for Saizen (somatropin) that automatically inserts a needle and delivers a preset dose to the patient. The device allows automatic recording, storage, and transmission of drug adherence data, thus providing insight into suboptimal adherence (through dose frequency) and its resulting effect on growth. Patients and caregivers can access the information via a patient app (Growlink), and physicians and nurses can access the information via the web-based Easypod connect platform.

Discussion

Principal Findings

The purpose of this paper was to describe the development of a patient support program aimed at supporting patients who have been prescribed Saizen in order to maximize their growth potential. A structured approach based on the behavior change wheel and the COM-B framework was used to identify the drivers of behavior and to systematically explore how these could be addressed through a pharma-funded patient support program.

The final design of the patient support program incorporated a patient-centric digital component featuring an online app linked to the injection device and frequent SMS text message delivery. The digital platform offers a convenient method for patients, caregivers, and health care providers to interact, to share, and to review adherence data for each patient. The addition of SMS text messaging allows adherence reminder messages and intervention content that was designed to address nonadherence to be sent to individual patients. SMS text messages have been successfully used in behavior change interventions as both reminders for appointments or for treatments [22], as well as to deliver interventions to change patient beliefs and to improve adherence [2]. A 2011 meta-analysis [23] of the efficacy of SMS text message reminders showed that they were effective across all age groups; there were also no differences in effect based on the timing of the messages or the rate that the messages were sent [23]. Messaging interventions have been shown to improve adherence to medications across a wide variety of clinical applications including asthma, antiretroviral treatments, and schizophrenia, in both adult and pediatric populations [22,24,25]. The effect of personalized messaging on behavior has also been shown to be more effective than that of nontailored messaging [17]. In line with the recommendations of Yardley et al [16], tailored content may also help increase engagement with digital interventions. In this patient support program, tailored content was achieved through a personalization screening questionnaire designed to determine the content and sequence of SMS text messages and nurse-led phone calls for delivery of the intervention; the online app was also designed to provide personalized adherence feedback.

Personalized telephone calls with a specialist nurse add a human element to the patient support program which may help to support continued engagement. Evidence has shown that nurses can successfully be trained to use behavior change techniques and to implement motivational interviewing techniques by a simple, brief course [26,27]. Nurse-led calls that implement motivational interviewing principles and that teach behavior change techniques have been shown to result in meaningful behavior change [28,29]. In addition, telephone-based support has been shown to be an effective delivery channel for promoting behavior change across different health conditions such as smoking cessation, increasing physical activity, and improving diet [30], as well as demonstrating a positive impact on treatment adherence [31,32]. Research has also shown that, in general, multicomponent interventions are more successful in having an impact on behavior than single-component

interventions are [33]. Thus, the nurse-led coaching phone calls are likely to enhance and complement the support provided through the digital components.

Another important consideration for any patient support program is the level of health literacy. Yardley et al [16] argued that digital behavior change interventions should be accessible and engaging for people with low levels of health literacy and should also be acceptable and usable for those with higher levels of health literacy. All content that was developed for the patient support program was reviewed by an experienced health psychologist and writer, and by a creative team to ensure the pitch, tone, and level was appropriate for the range of health literacy levels in the patient group.

Future Work

Our patient support program will be piloted with the aim of establishing its perceived acceptability and usefulness. The evaluation of the pilot patient support program will be conducted using an observational (real-world evidence) within-subjects design. Three categories of data will be captured: operational data, user experience data, and impact data. The primary outcome will be patient perception of the helpfulness of the patient support program. Secondary outcomes will include change in adherence and change in quality of life over the course of the patient support program, and multiple regression modeled predictors of these outcomes. Finally, data will be captured to identify ways in which various components of the patient support program could be improved, in line with the principles of continuous development in patient support program design, behavior change technique, and digital interventions proposed by Michie et al [34]. These data will be captured during routine operation via the patient support program (such as number and length of sessions), supplementary behavior-changing customer relationship management, and follow-up evaluation surveys.

Strengths and Limitations

The patient support program was developed using a systematic and structured approach, by drawing on relevant literature, and using appropriate evidence-based behavior change theories and frameworks. To the best of our knowledge, this represents a novel approach to the development of patient support programs in growth hormone deficiency; however, despite this, the use of the behavior change wheel inevitably required that the intervention development team make subjective and practical decisions regarding the most appropriate strategies and delivery channels. Since there was limited data on the most appropriate intervention channels and implementation of behavior change techniques for this patient population; the team drew from their own experience working in this patient population to guide some of these decisions.

The first part of the design process involved a narrative review of relevant literature. While this review captured a large volume of relevant literature, the methods were not exhaustive. Key search terms were provided, but to ensure that all relevant papers had been captured in an entirely reproducible format, a full systematic review was required. To be efficient, this paper focused, where possible, on meta-analyses and systematic

reviews such as [18] which partially summarized large quantities of the literature.

Conclusions

Using the approach outlined by the behavior change wheel, a multicomponent patient support program for patients with growth hormone deficiency (and their caregivers) to achieve

their growth potential through adherence using the Easypod connect platform was developed. By incorporating personalization screening questionnaires into the patient support program, personalized intervention messages and nurse-led phone support can be offered to patients. Work is underway to implement and validate the patient support program, to establish whether it can improve adherence in a real-world setting.

Abstract

Background: Suicide is a prominent cause of death worldwide, particularly among young people. It was the second leading cause of death among those aged 15-29 years globally in 2016. Treatment for patients with suicidal thoughts or behaviors often includes face-to-face psychological therapy with a mental health professional. These forms of interventions may involve maintaining and updating paper-based reports or worksheets in between sessions. Mobile technology can offer a way to support the implementation of evidence-based psychological techniques and the acquisition of protective coping skills.

Objective: This study aims to develop a mobile app to facilitate service users' access to mental health support and safety planning. This process involved eliciting expert input from clinicians who are actively engaged in the provision of mental health care.

Methods: A survey was distributed to targeted health care professionals to determine what features should be prioritized in a new mobile app relating to suicide prevention. On the basis of the survey results, a clinical design group, comprising 6 members with experience in fields such as mobile health (mHealth), clinical psychology, and suicide prevention, was established. This group was supplemented with further input from additional clinicians who provided feedback over three focus group sessions. The sessions were centered on refining existing app components and evaluating new feature requests. This process was iterated through regular feedback until agreement was reached on the overall app design and functionality.

Results: A fully functional mobile app, known as the SafePlan app, was developed and tested with the input of clinicians through an iterative design process. The app's core function is to provide an interactive safety plan to support users with suicidal thoughts or behaviors as an adjunct to face-to-face therapy. A diary component that facilitates the generalization of skills learned through dialectical behavior therapy was also implemented. Usability testing was carried out on the final prototype by students from a local secondary school, who are representative of the target user population in both age and technology experience. The students were asked to complete a system usability survey (SUS) at the end of this session. The mean overall SUS rating was 71.85 (SD 1.38).

Conclusions: The participatory process involving key stakeholders (clinicians, psychologists, and information technology specialists) has resulted in the creation of an mHealth intervention technology that has the potential to increase accessibility to this type of mental health service for the target population. The app has gone through the initial testing phase, and the relevant recommendations have been implemented, and it is now ready for trialing with both clinicians and their patients.

KEYWORDS

mobile apps; suicide; mHealth

Introduction

According to the Global Observatory for eHealth, mobile health (mHealth) is defined as “medical and public health practice supported by mobile devices, such as mobile phones, patient monitoring devices, personal digital assistants (PDAs), and other wireless devices” [1]. The World Health Organization (WHO) states that “mHealth involves the use and capitalization on a mobile phone’s core utility of voice and short messaging service as well as more complex functionalities and applications including general packet radio service, third and fourth generation mobile telecommunications (3G and 4G systems), global positioning system, and Bluetooth technology” [1].

Mobile devices have the potential to deliver evidence-based interventions with greater customization to the individual and at the time when the intervention is required. mHealth programs use mobile technology for a variety of functions, ranging from data collection tools for health care professionals and clinical decision support systems to support health behavior change by patients in the community [2].

The WHO reported that an estimated 800,000 people die by suicide each year globally, constituting a major public health concern. Suicide is the second leading cause of death in young people aged 15 to 24 years [3]. In Ireland, provisional figures indicate that 352 individuals died by suicide in 2018 [4]. Approximately one-third of people who died by suicide had been in contact with mental health care in the year before their death, and approximately 1 in 5 people had contact with a professional in the month before death [5]. Therefore, self-harm and suicide attempts (SAs) represent a pivotal opportunity for intervention. Suicide prevention guidelines recommend safety planning alongside treatment as usual for patients at risk for

mental health care [6]. However, safety planning is often not implemented in practice [7], and the feasibility of carrying paper-based plans may be limited, given the transient nature of suicide risk states [8]. Stigma and geographical isolation are two major barriers to help seeking for individuals at risk of suicide [9]. Advancements in mHealth technology could lower these main barriers by directing individuals at risk of suicide, who would not otherwise seek help, to appropriate evidence-based, web-based apps or traditional mental health interventions [10]. Research has indicated the probable benefits of internet-based suicide prevention methods [11]. Furthermore, a survey completed by psychiatric outpatients outlined that 69 of 98 participants (70%) expressed an interest in using a mobile app to track their mental health on a daily basis [12]. Given the established challenge of suicide in young people [3], there was an identified need to design and develop an app for use by 17- to 35-year-old secondary-level mental health service users (adult mental health or child and adolescent mental health). Specifically, those who present with suicidal ideation, nonsuicidal self-injury, or a history of a previous SA. A new mobile app, which is titled SafePlan and developed by the National University of Ireland Galway, was designed to be used as an adjunct to therapy for this at-risk group.

Before the design and development process of SafePlan, a review of existing mobile apps (N=5) providing support in the area of mental health and suicide prevention was conducted (Table 1). These apps were selected based on their subject and overall app store ranking. The review identified a functionality gap whereby none of these apps were combining the capabilities of safety plans, diaries, and other therapeutic intervention worksheets in one. The reviewed apps tended to focus on only one of these support methods, and the majority of them failed to provide any reporting tools for sharing user data.

Table 1. Review of existing apps in the area of mental health and suicide prevention.

^cDBT: dialectical behavior therapy.

Dialectical behavior therapy (DBT) is an evidence-based program aimed at helping people with ongoing difficulties in managing intense emotions. It is used in the treatment of mood disorders, suicidal ideation, and changing behavioral patterns, such as self-harm and substance abuse [18]. In clinical practice, both safety planning and DBT interventions may be combined

to provide a tailored approach to suicide prevention treatment. There are many apps currently on the market that specialize in one of these methods, which require a user to download and maintain two unrelated apps if they wish to support these treatments electronically. The lack of a centralized resource for safety planning and DBT supports was a highly motivational

factor in the development of a new app that would combine these prevention techniques. Early design meetings also identified that this approach should support additional intervention methods in future versions of the app by using a modular and flexible design architecture. The user could then enable or disable these options within the app's settings menu. This idea of intervention flexibility was well received by all members of the design team as they felt it had the potential to open the app to a much wider user base.

The proposed new app should have the added advantage of being co-designed with professional clinicians to support best practice patient-professional interaction based on valid data. Traditionally, both safety planning and DBT treatments involve patients maintaining and updating paper-based reports or worksheets between sessions. Mobile technology can provide an opportunity to streamline this process by eliminating the need for these paper-based resources and hence reduce human error and potential loss of material. It also helps to facilitate the recording of real-time data in a timely manner. The migration of these records to a mobile app could have a major impact on the accuracy and completeness of the data being collected [19].

Finally, the lack of any sharing functionality within existing safety planning apps summarized in Table 1, highlighted a further key requirement for the SafePlan app. This was particularly relevant because of the app's intended use envisaged as being an adjunct to therapy, that is, the information within the app should play a key role in patient-professional sessions. The ability to share data with a clinician or trusted helper was a core focus for the early stages of design. Users taking control of their own health information is a growing trend in digital and participatory health care [20,21]. A number of methods were analyzed for the extraction of app data in a user-friendly format, and a consensus was reached whereby a user could wirelessly print a safety plan or DBT report directly from their phone through the app's *My Reports* screen. This option was chosen

primarily for its ease of use; however, it also plays an important role in the overall security and privacy of the app. Passing data to web-based portals or cloud accounts was considered too risky an approach based on the confidential nature of the app's data. This is also the reason why it was decided to store all the app's user-entered data locally on the user's device as opposed to an external server. In summary, the aim of this study was to investigate whether mobile technology can offer a way to support the implementation safety planning approaches and therefore support the acquisition of protective coping skills for patients at risk.

Methods

Design Process

The SafePlan app was built using an agile software development approach [22]. The agile methodology is an incremental model of app development where requirements are planned and delivered in short, fixed-length time slots, also known as sprints or iterations [23]. Application requirements are established and refined through active user involvement within the software development process. In this case, external clinicians were recruited to fulfill the role of the user because of the sensitive nature of SafePlan's target audience.

Once the initial app requirements were gathered, they were prioritized into a feature backlog based on their importance and completeness, that is, a proposed app feature was placed toward the bottom of the backlog if it was not yet fully defined. The sprints were typically 2-3 weeks in length and contained a number of stages (Figure 1). A full team review took place at the end of each sprint where the development team and external clinicians provided feedback on the tasks that had been carried out and any possible improvements that could be made. This effectively provided a form of continuous acceptance testing throughout the app's development lifecycle.

Figure 1. Design workshop process.

Requirements Elicitation

A survey ([Multimedia Appendix 1](#)) was circulated to frontline health care professionals to assess what features they would prioritize in a new mobile app relating to mental health and suicide prevention. The survey comprised a list of questions relating to the overall usefulness of mobile app technology to their service needs and consisted of 18 potential components that could be incorporated in the new app. There were 15 respondents to the survey, all health care professionals involved in the treatment of adults or children with mental health difficulties.

The majority of respondents were confident that mobile apps could be used in their service, for example, in session, between sessions, as an intervention itself, as an adjunct to other interventions, for younger clients, or as a tool for staff. All but 4 of the respondents used apps in their work or signposted/recommended particular apps to their clients. The most popular apps used and recommended were mindfulness-based apps, including Headspace and Smiling Mind [24,25].

There were concerns raised around using mobile technology to treat patients relating to confidentiality, accessibility, usability, and reliability. These concerns were noted and significantly informed about the app design process, as will be discussed in detail later. The respondents were also asked to independently rank the 18 potential app components in order of usefulness. The top 5 ranked features are set out below:

1. Interactive safety plan that can be recorded and potentially shared
2. Coping skills/training tools (eg, mindfulness exercises, DBT worksheets)

3. Tracking of symptoms/behaviors (eg, behavioral activation, urge to self-harm, suicidal thoughts, and coping skills used)—guided by DBT cards
4. Opportunity to link warning signs with specific coping skills to aid problem solving in times of distress (with a therapist)
5. Details of crisis support services/contacts

These features formed the basis for the initial app design. A number of features were deemed less important but still desirable, and as a result, they were placed on the *nice to have* list, that is, they would be implemented, time and resource permitting. These included components for tracking sleep, mood, and exercise, a capability to visually represent user data using graphs and allowing for a privacy function, that is, the app requires a log-in or passcode to gain access.

Design Process

A design group was established to design and develop the app. The group consisted of 6 members and was multidisciplinary in nature with expertise in a variety of fields such as mHealth, computer science, clinical psychology, and suicide prevention.

In addition to this core group, the design process was supplemented with the inclusion of 5 additional health care workers who took part in the clinician survey. It was agreed that their input would be captured in the form of design workshops over the course of the app's development lifecycle. This iterative method of having regular checkpoints with external clinicians proved to be a valuable way to ensure that the app's construction was aligned with the initial requirements. The design workshops took place at the National University of Ireland, Galway (NUIG), and were held every 2 months during the SafePlan's design and development phases.

Input and evaluation were provided through the design workshops, and this informed which app features were worked on for that particular development cycle. In an agile approach to software development, these features are formed through the process of refining *User Stories*. A user story is a short, simple description of a requirement told from the perspective of the person who desires the new capability, usually a user or customer of the system [26]. In the context of SafePlan, the user stories originated from the initial requirements survey and were refined over the course of the design workshops.

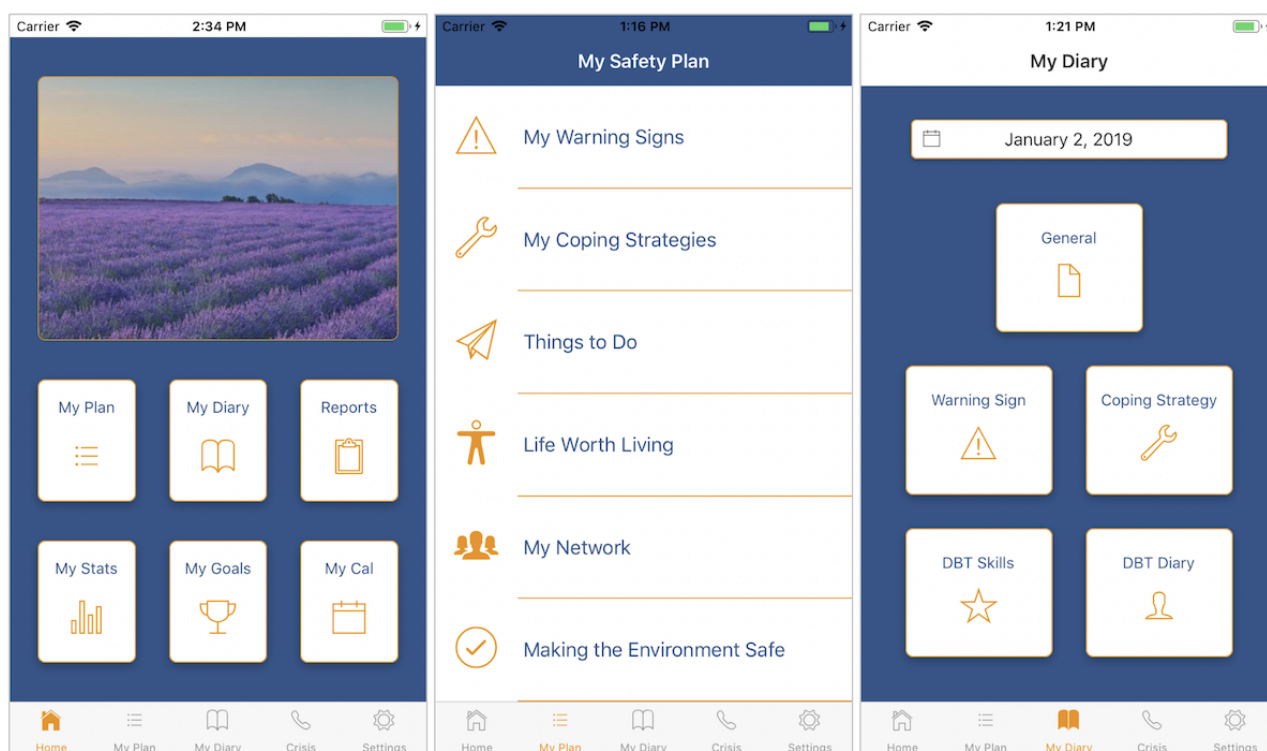

User Interface Design

Before any development work was carried out, a significant amount of time was spent on creating a user interface (UI) design for SafePlan. Early prototype designs were developed based on the functionality gathered during the requirements elicitation process. These prototypes were designed in accordance with industry-standard design guidelines for mobile app development as well as being informed by a human-computer interaction expert on the design team (with extensive experience of UI design in both industry and academia). Using JustInMind [27], a tool for creating interactive wireframes, a variety of screen mockups were presented during the first design workshop where a number of adjustments were

suggested by the attending clinicians based on their experience of working with patients in the area of suicide prevention. These suggestions were mainly focused on usability and resulted in minor updates to the app's overall UI design. For instance, the initial mockups used individual buttons to capture a user's feelings or urges within the DBT diary section of the app. The clinicians were all in agreement that this would be better presented in the form of a slider scale, as this approach should be more familiar to potential users based on their experience with similar apps.

Owing to the vulnerable nature of SafePlan's intended users, it was of extreme importance that the app's content was presented in a simple and well-structured manner. The design team felt it was crucial that navigation to the app's 2 core components—Safety Plan (*My Plan*) and Diary (*My Diary*)—was always evident to the user no matter where they were located in the app's screen hierarchy. This is why both components can be accessed through shortcut buttons on the home screen and via the bottom tab bar, which remains visible on every screen within the app. This can be seen in the screenshots that display the app's Home, Plan, and Diary UI (Figure 2). Care was also taken to ensure that the pictorial imagery available was of a sensitive nature.

Figure 2. Screenshots from Home, Plan and Diary tabs within the SafePlan app.

The final step in completing SafePlan's visual design was devising a color scheme for the app's UI. Following a presentation of alternate themes, the design team decided on a complementary color scheme for SafePlan. A complementary color scheme uses one base color and its complement, the color on the exact opposite side of the color wheel [28] as an accent color to draw attention to important elements on the screen. A base color of deep blue was chosen by the design team, as blue is a calming color, with the associated accent color being orange.

Other color schemes, such as monochromatic and analogous, were explored in earlier design workshops; however, a consensus was reached to proceed with a complementary approach.

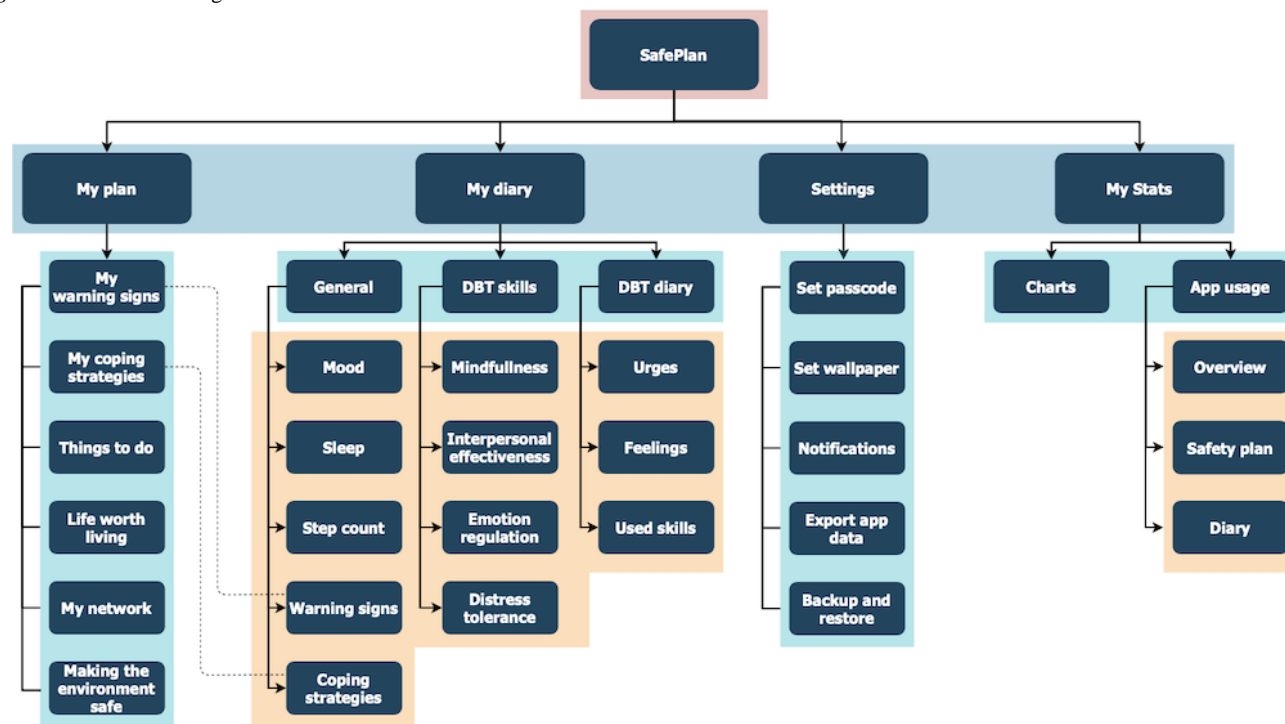

Use Cases

A functional design structure chart (Figure 3) was created based on the requirements feedback obtained from the clinician survey. This outlines the overall depth of the app's wide variety of use

cases that are spread across its core components. These use cases were approved at the first design workshop, and a development schedule was prepared to identify the priority of

each app component and the timeline expected to complete each one.

Figure 3. Functional design of SafePlan use cases.

Safety Plan

As discussed, the highest ranked and most requested feature for the app was a shareable interactive safety plan. The safety plan was based on the text-based Safety Plan Template by Brown and Stanley [29], and was digitally enhanced to enable attaching of relevant media to the various sections within the plan, that is, images and videos could be associated with a user's particular coping strategy.

It was also suggested that a user should be able to link their warning signs with specific coping strategies to help with problem solving in times of distress. This feature was added via the *New Warning Sign* screen, where the user can select appropriate strategies from a list of their saved coping strategies within the app. This is a crucial attribute in any safety plan; the user can address a particular warning sign before it fully manifests by following the applicable linked coping strategies. This highlights another key benefit in maintaining a user's safety plan in digital format, as this type of automatic linking could not be achieved using a paper-based approach.

Diary

The diary element of the app is divided into 2 distinct parts. The first is a general diary where a user tracks their overall mood, sleep, or any thoughts they want to note for that day. The second centers around DBT, a well-researched treatment program that aims to help people who have difficulties managing intense emotions [30]. All health care workers participating in the focus group were in favor of including an interactive version of a DBT diary card within the app. This involves the user entering a rating, generally between 0 and 5, for specific feelings

and urges they experience throughout the day. It would also enable the user to track what DBT skills they have used over a certain time frame.

One of the key objectives behind the development of the SafePlan was to ensure that it provided access to mental health support for as many people as possible. Appropriately, the DBT option was added to the app's settings menu, whereby a user could activate/deactivate the DBT material within the app. This was to safeguard against users with no experience of DBT treatment feeling overwhelmed or that the app would not be suitable for them. When the DBT option is switched off, the diary component is still a valuable tool as the user can track mood, sleep, and save any warning signs or coping strategies they have encountered during that day. The DBT option is switched off as a default setting when initially downloaded from the respective app stores.

It was also felt that this customization could provide a unique feature for future versions of the SafePlan. The ability to enable or disable the DBT material allows for the potential to incorporate further treatments within the app. For instance, following the same format, other therapeutic interventions could be integrated into a newer version with the same activation functionality, for example, cognitive behavioral therapy (CBT) for suicide prevention. Facilitating this type of tailored approach to mental health treatments could possibly expand the app's user base even further.

Clinician Reports

Eliminating the need for patients to maintain paper plans and worksheets was an important motivation for developing the app.

This was a common challenge reported by clinicians involved throughout the focus group sessions. They explained how easy it is for paper reports to get lost or damaged between weekly sessions and that this can lead to a lack of consistency in patient data. Informed with this knowledge, the design group invested significant effort in establishing the correct format in which to summarize the safety plan and DBT data so that they could be used by clinicians and be available as a replacement for paper reports.

It was agreed that the report structures would remain similar to their paper counterparts. The safety plan report is a point-in-time PDF document that compiles all the entries in the various plan sections. The DBT diary card report is slightly different in that the user can select the specific seven-day period in which they would like to view their entries. This was to ensure that consistency was maintained between traditional DBT diary cards, which are generally updated on a weekly basis.

The aggregation of a user's digital data and its presentation proved challenging for the design team. The collected data relates both to the user's *diary*, stored in the app's local database, and their overall app usage. It was agreed that this information would be most effective in chart form. The user can access the diary charts through the *My Stats* section of the app. The charts are dynamic in that the following options can be selected:

1. Diary item to analyze
2. Period (eg, past 7 days, past 30 days)
3. Diary item to compare with (not applicable with DBT skills)

Tracking a user's overall usage of the app was identified as a potential key tool for clinicians during the second focus group session. Being able to know when a user has viewed a certain safety plan item or even how many times an item has been viewed could provide key insights to not only the therapist or clinician but also the user themselves. Similar to the diary data, these insights can be viewed through the *My Stats* section of the app. They are predominantly centered around the safety plan inputs and are divided into 3 types (last entered, last viewed, and most viewed) for each plan section, that is, warning signs, coping strategies, and contact.

One final method for data analysis that was incorporated into the app is the facility to export diary and usage data as a comma-separated values (CSV) file. This was requested by the clinicians, as it enables further analysis of the CSV data, using statistical software, into long-term trends that are captured through the various diary inputs and usage patterns of their patients. It could also support cohort analysis of patients to identify associations between variables. From these data, a clinician might, for example, observe that a patient's overall mood is significantly affected by either their quality of sleep or one of the many DBT diary card urges/feelings, such as suicide, self-harm, and anger. Patients could then work with their

clinicians to identify the necessary steps to take to help manage their mood more effectively.

In collaboration with their clinician, the user is invited to set up regular notifications to remind them to (1) record agreed-upon behaviors and (2) share their data. This feature is included to enhance adherence. Importantly, and following considerable stakeholder input with clinicians, the user will share their data in person with their clinician. User data will not automatically be shared and will not be monitored outside of these agreed-upon times, and this will be made clear to users upon app download. In addition, a copy of the Safety Plan created in-session (to include who will support the person in times of crisis and how) will be shared with the named individuals identified in the plan to ensure that the safety plan is adhered to and supported. To ensure that data are not lost if a user changes the device, for example, users are reminded to back up their data regularly.

The method for sharing CSV files is discussed in the following section.

Technologies Used

The app was built using React Native, a framework for building native mobile apps for iOS and Android devices [31]. It enables the development of native apps using JavaScript and hence greatly reduces implementation time, as two codebases do not have to be maintained when building an app for both platforms.

Owing to the confidentiality and security concerns that were highlighted as part of the clinician survey, it was decided that the app's data should be stored on a device's local database rather than being uploaded to external servers. SQLite was used for the local database because it is lightweight, fast, and reliable [32].

Sharing and exporting data from the app also impacts privacy and security-related concerns raised by the clinicians. In order for the app to be effective, it is essential that a user shares their safety plan or weekly diary card with their clinician in a secure manner. This requires a thorough analysis, and many sharing strategies are considered. A detailed review (Table 2) was carried out to establish what approaches similar apps (mobile apps used as an adjunct to therapy) had used to extract user data for an external party, that is, a clinician. The review examined a wide variety of methods that have been used previously to share user data between mHealth apps and invested third parties, that is, clinicians. The majority of apps reviewed were using some form of an external server or cloud portal where the user could upload their data for a clinician to access. This sharing technique requires additional security resources because of the handling of sensitive user data and, consequently, may result in further legal and ethical considerations. A different approach, adopted by CBT-I Coach, provided functionality, whereby the user could email their sleep data to themselves so that they could print it and share with their clinician.

Table 2. Review of existing apps' sharing strategies.

References	App names	Sharing methods
Kuhn et al [33]	CBT-I Coach	Users can email data to themselves
Matthews and Doherty [34]	Mobile Mood Diary	Users asked if they would like to upload their data from the app to an external server. A web-based tool allows users to visualize their recorded data. Only users have log-in credentials for this tool, and the idea was that they would log on at the beginning of their session with their therapist so they could review
Rivzi et al [35]	DBT Coach	Button within app's settings menu that a user could press to send data. Data would be uploaded to a cloud file that could be accessed by research staff
Reger et al [36]	PE Coach	App did not facilitate electronic sharing of any data. This was noted as a limitation of the app by the researchers
Pramana et al [37]	SmartCAT	Therapist can access user's data through a web-based portal

Having conducted the review and discussed the potential implications of each strategy with the app stakeholders, a safety-first approach was adopted to extract user data. The design group concluded that all the control should remain with the user and decided against the facility to upload data to any cloud file or external server. In the current version of the app, a user can generate a report of either their safety plan or DBT diary card for a specified period. These reports can then be printed directly from the user's device or can be saved as a PDF file and distributed as they themselves might require. This solution satisfied the criteria for ensuring that the user is fully responsible for their data and that it will stay within the user's environment unless they decide otherwise.

Implementation and Testing

Following the design workshops and development sprints, the first version was implemented for beta testing. The app was tested internally by the core design team, after which final changes were made to remove bugs and prepare the app for external interaction.

Ethical approval was granted by the School of Psychology Ethics Committee at the NUIG on May 05, 2016, to evaluate the Corofin Abbeyknockmoy, Athenry, Turloughmore Community Health (CAATCH) app. This app was also developed by the design group to raise awareness and provide information about local support services. Ethical approval was granted by the School of Psychology Ethics Committee NUI Galway on May 28, 2019, with respect to the SafePlan study.

On completion of beta testing, students (N=18) were recruited from a local secondary school for an evaluation session. The group was representative of age (14-16 years) and technology experience (they used their own mobile phones, both Android and iOS, with the devices and user technology experience being representative of this demographic) of one of the target user populations. Their role was to test the usability and functionality of the app, rather than the actual content. The students were carefully screened in advance of participating in the testing process, via a consent process involving parents ([Multimedia Appendix 2](#)), and clinicians were available onsite during the evaluation session to answer any questions. The need for representative users was required due to the sensitive and vulnerable nature of SafePlan's intended audience. In addition, any interaction with this audience would require intervention by clinicians over a longer period. There are plans for this type

of testing in the next stage of the SafePlan project through the form of a randomized controlled trial (RCT).

The students were asked for their opinion on the overall functionality and usability of the app. A proposed task list was created ([Multimedia Appendix 3](#)) to ensure that coverage of the app's features mirrored its expected long-term normal usage. This is a typical approach adopted for the usability testing of mHealth apps [1]. After the students had carried out these tasks, they were asked to complete a system usability survey (SUS) [38], a well-known tool in usability practice and research, and an open-ended evaluation questionnaire. The SUS is an industry-standard 10-item scale that explores the perceived usability of a technological application. The scale has excellent psychometric properties with measures of reliability scoring over 0.90, good indicators of validity, and sensitivity [39]; and a Cronbach alpha of .92 [38]. Norming studies [39] have presented normative data providing an empirical basis for the interpretation of SUS scores. According to such normative data, an SUS score of 65 can be interpreted as a marginally acceptable result. More recently, Finstad [40] compared the original five-point Likert scale instrument with a modified seven-point Likert scale version. The findings supported the conclusion that seven-point Likert items provide a more accurate measure of a participant's true evaluation, and therefore, this was the approach adopted in this study.

Results

Quantitative Analysis

The quantitative data determined from the SUS are presented in [Multimedia Appendix 4](#). Participants recorded higher scores for ease of use and confidence in using the app. There was a relatively high mean score (3.17) in the last question on the SUS with regard to users needing to learn many things before commencing using the app. However, this question also resulted in the highest SD (1.95), suggesting that a greater spread of ratings occurred for this question.

The question relating to inconsistency within the app received the lowest mean score (2.28) and the lowest SD (0.89). These markers indicate that the participants came to a consensus that the app provides users with an overall cohesive experience. The mean overall SUS rating was 71.85 (SD 1.38). An SUS score above 68 is considered above average based on research in this area [41]. Although the SafePlan scored well in this regard, the

usability testing was carried out by representative users, and therefore, the app's functionality was not entirely relevant to them. This score is likely to increase when tested with real users.

Qualitative Analysis

The feedback collected through the evaluation questionnaire is categorized and summarized below. This was carried out following a thematic analysis approach. Thematic analysis is a method for identifying, analyzing, and reporting patterns within data [42].

Theme 1: UI Design

The SafePlan design and UI were well received by the majority of participants. The intuitive structure and overall simplicity of the visual appearance were frequently noted in the questionnaire responses:

I like the set up. It's visually pleasing and easy to read. Planning was somewhat fun! [P4]

Simple easy UI. Many different uses for all users and cases. [P5]

The shade of orange used in the color scheme was disliked by two of the participants. They noted that this color was quite sharp and may potentially unsettle users. However, this particular participant also remarked that the app's primary color of blue worked well because of its calming nature:

I didn't like the colour orange on the apps cover. The blue was a good idea because it's a relaxing colour but the orange is intense. [P10]

Two more participants commented on the switch interface used to change the app's home screen wallpaper. During the session, they suggested that this would be more intuitive if it was implemented with a button instead:

...the fact that the set wallpaper has a slider. [P5]

Theme 2: SafePlan Tutorial

Although the overall UI was rated highly by the participants, it was suggested that adding some form of tutorial for first-time users would be helpful. This could possibly be in the form of a video directly linked within the app or, alternatively, a number of nonintrusive dialog boxes could appear on initial downloads containing instructions for key components within the app:

...quick tutorial the first time you enter each screen (speech bubbles of important points). [P5]

Some features were initially a bit difficult to locate and understand but other than that it was excellent (tutorial would be helpful). [P9]

Similarly, the high number of functions available within the app proved to be overwhelming and difficult to locate for some participants during the evaluation session:

Not everything is completely obvious with how to use. [P17]

However, there was a sense that once they got the required directions and after some time had elapsed, the app's value became more apparent:

It is a bit confusing to get into the flow of the app, but you can understand it quickly. [P16]

Theme 3: Confidentiality

At the beginning of the evaluation session, the participants attended a presentation that detailed the background and development of the app. The storage of user data created within the app was explained, and this was positively noted by one participant in the questionnaire:

I liked how the information was strictly confidential. I feel it will allow the user to be more at ease using the app. [P8]

The ability to secure the app with a passcode was also remarked upon favorably by the participants. They felt this was a fundamental feature for the app because of the nature of the information being recorded and stored:

I liked how organised and accessible the app was. I also thought that the way you could put a passcode on the app was important. [P11]

Theme 4: Additional Functionality

The final point in the evaluation questionnaire asked the participants if they would like to see any additional features incorporated into the app. This is a valuable open-ended question, as some of these suggestions may influence future versions of the app.

The idea of a food tracker diary was mentioned by more than one participant. A place where a user could record the food they have eaten for a particular day and obtain insights based on the data collected over a specified period of time. This would be a natural supplement to the app's diary component, where the user already has the ability to record their mood, sleep, and step count on a given day:

...maybe a food tracker because some people may not believe they are eating too much / too little when they are. [P9]

Another recommendation from one of the participants focused on providing the app user with motivational messages each morning through the form of push notifications:

Maybe some relaxing videos or a notification each morning with something motivational. [P1]

Finally, adding calming music or sounds to the app was also quite a popular suggestion. The following participant brought this idea up in connection with aiding the user to fall asleep. This feature could potentially be linked with the app's sleep diary in future versions of the app:

You should add a feature where you can add in calming music or noises to fall asleep. [P10]

Discussion

Principal Findings

The principal findings of this project were obtained from acceptance and usability tests, which were based on feedback from health care workers and representative users. Health care workers were recruited to provide iterative feedback on the

app's design and functionality throughout its development lifecycle. This feedback was key to finalizing the app from a clinical perspective, as it ensured that no unnecessary or inappropriate features were added to the app's portfolio. Usability testing was undertaken with representative users in terms of age (14-16 years) and technology experience. Representative users were necessary at this early stage of testing because of the sensitive nature of SafePlan's intended audience. Carefully screened students from a local secondary school were invited to attend an evaluation session, where they were presented with a number of specific tasks to carry out on the app to determine its overall usability.

The feedback received from the usability testing day was largely positive. The participants perceived the main benefits of the SafePlan app were its overall UI design and emphasis on user confidentiality. In particular, the acknowledgment of the app's privacy features was a strong vindication for the design team, as this was an area of significant focus during the initial planning meetings. The most common issues in mHealth are privacy and data security [43]. These concerns were addressed from the outset of SafePlan's development by ensuring that all user data are stored locally on their own device and providing the user with an option for securing the app with a passcode.

Although the majority of evaluations were positive, a small number of potential improvements were identified for future versions of the app. The amount of information content and functionality within the app was somewhat overwhelming for some participants on initial use. There were suggestions that an introductory tutorial video for first-time users could be extremely beneficial to give them a general overview of the app's features and use cases. On this point, it is also worth noting that the participants' experience with SafePlan was not representative of real, ongoing use. It is expected that the majority of the app's users will be guided through its content by a clinician, and this may mitigate any confusion they may experience on initial use. Another participant proposed that the app provides users with motivational messages or relaxing videos each morning through the form of push notifications.

Limitations

Although the usability and acceptance testing proved to be beneficial in designing and developing a clinically informed, user-friendly mobile app, further ethically conducted evaluations involving patients with suicidal thoughts or behavior will provide much greater insight into whether participants interact with the app in the way it was intended. Previous researchers have highlighted the need for more robust testing of mHealth apps within clinical settings [44]. The research team has established experience in co-design, iterative design processes, and the selection and use of measures to evaluate user engagement and digital intervention usability [45-47]. A pilot RCT investigating the feasibility of using SafePlan as an adjunct to therapy in mental health services is currently being planned (HRB CSF 2020-010). The aims of this trial are to (1) assess the feasibility and acceptability of the SafePlan intervention as an adjunct to therapy for individuals at risk of suicide accessing Irish mental health services, (2) examine the feasibility of a definitive RCT of the SafePlan intervention, and (3) assess the

feasibility and acceptability of the SafePlan data collection methods (including in-built ecological momentary assessment) for clinicians and patients.

This is particularly relevant when it comes to observing a user's long-term interaction with the app's various diary and safety plan functions. It is anticipated that a user will maintain and update their data within the app on a regular basis, and this is where the most value will be gained, both for the user and their clinician. The long-term usage of health apps is highly significant, as some studies have reported log-ins dropping sharply to nearly zero after 1 month from download, even for the highest rated apps [18]. With this in mind, further recording of user feedback during the pilot stage is required to determine if the app has the desired lasting effect on its users, and this would be a key element of a follow-on study with end users. Currently, there is no warning on the app in terms of usage, and a cautionary preamble section will be added to the app stating that it is only to be used after undergoing an orientation session. Furthermore, currently, there are no automated warning notifications built into the system, and this has been identified as a future requirement, whereby patients will be informed when they should consider seeking professional help.

Comparison With Prior Work

Many members of SafePlan's core design team were previously involved in the development of another app relating to improving outcomes in suicide prevention. The CAATCH app [44] was released in 2014, and its main goal was to raise awareness, provide information, and signpost to education and training programs available at the community level within the local area. In terms of the involvement of end users, CAATCH involved members of the public and patients in the design and testing phases, which guided the overall intervention and subsequently shaped the design of the current SafePlan app. It was the experience of young people accessing mental health services and actively seeking a digital means of storing and using their SafetyPlan/DBT code cards, which ultimately led to the development of the SafePlan.

Although SafePlan also aims to raise awareness and provide information, it operates at a patient-clinician level where it can be used as an adjunct to treatment. It is a significantly more interactive app in that it accepts various forms of user input and provides tools for visualizing this input in the form of charts and reports, so that users can analyze their data over a specified period.

Conclusions

In conclusion, through the process of iterative design with the input of targeted clinicians and key design personnel, a fully functional version of the SafePlan mobile app was developed. This app has the potential to offer an accessible adjunct to face-to-face therapy and to support the generalization of skills acquired in-session to beyond the clinical setting. It also provides useful functionality that may lead to improvements in the interaction between a patient and their clinician. This can primarily be demonstrated through the process of transferring previously recorded paper-based reports and worksheets to specific sections within the app. This facilitates more accurate

and timely data recording practices and subsequent analysis, with a correspondingly positive impact on treatment outcomes.

Following on from our review of existing mobile apps providing support in the area of mental health and suicide prevention (as presented in Table 1), further apps have been added to the app stores [48]. With approximately 20,000 mental health apps now reported in the app stores by the American Psychological Association [49], this number will continue to grow, whereas the core challenge of maintaining privacy, providing reporting tools for controlled sharing of user data, and combining safety planning with other therapeutic interventions remains. Safety planning intervention is an evidence-based brief intervention for suicidality, which is increasingly considered to be the best practice in terms of health care practice [6]. SafePlan potentially operationalizes a more interactive and individualized means of implementing this intervention while also offering the potential

to combine this safety planning intervention with other prevention techniques (eg, DBT or CBT) in one flexible app. This intervention flexibility was welcomed by all participating clinicians, as it provides the potential to open the app to a wider user cohort.

SafePlan will require further evaluation from users within the target population. This was a topic of consideration for the design team, and it was agreed that because of the nature of the app's intended users, it would not be appropriate to involve patients at this early stage of development. The combination of input from clinicians and groups that were partially representative of the end users was seen as a valid substitute for patients' evaluation until sufficient evidence was gathered to carry out a pilot implementation with the app's intended audience, for example, a pilot study with patients and clinicians to gain further insight.

Acknowledgments

This work was funded by the Health Service Executive (HSE) National Office for Suicide Prevention and carried out with the support of the NUIG and HSE Community Healthcare West and Midwest.

Abstract

Background: The World Health Organization recommends the development of participatory sexuality education. In health promotion, web-based participatory interventions have great potential in view of the internet's popularity among young people.

Objective: The aim of this review is to describe existing published studies on online participatory intervention methods used to promote the sexual health of adolescents and young adults.

Methods: We conducted a systematic review based on international scientific and grey literature. We used the PubMed search engine and Aurore database for the search. Articles were included if they reported studies on participatory intervention, included the theme of sexual health, were conducted on the internet (website, social media, online gaming system), targeted populations aged between 10 and 24 years, and had design, implementation, and evaluation methods available. We analyzed the intervention content, study implementation, and evaluation methods for all selected articles.

Results: A total of 60 articles were included, which described 37 interventions; several articles were published about the same intervention. Process results were published in many articles (n=40), in contrast to effectiveness results (n=23). Many of the 37 interventions were developed on websites (n=20). The second most used medium is online social networks (n=13), with Facebook dominating this group (n=8). Online peer interaction is the most common participatory component promoted by interventions (n=23), followed by interaction with a professional (n=16). Another participatory component is game-type activity (n=10). Videos were broadcast for more than half of the interventions (n=20). In total, 43% (n=16) of the interventions were based on a theoretical model, with many using the Information-Motivation-Behavioral Skills model (n=7). Less than half of the interventions have been evaluated for effectiveness (n=17), while one-third (n=12) reported plans to do so and one-fifth (n=8) did not indicate any plan for effectiveness evaluation. The randomized controlled trial is the most widely used study design (n=16). Among the outcomes (evaluated or planned for evaluation), sexual behaviors are the most evaluated (n=14), followed by condom use (n=11), and sexual health knowledge (n=8).

Conclusions: Participatory online interventions for young people's sexual health have shown their feasibility, practical interest, and attractiveness, but their effectiveness has not yet been sufficiently evaluated. Online peer interaction, the major participatory component, is not sufficiently conceptualized and defined as a determinant of change or theoretical model component. One potential development would be to build a conceptual model integrating online peer interaction and support as a component.

sexual health; health promotion; internet; participatory interventions; adolescents and young adults; methods

Introduction

Adolescent sexual exposure is of concern due to the risk of contracting sexually transmitted infections (STIs), experiencing an unwanted pregnancy, and unexpected paternity/maternity [1]. Among the 333 million new cases of STIs each year, the highest rates occur among those aged 20 to 24 years, followed by those aged 15 to 19 years [2]. Among a group of 21 countries, the pregnancy rate among those aged 15 to 19 years is highest in the United States (57 pregnancies per 1000 females) [3]. The proportion of teenage pregnancies that result in abortion varies by country, but in half of those for which recent information is available (mainly in Europe, North America, and Oceania), 35%-55% of pregnancies ended in abortion [3]. In 2014, in the United States, females aged <15 years and 15 to 19 years accounted for 0.3% and 10.4% of all reported abortions in the country, respectively [4].

Adolescence and the transition to adulthood marks the entry into sexuality. Sexual health requires a positive and respectful approach to sexuality and sexual relations, and the ability to have enjoyable and safe sexual experiences that are free from coercion, discrimination, and violence [5]. Adolescents and young adults (AYA) represent a priority population for sexual health promotion and education [6]. The associated fields of intervention encompass the development of knowledge and level of information, the development of attitudes to sexual health (attitudes toward safe sex practice, including attitudes to condom use or voluntary testing for STIs), and the development of personal competencies and supportive relational skills (critical thinking, consent, negotiation, open-mindedness, respect, self-esteem).

For example, as stated by the Information Motivation Behavioral Skills (IMB) model (applied and validated for HIV risk reduction), behavioral competencies and therefore health behaviors may be influenced by the level of information, but also by motivation, namely beliefs and attitudes toward a particular health behavior and the perceived social support (or social norm) to engage in this behavior [7]. In addition, health literacy is the ability of individuals to obtain, process, and understand the information and services necessary to make appropriate health decisions [8]. Increase health literacy would enable the improvement of appropriate health decision making with regard to sexual health, promoting equity and achieving the United Nations' Sustainable Development Goals 2030 [9].

The recommendations of the World Health Organization are clearly stated [10]: sexuality education must be participatory (young people should not be mere passive receivers), interactive (with educators and program designers), and continuous. This education must be adapted to the language of the young people, while also teaching appropriate terminology to strengthen their communication skills.

In health promotion, digital media interventions for sexual health have great potential because of the scope and popularity of technologies such as the internet and mobile phones, especially

among young people [11,12]. Interactive online interventions for sexual health promotion can also lead to better knowledge, self-efficacy, and positive sexual behavior, and have demonstrated a reduction in STIs [12].

The internet is a major health information resource, and online health information research is an important prerequisite for health empowerment and literacy [13,14]. Moreover, research on information flows and attitudes within social networks suggests that links between people can promote the exchange of relevant information between peers, and affect their attitude toward this information, as individuals are more receptive to information shared by others who are like them [15]. For example, the popularity of social networking sites and their interactive features have great potential to reach young people, and offer a new way to engage and communicate with AYAs, including the provision of appropriate education [16]. Nevertheless, their uses are for the most part "passive," and social networking sites are not yet used as tools for multidimensional communication and networking [17].

Our research question is whether interventions for the promotion of young people's sexual health include participatory components, and if so, how they are integrated and how the interventions are evaluated. Some publications and literature reviews have investigated sexual health interventions on the internet, social media [12,18], online serious games [19], or in digital media [12,20,21]. However, no publication has focused on the participatory aspects of this type of intervention in sexual health specifically aimed at young people (participation in an activity such as online games, quizzes), particularly interactive features such as the exchange of information and experiences between peers (persons of the same age, social context, function, education, or experience) or with professionals. The aim of this review is to identify and describe existing studies and the methods used to assess online participatory interventions aimed at promoting AYA's sexual health.

Methods

Overview

This systematic review was based on international scientific literature and grey literature. The review is structured in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) statement [22] and follows the associated guidelines (Multimedia Appendix 1). The systematic review protocol has previously been published on the PROSPERO International Prospective Registry of Technical Reviews (ID CRD42018088240).

Inclusion Criteria

Articles were included without time restriction according to the 5 following criteria: (1) Study of an intervention including a sexual health theme; (2) Population aged between 10 and 24 years (with an average age or an interval comprising all or at least part of this age group), because the WHO defines adolescents as aged 10 to 19 years and young people as aged

15 to 24 years [23,24]; (3) Study of a participatory intervention; (4) Study of an intervention conducted on the internet (website, social media, online gaming); (5) Design, implementation, and evaluation methods must be available via the article.

Strategy Search

The electronic search strategies are described in [Multimedia Appendix 2](#). We used the PubMed search engine for our main search. For complementary research, we used the Aurore database of Institut National d'Études Démographiques (INED; a French public research institute), which includes scientific databases and grey literature, allowing access to a range of databases and electronic journals (see [Multimedia Appendix 2](#) for selected international search engines). The last update was on January 28, 2019.

Study Selection

Reports were assessed by two reviewers (PM and LC), who screened the titles and abstracts to identify relevant studies. Full texts were read when abstracts met inclusion criteria, and when abstracts were not clear enough to determine eligibility. Disagreements between reviewers were resolved by discussion. When the full text was not available, authors were contacted by email; all the contacted authors responded favorably and shared their articles with us.

Data Collection

A standardized data collection form was developed, and two reviewers independently extracted data from studies. Our extraction grid was developed using the PICOTS (populations, interventions, comparators, outcomes, timing, and setting) elements [22], and was completed using Michie's taxonomy [25] to collect information on the behavior change techniques (BCT) used by interventions. The studies were classified according to different types: research protocol only, effectiveness evaluation, and process evaluation. Protocol articles are planned studies containing only the conceptual and evaluative methods intended for intervention research. An effectiveness study is defined as a demonstration of an intervention's efficacy in natural situations. It provides evidence of the intervention's effect on determinants or health outcomes. A process study provides evidence on the implementation and feasibility of an intervention, and also rates the intervention for attractiveness and acceptability. It helps to assess the reliability and quality of implementation, to clarify causal mechanisms, and to identify contextual factors associated with variations in outcomes [26].

Analysis

For the final studies selection phase, the degree of interreader agreement was assessed for both readers through the calculation of the κ coefficient.

We conducted descriptive analyses on data collected from studies on the following points: description of the population; characteristics of study methodology; description of the intervention; description of the media used; description of methods used for effectiveness, and process evaluation. We used Michie's [25] taxonomy to analyze the BCT used by interventions, depending on the information available in the intervention.

Results

The electronic search strategies used identified a total of 2555 references after removing duplicates. After selection based on title and abstract screening, the full text of 125 references was evaluated. After this inclusion phase, 49 articles describing 37 interventions were included. For each intervention included, we searched for other publications concerning it, and 11 additional studies were included, based on the references cited in the included articles. A total of 60 articles describing 37 interventions were included; several articles were published for the same intervention ([Figure 1](#)). The degree of interreader agreement for the final selection of the 60 articles was calculated with the κ coefficient and it was equal to 0.98. All the studies included in this systematic review are available in [Multimedia Appendix 3](#). Descriptive data for the included studies and interventions are available in [Table 1](#). Of the 60 articles included, 52% ($n=31/60$) were published in the last 5 years ([Table 2](#)).

Overall, 62% of the studies ($n=36/58$) were conducted in the United States. Of the types of studies, 45% ($n=27/60$) exclusively concerned process results, 22% ($n=13/60$) included process results and effectiveness results, 17% ($n=10/60$) exclusively had effectiveness results, and 17% ($n=10/60$) were exclusively protocol publications. Of the 37 interventions, 51% ($n=19/37$) addressed sexual health holistically. Overall, 51% ($n=19/37$) targeted a general population. In cases where specific populations were targeted (49%, $n=18/37$), 44% ($n=8/18$) were identified by their sexual orientation. In total, 65% ($n=24/37$) of all interventions were for both sexes, 22% ($n=8/37$) were for males only, and 11% ($n=4/37$) were for women only. The targeted population in terms of age was mainly individuals aged 10 to 24, strictly defined in 35% of the interventions ($n=13/37$). However, other studies had a less specific or different range of age targeted: aged 10 to 17 years, aged 10 to >24 years, aged 18 to 24 years, or aged 18 to >24 years; some studies simply referred to "students" or "youth." In total, 43% ($n=16/37$) used multiple recruitment methods.

Figure 1. Flow chart of the literature reviewing process. Aurore is a database of Institut National d'Études Démographiques (a French public research institute) that combines scientific databases and grey literature, allowing access to a range of databases and electronic journals.

Descriptive data on the intervention types, online supports, and features are shown in [Table 3](#) (for a description of each intervention, see [Multimedia Appendix 4](#)). Concerning intervention types, 41% (n=15/37) involve a dissemination of information with participatory components (game, quizzes, discussions). The medium used is a website in 54% (n=20/37) of cases, followed by online social networks (35%, n=13/37), with Facebook used in 22% (n=8/37) of cases. Furthermore, 14% (n=5/37) use several different online supports for the implementation of the intervention. To protect the identity of participants, 49% (n=18/37) of the interventions provide anonymity. Of these, 72% (n=13/18) allow participants to use personal identifiers, and 67% (n=12/18) use private websites. The interventions based on social networking sites do not mention anonymity because this is not possible on such sites.

However, on Facebook, one (n=1) intervention used a secret group for greater confidentiality, another (n=1) used a private SMS text messaging system, and another (n=1) used a private page that only registered participants can access. Concerning participatory features, 68% allow interaction, either between peers (62%, n=23/37) or with a professional (43%, n=16/37). This interaction is mainly through online social networks (22%, n=8/37) and discussion forums (19%, n=7/37). Overall, 5% (n=2/37) use multiple supports for interaction. Involvement in a game-type activity was possible in 27% (n=10/37) of cases. Videos were broadcast in 54% (n=20/37) of cases. Finally, 43% (n=16/37) of the interventions were constructed from a theoretical model, with 19% (n=7/37) using the Information-Motivation-Behavioral Skills model.

^aAn intervention can use several theories or several supports and contain different functionalities. Totals are not always equal to 100%.

The five most commonly used behavior change techniques are as follows ([Multimedia Appendix 5](#)). First, 78% (n=29/37) of interventions introduce or define an environmental or social stimulus to encourage or guide behavior. Second, 78% (n=29/37) provide information on the health consequences of performing the behavior. Third, 73% (n=27/37) present information from a credible source in favor of or against the behavior. Fourth, 70% (n=26/37) organize and provide some form of social support within the intervention. Fifth, 65% (n=24/37) provide information on what others think about the behavior. No intervention provides punitive measures or remuneration for the conduct of the behavior sought.

Of the 37 interventions, 57% (n=21/37) indicate that they called on young people for community-based participatory research (collective construction). This takes various forms: 38% (n=14) of the interventions conducted focus groups to discuss the proposed intervention, 27% (n=10) directly included youth in the development of content, 8% (n=3) adapted their content based on feedback from young people in pretest studies, 5%

(n=2) involved youth in the evaluation, and 3% (n=1) formed a youth advisory committee.

Data on the design and evaluation methods are available in [Table 4](#). For a description of the methods of each intervention, see [Multimedia Appendix 6](#). In total, 43% (n=16/37) were evaluated according to a randomized controlled trial (RCT) design. Overall, 22% (n=8/37) provided a follow-up between 1 and 2 years, while the remainder reported a follow-up shorter than 1 year (59%, n=22/37) or did not specify a follow-up time (19%, n=7/37). For process evaluation, 35% (n=13/37) did an acceptability study, 30% (n=11/37) did an attractiveness study, and 27% (n=10/37) assessed feasibility. Regarding effectiveness, 46% (n=17/37) of the interventions were subject to an outcome evaluation and 32% (n=12/37) had a planned outcome evaluation. Among the outcomes evaluated (conducted or planned evaluation), sexual behaviors were the most evaluated (38%, n=14/37), followed by condom use (29%, n=11/37) and sexual health knowledge (22%, n=8/37).

Discussion

Principal Results

Our review identified 37 different interventions, which were the subjects of 60 articles. The number of online participatory interventions for the promotion of young people's sexual health has increased significantly over the past 5 years, especially in the United States. Three key points drew our attention: (1) Several different online supports are used by interventions and we would recommend adapting these to young people's preferences; (2) Online peer interaction is the participatory element most often used in interventions and is a promising health promotion approach; (3) In view of the limited number of effectiveness evaluations, it is necessary to define a conceptual model of interventions to enable comprehensive and rigorous evaluation and to understand the effect of peer interaction and participatory components.

How to Adapt to the Favorite Media of Young People?

Concerning the online support used, interventions are mainly first developed on websites. The second most popular medium

is social networks, with Facebook dominating, as already shown in a previous review of social networking sites [18].

Surprisingly, young people's favorite social networks [27] are rarely used. Only one intervention was on Instagram [28], three were on YouTube, and none were on Snapchat. However, these three media have been described as the new preferred ones of youth, whereas the popularity of Facebook is declining [27]. The future challenge for researchers will be to develop interventions that can evolve with young people's preferences, keeping up with rapid generational changes. In our review, few interventions use more than one online medium. One option would be to use a multichannel approach for interventions. Such an approach already exists to some extent in the American intervention "weCare," which allows young people to choose how they connect with educators, with three possible contact modalities: Facebook Messenger, SMS text messaging, and app-based instant messages [29].

Our findings also highlight the need to design interventions adapted to the uses, languages, interests, and realities of young people, particularly through interactive and playful components. One way to remain close to the interests of young people is to

integrate promising new media in interventions, such as videos and games. It is also possible to allow users to insert their own content or to customize websites. Integrating attractive components that are correctly implemented will ensure better group retention. To know what is preferred by young people, it is therefore necessary to have measures of attractiveness. This review has cited different measures: online media usage, process data (number of visits, time spent, and interaction rate), technical recommendations, content adapted to the target audience (specificity and age), satisfaction, points of view, and involvement of participants (especially sexual minorities).

Web-based interventions also raise the challenges of security, privacy, and anonymity. For example, the lower use of social networking sites for research compared to websites may also be due to the fact that the ownership of the data from youth participation belongs to these media. This data would be less easy to protect in terms of security, confidentiality, and privacy, especially against cyberstalking, requiring moderation at all times. In the studies reviewed here, authors provided little information on how they protected participants' data. On social networking sites, some researchers use closed groups to control the exchange of participants' data. Others host the data through a secure external website. Technical partners, such as social networking sites, are bound by specific laws and contractual data protection clauses, and there is a clear regulatory framework for many countries [30]. As noted by some authors [11,31,32], ethical and data security frameworks need to be strengthened. For example, the importance of blocking public access to online interventions and developing powerful security features is underlined [33]. Concerning anonymity, protection of the identity of participants is possible mainly on private websites, which is especially important in the context of sexual health, where the internet is used to avoid embarrassment and overcome privacy issues [34].

How to Implement Peer Dynamics in Interventions?

All media can be used to disseminate information among young people, either top-down (from an educator to a young person) or cross-functionally (between peers). The interest of the 37 interventions assessed here rests on their participatory activities, of which peer interaction is the most frequent component.

Peer exchanges were described in different ways: counselling, experience-sharing, community involvement, personal stories, self-help, and peer support. Peers were considered not only as participants, but also as peer educators (opinion leaders) previously trained by professionals [35-37]. In one study, the potential for sharing and comparing real experiences was supported [38], with an expressed need for sharing experiences among peers. Participants also expressed the desire for social interaction online with other young people [39].

More personalized approaches better target the concerns of each individual, as seen in the Media Aware [40] and Queer Sex Ed [41] interventions (individuals' goals). Participants could also disseminate their own content, as seen in the HealthMpowerment intervention [42-44]. Peer dynamics also occur when young people are directly involved in the community-based participatory research process, especially in sexuality education programs [10]. This process can validate the role of community

members and academics as equitable partners [45]. In our review, we determined that this process is widely used at the design stage. Peer interaction is thus enabled by most interventions and is described as strengthening an intervention's capacity to change behaviors, even if professionals are involved. The dynamics between peers, and the feeling of being "between young people," are seen as potentialities. Surprisingly, the term "peer education" is not a term used in the reviewed articles. "Peer education" is actually an exchange of experiences and information between peers in "real life," integrating the notion of "shared education" [46], and is thus well suited to these interventions. One intervention did use the term "peer-led" [35]. Peer dynamics are little conceptualized by the authors, and a model for designing and evaluating interventions is lacking.

How to Evaluate Interventions?

The objective of interventions is to change sexual health outcomes positively. For the moment, although experimental plans are defined, publications focus more on intervention processes than effectiveness in terms of health outcomes. This probably reflects the need to identify implementation problems beforehand, as a lack of effect may reflect a failure in implementation rather than the ineffectiveness of the intervention [26]. Implementing an intervention correctly will ensure better group retention. To evaluate effectiveness, the randomized controlled trial remains the most widely used or planned design. It does not preclude assessing the effect of an intervention on a range of outcome measures [47].

In interventions dealing with evaluation, behaviors were most often the main outcome, followed by knowledge, self-efficacy, and attitudes. A majority of follow-up interventions lasted less than 1 year. Nonetheless, it would be interesting to have a long-term follow-up to determine whether short-term changes persist [21]. Behavior measures are based on self-reported data, and many authors have highlighted the issue of social desirability bias as a limitation [36,40,41,48-51].

Our review found few plans to observe a robust indicator, such as STI incidence [52], HIV-related care engagement and viral suppression [29], or pregnancy [53,54]. These indicators can measure the real impact of an intervention on sexual health. Nevertheless, this requires a large sample size in order to have sufficient power to detect the effects of the intervention, especially when the expected outcomes have a low baseline rate of incidence (eg, HIV incidence), unless these studies are conducted on high-risk groups.

In this context of complex intervention, mechanisms of action should be identified and interventions should rely on a theoretical, conceptual, and operational model. This will enable all the participatory, social, and collective variables involved in the process to be measured and validated. Based on a literature review, Borek and Abraham developed a conceptual model of mechanisms of change in small groups [55]. For peer interventions, Simoni et al [56] argue for a strong theoretical framework to support behavior promotion, link to outcomes, and justify peer inclusion. In addition, strategies combining several theories and concepts may have a greater effect [57], as seen in the TeensTalkHealth intervention [58], which used the IMB model [7] combined with communication theory [59].

Several interactive processes (group development, group dynamics, social change) have been highlighted and could be used for the constitution and animation of social groups [55]. Finally, applying a comprehensive model of internet-based peer education (or peer-led behavior change) for sexual health is a promising approach, as long as a proliferation of concept and theoretical models does not occur. Rigorous methods, such as the 5 steps of the Intervention Mapping protocol, can contribute to the development of more effective behavior change interventions and methods of evaluation, assessing all stages of adoption, implementation, and sustainability of the intervention [60,61].

Limitations

Our review was conducted with a cross-validation methodology based on two search tools (PubMed and Aurore), but we cannot rule out that some interventions escaped our research. Participatory or interactive interventions may exist but may not be evaluated and published (for example, the website Sex, Etc [62]). Finally, wide variations in interventions made it inappropriate to synthesize the results using a meta-analysis.

Conclusions

This review describes existing interventions in participatory sexuality education for young people on the internet. It aims to provide guidance for interventions that meet the expectations of national and international strategies on youth sexuality education. Identified interventions are deployed on many internet media and have shown their feasibility, practical interest, and attractiveness. However, they are still in the early stages of design and evaluation, particularly as regards the effect of peer interaction, and do not always adhere to existing theoretical models. We recommend building a conceptual, theoretical, and evaluation model for community-based interventions involving peer interaction and participation in activities, providing the necessary operational and evaluative tools. Interventions must be designed with regard to media multiplicity, youth populations (orientations, gender identities), and a holistic sexual health approach. To improve these interventions, we recommend having a more participatory approach, involving young people in the whole process, including the design phase.

Acknowledgments

First, we would like to thank the National Association for Research and Technology, which funded this project. We would like to thank all members of the Institut National de la Santé Et de la Recherche Médicale (Inserm) Unit 1123 and Ined-Inserm-Univ. Paris-Sud-UVSQ (Université Versailles Saint-Quentin) Unit 14 teams for their support of our work. We also thank the following librarians for their research articles and methodological support: Catherine Sluse (Ined), Catherine Le Huu Nho (Paris Diderot University), and Fabienne Warin (Paris Diderot University). We also thank all Ined members for their feedback in workshops. We would like to thank our translator Duncan Fulton for proofreading the article. Finally, we thank all the authors included in our review who sent us their publications. and the joint authors of this article, according to their respective roles: PM for all stages of the project, EDLR and CA for participation in the design of the project, LC for his reading of the journals, and all authors for analyzing results and writing the article.

Abstract

Background: The prevalence of depression is high and has been stable despite increased treatment, research, and dissemination. People encounter barriers to seeking traditional mental health services, which could be mitigated by using web-based prevention methods.

Objective: This study aims to understand what people at high risk for depression perceive as effective aspects of web-based mental health programs and what motivates people at high risk for depression to use web-based mental health programs.

Methods: We conducted an inductive content analysis using telephone interview data from 77 participants at high risk for depression who were recruited from 2 randomized controlled trials (RCTs). Participants from the first RCT were working men who had been randomly assigned to 1 of the following 3 groups: control group, who had access to general depression information from a website called BroMatters; intervention group 1, who had access to the BroMatters website along with the associated BroHealth web-based mental health program; and intervention group 2, who had access to the BroMatters website, the BroHealth web-based mental health program, and telephone sessions with a life coach. Participants from the second RCT were men and women who had been assigned to the intervention group, who received access to the HardHat web-based mental health program, or the control group, who only received access to the HardHat web-based mental health program following completion of the RCT. Participants for this inductive content analysis study were recruited from the intervention groups in both RCTs. Two groups of participants (n=41 and n=20) were recruited from the BroHealth RCT, and a third group comprised 16 participants that were recruited from the HardHat RCT.

Results: We generated four categories regarding the perceived effectiveness of web-based programs and five categories related to what motivates the use of web-based programs. Participants identified awareness, program medium and functionality, program content, and coaches as categories related to the effectiveness of the programs. Categories of motivators to use web-based programs included providing reminders or incentives, promotion of the programs, providing appropriate medium and functionality, appropriate

content, and perceived need. The final category related to motivators reflects perceptions of participants who were either unsure about what motivates them or believed that there is no way to motivate use.

Conclusions: Conflicting evidence was obtained regarding the perceived effectiveness of aspects of the content and functionality of web-based programs. In general, web-based mental health programs were perceived to help increase mental health awareness, especially when it includes live access to a coach. However, the results also revealed that it is difficult to motivate people to begin using web-based mental health programs. Strategies that may motivate the use of such programs include perceived personal need, effective promotion, providing incentives and reminders, and improving functionality.

Introduction

Background

Depression is a prevalent mental health disorder [1], is associated with an increased risk of suicide [2], and has comorbidities with multiple physical health conditions such as cardiovascular diseases [3], diabetes [4], and fibromyalgia [5]. Depression also impacts the economy, costing employers US \$44 billion every year in the United States [6]. Globally, workplace stress can cost between US \$220 million and US \$200 billion per country [7]. Despite the growth in treatments for depression [8-10], the rate of depression has remained stable for more than 10 years [11,12]. Thus, treatment alone is unlikely to substantially reduce the prevalence and incidence of depression [13]; instead, a focus on prevention is necessary. Indeed, in a recent Alberta-based research project examining views from a range of mental health stakeholders, preventative measures were identified as a top priority for future depression research [14,15]. Preventing the occurrence or delaying the onset of depression can decrease symptoms [16] and reduce the burden for employers [17].

Barriers to seeking help related to treating and preventing depression are numerous and include stigma and availability of and access to services [18,19]. Web-based methods for treating and preventing depression have the potential to mitigate these barriers; in fact, web-based programs have been shown to be as effective as traditional methods [20-22] and web-based education tools [23]. Facilitators reported in the literature about web-based mental health programs include ease of website navigation and user characteristics such as curiosity about web-based mental health programs [24]. Web-based methods may be especially beneficial in rural communities where self-sufficiency is highly valued and access to therapeutic treatment may be particularly limited [25]. However, the usage of web-based mental health programs remains low. A study comparing face-to-face and web-based program usage reported completion rates of 84% and 65%, respectively [26]. Other studies of web-based mental health programs offered participants access to the program beyond the study time frame and reported that approximately 51% of participants wished to have continued access. Of those given continued access, only 38% went on to log on to the program [27].

People are often concerned about privacy and confidentiality for fear of being stigmatized for accessing mental health services [28]. These concerns may leave people reluctant to use web-based mental health programs. Furthermore, given the relative novelty of web-based mental health programs, many people are skeptical of program effectiveness for reducing or preventing depression compared with face-to-face therapies and, correspondingly, are less likely to use such programs [28,29]. However, few studies have investigated how users perceive web-based mental health programs for depression prevention [30].

Objectives

In view of user skepticism and the need for a fuller understanding of user perceptions of web-based mental health programs, our purpose is to identify factors that motivate use (initiation and adherence) of such programs and the perceived effectiveness of the programs. We achieve our purpose by analyzing data drawn from qualitative interviews conducted with a sample of web-based mental health program users who are at high risk of developing depression.

Methods

Research Design

This qualitative study complements 2 randomized controlled trials (RCTs). The RCTs were aimed at understanding strategies for preventing depression and evaluating user perceptions of the effectiveness of web-based mental health programs. This qualitative component elaborates on the understanding derived through the RCT studies by illuminating what users perceive as effective about web-based mental health programs and what motivates the use of such programs. In using a qualitative approach, we align ourselves with researchers who highlight the power of qualitative research to support contextual understanding of complex mental health phenomena [31] and to engage users in determining how to implement findings with respect to mental health in real-life settings [32].

We studied the perceived effectiveness of web-based mental health programming and what motivates the use of web-based mental health programs, and we treated these topics as emerging and yet to be coherently understood. Accordingly, we employed an inductive content analysis approach [33] of data collected through telephone interviews. Although we had some

predetermined goals, our study was inductive in 3 important ways: (1) although we had always planned to study user perceptions of web-based mental health program effectiveness, our decision to study what motivates the use of web-based mental health programs emerged as we noted trends of nonuse among our RCT sample; (2) correspondingly, we selected participants because they were nonusers; and (3) the findings we present were derived from the data and not in accordance with predetermined categories.

Below, we outline the broader RCT studies from which participants for this inductive content analysis study were drawn. We follow this with a description of our qualitative sample, data collection, and data analysis, including trustworthiness measures.

Broader RCT Study Context: BroHealth and HardHat

BroHealth RCT

The BroHealth RCT was about participants' perceptions of the effectiveness of the BroHealth web-based program, which was designed to prevent depression in working men who are at high risk of having a major depressive episode (MDE) in the next 4 years. BroHealth includes modules that provide information about stress and depression, web-based self-checks that help monitor symptoms, and a variety of self-help components such as cognitive behavioral therapy (CBT) and goal setting and tracking. Qualified coaches were also available to participants for 40-min sessions to a maximum of once per week. Coaches help participants set goals and help them work through problems. The study protocol from which BroHealth was developed is available elsewhere [34].

BroHealth RCT participants were recruited across Canada using the random digit dialing method. Participants were men who were (1) older than 18 years, (2) working for pay, and (3) at high risk for an MDE determined by the depression risk calculator developed and validated by Wang et al [35] but who had not had an MDE in at least two months. Participants were also required to be able to communicate in English or French and have access to a telephone and the internet. BroHealth RCT participants were interviewed at baseline, at 6 months, and at 12 months, and it was after the baseline interview that participants were randomized into the control group or into 1 of the 2 intervention groups:

1. Control group: participants received general information about depression through the BroMatters website
2. Intervention group 1: participants received general information about depression through the BroMatters website as well as access to the associated BroHealth web-based program
3. Intervention group 2: participants received general information about depression through the BroMatters website, access to the BroHealth program, and access to a qualified coach with whom they could schedule telephone sessions.

Every other week, participants received reminders via email to encourage their engagement with the BroHealth program. Participants received incentives (about Can \$25 [US \$19] gift

cards) for completing each interview, but they did not receive any incentive for completing the web-based program.

HardHat RCT

The HardHat RCT was about participants' perceptions of the effectiveness of the HardHat web-based program designed to prevent depression in both men and women who are at high risk of having an MDE in the next 4 years. The HardHat program is coach assisted and comprises 5 compulsory and 4 supplementary sessions, which include short homework and in-class assignments. The 5 compulsory sessions had to be completed sequentially, and finishing one would unlock the next session. The 4 supplementary sessions could be accessed at any point in time. The sessions entail problem-solving therapy and components of CBT. Coaches had a minimum of a Bachelor of Science degree and had attended an intensive 2-day training session provided by a psychiatrist with CBT expertise. Coaches answered questions, guided users through the program, and provided feedback on homework and assignments. Coaches met weekly to discuss the participants' cases and any issues encountered during coaching. Coaches also met with the psychiatrist on a quarterly basis.

HardHat RCT participants were recruited through a partnership with Green Shield Canada, a not-for-profit Canadian health and dental insurance company. An advertisement and link were posted on the Green Shield Canada health portal. Prospective participants could click the link and complete the eligibility questionnaire, which included a depression risk assessment using the same risk calculator used with participants in the BroHealth RCT [34]. Participants were men and women who were aged 18 years or older and at high risk of having an MDE in the next 4 years or had experienced an MDE in the past but who had not experienced symptoms for at least two months. Participants also needed to be able to communicate in English or French and have access to a telephone and the internet. HardHat RCT participants were interviewed at baseline, at 3 months, and at 6 months. Following the baseline interview, participants were randomized to the wait-list control group or the intervention group:

1. Wait-list control group: participants gained access to the HardHat program following their final (6 months) interview
2. Intervention group: participants were given immediate access to the HardHat program.

HardHat participants received incentives (about Can \$25 [US \$19] gift cards) for completing each of the baseline, 3-month, and 6-month interviews. Every other week, participants in the intervention group received email reminders to engage in the HardHat program. Unlike the BroHealth RCT participants, HardHat participants were also incentivized to complete program sessions. For each session completed, participants earned 100 Green Shield Canada points and were given a ballot for a monthly draw to win a US \$100 gift card. The Green Shield Canada points could be used to buy additional ballots for the chance to win rewards such as gift cards.

Sample Description

The original qualitative study design entailed a plan to interview a random sample of the BroHealth RCT intervention group

completers to ask them about their experience using the BroHealth program and what aspects of the program they found effective. However, after the initial month of both the BroHealth and HardHat RCTs, we noted that the use of the web-based programs was low among participants in both BroHealth intervention groups and the HardHat intervention group. The sampling plan was shifted to encompass a random sample of participants from these 3 intervention groups; we asked these participants about their perceptions of the effectiveness of their respective web-based programs as well as about what might motivate them to use web-based programs.

A total of 77 participants provided data for this study. Sixty-one participants were from the BroHealth intervention and were organized into 2 groups as follows: BroHealth qualitative group 1 comprised 41 participants who were randomly selected from either of the BroHealth intervention groups (BroHealth intervention group 1=370 participants and BroHealth intervention group 2=374 participants) because they had logged in to BroHealth a maximum of one time during the RCT and were interviewed 2 to 10 months after commencing the program; BroHealth qualitative group 2 comprised 20 participants who were also randomly selected from either of the BroHealth intervention groups, regardless of whether and to what extent they had used the BroHealth program. The BroHealth qualitative group 2 participants were interviewed following the completion of the RCT. Rounding out our sample, a third qualitative group comprising 16 HardHat participants was randomly selected from the HardHat intervention group (HardHat intervention group=103 participants) because they had logged in to HardHat a maximum of one time. HardHat participants were interviewed 1 month into the RCT.

Data Collection

Semistructured telephone interviews were conducted with participants, and interview duration ranged from 2 to 35 min and averaged approximately 9 min. Interviews were audio recorded and transcribed verbatim. All interviews included questions about aspects of the web-based programs that participants found effective, why they did not use the programs, and what did or would motivate program use. The interviews with the BroHealth group 2 participants tended to be lengthier, as these interviews included questions about experience with the RCT overall. The qualitative interview guides are included in the [Multimedia Appendix 1](#).

Sample Size Justification

We sought to capture a full range of both aspects of participants' perceptions of the effectiveness of the web-based programs as well as factors that would motivate the use of such programs. As such, we were guided in our sample sizes by the principle of *data saturation*. Although aligning with Saunders et al [36] (among others) to recognize the multidimensional and contested nature of saturation, in our study, we aimed for data saturation, which we defined as "the degree to which new data repeat what was expressed in previous data." In their discussion and review of guidelines for determining sample sizes needed to achieve *saturation*, Sim et al [37] presented sample size recommendations from an array of qualitative methodologists. Although saturation is contingent on the goals of the study being

conducted, Sim et al [37] note that for studies that entail interview data collection, methodologists tend to argue that saturation can be achieved through interviews with as few as 10 and as many as 40 participants. Guided by these numbers, and in light of the particular but novel nature of our study focus, we began with a relatively large sample of 41 participants in our first group (BroHealth group 1). Well before interview 41, interviews became repetitive and did not provide new information. Consistent with our inductive analysis approach, for our second group (BroHealth group 2), we conducted 20 interviews; before the 20th interview, interviews became repetitive both within our second group and between our first and second groups. Accordingly, we reduced our sample size slightly for group 3 (HardHat group) to 16 participants, and we again found data saturation both within and between groups.

Data Analysis

For this inductive content analysis, we began data analysis concurrent with interview data collection. After each interview, the recording was transcribed and reviewed by the research team. We then followed Elo and Kyngas' [33] steps of *open coding* and *creating categories*. These steps began with immersion in the data achieved as a researcher read and reread interview transcripts. This researcher then open coded by rereading transcripts and highlighting pieces of data—words, phrases, or sentences—that reflected meanings in response to our interview questions about aspects of the web-based program that participants considered effective and factors that would motivate participants' use of web-based programs. At this stage, this researcher created as many codes as necessary to reflect the meanings manifested in the interview content. Following this open coding, codes were grouped and collapsed into higher-order categories that captured the overall data set [38,39]. Transcript data and corresponding codes and categories were organized using NVivo 12 software.

Trustworthiness

We enhanced the trustworthiness of our findings by using the triangulation of investigators in our analysis. Specifically, author 2 (MN) conducted a brief analysis by reading select transcripts and providing a summary of key issues evident in the transcripts. All transcripts were then reviewed and coded by author 1, looking for important pieces of data. Authors 1 (HE) and 2 (MN) reviewed both analyses for the similarity of issues identified in the transcripts. A third researcher who was external to this project was brought in to ensure that the broader categories were a fair representation of the codes that were identified. The 3 researchers then discussed and reached consensus about any inconsistencies in codes and categories.

This project was approved by the Research Ethics Board of the Royal Mental Health Centre in Ottawa, Canada.

Results

Sample Demographics

Of the 77 participants, 70 were males and 7 were females. Response rates in the form of the number of prospective participants contacted versus the number who agreed to participate in the interviews are depicted in [Table 1](#).

The average age of the participants was 40.6 years (SD 1.34) and ranged from 20 to 65 years. The average risk of depression in the next 4 years was 23.1% and ranged from 7% to 87%. We generated 4 categories pertaining to the perceived effectiveness of the web-based mental health programs: awareness of health, functionality and medium, content, and coaches. We generated

5 categories pertaining to what motivates the use of web-based mental health programs: reminders and incentives, promotion of the programs, appropriate medium and functionality, perceived need, and questioning how or if motivating use is possible. Table 2 shows a summary of all categories generated through the content analysis.

Table 1. Response rates of each group of qualitative interviews.

Interview groups	Population (n)	Contacted, n (%)	Interviews, n (%)
BroHealth low usage	744	81 (10.9%)	41 (5.5%)
BroHealth after randomized controlled trial	744	101 (13.6%)	20 (2.7%)
HardHat	103	61 (59.2%)	16 (15.5%)

Table 2. Summary of the categories that were found through content analysis divided into their respective topics.

Topics	Categories
Effectiveness	<ul style="list-style-type: none"> Web-based programs increase awareness of mental health Contrasting perceptions of content effectiveness Coaches increase perceived effectiveness of programs
Motivators	<ul style="list-style-type: none"> Providing reminders and incentives increases motivation Promotion of web-based health programs increases motivation Providing appropriate medium and functionality increases motivation Perceived need for use increases motivation Motivating the use of web-based programs may be impossible

Perceived Effectiveness of Web-Based Mental Health Programs

Web-Based Programs Increase Awareness of Mental Health

The most common benefit of web-based mental health programs identified by participants is that such programs improve mental health awareness. Some participants spoke positively about increased self-awareness resulting from the use of the programs. For instance, "...it forced me through some of the issues that I am having" and "I think it helped just be aware of some of the problems writing them down. You know, I just didn't really focus on them that much."

Participants appreciated being aware of a resource that they could count on to support their needs currently and in the future. One participant explained:

I'd like to have it as a resource I can get to because there are times where like work, life and what not is more stressful than normal...and I want to make sure that I have help when I need it.

Participants believed that web-based programs are especially beneficial for individuals who are unwilling or financially unable to seek professional help.

Moreover, participants believe that web-based mental health programs can increase society's awareness of mental health. Participants viewed the web-based programs as a "step in the right direction" in terms of reducing stigma and increasing access to help, especially for men:

...it also makes it a nice tool for people who don't want to talk about mental health among men. It's still a big stigma right now. Not a lot of people that want to admit to it, but it's nice that it's there.

Perceived Program Functionality and the Internet as a Medium

Functionality and medium were important considerations with respect to the perceived effectiveness of web-based health programs. Participants expressed conflicting views about using the internet. On the one hand, participants endorsed the idea of having 24/7 access and an increased level of privacy. For instance, one participant mentioned:

I would say that that makes it effective to me because it's available to me at 1 o'clock in the morning if I wake up and I can't sleep...or feeling anxious about something, that's an advantage to uh, to be able to look at something and at that time.

Another participant said:

I assume a lot of people who are in my situation are in a crazy schedule so like you know the ability to do something on your own time and not always have appointments booked for you is good.

On the other hand, participants mentioned having procrastinated because there was nobody to ensure their participation. Furthermore, many participants had limitations to their computer use for reasons such as long hours on the computer for work, not being comfortable with computer use, and not having internet access. For instance:

I work on computers all day in my job so to then after sit on a computer um you know, when I walk away from my work I cannot just spend a lot of time on computers.

Although there was little reference to specific aspects of web-based program functionality, most participants were happy with the overall functionality and ease of use of both programs. However, some participants in both programs expressed finding it difficult to navigate the websites:

It was okay, for the first little bit it might have been a little bit confusing and not really sure where to go, what I'm looking for.

Some participants also noted technical issues such as broken links that may inhibit the effectiveness of the program.

Contrasting Perceptions of Content Effectiveness

Participants had varying opinions regarding the effectiveness of the content of the web-based mental health programs. Some found the content to be appropriate, detailed and engaging, and effective at decreasing stress. One participant remarked:

What was helpful is that, I do need to get back to listing what my challenges and goals are.

Conversely, some participants did not find the program content useful for the following reasons: the content was too similar to other resources, the content was not relevant to the user, the program had a poor flow, and the program lacked appropriate information on mental health. One participant stated:

after a half a dozen times I found that the content was redundant with what I had already gotten from my healthcare provider.

Some participants believed that the amount and type of content were comprehensive and covered a wide area related to mental health, whereas other participants felt there was too much information and that "...there was lot of text so sometimes it became a bit heavy," discouraging them from using the program.

Participants also recommended having personalized profiles to allow them to more quickly and easily narrow in on appropriate resources. Participants who believed the content to be appropriate and helpful cast their feedback in broad terms such as "It was engaging. It was appropriate." The few people who gave specific positive feedback appreciated the elements that they could adopt and implement in their daily lives, thus increasing their personal benefits of program use. Participants also suggested that periodically updating the content would have encouraged ongoing use.

Coaches Increase the Perceived Effectiveness of Programs

Although 45 participants had access to a coach (intervention group 2 of BroHealth and HardHat intervention group participants), very few used their coach. Of the 29 participants in BroHealth intervention group 2 who had access to a coach, only 2 utilized the coach and they believed that it was a great feature of the program:

I think I called at least 6 to 8 times and each time I was really happy to talk to him...to bring me back and

to give me good advice and to take me back to planet earth a little.

None of the 16 HardHat intervention group participants used their coach. Most were not aware that there was a coach included in the program or were unsure of the role of the coach. A few participants expressed not feeling comfortable talking with a coach because they were unsure about what to say. Participants who were either not given access to a coach (intervention group 1 in the BroHealth RCT) or who did not use their coach speculated that having a counselor to talk to would be an added benefit of the program. One participant compared the availability of BroHealth coaches with the availability of counselors in another program:

...they utilize an interesting way of connecting live counsellors with people who are actively looking to chat right now. And that's the only thing that wasn't there.

HardHat participants also believed that coaches would benefit them:

I think that getting that personal connection with the coach to be able to have that personal connection and possibly be able to relate to them.

Participants from both programs recommended having counselors that they could speak to via text, phone, or in person by appointment or on a 24/7 basis. Participants believed this would improve the web-based programs in 2 ways: (1) by keeping participants accountable by scheduling appointments and (2) by giving them someone to talk to if they need extra help with their mental health.

What Motivates the Use of Web-Based Mental Health Programs

Providing Reminders and Incentives Increases Motivation

Most participants believed that the reminders were beneficial in increasing their program use:

...when I got an e-mail from you before that sort of was a trigger to take a look.

At the same time, many participants did not recall receiving these reminders, thus limiting the perceived effectiveness of reminders. Many participants believed that text message reminders, rather than email, would be a more effective way to motivate program use:

I don't always check my emails, it's not something that I necessarily sit down and do on a daily basis. Everybody always has their phone with them.

Participants also acknowledged that the follow-up interviews conducted as part of the RCTs served as reminders to use the programs:

A lot of it was after interviews that I've done previously. It was a good reminder that the website was there.

Participants in the HardHat RCT received incentives to engage in the program, whereas participants in the BroHealth RCT did

not. Participants who received incentives and participants who did not receive incentives indicated that incentives were a good motivator for program use. For instance, one participant commented:

Something like points or rewards for progress as you work through it kind of thing might be a motivator to go back to it.

Promotion of Web-Based Health Programs Increases Motivation

Overall promotion and marketing of web-based mental health programs are major motivators to use the program. Participants believed that better promotion, and thus awareness and knowledge of the program, is the first step in motivating program use. For instance, one participant said:

It really is just trying to motivate the person to click it once, I suppose, and go on there.

Moreover, participants believed that having a good understanding of the program and its benefits before starting the program would motivate use. Various ways to promote use to people not already using the web-based programs were described by participants, including emails, text messages, word of mouth, and social media. One participant suggested using employers and workplaces to distribute information about the program, ensuring that a support system in the workplace is in place, and even having the program integrated within the workplace. Another participant said:

...it would be nice if things were within the workplace. In the workplace there's more structure. A lot of my stress derived from being self-employed and not having uh the workplace environment there to support me.

Providing the Appropriate Medium and Functionality Increases Motivation

The type of medium and functionality of the web-based programs were significant motivators. Many participants mentioned the importance of personal preference, noting that younger generations tend to be drawn to web-based media. Participants conveyed the importance of the medium fitting into their everyday life to motivate them to use the program. For instance, having notifications on their social media accounts and/or being able to access the program as an app on their mobile device were motivators. One participant explained:

whatever kind of sites that a person connects through....so you know if I get, if I get Facebook updates like that.

Many participants mentioned that being able to talk to a person (via text messaging, phone, or in person) in some capacity is beneficial for web-based mental health programs and would motivate use by increasing accountability. Ease of use (ie, "quick, easy, and convenient") was also a motivator to use the programs, as these characteristics allow the programs to fit into the busy lives of the participants.

Perceived Need for Use Increases Motivation

Participants perceiving that they need the program and perceiving the program as beneficial are major motivations for program use. Many nonusers anticipated that they would use web-based mental health programs in the future if they perceived a need for it. These nonusers did not believe that they were currently going through a hard time or having any symptoms; thus, they did not believe they had a personal need for the program.

Participants who did perceive themselves as having a need for the program were more motivated to continue using the program when program content was relevant to their lives. For instance, one participant said:

That one time I did go into it, I liked what I saw so I'm going to be going back.

Having content relevant to participants' experiences makes participants more likely to achieve the benefits of the program, in turn, improving motivation to use the program on a continuous basis. Updating the content may also lead to continued use.

Motivating the Use of Web-Based Programs May Be Impossible

Although motivating the use of web-based mental health programs is an important endeavor to ensure the use of mental health programs, many participants were simply unsure of how to do so or felt that motivating use was not possible. For instance, one participant stated:

...that's a really good question and if it was an easy answer, I wish it was an easy answer.

Others felt that the barriers to using such programs, such as lack of prioritization and stigma, are unsurmountable. For example, one participant explained:

when it comes to stacking priorities, how would you get around that, I really don't know.

Another participant commented:

...in my opinion, probably can't...I just come from a different school of thought I guess. That's just not a man thing to do.

Discussion

Principal Findings

Web-based mental health programs are valuable in preventing and treating depression [20-22]. To increase the use of prevention programs, it is important to understand what motivates the use and the perceived effectiveness of various components of the programs. Functionality and medium, awareness of mental health, and appropriate content were identified in this study as important factors for judging the perceived effectiveness of web-based mental health programs. Motivators to use such programs include providing reminders and incentives; promoting the programs (including endorsement by employers); providing appropriate medium, functionality, and content; and having a perceived need. At the same time,

some participants were unsure of how they could be motivated to use the programs or felt that there may be no way to do so.

Past literature describes many benefits of using web-based mental health programs, including convenience, accessibility, and cost-effectiveness [24]. Furthermore, having both increased awareness of one's mental health and good mental health literacy (ie, having knowledge about symptoms, treatments, and resources) is an important element of depression prevention [40,41]. Increased awareness reduces stigma and encourages individuals to access mental health services before the onset of depression. Our study echoes these findings, as mental health awareness was perceived as the largest benefit of the programs that we investigated.

Implications for Future Programs

Despite the benefits described earlier, adherence to web-based programs for mental health is low. Thus, the question is, how can we motivate people to use web-based health programs for mental health? Furthermore, how can we motivate people to use web-based programs before developing depression?

Promoting Web-Based Mental Health Programs

The first and, arguably, the hardest step is to convince people to use such programs for the first time. To convince people to use these programs, people need to (1) have the knowledge that such programs exist and (2) believe that they have a need for the services provided by the web-based mental health programs. Useful marketing of the programs was a very strong motivator uncovered in this study. Primary care providers are the number one source of mental health information [42], but many people are reluctant to see their physician about mental health problems, especially for prevention. As a result, a large proportion of people are not receiving the resources they need. The results of this study indicate that men who are reluctant to see mental health professionals and use mental health resources may be more open to discussing resources with people close to them. Although men are often afraid of stigmatization, recent studies have reported that many men have a small social circle with whom they feel they can share their concerns [43]. Men are also very willing to support the mental health of other people in their lives [43]. This close social circle/familial support adds an avenue through which to promote the initiation of web-based mental health programs.

Mental health programs within the workplace have been reported in the literature as decreasing stigmatization of poor mental health [44]; workplace mental health programs may contribute to an increase in web-based program use. This study uncovered a complementary finding that participants may be more likely to use web-based mental health programs if these programs are somehow incorporated into the workplace setting. In addition, having a program in the workplace was found in this study to increase feelings of mental health support. Thus, promoting web-based programs in the workplace may help to increase awareness about the program and more effectively encourage initial and ongoing participation.

Once a person has decided to initiate the use of a mental health program, they need to complete it to reap the full benefits [45].

Many methods have been noted in the literature to increase adherence to web-based programs.

Improving the Continued Use of Web-Based Mental Health Programs

Our study found that appropriate content was an important factor for increasing the perceived effectiveness and, consequently, the increased use of web-based mental health programs. However, as content needs often vary significantly from person to person, the participants in this study postulated that having individually tailored content may motivate the continued use of a web-based program. Moreover, meta-analyses and systematic reviews have shown that having tailored content can decrease symptoms of depression in study populations [46,47]. Having future programs tailored to a specific group or having the ability to tailor to each specific user would be beneficial to improve adherence and effectiveness of the program. In addition, the results of this study suggest that tailoring the web-based mental health program to people with lower mental health literacy would make the content less redundant. Lustria et al [46] found that computer assessments could be used to narrow down the content to that users' specific needs. Future research should focus on how to effectively tailor content to specific groups.

In addition, reminders not only increase adherence to [48] and perceived effectiveness of [49] web-based programs but also help foster a positive attitude toward them [50]. In this study, the reminder emails motivated program use. However, email reminders were often discarded immediately by participants without being read. Many participants speculated that reminders sent via text messages may be a better format. Having a direct link to the program to make it faster and easier for participants was endorsed by this study. Although studies have found results consistent with this finding [51], more research is needed to find the optimal medium for reminders to motivate program use.

The use of the internet as a medium was a polarizing topic, as web-based programs are not preferred by everyone. Although some participants believe using the internet as a medium is ideal because of privacy and convenience, others preferred alternate media as they had limited computer use. This discrepancy is consistent with other studies [52]. For instance, a study by Smail-Crevier et al [53] found that younger generations are more likely to engage with web-based programs compared with older generations. Another study found that high computer/internet use is negatively associated with the use of web-based mental health programs [54]. Moreover, having a live person to speak to is associated with increased use and completion of the program [54]. Agreeing with the literature, the results from this study demonstrate that having access to someone to speak to may make the programs more effective and meaningful to users and thus could increase motivation and adherence to future web-based programs. The results of this study indicate that although coaches or guides in programs could potentially be effective, unless participants are aware that they have access to a coach and understand the role of the coach, they are unlikely to use it.

Impact of Society on Web-Based Mental Health Programs

Although the methods to motivate use described above have been found to be effective, there are many individuals who are unsure of how to motivate their own use or who simply do not believe that it is possible to motivate people in general because depression and help-seeking remain highly stigmatized [55-58]. Specifically, at-risk individuals tend to have lower mental health literacy and are less likely to seek treatment [59]. The Health Belief Model suggests that a person will only take action to prevent disease if (1) they believe they are vulnerable to the disease, (2) the disease is severe enough to negatively affect them, and (3) there is a benefit to the prevention that outweighs the cost [60]. These findings have been echoed in previous research on depression [61-63] and in our study, as participants were more likely to use the programs if they believe that they needed it.

Limitations

This study is limited in several ways. First, given the specific and detailed nature of this study, we make no claims that our findings can be extrapolated to larger populations or to other web-based mental health programs. Second, there is a chance that a different research team with different backgrounds would generate different categories from our data. To offset this limitation, multiple researchers collaborated and achieved a consensus on the analysis. We note further that some participants

were interviewed a few months after they had used the program and thus may have had difficulty with recall. Our study did not examine how demographics, such as age, income level, and occupation, could influence participants' perceptions about web-based mental health programs. Finally, very few participants engaged with their coaches. As a result, the views that they expressed about coaches were often not based on personal experience and should therefore be interpreted with caution.

Conclusions

In conclusion, awareness of one's own mental health is a benefit of using web-based mental health programs. The content and functionality of the programs are important factors when assessing perceived effectiveness. However, perceived effectiveness varies from person to person, and what may be effective for one person may not be effective for another. Access via chat to a real person and being able to customize content to fit the users' personal needs are improvements that could increase the perceived effectiveness and use of similar programs. Motivating people to use such programs is difficult; even current program users are unsure of the best ways to motivate use. Motivators include providing reminders or incentives, promoting the programs, providing appropriate medium and functionality, and perceived need, which, if adequately incorporated into web-based program design and implementation, may lead to increased use.

Abstract

Background: The uptake of traditional pulmonary rehabilitation classes by patients with chronic obstructive pulmonary disease (COPD) is poor because of personal factors that prevent accessibility to the venue. Therefore, there is a need for innovative methods of pulmonary rehabilitation, and virtual reality (VR) could be a promising technology for patients with COPD to access services remotely.

Objective: This study aimed to investigate whether VR improves compliance with pulmonary rehabilitation among patients with COPD, a particularly vulnerable patient group (Medical Research Council [MRC] 4 or 5), and whether VR provides a credible alternative to traditional pulmonary rehabilitation programs.

Methods: This was an 8-week patient trial using an innovative VR pulmonary rehabilitation program. A purposive sample of 10 patients with COPD graded MRC 4 or 5 and registered at a selected health care center and a hospital in Cumbria, United Kingdom, were included. Qualitative (focus groups and interviews) data were collected, and to further support the qualitative findings, quantitative data (self-report patient surveys) were gathered before and after the 8-week trial. The 5 self-reported surveys included the Patient Activation Measure, Generalized Anxiety Disorder-7, Patient Health Questionnaire-9, Short Physical Performance Battery, and the Edmonton Frail Scale.

Results: In a thematic analysis of the qualitative data, 11 themes emerged specific to delivering pulmonary rehabilitation using VR. The quantitative data further support the qualitative findings by revealing significant improvements in all physical measures.

Conclusions: Overall, this study demonstrates how remotely supervised VR-based pulmonary rehabilitation could help to overcome current issues and limitations associated with providing this service to patients with COPD at scale.

KEYWORDS

virtual reality; COPD; rehabilitation

Introduction

Background

Pulmonary rehabilitation is a nonpharmacological intervention designed for patients with chronic obstructive pulmonary disease (COPD), involving supervised exercise training, disease

education, and behavioral interventions [1]. It is now one of the most effective treatments for significantly improving symptoms of dyspnea (ie, breathlessness) [2-4], exercise capacity, and improved quality of life [2,4-6] and reducing anxiety and depression in patients with COPD [1,7]. However, the uptake of pulmonary rehabilitation is poor, and completion rates are low [1,7,8]. Patients who qualify for pulmonary rehabilitation

are those graded 3 or above on the Medical Research Council (MRC) breathlessness scale, which is a validated measure of disease severity used in many scientific studies across the world, given that this particular group is at high risk of exacerbation and hospital admission [9-11]. However, patients have difficulty attending classes because of lack of transport and geographic distance to a program, fatigue, lack of motivation, inconvenience, disruption caused to daily activities, and the quality of conversation that health care professionals have with patients about pulmonary rehabilitation [12,13]. Depression, burden of illness, low awareness of rehabilitation, and knowledge of and disbelief in beneficial rehabilitation outcomes are also considered barriers to patient uptake [14-16]. Therefore, researchers and practitioners are searching for innovative methods to deliver more engaging rehabilitation for patients with a variety of long-term conditions that affect physical activity.

More recently, there has been an increase in research focusing on the effects of virtual reality (VR) for patients with chronic diseases that inhibit physical activity. For example, studies focusing on individuals with Parkinson disease have investigated the effects of gait training with VR [17], whereas others have compared home-based VR balance training with conventional home-based balance training [18]. The physical and psychological benefits of VR for patients who have had a stroke have also been explored [19,20]. However, despite the extant research in this area, studies investigating VR for physical training rehabilitation programs have demonstrated varying results, which means that researchers and practitioners are unsure about its true impact [21,22]. The need for innovative methods of pulmonary rehabilitation is evident, and VR could be a promising technology for providing a convenient and remotely accessible pulmonary rehabilitation program to patients with COPD. COPD places a significant financial burden on individuals and societies worldwide and is a global public health burden that needs to be addressed to reduce the substantial cost associated with the disease and improve patients' quality of life [23,24]. Remotely supervised VR could complement conventional therapy [25], which has demonstrated poor uptake because of patients' personal barriers [8]. However, to the best of our knowledge, limited research has investigated the benefits and outcomes of VR for pulmonary rehabilitation, which leaves an important area of research requiring further investigation. To address this gap, this study aimed to investigate whether VR improves the compliance of patients with COPD for pulmonary rehabilitation, with a particular focus on the vulnerable patient group (MRC 4 or 5), and whether this technology provides a credible alternative to traditional pulmonary rehabilitation programs. The results of this study provide significant theoretical contributions to the field of health care research and provide important implications for health practitioners.

What Is Already Known on This Topic?

- COPD is a global public health burden that needs to be addressed to reduce the substantial cost associated with the disease and improve the patient's quality of life.
- Remotely supervised VR could complement conventional therapy, which has demonstrated poor uptake due to patients' personal barriers.

- Limited research has investigated the benefits and outcomes of VR for pulmonary rehabilitation, which leaves an important area of research requiring further investigation.

What This Study Adds?

- VR provides the opportunity for an interactive and visually stimulating approach for use in clinical treatment and could provide pulmonary rehabilitation to patients with COPD who cannot easily access traditional rehabilitation methods.
- This study provides a significant contribution to health care research investigating the benefits of implementing digital technologies to improve rehabilitation, with particular contribution to pulmonary rehabilitation research.
- Important practical implications for the health care industry and medical practitioners on the benefits of VR for pulmonary rehabilitation are offered.

Literature Review

Technology-Facilitated Methods for Pulmonary Rehabilitation

COPD is characterized by progressive airflow obstruction and cannot be fully reversed [26]. Patients with COPD find it difficult to engage in physical activity and often have episodes of exacerbation, including breathlessness and coughing, which provoke anxiety and episodes of panic leading to an overall decline in everyday function and overall quality of life [26-29]. The psychological consequences of COPD include symptoms of depression; general anxiety [30-35]; and psychological repercussions, including fear, panic, loss of confidence, and social isolation [36,37], which have important implications for the adoption and maintenance of healthy behaviors [38]. In turn, this restricts the patients' ability to perform daily activities, and owing to the fear of dyspnea, they often avoid physical activity and social events, which may contribute to an increased likelihood of depression in elderly patients with COPD [30,36,37]. In addition, an increasingly sedentary lifestyle leads to muscle weakness, further reductions in physical activity, reduced exercise capacity, and even more severe symptoms [39,40]. The MRC breathlessness scale measures perceived respiratory disability and is widely used to describe patient cohorts and stratify them for interventions such as pulmonary rehabilitation in COPD [29,40]. More specifically, patients graded MRC ≥ 3 are considered eligible for pulmonary rehabilitation services [9].

Rehabilitation facilitated by information and communication technologies is known as telerehabilitation [41,42]. Over the past few years, there has been an increase in telerehabilitation apps owing to the development of new technologies [43]. Compared with traditional inpatient or person-to-person rehabilitation, telerehabilitation allows for remote communication and is, therefore, more cost-effective for both health care providers and patients [43]. Some examples include in-home videoconferencing [44,45], mobile phone-based exercise programs [46], web-based self-monitoring [47-49], and more recently, socially assistive robots [50] and VR. Studies have suggested that telerehabilitation is suited to older people as it can improve the quality of life, allows for more independent living, is more convenient in terms of not having to travel for

appointments, and enables cost-effective services [51-54]. However, despite growing evidence-based research demonstrating positive clinical outcomes and increasing telehealth utilization, patients are faced with equipment setup-related difficulties, limited scope of exercise, and connectivity [55].

Although the completion of pulmonary rehabilitation is associated with improved outcomes, including reduced subsequent hospital admission rates and better survival [10], the uptake and completion rates remain poor because of personal barriers associated with time, costs, fatigue, motivation, and inconvenience [8]. COPD is the third leading cause of death worldwide. In 2016, the Global Burden of Disease study reported a prevalence of 251 million global cases of COPD that year [56,57]. Research has indicated that COPD affects at least 320 million people and has a global economic cost of US \$2.1 trillion [58,59]. Significant health care costs are associated with the treatment of exacerbations, including hospital visits and medication costs for maintenance therapy and outpatient treatment [24,29]. Over the past few years, general practice has been encouraged to explore new ways to improve COPD management and reduce hospital admissions [60]. A deeper understanding of the barriers associated with the acceptance and uptake of pulmonary rehabilitation by patients with COPD could reveal new methods to improve its uptake [10,60], which would reduce the considerable health care burden of COPD on the patients' quality of life and the health economy. In addition, self-management interventions could lead to a reduction in COPD-related health costs by reducing hospital admissions [61-63]. Therefore, researchers and practitioners have sought innovative methods to create more exciting rehabilitation programs for patients such as VR, which is said to increase their excitement and interest, and excitement often leads to increased motivation to complete the rehabilitation program [21,64-66].

The Use of Virtual Reality for Physical Training and Rehabilitation

With recent technological advancements in VR, innovative approaches to improve traditional physical therapy and rehabilitation programs can be explored [21,67,68]. VR can be defined as a computer-assisted technology that provides the user with an immersive, interactive, and multisensory experience in a 3D virtual environment. The most cutting-edge hardware to facilitate VR is the head mounted display. Patients can control the digital recreations of their physical bodies (ie, avatars) to perform practice behaviors in the virtual environment [21]. Several studies have demonstrated that VR rehabilitation programs may develop physical outcomes [69-72]; outperform traditional rehabilitation programs [17,73,74]; and provide greater benefits to improve walking speed, balance, and mobility [75]. Many VR programs are designed with tasks that challenge the user, and well-designed VR rehabilitation programs could lead to improvements in cognitive, motor, and social aspects [76,77]. Given that VR can be accessed without supervision, an increased dosage of therapy can be provided without increasing staffing levels [77]. Remotely supervised VR interventions could complement conventional therapy programs and would be particularly suited in situations where cost savings are mandatory and/or when transport to the clinic is difficult

for the patient [25]. From the patients' perspective, VR environments for rehabilitation are naturally considered to be more exciting and enjoyable than traditional rehabilitation methods, which means that patients exert more effort and are more motivated to participate in VR rehabilitation compared with traditional rehabilitation methods [21,64,78,79]. As a result, patients benefit from greater autonomy and mobility in performing their daily activities [17]. However, few studies have investigated whether increased motivation explicitly leads to positive rehabilitation outcomes [21]. As VR is still a fairly recent addition to delivering physical therapy and rehabilitation, there is uncertainty on the benefits, despite the emerging research in this area [22,80]. However, as VR technology becomes more accessible and affordable, it will likely become more widely used in clinical rehabilitation settings [80-82]. Therefore, additional trials are required to evaluate the efficacy and determine the acceptability and feasibility of VR to guide future design and implementation of these systems in clinical practice [22,42].

Methods

Study Design

Patients participated in an 8-week trial using the Pulmonary Rehabilitation in Virtual Reality (*PR in VR*) program, and both qualitative and quantitative data were collected. During the trial, each patient was provided with a VR headset which was manufactured by Pico Interactive (Pico) Goblin and whose concept is developed by Concept Health Technologies. The headset was embedded with the PR in VR app and a small probe Nonin 3150 at home for an 8-week period. The patients wore the probe when exercising to measure their heart rate (HR) and oxygen saturation levels (displayed as a percentage). Pulse oximeter data were used by clinical staff to remotely measure the patients' oxygen saturation and HR when the patients were exercising. The clinical staff used a web-based dashboard to observe these data remotely during the rehabilitation session. PR in VR was designed to enable patients to perform various exercises in their homes as displayed in the VR environment and comprised 8 separate modules. It was anticipated that the patients would spend at least 20 min per day using the VR rehabilitation program and complete 1 module per day during the 8-week period. Specifically, the app was divided into 2 subgroups: (1) education and (2) rehabilitation. Each subgroup has additional modules that can be accessed from within the app. The education section contains high definition videos with cinematic effects (visuals and audio) to increase retention of patients. The rehabilitation section (modules 5-7) comprises physical exercises led by a virtual instructor in the form of a 3D avatar. The physical exercises were drawn from the traditional pulmonary rehabilitation program and tailored to be suitable for patients while wearing the VR headset (eg, seated exercises). The final module (module 8) is a summary of the PR in VR program. The app is designed to send these data in real time to the server, and patients can monitor these data while exercising as they are displayed in the corner of the VR display screen.

Participants

A total of 10 elderly patients with COPD (graded at MRC 4 or 5), aged between 63 and 75 years, were recruited in the United Kingdom. Overall, 6 patients from a health practice in South Cumbria and 4 patients from a general hospital in West Cumbria were recruited by the local physiotherapist at each location. Ethical approval was granted by the ethical committee of the Manchester Metropolitan University before data collection. Patients graded MRC 4 and 5 were provided the option to trial the PR in VR program or wait for 1 year to attend the traditional

rehabilitation classes at the local rehabilitation center. All patients invited to take part in the trial agreed; however, because of the limited number of devices, only the patients who confirmed their interest first were recruited. There were 6 out of 10 male patients. Table 1 provides the patients' demographic profile and entails the coding (patient [P]; P1-P10) used for the qualitative analysis. The average age of male patients in this study was 70 (SD 4.80) years, and the female participants were aged 3 years younger than the male participants on average (mean 67 years, SD 5.2 years).

Table 1. Demographic profile of the patients.

Patient number	Age (years)	Gender
P1	75	Male
P2	68	Male
P3	69	Male
P4	73	Female
P5	62	Female
P6	71	Male
P7	76	Male
P8	69	Female
P9	63	Female
P10	63	Male

Data Collection

Before using PR in VR, the functional ability of the patients was assessed, and together with the physiotherapist, they were each asked to set a short-term goal (eg, increase walking distance without breathlessness) and a long-term goal (eg, feeling confident to leave the house on his/her own). The patients completed 5 self-reported surveys before and after using PR in VR.

In health and well-being research, qualitative methods are widely used as they provide insights into the perceptions and experiences of patients and health care professionals [83]. During June 2018, 2 focus groups and 6 one-to-one interviews were conducted in Cumbria. Each focus group was led by 2 researchers, 1 physiotherapist, and 1 health care assistant in each location. The first focus group, comprising 3 patients with COPD, was conducted at a health practice in South Cumbria and lasted approximately 75 min. Later, 4 one-to-one interviews were conducted by the physiotherapist in the same location and lasted between 11 min and 25 min each (interview 1: 12 min; interview 2: 11 min; interview 3: 15 min; and interview 4: 23 min). The second focus group, comprising 2 patients with COPD, took place at a general hospital in West Cumbria and lasted approximately 45 min. Then, the physiotherapist and health care assistant conducted 2 more one-to-one interviews at the same location, which lasted 16 min (interview 5) and 15 min (interview 6). The focus groups and interviews were conducted at the end of each patient's 8-week VR-based rehabilitation program. During the focus groups and interviews, the questions aimed to explore how the patients benefited from the PR in VR program, explore how satisfied they were with

using it, and identify the areas requiring further development. Drawing on the integrated educational aspect, the questions explored the effectiveness and benefits of immersive training in this specific context and further explored the usability of the VR device and app as well as the patients' intention to use PR in VR in the future.

Data Analysis

The qualitative data were transcribed verbatim before being analyzed using thematic analysis, which is a method used to identify patterns (ie, themes) within a dataset through a rigorous process of identification, analysis, organization, description, and reporting of those themes [84]. Thematic analysis is widely used in health care research [55,85-87] and was considered the most appropriate for this study as it is suited to questions related to people's experiences or views and perceptions such as in this study.

In addition, the patients completed the 5 self-reported surveys before and after the trial to ensure that a comparison could be made between each patient's scores. This was important to determine whether the patient showed improvements after using the PR in VR program. An analysis of the survey results before and after using VR was conducted using Excel.

Results

Qualitative Analysis

The purpose of the focus groups and interviews was to explore how the patients benefited from the PR in VR program, explore how satisfied they were with using it, and identify the areas requiring further development. In addition, the effectiveness

and benefits of immersive learning in this specific context, the usability of the VR device and app, and the patients' intention to use PR in VR in the future were explored. From the analysis,

11 themes emerged and are presented in Table 2. The themes are discussed in further detail below and provide support with direct quotations from the qualitative data collection.

Table 2. Themes and description of each theme.

Themes	Description
Increased compliance	Significant increase in the patients' compliance with pulmonary rehabilitation (ie, doing their exercises)
Increased engagement	Increased engagement in pulmonary rehabilitation when using virtual reality because of enjoyment
Physical improvements	Significant improvements in patients' physical health (ie, strength, mobility, and flexibility)
Improved psychological well-being	Patients' psychological well-being has significantly improved
Improved health-related quality of life	Patients feel healthier and fitter (ie, they can confidently leave the house and socialize more than before)
Increased confidence	Significant improvements in confidence in terms of the patients managing their condition and performing daily activities and physical exercises
Patient satisfaction	Patients are satisfied with completing the Pulmonary Rehabilitation in Virtual Reality program and achieving their short-term and long-term goals
Increased feeling of security	Patients feel more secure, reassured, and confident to exercise, knowing their physiological data are being remotely supervised
Effective immersive learning	Effectiveness of immersive learning for patients with COPD ^a was demonstrated
Personalized programs	A recommendation to provide programs tailored to suit various levels of COPD
Need for technological improvements	Need for technological improvements of both the device (eg, a more lightweight headset) and the content of the app (eg, additional functions to control the pace and standing-up exercises) to improve the patients' experience

^aCOPD: chronic obstructive pulmonary disease.

Increased Compliance

The findings demonstrate that PR in VR significantly increased the patients' (P1-P10) compliance with the frequency and consistency of performing their exercises. For example, patients had difficulty attending the rehabilitation center because of barriers associated with time and other personal commitments taking priority:

I couldn't complete traditional rehabilitation. There was always something cropped up. [P9]

In comparison, using PR in VR remotely was "easier" (P9) and "pleasurable rather than chore-like" (P9), given that it could be integrated into their daily routine in a more flexible basis. For patients with COPD, this is an important factor as several patients (P1-P10) mentioned that some days they do not feel well enough, physically and/or mentally, to travel to the rehabilitation center. Therefore, being able to access pulmonary rehabilitation anywhere at any time is highly beneficial and attractive for this target group:

VR is more akin to my needs. I did not feel like traditional classes were doing anything for me. [P9]

I prefer to do it at home, partly because of getting to the venue. [P2]

Increased Engagement

Compared with previous pulmonary rehabilitation methods, PR in VR increased engagement for all participants (P1-P10) as it was more enjoyable, and more importantly, having the 3D avatar gave the experience a social aspect. Therefore, patients were

more disciplined with PR in VR than they had been with previous methods such as the booklet:

I was amazed how I actually looked forward to doing [PR in VR] and getting on it and seeing the chap and doing [the exercises] with him. [P8]

You discipline yourself to use it. If it's not there, then I don't think I would. You just don't do them [exercises using the booklet]...but [with VR] the guy is there and he's talking to you, and you feel as though you are with the two people, it's just the feeling it gives you. [P9]

Patients were more engaged with PR in VR as they felt more comfortable performing their exercises in their home environment at their own leisure:

Because it was at home, I think I did it more. Whereas I would have been ringing the class to tell them I cannot make it because I don't feel well enough. [P8]

Physical Improvements

Participants (P1, P3-P5, and P7-P10) demonstrated physical improvements, including increased strength, mobility, and flexibility:

I know certainly my legs are stronger. I can feel that even just getting up off the chair. [P8]

I can't walk to the car without having to stop usually. But when I am not doing the exercises, I could walk to the car without having to stop. [P4]

I am a lot more flexible and without the pain! [P1]

Several exercises in the PR in VR program focused on developing strength in the thigh muscles, which subsequently improved the patients' cardiovascular fitness, enabling them to walk further (P1-P10). In addition, patients reported increased strength in their upper body, which resulted in them feeling less breathless and having a much quicker recovery time when breathlessness occurred. As a result of the consistent physical activity, as opposed to minimal daily movement, patients felt healthier both physically and mentally:

After using VR, I am less breathless...my recovery time is much quicker. [P9]

I do feel healthier in myself...I feel a lot better with myself, with the movement, physically. I used to just sit in my chair and do nothing. [P1]

Improved Psychological Well-Being

In relation to the previous theme (physical improvements), the patients' psychological well-being significantly improved:

When I've finished the Thai Chi, I do feel physically and mentally relieved. [P1]

All patients (P1-P10) confirmed that they would recommend the PR in VR program to others in their situation largely because of the psychological benefits, which are particularly important for patients with COPD, given the associated mental health problems (eg, depression) often experienced from the initial diagnosis to adapting to living with COPD. In line with this, motivation played a key role in the patients' enthusiasm to continue with PR in VR. Overall, this could assist in overcoming mental health problems and improving their general psychological well-being:

Motivation is my main reason to continue. Because I get depressed really easily. [P4]

It gets me motivated and I'm in the [wheel]chair a lot because of my health so doing the exercises does motivate me but sometimes I don't like being honest about it, but I have to mentally build up to do it because of the way I am feeling. But yes, I would recommend it. [P3]

Improved Health-Related Quality of Life

Improvements in physical and psychological well-being were positively associated with health-related quality of life (HRQoL), as demonstrated by all participants (P1-P10). Performing daily activities was more enjoyable than before, and patients were more sociable:

It has made my daily activities easier...I am more comfortable with what I do. [P9]

I am getting out and about now. [P7]

For example, P4 had not left the house for almost 2 months before starting PR in VR. In addition, patients felt happier as they could spend more quality time with friends and family:

From sitting on a sofa, I had been able to go with my husband for a coffee, to go out in the car, and I had not done any of that for 7 weeks. It had got me to the stage again where I felt I could go out and go

shopping with the trolley. I have done none of that for about 2 months. [P4]

Going out every day has made a difference; I have been seeing my friends. [P7]

Increased Confidence

Most patients (P1-P5 and P7-P10) reported significant improvements in confidence in terms of managing their condition, conducting daily activities, participating in social activities, and managing their breathing:

I can get upstairs in one go now. [P7]

It builds my confidence up because I can go out more. [P4]

It has given me more confidence in breathing along with what I am doing. [P9]

Reflecting on this, patients discussed how they had previously lost motivation and confidence in their ability to manage tasks themselves without the support of their partners and several had "given up" (P3, P4, and P7-P10). However, with the PR in VR program, the patients had gained back more control in their lives:

I think I had given up. I decided that the illness had gone so far that I was not going to get better, I was not going to get out again, or enjoy life. It has completely reassured me that way and given me the energy to get going again. [P8]

Possibly it was a mental thing. I felt confident enough. I started filling my own flasks. [P7]

Patient Satisfaction

Successful completion of their exercises within a given day using PR in VR was positively associated with patient satisfaction (P1-P10). Noticing improvements in physical wellness enabled patients to feel satisfied and confirmed the benefits associated with following the PR in VR program:

What I enjoyed most was knowing that I could get through the exercises. Knowing that my oxygen was not dropping. It was a real achievement for me. I was used to going to the toilet and coming back and having to catch my breath. All of a sudden, I could do these exercises and after a few times I was still breathing normal. [P8]

Given that PR in VR is self-managed and remotely supervised, patients' self-motivation played a critical factor in their consistency with exercising and subsequent self-satisfaction:

I feel satisfied that I motivated myself to do it. It did help me to do it. I feel satisfied when I sit down and think that's me done for tonight. [P4]

Increased Feeling of Security

A primary concern for patients was experiencing exasperation when exercising alone at home. In comparison to previous methods, PR in VR is advantageous as it allows for remote supervision, meaning that the patients' physiological data (ie, HR and oxygen level) are continuously tracked and monitored by health practitioners. Therefore, this function improved the

patients' experience as they felt more secure (P9), confident (P7 and P9), and reassured (P8), knowing that they were being monitored while exercising in real time should exacerbation occur:

The minute I am getting out of breath [at home] I go into panic. [P8]

It has given me more confidence in breathing along with what I am doing. [P9]

It reassured me being able to see my oxygen level and heart rate while I was exercising. I feel it has increased my confidence. [P8]

Furthermore, this function assisted patients with better management of their condition and to avoid overexerting themselves into exasperation:

[PR in VR] has improved my breath...in the VR it shows the oxygen go up and back down again, it gave me that back again where I could settle myself down. [P8]

Effective Immersive Learning

PR in VR provides patients with information on COPD with the aim of helping them better manage their condition. The findings demonstrated the effectiveness of immersive learning for patients with COPD as it educated them on the disease, which some participants were never informed of. For instance, P1 found the learning aspect useful and "very informative to find out what is actually happening." During the focus groups, P1 could reiterate what he had learned from the program 5 weeks prior:

That's the first time I have seen on screen what emphysema actually is. [P1]

The PR in VR program had increased the patients' awareness of their breathing techniques (P1, P3, and P8) and the variety of exercises required to target various muscles and support their overall health and well-being. The findings further support the effectiveness of immersive learning, specifically using VR for patients with COPD:

He says breath out when you do the exertion, I was not doing that before...it has improved my breath...the voice over was helpful and reassuring. [P8]

I think it's a good idea. It reminds you that you've got to do different exercises to target different muscles. [P3]

Personalized Programs

Recommendations to improve the patients' experience of PR in VR were provided. Patients (P1-P6, P8, and P10) suggested various levels of exercises (ie, harder set of exercises and easier set of exercises) to suit the many levels of patients with COPD to improve the program. More specifically, patients (P2, P5, and P10) explained how the first 2 to 3 levels were "too easy" (P5), slow paced (P5), and too long (P10) and were eager to push onto more "severe" modules (P10). Therefore, these patients required more advanced exercises to ensure that they were constantly being challenged. On the contrary, the more advanced exercises were too challenging for other patients (P1,

P3, P4, and P5) on the first attempt and required repetition, given that they might not have exercised for a prolonged period before using PR in VR. Indeed, those patients enjoyed the flexibility of being able to move back and forth throughout the modules depending on their well-being at that time:

It is beneficial to have the different levels so I can drop down depending how I feel each day. [P4]

Furthermore, it was suggested that a variety of exercises at the same difficulty level would retain engagement:

I would like two or more routines in each module instead of doing the same thing all the time. For longer than six weeks it would become boring. [P5]

Needs for Technological Improvements

Furthermore, to improve the patients' experience of PR in VR, technological improvements of both the device and app were required (P1-P10). For instance, the main technical issue within the app whereby the camera moved to the right and took several seconds to re-center was a recurrent topic of conversation. Hence, improved graphics could enhance the experience but was considered a minor factor in the overall rehabilitation experience that could easily be solved:

The whole thing was excellent it really was except for the glitches but I am sure that can be overcome. [P5]

Suggestions for additional functions included a fast-forward and pause button (P1-P5) to allow patients to have more control over the program and pause it while they recovered:

If you could pause it when you know that you're going to get out of breath. [P1]

All patients (P1-P10) found the headset easy to use; however, some required it to be more lightweight (P4, P5, and P9). With regard to the content, some patients (P1-P5) enjoyed the standing-up exercises.

Quantitative Data Analysis

In addition to the focus groups and interviews, quantitative data were collected, and the findings further support the qualitative findings. Table 3 presents the results of the outcome measures. The average of each of the 5 surveys was calculated based on the patient data gathered before and after the VR rehabilitation program. As can be seen, the findings demonstrate an improvement of all outcome measures after patients used the VR program. The Chronic Respiratory Disease Questionnaire (CRQ) measures both physical and emotional aspects of chronic respiratory disease. The results indicate that the patients had improved dyspnea, fatigue, and emotional function after completing VR-assisted treatment. The female participants collectively showed more improvements in both dyspnea and emotional function than the male participants. The Patient Health Questionnaire-9 and generalized anxiety disorder-7 demonstrated that a substantial proportion of patients had reduced feelings of depression and anxiety, respectively, which further supported the theme of improvements in the patients' psychological well-being. The Short Physical Performance Battery is used to assess lower extremity physical performance status by combining the results of the gait speed, chair stand, and balance tests. The results of the Edmonton Frail Scale and

Short Physical Performance Battery were positively associated with the patients' physical improvements, including strength, mobility, and flexibility. Finally, the Patient Activation Measure

results demonstrated the patients' progression with knowledge, skills, and confidence in self-managing their condition after using VR.

Table 3. Outcome measure results before and after using virtual reality.

Outcome measures	Before using virtual reality, mean (SD)	After using virtual reality, mean (SD)
Short Physical Performance Battery	6.78 (2.95)	8.43 (1.72)
CRQ ^a -dyspnea	2.22 (1.09)	2.96 (1.15)
CRQ-fatigue	3.11 (1.43)	3.27 (1.15)
CRQ-emotional	3.85 (1.52)	4.36 (1.01)
CRQ-mastery	3.83 (1.19)	4.22 (0.74)
Patient Activation Measure	60.81 (10.83)	63.46 (15.89)
Edmonton Frail Scale	6.56 (2.07)	5.38 (2.00)
Patient Health Questionnaire-9	8.44 (5.90)	6.11 (4.76)
Generalized Anxiety Disorder-7	5.78 (5.89)	4.22 (3.11)

^aCRQ: Chronic Respiratory Disease Questionnaire.

Discussion

Principal Findings

This study aimed to assess the benefits and outcomes of VR as an innovative method for pulmonary rehabilitation in 2 aspects. First, the study aimed to investigate whether VR improves compliance with pulmonary rehabilitation in patients with COPD, particularly the vulnerable patient group (MRC 4 or 5). Finding innovative pulmonary rehabilitation treatment methods that engage this particular patient group is vital, given the severity of the disease that affects the HRQoL and the barriers associated with attending traditional rehabilitation classes [12-15]. This study demonstrates that PR in VR significantly increases the patients' compliance with pulmonary rehabilitation compared with traditional methods mainly because of the flexibility to exercise at any time of the day and location and as it is not restricted to home- or clinic-based scenarios, which is more accommodating for their daily psychological and physical well-being [88]. The second research question was to investigate whether VR provides a credible alternative to traditional pulmonary rehabilitation. Thematic analysis revealed nine themes illustrating the benefits associated with PR in VR compared with traditional methods.

Conclusions

The patients demonstrated significant improvements in physical ability and psychological well-being because of their consistency with exercises, thus improving their HRQoL. These findings are consistent with both the quantitative results of this study and previous research investigating the benefits of VR for other chronic diseases [17,64,69-71,73,74,78] and provide evidence specific to patients with COPD. Owing to its remote accessibility, PR in VR provides a solution to overcome the associated barriers of attending traditional rehabilitation classes (ie, transport and travel, fatigue, motivation, inconvenience, burden of illness, disruption caused to daily activities, low awareness of rehabilitation, and knowledge of and disbelief in the beneficial outcomes of the rehabilitation) [12-15]. Indeed,

patients feel secure and confident enough to exercise without face-to-face supervision as health practitioners can remotely monitor their physiological performance data when using PR in VR. Pulmonary rehabilitation is delivered to a low proportion of the population despite its demonstrated benefits for patients with COPD [8]. However, PR in VR can be deployed at scale, which provides a solution to the recurring issue of too long a waiting list for rehabilitation classes [10] and allows health practitioners to measure patient performance in real-time. Overall, this study demonstrates how remotely supervised VR-based pulmonary rehabilitation can help to overcome current issues and limitations associated with providing this service to patients with COPD at scale. Compared with previous methods, VR could provide a more cost-effective solution for the health treatment to deliver pulmonary rehabilitation to a vast majority of this patient group nationwide.

Contribution, Implications, and Future Research

Key Contributions

Previous studies have investigated the benefits of using VR for rehabilitation for long-term conditions [17,18,89]. However, its benefits for self-managed and remotely supervised pulmonary rehabilitation remain unexplored, and to the best of the researchers' knowledge, this study is one of the first to provide empirical evidence using qualitative data that are further supported by quantitative results. Therefore, this study contributes important findings demonstrating that PR in VR represents an effective form of self-managed and remotely supervised pulmonary rehabilitation that can be delivered at scale. Overall, this study provides a significant contribution to health care research investigating the benefits of implementing digital technologies to improve rehabilitation, with particular contribution to pulmonary rehabilitation research. Moreover, this study provides important practical implications for the health care industry and medical practitioners on the benefits of VR for pulmonary rehabilitation. PR in VR is an innovative app distinct from previous self-managed rehabilitation methods as it allows health practitioners to supervise patients with COPD

remotely and at scale and to immediately measure patient performance. This investigation offers proof of concept that PR in VR intervention can be used for elderly patients with COPD. With evidence, this alternative intervention platform provides an interactive and visually stimulating approach for use in clinical treatment and could provide pulmonary rehabilitation to patients with COPD who cannot easily access traditional rehabilitation methods.

Possible Future Research

This study has several limitations that could be mitigated by further research. The first limitation pertains to the limited

sample size; however, this is common in other exploratory studies investigating VR for rehabilitation [18,89]. This study employed 10 patients with COPD, aged between 63 and 75 years, from the United Kingdom. Although small sample sizes can provide important initial inferences about a topic, they can provide few firm conclusions [21]. However, as this is the first study investigating VR for pulmonary rehabilitation, a small sample size offers promising pilot data as a first phase trial. Furthermore, COPD in the United Kingdom is common among people aged ≥ 40 years [90]; therefore, it is important that future studies employ a larger sample covering the majority of the respective age groups.

Abstract

Background: Mobile technology has an impact on the health care sector, also within dietetics. Mobile health (mHealth) apps may be used for dietary assessment and self-monitoring, allowing for real-time reporting of food intakes. Changing eating behaviors is quite challenging, and patients undergoing hemodialysis, particularly, struggle to meet the target intakes set by dietary guidelines. Usage of mobile apps that are developed in a person-centered approach and in line with recommendations may support both patients and health care practitioners.

Objective: This study is a pilot that aims at estimating the potential efficacy of a dietary intervention using a theory-based, person-centered smartphone app. Results will be used to improve both the app and a planned large-scale trial intended to assess app efficacy thoroughly.

Methods: A prospective pilot study was performed at the hemodialysis unit of Al Qassimi Hospital (The Emirate of Sharjah). All patients that fulfilled the study inclusion criteria were considered eligible to be enrolled in the pilot study. Upon successful installation of the app, users met with a dietitian once a week. Outcomes were measured at baseline (T0) and 2 weeks post app usage (T1). This pilot is reported as per guidelines for nonrandomized pilot and feasibility studies and in line with the CONSORT 2010 checklist for reporting pilot or feasibility trials.

Results: A total of 23 patients completed the pilot intervention. Mean energy intakes increased from 24.4 kcal/kg/day (SD 8.0) to 29.1 kcal/kg/day (SD 7.8) with a medium effect size ($d=0.6$, 95% CI 0.0-1.2). Mean protein intakes increased from 0.9 g/kg/day (SD 0.3) to 1.3 g/kg/day (SD 0.5) with a large effect size ($d=1.0$, 95% CI 0.4-1.6); mean intake of high biological value (%HBV) proteins also increased from 58.6% (SD 10.1) to 70.1% (SD 10.7) with a large effect size ($d=1.1$, 95% CI 0.5-1.7). Dietary intakes of minerals did not change, apart from sodium which decreased from a mean intake of 2218.8 mg/day (SD 631.6) to 1895.3 mg/day (SD 581.0) with a medium effect size ($d=0.5$, 95% CI 0.1-1.1). Mean serum phosphorus, potassium, and albumin levels did not change relevantly. Mean serum iron increased from 7.9 mg/dL (SD 2.8) to 11.5 mg/dL (SD 7.9) postintervention with a medium effect size ($d=0.6$, 95% CI 0.0-1.2).

Conclusions: This pilot study showed that the KELA.AE app has the potential to improve dietary intakes. Processes related to procedure, resources, tools, and app improvement for a future trial were assessed. A more extended intervention using a randomized controlled trial is required to estimate parameters concerning app efficacy accurately.

KEYWORDS

mHealth; dietary app; hemodialysis diet

Introduction

Mobile technology has the potential to improve health care coverage, especially in low- to middle-income countries where people may be more likely to have access to a smartphone than to basic needs such as safe water and electricity [1]. Self-tracking and wearable technologies have become popular, particularly in the areas of diet and fitness [2]. Previous research on mobile health (mHealth) interventions provides evidence regarding their effectiveness [3-5]. However, their role as educational tools or as supportive tools to standard care remains inconclusive [3,6].

Mobile technology may assist in the introduction of new methods of dietary assessment and self-monitoring, allowing for real-time reporting of food intakes [7]. Self-monitoring is an important factor in successful dietary behavior changes [8]. In a previous study on a weight loss intervention, the more participants recorded food intakes on a mobile app, the more likely they were to lose weight [9]. However, patients may not always be interested and willing to track intakes [10], and commitment to self-monitoring decreases over time, even with the use of mobile technology [11].

Changing eating behaviors is difficult [12], and adherence to guidelines is challenging, especially for patients with chronic conditions such as chronic kidney disease (CKD) [13]. In particular, patients undergoing hemodialysis struggle to meet the target intakes set by dietary guidelines [14]. The diet during hemodialysis is somewhat restrictive, requiring the management of potassium, phosphorus, sodium, and fluids while maintaining adequate protein and energy intakes to prevent malnutrition [15]. In a recent study assessing adherence to diet guidelines among patients undergoing hemodialysis, 77% and 50% of the patients, respectively, consumed less energy and proteins than recommended. These low intakes could be attributed to the restrictive nature of the dialysis diet. In the same study, participants were also found to consume excessive saturated fats and inadequate intakes of fibers and micronutrients [14]. Maintaining adequate intake of minerals such as potassium, phosphorus, and calcium is essential in the prevention of dialysis-related complications such as heart failure, metabolic bone disorders, and mortality [16,17]. Protein-energy malnutrition is also a contributor to complications, and malnutrition among patients undergoing dialysis is a predictor of mortality [18]. Accordingly, it seems that the diet quality of these patients is often poor and that they do not follow dialysis-specific guidelines [14,19].

The main challenge in changing dietary behavior is developing interventions that are comprehensive and sustainable, promoting

long-term changes in eating habits and lifestyle [12]. There is a need for nephrologists and dietitians to adopt approaches that strengthen educational and clinical interventions [14]. Possibly, mobile technology could be used to enhance dietetic practice by providing support to patients and dietitians. Thus, adding mobile apps to in-person counseling may provide more accessible and flexible dietetic services at lower costs [20]. However, research on the role of mHealth in dietary behavior in patients undergoing hemodialysis is still scarce [21].

This is a pilot study that aims at estimating the potential of a dietary intervention using a smartphone app in patients undergoing hemodialysis. The results from this pilot study will be used to improve the app itself as well as the study design of the planned randomized controlled trial.

Methods**Participants**

All patients at the hemodialysis unit of Al Qassimi Hospital (The Emirate of Sharjah) who fulfilled the study inclusion criteria were considered eligible to be enrolled in the pilot study. Inclusion criteria were patients undergoing hemodialysis for at least three months; free of life-threatening conditions; able to read, write, listen, and communicate; owning an Android smartphone; and not having been hospitalized in the past 6 months. All patients approached who accepted to enroll in the study signed written consent forms. A total of 26 participants were enrolled in the pilot, of which 23 downloaded and used the app for 2 weeks. Data were collected between February 2019 and April 2019. Post-hoc calculations of sample size in pilot studies, assuming detection of unanticipated problems with a probability of at least 15% ($\pi=0.15$) and a 95% confidence level, resulted in a required sample of 19 patients [22].

KELA.AE App

KELA.AE (Kidney Education for Lifestyle Application) is an Arabic, culturally specific, educational, and self-monitoring app that was developed in a person-centered, theory-based approach. Educational materials were developed based on the transtheoretical model [23] and constructs of the reasoned action approach [24]. Included educational materials are podcasts, videos, notifications, and recipes. The app also provides self-monitoring features that allow patients to track food intakes and blood parameters. The app was developed following the IDEAS (integrate, design, assess, and share) framework [25]; a detailed description of the app development is described elsewhere [10]. Figure 1 depicts screenshots from the app.

Figure 1. Screenshots of the KELA.AE app used during the pilot study.

Procedure

This pilot is reported as per guidelines for nonrandomized pilot and feasibility studies [26] and in line with the CONSORT 2010 checklist for reporting a pilot or feasibility trial (items pertinent to randomization were considered not applicable) [27]. Ethical approval was received from the Institutional Review Board of Zayed University, Dubai (Ethical Approval number ZU17_066_F).

Participants who consented to enroll in the pilot study downloaded the app and were provided with usernames that allowed them to sign-in to the app. Upon successful installation of the app, users met with a dietitian once a week (two times in total); the dietitians responded to concerns pertinent to app usage, as well as questions about the renal diet by reinforcing the critical messages relayed by the educational materials. The dietitians also collected the data from patients before and after app usage. All outcomes were measured before (T0) and after 2 weeks (T1) of app usage.

Dietary Intakes

Face-to-face 24-hour recalls were collected [28] at T0 and T1 for all participants; nutrient compositions were derived for energy, carbohydrates, proteins, high biological value (%HBV) proteins, total fat, potassium, phosphorus, and sodium. Intakes were then compared with dietary guidelines for patients undergoing hemodialysis [15,29]. Protein targets were considered as 1.2 g/kg or more with 50% or higher HBV protein; energy as 30-35 kcal/kg; phosphorus as 1000 mg/day for participants with serum phosphorus below 5.5 mg/day and 12 mg/g of protein intake for participants with serum phosphorus below 5.5 mg/dL. Sodium and potassium targets were considered less than 2400 mg/day [15,29]. Standard body weight from the National Health and Nutrition Examination Study was used for calculations; however, adjusted edema-free body weight was used for calculating nutrient needs for individuals with less than 95% or greater than 115% of standard body weight [29]. Textbox 1 illustrates the dietary guidelines that were used as targets and that are also included in the adherence index.

Textbox 1. Dietary guidelines for patients undergoing hemodialysis used for adherence index [15,29]. HBV: high biological value, PTH: parathyroid hormone, aBW_{ef}: adjusted edema-free body weight, SBW: standard body weight, BW_{ef}: edema-free body weight.

1. Protein ≥ 1.2 g/kg of body weight, $\geq 50\%$ HBV protein
2. Energy for those < 60 years of age: kilogram (kg) of body weight $\times 35$ kcal; > 60 years of age: kilogram (kg) of bodyweight $\times 30$ kcal/kg to 35 kcal/kg
3. Sodium less than 2.4 g/day
4. Potassium less than 2.4 g/day
5. Phosphorus 800 mg/day to 1000 mg/day or 10-12 mg phosphorus/g of protein when serum phosphorus > 5.5 mg/dL or intact PTH is elevated
6. aBW_{ef} is recommended for calculating nutrient needs for individuals with $< 95\%$ or $> 115\%$ of SBW using the formula $aBW_{ef} \text{ (kg)} = BW_{ef} + [(SBW - BW_{ef}) \times 0.25]$. SBW from the National Health and Nutrition Examination Study is used otherwise

Biochemical Parameters

Serum phosphorus, potassium, and iron were retrieved from the patients' medical records. These biochemical parameters were measured as part of the routine tests performed in the hemodialysis unit. All tests were conducted postdialysis (in sessions). Comparative standards for serum potassium were

considered between 3.5 and 5.5 mEq/L; and between 3.5 and 5.5 mg/dL for phosphorus [15,29].

Statistical Analysis

The Shapiro–Wilk normality test was performed to ensure that data are normally distributed. Cohen *d* effect sizes and confidence intervals (95%) were derived from means and pooled

standard deviations. The effect size was considered small at 0.2, medium at 0.5, and large at 0.8 and above [30]. Effect sizes were calculated to understand the magnitude of the reported effects along with the probability by means of *P* values [31]. Paired *t* tests were performed to compare the mean scores before and after the intervention. Two-tailed *P* values are reported. Frequencies and percentages were used to describe categorical variables, whereas means and standard deviations were used for continuous variables. Statistical software IBM SPSS Statistics 21 Data Editor was used to perform all statistical analyses.

Results

Participant Eligibility and Baseline Characteristics

Of the 149 patients at the hemodialysis unit, 26 were eligible, of which 23 downloaded the app and completed the study. Participants that were not eligible were mainly those who did not own a smartphone or who owned a smartphone with an iOS operating system; 2 participants did not download the app due to limitations in phone storage, and 1 was not interested in downloading the app. Figure 2 depicts the CONSORT flow diagram. The sample's mean age (years) was 48.5 (SD 13.7), and mean BMI (kg/m^2) was 31.9 (SD 7.9); participants had been on dialysis for a mean of 29.7 (SD 37.3) months. More than half of the participants were males ($n=14$), and more than half suffered from hypertension or diabetes or both. Demographic data are detailed in Table 1.

Figure 2. CONSORT study flow diagram.

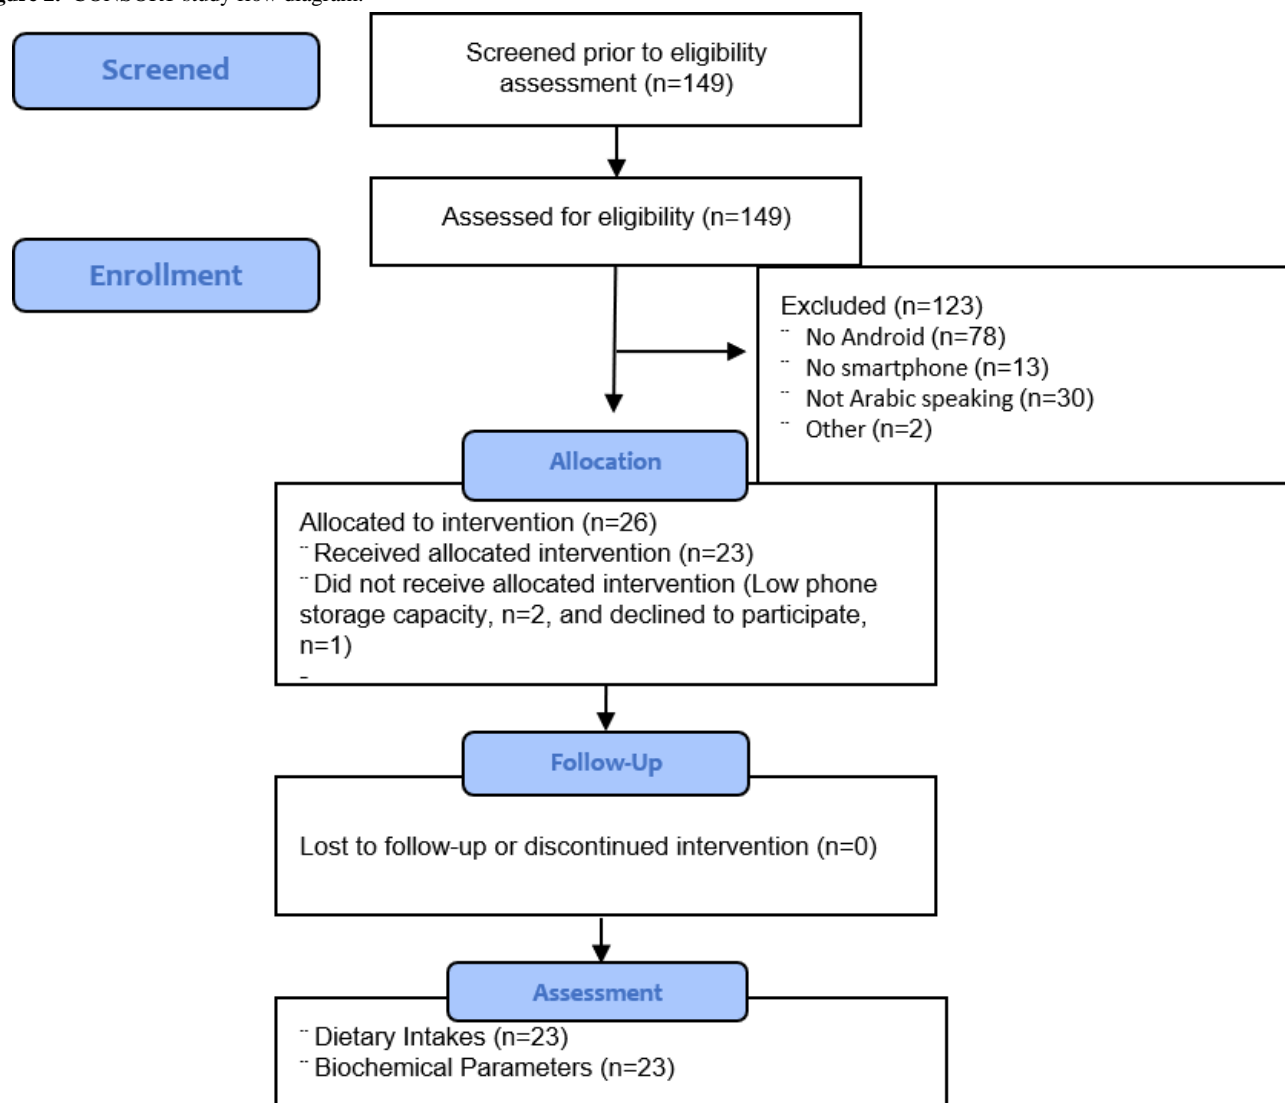

Table 1. Demographic and baseline characteristics of the sample (N=23).

Characteristics	Value
Age, mean (SD)	48.5 (13.7)
BMI, mean (SD)	31.9 (7.9)
Months on dialysis, mean (SD)	29.7 (37.3)
Gender, n (%)	
Male	14 (61)
Smokers, n (%)	6 (26)
Comorbidities, n (%)	
Hypertension	16 (70)
Diabetes	11 (48)
Dyslipidemia	2 (9)
Cancer	1 (4)
Liver disease	1 (4)

Anthropometry and Dietary Intakes

There was no change in weight and BMI postintervention; however, mean dietary intakes changed mainly for energy and macronutrients. Mean energy intakes increased from 24.4 kcal/kg/day (SD 8.0) to 29.1 kcal/kg/day (SD 7.8) with a medium effect size ($d=0.6$, 95% CI 0.0-1.2). Mean protein intakes increased from 0.9 g/kg/day (SD 0.3) to 1.3 g/kg/day (SD 0.5) with a large effect size ($d=1.0$, 95% CI 0.4-1.6); mean intake of HBV protein (%) also increased from 58.6% (SD 10.1) to 70.1% (SD 10.7) with a large effect size ($d=1.1$, 95% CI 0.5-1.7). Total fat intakes increased from baseline with medium

effect size ($d=0.5$, 95% CI 0.0-1.1). Dietary intakes of minerals did not change, apart from sodium which decreased from a mean intake of 2218.8 mg/day (SD 631.6) to 1895.3 mg/day (SD 581.0) with a medium effect size ($d=0.5$, 95% CI 0.1-1.1).

Biochemical Parameters

Serum phosphorus, potassium, and albumin did not change relevantly. Mean serum iron increased from 7.9 mg/dL (SD 2.8) to 11.5 mg/dL (SD 7.9) postintervention with a medium effect size ($d=0.6$, 95% CI 0.0-1.2). [Table 2](#) details the results of the anthropometry, dietary intakes, and blood parameters.

Table 2. Dietary intakes and laboratory data at baseline and postintervention.

Dietary intakes and laboratory data	Baseline (T0), mean (SD)	Postintervention (T1), mean (SD)	Cohen <i>d</i> (95% CI)	<i>P</i> value
Weight (kg)	85.5 (23.1)	84.1 (24.1)	0.1 (–0.5 to 0.6)	.37
BMI (kg/m ²)	31.9 (7.9)	31.3 (8.5)	0.1 (–0.5 to 0.6)	.39
Energy intake (kcal/day)	1918.3 (570.4)	2206.2 (378.2)	0.6 (0.0 to 1.2)	.003*
Energy intake (kcal/kg/day)	24.4 (8.0)	29.1 (7.8)	0.6 (0.0 to 1.2)	.002*

**P*<.05.^aHBV: high biological value.^bCHO: carbohydrates.

Adherence to Dietary Guidelines in Hemodialysis

Adherence to dietary guidelines in hemodialysis improved for energy intakes, protein intakes, and %HBV proteins with medium to large sizes, respectively ($d=0.4$, 95% CI 0.2–1.0 for energy; $d=0.9$, CI 0.3, 1.5 for proteins; $d=1.1$, 95% CI 0.5–1.7 for %HBV proteins). Adherence to fat, potassium, and phosphorus intakes did not change, whereas adherence to sodium further dropped to achieve intakes below 2400 mg/day with a

medium effect size ($d=0.5$, CI 0.1–1.1). The number of patients adhering to dietary guidelines increased for energy, proteins, and sodium, whereas a larger number of patients became nonadherent to fat and phosphorus intakes. There was no relevant change in the number of patients concerning adherence to potassium intakes. Table 3 describes the difference between the recommended intakes and dietary intakes before and after the intervention. Figure 3 details the results of percent compliance to dietary recommendations.

Table 3. Adherence to dietary intakes reported as the difference between intake and recommendation at baseline and postintervention.

Dietary intakes	Baseline, mean (SD)	Postintervention, mean (SD)	Cohen <i>d</i> (95% CI)	<i>P</i> value
Energy (kcal/day)	–903.1 (705.4)	–581.3 (779.8)	0.4 (0.2 to 1.0)	.004*
Dietary protein (g/day)	–27.3 (26.6)	+6.5 (43.9)	0.9 (0.3 to 1.5)	<.001*
HBV proteins ^a (%)	58.6 (10.1)	70.1 (10.7)	1.1 (0.5 to 1.7)	<.001*
Total dietary fat (% energy)	41.0 (7.6)	41.9 (7.3)	0.1 (–0.7 to 0.4)	.66
Dietary potassium (mg/day)	–568.1 (728.4)	–353.9 (555.1)	0.3 (–0.9 to 0.2)	.19
Dietary phosphorus (mg/day)	+84.7 (445.8)	250.3 (369.9)	0.4 (–0.9 to 0.2)	.14
Dietary sodium (mg/day)	–181.1 (631.6)	–504.6 (581.0)	0.5 (0.1 to 1.1)	.03*

^aHBV: high biological value.

Figure 3. Percent (%) adherence to dietary intakes pre- and post-intervention. Values are presented as mean (SD).

User Acceptability and App Usability

A user acceptability tool was used during this pilot; however, all participants responded to all questions with a *strongly agree* option based on a Likert scale. Accordingly, the results were not considered useful to understand better the acceptability and, therefore, have not been reported. Assessment of acceptability will be reassessed in the future trial. The validated end-user version of the Mobile App Rating Scale (uMARS) [32] will be used in the trial. Participants may not have well understood that the questionnaire aims to improve the app; thus, qualitative data will also be collected to ask specific questions about the KELA.AE usability and acceptability by referring to each feature in the app individually. Qualitative data will also address the culturally specific features of the app such as language and recipes.

Field notes revealed that all 23 participants attended the weekly sessions with the dietitians. Usage data available from analytics were only able to provide the last date of access for each participant, and all 23 had accessed the app in the last week of the trial. No data on usage frequency could be retrieved due to a lack of in-app analytics.

Discussion

Principal Results

Potential Efficacy

In this study, short-term app usage had a potential impact on energy and protein intakes among patients undergoing hemodialysis. In comparison to the target dietary guidelines for hemodialysis, patients started with a baseline intake of energy

and proteins below recommendations. As an outcome of the intervention, mean energy intakes reached 29.1 kcal/kg/day (SD 7.8) as compared with the recommended 30-35 kcal/kg/day. In addition, protein intakes were also considerably low as compared with guidelines (mean consumption at baseline of 0.9 g/kg/day [SD 0.3]) and improved to become in line with the recommended 1.2 g/kg or more of body weight and 50% or higher HBV protein [15,29].

No changes were observed in intakes of minerals; nonetheless, baseline intakes of potassium and sodium were already within the recommendations of less than 2400 mg/day. Mean sodium intakes further dropped to 1895.3 mg/day (SD 581.0). Fat and phosphorus intakes, however, were already elevated at baselines and remained above recommendations after the intervention.

No changes were observed in the serum laboratory parameters for potassium and phosphorus; levels remained within recommendation at baseline and after the intervention. The duration of the intervention is not long enough to detect relevant changes in serum values; accordingly, the upcoming trial is expected to capture the effect of app usage on laboratory parameters better. Mean serum iron increased with a medium effect size from 7.9 mg/dL (SD 2.8) to 11.5 mg/dL postintervention. The latter may be explained by the increase in the dietary protein of HBV, which mainly consists of animal protein sources.

Study and App Feasibility

Research methodology, resources, and tools used in this pilot were assessed to refine and modify the planned trial and improve the app. The feasibility of the processes related to recruitment, retention, and refusal seemed adequate; there were no patients

that withdrew from the study; and all eligible patients agreed to participate. However, the number of eligible patients were about 17.4% (26/149) out of all patients undergoing dialysis at the unit. It would mean that to achieve an appropriate sample size for the planned randomized trial, many dialysis units will need to be recruited. Thus, the number of dietitians needed to be involved in the future study will need adequate resources to meet patients weekly, as it was the case in this study. Accordingly, an assessment of resource allocation should be performed to consider app improvement and development on iOS mobile operating system to increase eligible patients within the same dialysis unit.

Digital interventions may be used as tools to support a reciprocal relationship between patients and health care practitioners and enhance patient-centered care [33]. Accordingly, dietitians would be expected to manage and recommend the usage of KELA.AE app in real practice settings. Thus, the future trial will include dietitians following up with patients to simulate app integration in real practice.

In-app analytics are also essential for the future trial to assess the effect of app usage on outcomes. In-app analytics should track usage frequency as well as the usage of each feature separately. The results would help to better understand if educational or self-monitoring features of the app are preferred by the user.

The future trial should further analyze the fatty acid profile (saturated, monounsaturated, and polyunsaturated) on top of total fats to assess diet quality from an atherogenic point of view. In addition, further assessment of the nutritional status of patients undergoing dialysis should be performed to identify patients with malnourishment that may need additional support from the research dietitians.

The KELA.AE app will be re-evaluated to include educational materials addressing diet quality pertinent to dietary fatty acid profiles to promote dietary intakes in line with the KDOQI Clinical Practice Guidelines for the Management of Dyslipidemias in Patients With Kidney Disease [34]. This is an update to be considered in the next version of the app should dietary fat intakes not be in line with guidelines.

This pilot study has demonstrated that it is feasible to integrate a dietary app into dietetic practice, allowing it to be a tool in addition to regular meetings with dietitians. The study has also identified how to adjust the design, procedures, data collection tools, and outcome measurements for a future trial. Based on the information collected, we feel ready to proceed to a larger randomized controlled trial.

Comparison With Prior Work

Energy and protein recommendations in hemodialysis are higher than the recommendations for healthy individuals. Whereas in the general population, intakes of 0.8 g/kg are adequate to maintain nitrogen balance [35], such intakes are inadequate in hemodialysis [36]. Hemodialysis sessions cause losses in proteins and amino acids that need to be replenished by the diet [36]. Protein-energy wasting is dangerous and has been correlated with mortality, adverse clinical outcomes [37], and poor quality of life [18]. Both Inadequate dietary proteins and

energy intakes are criteria used in the diagnosis of protein-energy wasting in patients undergoing hemodialysis [38]. Similar to the findings in this pilot, many studies have identified inadequate energy and protein intakes among patients undergoing dialysis [14,39,40]. This pilot intervention seems to show potential in the improvement of energy and protein intakes among this population.

However, multiple dietary components need to be adjusted to improve the clinical outcomes of these patients, and the latter includes management of potassium and phosphorus, along with a diet quality that is cardioprotective [15]. In the sample studied in this pilot, both serum potassium levels and potassium intakes were within targets before and after the intervention. This was also observed by others [14,19], whereby similar to our findings, patients undergoing hemodialysis tend to be adherent to potassium intakes and laboratory targets. However, serum phosphorus and phosphorus intakes were borderline high both before and after the intervention. This is also a common finding in this population, in which the discrepancies between the phosphorus and protein recommendations [15] make it challenging to achieve the required targets. Accordingly, it seems that further assessment of the factors that may influence phosphorus management, such as food sources of phosphorus and compliance to phosphate binders, should be explored. In addition, it is expected that a longer intervention that includes education and follow-up with dietitians may lead to better outcomes.

Total fat intakes were also found to be elevated by our pilot study, and their intakes remained elevated after the intervention as well. Others have previously explored the diet quality of patients undergoing hemodialysis as compared with the recommendations of the American Heart Association and KDOQI Clinical Practice Guidelines for Management of Dyslipidemias in Patients With Kidney Disease [34], and found the current diet intakes to be proatherogenic in nature [14]. Given that protein intakes increased and that their sources are mainly from animal proteins (an increase in %HBV proteins were also observed), it can be predicted that saturated fat intakes also increased as a result of these changes.

There are only few available apps that target patients with CKD specifically; however, most of them are available on app stores, and information on their efficacy and usability are rather scarce [41]. A recent content analysis of mobile apps for CKD revealed that available apps fail to provide the continuity of patient-centered care that is needed to support patients with CKD [42].

Limitations

Given the pilot nature of the study, some limitations may lead to a bias in the interpretation of the results and their generalizability. The duration of this study was short; therefore, its effects are only focused on dietary intakes and laboratory parameters. Behavioral interventions need to be of longer duration and should be comprehensive to change dietary intakes [43]. The results of this pilot will instead be used to improve the app and modify the study procedures in the future trial.

In addition, the results identified a possible improvement in nutritional status and a potentially proatherogenic diet quality among the study's sample. Thus, the future trial should assess the prevalence of patients with malnourishment along with the fatty acid profile of the diet in line with the KDOQI Clinical Practice Guidelines for Management of Dyslipidemias in Patients With Kidney Disease [34].

The intervention included face-to-face sessions with dietitians that may have influenced the outcomes. The reinforcement of the dietitians and their availability may have impacted the results similarly or more than the app itself. Accordingly, the future trial should include a control group whereby dietitians see patients with the same frequency but without app usage.

Given that app analytics were not available, we were unable to track how many times the users accessed the app. The only available data are the last access for each user, and all users had accessed the app during the last week.

Conclusions

This pilot study showed that KELA.AE app has the potential to improve dietary intakes. Processes related to the procedures, resources, tools, and app improvement for a future trial were assessed. A more extended intervention using a randomized controlled trial is required to estimate parameters concerning app efficacy accurately.

Acknowledgments

We acknowledge the staff and students from Zayed University who volunteered by contributing to the app development at many steps. A research grant by Zayed University, Dubai, funded the study (Grant No. R18060).

Abstract

Background: Most commercial activity trackers are developed as consumer devices and not as clinical devices. The aim is to monitor and motivate sport activities, healthy living, and similar wellness purposes, and the devices are not designed to support care management in a clinical context. There are great expectations for using wearable sensor devices in health care settings, and the separate realms of wellness tracking and disease self-monitoring are increasingly becoming blurred. However, patients' experiences with activity tracking technologies designed for use outside the clinical context have received little academic attention.

Objective: This study aimed to contribute to understanding how patients with a chronic disease experience activity data from consumer self-tracking devices related to self-care and their chronic illness. Our research question was: "How do patients with heart disease experience activity data in relation to self-care and chronic illness?"

Methods: We conducted a qualitative interview study with patients with chronic heart disease (n=27) who had an implanted cardioverter-defibrillator. Patients were invited to wear a FitBit Alta HR wearable activity tracker for 3-12 months and provide their perspectives on their experiences with step, sleep, and heart rate data. The average age was 57.2 years (25 men and 2 women), and patients used the tracker for 4-49 weeks (mean 26.1 weeks). Semistructured interviews (n=66) were conducted with patients 2-3 times and were analyzed iteratively in workshops using thematic analysis and abductive reasoning logic.

Results: Of the 27 patients, 18 related the heart rate, sleep, and step count data directly to their heart disease. Wearable activity trackers actualized patients' experiences across 3 dimensions with a spectrum of contrasting experiences: (1) knowing, which spanned gaining insight and evoking doubts; (2) feeling, which spanned being reassured and becoming anxious; and (3) evaluating, which spanned promoting improvements and exposing failure.

Conclusions: Patients' experiences could reside more on one end of the spectrum, could reside across all 3 dimensions, or could combine contrasting positions and even move across the spectrum over time. Activity data from wearable devices may be a resource for self-care; however, the data may simultaneously constrain and create uncertainty, fear, and anxiety. By showing how patients experience self-tracking data across dimensions of knowing, feeling, and evaluating, we point toward the richness and complexity of these data experiences in the context of chronic illness and self-care.

Introduction

Consumer Wearable Activity Trackers in Chronic Care

Consumer health information technologies such as wearable activity trackers are increasingly being considered to improve chronic care management [1-4]. Contrary to traditional health information technologies, these devices are developed as consumer devices and not as clinical devices. Most commercial activity trackers aim to monitor and motivate sport activities, healthy living, and similar wellness purposes. Wristbands such as Fitbit and smart watches that track bodily signs (eg, heart rate) do not provide diagnostic services or disorder-specific information, and they are regulated less rigorously than are monitoring devices aimed at specific patient groups and clinical measures. This makes them readily available to consumers. Moreover, their designs aim at easy and noninvasive integration into everyday life, by way of automated tracking. These features are attractive for application in chronic disease management, where a healthy lifestyle can be a central part of treatment, rehabilitation, and prevention [1,5-8].

The separate realms of “wellness tracking” and “disease self-monitoring” and “activity data” and “medical data” are thus blurred, which is somewhat mirrored in an increasing prominence of concepts such as “patient-generated health data” and “personal health technology” where the focus is on the individual producer of data, rather than on the specific context or purpose of use. Applying leisure activity tracking to chronic care management provides new opportunities but is often based on assumptions about what characterizes these devices: easy, applicable, user-friendly, empowering, and motivating technology that can collect data with relevance for self-care and treatment. While there are great expectations and promising results emerging [2,3,9], little attention has been paid to the embodied and embedded experiences of self-tracking among patients with a chronic disease using consumer devices, which are not integrated in the health care system.

In this paper, we explored how patients who use consumer wearable devices make sense of them and of the data they produce and display vis-à-vis their embodied disorders. We recruited 27 patients with chronic heart disease who had an implantable cardioverter-defibrillator (ICD) to wear a Fitbit wearable tracker to understand the experiential qualities of how they relate self-tracking and activity data to their disease to explore the question: How do the embodied experiences and self-care practices of dealing with a specific health condition respond to the introduction of activity trackers?

Background and Significance: Experiences with Self-Monitoring in Health Care and Leisure Contexts

The existing literature of experiences with self-tracking comprises two related fields: (1) rich literature on how patients, as part of their prescribed treatment, engage in and make sense of clinically validated data related to self-care for chronic illnesses and (2) emerging literature that primarily explores users' experiences with leisurely oriented self-tracking technologies that are outside of the health care system. Patients'

experiences with consumer activity-tracking technologies designed for use outside the clinical context have received scant academic attention. There is an important research gap in understanding the relation between the rich human-information interaction and the contexts of activity tracking such as self-care [1,10]. Consequently, studies that explore the experiences of people coping with illnesses — while recognizing the specific ramifications that self-tracking might have for those who have severe health problems — are necessary.

Self-Care and Chronic Illness in eHealth

Many patients routinely engage with data from digital devices that are part of the prescribed treatment. These clinically integrated data-producing devices affect self-care activities as they enable managing symptoms, taking medicine, dealing with the emotional impact, and tackling lifestyle changes [11-13]. Fostering self-care has been a central ambition of much telecare and electronic health (eHealth) development during the last 20 years. Early telecare technologies were typically designed from a clinical standpoint with measures to support remote decision making such as blood glucose tracking in diabetes [14,15], oxygen saturation, pulse rate and respiration rate tracking in chronic obstructive pulmonary disease [16], and heart arrhythmia detection through remote monitoring of cardiac implantable electronic devices such as pacemakers and ICDs [17]. In recent years, a more participatory agenda frames eHealth innovation, aiming to enhance independence and enable patients to become more active participants in managing their own disorder (eg, through use of wearable activity trackers) [18,19].

While much research has focused on measurable outcomes of digital self-tracking and self-management on clinical parameters, emergent studies have also explored the experiential qualities of patients' “data work” [20-22]. Central to such data work, along with the experiential qualities of patients engaging with self-tracking data in chronic care management, are the affective aspects. It is known that self-monitoring of blood glucose data by patients with diabetes and their caretakers is tightly bound to an emotional struggle ranging between control and freedom, peace of mind and anxiety, and empowerment and the burden of managing technology [23]. Similarly, it is found that self-tracking data in fertility self-monitoring promotes the achievement of certain positive goals but may accentuate negative emotions such as feeling burdened or abandoned [24]. Others have studied patient experiences in heart arrhythmia telemonitoring and found that not having access to data or feedback from clinicians has an emotional and life-changing impact, which in turn creates doubt, guilt, and concern [25].

Self-Tracking and Activity Data

While clinically validated self-monitoring technologies have become the standard in chronic care, the rise of low-cost sensors has accelerated the consumer market, making wearable activity trackers and mobile data-logging applications a widespread commodity. Large corporations like FitBit and Apple are entering the medical domain with consumer wearable devices, most prominent through automated activity measures like step count [1,26] to support disease monitoring and rehabilitation of cardiac, pulmonary, and cancer patients [8,27-29], among

others, and most recently, through large-scale interventions using the Apple Watch for screening of atrial fibrillation.

Literature on the so-called Quantified Self over the past decade has explored users' (ie, self-trackers) experiences with these technologies and the data they produce when applied voluntarily for leisure or wellness activities [30-34]. Lomborg and Frandsen [35] showed that, while self-tracking is often depicted as an entirely individual endeavor to retrieve calculable, reliable knowledge, it is experienced by users as a deeply communicative activity, with an often playful and pleasurable quality to it.

In their exploration of self-tracking cycling, Lupton et al [36] presented the concept of "data sense" to describe how people's experience with data from sensors is not just a matter of cognitive "knowing" — as often assumed in data literacy approaches — but equally involves sensory and affective dimensions such as alerting cyclists to new bodily sensations while possibly invoking feelings of frustration or even embarrassment. Thus, what emerges are accounts of self-tracking experiences as complex encounters between the metric and sensuous, between knowing and feeling. This, in turn, suggests that self-tracking, while often a purposeful and systematic practice, is not necessarily guided by goals of improving the self, forming new and healthier habits, or getting to know oneself better, as suggested by many of the wellness technologies currently entering the market [37].

The critical question is then: what happens when technologies, practices, and data from the consumer market for self-tracking are introduced in the context of chronic self-care? What kinds of experiences do they offer in a setting where self-tracking is "pushed" [38] to patient-consumers who live with a chronic disorder?

Several studies have examined patients' experiences with wearable activity trackers, and the focus tends to be on patient acceptability and feasibility among the elderly [39-41] and in the chronic care context [1,5-8,28]. Some support positive outcomes like ease-of-use and willingness among patients to wear activity trackers and integrating them into clinical care [5,28]. Rosenberg et al [28] conducted a 3-week study examining the acceptability of the Fitbit Zip and attitudes towards integrating fitness tracking into clinical care among men with prostate cancer. All participants were willing to wear the device and endorsed its value in ensuring they engaged in a "minimal amount of activity." However, several barriers to use were found, including health-related limitations (like pain and injuries making it difficult to walk) and practical or technical problems with syncing devices and experiencing data inaccuracies (eg, not capturing the activities).

Other studies present negative aspects and challenges with integrating patient-generated data in clinical settings [6,7]. Zhu et al [6] found technical challenges (such as security and privacy issues and the practical work of clinicians transferring self-tracking data to the electronic medical record), social challenges (such as health professionals adapting to new forms of care where patients are collaborative partners), and organizational challenges (like organizational policies and workflows that do not include attending to patient-self tracking data). Ancker et al [7] conducted an interview study to explore

self-tracking among patients with multiple chronic conditions. They found that patients associated several negative experiences with self-tracking and self-tracking data can negatively influence the patient-clinician relationship owing to a lack of trust in the data. For these patients, self-tracking thus became burdensome, which contrasts the pleasurable and playful experiences promoted in wellness self-tracking.

Objective

The objective of this study was to understand how patients with chronic heart disease, as opposed to healthy individuals, experience activity data from consumer self-tracking devices when engaging in self-care. With this study, we contribute to the emergent literature on how patients' experiences with consumer wearable activity trackers are related to their illness and their self-care activities and the implications that arise for design and deployment of these devices. There is a need for going beyond acceptability and feasibility studies and conducting more fine-grained analysis of the experiential qualities of interacting with personal health data outside the context of clinical practice among the increasing number of people with chronic illnesses.

Methods

Overview

We conducted a qualitative study to understand how patients with an ICD experience self-tracking of activity data in relation to their embodied condition and daily practices of dealing with a chronic heart condition. As we know from the self-tracking literature, such experiences may change over time [33]. To grasp this, we followed patients over a 49-week period from January 2018 to December 2018, during which we observed their activity tracking data and interviewed them repeatedly (2-3 times each) about their experiences and insights gleaned from the data.

Setting

This study was part of a larger research and development project, SCAUT (Self-, Collaborative- and AUTo-detection of signs and symptoms of deterioration), 2014–2018, which aimed to improve early detection of deterioration and communication among patients with a cardiac device and health professionals. The overall project was carried out at a cardiac device clinic at the Rigshospital, University of Copenhagen, Denmark, which is one of the largest cardiac device remote monitoring centers in Europe, following more than 3500 patients.

Recruitment of Participants

The study comprised a sample of 27 patients with chronic heart disease who had a secondary prevention ICD and were already part of an (R&D project). Secondary prevention ICDs were offered to individuals who survived sudden cardiac arrest or had a history of dangerous and recurrent abnormal heart rhythms, which is relevant for this study due to the chronicity of the disease and related self-care activities. While patients were similar in having an ICD, their underlying cardiac diagnosis, possible comorbidities, and psychosocial situation differed substantially. Participants were recruited through a mix of purposive sampling and self-signup to ensure that patients

were interested and not too ill to participate. Of the 65 ICD patients we invited to participate, 27 ICD patients provided written informed consent to this study, which explored the experiences of activity data as related to being an ICD patient and the data's potential for predictive analytics of dangerous arrhythmias. Of the 27 patients, 25 patients were male (93%), and 2 patients were female (7%); the average age was 57 years. The sample largely reflected the demographic profile of ICD patients in Denmark in 2017, when 18% of patients were female and the majority of procedures were carried out on patients aged 55-74 years [42].

The participants were provided with and instructed to wear a Fitbit Alta HR (Fitbit, San Francisco, CA), which is a wristband activity tracker that can record and visualize heart rate, sleep, and steps onscreen and in a Fitbit mobile app. They were informed that wearing the activity tracker was unrelated to their treatment at the clinic and that our purpose was to explore how they experience the relationship between activity data and their heart disease.

Data Collection: Semi-Structured Interviews

Data were collected with 66 semistructured interviews in 3 overall iterations using 3 interview guides. The first iteration aimed to create a baseline of patients' expectations concerning activity-illness relationships and get a sense of their embodied experience of everyday living with an ICD. The second iteration aimed to understand the initial 2-week experiences with activity tracking using concrete examples from their own tracking data and asking them what they had learned or wondered about when using the Fitbit and looking at the data. The third iteration aimed to understand the longer-term experiences and data-sensing practices and any ambivalences arising from using the Fitbit (4-49 weeks).

Patients were interviewed individually (sometimes with relatives) in their homes or in locations convenient to them (eg, workplace or hospital office space). Each interview lasted between 25 minutes and 1 hour and 40 minutes. During interviews, the interviewers took field notes and pictures of participants showing concrete examples of activity data in the Fitbit mobile app to support the analysis of the data. All interviews were audio-recorded and transcribed either in full or in selected passages.

Data Analysis

The interview transcripts were hand-coded iteratively, following an abductive reasoning logic [43,44], starting with a joint analysis workshop after the second interview with all 27 patients to identify emergent themes regarding data sensing and insights from the data to be followed up in the final interviews. At this stage, field notes and pictures from the interviews offered an interpretive aid, offering contextual guidance for those of us who had not been present at the interview. Upon the final round of interviews, another joint workshop solidified and elaborated the initial insights and ideas against the body of related work, to develop a joint analytical framework and coding protocol.

This framework combined dimensions of data sensing — knowing, feeling, and evaluating the self through data with contextual embedding and experiences of illness in daily chronic living [45] — to clarify how patients with an ICD make sense of Fitbit data relating to their heart disease. Finally, we recoded the complete empirical material manually according to these dimensions, first individually and then together, to ensure reliability in producing a thematically organized analysis of patients' data sensing [46].

Study Approval and Ethical Considerations

This paper was based on a substudy of the SCAUT research and development project, which was approved by the Danish Data Protection Agency and reviewed by the National Board of Health and Danish National Committee on Health Research Ethics (H-19029475). We took several measures to respond to possible ethical concerns. First, we ensured voluntary participation through an open invitation with self-signup, and we emphasized in interviews that participants could opt out at any time. Second, we communicated with all participants between interviews to ensure they were comfortable with wearing the wristband. We made sure that the participants understood that the Fitbit activity tracker was a consumer device and not a clinical device and that the data did not have diagnostic validity. Finally, we adjusted the conversation in interviews accordingly if patients expressed specific health concerns brought on by their interaction with the Fitbit; specifically, we urged them to contact their health professional for guidance.

Results

Device Engagement

Our results showed how patients with an implanted ICD device engaged with and made sense of activity data from the Fitbit in the context of chronic illness and self-care. Most (18 of the 27 participants) related their real-time heart rate, sleep, and step count data directly to their heart disease (Table 1). The remaining participants, however, connected the data to leisure activities, wellness, and exercise. Some portrayed themselves as not being a patient, explaining that they mostly did not have symptoms. Two patients chose to opt out after only wearing the tracker a few times owing to finding the wristband annoying to wear or simply losing interest (P6, P7). Patients used the activity tracker for an average of 26.1 weeks and took breaks from using it an average of 5.9 weeks.

The patients who did relate the data directly to their illness did so in 3 overall dimensions (Table 2): as something that generated new knowledge, as something that raised affective responses, and as something that could be used to evaluate themselves and their overall health. Within these 3 dimensions of experience, patients accounted for a range of positive, negative, and ambivalent experiences with activity data. For an extended analysis of the affective dimension and the consequences for patients' interpretation of Fitbit data, see [47].

Table 1. Overview of participating patients with chronic heart disease and an implantable cardioverter-defibrillator (n=27).

Patient number	Age (years)	Sex	Year of ICD ^a implant	Symptoms experienced	Number of weeks using the Fitbit (not using)	Experienced Fitbit data relating to heart disease
P1	67	Male	1998	No symptom experiences; experienced palpitations before	18 (0)	No
P2	61	Male	2015	Severe chest pain and shortness of breath	47.5 (0.5)	Yes
P3	41	Male	2009	No symptom experiences; experienced shortness of breath before	41 (6)	No
P4	55	Male	2014	Dizziness and sometimes fainting	13 (5)	Yes
P5	66	Male	2010	Dizziness and sometimes fainting	8 (23)	Yes
P6	67	Male	2015	No symptom experiences	9.5 (1.5)	N/A ^b
P7	28	Male	2008	No symptom experiences	6 (3)	N/A
P8	69	Male	2015	No symptom experiences (primary prophylaxis)	36.5 (11)	Yes
P9	47	Male	2008	No symptoms experiences related to his heart disease; lung disease; difficulties exercising	33.5 (14.5)	Yes
P10	61	Male	2010	Sometimes feeling very tired	30 (8)	Yes
P11	59	Male	2006	Shortness of breath and sometimes sleep problems; finds it difficult to feel his heart rate	8.5 (0.5)	Yes
P12	66	Male	2015	Dizziness and sometimes fainting; anxious about getting a shock and experiences depression	49 (0)	Yes
P13	67	Male	2017	No symptom experiences; rarely experience fainting; leg tenderness and muscle fatigue	44.5 (0.5)	Yes
P14	52	Female	2008	No symptom experiences	49 (0)	No
P15	61	Female	2004	No symptom experiences; sometimes being anxious about the ICD/irregular heartbeats	14 (1)	Yes
P16	47	Male	2014	Dizziness and sometimes fainting	35.5 (11.5)	No
P17	45	Male	2013	Dizziness and shortness of breath during high activity levels	35 (7)	Yes
P18	67	Male	2009	No symptom experiences	18 (29)	Yes
P19	66	Male	2005	Palpitations daily; experiences periods of depression and has restless leg syndrome	20.5 (1.5)	No
P20	69	Male	2014	No symptom experiences, except sometimes shortness of breath	39.5 (8.5)	Yes
P21	38	Male	2008	No symptom experiences; worries daily about having a cardiac arrest again	13.5 (0)	Yes
P22	59	Male	2001	Shortness of breath and sometimes dizziness when exercising and running; rapid heartbeats and chest pain	19.5 (0.5)	Yes
P23	49	Male	2017	No symptom experiences	47 (2)	Yes
P24	74	Male	2017	No symptom experiences	42.5 (6)	Yes
P25	51	Male	2014	No symptom experiences	9 (15)	No
P26	56	Male	2010	No symptom experiences; sometimes feels palpitations and shortness of breath	4 (0)	No
P27	58	Male	2014	Shortness of breath; sometimes sleep problems; knee-pain due to osteoarthritis	12 (5)	Yes

^aICD: implantable cardioverter-defibrillator.^bN/A: not available because the patient did not describe a relation between the activity data and his or her heart disease.

Table 2. Dimensions of how patients experienced activity tracking related to their disease.

Experiential dimension	Experience
Knowing	
Positive: gaining insight	Learning that heart disease increases one's average resting heart rate (P2, P4)
	Learning that medication influences the heart rate (P5, P22, P23, P27)
	Learning that activity improves one's average heart rate (P4, P21)
	Using activity data to monitor heart pumping ability (P10)
Negative: evoking doubts	No new learnings: Sensing is more useful than activity data (P1, P5, P16, P22)
	Doubting heart rate data (P2, P22)
	When doubt becomes mistrust (P12)
Feeling	
Positive: being reassured	Feeling safe through Fitbit reassurance (P11, P12, P17)
	Reassurance prompts activity (P24)
Negative: becoming anxious	Both insights and doubts can introduce new anxieties (P12, P13, P15, P23)
Evaluating	
Positive: promoting improvement	Being nudged and getting praise (P19, P20, P23, P24)
Negative: exposing failure	Recognizing a nudge but not knowing what to do about it (P13)
	Not getting the proper reward: the invisibility of "good" activities (P18)
	Self-disappointment with poor numbers (P8, P17, P24)
	Ignoring or resisting nudges (P18, P19)

Knowing: Gaining Insight and Evoking Doubts

As part of their motivation for participating in the study, many participants expressed an interest in knowing more about their health and body and about the possible relationships between their daily activities and their heart. In our interviews, it became clear that patients actively sought knowledge about their heart and health through the readings on the Fitbit and that some gained insight from the data. For others, the knowledge they gained from sensing their own bodies was more useful than the Fitbit data. Finally, some participants experienced that the data did not align with their activities and sensory experiences; thus, they doubted the accuracy and trustworthiness of the data.

Learning That Heart Disease Increases One's Average Resting Heart Rate

One patient gained insight into his average resting heart rate and discovered it was higher than he expected:

My resting heart rate ought to be 60, but it is 80, and as soon as I start moving, it goes up to 100 or 120. [P2]

It did not concern him since there is not much the clinicians can do about it, as he said. Another patient had the same kind of insight:

Then, the pulse is in a zone where I am physically active. That is what it signals. But I am not physically active. I am just walking. That has been an eye-opening experience. [P4]

Learning That Medication Influences the Heart Rate

Several patients knew, speculated, or learned about how medication can affect the heart rate. By looking at the Fitbit data, P5 noticed that his average heart rate decreased when on vacation, and he considered that his medication might have an effect. P27 also noticed that his medication influenced his heart rate:

Obviously, the heart rate follows how active you are; but, for healthy people, it's not abnormal that it reaches 116. But I get 13 pills in the morning and 3 in the afternoon.

P23 also noticed that medication influences his heart rate:

My beta blockers have been reduced in dose, which may also have something to do with the changes in the resting heart rate.

P22 had always been exercising; however, after an event a few years ago, he was prescribed a double dosage of beta-blockers, and it was decided to reduce the dosage again because his heart rate had dropped too low. Now, he finds it exciting to use Fitbit to learn about the relationship between medication, exercise, and heart rate and to confirm his heart rate data:

I still monitor what happens. This morning I saw an increase in my average heart rate of 12% and my maximum heart rate of just over 15%. And that's what's fun and what I use it for because it has annoyed me extremely that I couldn't run like I used to.

Learning That Activity Improves One's Average Heart Rate

P21 noticed that there is a relationship between exercising and average heart rate:

After serious ice hockey training, the average heart rate is higher on the day after, and then it drops in the weekend.

Similarly, P4 discovered that when he is more active, his average heart rate drops:

During the 20 days I have been wearing the Fitbit, I have seen a drop in my heart rate by 10 heartbeats per minute. I think that's crazy. I have been more active, yes, and I have been walking more. I have set exercise goals.

He experienced this as a positive thing:

I think it's fine that my resting heart rate goes down because, if it goes down, the heart does not have to work as hard. It makes a difference whether my heart rate is 70 or 60 beats per minute when resting.

Using Activity Data to Monitor Heart Pumping Ability

Several patients had experience with other activity trackers. One patient (P10) described how he used the data to monitor his heart condition. He was diagnosed with heart failure, and his heart had a reduced pumping ability, "Down to around half of what is normal," he said. He used the Fitbit to address his concern that his heart rate will drop even lower:

I use it to keep an eye on my condition. When I go spinning, I do the same intervals, and I can therefore see if I have burned the same calories in that hour. So, I can say, okay, I'm fairly stable, or I can see if it has gone down. Because then it might be my heart getting worse in its ability to pump.

No New Learnings: Sensing is More Useful Than Activity Data

Several patients had learned over the years to sense developments in their heart condition. One patient explained that, in the past, when he got rapid and dangerous heartbeats and the ICD began treatment with antitachycardia pacing to terminate the arrhythmia, he sat down and waited until it passed. He used to call the Heart Centre when he felt the symptoms to get confirmation about the episodes. For him, the Fitbit did not generate any new insights apart from what he already knew from sensing and listening to his body when exercising in the gym:

I know I cannot do physically very demanding exercises. I have come to terms with that. So, I have not received any new extra information via Fitbit. [P1]

P22 found it useful to use the activity tracker to get confirmation on fast heartbeats, for example, when running in the woods. However, he trusts his senses more:

If there is a connection between what I feel in my body and what the tracker shows, then I react. But when

the tracker shows something that I don't notice in my body, I consider it an IT error.

Another patient explained that he has tried to look at the Fitbit data when he gets sudden dizziness; however, it provides no explanation:

Sometimes I suddenly experience a "dive," and then I just have to hold on to something. It's very different how often it happens. But when I look at [the Fitbit activity data], it does not show anything. So, I can't find the reason for getting so dizzy. [P5]

Similarly, P16 explained that there is no connection between symptoms and heart rate:

There is no connection. I've tried to get symptoms when doing gymnastics where I had the pulse all the way up, and I've tried to get symptoms while I was sleeping. I have not found any connection at all.

Doubting Heart Rate Data

Heart rate data also created doubt among some participants. One patient doubted that the heart rate data presented on his Fitbit were accurate when walking:

But I have seen sometimes when out for a walk, my heart rate is really high. Average 166—I think that is a little high. And, sometimes, I have seen it going up to 197 beats, and I don't know why. [P2]

Another patient found the heart rate data "weird" at times. He experienced chest pain a few times when he was out running; however, no answers could be found in the activity data:

I felt a little uncomfortable — one might suddenly think of a blood clot. But I can't see in any of the trackers that the pulse has been particularly high or particularly low. [P22]

At other times, when he was just walking, there were sudden peaks in the heart rate data:

It seems strange. It's just right there — a peak up. It almost seems like a mistake that it goes from 80 to almost 170. It seems completely messed up what happens here. [P22]

Several other patients experienced that their heart rate showed unusual fluctuations on Fitbit.

When Doubt Becomes Mistrust

One patient had disease-related anxiety and had difficulties sleeping. Initially, the Fitbit data concerning his sleep revealed that he slept more than he thought he did when he woke in the morning after a difficult night. However, when he later saw that the Fitbit had registered "sleep" while he was calmly watching a movie, he and his wife started distrusting the measurements of sleep altogether:

This Saturday, we looked at sleep, for instance, and we could not make the numbers fit because he had been awake a lot. The data was wrong, and we do not know how it works. Then you go on to think, can you trust this device at all? [wife of P12]

Across participants, the sleep tracking measures of Fitbit were noted as unreliable and not reflective of actual sleep. For some participants, discovering that sleep data were inaccurate led to mistrust and a general, critical understanding of the measurements provided by Fitbit.

Feeling: Being Reassured and Becoming Anxious

Being diagnosed with a heart condition often introduces profound anxiety into patients' (and their relatives') lives. It is well-known that patients with an ICD are at an increased risk of being diagnosed with depression and anxiety [48]. In our interviews, some patients had different levels of anxiety and used the Fitbit to reassure themselves that their heart was doing okay. For some, this helped them engage more in physical activity — something they might have held back on owing to fear of provoking an attack (ie, kinesiophobia) [49]. However, the Fitbit — partly owing to the doubts and uncertainties introduced as described — could also spark new and additional anxieties and negative feelings regarding participants' health.

Feeling Safe Through Fitbit Reassurance

For some patients, having a heart condition raised their embodied attention, making them very alert to bodily signs:

As soon as there is even a little thing in these zones [in his chest region], and I would even say just one, like a sprain, I get nervous. [P12]

This patient, who is very affected by anxiety and depression, used the Fitbit to reassure himself that he is not having a cardiac arrest:

Then, I was out chopping firewood. I felt like it began to beat both in a weird way, and it felt like it beat really fast, but it did not. There was nothing. There was nothing to be seen [on the Fitbit] anyway. [P12]

For this patient, seeing his heart rate within the normal spectrum reassured and calmed him down:

Now I get certainty. Is something wrong or not.

Another patient, who experienced getting a shock from his ICD after walking the stairs, explained that:

Being able to see my heart rate is normal creates a sense of security because I'm not able to feel when my heart rate rises. A normal rhythm means that there is nothing to be afraid of — no danger is underway. [P11]

Similarly, P17 used the heart rate data as support in vulnerable situations:

I've tried it so many times, to have those VTs [rapid heartbeat] and I know what it leads to, and that's what I fear.

One time he was lying down, and he used the heart rate on the Fitbit tracker to get confirmation on the duration of rapid heartbeats:

If it lasted more than 5 minutes, I would have called 112 [emergency services]. Because, sometimes, I think when I get that feeling of fast heartbeats, it may well be imagination.

Reassurance Prompts Activity

Holding back during physical activity was something several of the informants touched upon, as some had had a heart attack while exercising or had experienced an ICD shock when climbing a flight of stairs. Checking their heart rate while doing more physically demanding tasks and sports motivated them to increase their activity:

I'm not afraid to have a high pulse when we do the Bikefit exercise at gymnastics ... because I can see it goes down again [his heart rate]. [P24]

Both Insights and Doubts Can Introduce New Anxieties

In the first section, we touched upon some of the doubts concerning the validity of the Fitbit data. For the anxious patient in need of reassurance, this uncertainty can be stressful, as noted by the wife of P12. P15 described it as follows:

There are plenty of worries when you have a heart disease. You don't need unnecessary things that make you worry more.

The Fitbit sleep data, for example, created unwanted attention to what it meant for her health:

What does it mean for my health? Am I sleeping enough or too little, and what can I do about it? Such concerns arise, which I could do well without.

She also experienced getting a high pulse that was “completely unprovoked” and then seeing it on the Fitbit:

But I can't do anything about it, and I can't use it for anything—unless they can see it in the clinic.

One patient noticed that Fitbit wants him to sleep 8 hours per night — a goal he rarely reaches:

I have always had this sleep pattern, and it did not bother me until I got this Fitbit, which says I should sleep 8 hours a night ... I get worried and start to question whether I ought to sleep more. [P13]

Finally, the introduction of new concerns and anxieties by Fitbit goes beyond patients' individual experiences. P23 explained that he tried to avoid drawing attention to his Fitbit wristband when being around his teenage kids:

I think it reminds them a little bit of something bad ... it's interpreted negatively—like someone has to keep an eye on me.

Evaluating: Promoting Improvement and Exposing Failure

As we presented in the previous sections, patients used Fitbit's numerical representations to make sense of their bodily sensations in the context of self-care. The fact that the Fitbit device allows them to see — as numbers, icons, and graphics — something that they usually relate to as sensations provides a new form of motivation. Setting targets for activity, getting notifications, and seeing achievements represented visually can be encouraging. Concurrently, however, the Fitbit also exposes unmet goals, thereby inducing self-disappointment or even shame. The Fitbit does not register or “see” all the activity that the patients found to be relevant as fair representations.

Being Nudged and Getting Praise

Several of the patients talked about how the Fitbit nudged them to stay physically active — it is “a kick in the butt,” as one patient noted (P19). Users can set their activity goals as they please; however, most went with the default setting of 10,000 steps a day. All patients looked daily to see if they had reached that goal, and some found it motivating to see the numbers and get positive feedback (visually provided in the form of stars) from the user interface. One patient described himself laughingly as:

Addicted to it because it says you have to walk 10,000 steps a day, and that fits with some of our walks. It becomes a sport; it gets me going. [P20]

Others noted how the gamification element invoked in the Fitbit led to small changes in their daily activities. For P23, Fitbit prompted him to take the stairs instead of the elevator to get more steps. It also prompted him to get up when it beeped every hour to take 250 steps by walking up and down the hall during work breaks. For these patients, Fitbit is “a little push in the right direction” (P23) and “an inspiration to continue” (P24).

Recognizing a Nudge But Not Knowing What to Do About It

Whereas simple nudging features such as awarding stars for accomplishing specific activity benchmarks seemed to motivate participants, there were also examples of participants becoming unsure of what constitutes appropriate activity. For example, Fitbit (by default) beeps once every hour during the day to pace the wearer to walk 250 steps every hour. For P13, this nudge suggested that average but regular activity throughout the day might be preferable to his usual practice of lumping activity together for more intense periods of exercise. It made him wonder if he should organize his workout differently, even if this wondering did not lead him to make any actual change.

Not Getting the Proper Reward: The Invisibility of “Good” Activities

After wearing the Fitbit for some time and having acquainted themselves with the collected activity data, some participants reported being frustrated that the Fitbit did not really measure all their activity. They did not feel “seen” by the device and rewarded properly for their efforts. This is particularly the case for those participants who did cycling, CrossFit, and other activities beyond walking and running as part of their everyday life activities. One participant lamented:

It is actually misleading because most of my activity is on a bike, and it does not register this. But it is also exercise. [P18]

These experiences added to the doubt in the data and the accuracy of measurements described previously.

Self-Disappointment With Poor Numbers

If positive feedback is seen as motivating further activity tracking, conversely, the negative feedback from Fitbit made some participants feel disappointed with or ashamed of themselves because it highlighted that they had not been active enough:

Well, I guess it has to do with that bad conscience you get the next day, if you cheat. [P8]

This was mentioned by several patients, and, for some, it made the Fitbit less attractive. P24 talked of self-disappointment when receiving negative feedback from Fitbit and noted that there might be someone else looking at their data, surveilling whether they reached their goals:

Yes, because it gossips all the time, noting that I have not walked far enough ... I think you could always find an excuse for not walking; like, it's raining.

For P17, the low step count created negative emotions on “bad days” and became linked to his heart condition:

It gives me a little guilty conscience that I do not get much exercise because, I have no doubt, the more weight I gain, the more fat is generated around my heart, and the harder it is for the heart to pump.

Ignoring or Resisting Nudges

Some participants tempered their engagement with Fitbit by actively resisting to do what the device suggests:

I know that it tells me, every once in a while, that it is time to go for a walk. But I decide when it is time to go for a walk. And then it says, let's go, and I'm like no way because I don't have the time right now. [P18]

For some, the Fitbit's nudging was simply a source of annoyance:

It can be a little irritating watching all the green “pling pling.” I don't want that; I don't care about it. I just want the info. [P19]

Yet, for others, such as P18, resisting the nudge to walk every hour was followed by a deeper reflection about whether activity tracking is good at all for his health:

I actually think it is a little unhealthy to measure oneself all the time. It comes to take up a lot, in my life, and I don't think it is that important.

Discussion

Principal Findings

Our study contributes to understanding how patients with chronic heart disease, as opposed to healthy individuals, experience activity data from consumer self-tracking devices in self-care. We found that patients with an implanted ICD relate the activity data to their illness experience and their self-care activities in 3 overall dimensions: as something that generated new or destabilized existing knowledge, as something that raised affective responses, and as something that could be used to evaluate themselves and their overall health.

The distribution of patients' experiences on a continuum from positive to negative suggests that activity data had “dual effects,” which means that the data created as much as it solved the problem of chronic illness [50]. The problems that people with chronic illness have to deal with become mediated in new ways and what may count as “normal,” “good,” “problematic,” or

“bad” may change accordingly. Positive and negative effects potentially co-exist and support the experiential ambivalence that studies of self-tracking and activity data have also found among leisurely users and quantified self-enthusiasts [22,45,51,52]. The concept of “ambivalence” unites this stream of research in which patients’ attitudes towards digital health devices “neither are consistently negative (implied by the notion of ‘rejection’) nor consistently positive (implied by the notion of ‘acceptance’)” [45]. Conflicting or ambivalent experiences appear constitutive of self-tracking: “doubt, guilt, fear, shame, dismay, disappointment, and hesitation as well as joy, relief, excitement, enthusiasm, and pride” [51].

Generating knowledge from interpreting activity data is often portrayed as the essence of self-tracking. For healthy individuals, it may comprise discoveries about physical performance in everyday life and adopting healthier behavior [33,35]. For the patients in this study, performance-oriented and fitness-oriented development of self-knowledge also surfaced. Patients obtained new insights about how exercising improves their average heart rate and that their heart disease may be the reason for a higher resting heart rate.

Other more disease-specific reflections surfaced as using Fitbit data to monitor the status and development of heart failure (heart pumping ability) and speculating about how heart medication affects the pulse. Unusually high heart rate data created doubt when walking or when connected to chest pain while running. Therefore, Fitbit data became part of generating a type of lay and personal expertise for, at best, supporting day-to-day self-care activities and living with a chronic disease and, at worst, creating uncertainty. This kind of “experiential knowledge” or “patient knowledge” [53–55] is often considered distinct from medical and scientific knowledge in that it is a by-product of bodily sensing and coping with daily practicalities of the disease as well as it is re-appropriated medical knowledge used to contribute, but also dispute, the biomedical perspective [55].

For patients, Fitbit data can provide support for self-care with informational cues alongside bodily sensations and experiences in the development of “know-now” [53] (ie, understanding what is going on or deciding what action to take). As opposed to healthy individuals’ knowledge-making with Fitbit, the unsupported lay interpretation of medically unvalidated heart rate data poses a risk for patients taking inappropriate action, for example, using Fitbit heart rate numbers to diagnose a cardiac arrest when running and deciding whether to keep on running or when getting chest pain and becoming dizzy in the office and then using Fitbit to decide what to do. The practical implications of patient knowledge generation from Fitbit suggest that patients should not be left alone with interpreting activity data as part of self-care. Deploying self-tracking and activity data in chronic care should be carefully accompanied by a purposeful clinical intervention such as rehabilitation and training programs where clinical staff can support patients in interpreting activity data, and data visualization should be designed to support meaningful action in the context of self-care.

The affective dimension of self-tracking when living with a chronic heart disease also emerged as loaded with ambivalence.

Fitbit numbers may provide numerical reassurance, which can relieve acute anxiety related to unclear bodily sensations and provide confidence to exercise. Concurrently, heightened attention to Fitbit data can also introduce new uncertainties and anxieties. Moreover, it is important to underline that the reassurance of the Fitbit data is not based on clinical evidence and, while reduction of acute anxiety is important to patients’ wellbeing, there is a risk that the numbers provide pseudoproof not sufficiently reliable to indicate anything clinically relevant about the patient’s condition. Given the prevalence of mental health issues, such as anxiety and depression, related to heart disease and the lack of mental health services for these patients, it is vital to consider the potential negative interactions between health tracking and mental health. Patients with chronic mental health comorbidities should not be left to try to cope with serious mental health issues alone with consumer devices.

Taken together, we see a tension between Fitbit’s promotion of success and exposure of failure to comply with set standard activity levels in the actual experience of using Fitbit. The ambivalence of knowing, feeling, and evaluating one’s chronic health condition against activity data from consumer devices, as opposed to clinically validated instruments, poses a concern for how engagement with data is placed in chronic care contexts as well as the purposes inscribed in the design of these new devices. In their analysis of ambivalence in mobile health for HIV care, Marent and colleagues [45] argued for the need to consider how the tension implied with ambivalence is embodied by particular bodily conditions and embedded in particular relationships and environments. Our study concerns people who, in clinical terms, have a chronic condition; however, the embodiment of this condition varies among participants. For some, the disease has a continuous and very challenging presence related to managing and coping with severe symptoms (see Table 1), while others tell us they do not feel sick at all. We suggest that the ambivalence of Fitbit data is more problematic when used by people who have a chronic condition and even more so for people who feel very challenged by their disease.

This relates to a second point about embeddedness. The ambivalence of Fitbit data should be understood in relation to its embeddedness in everyday contexts unrelated to clinical contexts of treatment. To what extent do people in these contexts have support from others such as relatives, peers, or health professionals who choose to engage in handling the ambivalences they encounter? What resources can they mobilize to act when experiencing doubt, anxieties, or other concerns when self-monitoring with Fitbit? With our paper being specifically concerned with patients who engaged with Fitbit data outside the established relationships of health care institutions, these questions become critical. Navigating benefits and harms of this form of active engagement with personal health data is, to a large degree, dependent on individual circumstances, resources, and networks, leaving inequalities potentially less mitigated by public health systems. We find that these are very central insights to take into account in research that focuses on how self-care practices can be furthered by harnessing the power of data and personal health technology. Too often, this literature focuses narrowly on individual

information processing and empowerment while disregarding the relational and situational embeddedness of chronic disease management. It not only neglects insights from health information-seeking literature, which has convincingly shown that patients' information behavior is more often based on serendipity, avoidance, blissful ignorance, indolence, bewilderment, and indolence than on rational choices and reflections [56], but also neglects that self-care practices are always collective in the sense that they are embedded in complex sociomaterial relationships [57,58]. What our study further adds to the literature on self-care and technology, then, is that technology and data mobilized outside the established arrangements of health care with consumer tracking devices may introduce new ambivalences that some patients may have difficulties managing without professional assistance.

For human-computer interaction research and the design of activity-data visualization for patients, our study aligns with the understanding that data supports different levels of reflection and serves multiple purposes [59]. The implications of our study, we suggest, is that consumer activity-tracking devices deployed in health care contexts should be designed to also support collaborative reflection (ie, "co-reflection") with health professionals, rather than focusing mainly on individual reflection [60]. Research on ways to support the shared work of tracking [61], co-reflection, and "co-care" [62] might be necessary to consider for personal informatics research in chronic self-care [25,47,63].

As an increasing number of people are generating and interacting with digital and individual health data outside the context of clinical practice, issues of inequality in health must be considered. Thus, there are important implications to consider in this typically optimistic, yet blurred, realm of "personal health data" (actualized for wellness purposes) and "patient-generated data" (actualized for clinical purposes).

Conclusions

We presented the findings from an explorative intervention study of how patients with a heart arrhythmia who have an implanted ICD experience activity data from Fitbit concerning their self-care and chronic illness. The aim was to further emergent literature and offer crucial empirical insight into the introduction of wellness tracking devices to various forms of chronic care management and the associated user experiences.

Through repeated semistructured interviews with 27 patients equipped with a Fitbit wristband, we offer support and further elaboration on existing work on patients' ambivalent experiences. We found that wearable activity trackers actualize patients' experiences across 3 dimensions on a spectrum: (1) gaining new knowledge versus evoking doubt, (2) feeling reassured versus becoming anxious, and (3) evaluating one's health by celebrating improvements and exposing failure. The experiences of individual patients can reside more on one end of the spectrum, can reside across all 3 dimensions, or can combine contrasting positions and even move across the spectrum over time. While activity data from wearable devices may be a resource for self-care through reassurance and motivation, they may also constrain patients and create increased uncertainty, fear, and anxiety.

The ramifications of knowing, feeling, and evaluating one's chronic health condition against activity data from consumer devices, as opposed to clinically validated instruments, are largely unexplored. Our study suggests that we need critical attention in scholarship and health care practice concerning how engagement with such data is practiced in chronic care contexts, not least to assess how the purposes inscribed in the design of these new devices may be molded and twisted in self-care when meeting the logics, needs, and abilities of patients in different health care circumstances. Designers and health authorities should consider this complexity and ambiguity when determining the usefulness of self-tracking data in chronic illness.

Acknowledgments

The authors wish to thank all the patient participants and their relatives who shared their experiences with us for this study. We also thank Tanja Munk Warmdahl, Amalie Lund Bendtsen, Oliver Carl Clemmensen, Andreas Millarch, and Anders Riis Vestergaard for their collaboration in interviewing, transcribing, and analysis workshops. This study is cofunded by the Innovation Fund Denmark #72-2014-1 and the University of Copenhagen, Vital Beats, and Medtronic. This study was also, in part, supported by a grant from the Danish Velux Foundations #33295.

Conflicts of Interest

None declared.

Abstract

Background: Despite the development of effective drugs for treatment, tuberculosis remains one of the leading causes of death from an infectious disease worldwide. One of the greatest challenges to tuberculosis control is patient adherence to treatment. Recent research has shown that video-based directly observed therapy is a feasible and effective approach to supporting treatment adherence in high-income settings. However, few studies have explored the potential for such a solution in a low- or middle-income country setting. Globally, these countries' rapidly rising rate of mobile penetration suggests that the potential for translation of these results may be high.

Objective: We sought to examine patient perceptions related to the use of mobile health, and specifically video-based directly observed therapy, in a previously unstudied patient demographic: patients with tuberculosis in a low-income country setting (Cambodia).

Methods: We conducted a cross-sectional qualitative study in urban and periurban areas in Cambodia, consisting of 6 focus groups with tuberculosis patients who were receiving treatment (standard directly observed therapy) through a nongovernmental organization.

Results: Familiarity with mobile technology and apps was widespread in this population, and overall willingness to consider a mobile app for video-based directly observed therapy was high. However, we identified potential challenges. First, patients very much valued their frequent in-person interactions with their health care provider, which may be reduced with the video-based directly observed therapy intervention. Second, there may be technical issues to address, including how to make the app suitable for illiterate participants.

Conclusions: While video-based directly observed therapy is a promising technology, even in country settings where mobile penetration is reportedly almost universal, it should be introduced with caution. However, the results were generally promising and yielded important insights that not only will be translated into the further adaptation of key features of video-based directly observed therapy for tuberculosis patients in Cambodia, but also can inform the future design and successful implementation of video-based directly observed therapy interventions in low- and middle-income settings more generally.

Introduction

Background

Despite the development of effective drugs for treatment, tuberculosis (TB) remains one of the leading causes of death from an infectious disease worldwide [1]. One of the greatest challenges to TB control is patient adherence to treatment: the need to take drugs daily for 6 months often proves too burdensome, leading to late initiation (treatment delay), disruption (missed treatment), or early termination (treatment default). Nonadherence prolongs the period of infectivity, potentiates relapse, and contributes to the emergence of multidrug-resistant TB cases every year [2].

Conventional directly observed therapy (DOT; the standard TB care whereby patients are strictly monitored daily over the course of their treatment, either by a health care worker or by trained community or family members [3]) faces significant implementation challenges. For patients and their households, adherence entails continuing nonpecuniary costs even when TB drugs themselves are free, including physical side effects, foregone productive time, travel costs, social stigma, and potential affront to autonomy [3]. Reliance on in-person interactions for oversight and support, particularly in resource-poor settings where patients are geographically isolated and hard to reach, is another persistent difficulty.

To address these challenges, numerous adherence-enhancement strategies based on DOT have been tried. Interventions that aim to enhance adherence (eg, reminder systems, defaulter action, education, and peer assistance) without addressing the underlying incentive problem have either shown mixed results or suggested that more high-quality context-specific evidence is needed [4,5]. Studies of financial incentives, however, have shown that patients receiving material rewards are significantly more likely to complete TB treatment [6,7], although these findings were mostly obtained in developed country settings.

With the spread of mobile technology, TB stakeholders are also increasingly eager to explore mobile health (mHealth) solutions to overcoming these constraints [8,9]. The simplest and most widely available approach is the use of text messages or apps to provide support or reminders. However, in the case of TB, use of text message reminders in low- and middle-income country (LMIC) populations has had limited effectiveness [10,11]. More sophisticated interventions, such as smart pills and electronic pill boxes, have been explored and some have shown promise, but practical apps suited to public TB control programs in LMICs are still limited [12-18].

Video-based DOT (VDOT) apps are another mHealth solution that can be integrated into a model of care. By leveraging the ability to take and share videos, VDOT platforms offer a wide range of intervention approaches beyond reminders alone, enhancing monitoring and support by allowing patients to record and send videos of themselves taking medication and enabling

new modes of communication with health workers. If successful, such apps would reduce ongoing labor and transport costs by eliminating the need for health workers to travel to patients' homes and allowing patients to take the drugs daily when convenient, further reducing patient opportunity costs. VDOT has already been shown to be effective in increasing adherence in some high-income country settings [19-25]. However, few studies have explored the potential for such a solution in an LMIC setting; where studies exist (eg, in India, Vietnam, Kenya, and Uganda) they show promise terms of feasibility and acceptability [15,26-29]. Globally, these countries' rapidly rising rate of mobile penetration suggests that the potential for translation of these results may be high, but at the same time, the speed of such development may result in new and unanticipated challenges.

Objective

In this context, we sought to examine patient perceptions of issues relevant to the use of mHealth, specifically perceived barriers to treatment adherence, current experience with mobile phone features, and acceptability of VDOT and mobile cash transfers, in a previously unstudied patient demographic: TB patients in a low-income country setting undergoing rapid expansion of mobile penetration. Ultimately, the study aimed specifically to inform the future implementation of an mHealth platform to support TB treatment adherence in this population in Cambodia and, more generally, to highlight considerations when planning and developing such an intervention.

Methods

Setting

Our study location, Cambodia, presents a unique opportunity, with a high prevalence of TB, declining TB treatment completion, and increased mobile phone penetration. Approximately two-thirds of all Cambodians carry the TB bacterium, one of the highest rates in the world. DOT can be a challenge for the 80% of the population that lives in rural communities with poor roads and difficult access, served by a mix of health care workers and DOT volunteers. Although Cambodia has maintained outstanding national average treatment success rates of over 90% for well over a decade, disturbing overall trends and subnational disparities have emerged. Since 2009, treatment success and completion rates have declined steadily. Rising rates of drug-resistant TB also indicate that poor adherence may be a concern [30].

Regarding mobile phone penetration, in 2019 there were more mobile phones than people in Cambodia, with more than half the population owning smartphones [7]. This is an increase of 30% over the previous year, a trend that is likely to expand in the lower-income segments of the population, supported by continued declines in prices, as well as the recent introduction of Khmer-language support and system translation for Android version 4.4 and higher (previously available on Nokia and

iPhone only). These conditions suggest a large and growing opportunity for mHealth to improve monitoring and enhancement.

Study Design

We conducted a cross-sectional qualitative study in urban and periurban areas of Cambodia, with the support of Operation ASHA, a nongovernmental organization providing TB treatment and other health services to low-income communities in Cambodia and other Asian countries. Operation ASHA's community health workers visit patients in their homes every day during the first (intensive) phase of treatment and once weekly during the second (continuous) phase, with patients self-administering the drug the rest of the week.

We conducted 6 focus groups with TB patients being served by Operation ASHA: 3 groups in Phnom Penh (an urban setting) and 3 in Takeo (a semirural province). We determined the number of focus groups using a rule of thumb typically cited in the qualitative literature, namely, that 2 to 5 groups are required per category of participants. Because we had 2 locations (urban and periurban) and for logistical reasons limiting a greater number of focus groups, we settled on 3 groups per location. We recruited 12 participants per group to ensure a minimum of 8 assuming some attrition; ultimately, each group had between 10 and 12 participants. The 2 areas have similar rates of smear-positive results, at around 9% [31].

Participants

Study participants were men and women aged 18 years and older who had a diagnosis of TB and were currently receiving treatment from Operation ASHA, and who were physically able to travel to Operation ASHA local headquarters. Participants were recruited by Operation ASHA staff using the recruitment script developed by the research team and approved by the institutional review board of the University of Southern California, Los Angeles, CA, USA, which also covers Operation ASHA's Cambodia work by an agreement of deferral for this study. All participants in the study were assured of confidentiality and anonymity and all identifiers have been removed to protect participant confidentiality. Participants provided oral informed consent, including for audiotaping and transcription, both during recruitment and at the start of the discussion. As a token of appreciation, participants received a US \$10 cash incentive for participation. Participants who did not or were unwilling to provide informed consent were excluded from the study.

Instruments

A semistructured discussion protocol was designed by the lead author with qualitative research expertise (LR) to collect information on patient perceptions of adherence and mHealth interventions in general, as well as to inform the development of a mobile VDOT intervention to support TB treatment adherence. Issues for discussion included perceived barriers to treatment adherence, views on mHealth, and the acceptability of a potential VDOT approach to treatment. The protocol further focused on general issues related to basic features of a VDOT system: (1) sending and receiving text messages, (2) taking and sending videos, and (3) providing incentives via cash or mobile

payments as incentives for treatment adherence. We pilot tested the instrument in the first focus group, after which we made minor amendments (primarily clarifying certain questions) for the subsequent groups.

Participants were also asked to assess an existing VDOT app developed by members of the study team (NIJP, JSM, WTO) and asked to evaluate the usability of such an app [32,33]. To avoid priming participants, we presented them with a short description of this VDOT mHealth app only after the general discussion about mobile phone ownership and current use. Users of this platform are provided with a personalized pill schedule that is monitored via the VDOT app. Using the VDOT mobile app, users are able to take a video of themselves taking their medication daily and upload the recorded video for a review by their health worker, together with a report of any adverse effects from the day before. Other features include a color-coded calendar indicating video submission and approval status by day, a function for explaining reasons for missing entries, and a messaging function for communication with the health worker. We also showed participants printouts of what the various screens of the app would look like. We then solicited impressions of the app, including their interest in such an approach, and concerns about its introduction.

We designed a short survey to collect background information prior to the focus group discussion. The questionnaire included questions on demographic and socioeconomic status to provide a complete picture of the background characteristics of our sample. All instruments and the screenshots of the VDOT app were prepared in English, translated into Khmer by bilingual translators, reviewed by an experienced local physician, and further refined where required.

Data Collection

We conducted all focus groups in July 2018. The focus groups were held in private meeting rooms within Operation ASHA's health facilities in both study locations and facilitated by a moderator and note taker, both of whom were bilingual native Khmer speakers locally hired and trained in study protocols, facilitation methods, and data capture by 2 study leads (JY and LR). All groups were facilitated in Khmer with only the moderator, note taker, and 1 researcher from the University of Southern California present during the discussion. Discussions lasted approximately 90 minutes and were recorded with permission, transcribed verbatim, and translated into English for analysis.

Coding and Analysis

We conducted a thematic analysis, in which we coded transcripts using a deductive approach, with codes generated from a review of the transcripts and the study's research questions and aims. This approach aimed to uncover the key themes and the most significant messages inherent in the raw data [34]. Where needed, the resulting codes were organized into broader, overarching categories. All transcripts were coded by the lead author (LR) using the final version of the codebook. We used the qualitative data analysis software ATLAS.ti version 8.4.4 (1135) (ATLAS.ti Scientific Software Development GmbH) to support the organization, review, and coding of the raw data.

Results

Sample Characteristics

We recruited 64 adults receiving TB treatment from Operation ASHA into our study. The sample comprised 34 men and 30 women with a median age of 55 years. The majority (n=44) were married, and 10 were widowed. This is broadly in line with available statistics on TB patients: in the most recently available Cambodian national TB prevalence survey, those aged 45 years or older accounted for 75% of smear-positive TB and 63% of smear-negative, culture-positive TB cases identified, with more males than females having smear-positive and smear-negative, culture-positive TB [35]. Educational attainment was generally low, with 19% (12/64) having no education, 53% (34/64) having an elementary school education, and the rest (18/64, 28%) having either lower or upper secondary education. No one in our sample had any tertiary education. While data are limited on the educational background of TB patients, these numbers show that our sample had overall lower educational attainment than the national population: in 2017, 19% of Cambodians aged 25 years and older reported having no or less than primary education, and 6% reported tertiary education [36]. In our own sample, almost half of participants required assistance from the research staff to complete the paper-based prefocus group questionnaire.

In terms of labor force participation, less than half our sample (29/64) were employed full-time, and 31% were not working at all (20/64). The rest were working part-time (8/64), retired (n=3), or students (n=1). Our sample differed from the general population in this respect: in 2018, labor force participation for all adults aged 15 years and older was estimated at 85% [37]. This difference is likely a function of at least both the median age of our sample (55 years) and the fact that they were all TB patients in treatment.

Regarding TB treatment, 61% (39/64) of our participants had begun their TB treatment less than 4 months previously, with the rest (n=25) in treatment for 5 months or longer.

Reported Adherence to TB Treatment

In addition to basic sociodemographic information, the questionnaire asked participants about their experience with TB treatment, and their mobile phone ownership and use. The vast majority of our participants reported never having missed any of their medication (55/64, 86%); this is likely because Operation ASHA makes home visits. However, these home visits are not uniformly performed daily [2]: most reported seeing their health worker as part of their TB treatment only once a week (35/64, 55%) or less (n=7, 11%); the rest (n=22, 35%) reported seeing their health worker twice or more a week.

Our focus group discussions revolved around 3 main themes that would inform the rollout of a VDOT intervention in Cambodia: (1) challenges to TB treatment adherence, (2) familiarity with and likely acceptability of features of such a platform, and (3) receptiveness to an mHealth app to support treatment, including use of appropriate cash incentives. We discuss our findings in detail below and provide translated direct

quotations to illustrate participants' views of these different themes.

Challenges to Treatment Adherence

As expected, participants agreed that access to treatment itself had been easy for them because Operation ASHA provides treatment free of charge and through home visits. Across the groups, participants expressed high levels of satisfaction with the existing Operation ASHA model of home visits:

I speak truly, there is no difficulty [adhering to treatment]. The medicine, they bring it home; [when it] runs out, they bring [more] home. [Female, focus group 5]

It was not difficult like before, [when] we took the medicine at the doctor's place. Now they bring the medicine to our home. [Male, focus group 2]

[For] some patients [it is] difficult to travel to the health center, so now we [have] home-based service, it's [easier] for patients. [Female, focus group 3]

Participants tended to highlight the practical benefits of the home visits more than they did the financial benefit of medications for which they did not have to pay out of pocket. Issues of stigma and privacy regarding an individual's TB and treatment status were not reported as significant concerns, even in the context of receiving a health care worker at home. In addition, there was widespread agreement that home visits not only were more convenient, but also enabled the health care provider to provide the encouragement, reassurance, and support that patients needed to adhere to the treatment, especially in the difficult first 2 months:

The doctor in charge of TB is very helpful. He is very attentive to patients. When I was on treatment he would come in every day to make sure I wouldn't miss [any dose of] my treatment. I would have missed my treatment if he didn't push me. After I took the medications I felt so nauseated. [Male, focus group 4]

Some [patients] could give up the medicines, so the doctor has to come every day. They travel by motorcycle on difficult road conditions. [Female, focus group 4]

While most participants agreed that the no-cost, home-based nature of their TB treatment was a critical factor for accessibility and adherence, they nevertheless recognized that, for themselves and for people they knew, there are significant challenges to treatment adherence, even when the medication is provided at home and at no out-of-pocket cost to the patient.

The main challenges participants identified were physical adverse effects, which can include itching and rashes, nausea, vomiting, lack of appetite, abdominal pain, and fatigue. Across the groups, participants told us of many individuals they knew in their communities who had interrupted treatment because of intolerance to adverse effects:

[Some people] do not want to be healed. They throw away the medicine which cause them some adverse effects. [Male, focus group 1]

The reason why patients refuse to take medicines is because of adverse effects. They make them nauseated or feel itchy. [Male, focus group 4]

[A neighbor] did not take [the medicine]. He said it's difficult and [has a] bad smell. [Male, focus group 5]

Many also reported that they themselves had experienced difficulties “because there are very terrible adverse effects” (female, focus group 1). Adverse effects, they explained, can be confusing and scary, as in this participant's experience:

For me after I took the medicines I developed numb joints and the lower part of my body became numb. I was panicked... [Male, focus group 4]

Our participants noted that a key difference between nonadherent patients and themselves was that the participants were able to overcome their discomfort with the adverse effects and remain in treatment, as well as their determination to complete their treatment:

When the doctor came here he gave me some medications, which were difficult to swallow for the first 2 months. I had itching, couldn't stand their strong odor, and felt nauseated. I had so much discomfort for the first 2 months. It was so horrible that I felt I was going to die. My weight then dropped to 56 kg, down from 60 kg. The smell was so repugnant and even if my children cooked porridge and fried or grilled cured dry beef for me I turned them away. But when I finished the larger tablets [and] I began to take the smaller ones I could eat very well and was able to eat anything including pickled vegetables, and my weight now is 63 kg. [Male, focus group 4]

We want to be cured, we have to try to be patient with eating, have to think appropriately for taking medicine to be cured. Do not give [away], do not throw [it] out, [we] take it all, and do not leave it. [Female, focus group 5]

Another issue participants identified was the pill itself. When asked what may lead a TB patient to interrupt treatment, a few participants agreed that the pills are large and difficult to swallow, which may lead some patients to interrupt treatment very early on. As one participant noted: “Some people complain that the medicine is too big to take” (male, focus group 6). Another one argued that the pill size was especially hard for a particular group: “For elders, [they] cannot swallow” (male, focus group 5). A participant told the group about a neighbor's experience:

I saw one neighbor, she is a woman. She said when she takes medicine in the first session, the tablets are big. She said when she took medicine, it's difficult to take it, and [she was] afraid of the medicine. So, she took [it] only for a few days, [then] she gave up, stop taking [the medicine]. [Female, focus group 3]

A few participants recognized that the length of treatment poses challenges for adherence, even as the majority agreed that following the health care professional's advice and continuing

treatment exactly as prescribed are the key to recovering from the disease. Some admitted that this was true even for themselves, as in the following example:

[W]hen we take [the] medicine, it is difficult and sometime it's too long time to take. Even I sometime do not want to be cured. [Female, focus group 3]

Another participant commented more generally:

[S]ome people take [the medicine] for half the period, and they feel better, then they give up at the half period. They think they are better, they are cured. Actually, this disease, we need time. So, they give up at the half period, they think they are better, they don't think it will be reactive. [Male, focus group 3]

Some participants also expressed the view that there are people with TB who may be “less likely to believe in medicines; they believe in traditional medicine” (male, focus group 1). For example, speaking of a neighbor who had received treatment but not followed it appropriately, a participant said: “Maybe he does not believe. He does not believe that the medicine could treat well” (male, focus group 6).

Experience With Mobile Phone Features

Most participants (n=41) said they owned a mobile phone, but a significant minority (n=23) reported they did not own one or use a phone owned by a family member. This is well below estimates in 2016 that over 96% of Cambodians aged 18 to 65 years reported owning a mobile phone [7]. A possible explanation for this discrepancy is the higher concentration of older participants in our sample (n=24, 38% individuals ≥60 years old) relative to the national average (estimated at around 7%) [38].

The majority of our participants who owned mobile phones used them for making and receiving phone calls. Other basic functions were far less common. Only 8 people reported using their phones to send or receive text messages, 7 reported using their phones to send or receive money, and only 1 used them to send or receive videos. Nevertheless, while the use of mobile phones to send and receive money was not widespread, many people reported being familiar with Wing (the largest mobile money platform in Cambodia) and other mobile money services when these were brought up in the discussion.

We probed our participants about reasons for not using their phones for money transfers, an element that would allow integration of incentives directly into a mobile app. Those who did not make any mobile cash transfers typically said that it was either because they did not know how to use these apps, or because they had no one to transfer money to or from (or a combination of both these reasons). Among those who had used their mobile phones to send and receive money, the view was that these services were convenient and easy to use:

In terms of using phones to transfer money, I think if we know [how to use it], it's easier than going to receive [the money] at the bank or organization. It's easier because the phone is in our hands. [Male, focus group 6]

Receptiveness to VDOT and Cash Incentives

Overall, participants were receptive to the general concept of a mobile app for VDOT. There was widespread recognition that an app could be convenient, as it would save time for both patients (in particular those who still had to attend health facilities for their treatment) and providers:

If we spend time to meet doctor at the health center, it's difficult. It takes a long time. Sometime, some patients do not have time. So, if you introduce us to use this, it's easier and saves time. [Female, focus group 3]

We can alleviate the doctor's workload because he would not have to come every day. [Female, focus group 4]

At the same time, participants expressed some concerns about this approach. First, some participants worried about the implications of seeing less of their health care provider, since VDOT would replace most of the home visits of the provider. A few individuals across the groups wondered where they would get their medications from if the home visits were discontinued: "If we don't go to meet the doctor, where can we get the medicine, if he does not bring it for us?" (female, focus group 5).

Second, a related question was whom they would ask questions about their health if their face-to-face interactions with their providers were decreased. Two participants, for example, expressed a clear preference for seeing their health care providers in person rather than having them follow their treatment remotely:

Seeing the doctor in person is better, as she can explain and advise us more. [Male, focus group 4]

Go to meet doctor is better...because we can talk face to face for longer discussion. [Male, focus group 5]

When presented with the concrete example of the existing VDOT app, there was widespread concern about the technical aspects of the app. Even though the moderator described the app in some detail using printouts with pictures of the various screens and functions, there remained some apprehension among participants that they would not know how to use the app. Nevertheless, there was also agreement that if participants were taught how to use it on their phones they would be willing to try it.

Third, participants who did not own phones at the time of our focus group wondered how the app would apply to them.

In a few instances, participants worried about illiterate patients and how they would be able to navigate an app that, as they saw in the printouts, includes some text.

We also asked participants about their views of cash transfers proposed as incentives to adherence, which could potentially be a component of VDOT platforms. Most people welcomed the incentive idea, but many did not want to comment on how much the incentive should be or said they did not know what would be suitable. Those who agreed to comment on how much would be appropriate argued that somewhere between US \$0.50 and US \$1 per intake would be acceptable (although a very

small number of participants argued for higher incentives, of US \$2 or more).

Nevertheless, while our participants generally welcomed a cash incentive, many said that getting the medicines for free was sufficient incentive and money was unnecessary: "Having medicines is good already, sir. There is no need to have cash prize" (female, focus group 4).

Discussion

Principal Findings

Our findings showed that familiarity with mobile technology and apps was widespread in this population, and overall willingness to consider a mobile app for VDOT was high. The themes that emerged are in line with VDOT acceptability studies in low-income countries including India, Vietnam, Kenya, and Uganda [15,26-29] and broadly consistent with well-accepted frameworks for assessing the potential acceptability of technology to individuals, such as the technology acceptance model or the unified theory of use and acceptance of technology [39,40].

Our results, however, also highlighted some potential challenges that might arise with transitioning from a face-to-face interaction to VDOT and the resulting implications for interventions. First, many patients related their overall levels of satisfaction with and adherence to frequent, reliable, and high-quality in-person interactions and encouragement. This may then manifest in erosion of both patient satisfaction and adherence in the context of an app-only intervention. In addition, the most frequently cited barriers to adherence were adverse effects, which required physician intervention, and dissatisfaction with the treatment regimen in general, rather than forgetfulness or inconvenience (which are typical factors that work in favor of introducing regular VDOT over periodic in-person visits). Any VDOT intervention may thus need to prioritize timely and frequent feedback and encouragement, as well as ensuring regular interactions with health professionals at intervals, in particular during the first (intensive) phase of treatment, to ensure mitigation of any potential physical and mental harms from less frequent in-person contact.

Second, despite good internet network coverage in our selected areas, not all patients in our study owned a phone. However, almost all patients had access to one. In addition, for most individuals, especially in less urban areas, the use of the phone beyond calls was limited, and familiarity with key aspects of a VDOT platform such as texting and videos was low, with only 1 individual using video regularly. With access to a phone being household-based rather than individual, there may be implications for patient privacy and adherence to a regular schedule of use.

Third, given the rapidly expanding penetration of mobile networks across Cambodia, we expected a higher degree of ownership than we found in our focus group sample, with only 41 individuals personally owning a mobile phone. This may limit the accessibility of an app and lead to concerns such as confidentiality and reliability of access, which may not be assured on a borrowed phone. On the other hand, these findings

also suggest that providing phones to participants as part of the intervention may prove a strong incentive to participate. In the focus groups, when the moderator explained that those without phones could be provided with one, enthusiasm and receptiveness to an app significantly increased.

Fourth, the benefits of the app are not likely to accrue to all groups equally. The demographic profile of users may be significant. Younger, more educated, and employed individuals may be most able to use the app and most likely to benefit from a more efficient interaction, whereas older adults may not only find the app more challenging, but also be most likely to experience adverse effects or be averse to losing the in-person interaction. Another issue is how to make the app suitable for illiterate patients. Literacy rates among Cambodian adults have been estimated at around 80%, which makes illiteracy a very significant problem [41]. While the proportion of illiterate TB patients is unclear, it is likely that it will at least mirror, if not exceed, that of the general population. The initial response to the presentation of a specific app platform was relatively subdued among illiterate users. The rollout of such an app may therefore not be universal, and instead would need to take the likely user profile into consideration, with training possibly extended to family members living with or close to the patient, who may act as treatment supporters especially with illiterate or older patients. Future development could focus on designing a language-free interface with visual cues in the form of symbols or icons instead of words.

In spite of these concerns, it is clear from our focus groups that participants were broadly receptive of our proposed innovation, as long as basic safeguards are put in place (in particular phone provision, training, uninterrupted access to the medications, continued access to a health care provider, and suitability for illiterate patients). Moreover, an app was perceived to be convenient not only for themselves; surprisingly, patients felt positive about lessening the burden on providers as well, which is likely to ease a transition to a new platform.

Limitations

First, one limitation of our study was the reliance on a convenience sample. Individuals who are willing to attend focus groups about adherence may be more likely to be generally adherent or positively disposed toward treatment or Operation ASHA in general.

Second, the use of a hypothetical, graphical presentation of a possible mobile app limited our ability to predict real acceptability and use. This may be especially problematic, as our sample demonstrated remarkably low exposure to apps overall, in spite of network coverage and access to smartphones, potentially due to a lack of familiarity or the lack of relevant service provision via apps at the time of the study. While a more in-depth investigation of factors driving this lack of exposure is beyond the scope of our study, it is worth more detailed exploration. We should reiterate, regardless, that participants were enthusiastic about the possibility of using an app as it was presented to them.

Third, some of our findings are context specific. The level of care provided by ASHA with extensive outreach may not be typical of DOT models in many parts of the world. Furthermore, none of our participants had used mobile apps for TB treatment, let alone health, before. These circumstances may limit broader generalizability across other treatment settings and models of care.

Conclusion

Our findings suggest that, while VDOT is a promising technology as long as appropriate safeguards are put in place, even in country settings where mobile penetration is reportedly almost universal, it should be introduced with caution. However, the results are generally promising and yield important insights, which not only will be translated into the further adaptation of key features of the VDOT app for TB patients in Cambodia, but also can inform the future design and successful implementation of VDOT interventions in LMIC settings more generally.

Abstract

Background: Suicide risk assessment usually involves an interaction between doctors and patients. However, a significant number of people with mental disorders receive no treatment for their condition due to the limited access to mental health care facilities; the reduced availability of clinicians; the lack of awareness; and stigma, neglect, and discrimination surrounding mental disorders. In contrast, internet access and social media usage have increased significantly, providing experts and patients with a means of communication that may contribute to the development of methods to detect mental health issues among social media users.

Objective: This paper aimed to describe an approach for the suicide risk assessment of Spanish-speaking users on social media. We aimed to explore behavioral, relational, and multimodal data extracted from multiple social platforms and develop machine learning models to detect users at risk.

Methods: We characterized users based on their writings, posting patterns, relations with other users, and images posted. We also evaluated statistical and deep learning approaches to handle multimodal data for the detection of users with signs of suicidal ideation (suicidal ideation risk group). Our methods were evaluated over a dataset of 252 users annotated by clinicians. To evaluate the performance of our models, we distinguished 2 control groups: users who make use of suicide-related vocabulary (focused control group) and generic random users (generic control group).

Results: We identified significant statistical differences between the textual and behavioral attributes of each of the control groups compared with the suicidal ideation risk group. At a 95% CI, when comparing the suicidal ideation risk group and the focused control group, the number of friends ($P=.04$) and median tweet length ($P=.04$) were significantly different. The median number of friends for a focused control user (median 578.5) was higher than that for a user at risk (median 372.0). Similarly, the median tweet length was higher for focused control users, with 16 words against 13 words of suicidal ideation risk users. Our findings also show that the combination of textual, visual, relational, and behavioral data outperforms the accuracy of using each modality separately. We defined text-based baseline models based on bag of words and word embeddings, which were outperformed by our models, obtaining an increase in accuracy of up to 8% when distinguishing users at risk from both types of control users.

Conclusions: The types of attributes analyzed are significant for detecting users at risk, and their combination outperforms the results provided by generic, exclusively text-based baseline models. After evaluating the contribution of image-based predictive models, we believe that our results can be improved by enhancing the models based on textual and relational features. These methods can be extended and applied to different use cases related to other mental disorders.

KEYWORDS

social media; mental health; suicidal ideation; risk assessment; machine learning

Introduction

Background

Mental disorders are a serious health issue worldwide. According to the mortality data presented by the World Health Organization, the number of deaths because of suicide is equivalent to a person dying every 40 seconds [1]. Considering that the signs and symptoms of these disorders have been proven to be traceable on social media, scientists have started to work on the development of automated methods to detect signs and symptoms of these conditions [2-5] by addressing the importance of early detection [6,7].

State-of-the-art approaches for the detection of mental disorders in social media involve the use of machine learning techniques mainly based on textual features extracted from the posts [8-11]. These models require the previous acquisition of annotated data, which are extracted from a selected social platform. Considering this as a classification task, which manipulates sensitive data [12], a proper annotation process is required to obtain a reliable dataset. This has become one of the main challenges because diagnosing mental disorders involves the intervention of specialized and experienced clinicians who follow strict screening proceedings [11].

The methods used for analyzing user-generated data related to suicide focus on tracking social networks at a post level, *that is*, a tweet [13,14], or at a user level, *that is*, a sample of their tweets or posts [15]. The latter is more related to risk assessment, as more data from a single user can be explored. In terms of the type of information extracted and explored, state-of-the-art approaches perform an exhaustive analysis of textual information contained in posts. This has been proven to be relevant for screening and risk assessment tasks [16]. The methods applied often consider bag of words (BoW) models, topic models, lexicons, sentiment analysis tools, and readability and syntactical analysis features [5,15,17]. The most recent work with deep learning approaches consists of exploring sequence models encoding vector representations of terms known as word embeddings [3,11,15].

There are a few approaches that analyze features containing behavioral and relational information. Colombo et al [18] examined the connectivity and communication of users with suicidal ideation on Twitter based on the evaluation of retweets, whereas the work of De Choudhury et al [16] on Twitter defines an egocentric social graph for depression detection. However, these studies do not evaluate the performance of relational elements combined with image-based data.

Regarding the use of visual information from posts shared in social networks to address mental disorders, the closest approaches to our goal are methods for personality prediction [19], and a few recent approaches address self-harm, depression, and anxiety [20-22]. We believe that our study is the first

image-based approach for suicide risk assessment on social media at the user level.

When we refer to suicide-related collections, to the extent of our knowledge, no previous publications have been reported on the generation of a suicide-related dataset built over Twitter where the annotation process involves expert clinicians labeling tweets according to the presence of suicidal thoughts focused on two types of control groups. Furthermore, our annotation was performed at the user level after having processed and analyzed sequences of posts within a period of a year. This allowed us to explore changes in time, as it has been proven to be useful for behavior analysis [23] and for the evaluation of early risk detection methods for depression [7,24].

Objectives

This study addressed the detection of mental health issues on social media, with suicide risk assessment as our use case. Our main contributions are listed as follows: (1) we defined a methodology to generate a reliable Twitter dataset for suicide risk assessment, which is also the first user-level dataset of this type dedicated to posts in Spanish; (2) we presented a method to obtain a subset of the user tweets related to a specific topic, in this case, *suicidal ideation*; (3) we generated models that explore the impact of not just relational and behavioral factors but also elements identified by specialists during consultations, which have been mapped to social networks; (4) we developed image-based predictive models to detect suicidal ideation; (5) we integrated the previous elements into a method that combines multimodal data to build predictive models that address the detection of mental health issues using cross-platform information (Reddit, Instagram, and Twitter); and (6) we refined the evaluation process of predictive models for mental health issues by considering 2 different types of control groups within the social media context: users with posts that might not use terms related to mental conditions (generic control cases) and users who make use of terms related to mental disorders (focused control group).

Methods

Data Collection

In this section, we described the methodology designed to generate a reliable Twitter dataset for suicide risk assessment. We selected Twitter as our main data source, as it has been proven to be suitable for analyzing mental disorders on social media [3,13,18,25-27], including suicidal ideation. We also highlighted the following aspects that this platform offers for our research: (1) the possibility of selecting posts in multiple languages; (2) the availability of relational and behavioral factors; and (3) the provision of a set of chronologically ordered posts from each user, which allowed us to do a cumulative analysis of the data referring to suicidal ideation.

Combining Reddit and Twitter for Gathering Suicide-Related Data

Before starting the crawling process on Twitter, we elaborated a list of suicide-related sentences to build a first filtering approach to obtain tweets coming from users at risk. In doing so, we started by collecting a sample of 500 titles of posts published in Reddit's Suicide Watch forum [28]. These posts were mostly written by users with suicidal ideations, so their titles can be considered to be suicide-related sentences.

These phrases were then translated to Spanish and reviewed by clinic psychologists. Some sentences were added, discarded, and/or adapted by the clinicians. We kept 454 phrases after the analysis by experts. Then, based on their relevance and link to suicide risk factors [29], a subset of 110 phrases were selected for use as search terms on Twitter. A total of 98,619 tweets containing these phrases were extracted for a year, that is, from December 21, 2017, to December 21, 2018. These tweets corresponded to 81,572 Twitter users, with 9559 users having more than one tweet matched with the search terms. At the same time, for all users, we extracted all their tweets posted within the same search period.

Two-Level Annotation Process

First Level

In total, 2 labeling stages were followed to identify users with suicidal ideation. As our intention was to follow a manual labeling process done by clinicians, we selected a random sample of 1200 users among those who had at least two tweets matching our search phrases. The user names were anonymized, and 3 tags were defined for labeling purposes: (1) *control*—defining users who on their tweets did not seem to manifest suicidal ideations, users who did not refer to their own conditions, and users who were reporting news or opinions regarding suicide; (2) *suicidal ideation risk*—labeling users who, judging by their writings, seemed to present suicidal ideation signs; and (3) *doubtful*—dedicated to cases where psychologists were not sure about labeling users within any of the other categories. At the first labeling stage, a clinician specializing in this topic was asked to classify users within these 3 categories based only on the tweets containing the suicide-related keywords. After the labeling process, 73.8% (885/1200) of users were classified as control cases, 9.6% (115/1200) were classified as suicidal ideation risk cases, and 16.7% (200/1200) fell within the doubtful category.

Second Level: Short Profile Version

A second labeling process was followed for the users tagged as suicidal ideation risk cases. We analyzed more of their collected tweets to confirm their labels. Annotators noticed that there was a high number of tweets that were not related to suicidal ideation and even sometimes no tweets related to suicide were caught in the sample. To address this issue, we developed a classifier at a tweet level to distinguish tweets containing signs of risk from those that were not related at all with suicide. Thus, we could provide the second annotator a summarized version of a user profile, which we call short profile version (SPV), that contained mainly tweets related to suicide and its risk factors.

We built a binary classifier distinguishing 2 classes: (1) *suicidal ideation-related tweet* and (2) *control tweet*. To train the model, we chose as instances for the *suicide tweet* class the tweets of users tagged as *suicidal ideation risk* cases (513 tweets) and 346 phrases evaluated by the clinicians. For the *control tweet* class, we selected an equally proportional set of random tweets related to other topics, using Twitter's Sample Tweets application programming interface (API) [30]. A BoW model with 1 to 5 grams was generated, and after applying principal component analysis and logistic regression analysis, we achieved $F1=0.90$, precision (Pr)= 0.91 , and recall (R)= 0.89 , with a 10-fold cross-validation procedure. This is considered as our *short profile version classifier* (SPVC).

The SPVC was applied to every tweet of the profile of all users labeled as *suicidal ideation risk* and, for each user, we selected the top 15 *suicide-related tweets* with the highest predicted probability values given by the SPVC. We considered these tweets as the sample to be evaluated by 2 additional annotators: a specialized clinician and a nonspecialized annotator. This second annotator was given detailed instructions and information on risk factors related to suicide. The annotators at this stage were asked to classify users into 2 categories: (1) *suicidal ideation risk* or (2) *control*, now having more information about each user. Once the second annotation process was completed, we only retained the positive cases ($n=84$) on which both annotators agreed, corresponding to 89% (84/94) of all the cases labeled as suicidal ideation by at least one of the annotators in this second stage. Thus, we ensured that the users labeled as *suicidal ideation risk* were classified under the agreement of 3 annotators at different stages.

We defined 2 different control groups with the same size as the *suicidal ideation risk* class:

- *Focused control group*: users writing suicide-related keywords in a non-suicidal ideation risk context, that is, users who trivialize about suicide, news reports, and information regarding the topic; or users who simply manifest their support or opinions to people at risk. Identifying these users is challenging for classification systems but is key in reducing false-positives. These users were chosen at random among the users labeled as control cases during the first annotation process.
- *Generic control group*: a set of Twitter users who might not necessarily use terms related to suicide. These users were selected randomly using the Sample Tweets API [30] and anonymized as had been done for the other groups.

For both the control groups, the second annotation process was followed to discard possible cases of users at risk within these samples.

Combining Multimodal Data for Detecting Suicide Risk

We proposed a method that given the profile of a user: (1) it uses a text-based model, described previously as the SPVC, which selects a subset of relevant tweets related to suicidal ideation. The set of tweets for which the SPVC provides a score over a given threshold is retained in SPV itself; (2) mostly from the outputted SPV, it extracts a set of relational, textual,

behavioral, lexical, statistical, suicidal ideation-related, and image-based features from the content and metadata of the tweets; and (3) it builds and evaluates different predictive models resulting from the combination of these features. Our features are organized into 3 different groups: (1) *BoW or n-grams and word embeddings* as a representation of textual features; (2) a set of features known as *social networks and psychological (SNPSY) features* containing a group of relational, behavioral, lexical, sentiment analysis, and statistical features, in addition to a set of features that attempt to map to the social media context certain signs and symptoms, which are usually considered by clinicians at the time of screening; and (3) an *image-based score*.

Features Definition

Generic Text-Based Features

Bag of Words and N-Grams

These are features that have been used to address similar tasks, such as depression detection and eating disorders screening [7,31]. These models represent terms or sequences of terms (n-grams) based on their frequencies on the documents analyzed. In our case, each user was represented by a document consisting of the concatenation of the text of all their tweets. Afterward, we used the *Scikit-learn* [32] Python library: *TfidfVectorizer* to generate a *tf.idf* representation of 1 to 5 grams at the word level. A set of Spanish stop words were considered to build this representation [33]. These features are referred to as BoW features in further sections. We also used *ekphrasis* [34] as a text preprocessing tool to replace generic tag elements such as money, phone numbers, digits, hashtags, and emoticons. We also removed the n-grams that appeared in less than 5% of the documents to reduce the feature space. This is done considering that the features' number is given by the size of the vocabulary of all the writings of the users, and in Twitter, we found cases in which terms are misspelled or elongated (ie, *hellooooo* instead of *hello*); therefore, we avoided having multiple representations for the same term assuming that each spelling mistake and elongation is different and less likely to be repeated over most of the documents.

Word Embeddings

Word embeddings are representations of textual terms as vectors of real numbers. Words that are semantically related have a similar representation over the vector space. Most of the recent predictive models dealing with textual features using deep learning techniques make use of word embeddings to represent terms. The sequences of these representations are fed as inputs to train the predictive models. These types of representations have been recently used in state-of-the-art approaches to address suicide risk assessment [3,11]. We made use of word embeddings previously learned over a dataset with 2 million Spanish tweets [35].

Social Networks and Psychological Features

These consist of a group of features based on generic lexicons [36], statistics measured from the users' writings, information of interest for clinicians regarding the behavior of users in time, the users' social network (relational features) [16], and n-grams lexicons, which include terms referring to suicidal ideation or

suicide risk factors (we referred to these features as suicide-related lexicon features). Each of these types of features is described in the next subsections.

Behavioral Features

These features are based on the information extracted from the metadata of tweets. Here, we measured the behavior of users based on their activity within certain periods, which are defined at different granularity levels. These features are detailed in Table 1.

The intention of the sleep time tweets ratio (STTR) and the daytime tweets ratio (DTTR) features is to identify the differences between control users and users at risk regarding the periods of the day on which they post. Considering that our data collection is delimited by language but not by location, that the posting time provided for a tweet is in coordinated universal time and not the time of the user location, and that not enough information from our data was found to automatically identify the location of all the users, we defined an approach to address this issue. As explained in Equation 1, a day was divided into 8 fixed time slots of 3 hours each. Afterward, we assumed that an average user had at least around 6 hours of sleep time, and within this 6-hour period, a smaller number of tweets would be created compared with the rest of the day, so we counted the number of tweets (*t*) created within each 3-hour time slot for all the tweets of the SPV of a user. Next, for each user, we calculated the sum of the number of tweets within each pair of continuous time slots and selected the minimum score obtained by all the pairs. We also assumed that the first and last slots can be continuous. Finally, this value was normalized according to the total number of tweets of the full profile of the user (*T*). This feature was considered as the STTR:

The DTTR was given by the difference between 1 and the sleep time ratio: that is, $DTTR = 1 - STTR$. It is important to recall that for the measurements that refer to a bigger granularity such as weekdays, weekends, and months, the impact of time difference is not as big as for features based on day periods.

Tweets Statistics

This group refers to 5 types of features that correspond to statistical measures calculated from the tweets of users. We considered elements such as the number of tweets created and their length and the number of tweets that were retained for each user at the SPV in relation to the total number of tweets posted. These features are described in Table 2.

Relational Features

These are informative features regarding the relationships and interactions between users. Elements such as the count of retweets and favorites received and given by the users can provide insight on the social support they receive, along with information regarding the number of followers and users followed, as previously considered for depression screening [16]. Table 3 describes the relational features extracted for our evaluation.

Table 1. Description of behavioral features.

Feature	Description	Source
Working week tweets count ratio	Total number of tweets on weekdays (Monday to Friday) normalized by the total amount of tweets	SPV ^a tweets
Weekend tweets count ratio	Total number of tweets on weekend days (Saturday and Sunday) normalized by the total amount of tweets	SPV tweets
Median time between tweets	Median of the time (in seconds) that passes between the publication of each tweet	SPV tweets
Sleep time tweets ratio	Ratio of tweets posted during the inferred sleep period of the user	Full profile tweets
Daytime tweets ratio	Ratio of tweets posted during the period the user is usually awake	Full profile tweets
Normalized tweet count per quarter (4 features)	Number of tweets posted by the user within each quarter of the year, normalized by the total amount of tweets generated by the user during the year	SPV tweets

^aSPV: short profile version.

Table 2. Description of features based on tweet statistics.

Feature	Description	Source
Suicide-related tweets ratio	Ratio of tweets retained by the SPVC ^a over all the tweets of the full profile	SPV ^b and full profile tweets
Median SPVC score	Median of the scores obtained by the tweets that are part of the SPV after applying the SPVC	SPV tweets
Median tweet length	Median length of all the user tweets (word level)	SPV tweets
Number of SPV tweets	Number of tweets	SPV tweets
Number of user tweets	Number of tweets posted by the user since the creation of the account	Tweet metadata

^aSPVC: short profile version classifier.

^bSPV: short profile version.

Table 3. Description of relational features.

Feature	Description	Source
Followers number	Number of followers	Tweet metadata
Friends number	Number of accounts followed by the user	Tweet metadata
Favorites given	Total number of favorites given by the user	Tweet metadata
Median favorites count	Median of the favorites received by the user	SPV ^a tweets
Median retweets count	Median of the retweets received by the user	SPV tweets

^aSPV: short profile version.

Lexicons and Suicide Risk Factors Vocabulary

The use of lexicons has been proven to be successful for tasks dedicated to screen mental disorders [9]. For our approach, we counted the frequency of words belonging to all the categories of the Linguistic Inquiry and Word Count (LIWC) 2007 Spanish dictionary [36,37] normalized by the size (in number of terms) of the concatenated writings of the users. It is important to recall that LIWC also contains categories that identify syntactical elements such as verbs, nouns, adverbs, and pronouns, among others. To this dictionary, a group of other categories was added containing vocabulary and up to 3-gram phrases that could be mapped to suicide-related terms and risk factors such as suicide methods; terms referring to self-injuries; explicit suicidal ideation references; self-loathing terms; words that might imply disdain, insomnia, and fear; and possible references to previous

suicide attempts, experiencing racial or sexual discrimination, eating disorders, substance abuse, bullying, lack of social support, and family and money issues, along with vocabulary that might imply that some sort of discrimination or abuse has been suffered, that someone close has died from suicide, and even vocabulary regarding the lack of spiritual beliefs, as religion is considered to be a protective factor for screening tasks [29]. The terms and phrases selected for these categories were based on manually mapping common terms and phrases seen in a sample of tweets labeled as suicide related during the first labeling process with the assessment of clinicians. These features were calculated using SPV.

Sentiment Analysis

We obtained a score for each tweet in terms of its polarity. For this purpose, we used *senti-py* [38], trained on Spanish texts

from different sources, including Twitter. It is based on a BoW model with an intermediate feature selection process. To obtain a score per user, we calculated the median of the scores of all the tweets from the SPV.

Image-Based Feature

We followed the methodology proposed in the study by Rodriguez et al [39], where a method for inferring the personality under the OCEAN model was presented. In this sense, we created a classifier trained on images extracted from Instagram using a subset of the phrases and keywords used in the data collection process for Twitter. These images were considered suicide related, whereas a set of unrelated images was considered as our control cases. Afterward, this first model was applied to each of the images extracted from the users' tweets of our dataset. To create this model, we used 90,000 images for training and 60,000 images for validation. To obtain a single score per user (*images user score*), the average of the individual scores of the images of each user was considered as the user's aggregated score.

To define the image classifier, we used a convolutional neural network (CNN) [40] because CNNs are especially suited for image data. There are several variants of this type of network, but the most popular ones are based on the residual networks introduced by He et al [41]. They used skip connections between layers that force the gradient to flow directly between convolutional blocks. This makes backpropagation much more effective in deep architectures.

The training process is performed by minimizing the cross-entropy loss function through gradient descent. The problem when training CNNs is that they require many images (often in the range of millions) to successfully extract relevant features for the final classifier. As most of the time datasets are not large, networks are usually trained on a large dataset (eg, ImageNet [42]) and then fine-tuned on the target dataset. Fine-tuning refers to the process of using an already trained model and retraining it to fit a new distribution. This is much faster because the weights in the model are not randomly initialized, and one can often skip the training of the shallower layers, given the fact that they focus on detecting corners and edges, and thus the model converges faster. Note that the fully connected layer that acts as a classifier in the network must be trained from scratch because the target classes between datasets vary.

For our experiments, we used 101-layer ResNeXt [43], which is a residual architecture that uses grouped convolution. This particular architecture uses convolution groups of size 32 with a dimensionality of 8 and a fully connected layer at the end that performs the actual classification. The output of the CNN is a vector that holds the scores for each of the classes; in our case, there were only 2 classes. The network was trained on ImageNet, and we fine-tuned it on our Instagram images. We trained for 8 epochs using stochastic gradient descent with warm restarts [44] with a weight decay of 0.001 and a learning rate of 0.0001 using Nesterov with a momentum of 0.99 on 2 GTX 1080 Ti. We used dropout (50%) to avoid overfitting at the training stage.

Classification Tasks

As we wanted to evaluate the change in the performance of models that use 2 different types of control groups, one constituted by users who make use of vocabulary related to suicide (focused control) and another group of users who might not make use of these terms at all (generic control), we created experiments for comparing (1) users at risk versus focused control users (task 1) and (2) users at risk versus generic control users (task 2). These were selected as our 2 supervised predictive tasks. Our instances and their features for the predictive models were previously defined following the process described in the Combining Multimodal Data for Detecting Suicide Risk section.

Baselines

We defined as baselines 2 models exclusively based on generic text representations. These models were generated using the previously extracted features and representations from the users: (1) full profile and (2) from their SPV. The first one is a BoW model trained with 1 to 5 grams, and the second one consists of a deep learning model defined by a CNN architecture that has been proven to be successful for text classification [45] and has been used in a similar task that addresses suicide risk assessment on Reddit users [11].

We adopted the approach of Shing et al [11] to define our user-level instances. Therefore, given a user represented by a set of sequential posts, we concatenated all these posts and represented each post as a concatenation of words, where each word is represented by a vector (word embedding), as described in the *Features Definition* section. As in the study by Coppersmith et al [3] and as it has been proven successful on similar tasks, we used a set of word embeddings previously learned on Twitter [35] to define the starting weights for our embedding layer and performed further fine-tuning to learn over the training set and adapt the representations to the task domain.

We considered the 2 models previously described as state-of-the-art approaches for the creation of generic and exclusively text-based models for the task, as it is one of the purposes of our work to analyze the contribution of the additional feature types defined. We therefore defined 4 baseline models. Baselines 1 and 3 correspond to the BoW model generated over the full profile tweets sample and the SPV, respectively. Baselines 2 and 4 correspond to the deep learning model built over the same data samples (full profile and SPV).

Classifiers

With the intention of evaluating the individual contribution of the types of features defined, along with their combinations toward a classification/detection task, we considered 4 types of classification algorithms and a deep learning model. We evaluated the performance of random forest, multilayer perceptron, logistic regression, and support vector machines as classifiers. For each feature combination approach, models were built for all these classifiers using the *Scikit-learn* [32] library's implementation, with a grid search for the best parameters. We used a CNN architecture for the embedding models.

Approaches for Combining Features

We evaluated several ways of combining our 3 main feature types defined: generic text-based features, SNPSY features, and the image-based feature (*image user score*). As can be seen in Table 4, we first generated individual models using exclusively all the features corresponding to the *BoW model*, the *embedding's model*, and the *SNPSY model*, with features mainly obtained from the users' SPV, as described in Tables 1-3. Afterward, we explored the combination of our different feature types using the BoW model to represent text-based features. Our first approach involves combining the BoW features with the SNPSY features. In this case, given the large number of BoW features and their sparsity, we opted to use the BoW model-predicted probabilities as values for a single feature, denoted as the *BoW outputted feature*, to be added to the SNPSY set of features. This is described in Table 4 as the *BoW+SNPSY model*. Subsequently, we evaluated the combination of the BoW features with the image feature. For this case, we simply added to the BoW set of features the *image user score* as another attribute; this combination is described by the *Images+BoW model*. Afterward, to combine the SNPSY features with the image feature, we used the *image user score* as a new feature in addition to the SNPSY feature set, which is the *Images+SNPSY model*.

Finally, to combine the 3 feature types, we defined 2 approaches. The first approach is an ensemble model where we consider the outputs (predicted probability scores) of the BoW model (*BoW outputted feature*) and SNPSY model (*SNPSY outputted feature*)

along with the *image user score*. This approach corresponds to the *Images+BoW+SNPSY model 1* with 3 attributes based on the combination of the 3 independent models with all their features. The second approach consists of using all the features of the SNPSY type as attributes in addition to the *BoW output feature* and the *image user score*, which lead to the definition of *Images+BoW+SNPSY model 2*. It is necessary to recall that the predicted probability scores from the BoW and SNPSY individual models that were used for some of the feature combination approaches at the training stage correspond to the outputs of the classifiers on the test folds during the cross-validation process executed on the training set. This was done to avoid overfitting.

In addition to the combination approaches described, we created 2 other models over which we performed a feature selection procedure over all the feature types. We chose the features with statistically significant differences among the suicide and control groups to evaluate their contribution exclusively to a predictive model. We presented 2 models with features selected based on the *P* values obtained after performing a Mann-Whitney *U* test to compare the samples of each class. This is a feature selection method that has been previously used in medical applications [46]. In addition, we took into account the efficiency of this feature selection approach, given the large feature space considered (Table 4). These models are defined as the *selected features model 1* with the features where $P < .05$, when comparing the suicidal ideation risk and control groups; and the *selected features model 2*, where $P < .001$. The number of features obtained for each model is also given in Table 4.

Table 4. Models and features.

Model	Features	Number of features	
		Task 1	Task 2
BoW ^a model	BoW features generated with the Tf.Idf vectorizer with 1- to 5-gram features	24,645	24,336
Embeddings model	Word embeddings representations as input for a text-based convolutional neural network model	200	200
SNPSY ^b model	SNPSY features=behavioral+relational+tweets statistics+lexicons+suicide risk factors vocabulary+sentiment analysis features	112	112
BoW+SNPSY model	BoW outputted feature+SNPSY features	24,757	24,448
Images+BoW model	Images user score+BoW features	24,646	24,337
Images+SNPSY model	Images user score+SNPSY features	113	113
Images+BoW+SNPSY model 1	Ensemble model=images user score+BoW outputted feature+SNPSY outputted feature	24,758	24,449
Images+BoW+SNPSY model 2	SNPSY features+images user score+BoW outputted feature	114	114
Selected features model 1	Selected features from all the feature types with $P < .05$	5807	14,882
Selected features model 2	Selected features from all the feature types with $P < .001$	522	3250

^aBoW: bag of words.

^bSNPSY: social networks and psychological features.

Experimental Setup

Dataset Description

Following the description of the Data Collection section, to evaluate our approach, we selected a sample of 252 users with

a total of 1,214,474 tweets and 305,637 images, from which up to 1000 images per user were selected for our experiments. We selected a balanced sample of 84 users presenting signs of suicidal ideation (users at risk), 84 focused control users, and 84 generic control users, who were classified within these groups by clinicians after seeing samples of their posts. Table 5 shows

the statistics regarding the users belonging to each of the defined groups. We can notice that the median tweet length (in words) is lower for users at risk than for the control and generic cases.

Table 5. Full dataset labeled group statistics.

Description	Suicidal ideation risk group	Focused control group	Generic control group
Number of users	84	84	84
Number of tweets	313,791	766,437	134,246
Median number of tweets per user	2797.5	2984	716
Median tweet length	11	19	14
Number of images	37,801	251,830	16,006

Detection Tasks and Evaluation Framework

We considered 3 different aspects to analyze: (1) the utility of having defined the SPV, as we believed that this would allow us to focus on the topic we are analyzing by getting rid of the noise provided by tweets that make no reference to our subject of interest; (2) the individual and combined contribution of the different aspects we analyzed: textual, relational, behavioral, and image-based information; and (3) the change in the performance of models that use 2 different types of control groups, one constituted by users that make use of vocabulary related to suicide (focused control) and another group of generic users who might not make use of these terms at all.

All posts from the full profile of the user were considered for baseline 1 and 2 models, whereas most of the features for our proposed models and combinations were extracted exclusively using the SPV, except for some elements extracted from the user's tweets metadata and features such as the STTR and DTTR, which required the usage of the posts from the full profile. For each task, 70% of all the instances were retained for training, and the remaining 30% (around 25 users per class) were left for testing purposes as unseen cases. To keep balanced instances from each class, we used stratification for these sets. In addition to these test sets, we also evaluated our best models over a sample of 200 users labeled as doubtful cases. This is done to verify if, as the human annotator, the models are capable of identifying most of these cases as users that are likely to be at risk.

The *PowerTransformer* class from Python's *Scikit-learn* library was used to transform the feature values to a normal distribution-like representation using Yeo-Johnson's [32]. To choose the best classifier, a 10-fold cross-validation process was followed over the training set with all the algorithms to evaluate. Afterward, the ones with the best performance were selected to perform a second 5-fold cross-validation along with a grid search to find the most suitable parameters for the classifier chosen.

We considered the Pr, R, F1 score (F1), accuracy, and area under the receiver operating characteristics curve (AUC-ROC) score denoted as AUC, which was the measure on which we based the parameter optimization of the grid search. The values for Pr, R, F1, and AUC corresponded to the suicidal ideation risk class, as it is our main class of interest. We reported on accuracy to analyze the performance of both classes. The results

We also saw that generic control users produce lower amounts of tweets compared with other types of users.

obtained by certain classifiers such as the CNNs were averaged results of multiple runs because of the randomness they can add.

Results

Statistical Analysis

We performed an analysis of the features extracted to identify significant differences between the samples of users at risk and our control groups. For each feature extracted for the groups analyzed, we conducted an independent 2-sample Mann-Whitney *U* test among the suicidal ideation group of users and the different control groups. We also conducted this test to compare both of our control groups (focused and generic control groups). We performed a nonparametric test considering that our features do not follow a normal distribution and that there was no homogeneity of variance for most of them.

When comparing the suicidal ideation risk and focused control groups at the SNPSY features, we found significant differences with $P < .001$ among the following features: overall ratio, median time between tweets, verbs, verbs conjugated in singular of the first person ("I"+verb), cognitive mechanisms, anxiety-related terms, usage of personal pronouns, usage of the pronoun "I," negations, terms to express feelings, and cursing terms. Regarding suicide-related lexicons, the usage of suicide explicit terms, depression-related terms, self-loathing, substance abuse, self-injuries, and terms expressing lack of social support also presented an important significance ($P < .001$). Regarding the features from the BoW model, after conducting the same test, we found significant differences with $P < .001$ for n-grams such as *I feel, sad, kill myself, cry/crying, depression, to die, horrible, anxiety, die, pills*, among others. Considering all the features used (24,758), a total of 522 features were significant for distinguishing the groups according to these tests with $P < .001$. Table 6 shows the medians and the distributions overlapping index [47] for both groups on a sample of relevant features.

When repeating the independent two-sample Mann-Whitney *U* test to compare the suicidal ideation risk group with the generic control set of users regarding the SNPSY features, among the ones with $P < .001$, we found the median classifier score, the number of tweets generated, and the median time between tweets to be different among both groups (suicidal ideation risk vs generic control). We identified differences in discussion topics such as money and work, about which the generic control users

seem to discuss more, whereas the members of the suicidal ideation risk group use terms more related to health and biological aspects. As in the previous case, the use of self-references was higher in the suicidal ideation risk group. Within the significant n-grams from the BoW model, we found terms such as *feel*, *to die*, *songs*, *someone*, *cry/crying*, *anxiety*, *life*, *breath*, *bad*, and *fear*. This is shown in Table 7, which displays the median value and overlapping index of the distributions of the groups in terms of some of the attributes mentioned. Again, taking into account all the features used (24,449), 3250 were significant for distinguishing between the suicidal ideation risk and the generic control group in terms of this test with $P<.001$.

Regarding other features explored, considering a 95% CI, for *task 1* (suicidal ideation risk vs focused control), the number of friends ($P=.04$) and median tweet length ($P=.04$) were significantly different. For these cases, the median number of friends for a focused control user (578.5) was higher than the median number of friends at risk (372.0). The same was true for the median tweet length, based on the SPV, which was higher for focused control users with 16 words against 13 of the suicidal ideation risk users. In addition, there were significant differences in the STTR ($P=.049$) and weekday count ratio ($P=.01$). Under the same CI, for *task 2*, the weekday count ratio ($P=.001$), the STTR ($P=.004$), along with the number of followers ($P=.05$), and the total amount of favorites given ($P=.006$) showed significant differences. In this sense, generic control users appeared to tweet more on weekdays (Monday to Friday) as well as focused control users, whereas the opposite behavior was found for suicidal ideation risk users. Regarding the median

STTR, generic control users obtained an STTR value of 0.02, whereas users at risk obtained an STTR value of 0.04, meaning that users at risk seemed to tweet more at night compared with the generic and focused control users as well.

The image scores were also significantly different according to the test with $P=.002$ for the comparison between the suicidal ideation risk and generic control groups, considering a 95% CI. Curiously, for the comparison of the image scores between the suicidal ideation risk group and the focused control group, the test scores were different, with $P=.05$. This can be explained by the fact that users providing information or news about suicide make use of similar images, which characterize the condition, making it difficult to find a significant difference only judging by pictures. As can be seen in Table 8, for both the control groups and the suicidal ideation risk group, the median image scores were slightly higher for the suicidal ideation risk group.

Finally, to compare our control groups (focused and generic control groups), we performed the same test (Mann-Whitney U test) and found significant differences between some of these groups' features ($n=181$) with $P<.001$. Among these features, we found mainly suicide-related lexicons, such as suicide methods, suicide explicit terms, bullying, discrimination, and substance abuse-related terms. We also found differences ($P<.001$) in other textual, relational, and behavioral attributes, such as the number of tweets, number of friends, number of followers, median favorites and retweet counts, overall ratio, polarity score, median time between tweets, and STTR, among others. These differences confirmed our previous assumptions regarding the differences among the control groups.

Table 6. Medians and Distribution Overlapping Index for some of the attributes with the most significant differences between the Suicidal ideation and Focused control groups.

Attribute	Suicidal ideation median	Focused control median	Overlapping index
Anxiety	10.94	0	0.25
Coursing terms	21.52	7.68	0.43
To die (self-reference)	5.45	0	0.25
I feel	46.25	6.71	0.32
Self-loathing	0.03	0	0.35
Verb I	22.66	12.11	0.41

Table 7. Medians and Overlapping Index for some of the attributes with the most significant differences between the Suicidal ideation and Generic control groups.

Attribute	Suicidal ideation median	Generic control median	Overlapping index
Median classifier score	0.72	0.65	0.46
To die	19.5	0	0.25
Number of user tweets	2076.5	453	0.38
Health	17.19	8.18	0.44
Work	35.46	49.59	0.44
I	41.32	9.60	0.23

Table 8. Medians and Overlapping Index for the images score between the suicidal ideation, focused control and generic control classes.

Attribute	Group	Median value	Overlapping index
Images score	Suicidal ideation	0.24	0.64
	Focused control	0.23	
	Suicidal ideation	0.24	0.52
	Generic control	0.23	

Classification Task Results

In this section, we reported the results of our experiments. [Table 9](#) presents the evaluation measure results for each task on the

test sets. We reported the results for the best models, as described in [Table 4](#), along with the baselines.

Table 9. Predictive task results.

Model	Suicidal ideation versus focused control group					Classifier	Suicidal ideation versus generic control group

Short Profile Version Definition Results

As can be seen in [Table 9](#), the definition of the SPVC is successful as the first filter for both the predictive tasks. Indeed, the BoW models trained exclusively on the SPV (baselines 3 and 4) outperformed baselines 1 and 2 for most of the measures

on both tasks. For these representations, tweets unrelated to the topic seem to introduce noise, as they generate a bigger feature space. In contrast, setting a high decision threshold for the classifier implies reducing the vocabulary for the BoW model, which might reduce the performance of the model with the test data.

Regarding the CNN embedding models trained exclusively on the SPV, we can see that the model of task 1 obtains slightly better results compared with the baseline 2 model, whereas the results do not differ much for task 2. In general, we observed a better performance with the SPV for BoW models. Therefore, the combinations evaluated take into account these text-based representations (BoW).

It is important to recall that for the focused control cases, after applying the SPVC with a decision threshold over 0.5, 4 users were left without an SPV because any of their tweets obtained a predicted probability over the threshold. Considering that with higher thresholds, more focused control and generic users could be lost for training our next classifier, this is the threshold we kept for our further experiments (0.5). However, these results also showed that using SPVC reduces the number of control users with an SPV as the threshold value rises and that the definition of the SPV is useful for discarding users who do not present tweets similar to those of the users at risk. Initially, we found that focused control users were more easily discarded than generic users. However, this could be explained by the fact that the control users discarded might correspond to informative accounts such as newspapers, which we assumed to make use of certain terms referring to suicide in a way that does not make use of terms that imply a personal reference or opinion; therefore, the first classifier might find it easier to discard. In any case, this is a supposition as we did not have further access to the writings of users after the annotation.

Combining Model Results

Regarding the methods considered for combining the types of features extracted, we can observe that when these types are evaluated independently from each other, each has a good accuracy, with the SNPSY model obtaining the best results. For the combinations reported in Table 4 for the suicidal ideation risk versus focused control groups, we can observe that the models that use the 3 types of features do not significantly improve the results obtained by the SNPSY model. However, for Images+BoW+SNPSY model 2, we can see a 7% and 11% increase in the AUC score compared with baseline 3 and baseline 1, respectively, for the suicidal ideation versus focused control cases. The AUC difference of their ROC curves using the Delong method was $P=.04$, which is statistically significant, considering a 95% CI.

For task 2, the Images+BoW+SNPSY combination obtained results that improved baseline 1 for the suicidal ideation versus generic control task. For the Images+BoW+SNPSY model 1, we noticed a 4% increase in accuracy compared with baseline 3, and it increased to 8% compared with baseline 1. There was also an increase in the AUC value of up to 4% with the selected features model 2. We also noticed the same measured results between the SNPSY model, the BoW+SNPSY model, and the Images+BoW+SNPSY model 1, implying that we might not improve the performance of the SNPSY model by adding other feature types. In fact, after conducting a Delong test to compare the ROC curves of these models with the baseline 1 model, we could not find significant differences, implying that their performance was not significantly different from the baseline in terms of the AUC measure for this task. However, this also

implied that the use of the SNPSY features alone allowed us to have a model with a reduced number of features that perform as well as the BoW model with thousands of features.

Regarding the role of the images, we can see that when they are individually combined either with the BoW features or the SNPSY features, either the F score or the AUC score increases minimally compared with baseline 3. As part of the experiments for this approach, it is necessary to mention that as some image scores were missing for a few users (up to 4 for each task), the approach considered to address this issue was to replace the scores by the mean of all the users except for the model where only a single score for each feature type was considered; for this case, the instances with missing values were removed.

In reference to the models with a set of selected features, we can notice that these models also outperform baselines 1 and 2 in terms of F1, accuracy, and AUC. The selected features model 1 for both tasks outperformed baselines 3 and 4 on F1 and AUC. It should be noted that these models consider a reduced number of features compared with the baseline models, and the Images+BoW model, as they attempted to reduce the overfitting that the usage of thousands of features might imply.

It is important to mention that for the models evaluated; we did not address the definition of specialized decision thresholds for the classifiers. Therefore, for future work, this should be considered because false-negative predictions should be minimized, and a threshold should be defined to maximize the R value of the suicidal ideation class without leaving aside the tradeoff with Pr. Regardless of this, we can see that most of our models outperformed the baselines in terms of the AUC score, which implies that our models are capable of distinguishing between the classes successfully. In this sense, the definition of a better decision threshold can only contribute to improving the performance of our models.

Comparative Results of Tasks

When comparing the results of both tasks, we saw that the results obtained by the models to distinguish between users at risk from generic control users were not that different from those trained over focused control users. However, we noticed always higher levels of certainty for the models trained to compare users at risk and generic control users. This can be observed when comparing the AUC scores, which are always higher for the models of task 2. In fact, for this task, we can see that a high AUC score is already obtained by the baseline models, and it does not improve significantly with other models. This differs from task 1, where the feature combination is relevant for improving the certainty of the models compared with the baseline.

Figure 1 shows the top 10 most correlated features with the class for each task considering the features of Images+BoW+SNPSY model 2. The most correlated features were given by textual elements such as the BoW model scores and lexicons. It is interesting to see that a behavioral feature as the median time between tweets is relevant for task 2. We can also notice that for both tasks, self-references are relevant and that the usage of explicit suicide terms and health-related terms

is relevant for task 2, as generic control users are not characterized by the usage of terms related to suicide.

Referring to the features that were more predictive for the models generated, we considered the random forest's feature importance function, which is based on its measure of impurity. In this sense, we can see how much each feature decreases the impurity. The more a feature decreases the impurity, the more important is the feature. In this case, because random forest uses multiple trees, the impurity decrease from each feature was averaged across all trees to determine the final importance of the variable. The most important features based on this approach, considering the features of Images+BoW+SNPSY model 2 is shown in Figure 2. For this case, we confirmed that for task 2, the usage of terms related to work and health is distinctive for both classes, as mentioned in the *Statistical Analysis* section.

For both approaches, we can see that the image scores do not appear within the features more relevant for the tasks, implying that textual and behavioral features can be more relevant. Regardless of this, the scores given by certain feature combinations showed that the inclusion of the image scores improves minimally the results of these predictive tasks. Some of the images that most activated neurons at the image processing stage involve pictures of people crying and images containing the term suicide written within them.

We also evaluated the *selected features model 2*, as one of our models with the best results for AUC for both tasks, over a sample of 200 users who were initially labeled as *doubtful* cases. We evaluated 2 models, one trained with the data of task 1 (selected features model 2—task 1) and another trained with the data of task 2 (selected features model 2—task 2). For the first model, we predicted 65% of the doubtful cases as positive (risk), whereas for the second model, 73% of the doubtful cases were found to be at risk. This indicates that our models detected signs of suicidal ideation in more than half of the doubtful users, which is in concordance with the criteria of the first annotator.

Finally, we evaluated the *selected features model 2—Task 1* over a test set of suicidal ideation and generic control users to evaluate the performance of this model over users who do not use a suicide-related vocabulary. We obtained the following results: $Pr=0.91$, $R=0.77$, $F1=0.83$, accuracy=0.84, and AUC=0.95. These results showed that the model obtains better results than generic control users in comparison with its performance over focused control users. Similarly, we evaluated the *selected features model 2—task 2* over a test set of suicidal ideation and focused control users obtaining $Pr=0.83$, $R=0.80$, $F1=0.82$, accuracy=0.82, and AUC=0.91. The performance of this model was worse than that of generic control users and was consistent with the fact that distinguishing these 2 cases is much harder.

Figure 1. Features more correlated with the class to predict for both tasks: Suicidal ideation risk vs Focused control (left), and Suicidal ideation risk vs Generic control (right).

Figure 2. Most predictive features for both tasks: Suicidal ideation risk vs Focused control (left), and Suicidal ideation risk vs Generic control (right).

Discussion

Principal Findings

This study presented a methodology for suicide risk assessment on social media. We extracted information from multimodal

data to build statistical and deep learning-based predictive models. Our models consider a set of features based on BoW and n-grams, lexicons, relational, statistical, and behavioral information, in addition to an image analysis. To the best of our knowledge, this is the first approach that addresses the

combination of all these types of features for suicide risk assessment at the user level. Moreover, we highlighted the usefulness of discarding the noise of writings not related to the topic of study through the definition of an SPV, which outperforms the baseline given by the analysis of the full profile of the user, with an increase in accuracy and F1.

We also compared the performance of predictive methods trained on different control groups with the goal of making a more specialized classifier capable of distinguishing users at risk from control cases, even when the discussed topic is similar. Better results are achieved in terms of AUC-ROC when using generic control users instead of users who make use of suicidal vocabulary. We also highlighted the importance of the interpretability of our features, considering elements that can be understood by clinicians and mapped to their screening practice. The results of our experiments showed that within the types of features analyzed, there are multiple significant features that may lead to the detection of risk situations, the most relevant ones are based on the identification of textual and behavioral elements such as self-references, the number of tweets posted, and the time that passes between each post ($P < .001$).

Text-based features were the most relevant for our model; however, their combination with image-based scores, along with relational and behavioral aspects, allowed us to obtain models that outperform the results provided by an exclusively text-based model.

Limitations

Our study presents some limitations, given mainly by the fact that this is an observational study where there is no access to the personal and medical information that is often considered in risk assessment studies. Limitations are given by the accuracy of the methods applied to infer some of these aspects based on the vocabulary and behavioral patterns of the users. For instance, the weekend tweets count ratio is because of the difference in the posting time according to the user's time zone and the sleeping time tweets ratio, for which we assume that the sleeping time is the period in a day when the user has less activity.

A representativeness analysis regarding age, gender, and location of the users analyzed was not performed, considering that this type of information is not available on Twitter. However, the biases existing in our data samples, regarding these aspects, follow similar gender and age biases for suicides [48], as most Twitter users are male and middle aged [14]. In addition to this, the fact that the lexicon used to extract data was obtained from a different source such as Reddit might imply biases introduced by the type of vocabulary used in Reddit, along with the limitations that the translation to Spanish might introduce even if the terms and phrases used were thoughtfully inspected and verified by specialized clinicians.

Finally, there are also limitations given by the nature of the users who post on Twitter, as they might differ from users at risk who do not choose to make their profiles public or even from users at risk who do not have a Twitter account. In addition, it is not guaranteed that the users annotated as users

at risk are actually at risk because the annotation was performed just from reading a few tweets.

Reproducibility and Ethical Concerns

The analysis of data provided by social networks to detect health problems and assist clinicians is an open issue, not uncontroversial. The aim of our proposal, however, is to shed light on the real capabilities of these systems in a specific theoretical application: suicide risk prevention. Before such systems become available, a careful risk-benefit assessment along with a proper analysis of applicable legal framework compliance and the potential threats to users' privacy and civil liberties shall be conducted [12,26,49].

On the reproducibility of this work, we should respect Twitter's policies on the distribution of the data collected through its API. Taking into account the restrictions of sharing any information that can lead to identifying the users of our study [12], only the calculated features of our experiments along with the code and parameters used on the classifiers will be available under request with a proper explanation of the usage intended for the models. Finally, it is also necessary to address the potential scenarios of misuse of tools based on these models. Guntuku et al [9] mentioned hypothetical cases where these types of screening tools can be used by employers or insurance companies against the interests of people with mental disorders; therefore, policies against these applications shall be defined before their release.

Future Work

By observing the performance of image-based predictive models, we believe that our results can be improved by enhancing the contribution of the textual and relational features. This can be done by exploring other text representation methods and analyzing deeply the network and interactions between users. In addition, we believe that these methods can be extended and applied to different use cases related to mental disorders, such as depression, anxiety, or eating disorders.

We believe that the approach presented in this study can evolve into a real-time system that emits alerts when users at risk are found. It is necessary to recall that given that scenario, the idea of such a tool is to be the first filter to assist clinicians and does not intend by any means to replace their work. In fact, a readable subset of tweets from the SPV, with the top k tweets ordered according to the SPVC, can be an output of the system for clinicians to evaluate and proceed with future screening steps, if allowed. Indeed, legal and ethical issues for the deployment of such systems should be analyzed before. However, we believe that a tool of this kind can be the starting point for the development of noninvasive interventions where specialists and social media community members can contribute to the recovery and prevention of mental health issues and suicide. Again, the appropriate protocols and procedures should be defined for this instance. In particular, there should be a deep analysis of the implications of a potential intervention taking into account the legal boundaries set for the treatment of personal data in this context.

Acknowledgments

Abstract

Background: A 2012 World Health Organization report recognizes betel nut use as an urgent public health threat faced by the Western Pacific region. However, compared with other addictive substances, little is known about how betel nuts are depicted on social media platforms. In particular, image-based social media platforms can be powerful tools for health communication. Studying the content of substance use on visual social media may provide valuable insights into public health interventions.

Objective: This study aimed to explore and document the ways that betel nut is portrayed on the photo-sharing site Instagram. The analysis focuses on the hashtag #pugua, which refers to the local term for betel nut in Guam and other parts of Micronesia.

Methods: An exploratory content analysis of 242 Instagram posts tagged #pugua was conducted based on previous research on substance use and Instagram and betel nut practices in Micronesia. In addition, the study examined the social engagement of betel nut content on the image-based platform.

Results: The study findings revealed content themes referencing the betel nut or betel nut tree, betel nut preparation practices, and the unique social and cultural context surrounding betel nut activity in Guam and Micronesia. In addition, certain practices and cultural themes encouraged social engagement on Instagram.

Conclusions: The findings from this study emphasize the cultural relevance of betel nut use in Micronesia. These findings provide a basis for empirically testing hypotheses related to the etiological roles of cultural identity and pride in shaping betel nut use behavior among Micronesians, particularly youths and young adults. Such research is likely to inform the development of culturally relevant betel nut prevention and cessation programs.

KEYWORDS

betel nut; areca catechu; areca; cancer; health; Guam; Micronesia; Instagram; mobile phone; culture

Introduction

Background

Betel or areca nut is the fruit of a palm tree (*Areca catechu*) consumed as a psychostimulant by over 600 million people worldwide [1]. Betel nut chewing stretches from the African continent to the islands of Micronesia and has been prevalent

since the dawn of recorded time [2]. Betel nut is enjoyed by both men and women as well as the young and old, often in combination with tobacco. Similar to other psychostimulants, betel nut chewing is known to cause a sense of euphoria, well-being, feelings of warmth, and increased capacity to work [3]. However, there are a number of health issues associated with betel nut consumption, most notably oral cancer [4].

Betel nut use is best understood as an orphan disease in the medical sense. It is consumed by non-Europeans in poor countries and under researched both in the West and in countries where it is endemic [5]. Increasingly, governments and health organizations are viewing betel nut chewing as a preventable threat to public health and a drain on medical resources.

In 2004, the International Agency for Research on Cancer classified the use of betel nut, with or without tobacco, as carcinogenic to human beings [6]. A 2012 World Health Organization report recognizes betel nut use as an urgent public health threat faced by the Western Pacific region, including Micronesia. Micronesia includes US territories such as the Northern Mariana Islands and Guam and island nations in free association with the United States, such as the Republic of Palau, Federated States of Micronesia, and the Republic of the Marshall Islands [7]. Cancer is 1 of the 2 leading causes of mortality in the US-Affiliated Pacific Islands (USAPI) [8,9]. Lung and oral cancer incidence and mortality rates are markedly higher in the USAPI than in the mainland United States [10].

Scholars have begun examining how social media platforms such as Facebook, Twitter, and YouTube contribute to alcohol use [11-13], smoking [14,15], and other health concerns [16,17]. Social media use in public health communication has been characterized as still in a *wild west* phase, where practitioners design and employ untested strategies [18], and the role of image-based social media platforms remains unexplored [19]. Systematic research is required to investigate how social media can be utilized to improve health communication.

As images are powerful tools of health communication [20], Instagram represents a unique social media platform that focuses on visual communication and the everyday ubiquity of smartphones. The use of betel nut in its various forms occurs throughout Southeast Asia and the Pacific Islands, where more than half of the world's mobile subscribers live [21]. A recent study found that betel nut content is trending on Instagram, with evidence of increasing user engagement [22]. Therefore, it is important to explore how betel nut use is depicted on an image-based social media platform such as Instagram.

Use of Social Media to Understand Betel Nut Use

Two theories that have been used to explain the uses and effects of social media include uses and gratifications (U&G theory) [23] and social cognitive theory (SCT) [24]. As originally conceived, the U&G theory suggests that individuals are driven to use media to satisfy certain social and psychological needs, such as, among others, wanting to integrate themselves into society and escape the real world [25]. Recent studies have identified factors that may motivate individuals to use Instagram, including wanting to interact with others, archiving or documenting one's experiences, expressing oneself, escaping, and peeking or surveillance [23,26]. Such motives might also explain why individuals may choose to post betel nut-related content on Instagram.

On the other hand, SCT [27] posits that individuals can learn to adapt behaviors by modeling what they observe in the media. This assumption of SCT is consistent with the findings of recent studies, which indicate that as individuals are exposed to

depictions of the use of a particular substance on social media, they become more likely to use the substance [28-30]. Using SCT as a framework may help understand how substance use behaviors are promoted on social media platforms [31]. Similarly, this study seeks to examine distinctions of betel nut-related content on Instagram to see how the social media platform may be used to promote betel nut use.

With 800 million users and 500 million users using the site daily, Instagram is the leading photo-sharing social media platform [32]. The majority (71%) of Instagram users are aged between 18 and 24 years and visit Instagram daily, with 55% using the platform several times a day [33]. As a networked visual social media platform, Instagram's images, videos, and interactive content engagement can have a notable impact on people's knowledge, attitudes, and perceptions of betel nut use. As Instagram is primarily a smartphone app, it is a technology that takes advantage of the portability and habitual use of mobile media [34]. As a result, the omnipresent nature of smartphones could offer a candid examination of betel nut practices within the everyday lives of its users. Furthermore, Instagram images and videos are uploaded and shared directly from a smartphone where other users interact with the content through likes and comments. The power of Instagram likes and comments has health implications, particularly among teenagers and young adults [35,36].

Depicting Substance Use on Instagram

Instagram and similar image-sharing platforms have been the subject of several content analyses related to the promotion and use of addictive substances. For the most part, these studies favored visual over textual content utilizing topical hashtags to capture and document the context of individual use and marketing tactics undertaken on the platforms.

As a plant-based carcinogen, betel nut and betel quid have certain qualities that are similar to the marijuana plant. Instagram posts in marijuana-related hashtags showcased visual images of the marijuana plant [37]. Popular images included marijuana in its traditional forms (ie, buds and leaves) and nontraditional forms (ie, marijuana concentrates and marijuana-infused edibles). In addition, evidence of individuals using marijuana as well as marijuana-related advertisements demonstrated that marijuana content is prevalent on Instagram and helps to normalize and promote its use.

There is also evidence for the presence of hookah (water pipe) tobacco smoking content on visual social media platforms. Tumblr features prominent images of hookah pipes and smoke [38]. To a lesser degree, Tumblr also depicts the presence of waterpipe-related items such as hookah tobacco flavors, electronic hookahs, marijuana, alcohol, and tobacco products. Evidence of social gatherings, particularly between men and women, was also observed. Similarly, Instagram content using the hashtag *#hookah* found images featuring individual waterpipe use, paraphernalia, and social gathering [39]. The presence of promotional material was prominent on Instagram and often cross-promoted alcohol use. In this regard, the marketing power of Instagram [40] may be well-suited to promote waterpipe use and nightlife entertainment.

Recent studies have also documented electronic cigarettes (e-cigarettes) and vaping content on Instagram. In a dataset of 2208 Instagram images, the 3 most prominent themes were advertisements, products, and activity [41]. Advertisement themes explicitly promoted a commercial product and demonstrated the power of Instagram as a marketing tool. Activity themes showcased individuals exhaling aerosols, whereas product themes featured e-cigarettes or electronic juice (e-juice) bottles. An important finding is that likes and comments were found more with activity and product themes than with advertisement-themed images. Therefore, interactivity may prioritize particular Instagram content to larger audiences through social engagement on the platform [42]. A similar study considered e-cigarette visual content on both Instagram and Pinterest. Examining 1800 images from both image-based social media platforms, the popularity of marketing was evident, with 60% of Instagram posts devoted to marketing e-cigarettes. The second most common theme was customization, where users shared information about modifying e-cigarette devices for both functional and aesthetic purposes [43]. Product-related themes (ie, e-juice or flavors) were also evident. As Instagram is a very popular social media platform among teenagers, there is particular concern that Instagram postings may be especially attractive to youth, and that interest in flavors and juices will lure youth and others to try e-cigarettes.

Other health behaviors have been the subject of content analysis on Instagram. For example, a recent study examined the visual content of cigars and cigarillos on Instagram [44]. The findings indicated that Instagram promotes marijuana and tobacco use and promotion. In particular, Swisher products are used to promote the use of marijuana through blunt-making. Instagram images depicted individuals smoking little cigars and cigarillos as well as joints and blunts, though this was a less popular theme.

Social and Cultural Characteristics of Betel Nut in the Western Pacific

Chamorros inhabited the Mariana Islands, an archipelago located in the Western Pacific, when European explorers first arrived in 1521. The Chamorro word for betel nut is *pugua*. Although betel nut is known for its lexical diversity [5], it is the preferred term for betel nut among the various ethnicities of Guam. There are several ways to prepare betel nut for consumption, but 2 distinct practices have emerged in Guam and Micronesia. Betel nut may be chewed with slaked lime (*afok*) and betel pepper leaf (*pupulu*) in the form of a betel quid [45]. This is the most common and traditional preparation throughout the world [46]. Peoples across Micronesia consume betel nut (typically unripened) in this way and spit out the juices as well as masticated quids [47]. However, most Chamorro chewers prefer mature nuts without lime and betel pepper leaves. Moreover, they ingest the juices and the betel nut itself [47]. In fact, Guam is the only island in Micronesia where people chew the mature areca nut [7].

Social and cultural motivations are prominent in the use of betel nut and prove difficult for sustaining health interventions [48,49]. *Pugua* represents Guam's social glue, the bond that builds and maintains social networks among Chamorros and

Micronesians [50]. It is shared among friends and family at weddings, anniversaries, and countless other social gatherings. Chewing betel nut is a habit that many Chamorros and Micronesians actively pass on to the next generation because it is a part of their heritage and is viewed as an important cultural identifier [47,51]. As a result, youth are continually exposed to betel nut practices leading to early onset of oral pathologies [46].

Health and the Native Hawaiian and Pacific Islander Populations

As an image-based social media platform with health implications, Instagram intersects with 3 important concerns for the Native Hawaiian and Pacific Islander (NHPI) population. In comparison with other groups, the NHPI population is young and increasing at a higher rate [52]. As teens and young adults increasingly move toward visual social media platforms [53-55], image-based platforms represent an important space for public health interventions that speak to the changing demographics in NHPI communities. Furthermore, adolescents and young adults consume betel nut, and social pressure is an important contributing factor for deciding to chew [56]. Second, few data are available for NHPI on health and wellness; however, there is much need to address inequalities in vital areas of NHPI community life [57]. All too often, NHPI population data are aggregated with other Asian American groups [52]. Finally, the NHPI population faces challenges in maintaining their unique languages and cultures. Previous research has shown that Pacific Islander communities value social media as a way to preserve culture and indigenous knowledge [58,59]. Betel nut use is closely tied to culture in Guam [47,51,60,61] and throughout the USAPI [62,63]. All these denote important aspects for exploring how social media can promote health and behavioral change [64].

The Goal of the Study

This study is an attempt to explore the ways in which betel nut is depicted on the photo-sharing site Instagram. As an image-based social media platform, little is known about what betel nut content is depicted on Instagram. This leads to the first research question:

- Research Question 1: How is betel nut portrayed and represented on Instagram in Micronesia?

Instagram interactivity through user content may shape user perceptions and choices undertaken on the site. For this study, social media engagement takes the form of *liking* and *commenting*. Thus, the second research question is as follows:

- Research Question 2: How do Instagram users engage with Instagram's betel nut images and videos they encounter?

Methods

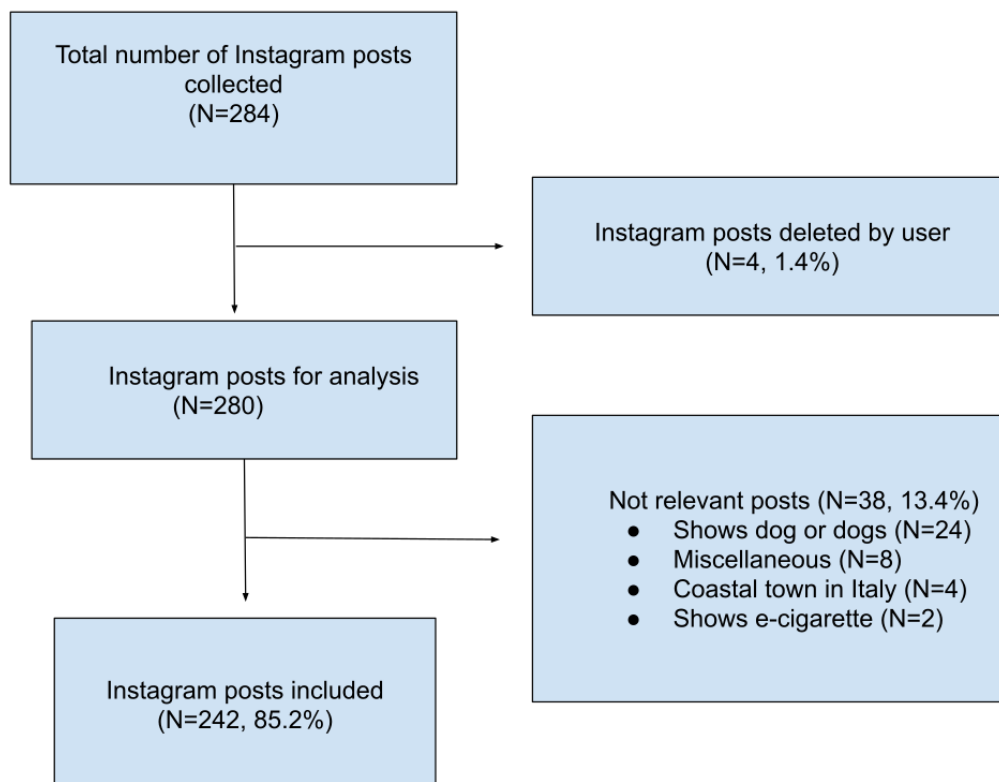

Data Collection and Analysis

To acquire Instagram content, Netlytic was employed as a cloud-based social media analytics tool [65]. Netlytic has been used to collect, analyze, and visualize social media data on a variety of research topics from political discussion on Twitter [66] to health care community practice [67]. On May 22, 2017,

public Instagram posts tagged #pugua were collected using the Instagram application programming interface (API) accessed through Netlytic. Data collection consisted of 284 Instagram posts dating back to 2011, uploaded by 180 unique Instagram users. A total of 4 posts were deleted from Instagram 1 month

after data collection. All nonrelevant images and videos were also removed, resulting in a final dataset of 242 Instagram posts (234 images and 8 videos, 156 unique users). Figure 1 shows the number of posts identified and reasons for exclusion.

Figure 1. Inclusion of Instagram #pugua posts and reasons for exclusion. E-cigarette: electronic cigarette.

The unit of analysis was an Instagram post (metadata, image, caption, and comments). All images and videos were captured for data analysis. In addition, engagement was measured by adding the number of likes and comments for each post.

Content Analysis

A coding scheme was constructed based on prior content analysis studies on substance use and Instagram and the existing literature on betel nut use [37,39,47]. Images and videos were coded in content categories that addressed the type of betel nut depicted in the image and any paraphernalia present. This provided the category *betel nut type* that concerned the depiction of betel nut tree or leaves, betel nut paraphernalia, and the type of betel nut. The codebook accounts for 2 distinct practices between Chamorro betel nut preparation (mature nut) and non-Chamorro, Micronesian (Chuukese, Palauan, and Yapese) preparation (unripe nut with slaked lime and/or tobacco). Depictions of betel nut use formed an additional category, though later removed in pilot testing. Similar to marijuana, betel nut provides the medium for products and accessories such as jewelry and other consumer goods. Betel nut product advertisements were coded.

Drawing on the strong link between betel nut and Chamorro culture [47], the codebook accounted for the visual and textual depiction of Chamorro culture. In addition, posts that referenced island life in Guam were considered a separate category. Working through the data, *stereotype* accounted for the

contentious use of betel nut by Micronesians in Guam [60]. All 3 categories were placed under an umbrella theme of *cultural identifier*.

Prior studies have shown that betel nut use has notable social characteristics, such as encouraging social acceptance and social meetings [47,51,68]. For example, a bag of betel nut can promote future social acceptance among peers through respect for tradition and social promotion [51]. In addition, betel nut is often brought as a gift or favor for celebrations and social meetings [47]. Two content categories documented *social acceptance and promotion* and *social gathering*. Social gathering was further divided into 2 subthemes for either *celebration* or *social meeting*.

Betel nut practices intertwine with familial relations. Thus, children and youth are exposed to betel nut at an early age. The initial codebook accounted for the presence of youth (ie, children, adolescents, or young adults) in image or video content. The last content category referenced traditional or independent media coverage of betel nut use.

For coding, images and videos can be placed in multiple content categories. For example, if an image depicted the betel nut tree ripe with betel nut, the image was coded to both *betel nut tree or leaves* and *Yapese style* (if Yapese-style betel nut was shown in the tree). If the image also included the presence of young

children, the image would receive an additional code for *children under youth presence*.

To judge the effectiveness of the codebook, 2 student coders assessed a sample ($n=60$) of the images and videos. A codebook with instructions and examples was created. After the first round of testing, codebook deficiencies led to improved content category definitions and the elimination of inadequate categorizations. For example, the depiction of betel nut use was difficult to detect in Instagram posts as it involves closed-mouth chewing. In addition, there were few perceived instances of betel nut chewing in the dataset, which were subsequently removed from the codebook.

A second round of interrater agreement was undertaken with a different set of more experienced coders. Utilizing their feedback on the coding instrument, a revised codebook was created, eliminating some content categories and improving the clarification of existing content categories. In all, 3 agreement measures demonstrated codebook validity: percentage concordance, Kappa α , and Krippendorff α . Given the multiple content categories and exploratory nature of the study, codebook concepts were considered reliable if percent agreement was

$\geq 85\%$, and reliability coefficients were 0.50 or higher. A total of 6 primary content categories produced favorable levels of interrater agreement ([Multimedia Appendix 1](#)). Subthemes found in the betel nut type, cultural identifier, and youth presence categories yielded acceptable levels of interrater agreement ranging from 0.57 (betel nut tree or leaves, 85% agreement) to 1.00 (cultural stereotype, 100% agreement).

Results

Content Analysis

To answer the first research question, the 242 Instagram posts produced 386 top-level codebook references using NVivo 11. Of these, *betel nut type* was the most frequent primary content category, yielding 209 references or 54.1% (209/386) of the coded content. As shown in [Table 1](#), betel palm tree or leaves and Chamorro, or Yapese-style betel nut, represented the majority of content references (182/209, 87.1%). Many of the Chamorro (56/64, 88%) or Yapese-style (34/48, 71%) betel nut were in a prepared state ready for consumption. Betel nut paraphernalia (mainly betel nut cutters) was displayed in 12.4% (26/209) of the referenced category content.

Table 1. Distribution of betel nut type categories (N=209).

Theme	References, n (%) ^a
Betel nut tree or leaves	70 (33.5)
Chamorro style nut	64 (30.6)
If Chamorro style nut, is it prepared?	56 (26.8)
Yapese style nut	48 (23.0)
If Yapese style nut, is it prepared?	34 (16.3)
Betel nut paraphernalia	26 (12.4)

^aPercentages do not total to 100% because of the two conditional categories with their listed percentages.

The second most frequent content referenced on #pugua was images and videos addressing various aspects of cultural identification. Cultural identification references accounted for 22.3% (86/386) of the coded data ([Table 2](#)). Of these, posts referencing visual and/or textual aspects of Chamorro culture represented more than half (55/86, 64%) of the content category. A total of 23% (20/86) of cultural content displayed elements

of island life in Guam. As spitting has become a sign of racial tension on the island, the remaining content (12/86, 14%) depicted stereotypical images of Micronesian use of betel nut. This included images of red spittle on the ground or public *no spitting* signs, which serve as blatant racialized markers of tension between Chamorros and Micronesians.

Table 2. Distribution of cultural identification categories (N=86).

Theme	References, n (%)
Chamorro culture	55 (64)
Island life	20 (23)
Stereotype	12 (14)

Social acceptance and promotion comprised approximately 10.1% (39/386) of the dataset. As shown in [Table 3](#), social acceptance and promotion included a bag or bags of betel nut. Youth presence (N=24) and betel nut product advertising (N=23) represented 6% of the overall content. Youth presence was equally split between children (aged 0-10 years) and adolescents (aged 11-17 years). Some Instagram posts showed children or

adolescents handling betel nut in a playful manner. A total of 23 image or video references attempted to use #pugua to sell or market betel nut products, clothing, or accessories. A total of 5 #pugua Instagram posts depicted media coverage referencing documentaries addressing health concerns or the practice of betel nut chewing.

Table 3. Distribution of social acceptance and promotion, youth presence, betel nut products and accessories, and media coverage categories (N=386).

Theme	References, n (%)
Social acceptance and promotion	39 (10.1)
Youth presence	24 (6.2)
Betel nut products and accessories	23 (6.0)
Media coverage	5 (1.3)

Social Engagement in #pugua

The average engagement score (likes + comments) was 43.33 (SD 48.47) and displayed an upward trend (Figure 2).

To determine if particular #pugua content related to social media engagement, engagement scores were classified into 3

categories: low (0-18), medium (19-49), and high (≥ 50). Matrix coding resulted in 68 low engagement posts, 111 medium engagement posts, and 62 high engagement posts. For each engagement group, we ranked the 3 most frequent categories (Table 4).

Figure 2. Social media engagement on #pugua (N=242).**Table 4.** Top 3 content categories by level of engagement.

Ranking	Low	Medium	High
1	Chamorro-style betel nut (22) ^a	Betel nut tree or leaves (35)	Chamorro culture (18)
2	Betel nut tree or leaves (20)	Chamorro culture (30)	Chamorro-style betel nut (16)
3	Yapese-style betel nut (17)	Chamorro-style betel nut (27)	Betel nut tree or leaves (15)

^aNumbers in parentheses indicate the frequency of the content category appearing in the matrix cell.

For the second research question, Instagram posts featuring betel nut tree or leaves (Figure 3) and Chamorro-style betel nut (Figure 4) consistently appear regardless of the level of social engagement. When Chamorro-style betel nut is shown, it is often in a prepared state. At the medium and high engagement level, 95% (41/43) of the Chamorro-style betel nut posts showed betel nut in a Chamorro-prepared style (diced or cut). For low

engagement, 68% (15/22) of Chamorro-style betel nut posts were in a prepared state (8/17, 47% for Yapese-style betel nut). For Instagram posts that generated medium and high engagement levels, visual or textual aspects of Chamorro culture were notably present. Highly engaged #pugua posts were more likely to feature Chamorro betel nut preparation or culture compared with other content categories.

Figure 3. Artist's impression of a typical high engagement #pugua image featuring a betel palm tree and mature betel nut. Illustration by Jessica K Sato.

Figure 4. Artist's impression of a typical high engagement #pugua image featuring mature betel nut, betel pepper leaves, slaked lime, and betel nut cutter. Illustration by Jessica K Sato.

Discussion

Principal Findings

As shown in previous studies, betel nut use and practice vary by geographic region [69,70], and Guam is a unique case [47,51,68]. For Guam, betel nut chewing practices that are exhibited offline may replicate themselves on the web within the pugua hashtag. Prior evidence indicated 2 distinct betel nut chewing practices in Guam: Chamorro style and Yapese style [47]. Content analysis confirmed these 2 distinct preparation practices by noting the type of betel nut displayed (mature or unripe), as well as the distinct preparation practices before consumption. The Chamorro style prepares a mature betel nut that is often diced before consumption. In contrast, the Yapese style reflects Micronesian cultural preferences to consume an unripe nut with a piper betel leaf mixed with slaked lime or tobacco to form a betel quid. Aside from Instagram posts that featured betel nut tree or leaves, Chamorro- and Yapese-style betel nut and their respective preparation states were the most frequently occurring content in #pugua. In addition, approximately 10% of Instagram posts showed betel nut cutters that slice betel nut for consumption. As a result, it is plausible that #pugua users on Instagram have opportunities to observe how the betel nut moves from a whole nut to a chewable form. Further studies could determine if these visual depictions of betel nut cultural practices lead to greater uptake in betel nut use, especially among adolescents and young adults.

Approximately 1 out of every 5 #pugua posts referenced Chamorro cultural content either through image/video, text, or both. Pugua has been referenced as the social glue for Chamorro culture. In the exploration of #pugua, there were depictions of Chamorro culture such as dance, art, and festivals without the display of betel nut in the Instagram content. As prior work has demonstrated that Chamorros use social media to learn, capture, and preserve their culture [59], public health interventions should carefully consider how their visual messages link betel nut content on Instagram to Chamorro cultural identification.

#pugua and Social Engagement

As Instagram is a visual social media platform, the circulation of the image through likes and comments may have more value than the image content [71]. The findings from this study determined that certain Instagram #pugua posts had higher social engagement than others. Instagram #pugua posts with moderate or high amounts of social engagement centered around visual content privileging Chamorro culture, Chamorro-style betel nut, and betel nut tree and leaves. Instagram and the smartphone favor *in the moment* sharing often reflecting everyday life instances. As betel nut use is an underexamined research phenomenon, there is a need to understand who, where, when, how, and why people chew betel nut [72]. The exploratory results of this study provide insights into the who, how, and why people in Guam and Micronesia chew betel nut and confirm the existing limited research in this area. Thus, this study represents a first step toward understanding how image-based social media platforms capture and collate information on betel nut practices.

Comparison With Prior Work

As a plant-based carcinogen, the areca nut and betel pepper leaf share certain qualities with the marijuana plant. These psychoactive plants provide facilities for ingesting and supplementing the use of the product. For example, betel nut may be consumed within the betel pepper leaf. Similarly, marijuana buds or leaves may be consumed or form additional use practices. Both plant-based products supply the medium for additional products and accessories. As a result, betel nut practice and use on Instagram may closely resemble the practice and use of marijuana on Instagram. Comparing the study's findings with the large-scale work on marijuana and Instagram [37], there are some similarities, but also notable differences.

As indicated by previous research on marijuana and Instagram [37], the most frequent Instagram posts involved showing the betel palm tree and leaves, mature or unripe betel nut, and its various consumption practices. In this regard, the betel nut and marijuana plant share certain visual characteristics that appeal to their respective audiences on Instagram. Therefore, public health professionals should consider how to balance appealing visual content with helpful information for young people about the known risks of betel nut use.

The consumption and masticatory use of betel nut did not appear to be compelling content on Instagram. Very few Instagram posts featured chewing of betel nut or betel quid. If it was displayed, it was only through a closed mouth where a lump could be witnessed in the person's jaw. Previous studies have shown that betel nut chewing and spitting are bad habits that undermine public health [73]. On a visual communication medium such as Instagram, it is difficult to portray betel nut chewing as novel and interesting to facilitate social networking. This finding is in contrast to the work done on the use of marijuana in social media [37,74]. Previous research has shown that marijuana use on social media facilitates social networking about marijuana, particularly among young adults and underage youth. Ingesting marijuana in its traditional plant-based and novel forms (edibles and concentrates) is perhaps more visually appealing and also helps to normalize and promote marijuana use as a form of practice. Similarly, e-cigarette, hookah, and cigar/cigarillos Instagram content featured activity and use themes such as smoking, exhaling clouds, and smoke tricks [38,39,41,43,44]. The exploratory findings in this study did not observe the use of betel nut on an image-based social media platform.

Advertising and marketing tactics have been well documented for e-cigarette and marijuana use on Instagram [30,37,41]. However, there was little evidence of advertising and product promotion of betel nut in #pugua. This is most likely a reflection of the lack of a clear marketplace that sells specific accessories and products related to its consumption, such as vape shops and marijuana dispensaries. Betel nut products that were advertised tended toward clothing or jewelry accessories made from betel palm tree or pepper leaf fibers. These Instagram posts are often linked to specific references to Chamorro culture. Therefore, it is plausible that #pugua on Instagram functions less as a marketplace and more as a cultural space.

Limitations

There are limitations to this study. The dataset was small and limited the generalizability of the study findings. A paid Netlytic account captured all posts that met the inclusion criteria. Given the size of the dataset, all #pugua posts were analyzed, and there was no sampling required. However, data collection and sampling remain a challenge for capturing image-based social media content because of API restrictions and privacy concerns [19]. Algorithms on Instagram also influence the visibility of the #pugua content [75] and certainly contribute toward its social engagement. Nonetheless, caution should be exercised to avoid generalizing the findings of #pugua to all Instagram users and contexts. Future work should empirically test the study's implications through experiments documenting image content effects on Instagram betel nut users or pursue large-scale data collection of #betelnut and regional betel nut terms as hashtags on social media platforms.

Conclusions

This study analyzed the ways in which betel nut is depicted on the photo-sharing site Instagram. A content analysis of #pugua

explored betel nut practices in #pugua and its engagement on the platform. The study findings suggest that betel nut preparation practices reflect offline practices in Guam and Micronesia. In addition, socially engaged content is more likely to reflect the areca nut, betel palm tree or leaves and Chamorro cultural sensibilities. Compared with prior work on substance use and Instagram, #pugua content demonstrated similarities to marijuana in terms of depicting the betel palm tree, areca nut, and quid ingredients. In addition, advertisements of betel nut clothing and accessories were observed. In contrast to prior work, there was little evidence of actual betel nut use and consumption, which is typically a prominent feature in marijuana, hookah, and vaping content on image-based social media.

The findings from this study emphasize the cultural relevance of betel nut use in Micronesia. The findings provide a basis for empirically testing hypotheses related to the etiological roles of cultural identity and pride in shaping betel nut use behavior among Micronesians, particularly youths and young adults. Such research is likely to inform the development of culturally relevant betel nut prevention and cessation programs.

Acknowledgments

The authors would like to acknowledge the U54 University of Guam (National Institutes of Health [NIH] Grant 1U54CA143728)/University of Hawaii Cancer Center Partnership (NIH Grant 1U54CA143727) for their support. The authors would also like to thank Dr Lala Hajibayova, Mallory McCorkhill, Hannah Mettias, and Lauren Muraoka for their valuable assistance with our research project. We are very grateful to freelance designer and strategist Jessica K Sato for her artist illustrations.

Abstract

Background: Stopping the epidemic of e-cigarette use among youth has become the common goal of both regulatory authorities and health departments. JUUL is currently the most popular e-cigarette brand on the market. Young people usually obtain and exchange information about JUUL with the help of social media platforms. Along with the rising prevalence of JUUL, posts about underage JUUL buying and selling have appeared on social media platforms such as Reddit, which sharply increase the risk of minors being exposed to JUUL.

Objective: This study aims to analyze Reddit messages about JUUL buying and selling among the users of the UnderageJuul subreddit, and to further summarize the characteristics of those messages. The findings and insights can contribute to a better understanding of the patterns of underage JUUL use, and help public health officials provide timely education and guidance to minors who have intentions of accessing JUUL.

Methods: We used a novel cross-subreddit method to analyze the Reddit messages on 2 subreddits. From July 9, 2017, to January 7, 2018, we collected data from the UnderageJuul subreddit, which was created for underage JUUL use discussion. The data set included 716 threads, 2935 comments, and 844 Reddit users (ie, Redditors). We collected our second data set, comprising 23,840 threads and 162,106 comments posted between July 9, 2017, and January 8, 2019, from the JUUL subreddit. We conducted analyses including the following: (1) annotation of users with buying/selling intention, (2) posting patterns discovery and topic comparison, and (3) posting activeness observation of discovered Redditors. Term frequency-inverse document frequency and regular expression-enhanced keyword search methods were applied during the content analysis to extract the posting patterns. The public posting records of the discovered users on the JUUL subreddit during the year after the UnderageJuul subreddit was shut down were analyzed to determine whether they were still active and interested in obtaining JUUL.

Results: Our study revealed the following: (1) Among the 716 threads on the UnderageJuul subreddit, there were 214 threads related to JUUL sale and 168 threads related to JUUL purchase, which accounted for 53.5% (382/714) of threads. (2) Among the 844 Redditors of the UnderageJuul subreddit, 23.82% (201/844) of users were annotated with buying intention, and 21.10% (178/844) of users were annotated with selling intention. There were 34 users with buying/selling intention that self-reported as being <21 years old. (3) The most common key phrases used in selling threads were “WTS,” “want to sell,” “for sale,” and “selling” (154/214, 72.0%). The most common key phrases used in buying threads were “look for/get JUUL/pods” (58/168, 34.5%) and “WTB” (53/168, 31.5%). (4) The most important concern that UnderageJuul Redditors had in obtaining JUULs was

the price (311/1306, 23.81%), followed by the delivery service (68/1306, 5.21%). (5) The most popular flavors among the users with buying/selling intention were mango, cucumber, and mint. The flavor preferences remained consistent on both subreddits. Adverse symptoms related to the mango flavor were reported by 3 users on the JUUL subreddit. (6) In total, 24.4% (49/201) of users wanted to buy JUULs and 46.6% (83/178) of users wanted to sell JUULs, including 11 self-reported underage users, who also participated in the discussions on the JUUL subreddit. (7) Within one year of the UnderageJuul subreddit shutting down, there were 40 users who continued to post 186 threads on the JUUL subreddit, including 10 threads indicating buying/selling willingness that were posted shortly after the UnderageJuul subreddit was closed.

Conclusions: There were overlapping users active in the JUUL and UnderageJuul subreddits. The buying/selling-related content appeared in multiple venues with certain posting patterns from July 9, 2017, to January 7, 2018. Such content might lead to a high risk of health problems for minors, such as nicotine addiction. Based on these findings, this study provided some insights and suggestions that might contribute to the decision-making processes of regulators and public health officials.

KEYWORDS

JUUL; e-cigarette; Reddit; cross-sectional analysis; electronic nicotine delivery system; underage JUUL use

Introduction

The use of Electronic Nicotine Delivery Systems (ENDS; also called “e-cigarettes”) has been increasing rapidly among youth. In 2019, a cross-sectional survey with 19,018 participants showed the prevalence of self-reported current e-cigarette use was 27.5% among US high school students and 10.5% among middle school students [1]. At present, JUUL (by JUUL Labs) is the most popular brand, with more than 70% of the market share of e-cigarettes [2]. The appealing flavors and its relaxing effect cause potential intention and actual use among nonsmoking teenagers [3-5]. In addition, because of the lax regulatory environment in the United States, unregulated constituents in e-liquids as well as high nicotine delivery have led to concerns about addiction potential and pulmonary risks from the use of ENDS products [6-8]. To protect the physical health of young people, in April 2018, the Food and Drug Administration (FDA) issued a statement on preventing teenagers from using and buying JUUL and similar products [9]. As the FDA indicated [9], JUUL was more difficult for parents and teachers to recognize and detect than other e-cigarette products. Therefore, increased efforts to strengthen the regulation of minors' access to JUUL have been implemented.

JUUL's marketing heavily relied on social media platforms like Twitter and Instagram [10]. As a result, young people read and spread information about JUUL with the help of social media platforms [11]. Common JUUL discussions on social media included flavor preference [12-14], use experience [12-16], use location [12,14], purchasing methods [17], etc. Allem et al [12] found that JUUL use occurred in school locations, such as classrooms, bathrooms, libraries, and gyms. Brett et al [14] found teenagers used JUUL because the use of this product was part of a popular trend and to feel the “buzz” (ie, a feeling caused by nicotine). Multiple researchers have noted that adolescents prefer the mango and mint flavors [14,17,18]. Li et al [19] found that the fruit flavor was associated with multiple adverse symptoms, including cough, headache, and lung tightness, though the causal relationship is unclear. With the rise of youth exposure to JUUL, Zhan et al [17] analyzed their purchasing methods. They found that peer-to-peer purchase and

shipping was the most common method for UnderageJuul subreddit users.

As an online forum that allows users to create communities, Reddit has multiple sections (also called “subreddits”) related to JUUL discussion. Previous research determined that underage Redditors post about their JUUL use on Reddit [20]. To better understand and surveil youth JUUL use, researchers have conducted analyses on Reddit data focusing on underage JUUL users and their posting content, such as topic discovery [14,15], age and location distribution [17], popular flavor discovery [15,17], and negative symptoms analysis [19].

Previously, there was a public subreddit on Reddit called UnderageJuul, which was dedicated to discussing underage JUUL use. This subreddit was created in July 2017 and had almost 1000 users at its peak. Right before it was shut down in January 2018, the UnderageJuul subreddit was gaining 8 new members per day [20,21]. Previous studies conducted qualitative analysis on the UnderageJuul subreddit and found that posts in this subreddit included content such as self-reported underage JUUL users seeking sellers, sale advertisements without age verification, and adult users buying for minors to earn money, researchers thought such trade-related content indicated that minors had increased access to JUUL, and there might be other similar communities on social media platforms [17,20,21]. However, the characteristics of the buying/selling-related messages among the users of the UnderageJuul subreddit have not been further identified.

This study aimed to analyze the content on the UnderageJuul and JUUL subreddits that indicated JUUL buying and selling, which provides a more comprehensive understanding of underage JUUL use. Specifically, this study was designed to address the following questions:

First, what are the posting patterns of messages related to JUUL buying and selling on the UnderageJuul subreddit? The “posting patterns” refer to the common key phrases, way of expression, variants, or abbreviations the Redditors used when publishing buying/selling-related posts. For instance, Redditors usually use “look for/need + juul/pods” or “WTB” (short for “want to buy”) to express their buying willingness. Discovering users' posting patterns could enable researchers to extract the core

features of this kind of message, and help regulators continue to identify similar content on social media, thus contributing to the prevention of minors' access to JUULs.

Second, what are the concerns of the users of the UnderageJuul subreddit when they want to buy or sell JUULs? While UnderageJuul users had a willingness to buy and use JUULs, they also expressed concerns regarding JUULs, such as the choice of flavors. Given this subreddit was created to discuss underage JUUL use, identifying the concerns of its users has the potential to uncover specific characteristics of minors or others using that subreddit who intend to buy or sell JUUL. Understanding the topics and concerns discussed in this subreddit could be useful for health departments or educators responsible for the development and implementation of education programs on potential ENDS risk, as well as for regulatory agencies responsible for developing media and educational programs for young people.

Third, will users of the UnderageJuul subreddit cross-publish their comments, questions, and concerns on multiple subreddits at the same time? Will they continue to be active after the UnderageJuul subreddit is closed? We adopted the evaluation of "posting activeness" to address these questions, which involves counting the total number of different posts by users [22]. We chose the JUUL subreddit (ie, the general JUUL discussion subreddit) as a contrast. The posting activeness across subreddits will be compared during two time periods: the time period when UnderageJuul was accessible, and the year after UnderageJuul was shut down. This analysis could provide a deeper understanding of the buying and selling behavior of UnderageJuul users, including the extent to which shutting down one social media channel impacts information-sharing on other platforms, which could have significance for both understanding the breadth and scope of social media networks and the implementation of social media-based educational programs.

By answering the 3 questions above, we hope to provide valuable information to regulators to help them establish practices and policies to minimize adolescent e-cigarette use and safeguard their health. Note that the user analysis in this study was for the users who had public posting records on the UnderageJuul subreddit. The ages of underage users were based on their self-reported age information.

Methods

Overview

We applied a novel cross-subreddit method to analyze the content related to JUUL buying and selling, with a focus on

comparing those using the UnderageJuul subreddit (which was originally designed for young people to discuss the use of JUULs, but soon became a platform to explore and share ways to illegally obtain JUULs) with those using the general JUUL subreddit (which is the main Reddit channel for discussing general JUUL-related topics). Figure 1 shows the framework for our cross-subreddit analyses. It consists of three components: data collection; cross-subreddit content and posting activeness analysis; and results.

Data Collection

The data used in this research consisted of two parts: data from the UnderageJuul subreddit and data from the JUUL subreddit.

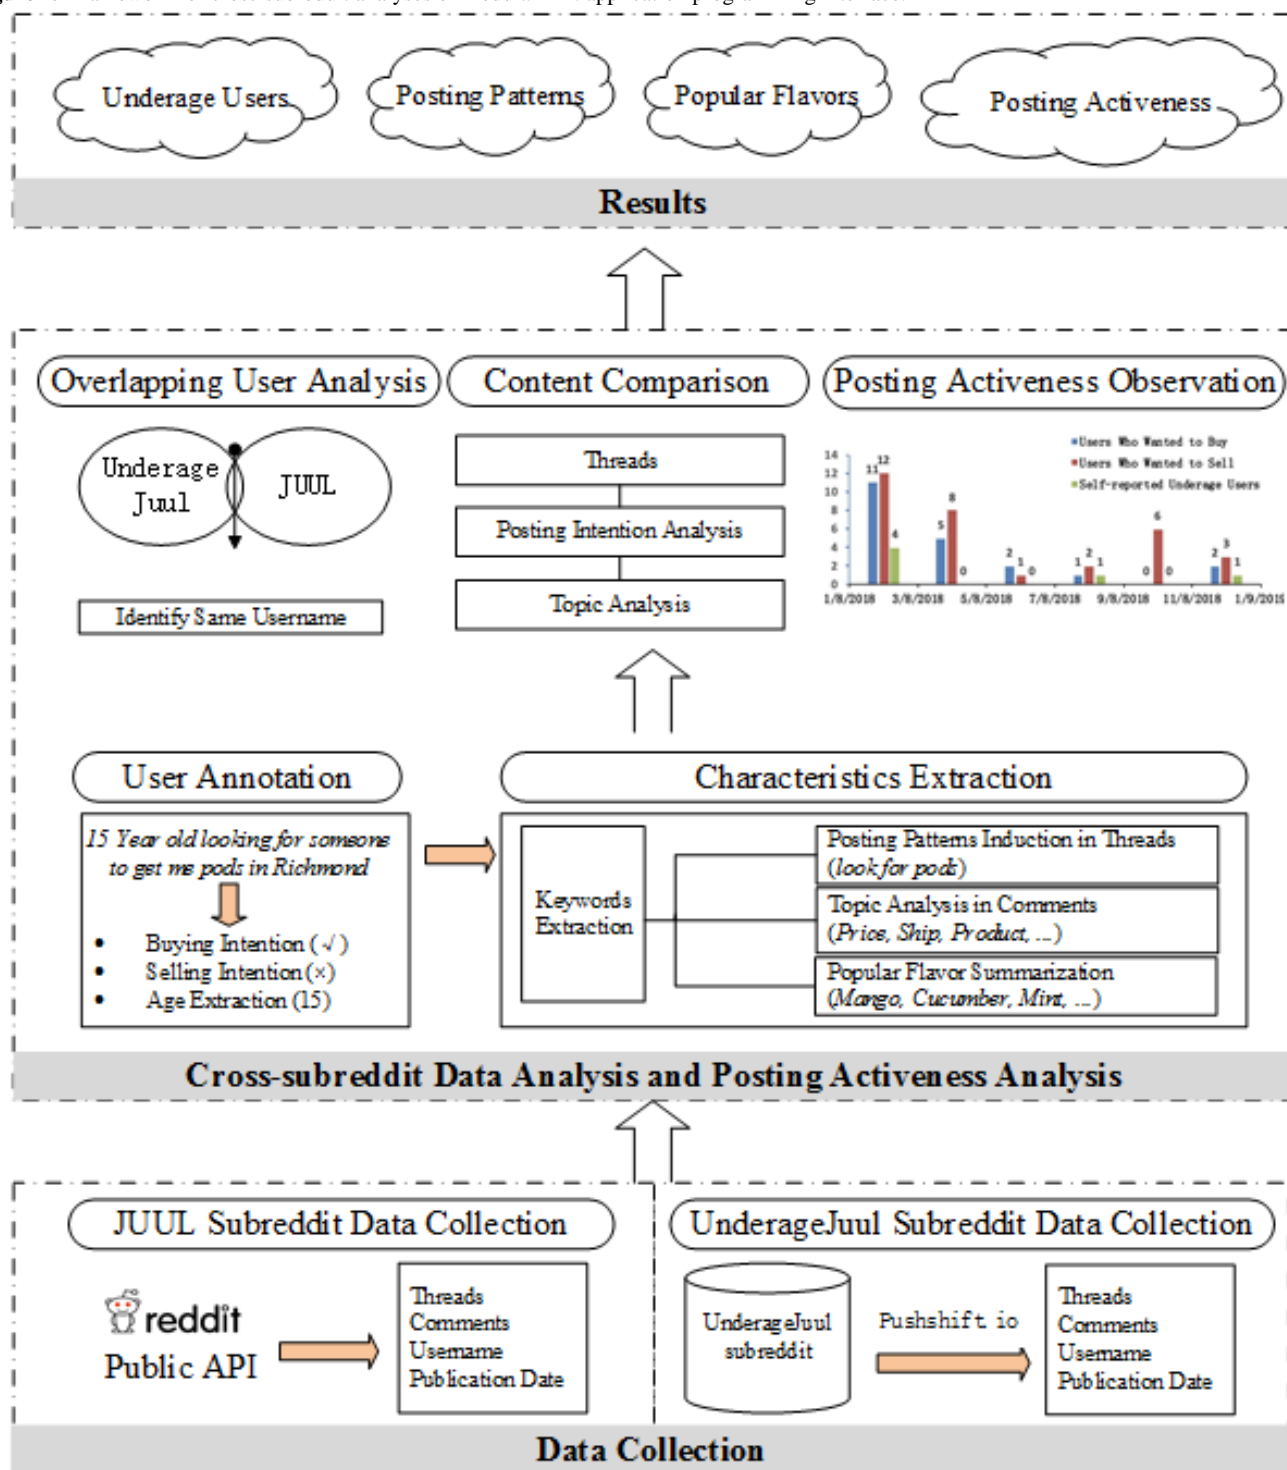

UnderageJuul Subreddit Data Collection

Since the UnderageJuul subreddit was shut down by the time we began our analysis, we collected data from the UnderageJuul subreddit through the application programming interface (API) provided by pushshift.io [23], which is a website that stores all publicly available Reddit threads and comments. The UnderageJuul subreddit was created on July 9, 2017, and was shut down on January 8, 2018. We obtained the complete UnderageJuul subreddit posting and user information data set from that period, including 716 threads, 2935 comments, and 844 Redditors.

JUUL Subreddit Data Collection

We collected data from the JUUL subreddit via Reddit's API [24] from July 9, 2017, to January 8, 2019, which covered two continuous time periods: (1) the same time period of the UnderageJuul data set (from July 9, 2017, to January 7, 2018), and (2) the year after the end of UnderageJuul activities (from January 8, 2018, to January 8, 2019). The first data set (ie, the JUUL-overlap data set) contained 3978 threads, 31,589 comments, and 5785 Redditors. The second data set (ie, the JUUL-afterwards data set) contained 19,862 threads, 130,517 comments, and 18,460 Redditors. Table 1 shows a detailed description of these three data sets.

Note that the data we used in this research were all publicly available on Reddit, and no personal information (eg, account profile) was included. The usernames contained in these data sets are not presented in this paper, for the privacy protection of the Redditors involved in this study.

Figure 1. Framework for cross-subreddit analyses on Reddit. API: application programming interface.**Table 1.** Data set description.

Data set	Time span	Threads, n	Comments, n	Redditors, n	Threads per Redditor, n	Comments per Redditor, n
UnderageJuul	07/09/2017-01/07/2018	716	2935	844	1.95	4.11
JUUL-overlap	07/09/2017-01/07/2018	3978	31,589	5785	2.45	5.95
JUUL-afterwards	01/08/2018-01/08/2019	19,862	130,517	21,186	2.49	7.07

Data Analysis

Overview

The data analyses consisted of three steps. The first step was to annotate the users on the UnderageJuul subreddit that indicated buying/selling intention. Second, the text features were extracted to discover the posting patterns in their posting content. Finally, the activeness of the Reddit accounts was analyzed. We used a cross-subreddit analysis method in this study, thus the results of each step were all compared with the content on the JUUL subreddit.

User Analysis Across Subreddits

Overview

We first set the rules for annotation, then manually labeled Redditors who wanted to buy or sell JUUL on the UnderageJuul subreddit. Based on the results of user annotation on the UnderageJuul subreddit, the overlapping users were detected to discover how many of these users also participated in the JUUL subreddit during the same time period.

Step 1: User Annotation on the UnderageJuul Subreddit

First, two annotators labeled the users who wanted to buy or sell JUULs according to the descriptions in Table 2. Users interested in buying or selling usually post a specialized thread to attract sellers or to advertise the product to be sold, so we

went through all threads on UnderageJuul subreddit. For example, when a Redditor posted a thread saying “[WTB] Looking to buy blue Juul and cucumber pods for under \$75,” he/she was labeled as a user who wanted to buy JUULs; when a Redditor posted a thread saying “I am selling Juul warranty codes, ..., 25\$ per code, 20\$ per code (if you buy 3 or more at once),” he/she was labeled as a user who wanted to sell JUULs. The threads were also tagged with corresponding labels. A Redditor could be annotated as a user who wanted to buy JUULs as well as a user who wanted to sell JUULs, if he/she posted multiple threads indicating both buying and selling intentions. Then, we annotated all comments below these labeled threads to discover users who did not post themselves but replied to those threads and showed buying/selling willingness. The Cohen κ coefficient of the annotation from two annotators was 0.83. We next extracted age information from the posts of these users to discover underage JUUL users. Since the US federal minimum age for sale of tobacco products had been raised from 18 to 21 years (ie, the Tobacco 21 legislation [25]), we labeled Redditors who self-reported that they were under 21 years old as the self-reported underage users. We used regular expressions to extract phrases like “# years old” or “I’m #” to detect age information of corresponding users. Some users did not mention a specific age but had expressions like “I’m underage” in their posts. These users were also labeled as self-reported underage users.

Table 2. Annotation categories and description.

Label	Description
User who wanted to buy JUULs	User who wanted to purchase JUULs peer-to-peer or face-to-face, asked others to buy JUULs for him/her, or wanted to buy a JUUL replacement code to get JUULs.
User who wanted to sell JUULs	User who wanted to sell JUULs to others through shipping or face-to-face trade, buy JUUL for others for a fee, or sell JUUL replacement codes.
Self-reported underage user	User who wanted to buy or sell JUULs and had a self-report age under 21 years old or a description indicating underage.

Step 2: Overlapping User Analysis on the JUUL Subreddit

The username is the unique identifier for each Redditor [26]. We compared the public posting records of these users on the two subreddits UnderageJuul and JUUL (ie, the JUUL-overlap data set). Redditors with the same usernames were regarded as overlapping users.

Content Analyses and Comparison

Overview

The following content analyses consisted of two steps. First, we extracted the common key phrases and words from the user-generated content to summarize the regular posting patterns. Second, we compared the overlapping users’ posts between the UnderageJuul subreddit and the JUUL subreddit.

Step 1: Posting Patterns Extraction on the UnderageJuul Subreddit

First, the textual features needed to be extracted from users’ posts. To achieve this, we used term frequency-inverse document frequency to uncover important words in each post automatically. Based on the frequency of these important words,

we adopted regular expression-enhanced keyword search [27] on each post to discover key phrases. The trigrams near the important words were extracted from the buying/selling-related threads. The key phrases were determined according to the frequency rank and whether the expression was complete. For example, the key phrase “need juuls/pods” was determined because it was a complete expression and had a top rank in the search results of the word “need.” We manually classified the important words and key phrases into several posting patterns based on semantics and phrase structure.

Step 2: Content Comparison on the JUUL Subreddit

We compared the user-generated contents of overlapping users between the JUUL and UnderageJuul subreddits to discover whether these users also published trade-related content on the JUUL subreddit, and whether their concerns remained consistent. For the first perspective, each thread posted by the overlapping users on the JUUL subreddit was automatically labeled if it implied a willingness to buy or sell JUULs using the posting patterns discovered in Step 1. For the second perspective, we conducted a qualitative content analysis on users’ posts on both subreddits. To acquire more detailed and

specific concerns, our analysis was applied to all the comments under trade-related threads on the UnderageJuul subreddit, as well as all the content they posted on the JUUL subreddit (ie, threads and comments). We used the inductive category development method [28] to generate the topics based on the posts' semantics and JUUL background information. For example, expressions like "v1" and "v2" represented versions of JUUL device. When they were identified in the posts, they were categorized with other words (eg, "leak," "refill") that were previously found to be related to JUUL devices, regarded as the "device description" topic. Because flavor is one of the most important factors in ENDS products that appeal to teenagers, we specifically counted the occurrences of JUUL's seven flavors (ie, mango, mint, cucumber, menthol, fruit, crème, and tobacco) among the discussions of these users to discover their preference.

Posting Activeness Observation

Finally, the online posting activeness of these users on the JUUL subreddit was observed during the year after the UnderageJuul subreddit was shut down. We analyzed the posting activeness

of users to find whether they continued to express a willingness to buy or sell in other communities after the UnderageJuul subreddit was closed. Specifically, we searched through the JUUL-afterwards data set to count the number of threads and comments posted by these users, recorded their posting dates to get the posting trend changes, and analyzed their posts. Thus, we manually checked their content to determine whether their posts showed the intention to buy/sell JUUL.

Results

User Analyses Across Subreddits

Among 844 Redditors on the UnderageJuul subreddit, we discovered 201 users who wanted to buy JUULs, 178 users who wanted to sell JUULs, and 45 users with both intentions. Among the 334 discovered users, there were 34 users that were self-reported underage. Of these, 30 indicated a willingness to purchase and 4 were willing to sell JUUL. Table 3 shows the proportion of each self-reported age group. The "teenager, age unknown" group represents users that did not mention a specific age but used expressions like "I'm underage" in their posts.

Table 3. Groups of discovered users with self-reported age.

User age (years)	Number of discovered users
≤15	5
16-18	14
19-21	3
Teenager, age unknown	5

After analyzing the users across subreddits, we found 49 of 201 (24.4%) users who wanted to buy JUULs and 83 of 178 (46.6%) users who wanted to sell JUULs also participated in discussions on the JUUL subreddit. Among the overlapping users, 11 underage users (8 users with buying willingness and 3 users with selling willingness) were discovered. Table 4 shows the detailed statistics of the overlapping users.

We also counted the threads and comments posted by the discovered users on each subreddit. They posted 382 threads in

the UnderageJuul subreddit and there were 1306 comments under their threads. In addition, they also posted 123 threads and 1600 comments in the JUUL subreddit. Table 5 shows the detailed statistics of their posts. We ranked the activeness of all overlapping users according to their posting amount. The most active self-reported underage user published 16 threads and 96 comments on the JUUL subreddit, as well as 1 thread and 44 comments on the UnderageJuul subreddit. There were 128 Redditors that posted 182 replies to this user.

Table 4. Statistics of the discovered users and overlapping users.

User types	UnderageJuul subreddit, n/N (%)	JUUL-overlap subreddit, n/N (%)
Users who wanted to buy JUULs	201/844 (23.8)	49/201 (24.4)
Users who wanted to sell JUULs	178/844 (21.1)	83/178 (46.6)
Self-reported underage users	34/334 (10.2)	11/34 (32.4)

Table 5. Statistics of posts from discovered users and overlapping users.

Data set	Users who wanted to buy JUULs			Users who wanted to sell JUULs		
	Threads, n/N	Comments, n/N	Total, n	Threads, n/N	Comments, n/N	Total, n
UnderageJuul	168/716	180/1306	348	214/716	238/1306	452

Content Analyses and Comparison

Posting Patterns Analysis

We summarized 10 patterns observed in the threads posted by the users discovered on the UnderageJuul subreddit. [Table 6](#) presents each pattern and its ratios. Since one thread may contain multiple key phrases, the total post numbers of the key phrases groups are greater than the total number of posts mentioned in [Table 5](#).

The posting patterns in the threads from users who wanted to buy JUULs all expressed buying willingness directly. They

usually included “looking for juul/pods” (58/168, 34.5%) and “want to buy (WTB)” (53/168, 31.5%) in the title, then described the buying requests in the body, such as the flavor and the location. An example is “Need Pods In Orlando Area. Just an underaged kid looking for pods in the Orlando area any flavor.” The body of these threads also contained the key phrases like “need juul/pods” or “need help for getting juul/pods” (36/168, 21.4%). Alternative expressions were also used to show buying willingness, such as “anyone selling juul/pods” and “anyone know seller in somewhere” (28/168, 16.7%).

Table 6. Regular posting patterns of discovered users on the UnderageJuul subreddit.

User type, topic number, and key phrases	Post, n (%)
Users who wanted to buy JUULs (n=168)	
1 WTB ^a , want to buy, buy juul/pods	53 (31.5)
2 Need juul/pods, need help, need seller	36 (21.4)
3 Look for juul/pods, get juul/pods	58 (34.5)
4 Anyone selling, anyone know seller	28 (16.7)
5 Other	57 (34.0)
Users who wanted to sell JUULs (n=214)	
1 WTS ^b , want to sell, for sale, selling	154 (72.0)
2 Ship, discreet	97 (45.3)
3 Charger, refill, starter	55 (25.7)
4 Sealed ^c , unboxing, unopen, brand new	40 (18.7)
5 Other	39 (18.2)

^aWTB: want to buy.

^bWTS: want to sell.

^c“Sealed” indicates that the product is new and has not been opened.

The posting patterns in the threads from users who wanted to sell JUULs included multiple kinds of information. They usually contained key phrases such as “WTS,” and “something for sale” (Pattern 1, 154/214, 72.0%) in the title to draw attention. Pattern 2 (97/214, 45.3%) was about shipping services, such as the shipping scope and discretion. Pattern 3 (55/214, 25.7%) involved a description of the product, including the accessories. If the product was brand-new, that was emphasized (40/214, 18.7%). For instance, a user who wanted to sell JUULs posted the following thread: “[WTS] JUUL V3 Starter Kit \$40 in BTC. Brand new, sealed starter kit. Will ship quickly and discreetly.”

Based on the above posting patterns, we further analyzed the threads posted by the overlapping users on the JUUL subreddit and found 17 threads with buying purpose and 18 threads with selling purpose.

Content Comparison

We summarized the 15 topics discussed by the discovered users in the UnderageJuul and JUUL subreddits. [Table 7](#) shows the 10 topics discussed in the UnderageJuul subreddit and the 5 topics discussed in the JUUL subreddit.

Table 7. Topic comparison of the UnderageJuul and JUUL subreddits.

Subreddit, topic number, and topic	Key phrases	Posts, n (%)
UnderageJuul subreddit (n=1306)		
1 Price	Price, how much, \$number	311 (23.81)
2 Contact	PM ^a , message	63 (4.82)
3 Ship	Ship, shipping	68 (5.21)
4 Scam	Scammer, scam, fake	83 (6.36)
5 Product description	v1, v2, v3 ^b , refill	53 (4.06)
6 Purchasing method	eBay, website, .com, store	20 (1.53)
7 Paying method	Gift card, PayPal, Bitcoin, BTC	40 (3.06)
8 Stock	Still available, still selling, how many, still have, SOLD	15 (1.15)
9 Flavor	Mango, mint, fruit, cucumber, crème, menthol, tobacco	27 (2.07)
10 Other	Posts did not contain the words above	626 (47.93)
JUUL subreddit (n=123)		
1 Buying/selling	This was annotated manually.	35 (28.46)
2 Flavor	Mango, mint, fruit, cucumber, crème, menthol, tobacco	16 (13.01)
3 Product description	Leak, refill, charged, help, real, fake, charger, battery	25 (20.33)
4 Experience sharing	Buzz, cough, lung	9 (7.32)
5 Other	Posts did not contain the words above	38 (30.90)

^aPM: private message.

^bv1, v2, and v3 represent the different versions of JUUL devices.

In the UnderageJuul subreddit, discussions were primarily focused on buying and selling JUULs. Topic 1 (311/1306, 23.81%) refers to users raising questions about the price. The replies usually contained specific prices in the form of \$number. Topic 2 (63/1306, 4.82%) refers to posts in which authors would ask others to contact them through private messages if they did not want to directly answer questions in public replies. Topic 3 (68/1306, 5.21%) was about shipping services. Topic 4 (83/1306, 6.36%) includes posts in which some users commented under the threads with selling purposes that the post author is a scammer. Topic 5 (53/1306, 4.06%) refers to descriptions of the selling product, including the version of the product and whether it was refilled. Topic 6 (20/1306, 1.53%) and Topic 7 (40/1306, 3.06%) refer to the methods of purchasing and paying. Since some users self-claimed they were vendors from eBay or other websites, they accepted payment methods such as VISA gift cards and PayPal. Some users offered to buy JUULs from stores for underage users for a fee. Bitcoin was sometimes accepted as a form of payment. Topic 8 (15/1306, 1.15%) is related to users asking post authors about their stock. The post authors might update the threads with “SOLD” to indicate that they had sold out. Topic 9 (27/1306, 2.07%) represents the flavors discussed in the threads and comments; this topic is analyzed in detail in the next section.

In the JUUL subreddit, Topic 1 (35/123, 28.46%) represented the threads about buying and selling JUULs, which suggested the most popular topic discussed by these users did not change on this subreddit. Topic 2 (16/123, 13.01%) was about the flavors discussed by the overlapping users. The flavor topic is

also analyzed individually in the next section. However, the focus of this topic was different from that on the UnderageJuul subreddit. Topic 3 (25/123, 20.33%) referred to the product descriptions. Unlike the product description topic (Topic 5) on the UnderageJuul subreddit, the discussions about this topic on the JUUL subreddit were about describing the device’s problems and seeking help. For instance, a post about this topic stated, “... All my official juul pods keep leaking out all over my juul. Idk what’s going on.” Topic 4 (3/123, 2.44%) was about negative experience sharing. For example, one user said, “I used the juul to stop smoking but have noticed a chronic cough starting to begin.”

It can be seen that access to JUUL was a common topic for the discovered users in both subreddits. However, the content in the UnderageJuul subreddit included more details about JUUL transactions. The flavor topic and the product description topic appeared on both subreddits. The focal point in the UnderageJuul subreddit was users describing their buying/selling demands, while in the JUUL subreddit, users commonly shared their JUUL use experience.

We identified the 10 users who posted the most for each topic as the active users. In the UnderageJuul subreddit, there were 16 users who were active in multiple topics. There were 4 active users who were active in 3 topics at the same time. The most active user was in the top 10 among 6 topics. In the JUUL subreddit, there were 6 users active in multiple topics. The most active user posted about 4 topics at the same time. Notably, there were 7 users who were active in both subreddits, and the topics they promoted were related to JUUL buying and selling.

Flavor Analysis and Comparison

We counted the word frequency of the 7 flavors mentioned above and compared their popularity in the two subreddits. Among 382 threads and 1306 comments in the UnderageJuul subreddit, mango (n=50) was the most popular flavor, followed by cucumber (n=39) and mint (n=31). Fruit (n=9), tobacco (n=7), menthol (n=5), and crème (n=5) were not mentioned frequently. These flavors were mentioned when users described the selling products or the buying requests, as shown in the two examples given here:

Pods Available: I have 8 tobacco, 16 cucumber, 8 mint, 12 menthol, 8 mango, and 4 fruit. ...

... Looking for 2 packs of mango pods let me know if you have any for sale.

Among the 123 threads in the JUUL subreddit, there were 16 threads that mentioned flavor. The most popular flavor was mango (n=8), followed by cucumber (n=7) and mint (n=7). These results were similar to those found in the UnderageJuul subreddit, which indicates that users' flavor preferences did not

change between subreddits. There was not much discussion of the crème (n=2), menthol (n=2), tobacco (n=2), and fruit (n=1) flavors. One example of a flavor topic post is as follows:

Just got my hands on a couple packs of cool cucumber. ..., it's really good and up there with mango.

However, we found 3 reports of adverse symptoms among the 8 threads that mentioned the mango flavor in the JUUL subreddit. Two users reported mouth burning and one user reported a stomachache, as shown below:

...when ever I hit a mango pods my stomach almost immediately starts hurting.

Posting Activeness Observation

We observed the posting activeness of all labeled users in the year following the shutdown of the UnderageJuul subreddit (January 8, 2018, to January 8, 2019). Table 8 shows the number of labeled users who had posted during this time period, and Table 9 shows the number of posts they made. For both tables, values were summed across consecutive 2-month periods.

Table 8. The number of users who posted messages in the year after the UnderageJuul subreddit was removed.

Time period	Users who wanted to buy	Users who wanted to sell	Self-reported underage users
1/8/2018-3/7/2018	11	12	4
3/8/2018-5/7/2018	5	8	0
5/8/2018-7/7/2018	2	1	0
7/8/2018-9/7/2018	1	2	1
9/9/2018-11/7/2018	0	6	0
11/8/2018-1/9/2019	2	3	1

Table 9. The number of posts by the labeled users in the year after the UnderageJuul subreddit was removed.

Time period	Posts by users who wanted to buy	Posts by users who wanted to sell	Posts by self-reported underage users
1/8/2018-3/7/2018	34	48	17
3/8/2018-5/7/2018	12	24	0
5/8/2018-7/7/2018	6	3	0
7/8/2018-9/7/2018	1	3	1
9/9/2018-11/7/2018	0	23	0
11/8/2018-1/9/2019	4	28	2

In the first 4 months after the UnderageJuul subreddit was shut down, the discovered users were still active in the JUUL subreddit. They posted 10 threads with the purpose of buying or selling. In the next 2 months, these users were less active and did not post threads with buying or selling willingness. One possible reason was that the administrators of the JUUL subreddit started to prohibit posts about trading JUULs. In the second half of the year, the discussions changed to flavor and device-related topics. There were 2 users who expressed the intention of quitting JUULs because of nicotine addiction and the high price.

Discussion

Principal Findings

This paper used a cross-subreddit method to analyze underage JUUL use. Based on our previous study [17], this paper further analyzed the content related to underage JUUL buying and selling on Reddit, and summarized its characteristics and patterns. Additionally, this paper analyzed the posting activeness of the discovered users in the JUUL subreddit after long-term observation.

In summary, we found 214 threads related to JUUL sale and 168 threads related to JUUL purchase on the UnderageJuul subreddit, which accounted for 53.5% (382/714) of the

UnderageJuul subreddit's threads. In addition, we found that these threads were posted with certain regular word-level patterns. The most common key phrases used in selling-related threads were "WTS," "want to sell," "for sale," and "selling" (154/214, 72.0%). The most common key phrases used in buying-related threads were "look for/get JUUL/pods" (58/168, 34.5%) and "WTB" (53/168, 31.5%). The FDA has already announced policies about preventing youth use of and access to JUUL e-cigarettes, and reducing the marketing and promotion of tobacco products toward minors [29,30]. Though the UnderageJuul subreddit has been removed, there might be other similar communities that support underage JUUL trading. The posting patterns could help discover this type of content among other communities on Reddit and different social media platforms such as Twitter and Instagram. Once such content is discovered, a link to the official educational page about the tobacco products' adverse health effects could be automatically added below such posts or sent to the content publisher via private message. This could have implications for interventions to reduce youth ENDS use.

We have demonstrated that discussions about obtaining and using JUUL e-cigarettes occur in multiple venues, and not just the subreddit dedicated to underage JUUL use (UnderageJuul). Among the 844 Redditors of the UnderageJuul subreddit, 23.82% (201/844) of users were annotated with buying intention, and 21.10% (178/844) of users were annotated with selling intention. We found that 24.38% (49/201) of users who wanted to buy JUULs and 46.63% (83/178) of users who wanted to sell JUULs had posting activeness on the JUUL subreddit. The results are consistent with our earlier research [17] regarding the approaches of illegally obtaining JUUL products. The buying/selling topics were common concerns for users on both subreddits during the same time span. This indicates the people who want to access to JUULs may not express their desires on only one platform and may seek multiple resources. When regulatory organizations take action to reduce youth's access to JUUL and similar products, they might need strategies on multiple social media platforms simultaneously. When selling ENDS products via online shopping sites and other vaping-related websites, necessary warning statements should be clearly presented alongside, including the health risks and nicotine strength [31].

In our cross-subreddit analysis, we developed a procedure to evaluate the effect that the discovered users had based on their posting activeness and user-generated content. The most active self-reported underage user we discovered had published content that at least 128 Redditors read about, so there was a social network effect that could impact youth use of ENDS products like JUUL. Evaluation of JUUL-related content posted by those active users on social media platforms, especially the underage ones, is highly relevant to educators and those involved in tobacco regulation. In addition, it is not clear from these analyses whether these active users are paid by vendors or companies for advertising tobacco products to minors, and this is an important analysis that should be conducted to understand the motivation of those who post about these products on social media.

Our findings suggest that price was what the UnderageJuul users most cared about, along with the delivery services. The mango, mint, and cucumber flavors were the favorite flavors among these users. In January 2018, the UnderageJuul subreddit was banned. We found there was a self-reported underage user that posted a message on the JUUL subreddit asking for an alternative to the mango flavor, such as mint. In addition, we discovered negative health symptoms were reported on the JUUL subreddit after the use of the mango flavor. These popular flavors are still available in many countries and young people continue to discuss ways to acquire ENDS products like JUUL on Twitter, Reddit, etc. Despite regulatory and company efforts to reduce access to flavored ENDS products [32], considerable research is still needed on the role of flavors regarding the addiction potential of ENDS products [13,18,19,33]. In particular, since social media can provide timely and rapid information on what is being discussed about a particular ENDS product, continued analysis of social media is an essential early warning surveillance method for identifying addiction and the health risks of JUUL and other products (eg, the NJOY Ace product that has steadily increased in sales).

In our posting activeness observation, we found that in the year after the UnderageJuul subreddit was removed, 40 users (including 4 self-reported underage users) continued to post 186 threads in the JUUL subreddit. There were 10 threads with buying/selling willingness during the first 2 months. This result indicates that shortly after the UnderageJuul subreddit was closed, users transferred to other subreddits to have discussions, and continued to publish messages about buying/selling JUUL pods through social media platforms.

In conclusion, this study highlights the need for continued research on how social media can become a more fundamental component of the tobacco and nicotine surveillance system. In particular, rapid and extensive analyses of social media can serve as an early warning system of the rapid rise in the use of new products and health problems that are occurring as a result of using those products.

Limitations and Future Work

Since the data we used for analysis was user-generated public information (ie, post, publication date, and username), there were many limitations for us regarding determining the authenticity and legitimacy of users' claims like self-reported age, their stock of JUUL devices, and the completion of trading. As the UnderageJuul subreddit was built specifically for discussing underage JUUL use, we thought the age distribution analysis was valuable and necessary. In addition, we noticed the scam topic (ie, Topic 4 on the UnderageJuul subreddit on Table 7) during the content analysis, which indicates some Redditors who claimed to have JUULs to sell might post such content to scam other users, rather than to trade JUULs. This might cause discrepancies for regulators when trying to identify actual buyers and sellers.

In addition, the conclusions and insights of our study were based on content analysis of the two specific subreddits during the specific time span. Our findings might not be generalizable to other subreddits or other time periods, considering the different barrier policies being carried out. However, future studies could

be extended to other subreddits that are about JUULs and other social media platforms (eg, Twitter) with the same methodology and mechanism.

Conclusion

This is the first study to investigate the patterns of buying and selling among underage JUUL users by utilizing information from multiple connected online forums. We hope these findings can be conducive to timely guidance and education of underage JUUL users, thus protecting the health of young people.

Abstract

Background: Social media has recently provided a remarkable means of delivering health information broadly and in a cost-effective way. Despite its benefits, some difficulties are encountered in attempting to influence the public to change their behavior in response to social media health messages.

Objective: This study aimed to explore the factors that affect individuals' acceptance of using social media as a tool for receiving health awareness messages and adapting such content accordingly by developing a smart health awareness message framework.

Methods: A quantitative method was adapted to validate the hypotheses and proposed framework through the development of a survey based on the technology acceptance model with the extension of other constructs. The survey was distributed on the web to 701 participants from different countries via Qualtrics software; it generated 391 completed questionnaires, and the response rate was 55.8% (391/701).

Results: Of the 391 respondents, 121 (30.9%) used social media platforms often during the week, and 27 participants (6.9%) did not use social media. In addition, 24.0% (94/391) of the respondents used these platforms to seek health information. On the basis of the results, perceived usefulness ($\beta=.37$; $P<.001$), gain-framed message ($\beta=.04$; $P<.001$), and loss-framed message ($\beta=.08$; $P<.001$) were seen to positively and significantly influence people's intention to use social media as a means to spread information about health promotion. The proposed smart health awareness message framework identifies 64.2% of the variance in intention to use, 55.4% of the variance of perceived usefulness, and 26.2% of the variance of perceived ease of use.

Conclusions: This study sheds light on the factors that are associated with people's intention to use and adopt social media in the health promotion domain. The findings reveal that the intention of using social media for health awareness purposes is positively impacted by the perception of usefulness of social media and the design of health messages. Future research might seek to explore other factors that relate to people's behavior. This point of view will assist health organizations in developing their health messages more effectively and to be patient friendly.

KEYWORDS

social media; health promotion and social media; health awareness; health promotion; eHealth; technology acceptance theory

Introduction

Background

The advent of the internet has become a fundamental avenue for gaining health information [1] and for the provision of interventions to enhance healthy behaviors [2]. Rapid and easy access to the internet has driven individuals to go on the web to seek health information [3]. The internet has contributed to

the evolution of a new era of communication, known as social media. The phenomenon of social media is defined as a collection of web-based social networking apps that enable individuals or groups of people to communicate and interact with each other, share information, collaborate, and exchange content [4,5]. The advancement of the internet, web-based health information, and social media has driven the emergence of electronic health (eHealth). According to the World Health Organization [6], eHealth can be defined as "the use of

information and communication technologies (ICT),” which involves the development of spreading health information through digital methods [7,8].

One aspect of public health communication, which has received increasing attention, is the media channels through which health messages could be successfully conveyed to a wide range of relevant audiences. Several studies have found that mass media (eg, television, radio, newspaper, leaflets, and posters) have a positive impact on health promotion [9-12]. However, others have marked the ineffectiveness of this impact [13], unlike social media, which has greater potential in health promotion for individuals and health care professionals because of its ability to deliver meaningful health content [14] in different formats such as text, images, and videos [15]. It can be argued, therefore, that social media has largely proved to be an effective and influential instrument in spreading health awareness messages [16] because of its easy access by all socioeconomic strata and its cost effectiveness [3]. Due to the evolution of eHealth and social media tools, health organizations reinforce practitioners in providing health-related information to increase health awareness and obtain better health outcomes [17,18].

Despite the increasing utilization of social media by health organizations in disseminating health awareness, the actual impact of social media interventions demands further research to explore the factors that may affect users’ acceptance of this technology and adoption of the content [15,19]. These factors include the frame of the message, trust of the content, and the degree of technology acceptance [20-22]. This study is motivated by the need to take into consideration such key factors that lead to effective acceptance of social media as a means to receive, read, and apply health awareness messages.

The paper provides the results of the smart health awareness message framework development and, in turn, ensures spreading health awareness messages effectively on a faster and wider scale through social media. The focus of this paper presents the identification of the factors influencing an individual’s intention to use social media as a means to receiving health awareness messages and following its instructions for the well-being of the individual by using the technology acceptance model (TAM) [23], task technology fit (TTF) [24], and prospect theory [25].

The research approach starts with a review of related literature concerning health awareness messages and the use of social media in spreading such messages to a wider community. The second stage involved developing a conceptual framework of the factors influencing an individual’s intention to use social media for health promotion. The effectiveness of the proposed framework was evaluated based on the hypotheses developed in this study. To validate these hypotheses, public opinion was analyzed based on a web-based survey using the Qualtrics software with 391 participants.

Such a random sample size would be a good representative because it reflects the characteristics of the population from which it has been drawn (ie, from a wide range of countries) and different opinions that were relatively close to each other.

The remainder of this paper is structured as follows. The first section includes an introduction that presents the research

motivation, research approach, and the aim of this paper. The second section presents a review of the related literature. The third section presents the conceptual framework along with the proposed hypotheses. In the fourth section, methods of data collection and measurement development are presented. The section following the fourth section presents some public perspectives of the smart health awareness message framework through data analysis, including testing hypotheses. Finally, the authors conclude with a discussion of the research limitations and future work.

Literature Review

Public health communication has emerged as a modern strategy to change public behavior by raising awareness of risk diseases. Public health communication refers to “the scientific development, strategic dissemination, and critical evaluation of relevant, accurate, accessible, and understandable health information communicated to and from intended audiences to advance the health of the public” [26]. Therefore, health promotion encompasses the development of approaches that supply health knowledge to individuals, motivating them to adopt the healthy behaviors and change their current ones [27]. Traditionally, mass media has been used as a tool for public health promotion, which has involved a variety of forms including television, newspapers, radio, booklets, billboards, leaflets, and posters [9,12,28]. Each format varies according to the level of effectiveness and drawbacks. For example, numerous studies have explored the efficacy of using television campaigns to promote smoking cessation [29,30]. However, exposure to such campaigns has been found to be expensive in comparison with radio broadcasts [12,30].

Although several studies have highlighted the effectiveness of promoting health awareness via leaflets and posters [31-33], the reality is that they are still an expensive media to be published. This is due to the long process and expense of publishing paper-based media and also the factors such as time and labor consumption, limited information being given to the audience [34], poor health content [35], and overlapping information [36]. These reservations also include editing the health content, graphical design, printing, and distributing. Updating any of these printed media requires a further long loop of modification.

Social media has a great potential in public health communication, as it provides patients and the public with the best opportunity by delivering meaningful health content. Ba and Wang [14] found that online social groups have an essential role to play in an individual’s routine in terms of encouraging them to adopt a healthy lifestyle through observing their daily diet. Previous research has focused on customized digital health interventions that help individuals to control chronic disease and make proper decisions accordingly [37]. Roland et al [38] developed an online community represented by #FOAMed on Twitter for the purpose of sharing medical knowledge. Similarly, Diddi and Lundy [39] indicated the usage of Twitter to spread breast cancer awareness by 4 different health organizations, presenting different factors of the health belief model in the content of the message. A previous study has supported diabetic

people by offering a forum for sharing personal experience and providing feedback on performance by physicians [40].

So far, few research studies have examined the influential factors that affect people's intention to use social media in the health promotion context [15,20]. However, understanding these factors is important for designing health promotion messages that incorporate content strategy and simplicity [41]. To fill this research gap, a conceptual smart health awareness message framework was developed based on the TAM, TTF, and prospect theory, as presented in the following section.

The TAM assumes that the extent to which the technology is accepted and used by an individual is predicted by 2 main constructs (factors): perceived usefulness and perceived ease of use [23]. TTF focuses mainly on the features that the technology offers, and thus, it believes that technology must match the task it supports to have performance impact [24]. TTF has 4 key constructs (elements), one of which is technology characteristics. Prospect theory postulates that health communication messages can be designed to shed light on the benefits (gain) or the consequences (loss) of performing a specific behavior [25].

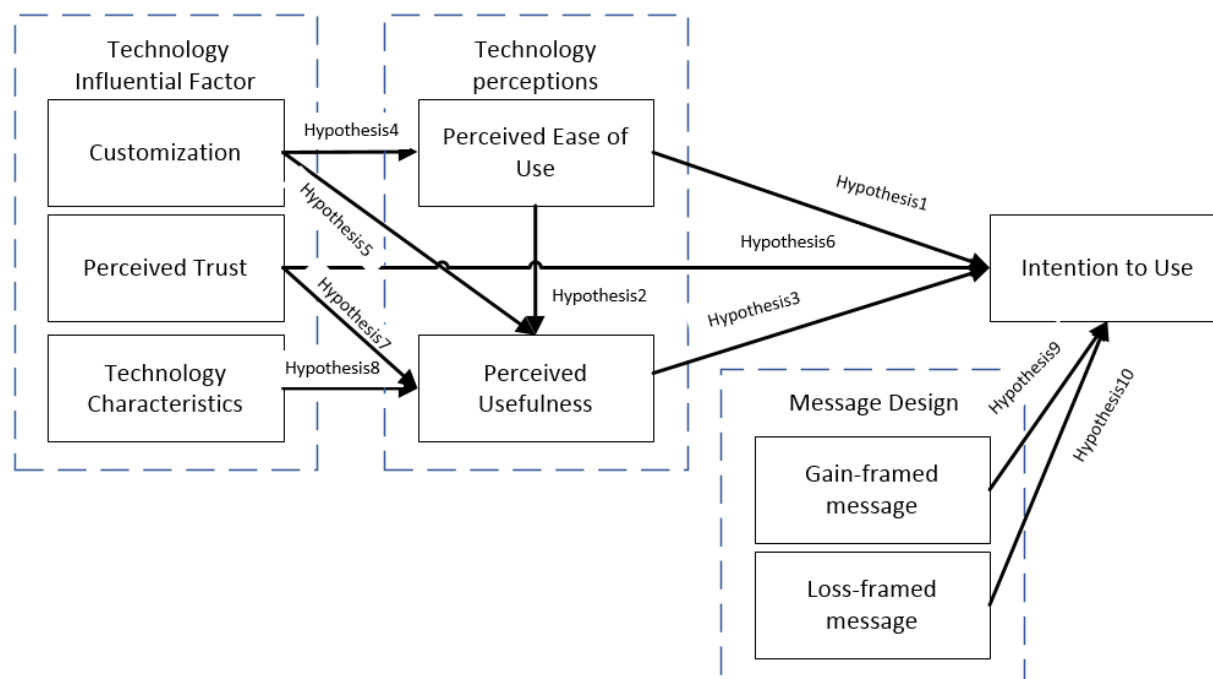

Smart Health Awareness Message Framework and Hypothesis Development

The smart health awareness message framework includes different elements, which are called constructs, and each construct represents the key factor of a different adapted theory. Thus, this study investigates the impact of such constructs that

influence an individual's acceptance of using social media as a tool for receiving health awareness messages and consequently following its instructions for the individual's well-being. The authors adapted the key constructs of 3 theoretical foundations: (1) TAM, (2) TTF, and (3) prospect theory. The TAM serves as a concrete base to develop the conceptual framework. The TTF offers a key element of social media characteristics, whereas the prospect theory provides a theoretical framework for designing such messages. The proposed framework, therefore, will help in designing health messages that will be spread via social media apps.

Figure 1 illustrates smart health awareness message framework, where the authors proposed different hypotheses that provide a statement based on the feature extracted from the intended theory to represent a specific state of an individual's beliefs. This is to be used in a survey to obtain public perspectives on the use of social media technology in receiving health messages. First, they hypothesized that intention to use is influenced by perceived ease of use, perceived usefulness, perceived trust, gain-framed message, and loss-framed message (hypotheses H1, H3, H6, H9, and H10). Second, the authors hypothesized that perceived usefulness is impacted by perceived ease of use, customization, perceived trust, and technology characteristics (H2, H5, H7, and H8). Finally, it was hypothesized that perceived ease of use is influenced by customization (H4). Each defined hypothesis supports the relationships among the constructs of the framework. The following subsections present in detail the constructs of smart health awareness message framework.

Figure 1. Smart Health Awareness Message Framework.

Technology Perceptions

Technology perceptions include the key elements of the TAM, namely, perceived ease of use and perceived usefulness.

Perceived ease of use, as proposed by Davis [23], alludes to the extent to which the user of the technology will think that the use of a certain tool will be easy or free of effort. As social media supports easy access, easy engagement with its interactions (ie, reply, like, retweet, and repost) [42,43], and

easy navigation, people's intention will be enhanced to receive and apply health messages accordingly [44]. Exposure to such interactions is generally dynamic, resulting in encouraging health care professionals to create online communities where medical knowledge can be easily shared and freely accessed [38].

A positive association was supported between perceived ease of use and usefulness of technology usage that involved different contexts [45-47]. Therefore, H1 states that perceived ease of use of social media positively influences people's intention to receive and follow health awareness messages. H2 states that perceived ease of use positively influences perceived usefulness of social media to receive and follow health awareness messages.

Perceived usefulness is widely defined as "the degree to which an individual believes that using a particular system would enhance his/her job performance" [23]. In this study, perceived usefulness refers to the degree to which an individual considers that the benefits of social media will enhance his or her intention to receive and then follow health awareness messages. Some individuals may perceive social media as a personal digital assistant with the purpose of improving medical usage [48].

The link between the usefulness of social media and the intention to adopt such technology as a means to acquire and share health information has been explored by a number of studies [47,49]. Moreover, Deng et al [50] investigated the association between perceived usefulness and the individual's intention to adapt to mobile health. Therefore, H3 states that perceived usefulness of using social media will positively influence people's intention to receive and follow health awareness messages.

Technology-Influencing Factors

This section includes 3 technology factors, customization, perceived trust, and technology characteristics, which influence the overall perceptions of social media to receive and follow health awareness messages.

Message customization means reaching target people with individualized health messages that work well to engage with the messages effectively [51]. Patrick et al [52] found that people who were exposed to customized text messages with the purpose of promoting dietary behaviors were more likely to achieve weight loss compared with those related to printed materials. Customization in the conceptual framework refers to the empowerment that enables intended systems to understand its users' demographics and interest topics and then tailor their health messages accordingly, for example, the preferable time, the frequency of the messages, the type of disease, and the type of social media platforms. Social media customization provides a number of features that encourage users to prioritize particular accounts to view and act accordingly. On Twitter, Instagram, Facebook, and WhatsApp, by selecting get notifications, a user will automatically be notified every time these accounts post. Thus, such features allow users to easily access and efficiently follow social media posts. By leveraging social media customization efficiently, such technology can be harnessed to be most instrumental and useful in practice.

Customization correlates to perceived usefulness, as evidenced by Ho [53], who found that customized information technology services offer considerable benefits to customers that involve producing right content and format at the proper time for usage motivation purposes. In addition, customization in web-based interfaces has optimized web-based shopping due to its ease of use [54]. Therefore, H4 states that customization will have a positive impact on perceived ease of use of social media platforms to receive and follow health awareness messages. H5 states that customization will have a positive impact on perceived usefulness of social media platforms to receive and follow health awareness messages.

McAllister [55] defined trust as "the extent to which a person is confident in, and willing to act on the basis of, the words, actions, and decisions of another." He studied the trust between patients and the source of health-related information. Undoubtedly, the trust that individuals place in web-based health knowledge varies with the source of such knowledge. Thus, trust is a significant factor that affects people's adoption of health awareness messages [56,57]. Perceived trust in the framework will evaluate the contextual part of health-related information, and perceived usefulness will evaluate the practical part of social media use for passing health messages.

The association between trust and perceived usefulness has been discussed in several studies, confirming that the more the user perceives the technology to be useful, the greater the likelihood of trusting the content of such technology and therefore their intention to use it [58-60]. Thus, H6 states that perceived trust will positively influence people's intention to use social media to receive and follow health awareness messages. H7 states that perceived trust will positively impact perceived usefulness of social media to receive and follow health awareness messages.

Technology characteristics constitute a key element of the TTF model identified by Goodhe and Thompson [24], which refers to the extent to which a technology fits when the required tasks are met. The more individuals perceive that the technology suitably fits the intended tasks, the greater the likelihood that they will use that technology [61]. TTF has been used to measure social media appropriateness in many topics, such as sharing information about flood anticipation [62]. A previous study proposed that sharing is a fundamental characteristic that social media provides [63], which refers to the extent to which content can be exchanged among users [64]. For Facebook, Twitter, and Instagram, qualities that correspond to sharing are the message itself and media representation, which involves photographs and videos in terms of photograph quantity and video length [22].

The suitability of TTF depends on the user selection of the technology, which is based on technology characteristics that perfectly correspond to the task's attributes. Hence, this research demonstrates that social media features are capable of boosting the adaptation of this technology in viewing health awareness messages. Earlier studies have investigated the relationship between TTF constructs and perceived usefulness of using SMS for health awareness purposes [65]. Therefore, H8 states that technology characteristics will positively impact perceived usefulness of social media to view health awareness messages.

Message Design

This section presents a technique that aids in designing health awareness messages through prospect theory.

In loss- and gain-framed message design, health messages that aim at a particular behavior in terms of its benefits (gains) or costs (losses) play a significant role in health communication [57,66]. Health messages, therefore, might be designed either to emphasize the benefits of complying with the message content or the consequences of failure to comply with it [67,68]. For instance, a gain-framed message targeting increasing water intake could be *drinking a lot of water daily can help you lose weight*. In contrast, a loss-framed message could be *not drinking enough water causes you to gain weight* [69]. According to the prospect theory, the associated persuasion of gain- and loss-framed appeals is linked to the level of risk involved in the relevant actions [25]. The more individuals believe that they are at risk, the more motivated they are to the loss-framed message [57]. Therefore, the effectiveness of gain- and loss-framed messages varies depending on the goal of the message, either preventing or detecting health problems [66,70]. Therefore, positive messages are manifested to be more powerful in disease prevention messages [68], such as skin cancer prevention [66], whereas loss-framed messages are more likely to be useful in disease detection [71]. A number of studies have examined the effectiveness of negative messages in designing persuasive health messages. Meyerowitz and Chaiken [71] investigated the issue of women's breast self-assessment, indicating that female students were more encouraged to perform the assessment through passive messages rather than positive ones. Levin et al [72] developed a framing effect-based typology to check the influence of negative- and positive-framed information on decision makers. They concluded that passive goal framing was more convincing and influential than positive ones.

Message frame is believed to have a significant relationship with an individual's intention to adapt to technological invention [73]. Hence, H9 states that the positive effect of gain-framed messages on consumers' intention to use social media for health awareness purposes would be stronger. On the other hand,

hypothesis 10 states that the positive effect of loss-framed messages would be stronger.

Methods

Data Collection

The authors developed the questionnaire items based on an understanding of the literature, as presented in [Multimedia Appendix 1](#). Before conducting the survey, it was validated by 5 experts in different industrial and research fields, including community medicine consultants, family medicine consultants, oncologists, and public health specialists based in Saudi Arabia, the United Kingdom, and the United Arab Emirates. Including qualified experts' opinions will assure that items are clarified, accurate, and free of confusion. The survey was distributed on the web through Qualtrics over a 2-month period in 2019, and it produced 701 responses from different countries, with 391 completed surveys.

Development of Questionnaire Items

The questionnaire included 3 parts: the first part presented the survey's introduction and consent form, the second part focused on the participant's demographics, as shown in [Table 1](#), and the third part included 27 items. Each item is a statement that has been adapted from the literature to measure the opinion of the end user regarding the 7 identified constructs of the conceptual framework. List of items are presented in [Multimedia Appendix 1](#); both items and scales were adapted from previous studies with some modifications to fit the research context. Perceived ease of use and intention to use social media items were adapted from Hong et al [74]. The items of perceived usefulness on the intention to use social media were borrowed from El-Wajeeh et al [75]. Items on customization were adapted from Bandyopadhyay et al [65]. The items on the perceived trust construct were adapted from El-Wajeeh et al [75], and items on technology characteristics were derived from Bandyopadhyay et al [65] and Zaini et al [76]. All questionnaire items were rated using a 5-point Likert scale, ranging from *strongly disagree* (1) to *strongly agree* (5), in which participants were required to choose the most suitable answer.

Table 1. Respondent demographics (N=391).

Measure	Values, n (%)
Gender	
Male	154 (39.4)
Female	237 (60.6 ^a)
Age (years)	
20-29	91 (23.3)
30-39	142 (36.3 ^a)
40-49	64 (16.4)
50-59	52 (13.3)
≥60	42 (10.7)
Level of education	
Secondary school	9 (2.3)
Bachelor's degree	125 (32.0)
Master's degree or above	227 (58.1 ^a)
Others	30 (7.7)
Job	
Governmental employee	184 (47.1 ^a)
Private employee	85 (21.7)
Self-employed	21 (5.4)
I do not work	101 (25.8)
Frequency of using social media during the week	
Always	74 (18.9)
Very often	75 (19.2)
Often	121 (31.0 ^a)
Hardly often	94 (24.0)
Never	27 (6.9)
Frequency of using social media for seeking health information (years)	
<2	121 (31.0 ^a)
2 to <4	84 (21.5)
4-6	94 (24.0)
>6	92 (23.5)

^aIndicates the highest percentage.

Respondent Profile and Descriptive Statistics

The respondents' demographics are illustrated in Table 1. Of the 391 participants, 121 used social media platforms often during the week, with a percentage of 30.9% (Table 1). In total, 18.9% (74/391) and 19.2% (75/391) of the participants used them always and very often during the week, respectively (Table 1). Conversely, 6.9% (27/391) of the participants never used social media (Table 1). In addition, 24.0% (94/391) of the respondents utilized these platforms to seek health information (Table 1). This is due to several reasons, including easy and free access to social media, with no physical existence

requirement as with health care centers, and no storage capacity is needed as with printed media.

Results

Data Analysis

Smart health awareness message framework has been proposed to elicit the opinion of the end user about different constructs, and the results of the survey require a range of statistical methods. First, SPSS (version 25; IBM Corp) was used to acquire respondents' descriptive statistics. Then, data were analyzed using the IBM SPSS Analysis of a Moment Structures

(AMOS) version 25, which requires 2 stages of assessment: measurement model assessment and structural equation modeling (SEM) assessment. The measurement model was assessed to confirm that the survey items reflected the corresponding constructs of the conceptual framework [77]. SEM was used to test hypothesized relationships among the constructs after conducting confirmatory factor analysis (CFA). The following subsections present the results of exploratory factor analysis (EFA), which includes a measurement model followed by SEM.

Measurement Model

In the first stage, an EFA was conducted to determine the correlation among observed variables or items being tested. A correlation matrix presented in [Multimedia Appendix 2](#) shows the internal correlations between variables, which are higher than ± 0.3 , and not exceeding the cut-off threshold, ± 0.8 , refers to the absence of multicollinearity [77]. Then, EFA was conducted and provided a factor structure of 27 items ([Multimedia Appendix 1](#)). These variables are grouped into 7 factors: perceived ease of use, perceived usefulness, customization, perceived trust, technology characteristics, gain- and loss-framed message, and intention to use. The factor analysis results are illustrated in [Table 2](#) using maximum likelihood with a promax rotation of data. This analysis shows a clean factor loading pattern, no major cross loading, where values ranged between 0.3 and 0.8, cut-off criteria [78].

Another issue to be considered in EFA is the appropriateness of the data set that has been verified using the Kaiser-Meyer-Olkin (KMO) statistics and Bartlett test of sphericity. According to Kaiser [79], the KMO value is recommended to be greater than 0.7 to obtain meaningful and

good EFA. To assure the factorability of the correlation matrix among variables, the Bartlett test value should be significant ($P < .01$) [80]. The KMO yielded data adequacy with a value of 0.80, and the sphericity test showed a statistically significant $\chi^2_{190} = 2467.0$ ($P < .01$; [Multimedia Appendix 3](#)). Thus, it is evident that the factorability of the correlation matrix is adequate. Then, construct reliability was measured by Cronbach alpha (CA), composite reliability (CR), and average variance extracted (AVE). CA was .893 for the total items; thus, the value was greater than the recommended .7 [78]. [Table 3](#) presents CA for each construct, ranging between .733 and .826, leading to fit reliabilities of the data. Convergent validity can be assessed by calculating the average variance extracted and CR where the values should be greater than 0.5 and 0.7, respectively [81]. The results in [Table 3](#) reveal that the AVE and CR applied such criteria. Although the AVE of technology characteristics is below the recommended value, Fornell and Larcker [82] confirmed that a researcher may conclude that the convergent validity of the construct is adequate, as CR is higher than the acceptable range.

Discriminant validity refers to the extent to which the constructs are varied from each other, which can be assessed using the Fornell-Larcker criterion [82]. In this method, the square root of AVE is compared with the correlation of constructs or variables. The variance between constructs and their items should exceed the variance explained with other constructs [82]. [Table 4](#) illustrates that all diagonal square roots of the AVEs were higher than the off-diagonal values, which present constructs' correlations. Given the adequate reliability and acceptable convergent and discriminant validities, it is concluded that the measurement model is satisfactory.

Structural Equation Modeling

In the second stage, CFA was conducted before testing the hypothesized relationships among the constructs in smart health awareness message framework using SEM [83]. To proceed with CFA, standardized loadings for each item were obtained, in which these values should be at least 0.5 or ideally 0.7 or higher [78]. As shown in Table 5, of the 27 items, CUST3, CUST4, TECH7, and Message5 are attributed to deletion from the research model because of their lower loadings, whereas others are well related to their associated constructs. Given the significant standardized residual covariances, which means the largest values (in absolute value) for items PEU3, PEU4, TECH5, TECH6, Message4, and INT3, they require removal as they affect the goodness fit of the model [84] (Multimedia Appendix 4). The analysis illustrated in Multimedia Appendix 5 confirmed that the linear regression model is adequately fit, with χ^2_{104} value of 299.0 and $P < .001$.

In the second step of the CFA, model fit indexes were measured: χ^2 divided by df , root mean square error of approximation (RMSEA), normed fit index (NFI), incremental fit index (IFI), comparative fit index (CFI), and Tucker-Lewis Index (TLI) [83]. The CFA results showed an acceptable fit model

($\chi^2_{97}=145.8$; χ^2 divided by $df=1.503$; RMSEA=0.036; NFI=0.937; IFI=0.978; CFI=0.978; TLI=0.969; Multimedia Appendix 6). The results also confirm that the linear and covariance fit models meet the standards, thus emphasizing the acceptance of model fit (Multimedia Appendices 7 and 8, respectively).

The next step is measuring the path coefficient, coefficient of determination, and t value using SEM. A path coefficient or path analysis indicates the relationships among the constructs. The coefficient of determination (R^2) is a measure of the percentage of the total variation of the dependent variable that is explained or predicted by the independent variable(s) or predictor(s) [78]. The larger the value of the coefficient of determination, the greater the prediction of the dependent variable. Table 5 illustrates the path analysis and hypotheses testing. The results show that the coefficient of determination (R^2) is 0.642 for the *intention to use* construct. This means that the 4 constructs (perceived ease of use, perceived usefulness, perceived trust, gain-framed message, and loss-framed message) moderately explain 64.2% of the variance in intention to use social media. Perceived ease of use, together with customization, perceived trust, and technology characteristics, explain 55.4% of the variance in perceived usefulness. Finally, customization explains 26.2% of the variance in perceived ease of use.

Table 5. Summary of testing hypotheses.

Hypothesis	Hypothesized path	Beta ^a	P value	Result
H1	PEU ^b -INT ^c	.05	.43	Not supported
H2	PEU-PU ^d	.37	<.001	Supported
H3	PU-INT	.43	<.001	Supported
H4	CUST ^e -PEU	.12	.12	Not supported
H5	CUST-PU	.16	.05	Supported
H6	PT ^f -INT	.11	.08	Not supported
H7	PT-PU	.07	<.001	Supported
H8	TECH ^g -PU	.12	<.001	Supported
H9	Gain-framed message-INT	.04	<.001	Supported
H10	Loss-framed message-INT	.08	<.001	Supported

^aBeta is standardized.^bPEU: perceived ease of use.^cINT: intention to use.^dPU: perceived usefulness.^eCUST: customization.^fPT: perceived trust.^gTECH: technology characteristics.

Path analysis results also reveal that perceived ease of usefulness has little effect on intention to use ($\beta=.05$; $P=.43$), unlike the significant effect on perceived usefulness ($\beta=.37$; $P<.001$). Thus, H1 is not supported, whereas H2 is supported. The impact of perceived usefulness on intention to use is significant ($\beta=.43$; $P<.001$), supporting H3. However, the results indicate that customization has no significant impact on perceived ease of use ($\beta=.12$; $P=.12$), whereas it has a significant impact on perceived usefulness ($\beta=.16$; $P=.05$). Hence, H4 is not supported, and H5 is supported. The results also indicate that there is no significant impact between perceived trust and intention to use ($\beta=.11$; $P=.07$). In contrast, perceived trust significantly impacts perceived usefulness ($\beta=.07$; $P<.001$). Therefore, H6 is not supported, whereas H7 is supported. Technology characteristics are considered to be related and have a significant impact on perceived usefulness ($\beta=.12$; $P<.001$), lending support to H8. Finally, it was found that gain-framed messages and loss-framed messages are significantly and positively related to intention to use social media ($\beta=.04$; $P<.001$) and ($\beta=.08$; $P<.001$), respectively. Thus, H9 and H10 are supported.

Discussion

Principal Findings

Nowadays, social media plays a considerable role in an individual's daily routine, as it provides different features that

encourage people to adapt it for a range of uses, including health promotion. Therefore, the motivation of this paper was to examine the factors that affect people's intention to use social media as a way of receiving health awareness messages, which, in turn, will help them to maintain their diet and reduce the incidence of diseases. In turn, the challenges that arise from printed media, involving paper and power consumption, storage capacity, and labor intensity, will be reduced. The results in [Table 1](#) show that 69.0% (270/391) of the public surveyed used social media always, often, or very often, and 31.0% (121/391) of them hardly or never used social media. This indicates that eHealth that involves using social media to convey health messages has the potential to reach about 70% of the public. Findings (shown in [Figure 2](#)) confirm that perceived usefulness and message design relating to health message frames (positive vs negative) are the leading predictors of people's intention to use social media in the health promotion context. Loss-framed messages have been examined in previous studies [85,86] to be a motivating factor that influences people to engage and comply with health behavior on social media. A recent study has come to an opposing conclusion where people are encouraged to acquire and trust health information on social media when they are exposed to gain-framed messages [87]. Regarding social media usefulness, the results of this study are consistent with those of Lin and Ho [49], indicating that perceived usefulness significantly affects people toward social media adaptation in sharing health information.

Figure 2. Hypothesized Smart Health Awareness Message Framework. * $P < .05$, ** $P < .01$, *** $P < .001$; ns: nonsignificant.

In addition, health message customization encourages the prediction of perceived usefulness, whereas it has no effect on perceived ease of use of social media. Thus, it can be indicated that social media users perceive the acquired benefits from social media when they receive health messages tailored to their preferences [51]. Regarding the relationship between technology characteristics and perceived usefulness ($\beta = .12$; $P < .001$), it can be concluded that the higher the characteristics offered by social media, the greater the perceptions of the benefits of adopting health messages received via social media. These characteristics involve hyperlinks and hashtags provision, which, in turn, generate higher engagement with messages [88]. Moreover, posting photographs and videos that enhance the message by being more visual encourage individuals to adopt social media for health promotion [15]. The results reveal that the design of health messages plays a significant role in people's intention to use social media. Consequently, the key factors specified are essential for health organizations to promote eHealth by developing and spreading health messages effectively, which, in turn, will enhance people's health.

Conclusions

The study's results demonstrate the use of social media in health promotion purposes, which will enhance the outcomes of an individual's well-being. This paper aimed to investigate the influential factors that affect people's intention to adopt such technology in health communication campaigns. Undoubtedly, high levels of health message success cannot be achieved without emotions embedded in the content of health messages [89]. The study's findings indicate that health message frames would be efficacious in improving public health communication toward social media adaptation. Furthermore, perceived usefulness has an impact on people's intention to adapt to social media to acquire health awareness information. These results can be explained by the adaptation of the TAM and the prospect theory.

Given the findings of smart health awareness message framework, designing health awareness messages to include loss- or gain-framed content to evoke high emotions might contribute to boosting the effectiveness of health promotion interventions. Hence, this study offers implications for health awareness message developers that guide them to establish materials that are more patient friendly and technologically outstanding by adapting social media as a delivery method. Accordingly, this strategy will encourage individuals to exchange these messages among social media users.

Limitations and Future Work

This study has several limitations and indicates several directions for future work. First, for the construct of message design, there are few studies associated with the prospect theory that examine the public perspective in terms of their preferences. Thus, the authors developed a number of items, validated by experts, and adapted in this study to ensure the validity of the construct. Future works might examine this construct more broadly to determine the extent to which the public might receive this message in a more positive or negative manner. Second, although the study involved 391 respondents from different countries, in which sample size is convenient for testing the framework, future studies with larger samples are needed to reinforce the generalization of results. In addition, the participants were English speakers, and findings related to a particular language might restrict generalization to others. Thus, future research might duplicate this study with different languages.

Smart health awareness message framework will also be used to define the right content and format of the health awareness messages to be spread via a software system that is integrated with different social media platforms. Furthermore, a computer-based knowledge framework based on the use of social media apps will be developed to spread health awareness messages. Finally, a specific statistical technique will be used

to validate the impact of the health awareness message on recipients.

Abstract

Background: Sudden unexpected infant death (SUID), which includes the diagnosis of sudden infant death syndrome (SIDS), is a leading cause of infant mortality in the United States. Despite prevention efforts, many parents continue to create unsafe infant sleep environments and use potentially dangerous infant sleep and monitoring devices, ultimately leading to sleep-related infant deaths. Analyzing Facebook conversations regarding SIDS may offer a unique maternal perspective to guide future research and prevention efforts.

Objective: This study aims to describe and analyze conversations among mothers engaged in discussions about SIDS on a Facebook mother's group. We were interested in understanding maternal knowledge of SIDS, identifying information sources for SIDS, describing actual infant sleep practices, exploring opinions regarding infant sleep products and monitoring devices, and discovering evidence of provider communication regarding SIDS.

Methods: We extracted and analyzed 20 posts and 912 comments from 512 mothers who participated in a specific Facebook mother's group and engaged in conversations about SIDS. There were 2 reviewers who coded the data using qualitative descriptive content analysis. Themes were induced after discussion among researchers and after the study objectives were addressed.

Results: The theme of social support emerged, specifically informational and emotional support. A variety of informational sources for SIDS and safe sleep were identified, as was a continuum of infant sleep practices (ranging from unsafe to safe sleep per the American Academy of Pediatrics standards). There was widespread discussion regarding infant sleep products and monitoring devices. Embedded within conversations were (1) confusion among commonly used medical terminology, (2) the practice of unsafe infant sleep, (3) inconsistency in provider communication about SIDS, and (4) maternal anxiety regarding SIDS.

Conclusions: We uncovered new findings in this analysis, such as the commonality of infant sleep products and monitoring devices and widespread maternal anxiety regarding SIDS. Additionally, mothers who participated in the Facebook group provided and received informational and emotional support regarding SIDS via this social media format. Such results can guide future prevention efforts by informing health communication regarding SUID and safe sleep. Future provider and public health agency communication on the topic of SUID and safe sleep should be simple and clear, address infant sleep products and monitoring devices, address maternal anxiety regarding SIDS, and address the common practice of unsafe sleep.

sudden infant death; SIDS; infant mortality; safe sleep; social media; social support; health communication; maternal health; qualitative research; health care providers

Introduction

Background

Sudden unexpected infant death (SUID) and sudden infant death syndrome (SIDS) are a leading cause of infant mortality in the United States, resulting in approximately 3500 infant deaths annually [1]. SUID includes the diagnosis of SIDS and other unintentional causes of infant death: asphyxia, accidental suffocation and strangulation in bed, or ill-defined deaths. Risk factors for SUID include prone sleeping, bed sharing, soft bedding, unsafe sleep surfaces, prematurity, and smoke exposure [1]. Although the Back to Sleep campaign [2] reduced SIDS deaths by more than 50%, SIDS remains to be the leading cause of postneonatal mortality in the United States [3]. Furthermore, there has been an increase in infant deaths because of accidental suffocation [4].

Despite recommendations for SUID prevention, as of 2015, approximately 21% of mothers reported placing infants on their stomach to sleep, 61.4% reported bed sharing, and 38.5% reported using soft bedding, such as blankets or bumper pads [5]. Another study found that 54.7% of mothers reported the use of hazardous bedding for their infants [6]. Furthermore, potentially dangerous infant sleeping devices (eg, Rock 'n Play [7], baby swings) and sleep monitoring devices (eg, Owlet, Snuza) are increasingly common, yet little is known about their use [8].

Mothers place infants to sleep in the prone position for perceived safety, infant comfort, and concern for choking [9,10]. Colson et al [11] found that mothers who were advised consistently by their doctors to practice supine sleeping were less likely to place infants prone. Mothers were also more likely to follow social norms or model behaviors that were perceived as positive [11]. Such perspectives may be influenced by cultural norms and family members [10]. Extended social networks, such as social media, are also potentially influential. Social media is available 24/7 for people to seek information or leave messages for peers [12]. Thus, mothers are increasingly using social media for parenting and health information [13,14]. As of 2015, 75% of parents used social media, often for parenting information or support [14]. In a review of parental use of social media for parenting in the United States, Facebook was the most common social media format [15]. Facebook was popular among all races or ethnicities, including African Americans [15]—those most at risk for SUID [1].

Objectives

Thus, this study aimed to (1) understand maternal knowledge of SIDS, (2) identify information sources for SIDS, (3) describe actual infant sleep practices, (4) explore opinions regarding infant sleeping devices and sleep monitoring devices as they relate to SIDS, and (5) discover evidence of provider communication regarding SIDS among mothers engaged in discussions about SIDS on a Facebook mother's group.

Methods

This is a qualitative study of publicly available data extracted from a Facebook mother's group in May 2019. At that time,

there were 17,545 members in the group. Once on the Facebook page, *SIDS* was entered in the search toolbar. The results were filtered to include the following: *all posts*, *most recent*, posted by *anyone*, tagged location of *anywhere*, and *any date* posted. The phrase *safe sleep* was trialed but ultimately not selected as this resulted in erroneous conversations. The term *SIDS*, on the other hand, resulted in a total of 20 posts that were all relevant to SIDS or safe sleep. Each post and related conversations (912 comments) were manually copied and pasted into a spreadsheet. To protect the identity of the participants, only the initials of the participant were copied to the spreadsheet to enable the researchers to follow the conversations. After the posts and replies were copied, the spreadsheet was manually compared with the actual Facebook page to ensure accuracy. Personal and identifying information were removed to maintain confidentiality.

The posts and related conversations were then converted to 20 documents to be uploaded to Atlas.ti [16] for further analysis. The qualitative descriptive analysis process was completed as per Miles et al [17], and inductive coding was allowed for codes and themes to emerge progressively.

After analyzing 25% of the content, a preliminary codebook [18] was developed as coding became redundant at that time. To ensure trustworthy findings and increase reliability [17], 2 investigators coded all of the data. First-cycle coding [17] was completed by 2 investigators (KP and EC or SK) to assign descriptive coding of the data using qualitative analysis software (Atlas.ti, version 8.4.2). The discrepancies in coding were discussed among the members and the codebook was adjusted as needed. Second-cycle coding was then completed to identify themes [17]. This study was submitted for review by the institutional review board at the University of Texas at Austin and deemed exempt given that this research project utilized information from publicly available datasets.

Results

General Description of the Data

A total of 526 individual mothers participated in the 20 posts and 912 related comments. The number of comments on the posts ranged from 4 to 152, with an average of 45.6 comments per post. Of the 20 posts, 6 included pictures. Table 1 includes a general description of each post and the total number of comments for each post.

The post that received the most likes (n=20) was a *Seattle Times* article about a doctor who linked hearing dysfunction to SIDS; if infants failed the screening, they would undergo a more thorough exam because they were more at risk than those who passed. The post that received the second highest number of likes (n=12) was a post from a mother who wanted to know who else “went against the recommendations” and let their babies sleep prone. Multiple posts received 0 likes and included the following topics: breathable bumpers, babies rolling prone, co-sleeping, and an infant who “hated” sleeping flat. Table 2 demonstrates the Facebook emotions and the number of comments that received such emotions. Of note, people who participated in *liking* a comment did not necessarily add a

remark to the post. Therefore, the total number of participants in the analyzed conversations may have actually exceeded 526.

Table 1. General description of the Facebook posts and number of comments (in order, from most to least number of comments).

Comments, n	General content of original post (and ultimate conclusion, if known)
155	Mother attended a baby safety class and was told she should keep her baby in the same room for a year to prevent SIDS ^a . She was not planning on doing this and wanted to know what other moms' opinions were on this topic
152	Mother is terrified of SIDS and is concerned because her husband would like to co-sleep. She would also like to co-sleep but is very anxious about it. She ultimately decided to co-sleep after receiving much input from other mothers
89	Mother has newborn who did not sleep well in bassinet and slept well in the Rock 'n Play. She is not sure if the Rock 'n Play is safe because of SIDS and asked if other mothers use it for sleep. After much input from other mothers, she chose not to use the Rock 'n Play because her pediatrician advised against it
85	Mother cannot stop thinking about SIDS; she is terrified and asked other mothers how to cope with this stress. After much input from other mothers, she mentioned that she will likely proceed with purchasing a baby monitoring device
81	Mother wanted to know how many "went against the recommendations" and allowed their babies to sleep prone. Her mother and mother-in-law reassured her that prone sleeping is acceptable
42	Mother's friend lost a baby to SIDS and she asked for suggestions on how to support her. After much input from other mothers, she thanked the group and shared her appreciation for the Facebook group
41	Mother is pregnant with her third baby and is scared of SIDS. She asked about other mothers' experiences with the Owlet. After much input from other mothers, she mentioned that she will likely co-sleep but may consider placing the baby in a crib if she has reassurance from a monitor
36	Mother is terrified of SIDS and sleeps with baby in an in-bed bassinet and with a baby monitor. She asked if her feelings were normal
36	Mother shared link to an article discussing a study that found swaddling may cause SIDS. There was much input from mothers; some comments made light of the article and scrutinized scientific studies
31	Mother asked for input regarding co-sleeping. She fell asleep at the hospital with her baby and the hospital "freaked" her out because of SIDS, but she is considering co-sleeping because she breastfeeds
27	Mother asked other "tummy sleeper" mothers for reassurance. She quoted Dr Sears, who condones prone sleeping, and mentioned that other SIDS risks were low. After much input from other mothers, she mentioned that she found a swaddle on the web and that her baby was able to sleep supine
25	Mother asked for input about crib bumpers, mentioning that SIDS is no longer an issue because her baby is older than 6 months. After much input from other mothers, she mentioned that she will try bumpers and put stuffed animals in the crib corners (a suggestion from another mother)
24	Mother asked if other mothers let their babies sleep prone as her baby sleeps better this way; however, she is worried about SIDS
23	Mother asked if she can leave her baby prone once he or she rolls on his or her own; she is nervous because her baby is at the peak age for SIDS
20	Mother asked if she can leave her baby on stomach once he or she rolls on his or her own; she is following safe sleep guidelines and has a baby monitor but is still nervous about SIDS. After much input from other mothers (including recommendations for sleeping devices or monitors), she thanked the group and said that she felt better
18	Mother asked when she can stop worrying about SIDS because she would like to use crib bumpers and a blanket
11	Mother is concerned about SIDS after hearing "horror stories" and is considering the Owlet. She asked if anyone is selling one
6	Mother asked if other mothers' babies will not sleep flat. Her baby is sleeping on a blanket on top of a nursing pillow, but she is scared of SIDS and knows flat is safer
6	Mother asked about breathable crib bumpers. She knows crib bumpers are controversial because of SIDS but wants to keep baby from hitting the crib and waking up. After much input, she thanked the group and says she will wait a bit longer but wanted to get input beforehand
4	Mother shared link to an article about a researcher who linked SIDS to children with audiologic problems

^aSIDS: sudden infant death syndrome.

2 sad	3

Themes

In this analysis, the theme of social support emerged. Two types of social support were evident: informational and emotional support. The types of social support have been defined and modified by Cutrona and Suhr [19]. Informational support involves advice or suggestions, and emotional support involves sharing concern. Such categories of social support are applicable to web-based environments [20,21].

Informational Support

Informational support was evident in the following discussions among mothers: (1) asking questions about SIDS, infant sleep, or baby products; (2) sharing personal experiences of provider communication regarding SIDS or safe sleep; (3) sharing personal definitions or beliefs regarding SIDS or safe sleep (including discussions on vaccines and SIDS); and (4) sharing informational sources for SIDS or safe sleep. Overwhelmingly, the information shared demonstrated misinformation and inaccurate use of terminology.

Asking for Recommendations

Mothers openly asked for recommendations or feedback regarding infant sleep practices, use of baby products or monitoring devices, or other topics related to SIDS or safe sleep. Mothers asked for opinions about “what other moms’ opinions [were] on the subject” of prone sleeping, the use of the Rock ‘n Play, when to transition to a crib, crib bumpers, whether they should seek help for their anxiety about SIDS, or what monitor system to purchase (Owlet vs Snuz). Many of the responses involved information sharing of provider communication, personal definitions or beliefs, and information sources.

Provider Communication

Mothers shared information provided by their health care provider regarding SIDS, safe sleep, and the use of baby products. Some mothers shared their doctor’s knowledge of SIDS, such as the risk of SIDS being highest before 4 months of age or that the risk of SIDS from prone sleeping was “incredibly slim.” Another mother tried to distinguish co-sleeping from bed sharing; she mentioned that her doctor helped her understand that they were different. Some communication with providers endorsed safe sleep, whereas others condoned unsafe sleep. For instance, mothers mentioned

that their pediatricians recommended supine sleeping and pacifier use and encouraged mothers not to use the Rock ‘n Play; however, other mothers mentioned that their pediatricians were “ok” with the Rock ‘n Play. One mother said that her pediatrician was “ok” with her use of a breathable crib bumper, and another mother said that her pediatrician endorsed prone sleeping for naptime, just not bedtime.

Personal Definitions or Beliefs

Mothers also shared information by providing their own personal definitions or beliefs regarding SIDS or safe sleep. There were approximately 80 personal definitions or beliefs shared, some of which were accurate and some were not. Some mothers felt the risk of SIDS was exaggerated; one mother did her “own research” and said that SIDS is actually not common as only “2000” infants die yearly. Another mother mentioned that “they are overzealous about the SIDS thing,” whereas another mother agreed that it is very rare. Similarly, another mother, who self-identified as a pediatric provider, said that most babies were not at risk for SIDS if they did not have other risk factors such as smoking, neurological issues, or vaccines. One mother even expressed anger with the Back to Sleep campaign—she felt the campaign caused flat heads and developmental delays. There was also confusion about SIDS versus suffocation death and co-sleeping versus bed sharing. One mother said that co-sleeping was not a risk for suffocation, especially if one was following safe bed-sharing guidelines. Many mothers felt that that co-sleeping was “ok” if done safely and that SIDS had “nothing to do with bed sharing.” One mother mentioned that “statistically it is safe for breastfed babies to co-sleep.” Although many of the shared definitions and beliefs were inaccurate, including a long discussion of how vaccines cause SIDS, some mothers shared accurate information. For instance, some mothers commented that SIDS can occur anywhere and that co-sleeping is a risk for suffocation. Other mothers explained ways to prevent SIDS: keeping the house cool, use of a pacifier, no blankets, not smoking, and placing the baby supine. Finally, some mothers disagreed that vaccines cause SIDS.

Information Sources

Mothers shared information sources with other mothers, as it related to SIDS or safe sleep. The list of information sources is shown in Table 3. Mothers also shared links to baby products or monitoring products to facilitate purchases.

Table 3. List of information sources shared or discussed in the Facebook group (in alphabetical order).

^cNPR: National Public Radio.

Emotional Support

Emotional support was evident in the following discussions among mothers: (1) encouraging each other to "do what's best for you or your family," (2) telling each other that "it will get better with time," (3) stories of infant or child death, (4) expressions of maternal anxiety about SIDS, and (5) general comments that relayed support.

Do What's Best

Mothers offered emotional support by encouraging each other to do what was best for their family when talking about SIDS or safe sleep, regardless of the infant sleep environment or use of baby products. For example, it was common for a mother to comment "I think you need to do whatever you are comfortable with" or "you have to do whatever you feel comfortable with because if not, you'll never sleep" regarding infant sleep environments. Many mothers supported following a "mother's instinct" or "mother's gut." For example, one mother said "research, educate yourself, and trust your mama gut" when discussing how to help a new mother ease her worries about SIDS. Another mother commented: "whatever you choose to do will be right, because you are the mom. Your instincts will most always be correct." There was also a focus on doing what was best for each family, despite what the safe sleep recommendations might be. For instance, it was common to see mothers comment "I think every family is different and not everything works for everyone" or "I think whatever you feel is right for you and your baby, just because it's recommended doesn't mean you have to follow." One mother addressed the changing infant sleep recommendations, saying "...info changes all the time and we should all do what works for us and our baby." However, some mothers did caution about the support and advice being given. For example, one mother said, "do what works best for you but keep in mind you're asking for opinions and opinions do not change the research or statistics."

It Gets Better With Time

Similar to the emotional support for mothers to do what was best for their family, emotional support was also prevalent in discussions of how worrying about SIDS gets better with time. Mothers reassured each other that the "worry of SIDS" was normal and that it would get better over time. One mother celebrated when her infant turned 4 months old and encouraged another mother that with time, she will realize "wow. I haven't thought about SIDS in weeks." Another mother said that her concerns subsided eventually, even though she still found herself standing over the crib at times.

Stories of Death

Emotional support was also prevalent in conversations surrounding stories of infant or child death. These conversations included mothers asking how to support mothers who lost an infant or child. For example, when discussing how to support a mother who had recently lost an infant to SIDS, one mother said, "my friend lost her daughter to SIDS and talking about her daughter makes her happy." Other mothers shared stories of infant or child death, including infants who died from co-sleeping or from "sleeping in rock and plays."

Maternal Anxiety

Emotional support was evident in conversations surrounding the concept of maternal anxiety related to SIDS. Mothers openly asked if their anxiety about SIDS was normal and how to cope with such feelings. One mother said that postpartum stress is "absolutely awful," she explained that she cried daily for weeks and felt that this was normal. Many mothers shared stories of watching their baby sleep throughout the night, mentioning they were "terrified of SIDS". Mothers replied by offering support, by encouraging the use of baby products (Owlet or Snuza), recommending that the mother speak with a health care provider, or normalizing such feelings. For instance, it was common for a mother to say the Owlet was the "only way I [could] sleep...and helped my anxiety."

Supportive Comments

Finally, emotional support was embedded within conversations around SIDS or safe sleep when mothers frequently shared supportive or encouraging comments. There were approximately 100 comments demonstrating support, evident in conversations of various topics. It was common to read “Good luck, mama,” “I was right there with you,” or “Hang in there.” Mothers demonstrated unity in feeling anxiety about SIDS, encouraged each other to not worry so much, and to get some sleep. Often, these words of encouragement were accompanied by emojis, such as hearts or kisses.

Information Sources

Of the 20 main posts, 4 included references to an information source. Of those, the following were mentioned: *Seattle Times*, *Time Magazine*, Dr Sears, and Baby Safety Academy. It is worth noting that the American Academy of Pediatrics (AAP) was mentioned at least nine times throughout the posts and related comments. Table 3 lists the information sources that were shared in the posts and related conversations, with a brief description or direct link, if provided by the participant.

Parental Practices of Infant Sleep

Of the 20 main posts, 12 involved infant sleeping practices. Of these, 2 were considered safe sleep environments; both of these posts were from mothers inquiring about what to do once their infant began rolling onto their stomach. Of the 12 posts that involved infant sleeping practices, 10 were considered unsafe practices. These included discussions about the following infant sleep practices: co-sleeping (2), sleeping on a nursing pillow (1), prone sleeping (3), crib bumpers (3), and the Rock ‘n Play (1). In analyzing the data, it became apparent that parental practices of infant sleep are best understood on a continuum rather than as a black and white matter. Infant sleep practices are surprisingly complex, and mothers adjust to the baby’s needs as well as their own family’s needs.

Unsafe Sleep

Many mothers changed sleep practices based on the infant and the needs of the family. For instance, many mothers did not bed-share with their first child, but chose to bed-share with their second. One mother encouraged other mothers to “listen to [their] instincts.” Another mother said that it just depends on the “family dynamic.”

Many mothers were aware of safe sleep recommendations but chose to practice unsafe sleep. For example, one mother encouraged others to join an evidenced-based group on safe sleep but mentioned that she bed shared with her first child and might with her second. There was also confusion around safe sleep recommendations and infant sleep practices. For example, one mother bed shared with her children, but only for the first few months before transitioning them to a crib, because “SIDS is less likely if they’re in bed.” Many mothers also allowed infants to sleep prone for nap time, but not at nighttime. One

mother had 2 of her children sleep in the Rock ‘n Play and her third in a DockATot; she wanted them next to her, but in their own safe space, because she was “SIDS traumatized.”

Within conversations surrounding such practices, there was also evidence of motivation for unsafe sleep practices. One mother chose to bed-share because she had a cesarean section and it was a “chore” to walk to a crib. Many mothers chose to bed-share because their babies had reflux and they wanted to “be right next to [the baby] if anything happened.” Some mothers simply believed that their baby was safer next to them in bed. Many mothers “didn’t plan to co-sleep” but had a baby that would only sleep in bed with the mother or had choking because of reflux. Another mother allowed her infant to sleep in bed on a pillow because the mother could not rest “without [the baby] being near,” despite knowledge that such practices were not recommended. Mothers also explained that it was not feasible for infants to sleep in their bedrooms for the recommended 6 to 12 months because of personal difficulty sleeping and returning to work.

Among discussions of unsafe sleep practices were elements of confidence in such practices. Mothers felt confident they would “wake up the moment anything [happened]” or mentioned that they would never roll onto their infant when bed sharing. Another mother who was bed sharing explained that she was not worried about suffocation as the blanket did not reach the infant’s head and that she and her husband do not move throughout the night.

Safe Sleep

Although many comments described unsafe sleep environments, some mothers encouraged safe infant sleep environments. For instance, in responding to a mother who asked for advice about her infant who preferred to sleep prone, whereas many mothers endorsed this practice and recommended the Rock ‘n Play, one mother commented “SIDS is most common at 3 months old. Back is best.” Other mothers commented that the mother was taking a significant risk, and some explained why the mother should follow the “AAP safe sleep guidelines.”

Sleeping Devices or Sleep Monitoring Devices

Discussions surrounding infant sleeping devices or monitoring devices permeated many conversations regarding SIDS or safe sleep. Mothers asked specific questions about the use of infant monitoring devices or sleep devices and encouraged other mothers to use devices to cope with their fear of SIDS. Of the 20 main posts, 10 involved the topic of sleeping devices or monitors. The breakdown of the sleeping device or sleep monitoring devices discussed in the original 20 posts are displayed in Table 4. Throughout all of the data analyzed, the device most commonly mentioned was the Owlet monitor, which was mentioned 112 times. The Snuza monitor was mentioned 53 times and the Angelcare monitor, 5 times. The Rock ‘n Play was mentioned 26 times and the DockATot, 4 times.

Table 4. Sleeping device or sleep monitoring device mentioned in main posts.

Sleeping devices or sleep monitoring devices	Posts, n
Crib bumpers	4
Owlet monitor	2
In-bed bassinet	1
Nursing pillow	1
Rock ‘n Play	1
Mimo Monitors	1

Mothers frequently mentioned that sleep monitoring devices provided “peace of mind” and used Facebook as a marketplace to buy and sell such devices. It was common for mothers to ask other mothers about their experience with the Owlet; one mother was considering purchasing one to “ease my mind... [and] help me to sleep better at night instead of always getting up to check that they’re still breathing.” Many responses encouraged the use of sleep monitoring devices. For example, many mothers said, “Owlet is my life” or “Owlet helped my SIDS anxiety” and expressed that the Owlet was one of the necessities of being a mom. For instance, one mother said that she could not live without the Owlet, diapers, and clothing. In comparison to many mothers recommending sleep monitoring devices, there were few mothers who advised against the use of sleep monitoring devices. One mother explained that the false alarms caused her more distress and advised against using the Owlet. Another mother said that it would be “one more thing to obsess over.”

There were also frequent conversations about other baby products. The Rock ‘n Play was by far the most frequently discussed device; however, mothers also discussed the HALO SleepSack, Merlin’s Magic Sleepsuit, DockATot, Love To Dream SWADDLE UP, Woombie, Snuggle Nest, etc. These discussions suggested strategies for improving infant sleep and either encouragement for use for a safer option (vs the Rock ‘n Play) or sometimes encouragement of use despite the known risk of SIDS.

Provider Communication

In the dataset, there were approximately 30 mentions of health care provider communication regarding SIDS. Of the 20 original posts, 2 included health care providers and involved provider communication. These 2 examples include a mother who described how the hospital “freaked” her out when she fell asleep with the baby in the hospital bed and another mother who asked about prone sleeping—as doctors used to recommend this practice. Other conversations included pediatricians recommending safe sleep practices and pediatricians condoning unsafe sleep practices. For example, one pediatrician “had no problem” with a baby sleeping in the Rock ‘n Play, and a self-identified pediatric nurse claimed that she had never heard of some of the safe sleep recommendations. However, when one mother told her pediatrician about her use of the Rock ‘n Play, she was informed of the risks of suffocation.

Discussion

Principal Findings

As suggested by Huo and Turner [12], studies on social media user perspectives are needed to guide the development of social media interventions. However, we believe this analysis guides future SUID prevention interventions beyond social media, providing guidance for health care providers, public health agencies, and health campaigns. Similar to prior social media analyses [22,23], this analysis has revealed new findings regarding maternal perspectives of SIDS and safe sleep that are otherwise not discussed in the literature. This analysis also supports prior findings regarding parental practices of infant sleep and provider communication of SUID prevention.

Themes

Social media has been identified as a supportive environment in prior analyses and studies [15,24–26], which was consistent with the identified theme of support. Understanding the types of support, informational and emotional, provided among mothers and in this format is a new finding. This Facebook mother’s group promoted participant engagement and honesty about very personal health-related concerns, resulting in discussions about maternal anxiety, personal practices of infant sleep, and discussions about infant sleeping devices and sleep monitoring devices. This frankness among social media users has previously been discovered in discussions about health-related topics [23]. One implication of this finding is the potential of emulating this type of supportive environment in other settings. For instance, health care organizations could consider creating more supportive environments in our current health care system to promote open discussions with parents. Additionally, many of the comments and conversations in this analysis provided opportunities for correction of misinformation or discussions regarding options for safer infant sleep. Although mothers receive information via many different routes [13], social media remains incredibly popular [27] and is a platform where patients can receive and communicate health information. Since Facebook mother groups are available 24/7, and most health care providers are not, health care organizations should also rethink how services are structured. For instance, if a nurse or provider were truly accessible 24/7 for advice via a social media format, this could potentially influence and impact parental decisions and decrease the spread of misinformation that is otherwise widespread among social media sites [28].

Information Sources

The information sources shared among the mothers regarding SIDS or safe sleep demonstrated a variety of sources. We know that mothers obtain information from many different sources [13], and this study supports this. However, this study identified sources specific to SIDS and safe sleep. Consistent again with a Twitter analysis on SIDS and safe sleep [24], there was evidence of news media organizations, such as *National Public Radio*, being shared. However, a concerning finding was the sharing of informal and potentially inaccurate information sources, such as Dr Sears, other Facebook groups, and controversial books such as *Babywise*. Thus, shared sources were often inconsistent with the AAP recommendations. This is similar to the findings from a prior study of Google searches that identified information largely contradicting AAP recommendations of infant safe sleep [29]. The commonality of shared links for purchase of baby products was also worrisome given that many of the shared products are not considered safe for infant sleep nor recommended by the AAP [3]. Thus, health care providers may consider asking parents where they obtain health information to openly discuss and potentially correct any misinformation that is shared in that format.

Parental Practices of Infant Sleep

Another finding is that infant sleep practices are not straightforward; safe sleep and unsafe sleep are best described on a continuum. Mothers alter infant sleep practices based on the infant and family's needs. Many mothers in the group were aware of safe sleep recommendations but chose not to follow them because they were not feasible. This finding supports a prior study's conclusion that parental motivation to bed-share trumped known risks of unsafe sleep [30]. The discovery of mothers who are practicing unsafe and ever-changing infant sleep practices is also consistent with studies demonstrating parental practice of unsafe sleep [5,6,31,32] and the changing of infant sleep environments throughout the night [33]. In this Facebook group, some mothers endorsed safe sleep and recommended following the AAP guidelines; however, other mothers believed they were following the recommendations and were actually creating dangerous infant sleep environments. Safe sleep is seemingly complex and further complicated by the confusion surrounding definitions of SIDS and safe sleep. For instance, this analysis demonstrated wide confusion and inaccurate use of the terms *co-sleeping* and *bed sharing*. These findings imply that simpler terms should be used in public health campaigns and when educating families about SUID prevention. This finding also informs health communication; health communication about safe sleep and SUID prevention should use simple language, be direct, and be clear.

Sleeping Devices or Sleep Monitoring Devices

This study demonstrates the popularity and commonality of infant sleep monitoring devices and baby products; thus, this topic can no longer be ignored. This is similar to the findings from a Twitter analysis on SIDS and safe sleep, where conversations and advertising about such products were widespread [24]. It is worth noting that the literature is sparse regarding infant sleep monitoring products and baby products.

Health care providers need to educate themselves on popular products, so they can effectively discuss this topic with parents. For example, it may be helpful for health care providers to directly ask parents "What devices are you using to help your baby sleep?" Public health agencies should also consider addressing such devices in campaigns and in health messaging.

Provider Communication

Furthermore, when discussing the topic of SUID and safe sleep, health care providers and public health agencies need to continue to provide accurate information on a consistent basis. Health care provider advice on safe sleep impacts parental decisions [11], and inconsistency has been demonstrated among safe sleep messaging provided by health care professionals [34,35]. As this study also supports inconsistency in health care provider communication about safe sleep, there is room for improvement. Instead of assuming parental knowledge of safe sleep guidelines and that families are following such guidelines, health care providers should encourage open and honest conversations about infant sleep practices that occur throughout the night and at naptime. Health care providers should also recognize the need to consistently and correctly share safe sleep recommendations with families and caregivers.

Maternal Anxiety

Finally, the prevalence of discussions surrounding the topic of maternal anxiety related to SIDS and how mothers reassured each other that these feelings were normal is concerning. Many mothers coped with these feelings by using baby monitoring devices or baby sleeping devices rather than taking precautionary measures to prevent SUID and sleep-related infant death. Persons with mental illness who openly share their stories and feelings offer insight into various illnesses and symptomology [36]; thus, this analysis may have actually identified mothers who have postpartum disorders. According to O'Hara and Wisner [37], the prevalence of major and minor depression in pregnancy and the postpartum period is 20%; early symptoms can be detected through screening, and early treatment is essential for the well-being of the mothers and children. Although some mothers shared that they had sought medical treatment for postpartum disorders, many did not. This topic raises the question of whether our health care system is successfully screening and identifying mothers who may need additional support and treatment for postpartum anxiety and depression.

Limitations

Although this study provides new insights into maternal perspectives regarding SIDS and safe sleep, it is not without limitations. This particular Facebook mother's group was selected because of the large number of participants; however, the views expressed may not represent potential opinions, concerns, and views of other Facebook mother group participants (or other mothers for that matter). Furthermore, demographic information of the participants was not obtained, limiting the generalizability of the findings. This analysis only included mothers; therefore, other perspectives (such as that of the father or other caregivers) were missed. Although many of the findings were consistent with a different social media

analysis on SIDS and safe sleep [24], an analysis of another social media format may have resulted in contradictory findings. Additionally, social media language can be difficult to analyze; there are often typos, informal writing, or abbreviations that can make the analysis challenging [38]. Although measures were taken to prevent misinterpretation and the research team refrained from interpretation as much as possible, it is possible that some of the original content may have been misunderstood or misinterpreted. Finally, the participants often used safe sleep definitions inaccurately, potentially impacting the analysis. For instance, *co-sleeping*, *bed sharing*, and *room sharing* were often used interchangeably. The research team interpreted the meaning of the terms in the context used; however, it is possible that this was interpreted inaccurately.

Conclusions

Despite such limitations, this analysis provides new information regarding maternal perspectives on SIDS and safe sleep: (1) a

wide variety of information sources, (2) widespread utilization of infant sleep products and monitoring devices, and (3) maternal anxiety regarding SIDS. This study demonstrated confusion among the terminology commonly used in the medical community when speaking of SUID and safe sleep, implying that future communication should aim for simpler and clearer terms. Widespread practices of unsafe sleep and inconsistency in provider communication regarding SUID prevention are not new findings but emphasize the need for continued efforts in SUID education and prevention. Health care providers, health care organizations, and public health agencies should incorporate these findings in future research and health campaigns and when directly communicating with families about SIDS prevention and safe sleep. Furthermore, such organizations should consider using social media in their marketing efforts and actively engage in such formats to correct misinformation.

Acknowledgments

The authors would like to thank Dr Lynn Rew for her invaluable input throughout the study. The authors also acknowledge financial support from Sigma Theta Tau and the National Association of Pediatric Nurse Practitioners.

Authors' Contributions

KP conceived the idea for the study and extracted the data. KP, EC, and SK analyzed the data. MM provided feedback during the design and analysis phases. KP wrote the manuscript, and all authors discussed the results and reviewed the manuscript before submission.

Abstract

Background: Nutrition science is currently facing issues regarding the public's perception of its credibility, with social media (SM) influencers increasingly becoming a key source for nutrition-related information with high engagement rates. Source credibility and, to an extent, authenticity have been widely studied in marketing and communications but have not yet been considered in the context of nutrition or health communication. Thus, an investigation into the factors that impact perceived source and message credibility and authenticity is of interest to inform health communication on SM.

Objective: This study aims to explore the factors that impact message and source credibility (which includes trustworthiness and expertise) or authenticity judgments on SM platforms to better inform nutrition science SM communication best practices.

Methods: A total of 6 databases across a variety of disciplines were searched in March 2019. The inclusion criteria were experimental studies, studies focusing on microblogs, studies focusing on healthy adult populations, and studies focusing on either source credibility or authenticity. Exclusion criteria were studies involving participants aged under 18 years and clinical populations, gray literature, blogs, WeChat conversations, web-based reviews, non-English papers, and studies not involving participants' perceptions.

Results: Overall, 22 eligible papers were included, giving a total of 25 research studies. Among these studies, Facebook and Twitter were the most common SM platforms investigated. The most effective communication style differed depending on the SM platform. Factors reported to impact credibility included language used online, expertise heuristics, and bandwagon heuristics. No papers were found that assessed authenticity.

Conclusions: Credibility and authenticity are important concepts studied extensively in the marketing and communications disciplines; however, further research is required in a health context. Instagram is a less-researched platform in comparison with Facebook and Twitter.

Introduction

Background

Science, particularly the discipline of nutrition science, is currently facing credibility issues in the eyes of the general public [1,2]. Although nutrition science has contributed to

countless discoveries and progressions in science, it is more complicated than other scientific disciplines in multiple ways. First, food is an essential part of every human's life; thus, many people have a vested interest in nutrition and care greatly about their health [3]. Second, the significant research funding provided by the food industry creates conflicts of interest and

often high levels of skepticism from the public [1,4,5]. Researcher Marion Nestle identified 76 industry-funded studies between March and October 2015, of which 70 reported results that were favorable to the sponsor's interest, highlighting the potential bias in the industry [6]. Finally, there is an ongoing challenge to produce evidence-based science to facilitate recommendations that promote health on a population level, such as dietary guidelines [1].

The advent of the internet and, in particular, social media (SM; see [Multimedia Appendix 1](#) for a glossary of terms) has permanently changed communication worldwide. Similar to traditional media (eg, newspapers, television, and radio), websites initially existed for one-way information dissemination through static web pages, known as *Web 1.0* [7]. However, progression to the second generation of the internet, *Web 2.0* (which includes SM), has facilitated a two-way interaction between users, creating a platform for collaboration, sharing, and socialization [7].

Currently, the use of SM in health interventions has had limited effectiveness, with participant engagement rates ([Multimedia Appendix 1](#)) being highly variable, ranging from 3% to 69% [8,9]. Health promotion organizations have maintained a one-sided communication approach, sharing serious and factual messages across their platforms, often reaching only a limited audience [10,11]. In contrast, product and corporate brands ([Multimedia Appendix 1](#)) have effectively adapted their marketing strategies to utilize the features of SM by being more likely to use hashtags to increase the reach of their posts, interact with their followers to create a two-way communication channel, and run promotions such as competitions to encourage user engagement [10]. Many large and well-known corporations such as soft drink companies are faceless and do not have a permanent ambassador and instead utilize celebrity endorsers ([Multimedia Appendix 1](#)) periodically to promote their products and improve their image and reputation [12].

Similar to celebrity endorsers, SM influencers (SMIs) or “individuals or groups of individuals who can shape attitudes and behaviours through online channels,” are arguably human brands ([Multimedia Appendix 1](#)), which often enable consumers to see them as regular individuals with whom they share common values [11,13]. SMIs are often referred to as microcelebrities ([Multimedia Appendix 1](#)) as they provide insight into their private lives and create the perception that they are constantly accessible and intimately invested in their audience [14]. The number of people that connect and engage with posts by SMIs is high, as their audience consists of like-minded people, allowing brands that partner with them to target specific demographic and lifestyle groups [15]. In contrast, nutrition professionals ([Multimedia Appendix 1](#)), who typically promote evidence-based science on SM, must maintain a sense of professionalism online and, therefore, cannot create the same type of content without risking their career prospects [16].

In the existing posttruth era ([Multimedia Appendix 1](#)), science experts (including nutrition professionals) are often less highly regarded, and emotional appeals are often the most effective methods of communication [2,17]. Consumers are frequently

turning to celebrities and SMIs (who hold no formal qualification) for health and lifestyle advice, creating many implications for their health and well-being [18,19]. In particular, health and wellness advice spread on online platforms tends to be misinformation rather than evidence-based information [20]. For example, the *A-list* celebrity Gwyneth Paltrow has consistently been in the public eye after controversial and dangerous health claims were made by her health and wellness brand, *Goop* [21,22]. Numerous articles on *Goop's* website and Instagram promote detoxifying the body (a process that is naturally performed by the liver) and cutting out essential food groups from the diet (eg, carbohydrates) [23]. These recommendations are based on anecdotal evidence and pseudoscience, perpetuating disordered eating habits and nutritional imbalances [24].

In the marketing literature, underlying factors such as the endorser's expertise, trustworthiness, attractiveness, and authenticity have been shown to influence people's behavior in traditional forms of advertising (eg, television commercials, celebrity partnerships) [25,26]. This review was focused on various theories and models from psychology literature that draw on the concepts of expertise, trustworthiness, and authenticity: self-determination theory (SDT; [Multimedia Appendix 1](#)), source credibility model ([Multimedia Appendix 1](#)), and the elaboration likelihood model (ELM; [Multimedia Appendix 1](#)). The following section (*Theoretical Framework*) summarizes these concepts and their nexus.

Theoretical Framework

Authenticity is the concept of “being true to the self in terms of an individual's thoughts, feelings, and behaviours reflecting their true identity” [27]. SDT encompasses the concept of authenticity with 3 primary components: autonomy, competence, and relatedness [28]. SDT posits that authenticity involves an individual's engagement in intrinsically motivated behaviors, *behaviors that come from a person's innate desires and passions* [28]. In marketing literature, individuals tend to perceive another person (eg, a celebrity) as authentic when the other person's actions reflect his or her autonomous, self-determining, true self [26]. Celebrities who are perceived as authentic have a higher level of influence over others, both online and offline [29]. Many young people do not verify information found online, leaving them particularly susceptible to celebrity influence [30]. Therefore, exploring the factors that impact authenticity on SM could be useful to inform health communication and behavior change campaigns.

The source credibility model suggests that a credibility judgment is determined based on the source's (eg, a celebrity's) expertise, trustworthiness, and attractiveness [31]. The 3 dimensions of source credibility differ: (1) expertise refers to the perceived knowledge and education level of the source, (2) trust refers to the listener's confidence in and level of acceptance of the speaker or message, and (3) attractiveness refers to the perceived physical attractiveness of the source. As a credible message is influential, many individuals and brands place a high level of importance on creating and maintaining credibility [32]. Typically, SMIs are perceived as credible as they are physically attractive and share aesthetically pleasing photos relevant to

their field of perceived expertise (eg, health) to showcase their desirable lifestyle [33]. Similarly, large corporations utilize attractive and trustworthy celebrity endorsers to be the face of their marketing campaigns to increase the brand's credibility [25]. More recently, the use of SM platforms for health advice has made it difficult for laypeople to differentiate a credible, evidence-based message from a noncredible message in an environment where everyone appears to have expertise [34].

Message content is assessed through cognitive processing (Multimedia Appendix 1), explained by the ELM (Multimedia Appendix 1). The ELM describes how people manage the information they encounter and the way in which it influences attitude change [35,36]. There are 2 processing routes: central and peripheral [35,36]. This review focuses on the peripheral route of processing, where messages are evaluated using heuristics as there is low motivation to critically evaluate the content of a message [37]. On SM, heuristics are commonly used to assess the credibility of a message, for example, using celebrity endorsers to promote a product triggers familiarity and infers the product's credibility by association. Before Facebook (Australia only) and Instagram trialed the removal of the number of publicly visible likes on a post, consumers assessed credibility through bandwagon heuristics (Multimedia Appendix 1), triggered by a mass of user opinion (eg, seeing a high number of comments on a SM post) [38]. The herd mentality (Multimedia Appendix 1) of liking what others like arises through the process of status-seeking and the need to be associated with others [39]. Another common way for consumers to make prompt judgments is via the expertise heuristic, cued when a consumer sees an official authority (such as an organization) as the source of information, whether it is an SM post, a news article, or a website [40]. By quickly associating an organization or individual as an expert source, less motivation is required to assess source credibility.

Purpose and Objective

Previous reviews have assessed the credibility of health information online, finding that factors such as clear website layout and professional design increased credibility [41-43]. However, much of this research is not applicable to SM platforms, which are often less curated and focus on fast-paced status updates.

As SM is a relatively new area of research, a scoping review was considered the most appropriate method to explore the topic area. Our research in applying social marketing techniques to the field of nutrition has led us to recognize the importance of

using marketing and communication techniques, particularly on SM [9,11,44]. The aim of this scoping review was to understand and explore the factors that affect consumers' perceptions of message and source credibility (ie, expertise and trustworthiness) and authenticity on SM platforms to better inform nutrition science SM communication best practices. A secondary objective was to examine the fields that are currently undertaking this type of research and the theories used to inform the research.

Methods

Search Strategy and Databases

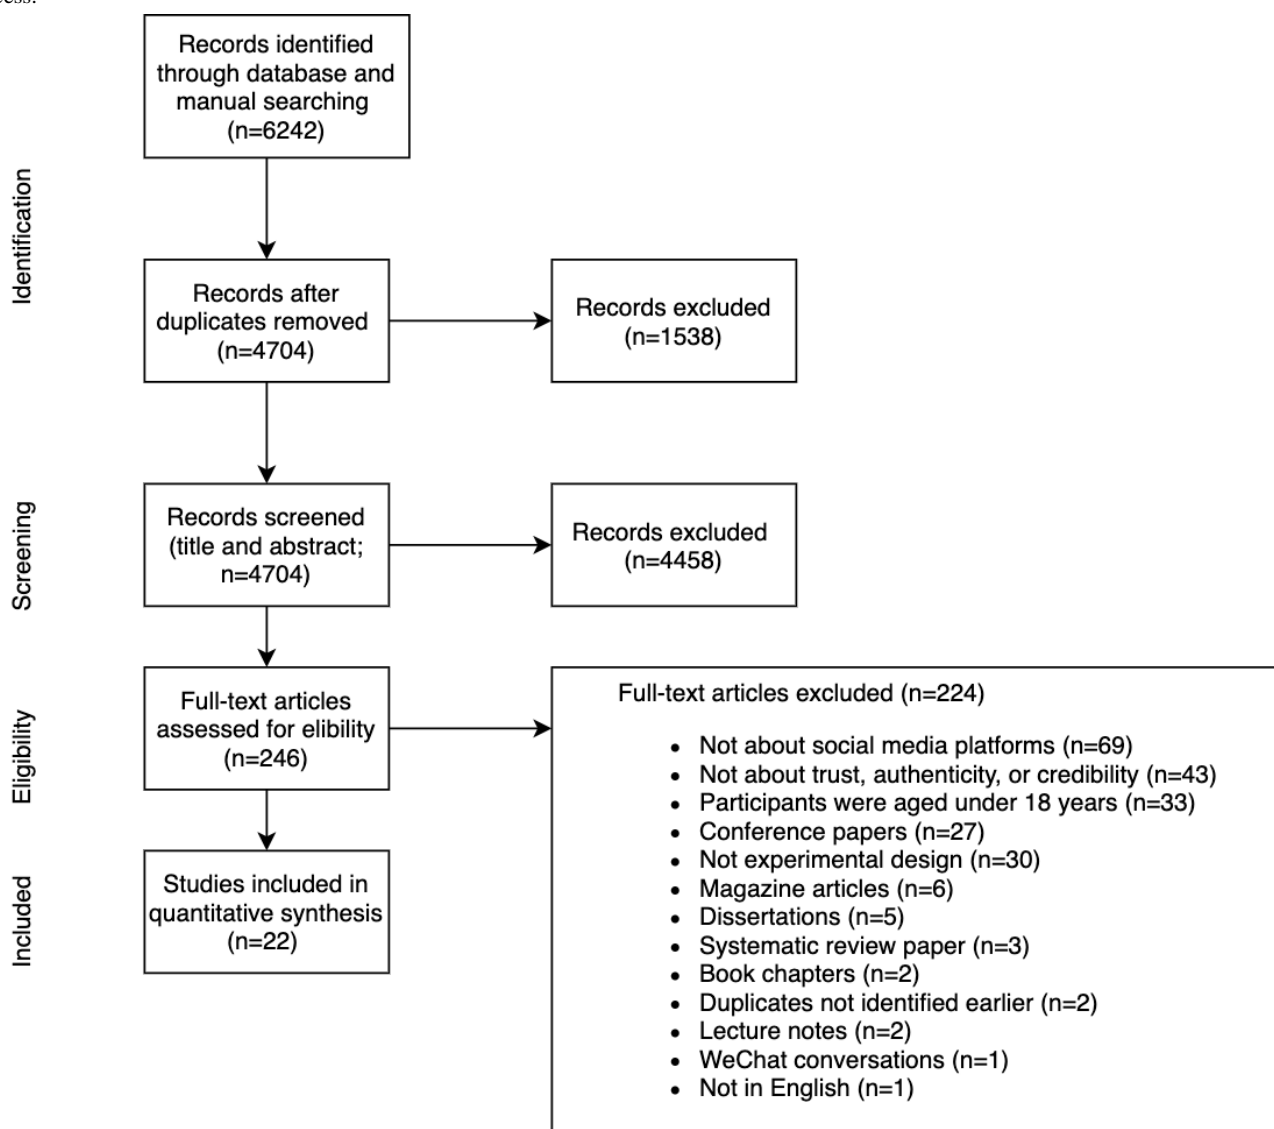

The Preferred Reporting Items for Systematic Reviews and Meta-Analyses Scoping Review Checklist and the Joanna Briggs Institute Reviewer's Manual were used throughout the review process [45,46].

Key databases from health, psychology, and business disciplines were used to conduct the final search in conjunction with a university librarian on March 27, 2019. Cumulative Index of Nursing and Allied Health Literature (CINAHL) Plus (422 results), Scopus (2199 results), Excerpta Medica dataBASE (EMBASE; 697 results), Ovid Medical Literature Analysis and Retrieval System Online (MEDLINE; 326 results), PsycINFO (1223 results), and Business Source Complete (1375 results) were searched for title, abstract, and keywords to identify the initial 6242 articles (example search strategy provided in Multimedia Appendix 2). All articles were imported into Covidence online software (Veritas Health Innovation) to manage the reviewing process. Manual searches were conducted by checking the reference lists of included studies to identify additional papers that the search may have missed; however, no papers were found.

Inclusion and Exclusion Criteria

The inclusion criteria were experimental studies (ie, stimuli provided), studies focusing on microblogs (eg, Facebook, Twitter; Multimedia Appendix 1), studies focusing on healthy adult populations (as clinical populations often use SM to search for very specific health information), and studies focusing on source credibility or authenticity. No date restrictions were used. Exclusion criteria were studies involving participants aged under 18 years and clinical populations, gray literature, blogs, WeChat conversations, web-based reviews, studies that did not involve participants' perceptions, and non-English papers (Figure 1).

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses for Scoping Reviews flow diagram of the search and study selection process.

Screening

Overall, 2 investigators (ELJ and AMB) independently screened the title and abstract of the included papers against the inclusion and exclusion criteria. This process was repeated for full-text screening, with any conflicts being discussed until a joint consensus was reached. There were 22 final papers (Figure 1).

Data Extraction

Data extraction was conducted independently by a researcher (ELJ) using Microsoft Excel 2019 (Microsoft Corporation) and was then cross-checked by a fellow researcher (AMB). Following data extraction, the results were collated based on various parameters such as SM platform focused on manipulation stimuli, outcome, and scales used for data collection. All papers were given a category to summarize their topic area, such as *celebrity*, *political*, *marketing*, *health*, or *general* (for studies that assessed source credibility without an overarching theme).

Results

Key Characteristics

Of the 22 papers that met the inclusion criteria, 3 papers reported on 2 separate studies, giving a total of 25 research studies [47-49]. The number of participants in the included studies ranged from 85 to 3476 [49,50]. Most studies were conducted in the United States (n=16) and had between-subject experimental designs (n=19). All studies used convenience sampling, excluding one that used random sampling [51]. Many studies (n=19) had no inclusion or exclusion criteria for recruitment, whereas only 2 studies specified exclusion criteria that required the participants to have an active SM account [52,53]. Student populations were predominant (n=17), where college students participated in exchange for course credit. Paid online participants were recruited in 5 of the studies via either Mechanical Turk (an Amazon platform) or professional market research companies [50-52,54,55]. Generally, the student population had a lower average age than the paid participants. Demographic data were not reported in 3 studies [56-58].

A total of 4 microblogging platforms were used: Twitter (n=10), Facebook (n=8), Instagram (n=3), and YouTube (n=3; [Multimedia Appendix 1](#)). Furthermore, 2 papers focused on both Facebook and Twitter [50,59]. Credibility was the most reported outcome (n=18), followed by trust (n=4); authenticity was not reported in the included studies. The predominant fields of research included communications (n=11), psychology (n=4), and marketing (n=2). The source credibility model (n=13) and the modality, agency, interactivity, and navigability (MAIN) model (n=7) were frequently used to inform research across disciplines. Other theories included social capital theory (n=2) and self-disclosure theory (n=2). The most commonly manipulated variables were the number of likes (n=4), source of the post (n=4), number of followers (n=3), and number of retweets (n=3).

Scales

All papers used a scale to assess credibility, with the most common being McCroskey and Teven's Source Credibility Scale (n=6; $\alpha=.94$) and Ohanian's Source Credibility Scale (n=4; $\alpha>.8$) [31,60]. McCroskey and Teven's validated scale, used to assess the credibility of political and public figures, includes 3 constructs: goodwill, trustworthiness, and competence [60]. Ohanian's validated scale, created to assess the credibility of celebrity endorsers, also includes 3 constructs: attractiveness, trustworthiness, and expertise [31]. Other studies created their own scales for data collection, sourcing items from the literature, and were not validated before use [47,51,61,62].

Main Observations

Most papers (n=15) involved the manipulation of text (eg, in a SM post) via Facebook or Twitter feeds to assess credibility (n=11), trust (n=4), or both (n=2). Studies primarily explored

the tone of voice, bandwagon cues, and expertise [47-49,51,56,58,59,63-66]. Full details of the studies are reported in [Multimedia Appendices 3-7](#).

Language Use

Overall, 3 papers included in the review assessed message credibility: how message characteristics impact credibility perceptions ([Multimedia Appendix 1](#)). In a study conducted on Facebook with a student sample (mean age 19 years), language usage was found to impact credibility judgments, with a gain-framed post (focusing on the benefits of exercise) eliciting positive emotions and increasing credibility when compared with a loss-framed post (focusing on the risks of not exercising; [Tables 1 and 2](#); [Multimedia Appendix 3](#)) [47].

On Twitter, Houston et al [51] found that the tone of voice impacted credibility; nonopinionated tweets (written as a headline), which conveyed no personal opinion, were more credible than opinionated tweets that used humor or sarcasm and conveyed strong personal opinion among consumers aged over 18 years, participating for monetary rewards ([Tables 1 and 2](#); [Multimedia Appendix 4](#)).

Similarly, Yilmaz and Johnston [59] compared language framed with personal experiences to depersonalized language (ie, factual and data-based) on Facebook and Twitter in a sample of 257 students ([Tables 1 and 2](#); [Multimedia Appendix 5](#)). Differing results were found among the SM platforms; personalized Facebook posts were more competent and trustworthy than personalized tweets [59]. However, depersonalized tweets were more competent and trustworthy than depersonalized Facebook posts [59]. Thus, personalized language was an effective way to increase credibility on Facebook but not on Twitter [59].

Table 1. Main findings of included papers and their effect on credibility or trust, separated by manipulated variable: number of likes, number of followers, number of retweets, source, and language.

Outcomes/author (year) [citation]	Population group	Key significant results
Number of likes		
Borah and Xiao (2018) [47]	Students	In the 2 studies conducted, the number of likes did not affect source credibility overall when looking at Facebook posts (study 1: $P=.93$; study 2: $P=.09$)
Phua and Ahn (2016) [66]	Students	Brand trust was higher when likes were high on Facebook post ($P<.005$) or when friends' likes were high ($P<.001$). Friends' likes were more important in trust than overall total likes ($P<.005$). The number of likes had no direct effect on brand trust when the intensity of Facebook use was controlled for ($P=.89$)
Shen et al (2019) [50]	Paid online workers	Bandwagon cues did not impact credibility when looking at images on Twitter and Facebook ($P=.85$)
Number of followers		
Jin and Phua (2014) [48]	Students	A higher number of Twitter followers on the celebrity's account increased source credibility and intention to build an online friendship with the celebrity endorser for all dimensions of source credibility: physical attraction ($P<.05$), trustworthiness ($P<.05$), and competence ($P<.01$)
Lee (2018) [49]	Students	The number of followers on Facebook made a statistically significant difference on the believability of the answer ($P<.05$), with a high number of followers increasing believability. There were no significant results for trustworthiness or accuracy
Westerman et al (2011) [57]	Students	Trustworthiness indicated an inverted U-shaped relationship with the number of followers on Twitter ($P=.02$)
Number of retweets		
Lin and Spence (2018) [63]	Students	The highest level of trust (on Twitter) was when participants viewed the post with 400 retweets, followed by 40 retweets, whereas 4000 retweets had the lowest level of trust ($P=.01$). Participants perceived the highest levels of source competence when viewing the post with 40 retweets, followed by 400 retweets. The post with 4000 retweets had the lowest perceived competence ($P=.01$)
Lin and Spence (2019) [64]	Students	There were significant differences in trust perceptions across varying retweet conditions ($P=.046$). People who viewed the FDA's ^a Twitter page containing 4000 retweets were more likely to perceive lower organizational trust than the condition of 40 retweets ($P<.05$)
Lin and Spence (2016) [65]	Students	Participants perceived lowest competence when viewing a peer's Twitter page with no retweets ($P<.001$). The highest level of perceived source goodwill, trustworthiness, and competence was when participants viewed the CDC ^b page with no retweets ($P<.001$)
Source (expert, peer, or stranger)		
Borah and Xiao (2018) [47]	Students	In the 2 studies conducted on Facebook, the CDC and WebMD authors were seen as more credible than unknown authors (study 1: $P<.01$; study 2: $P<.01$)
Lin and Spence (2018) [63]	Students	Participants viewing an FDA expert's Twitter account were more likely to perceive higher trust ($P=.01$), competence ($P<.001$), and goodwill ($P<.001$) than those viewing a peer or stranger's account
Lin and Spence (2016) [65]	Students	Higher credibility was assigned to risk information from an expert compared with a peer and a stranger on Twitter ($P<.001$)
Language (message credibility)		
Borah and Xiao (2018) [47]	Students	In the 2 studies conducted, a gain-framed message was more credible than a loss-framed message on Facebook (study 1: $P<.001$; study 2: $P<.001$)
Houston et al (2018) [51]	Paid workers	Nonopinionated tweets were perceived as more credible than opinionated tweets ($P<.001$)
Yilmaz and Johnson (2016) [59]	Students	Personalized status updates on Facebook were seen as more competent and trustworthy than personalized tweets ($P=.007$, $P=.001$ respectively). Depersonalized tweets were more trustworthy than the source of depersonalized status updates on Facebook

^aFDA: Food and Drug Administration.^bCDC: Centers for Disease Control and Prevention.

Table 2. Included papers, main outcomes, and the effect on either brand trust, message credibility, or source credibility (including trustworthiness, believability, and competence) as specified in their results.

Factors	Platform	Population	Outcome	Result ^a	Relevant papers
Language use^b					
Gain-framed language					
	Facebook	Student	Message credibility ^{b,c}	Increase	Borah and Xiao [47]
Personalized language					
	Twitter	Student	Competence and trustworthiness	Decrease	Yilmaz and Johnson [59]

^aOn the basis of reported results from studies summarized in [Multimedia Appendices 3-7](#).

^bFor further context, explanation, and examples of these factors, refer to [Multimedia Appendices 3-7](#).

^cCredibility comprises trustworthiness, expertise, and sometimes attractiveness, depending on the individual paper.

Bandwagon Heuristics

Bandwagon cues such as the number of followers, number of retweets, and number of likes were a way in which student participants (mean age range 19-22.9 years) assessed source credibility across 30% (8/22) of the included papers; however, the findings were inconsistent among studies [47-49,56,63-66].

Borah and Xiao [47] assessed the number of likes on a Facebook post (150 likes or 2 likes) and found that the manipulation had no significant effect on credibility or trust levels ([Tables 1 and 2](#); [Multimedia Appendix 3](#)). This differed from the study by Phua and Ahn [66], which found that brand trust increased when overall likes or friends' likes on the post were higher ([Tables 1 and 2](#); [Multimedia Appendix 3](#)). Similarly, Lee's experiment [49], which involved a question-and-answer format on a Facebook post, found that when the source had a higher number of followers, the answer posted was rated as more believable than an answer posted by a source with a lower number of followers ([Multimedia Appendix 3](#)). However, this relationship was not observed for the accuracy or trustworthiness dimensions of source credibility. Lee's second experiment assessed the credibility of a source with a high number of friends compared with a low number, finding that the source with more friends was seen as more believable and trustworthy ([Multimedia Appendix 3](#)) [49].

On Twitter, Westerman et al [57] found no linear relationship between the number of followers and credibility. In fact, too many followers (n=70,000) or too few followers (n=70) reduced the level of trust compared to those with 7000 followers, who had the greatest level of trust ([Multimedia Appendix 4](#)) [57]. However, Jin and Phua [48] reported that a higher number of followers (n=14,677,050) increased source credibility ([Tables 1 and 2](#); [Multimedia Appendix 4](#)). The ratio of the number of followers to the number of follows on Twitter provided a cue for participants to assess credibility, with a narrow gap (ie, similar ratio of Twitter followers to follows) being perceived as more competent than a wide gap (ie, more Twitter followers compared with follows; [Multimedia Appendix 4](#)) [57]. High numbers of retweets (from other Twitter profiles) reduced credibility in 3 studies [63-65]. When using an organization's

Twitter page (*Centers for Disease Control and Prevention* [CDC] or *Food and Drug Administration* [FDA]), a post with 4000 retweets was found to be less trustworthy and competent than posts with 40 or 400 retweets ([Table 1](#); [Multimedia Appendix 4](#)) [63-65].

Expertise Heuristics

Manipulating the source of the Facebook or Twitter posts was found to impact source credibility in 3 studies with student participants [47,63,65]. Expert sources, such as the CDC, were perceived as more credible than strangers when disseminating health information in Facebook status updates ([Multimedia Appendix 3](#)) [47].

Similarly, expert sources (eg, FDA) were considered more trustworthy and competent and, thus, overall more credible than strangers or peers on Twitter ([Tables 1 and 2](#); [Multimedia Appendix 4](#)) [63,65]. Jin and Phua [48] assessed celebrity source credibility by manipulating a news story of the celebrity (shared on Twitter) to be either prosocial (donating to a charity) or antisocial (drug abuse; [Multimedia Appendix 4](#)). Consumers were more likely to identify with prosocial celebrity and perceive them as more credible, suggesting that reputation can affect credibility perceptions [48].

Discussion

Principal Findings

Surprisingly, there were no studies in the field of health and nutrition research included in this scoping review; however, there are some important learnings that could be utilized for nutrition and health communication. There were many different factors that affected the perceived credibility of a message and source on SM, such as language usage, expertise heuristics, and bandwagon heuristics. However, no information was found on the factors affecting perceived authenticity in this context. The scales used as well as the different models and theories to inform various fields of research are reported.

Language Usage

The results of the included studies indicated that the language used in tweets affected message credibility. Personalization was more effective on Facebook, whereas depersonalization was more effective on Twitter [59]. This can be explained by the differing functions of these platforms. The audience of a tweet is largely unknown as the public nature of Twitter allows anyone with or without an account to view a profile (provided the profile is not locked) [70]. Having a large and primarily unknown audience creates a challenge to balance self-expression and impression management; users want to share information but do not want to be negatively judged [70]. The fear of other people's negative opinions and judgment makes it easier to post factual, depersonalized tweets with no personal opinion involved [70]. Furthermore, the linguistic style of Twitter differs from other SM platforms because of the 280-character (previously 140) limit for tweets [59]. When users share long personal stories, it differs from the concise updates that are typically shared on Twitter, reducing the contextual appropriateness of the information [59]. This differs from Facebook, which has an extremely high character limit for status updates (63,206 characters) and requires both parties to accept a friend request before viewing each other's content (provided the privacy of the page is not set to public) [59]. Thus, when a personal status update is made on Facebook, the recipients are generally people who have an existing relationship with the user and an established level of trust, instantly increasing the credibility of the post [59]. Therefore, message characteristics such as language style and the platform being used should be considered by health professionals when creating SM posts.

Expertise Heuristics

Each study in the review that compared an expert to a stranger or peer found that the expert was more credible [47,63,65]. This is explained by the expertise heuristic, which is triggered when a consumer sees an official authority as a source [71]. For example, when tweets were posted from the CDC's Twitter account, they were seen as more credible than when an unknown person tweeted [65]. These findings are consistent with the existing literature on website credibility, whereby listing an author's affiliations, credentials, or qualifications triggers the expertise heuristic and increases the credibility of the information or message presented [72,73]. In addition, a recent review found that websites run by health institutions (such as the CDC) were considered more trustworthy than private websites [42]. Health practitioners should include their credentials (relevant to their field of research) on their SM page, so that their expertise is clear to the audience and credibility can be established.

Bandwagon Heuristics

A key focus of the included papers was bandwagon heuristics, which relate to the number of likes, followers, or retweets assigned to information on SM [71]. It is known that people base their own decisions on other people's endorsements and opinions, particularly when purchasing products [74]. Typically, a bigger bandwagon (ie, a high number of likes, comments, or shares) will result in a greater perception of source credibility [40,75]. However, the reviewed papers that manipulated

bandwagon cues provided differing results than expected; a high number of retweets ($n=4000$) had the lowest perceived trustworthiness of the conditions, and two papers found no difference in credibility between the low and high like manipulations (Multimedia Appendices 3 and 4) [47,50,63,64]. Some consumers perceived popular content as having lower credibility, described as a *reverse bandwagon heuristic* (Multimedia Appendix 1) or the *snob effect* (Multimedia Appendix 1) [39,76]. This arises from the consumer's need to identify as an individual in society, without conforming to social norms [39,76]. Some people do not follow trends and are not willing to follow others without independently thinking and making their own judgments. The *snob effect* causes a deviation from the norm (ie, liking the post) and, thus, when a consumer sees a high amount of engagement on SM, it can result in negative opinions of the source and information presented, reducing the perceived credibility [63]. However, in 2019, attempting to reduce the pressure people feel when they post online, Instagram (globally) and Facebook (in Australia) trialed removing the number of likes on posts so that likes are no longer publicly visible to others [77]. Rather than displaying the number of people who have liked the post, the display now shows one user who has liked the post followed by the phrase "and others" [77,78]. Therefore, in the future, the use of bandwagon cues to judge credibility may be less prevalent as the engagement of a post can no longer be viewed publicly in a numerical format [77].

Scales

The most commonly used scale in the research papers was McCroskey and Teven's Source Credibility Scale ($n=6$), used to assess the credibility of a source of information (ie, a person). In contrast, message credibility was assessed by examining the characteristics of a message such as the structure, perceived accuracy, and language used [79]. Flanagin and Metzger's Scale of Message Credibility Online (2013) assesses 5 dimensions of credibility—believability, accuracy, trustworthiness, bias, and completeness—and was utilized in 2 papers [49,50]. Other papers that assessed message credibility adapted their own scale from multiple sources in the literature to evaluate the language used in Facebook posts, tweets, or message appeals in YouTube videos [47,51,61]. Internal reliability was assessed with Cronbach alpha values at an acceptable level ($\alpha>.7$) in all three papers that adapted their own scale. However, there was no exploratory or confirmatory factor analysis conducted, creating implications for the validity and generalizability of the research.

Fields of Research

Communications and psychology were the predominant fields of research within the included papers. The theories and models used to underpin research overlapped among disciplines, with the source credibility model being the most common within communications, information research, psychology, and business. The MAIN model (a digital extension of source credibility model) was also used frequently in communications, information research, computer science, and psychology. Previously, source credibility and its impact have been investigated more broadly in the health discipline to assess consumers' perceptions of health information online, but this

was limited to websites and did not include SM [80]. To our knowledge, health communication research has not utilized the MAIN model or source credibility model. Using these models to inform research in different fields resulted in the perception of credible spokespeople on SM. Thus, these models should be utilized to increase the effectiveness of health communication within nutrition research.

Gaps in Knowledge

On the basis of the search strategy and the inclusion and exclusion criteria, the concept of authenticity has not been explored in this specific context. In addition, there was a lack of research regarding SMIs or nutrition professionals as the source of SM posts. Most studies focused on organizations or an unknown fictional author as the source. As SMIs are key to digital marketing and health communication, research into consumer perceptions of the source credibility and authenticity of SMIs would be beneficial to further understand how they communicate effectively with their followers. Results from these future studies would be beneficial for informing the delivery of health communication in various digital formats.

Strengths

The strength of the papers included in the scoping review was the large sample size that was achieved (range of the number of participants from included studies was 85-3476). As most papers had a student cohort participating for university credit, large numbers of participants were recruited. In addition, many of the papers completed a manipulation check during the pilot of the survey to ensure that the mock scenario they were creating was robust, for example, testing if the *high retweet* condition of 4000 retweets was actually considered *high* by the participants, limiting the confounding factors that could arise if the manipulations were perceived differently than intended [63].

Limitations

As most papers (n=21) used convenience sampling, selection biases were inherent. Furthermore, generalizability was limited to the geographical area in which the research was conducted, making it difficult to draw conclusions without conducting further research. Student samples were predominant (n=17), further limiting the variability and generalizability of results as student samples (referred to as western, educated, industrialized, rich, and democratic [WEIRD]) [81] are seen as more homogenous in terms of education level and socioeconomic status than the general public [81,82]. Furthermore, cross-sectional questionnaires were used as the method of data collection, which is self-reported, adding a level of bias to the results as participants can be deceiving intentionally or unintentionally [83]. A methodological limitation of undertaking a scoping review is the omission of quality appraisal of studies, usually conducted during data extraction in a systematic literature review.

Conclusions and Recommendations

Fostering credibility online should be considered by corporate and human health brands to create a stronger relationship with their audience. This scoping review highlighted that message and source credibility can be affected by language usage, expertise heuristics, and bandwagon cues. Gaps in the literature were identified, highlighting the need for further research on SM platforms, as Instagram and YouTube were studied less than Facebook and Twitter. The main field of research identified from the included papers was communications, with no papers from health or nutrition science. Currently, there is a limited understanding of the use of SMIs and science experts to relay health messages. Further research needs to be undertaken to apply information from communications (on source and message credibility and authenticity) in a health context and in populations other than students.

Acknowledgments

The authors thank Monash University librarian, Anne Young, for assistance when developing the search strategy.

Communicating Health is funded by the National Health and Medical Research Council (grant number GNT1115496).

Authors' Contributions

ELJ and AMB completed the screening and data extraction of the included papers. The manuscript was drafted by ELJ, with critical revisions suggested by TAM and JI. All authors read and approved the final manuscript.

Abstract

Background: Sexualized drug use (SDU; the use of any psychoactive substance before or during sexual intercourse) is prevalent among men who have sex with men (MSM) and may aggravate the worsening HIV epidemic in this key population.

Objective: This observational prospective cohort study investigated factors predicting the occurrence of SDU within a 6-month follow-up period among a sample of MSM in Hong Kong. We hypothesized that perceptions related to SDU would mediate the association between the influence of social media/gay social networking apps and SDU during the follow-up period.

Methods: Participants were Chinese-speaking men in Hong Kong, China who had anal intercourse with at least one man in the past year. Among 600 participants who completed the baseline telephone survey, 407 (67.8%) completed another telephone survey 6 months later. Logistic regression models and path analysis were fitted.

Results: At Month 6, 6.9% (28/407) and 4.4% (18/407) of participants reported SDU and chemsex during the follow-up period. After adjustment for significant baseline background variables (use of pre-exposure prophylaxis; history of HIV and other sexually transmitted infections; anal intercourse with nonregular male sex partners, condomless anal intercourse with men, multiple male sex partnerships, and SDU at baseline), three constructs of the Theory of Planned Behavior (TPB) were significantly associated with SDU during the follow-up period: (1) positive attitudes toward SDU (adjusted odds ratio [AOR] 1.19, 95% CI 1.05-1.36), (2) perceived support for SDU from significant others (AOR 1.15, 95% CI 1.01-1.30), and (3) perceived behavioral control of refraining from SDU (AOR 0.76, 95% CI 0.59-0.98). Exposure to information supporting SDU on social media and gay social networking apps was also significantly associated with SDU (AOR 1.11, 95% CI 1.01-1.22). Bootstrapping analyses indicated that social media influence was indirectly associated with SDU through TPB-related perceptions of SDU ($\beta=.04$; $B=.002$, 95% CI 0.001-0.01).

Conclusions: Social media and gay social networking apps may be a major source of influence on MSM's perceptions and actual behaviors related to SDU.

Introduction

Psychoactive substance use and HIV are intertwined epidemics among MSM [1]. Sexualized drug use (SDU) refers to the use of any psychoactive substance before or during sexual intercourse [2]. Chemsex is considered a subset of SDU, which is commonly defined as the use of specific drugs (methamphetamine, mephedrone, γ -hydroxybutyrate [GHB/GBL], ketamine and cocaine) before or during sexual intercourse [3-5]. Two published systematic reviews addressed SDU and chemsex among MSM and found these practices prevalent across settings [3,6]. A recent study found that 54% of MSM visiting sexually transmitted infection (STI) clinics in the Netherlands reported SDU [4]. The prevalence of using alcohol or illicit psychoactive substances before or during sexual intercourse was 41% among an online sample of MSM in the United Kingdom [5]. In Hong Kong, China, 12.0% of MSM reported SDU in 2017 [7]. The prevalence of chemsex among MSM ranged from 3% to 35% across countries [3,8-10]. Psychoactive substances such as those used for SDU/chemsex adversely affect users' capacity to perceive and respond to risks during sexual encounters, and may prompt them to engage in high-risk sexual practices [11]. Studies have consistently shown that SDU and chemsex were associated with a higher risk of condomless anal intercourse (CAI), group sex, and fisting, resulting in a higher risk of HIV and other STIs [3,8,12]. SDU/chemsex among MSM in Hong Kong may aggravate the worsening HIV epidemic in this group (6.54% of MSM were HIV-positive in 2017) [13]. However, there is a lack of effective behavioral interventions targeting SDU/chemsex [14-17].

Factors associated with SDU/chemsex among MSM included those related to sociodemographics (eg, age, ethnicity, income, education level, and employment status), sexual orientation, and utilization of HIV testing and other HIV/STI prevention services [3,5,9]. Studies also showed that MSM with SDU/chemsex experience were more likely to access pre-exposure prophylaxis (PrEP) [10,12]. These factors were considered in this study. Perceptions related to SDU also play important roles, and are important for theory-based interventions to address. Qualitative studies found that a key reason MSM engaged in SDU/chemsex was the belief that psychoactive substances could increase stamina and arousal levels, so that an individual could engage in sex for a sustained period [3]. Other reasons given included the following: overcoming underconfidence, enhancing the emotional connection with sex partners, and coping with stress [3]. Although a qualitative study suggested that MSM are under peer pressure to have SDU and chemsex [18], other social network-related factors (such as fear of loss of partners or friends) deterred MSM from using psychoactive substances before or during sexual intercourse [3]. Only one quantitative study showed that a perceived lower confidence of practicing safe sex consistently was associated with a higher likelihood of chemsex among MSM in the United Kingdom [5]. In this study, we chose the Theory of Planned Behavior (TPB) as the framework to guide our examination of

perceptions related to SDU [19]. The TPB has commonly been applied to explain various types of risk behaviors [20] and design various health-related interventions [21]. The TPB specifies that attitudes, subjective norms (ie, whether others approve of certain behaviors), and perceived behavioral control (perceived availability of resources and opportunities that enable a person to perform behaviors) determine health behaviors [19]. This framework is potentially applicable for understanding the factors related to SDU/chemsex among MSM, given findings from previous studies that noted the importance of attitudes, norms, and perceived control on this behavior.

Constructs from the TPB and subsequent behaviors may be shaped by social network-related factors as well as the use of social media and gay social networking apps. In Hong Kong, 96% of residents have access to a smartphone [22]; 85% and 57% use Facebook and Instagram, respectively [23]; and about 70% of local MSM use gay social networking apps to seek sex partners [24]. Social media (eg, Facebook, Twitter, Instagram, Weibo) and location-aware gay social networking apps (eg, Grindr, Jack'd, Blued) have facilitated drug purchasing and seeking SDU and chemsex in one's geographical location [18,25,26]. Across countries, MSM reported that it was common to encounter information related to SDU/chemsex when browsing these social media and apps [18,25,26]. Many MSM openly solicit chemsex in their online profiles [18,25,26], while others reported being asked to use psychoactive substances or engage in SDU/chemsex by other MSM through these apps [18,25-28]. In addition, posts on social media such as Facebook or Twitter usually portray psychoactive substance use as normative, which may increase intentions to practice SDU or chemsex [29,30]. Despite the potential for social media and apps to increase SDU and chemsex among MSM in Hong Kong, no quantitative studies have investigated the influence of these factors.

In addition to social media and gay social networking apps, peer behaviors may also influence SDU and chemsex practices among MSM. Compared to other HIV key populations, MSM tend to have large and dense social networks [31]. Most Chinese MSM are heavily involved in the MSM community, and have strong ties to each other [32]. As MSM are a highly marginalized community in Hong Kong, individuals within it may perceive a high level of similarity to their MSM peers and may consequently find their peers' experiences particularly valuable and influential. Prior studies have found that peers within an individual's social network are the most common source for obtaining psychoactive substances [33,34]. Qualitative studies have suggested that MSM often introduce SDU and chemsex to their peers. Previous studies suggested that a higher number of psychoactive substance users in one's social network was positively associated with substance use in various populations [35-37], including MSM [36].

The Social Learning Theory posits that people learn by both direct experience and observation [38]. Observation of peers is a major source of influence on people's health attitudes and

behaviors [39]. Given the close relationships and high level of perceived similarity among MSM, observing peer behaviors plays an important role in influencing MSM's attitudes and behaviors related to SDU/chemsex. Such interactions and observations may occur online and offline. In this study, we hypothesized that being exposed to information supporting SDU on social media/gay apps and observing SDU among peers would influence MSM's perceptions related to SDU, which would influence the occurrence of SDU.

To address these gaps, this study investigated predictors of SDU within a 6-month follow-up period among a sample of MSM in Hong Kong. Potential predictors measured at baseline included sociodemographics and behavioral characteristics of the participants, perceptions related to SDU based on the TPB, and the influence of social media/gay social networking apps and peers. We further tested the hypothesis that perceptions of SDU would mediate the associations between the influence of social media/gay social networking apps and peers on SDU.

Methods

Participants and Data Collection

We conducted an observational prospective cohort study among MSM in Hong Kong, China from April 2018 to July 2019. Inclusion criteria for participants of the cohort study were the following: (1) Chinese-speaking men in Hong Kong, (2) aged 18 years or above, and (3) had anal intercourse with at least one man in the last 12 months. Participants were recruited through multiple sources. A recent mapping exercise was conducted by the government, which identified 12 gay bars and 16 gay saunas in Hong Kong. Upon obtaining the approval of the owners, trained and experienced fieldworkers approached prospective MSM participants in these venues at different time slots during weekdays and weekends. They briefed prospective participants about the study details and gave them an information sheet. The research team also conducted online outreach by posting information about the study periodically as discussion topics on the two gay websites with the highest traffic in Hong Kong. If prospective participants were interested in this study, they could contact the interviewers through private messaging or other means (eg, WhatsApp, telephone, email). Recruitment was supplemented by peer referrals. Participants were guaranteed anonymity during the study, and had the right to end participation in the study at any time. Their refusal or withdrawal from the study would not affect their access to any future services. Verbal consent was obtained instead of written consent to allow participants to maintain anonymity, and the fieldworkers signed a form pledging that the participants had been fully informed about the study. Multiple forms of contact information were obtained to make an appointment to conduct a baseline telephone interview. Trained telephone interviewers confirmed participants' eligibility and consent to participate in the study, and conducted telephone interviews that took approximately 30 minutes to complete. Another telephone survey was conducted 6 months later. At least 5 follow-up calls were made during different time slots during weekdays and weekends before considering the participant lost to follow-up. Upon completion of both surveys, a HK \$50 (US \$6.45)

supermarket or café coupon was mailed to participants as compensation for their time. Telephone numbers and addresses were cross-checked to avoid repetition. Of the 1131 prospective participants approached through outreach in gay venues (n=211), online recruitment (n=607), and peer referral (n=313), 711 were eligible for participation after screening (venues: n=117; online: n=401; referral: n=193). Of these, 600 provided verbal informed consent and completed the baseline telephone interview (venues: n=85; online: n=345; referral: n=170). The response rate was 84.3%. At Month 6, 407 (67.8%) participants completed the follow-up survey. The Survey and Behavioral Research Ethics Committee of the Chinese University of Hong Kong approved this study (reference number 160051).

Measures

Design of the Questionnaires

A panel consisting of a public health researcher, an epidemiologist, a psychologist, an MSM community member, and a community-based organization worker was formed to develop the questionnaires. The questionnaires were tested by 10 local MSM. Based on their feedback, the questionnaires were then finalized by the panel.

Baseline Background Characteristics

Information collected included sociodemographics (age, highest education level attained, current marital status, monthly personal income, and current employment status), sexual orientation; utilization of HIV prevention services and PrEP; history of HIV and other STIs; and sexual behaviors with regular and nonregular male sex partners in the last year. A regular male sex partner (RP) was defined as a stable boyfriend, while a nonregular male sex partner (NRP) was defined as a casual sex partner or a male sex worker.

Patterns of SDU/Chemsex

In this study, SDU is defined as the use of any of the following psychoactive substances before or during sexual intercourse: ketamine, methamphetamine, cocaine, cannabis, ecstasy, Dormicum/Halcion/Erimin 5/nonprescription hypnotic drugs, heroin, cough suppressant (not for curing cough), amyl nitrite (popper), GHB/GBL, 5-methoxy-N, N-diisopropyltryptamine (Foxy), and mephedrone. We defined chemsex as the use of ketamine, methamphetamine, cocaine, GHB/GBL, or mephedrone before or during sexual intercourse. Such definitions have been used in a number of studies [3-5]. Participants were asked whether they had used any of the aforementioned psychoactive substances at baseline and Month 6 during different reference periods (baseline: lifetime and past year; Month 6: in the past 6 months).

Participants with SDU experience were asked about behavioral details, including the following: (1) types of psychoactive substance used during sexual intercourse, (2) poly-use of psychoactive substances during sexual intercourse, (3) time since the first episode of SDU, (4) frequency of SDU, (5) CAI during SDU, and (6) sexual risk behaviors during their most recent episode of SDU (ie, the number of participants; the use of alcohol and erectile dysfunction drugs; and the occurrence of CAI or group sex).

Influence of Social Media/Gay Social Networking Apps and Peers Measured at Baseline

Participants were asked to report the frequency of their exposure to the following information related to SDU on social media (eg, Facebook, Twitter, Instagram, Weibo) or gay social networking apps (eg, Grindr, Jack'd, Blued) in the last 12 months (eg, "Frequency of exposure to others' personal experiences supporting psychoactive substance use") with the following response categories: 1=Never, 2=Seldom, 3=Sometimes, and 4=Always. The Influence of Social Media Scale was formed by summing up individual item scores, with higher scores indicating higher levels of exposure to information supporting SDU from social media and gay social networking apps. The Cronbach α for this scale was .70, and a single factor was identified by exploratory factor analysis, explaining 70.1% of total variance. Additionally, the questionnaire also measured the number of peers in one's social network who had experience with SDU (response categories: None, 1-2, 3-5, 6-10, and >10).

Perceptions Related to SDU Based on the TPB

Five scales derived from the TPB were constructed [40]. Positive attitudes toward SDU were measured by four items (eg, "It is easier for you to find sex partners when using psychoactive substances before/during sexual intercourse"). The Positive Attitude Scale was formed by summing up individual item scores (from 1=Strongly disagree to 5=Strongly agree). Higher scores on the scale indicated more positive attitudes toward SDU. The Cronbach α of the Positive Attitude Scale was .82; one factor was identified by exploratory factor analysis, explaining 65.1% of total variance.

Four items (with response options ranging from 1=Strongly disagree to 5=Strongly agree) were used to measure negative attitudes toward SDU (eg, "Using psychoactive substances before/during sexual intercourse would increase your risk of having CAI"). The Negative Attitude Scale was formed by summing up individual item scores. Higher scores on the scale indicated more negative attitudes toward SDU. The Cronbach α of the Negative Attitude Scale was .62; one factor was identified by exploratory factor analysis, explaining 63.0% of total variance.

Four items were used to measure participants' perceived support from their significant others (referring to regular and nonregular male sex partners and MSM friends) for SDU. Items were measured on a 5-point Likert Scale from 1=Strongly disagree to 5=Strongly agree. The Perceived Subjective Norms for SDU among MSM Scale was constructed by summing up individual item scores. Higher scores indicated perceived subjective norms that were more supportive of SDU. The Cronbach α of the Perceived Subjective Norm Scale was .90; one factor was identified by exploratory factor analysis, explaining 76.8% of total variance.

Perceived behavioral control in refusing SDU and perceived behavioral control in refraining from SDU were measured by two items each. The Perceived Behavioral Control of Refusing SDU Scale and the Perceived Behavioral Control of Refraining from SDU Scale were formed by summing up individual item scores (from 1=Strongly disagree to 5=Strongly agree). Higher

scores of the Perceived Behavioral Control of Refusing SDU Scale indicated lower levels of control of refusing SDU, while higher scores in the Perceived Behavioral Control of Refraining from SDU indicated higher levels of control of refraining from SDU. The Cronbach α of the Perceived Behavioral Control of Refusing SDU Scale and the Perceived Behavioral Control of Refraining from SDU Scale were .93 and .95, respectively; single factors were identified by exploratory factor analysis, explaining 93.5% and 95.6% of total variance, respectively.

Data Analyses

Baseline background characteristics of participants who were followed up at Month 6 and those who were lost to follow-up were compared using chi-square tests (for categorical variables) or independent sample *t* tests (for continuous variables). The subsequent analysis was performed among those who had completed both surveys. Using SDU during the follow-up period as the dependent variable, and background characteristics measured at baseline as independent variables, univariate odds ratios (OR) predicting the dependent variable were obtained using logistic regression models. After adjusting for variables with $P < .05$ in the univariate analysis, associations between independent variables of interest (ie, perceptions, the influence of social media and gay social networking apps and peers) and the dependent variable were then assessed by adjusted OR (AOR). Each AOR was obtained by fitting a single logistic regression model, which involved one of the independent variables of interest and the significant background variables.

Path analysis was conducted to test the mediation model. The means for social media influence and peer influence were used as independent variables, while SDU during the follow-up period was used as the dependent variable. The means of the Positive Attitude Scale, the Negative Attitude Scale, the Perceived Subjective Norm Scale, the Perceived Behavioral Control for Refusing SDU Scale, and the Perceived Behavioral Control for Refraining from SDU Scale were used as indicators to represent the latent variable of perceptions related to SDU based on the TPB; confirmatory factor analysis was then conducted to test the goodness of fit of this construct. All significant background variables were controlled for in the model. Goodness of fit was tested by using the chi-square test, the Comparative Fit Index (CFI), the Non-Normed Fit Index (NNFI), and the root mean square error of approximation (RMSEA). A CFI and NNFI greater than .90 and RMSEA lower than .08 indicated acceptable goodness of fit [41]. Standardized path coefficients (β) and unstandardized path coefficients (B) were reported. We tested the mediation analyses using bootstrapping. The 95% CI of the indirect effects were obtained from 5000 bootstrap samples. A statistically significant mediation effect was observed when the CI did not include zero. The level of statistical significance was .05. SPSS (Version 18.0, IBM Corp) and AMOS were used.

Results

Baseline Background Characteristics

Most of the 600 participants were 18 to 30 years old ($n=342$, 57.0%), currently single ($n=504$, 84.0%), employed full-time ($n=498$, 83.0%), with a monthly personal income of HK \$20,000 (US \$2580) or higher ($n=336$, 56.0%), and had attained at least

a college education ($n=505$, 84.2%). Over half had received HIV antibody testing ($n=430$, 71.7%) and utilized other HIV prevention services ($n=335$, 55.8%) in the last year; 3.8% ($n=23$) were using PrEP at the time of the baseline survey. Among the participants, 3.3% ($n=20$) self-reported as living with HIV and 20.5% ($n=123$) had a history of other STIs. In the last year, 85.0% ($n=510$) and 60.5% ($n=363$) had had anal intercourse with RP and NRP, respectively. Furthermore, 40.2% ($n=241$) and 69.0% ($n=414$) reported CAI with men and multiple sex partnerships, respectively. The lifetime prevalence of SDU and chemsex were 19.3% ($n=116$) and 8.7% ($n=52$), respectively.

Means and standard deviation of items/scales related to the influence of social media/gay apps, the influence of peers, and perceptions related to SDU based on the TPB were described in Table 1. No significant difference was found in baseline characteristics between those with follow-up data available ($n=407$) and those who were lost to follow-up at Month 6 ($n=193$), with the exception of self-reported HIV status ($P=.04$), the frequency of exposure to commentary/discussion about psychoactive substance use on social media/gay apps ($P=.001$), and the score on the Perceived Behavioral Control of Refraining from SDU Scale ($P=.04$).

Table 1. Baseline characteristics of the participants.

Characteristics	All participants (n=600)	Follow-up at Month 6 (n=407)	Loss to follow-up (n=193)	P value

Perceived Behavioral Control of Refraining from SDU Scale, mean (SD)	9.2 (1.7)	9.3 (1.5)	9.0 (2.0)	.04

^aSDU: sexualized drug use. Sexualized drug use is defined as the use of any of the following psychoactive substances before/during anal intercourse: ketamine, methamphetamine, cocaine, cannabis, ecstasy, Dormicum/Halcion/Erimin 5/nonprescription hypnotic drugs, heroin, cough suppressant (not for curing cough), amyl nitrite (popper), GHB/GBL (γ -hydroxybutyrate), 5-methoxy-N, N-diisopropyltryptamine (Foxy), and mephedrone.

Patterns of SDU and Chemsex at Baseline and Month 6

At baseline, 14.7% (88/600) and 6.7% (40/600) of the participants reported SDU and chemsex in the past year, respectively. During the 6-month follow-up period, their prevalence was 6.9% (28/407) and 4.4% (18/407), respectively. Among 58 participants with experience of SDU who completed the Month 6 follow-up survey, 36% (n=21) reported SDU during the follow-up period. Among 26 MSM who had chemsex at

baseline and completed the Month 6 follow-up survey, 14 (54%) reported chemsex during the follow-up period.

Patterns of SDU one year prior to the baseline and during the 6-month follow-up period were similar. Amyl nitrite, methamphetamine, and GHB/GBL were the most commonly used psychoactive substances during sexual intercourse. About half of MSM who reported SDU reported poly-use of psychoactive substances and CAI. SDU commonly involved more than two people, the use of erectile dysfunction drugs, and group sex (Table 2).

^aMSM: men who have sex with men.

Baseline Factors Predicting SDU During the Follow-Up Period

Baseline background variables that were significantly associated with SDU during the follow-up period included the following: (1) currently on PrEP, (2) self-reported living with HIV, (3) history of other STI, (4) any anal intercourse with NRP, (5) CAI with any male sexual partners, (6) multiple male sex partnerships, and (7) SDU in the past year ([Table 3](#)).

After adjusting for significant variables, three constructs of the TPB measured at baseline were significantly associated with SDU during the follow-up period. These constructs included:

(1) positive attitudes toward SDU (AOR 1.19, 95% CI 1.05-1.36), (2) perceived support for SDU from significant others (AOR 1.15, 95% CI 1.01-1.30), and (3) perceived behavioral control of refraining from SDU (AOR 0.76, 95% CI 0.59-0.98). A higher level of exposure to information supporting SDU on social media/gay apps as measured at baseline was associated with a higher likelihood of SDU during the follow-up period (AOR 1.11, 95% CI 1.01-1.22). The association between the number of peers in one's social network who had ever engaged in SDU and the dependent variable was of marginal statistical significance (AOR 1.43, 95% CI 0.95-2.16, $P=.06$; [Table 4](#)).

Testing the Mediation Effects of TPB Constructs in the Association Between Social Media/Peers Influences and SDU

Model Testing

The results of the confirmatory factor analysis found that perceptions related to SDU based on the TPB did not show adequate model fit to the data ($\chi^2_5=19.01$, $P<.01$; CFI=.94; NNFI=.89; RMSEA=.08). Modification indices suggested adding a covariance between the Perceived Behavioral Control

of Refusing SDU Scale's error and the Perceived Behavioral Control of Refraining from SDU Scale's error ($B=-0.58$, $P<.001$). Since the two scales are related constructs [19], we added the covariance accordingly. The modified model showed excellent fit ($\chi^2_4=3.81$, $P=.43$; CFI=.99; NNFI=.99; RMSEA=.01). The chi-square test showed that the model fit change was significant (χ^2 change=15.20, degrees of freedom change=1, $P<.05$). All factor loadings were significant at $P<.001$, with absolute values of standardized coefficients greater than .25. The mediation model fit the data well ($\chi^2_{147}=188.71$, $P<.05$; CFI=.92; NNFI=.91; RMSEA=.06; Figure 1).

Figure 1. The proposed mediation models with standardized path coefficients. * $P<.05$; ** $P<.01$; *** $P<.001$. SDU: sexualized drug use; TPB: Theory of Planned Behavior.

Path Coefficients

The influence of social media/gay apps was positively associated with perceptions related to SDU based on the TPB ($\beta=.20$, $B=.11$, $P=.001$), while it was not significantly associated with SDU ($\beta=.08$, $B=.004$, $P=.11$). Peer influence was positively associated with perceptions related to SDU based on the TPB ($\beta=.38$, $B=.68$, $P<.001$), while it was not significantly associated with SDU ($\beta=.04$, $B=.01$, $P=.50$). Perceptions related to SDU based on the TPB was positively associated with SDU ($\beta=.21$, $B=.02$, $P=.02$).

Mediation Effects

Bootstrapping analyses indicated that social media influence had a significant indirect effect on SDU through perceptions of SDU in the hypothesized direction ($\beta=.04$, $B=.002$, 95% CI 0.001-0.01). However, peer influence was not significantly associated with SDU through perceptions of SDU ($\beta=.08$, $B=.01$, 95% CI -0.002 to 0.04).

Discussion

We found that 6.9% and 4.4% of MSM in Hong Kong practiced SDU and chemsex at the end of the 6-month follow-up period. Such prevalence was lower than that reported among MSM in Western Europe. At Month 6, about half of participants having SDU or chemsex at baseline refrained from these behaviors, while very few initiated these behaviors. Studies with longer follow-up periods are needed in the future to understand trends in SDU and chemsex among MSM in Hong Kong. Such studies are useful to understand the effectiveness of SDU/chemsex interventions conducted by local community-based organizations.

Similar to studies conducted in Western countries, amyl nitrite, methamphetamine, and GHB/GBL were the most commonly used psychoactive substances during SDU at both baseline and Month 6 [7]. The prevalence of risky practices during SDU (ie, poly-use of psychoactive substance, CAI, and group sex) was

high at both time points. Effective risk reduction strategies should be explored to address these risky practices.

According to social marketing approaches, careful segmentation improves the effectiveness of health promotion programs [42]. First, health care workers and interventions should tailor SDU and chemsex reduction measures to MSM living with HIV. Similar to findings conducted in mainland China [43] and other countries [3], MSM living with HIV were more likely to practice SDU compared to HIV-negative or status unknown MSM. They have a high risk of HIV transmission through SDU. For MSM living with HIV, SDU may be a potential maladaptive coping method for stressful situations caused by perceived stigma and experiences of violence and prejudice [44]. Reducing substance use during sex should be an essential part of care for MSM living with HIV. Second, health care workers and interventionists should focus on MSM with multiple risk behaviors (eg, anal intercourse with NRP, CAI, and multiple male sex partnerships), as these participants were more likely to practice SDU. Those with experience of SDU at baseline also had a much higher risk of practicing SDU during the 6-month follow-up period compared to those who had never practiced SDU. Moreover, MSM who were on PrEP reported higher likelihood of SDU than those not on PrEP. Studies conducted both locally and internationally consistently demonstrated the significant association between SDU and PrEP use [3,24]. This association may be due to the fact that some MSM may continue or initiate SDU as PrEP has minimized their risk of HIV infection. Health care providers supervising MSM on PrEP should continue to provide education about other sexual risks of SDU, such as acquiring STIs, or reduced adherence to PrEP.

Our results showed that MSM in Hong Kong are frequently exposed to information about psychoactive substances and received invitations to use such substances or engage in SDU/chemsex on social media and gay social networking apps. This exposure was associated with a higher prevalence of SDU during the follow-up period. Previous studies consistently showed that social media and gay social networking apps have

facilitated access to psychoactive substances, SDU, and chemsex for MSM [18,25,26]. One of the important contributions of this study is that it examined the potential mechanism of the associations between social media and peer influences and SDU. Our results suggest that social media exposure may enhance positive perceptions of SDU, which in turn increase the risk of SDU. The significant mediation effect supports mechanisms proposed by the Social Learning Theory [38] to understand how social media may influence one's behavior related to SDU. Most social media sites allow users to leave comments, and express approval or disapproval of the contents. Therefore, users can see how many others (and sometimes exactly who) expressed approval when they view social media. This may explain why MSM find social media content to be a believable and influential source of information. Gay social networking apps provide a quick and convenient way to locate and connect with other MSM nearby, and MSM commonly use these apps to seek SDU or chemsex [18,25-28]. Gay social networking app users may perceive SDU as normative as many users may openly solicit SDU or chemsex in their online profiles [18,25,26]. Additionally, receiving a personal invitation of SDU through these apps may make MSM less likely to refuse. Interventions should consider disseminating messages on reducing harm associated with SDU and chemsex on gay apps platforms to reduce perceptions of SDU as normative.

The association between the number of peers in their social network who had experience with SDU/chemsex and SDU was of marginal statistical significance. Previous studies suggested that peers are common sources of obtaining psychoactive substances among MSM [33,34]. It is also common for MSM to introduce and invite peers to have SDU or chemsex [33,34]. However, the TPB perceptions of SDU were not a significant mediator between peer influence and SDU. Other potential theory-based mediators should be explored in future work. We found significant correlations between peer influence and social media influence, and between peer influence and TPB constructs. MSM in Hong Kong contact each other mainly through social media and gay apps. Some of these peers may be online friends that they have never physically met. Since MSM have very close connections to each other, they may find their peers' experiences particularly valuable [32]. Furthermore, knowing more peers who practice SDU may make MSM perceive such behavior as normative.

These results highlight the importance of modifying perceptions related to SDU based on the TPB. About 20% of the participants held positive attitudes toward SDU. They perceived that SDU would allow them escape from reality, increase their sexual pleasure, and facilitate finding sex partners. Given our findings about the indirect effect of social media influence on SDU behavior, interventions should use social media to shape these attitudes. Health communication messages about reducing

substance use during sex and increasing MSM's awareness of the harms associated with SDU and chemsex can be disseminated using the same keywords used to promote SDU and chemsex, allowing the messages to reach MSM at high risk of SDU and chemsex. Gay social networking apps are also useful for delivering such health communication messages. Some apps widely used in Hong Kong (eg, Blued) have incorporated HIV prevention information and referral to HIV testing services [45]. Although less than 5% of the participants perceived support for SDU from significant others, such perceptions were positively associated with SDU during the follow-up period. Health promotion efforts led by influential peers may be useful to cultivate subjective norms against SDU. Health promotion campaigns may also consider sponsoring support groups led by peers living healthy lifestyles to reduce the influence of substance-using peers. Perceived behavioral control of refraining from SDU needs to be further strengthened as it was a protective factor. Enhancement in self-control skills is warranted and rehearsals may be a useful component of future health promotion programs.

This study had some limitations. First, the results were self-reported and subject to social desirability bias, although anonymity likely reduced the bias compared to nonanonymously collected data. Second, participants were recruited by nonprobabilistic sampling in the absence of a sampling frame. As compared to a representative MSM survey in Hong Kong, our participants had a lower prevalence of HIV and sexual risk behaviors, but higher levels of HIV testing. Third, we were not able to obtain the characteristics of participants who refused to join the study; selection bias might exist. However, the response rate for our study was higher than in other published studies involving MSM in China. Fourth, we did not ask behavioral intention to have SDU or chemsex at baseline. Behavioral intention is an important construct of the TPB that predicts actual behaviors [46]. Furthermore, attrition bias might exist. Those who had lower perceived behavioral control in refraining from SDU were more likely to drop out. Perceived behavioral control in refraining from SDU was a protective factor of SDU. Therefore, the prevalence of SDU during the follow-up period is expected to be higher. Finally, the Negative Attitude Scale had a relatively low Cronbach α (.62) in our sample. Although previous studies suggested that Cronbach $\alpha \geq .60$ was acceptable for exploratory research [47,48], caution is still needed when interpreting the results. Future studies are needed to validate this scale.

In sum, MSM in Hong Kong reported a lower prevalence of SDU and chemsex than that of their counterparts in Western countries. Social media and gay social networking apps may be a major source of influence on MSM's perceptions and actual behaviors related to SDU, and interventions delivered on these platforms may be especially effective.

Acknowledgments

The authors would like to thank Ms Willa Dong at the Department of Health Behavior, Gillings School of Global Public Health, the University of North Carolina at Chapel Hill for proofreading and correcting the manuscript.

This study was supported by the Beat Drugs Fund, Narcotics Division, Security Bureau of Hong Kong SAR, China (reference number 160051). The funder had no role in study design; collection, analysis, or interpretation of the data; writing the manuscript, or the decision to submit the paper for publication.

Abstract

Background: The past few decades saw considerable advances in research and dissemination of evidence-based psychotherapies, yet available treatment resources are not able to meet the high need for care for individuals suffering from depression or anxiety. Blended care psychotherapy, which combines the strengths of therapist-led and internet interventions, can narrow this gap and be clinically effective and efficient, but has rarely been evaluated outside of controlled research settings.

Objective: This study evaluated the effectiveness of a blended care intervention (video-based cognitive behavior therapy and internet intervention) under real-world conditions.

Methods: This is a pragmatic retrospective cohort analysis of 385 participants with clinical range depression and/or anxiety symptoms at baseline, measured using Patient Health Questionnaire-9 (PHQ-9) and Generalized Anxiety Disorder-7 (GAD-7), who enrolled in blended care psychotherapy treatment. Participants resided in the United States and had access to the blended care intervention as a mental health benefit offered through their employers. Levels of depression and anxiety were tracked throughout treatment. Hierarchical linear modeling was used to examine the change in symptoms over time. The effects of age, gender, and providers on participants' symptom change trajectories were also evaluated. Paired sample t-tests were also conducted, and rates of positive clinical change and clinically significant improvement were calculated.

Results: The average depression and anxiety symptoms at 6 weeks after the start of treatment were 5.94 and 6.57, respectively. There were significant linear effects of time on both symptoms of depression and anxiety ($\beta = -.49$, $P < .001$ and $\beta = -.64$, $P < .001$). The quadratic effect was also significant for both symptoms of depression and anxiety ($\beta = .04$, $P < .001$ for both), suggesting a decelerated decrease in symptoms over time. Approximately 73% ($n = 283$) of all 385 participants demonstrated reliable improvement, and 83% ($n = 319$) recovered on either the PHQ-9 or GAD-7 measures. Large effect sizes were observed on both symptoms of depression (Cohen $d = 1.08$) and of anxiety ($d = 1.33$).

Conclusions: Video blended care cognitive behavioral therapy interventions can be effective and efficient in treating symptoms of depression and anxiety in real-world conditions. Future research should investigate the differential and interactive contribution of the therapist-led and digital components of care to patient outcomes to optimize care.

Introduction

Depression and anxiety are the leading causes of disability worldwide [1]. Within work environments, depression and

anxiety have been associated with decreased productivity for employees through absenteeism, presenteeism, increased disability leave, or sick leave [2-4]. Although effective psychological treatments for depression and anxiety exist, they

are difficult to access for many individuals [5,6]. Approximately half of the individuals meeting criteria for major depressive disorder in a given year remain untreated or under-treated [7]. Cognitive behavior therapy (CBT) has been rigorously tested and consistently shown to be efficacious in randomized controlled trials and effective in real-world applications for treating depression and anxiety, emerging as the initial treatment of choice [8]. Barriers to large scale dissemination of CBT include insufficient numbers of specialized mental health providers [9], long waitlists to see a provider [10], high cost of therapist delivered care, the stigma associated with seeing a therapist and receiving treatment for mental health disorders [11], as well as travel time required to see a provider in person.

Internet-administered automated cognitive behavior therapy (iCBT) has emerged as a promising cost-effective solution that could narrow the gap between clinical demand and availability of CBT for adults, adolescents, and children [12,13]. iCBT involves the delivery of clinical CBT content via the internet and can involve different formats such as text, video, audio files, and interactive elements. iCBT interventions can be delivered alone or with additional support and guidance from a therapist or a coach [14]. Among the advantages of iCBT over traditional therapist-delivered care are scalability, guaranteed treatment fidelity, increased geographical reach, full temporal availability, ability to progress at one's own pace, savings in travel time, and cost-effectiveness. Several meta-analyses have found iCBT interventions to be clinically effective for a wide range of clinical disorders, including depression, anxiety disorders, and eating disorders [12,15].

iCBT interventions with human support lead to better clinical outcomes compared to unsupported ones [16]. Results of iCBT interventions with human support are sustained in the long term, and supported interventions have higher adherence rates compared to unsupported ones [12,16]. For unsupported interventions, lack of support to sustain motivation for change and of accountability towards a professional can lead to decreased clinical efficacy and higher dropout rates [17,18]. Many iCBT interventions are relatively static and lack the sophistication to be able to adapt to the client's initial and evolving clinical presentation.

Blended care CBT treatments (BC-CBT) have emerged as a newer approach that integrates regular therapist-led CBT sessions with iCBT modules into an integrated treatment, taking advantage of the benefits of both approaches while mitigating their disadvantages. Blended interventions can take place with therapist-led sessions delivered in a face-to-face format [19] or via video [20]. Given that part of the treatment is taking place via Internet-based modules, BC-CBT has the potential to decrease the number of sessions with therapists while achieving similar outcomes to therapist-only treatments [21], which can improve the clinical efficiency and scalability of treatment. BC-CBT may also lead to faster improvements when weekly therapist-led sessions are supplemented with iCBT, resulting in a more intensive therapy experience [22]. BC-CBT addresses the fundamental disadvantages for iCBT, specifically the low initial engagement and high dropout rates, through its human component, by enabling the development of a therapeutic alliance found to be associated with higher motivation to initiate

and sustain engagement in care [23,24]. Importantly, having the therapist in charge of clinical assessment, treatment plan, and delivery in BC-CBT allows for more personalization of care compared to iCBT. Specifically, the therapist selects digital modules most relevant to the client's presenting concerns and explains the rationale to the client, linking digital tools to the client's goals, thereby increasing motivation and compliance to treatment. BC-CBT treatments are clinically efficacious in controlled studies for multiple mental health conditions such as depression, anxiety, and substance abuse [19] and multiple settings such as primary care [25], specialized mental health clinics [26], and inpatient [27]. The vast majority of BC-CBT applications described to date consist of in-person face-to-face therapy sessions supplemented with iCBT modules. However, by moving face-to-face BC-CBT therapy sessions to the telehealth modality (ie, the delivery of care via video or audio), the reach of the treatment can be extended, offering treatment to more individuals in need. It has consistently been found that telehealth mental health services are just as effective as in-person care [28].

To date, there have been very few large-scale studies examining the effectiveness of BC-CBT interventions delivered via telehealth on a large scale in real-world settings [20,29]. Dissemination of most interventions outside of tightly controlled research environments introduces challenges, including therapist drift, potentially more complex clinical presentations, as well as possible lower treatment engagement [30], and BC-CBT would likely face similar challenges. Additionally, for BC-CBT delivered by telehealth, acceptability of the video communication channel, as well as the iCBT care components by both therapists and clients, are likely necessary to prevent dropout and preserve clinical effectiveness.

The present study uses data gathered as part of routine care for clients who received BC-CBT treatment as a benefit offered through their employer. The BC-CBT program combines live video-based sessions with a therapist with technology and evidence-based care tools for clients to use in between sessions. BC-CBT therapists are supported in their work to implement BC-CBT via regular individual and group consultations; clients have access to and are encouraged to use evidence-based care tools at any time. These elements can make the psychotherapy experience more clinically efficient, enabling more clients to improve faster. To our knowledge, to date, no study in the United States has examined BC-CBT interventions at a large scale under real-world conditions.

Methods

Study Design

This pragmatic retrospective cohort study used data collected for quality control of a BC-CBT program. Participants resided in the United States and had access to the BC-CBT program as a mental health benefit at no cost to them from their employer companies. Lyra Health partners with Lyra Clinical Associates to offer a behavioral health benefit to companies through which employees and dependents have access to a video BC-CBT program. Employees and their dependents learned of this mental health benefit through information from their employer and

could then access the benefit through registering online with Lyra Health, searching for a provider, and directly enrolling in the BC-CBT program. The program's rigorous quality assurance elements included ongoing individual and team-based clinical consultations and clinical case reviews informed by routine outcome monitoring of depression and anxiety symptomatology.

All participants who engaged in the BC-CBT program were asked to complete electronically secure, standardized measures of depression and anxiety every week as well as a satisfaction measure at the end of treatment. No specific length of care was defined. Participants had access to a minimum of 12 sessions, depending on the benefit offered by the sponsoring company. This post-factum analysis of deidentified data gathered from treatment offered by Lyra Clinical Associates was determined to be not human subject research by the Palo Alto University Institutional Review Board.

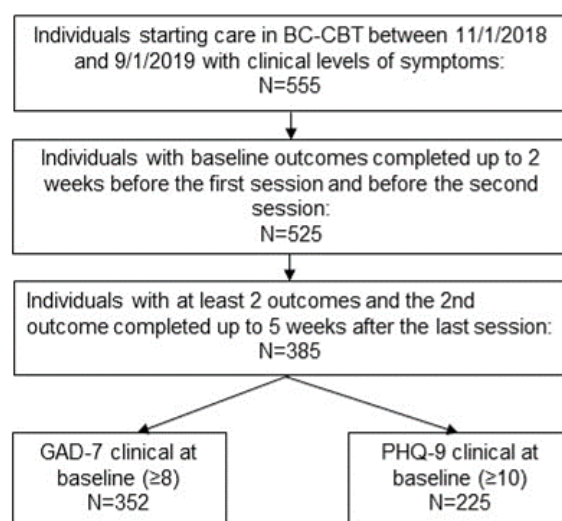

Participants and Data Inclusion

Participants were individuals who started BC-CBT treatment between November 1, 2018, and September 1, 2019. Participants who sought psychotherapy went through an online onboarding process and answered questions about their symptoms, the impact of symptoms on their general functioning, and their interest in receiving care via video. Those who were not open to seeing a provider via video were referred to in-person therapy

and not offered BC-CBT. Exclusion criteria for the BC-CBT program were: being under 18 years of age, active suicidality/self-harm, active homicidality, a current diagnosis of a mental health disorder with psychotic features not stabilized on medications, unstable bipolar disorder, and a current diagnosis of severe alcohol or substance use disorder. Participants also had to score above the clinical cut-off for either the Patient Health Questionnaire-9 (PHQ-9 \geq 10) or the Generalized Anxiety Disorder-7 (GAD-7 \geq 8) on a baseline assessment (n=555). No additional diagnostic assessment was conducted for the study, though each therapist conducted independent clinical interviews for treatment purposes. We considered a baseline assessment to be invalid if it was collected more than 2 weeks before the first therapy session or after the second therapy session. We excluded 30 records with invalid baselines from analyses based on this definition. Participants for whom no assessment was available within 5 weeks after the last therapy session were excluded. We excluded from the analysis 140 records with invalid second assessments per this definition, leaving 385 participant records for analysis. The final scores were the last valid available datapoint after baseline.

For two-thirds of the included records (63%, n=242), final scores were collected after the final therapy session (but <5 weeks after the final session), and the remainder was collected from an earlier session (Figure 1).

Figure 1. Participant flow.

Self-Report Measures

Assessments consisted of the PHQ-9 [31] and the GAD-7 [32], well-validated measures of depression and anxiety, respectively. Clinical cut-offs were PHQ-9 \geq 10 and GAD-7 \geq 8, as research suggests that participants who score at or above these cut-offs are very likely to meet criteria for major depression [31] or to have an anxiety disorder diagnosis [33].

Treatment

The BC-CBT program combined live video-based sessions with a therapist plus digital care tools (lessons and exercises) that clients could access and were encouraged to use between sessions (Multimedia Appendix 1). The digital therapy platform

supporting BC-CBT had separate portals with customized functions for clients and therapists, respectively.

Individual Video Psychotherapy

Therapy sessions were conducted on a secure, proprietary HIPAA-compliant video platform developed by Lyra Health. Therapy staff consisted of 49 licensed therapists (licensed clinical psychologists, licensed marriage and family therapists, licensed clinical social workers, or licensed professional counselors) vetted for their commitment to and proficiency in CBT via extensive application reviews and clinical interviews. Approximately 41% (n=20) of the therapists had less than 5 years of experience, 32% (n=16) had between 5 and 10 years of experience, and 27% (n=13) had over 10 years of experience. All therapists were trained on-site with a 2-day workshop on

BC-CBT. The mean number of clinical cases per therapist was 8.2 (SD 7.1). Participants engaged in BC-CBT met with their therapists, either weekly or bi-weekly. A core focus of the program was to ensure a high quality of evidence-based clinical care via providing therapists with peer supervision. Providing clinicians with ongoing consultation and support has been identified as a critical component of treatment dissemination [34] that helps maintain and enhance clinicians' skills [35,36]. Sessions were recorded with the participant's consent. Quality adherence of clinical care was ensured via session review, bi-weekly individual consultation video calls, and video consultation groups with other licensed therapists. The weekly assessment of depression and anxiety symptoms represented important information helping to focus the quality assurance process on clients who were not making progress as expected.

Digital Lessons and Exercises

Following each session, therapists assigned educational digital lessons and exercises to be completed by clients before their next session. The digital treatment components were developed by Lyra Health based on transdiagnostic treatment approaches, such as the Unified Treatment Protocol [37], Acceptance Commitment Therapy [38], and Dialectical Behavior Therapy [39,40]. Example principles and skills taught in the digital lessons and exercises included: clarifying values, understanding emotions, mindful awareness, cognitive restructuring, challenging avoidance (via behavioral activation and exposure), and communication skills.

The digital lessons consisted of animated videos and quizzes to test comprehension and provide corrective feedback. The digital lessons utilized a storytelling approach wherein viewers followed the therapy journey for characters presenting with symptoms of depression or anxiety. This approach has been used in other efficacious iCBT interventions [41] and found to have a normalizing effect for clients. Therapists personalized digital tools in several ways. First, therapists selected digital lessons and exercises to match clients' case formulation (clinician's understanding of clients' presenting concerns viewed from a CBT perspective). Second, to increase motivation for completion of the personalized digital tools, therapists introduced them by linking them to issues immediately relevant to the client and discussed during that specific session, as well as to clients' broader goals. Third, therapists received alerts when clients completed assigned digital lessons and exercises and could send personalized feedback to clients.

The BC-CBT Therapy Platform for Providers

The BC-CBT platform enabled therapists to conduct a variety of BC-CBT therapy tasks before, during, after, and in between therapy sessions seamlessly in a single environment.

Before therapy sessions, therapists could check whether clients had submitted PHQ-9 and GAD-7 outcomes to track their progress in treatment. They could also review clients' completion of assigned practices, clinical outcomes, and communicate asynchronously with clients via secure messaging to encourage them or support them in applying therapy principles and skills.

Therapists utilized the platform to hold their video sessions in a HIPAA secure environment and to record sessions for quality assurance with clients' consent. During sessions, therapists could also share their screen to collaboratively complete digital exercises with the client or preview specific exercises and digital lessons they intended to assign to the client. Modeling such activities was done to increase the likelihood that the client would later complete the exercise or lesson on their own. Providing users with the ability to perform a "virtual rehearsal" of a desired new behavior within a technology tool (such as completing a psychotherapy digital exercise) has been proposed as a feature that can change behavior in the real world [42]. Screen sharing also allowed therapists to review the clinical outcomes responses and progress with their clients, which has been found to make treatment more efficacious and efficient [43].

After sessions, therapists completed therapy notes in the BC-CBT platform. The notes were designed as a decision support system [42] to a) help clinicians create case conceptualizations for clients that would guide treatment goals and treatment plans, b) ensure that treatment goals were indeed addressed during session time, c) increase adherence to the digital elements of BC-CBT like assigning and reviewing digital lessons and exercises, and d) increase consistency and thoroughness of conducting more complex clinical tasks, such as safety risk assessments.

The BC-CBT Therapy Platform for Clients

The digital platform behind BC-CBT supported clients in completing clinical outcomes as well as assigned digital lessons and exercises in several ways. First, clients received automatic notifications encouraging them to complete the assigned outcome measures and digital lessons and exercises if they had not already, and a new session was approaching. Second, clients were also alerted if their therapist sent them feedback on a completed exercise. Third, "tunneling" was utilized as a digital persuasion technique to increase the completion of digital assignments [42]. For example, the client was guided through a digital lesson composed of multiple parts (animated videos, comprehension quiz) such that subsequent parts automatically started if the client did not explicitly stop the experience. Last, clients could revisit all digital lessons and materials assigned for the duration of treatment.

Data Analyses

Two analytical methods were employed to estimate the impact of BC-CBT on depression and anxiety symptomatology. Hierarchical linear modeling (HLM) was used to examine change over time. HLM is a statistical technique that is capable of modeling incomplete data over time. The routinely administered outcomes measures were included as weekly observations for participants. In cases when participants completed multiple outcomes measures during the same week in treatment, an average of the scores for that week was calculated. We included all participants who provided at least two outcome measures meeting all other inclusion criteria. In order to estimate the change in outcomes, we tested for a linear effect of time and a quadratic effect of time, modeling the slowing of the rate of change. HLM estimates the individual

slopes and intercepts for all participants, as well as the sample's average slope and intercept. Participants' age, gender, and provider were added to the analysis as level-2 predictors of the intercept, slope, and quadratic component. For both dependent variables we added level 2 predictors, age, gender, provider, at the intercept, slope, and quadratic effect. As a supplementary statistical analysis, we conducted paired samples *t*-tests between baseline and last available assessment scores for each measure. We calculated Cohen *d*, a conservative measure of effect size for within-subjects designs that controls for the correlation between measurements. We then assessed whether participants attained reliable clinical change (a measure of symptom change beyond what could be attributed to measure error alone), recovery (moving from the clinical range to the subclinical range), and clinically significant change (demonstrated reliable change and recovery; [44]) on either the PHQ-9 or GAD-7.

We used the Chi-square test to assess differences in the distribution of genders between records with a valid baseline assessment that were not included in the analyses (*n*=140) and those that were included (*n*=385). Independent samples *t*-tests were used to evaluate differences between those groups in age as well as baseline depression and anxiety symptoms scores. To provide more detailed information on rates of improvement, we performed the paired samples *t*-test and reliable clinical change and recovery analyses for the entire sample of clients but also separately for individuals scoring in the clinical range of symptoms for depression, anxiety, or both.

Results

Overview

There were no statistically significant differences between records with a valid baseline assessment versus those that were not included in the analyses by gender ($\chi^2_2=1.13$, $P=.56$), age ($t_{523}=1.08$, $P=.28$), baseline depression severity ($t_{523}=0.98$, $P=.33$) and baseline anxiety severity ($t_{523}=0.86$, $P=.39$).

Participants' mean age was 32.8 years (SD 8.0). The majority of participants were between 25 and 34 years old (55%; *n*=212), 25.4% (*n*=98) between 35 and 44 years old, 11.2% (*n*=43) were between 18 and 24 years old, and 8.3% (32) were above 45 years old. The majority of participants were women (63.4%; *n*=244), 35.8% (*n*=138) were men, and 0.8% (*n*=3) did not specify their gender. The mean number of sessions delivered during a course of BC-CBT was 5.2 (SD 2.9; range 1-17). The

mean number of weeks participants spent in treatment was 6.4 (SD 5.3; range 1-25).

Hierarchical Linear Models

Based on prior work that found a negatively accelerated relationship between the number of therapy sessions and improvement in care [45] as well as the observed sample mean in our dataset, we fitted an HLM with intercept, slope, and quadratic effect of time. The time variable was centered at the point of the average length of care (week 6) to reduce collinearity between the linear and quadratic components while keeping the interpretation of the model's parameters more meaningful [46].

Likelihood ratio testing revealed that a quadratic effect of time provided a significant improvement in model fit over a simple linear effect of time. A cubic effect of time was also attempted but found not to improve model fit significantly. The results of the model indicate that all growth effects were significant (Table 1). Specifically, the slopes were negative, suggesting that symptoms of depression and anxiety decrease with time in care. The quadratic slope effects were positive, suggesting that rapid progress initially in care tapers off as clients advance in treatment. There was also significant variability in the growth parameters, indicating that there were significant differences between individuals in how participant's depression and anxiety symptoms changed during care. Likelihood ratio testing revealed a better fit for models allowing both the linear and quadratic components to vary. In other words, participants varied in the trajectory and rate of change in treatment.

For depression symptoms, at 6 weeks after starting treatment (which represents the average length of care), the mean level of symptoms in the sample was 5.94. There was a significant linear effect in depression symptoms ($\beta=-.49$, $t_{99,24}=-20.64$, $P<.001$), indicating a .49 decrease in depression symptoms with each week in care. The quadratic effect was also significant ($\beta=.04$, $t_{90,41}=10.72$, $P<.001$), suggesting a decelerated decrease in depression symptoms over time (Table 1).

For anxiety symptoms at 6 weeks, the average length of care, the mean level of symptoms in the sample was 6.57. There was a significant linear effect in anxiety symptoms ($\beta=-.64$, $t_{274,62}=-22.43$, $P<.001$), indicating a .64 decrease of anxiety symptoms with each week in care. The quadratic effect was also significant ($\beta=.04$, $t_{89,79}=12.17$, $P<.001$), suggesting a decelerated decrease in anxiety symptoms over time (Table 2).

^a Generalized Anxiety Disorder-7

Age, gender, and provider identifier were included in the models for anxiety and depression symptoms as level-2 predictors of the intercept, slope, and quadratic slope in order to determine whether age, gender, and providers moderated the outcomes for participants. Likelihood ratio testing revealed a better fit for models including age, gender, and provider identifiers as level-2

predictors of the intercept only, thus that model was retained. For both depression and anxiety symptoms, neither the age, gender, or provider were statistically significant, suggesting that the intercept, slope, and quadratic slope were not related to these variables (Tables 3 and 4).

Paired samples t-tests

Participants Starting With Depression or Anxiety Symptoms in Clinical Range

The mean (SD) scores of pre-treatment GAD-7 across all participants with baseline clinical range of depression or anxiety

symptoms (n=385) was 11.72 (3.89) and of PHQ-9 was 10.77 (4.71), corresponding to moderate anxiety and moderate depression (Table 5).

Table 5. Changes in depression and anxiety symptoms for participants starting at clinical levels of depression or anxiety symptoms (n=385).

Measure	Baseline score, mean (SD)	Follow-up score, mean (SD)	Paired differences, mean (SD)	95% CI of the difference	<i>t</i> -value (<i>df</i>)	<i>P</i> value	Cohen <i>d</i>

^a Patient Health Questionnaire-9^b Generalized Anxiety Disorder-7

Reliable clinical change on either the PHQ-9 and/or GAD-7 measures was observed in 283 participants (73.5%), 319 participants (82.8%) recovered on either measure, and 258

participants (67%) demonstrated clinically significant improvement in either depression or anxiety (Table 6).

Table 6. Reliable improvement and recovery for participants grouped by their baseline levels of depression and anxiety symptoms.

^h Calculated as (reliable improvement OR recovery on PHQ-9) OR (reliable improvement OR recovery on GAD-7)

Participants Starting With Depression Symptoms in Clinical Range

At pre-treatment, 225 participants (58.4%) scored in the clinical range on the PHQ-9. The mean of the pre-treatment PHQ-9 score was 13.88 (SD 3.40), corresponding to moderate depression, while the post-treatment score was 6.76 (SD 5.35). Results of paired samples *t*-tests revealed that for this group, depression scores decreased significantly, with an average reduction of 7.12 (SD 5.74) points, ($t_{224}=18.62$, $P<.001$, Cohen $d=1.59$), suggesting a large effect of treatment on depression symptoms.

Reliable clinical change in depression scores was observed in 149 participants (66.2%), and 167 participants (74.2%) recovered on the PHQ-9. A total of 141 participants (62.7%) demonstrated clinically significant improvement on the PHQ-9, ie, meeting criteria for both reliable clinical change and recovery (Table 6).

Participants Starting With Anxiety Symptoms in Clinical Range

At pre-treatment, 352 participants (91.4%) scored in the clinical range on the GAD-7. The mean of pre-treatment GAD-7 score

for this group was 12.32 (SD 3.49), corresponding to moderate anxiety, while the post-treatment score was 6.24 (SD 4.56).

Anxiety scores decreased significantly by an average of 6.08 (SD 5.31) points, ($t_{351}=21.47$, $P<.001$, Cohen $d=1.50$), suggesting a substantial effect of treatment on anxiety. Reliable clinical change was observed in 245 (69.6%) participants, 247 participants (70.2%) recovered, and 217 (61.7%) participants demonstrated clinically significant improvement (Table 5).

Participants Starting With Depression and Anxiety Symptoms in Clinical Range

A total of 192 participants (49.9%) had pre-treatment PHQ-9 and GAD-7 scores in the clinical range, suggesting comorbid symptoms for both depression and anxiety. In this group, depression scores decreased significantly by an average of 7.13 (SD 5.93) points, ($t_{191}=16.67$, $P<.001$, Cohen $d=1.56$), and anxiety by an average of 6.79 (SD 5.92) points, ($t_{191}=15.88$, $P<.001$, Cohen $d=1.55$), suggesting large and similar effects of treatment on both anxiety and depression (Table 7).

Reliable clinical change in both measures was observed for 115 participants (59.8%), 120 participants (62.5%) recovered on both measures, and 105 participants (54.6%) demonstrated clinically significant improvement in both depression and anxiety (Table 6).

Table 7. Changes in depression and anxiety symptoms for participants starting at clinical levels of depression and anxiety symptoms (n=192).

Measure	Baseline score (SD)	Follow-up score (SD)	Paired differences mean (SD)	95% CI of the difference	<i>t</i> value (df)	<i>P</i> value	Cohen <i>d</i>
PHQ-9 ^a	14.14 (3.49)	7.01 (5.43)	7.13 (5.93)	6.21-8.05	16.67 (191)	<.001	1.56
GAD-7 ^b	13.60 (3.61)	6.82 (5.04)	6.79 (5.92)	5.91-7.67	15.88 (191)	<.001	1.55

Discussion

To our knowledge, this is the first study to examine the effectiveness of BC-CBT delivered via video at a large scale in a real-world setting within the US. The BC-CBT program evaluated combined live video-based sessions with a therapist plus technology-based care tools that clients had access to and were encouraged to use in between sessions. Our results suggest that BC-CBT can be effective in significantly reducing symptoms of depression and anxiety. Age, gender, and specific psychotherapists did not moderate the changes in symptoms observed. The within-subjects effect sizes were similar and similarly large for both depression ($d=1.59$) and anxiety ($d=1.50$) symptom improvements for individuals starting at clinical levels of depression and anxiety symptoms at baseline. These results were similar to those reported in various randomized trials for adult depression [47] and similar to those reported for effectiveness trials of adult anxiety disorders [48]. Notably, these results were observed after treatment lasting an average of 5.2 sessions and 6.4 weeks, which is significantly shorter than the conventional 12 to 16 weekly sessions protocol of most CBT treatments [49,50]. Outcomes collected more than 2 weeks before the first therapy session or more than 5 weeks after the last therapy session were considered invalid. If baseline outcomes were collected too early, or too much time had passed between the end of care and the last assessment, such data likely no longer reflected actual symptoms at the beginning and end of care. Our findings suggest that the BC-CBT program and its intense psychotherapy experience, resulting from combining video therapy sessions with personalized digital tools, were successful in delivering a clinically efficient treatment, as demonstrated by participants making great progress in a short duration of time. Thus, CBT can be delivered via alternative modalities, ie, via video and blended with technologically based approaches, in an ecologically valid manner, and remain both effective and efficient.

An essential component of CBT is engaging in homework between therapy sessions. Indeed, homework compliance has been consistently associated with better outcomes for CBT [51,52], yet compliance is commonly low [53]. In our BC-CBT program, therapists assigned homework such as digital lessons and exercises through a digital platform, which enabled them to monitor whether and when the participant did the homework. If the participant struggled or procrastinated to complete the homework, the therapist could send a personalized reminder and encouragement about the homework, which could increase

the client's motivation and compliance. The combination of individual provider-led therapy sessions with personalized digital components to foster consolidation of CBT skills allowed clients to receive personalized care and encouragement for increased treatment engagement and completion. Future research should investigate the specific impact of digital homework such as digital lessons and exercises, and personalized messages from the provider to encourage homework completion, on the effectiveness and efficacy of the BC-CBT treatment.

This study has several limitations. We did not utilize an RCT design, and our results should thus be interpreted with caution. Although an RCT design might offer a more precise understanding regarding the effectiveness of a treatment, randomization is not feasible in a setting where care is offered as an employer-sponsored benefit given ethical complexities related to limiting care options for participants. Given that no control group was included, we cannot be entirely certain that the results reported are indeed due to the BC-CBT intervention rather than due to the passage of time or other factors. However, comparing our outcomes to well-conducted RCTs, we have observed that our outcomes are comparable, lending support for the validity of our results. Another study limitation is that though we assessed for meaningful change by calculating reliable clinical change, recovery, and clinically significant change, whether symptom improvement was maintained in the long-term is not known. Participants were either employees or dependents of employed individuals, mostly younger, and without symptoms of severe mental illness or acute suicidality, or homicidality; thus, the results may not generalize to other populations or those with acute safety concerns. Outcomes were based on self-reported measures, which can be less reliable in assessing levels of symptoms compared to clinician-administered interviews due to possible misinterpretation of the questions by clients and the lack of follow-up clarifying questions from the provider.

In conclusion, this study demonstrates that BC-CBT can effectively reduce depressive and anxiety symptoms outside of the clinical trial environment. Future research should examine the separate and synergistic contributions of the therapist-led versus the digital components of care to treatment outcomes. Having a better understanding of the optimal ratio of the two modalities, as well as the matching of this ratio to client-specific variables in order to maximize treatment outcomes for different participants and presenting issues, will allow us to enhance and personalize BC-CBT.

Abstract

Background: Anxiety disorders and depression (emotional disorders) are highly prevalent mental disorders. Extensive empirical evidence supports the efficacy of cognitive behavioral therapy (CBT) for the treatment of these disorders. However, there are still some barriers related to their dissemination and implementation, which make it difficult for patients to receive these treatments, especially in public health care settings where resources are limited. Recent advances in improving CBT dissemination encompass different perspectives. One is the transdiagnostic approach, which offers treatment protocols that can be used for a range of emotional disorders. Another approach is the use of the internet to reach a larger number of people who could benefit from CBT.

Objective: This study aimed to analyze the effectiveness and acceptability of a transdiagnostic internet-delivered protocol (EmotionRegulation) with human and automated guidance in patients from public specialized mental health care settings.

Methods: A 2-armed randomized controlled trial (RCT) was conducted to compare the effectiveness of EmotionRegulation with treatment as usual (TAU) in specialized mental health care. In all, 214 participants were randomly assigned to receive either EmotionRegulation (n=106) or TAU (n=108). Measurement assessments were conducted at pre- and postintervention and at a 3-month follow-up.

Results: The results revealed the superiority of EmotionRegulation over TAU on measures of depression ($d=0.41$), anxiety ($d=0.35$), and health-related quality of life ($d=-0.45$) at posttreatment, and these gains were maintained at the 3-month follow-up. Furthermore, the results for expectations and opinions showed that EmotionRegulation was well accepted by participants.

Conclusions: EmotionRegulation was more effective than TAU for the treatment of emotional disorders in the Spanish public mental health system. The implications of this RCT, limitations, and suggestions for future research are discussed.

Trial Registration: ClinicalTrials.gov NCT02345668; <https://clinicaltrials.gov/ct2/show/NCT02345668>

Introduction

Disorder-Specific Cognitive Behavioral Therapy for Emotional Disorders

Anxiety and depressive disorders, also known as emotional disorders (EDs) [1], have the highest prevalence rates among psychological disorders [2,3], and are associated with substantial costs [4,5] and disability [6,7]. In the past three decades, research efforts to decrease the burden of these disorders have led to the development and evaluation of cognitive behavioral treatments in randomized controlled trials (RCTs) for each ED (ie, disorder-specific protocols), such as depression [8,9] and several anxiety disorders, including generalized anxiety disorder (GAD) [10,11], panic disorder (PD) and agoraphobia (AG) [12], social anxiety disorder (SAD) [13], and obsessive compulsive disorder (OCD) [14].

Although there is a large body of evidence showing the efficacy and effectiveness of *disorder-specific* cognitive behavioral therapy (CBT), in the past 15 years, an increasing number of researchers have agreed that there are some problems that hinder the optimal deployment of these treatments. The main drawback of disorder-specific treatments stems from the high comorbidity rates observed among anxiety disorders and between anxiety disorders and depressive disorders, with comorbidity estimates for these disorders ranging between 40% and 80% [15,16]. Thus, because disorder-specific treatment protocols focus on treating a specific diagnosis, the accompanying comorbid disorders do not receive therapeutic attention [17,18]. This problem becomes clearer when we take into account research linking comorbidity to aspects such as greater severity [3], increased chronicity rates [19], and a worse clinical course [20]. Another problem with disorder-specific treatments is that subthreshold symptoms that do not meet diagnostic thresholds for a particular disorder, but might be important to treat, normally go untreated [17]. Similarly, these protocols do not address diagnoses that do not fit any specific category, despite their clinical relevance, that is, *not otherwise specified* (NOS) anxiety and depressive disorders [15]. Finally, each disorder-specific treatment requires the use of different handbooks and protocols, which increases the economic costs and the amount of training needed to gain the knowledge and skills necessary to cover the array of anxiety and depressive disorders [17].

Transdiagnostic Treatments for Anxiety and Depression

Transdiagnostic treatments have emerged as an alternative to the traditional disorder-specific approach that has dominated CBT research for the past 30 years. Transdiagnostic treatments have been developed and tested in several RCTs for anxiety disorders [21-24] and anxiety and depressive disorders [25-27], and their number continues to grow. Moreover, the efficacy and effectiveness of transdiagnostic treatments have been shown in different meta-analytic reviews, comparing them with different control groups, such as waiting list, attention control, and treatment as usual (TAU) [28-31], with pooled effect sizes (Hedges g) in the medium to large range for overall measures of anxiety (0.65-0.82) and depression (0.79-0.84). Moreover,

an additional meta-analysis reported equivalent effects of transdiagnostic treatments ($g=1.06$) and disorder-specific treatments ($d=0.95$) on anxiety outcomes [32]. However, these meta-analyses include a number of mixed studies of different orientations, such as theory-based transdiagnostic treatments and tailored CBT. Therefore, these studies make it difficult to determine the effectiveness of each orientation (eg, the effectiveness of theory-based transdiagnostic treatments). The effectiveness of transdiagnostic treatments has also been shown in a meta-analysis by García-Escalera et al [33], with pooled effect sizes of $g=0.80$ for anxiety and $g=0.72$ for depression. Unlike the abovementioned meta-analyses, this study has the particularity that it only included theory-based transdiagnostic treatments. The main characteristic of theory-based transdiagnostic treatments, also known as *mechanistically transdiagnostic* treatments or transdiagnostic treatments based on *shared mechanisms* [34], is that they are designed to address the common psychopathological processes underlying anxiety and depression. Among the mechanistically transdiagnostic treatments for EDs, the Unified Protocol (UP) [35,36] stands out as one of the most empirically supported transdiagnostic protocols for anxiety and depression [23,37,38]. The UP is a CBT transdiagnostic protocol developed to address the underlying psychopathological processes that are common to anxiety and depressive disorders, with a particular focus on neuroticism, (low) extraversion, and emotion dysregulation, which have been shown to play a key role in the onset and maintenance of these disorders [39,40]. Thus, the main goal of the UP is to teach patients strategies to regulate their emotions in a more adaptive way through the following core treatment modules: (1) present-focused emotional awareness, (2) cognitive flexibility, (3) identification and prevention of emotional avoidance patterns, (4) increasing awareness and tolerance to emotion-elicited physical sensations, and (5) graded (interoceptive and situational) exposure procedures. The overall efficacy of the UP was first shown in an RCT where it was compared with a waitlist control group [23] and, more recently, in a larger RCT where it was compared with well-established disorder-specific CBT protocols for anxiety disorders [37]. In addition, some research shows the long-term effects of the UP [41] and its ability to produce changes in the temperament dimensions of behavioral inhibition (BI) and behavioral activation (BA) [42]. BI and BA have been conceptualized as 2 neurological systems representing motivational tendencies that are sensitive to threat and reward environmental cues, respectively [43]. These aspects have been intimately linked to neuroticism and negative affect and extraversion and positive affect [42]. Another treatment approach that includes principles or components that could be useful to target EDs is dialectical behavioral therapy (DBT) [44,45]. DBT initially emerged as a theoretical model and a treatment approach for the treatment of suicidal behaviors and borderline personality disorder, with the general aim of teaching strategies to change patterns of emotion dysregulation [46]. Of the range of strategies, DBT places a special emphasis on increasing experiential awareness and acceptance (mindfulness *what* and *how* techniques), but it also includes behavioral strategies such as the *opposite action*, designed to diminish distress by engaging in behaviors or actions opposite to those associated with negative emotions [44]. More

recently, DBT skills have been adapted and successfully applied to several anxiety and depressive disorders [47,48], which suggests that they could be used in a transdiagnostic manner to improve the symptomatology of these disorders. For example, DBT principles may be combined with other evidence-based components (eg, components of the UP) to strengthen their effectiveness. The strategy of integrating CBT principles and components from different evidence-based therapies and orientations is consistent with the notion of process-based CBT, defined by Hofmann and Hayes [49]. As the authors state, “modern CBT places much less focus on protocols for syndromes and more focus on evidence-based processes linked to evidence-based procedures” [49].

Internet-Delivered Interventions

In the past two decades, one of the most evident efforts made by researchers has been to take advantage of the possibilities offered by information and communication technologies to improve the assessment and treatment of psychological disorders. A clear example would be the use of the internet to increase the dissemination of empirically supported psychological treatments to anyone in need [50]. Research has shown promising and compelling evidence that internet-delivered psychological interventions are effective for a variety of psychosocial problems, including anxiety and depressive disorders [51,52]. The main advantages of internet-delivered treatments over traditional delivery methods (eg, face-to-face therapy) include widespread access and dissemination [53], a nonstigmatizing way of receiving psychological treatment [54], and increased cost-effectiveness [55].

Research has shown that transdiagnostic internet-delivered treatments are more effective than control groups [29] and that these treatments are at least as effective as individual and group face-to-face transdiagnostic treatments [33]. However, most of the existing literature on transdiagnostic treatments is limited to studies conducted in community settings, with few studies carried out in public contexts such as primary or specialized care [21]. Indeed, to our knowledge, no transdiagnostic internet-delivered treatments for anxiety and depression have been conducted in specialized public mental health care. This is somewhat surprising because transdiagnostic internet-delivered treatments in this particular setting could have several advantages for both clinicians and the patients attending these centers. First, anxiety and depressive disorders are disorders with the highest prevalence rates [2,3]. Second, resources in these settings are usually scarce, which affects both the quantity and the quality of the mental health care provided [56]. Third, a large percentage of patients with anxiety and depressive disorders do not receive treatment in mental health care centers [57]. In the specific case of Spain, most patients attending public mental health units suffer from anxiety and depressive disorders [58], the ratio of clinical psychologists to patients is one of the lowest in Europe [59], and patients have to endure long waitlists to receive treatment [60]. Fourth, transdiagnostic treatments can be provided at a lower cost (eg, in terms of training) [61]. Finally, the use of the internet can help improve mental health services, for instance, by reducing the waiting period to receive face-to-face treatment [62] or by

implementing these treatments as part of a stepped-care model that takes patients' profiles and needs into account. Thus, each patient can be assigned the most appropriate treatment [63], leaving face-to-face therapy for those patients who are less likely to benefit from internet-delivered interventions.

This Study

Taking all of this into consideration, in this study, an RCT was conducted to test the effectiveness of a transdiagnostic internet-delivered protocol for ED (EmotionRegulation), compared with TAU provided in Spanish public specialized mental health care. EmotionRegulation includes components of the UP and the skills from DBT (eg, mindfulness *what* and *how* techniques), and it was designed to target a wide range of EDs, including major depressive disorder (MDD), dysthymic disorder (DD), PD, AG, SAD, GAD, OCD, anxiety NOS, and depression NOS. It was hypothesized that (1) the EmotionRegulation group would outperform the TAU group on measures of overall anxiety and depression, temperament (ie, BI and BA), and health-related quality of life (QoL) at posttreatment; (2) these posttreatment changes would be maintained at follow-up; (3) a significantly greater clinical change would be observed in EmotionRegulation compared with TAU; and (4) participants in the EmotionRegulation group would rate the treatment as acceptable (scores on expectations and opinion $\geq 7/10$).

Methods

Study Design

A 2-armed RCT was conducted. Participants were randomly assigned in a 1:1 ratio to one of the following 2 conditions: (1) EmotionRegulation and (2) TAU. Participants were stratified by principal diagnosis, performing block randomization in blocks of 4 to ensure that all the principal diagnoses were equally represented across conditions. Computer-generated random number sequences were obtained using statistical software (Epidat 4.1, SourceForge). This task was performed by an independent researcher who was unaware of the characteristics of the study.

The study was conducted in compliance with the study protocol, the Consolidated Standards of Reporting Trials (CONSORT) statement [64,65], the CONSORT of Electronic and Mobile Health Applications and onLine TeleHealth guidelines [66], and the Declaration of Helsinki and good clinical practice. A full description of the study protocol has been reported elsewhere [67]. The RCT obtained ethical approval from the Ethics Committee of Universitat Jaume I (Castellón, Spain) and the Clinical Research Ethics Committees of 3 hospitals (Consorcio Hospitalario Provincial de Castellón, Hospital Universitario de la Ribera, and Hospital Universitario Vall d'Hebron). The study protocol was registered at ClinicalTrials.gov (NCT02345668) on July 27, 2015. The duration of the intervention period was 18 weeks for participants in both conditions, and participants' assessments were conducted at pre- and posttreatment and at 3- and 12-month follow-ups. Both the intervention (EmotionRegulation) and the assessment instruments, except the diagnostic interview, were delivered through a web platform designed by our research group [68].

All transferred data were secured via Advanced Encryption Standard-256 encryption. Study researchers conducting posttreatment and follow-up assessments (ie, diagnostic interviews) were blinded to the participants' treatment conditions. To ensure blinding of the evaluators, participants were informed that an independent researcher would contact them to conduct follow-up assessments, and they were asked not to disclose the treatment condition to which they had been allocated. This study reports pre- to posttreatment data and data at 3-month follow-up.

Sample Size

Several studies were considered for the calculation of the expected sample size [23,69,70]. On the basis of a minimum power of 0.80 in a 1-tailed test (ie, *t* test for differences between 2 independent means), an α of .05, and an estimated dropout rate of approximately 30%, a sample size of 78 participants per condition was determined to detect a posttreatment effect size of 0.40 (Cohen *d*) between the 2 conditions. In addition, based on the literature [71,72], an estimated dropout rate of approximately 30% was expected. Thus, the final sample size was set at 100 participants per condition (total of 200 participants). The G*Power software (version 3.1.9.4, Heinrich-Heine-Universität) was used to calculate the sample size [73].

Participants

Participants were recruited from adult outpatients attending Spanish public specialized mental health care services (mental health units) to seek psychological and/or psychiatric treatment between July 2015 and June 2019. Initial recruitment was performed by clinical psychologists and psychiatrists working in these centers, and it took place in 3 different hospitals: Consorcio Hospitalario Provincial de Castellón (Castellón de la Plana), Hospital Universitario de la Ribera (Valencia), and Hospital Universitario Vall d'Hebrón (Barcelona). Recruitment was performed as follows: (1) once psychiatrists and clinical psychologists had identified a potential candidate, they offered the patient the possibility of participating in the study and described the study characteristics to him or her; (2) patients who were interested in participating gave their informed written consent, and the clinician filled out a document with the participants' sociodemographic and clinical characteristics (moreover, in this stage, participants were provided with a document containing information about the study); (3) one of the researchers involved in the study contacted the participants by phone to schedule a face-to-face appointment to evaluate eligibility criteria using a structured diagnostic interview; and (4) whenever a participant met the eligibility criteria, an independent researcher (unaware of the study characteristics) was contacted to implement randomization, and participants completed the remaining assessment instruments (self-reported questionnaires) through web-based surveys.

Participants were selected based on the following inclusion criteria: (1) aged 18 years or older; (2) ability to understand and read Spanish; (3) having access to the internet at home and an email address; (4) meeting Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV) diagnostic criteria [74] for ED (ie, MDD, DD, depression NOS, PD, AG,

SAD, GAD, anxiety NOS, and OCD); (5) providing written informed consent; (6) not suffering from a severe mental disorder (schizophrenia, bipolar disorder, and alcohol and/or substance dependence disorder); (7) not presenting a high risk of suicide; (8) not suffering from a disabling medical disease that prevented the participant from carrying out the psychological treatment; and (9) not receiving another psychological treatment during the study (in the experimental group). Pharmacological treatment was allowed, but participants had to be taking the same dose during the 2 months before enrolling in the study. In addition, participants in the experimental group whose medication was increased or changed during the study period were excluded from the trial (decreases in pharmacological treatment were accepted). There was no monetary compensation for participation in the study under any of the treatment conditions.

Instruments

Clinical Outcomes

Diagnosis Interview

Clinical diagnoses were obtained using the mini-international neuropsychiatric interview (MINI) version 5.00 [75,76], a brief structured diagnostic psychiatric interview for the assessment of key DSM-IV and International Classification of Diseases, 10th Revision, diagnoses.

Principal Outcomes

Beck Depression Inventory, Second Edition

Beck depression inventory, second edition (BDI-II) [77,78], is a self-report questionnaire with 21 items about the different symptoms characterizing MDD, added together to obtain the total score, which can be a maximum of 63 points. The instrument has shown good internal consistency ($\alpha=.76-.95$). The Spanish version also showed high internal consistency ($\alpha=.87$) for both the general and clinical populations ($\alpha=.89$). Cronbach α for the BDI-II in this study was .90.

Beck Anxiety Inventory

The Beck anxiety inventory (BAI) [79,80] is a 21-item self-report scale that assesses anxiety, with a maximum score of 63 points. Each item has a 4-point severity scale (from *not at all* to *severely*) that addresses symptoms experienced during the previous week. Previous validation studies have shown an internal consistency ranging from 0.85 to 0.94 as well as convergent and divergent validity. The Spanish version of the BAI has demonstrated high internal consistency ($\alpha=.93$). Cronbach α for the BAI in this study was .92.

Secondary Outcomes

Behavioral Inhibition Scale and Behavioral Activation Scale

The behavioral inhibition scale (BIS) and behavioral activation scale (BAS) [81,82] contains 20 items rated from 1 to 4, with 7 BIS subscale items that evaluate emotional responses of individuals to impending negative events and 13 BAS items that evaluate the behavioral and emotional responses of individuals to potentially positive events. The BIS and BAS have shown good reliability in individuals with EDs ($\alpha=.73-.92$) and good convergent and discriminant validity as indicators of

temperament. The internal consistency of the Spanish version ranges between 0.65 and 0.82. Cronbach α for the BIS and BAS subscales in this study were .61 and .80, respectively.

Quality of Life EuroQoL-5D-3L Questionnaire

Quality of life EuroQoL-5D-3L (EQ-5D-3L) questionnaire [83,84] is a generic instrument that measures health-related QoL and consists of 2 parts. Part 1 assesses self-reported problems in each of the following 5 domains: mobility, self-care, daily activities, pain/discomfort, and anxiety/depression. Each domain is divided into 3 levels of severity corresponding to no problems, some problems, and extreme problems, yielding a population-based preference score or societal index (SI). A total of 243 theoretically possible health states can be obtained, and the SI is calculated on the basis of these health states. Values range from 1 (best health state) to 0 (death). However, this index may also provide negative values that correspond to health states perceived as worse than death. Utility scores for these health states were assigned using the available Spanish population tariffs. Part 2 records the subjects' self-assessed health on a visual analog scale (VAS), a 10-cm vertical line on which the best and worst imaginable health states score 100 and 0, respectively. In this study, health-related QoL was assessed using the VAS.

Disorder-Specific Measures

Disorder-specific symptoms were evaluated using 4 different self-report questionnaires. Symptoms of GAD were assessed using the Penn State Worry Questionnaire [85,86]. PD and AG symptoms were evaluated using the Panic Disorder Severity Scale, Self-Reported [87,88]. SAD symptoms were evaluated using the Social Interaction Anxiety Scale [89,90], and OCD symptoms were assessed using the Obsessive Compulsive Inventory-Revised [91,92]. All 4 instruments have shown adequate psychometric properties in both the original and Spanish validations. Cronbach α s for these scales in this study were .78, .89, .80, and .91, respectively. More details about these assessment instruments have been described elsewhere [67].

Treatment Acceptability

Expectations and Opinions of Treatment Scales

These questionnaires were adapted from the study by Borkovec and Nau [93]. Each scale is made up of 5 items, rated from 0 (*nothing at all*) to 10 (*completely*), which ask how logical the treatment seems to be (*How logical do you think this treatment is?*), to what extent it satisfies the patient (*How satisfied are you with the treatment?*), whether the patient would recommend it to a person with the same problem (*To what extent do you feel confident recommending this treatment to a friend who has the same problems?*), whether it could be used to treat other psychological problems (*To what extent do you think this treatment could be useful in treating other psychological problems?*), and its usefulness for the patient's problem (*To what extent do you think this treatment will be/was helpful to you?*). The expectation scale was applied after the treatment rationale was explained. Its objective is to measure subjective patient expectations regarding this treatment. The opinion scale

was administered when the patient had completed the treatment, and it was designed to assess satisfaction with this treatment.

Treatments

EmotionRegulation

Following randomization, participants in the treatment condition were contacted via telephone by a researcher who provided free access to EmotionRegulation, a 12-module transdiagnostic internet-delivered protocol for the treatment of ED, namely, MDD, DD, depression NOS, PD, AG, GAD, SAD, anxiety NOS, and OCD. The protocol is delivered through a web platform [68] designed by our research group. Access to the web platform is through a unique username-password combination and is available 24 hours a day. The treatment was first developed as a manualized transdiagnostic treatment protocol with handbooks for both patient and therapist and then adapted to be delivered through a web-based platform. The web platform has successfully been used in previous RCTs exploring the efficacy of internet-delivered treatments for several disorders, such as depression [94] and flying phobia [95].

The main core components are based on the UP [35,36], but the protocol also contains treatment strategies derived from DBT [46]. The principal aim of the treatment components in EmotionRegulation is to learn and practice adaptive ways to regulate emotions from a transdiagnostic perspective, with the following treatment components: present-focused emotional awareness, cognitive flexibility, emotional avoidance and emotion-driven behaviors, and exposure procedures (interoceptive and situational). The protocol also contains a module to facilitate the patient's engagement with the therapy (motivation for change), a module with psychoeducation about emotions, and a relapse prevention module. Regarding the DBT components, greater emphasis was placed on the present-focused emotional awareness component by adapting and including strategies such as the *what* and *how* techniques and the concept of radical acceptance. Moreover, the opposite action was integrated into the treatment as a way to address emotion-driven behaviors. EmotionRegulation includes a Welcome module that contains general information about the protocol and its goals as well as recommendations for benefiting from it and 12 treatment modules (described in Table 1).

The modules are sequential to enable step-by-step movement through the program. The program duration can vary among the users, and participants had access to the protocol for a maximum period of 18 weeks. Moreover, participants were allowed to use the program any time they wanted during the trial period (ie, during the follow-up periods).

Regarding guidance, all participants in this condition received therapist and automated support. Therapist support consisted of (1) an initial face-to-face session to explain the characteristics of the study and administer the diagnostic interview to confirm the eligibility criteria, (2) an initial phone call encouraging participants to start the intervention after the baseline assessments had been completed, (3) 1 weekly brief phone call (maximum of 10 min) during the treatment period, and (4) a final phone call (once the treatment had ended) to remind participants that they would be allowed to use the program at

any time during the trial period and that they would be contacted for follow-up assessments. Automated support consisted of 2 weekly text messages reminding participants about the importance of completing the homework tasks and encouraging them to review the treatment modules. Text messages were sent through a secure web platform [96]. This web platform was only used to send text messages (unidirectionally) with predefined contents, and they did not include personal information that could have identified the participants.

Additional details about the treatment and support protocols, as well as other functionalities of the web-based platform, have been published elsewhere [67]. Finally, it is important to note that all participants in this condition were allowed to continue to receive TAU, but only for monitoring of pharmacological treatment. Participants who received other forms of treatment during the study period (eg, psychological treatment) or who experienced increases or changes in pharmacological treatment were excluded from the analyses.

Table 1. Treatment modules and their objectives.

Module	Objective
1. Introduction to treatment	Provides a framework about the role of emotion regulation in ED ^a .
2. Motivation for change and goal setting	To analyze pros and cons of changing, emphasize the importance of being motivated, and help to establish significant life goals.
3. Understanding the role of emotions	Provides psychoeducation about the roles and functions of emotions and trains the patient to track the 3 components of emotional experiences.
4. Nonjudgmental emotional awareness and acceptance of emotional experiences	Aims to train the patient in nonjudgmental emotional awareness (ie, mindfulness <i>what</i> and <i>how</i> skills) and the acceptance of emotional experiences.
5. Practicing present-focused awareness	To continue to practice the acceptance of emotional experiences and increase awareness of physical sensations, thoughts, emotions, and daily activities.
6. Learning to be flexible	Focuses on the identification of maladaptive ways of thinking (ie, thinking traps).
7. Practicing cognitive flexibility	Aims to teach the patients strategies to modify thinking traps (ie, cognitive reappraisal). It also provides information about intrusive thoughts and how to deal with them.
8. Emotional avoidance	Aims to teach the patients to identify the emotion avoidance strategies that contribute to the maintenance of ED.
9. Emotion-driven behaviors	To learn the concept of EDBs ^b and replace their maladaptive EDB with other more adaptive behaviors.
10. Accepting and facing physical sensations	To teach the role of physical sensations in the emotional response and provide training in interoceptive exposure.
11. Facing emotions in the contexts in which they occur	To build exposure hierarchies to help the patients begin to face situation-elicited avoided emotions.
12. Relapse prevention	To review what patients have learned throughout the program, schedule the future practice of the learned strategies, and teach the patient how to identify and cope with future high-risk situations.

^aED: emotional disorder.

^bEDBs: emotion-driven behaviors.

Treatment as Usual

TAU was treatment as delivered in current daily practice by psychiatrists and clinical psychologists in the mental health centers in Spain. TAU in this study was provided by 3 hospitals: Consorcio Hospitalario Provincial de Castellón (Castellón de la Plana), Hospital Universitario de la Ribera (Valencia), and Hospital Universitario Vall d'Hebron (Barcelona). To maximize the external validity of this RCT, participants in this condition were allowed to receive either psychiatric treatment (ie, prescription and monitoring of antidepressant and/or anxiolytic medication), psychological treatment (including case management, group psychotherapy, empathic listening, and/or supportive counseling), or a combination of both. The frequency of visits during the 18-week treatment period varied depending on the type of treatment (ie, psychiatric or psychological) provided to the participant. Patients in the TAU condition who were already receiving any of the aforementioned treatments at the time of enrollment were informed that they would continue

to receive these services during the treatment period. Furthermore, participants receiving a treatment other than those provided in the mental health unit were excluded from the trial. All participants allocated to TAU were offered free access to the treatment platform after the study ended.

Therapists and Treatment Fidelity

The treatment and support protocols were administered by doctoral students with at least two years of experience in the diagnosis, psychological assessment, and application of CBT for different ED. Several steps were taken to ensure treatment fidelity. First, therapists had previously been trained in the application of the treatment modules. Second, a support protocol (ie, weekly phone calls and automated text messages) was developed to be applied to all the participants in the EmotionRegulation condition. This support protocol has been briefly described earlier, but more details can be found in the study by González-Robles et al [67]. Third, to increase diagnosis reliability, all therapists involved in the participants' assessment

were trained in the application of the diagnostic interview (MINI).

Data Analysis Plan

All analyses were performed using the Statistical Package for Social Sciences version 25.

First, chi-square tests for categorical data and independent samples *t* tests for continuous data were performed to confirm that there were no significant differences between the groups at baseline on any of the sociodemographic and clinical variables.

Intention-to-treat (ITT) analyses were performed following Newman's guidelines [97], using maximum likelihood (ML) estimation through the expectation maximization imputation method. To handle missing data, we followed the procedure suggested by Hair et al [98]. First, we explored the types of missing data and determined that data were missing at the construct level. On the basis of this, we concluded that the data were susceptible to imputation. Second, the quantity of missing data was analyzed to ensure that none of the measures exceeded the recommended limits to implement this method [99]. Third, Little's missing completely at random (MCAR) tests were carried out to analyze the pattern of missing data, concluding that all missing data were MCAR ($X^2_{25}=28.7$; $P=.28$). Finally, a sensitivity analysis was performed on the main outcomes to compare the results of the per-protocol sample (ie, completers) with the imputed values. This analysis revealed that the ML estimation was not likely to produce biased estimations in the main analyses, reaching the same conclusions in both the completers and the imputed dataset (per-protocol: $F_{BAI(1,127)}=6.1$; $P=.02$; and $F_{BDI(1,127)}=15.54$; $P<.001$; ITT: $F_{BAI(1,197)}=4.79$; $P=.03$; and $F_{BDI(1,197)}=12.97$; $P<.001$).

To test the first hypothesis and control for baseline differences, analyses of covariance (ANCOVAs) were performed to compare the effects of the groups on measures of anxiety, depression, temperament, and health-related QoL, taking condition as the between-subject variable and the pretreatment scores as covariates. The use of ANCOVAs for the analysis has been recommended by several authors as a more powerful tool to analyze data in studies with randomized designs [100,101].

To test the second hypothesis, a 2 (condition: EmotionRegulation vs TAU) \times 3 (time: pretreatment vs posttreatment vs 3-month follow-up) mixed analysis of variance (ANOVA) was performed to test whether the differences between EmotionRegulation and TAU (ie, between-subjects factors) were maintained at follow-up (ie, within-subject factor). The following assumptions for the mixed ANOVA were analyzed: normality (Shapiro-Wilk test), homoscedasticity (Levene test), independence (nonparametric Runs test), and sphericity (Mauchly test). The degrees of freedom were corrected using Greenhouse-Geisser whenever the sphericity assumption was violated. Moreover, pairwise Bonferroni-corrected tests were used for posthoc comparisons.

To compute the magnitude of both within-group and between-group changes, effect sizes (Cohen *d*) were calculated by dividing the differences between means by the pooled SD.

Effect sizes were interpreted according to Cohen convention: effect sizes of 0.20 are considered low, effect sizes of 0.50 are considered medium, and effect sizes of 0.80 and above are considered large [102].

To test the third hypothesis, we explored the clinical significance of the changes achieved by the participants as well as potential deterioration rates using Jacobson and Truax's reliable change index (RCI) [103] for the main outcome measures (BDI-II and BAI) in the completer sample for posttreatment and follow-up measurements. First, the cutoff points for the posttreatment and follow-up scores were determined to be within the range of a functional distribution. The RCI was then calculated to test the clinically significant change, with an RCI of $|1.96|$ or greater ($P<.05$). Finally, both criteria were taken into account to classify participants into the following 4 categories: (1) recovered: when the change is significantly reliable ($RCI \geq |1.96|$; $P<.05$) and the posttreatment score is located within the range of the functional distribution (mean [SD 2]), (2) improved: when the change is significantly reliable but the posttreatment score is below the functional level, (3) not changed: when the change is not significantly reliable and the posttreatment score does not reach the functional level, and (4) deteriorated: when the change is significantly reliable but the posttreatment score is worse than the pretreatment score.

Finally, to test the fourth hypothesis, the scores on expectations and opinions were analyzed by calculating means and SDs for each of the items on the expectation and opinion of treatment scales. In addition, 1-way ANOVAs were performed to analyze the significance of the differences between expectations and opinions.

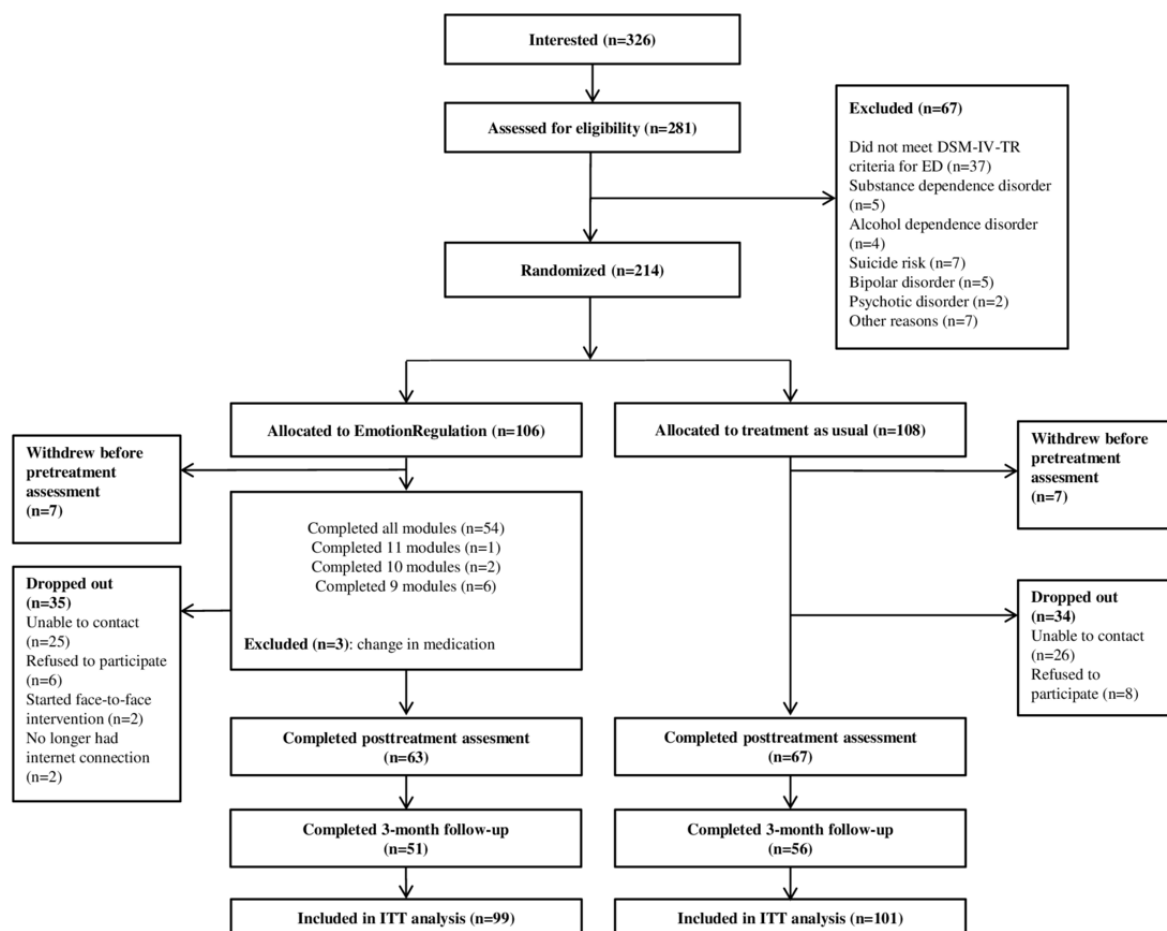

Results

Participant Flow and Attrition

A flowchart of the study participants is displayed in Figure 1. A total of 326 patients expressed interest in the study, 281 of whom were assessed for eligibility. Of these 281, 67 participants were excluded from the study. A total of 214 participants were randomized to either EmotionRegulation ($n=106$) or TAU ($n=108$). In addition, 7 patients in each condition withdrew from the study before the pretreatment assessment. Consequently, these participants were not included in any of the analyses.

Regarding attrition, 35 participants in the EmotionRegulation condition (35/106, 33.0%) and 34 in the TAU condition (34/108, 31.5%) dropped out of the study (reasons for dropout are shown in Figure 1). In addition, 3 participants in the EmotionRegulation condition had to be excluded from the trial because of a change in their pharmacological treatment during the treatment period. Posttreatment data were obtained from 63 participants (63/99, 64%) in the EmotionRegulation condition and from 67 participants (67/101, 66.3%) in the TAU condition. Follow-up data were collected from 51 participants (51/99, 52%) in the EmotionRegulation condition and 56 participants (56/101, 55.4%) in the TAU condition. Finally, 99 participants in the EmotionRegulation group and 101 participants in the TAU condition were included in the ITT analysis.

Figure 1. Flowchart of participants. ED: emotional disorder; DSM-IV-TR; Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision; ITT: intention-to-treat.

Baseline Characteristics

Participants (N=200) had a mean age of 38.44 years (SD 10.80; range 18-68), and they were mostly females (138/200, 69.0%). Table 2 provides the sociodemographic and clinical characteristics for both conditions at baseline. There were no

significant differences between the EmotionRegulation and TAU groups at baseline on any of the sociodemographic and clinical characteristics. Moreover, no significant differences were found for medication, principal diagnosis, number of comorbid diagnoses, or clinical severity on any of the measures.

Table 2. Demographic and clinical characteristics of the sample at baseline (N=200).

Amount of Support Provided

Participants in the EmotionRegulation condition were provided a mean of 49.97 min (SD 41.20 min) of clinician support delivered through phone calls. In addition, an initial face-to-face session was scheduled with all the patients in both conditions (EmotionRegulation and TAU) to explain the study and perform the screening assessment, with an approximate duration of 60 min for each participant. Regarding automated support, that is,

weekly text messages, participants in the EmotionRegulation group were sent a mean of 24.61 text messages (SD 8.80).

Effectiveness of EmotionRegulation on Primary and Secondary Outcome Measures

Table 3 provides the means and SDs for the 2 conditions at pre- and posttreatment and at 3-month follow-up on both primary and secondary outcome measures. Additional data on change scores and within-group effect sizes for diagnosis-specific measures are reported in Multimedia Appendix 1.

Pretreatment to Posttreatment Effects

Principal Outcome Measures

The ANCOVAs of the baseline-corrected postintervention scores revealed a significant condition effect on anxiety (BAI: $F_{1,197}=4.79$; $P=.03$; η^2 partial=0.02) and depression (BDI-II: $F_{1,197}=12.97$; $P<.001$; η^2 partial=0.06), reflecting that the EmotionRegulation group showed significantly lower posttreatment anxiety and depression scores than the TAU group.

Secondary Outcome Measures

Regarding the measures of BI and BA (BISBAS), the ANCOVAs yielded a significant condition effect for the BA dimension (BAS: $F_{1,197}=9.66$; $P=.002$; η^2 partial=0.05), indicating that patients in the EmotionRegulation group had significantly higher BA scores than those in the TAU group. Although patients in the EmotionRegulation group showed greater improvements in the BI dimension, no significant differences between groups were observed for this dimension (BIS: $F_{1,197}=2.44$; $P=.12$; η^2 partial=0.01). On the other hand, the ANCOVA revealed a significant condition effect on health-related QoL (EQ-5D-3L: $F_{1,197}=10.38$; $P=.001$; η^2 partial=0.05), indicating that health-related QoL scores were significantly higher in the EmotionRegulation group posttreatment than in the TAU group.

Follow-Up Effects

Principal Outcome Measures

For depression, a significant condition×time interaction effect was found ($F_{2,396}=6.18$; $P=.01$; η^2 partial=0.03). There was a significant time effect ($F_{2,396}=102.07$; $P<.001$; η^2 partial=0.34) and a nonsignificant condition effect on anxiety scores ($F_{1,198}=2.25$; $P=.14$; η^2 partial=0.01). In the EmotionRegulation condition, Bonferroni tests indicated that the differences between pre- and posttreatment were significant ($P<.001$), but the differences between posttreatment and follow-up were not

significant ($P>.99$), revealing that the reductions in depression scores were maintained at the 3-month follow-up.

The analyses showed no condition×time interaction effect on anxiety ($F_{1,62,319,88}=0.75$; $P=.45$; η^2 partial=0.004). However, there was a significant time effect ($F_{1,62,319,88}=29.35$; $P<.001$; η^2 partial=0.13) and a significant condition effect on anxiety scores ($F_{1,198}=4.20$; $P=.04$; η^2 partial=0.02). Although there was no interaction effect, we decided to perform posthoc tests to preliminarily explore the direction of the changes. In the EmotionRegulation group, posthoc comparison tests revealed significant differences between pre- and posttreatment ($P<.001$), but no significant differences between posttreatment and follow-up in the EmotionRegulation group ($P>.99$).

Secondary Outcome Measures

Regarding temperament measures, no significant condition×time interaction effect was found for the BIS subscale ($F_{1,49,295,29}=0.93$; $P=.34$; η^2 partial=0.005). A significant time effect was found ($F_{1,49,295,29}=15.33$; $P<.001$; η^2 partial=0.07), but the effect of condition was not significant ($F_{1,198}=2.51$; $P=.12$; η^2 partial=0.01).

For the BAS subscale, a significant condition×effect interaction effect was found ($F_{1,84,363,40}=5.62$; $P=.02$; η^2 partial=0.03). In the EmotionRegulation group, posthoc tests showed that BAS scores were significantly higher at posttreatment than at baseline ($P=.05$). However, these differences vanished at follow-up, as shown by the comparison between pretreatment and follow-up scores ($P>.99$).

Regarding health-related QoL, the analyses did not reveal a condition×time interaction effect ($F_{1,7,336,93}=2.73$; $P=.08$; η^2 partial=0.01). However, there was a significant time effect ($F_{2,396}=23.34$; $P=.001$; η^2 partial=0.11) and a significant condition effect ($F_{1,198}=6.3$; $P=.01$; η^2 partial=0.03), which indicated a significant improvement in health-related QoL at posttreatment in both EmotionRegulation and TAU and

generally higher health-related QoL in the EmotionRegulation group. Table 4 provides the effect sizes for the within- and between-group comparisons.

Table 4. Within- and between-group effect sizes and 95% CIs.

Significance of Clinical Improvements

The results for the significance of the clinical changes on measures of overall depression and anxiety (BDI-II and BAI, respectively) are summarized below.

Changes in Depression

Baseline to Posttreatment Changes

In the EmotionRegulation group, 84% (85/99) of the patients achieved a functional change in their depression scores, whereas

only 58.4% (59/101) did so in the TAU group, and these differences were significant ($X^2_1=10.5$; $P=.001$). In the EmotionRegulation group, 59% (58/99) of participants recovered, 25% (25/99) improved, 10% (10/99) did not change, and 6% (6/99) deteriorated; whereas in the TAU group, 38.6% (39/101) of participants recovered, 18.8% (19/101) improved, 32.7% (33/101) did not change, and 8.9% (9/101) deteriorated (Figure 2). Differences between groups were significant ($X^2_3=11.7$; $P=.009$).

Figure 2. Percentages of participants recovered, improved, did not change, and deteriorated on depression scores (Beck depression inventory-II) in EmotionRegulation (outer circle) and treatment as usual (inner circle). F/U: follow-up.

Baseline to Follow-Up Changes

In the EmotionRegulation group, 80% (79/99) of the patients achieved a functional change in their depression scores, whereas only 70.3% (71/101) of the patients did so in the TAU group, and these differences were not significant ($X^2_1=1.6$; $P=.20$). In the EmotionRegulation group, 65% (64/99) of participants recovered, 16% (16/99) improved, 16% (16/99) did not change, and 4% (4/99) deteriorated; whereas in the TAU group, 50.5% (51/101) of participants recovered, 19.8% (20/101) improved, 17.8% (18/101) did not change, and 12.9% (13/101) had deteriorated (Figure 2). No significant differences between groups were found ($X^2_3=3.7$; $P=.30$).

Changes in Anxiety

Baseline to Posttreatment Changes

There were no significant differences in the proportion of patients who achieved a functional change in their anxiety scores between the 2 conditions ($X^2_1=1.2$; $P=.28$). However, 73% (72/99) of participants in the EmotionRegulation group achieved a functional change in anxiety and 64.4% (65/101) did so in the TAU group. In the EmotionRegulation group, 56% (55/99) of participants recovered, 18% (18/99) improved, 21% (21/99) did not change, and 6% (6/99) deteriorated. In contrast, in the TAU group, 36.6% (37/101) of participants were recovered, 26.7% (27/101) were improved, 17.8% (18/101) did not change, and 17.8% (18/101) had deteriorated (Figure 3). Differences between groups were marginally significant ($X^2_3=7.3$; $P=.06$).

Figure 3. Percentages of participants recovered, improved, did not change, and deteriorated on anxiety scores (Beck anxiety inventory) in EmotionRegulation (outer circle) and treatment as usual (inner circle). F/U: follow-up.

Baseline to Follow-Up Changes

There were no significant differences in the proportion of patients who achieved a functional change in their anxiety scores between the 2 conditions ($X^2_1=0.9$; $P=.34$). In the EmotionRegulation group, 49% (49/99) of participants recovered, 14% (14/99) improved, 28% (28/99) did not change, and 10% (10/99) deteriorated. In contrast, in the TAU group, 47.5% (48/101) of participants were recovered, 22.8% (23/101) were improved, 8.9% (9/101) did not change, and 19.8% (20/101) had deteriorated (Figure 3). Differences between groups were significant ($X^2_3=8.2$; $P=.04$).

Treatment Acceptability

Table 5 provides the means and SDs for expectations and opinions about treatment in the completer sample of the EmotionRegulation condition ($n=63$). As hypothesized, the results indicate that participants reported high scores on all the items measuring treatment expectations (scores between 7.56

and 7.81): logic of the treatment, satisfaction with the treatment, recommending the treatment to other people with similar problems, usefulness of the treatment for other psychological problems, and usefulness of the treatment for one's specific problem. After receiving the intervention, scores for treatment opinions were generally higher than scores for treatment expectations (scores between 7.67 and 8.24).

A 1-way repeated measures ANOVA showed that, compared with treatment expectations, the opinion of treatment was significantly better for item 1 (logic of the treatment; $F_{1,62}=7.81$; $P=.007$; η^2 partial=0.11), item 3 (recommending the treatment to other people with similar problems; $F_{1,62}=4.80$; $P=.03$; η^2 partial=0.07), and item 4 (usefulness of the treatment for other psychological problems; $F_{1,62}=4.92$; $P=.30$; η^2 partial=0.07). No significant differences were found for item 2 (satisfaction with the treatment; $F_{1,62}=3.05$; $P=.09$; η^2 partial=0.05) or item 5 (usefulness of the treatment for one's specific problem; $F_{1,62}=.21$; $P=.65$; η^2 partial=0.003).

Table 5. Means and SDs for expectations and opinions of treatment ($n=63$).

Item	Expectations, mean (SD)	Opinion, mean (SD)
Treatment is logical	7.65 (1.88)	8.19 (1.62)
Satisfaction with the treatment	7.56 (1.81)	7.90 (1.71)
Recommend to others	7.81 (1.91)	8.24 (1.85)
Usefulness for other psychological problems	7.64 (1.86)	8.05 (1.65)
Usefulness for one's specific problems	7.76 (1.83)	7.67 (2.13)

Discussion

Principal Findings

The objective of this RCT was to explore whether a transdiagnostic internet-delivered protocol (EmotionRegulation) could be effective in treating a wide range of anxiety and depressive disorders, compared with TAU as provided in Spanish public specialized mental health care services. The effectiveness of EmotionRegulation was evaluated on measures of overall anxiety and depression, temperament (ie, BI and BA), and health-related QoL. Finally, expectations and opinions were evaluated to examine the acceptability of EmotionRegulation for the patients. To our knowledge, this is the first RCT to report data on a transdiagnostic internet-delivered protocol for ED in public specialized mental health care.

Regarding our first hypothesis, the ANCOVAs revealed that participants in the intervention group (EmotionRegulation) improved their depression and anxiety symptoms at posttreatment to a greater degree than participants in the TAU group. Regarding the magnitude of the changes at posttreatment, the analyses showed small but significant between-group effect sizes for both depression and anxiety. With regard to measures of temperament, the findings were mixed. Overall, although patients in the EmotionRegulation group showed better scores on the 2 subscales of the BIS and BAS than the TAU group, only the differences on the BAS subscale were significant, favoring the EmotionRegulation group. These results suggest that the intervention tested in this study was able to modify temperament, in line with a mechanistically transdiagnostic approach that assumes the existence of underlying mechanisms that account for the occurrence of specific symptoms. To our knowledge, only 1 study has previously investigated the effect of a mechanistically transdiagnostic treatment on the dimensions of BI and BA [42]. Similar to the results obtained in our study, in the study by Carl et al [42], both BI and BA improved following treatment with the UP compared with a waitlist control group, with small between-group effect sizes found for both the BIS and BAS temperament dimensions. Moreover, these authors showed associations between the gains in temperament dimensions and symptoms of anxiety and depression, particularly for BI, because lower BI scores were associated with greater improvements in anxiety and depressive symptoms. However, a limitation of this study was that the sample size was small, and so the findings were preliminary. Thus, future RCTs of mechanistically transdiagnostic treatments should analyze the extent to which these interventions are able to modify BI and BA and other related temperament dimensions such as negative and positive affect to shed more light on this question [104,105]. Finally, as hypothesized, EmotionRegulation was superior to TAU in improving health-related QoL, with a small but significant between-group effect size observed for the EQ-5D-3L scale. In this regard, it is known that pharmacological treatment could be linked to some variables associated with health-related QoL, such as fatigue and sexual functioning [106]. Therefore, decreases in medication may have indirectly influenced the QoL in some patients. However, these decreases were not measured, and hence, no analyses could be performed to analyze this aspect.

Furthermore, to evaluate the significance of the clinical gains, Jacobson and Truax's RCI was obtained for the principal outcome measures, that is, BDI-II and BAI.

Consistent with the aforementioned results, significant differences were observed in the proportion of patients who achieved a functional change in depression scores, with a significantly higher number of patients within the functional range in the EmotionRegulation condition (85/99, 84%) than in the TAU group (59/101, 58.4%). Regarding anxiety scores, although no significant differences were observed between the 2 groups in the proportion of patients reaching a functional change, a higher proportion of patients in the EmotionRegulation group (72/99, 73%) than those in the TAU group (65/101, 64.4%) reached a functional change. Furthermore, significant differences were found in the proportion of patients recovered, improved, did not change, and deteriorated, with better general results for the intervention group than for the TAU group. At follow-up, there were no differences in the proportion of patients reaching a functional change in either depression or anxiety. Therefore, it can be concluded that these differences tended to diminish between groups at follow-up.

Regarding the acceptability of EmotionRegulation, expectations about the treatment were high (scores ≥ 7). After receiving the treatment, compared with expectations, the participants rated the program as significantly more logical, more recommendable for other people with similar problems and more useful for the treatment of other psychological problems. The study of acceptability is important because expectations about treatment have been shown to affect treatment outcomes [107]. Furthermore, because most transdiagnostic internet-delivered protocols have been conducted in community samples [108], it is necessary to continue to explore the acceptability of these interventions in specialized care.

Overall, the findings showed that the transdiagnostic internet-delivered protocol tested in this RCT was more effective than TAU for the treatment of anxiety and depressive disorders in public specialized mental health care. On the one hand, the results show that EmotionRegulation led to greater improvements at posttreatment, and these gains were maintained at follow-up. Regarding TAU, the results reveal that patients undergoing TAU also experienced improvement over time, but it was slower and less pronounced than in patients receiving EmotionRegulation. The generally lower intensity of TAU (ie, lower frequency of therapy sessions) and the fact that for most patients TAU was limited to pharmacotherapy (with no access to psychological treatment) might partly account for these results. On the other hand, as anticipated, and in line with previous studies conducted by our research group using the same treatment platform [94,109], scores on expectations and opinions demonstrated EmotionRegulation's acceptability for participants.

The results obtained in this RCT have implications for both research and clinical practice, especially in the context of public specialized mental health care. First, the findings obtained in this study support the effectiveness of a mechanistically transdiagnostic internet-delivered protocol for the treatment of EDs, and they contribute to the literature in this particular field

[23,27,36,110-112]. Specifically, a combination of the components of the UP and DBT regulation skills was found to be more effective than TAU in treating ED. Second, as far as we know, this is the first study to explore a transdiagnostic internet-delivered treatment in public specialized mental health care. As mentioned earlier, most research on transdiagnostic web-based treatments has been conducted in community settings, with a few of these studies carried out in primary care [108]. The results showed that the intervention was found to be more effective than TAU on the measures of generic depression, anxiety, and QoL. These results are consistent with the literature showing the superiority of CBT over TAU. For instance, a meta-analysis showed that CBT outweighed TAU, with effect sizes in the medium range on measures of generic anxiety (Hedges $g=0.70$) and depression (Hedges $g=0.69$) [70]. As surprising as these data might seem, the truth is that current public mental health services still have to deal with a number of barriers that hinder appropriate care delivery, such as excessive waiting times to access mental health care [60], low frequency of sessions [113], or inadequate follow-up care [56]. Moreover, the lack of training in evidence-based treatments among professionals further adds to this problem [114]. Finally, in Spain, several RCTs have been conducted using the internet to provide evidence-based treatments, showing that they are effective for the treatment of ED and, in particular, depression, in community samples [94] and primary care [115,116], and others are underway [117]. This study demonstrated that an internet-delivered protocol for ED was effective in public specialized care, a setting with a high demand, but much less explored, thus adding to the literature on these treatments for ED. Furthermore, the use of TAU as the control condition may help to answer the question of “whether a new treatment or an evidence-based psychotherapy really surpasses in outcome effects what is ordinarily done at a given clinic” [118], thus helping to make clinicians, researchers, and policy makers aware of the limitations and aspects that should be improved in this specific setting.

Limitations

Although the results of this RCT are promising, they should be interpreted in light of the following limitations. First, although several measures were taken to minimize attrition (eg, guidance was provided to all the patients participating in EmotionRegulation), the number of patients who dropped out of the study was high (around 35%). However, this proportion was close to what is typically observed in the literature on internet-delivered psychological treatments (ie, approximately 30%-35%) [71]. Moreover, attrition in the TAU condition was similar (34/108, 31.5%). Second, this RCT was not powered to detect differences in disorder-specific measures (ie, for GAD, PD or AG, SAD, and OCD). Therefore, future studies that meet the minimum levels of statistical power to detect differences in these measures are warranted. Third, although the frequency of the session in TAU was low and most patients in this condition were receiving only pharmacotherapy (as observed by the

researchers), these data were not monitored during the trial. Finally, the results for acceptability (ie, expectations and opinions) might not be entirely representative because data from patients who dropped out of the intervention were not included in these analyses.

Conclusions and Future Directions

The effectiveness of a mechanistically transdiagnostic internet-delivered protocol for ED was compared with TAU in public specialized mental health care. Although the results are promising, more research in specialized care should be conducted to extend the findings obtained in this study. First, research on predictors and moderators of treatment outcomes and dropout in this specific setting can help to delineate the profiles of participants who are more likely to benefit from these treatments and help to answer the classic question, “what treatment, by whom, is most effective for this individual with that specific problem, under which set of circumstances?” [119]. Moreover, we believe that the integration of principles from different evidence-based protocols (eg, components of the UP and DBT) can be a powerful strategy that should guide future research on evidence-based psychotherapy. This strategy is in line with process-based CBT and the new foundational question proposed by Hofmann and Hayes [49] (ie, “What core biopsychosocial processes should be targeted with this client given this goal in this situation, and how can they most efficiently and effectively be changed?”). Second, despite the huge advances experienced by the field of internet-delivered treatments in the past two decades, high dropout rates remain a major challenge in the field. To continue to improve current and future internet-delivered interventions, future studies should strive to include dropouts in the analysis of acceptability using both qualitative and quantitative approaches. Moreover, to ensure the integrity, quality, and replicability of these studies, adherence to existing research guidelines is of paramount importance in this endeavor. Third, although we did not assess the acceptability of clinicians involved in the RCT (ie, psychiatrists, clinical psychologists, and nurses), it is worth mentioning that some of them refused to participate in the recruitment process, which might reflect negative attitudes toward internet-delivered interventions among these professionals. In this scenario, research efforts should be made to inform clinicians and state holders about the benefits of internet-delivered treatments, especially because they are seen as authority figures and, therefore, their attitudes can have a major impact on patients’ perceptions. Finally, although the need for efficacy studies is out of doubt, we believe that it is of paramount importance to conduct more implementation research [120]. These studies may provide a much deeper understanding of implementation variables that can either facilitate or hamper the effective uptake of evidence-based protocols in real clinical practice, such as the attitudes of clinicians and other professionals toward internet-delivered treatments, or economical and logistic aspects that are difficult to implement.

Acknowledgments

The authors would like to thank Consorcio Hospitalario Provincial de Castellón, Hospital Universitario de la Ribera, and Hospital Universitario Vall d'Hebrón for their invaluable contribution to this study. This research was conducted with the financial support of grants P1-1B2014-43 (Universitat Jaume I, Castellón), a PhD grant from the Ministry of Education, Culture and Sports (FPU13/00576), and CIBER Fisiopatología de la Obesidad y Nutrición-ISCIII CB06/03/0052. The funders had no role in the study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Abstract

Background: Information technology and video gaming have potential advantages in the treatment of schizophrenia. However, information regarding the habits and attitudes related to internet use and video gaming in people with schizophrenia is limited.

Objective: The aim of this study was to explore the habits and attitudes regarding video gaming and information technology usage and their associated factors in people with schizophrenia in Hong Kong.

Methods: In this cross-sectional survey, service users with schizophrenia were recruited from 6 halfway hostels and 7 integrated centers for mental wellness in Hong Kong. A 79-item self-report questionnaire was utilized to explore the habits of internet use and video gaming in these people with schizophrenia. The attitude toward video gaming was assessed using the Gaming Attitudes, Motivations, and Experiences Scales. Of the 148 individuals in a convenience sample who were invited to participate in this study, 110 willingly participated (a response rate of 74.3%). The data were analyzed using descriptive statistics, a two-tailed independent t test, Pearson correlation, and principal analysis with 3 methods of rotation (varimax, equimax, and promax).

Results: Most participants (100/110, 90.9%) had access to the internet and half of them (54/110, 49.1%) used the internet daily mostly to watch videos (66/110, 60.0%) or read news or books, etc (42/110, 38.2%). One-third of the participants (36/110, 32.7%) used the internet to play web-based games, and most of them (88/110, 80.0%) had played a video game in the past year. The most favorable gaming platforms were cellular phones (43/88, 49%) followed by computers (19/88, 22%) and arcade cabinets (6/88, 7%). The most favorable game genre was action games (34/145, 23.4%). Those who had a bachelor's degree or higher scored lower in social interaction than those with a lower education level ($P=.03$). Those who played video games daily scored higher in the category of story than those who did not play daily ($t_{86}=2.03$, $P=.05$). The most popular gaming category was autonomy and the least popular categories were violent catharsis and violent reward. Two motives, "social playing" and "evasive playing," were formed to describe the characteristics of playing video games.

Conclusions: Our data showed a high internet utilization rate among people with schizophrenia in Hong Kong. Only a few of them used the internet to search for health-related information. Our study also exemplified the unique habits of gaming among the participants. Health care professionals could utilize video games to engage people with schizophrenia and promote coping with stress and provide social skills training to such people with schizophrenia. Identification of the gaming attitudes can contribute to the development of serious games for the schizophrenic population. Further investigation is vital for the promotion of mental health through web-based platforms.

KEYWORDS

video gaming; internet; information technology; schizophrenia

Introduction

Schizophrenia is a serious mental illness that is associated with significant cognition and functioning disabilities [1,2]. According to the World Health Organization [3], there are more than 21 million people diagnosed with schizophrenia worldwide. Many of them live in isolation [4,5] and are lonely without social interactions [3,6,7]. A recent systematic review investigated the situation of schizophrenic patients in 24 countries and revealed that the annual cost for the population of patients with schizophrenia ranged from US \$94 billion to US \$102 billion per country, which consumes up to 1.65% of a country's gross domestic product [8]. These expenses cover antipsychotic treatments and long-term psychological interventions [9], which are the recommended treatments for schizophrenia [10], and these treatments have demonstrated optimal control over positive symptoms. However, multiple factors hinder the efficacy of this treatment, including the patients' limited insight into mental illness [11], noncompliance [12], and treatment resistance [13,14]. The management of negative symptoms also remains a clinical challenge [15]. Therefore, new types of treatment methods are needed to promote recovery and optimize rehabilitation [15].

In recent years, different types of video games, including computer games [16,17], mobile games [18], serious games [19-23], and virtual reality [24-26], have been created as adjunctive treatments for various illnesses and they have resulted in desirable outcomes. Scholars suggest that video gaming is a novel intervention for social reconstruction and skills training in people with mental illness [16,19,21,27]. The use of video gaming in psychiatric treatment is promising because video gaming is a rapidly expanding market. In 2018, there were 2.3 billion gamers making up the total revenue of US \$137.9 billion globally [28]. The Asia-Pacific region was the largest contributing region, which shared 52% of the worldwide revenue [28]. Mobile gaming has increased by 25.5% per year from 2017 and it now holds 51% of the market. In contrast, a downtrend has been noted for computer gaming [28]. Although the use of information and communication technologies has been rapidly expanding in the world, the accessibility, frequency, and purpose of using information and communication technologies vary among geographical and demographical areas [6,29-32]. In the United States, 97% of the citizens possess a personal computer and 81% have a smartphone, which they use every day [6].

In the United States, 89% of the people with schizophrenia possess a computer and 54% have a smartphone [29]. The majority of these people spend more than 1 hour per day on a computer and a mobile phone, and the main purpose of use includes surfing the internet, social networking, and playing web-based games. One study in Finland revealed that only 55% of the people with schizophrenia had a computer and even fewer had access to internet connection [30]. A recent pilot study

investigated the usage of mobile and computer devices among people with severe mental illness [31]. Despite up to 45% of them showing interest in using the devices to support recovery, the majority only used them for general purposes such as listening to music (60%), accessing the internet (59%), and for making calls (59%) [31]. Specifically, young people were more likely to possess a computer and have internet connection, and the main purpose of using the internet included seeking information, studying, web-based chatting, shopping, and gaming [6,30].

People with schizophrenia have positive attitudes toward modern information technology use [33], including gaming [34,35]. Gaming attitudes specifically refers to gamers' motives and preferences regarding video games [32] and these attitudes vary among gamers with different backgrounds [36]. Ryan et al [36] explored gaming attitudes through the application of the self-determination theory and suggested that if a gamer's preferences are satisfied, they experience enjoyment when playing the game. Researchers have also identified certain game features to describe the gaming attitudes of gamers, such as storytelling, individual games, and social games [32,36]. Hilgard et al [32] identified 9 factors to measure the motives and preferences of gamers: story, violent catharsis, violent reward, social interaction, escapism, loss aversion, customization, grinding, and autonomy. These factors vary among different players depending on their characteristics such as their social motives, favorite games, and gaming platforms [32]. In general, gaming serves as a primary source of entertainment while simultaneously aiding in constructing and maintaining interpersonal relationships [16]. Beyond enjoyment, players can learn and develop new skills through gaming [16,29]. A study in the United States found that video games are most frequently utilized as a stress reliever; gamers enjoy playing video games as it takes them away from reality. Most video gamers enjoy playing with friends, while male gamers prefer competitions and feel proud when they achieve awards in a game [37].

Recently, gaming has been seen as a possible method of rehabilitation for people with schizophrenia [34]. However, there is still a lack of knowledge about the habits and attitudes of video gaming among people with schizophrenia [15,21,22,24,27,38,39]. Additionally, cultural differences in the attitudes of gaming [40] among people with schizophrenia might exist and have a potential impact on the treatment focus. By exploring the knowledge gap, we might contribute to the development of new interventions for the management of schizophrenia in the future [15]. Therefore, we conducted a survey to explore the habits and attitudes of video gaming and information technology use among people with schizophrenia in Hong Kong and the factors that are associated with their gaming attitudes.

Methods

Study Design

A cross-sectional survey design was adopted in this study because it allowed us to explore the attitudes of the respondents by using a structured survey format [41-44].

Ethical Approval

This study was designed to fulfill the ethical assessments mentioned in the Declaration of Helsinki [45]. This study was assessed by the Human Subjects Ethics subcommittee at the Hong Kong Polytechnic University (HSEARS20180313005) and approved by study setting organizations. An information sheet with the explanation of the study and the rights of participants was provided to each participant. Informed consent was obtained from each participant and witnessed and countersigned by a researcher. The study was guided by the ethical principles of autonomy, confidentiality, anonymity, and nonmaleficence [45]. It emphasized voluntary participation and participants having the right to withdraw from the study at any time [41,45]. The personal identity of the participants was protected such that their identities were not reported in any publication [45]. Collected data were kept in a locked cabinet and password-protected files, which were only accessible to the research personnel [41]. If there was any concern of emotional burden, participants were free to contact the research team for support through the contact information printed on the information sheet [46].

Setting

This study was performed in 2 settings, which are both in Hong Kong: integrated community centers for mental wellness and halfway hostels. In Hong Kong, rehabilitation services for people with mental illness in the community are operated by nongovernmental organizations, which operate various services to support the rehabilitation of people with mental illness living in the community such as the settings used in this study. There are 24 integrated community centers for mental wellness providing community support to individuals and their families on a district basis [47] and 36 halfway hostels providing residential support in Hong Kong [48]. Altogether, these types of services cover more than 26,000 citizens annually [49]. An invitation letter was sent to all the nongovernmental organizations that operated integrated community centers for mental wellness and halfway hostels in Hong Kong. Out of the 13 possible nongovernmental organizations, 2 agreed to join the study. Finally, the study was performed at 7 integrated centers for mental wellness and 6 halfway hostels.

Target Population

The target population consisted of people with schizophrenia who were living in the community [1,3,5]. At the time of the study, there were approximately 48,000 citizens who had been diagnosed with schizophrenia in Hong Kong, and most of them resided in the community [49]. Unlike those who were receiving inpatient psychiatric treatments, people living in the community were free to access video games and information technologies [50]. Therefore, it was more appropriate to explore the habits

and gaming attitudes of the people with schizophrenia who resided in the community [27,32,38].

Recruitment and Sampling

This study adopted convenience sampling in the participant recruitment. Poster promotion and data collection sessions were first arranged at the respective study organizations. Second, inclusion and exclusion criteria for the study participants were screened by representatives of the nongovernmental organizations. This was done to protect the privacy of the participants [45]. The inclusion criteria were as follows: (1) primary diagnosis of schizophrenia (schizophrenia spectrum and other psychotic disorders) under the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition [1]; (2) aged 18 to 64 years and capable of giving informed consent without a legal guardian; (3) able to read and understand traditional Chinese, which was the prevailing language and understandable by the majority of the citizens in Hong Kong; (4) willing and able to give informed consent [45]; and (5) a resident in the community. The exclusion criteria were as follows: (1) aged <18 or >64 years; (2) meeting diagnostic criteria for a current major depressive, manic, or hypomanic episode (Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition), intellectually disabled, severe visual impairment [1]; (3) active gamer (ie, playing >5 hours/day), for screening purposes only [51]; (4) meeting the diagnostic criteria for substance use disorder (other than tobacco use) [1], head injury, hemiplegia, or other neurological disorders.

Instruments

Background Information of the Participants

Demographic characteristics were collected, including age, gender, education qualification, (no formal education, primary and middle school, high school, college or vocational training, bachelor's degree, master's degree, doctoral degree), employment status (unemployed, social welfare benefit, student, disability pension, employed [including sick leave], other), marital status (single, partnership or married, separated or divorced, widowed), residential condition (own household [with partner or family], own household [alone], flat share, parents' household, supported housing), and the age of the first contact with psychiatric services.

Internet Use

The use of the internet was explored using a set of questions extracted from Choi and DiNitto's study [52]. The questionnaire consisted of 6 items, that is, internet connection (yes/no), possession of email address (yes/no), frequency of using the internet (at least once a day, every few days, once a week, a few times a month, once a month or less often than that), purpose of using the internet (seeking information, communication, shopping, gaming, peer support, others), accessibility to web information (5-point Likert scale, 1=always easy, 5=very difficult), and issues that posed problems in using the internet (problems with limbs, hands, concentration, long-term sitting, eyes, others).

Habits of Video Gaming

Habits of video gaming were explored using 7 items, namely, video gaming in the past year (yes/no), seriousness of video gaming (5-point Likert scale, 1=very intense, 5=very casual), frequency of video gaming (daily, 2-3 times per week, weekly, 2-3 times per month, monthly, less than monthly), proportion of spare time for video gaming (5-point Likert scale, 1=almost all of the spare time, 5=almost none of the spare time), favorite and current video games (respondents could list 3 of each), and favorite gaming platform. Subjects were not required to continue answering questions if they indicated that they had not played a video game within the past year [6,47].

Gaming Attitudes

Gaming attitudes were assessed using the Gaming Attitudes, Motivations, and Experiences Scales (GAMES) [32]. The

GAMES has 59 items to measure the gaming attitudes, habits, and preferences of the gamers. The items are classified into 9 categories: story (12 items), violent catharsis (7 items), violent reward (6 items), social interaction (6 items), escapism (6 items), loss aversion (7 items), customization (4 items), grinding (6 items), and autonomy (5 items, Table 1) [32]. Each item was rated on a 5-point Likert scale (1=strongly disagree, 5=strongly agree). The summation of the items formed the subscores of the 9 categories; the higher the score reflected the higher preference for a specific category. Factor analysis procedures were conducted with split-halves exploratory factor analysis and confirmatory factor analysis [32]. This instrument possesses good internal consistency in all categories with the Cronbach $\alpha=.79-.92$ [32].

Table 1. GAMES^a categories, score range, and their definitions.

Category	Score range	Definition
Story	12-60	Game stories are important, engaging, and emotionally compelling.
Violent catharsis	7-35	Game violence is perceived to harmlessly help release negative moods or aggression.
Violent reward	6-30	Game violence provides positive or thrilling emotions such as satisfaction or power.
Social interaction	6-30	Playing games with a group; developing personal relationships with other players.
Escapism	6-30	Using games to regulate dysphoric moods or to escape the frustrations of daily life.
Loss aversion	7-35	Tendency of a loss to frustrate or to “spoil the fun.” Likely subsumes a search for a challenge.
Customization	4-20	Interest in in-game creative pursuits such as personalizing an in-game avatar or building a house.
Grinding	6-30	Attitudes toward performing repetitive actions or paying real-life money to earn in-game rewards; interest in performing every possible action in a game or collecting every in-game item.
Autonomy	5-25	Enthusiasm for games with many choices, options, multiple solutions to puzzles, and open areas to explore.

^aGAMES: Gaming Attitudes, Motivations, and Experiences Scales.

Translations of the Instruments and a Pilot Study

The original version of GAMES was written in English; thus, a translation and back translation were performed to ensure that the validity was preserved [41]. First, the original instrument was translated into traditional Chinese by the researchers. Then, a language expert translated it back into English. Third, the original and the translated English versions were compared to ensure that the validity was retained after the translation [41]. In cases of any discrepancy between the original and the translated versions, the translation was reassessed by a researcher, translator, and the original author of GAMES.

A pilot study was conducted to examine the data collection procedure and reliability of the instrument [53]. Meanwhile, the feasibility of the data collection was tested [54]. We recruited 20 people with schizophrenia who were living in their community in Hong Kong. Two identical 2-way translated questionnaires were distributed to participants with an interval of 2 weeks [55]. The intraclass correlation coefficient was assessed to identify the test-retest reliability, and the Cronbach α was assessed to identify the internal consistency of the instrument [53,54]. The test-retest reliability was moderate to good with an intraclass correlation coefficient of 0.58-0.95. The

internal consistency was good with a Cronbach α of .71-.94. The reliability of the translated version was comparative to that of the original GAMES.

Data Collection

The data collection period lasted for 16 weeks—from October 2017 to January 2018. A researcher promoted the study with posters and arranged venues for briefing and data collection. Identical sessions were run by the same researcher at different time points at each data collection site [41]. All eligible participants were invited to attend an information session organized together with the nongovernmental organization. Potential participants were informed about the purpose of the study, the rights of the participants, risks of participation, and possible benefits, both orally and in written format. They were also informed about their right to refuse and withdraw from the study at any time without any consequences [45]. After informed consent forms were signed, the questionnaire was distributed to each participant. After completion, questionnaires were collected using sealed envelopes [41]. Each participant received a supermarket redemption coupon worth HKD \$50 (US \$6.45) as compensation for their participation in the study. Data collection sessions lasted for 30-60 minutes [32]. A total of 18 data collection sessions were held at the 13 data collection sites.

Finally, 148 people were contacted and invited to participate in the study, and 110 (74.3%) eligible people were willing to participate in the study and they completed the questionnaire.

Data Analysis

First, collected data were processed through data input, data cleansing, and data reversing [41]. Second, frequencies, percentages, maximum score, minimum score, mode, median, mean, and standard deviation were used to describe the demographic characteristics and the participants' habits and attitudes regarding internet use and video gaming [52]. To facilitate the analysis of the current and favorite video games played, the entries were recategorized into different game genres. We utilized an extensive gaming archive [56] to sort the entries into 10 mutually exclusive game genres. Lastly, a two-tailed independent *t* test was used to describe the possible differences in the normally distributed variables of the gaming attitudes. The Pearson's correlation coefficient was used to quantify the linear relationship between the categories of the gaming attitudes. Statistical significance was established at $P=.05$. For the dimensions of the categories of the gaming attitudes that were the most intercorrelated, principal analysis with 3 methods of rotation (varimax, equamax, and promax) was used to confirm the convergence of the 9 categories of gaming attitudes into fewer principle factors for easy interpretation. The SPSS software for Windows 22.0 (IBM Corp) was used for the data analysis.

Results

Background Information of the Participants

The mean age of the 110 participants was 39.0 (SD 11.2) years. About two-thirds of the participants (70/110, 63.6%) were males. A clear majority (91/110, 82.7%) was single and had completed high school or higher education (73/110, 66.4%). Totally 26.4% (29/110) of the participants were receiving social welfare benefits, 18.2% (20/110) were receiving disability pension, while 25.4% (28/110) were employed and 23.6% (26/110) were unemployed. Of the 110 participants, 78 (70.9%) lived in supported housing (Table 2). The mean reported age at the first contact with psychiatric services was 24.7 (SD 8.5) years, and the average duration of illness was 14.3 (SD 10.3) years.

Internet Use

The majority of the participants had access to an internet connection (100/110, 90.9%). The most common purposes of using the internet were to watch videos (66/110, 60.0%), read the news, papers, magazines, and books on the internet (42/110, 38.2%), research information about other topics or issues of interest to them (41/110, 37.3%), and play web-based games (36/110, 32.7%). Participants found using the internet to be easy (69/110, 62.7%). The major causes that lessened the use of the internet were when eyes were tired easily (40/110, 36.4%) and when one had difficulty concentrating for long periods of time (26/110, 23.6%) (Table 3).

Table 2. Background information of the participants (N=110).

Variables	Values, n (%)
Gender	
Male	70 (63.6)
Female	40 (36.4)
Marital status	
Single	91 (82.7)
Partnership/Married	9 (8.2)

Level of education	
Primary and middle school	37 (33.6)
High school	51 (46.4)
College or vocational training	10 (9.1)
Bachelor's degree	12 (10.9)
Employment status	
Unemployed	26 (23.6)
Social welfare benefit	29 (26.4)
Student	2 (1.8)
Disability pension	20 (18.2)
Employed (including sick leave)	28 (25.5)
Other	5 (4.5)
Living situation	
Own household (with partner/family)	8 (7.3)
Flat share	17 (15.4)
Parents' household	7 (6.4)
Supported housing	78 (70.9)

Table 3. Patterns of internet use among the participants (N=110).

Patterns of internet use	Values, n (%)
Access location of the internet	
Home	77 (70.0)
Apartment complex	5 (4.5)
Family/friend's home	9 (8.2)
Library	4 (3.6)
Other	5 (4.5)
Not using the internet at all	10 (9.1)
Possession of an email address	
Yes	63 (57.3)
No	47 (42.7)
Frequency of using internet	
At least once a day	54 (49.1)
Every few days	14 (12.7)
Once a week	6 (5.5)
A few times a month	3 (2.7)
Once a month or less	33 (30.0)
Purpose of internet use	
Research health-related information	18 (16.4)
Communicate with health professionals about health-related issues	4 (3.6)
Communicate with other users about health-related issues	8 (7.3)
Research information about other topics or issues of interest to me	41 (37.3)
Send/receive email	24 (21.8)
Online shopping	15 (13.6)
Perform online banking/pay bills	13 (11.8)
Read web-based news, papers, magazines, and books	42 (38.2)
Play web-based games	36 (32.7)
Watch videos	66 (60.0)
Use social networking websites and/or dating sites	24 (21.8)
Other	9 (8.2)
Easiness to access the intended information on the internet	
Always easy	22 (20.0)
Sometimes easy	47 (42.7)
Not so easy	17 (15.5)
Difficult	11 (10.0)
Very difficult	13 (11.8)
Problems that lessen internet use	
Pain in the limbs	7 (6.4)
Unsteady hands	6 (5.5)
Difficulty concentrating for long periods of time	26 (23.6)
Difficulty sitting for long periods of time	18 (16.4)
Eyes that tire easily	40 (36.4)
Other problems	6 (5.5)

Habits of Video Gaming

The majority of the participants (88/110, 80.0%) reported that they had played a video game within the past year. The habits of video gaming of the 88 participants were explored (Table 4). Almost half of the participants (41/88, 47%) regarded themselves as playing games seriously or very seriously. Half of our participants played video games on a daily (22/88, 25%)

to weekly basis (26/88, 30%). The most favorable gaming platforms were cellular phones (43/88, 49%), computers (19/88, 22%), and arcade cabinets (6/88, 7%) (Table 4). Referring to the video games that participants were currently playing and their favorite video games, there were 118 and 145 entries, which included 81 and 84 games, respectively (Table 5). The favorite game genre among the participants was that of action games.

Table 4. Habits of video gaming of the participants (n=88).

Habits of video gaming	Values, n (%)
Seriousness of video gaming	
Very serious	14 (16)
Serious	27 (31)
Neither serious nor casual	17 (19)
Casual	25 (28)
Very casual	5 (6)
Frequency of video gaming	
Daily	22 (25)
2-3 times per week	15 (17)
Weekly	11 (13)
2-3 times per month	11 (13)
Monthly	8 (9)
Less than monthly	21 (24)
Proportion of spare time spent on video gaming	
Almost all of the spare time	4 (5)
Most of the spare time	6 (7)

Gaming Attitudes

The gaming attitudes of the participants were explored, and the results are summarized in Table 6. Of the 88 participants, the distribution of the scores in the category of story ranged from 21 to 50 with a mean score of 37.81 (SD 6.33) (Table 6).

To compare the scores among the 9 attitude measures, we standardized the raw score of each participant as a relative score for each attitude measure. The mean of the standard score in the last column of Table 6 suggests that the top 3 favorable

video gaming categories for participants were autonomy, escapism, and story, and the last two were violent catharsis and violent reward. Furthermore, the gaming attitudes of the participants were mostly correlated with each other (Table 7). A principal analysis with 3 methods of rotation (varimax, equamax, and promax) indicated that the categories of story, social interaction, customization, and autonomy formed one factor, which are related to social playing and explains 13.1% of the variation, and the rest of the categories formed another factor, which are related to evasive playing, thereby explaining 45.7% of the variation.

Table 6. A summary of the gaming attitudes of the participants (n=88).

Categories	Minimum score	Median score	Mode	Maximum score	Mean (SD)	Mean of standard score in % ^a (rank)
Social playing						
Story	21	38	37	50	37.81 (6.33)	54 (3)
Social interaction	6	19	20	30	18.55 (4.78)	52 (5)

Association of the Background Information with Gaming Attitudes

Several background characteristics such as marital status, education level, and employment status were found to be significantly associated with several categories of gaming attitudes ([Multimedia Appendix 1](#)). As for marital status, participants who were married or who were in a partnership had a higher score than those who were single, separated, or divorced in the violent catharsis category ($t_{86}=2.66$, $P=.01$). With regard to the education level, participants who held a bachelor's degree or higher had a lower score than those who were educated with college or vocational training or a lower level of education in the violent reward category ($t_{86}=-2.57$, $P=.01$). Likewise, the participants with a bachelor's degree or higher had a lower score in social interaction than those who did not ($t_{86}=-2.25$, $P=.03$). Further, the participants who had a bachelor's degree had a

lower score in customization than those who did not ($t_{86}=-2.08$, $P=.04$). Regarding the employment status, participants who were employed or studying scored lower than those who were unemployed or others in the violent reward category ($t_{86}=-3.11$, $P=.003$). Similarly, participants who were employed or studying scored lower than those who were unemployed or others in the loss aversion category ($t_{86}=1.98$, $P=.05$).

The gaming habits of the participants were also found to have a significant association with several gaming attitudes ([Multimedia Appendix 1](#)). Regarding the seriousness of video gaming, noncasual players had a higher score than casual players in the customization category ($t_{86}=2.00$, $P=.05$). Participants who played video games on a daily basis scored higher on story than those who played less than daily ($t_{86}=2.03$, $P=.05$). Participants who reported that they spent more spare time on video gaming (almost all/most of/some of their spare time)

scored higher on violent reward than those who spent less spare time (few/almost none of their spare time) ($t_{86}=2.14$, $P=.04$). Those who spent more spare time on video gaming also scored higher in escapism than those who spent less spare time on gaming ($t_{86}=2.79$, $P=.007$). However, no significant correlation was found between age, the age at the first contact with psychiatric services, or duration of illness and any of the categories of the gaming attitudes.

The analysis (Multimedia Appendix 2) based on the factor loading weighted mean score of the 2 summarized factors of the gaming attitudes, “social playing” and “evasive playing” provided further support for the above findings in a summarized manner. This analysis suggested that participants with a bachelor’s degree or above and employed or studying seemed to have lower scores in social playing than their counterparts, thereby reflecting a difference in their attitude regarding social interaction. However, the differences were not statistically significant owing to the sample being small. Participants employed or studying had significantly low scores in evasive playing ($t_{86}=2.16$, $P=.03$), which is a reflection of the significant differences in their attitudes on violent reward and loss aversion. The notable difference between the 2 gaming attitude components was that those in partnership/marriage scored much higher in evasive playing than single/separated/divorced individuals (68.73 vs 61.94, respectively), although they scored similarly in social playing (60.62 vs 61.38, respectively), that is, the difference was not significant in this study. The differences in the levels of seriousness and frequency were similar to the differences between the 2 factors of attitudes, but there was a larger difference in the proportion of spare time spent on video gaming; more spare time was spent on evasive playing than on social playing, with a borderline significance of $t_{86}=1.94$, $P=.06$.

Discussion

Principal Findings

This study is the first to describe the habits and attitudes of internet use and video gaming among people with schizophrenia in an Asian city. Similar to the global trends, the majority of the participants (100/110, 90.9%) utilized the internet with adequate skills and participated in video gaming [6]. Their favorite gaming platform and game genres were cellular phones and action games, respectively. However, only few of the participants had utilized the internet for seeking health information, and the efficacy of health education through web-based platforms to this population was limited. The gaming attitudes were identified and found to be associated with several characteristics. The participants valued autonomy in gaming and disfavored violence in video games. Through our analysis, we established the motives of the gamers. “Social playing” included social interaction, story, customization, and autonomy, while “evasive playing” included grinding, loss aversion, escapism, violent catharsis, and violent reward.

Use of Information Technology

The utilization of information technology was found to extend to almost the entire population of Hong Kong, which is a modern

city [57]. We found that the frequency of internet use by most of our participants was higher than those reported in the United States [29] and Finland [30]. The high accessibility to the internet could be explained by the affordable and extensive coverage of the internet network [58]. As reported in previous studies [6,30], our participants mainly utilized the internet to watch videos and obtain information by reading news, papers, magazines, and books. Over half of the participants (69/110, 62.7%) found it easy to obtain the intended information from the internet. Our study also demonstrates that most of the participants were able and willing to obtain information from the internet.

Despite the availability of web-based resources and the ability to use them, only 16.4% (18/110) of the study participants reported utilizing the internet for researching health-related information. This may imply that the efficacy of mental health promotion through web-based platforms is still limited. McCloud et al [59] suggest that the low motivation of internet users to search for health-related information might be due to users lacking the skills needed to gather and identify trustworthy sources of information. Athanasopoulou et al [60] and Schrank et al [33] also demonstrated that the quality of most of the easily accessed information sources about schizophrenia on the internet is poor. This can hinder internet users from receiving useful and nonstigmatized information about managing schizophrenia. It would be preferable for health care authorities to develop and use a trustworthy internet platform through which health-related information for health promotion could be easily distributed. Furthermore, our results reflect that there are physical constraints that pose barriers to the use of the internet. The major barriers were found to be tired eyes and concentration difficulties. The adverse effects of antipsychotic drugs, such as drowsiness, sedation, and anticholinergic effects, might be a cause of the barriers [61]. Thus, it is important for health care staff to address safe methods in promoting health-related issues through trusted web-based platforms on a daily basis.

Habits of Video Gaming

Video gaming is popular in Hong Kong, and approximately 94% of the adolescents comprise the gaming population [62]. Likewise, a majority of the participants had played video games within the past year (88/110, 80%). As reported globally [63], the most popular gaming platform among the participants was cellular phones. There has been a global shift toward playing games on cellular phones rather than sitting in front of a television or a desktop computer. With the high mobility and convenience of using phones, gamers can enjoy playing without geographical constrictions. Indeed, game developers have launched numerous games on mobile platforms in recent years [6,63]. However, since players use a limited-sized screen and gaming times are generally short in mobile gaming, designing games for mobile phones with long and complex stories is not preferred [62].

The participants also played video games frequently; more than half of them (48/88, 55%) played at least once a week and (22/88, 25%) played on a daily basis. About half of the gamers emphasized on video gaming, as they played seriously. As reflected in the best-selling video games of 2017, action games

were the favorite game genre among the participants. Action games challenge gamers through physical means and players usually control a character to complete tasks that require a certain level of hand-eye coordination and skills [6,64]. Action games attract players by rewarding them with excitement [62]. Contrary to the global best-selling trends, our results indicated that card and board games and strategy games were the next favorite types of games, while the best-selling games worldwide were role-playing and sports games [6]. This finding might be accounted for by the cultural and local context. Local game developers in Hong Kong have converted some culturally traditional board games such as Mahjong, Chinese Chess, and some card games into digital versions, which are easy to use. In addition, some traditional Chinese stories such as “Romance of the three kingdoms” has been converted to a series of strategy games. However, the characteristics of the players in Hong Kong do not seem to differ significantly from those of the rest of the world with regard to popular mobile games [63]. Thus, one possible explanation for our finding of people with schizophrenia favoring traditional games could be related to the negative symptoms of the disease, such as cognitive deficits and a lack of confidence about one’s own abilities [64]. These factors could lead to favoring familiar game genres.

Gaming Attitudes

Our study identified that autonomy was the most common motive for video gaming among the participants. This is seen in the preference of the participants to play games in which they could manipulate settings and make choices. Video games provide a normalized platform wherein people can exercise self-sufficiency and thus develop self-competence [65]. The next most common motive was escapism, which implies that participants played games to regulate dysphoria and escape from the hassles of daily life. Indeed, video gaming has been considered a culturally acceptable way to relieve the stress of reality [23,25]. On the other hand, some scholars argue that escapism is associated with gaming addiction and adverse emotional experiences [66-69]. A recent study examined the effects of video gaming on a group of military veterans with mental problems and found that video gaming contributed to their recovery by promoting individuals’ adaptive coping, eudaimonic well-being, and socializing [70]. As the evidence related to harm caused by gaming among people with schizophrenia is not yet conclusive, staff working in clinical practice need to be sensitive to and be aware of any potential harmful effects of the interventions and avoid any such threats.

Our participants regarded violent reward and violent catharsis as the least favorable motives for video gaming. Numerous studies suggest that violent games might contribute to aggression [70-72] and moral desensitization [73,74]. On the contrary, scholars also suggest that violent games support emotional coping after stressful events [75,76]. Interestingly, our results indicate that people with schizophrenia do not favor violence in video gaming. Moreover, several characteristics were associated with a preference of violent video gaming. People who were married or in a partnership tended to channelize their negative emotions by playing violent games to avoid hurting others. In contrast, the unemployed and those with lower education levels enjoyed the satisfaction they received from

playing violent games. These results implied that people with different sociodemographic characteristics achieve emotional coping through different ways. However, more studies are needed with larger sample sizes to confirm valid links between sociodemographic information and gaming motives.

Studies have shown that persons with schizophrenia are lonely and isolated and less motivated to socially engage with others [3-7]. Our analysis regarding gamers’ motives identified a factor, “social playing,” in several categories, namely, social interaction, story, customization, and autonomy. This factor refers to people who emphasize social processes in video gaming. These players enjoy games that enable them to customize and manipulate numerous settings. The story and settings of the video games strongly influence the gaming experience for the players. Gamers value the social interaction with friends and other players during the gaming process. Likewise, several background characteristics were related to social playing motives. In the past decade, there has been an expansion of multiplayer web-based role-playing games in the market. These have provided a virtual platform for players to interact with people worldwide [6,55,62,77]. Scholars have proven that the formation of social bonds in virtual communities through web-based video games facilitates the development of interpersonal skills in the real world [78,79]. This shows the potential of utilizing video games, regardless of the players’ education levels, to facilitate interpersonal skills among people with mental illness [80,81] and to increase feelings of relatedness [36]. Frequent game players in our data were more concerned with the game story. Likewise, noncasual players and people with a lower education level preferred games with customizable settings. With the rapid expansion of the gaming market, gamers have a higher expectation of the quality of games, including that of the story, settings, ability to personalize, and the gaming experience [82]. Indeed, gamers can exercise creativity and control their game by tailor-making their own game settings. Studies have shown that the ability to personalize games motivates people to play games [82-84].

On the contrary, another factor, “evasive playing,” was formed by the remaining categories, namely, grinding, loss aversion, escapism, violent catharsis, and violent reward. Evasive playing refers to when gamers emphasize the rewards from video gaming and spend time on achieving all gaming missions and collecting all possible props in a game. In this style of playing, the violence in games is utilized to channel negative emotions and attain enjoyment. Our results indicate that unemployed people have a high loss-aversion score, which could imply that gaming is significantly important to them. People who spent more spare time on gaming were more likely to utilize gaming to escape from the hassles of daily life. However, scholars suggest that these motives are linked to problematic use [15,85] and pathological gaming [32], which should be seriously considered when discussing gaming among people with mental illness. In the future, more studies should therefore be conducted in schizophrenic patient populations with increased sample sizes and a longitudinal design and follow-up to explore problematic uses of video games, both in clinical and community settings.

Strengths and Limitations

This study fills a knowledge gap by depicting a pattern of internet use and video gaming among people with schizophrenia. Despite the research aims being met, there are some limitations to address. First, participant recruitment was conducted using a convenience sample. Thus, the sample size was small, which limits the generalization of the results to the wide population of video game players in Hong Kong or in other parts of the world. Second, our participants were recruited from 2 nongovernmental organizations (supported housing); therefore, the results may be biased toward individuals who live in communities with better general levels of mental health. Third, the study may have attracted people who were interested and skillful in video gaming. Further, the life span and the popularity of video games are highly influenced by the social trends that might change rapidly.

Implications

The utilization of the internet as a platform for health promotion and education has been considered to be a cost-effective measure [86,87]. Most people with schizophrenia in our study were found to be able to utilize information technology to obtain information on the internet. This finding is promising. Based on a systematic review by Suenderhauf et al [15], regular video game playing could enable home monitoring of patients. For example, staff could use gaming as a tool for patient monitoring in order to initiate supportive measures to avoid relapses. Decreased login times could indicate diminishing compliance or worsening of disease. Likewise, alarming habits in computer use such as the lack of logins in the regular gaming schedule or playing beyond suggested gaming hours could be an indicator for health care professionals of changes in the patients' mental status. However, this type of monitoring would require specified technological devices and access for patients who play games remotely, which may increase potential concerns in patient privacy and security issues. It is therefore important to delineate the roles and responsibilities of health professionals in patient monitoring in any exceptional situation (eg, suicide attempt). Professionals should also support the use of digital health interventions; their attitudes are crucial for successful implementation of health technology in patient daily care [88]. Our previous studies have shown that staff members may still be less willing to adopt new technology-based interventions into mental health care [89,90] as they tend to prefer traditional face-to-face methods in mental health care services [91].

We found that the internet was less often used to seek health-related information. Scholars and health care professionals might need to investigate the cause of the low utilization rate of the internet with regard to searching for health-related information. To promote internet use in a population, health care authorities should consider developing an internet platform with high-quality health information for health promotion. Service organizations should provide equipment, training, and ongoing information technology support to the population in order to expand their social networks and maximize self-help abilities. Policy makers should promote the use of information technology in a schizophrenic population and offer support to the nongovernmental organizations for the abovementioned measures.

Over the last decade, numerous studies have shown video gaming as an intervention for various medical conditions. From the mental health aspect, health care professionals could utilize video games to promote patient engagement, stress coping, and social skills training. Our findings show that game developers could design video games to fit the needs of the population. Game developers and health care professionals could refer to the identified gaming attitudes to tailor-make attractive serious games for populations with mental health problems accordingly. Therefore, in the future, more studies should be conducted with more diverse samples to identify the potential benefits of video gaming for patients with mental problems. The use of health-related games should also be implemented and tested as part of the mental health recovery. Despite the huge potential that information technology has in the treatment of patients with mental disorders, we still may have a long way to go before research on computer-based interventions can realize its full potential in psychiatric services [92].

Conclusion

This study demonstrates that the internet utilization rate of people with schizophrenia was as high as that of the general population in Hong Kong. Relatively few of them used the internet to search for health-related information. Further investigation into the underlying reasons would be vital to mental health promotion through web-based platforms. Our study also exemplifies the unique habits of gaming among the study participants. Health care professionals could utilize video games to engage patients, promote stress coping, and provide social skills training. The identified gaming attitudes can be used to contribute to the development of serious games for the population in the future.

Acknowledgments

We would like to thank the Hong Kong Polytechnic University (code YBYB, grant holder MV) and the University of Turku, Finland (code 26003424, grant holder MV) who supported this study. We would also like to thank the mental health associations in Hong Kong for their assistance in recruiting participants for the study. In particular, we would like to thank all the participants and the staff from the associations who offered their kind assistance to our study.

Authors' Contributions

MV designed the study. WTHC, DKSY, and TW collected the patient survey data. WTHC conducted statistical analysis and wrote the manuscript. TL and MV wrote the manuscript, and MY conducted additional statistical analysis. All authors reviewed the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Smartphones have become ubiquitous in China, offering a promising way to deliver mental health interventions; however, little is known about the current use and characteristics of smartphone apps for mental health.

Objective: The purpose of this study was to gain insight into mobile mental health apps available in China as of December 2018.

Methods: A systematic search was conducted to identify and evaluate the most downloaded apps from iOS and Android platforms. Apps were categorized according to their main purpose and downloaded to evaluate their content. Each app's affiliation, cost, target users, information security, and evidence-based nature were evaluated.

Results: Of the 172 unique apps that were identified, there were 37 apps (21.5%) for psychological counseling, 50 apps (29.1%) for assessment, 12 apps (7.0%) to relieve stress, 24 apps (14.0%) for psychoeducation, and 49 (28.4%) multipurpose apps (ie, a combination of counseling and assessment). Most apps were developed for adults in the general population (166/172, 96.5%), rather than for psychiatric patients. App-based counseling was mostly provided by psychologists, and of the assessed apps, only 40% (70/172) used evidence-based scales to assess mental health problems such as anxiety or depressed mood. Guided meditation was used as the main technique in stress-relieving apps.

Conclusions: Many apps contained useful and evidence-based elements, such as good quality information, validated measurements, and useful meditation methods; however, for mobile apps to contribute significantly to mental health care in China, considerable challenges remain, including the need for more patient-focused apps that can actually take on the role of a health care provider. In addition, efficacy studies are needed.

KEYWORDS

smartphone; app; mobile mental health; mental illness; mental health problem; China

Introduction

Mental health problems cause significant distress and have a negative impact on social relationships, school performance, occupational attainment, and physical health [1]. Mental health disorders have been found to affect 12.0% to 47.4% of populations worldwide [2]. In China, the lifetime prevalence of mental health disorders has been found range from 16.6% [3] to 23.6% [4]. Unfortunately, the availability of mental health services in the existing Chinese health care system is currently

limited, and many patients cannot obtain appropriate treatment or help for their mental health problems [5,6]. In addition to the lack of available facilities and trained professionals, a low perceived need, poor knowledge of mental health disorders, and mental illness stigma have been identified as potential barriers to seeking help for mental illness [5].

Mobile health (mHealth) technologies could help to partly overcome the above-mentioned obstacles to seeking help, as they could extend the reach of mental health care beyond available health care providers and clinics. The smartphone was

one of the most rapidly adopted technological innovations in history [7]; it now provides ubiquitous internet access and the possibility to access, download, and run externally created software apps. As such, smartphone technology provides a unique opportunity to deliver cost-effective and evidence-based mental health care services to large groups of people [8]. Indeed, studies have shown that mental health care apps can play an important role in the assessment, prediction, and monitoring of mental health, as well as psychoeducation delivery, self-management strategies, recovery support, prevention, and promotion. In addition, apps can be used for the training of mental health providers [9-16].

The large number of smartphone users in China—estimated to have reached 748.3 million in 2019 [17]—as well as the large mobile health market in China—which grew by 74.5% between 2016 and 2017 [18]—indicates a large potential for mental health care apps in China; however, very few studies have been done to gain insight into the number and types of available apps and their potential effectiveness in China.

On the one hand, available literature [19-23] seems to suggest limited availability and use of mental health-related apps in China. For instance, a review study [19] on health apps in China found that there were many apps targeting both nonprofessional and professional users, but the study described only 1 app related to mental health. Another review [24] of mHealth technology for the treatment or prevention of mental health disorders in low-and middle-income countries found 6 studies about mHealth technology in China, among which only 1 applied to mental health. On the other hand, an examination of the Chinese iOS and Android app stores shows that, despite a scarcity of research, there is an abundance of publicly available mental health apps. Unfortunately, consumers currently have no access to information about the quality of the available apps beyond the star rating system and user reviews on the app stores. It is unlikely that these indicators of popularity also reflect the quality, effectiveness, or evidence base of an app. Previous studies [20-23] outside of China have found that most mental health apps in commercial marketplaces do not provide evidence-based therapies, do not follow clinical guidelines, and do not respect privacy regulations with respect to the handling of personal information. Consequently, it is a challenge for both patients and clinicians to find useful apps when needed. A recent search of 44 mental health apps (available as of October 2017) in China showed some common features, such as commercial purpose, and services that included counseling, education, and

assessment [25]; however, since this review, the market for mental health apps has grown considerably larger (eg, more than 100 available apps were found based on the search term representing mental in the Baidu app store) [26]. In addition, the important characteristics of the apps that are available have remained unclear, such as the target user population, the evidence base for their content, and consideration of data-safety issues. To determine if and how apps can play a role in Chinese mental health care delivery, these aspects should be thoroughly explored, and it is for this reason that this systematic search was undertaken.

The purpose of this study was to (1) characterize the purpose and content of the mental health smartphone apps available for use and most downloaded by the general Chinese public, (2) to evaluate whether app content is evidence-based, and (3) to gain insight into the app costs and into the quality and comprehensiveness of data safety in the apps.

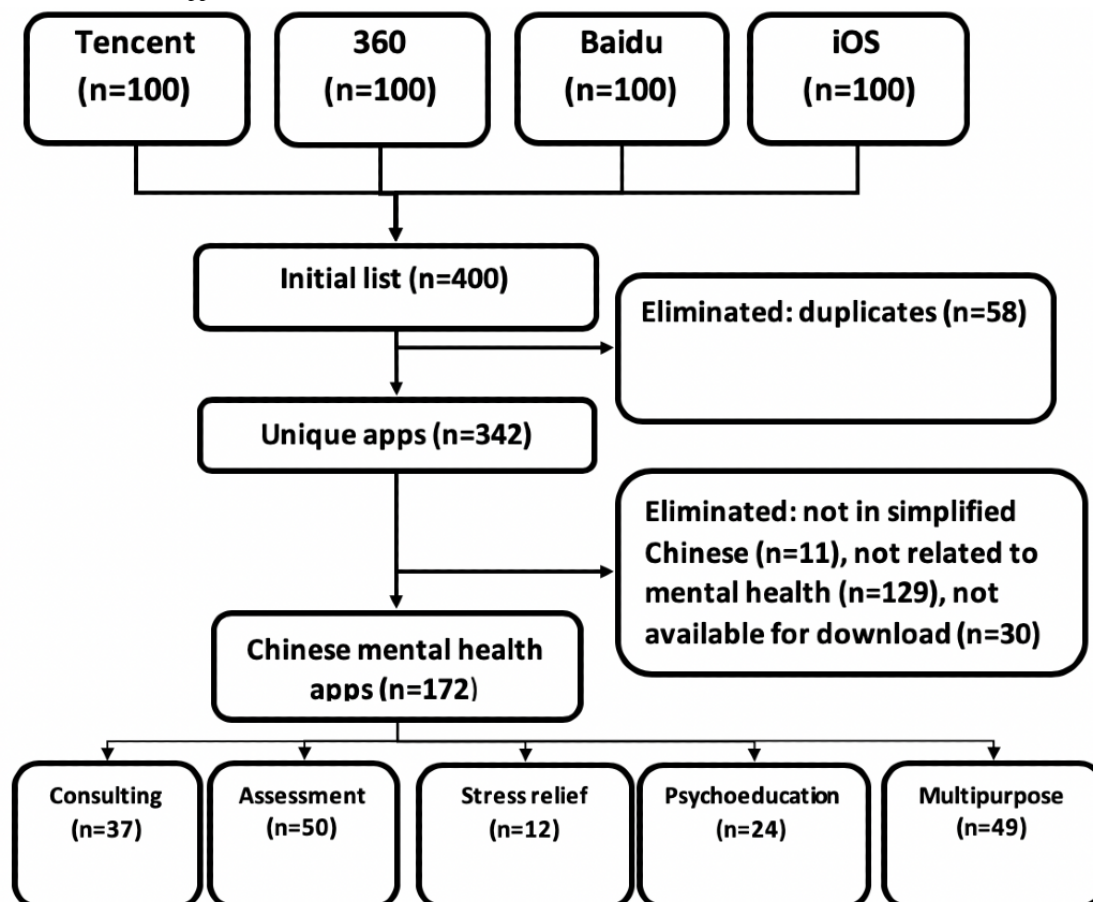

Methods

mHealth App Market Search

On December 26, 2018, we conducted a search in both Android (Google LLC) and iOS (Apple Inc) app stores in China. The 3 largest Android app stores in China are Tencent (Tencent Holding Ltd), 360 (Qihoo 360 Technology Co Ltd), and Baidu (Baidu Inc), and these were selected for the study because they constitute more than 50% of Chinese Android market share [27]. In addition, we used the Chinese iOS App store to gather a list of apps for the Chinese iOS market.

We restricted our search to apps that used the Chinese characters for 1 or more of the following keywords in the title or store description of the app:  (mental health) OR  (mental) OR  (psychology) OR  (psychiatry) OR  (psychological intervention) OR  (psychological prevention). The top 100 apps were collected for each app store.

Android apps are free to download, and iOS apps are either free or paid. We listed free and paid apps together, mainly because there were few paid apps. The eventual selection of apps for this study (Figure 1) was done according to the following inclusion criteria: The app should (1) be related to mental health, (2) be available for download, (3) use simplified Chinese so that any literate Chinese individual can easily understand the content of the app, and (4) be usable in mainland China.

Figure 1. Chinese mental health app inclusion and exclusion flowchart.

App Assessment

The apps that met the inclusion criteria were downloaded onto either a Huawei mate 9 (Android version 8.0.0), a Xiaomi 8 (Android version 8.0.0), or an iPhone 5s (iOS version 7.1) device for a complete assessment. The reason for downloading each app for inspection was that the app description may not be sufficient to allow for a full judgment of the nature and quality of its content. For instance, in a previous study [23], when the authors downloaded the apps, they found that some apps provided patients with poor or potentially harmful advice (such as a recommendation to people with a manic episode to drink alcohol before bedtime to assist with sleeping). Therefore, for each app, we evaluated if the information provided was evidence-based. For apps that were listed in multiple app stores, the consistency of the descriptions across stores was evaluated, and identical duplicates were eliminated. Some apps had a patient version and a clinician version. We assessed these versions separately because they might provide different services. If an app was available for both iOS and Android, the Android version was evaluated.

For each app, the following general information about the app was extracted (Table 1): (1) main purpose, (2) affiliation (ie,

commercial, medical center, or university), (3) cost, (4) target user, (5) whether or not information security was emphasized, and (6) whether the therapeutic contents were based on an evidence-based psychological theory, such as cognitive behavior therapy [28], acceptance and commitment therapy [29], interpersonal psychotherapy [30], or problem-solving therapy [31], or if the content was based on advice by professional certified staff including psychologists, psychotherapists, or psychiatrists. Based on the app description, the first author categorized the apps into 1 of 5 categories indicating their main purpose: psychological counseling, assessment, stress relief, psychoeducation, and multipurpose (incorporating components of assessment, education, psychological counseling, and stress relief). Each category of apps was then further investigated by 1 of the coauthors (HY, YW, NW, YZ, and WC; each author was randomly assigned to a category). If anyone found that the initially selected category did not fit an app, the 5 authors discussed until consensus was reached. For each category, specific additional information was extracted (detailed in Table 1). For mental health education apps, core aspects of mental health information (Table 2) were investigated. These aspects have previously been proposed by the National Health Commission of China [32] and are used to guide mental health education work in the whole country.

Table 1. The information collected for each of the selected apps.

Information extracted and content	Values
General information collected for each app	
Affiliation	Commercial, university, or medical center.
Cost	Pay for download, completely free, or partly free.
Target user	Children or adolescents, general public adults, specific for women, special for patients with mental health problems, or specific for professional staff.
Data safety information	Whether an app report relevant information security measures or not? (yes or no).
Professional background	Whether the contents of the app were based on a psychological theory or were based on advice by professional certified staff including psychologists, psychotherapists or psychiatrists? (yes or no).
Specific information for psychological counseling apps	
Counseling mode	Online (text typing or audio) or offline (eg, an app can help to make an appointment).
Counseling provider	Professional (including psychologists, psychotherapists, or psychiatrists) or trained lay health supporter.
Target users	Individuals with diagnoses of a mental health disorder or general public.
Specific information for assessment apps	
Assessment aspect	Personality, symptoms, intelligence, cognitive functions, or assessment just for entertainment (eg, constellations, fortune, or other).
Evidence	Are evidence-based measurements or scales used? (yes or no)
Specific information for stress relief apps	
Methods	Music, mindfulness, relaxation therapy, etc.
Evidence	Is there a reference in the app to work that shows the therapy is effective?
Specific information for education apps	
Apps for training mental health providers	Books, lectures, audio recordings, or other method.
Apps for mental health knowledge to public	According to 8 core information aspects (see Table 2).

Table 2. Eight aspects of mental health information.

Items	Content
1	Mental health is an integral part of health. No mental illness does not necessarily mean mental health. Everyone needs not only physical health, but mental health as well.
2	Mental health and mental illness, such as physical health and physical illness, are determined by multiple interacting biological, psychological, and social factors.
3	Given that anyone could encounter mental health problems in their life, it is necessary to pay attention to and maintain mental health.
4	Schizophrenia, depression, behavior disorders in children and adolescents, and senile dementia are China's current priorities for mental illness prevention and treatment.
5	A person suffering from psychological or behavior problems or mental illness should seek help from a medical institution as soon as possible to receive advice and formal diagnosis and treatment.
6	Mental illness can be prevented and treated.
7	Care for and do not discriminate against mentally ill patients, and help them return to their families, communities, and society.
8	Mental health is related to social harmony and development. Promotion of mental health and prevention and treatment of mental illness is the responsibility of society as a whole.

Results

General

Of the 400 apps that were screened, 172 unique apps met the inclusion criteria ([Figure 1](#)). Of these, 105 (61.0%) were available in the Android app stores, 28 (16.3%) were available

in the iOS app store, and 39 (37.1%) were available in both the iOS and Android app stores. Based on the descriptions of the main purpose of the apps, 21.5% (37/172) were for psychological counseling, 29.1% (50/172) were for assessment, 7.0% (12/172) were for stress relief, 14.0% (24/172) were for psychoeducation, and 28.4% (49/172) were multipurpose apps. The number of downloads per app ranged from 16 to 107 million

in the Android store. Download numbers could not be obtained in the iOS app store. Detailed information about the different groups of apps is shown in [Table 3](#).

Counseling Apps

There were 37 counseling apps, and they were all developed by commercial companies. Of the counseling apps, 7 (19%) apps were free to use, 29 (78%) apps could be downloaded for free but charged counseling fees to consumers wishing to use the app, and 1 (3%) app charged a download fee. In terms of the target population, 8 (22%) apps were aimed at adults and adolescents, 1 (3%) was aimed specifically at children and adolescents, and 27 (76%) were only aimed at adults. Of the 27 apps for adults, 1 (3%) app was only aimed at women and 3 (8%) apps were aimed specifically at professionals. Of the 37 counseling apps, 20 (54%) apps made explicit claims about information security measures. All of the counseling apps provided some kind of online consultation, which meant that staff was available online to give users feedback and consultation. Counseling by text-based messages was used in 34 (92%) apps. Users could voice-chat with staff in 26 (70%) apps. Of the 37 counseling apps, 20 (54%) provided services to make an appointment with a counselor and 4 (11%) provided services to register appointments at hospitals; 36 (97%) had professionals acting as consultation providers (eg, psychologists, psychotherapists, or psychiatrists), and only 1 (3%) app provided consultation by a trained lay health supporter.

Assessment Apps

Of the 50 assessment apps, 30 (60%) apps provided information about the affiliations of their developers and all were developed by companies; 44 (88%) were free to use, and the other 6 (12%) were free to download but charged a fee for some of the assessments that were offered. All apps were aimed at adults, and 3 (6%) apps were specifically for women. Only 5 (10%) apps made a claim about information security. Evidence-based scales were used in 17 (34%) apps (some had more than 1 type—12 assessed personality, 8 assessed emotional symptoms, and 1 assessed cognitive ability). The most popular validated questionnaires were the Eysenck personality questionnaire [33,34] used in 8 apps and the Sixteen Personality Factor Questionnaire [35,36] used in 4 apps. The Self-Rating Anxiety Scale [37,38] and Self-Rating Depression Scale [39,40] were used to assess anxious and depressive symptoms in 10 apps. The other 33 (66%) apps were mainly aimed at providing some form of entertainment; they assessed fortunes, mental age, marriage and love, and occupational abilities using assessment items of unknown source.

Stress Relief Apps

All 12 stress relief apps were developed by companies; 3 (25%) apps were free, and 9 (75%) apps were free to download but charged a fee for some of the content. Of the 12 stress relief apps, only 1 (8%) app made a claim about information security. Of the 12 stress relief apps, 9 (75%) provided evidence showing that meditation is an effective method to relieve stress. Audio was the main medium used in stress relief apps; of the 12 stress relief apps, 1 (8%) app played audio recordings of methods to maintain mental stability from the *Huangdi Neijing* (an ancient Chinese medical text that has been treated as the fundamental doctrinal source for Chinese medicine for more than two millennia), 1 (8%) provided audio of mood control courses, 2 (17%) provided nature sound recordings, and 7 (58%) apps provided audio recordings of guided meditations. Of the 12 stress relief apps, 2 apps (17%) were specifically aimed at children and adolescents and focused on improving their concentration and memory and on relieving examination anxiety, and only 1 (8%) provided an online community function, allowing users to communicate with each other to relieve stress. Meditation apps used different techniques such as respiration exercises (5/7, 71%), gradual relaxation exercises (7/7, 100%), and biofeedback therapy (1/7, 14%).

Psychoeducation Apps

All 24 psychoeducation apps were developed by commercial companies. Of the 24 psychoeducation apps, 23 (96%) were for adults of which 4 (17%) were targeted at mental health professionals and provided training courses or e-books about mental health, and the other 19 (79%) were aimed at the general population to provide education and knowledge about psychology and mental health. All of these apps were free to download; however, 3 of the apps for professionals charged a fee for some of the courses in the apps. None of the psychoeducation apps made a claim about data security. Of the apps aimed at the general population, 11% (2/19) were e-books about behavioral psychology and general psychology, 5% (1/19) provided a list of psychological website links, 5% (1/19) provided audio recordings about mental health, 5% (1/19) provided case descriptions showing users the how mental health disorders can manifest, 5% (1/19) provided information about the diagnostic process of mental health disorders, and 74% (14/19) apps included psychological popular science articles, in which common mental health problems in parenting, in the workplace, and in marriage and love were covered, and coping methods were described. We scanned the articles in the 14 apps to check whether they referred to any of the eight aspects of mental health information and found that 10 out of 14 referred at least one aspect, and 9 out of 14 apps covered all of the eight aspects.

Table 3. The characteristics of apps in different categories.

Content characteristics	Counseling (n=37), n (%)	Assessment (n=50), n (%)	Stress relief (n=12), n (%)	Psychoeducation (n=24), n (%)	Multipurpose (n=49), n (%)

^aThese subheading values do not add to n or 100% because it was possible for an app to assess more than one aspect.

^bThese subheading values do not add to n or 100% because it was possible for an app to address more than one item.

Multipurpose Apps

Of the 49 multipurpose apps, 44 apps (90%) provided affiliation information; 1 (2%) was developed by the Institute of Psychology of Chinese Academy of Sciences, and the other 43 (88%) were developed by companies. Of the 49 apps, 38 (78%) were mainly aimed at adults, 7 (14%) were for individuals of any age, and 4 (8%) were for children and adolescents. Of the 38 apps for adults, there was an app (*Guan Ai ++*) for people in the workplace, an app (*Guan Ai Ji Ceng Gan Bu*) for community-level officials, and an app (*Hao Xin Qing*) that had a version for clients and a version for clinicians. Of the 49 multipurpose app, data safety claims were found for 20 (41%) apps. All the multipurpose apps could be downloaded for free, but users were charged an additional fee for some content in 39 apps (80%). Most multipurpose apps (45/49, 92%) involved professional staff, evidence-based therapies, or references to evidence-based materials.

Consulting, assessment, psychoeducation, and stress relief were combined in 5 (10%) multipurpose apps; consulting, assessment, and stress relief were combined in 2 apps (4%); consulting, assessment, and psychoeducation were combined in 19 (39%) apps; none combined counseling and assessment; counseling and psychoeducation were combined in 5 (10%), assessment and stress relief were combined in 2 (4%), assessment and stress relief were combined in 2 (4%), and stress relief and psychoeducation were combined in 3 (6%).

Of the 49 multipurpose apps, 39 apps (80%) provided some kind of online counseling; with the exception of 2 apps, counseling services were provided by mental health professionals (31 apps involved a psychologist or psychological therapist; 6 apps involved a psychiatrist). In several apps, users could choose which professional to have counseling with, after looking through the profiles of listed professionals. Depending on the app, users could contact the professional by telephone, online video or voice chat, text-based messages, or they could

make an appointment with the professional; users had to pay a fee, depending on the price of the listed professional. Two apps offered online consults with a professional but also included a system to make an appointment with a professional at a hospital. One app (*Hao Xin Qin doctor version*) aimed to help professionals to manage their clients online.

Of the 49 multipurpose apps, 41 apps (84%) had some sort of assessment functionality; 80% (33/41) used evidence-based self-report questionnaires to evaluate personality (2 used the Eysenck personality questionnaire, and 1 used the Sixteen Personality Factor Questionnaire), anxiety (14 apps used the Self-Rating Anxiety Scale), and depression (26 apps use the Self-Rating Depression Scale, 1 app uses the Hamilton depression rating scale [41], and 1 used the Symptom Checklist-90 [42]), or social phobia (items from the Liebowitz social anxiety scale)[43]. Some entertainment assessments such as fortune, love, and marriage were also included in 23 apps. None of the apps aimed to assess intelligence or cognitive abilities.

Of the 49 multipurpose apps, 14 (29%) of the multipurpose apps had stress relieving sections and provided audio recordings of relaxing music or meditation guidance, and 36 apps provided either psychoeducation articles or audio recordings related to the eight key aspects of mental health knowledge.

There were 4 (8%) multipurpose apps specifically for children and adolescents; 1 app (*jie you nuan xin mao*) focused on assessing everyday mood, providing counseling services, and had the option for discussion with fellow users; 1 app (*xin li mei*) was developed specifically for students in a specific region's primary and secondary schools, providing multiple services including assessment, stress relief, counseling, and making appointments with a teacher-counselor; 1 app (*Q xin li*) provided counseling, questions and answers, microlectures, and psychoeducational articles for users; and 1 app (*Gao kao jian ya bao*) was developed to help students to reduce stress

induced by college entrance examinations by providing counseling, stress-reducing music, and assessment.

Discussion

Principal Findings

To our knowledge, this is the first study to search and evaluate the contents of the full range of available and most widely used mental health smartphone apps in China. Evaluation of each of the apps showed different primary aims, with most focusing on assessment, counseling, and a combination of multiple purposes (ie, assessment, counseling, stress relief, and psychoeducation). Most apps were developed for profit and focused on the adult population. Only 6 apps were specifically aimed at children or adolescents. A majority of the apps provided counseling or assessment, often enlisting online psychological counseling services from professionals such as psychologists, psychotherapists, or psychiatrists; however, even though psychometrically valid assessments of personality, anxiety, and depression were included in some assessment apps, assessments in most apps were more for entertainment than for assessment of psychiatric symptoms. Audio-recordings to guide or accompany meditation were the main materials provided by the apps that focused on stress reduction. Most psychoeducation apps provided information that aligned with national guidelines on mental health information.

Evaluation of the target populations for the reviewed apps provided clear insight into the perceived market opportunities by app developers. This study showed that developers of mental health apps prefer to target the general population rather than patients with mental health disorders: No reviewed app focused specifically on patients with mental health disorders. In addition, although there was a small number of mental health apps for specific adult populations (eg, women, workplace, staff) or for mental health professionals, most apps were aimed at a broad audience. This is understandable given that most developers will want to acquire as many users for their app as possible, but this does leave room for apps that focus on assisting patients with mental health disorders. Interestingly, only a few apps were developed for children and adolescents. This does not reflect the current situation, where the prevalence of mental health disorders in children and adolescents in China lies close to the high worldwide prevalence of 20% [44]. In fact, the mental health of children and adolescents is a point of attention for both policy maker and researchers [45]. The fact that app developers have largely ignored this population could be due to various reasons. For instance, app developers may be put off by worries in the public about negative effects induced by mobile phone use [46]. In addition, children and adolescents may be a less attractive market because many parents and schools impose time restrictions on smartphone use by children and adolescents [47].

Few apps provided special interventions for patients with mental health disorders. This may partly be motivated by market considerations (ie, smaller target user population), but could also reflect the current lack of consensus about evidence-based guidelines for mHealth therapy for mental health patients. There is a large body of international literature about the use of

mHealth interventions for people with mental health disorders [11,48-50] and similar work has been carried out in China [51]; however, the development of smartphone-based therapy is still in quite an early phase, and it may indeed be too early to offer it outside an experimental or academic mental health care setting. At this point, there is still a long way to go, both in terms of app development and efficacy evaluation, before evidence-based mHealth therapy can be routinely offered to patients in China.

With the exception of one, all apps could be downloaded for free; however, the actual cost of the services offered depended strongly on what was provided in the apps. In this study, more than 70% of the counseling apps, stress relief apps, and multipurpose apps charged a fee for some services, whereas a large part of the assessment apps and psychoeducation apps were free to use. This might be because counseling apps, stress relief apps, and multipurpose apps involved more user-specific services, offered either by paid professionals or as part of evidence-based stress relief methods that require a larger initial investment from the developer than, for instance, the inclusion of articles about mental health or the use of questionnaires that have developed by others. The cost of certain services in apps might present an obstacle for users, but this issue was not within the scope of this study.

Assessment was the most popular function across all apps; there were 49 assessment apps and 41 multipurpose apps that had an assessment section; however, most assessment apps (or sections) focused on assessment as a form of entertainment rather than on the assessment of real psychological problems or characteristics. Most multipurpose apps that also included counseling and stress relief sections, used assessments with psychological scales, whereas entertainment assessments were included in most single purpose assessment apps. Assessments of personality, anxiety, and depression were most common in apps that used psychological assessment scales, which makes sense given the high prevalence of anxiety and depression in China [3,4] and aligns with previous observations that people with anxiety and depression often do not seek help from professional institutes or physicians [52]. It could be that this group is relatively more likely to use a freely available mobile app for self-assessment.

Psychological counseling was the second most popular service and was provided in all 37 counseling apps and in 39 multipurpose apps. Psychologists were the main providers of counseling. Only 16 apps involved psychiatrists as providers of counseling. This indicates that psychologists in China play an important role in delivery of mental health care to the general population. This could be due to their larger number, which makes it easier for users to find a psychologist for mental health services. Indeed, in 2017, it was estimated that approximately 40,000 people in China held a national second- or third-level certificate in psychological counseling and provided psychological counseling on either a full- or part-time basis [53]. In contrast, the number of certified psychiatrists in China (in 2015) was 27,733. Another explanation for the relatively large number of psychologists involved in the reviewed apps could be that regulation in China leads psychologists and psychiatrists working in different settings. Psychologists work

in a broad range of settings, whereas all psychiatrists in China need to be registered to a mental health hospital or psychiatric ward in a general hospital that provides inpatient service [5]. According to the Mental Health Law of the People's Republic of China [54] psychologists should only perform counseling and are not authorized to perform psychotherapy, nor engage in the diagnosis or treatment of mental health disorders. If psychologists detect that a person receiving counseling may suffer from mental health disorders, he or she should recommend that the person seek services at a medical institute. As such, online counseling is a good way for psychologists to perform initial counseling in population-dwelling persons; however, it is currently hard to estimate the effectiveness of online psychological counseling by psychologists in China because of serious problems with the level of professionalism of psychological counseling (low performance levels, a lack of norms, and uneven levels of training and expertise across consulting staff) [55]. Unfortunately, we did not have any access to information about the kinds of problems users seek treatment for via the apps, nor did we have insight into the number of users that should be and the number that were, in fact, referred to medical care by consulting psychologists.

Another important finding was that most mental health apps simply served as a means to connect help seekers to health care providers, but did not use digital technologies (such as interactive computer-guided treatment algorithms) to deliver mHealth interventions that could (partly) replace a health care provider. This is not a problem per se, but it means that existing apps are unlikely to solve the current problem of insufficient mental health care providers for the demand in China. To achieve that, apps that can (partially) provide services that would otherwise be provided by health care professionals should be developed. More and more apps are being developed that offer a completely digital interactive therapy environment. For instance, cognitive behavior therapy-based mHealth apps have been developed for a large range of mental health problems, and the efficacy of such interventions has been confirmed in several studies [56-60]. To the best of our knowledge, such apps have not yet been developed for the Chinese population, nor have they been tested.

This study showed that meditation was the main intervention offered by apps that aim to help users relieve stress. Previous studies [61,62] have, indeed, shown that meditation supported by online tools can have a significant beneficial effect on depression, anxiety, and well-being and a large effect on stress. This seemed to be at least partially supported by the evidence-based nature of these apps; however, no research exists on the efficacy of mobile app-assisted meditation, specifically in China.

Most psychoeducation apps covered one or more of the eight core aspects of mental health information that have been proposed as part of national policy. As a result, the apps were usually quite complete and accurate in their information coverage. The fact that some psychoeducation apps were downloaded more than 100,000 times (eg, the app *geilixinli* had been downloaded 780,000 times, and the app

xinlizixunyiidianling had been downloaded 580,000 times), indicates that mHealth psychoeducation can play an important role in disseminating mental health knowledge, which in turn could help reduce levels of depression and psychological distress [63,64].

Limitations

This study has some limitations. First, we could not obtain the number of downloads for all apps because the iOS app store does not provide this information. In addition, even for the apps for which the download numbers were known, we could not be sure about the number of persons who actually used the app. Second, we based the evaluation of the apps on quite a superficial screening the app appearance and the information delivered by the developers. We did not check and cannot be sure that all services (eg, contact with certified professional) are provided as claimed and that all apps function correctly. Third, we evaluated if apps made any statements or claims about data safety, but could not evaluate if they, in fact, handled data securely. Fourth, we chose a set of search terms to make sure that we included many relevant apps; however, it is still possible that we missed some potentially relevant apps. Fifth, we did not carry out a formal evaluation of each app's quality as this was outside the scope of this study. This study looked at the landscape of services and functionalities that are provided by the apps and evaluated their potential to contribute to mental health care development; however, app quality is also an important factor in determining an app's usefulness. An interesting possibility for future studies could be to use a standardized measure to assess and compare the quality of individual apps (eg, the mobile app rating scale [65]); indeed, the mobile app rating scale has been used to evaluate the quality of mobile apps in other health-related fields in China [66]. Proper translation and validation of scales such as the mobile app rating scale in Chinese would be extremely useful for the systematic evaluation of mental health care apps. Sixth, all available apps were evaluated as of December 2018. Apps that have been newly added since then have not been included in this study; however, a new search (May 23, 2020) for the top 100 apps in the three Android app stores revealed that only 9 apps had been added since the initial search, making it unlikely that the current results and conclusions would have been significantly affected by their inclusion.

Conclusions

This study uncovered a large number of mental health apps available in China. The results show that there is a large variety in the aims and evidence-base among the apps. A considerable number of apps contained useful and evidence-based elements, such as good quality information about mental health, validated questionnaires, useful meditation methods, and access to counselors, which makes it likely that they can contribute positively to mental health care in China; however, for mental health care apps to substantially contribute, considerable challenges remain, including the need for more patient-focused and child- and adolescent-focused apps, the development of apps that can take over some of the roles of a health care provider, and efficacy studies.

Acknowledgments

This study was supported by a grant from the Tianjin Health and Family Planning Commission (the name has now been changed into Tianjin Health Commission) to the Tianjin Key Programs for Science and Technology Development in Health Industry (No. 13KG119).

Authors' Contributions

HY, GX, and RAS designed the study. HY, YW, NW, WC, and YZ downloaded the apps and collected data. HY analyzed the data. HY and KJW wrote the initial draft of the paper. All authors read, contributed to, and approved the final manuscript.

Abstract

Background: Influenza epidemics result in a public health and economic burden worldwide. Traditional surveillance techniques, which rely on doctor visits, provide data with a delay of 1 to 2 weeks. A means of obtaining real-time data and forecasting future outbreaks is desirable to provide more timely responses to influenza epidemics.

Objective: This study aimed to present the first implementation of a novel dataset by demonstrating its ability to supplement traditional disease surveillance at multiple spatial resolutions.

Methods: We used internet traffic data from the Centers for Disease Control and Prevention (CDC) website to determine the potential usability of this data source. We tested the traffic generated by 10 influenza-related pages in 8 states and 9 census divisions within the United States and compared it against clinical surveillance data.

Results: Our results yielded an r^2 value of 0.955 in the most successful case, promising results for some cases, and unsuccessful results for other cases. In the interest of scientific transparency to further the understanding of when internet data streams are an appropriate supplemental data source, we also included negative results (ie, unsuccessful models). Models that focused on a single influenza season were more successful than those that attempted to model multiple influenza seasons. Geographic resolution appeared to play a key role, with national and regional models being more successful, overall, than models at the state level.

Conclusions: These results demonstrate that internet data may be able to complement traditional influenza surveillance in some cases but not in others. Specifically, our results show that the CDC website traffic may inform national- and division-level models but not models for each individual state. In addition, our results show better agreement when the data were broken up by seasons instead of aggregated over several years. We anticipate that this work will lead to more complex nowcasting and forecasting models using this data stream.

Introduction

Background and Motivation

Every year, an estimated 5% to 20% of people in the United States become infected with influenza [1]. The typical influenza season begins in October and ends in May, with the peak occurring in the winter months. Annually, 3000 to 50,000 people die from the flu, with another 200,000 people requiring hospitalization [2]. The yearly flu burden is estimated to cost around US \$11.2 billion in lost productivity, with some estimates as high as US \$87 billion [2,3]. Timely surveillance of influenza can help reduce this burden, allowing health care facilities to more adequately prepare for the influx of patients when flu levels are high [4].

One common surveillance measure is the fraction of patients presenting with influenza-like illness (ILI), consisting of a fever of at least 100°F (37.8°C) and a cough or sore throat with no other known cause [5]. ILI data are collected from about 2900 volunteer health care providers throughout the United States, although each week, only about 1800 of them report their data. These data are then aggregated and made public after a time lag of about 1 to 2 weeks [1,6-10]. As the ILI data are collected from volunteer health care providers, the dataset is incomplete. If policies were enacted to provide incentives for health care providers who report these data or to make reporting compulsory, the result would be a more complete dataset. Other surveillance systems include virological data from the World Health Organization, emergency department visits, electronic health records, crowd-sourced ILI reports, Widely Internet Sourced Distributed Monitoring, Influenzanet, and Flu Near You [11,12].

Internet Data Streams

In the United States, 87% [13] of adults use the internet. Of those internet users, 72% [13] have used the internet to search for health information within the last year. The most common health-related searches are for information regarding a specific disease or condition (66%) and information about a specific treatment or procedure (56%) [13,14].

There are two main types of health-related internet activity. The first is health sharing, in which internet users post about health-related topics (eg, a tweet about being sick). The second is health seeking, in which users use the internet to obtain information about health-related topics [6]. In this paper, we focused on health-seeking behavior. Previous studies have shown that analyzing web-based health-seeking behavior can improve early detection of disease incidence by detecting changes in disease activity [9,15-19]. Similarly, other studies have shown that internet data emerging from search queries can aid detection of outbreaks in areas with large populations of internet users [20] because web-based health-related search queries and epidemics are often strongly correlated [20,21].

Internet data have been used to forecast disease incidence in other models. Polgreen et al [9] developed linear influenza forecasting models with lags of 1 to 10 weeks for each of the 9 US census regions using search queries from Yahoo [9]. The best performing models had lags of 1 to 3 weeks and an average

r^2 value of 0.38 (with a high of 0.57 in the East South Central region) [9]. These low r^2 values demonstrate potential problems in relying on search information alone. Ginsberg et al [15] were able to predict influenza epidemics 2 weeks in advance using Google search queries to fit linear models using log-odds of ILI visits and related searches.

Using a Poisson distribution and Lasso regression, McIver and Brownstein [8] obtained an r^2 value of 0.946 using Wikipedia data, although some data were excluded from analyses because of increased media attention and higher than normal influenza activity. Generous et al [7] used Wikipedia data to train a statistical model with linear regression, which demonstrated its potential for forecasting disease incidence worldwide, including influenza in the United States, which had an r^2 value of 0.89. Hickmann et al [1] conducted a similar study of linear regression models, which showed that using Wikipedia to forecast influenza in the United States for the 2013 to 2014 season resulted in an r^2 value greater than 0.9 in some instances.

Integrating both Wikipedia data and Google Flu Trends, Bardak et al [22] obtained r^2 values of 0.94 and 0.91 using ordinary least squares (OLS) and ridge regression, respectively, for forecasting influenza outbreaks. For OLS nowcasting, the r^2 value was 0.98 in the best case. For the best fit, the weekly data were offset by 1 week, so that ILI visits were correlated with internet data from the prior week [22].

As part of the Centers for Disease Control and Prevention (CDC)'s 2013 to 2014 Predict the Influenza Season Challenge, 9 teams used digital data sources to create forecasting models. The digital sources these teams used were Wikipedia, Twitter, Google Flu Trends, and HealthMap. The teams used either mechanistic or statistical models to create their forecasts, with the most successful team using multiple data sources, which may have reduced biases usually associated with internet data streams [23]. Broniatowski et al [24] used Twitter data to detect increasing and decreasing influenza prevalence with 85% accuracy. Zhang et al [25] used Twitter data to inform stochastically, spatially structured mechanistic models of influenza in the United States, Italy, and Spain.

Internet data streams have also been used to supplement traditional surveillance techniques with nowcasting models. Paul et al [26] used Twitter along with ILI data from the CDC to produce nowcasting influenza models as well as nowcasting models using solely ILI data. They concluded that the addition of Twitter data led to more accurate nowcasting models. Santillana et al [27] combined Google Trends data and CDC-reported ILI data to create models for nowcasting and forecasting influenza. Lamos et al [28] used search query data to explore both linear and nonlinear nowcasting models. Yang et al [29] used Google search data to create an influenza tracking model with autoregression.

In contrast, we considered data on page views of the CDC website rather than search data from sites not solely devoted to public health. We used this dataset because we expect it to be inherently less noisy because of its focus on public health issues. We used OLS to nowcast influenza nationally, across the 9 US

census divisions, and across 8 states using access data from 10 influenza-related CDC pages. Our nowcasting models cover influenza seasons from 2013 to 2016, with the 2012 to 2013 season being partially included because the CDC page view dataset begins on January 1, 2013. The inclusion of an incomplete influenza season serves to inform if this dataset can be used given a more restrictive time frame. We included both positive and negative results to advance our knowledge regarding when internet data may or may not work. The negative results are crucial to advancing the field of disease surveillance using internet data, as they demonstrate when these data sources contribute to unreliable surveillance. We focus on answering the following two research questions: (1) Can CDC page visits be used as an additional data source for monitoring disease incidence? and (2) What is the appropriate time shift of the page view data needed to obtain the best data fit?

Methods

Data Sources

We used page view data provided by the CDC. Each data point contains the page name, date and time of access, and the geographic location from where the page was viewed. These data are available at geographic resolutions of national and state levels and include some metropolitan areas (eg, New York City). The data are available at a number of temporal resolutions beginning on January 1, 2013. For these models, we used weekly page view data to coincide with the ILI data temporal resolution. The data are available as raw page view counts and page view counts normalized with respect to all CDC page views, and we considered the latter for this work. We selected pages associated with general influenza information, treatment, and diagnosis. Pages were sometimes renamed, but we were able to follow the evolution of each selected page by using keywords in the page titles as well as the date ranges for available data.

As the majority of health-related internet searches concern specific conditions, treatments, and procedures [14], we selected pages related to those topics. These pages also align with the study by Johnson et al [30], who used pages in the categories of diagnosis and treatment as well as prevention and vaccination for influenza surveillance [30]. Specifically, we used the following pages: antivirals, flu basics, FluView, high risk complications, key facts, prevention, symptoms, treating influenza, treatment, and vaccine. We then aggregated the page views of interest for each of our models. FluView has the potential to be an outlier page, especially when used alone, as

this page tracks the severity of the influenza season and could have higher page views as a result of media attention and severe influenza seasons. However, when combined with other pages focused on treatment and prevention, we expected these page view data to be useful for our models. A complete list of pages can be found in [Multimedia Appendix 1](#).

The states we selected were based on the severity of flu (determined from FluView) during the available seasons and the availability of ILI data at the time of the study, which is not standardized and is dependent on each state's reporting mechanism. ILI data for each state include the week ending or starting date and the percentage of ILI for the specified week. Although some states also report additional data, such as school closures and hospitalizations, these data are not made available by every state. Note that ILI reporting and accessibility vary across all states. The states we selected were (1) California, (2) Maine, (3) Missouri, (4) New Jersey, (5) New Mexico, (6) North Carolina, (7) Texas, and (8) Wisconsin. With the exception of Texas, these states did not release ILI data outside of the typical flu season. As the purpose of this study was to demonstrate the viability of nowcasting, we considered only those ILI data available during the study period. Although some states have made their ILI more accessible since the end of the study, we did not consider these data, as they were not available during the study period. The exclusion of additional data not available during the study period helps to preserve the premise of nowcasting by focusing only on data sources available during the study period. Likewise, our state ILI data often came from the state's individual weekly reports during the seasons used in the study. A complete list of the data sources for the state ILI can be found in [Multimedia Appendix 2](#), and the clinical data are available in [Multimedia Appendices 3 and 4](#).

[Figure 1](#) shows the percentage of ILI visits for each state considered in this study and the national percentage of ILI visits. We see distinct spikes that indicate the peaks of the flu seasons. With the exception of Maine, which behaves as an outlier at times, the figure shows spikes indicating there are peak weeks for influenza-related page views. Texas also exhibits outlier behavior with ILI percentages consistently higher than the typical national baseline of 2%, which is used to determine when the flu has reached epidemic status. These 2 outliers are shown in teal (Texas) and dark blue (Maine). The national ILI is shown in black. The remaining states exhibit behavior consistent with the national ILI trend. [Figure 2](#) shows the CDC page view data as a heat map: weeks with more page views are shown darker than weeks with fewer page views.

Figure 1. Percentage of ILI visits per state compared with the typical national baseline of 2%. Maine (dark blue) and Texas (teal) exhibit outlier behavior, with Texas having a greater ILI percentage and Maine having a lesser ILI percentage. The remaining states follow the national ILI trend, shown in black. ILI: influenza-like illness.

Figure 2. Normalized CDC web traffic as a heat map. Darker areas indicate more page views and appear to correlate with increases in influenza-like illness. The page views also appear to be more prevalent during the typical influenza season, October to May. CDC: Centers for Disease Control and Prevention.

In addition to selected states, we also considered the 9 US census divisions: New England, Middle Atlantic, East North Central, West North Central, South Atlantic, East South Central, West South Central, Mountain, and Pacific. [Multimedia Appendix 5](#) provides a list of states included in each division. Data for the census divisions were obtained from the CDC and are presented in [Multimedia Appendix 3](#).

Linear Regression

We used statsmodels version 0.9.0 [31], a statistical analysis module for Python, to perform linear regression on our datasets using OLS. This creates a linear model M , the summation of regression coefficients multiplied by page view data. [Figure 3](#) shows the mathematical formula of M , where β are the regression coefficients and $X=1, X_1, \dots, X_n$ is the vector of CDC page view data, with n representing the number of CDC pages used for the model, ranging from 1 to 10. M is a value between 0 and 1, representing the fraction of ILI visits. To plot the models and data on the same axes, we normalized M for visualization purposes, with $M=1$ corresponding to the ILI percentage during the peak week of the influenza season. We correlated ILI and CDC page views for the same week or with

a 1-week shift. In the shifted cases, we shifted the ILI data forward by 1 week, so that the model associates the current week's page views with the following week's ILI data. This shift is performed to account for the incubation period of influenza and the time between the onset of symptoms and the first doctor visit. Statsmodels [31] uses the CDC page view and ILI data to determine the appropriate regression coefficients; fits parameters with OLS; and computes the goodness-of-fit, r^2 , also referred to as the coefficient of determination. The r^2 value measures how well 2 time series correlate. An r^2 value of 1 indicates a perfect fit, whereas an r^2 value of 0 indicates no correlation. Although r^2 is not necessarily the best metric to judge goodness-of-fit [6], it is nonetheless the most common metric used and still provides one with a decent overall sense of fit quality. In addition, we examined the root mean square error (RMSE) and the normalized root mean square error (NRMSE) using Python scikit-learn libraries. The RMSE and NRMSE metrics measure how the model prediction differs from the actual data, with the NRMSE normalized so that the greatest possible value is 1. For these metrics, lower numbers indicate a better fit.

Figure 3. Mathematical formula of the linear ILI models created in this study. The model M represents the fraction of ILI visits, where α_i are the regression coefficients and $X=1, X_1, \dots, X_n$ is the vector of CDC page view data, with n representing the number of CDC pages used for the model, ranging from 1 to 10. ILI: influenza-like illness; CDC: Centers for Disease Control and Prevention.

$$M = \sum_{i=0}^n \alpha_i X_i$$

Results

Format of Results

We analyzed the data at the national, division, and state levels and computed r^2 for each geographic resolution. In this section, we discuss the results of our experiments, both successes and failures. We include figures of models at the national, census division, and state levels. Owing to the varying scales between page views and ILI percent, we chose to normalize the data and our models to plot them on the same axes. Raw data were used to create the models and then each model was normalized with respect to its maximum. We also normalized the ILI data and CDC web traffic data with respect to their maximums for the given period so that all 3 curves may appear in the same plot. Additional model successes and failures not discussed here can be found in [Multimedia Appendix 6](#).

National Results

We selected pages that corresponded to the topics most often searched during web-based health-seeking activities. Aggregating all 10 pages in a single model, we were able to achieve an r^2 value of 0.889 for the national 2012 to 2013 influenza season after implementing a 1-week shift. We also succeeded in modeling the national 2015 to 2016 influenza season with no shift, achieving an r^2 value of 0.834. We obtained better results when limiting the pages to FluView, Symptoms, and Treatment, which we attribute to the information on these pages aligning with topics most commonly used for internet health seeking. For these pages, the most successful models did not have a shift. For the 2012 to 2013 influenza season, we achieved an r^2 value of 0.906. The model for the 2015 to 2016 season had an r^2 value of 0.891. [Table 1](#) shows the most successful model for each influenza season included in this study. [Figure 4](#) shows these models, with each figure caption indicating which page(s) comprise CDC web traffic, which appears in each figure and are the data used in the model.

Table 1. Pages and shifts for the most successful models for each influenza season at the national level.

Pages used in model	Season	Shift	r^2	Root mean square error	Normalized root mean square error
FluView, Symptoms, and Treatment	2012-2013	None	0.912	0.423	0.070
Symptoms	2015-2016	None	0.892	0.213	0.060
FluView	2013-2014	None	0.802	0.510	0.111
Antivirals and Prevention	2014-2015	None	0.778	0.615	0.103

Figure 4. These plots show national models and the associated pages and influenza seasons. (A) FluView, Symptoms, and Treatment, 2012 to 2013. (B) Symptoms, 2015 to 2016. (C) FluView, 2013 to 2014. (D) Antivirals and Prevention, 2014 to 2015. CDC: Centers for Disease Control and Prevention; ILI: influenza-like illness.

Census Division Results

Using the data for each of the 9 census divisions, we were able to achieve an r^2 value greater than 0.7 for at least one case for each division. We considered all seasons together and separately, with the better results obtained from modeling each individual season. We considered all 10 pages together as well as combinations of one or more of these pages. In the most

successful case, the model was able to closely match the 2015 to 2016 influenza season for the West North Central division, with an r^2 value of 0.955 using the FluView, Symptoms, and Treatment pages. Although we had successes using all 10 pages, the most successful model for each division involved only these 3 pages. Figure 5 shows some of these models, and Table 2 highlights these successes.

Figure 5. Census division model successes using the FluView, Symptoms, and Treatment pages for the 2012 to 2013 influenza season. (A) West North Central, 2012 to 2013. (B) Mountain, 2012 to 2013. (C) East North Central, 1-week shift, 2012 to 2013. (D) Pacific, 2012 to 2013. (E) West South Central 2012 to 2013. These plots represent the census division models that had the highest r^2 value in the 2012 to 2013 influenza season. CDC: Centers for Disease Control and Prevention; ILI: influenza-like illness.

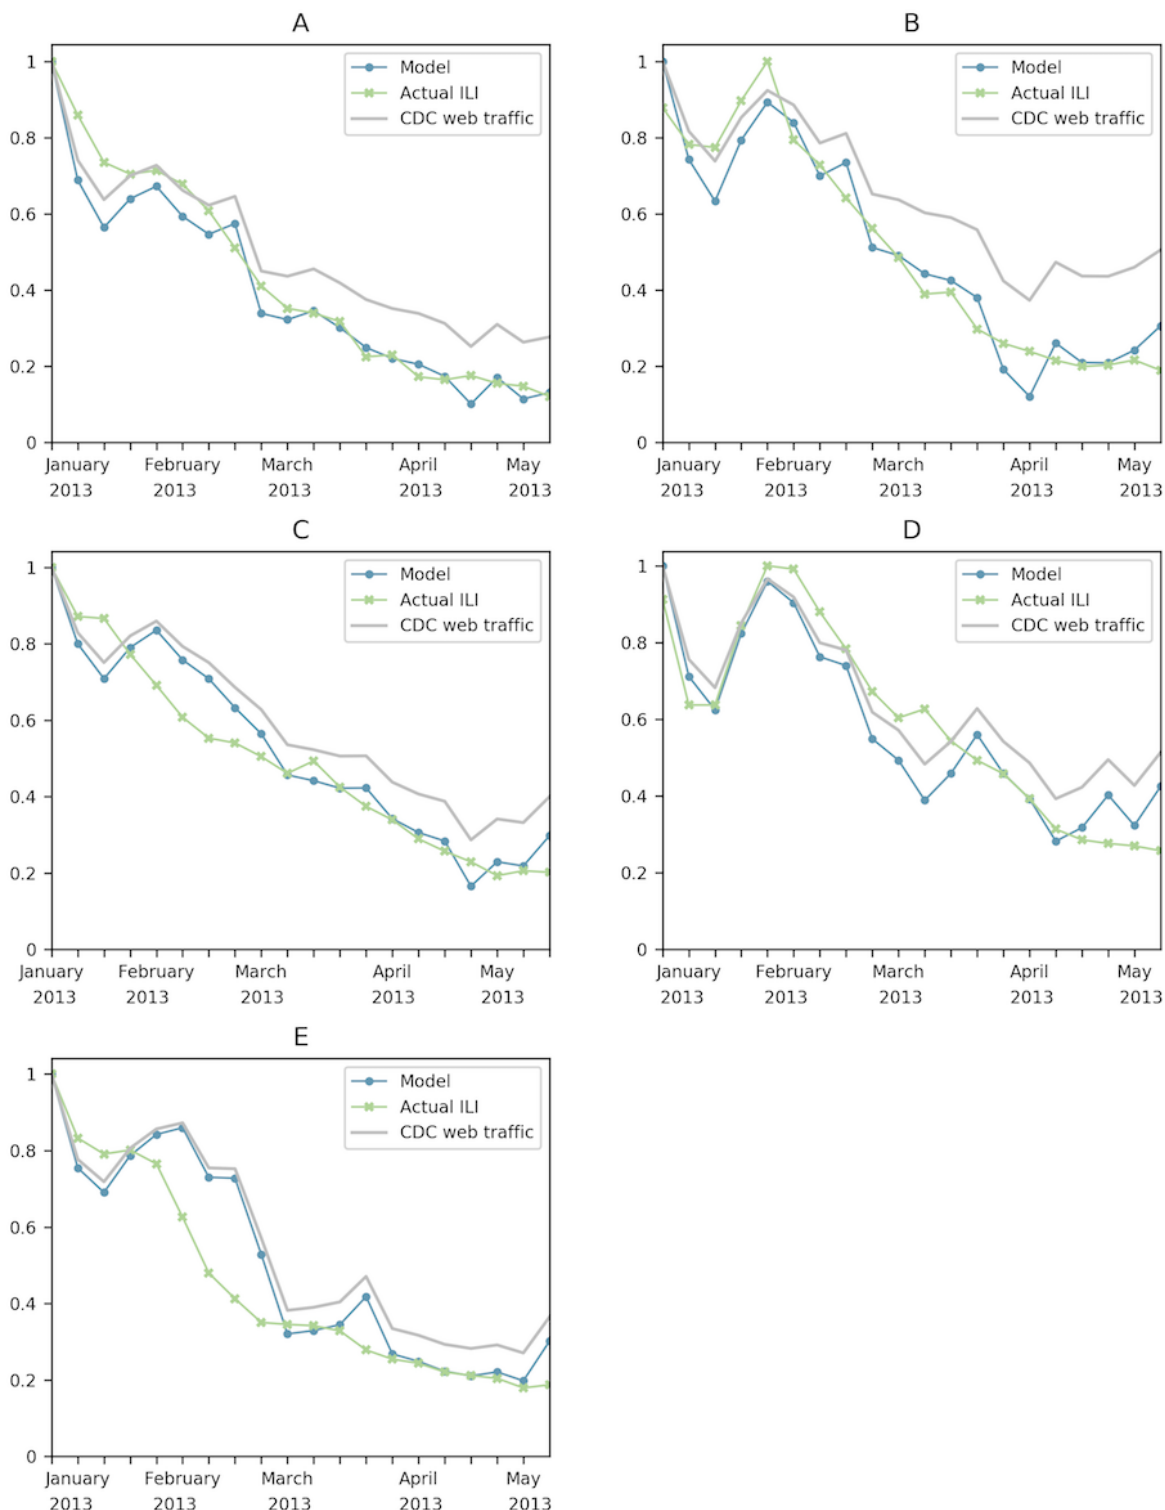

Table 2. The 9 census divisions and the season and shift for which the division's model had the highest r^2 value. The table also shows the root mean square error and the normalized root mean square error. The results presented correspond to the FluView, Symptoms, and Treatment pages aggregated.

Division	Season	Shift	r^2	Root mean square error	Normalized root mean square error
West North Central	2012-2013	None	0.955	0.367	0.057
Mountain	2012-2013	None	0.921	0.336	0.077
New England	2015-2016	None	0.920	0.096	0.096
East North Central	2012-2013	1 week	0.899	0.331	0.076
South Atlantic	2015-2016	None	0.893	0.218	0.065
Middle Atlantic	2015-2016	None	0.861	0.302	0.073
Pacific	2012-2013	None	0.849	0.503	0.094
West South Central	2012-2013	None	0.828	0.986	0.105
East South Central	2015-2016	1 week	0.793	0.365	0.082

State Results

We found r^2 for each of the states considered in this study, using a variety of pages and page combinations. Table 3 lists the most

successful models for each state, the season, the data shift, and the r^2 value.

Table 3. The most successful results for each state considered in this study.

State	Page(s)	Season	Shift	r^2	Root mean square error	Normalized root mean square error
Texas	All ^a	2012-2013	1 week	0.930	0.667	0.067
Wisconsin	FVST ^b	2012-2013	None	0.833	0.533	0.127
New Jersey	All	2012-2013	1 week	0.832	0.767	0.117
Missouri	FVST	2012-2013	1 week	0.823	0.801	0.127
North Carolina	FVST	2015-2016	1 week	0.781	0.455	0.106
New Mexico	All	2015-2016	1 week	0.771	1.184	0.197
California	FVST	2012-2013	1 week	0.758	0.777	0.125
Maine	Antivirals	2012-2013	None	0.662	0.445	0.171

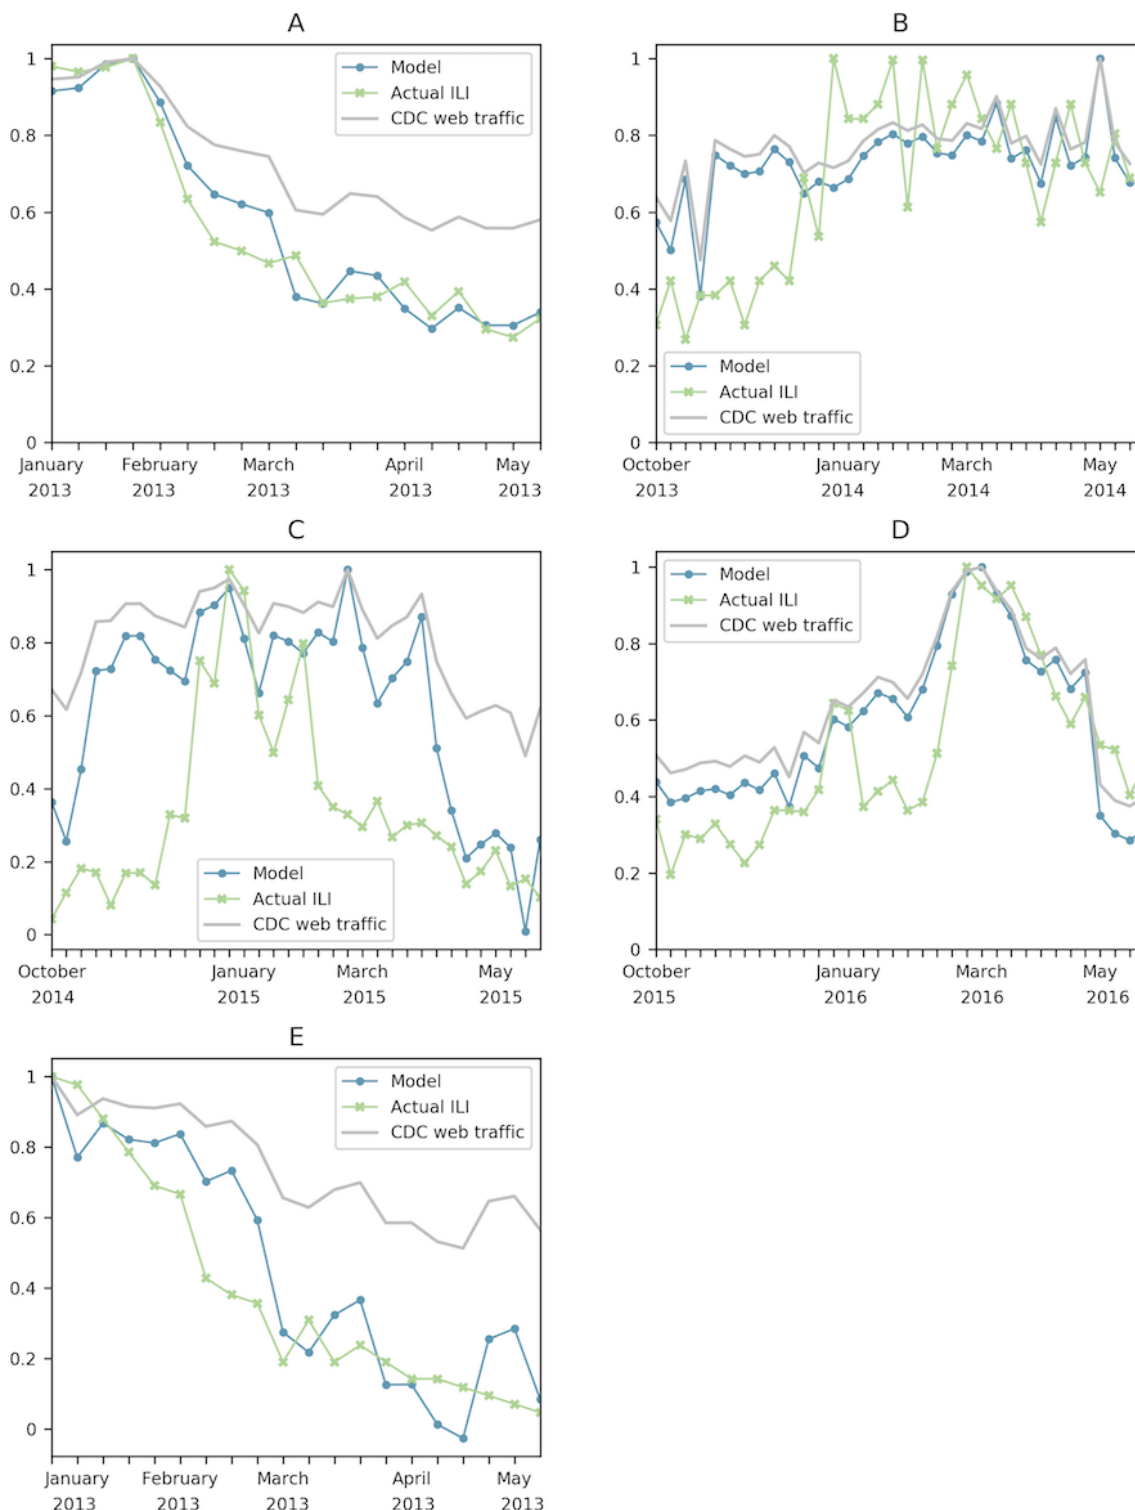

^aAll refers to the aggregation of all 10 pages.

^bFVST refers to the aggregation of the FluView, Symptoms, and Treatment pages.

Figure 6 shows both successes and failures at the state level. Adding all the pages together, we were able to obtain r^2 values of 0.930 and 0.801 for Texas and Wisconsin, respectively, for the 2012 to 2013 influenza season. For the 2013 to 2014 season,

the highest r^2 value was 0.187 for Wisconsin. For the 2014 to 2015 season, the highest r^2 value was 0.322 for Missouri. For the 2015 to 2016 season, the highest r^2 value was 0.647 for North Carolina.

Figure 6. Different states during different seasons. (A) Texas, 1-week shift, 2012 to 2013. (B) Wisconsin, 2013 to 2014. (C) Missouri, 2014 to 2015. (D) North Carolina, 2015 to 2016. (E) Wisconsin 2012 to 2013. The r^2 values of each of these models ranged from 0.187 to 0.930. These models aggregated all 10 pages, and the success varied by state. CDC: Centers for Disease Control and Prevention; ILI: influenza-like illness.

We were not surprised that Texas had the best fit. Texas was the only state we included that provided ILI data not only for the typical influenza season but also for the off-season. These additional data likely contributed to the success of the Texas models. In keeping with our nowcasting scenario, we only included data available during the study period. During that period, Texas was the only state that provided off-season ILI

data. These data have since been made available from other states, but the availability was not present during the study. The lack of success we encountered in modeling Maine was also expected because of Maine's outlier behavior in ILI, having values considerably lower and out of pattern with other states. The models in Figure 6 included all 10 pages aggregated together. However, as indicated by the individual state results,

this does not always lead to the best fit. Successful models often include a combination of select pages (such as FluView, Symptoms, and Treatment) but not an aggregation of all 10. Furthermore, aside from Texas, we did not have ILI data for the states outside of the typical flu season. Without these additional data, we are unable to determine how strongly the

lower page views in the off-season correlate with off-season ILI.

We then shifted the ILI data forward by 1 week. The regression analysis yielded 7 state/season combinations with r^2 values greater than 0.7 (Table 4). The table also includes both the regular RMSE and NRMSE.

Table 4. States with models that had an r^2 value greater than 0.7 when aggregating all 10 pages and shifting the influenza-like illness data forward by 1 week. The regular and normalized root mean square errors are also displayed.

State	Season	r^2	Root mean square error	Normalized root mean square error
Texas	2012-2013	0.930	0.667	0.067
New Jersey	2012-2013	0.832	0.767	0.117
New Mexico	2015-2016	0.771	1.184	0.197
California	2012-2013	0.746	0.797	0.129
Wisconsin	2012-2013	0.727	0.626	0.153
North Carolina	2015-2016	0.708	1.028	0.204
Missouri	2012-2013	0.702	1.039	0.165

Adding only the FluView, Symptoms, and Treatment pages, we obtained an r^2 value of 0.7 or greater for 6 state/season combinations. For the 2013 to 2014 season, the highest r^2 values were 0.612 for California and 0.568 for Wisconsin. Although this is still less than desired, it is a vast improvement from the r^2 values found from adding all 10 pages. For the 2014 to 2015 season, the highest r^2 was 0.575 for Missouri. Again, although the correlation appears to be weak, it is a stronger correlation than taking all 10 pages together. Using the same 3 pages and implementing a 1-week shift, we obtained an r^2 value of 7 or greater for 10 state/season combinations. For the 2014 to 2015 season, the highest r^2 value was 0.548 for Missouri.

State Influenza-Like Illness Data Availability

The purpose of this study was to demonstrate the viability of near real-time nowcasting during the influenza seasons from 2013 to 2016. To maintain the premise of nowcasting, we chose states with publicly available data, or data available on request, during the period of the study. During the study period, state ILI data were not readily available on the CDC website. Instead, we had to rely on data available through state health-related organizations for each state. In addition, throughout the course of influenza seasons, ILI numbers are often updated as delayed data are reported and made available. However, because we are focusing our study on a nowcasting scenario, we do not consider the ILI data from those seasons as they are reported today but rather as they were reported during the study period.

Model Failures

We generally found the models to be successful when considering pages most closely related to typical health-seeking behavior and when considering each flu season individually. When trying to model multiple influenza seasons together, we had a number of unsuccessful models. Considering all pages and national ILI data, the model combining the 2012 to 2013 and 2013 to 2014 influenza seasons had an r^2 value of 0.061

and RMSE of 0.553. The combined 2013 to 2014 and 2014 to 2015 model had an r^2 value of 0.241 and RMSE of 0.208. The combined 2014 to 2015 and 2015 to 2016 model had an r^2 value of 0.251 and RMSE of 0.286. At the state level, combining all pages resulted in a number of unsuccessful models. For the 2013 to 2014 season, the Wisconsin model had an r^2 value of 0.187 and RMSE of 0.523. For the 2014 to 2015 season, the Missouri model had an r^2 value of 0.322 and RMSE of 1.845. Model failures not included in this section can be found in [Multimedia Appendix 6](#).

We speculate that a number of factors could contribute to these negative results. Although influenza is a seasonal disease, similar strains can span multiple years, affecting the susceptible populations in subsequent years. Our data stream may be biased toward individuals with more awareness of the CDC. Furthermore, individuals who search for influenza information in one season may not search for that information the next year. Finally, with the exception of Texas, we only have ILI data for the influenza season itself. Thus, although we do have internet data for off-season influenza page views, we do not have corresponding ILI data.

Discussion

Conclusions

Internet surveillance data have proven beneficial in predicting ILI incidence during flu seasons. However, our results show that the benefit of internet data streams on informing disease is inconclusive; that is, this study shows that the CDC website traffic can be informative in some cases (eg, national level) but not in others (eg, state level). To determine the extent, we must return to our original research questions.

Research Question 1

Given the successes of some of our models, we can conclude that CDC page view data can be used as an additional data

source for monitoring disease incidence in some cases (eg, at the national level). The degree to which these data can be used appears to rely on the page selection and time frame. The results of the best models varied across geographic and temporal resolutions, but some trends were consistent in most cases. We obtained successful nowcasts when selecting pages related to topics most commonly used for web-based health queries (specific diseases and treatments) during the time span of a typical influenza season. Longer time spans and pages less associated with specific diseases and treatments led to less successful models. Outlier behavior, such as the ILI data in Maine, affected our models and resulted in less successful models than states with ILI curves exhibiting expected behavior. These results can assist others in selecting appropriate supplemental datasets for disease surveillance as well as appropriate spatial and temporal resolutions.

Research Question 2

We obtained our most successful results using a 1-week shift. Moreover, 2-week shifts were successful in some cases but were overall less correlated than 1-week shifts ([Multimedia Appendix 6](#)). Using no shift at all proved successful in some cases but not in others. We surmise that the shift required for the best fit depends on the incubation period for the disease in question as well as the period of reporting. The CDC internet data are available daily; however, ILI data are available weekly, so we are limited in the types of shifts we can apply to the datasets. Another factor that could contribute to the need for a 1-week shift is the amount of time between the page view and the subsequent visit to a health care center. If there are one or more days between the page view and the visit, then these 2 events could occur during different weeks. Shifting the data by 1 week accounts for this behavior.

Future Work

We conclude that more studies on internet data streams are needed to understand when and why internet data work. Our methods are consistent with other feasibility studies and provide insight into the conditions under which internet data streams may inform influenza models. Future work should include rigorously testing the predictive power of the models by separating data into training and testing sets [6].

More studies on geographic resolution could provide a better insight into why some models outperform others at various spatial resolutions. National models across single influenza seasons performed well, with each season included in the study having at least one model with an r^2 value greater than 0.75. We attribute the national model successes to the representation of all 50 states. Internet access may not be as prevalent in all states, but the inclusion of all 50 states allows for more data to be considered. Likewise, the census division models performed well, with overall r^2 values greater than those achieved from national models. Each census division had at least one model in the study with an r^2 value greater than 0.79. We attribute these successes to not only the inclusion of all states but also the division into geographic areas. There are instances in which a person may live in one state and seek medical care in another, perhaps because of working in a neighboring state. These instances are not accounted for by simply looking at states but can be accounted for by considering several neighboring states for 1 model. At the state level, models were overall less successful than at national and census division levels, but each state considered in the study had at least one model with an r^2 value greater than 0.65, and all but Maine had models with an r^2 value greater than 0.75. We attribute the overall lower success of state models to a combination of varying levels of internet access across populated and rural areas, the possibility of people living near neighboring states seeking health care in another state, and the inconsistencies in data availability during the study period. As our study focused on using data sources available during the study, we were limited in the states we could model because of the scarcity of the data.

More studies on temporal resolution could provide a better insight into how best to model seasonal diseases over multiple seasons. Models across multiple seasons were not successful, which we attribute in part to the off-season ILI data being unavailable during the study period. As influenza is a seasonal disease, modeling multiple seasons with 1 model may not be the correct approach, and our multiseason models support this idea. However, more exhaustive studies are needed to draw definitive conclusions on the appropriate spatial resolution for modeling influenza.

Acknowledgments

This work was supported by the Los Alamos National Laboratory Information Science and Technology Institute and the National Institutes of Health, the National Institute of General Medical Sciences, and the Modeling for Infectious Disease Agent Study program under grant U01-GM097658-071. Matthew Biggerstaff of the CDC provided integral insight and support. Curt Canada and the Data Science at Scale Summer School were integral to this project. Stephen Wirkus, Abigail Hunter, and Catherine S Plesko provided recommendations and clarifications. Jonathan Woodring, David H Rogers, and Francesca Samsel provided technical and visual assistance. Los Alamos National Laboratory is operated by Triad National Security, Limited Liability Company, for the National Nuclear Security Administration for the US Department of Energy (contract number: 89233218NCA000001).

Authors' Contributions

WC, GF, and SD conceptualized the project and performed data analysis. GF performed data curation. WC wrote the manuscript. GF and SD edited the manuscript. WC created the visualizations.

Abstract

Background: News media coverage is a powerful influence on public attitude and government action. The digitization of news media covering the current opioid epidemic has changed the landscape of coverage and may have implications for how to effectively respond to the opioid crisis.

Objective: This study aims to characterize the relationship between volume of online opioid news reporting and opioid-related deaths in the United States and how these measures differ across geographic and socioeconomic county-level factors.

Methods: Online news reports from February 2018 to April 2019 on opioid-related events in the United States were extracted from Google News. News data were aggregated at the county level and compared against opioid-related death counts. Ordinary least squares regression was used to model opioid-related death rate and opioid news coverage with the inclusion of socioeconomic and geographic explanatory variables.

Results: A total of 35,758 relevant news reports were collected representing 1789 counties. Regression analysis revealed that opioid-related death rate was positively associated with news reporting. However, opioid-related death rate and news reporting volume showed opposite correlations with educational attainment and rurality. When controlling for variation in death rate, counties in the Northeast were overrepresented by news coverage.

Conclusions: Our results suggest that regional variation in the volume of opioid-related news reporting does not reflect regional variation in opioid-related death rate. Differences in the amount of media attention may influence perceptions of the severity of opioid epidemic. Future studies should investigate the influence of media reporting on public support and action on opioid issues.

KEYWORDS

opioid epidemic; news media; geographic; socioeconomic; addiction; overdose

Introduction

Each day in the United States, more than 130 people die from opioid overdose and its death toll only continues to rise [1]. The unprecedented magnitude and growth of the opioid crisis have given it a prominent place in news reporting. As mass media is a powerful influence on public opinion, monitoring trends and differences in the volume of opioid-related news stories may offer important insights for addressing this crisis.

Analyzing the content of popular news coverage is an established method for studying the public discourse surrounding health and social issues and how this discourse may influence public attitudes [2-10]. Large bodies of research have demonstrated the agenda-setting function of news media [11,12]. By focusing coverage on some topics rather than on others, news media can influence which issues audiences perceive to be more important and in more need of response. For example, an analysis of over 25 years of General Social Survey data showed that greater rates of newspaper reading and television viewing were associated with higher likelihoods of public desire of funding to be directed to addiction [6]. In another study, a time-series analysis of changing public opinion about the importance of illegal drug use in the United States showed that public views were largely driven by news media describing drug abuse as a *crisis* [7].

Of particular interest is how differences in the volume of media attention may translate into differences in government policy, funding, and resource deployment, and thereby affect particular geographic regions and social groups. For example, a content analysis of 100 popular press articles revealed that differential media coverage of whites and blacks in the opioid epidemic of the 2000s may have led to different public responses and policy interventions [13]. Another study found evidence that biased media coverage directed policy to be disproportionately aimed at specific stereotypes of drug users [14]. In these ways, the uneven landscape of opioid media reporting may play a major role in the differences in public health outcomes of the current US opioid epidemic.

As the opioid crisis is a relatively new public health problem, previous research on media coverage of the opioid epidemic in the United States is limited. Borwein et al [15] found that print news media in North America portrayed the opioid analgesic oxycodone as a social problem, which coincided with the reduction in oxycodone prescriptions by doctors in Nova Scotia, Canada, but the authors were not able to determine a causal relationship. McGinty et al [9] studied how opioid analgesic use was depicted by the US print and television media from 1998 to 2012, revealing that in the United States, the issue was commonly framed as a criminal justice problem requiring legal solutions rather than a remediable public health issue. Lillian Seklir and Lori Dorfman [5] found contrarily that in media coverage in Northern California, opioid addiction is routinely presented as both a public health and a criminal justice issue, but public health advocates and medical practitioners are largely absent from the coverage.

In this study, we developed a platform called DrugMap.org, a novel multistream real-time surveillance system that aggregates

online news reports on opioid-related events, to investigate geographic and socioeconomic differences in the volume of opioid-related news reporting and opioid-related deaths in the United States. Our study expands on current research in four important ways: (1) Our real-time data set allows us to study the most recent (2018-2019) reports to uncover relevant trends in this fast-evolving public health issue. (2) Our expanded data set includes online news sources, which are significant because 93% of US adults report reading news online [16]. (3) The scope of our study encompasses all but 4 US states (Montana, North Dakota, South Dakota, and Wyoming). And (4) we dig more deeply into news trends by associating them with epidemiological data and study how differences in socioeconomic status and geography may contribute to potential discrepancies between news media and the true nature of the opioid crisis.

Methods

DrugMap Data

News Reports Mentioning Opioids From DrugMap

News reports about opioids from February 2018 to April 2019 were collected from DrugMap.org, a multistream news archive platform we developed that captures news media data using automated scripts. Using the Google News API, DrugMap extracts all online news articles from Google News whose body text contained key opioids and opioid-related terms that were developed in consultation with medical toxicologists: *opioid*, *oxycontin*, *dilaudid*, *suboxone*, *oxycodone*, *morphine*, *methadone*, *buprenorphine*, *hydrocodone*, *heroin*, *fentanyl*, *naloxone*, *vicodin*, *percocet*, *actiq*, *duragesic*, *sublimaze*, *naltrexone*, *codeine*, *tylox*, *tramadol*, *tapentadol*, *ultram*, *percordan*, *robitussin*, *demerol*, *roxicet*, *avinza*, *butrans*, *dolophine*, *embeda*, *exalgo*, *nucynta*, *opana*, *kadian*, *oxymorphone*, *levorphanol*, *dihydrocodeine*, and *zohydro*. Although we included a detailed list of terms, this search list may not be fully comprehensive. We did not limit search topics to opioid drug overdose or deaths and included all opioid-related news, in line with previous drug news studies that modeled drug epidemics based on volume of all media related to the drug of interest [17].

Geographic coordinates (latitude and longitude) were assigned to each report using a previously established geolocation engine, CLIFF-CLAVIN, a text mining tool that parses news articles to retrieve place mentions [18]. The location where the reported opioid-related event occurred was determined using place names mentioned in the news report text. US county information was derived by inputting latitude and longitude into the census geocode Python library [19].

The number of opioid-related news reports retrieved from DrugMap was 92,124, spanning from February 7, 2018 to April 8, 2019. Duplicate online news reports, news reports with the same body text and URL, and articles in geographies outside the United States were excluded. News reports that reported a granularity larger than state level (eg, New England) were also removed from the analysis as these articles could not be defined to a specific county. After data cleaning, the total number of

reports mentioning opioids was 35,758 and represented all 50 states and 1789 unique counties. The data covered 56.93% (1789/3142) of all US counties. Of the 1789 counties represented by the DrugMap data, 14.76% (464/3142) also contained Centers for Disease Control and Prevention (CDC) opioid-related death data, and this subset was used in the regression analysis. The 464 counties represent 46 states plus Washington DC, with the 4 states not included being Montana, North Dakota, South Dakota, and Wyoming. To account for variation in county population, adjusted news volume was defined as the number of news reports per population and was calculated by dividing total report count by county population times 100,000 total population.

County-Level Opioid-Related Deaths

Population-adjusted rates of opioid-related deaths in 2017 were obtained from the Multiple Cause of Death data set produced by the Division of Vital Statistics of the National Center for Health Statistics at the CDC, accessible through the WONDER portal of the CDC [1]. This CDC data set was compiled from death certificates for US residents, with each entry containing a single underlying cause of death and up to 20 additional contributing causes. Because death certificates for drug overdose are not complete in identifying drugs involved (in 2017, 12% of drug overdose death certificates did not provide information on specific drugs involved), we aimed to be broad in our inclusion criteria for opioid-related deaths, querying for all deaths that contained an opioid in the multiple-cause-of-death category rather than the underlying-cause-of-death category. Specifically, the criteria for inclusion were the following ICD-10 codes: opioids (T40.0, T40.1, T40.2, T40.3, T40.4, or T40.6); natural and semisynthetic opioids (T40.2); methadone (T40.3); synthetic opioids, other than methadone (T40.4); and heroin (T40.1). Death rates were given in units of deaths per 100,000 total population in county. Retail opioid prescriptions dispensed per 100 persons were collected from the CDC Opioid Prescribing Rate database [20].

County-Level Demographic and Socioeconomic Data

Demographic and socioeconomic variables were used to assess how media reporting and death rate differed in their relationship to external variables. Data on census region membership (Northeast, South, Midwest, and West), county population, high-school attainment in county, percent white in county, median income in county, and percent rurality in county were obtained from the US Census Bureau of Statistics [21].

Descriptive and Visual Analysis

To examine spatial trends, population-adjusted opioid news volume from DrugMap was visualized on a geographic map of the United States. To examine social and demographic trends,

2 heatmaps were created: one showing opioid news volume per 100,000 total population in county on the axes of rurality and educational attainment and another showing opioid-related death rates per 100,000 total population in county on the same axes. These maps were created in the following manner: first, we identified counties that contained both news data and death data. Of this subset of counties, we created 25 groups based on quintiles of percent rurality in county and high-school graduation rate in county. For each group, we computed the average opioid news rate and average opioid-related death rate by taking the mean of the individual rates of the counties in each group. This allowed us to visualize differences in associations with socioeconomic factors for opioid-related deaths versus opioid reporting.

Statistical Analyses

Ordinary least squares regression was used to model county death rate and county report rate. A Poisson model was initially considered with population as an offset, but upon evaluation this model was rejected because of overdispersion, a violation of model assumptions. We then chose ordinary least squares after checking that the assumptions of normality of the residual terms were met. Counties with both DrugMap and CDC death data were used for this analysis. In Model 1, we modeled opioid-related death rate in county as a linear function of county geographic, demographic, and socioeconomic variables to identify area-level characteristics of greater opioid-related mortality. In Model 2, we used ordinary least squares regression to model news reporting rate in county as a linear function of county death rate and county variables to identify areas of higher volume of news reporting. A number of studies have described county characteristics associated with opioid use [22,23]. These include educational attainment, racial composition, physician supply, opioid prescribing rate, income, and rurality. These variables were included as controls in Model 1 and Model 2. All analyses were conducted with Python statsmodels [24].

Results

Descriptive and Visual

The median number of reports per state was 565.5 (range 7-4169) and the median number of reports per county was 5 (range 1-1631). At the county level, the median was 9.35 reports per 100,000 total population (range 0.38-430.57 per 100,000 total population). Figure 1 displays the population-adjusted volume of DrugMap reporting across the United States by percentile category. As can be seen, opioid reporting volume is higher in the Northeast, especially in the areas of Maine, New Hampshire, Vermont, and Massachusetts. Other states with high opioid reporting relative to population size are Alaska and Nevada.

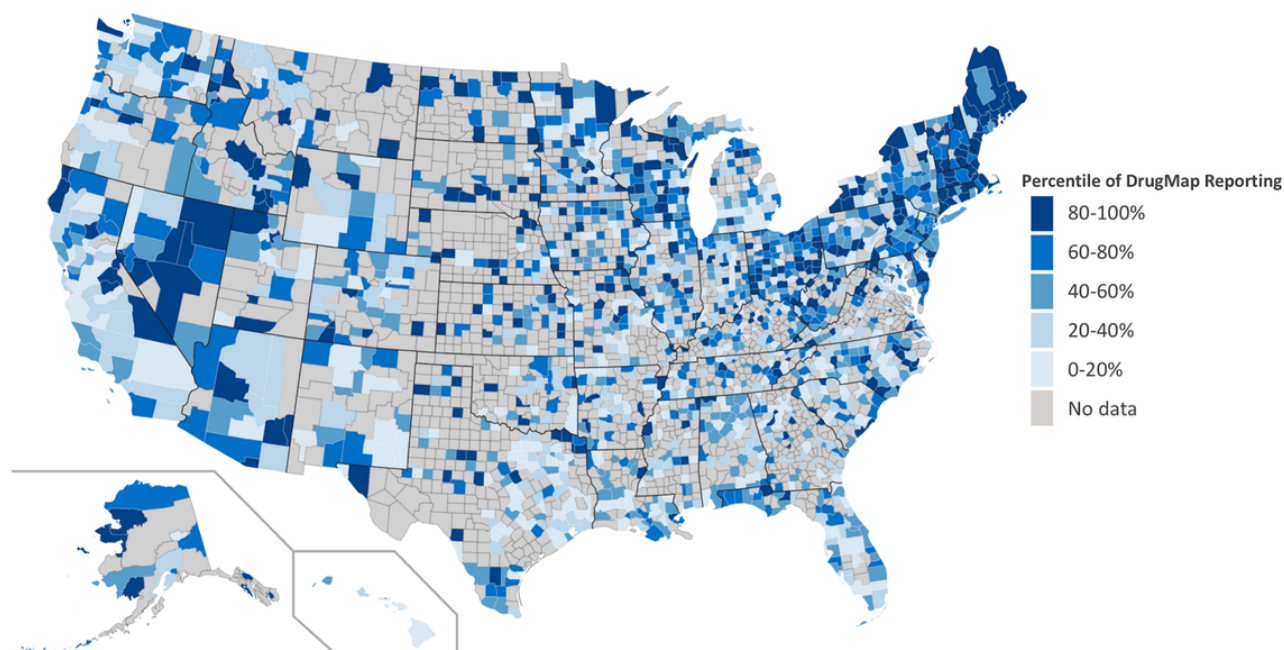

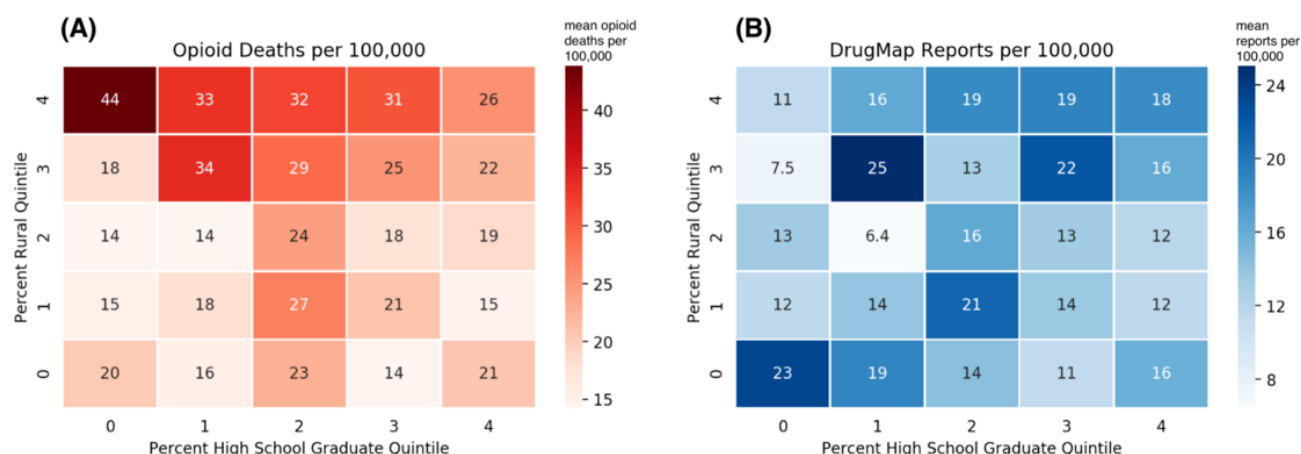

Figure 1. US Map of DrugMap reports in county divided by county population, 2018-2019.

Figure 2A shows the mean value of opioid-related death rate on the axes of percent rurality quintile and high-school graduation rate quintile, and Figure 2B shows the mean value of opioid reporting on the same axes. In the mortality heatmap, counties in higher quintiles of rurality and lower quintiles of education are shaded more darkly, indicating greater opioid-related death rates in rural and less educated populations. By contrast, the heatmap of DrugMap news reporting shows more variation and does not reflect the pattern observed for opioid-related death. When we compare the distribution of online opioid news from DrugMap with the US populations,

we find that for rurality, the news data represented 53.7% of the first quintile (least rural), 15.3% of the second quintile, 4% of the third quintile, and 0.4% of the fourth/fifth quintile (most rural). For high-school graduation rate, the news data represented 2.6% of the first quintile (least educated), 8.5% of the second quintile, 18.2% of the third quintile, 23.9% of the fourth quintile, and 18.9% of the fifth quintile (most educated). These differences show that there exists greater news coverage about opioids relative to opioid mortality in urban and more educated areas.

Figure 2. Heatmap showing distribution of opioid-related death rate (A) 2017 and DrugMap report rate (B) 2018-2019 by percent rural and percent high-school graduate.

Regression

Model 1 regression results are presented in Table 1. For every percentage point increase in percent white at the county level, there was on average 28.02 less opioid-related deaths per 100,000 total population ($P<.001$), controlling for median income, rurality, high-school graduate rate, opioid prescribing rate, and geographic region. For every percentage point increase in percent rurality at the county level, there was on average 0.14

more opioid-related deaths per 100,000 total population ($P<.01$), controlling for all other variables. For every percentage point increase in percent high-school graduation rate at the county level, there was on average 0.86 less opioid-related deaths per 100,000 total population ($P<.001$), controlling for all other variables. Compared with the Midwest, the West had on average 9.99 less opioid-related deaths per 100,000 total population ($P<.001$), whereas there was no significant differences for the

Northeast or South. Median income and opioid prescribing rate at the county level were not significantly associated with opioid-related death rate.

Model 2 regression results are presented in Table 1. Opioid mortality was positively associated with opioid news reporting; for every additional death per 100,000 total population at the county level, there was on average 0.40 more news reports per 100,000 total population ($P<.001$), controlling for median income, percent white, rurality, high-school graduate rate, opioid prescribing rate, and geographic region. For every dollar increase in median income at the county level, there was on average 0.0003 more news reports per 100,000 total population ($P<.001$), controlling for all other variables. For every

percentage point increase in percent rurality at the county level, there was on average 0.17 less news reports per 100,000 total population ($P<.01$), controlling for all other variables. For every percentage point increase in percent high-school graduation rate at the county level, there was on average 0.65 more news reports per 100,000 total population ($P<.01$), controlling for all other variables. For every additional opioid prescription per 100 persons at the county level, there was on average 0.112 more news reports per 100,000 total population ($P<.01$), controlling for all other variables. Compared with the Midwest, the Northeast had 10.12 more news reports per 100,000 total population ($P<.001$), whereas the South and West exhibited no significant differences. Percent white at the county level was not significantly associated with news reporting frequency.

Table 1. Summary of regression results of Models 1 and 2^{a,b}.

Dependent variable	Model 1				Model 2			
	Death rate				Report rate			
	Coefficient	Standard error	P value	95% CI	Coefficient	Standard error	P value	95% CI
Intercept	84.202	18.575	<.001	47.701 to 120.703	-24.040	19.152	.21	-61.678 to 13.598
Death rate	N/A ^c	N/A	N/A	N/A	0.397	0.047	<.001	0.305 to 0.489
Median income	-0.0001	6.28×10^{-5}	.11	-0.000 to 2.32×10^{-5}	-0.0003	6.37×10^{-5}	<.001	-0.000 to -0.000
Percent white	28.019	6.431	<.001	15.382 to 40.656	0.410	6.652	.95	-12.662 to 13.483
Percent rural	0.143	0.054	<.01	0.036 to 0.249	-0.172	0.056	<.01	-0.282 to -0.061
Percent high-school graduate	-0.857	0.242	<.001	-1.332 to -0.381	0.649	0.248	<.01	0.162 to 1.135

Northeast	-0.786	2.054	.70	-4.823 to 3.251	10.115	2.078	<.001	6.031 to 14.200
South	-1.919	1.911	.32	-5.675 to 1.836	0.779	1.954	.69	-3.062 to 4.619
West	-9.991	2.418	<.001	-14.743 to -5.238	0.129	2.485	.96	-4.755 to 5.013

^aMidwest was used as the reference group in both models.

^bFor both models, N=464.

^cN/A: Not applicable.

Discussion

Results from our study show that opioid-related mortality and opioid-related news reporting were positively correlated with each other: increases in opioid-related death rate at the county level were associated with increases in news reports. However, opioid-related mortality and opioid-related news reporting differed in how they related to geographic, demographic, and socioeconomic factors. Opioid-related deaths are less common in the geographic region of the West and more common in communities that are less educated, have a greater proportion of whites, and are more rural. While this finding regarding how opioid mortality relates to geography, education, and racial breakdown is consistent with prior studies [25], our analysis suggests that opioid-related news reporting follows different trends. Areas with greater news reporting tended to be more educated, more urbanized, and located in the Northeast. These discrepancies in news reporting rate and death rate, which can be interpreted as a sign of the magnitude of the opioid crisis in

a certain area, highlight potential differences in the relative attention of news coverage across regions, rural areas, and socioeconomic status. More urban and educated areas receive greater media attention even though the opposite pattern is observed for opioid-related deaths. Previous research has shown that greater media attention and coverage increase public and governmental responses [6,13]. This increased attention may lead the public and the government to devote more resources and develop policy intervention targeted to areas that are less affected by the opioid epidemic.

In recent years, mass media has become increasingly relevant because its online transmission is immediate and its reach is broad. Because online news is often the first point of contact people have with current events, online sources prime people's perceptions of the reported issues going forward and potentially override conflicting information received afterward [26]. For example, during the 1980s War on Drugs, media depiction of the cocaine epidemic as a "ghetto" problem is widely believed to have contributed to the public's perception of African

Americans and Latinos as addicts and criminals and white drug users as casualties and victims [13,27,28]. Another devastating case of differential media attention is the widely circulated news associating the measles vaccine with autism. News headlines prominently reported this association, and even though academics have long dispelled and discredited this link, this belief still persists because of the heightened media attention received by the original report and the lower media attention received by the studies that dismissed this association [29-31]. Through examining media trends for the current US opioid epidemic, we see that patterns of opioid media attention do not reflect the distribution of opioid-related deaths. This may lead to exacerbations of health disparities as previous studies have linked media attention with resource allocation. Lower media volume in areas with greater opioid use risk may reduce attention from government officials or public health agencies for these regions, leading to an increase in disparities. For instance, opioid-related deaths occur most in rural areas with lower education, suggesting that these areas are being affected the most. However, our results indicate that there may be less opioid-related news reporting and coming from these areas. This relative lack of news discussion could signal less awareness, interest, and investment in opioid issues in regions that are at greater risk.

Limitations

Results from this study were obtained at the area level based on county variables, so conclusions must be drawn at the ecological and not at the individual level. First, issues of collinearity across these demographic and socioeconomic variables prevented us from including all socioeconomic and demographic variables into the model. The specific variables selected in this study were based on previous research on opioid-related events. Second, our regression models provide information on associations and cannot be deemed causal. Third, while we adjusted news volume to consider differences in county population, the measures of baseline news output and readership may have been more direct control variables; however, these were unavailable during the study. Using these measures may have yielded different results.

There are benefits and drawbacks to our methodology of using opioid-related deaths as opposed to opioid-related overdose deaths for our analysis. Although the variable of opioid overdose deaths is more specific and perhaps more directly interpretable, overdose death data from the CDC are limited in important

ways. Specifically, CDC data on drug overdose deaths are derived from information provided on death certificates, and not all death certificates for overdose include information on drugs involved.

We chose not to specify drug overdose as the underlying cause of death for opioid-related mortality in order to encompass a broader view of the impact of the opioid epidemic across the United States. Although our data are still subject to the aforementioned data limitations, the broader scope of our inclusion criteria allows us to achieve a more comprehensive analysis. These limitations in national databases are reflected in our analysis as counties with poorer reporting, which tend to also be more rural, and are thus excluded. However, even with greater representation in more urban areas, our results demonstrate a relative lack of media opioid reporting in rural and less educated areas, thereby supporting the existence of biases in media reporting on opioids.

Finally, our study did not examine the language or content of opioid-related news reporting, such as positive and negative connotation or types of vocabulary used. Textual examination of media content should be conducted in follow-up studies as previous research has shown that framing can impact public perceptions and judgments toward certain socioeconomic groups [8,12,13,32]. Furthermore, while our study supports the existence of differences in reporting volume, it does not measure the effect of such trends on government support and action on opioid issues. Future studies should be carried out to empirically investigate the relationship between variation in news reporting volume and variation in realized efforts.

Conclusion

Our study brings to light potential differences in the volume of media portrayal of the current opioid epidemic. Previous research and theory have demonstrated a strong link between media attention and its impact on public perception, future resource allocation, and population-level opioid use behaviors. Although our study did not directly test these consequences, our results provide evidence supporting the existence of these media disparities across the United States. Given the importance of news media in shaping public attitudes and government efforts, it is critical that news reporting on opioids is distributed equitably and accurately to prevent misperceptions. Future studies should investigate trends in the content of news reporting on the opioid epidemic and how framing of news stories may be affecting government support and action on opioid issues.

Acknowledgments

Funding for this study was provided by an NIH/NLM Institute grant (No. 3R01LM011965-03S1). The NIH/NLM had no role in the study design, collection, analysis or interpretation of the data, writing the manuscript, or the decision to submit the paper for publication.

Authors' Contributions

YH retrieved funding to conduct research; conducted literature searches; summarized previous research studies; designed the study; and wrote the protocol, the first draft, and the final manuscript. AZ conducted literature searches, provided summaries of previous research studies, designed the study, conducted the statistical analysis, and contributed to writing the manuscript. CF

retrieved the data, built the database, and edited the manuscript. JSB retrieved funding to conduct research and contributed to the edits. All authors have approved the final manuscript.

Abstract

Background: Health awareness initiatives are frequent but their efficacy is a matter of controversy. We have investigated the effect of the Eating Disorder Awareness Week and Wake Up Weight Watchers campaigns on Twitter.

Objective: We aimed to examine whether the Eating Disorder Awareness Week and Wake Up Weight Watchers initiatives increased the volume and dissemination of Twitter conversations related to eating disorders and investigate what content generates the most interest on Twitter.

Methods: Over a period of 12 consecutive days in 2018, we collected tweets containing the hashtag #wakeupeightweightwatchers and hashtags related to Eating Disorder Awareness Week (#eatingdisorderawarenessweek, #eatingdisorderawareness, or #EDAW), with the hashtag #eatingdisorder as a control. The content of each tweet was rated as medical, testimony, help offer, awareness, pro-ana, or anti-ana. We analyzed the number of retweets and favorites generated, as well as the potential reach and impact of the hashtags and the characteristics of contributors.

Results: The number of #wakeupeightweightwatchers tweets was higher than that of Eating Disorder Awareness Week and #eatingdisorder tweets (3900, 2056, and 1057, respectively). The content of tweets was significantly different between the hashtags analyzed ($P<.001$). Medical content was lower in the awareness campaigns. Awareness and help offer content were lower in #wakeupeightweightwatchers tweets. Retweet and favorite ratios were highest in #wakeupeightweightwatchers tweets. Eating Disorder Awareness Week achieved the highest impact, and very influential contributors participated.

Conclusions: Both awareness campaigns effectively promoted tweeting about eating disorders. The majority of tweets did not promote any specific preventive or help-seeking behaviors.

KEYWORDS

awareness campaigns; eating disorders; Twitter; social media

Introduction

Eating disorders belong to a wide group of disorders characterized by weight concern, body image preoccupation, and persistent disturbances in eating that impair health and psychosocial functioning [1]. These diseases occur worldwide, mostly commonly in young women, with an estimated lifetime prevalence of 0.8% for anorexia nervosa and binge eating disorder and 0.3% for bulimia nervosa [2,3]. The etiology of these disorders is complex and not fully understood. Nonetheless, many aspects of Western culture, such as the “thin ideal” or media pressure, promote an obsession with weight loss and body image [4].

Several strategies have been established to reduce the prevalence of eating disorders [5]. Health awareness initiatives have become a frequent intervention strategy, as high-visibility programs have stimulated the discussion of certain health risks and enhanced public exposure to these issues [6]. For instance, Eating Disorder Awareness Week is an annual event sponsored by a wide range of partners that aims to increase public recognition of the preventive and supportive options for individuals suffering from eating disorder behaviors [7]. However, some initiatives are not scheduled in advance, as was the case with Wake Up Weight Watchers. On February 6, 2018, many health care providers were concerned when Weight Watchers announced free memberships for teenagers, because dieting as a teenager increases the risk of developing eating disorders and risky behaviors [8,9]. Thus, the Wake Up Weight Watchers initiative was developed to counteract the potentially negative effects of adolescent dieting [10]. Although the efficacy of health awareness initiatives is a matter of controversy, analytical studies of those related to eating disorders are particularly scarce [11].

Notably, research using Twitter has been an effective assessment strategy for analyzing patient attitudes toward various medical topics, including mental health [12,13]. Additionally, Twitter has been used to assess the impact of disease awareness programs on users, especially young adults and adolescents [14]. Thus, this platform could help health care providers effectively reach many young people troubled by eating disorders [15]. It has been shown that medical interventions conducted through Twitter can modify health-related behaviors [16]. Therefore, this platform could provide a good setting for the promotion of healthy lifestyles among at-risk individuals and encourage them to get in touch with health providers [17]. Previous research has found that engaging in help-seeking behavior has been an important factor in protecting the mental health of young people [18]. Despite these efforts to help, evidence nevertheless suggests that those experiencing eating disorder thoughts and behaviors are less likely to seek help for their mental health difficulties [19]. One recent study even reported that body image was the second leading personal concern for which people between the ages of 18 and 25 years sought help online [20].

The aims of this study are the following: (1) Examine the volume of Twitter conversations related to eating disorders generated by the Eating Disorder Awareness Week and Wake

Up Weight Watchers initiatives, and compare the dissemination of these tweets with tweets related to eating disorders that did not use the official hashtags of these campaigns. (2) Describe the main content themes of tweets from both initiatives and compare them to those of typical tweets related to eating disorders. (3) Investigate what content generates the most interest on Twitter. (4) Identify and categorize the most active and influential users among those that participate in these conversations.

Methods

Research Strategy

In this observational quantitative and qualitative study, we focused on searching for tweets that referred to two eating disorder campaigns in particular: Eating Disorder Awareness Week (#eatingdisorderawarenessweek, #EDAW, #eatingdisorderawareness) and Wake Up Weight Watchers (#wakeupweightwatchers). As a control, we simultaneously studied those tweets related to eating disorders stemming from the hashtag with the name of the disease (#eatingdisorder). The inclusion criteria for tweets were the following: (1) tweeted by a public account, (2) included the previously mentioned hashtags, (3) posted between February 24 and March 7, 2018, and (4) posted in English. The 12-day period was chosen to align our research with the dates of the two campaigns included in this study. Eating Disorder Awareness Week 2018 started February 26, 2018, and the Wake Up Weight Watchers initiative began in February 2018. In addition, we obtained the number of retweets and favorites each tweet generated, the date and time of each tweet, the potential reach and impact of each hashtag, as well as the user's profile description.

Search Tool and Data Collection

For this study, we used the Twitter Firehose (Gnip) data stream, which allows access to 100% of all public tweets that match a certain criteria (query) [21]. In our study, the search criteria were the previously mentioned hashtags. Tweet Binder, the search engine we employed, uses automatic machine learning text analysis algorithms, as well as node.js and PHP language; this enabled us to analyze tweets in a JavaScript Object Notation (JSON) format, which is used by Gnip.

Content Analysis Process

All 7468 retrieved tweets were directly inspected by two raters (authors IV and MAAM). First, we scanned all of the tweets, and excluded 455 tweets that provided information that was too limited (ie, tweets consisting mainly of hashtags), contained only pictures, or included hashtags of both initiatives. All remaining tweets were considered for content analysis. Second, we created a codebook based on our research questions, our previous experience in analyzing tweets, and what we determined to be the most common tweet themes. Third, IV and MAAM analyzed 300 tweets separately to test the suitability of the codebook. Discrepancies were discussed between the raters and with another author (MLV). After revising the codebook, the interrater reliability was reassessed with a different set of 159 tweets. As this resulted in adequate κ values (range 0.89-0.99), the raters then proceeded to perform a content

analysis of 1500 tweets, including 500 tweets each from the three different groups of hashtags, randomly selected. Each tweet, depending on the content, was rated as medical, personal testimony, pro-ana (tweets glorifying or encouraging ED behaviors or portraying them as a lifestyle choice), anti-ana (tweets confronting pro-ana ideas), awareness, or help offer.

The coding categories were not mutually exclusive. If the contents of a tweet were repeated exactly or almost identically in other tweets, they were classified in the same way as the first tweet encountered. The classification criteria we used and examples of tweets according to category are shown in [Table 1](#).

Table 1. Category definitions and examples of classification^a.

Categories and definitions	Examples of classification
Medical (clinical or epidemiological information)	“For #EatingDisorderAwarenessWeek remember that 1) ppl with eating difficulties are not always underweight 2) it's not about wanting to diet and be thin 3) recovery is not as simple as “eat a bit more to recover” 4) ED's are life threatening illnesses”
Testimony (expression of experience)	<ul style="list-style-type: none"> “When I was about to become a teenager, my parents put me on Weight Watchers. I have been battling Anorexia since then. Dieting is one of the most common antecedents of disordered eating in young people. #WakeUpWeightWatchers” “We are warriors whether we are still battling this war or we have overcome and conquered it. We stand together in a battle which costs lives and relationships but we stand together. #EatingDisorderAwarenessWeek” “My younger sister has this too - as if she is cured and we can now resume normal life and carry on from where we left off. But everything has changed. #StateNotWeight #EatingDisorderAwarenessWeek” “As someone who suffered from an ED after dieting I am so worried about promoting weight watchers to teenagers. It may be dangerous. #WakeUpWeightWatchers”
Pro-ana (pro-eating disorder content, promoting compensatory behaviors or disordered eating for weight loss)	<ul style="list-style-type: none"> “Ohh wow my dad really bought me the scale I wanted. I'm so excited but at the same time it's better he doesn't know why I really wanted it so bad. #eatingdisorder #proana #ed #rexi” “I can't eat because I'm allergic to calories. #ana #mia #anorexia #anorexic #anoressia #anoressica #anorexie #anorexique #vita #lavie #mystory #Mylife #conversation #quote #quotes #meme #memes #MEMES #anamia #proana #eatingdisorder #diary #mydiary #me #life” “Skip dinner, wake up thinner. #Eatingdisorder.  “Just think how all of this pain will be worth it in the end #thinspo #thin #skinny #eatingdisorder #anorexic #anorexia #mia”
Anti-ana (expressing concerns regarding pro-ana content)	“As the mom of a teen who struggles with an eating disorder, seeing WW target teens makes me worry. It is not correct to tell kids that a number on the scale is what gives them their value. #livelife #smile #behappy #BodyPositivity #WakeUpWeightWatchers”
Help offer (promoting help- and treatment-seeking behaviors)	<ul style="list-style-type: none"> “It's #EatingDisorderAwarenessWeek If you have concerns about your loved ones or if you feel keen to talk to a professional counselor about your difficulties, call our confidential helpline at XXX #EDAW18 #NotAlone #HeretoHelp” “Are you concerned that your child may have an #eatingdisorder? Help and support is available from @XXX”
Awareness (aim to raise awareness, combat misconceptions, or educate)	<ul style="list-style-type: none"> “Sign this petition against @WeightWatchers' insidious campaign to recruit teens to their dangerous business #WakeUpWeightWatchers” “Eating disorder experts, dietitians, physicians, and advocates around the world are standing together against @weightwatchers marketing dangerous “free” summer memberships to vulnerable young people. A season of fat-shaming, a lifetime of weight cycling.” “Spotting the signs: “If you suspect an eating disorder you should talk to them directly, and express your concerns –because the sooner you get help the better” #EatingDisorderAwarenessWeek #SpeakYourMind”

^aUsername and personal names have been removed.

Measuring Influence on Twitter: Retweets, Favorites, and the Reach and Impact of Hashtags

We analyzed the number of retweets and favorites generated by each tweet as an indicator of user interest in a given topic. We also measured the potential reach and impact of all analyzed hashtags to best assess tendencies in the dissemination of tweets. For the purpose of this study, impact is defined as a numerical value representing the potential views a tweet may receive, while reach is defined as a numerical value measuring the potential audience of the hashtag. These metrics are analyzed

by Tweet Binder, a Twitter tool that automatically tracks hashtags. A more detailed explanation is shown in [Multimedia Appendix 1](#).

User Categorization

The number of tweets that each Twitter user (contributor) posted with a certain hashtag was automatically quantified by Tweet Binder. We defined the contributors as very active if posting at least 6 tweets with a certain hashtag. The number of followers of the contributors was automatically quantified by Tweet Binder at the time of the study. We classified those with at least 5000 followers at the time of our analysis as very influential

contributors. Furthermore, we collected the profile description of the ten most influential and active users that participated in these conversations. The user profile description was used to determine whether a tweet was posted by health providers (such as physicians or nurses), health organizations (hospitals, journals, medical societies, or research institution), or by non-health-related users.

Ethical Considerations

This study was approved by the Research Ethics Committee of University of Navarra. This study did not directly involve human subjects and did not include interventions, but instead used publicly available tweets. Nevertheless, we have taken care to not reveal any username and to avoid citing the tweets that could reveal usernames.

Statistical Analysis

A descriptive study of the sample was performed, describing the variables by their absolute and relative frequencies. The percentages found were compared using the chi-square test. The mean and median numbers of retweets or favorites per original tweet about the different hashtags studied were compared using the Kruskal-Wallis test. All statistical analyses were performed using SPSS (Version 20, IBM Corp).

Results

Public Awareness Initiatives Succeeded in Spreading Their Tweets

Our search tool found that the total number of tweets generated with the hashtags associated with the Eating Disorder Awareness Week and Wake Up Weight Watchers awareness campaigns and the control hashtag #eatingdisorder were 7468. Of these, 455 were excluded according to the criteria of the study. The number of #wakeupweightwatchers tweets (3900) was double that of the Eating Disorder Awareness Week tweets (2056 tweets included the hashtags #eatingdisorderawarenessweek, #eatingdisorderawareness, or #EDAW). There were 1057 tweets using the control hashtag #eatingdisorder.

As shown in Table 2, we found that the potential impact and reach of the tweets was higher among Eating Disorder Awareness Week hashtags (54,143,739 and 9,547,326, respectively) and #wakeupweightwatchers (28,371,411 and 9,332,345, respectively) than observed with the #eatingdisorder hashtag (7,384,797 and 4,175,017, respectively).

Table 2. Potential impact, potential reach, number of contributors, percentage of very active users, and percentage of very influential users in the 3 groups.

Parameters	Eating disorder	Eating Disorder Awareness Week	Wake Up Weight Watchers
Potential impact, n	7,384,797	54,143,739	28,371,411
Potential reach, n	4,175,017	9,547,326	9,332,345
Contributors, n	1243	2531	4609
Very active contributors, n (%)	70 (5.6)	59 (2.3)	383 (8.3)
Very influential contributors, n (%)	127 (10.2)	186 (7.4)	289 (6.3)

Eating Disorder Awareness Campaigns Fail to Promote Medical Content, Help Offers, Or Personal Testimonies But Can Increase Pro-Ana Criticism

We performed a content analysis of 1500 tweets, including 500 randomly selected tweets each from the three different groups of hashtags. First, we studied the medical contents of the tweets. Although the frequency was low, there were significant differences between the 3 groups ($P<.001$; Figure 1). The percentage of tweets with medical content was higher in those with the #eatingdisorder hashtag than in those with the awareness campaign hashtags. The lowest frequency was found in the #wakeupweightwatchers group.

We also analyzed the content of the 1500 tweets according to the other five established categories: personal testimony, help offer, awareness, pro-ana, and anti-ana. Different patterns of

distribution among the five categories were found between the 3 groups of hashtags ($P<.001$). The percentage of tweets with personal testimony content was similar in #eatingdisorder tweets and tweets using Eating Disorder Awareness Week hashtags, while the percentage was lower in #wakeupweightwatchers tweets (Figure 1). The frequency of awareness tweets was higher in the tweets with Eating Disorder Awareness Week hashtags and lower in the tweets with the #wakeupweightwatchers hashtag (Figure 1). Help offer tweets were more prevalent in tweets with the #eatingdisorder hashtag and Eating Disorder Awareness Week hashtags. The frequency of anti-ana tweets was clearly higher in the #wakeupweightwatchers group and minimal in Eating Disorder Awareness Week tweets (Figure 1). Pro-ana content was absent in #wakeupweightwatchers tweets and the frequency was highest in #eatingdisorder tweets (Figure 1).

Figure 1. Different percentages of tweets in each category generated about the awareness campaigns #eatingdisorderawarenessweek (including #eatingdisorderawareness and #EDAW) and #wakeupweightwatchers, with #eatingdisorder as the control. Percentages were calculated with respect to the 500 tweets analyzed for each of the three categories of hashtags. Chi-square test; $P<.001$.

Pro-Ana and Medical Contents Did Not Attract Much Attention Among Twitter Users

We measured the number of retweets and favorites generated by each hashtag and category. Since these hashtags have different contribution numbers, we used ratios, dividing by the total number of tweets in each campaign. We found that the retweet-to-tweet and favorite-to-tweet ratio between the three hashtag groups were significantly different ($P<.001$; Table 3). As whole group, #wakeupweightwatchers was the hashtag with the highest retweet-to-tweet and favorite-to-tweet ratio. We found that the retweet-to-tweet and favorite-to-tweet ratio between the six categories were significantly different ($P<.05$;

Table 4). Regarding the medical content, the highest ratios were found in #wakeupweightwatchers tweets, while they were low among the #eatingdisorder and Eating Disorder Awareness Week hashtags. Furthermore, tweets with personal testimony, help offer, and awareness content showed higher retweet-to-tweet and favorite-to-tweet ratio in #wakeupweightwatchers than those found in the other two groups. The tweets with anti-ana content generated higher ratios in #eatingdisorder tweets and lower ratios in Eating Disorder Awareness Week tweets. We found that the pro-ana tweets generated no or low numbers of retweets and likes in the 3 groups of tweets studied.

Table 3. Retweet-to-tweet and favorite-to-tweet ratio per hashtag analyzed.

Parameter and value	Eating disorder	Eating Disorder Awareness Week	Wake Up Weight Watchers	<i>P</i> value ^a
Retweet				
Mean (SD)	0.84 (7.21)	0.1 (0.79)	4.23 (21.51)	N/A ^b
Median (IQR)	0 (0-0)	0 (0-0)	1 (0-3)	<.001
Favorite				
Mean (SD)	1.76 (16.46)	0.2 (1.43)	9.52 (58.09)	N/A
Median (IQR)	0 (0-0)	0 (0-0)	2 (0-7)	<.001

^aThe Kruskal-Wallis test was used.

^bN/A: not applicable.

Table 4. Retweet-to-tweet and favorite-to-tweet ratio per category in each hashtag analyzed.

Category and parameter	Eating disorder, median (IQR)	Eating Disorder Awareness Week, median (IQR)	Wake Up Weight Watchers, median (IQR)	P value ^a
Medical				
Retweet	0 (0-0)	0 (0-0)	4 (3)	.03
Favorite	0 (0-1)	0 (0-0)	4 (1-4)	.02
Pro-ana				
Retweet	0 (0-0)	0 (0-0)	— ^b	.88
Favorite	0 (0-1.75)	0 (0-0)	—	.72
Anti-ana				
Retweet	2 (0-7.5)	0 (0-0)	1 (0-3)	.002

Awareness				
Retweet	0 (0-1)	0 (0-0)	1 (0-3)	<.001
Favorite	0 (0-2)	0 (0-0)	3 (1-6.75)	<.001

^aThe Kruskal-Wallis test was used.^bNot available.

Eating Disorder Awareness Campaigns Increased the Participation of Twitter Users, But Not of Those Considered Very Active or Influential

We also analyzed the number and type of users that participated in conversations using any of the three hashtag groups (Table 2). The total number of contributors was higher in the #wakeupweightwatchers group (4609) than in the Eating Disorder Awareness Week (2531) and #eatingdisorder groups (1243). The frequency of very active users was higher in the #wakeupweightwatchers group (8.3%) than in the #eatingdisorder (5.63%) and Eating Disorder Awareness Week groups (2.33%). The percentage of very influential participants

was highest in #eatingdisorder group (10.22%) than in the #wakeupweightwatchers (6.27%) and Eating Disorder Awareness Week groups (7.35%). The percentage of health providers or health organizations among the ten most active or influential users that participated in these conversations was higher in the #wakeupweightwatchers group (40%) than in the #eatingdisorder (30%) and Eating Disorder Awareness (20%) groups.

Finally, we analyzed the 5 hashtags more frequently associated with the 3 groups of hashtags studied (Table 5). We found that the hashtags most frequently associated with the 3 groups analyzed were different.

Table 5. Top 5 hashtags associated with the 3 groups of hashtags analyzed.

Hashtag group	The top 5 hashtags and the number of tweets per hashtag
Eating disorder	Anorexia (n=199), HAES (Health At Every Size; n=195), HelpfaithHeal (n=193), bodypositive (n=171), recovery (n=156)
Eating Disorder Awareness Week	GlobalGoodEmi (n=1201), Winsday (n=289), Wednesday (n=287), Giveaway (n=196), Flash (n=180)
Wake Up Weight Watchers	HAES (n=341), simplyNYC (n=283), MNYFashionweek (n=281), sheopenedthedoors (n=281), weightwatchers (n=198)

Discussion

Principal Findings

In this study, we have demonstrated that the eating disorder awareness campaign initiatives Eating Disorder Awareness

Week and Wake Up Weight Watchers generated a greater number of tweets, with more far-reaching dissemination than the control eating disorder hashtag. Nonetheless, they failed to increase the frequency of tweets containing medical content, personal testimonies of recovery, or offers for treatment.

Moreover, those Twitter users classified as “very influential” did not command a strong presence in driving awareness of the aforementioned initiatives; on the whole, medical institutions also did not have a strong presence. Lastly, hashtags commonly used by pro-ana social networks are not used to any great extent by the awareness campaigns studied, thus making the campaigns less likely to reach at-risk individuals.

Our findings show that awareness initiatives generated a greater number of eating disorder-related tweets than those spontaneously posted. This finding suggests that awareness initiatives trigger conversations and social responses to eating disorders that would not have occurred otherwise. The total number of tweets related to the 3 groups of hashtags we analyzed over a period of 12 days was higher than the numbers of tweets associated with other mental health conditions [22]. However, the interest in eating disorders shown by the American media overall can be classified as low [23]. Notwithstanding, our results show that the Eating Disorder Awareness Week and Wake Up Weight Watchers campaigns had a positive effect on Twitter users. Furthermore, the potential impact and reach of the tweets related to the two campaigns were clearly higher than those achieved by our eating disorder control group.

According to the analysis of the generated tweets, both awareness initiatives have limitations. They failed to increase the percentage of tweets related to medical content, in contrast to previous evidence showing that tweets with medical content generated special interest among Twitter users [24]. A study performed within a population of young people highlighted the use of scientific data as being a key indicator of credibility in online resources [20]. The scarcity of medical content found by our study has also been reported in other awareness initiatives focused on other medical diseases, such as several prevalent types of cancer [25]. For example, Breast Cancer Awareness Month tweets most commonly contained content related to the practices of wearing pink, promoting walks/runs, and promoting fundraisers, as opposed to direct medical advice and preventive measures [25]. Furthermore, the frequency of tweets generated with help content was not higher in tweets related to awareness campaign hashtags. These results are concerning due to the existence of evidence that interventions that included help resources increased participants’ knowledge of treatment resources [7].

Interestingly, one-third of the tweets analyzed have personal testimonies. This finding supports the value of Twitter as a means of communicating personal content related to eating disorder symptoms [26,27]. One-third of US teenagers use Twitter and this share has remained consistent over the past several years [28]. In general, Twitter users tend to be younger, have more education, and have higher incomes than the overall US population, but these differences are minimal among teenagers [29]. In addition, similar results have been reported in other countries. Twitter is a predominantly public-facing platform. It gives anonymity to user testimonies, encourages communication by people with real or perceived personal or social restrictions, and prevents the potential stigmatization of those with mental health diseases [30]. In addition, it provides an insight into the potential value of Twitter as a tool to reach these patients and encourage them to get in touch with health

care providers. Unfortunately, neither campaign increased the percentage of tweets that included testimonies. It has been shown that young people value resources that allow them to access the personal stories of peers with lived experiences [31]. As expected, Eating Disorder Awareness Week had the highest proportion of awareness tweets. There is no evidence that this type of content increases the odds of seeking help or changing behaviors.

The awareness initiatives increased the frequency of tweets with anti-ana content. Additionally, pro-ana contributors were absent. The analysis of the eating disorder tweets showed a very low percentage of pro-ana content. Several reasons that are not mutually exclusive may explain this finding. First, Twitter has a policy of excluding pro-ana content [32]. Second, the pro-ana community may communicate through other web-based means, such as pro-ana websites [33]. Third, pro-ana social media posts are often tagged using specific hashtags, such as #thinspo, #thinspiration, #Thin15, #edprobs, and #proana. Pro-ana communities on social media have been described as tighter and more cohesive than others, as well as more secretive and exclusive [34]. Our findings show that these pro-ana hashtags have not been included in tweets related to the awareness campaigns or tweets tagged with #eatingdisorder. These findings suggest that Twitter awareness campaigns should include hashtags commonly used by these pro-ana communities to increase the likelihood of reaching people in need of interventions for disordered eating behaviors [35,36].

Retweet frequency is a parameter that indicates user interest in the topic of each tweet [37]. We also measured the number of favorites generated as an additional parameter of user interest, as previously shown [38]. Our results show that the Wake Up Weight Watchers hashtag obtained higher retweet and favorites frequencies than Eating Disorder Awareness Week hashtags and the control #eatingdisorder hashtag. Other Twitter metrics of diffusion (such as the potential impact and reach of tweets) were higher in Eating Disorder Awareness Week and Wake Up Weight Watchers tweets than in #eatingdisorder tweets. Furthermore, the awareness campaigns were associated with an increased number of contributors and tweets generated; there was an increased frequency of posting by very active users. However, these campaigns failed to promote the activity of very influential participants that were identified by the number of followers. It has been shown that verified accounts influence Twitter users [39].

Strengths and Limitations

This study has some limitations. First, Twitter may not be reflective of the general population. Second, researchers cannot directly measure eating disorder behavior or clinical outcomes from tweets. Third, the codebook design and text analysis imply a degree of subjectivity. However, this methodology is consistent with previous medical research studies using Twitter and could be applied to different topics by different authors [40-42]. Furthermore, to address this issue, the study comprised a series of steps including the initial review, design of the codebook, and agreement between the coders. Although computerized machine learning methods have been tested to automatically identify and classify topics in medical research

in social media [43], we used an analysis strategy based on the raters' clinical expertise in mental health and endocrinology, which constitutes a qualitative advantage compared to automated strategies. On the other hand, it can be argued that #eatingdisorder content may be influenced by awareness campaigns. However, to our knowledge, there is no evidence of content seasonality. The time frame was selected according to awareness campaign dates. To collect data, we used the Twitter Firehose data stream, which is managed by Gnip and allows access to 100% of all public tweets that match a set of search criteria, which enables the creation of a very representative database. For the content analysis, we randomly collected a number of tweets that enabled us to make inferences from the text to summarize the content [44]. Finally, we did not determine whether a campaign prepared in advance (eg, Eating Disorder Awareness Week) affected Twitter activity differently (eg, user engagement) than a campaign that was more spontaneous (eg, Wake Up Weight Watchers).

Conclusions

The initiatives Eating Disorder Awareness Week and Wake Up Weight Watchers increased the volume of eating disorder-related tweets, but the content of most tweets focused on raising awareness rather than promoting treatment-seeking behaviors, which would likely have a more significant outcome. Our findings support the need to reconsider the message and communication strategy employed by eating disorder awareness campaigns. The involvement of health institutions appears to be desirable because they are an important indicator of credibility and generated more tweets focused on medical information. Furthermore, the testimony of patients who have recovered from eating disorders should be promoted in these campaigns. Awareness campaigns may also wish to consider a strategy in which hashtags targeted toward those with eating disorders are included.

Acknowledgments

This work was partially supported by grants from the Fondo de Investigación de la Seguridad Social, Instituto de Salud Carlos III (PI18/01726), Spain, and the Programa de Actividades de I+D de la Comunidad de Madrid en Biomedicina (B2017/BMD-3804), Madrid, Spain.

MAAM was affiliated with Clinica Universidad de Navarra at the time of the study and is currently affiliated with Hospital Universitario Infanta Leonor.

Authors' Contributions

IV and MAAM participated equally as principal contributors in the research design and content analysis, as well as manuscript writing, review, and submission. MLV participated in the content analysis and review. AAdB conducted and reported statistical analysis. MAM and FO supervised all stages of the research.

Conflicts of Interest
