Abstract

Background: Although chemotherapy was first introduced for the treatment of cancer more than 60 years ago, the public understanding and acceptance of chemotherapy is still debatable. To the best of our knowledge, no study has assessed the conversations and misconceptions about chemotherapy as a treatment for cancer on social media platforms among the Arabic-speaking populations.

Objective: The aim of this study was to assess the types of conversations and misconceptions that were shared on Twitter regarding chemotherapy as a treatment for cancer among the Arabic-speaking populations.

Methods: All Arabic tweets containing any of the representative set of keywords related to chemotherapy and written between May 1, 2017 and October 31, 2017 were retrieved. A manual content analysis was performed to identify the categories of the users, general themes of the tweets, and the common misconceptions about chemotherapy. A chi-square test for independence with adjusted residuals was used to assess the significant associations between the categories of the users and the themes of the tweets.

Results: A total of 402,157 tweets were retrieved, of which, we excluded 309,602 retweets and 62,651 irrelevant tweets. Therefore, 29,904 tweets were included in the final analysis. The majority of the tweets were posted by general users (25,774/29,904, 86.2%), followed by the relatives and friends of patients with cancer (1913/29,904, 6.4%). The tweets were classified into 9 themes; prayers and wishes for the well-being of patients undergoing chemotherapy was the most common theme (20,288/29,904, 67.8%), followed by misconceptions about chemotherapy (2084/29,904, 7.0%). There was a highly significant association between the category of the users and the themes of the tweets ($\chi^2_{40} = 16904.4, P < .001$).

Conclusions: Our findings support those of the previous infodemiology studies that Twitter is a valuable social media platform for assessing public conversations, discussions, and misconceptions about various health-related topics. The most prevalent theme of the tweets in our sample population was supportive messages for the patients undergoing chemotherapy, thereby suggesting that Twitter could play a role as a support mechanism for such patients. The second most prevalent theme of the tweets in our study was the various misconceptions about chemotherapy. The findings of our exploratory analysis can help physicians and health care organizations tailor educational efforts in the future to address different misconceptions about chemotherapy, thereby leading to increased public acceptance of chemotherapy as a suitable mode of treatment for cancer.

KEYWORDS

internet; chemotherapy; cancer; Twitter; social media; Arab world; misconceptions; infodemiology; infoveillance

Introduction

Although chemotherapy linguistically refers to any type of treatment with chemicals, it is now specifically used to describe cytotoxic anticancer medications, which are used to treat hematological and solid tumors [1,2]. Chemotherapeutic agents can be used alone or in combination with surgery or radiotherapy to achieve the goal of the treatment, which varies among patients based on many factors. The goal of the treatment may be to cure the cancer completely, control the cancer, stop it from spreading, or to use these agents as a palliative means to ease the symptoms and improve the patients' quality of life [3]. However, the natural mechanism of action of these chemotherapeutic agents results in relatively a wide spectrum of side effects, which might be unpleasant to the patients.

Despite continuous improvements in chemotherapy for increasing its effectiveness in treating cancer, the public understanding and acceptance of chemotherapy is still debatable. Many misconceptions can occur, thereby causing compliance issues and other problems related to the acceptance of chemotherapy as a treatment modality [4]. Most of the previous studies that assessed the perceptions and experiences of chemotherapy were performed with selected groups of patients who were either surveyed or interviewed [5-8]. However, large-scale studies attempting to understand the public views and conversations on chemotherapy are lacking. Retrieving and analyzing the contents of various social media platforms on this matter serves as an evolving method to gather information about the perceptions, misconceptions, and experiences with chemotherapy as a treatment for cancer. One of the most popular social media platforms that has been explored is Twitter, which is a large microblog wherein users can write up to 280-character messages called tweets and share them with their followers and the public. There are almost 313 million monthly active users who write around 500 million tweets daily [9,10]. In March 2017, it was estimated that the number of the monthly active Twitter users in the Arab world was around 11.1 million [11]. Moreover, the number of their tweets per month in March 2016 was estimated to be 849.1 million tweets, and 72% of them were written in Arabic [11].

Twitter can be useful for exploring public opinions on health-related matters and it may play an important role in clinical settings by providing an avenue for patients to increase their knowledge regarding their diseases and by leading to a positive impact on their medical outcomes [12-14]. For example, a study showed that the mental health of the patients was affected by social media content, as positive messages were shown to reduce anxiety in patients with breast cancer who were using Twitter [12]. Moreover, social media contents show the public impression and knowledge in addition to their emotions and stress regarding diseases and their associated factors in real time [15,16].

The aim of this study was to report a content analysis of the Arabic tweets regarding chemotherapy to determine the categories of the contents and to explore the possible cases of misconceptions about chemotherapy in the Arab world. This study addresses the common areas of misconceptions on

cytotoxic chemotherapies in Arabic Twitter conversations, which may help to direct the future educational efforts to address these areas of misconception.

Methods

Data Collection

This observational study was conducted on Arabic tweets about chemotherapy over a 6-month period, and the main themes to which these tweets belonged were determined. A search was conducted on every publicly available tweet in Arabic containing any of the keywords mentioned in the supplementary file ([Multimedia Appendix 1](#)). Keywords were chosen on a linguistic basis; therefore, they represented all the possible spellings and abbreviations of the word "chemotherapy" in Arabic. The Twitter Archiver add-on to Google Sheets was used to collect the data [17]. This tool searches for new public tweets every 15 minutes that include any prespecified keywords and allows users to download them on a Microsoft Excel spreadsheet. Further, this tool collects the related data of every user whose tweet has been collected such as the number of people who follow those users, whom they follow, and a brief biography that users may share about themselves on the profile page. All Arabic tweets from May 1, 2017 to October 31, 2017 that contained any of the predetermined keyword(s) were retrieved. Among these, we excluded all retweets because they might deviate from the thematic analysis as they do not necessarily imply endorsement and we excluded irrelevant tweets containing the keyword but that were used in a context other than chemotherapy as a medical intervention (eg, chemical weapon attacks in Syria).

Data Analysis

To help expand the knowledge on the tweets circulated on chemotherapy, the main questions asked to generate the coding scheme were if there were misconceptions or not about chemotherapeutic agents as cancer treatments and what other patterned meanings appeared in the data set. After a thorough study of a sample of 150 tweets, the primary author generated a preliminary list of the themes of the tweets and the categories of the users. This list was used by the rest of the authors to code the same 150-tweet sample for the themes and the categories of the users, which resulted in the modification and addition of a few themes. Thereafter, another 150 tweets were used to finally test the comprehensiveness of the themes and the categories of the users along with assessing the inter-rater reliability of the coders of the main data set (JA and KA) by using the Cohen kappa coefficient. The Cohen kappa coefficients were estimated as 0.90 and 0.92 for themes and categories of users, respectively. [Table 1](#) describes the themes of the tweets and the illustrative quotes translated from Arabic. [Table 2](#) describes the different categories of the users who were identified on the basis of the information provided in their biographies mentioned in their Twitter profile page or on the basis of their tweets.

Using the coding scheme, 2 of the investigators (JA and KA) independently assigned each tweet and the user who shared it to the proper mutually exclusive theme and user category. Cases of ambiguity were resolved by consensus among the authors.

Tweets under the misconception theme were further analyzed to establish the most common misconceptions among the studied groups of users.

Table 1. Descriptions of the different themes of the tweets on chemotherapy and the illustrative tweets.

Theme of the tweet	Description	Examples of the translated tweets
Advice and information	Disseminating true information and advice about chemotherapy	<i>...We use chemotherapy because its efficacy is proven—that is why it is called as evidence-based medicine.</i>
Experience	Sharing an experience of chemotherapy either by the patients themselves or by the people who surround them	<i>...My brother is on chemotherapy—the first session was on his birthday. It was like a birthday present—a painful and sad present.</i>
Misconception	Sharing a false concept or a false idea about chemotherapy	<i>...a long time ago I heard that a cure for cancer was discovered, but the person who discovered it was killed because companies wanted to benefit from the profits that are generated from selling chemotherapeutic drugs.</i>
Prayers and wishes	Saying a prayer or a wish for recovery for people receiving chemotherapy	<i>...They have been worn out by cancer, by chemotherapy...oh Allah heal our patients and all Muslim patients.</i>
Seeking medical information/advice	Asking for medical information about chemotherapy	<i>...If a patient has started chemotherapy for treating cancer, does he lose only the scalp hair or does he lose the hair all over his body?</i>
Seeking medical/financial help	Asking for medical or financial help for patients receiving chemotherapy	<i>...My mother is supposed to receive chemotherapy this week but we cannot afford it. All radiographic images and reports are attached. We need your help.</i>
Offering medical intervention/financial help	Offering medical or financial help for patients needing or receiving chemotherapy.	<i>...If anyone is in need of paclitaxel, which is a chemotherapeutic drug that is well over 3000 Egyptian pounds (US \$187), please do not hesitate to contact me.</i>
Analogy	Using chemotherapy in an analogic way to share an idea or a concept.	<i>...Whatever concerns you now is nothing compared to those who are waiting for chemotherapy or hemodialysis tomorrow.</i>
Miscellaneous	Tweets that did not fit any of the other categories.	<i>...I hope I can discover a cancer treatment better than chemotherapy.</i>

Table 2. Description of the categories of the different Twitter users who tweeted on chemotherapy.

Category of the Twitter user accounts	Description of the Twitter user accounts
Patients with cancer/survivors	Accounts of patients with cancer receiving chemotherapy
Relatives/friends of patients with cancer	Accounts of a relative or a friend of a patient receiving chemotherapy
Cancer specialists	Accounts of people working in the oncology field
Health-related accounts	Accounts of an organization in the medical field or of a person working in a medical field other than oncology
Media-related accounts	Accounts of media platforms such as newspapers and news channels
General users	Accounts of anyone who does not belong to the other categories or who belongs to unidentified accounts.

Statistical Analysis

Statistical analysis was performed using the SPSS software (release version 23.0.0.0, IBM Corp). Descriptive statistical analyses were used to report the frequencies for each theme and the category of the users. The chi-square test for independence was used to assess any significant associations between the types of users and the themes of the tweets. To further identify the cells that contributed to the overall significant results, adjusted residuals (z-scores) were calculated for each cell along with the *P* values, as described by Beasley and Schumacker [18]. Taking into consideration the multiple comparisons in this analysis that might lead to type I error, a Bonferroni-adjusted *P* < .001 was utilized to indicate statistical significance.

Results

Frequency of Themes and Categories of Users

A total of 402,157 tweets were retrieved. Of these, we excluded 309,602 retweets and 62,651 irrelevant tweets (Figure 1). Therefore, 29,904 tweets were included in the final analysis. Table 3 provides the frequencies of all the themes and the user categories. Under the 9 previously identified themes, over two-thirds of the tweets (20,288/29,904; 67.8%) expressed “prayers and wishes” for the recovery of patients with cancer on chemotherapy. Approximately 7.0% (2084/29,904) of the tweets contained misconceptions regarding various aspects of chemotherapy. Providing “advice and information” was the third most frequent theme (1888/29,904, 6.3%), followed by tweets expressing “experience” (1847/29,904, 6.2%) with

chemotherapy for cancer management and, lastly, tweets that used 1 or more of the keywords for “analogy” (1556/29,904, 5.2%).

Figure 1. Overview of the process of collecting and filtering the data.

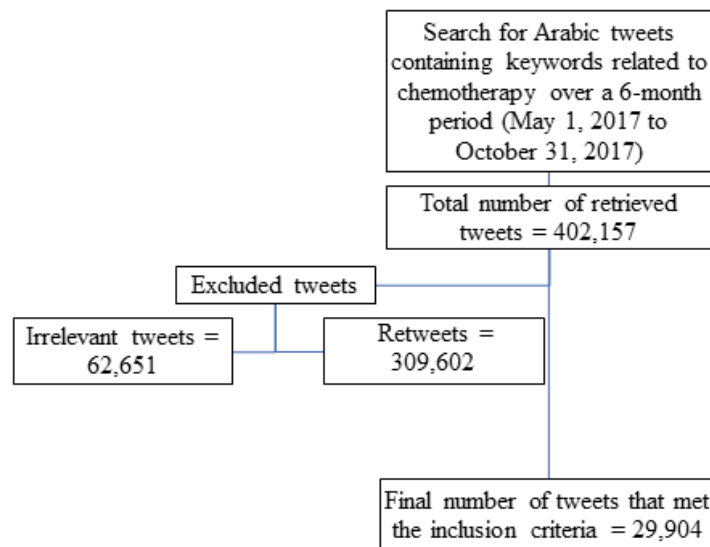

Table 3. Frequency analysis of the themes of the tweets on chemotherapy and the Twitter user categories (N=29,904).

Variable	n (%)
Themes	
Miscellaneous	932 (3.1)
Advice and information	1888 (6.3)
Experience	1847 (6.2)
Misconception	2084 (7.0)
Prayers and wishes	20,288 (67.8)
Seeking medical information/advice	487 (1.6)
Seeking medical/financial help	754 (2.5)
Offering medical/financial help	66 (0.2)
Analogy	1556 (5.2)
Category of users	
General users	25,774 (86.2)
Patients with cancer/survivors	854 (2.9)
Relatives/friends of patients with cancer	1913 (6.4)
Cancer specialists	222 (0.7)
Health-related accounts	459 (1.5)
Media-related accounts	680 (2.3)

In terms of the proportions of the categories of the users, general users represented the majority of the users in the analyzed data set (25,774/29,904, 86.2%). The relatives and friends of patients with cancer were the second most common contributors (1913/29,904, 6.4%), followed by patients with cancer and survivors (854/29,904, 2.9%). Cancer specialists, health-related accounts, and media-related accounts represented the remaining less than 5% (1361/29,904, 4.5%) of the tweets. Tweets under the theme “misconceptions” were further analyzed to capture the most common misconceptions, as described in detail in

Table 4. Falsified and unrealistic side effects of chemotherapy were the most common misconceptions (1271/2084, 60.9%) in the studied data set. The other misconceptions were that chemotherapy causes cancer to spread (282/2084, 13.5%) and that chemotherapy has no therapeutic benefit (214/2084, 10.3%).

We compared the volumes of the tweets of misconception with the volumes of the tweets by cancer specialists and health-related accounts for the same period, and we found that the 2 noticeable spikes on June 1-16, 2017 and July 1-16, 2017 in the volume

of the tweets containing misconceptions seemed to drive both categories of users to tweet more (Table 5).

Table 4. Frequency of the main misconceptions about chemotherapy in the Arabic tweets (n=2084).

Misconceptions	n (%)
Falsified and unrealistic side effects about chemotherapy; the main shared tweet was that “a drop of chemotherapy spilled on a healthy man’s skin would severely burn the skin.”	1271 (60.9)
Chemotherapy causes cancer to spread.	282 (13.5)
Chemotherapy has no therapeutic effect on cancers.	214 (10.3)
Claims that there are natural products/preparations (eg, olive oil, <i>Nigella sativa</i> , ginger, almonds, camel milk or urine) or other practices (eg, blood cupping, carbohydrate restriction), which are more effective than chemotherapy for treating cancers	170 (8.2)
Chemotherapy is prescribed so that pharmaceutical companies and physicians can make huge profits.	67 (3.2)
Claims about some pharmaceutical products (eg, vitamin B17, antibiotics, vitamin C) being more effective than chemotherapy for treating cancers	47 (2.3)
Claims that there are few religious practices (eg, Roqya, Zamzam water intake, seclusion in mosque, fasting from dawn to sunset), which are more effective than chemotherapy for treating cancers	33 (1.6)

Table 5. Comparison of the number of tweets containing misconceptions by any user category and the number of tweets by cancer specialists and health-related accounts during the study period.

Time period (2017)	Tweets containing misconceptions (n)	Tweets by cancer specialists and health-related accounts (n)
May 1-16	1616	35
May 17-31	1992	33
June 1-16 ^a	4365	108
June 17-30	2561	41
July 1-16 ^a	3441	104
July 17-31	2854	84
August 1-16	2486	21
August 17-31	2758	59
September 1-16	2026	49
September 17-30	2670	51
October 1-16	1372	52
October 17-31	1761	44

^aNoticeable spikes in the number of tweets containing misconceptions and tweets by cancer specialists and health-related accounts.

Comparison of the Themes by the Categories of the Users

The initial Pearson chi-square test of independence showed a highly significant association between the category of the users and the themes of tweets ($\chi^2_{40}=16904.4$, $P<.001$). Further post-hoc analyses revealed the cells that contributed the overall significance (Table 6).

Table 6 shows that general users were more likely to support patients with cancer by tweeting prayers and wishes and less likely to tweet about experiences, seeking medical intervention, and advice and information themes. Patients with cancer and the relatives and friends of patients with cancer tweeted

significantly more about experiences and seeking medical advice and intervention than all other themes. They were less likely to tweet misconceptions. Cancer specialists were more likely to tweet advice and information about chemotherapy and less likely to tweet either prayers and wishes or misconceptions. Health-related accounts showed a similar statistically significant tendency as the cancer specialists to tweet more about advice and information, but they had a greater tendency to tweet about offering medical interventions. Finally, media-related accounts were more likely to tweet about advice and information but also more likely to share misconceptions than all others. In contrast, they were less likely to share tweets on prayers and wishes or tweets containing analogy.

Table 6. Distribution of the themes by the source category.

Total number of tweets in each user category (n)	Theme-wise tweets								
	Miscellaneous, n (%)	Advice and information, n (%)	Experience, n (%)	Misconception, n (%)	Prayers and wishes, n (%)	Seeking medical advice, n (%)	Seeking medical/financial help, n (%)	Offering medical/financial help, n (%)	Analogy, n (%)
General users, n=25,774	760 (2.9) ^a	1120 (4.3) ^a	613 (2.4) ^a	1864 (7.2) ^a	19,294 (74.9) ^a	260 (1.0) ^a	291 (1.1) ^a	35 (0.1) ^a	1537 (5.9) ^a

Discussion

The aim of this study was to assess the types of conversations and misconceptions regarding chemotherapy among Twitter users in Arabic-speaking populations. Given the large number of tweets retrieved, with their further spread via retweets, our study solidified the conclusions of previous studies that showed Twitter as a rich social media platform for obtaining health-related information [19-23]. Therefore, understanding these social media websites and having a glimpse of what is shared on these websites might serve as an important step for physicians to improve the health care delivered to their patients.

Twitter also represents a growing venue for researchers to analyze on what is shared about various topics of interest in health care either related to oncology [13-19] or related to topics on other health care fields (eg, antibiotics [24], vaccinations [25], smoking [26,27]). Twitter provides researchers and health care organizations with an opportunity to outreach a wide group of participants, overcome barriers pertaining to research resources, and track emerging health-related discussions and problems in real time [28,29].

In our manual content analysis, the most common theme of the tweets was “prayers and wishes.” This finding highlights a possible role of social media platforms as a support mechanism for patients with cancer receiving chemotherapy. Previous studies have also shown that social media platforms play a positive role in optimizing health care interventions [30], particularly in oncology settings [31].

Tweets containing misconceptions accounted for 7.0% (2084/29,904) of the total tweets in our sample population, making it the second most common theme. A further analysis of the misconceptions showed that most of these misconceptions were on the unrealistic side effects of chemotherapeutic agents, and people who do not have the knowledge or the experience

of chemotherapy may tend to exaggerate their harmful effects, as reported in a previous study [5]. Therefore, health care organizations and professionals must tailor their awareness activities to target such common misconceptions in a given population.

Most of the tweets on media-related accounts delivered misconceptions about chemotherapy. We also found that when there was a spike in the misconceptions during the study period, the contributions of the cancer specialists and health-related accounts also increased proportionately to correct these misconceptions and to answer the questions of other users. This proportionate increase can limit the dissemination of misconceptions because cancer specialists and health-related accounts check the medical information that is tweeted and provide reliable information through tweets prior to sharing with the followers on Twitter. Further, health care organizations can promote the true information shared by cancer specialists and health-related accounts by using the payable option offered by Twitter to show a certain tweet in search results and user feeds so that wide groups of the targeted population can be reached with reliable information [32].

Among the themes of the studied tweets, those containing prayers and wishes were the most common. This finding corroborates that reported in previous studies that showed that religious coping strategies were the most commonly followed strategies by patients with cancer [33]. A study on Arab women in Israel who had breast cancer showed that most of them used religious coping skills to actively cope with their disease [34].

This study had the following limitations. First, even though we searched for tweets containing representative spelling variations and abbreviations for the word “chemotherapy” in Arabic, there is still a possibility of some tweets being missed. For example, some tweets may have not mentioned chemotherapy directly but may have tweeted about it indirectly. Second, even with the large number of tweets retrieved and analyzed, the

representativeness of the users and their age groups to the whole Arabic-speaking populations cannot be guaranteed. Third, the period of the study was 6 months. Longer study periods (eg, 1 year) will possibly give a broader view and include seasonal spikes such as special occasions such as Ramadan wherein prayers and wishes for recovery can increase, which might add valuable information to the current findings. Fourth, lacking automated content analysis might limit the reproducibility of the findings to some extent. Fifth, the generalizability of the findings is limited as tweets were subjected to multiple external factors that could not be controlled such as the timing of the tweets and the geographical place wherein the users lived [35]. Lastly, some users may have appeared multiple times within the data set which, to some extent, limits the interpretation of the statistical analysis, as their views on the matter being discussed might be overrepresented. Future studies should

account for bots and assess for their contributions in conversations about chemotherapy on Twitter.

In conclusion, our findings corroborate those of the previous studies that showed Twitter as a valuable social media platform to assess public perception and misconceptions about various health-related topics. Most of the tweets in our sample population showed supportive messages for patients undergoing chemotherapy, thereby suggesting that Twitter could play a supportive role for such patients, while the second most prevalent theme of the tweets in our study was misconceptions about chemotherapy. The findings of our exploratory analysis can help physicians and health care organizations tailor educational efforts in the future to address the common areas of misconceptions about chemotherapy, thereby leading to increased public acceptance of chemotherapy as a suitable mode of treatment for cancer.

Conflicts of Interest

None declared.

Abstract

Background: The popularity of dengue can be inferred from Google Trends that summarizes Google searches of related topics. Both the disease and its Google Trends have a similar source of causation in the dengue virus, leading us to hypothesize that dengue incidence and Google Trends results have a long-run equilibrium.

Objective: This research aimed to investigate the properties of this long-run equilibrium in the hope of using the information derived from Google Trends for the early detection of upcoming dengue outbreaks.

Methods: This research used the cointegration method to assess a long-run equilibrium between dengue incidence and Google Trends results. The long-run equilibrium was characterized by their linear combination that generated a stationary process. The Dickey-Fuller test was adopted to check the stationarity of the processes. An error correction model (ECM) was then adopted to measure deviations from the long-run equilibrium to examine the short-term and long-term effects. The resulting models were used to determine the Granger causality between the two processes. Additional information about the two processes was obtained by examining the impulse response function and variance decomposition.

Results: The Dickey-Fuller test supported an implicit null hypothesis that the dengue incidence and Google Trends results are nonstationary processes ($P=.01$). A further test showed that the processes were cointegrated ($P=.01$), indicating that their particular linear combination is a stationary process. These results permitted us to construct ECMs. The model showed the direction of causality of the two processes, indicating that Google Trends results will Granger-cause dengue incidence (not in the reverse order).

Conclusions: Various hypothesis testing results in this research concluded that Google Trends results can be used as an initial indicator of upcoming dengue outbreaks.

Introduction

Dengue is known as an infectious disease, which is caused by the dengue virus from *Flaviviridae* and genus *Flavivirus* families. This virus has four serotypes, namely DEN-1, DEN-2, DEN-3, and DEN-4 [1-3]. Infection by one of these four

serotypes does not give cross-protective immunity. Hence, people who live in endemic areas can be reinfected by the other three serotypes throughout their lifetime [4]. *Aedes aegypti* and *Aedes albopictus* mosquitoes are vector transmitters of dengue. The disease is transmitted by mosquitoes through arthropod vectors in tropical and subtropical areas around the world [5]. As the most rapidly spreading mosquito-borne disease in the

world, dengue fever has affected the lives of approximately 1.8 billion people in Southeast Asia alone. In the dengue-endemic region, Indonesia is one of the largest countries, with a population of 267 million [6]. Since the first dengue incidents reported in 1968, the number and range of dengue incidents in Indonesia have increased nationwide [7]. All 34 provinces in Indonesia have been reported to have dengue cases, showing the extensive range of the disease [8]. Early detection of disease activity can reduce the impact of the disease [9].

Bandung is one of the crowded cities in Indonesia. It has the highest dengue incidence, especially in West Java. Daily habits, landscape structures, weather, and the ecosystem in the city play roles in dengue vector breeding as primary factors for dengue transmission. The climate in Bandung is a mountainous climate (humid and cold), with an average temperature of 23.5°C. The average rainfall is 200.4 mm, and there are on average 21.3 rainy days per month. It is an ideal environment for *Aedes aegypti*. According to the Extraordinary Early Childhood Awareness System (SKDKLB-DBD) report, Bandung had the highest dengue incidence from 2002 to 2006, with a total of 22,335 infected people. In January 2019, the West Java Provincial Health Office recorded 236 dengue cases in Bandung. For these reasons, we selected Bandung as our study area to investigate and analyze the association between dengue data from Google Trends and dengue incidence data from a reputable hospital in Bandung.

In this modern world, it is impossible to say that technology, especially the internet, does not influence human lives. Over the years, research has been performed to investigate the accuracy of using internet search engine data to predict real-life phenomena, such as influenza epidemics and flu trends [9], stock markets [10-12], house prices [13,14], and tourism demand [15-17]. Google Trends is a public website belonging to Google Inc that offers data based on Google Search, which shows how frequently a particular search term is entered.

According to StatCounter, in 2016, Google was the most used text search engine in Indonesia. About 97% of people who use the internet in Indonesia use Google. It is assumed that Indonesian people show the trends to find information about dengue on the internet [18]. Therefore, we hypothesized that the popularity of dengue on Google has a correlation with the dengue incidence in Indonesia. Several studies about Google Trends results and the relationship with various diseases have been carried out, such as a study on dengue fever in Indonesia by using moving average analysis [19]. Other Google Trends-related work is presented in the following sentences. Dengue in several countries (Bolivia, Brazil, India, Indonesia, and Singapore) has been studied to maximize a fitting model by using a univariate linear model [20]. A spatiotemporal analysis of dengue incidence has been performed by using an exponential generalized autoregressive condition heteroscedastic model [21]. In other studies, we can see a web-based search for the early identification of the disease prevalence of coronary heart disease [22], forecasting of influenza cases using internet

data [23], the use of Google Trends in health care research by using correlation analysis [24], infodemiology and infoveillance [25-27], a framework of social media data and quality assessment for a reporting standard [28], the spread of pertussis in Europe [29], and the spread of AIDS in the United States [30]. This led us to hypothesize that dengue incidence and Google Trends results have a long-run equilibrium.

We started our research with an initial hypothesis that the popularity of dengue on Google correlates with dengue cases in Bandung. We then investigated the relationship between these two data by using the Dicky-Fuller test, error correction model (ECM), impulse response function, and variance decomposition. We hoped that information from Google Trends can be used for the early detection of upcoming dengue outbreaks so that policymakers can prepare for the early prevention or control of the epidemic.

Methods

Collected Data

Google Trends is a website that analyzes the popularity of a topic in various countries and various languages based on search requests. The data source is over the internet and open source and can be easily accessed by everyone. In Google Trends, a user can enter a keyword in the form of words or phrases related to the selected topic or cases. Google Trends is not case sensitive but takes into account spelling errors that might occur. Users can specify the duration of time they want to review by selecting a time range or specifying a date. In addition, users can specify the area to be reviewed by selecting the appropriate country, city, or province or state. They can also see the popularity of these keywords globally by selecting the option *worldwide*.

Data used in this study are time-series data of dengue incidence from Santo Borromeus Hospital in Bandung, as well as popularity data taken from Google Trends via the website (Figure 1). The time range used in this paper is from September 9, 2012 until September 7, 2017. We consider weekly data over the time interval, and there were 261 data points. We assumed that the incidence data represent all dengue cases in Bandung owing to the location of the hospital in the city center. Google Trends data were obtained from the Google Trends website on google [31] by entering the keyword “demam berdarah dengue” plus “dbd.” With regard to the technique of taking data, we followed previous guidelines [32] when using Google Trends for valid results in our study by selecting the appropriate keyword(s), region(s), period, and category. Quotation marks were used so that the search results only showed the popularity of keywords in that exact order. The data represented the popularity of the keyword “demam berdarah dengue” plus “dbd” found on Google. Google Trends normalizes its popularity data by dividing each data point by the total amount of searches at a given time and location. This results in a proportion scaled in a range from 0 to 100. This scale shows the popularity of specific keywords relative to the time and location of the query.

Figure 1. Dengue data plot from Google Trends and reported cases in Bandung.

Stationary Test

We performed a stationary test for the time series data of Google Trends (X_t) and the dengue incidence (Y_t). A time series $\{y_t\}$ is said to be stationary if it satisfies the following conditions: (1) $E[y_t] = \mu < \infty$; (2) $Var[y_t] = \sigma^2 < \infty$; and (3) $Cov[y_t, y_{t+s}] = \gamma_s < \infty$, for $s > 0$.

Differencing a series produces another set of observations, such as the first differenced values, where $\Delta y_t = y_t - y_{t-1}$. Generalizing this operation and performing the difference operation as much as n times can be written as $\Delta^n y_t = y_t - y_{t-n}$. If a series is stationary without any differencing, it is said to be integrated of the order 0 or $I(0)$. However, if it is stationary only after differencing once, it is said to be integrated of the order 1 or $I(1)$. The Dickey-Fuller test was used to detect the presence of a unit root and determine the stationarity of Google Trends and dengue fever incidence series.

Cointegration Test

For cointegration, Engle and Granger [33] used the stationarity test of the residual series obtained from the long-run equilibrium equation. If the residual series, denoted by $\{e_t\}$, is stationary, given that y_t and z_t are first-order stationary, they are cointegrated.

After finding the Google Trends and dengue incidence series to be first-order difference stationary, the long-run equilibrium relationship can be stated in the following form:

$$Y_t = \beta_0 + \beta_1 X_t + e_t \quad (1)$$

where e_t denotes the residual.

Let $\{\hat{e}_t\}$ be the residual sequence. The series $\{\hat{e}_t\}$ contains the estimated values of deviations from the long-run relationship.

By using the Dickey-Fuller test to check its stationarity, it was found that the level values of $\{\hat{e}_t\}$ were stationary.

Estimation and Analysis of a Vector ECM

After a cointegrating relationship has been established, an ECM can be built to establish the short-run relationship between two variables. A likelihood ratio test can be used to determine the time lag of the vector ECM or the value of p . The regression equation for an ECM is as follows:

$$\Delta y_t = \alpha_1 (y_t - z_t) + \epsilon_t$$

Analysis of cointegration shows that Google Trends and dengue incidence have a long-run equilibrium relationship. However, they are in disequilibrium in the short term. View equations 2 and 3 as a vector autoregression (VAR) model as follows:

$$\begin{bmatrix} \Delta y_t \\ \Delta z_t \end{bmatrix} = \begin{bmatrix} \alpha_{11} & \alpha_{12} \\ \alpha_{21} & \alpha_{22} \end{bmatrix} \begin{bmatrix} y_{t-1} \\ z_{t-1} \end{bmatrix} + \begin{bmatrix} \epsilon_{1t} \\ \epsilon_{2t} \end{bmatrix}$$

Hence, the vector ECM at hand can be written as a VAR model as follows:

$$\begin{bmatrix} y_t \\ z_t \end{bmatrix} = \begin{bmatrix} \alpha_{11} & \alpha_{12} \\ \alpha_{21} & \alpha_{22} \end{bmatrix} \begin{bmatrix} y_{t-1} \\ z_{t-1} \end{bmatrix} + \begin{bmatrix} \epsilon_{1t} \\ \epsilon_{2t} \end{bmatrix}$$

Before estimating the vector ECM, the optimal lag order is first determined.

Causal Relationship Between Google Trends and Dengue Incidence

One way to test causality is to see whether the time lag of one variable is relevant for another variable. In a two-equation system with stationary variables y_t and z_t with p lags, it is said that $\{y_t\}$ does not Granger-cause $\{z_t\}$ if and only if the coefficients of y_t in the equation for z_t are equal to zero. In other words, if $\{y_t\}$ does not provide improvement for the forecasting performance of $\{z_t\}$, $\{y_t\}$ does not Granger-cause $\{z_t\}$. Granger

causality only shows the effects of past values of $\{y_t\}$ toward the current values of $\{z_t\}$.

In order to test Granger causality, a standard F test of the restriction $a_{21}(1) = a_{21}(2) = \dots = a_{21}(p) = 0$ is performed.

In a cointegrated system, X_t does not Granger-cause Y_t if the values of ΔX_{t-i} do not enter in the equation of ΔY_t and if Y_t does not respond to deviation from the long-run equilibrium.

Impulse Response Function and Variance Decomposition

To analyze the dynamic effects of the model in response to shocks and the effects on the two variables, the impulse response function and variance decomposition were examined.

Table 1. Dickey-Fuller test for Google Trends data, dengue incidence data, first differenced Google Trends data, and first differenced dengue incidence data.

Variable	Dickey-Fuller test statistic (value)	Dickey-Fuller critical value (N=250)
X_t^a	-2.42 (.02)	-2.58
Y_t^b	-2.24 (.03)	-2.58

^cFirst differenced Google Trends data.

^dFirst differenced dengue incidence data.

Figure 2. (A) $\{X_t\}$ and (B) $\{Y_t\}$ plots with one-time difference. X_t : Google Trends data; Y_t : dengue incidence data.

Cointegration Test

The cointegration test results of ordinary least squares regression yielded that the long-run equilibrium relationship can be shown as follows:

$$\begin{bmatrix} X_t \\ Y_t \end{bmatrix} = \begin{bmatrix} \alpha_1 \\ \alpha_2 \end{bmatrix} + e_t$$

with e_t denoting the residual.

Results

Stationary Test

The stationary test results can be seen in Table 1, Figure 2A, and Figure 2B. The table shows that the level values of the Google Trends and dengue incidence series were nonstationary. However, Google Trends and dengue incidence data were found to be stationary after being differentiated once. This was done to reduce the fluctuations in the data.

Let $\{\hat{e}_t\}$ be the residual sequence. The series $\{\hat{e}_t\}$ contains the estimated values of deviations from the long-run relationship. By using the Dickey-Fuller test to check its stationarity, it was found that the level values of $\{\hat{e}_t\}$ were stationary. The results are shown in Table 2.

From previous results, it was seen that $\{X_t\}$ and $\{Y_t\}$ are $I(1)$, and because the $\{\hat{e}_t\}$ series is stationary, $\{X_t\}$ and $\{Y_t\}$ are cointegrated. Hence, a vector ECM can be constructed.

Table 2. Dickey-Fuller test for the residual sequence.

Variable	Dickey-Fuller test statistic	Dickey-Fuller critical value (N=250)
e_t^a	-8.77	-2.58

^aresidual estimated as follows: $e_t = Y_t - 12.609 - 0.455X_t$

Likelihood Ratio Test to Find the Time Lag

The longest feasible lag length was set as 8 weeks. Thereafter, the value of the determinant of the variance-covariance matrix of a model with lag length eight was examined (denoted as Σ_8) and compared with that of a model with lag length seven (denoted as Σ_7). The likelihood ratio is $(T - c)(\ln \Sigma_7 - \ln \Sigma_8)$, where T is the number of observations and c is the number of parameters that are estimated in each equation of the unrestricted

system. In the case of comparing the eight-lag model to the seven-lag model, the value of c is $1 + 8n$, with n being the number of variables, which is two in this case. If the likelihood ratio is smaller than the critical value (χ^2_4 at a significance of $\alpha=1\%$), the null hypothesis of the restriction $A_8=0$ is rejected. This is done until lag 1.

The results of this test are shown in Table 3. The likelihood ratio test showed that the optimal number of lags needed for this vector ECM is three.

Table 3. Likelihood ratio test for lag length.

Number	H_0	H_1	Likelihood ratio	χ^2_4	Verdict
1	$A_8=0$	$A_8 \neq 0$	7.655	13.277	H_0 rejected
2	$A_7=0$	$A_7 \neq 0 A_8=0$	3.291	13.277	H_0 rejected
3	$A_6=0$	$A_6 \neq 0 A_8=A_7=0$	0.221	13.277	H_0 rejected
4	$A_5=0$	$A_5 \neq 0 A_8=\dots A_6=0$	2.543	13.277	H_0 rejected
5	$A_4=0$	$A_4 \neq 0 A_8=\dots A_5=0$	6.191	13.277	H_0 rejected
6	$A_3=0$	$A_3 \neq 0 A_8=\dots A_4=0$	19.666	13.277	H_0 rejected
7	$A_2=0$	$A_2 \neq 0 A_8=\dots A_3=0$	27.887	13.277	H_0 rejected
8	$A_1=0$	$A_1 \neq 0 A_8=\dots A_2=0$	60.361	13.277	H_0 rejected

Estimation of the ECM

After finding the optimal number of lags, an ECM model was built. The estimated vector ECM is as follows:

From the equation, it is seen that the speed of the adjustment parameter is -0.1816 for $\{Y_t\}$ and -0.0267 for $\{X_t\}$. This means that when there is a deviation of 1 from the long-run equilibrium in the period $t - 1$, the number of dengue incidences will decrease by 0.1816 and dengue popularity in Google will decrease by 0.0267.

The speed of adjustment parameter for dengue incidence was nine times larger than the value for Google Trends, meaning that dengue incidence is more responsive to deviations from the long-run equilibrium. On the other hand, Google Trends only responds slightly to the aforementioned deviation.

It was found that this model has an R-squared value of 0.4128 for the ΔX_t equation and 0.1511 for the ΔY_t equation, as well as an Akaike Information Criterion (AIC) value of 2370.2. Since the R-squared value is quite low, it can be said that the model cannot explain the data at hand accurately.

Causal Relationship Between Google Trends and Dengue Incidence

Based on the vector ECM in equation 7, Granger causality was tested between Google Trends and dengue incidence. It was noted that at lag 2 and 3, X_t Granger-causes Y_t at a significance of $\alpha=5\%$, since the P obtained was similar (.04). However, Y_t does not Granger-cause X_t . This means that information from past values of Google Trends regarding dengue at a lag of 2 and 3 weeks is useful for explaining the present value of dengue incidence. The results are shown in Textbox 1.

 $H_0: \beta_1 = \dots = \beta_j = 0$ (incidence does not Granger-cause Google Trends)

☐

Impulse Response Function and Variance Decomposition

The results for 12 periods (3 months) are obtained as presented below.

Impulse Response Function

As shown in [Figure 3B](#), a positive shock in dengue popularity on Google Trends has a relevant impact on dengue incidence. Dengue incidence shows a large increase after two periods. Thereafter, it shows a slight decrease, but then, it increases again slowly. Its effects seem to be long term, since the incidence keeps increasing until the end of the 12 periods. This phenomenon suggests that shocks in dengue fever popularity on Google have a relevant impact on dengue fever incidence.

On the other hand, through analysis of the response of dengue incidence to a positive shock, it was found that dengue popularity increases slightly and then remains constant. This behavior is presented in [Figure 3A](#). After a positive shock in dengue incidence, there is little fluctuation in its popularity on Google Trends. This suggests that shocks in dengue incidence do not have a relevant effect on its popularity on Google Trends. Its effects are only short term and do not remain in the long run.

Generally, the impulse response function shows that Google Trends has a relevant impact on dengue fever incidence and has a long-term effect. On the contrary, dengue incidence has only a short-term and small effect on the popularity of dengue on Google.

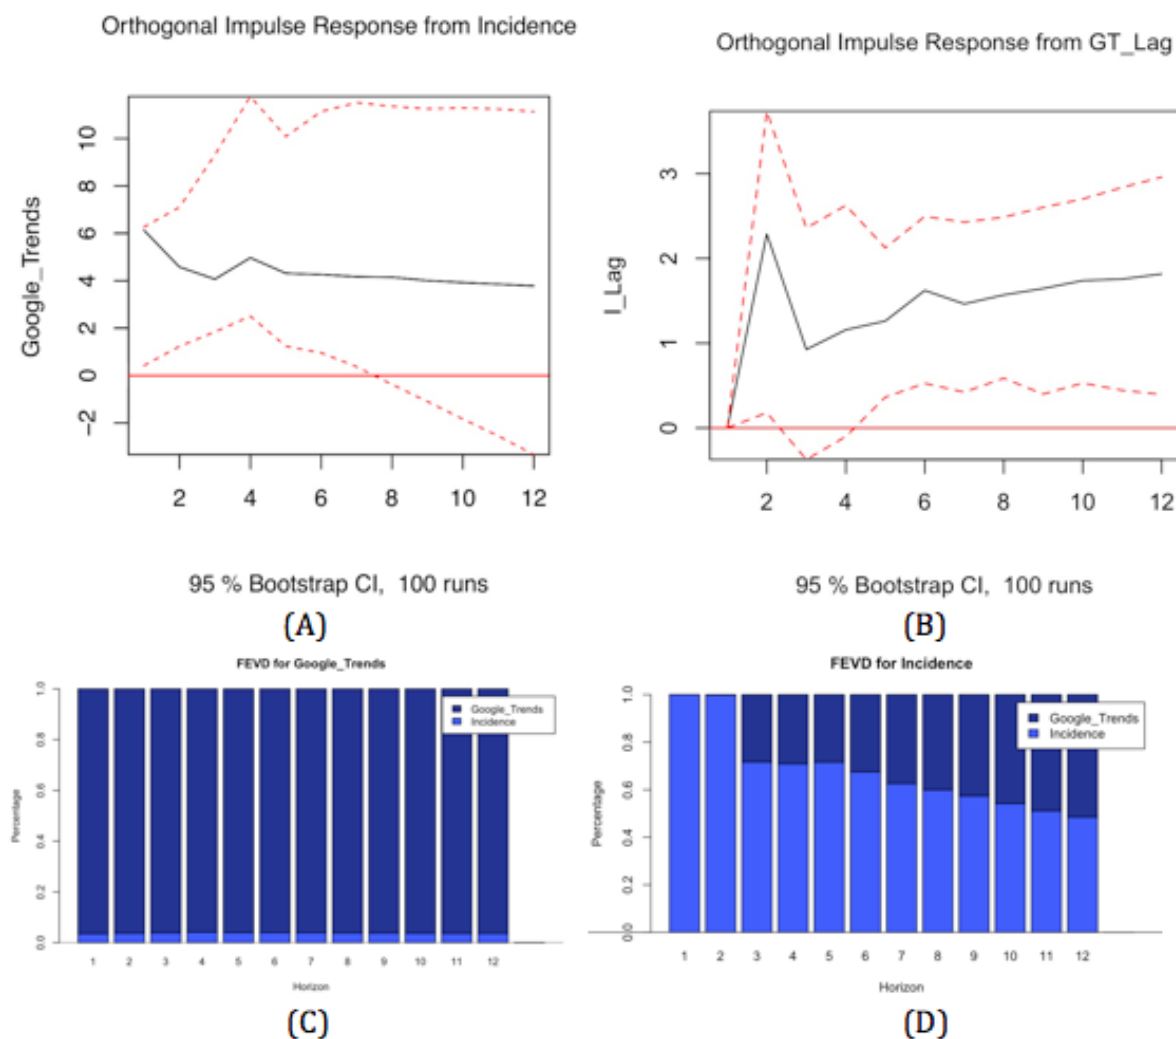

Variance Decomposition

Variance decomposition estimates the contribution of shocks in a variable toward the response of another variable. As shown in [Figure 3D](#), the contribution of dengue incidence to its variance gradually declines in the first two periods. Thereafter, it declines further until the contribution of dengue incidence is finally only around 40%. In the first period, Google Trends only has a small contribution to dengue incidence variance with only 0%. Thereafter, during the second period, it increases to around 28% and then continues to climb gradually. After the 12 periods, Google Trends has up to 60% contribution to dengue incidence variance.

On the other hand, [Figure 3C](#) shows that Google Trends variance mainly comes from itself, where dengue incidence only contributes at a rate of approximately 4%. This rate increases in the first four periods (from 3.6% in the first period to 4.2% in the fourth period). Thereafter, the contribution rate from dengue incidence remains around 3.7%. This means that dengue incidence very slightly influences Google Trends in the short term, but does not influence the popularity of Google Trends in the long term.

In summary, it can be seen that Google Trends influences dengue incidence in the long term, but dengue incidence only influences Google Trends in the short term and not in the long term. As presented in the model, dengue incidence is related to not only the popularity of dengue in Google but also its lagged value of up to 1 week.

Figure 3. Impulse response function of (A) dengue data from Google Trends with respect to reported cases and (B) reported cases with respect to dengue data from Google Trends. Forecast error variance decomposition of (C) dengue data from Google Trends and (D) reported cases.

Discussion

Principal Findings

Our results show that there is indeed a causal relationship between dengue popularity in Google Trends and dengue incidence in Bandung. A Granger cointegrated relationship between dengue popularity in Google Trends and dengue incidence in Bandung was noted. This is justified because both data sets were found to be $I(1)$, and the residual from the ordinary least squares regression was also found to be stationary.

Based on the ECM, it can be seen that there is a relationship between Google Trends results and dengue incidence. Through Granger analysis, it was seen that Google Trends Granger-causes dengue incidence in Bandung at a lag of 2 and 3 weeks. This was further supported by the impulse response function, where shocks in dengue popularity in Google cause dengue incidence to increase. It was also supported by the variance decomposition, where after 1 week, the contribution from Google Trends to dengue incidence variance increases. Granger analysis also showed that dengue incidence does not Granger-cause its popularity in Google.

The vector ECM also showed that dengue incidence is more responsive to deviations from the long-run equilibrium, since it has a larger value of the speed of adjustment, which is nine times the value for Google Trends.

Limitations

The results showed a causal relationship between dengue popularity in Google Trends and dengue incidence in Bandung. However, this exact ECM cannot be used for forecasting or early detection owing to the low R-squared values of 0.4128 for the Google Trends equation and 0.1511 for the dengue incidence equation. A further improved model will need to be built for future forecasting.

The results of this study can help provide a more real-time indication of dengue outbreaks in Bandung. Owing to Indonesia's standard and traditional approach to dengue surveillance, the data of dengue cases have several weaknesses, such as low accuracy and timeliness [20]. In addition, data available from Santo Borromeus Hospital were only from 2008 until 2017. Owing to the limitations of Google Trends, it was preferable to use weekly data with a 5-year period (giving 260 data points) rather than data from 2008 to 2014 on a monthly

basis with only 84 data points. Another limitation is that people searching for dengue-related information may not necessarily have the disease, as they could be searching because a relative or friend is ill. Besides, a search in Bandung does not necessarily mean that the intended sick person is in Bandung. The individual could be searching for someone else who is ill in another city.

Our proposed model used strong assumptions, such as the behavior of the use of gadgets and social media in the

community, which is quite high, and a good internet signal in the observation area (Bandung in this case). Therefore, it is risky to implement the findings in areas with low internet access.

Conclusions

Google Trends data may be used as an initial indicator of a dengue outbreak in Bandung. However, further improvements to the ECM need to be made by using more data points to gain more extensive insights.

Abstract

Background: Discrimination in the health care system contributes to worse health outcomes among lesbian, gay, bisexual, transgender, and queer (LGBTQ) patients.

Objective: The aim of this study is to examine disparities in patient experience among LGBTQ persons using social media data.

Methods: We collected patient experience data from Twitter from February 2013 to February 2017 in the United States. We compared the sentiment of patient experience tweets between Twitter users who self-identified as LGBTQ and non-LGBTQ. The effect of state-level partisan identity on patient experience sentiment and differences between LGBTQ users and non-LGBTQ users were analyzed.

Results: We observed lower (more negative) patient experience sentiment among 13,689 LGBTQ users compared to 1,362,395 non-LGBTQ users. Increasing state-level liberal political identification was associated with higher patient experience sentiment among all users but had stronger effects for LGBTQ users.

Conclusions: Our findings highlight that social media data can yield insights about patient experience for LGBTQ persons and suggest that a state-level sociopolitical environment influences patient experience for this group. Efforts are needed to reduce disparities in patient care for LGBTQ persons while taking into context the effect of the political climate on these inequities.

Introduction

Health Disparities and Discrimination in Health Care Among Lesbian, Gay, Bisexual, Transgender, and Queer Patients

Across several health indicators, lesbian, gay, bisexual, transgender, and queer (LGBTQ) people consistently experience worse health outcomes than their non-LGBTQ counterparts [1]. Discrimination in the health care system is associated with worse health outcomes [2-4]. Previous studies have shown that LGBTQ persons report increased rates of discrimination from medical providers and other staff across a wide variety of health care settings [5,6]. In one study, almost one-third of transgender survey respondents reported postponing medical care because they experienced discrimination [6]. In addition, many LGBTQ persons report reluctance to disclose their sexual orientation or gender identity to their health care providers [7,8]. Such an environment results in a lack of understanding and acceptance of LGBTQ people and their specific health care needs, and leads to inadequate treatment and an erosion of trust in the health care services for this group [7,8]. Although there has been increasing awareness and understanding of LGBTQ patient experiences, many recent studies have consisted of small qualitative inquiries focused on specific LGBTQ populations [9-12]. Furthermore, there is a dearth of valid scales and indices that measure LGBTQ patient experience [13] as well as limited research on the sociopolitical cultural factors that contribute to these discriminatory accounts.

Geographic Disparities in LGBTQ Health Care

There is a large body of evidence characterizing regional variation in health care and patient experiences across the United States [14-16]. Some studies have further stratified this variation by social variables such as socioeconomic status and race [15,17]. However, research has yet to explore the geographic disparities for LGBTQ care due to methodological limitations in the identification of LGBTQ patients [18]. US states vary considerably in their policies and practices that provide protection against sexual orientation and identity-based discrimination. In the areas of employment, housing, public accommodations, and health care services, there is wide variation of legislatures and pre-empt local protections that help protect LGBTQ persons by ensuring fair and equal treatment [19,20]. Although certain states have adopted protection laws for LGBTQ persons, other states have not been committed to the passage or enforcement of local nondiscrimination laws [21]. In fact, some states have policies that explicitly prevent the passage or enforcement of local nondiscriminatory laws, including those that relate to health care [21]. States without LGBTQ protective policies also tend to have higher percentages of conservative voters [22], and the social climate of a geographic area has been shown to be associated with differences in health outcomes for LGBTQ persons [23,24]. Prior research has also shown that residence in areas with a higher percentage of Republican voters is associated with a greater risk for depression among LGBTQ youth at the neighborhood level [25] and health care refusal among transgender patients at the state level [21]. In addition, physician

political identity has been shown to be highly correlated with treatment decisions, with physician partisan bias leading to variation in patient care [26]. However, a large-scale, geographically contextual analysis has not been conducted to study the effect of the political environment on LGBTQ patient experience.

Twitter as an Outlet for Patient Feedback

Recently there has been a shift in US health care to emphasize patient experiences, as this has been linked with quality of care [16]. Novel methods based on online data have been applied to studying this field [27]. For instance, the social media platform Twitter has been shown to be an effective resource for obtaining unsolicited feedback on quality of hospital care [16,27-29]. It has also been validated as a method to characterize differences in LGBTQ hospital care across the United States [30]. This previous study assessed how hospitals either supported or did not support LGBTQ care and showed that hospitals deemed as having LGBTQ equitable policies were also shown to be more supportive toward LGBTQ practices on Twitter. However, it did not investigate LGBTQ patient users' experiences or how geopolitical state-level factors may influence the sentiment of these experiences. Other studies have demonstrated the feasibility and promise of real time social media sites to study the patient experiences of LGBTQ communities but only in small-scale content analyses, and they did not consider how geographic variation in political identity may shape these experiences [31,32]. In these ways, online social media information from LGBTQ patients can provide researchers with unfiltered accounts of patient experience and help develop an understanding of the complexities surrounding LGBTQ health disparities [33,34].

This study sought to fill the gap in research by examining the geographic variation in patient experiences among LGBTQ persons in the United States using novel computer science methods to curate a large-scale data set from the online social media platform Twitter. The goal of this research was to identify differences in patient experience among LGBTQ and non-LGBTQ patients, and to statistically model the state-level geopolitical factors that are associated with LGBTQ patient experiences using Twitter. Understanding the political factors associated with LGBTQ patient experience can be used to uncover reasons for these LGBTQ disparities in care and inform the development of targeted interventions to improve equity and advocate for this marginalized group.

Methods

Sample

Health Care Patient Experience Twitter Data

Tweets relating to patient experience from February 16, 2013, to February 15, 2017, were collected. A supervised machine classifier was built from a combination of keywords and rule-based learning algorithms to identify tweets related to health care patient experiences in the areas of medical facility and staff, medical procedures, hospital visits and stays, medications, hospital bills and insurance, care condition, and pain. Tweets repeated more than 5 times from the same user were deemed

irrelevant based on manual inspection and the tweet was removed from the data set. Geolocation was collected through the metadata of Twitter. Using the geolocation inference engine, we identified the latitude and longitude of tweets. We verified the accuracy of our geolocation classifier by using Amazon Mechanical Turk (MTurk) to manually curate 10,000 randomly selected tweets and found that using MTurk validated 91% ($n=9100/10,000$) of the inferred locations through the geolocation engine were correct (with 87%, $n=8700/10,000$ agreement between two MTurk curators). Only tweets with geolocation data were used for locational analysis. The detailed methods and validation of the patient experience data set procedure is documented in [Multimedia Appendix 1](#), which has been validated in a previous study [35].

LGBTQ Users

The Twitter user descriptions were collected. A user who used any of the terms “lesbian,” “gay,” “bisexual,” “transgender,” “trans,” “queer,” “LGBT,” “LGBTQ,” “intersex,” “homosexual,” or “cis” in their profile description was deemed an LGBTQ user. A non-LGBTQ user was defined as any Twitter user who did not use these terms in their profile description. The control population was comprised of the user population that did not self-identify as being LGBTQ on Twitter. The LGBTQ user was defined as a binary variable: tweets from LGBTQ users were labeled with 1, and tweets from non-LGBTQ users were labeled as 0. Tweets were labeled according to the user description at the time of the tweet; changes in LGBTQ or non-LGBTQ status over time were not considered. A conservative manual inspection of 200 user profile descriptions categorized as LGBTQ agreed 81% ($n=162$) of the time.

State Identification

Tweet latitude and longitude information were matched with the United States Census Bureau’s American Community Survey 5-year estimates to identify the corresponding state and generate a state-level field [36].

Geographic Regions

The geographic regions Northeast, Midwest, South, and West were determined by the US Census and were matched to the latitude and longitude of user’s tweets. The region of the Northeast includes Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, and Pennsylvania. The Midwest includes Ohio, Michigan, Indiana, Wisconsin, Illinois, Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, and Kansas. The South includes Delaware, Maryland, Virginia, West Virginia, Kentucky, North Carolina, South Carolina, Tennessee, Georgia, Florida, Alabama, Mississippi, Arkansas, Louisiana, Texas, Oklahoma, and Washington, DC. The West comprises of Montana, Idaho, Wyoming, Colorado, New Mexico, Arizona, Utah, Nevada, California, Oregon, Washington, Alaska, and Hawaii. Graphical map descriptions of patient experience sentiment maps of LGBTQ and non-LGBTQ users were conducted using the plotly Python (Python Software Foundation) visualization library [37].

Political Composition

Political party affiliation at the state level was retrieved through the Gallup Daily Tracking data set [22]. Political composition was defined as percent Republican and percent Democratic for each state. Democratic advantage was defined as percent Democratic minus percent Republican by each state and was included in the analysis as a continuous variable [22]. We chose to use political affiliation data from 2015 to represent the middle point of the study time frame. There may have been changes in political affiliation, but this was not measured for this study.

Dependent Variable: Sentiment of Patient Experience Tweet

Sentiment analysis has been frequently used to determine the attitude and emotion of the user (ie, author) with respect to a topic [38,39]. For instance, a user might tweet “the doctors were so knowledgeable and kind. Thank you!” that would be deemed as positive, whereas a tweet from a user that states “how could you allow patients to be treated so horribly” would be determined to possess negative sentiment. The sentiment of a patient experience tweet was defined as the attitude of the patient toward their health care experience. Sentiment analysis determines the attitude of the user by measuring the polarity of the sentiment which lies in the range of -1 to 1, where 1 is an extremely positive attitude and -1 means an extremely negative attitude. We measured the sentiment polarity using the widely accepted and used lexicon and rule-based sentiment classifier called Valence Aware Dictionary for Sentiment Reasoning (VADER) to identify the sentiment of the patient experience tweet [40]. VADER computes sentiment for each word and generates compound scores for the sentence by summing the sentiment score of each word. For VADER, a sentiment score is positive if the mean compound score is greater than or equal to 0.5 and negative if the score is less than or equal to -0.5. Mean compound scores between -0.5 and 0.5 are considered neutral. Scores of exactly 0.0 are discarded as they indicate that there is not sufficient context. We expanded on VADER’s dictionary and rules to better represent the microblogging style of platforms like Twitter. This included the incorporation of *emojis* and their respective sentiment scores.

Analysis

Data analysis was conducted using the scikit-learn [41] and statsmodels [42] packages in Python. Descriptive statistics were conducted to compare the frequency of tweets by each state-level factor between LGBTQ and non-LGBTQ Twitter users. Tweets were separated into LGBTQ user and non-LGBTQ user tweets, and the geolocation was identified. The proportion of LGBTQ or non-LGBTQ users in a region was calculated by dividing the number of either of these users in that region by the total number of users in the region. The mean democratic advantage was calculated by summing the democratic advantage of each user group and dividing it by the total number of users. Chi-square tests for proportions were conducted to compare the breakdown of LGBTQ users by geographic region compared to the breakdown of non-LGBTQ users by geographic region. An ordinary least squares regression was used to model the effect of state-level democratic advantage on patient experience sentiment while controlling for geographic region. The inclusion

of an interaction term between democratic advantage and LGBTQ status allowed for LGBTQ status to moderate the effect of democratic advantage on patient experience sentiment.

Regression Model

$$\text{tweet_sentiment} \sim \text{LGBTQ} + \text{democratic_advantage} + \text{LGBTQ} * \text{democratic_advantage} + \text{NE} + \text{S} + \text{W} + \epsilon$$

Results

The total number of users in the patient experience data set was 1,376,084 users. Out of these users, 13,689 (1.00%) self-identified as LGBTQ, and 1,362,395 (99.00%) did not self-identify as LGBTQ. The number of LGBTQ users that had

available geolocation data used in these analyses was 5545, and the number of non-LGBTQ users was 445,919. The data-cleaning process removed 171 out of 22,570 LGBTQ user tweets and 15,211 out of 1,946,795 non-LGBTQ user tweets. As shown in Table 1, the highest proportion for both LGBTQ and non-LGBTQ users came from the South, followed by the West, Midwest, and Northeast. A statistically significant lower proportion of LGBTQ users compared to non-LGBTQ users were present in the areas of the South and the Midwest. Alternatively, there were significantly higher proportions of LGBTQ users compared to non-LGBTQ users in the areas of the Northeast and the West. Mean democratic advantage was also significantly higher in areas with greater proportions of LGBTQ users relative to non-LGBTQ users.

Table 1. Descriptive analysis of LGBTQ (n=5545) and non-LGBTQ (n=445,919) tweets in the United States, 2013-2017.

Variable	LGBTQ ^a users	Non-LGBTQ users	Test statistic	P value
Northeast, n (%)	1053 (18.99)	75,761 (16.99)	3.78	<.001
South, n (%)	1786 (32.21)	167,635 (37.59)	−8.52	<.001
Midwest, n (%)	1166 (21.03)	98,354 (22.06)	−1.87	.06
West, n (%)	1540 (27.77)	104,169 (23.36)	7.29	<.001
Democratic advantage, mean	3.92	2.60	9.44	<.001

^aLGBTQ: lesbian, gay, bisexual, transgender, and queer.

The multilevel regression output is presented in Table 2, which illustrates the association between LGBTQ individual-level status and state-level predictors of patient experience sentiment from February 2013 to February 2017. Users in the Northeast had on average a 0.0444 ($P<.001$) lower patient experience sentiment, and users in the South had on average a 0.0390 ($P<.001$) lower patient experience sentiment compared to users in the Midwest, controlling for individual-level LGBTQ status

and the state-level political factor. Users in the West had on average a 0.0188 ($P<.001$) higher patient experience sentiment compared to that of users in the Midwest while controlling for all other variables in the model. Users that self-identified as LGBTQ had on average 0.0191 ($P=.01$) lower patient experience sentiment compared to users that did not self-identify as LGBTQ in areas with no difference in democratic or republican advantage, controlling for region- and political-level factors.

Table 2. Ordinary least squares regression results demonstrating association between LGBTQ status and state-level political leaning with patient experience sentiment in the United States, 2013-2017.

Variables	Coefficient	SE	t statistic	P value	95% CI
Intercept	−0.0407	0.001	−31.163	<.001	−0.043 to −0.038
Northeast	−0.0444	0.002	−20.199	<.001	−0.049 to −0.040
South	−0.0390	0.002	−23.217	<.001	−0.042 to −0.036
Midwest (reference group)	N/A ^a	N/A	N/A	N/A	N/A
West	0.0188	0.002	9.820	<.001	0.015 to 0.022
LGBTQ ^b user	−0.0191	0.006	−3.408	.01	−0.030 to −0.008
Democratic advantage	0.0008	<0.0001	4.467	<.001	0.000 to 0.000
Democratic advantage x LGBTQ user	0.0014	0.001	2.713	.007	0.000 to 0.002

^aNot applicable.

^bLGBTQ: lesbian, gay, bisexual, transgender, and queer.

Figure 1 shows the difference in average patient experience sentiment for LGBTQ users compared to non-LGBTQ users for each US state. Darker colors represent a more negative differential in LGBTQ user patient experience sentiment compared to non-LGBTQ users, while lighter colors represent a more positive LGBTQ user sentiment compared to

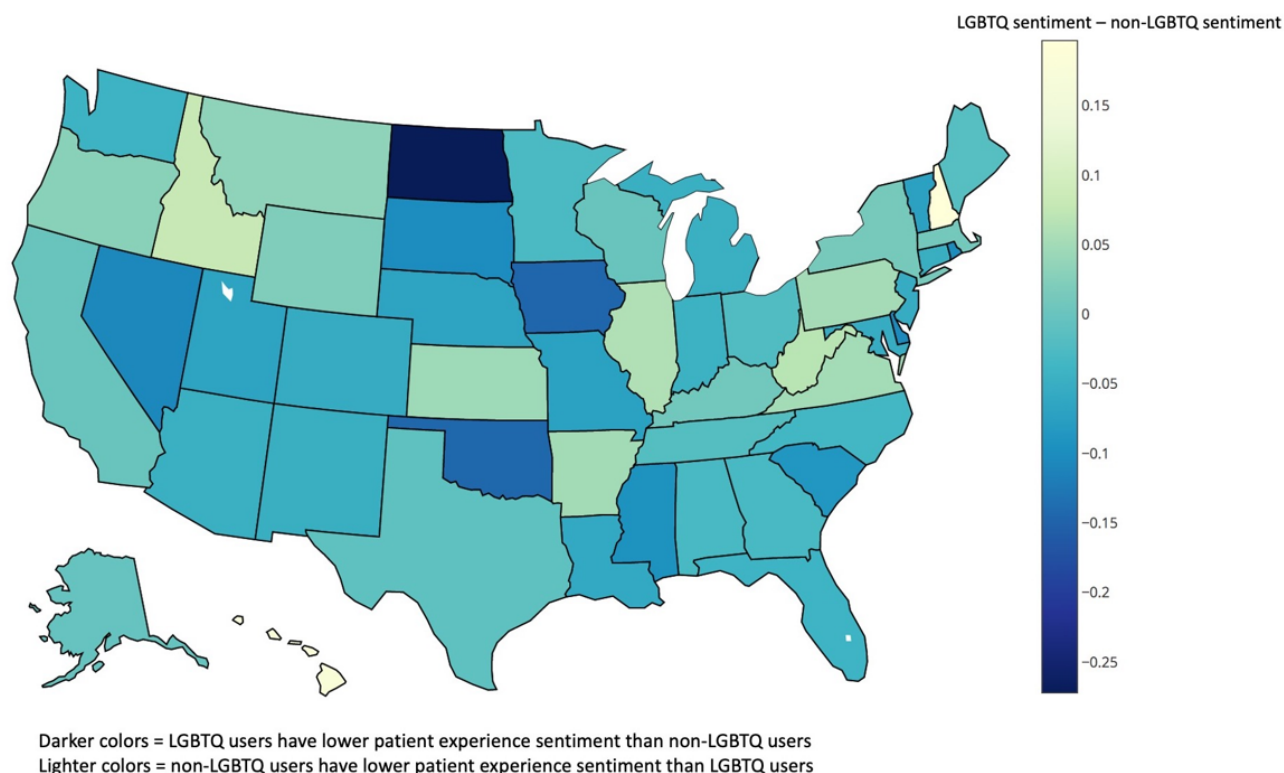

non-LGBTQ users. For non-LGBTQ users, each 1-point gain in state-level democratic advantage was associated with a predicted value increase of 0.0003 in patient experience sentiment, controlling for regional variation.

The effect of democratic advantage on patient experience sentiment is moderated by LGBTQ status. Democratic advantage

at the state level has a stronger effect on LGBTQ users compared to non-LGBTQ users' patient experience sentiment. For LGBTQ users, each 1-point gain in state-level democratic advantage was associated with a predicted value increase of 0.0017, controlling

for all other variables in the model. The positive effect of democratic advantage on patient experience was 5.67 times greater in LGBTQ patients than non-LGBTQ patients.

Figure 1. Map of patient experience tweets. LGBTQ: lesbian, gay, bisexual, transgender, and queer. (Note: Positive sentiment scores are ≥ 0.5 ; negative sentiment score ≤ -0.5 ; neutral sentiment scores are between ± 0.5).

Discussion

Principal Findings

Our analysis highlights geographical and political factors associated with patient experience sentiment for LGBTQ persons in the United States. As documented by the online social media network Twitter, LGBTQ status was associated with worse patient experiences compared to their non-LGBTQ counterparts even after adjusting for regional variation and political stance at the state level. This is consistent with previous reports that have documented the everyday discrimination experienced by LGBTQ individuals [43]. In 2016, the Center for American Progress showed that 1 in 4 LGBTQ persons reported discrimination that compels them to make significant changes to their everyday lives to avoid that discrimination [43]. These types of changes may include health care avoidance or not sharing their LGBTQ status to medical providers or others working in the health care system. Evidence has shown strong positive associations between patient experience and clinical effectiveness for a wide range of disease areas and outcome measures [44,45]. Therefore, based on our results, poorer patient experiences among LGBTQ patients may be contributing to the disproportional burden of disease and disparity faced by LGBTQ persons [46].

Regional analysis of quality of care for the general public have indicated that areas in the South often perform more poorly on

many quality measures [37]. Our results mirror such regional patterns, as we found that the South Region exhibited the worst patient experiences compared to all other regions in the United States. Findings in our study also revealed that Twitter users in the West reported the best patient experiences, which is also consistent with prior research, as this is an area that tends to perform better on the majority of quality measures [37]. However, users from the Northeast did not appear to rate their experience as well as those in the West or the Midwest. Although it has been documented that the Northeast tends to have a higher health care quality, many communities in the Northeast also have higher costs and elevated rates of avoidable hospital use, which could explain the poorer patient experience feedback reported among Twitter users in this area [36,37].

Based on our study, political values at the state level may influence the sentiment of individual-level patient experiences for LGBTQ persons more so than for non-LGBTQ persons. The political climate of a geographic area has been shown to be associated with health-related outcomes and access to care among LGBTQ persons [21,23]. However, prior studies have only focused on specific outcomes such as depression or on subsets within the LGBTQ community. For instance, one study identified that the percent of state residents voting republican was the strongest and most significant state-level predictor of health care refusal among transgender individuals [21]. Our results showed that an increasing democratic advantage at the state level contributed to better patient experiences reported at

the individual level for all users even after controlling for regional variation. Furthermore, this state-level political factor had a 5.67 times stronger positive effect on patient experience sentiment for LGBTQ users compared to non-LGBTQ users. These macrolevel political affiliations based on voting behavior can potentially serve as proxies for local attitudes and culture toward LGBTQ persons, and influence structural stigmatization in health care [21,47]. It has been demonstrated that Republican-identified voters are more likely to hold discriminatory attitudes toward LGBTQ persons compared to Democratic voters [47]. Therefore, LGBTQ persons living in states with more republican voters may be more likely to encounter and receive poorer quality care from biased providers or health care systems.

Limitations

There are limitations in this study that should be noted when interpreting our findings. First, our results examined state-level factors that were associated with patient experience sentiment and cannot be interpreted as causal. Second, the keywords methodology used to identify LGBTQ users may have incorrectly placed some LGBTQ users in the non-LGBTQ group and vice versa. The keywords list is not comprehensive and may have missed some LGBTQ-identifying descriptors such as shorthand phrases. Although we were able to manually confirm that 80-90% of LGBTQ categorized users were indeed LGBTQ users, we were not able to place a number on the accuracy of non-LGBTQ categorization. However, we believe that the percentage of LGBTQ users in the control group would not be more than the national percentage of 4.5% [48], which still provides a reasonable and valuable control population for this study. Third, there are limitations with the geo-tagged Twitter data set. Only 15% of online adults regularly use Twitter, with those 18-29 years of age being most represented. Only approximately 1% of users geo-tag the majority of the tweets they post [49,50]. Therefore, the sample population is likely not representative of the US patient population. Despite this potential limitation, many patient experience surveys have reported low response rates that range from 20-30% and have a greater proportion of older adult and female participants [51]. Our study may have a better representation of a demographic of patient participants that are normally excluded from mainstream or traditional surveys. For instance, Twitter users are generally more educated, younger, male [52], and have overrepresentation of ethnic minorities including blacks and Hispanics to a greater extent [48]. For our analysis on sentiment, previous studies have shown that the time of day, the ordering of activities within a day, and location can influence the sentiment of an individual's tweet [49,53]. We did not control for these temporal and spatial differences, which may have influenced the results of our study.

In the past, research on LGBTQ populations has been sparse due to methodological limitations or because of issues related

to homophobia (fear of people who are attracted to members of the same sex) and heterosexism (discrimination against homosexuals because of the assumption that heterosexuality is the norm of sexual orientation) [18]. Most national and state surveys lack appropriate questions pertaining to gender and sexual identity, making it difficult to conduct large-scale research [46]. Even large-scale studies typically identify few LGBTQ individuals, which has meant that LGBTQ research must rely on smaller qualitative studies or that investigation is lacking altogether [18]. Our study is the first to use a novel online social media data set captured from the popular Twitter platform to investigate LGBTQ patient experiences across the United States. Research shows that LGBTQ persons are more open to coming out and defining their LGBTQ status in their online social networks when compared to offline networks [54,55]. In fact, Twitter is a highly popular social media space for LGBTQ users when compared to other social media networks such as Facebook [55]. Finally, LGBTQ persons are more likely to search for health and medical information online when compared to their non-LGBTQ counterparts (81% vs 46%) [56]. Since LGBTQ persons face significant discrimination in typical health care settings [8], LGBTQ persons are less likely to voluntarily identify themselves as LGBTQ in the health care setting or in response to health surveys. This lack of identification prevents researchers from effectively capturing LGBTQ patient experiences. However, through our online big data set, we were able to identify an extensive number of self-identified LGBTQ users on Twitter. Based on this evidence, even though not all LGBTQ persons may have identified themselves as LGBTQ on Twitter, our study was able to capture novel insights into LGBTQ patient experiences that may not have been documented in the past.

Conclusion

The Institute of Medicine recognizes that LGBTQ persons experience a disproportionate burden of disease and poorer health outcomes compared to the general population, and there is growing recognition of the need to further study these disparities to identify the factors that contribute to them [57]. This is the first study to leverage an online social media data set to characterize the patient experiences of LGBTQ persons. This study demonstrated that LGBTQ users experience worse patient experiences compared to non-LGBTQ users and that the political climate of a state determined through voting percentages is a prominent factor influencing patient experiences, especially for LGBTQ persons. This is especially relevant given recent emphasis on how different US government administrations can directly impact policy decisions regarding equitable health care for LGBTQ persons [58]. By identifying the factors that impact patient experience, researchers, health care providers, and policy makers can begin to develop targeted practices and policies that improve health equity for LGBTQ persons and other marginalized groups.

Abstract

Background: Telemonitoring enables care providers to remotely support outpatients in self-managing chronic heart failure (CHF), but the objective assessment of patient compliance with self-management recommendations has seldom been studied.

Objective: This study aimed to evaluate patient compliance with self-management recommendations of an innovative telemonitoring enhanced care program for CHF (ITEC-CHF).

Methods: We conducted a multicenter randomized controlled trial with a 6-month follow-up. The ITEC-CHF program comprised the provision of Bluetooth-enabled scales linked to a call center and nurse care services to assist participants with weight monitoring compliance. Compliance was defined a priori as weighing at least 4 days per week, analyzed objectively from weight recordings on the scales. The intention-to-treat principle was used to perform the analysis.

Results: A total of 184 participants (141/184, 76.6% male), with a mean age of 70.1 (SD 12.3) years, were randomized to receive either ITEC-CHF (n=91) or usual care (control; n=93), of which 67 ITEC-CHF and 81 control participants completed the intervention. For the compliance criterion of weighing at least 4 days per week, the proportion of compliant participants in the ITEC-CHF group was not significantly higher than that in the control group (ITEC-CHF: 67/91, 74% vs control: 56/91, 60%; $P=.06$). However, the proportion of ITEC-CHF participants achieving the stricter compliance standard of at least 6 days a week was significantly higher than that in the control group (ITEC-CHF: 41/91, 45% vs control: 23/93, 25%; $P=.005$).

Conclusions: ITEC-CHF improved participant compliance with weight monitoring, although the withdrawal rate was high. Telemonitoring is a promising method for supporting both patients and clinicians in the management of CHF. However, further refinements are required to optimize this model of care.

heart failure; digital health; telemonitoring; remote monitoring; patient compliance; randomized controlled trial

Introduction

Chronic heart failure (CHF) is a severe chronic disease that affects more than 26 million people worldwide [1]. It significantly reduces the health-related quality of life and increases the risk of hospitalization and mortality [1]. To improve health outcomes, it is recommended that patients with CHF undertake self-management, such as daily monitoring of body weight to assess fluid balance and seek early clinical support in the event of symptoms, which may indicate decompensation. This has been consistently outlined by evidence-based clinical guidelines for CHF [2,3] and is practically supported by CHF clinics and rehabilitation programs in standard care. Despite these clinical efforts, patient compliance with self-management recommendations is often suboptimal for activities such as body weight recording, fluid restrictions, and medication adherence [4]. Time constraints [5], limited knowledge [6], and insufficient ongoing clinical support [7] are some of the reported barriers to the self-management of CHF. Poor compliance with self-management recommendations often leads to delays in essential treatment [4] and increases the risk of mortality and hospitalization [8].

In recent years, there has been significant research interest in telemonitoring as an innovative approach to remotely assist patients with CHF in self-managing their health [9]. However, to date, only 2 studies, to our knowledge, have evaluated patient compliance with weight monitoring in a randomized controlled trial (RCT) [10,11]. Although they demonstrated a higher rate of *compliant* participants in the telemonitoring arm (telemonitoring vs usual care: 88.6% vs 70.9% [10] and 91.7% vs 67.4% [11]), the studies relied on self-report, which is known to be influenced by recall bias [12]. In addition, the definition of *compliance* was loosely defined based on terms such as *most of the time* or *all of the time* and, hence, was not sufficiently accurate to reflect the daily weight monitoring recommendation. Moreover, patient adherence to telemonitoring systems has often been found to be low, even in large, well-designed RCTs (55% [13] and 55.4% [14]). This has led to an ongoing debate about the practicality of using telemonitoring to improve CHF care [13-15]. Therefore, further rigorous research for evaluating patient compliance is needed in telemonitoring studies for CHF care.

We evaluated an innovative telemonitoring enhanced care program for CHF (ITEC-CHF) in an open multicenter RCT. The ITEC-CHF program focused on assisting patients in daily weight monitoring and engaging with nurse-supported care in the event of weight fluctuations. This study aimed to examine whether the ITEC-CHF program improved patient compliance

with weight monitoring as well as other self-management behaviors and health outcomes.

Methods

Study Design

The protocol for the ITEC-CHF study has been previously published [15]. Images of the user interface and the Bluetooth-enabled scales are provided in [Multimedia Appendices 1](#) and [2](#). In this study, patients with CHF were recruited from 2 trial sites in Australia: one in Victoria (VIC) and one in Western Australia (WA). The trial sites were at 2 hospitals in VIC and WA, respectively. This study complies with the Declaration of Helsinki. All participants provided written informed consent. The clinical trial protocol was approved by the Human Research Ethics Committee at Peninsula Health, VIC (HREC reference: HREC/14/PH/27), and Royal Perth Hospital, WA (reference: 15-081 and reference: HR 181/2014), Australia. Participants were enrolled from January 2015 to October 2017. The latest data collection of hospitalizations and emergency department (ED) presentations was conducted in September 2018.

Randomization and Masking

Participants in the trial were individually randomized with an allocation ratio of 1:1 to receive either ITEC-CHF or usual care (control) for 6 months. Randomization was stratified by the 2 trial sites (VIC and WA) to ensure that the allocation ratio was consistent at each site. A block method was used to achieve a balanced number of participants between the ITEC-CHF and control groups throughout the trial. The random allocation assignments were sealed in opaque envelopes. Data analysts generated the randomization sequence and were blinded to the trial because of the use of deidentified patient data.

Inclusion and Exclusion Criteria

The inclusion criteria were as follows: patients (1) with CHF with reduced ejection fraction (EF; ie, $EF \leq 40\%$), (2) able to weigh themselves safely, (3) aged at least 18 years, (4) having a regular personal general practitioner (GP) or agreeing to use a designated GP, (5) with a permanent residential address, and (6) without significant cognitive impairments. The exclusion criteria were as follows: (1) patients with expected survival < 12 months, (2) patients with end-stage renal failure on dialysis, (3) long-term nursing home residents, or (4) patients participating in any other clinical trial.

Interventions

At baseline, control participants were provided with a standard package of a paper-based diary and the *Living Well with Chronic Heart Failure* booklet, produced by the Heart Foundation of

Australia. They were instructed to maintain their usual CHF care, as provided by clinics specialized in CHF and primary care physicians, and to undertake CHF self-management as previously instructed. Each participant was also provided with an electronic weight scale (FORA TN'G W550; ForaCare) and asked to use the scale to measure their body weight daily, immediately after waking, following voiding, without shoes, in light clothing, and before taking medication. Approximately every 3 months, project nurses visited the participants to download the weight entries from the weight scale.

Participants in the ITEC-CHF group received the same resources as those in the control group, in addition to the ITEC-CHF program. The ITEC-CHF consists of 3 major components: remote body weight monitoring, structured telephone support, and nurse-led collaborative care. The service was integrated with a telephone call center (MEPACS, VIC, Australia) and community nurse care services at the trial sites in VIC and WA. Each participant was provided with an electronic weight scale and a computer tablet (Galaxy Tab A, Samsung). Participants were asked to weigh themselves using the procedure described for the control group. After the measurement, the weight entry was automatically transmitted from the weight scale to the tablet via a wireless Bluetooth function. The tablet was preloaded with an Android app (Medtech Global). This app received the weight entry and uploaded the entry to a software package called Manage My Health (MMH; Medtech Global). A rule-based decision support system (a web app) in MMH automatically monitored the uploaded weight entries in real time. In response to the weight data generated by telemonitoring, 6 types of alerts were possible: (1) *rapid weight fluctuation* (an increase or decrease of 2 kg over 2 days), (2) *slow weight fluctuation* (an increase or decrease of 5 kg over 28 days), (3) *low-risk weight fluctuation* (an increase or decrease of 1 kg over 24 hours), (4) missed weight measurement, (5) low level of tablet battery, and (6) tablet connection lost. In the event of a *rapid weight fluctuation*, project nurses were alerted, and they called the participant to assist him or her in assessing symptoms and activating their CHF action plan, such as attending their GP, visiting a CHF clinic, or presenting to an ED as indicated. For an alert of *slow weight fluctuations*, the project nurses assisted the participants in assessing CHF symptoms and arranging clinical reviews at the participants' GP or CHF clinics as indicated. For *low-risk fluctuations*, a questionnaire was automatically triggered and sent to the participant's computer tablet to help him or her determine the need for further clinical follow-up. Finally, the generated alerts were distributed to project nurses and/or the MEPACS call center in the ITEC-CHF program. Call operators at the center responded to the alerts in real time (24 hours, 7 days a week), focusing on reminding participants to weigh themselves if they had not done so before 10 AM, helping assess CHF symptoms and manage diet, and arranging a nurse follow-up if needed. The project nurses reviewed their alert requests on weekdays and followed up with the participants via a telephone call. Some participants were unable to monitor their body weight for a short period, such as when they were hospitalized for medical treatment, traveled away from home, or experienced unresolved technical issues. Under such conditions, they were required to notify the call center, and weight monitoring was skipped. If a participant

notified the call center to skip the monitoring for a period, the telemonitoring intervention was then *switched off* during the skipped period, and the call center did not receive any alerts from the participant and provide intervention until the skipped period ended. Monitoring days that were *skipped* were still included in the per-protocol analysis for the ITEC-CHF group (described in the Primary and Secondary Outcomes section).

Primary and Secondary Outcomes

The primary outcome was in compliance with weight monitoring. The monitoring frequency was calculated as average weight monitoring days per week during the 6-month assessment period (monitoring frequency=weight monitoring days/180 days \times 7 days/week [for 6 months: 6 months \times 30 days/month=180 days]). A weight monitoring day was determined if at least one weight entry was practically recorded on the weight scale on that day, irrespective of time. In total, 2 frequencies were employed in the examination. One was that the participant monitored their weight on at least four days per week. This frequency reflects the compliance threshold of *most of the time*, as previously applied in questionnaire-based assessments [4,12]. The other frequency was at least 6 days per week, which more closely aligns with the advice for patients to monitor their weight *daily*.

Secondary outcomes included patient compliance with weight monitoring based on a per-protocol analysis (only undertaken in participants who completed the trial) and an analysis of other guideline recommendations assessed by the Heart Failure Compliance Questionnaire [12], health-related quality of life (five-dimension EuroQol, EQ-5D [16]), 6-min walk test distance [17], psychological state (cardiac depression scale short form 2 [18]), frailty (clinical frailty index [19]), and clinical outcomes of CHF-related and all-cause hospitalizations and ED presentations. CHF-related events were determined by using the International Classification of Diseases, Tenth Revision, Clinical Modification, diagnosis codes (Multimedia Appendix 3) [20]. Furthermore, we reported the alerts provided in ITEC-CHF and days when ITEC-CHF participants requested to *skip* weight monitoring.

Statistical Analysis

In the evaluation, a chi-square test was applied to analyze continuous variables such as age, and a Fisher exact test was used to compare categorical variables such as sex and subgroups of participants under a given weight monitoring frequency (participants who achieved a given monitoring frequency vs participants who did not achieve the monitoring frequency). The Wilcoxon signed-rank test was used to compare compliance scores from questionnaire-based assessments. An analysis of covariance model [21] was used to evaluate the improvement or change in the outcome variables between the 2 groups with an adjustment for baseline. The Andersen-Gill model [22] with an adjustment for sex and age was used to analyze the hazard of hospitalizations and ED presentations. The 95% CI was estimated for the hazard function in each group. A P value $<.05$ was considered statistically significant. The analysis was conducted using RStudio version 1.1.383 (RStudio Inc) [23] with the R package of *survival* version 2.43-3. The intention-to-treat principle was applied to the analysis of the

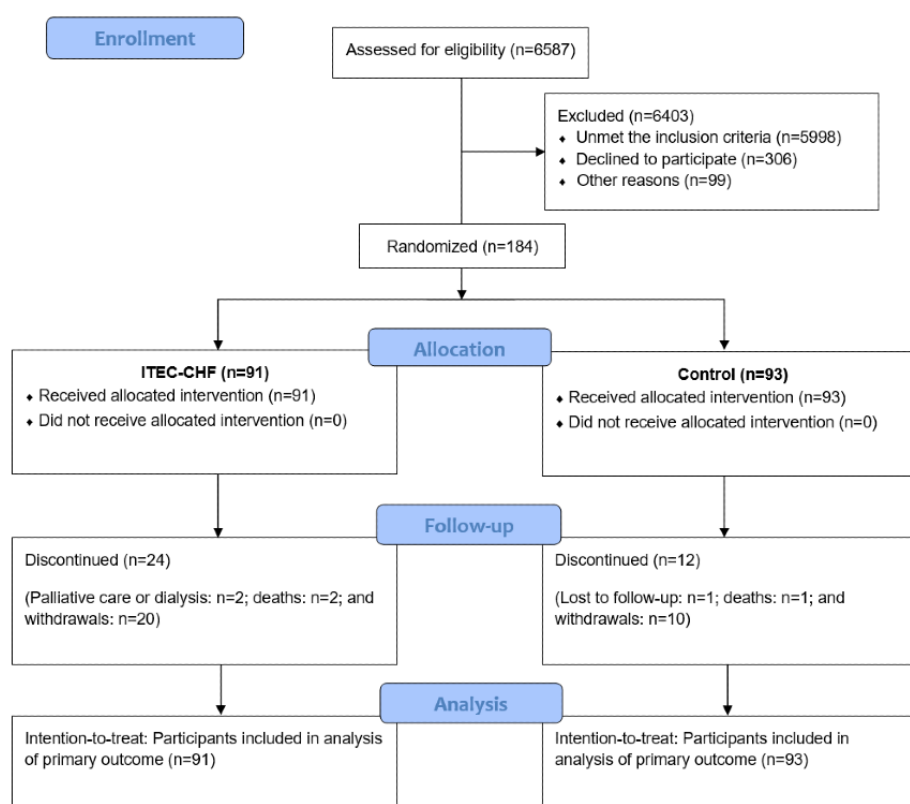

primary outcome of patient compliance with weight monitoring. It was also applied to the analysis of the hazards of hospitalization and ED. In the intention-to-treat analysis, all participants in the RCT were included. A per-protocol analysis was also applied to weight monitoring as a secondary outcome, only including participants who did not discontinue in the trial. A complete case analysis, which restricts the analysis to individuals with complete data, was used to analyze improvements in questionnaire-based assessments and 6-min walk distances.

Results

A total of 6587 patients were screened for eligibility. Among them, 6403 patients were excluded because of failure to meet

the inclusion criteria ($n=5998$), declined ($n=306$), or for other reasons ($n=99$), such as losing contact with the patient (Figure 1). Finally, 184 patients were randomized to the ITEC-CHF ($n=91$) and control ($n=93$) groups. During the 6-month intervention period, 24 participants in the ITEC-CHF group discontinued (palliative care or dialysis: $n=2$; deaths: $n=2$; and withdrawals: $n=20$), and 12 participants in the control group discontinued (lost to follow-up: $n=1$; deaths: $n=1$; and withdrawals: $n=11$). According to the intention-to-treat principle, all randomized participants (ITEC-CHF: $n=91$; control: $n=93$) were included in the analysis of the primary outcomes of patient compliance with weighing. They were also included in the analysis of the hazards of hospitalization and/or ED presentation.

Figure 1. Patient enrollment and disposition. ITEC-CHF: innovative telemonitoring enhanced care program for chronic heart failure.

Baseline Characteristics of the Participants

There were no significant differences between the characteristics of the ITEC-CHF and control groups at baseline (Table 1). The mean ages of the participants in the ITEC-CHF and control groups were 69.5 (SD 12.3) years and 70.8 (SD 12.4) years,

respectively. Participants were predominantly male, and a high proportion of participants were diagnosed with type 2 diabetes, chronic obstructive pulmonary disease, or asthma. Common medications included angiotensin-converting enzyme inhibitors, beta-blockers, loop diuretics, and/or aldosterone receptor antagonists.

Skipped Monitoring Days in the Innovative Telemonitoring Enhanced Care Program for Chronic Heart Failure

There were 1312 participant monitoring days when weight monitoring was *skipped*. Being away from home or traveling was the major reason for skipped monitoring, occurring on 515 participant monitoring days (39.3% of total skipped days) in 41

participants. Technical issues (Table 2) resulted in skipped monitoring on 390 participant monitoring days (29.7%) in 27 participants. Hospitalizations and ED presentations caused skipped monitoring on 232 participant monitoring days (17.7%) in 18 participants, whereas health conditions such as being unwell, falling, surgery, and chemotherapy led to 136 skipped participant monitoring days (10.4%) in 11 participants. The skipped days were regarded as noncompliant with daily weighing in the analysis of the primary outcome.

Table 2. The percentage of technical issues in the innovative telemonitoring enhanced care program for chronic heart failure group.

Technical issues	Value, n (%)
Bluetooth connectivity	203 (52.1)
Network connectivity	61 (15.6)

Weighing scale battery	18 (4.6)
Tablet battery	2 (0.4)

^aCHF: chronic heart failure.

Primary Outcome and Related Analysis Results

Applying the intention-to-treat analysis to the primary outcome of weight monitoring at least four days a week on average over the duration of the trial, the proportion of compliant participants in the ITEC-CHF group did not achieve statistical significance

compared with that of the control group (ITEC-CHF: 67/91, 74% vs control: 56/93, 60%; $P=.06$). However, ITEC-CHF was associated with significantly more participants who monitored their body weight on average for at least 6 days per week over the duration of the trial than the control (ITEC-CHF: 41/91, 45% vs control: 23/93, 25%; $P\leq.005$; [Table 3](#)).

Table 3. Comparison of participant compliance with daily weight monitoring between the innovative telemonitoring enhanced care program for chronic heart failure (ITEC-CHF) and the control groups. Under the conventional weight monitoring standard of at least 4 days per week, there was no significant difference between the ITEC-CHF and the control groups ($P=.06$). Under a stricter weight monitoring criterion of at least 6 days per week, more participants in the ITEC-CHF group were found to achieve this criterion than those in the control group ($P=.005$).

Compliance ^a	ITEC-CHF ^b , n (%)	Usual care, n (%)	<i>P</i> value
Participants who monitored body weight at least 6 days per week	41 (45)	23 (25)	.005
Participants who monitored body weight at least 4 days per week	67 (74)	56 (60)	.06

^aCompliance with daily weight monitoring.

^bITEC-CHF: innovative telemonitoring enhanced care program for chronic heart failure.

Secondary Outcomes

Applying a *per-protocol* analysis by excluding participants who discontinued the study (ITEC-CHF: 24/91 and control: 12/93), the difference in weight monitoring compliance was significant for weight monitoring at least 4 days a week (ITEC-CHF: 65/67, 97% vs control: 56/81, 69%; $P<.01$) and at least 6 days a week (ITEC-CHF: 41/67, 61% vs control: 23/81, 28%; $P<.01$).

In the complete case analysis, 147 participants (ITEC-CHF: 66 and control: 81) completed the Heart Failure Compliance Questionnaire at baseline and 6-month assessments ([Table 4](#)). ITEC-CHF was associated with a significantly improved score in the domains of health maintenance ($P<.01$), medication adherence ($P<.01$), and diet ($P<.01$). No significant differences were found in the category of exercise ($P=.10$), smoking ($P=.48$), or alcohol use ($P=.32$).

In the EQ-5D assessment, no significant differences were found in the change in category of mobility ($P=.44$), self-care ($P=.26$), usual activities ($P=.59$), discomfort ($P=.46$), and anxiety or depression ($P=.38$). The mean change in the overall score of EQ-5D was also not significantly different (ITEC-CHF: 4.05, SD 15.95 vs control: 1.10, SD 14.24; $P=.13$).

No significant effects were found for the 6-min walk test distance, frailty, and depression.

No significant differences were found in all-cause hospitalizations (ITEC-CHF: 73 vs control: 58; hazard ratio [HR] 1.18; $P=.49$) or emergency department (ED) presentations (ITEC-CHF: 36 vs control: 45; HR 0.83; $P=.55$), chronic heart failure (CHF)-related hospitalizations (ITEC-CHF: 15 vs control: 8; HR 1.98; $P=.24$), CHF-related ED presentations (ITEC-CHF: 4 vs control: 5; HR 0.98; $P=.98$), or unplanned hospitalizations (ITEC-CHF: 41 vs control: 39; HR 1.06; $P=.86$).

Table 4. Secondary outcomes of self-management behaviors, quality of life, 6-min walk test, frailty, and depression.

Discussion

Principal Findings

In this study of an innovative telemonitoring program (ITEC-CHF), facilitated by community nurses with call center support, we observed no significant differences in the weight monitoring frequency of at least 4 days a week but observed a significantly higher proportion of the intervention group achieving a weight monitoring frequency of at least 6 days per week compared with the control group receiving usual care. To our knowledge, this is the first study to use objective measures of weight monitoring and the intention-to-treat principle to comprehensively evaluate patient compliance with daily weighing in patients with CHF.

The higher weight monitoring frequency of at least 6 days per week reflects better compliance with the recommendation in contemporary clinical guidelines for patients with CHF to weigh themselves daily as a self-management strategy to maintain fluid balance and identify signs of edema [2,3]. This criterion for compliance is stricter than that applied to weight monitoring in previous studies of *most of the time* (or at least 4 days per week) and was limited by a questionnaire-based assessment of compliance, which is prone to bias [4,12].

In the intention-to-treat analysis, 45% of participants randomized to ITEC-CHF achieved a monitoring frequency of at least 6 days per week over the 6-month follow-up period of the trial. This figure was influenced by the relatively high proportion of participants who discontinued the trial from the intervention group and provides valuable insight into factors that are pertinent to telemonitoring in clinical practice. In the early stages of the trial, there were relatively frequent technical issues with the telemonitoring system, which may have led to the withdrawal of some participants. It has previously been reported that learning how to use telemonitoring technology is perceived as burdensome and creates anxiety in some patients, especially those who are older [24]. This may be further exacerbated in the event of technical issues. Technical issues also resulted in increased reliance on technical support, which would have increased the cost of telemonitoring, although this was not assessed in this study, highlighting the need for future telemonitoring studies with a health economics component. These issues highlight the importance of telemonitoring systems being seamless and reliable to not create an unnecessary burden on patients and their carers or health service providers [25]. Therefore, they underscore the need to improve the reliability and user experience of telemonitoring systems [26] for use in clinical CHF care.

In participants who completed the trial (the cohort in which the per-protocol analysis was conducted), compliance with weight monitoring in ITEC-CHF was high; 97% of participants monitored themselves for at least 4 days a week over the 6-month duration of the trial, and 61% of participants monitored themselves at least 6 days a week. In the ITEC-CHF group, 390 participant monitoring days were *skipped* because of technical issues, meaning that the difference in weight monitoring compliance between the ITEC-CHF and control groups is likely to be underestimated. These positive findings regarding weight

monitoring compliance in participants who adhered to the program are likely to be underpinned by the multifactorial support mechanisms provided. This is further supported by a substantial number of alerts reported in this study, which included the automated generation of reminder alerts on 715 patient days when a weight recording was not received by 10 AM as well as contact made by the call center and project nurses. These findings not only demonstrated the effectiveness of ITEC-CHF in supporting weight management but also indicated a strong need for such support in ongoing CHF care.

The ITEC-CHF group experienced a significant improvement in health maintenance compared with usual care, as measured by the Heart Failure Compliance Questionnaire. This positive result was consistent with a finding of improved self-care maintenance reported in 2 other RCTs of telemonitoring in CHF [27,28]. Similarly, there was a significant improvement in adherence to medication and diet recommendations in the ITEC-CHF group, but not in the control group. These findings imply increased engagement with the heart failure nurses that occurred following the alerts generated through the telemonitoring intervention. These interactions created the opportunity for *teachable moments*, enabling nurses to provide informal education to reinforce self-management practices. It has previously been acknowledged that patients often benefit from ongoing support in CHF care to effectively manage their health conditions through reinforcement of self-management strategies [29]. It is also possible that merely being monitored was sufficient to enhance adherence to more desirable patterns of care because of a surveillance effect [30]. Nevertheless, the combination of telemonitoring with nursing support resulted in improved self-management activities, although it is often difficult for researchers to identify which component of the ITEC-CHF program drove these improvements.

There were no significant effects of ITEC-CHF on hospitalizations and ED presentations, although it should be noted that the study was underpowered for this analysis. We observed that CHF-related events were not the major cause of hospitalizations (23/131, 17.5%) or ED presentations (9/81, 11%). CHF is a complex condition, more prevalent in older people, and associated with a range of comorbidities. Telemonitoring in the context of this study focused exclusively on daily weight recordings. This finding implies a need to extend telemonitoring intervention for comorbidity and critical non-CHF-related health conditions to more comprehensively address the range of health issues faced by patients with CHF. To date, the effectiveness of telemonitoring in improving hospitalization and mortality remains inconclusive [13,14]. However, it has been shown that reduction in health services utilization, including unscheduled hospitalizations and length of stay, can be achieved for broader chronic disease management by monitoring a range of vital signs using telemonitoring enhanced care coordination [31,32]. Further research to understand the underlying principles that impact hospitalizations and ED presentations related to a specific primary diagnosis such as CHF remains essential in future studies.

There are several limitations of this study that warrant discussion. First, the study was limited to a 6-month intervention, which may have been insufficient to translate to

meaningful changes in clinical characteristics of patients. In addition, a relatively high number of participants discontinued their involvement in the trial, which has the potential to bias the analysis of some secondary outcomes where the intention-to-treat principle could not be applied. High rates of discontinuation in the ITEC-CHF group suggest a potential bias in the per-protocol analysis. Participants who discontinued in the ITEC-CHF group were unlikely to be random because some were because of deteriorating health (palliative care or dialysis) and because some were deceased, as shown in Figure 1. Therefore, we did not use the multiple imputation approach outlined in the trial protocol [15]. The study did not achieve the target sample size ($n=300$), proposed in the trial protocol [15]; this might have compromised the power to detect significant effects in the analysis of the primary outcome. There are several reasons for the smaller than proposed sample size. We experienced technical issues with the telemonitoring software that were not apparent during an extensive testing phase before study commencement, which delayed recruitment. This highlights the challenges that arise in a real-world environment that may not be present in a testing scenario. We also experienced slower than anticipated recruitment; some patients were reluctant to engage in a model of care involving technology, whereas others were concerned about their ability to weigh themselves safely because of frailty and were therefore excluded from the trial. A substantial number of patients reported as having CHF did not have an echocardiogram documented in their medical records and were therefore excluded because they failed to meet the inclusion criteria of an EF of $<40\%$. Finally, a high proportion of patients who were residents of nursing homes were excluded on this basis. These

issues highlight that the clinical complexity of many patients with CHF, who are often older with multiple comorbidities, may complicate their ability to engage with telemonitoring and underpins the importance of telemonitoring models being developed that are reliable, easy to use, and accessible for patients across the clinical spectrum of CHF. Finally, the patient compliance rate in usual care (25% for at least 6 days per week and 60% for at least 4 days per week) was likely to be influenced by the provision of weight scales to participants, which kept a record of their weight recordings and, accordingly, might have resulted in a Hawthorne effect [33], reducing the difference between the ITEC-CHF and control groups.

Conclusions

The ITEC-CHF study is the first to report the effects of telemonitoring on weight monitoring compliance using an objective measure of weight recordings in patients with CHF. The proportion of participants in the ITEC-CHF program achieving a weight monitoring frequency of at least 6 days per week was higher than that in usual care controls. Furthermore, ITEC-CHF resulted in significant improvements in CHF self-management related to health maintenance, medication adherence, and diet. Among participants who completed the study, there was a high level of compliance with weight monitoring, underscoring the importance of telemonitoring platforms that are seamless to reduce the risk of patients disengaging with the technology. Although telemonitoring and digital health more broadly offer significant potential for supporting patients in self-managing chronic conditions such as heart failure, further research is required to refine these evolving strategies to achieve effective care outcomes.

Acknowledgments

The authors gratefully acknowledge (1) the members of the Project Control Board, including Mr David Anderson, Dr Phil Carrillo, Dr Fergus McGee, and Mr Mark Gravell for their management and guidance in the clinical trial; (2) the members of MEPACS, including Mr Dean Richardson and Mr Dhruv Singh, for implementing the telemonitoring system and managing the call service in the clinical trial; (3) the members of Medtech Global, including Mr Rama Kumble and GK Shridhar, for implementing and managing the telemonitoring system in the clinical trial; and (4) nursing and medical support provided by Julie Smith and Dr Matthew Best from the trial site in WA. This project is fully funded by the health market validation program by the Department of State Development, Business and Innovation, Victorian government (121 Exhibition Street, Melbourne, Vic, 3001, Australia. The contract was signed in May 2014), and the Western Australia Targeted Research Fund Grant by the Department of Health, WA (notification, February 4, 2014). These funding sponsors will not have any role in the design of this study, execution of the trial, analysis and interpretation of the trial data, and research publications.

Authors' Contributions

This outcome study was mainly developed by HD, AD, IE, and RJ. The first draft of the manuscript was written by HD, SC, and RJ. The statistical analysis was mainly conducted by HD and NG (a statistician at Commonwealth Scientific and Industrial Research Organization). All authors contributed to the design of the clinical study and/or critical revision of the manuscript.

Abstract

Background: Adhesive capsulitis (AC) of the shoulder is a common disorder that painfully reduces the shoulder range of motion (ROM) among middle-aged individuals. Although physical therapy with home-based exercises is widely advised to restore ROM in the treatment of AC, clinical results vary owing to inconsistent patient compliance.

Objective: In this study, we aimed to verify the feasibility of a treatment model that involves applying a wearable motion sensor device to assist patients conduct home-based exercises to improve training compliance and the accuracy of exercises, with the ultimate goal of improving the functional recovery of patients with AC.

Methods: The motion sensor device was comprised of inertial measurement unit–based sensors and mobile apps for patients and physicians, offering shoulder mobility tracing, home-based exercise support, and progress monitoring. The interrater reliability of shoulder mobility measurement using the motion sensor device on 10 healthy participants and 15 patients with AC was obtained using an intraclass correlation coefficient analysis and compared with the assessments performed by two highly experienced physicians. A pilot prospective control trial was then carried out to allocate the 15 patients with AC to two groups: home-based exercise group and motion sensor–assisted rehabilitation group. Changes in active and passive shoulder ROM, pain and functional scores, and exercise completion rates were compared between the groups during a treatment period of 3 months.

Results: Shoulder ROM, as measured using the motion sensor device, exhibited good to excellent reliability based on the comparison with the measurements of two physicians (intraclass correlation coefficient range, 0.771 to 0.979). Compared with patients with AC in the home-based exercise group, those in the motion sensor–assisted rehabilitation group exhibited better shoulder mobility and functional recovery and a higher exercise completion rate during and after 3 months of rehabilitation.

Conclusions: Motion sensor device–assisted home-based rehabilitation for the treatment of AC is a useful treatment model for telerehabilitation that enhances the compliance of patients through training, thus improving functional recovery. This helps overcome important obstacles in physiotherapy at home by providing comprehensible and easily accessible exercise instructions, enhancing compliance, ensuring the correctness of exercise, and monitoring the progress of patients.

Introduction

Adhesive capsulitis (AC) of the shoulder, which occurs in approximately 2% to 5% of the general population, is an idiopathic, progressive, and painful restriction of the active range of motion (aROM) and passive range of motion (pROM) [1,2]. AC typically affects patients older than 50 years, and involvement of both shoulders is noted in 20% to 30% of cases [1,2]. Although symptomatic improvement tends to occur naturally within years even with minimal treatment [3], approximately 50% of patients experience pain or some mild restriction of movement, and 11% experience some residual disability even several years after the resolution of their other symptoms [4,5]. Although AC is a common condition, high-quality evidence of successful treatment methods for AC has not yet been obtained [6]. The well-accepted standard treatment for AC mostly involves physical therapy and home exercises to restore ROM [7,8]. Evidence suggests that, compared with less frequent self-exercise in a home setting or joint mobilization sessions in a hospital setting, regular and daily self-exercise in a home setting could contribute to greater improvement in shoulder ROM and a shorter duration of symptoms [9].

Despite realizing the importance of daily physiotherapy, including mobilization and strength exercises, clinicians have achieved varied outcomes in patients who are trained in a home-based exercise program [10]. Challenges that affect the effectiveness of home-based exercises for AC may include training compliance and exercise correctness. Patients with AC do not maintain their training frequency and duration at home because the prescribed exercise programs are typically not followed without the constant supervision of a physiotherapist. Failure to incorporate exercises into daily life is the main form of noncompliance, as reported in up to 60% of patients whose treatment plan included home-based exercise [11]. Whether patients can correctly perform exercises at home after initial instruction by physiotherapists is also a concern [12]. Therefore, the development of methods to improve compliance and exercise correctness for patients with AC is worthwhile to maximize the effectiveness of home-based physiotherapy.

Techniques for detecting bodily motions are extensively used in health care to monitor and rehabilitate disabled patients. With the evolution of sensing and body area network technologies, wearable rehabilitation technology has opened up the possibility of independent training, which has advantages over traditional rehabilitation services [13]. Inertial measurement units (IMUs),

including accelerometers and gyroscopes, have been extensively used in technology-assisted rehabilitation, with sufficient efficacy [14-16]. However, despite the potential of using IMU-based sensors in neurorehabilitation and for treating musculoskeletal impairments [13,17,18], few such sensors have been used in clinical studies, especially those involving physiotherapy for AC.

Through this study, we tested wearable IMU-based sensors that integrated with interactive mobile apps using wireless telecommunication technology to enable physiotherapists to monitor the progress of patients with AC who were conducting home-based self-exercise and improve their training compliance. We hypothesized that the use of a wearable IMU-based motion sensor device could help patients perform home-based exercises correctly and increase their motivation and compliance regarding training, thereby improving functional outcomes.

Methods

Motion Sensor Device

A wearable motion sensor device (BoostFix wearable self-training kit, COMPAL Electronics Inc, Taipei, Taiwan) was used (see [Multimedia Appendix 1](#)). The motion sensor device was comprised of wearable IMU-based sensors that record the angular shoulder motion of a patient, a mobile app termed Patient App for use by the patient, and a mobile app termed Doctor App for use by a qualified health care professional.

Wearable IMU-Based Sensors

The IMU-based sensors were comprised of 6-axis microelectromechanical systems that included accelerometers and gyroscopes. These devices collect information about the angular motion of the shoulder of interest. Three sensors are required for angular measurements of the shoulder. In this study, they were strapped to the sternum, distal third of the lateral upper arm approximately 5 cm above the lateral epicondylar of the humerus bone, and dorsal wrist ([Figure 1](#)). Three sensors were calibrated in position A once the measurement began ([Figure 1A](#)). The initial calibration process involved placing the sensor on a horizontal fixture to measure the offset for each axis, to align the initial difference for each sensor. The calibration process involved obtaining the initial value of the sensor for relative offset correction instead of correcting the deviation caused by incorrect sensor placement. In addition, the process entailed identifying the original offset of the sensors to each other and applying the zero setting using an algorithm.

Figure 1. Angular measurement of the shoulder with motion sensors worn on the body for (A) calibration, (B) shoulder abduction, (C) shoulder flexion, (D) shoulder extension, (E) shoulder external rotation, (F) shoulder internal rotation.

Dual-sensor systems were used in the motion sensor device to accurately record the shoulder ROM angle. Using the sensors on the sternum as a reference datum point, the raw data from each sensor can be converted into a quaternion algorithm to convert the relative angle changes of the sensors on the upper arm and wrist into a 3-dimensional (3D) motion of the shoulder structure. Although one sensor can provide the angular change with the gyroscopes on one plane of motion, dual-sensor systems can provide relative angular changes in shoulder movements

between the arm and axial body (by compensating for the angle of the body tilting relative to the ground), which was superior for eliminating the error in the shoulder ROM measurement attributed to body tilting from a one-sensor system, especially for patients with AC and painful shoulder movement (Figure 2). Additionally, repeated angular measurements with the dual-sensor system on simulated shoulder motion was validated as highly accurate. This is referred to in Multimedia Appendix 2.

Figure 2. Dual-sensor system simulates the motion of (A) patients with adhesive capsulitis performing shoulder abduction using a (B) 3-dimensional avatar. θ_1 : angular motion reported by the sensor on the upper arm; θ_2 : axial body tilting angle reported by the sensor on the sternum; θ_3 : shoulder abduction angle (ie, $\theta_1 - \theta_2$).

Mobile Phone App for Patients

To design the mobile app for patients with AC for use on mobile phones, a cocreation process was used. The app has modes for measuring shoulder mobility, generating historical records of angular measurements and exercise completion rates, and providing daily shoulder exercises with detailed instructions (Figure 3). The mobile app determines shoulder ROM in all directions by calculating the relevant information regarding the angle measurement reported by the 3 wearable sensors (Figures 2B and 3B). The Patient App provides 7 sets of home-based shoulder exercises for training, including a forward wall walking

stretch, lateral wall walking stretch, and cane stretch for shoulder flexion, extension, abduction, internal rotation, and external rotation (Figure 4). The mobile app assigns each set of exercises as a “daily task” assigned by the supervising physiotherapist or physicians and provides a demonstration using a 3D avatar (Figure 3E). The app mirrors the user’s shoulder movement during the exercise using angular information collected from the worn motion sensors. Each user has an account in the Patient App to access his or her records, which includes daily progress and the completion rate of the daily exercises (Figures 3C and 3D).

Figure 3. Examples of screens on the mobile app for patients, including the (A) functional introduction, (B) shoulder mobility measurement, (C) historical records of shoulder range of motion, (D) historical records of daily exercise completion rate, (E) daily home-based exercise tasks.

Figure 4. Sets of home-based shoulder exercises displayed on the mobile app and demonstrated by participants: (A, H) forward wall walking stretch; (B, I) lateral wall walking stretch; (C, J) cane stretch for shoulder flexion; (D, K) cane stretch for shoulder abduction; (E, L) cane stretch for shoulder external rotation; (F, M) cane stretch for shoulder internal rotation; (G, N) cane stretch for shoulder extension.

Mobile App for Physiotherapists and Physicians

The Doctor App was designed for physiotherapists and physicians for use on a mobile tablet. This app provides each patient’s information, including the latest shoulder ROM measurements and exercise completion rates for the previous week (Figure 5A). Physiotherapists and physicians can assign

personalized daily home-based exercises with adjustable targeted angles, numbers of repetitions, and holding times for each patient based on the angular status of the affected shoulder (Figure 5B). Physiotherapists/physicians can directly communicate with the patients by sending text messages through the Doctor App.

Figure 5. Examples of screens on the mobile app for physiotherapists and physicians, including the (A) daily and weekly exercise completion rate of each patient displayed with patient information and (B) doctor-assigned daily exercises with specified targeted angles, holding times, and numbers of repetitions.

Study Protocol

This study included two investigations. The first evaluated the reliability of measurements of shoulder ROM using the motion sensor device, and the second confirmed the effectiveness of using the motion sensor device for the rehabilitation training of patients with AC. The Ethical Committee of Taipei Medical University approved the entire protocol and instrumentation (TMU-JIRB N201708048). All participants consented to participation in the study and the publication of data.

Reliability of Shoulder ROM Measurements Using a Motion Sensor Device

From January 2017 to August 2017, two groups of participants — 10 healthy participants and 15 patients with a confirmed diagnosis of AC — were prospectively enrolled for measurement of shoulder angular motion.

Volunteers aged 20 to 70 years were included in the group of healthy participants. Participants who reported discomfort or limited ROM of the shoulder within the preceding year were excluded. Patients were included in the AC group who (1) were aged between 40 and 70 years, (2) had spontaneous onset of a painful stiff shoulder and marked loss of active and passive global shoulder motion, (3) had reported local shoulder pain that was frequently present either over the anteromedial aspect of the shoulder extending distally into the biceps region or over the lateral aspect of the shoulder extending into the lateral deltoid region, and (4) had symptoms for at least 3 months, with normal findings on anteroposterior and axillary radiographs of the glenohumeral joint. Patients were excluded if they (1) had pathological findings of rotator cuff tear on physical examination (eg, abduction weakness and positive dropped arm test); (2) had glenohumeral osteoarthritis upon radiographic evaluation; (3) had clinical evidence of severe cervical spine disease; (4) had a history of severe trauma to the shoulder; (5) received a local corticosteroid injection or any physiotherapeutic intervention to the affected shoulder in the 3 months preceding the study start date; (6) had a history of inflammatory joint disease, infection, stroke, or thyroid diseases that affected the shoulder; or (7) were unwilling to undergo an intervention or participate in the trial.

For angle measurements, aROM and pROM for flexion, extension, abduction, and internal and external rotation at a neutral position for both shoulders of healthy participants and for the affected shoulder of the patients with AC were assessed. The shoulder ROM in all directions for each participant was first assessed using the motion sensor device. Two examiners (one well-trained physiotherapist and one highly experienced orthopedic surgeon) who were blinded to the angle measurements by the motion sensor device measured shoulder ROM in all directions using a universal goniometer.

Each participant stood straight, and scapular rotation was permitted to measure abduction, flexion, and extension (Figures 1B, 1C, 1D). External rotation was measured in a neutral position with the shoulder abducted, the elbow flexed at 90°, and the forearm in a neutral position; the angle between the long axis of the forearm and the sagittal plane of the trunk was measured as external rotation (Figure 1E). Internal rotation was determined by having the participants reach up the back to the highest point along the midline (Figure 1F). Six levels of internal rotation were defined according to the areas that the participant's hand reached, as follows: interscapular region (T7), T12 vertebra, waist (L3), lumbosacral junction, buttock, and lateral thigh. A high reach corresponded to better internal rotation. The aROM was measured by instructing participants to move their arm as far as they could, and the pROM was measured as the examiner moved the subject's arm to its mechanical limit or a limit imposed by pain.

Effectiveness of Motion Sensor Device for Rehabilitation Training of Patients with AC

The 15 patients with confirmed diagnoses of AC were allocated to 2 intervention groups: 7 patients to the home-based exercise group and 8 patients to the motion sensor-assisted rehabilitation group. The patients were allocated according to their willingness to use, and familiarity with, mobile apps. The patients in both groups received 3 months of rehabilitation.

Patients with AC in the home-based exercise group received comprehensive instructions on the daily shoulder exercises from an experienced orthopedic surgeon before beginning the exercise program. The information included instructions for home-based

exercises; a description of frozen shoulder; and advice on sleep, posture, and pain relief. Home-based exercises included Codman's or pendulum exercises (circumduction) and passive stretching exercises, including "wall walking stretch exercises" and "cane stretch exercises" (Figure 4). Further information regarding the standard protocol of the home-based exercises is available in Multimedia Appendix 3. The patients were instructed to perform these exercises within the painless range, maintain the maximal achievable angle for at least 10 seconds in each exercise, and repeat each exercise at least 10 times daily. All patients were instructed to follow the standard home-based exercise protocol, but individualized modification was permitted based on health professionals' judgment. In practice, an orthopedic surgeon reviewed the progress of each patient every month. They gave advice and modified the exercise program based on the patient's compliance and AC status. Therefore, if a patient had poor performance on a specific direction of shoulder ROM after the exercise program of the previous month (eg, on shoulder abduction), the orthopedic surgeon could make adjustments to the next month's exercise protocol by increasing the daily exercise frequency to 15-20 times and the holding time to 15-20 seconds per session for the "lateral wall walking stretch" and "cane stretch for shoulder abduction" exercises.

All patients in the motion sensor-assisted rehabilitation group received detailed instructions on operating the motion sensor device and Patient App on their own mobile phones before they began the rehabilitation program. The aforementioned orthopedic surgeon assigned the standard protocol of daily home-based shoulder exercises to each patient via the Patient App with individualized modifications according to the patient's performance. The completion rate of these daily tasks was calculated using the app for each patient and sent to the Doctor App over the internet, enabling the supervisor to immediately discuss the progress of each patient with them. In addition, patients in the motion sensor-assisted rehabilitation group were individually assigned each set of stretching exercises with the target angle on the mobile app by the orthopedic surgeon based on the patients' previous shoulder angular performance (Figure 5B). For example, if the patient had 100° shoulder abduction before starting the shoulder exercise program, the target angle for the "lateral wall walking stretch" and "cane stretch for shoulder abduction" would be assigned as 120° with an acceptable range of 30°. Achievement of the target angle of the assigned exercise could be recorded as a successful count for calculating the daily exercise completion rate on the mobile app (Figure 3D). In this manner, the patient could therefore stretch the involved shoulder to the maximal limit of the angle on each attempt, thereby effectively maximizing the training effect of stretching exercises.

Outcome Measurement

Basic demographic data, including age, gender, and educational status, were collected for each patient with AC through face-to-face interviews. For all patients, shoulder aROM and pROM in all directions of the affected shoulder were assessed and recorded by the motion sensor device at baseline and each month for 3 months following the initiation of the rehabilitation program. All patients received and completed questionnaires that allowed relevant metrics to be evaluated at baseline and at

the 1-month, 2-month, and 3-month follow-ups by an independent physiotherapist who was not involved in treating any patients and was blinded to the treatment allocation. This questionnaire was based on a pain severity visual analog scale (VAS) and the Quick Disabilities of the Arm, Shoulder, and Hand (qDASH) questionnaire. The monthly exercise completion rate, as reported by all participants and by the motion sensor devices in the motion sensor-assisted rehabilitation group, was recorded every month.

Instruments

Measurement of Shoulder Function

The self-reported qDASH, consisting of 11 items, was developed to measure the relevant physical function and symptoms of patients with upper limb disorders [19]. The Chinese version of qDASH has excellent reliability (Cronbach $\alpha=0.818$, intraclass correlation coefficient [ICC]=0.907) [20]. A higher qDASH score indicates poorer shoulder function.

Measurement of Pain

A VAS is an instrument that is regularly used to measure the intensity of pain [21]. A researcher asked the patients, "On a scale of 0 to 10, how severe has been the worst pain that you have experienced within the last week?" This question was repeated in the follow-up sessions.

Measurement of Exercise Completion Rate

The exercise completion rate reported by the motion sensor device was calculated by dividing the number of exercises completed daily by the number of assigned exercise tasks daily. The monthly exercise completion rate was the average of the daily exercise completion rates over an entire month. The patient-reported exercise completion rate in each month was obtained by asking each patient, "On a scale of 0%-100%, what was your average exercise completion rate in the previous month?"

Statistical Analysis

The ICC was used to calculate the interrater reliability between the shoulder aROM and pROM outcomes measured by the motion sensor device and the two experienced examiners. The ICC was obtained by conducting a 2-way analysis of variance in a random effects model. ICCs >0.8 and >0.9 were considered to indicate good and excellent reliability, respectively [22]. The ICC was further used to determine the minimal clinically important difference (MCID) in a distribution-based method. Specifically, the standard error of the measurement (SEM) was first computed using the following equation: $SEM = SD \text{ of the baseline measures} \times \sqrt{1 - ICC}$; then, the MCID was computed as follows: $SEM \times 1.96 \times \sqrt{2}$ [23,24].

In the second part of the study, in which the home-based exercise and motion sensor-assisted rehabilitation groups were compared, the Mann-Whitney *U* test was used to compare two independent, ordinal groups, regardless of the normal distribution of the metric of interest owing to small sample sizes. The Wilcoxon signed-rank test was used for within-group comparisons of the dependent variables at follow-up. The MCID computed from the first part of the study was used to illustrate whether the changes in aROM and pROM were meaningful.

Along with descriptive statistics concerning participant characteristics, generalized estimating equations were used to compare the two groups with respect to improvements in several outcomes (including aROM, pROM, VAS, and qDASH). All generalized estimating equations were analyzed using the restricted maximum likelihood estimation. They all controlled for the effects of time during follow-up. SPSS 23.0 (IBM Corp, Armonk, NY) was used for all data analyses. $P \leq .05$ was considered to indicate statistical significance.

Results

Regarding the first part of the study on the reliability of measurement by the motion sensor device, Table 1 presents the results for shoulder aROM and pROM in all directions for healthy participants and for patients with AC, as obtained by the motion sensor device and the two examiners.

Table 1. Active and passive ranges of motion of the shoulder measured by different examiners.

Examiner	Abduction (°), mean (SD)		Flexion (°), mean (SD)		Extension (°), mean (SD)		External rotation (°), mean (SD)		Internal rotation (level) ^a

Table 2 shows whether the interrater reliability for the measurement of shoulder aROM and pROM in all directions, except for shoulder extension, as assessed by the motion sensor device and the two examiners was good or excellent (ICC range

0.899-0.979). The interrater reliability of the measurement of active and passive shoulder extension was fair to good (aROM: 0.771; pROM: 0.799).

In the second part of the study on the effectiveness of the motion sensor device in rehabilitation training, one patient in the motion sensor-assisted rehabilitation group was excluded from the analysis owing to progressive shoulder pain and newly developed shoulder abduction weakness 1 month after rehabilitation. The patient received a subsequent diagnosis of

a full-thickness rotator cuff tear based on shoulder magnetic resonance imaging. Therefore, the comparison was of 7 patients in the motion sensor-assisted rehabilitation group and 7 patients in the home-based exercise group. Table 3 presents the patient demographics, which did not differ significantly at baseline between the two groups.

After 3 months of follow-up, patients in the motion sensor–assisted rehabilitation group exhibited a significant improvement from baseline in terms of shoulder aROM and pROM in all directions, pain score, and qDASH (Table 4). By contrast, patients in the home-based exercise group exhibited significant improvements only in aROM in shoulder abduction,

aROM and pROM in shoulder extension, and VAS score (Table 5). Additionally, when the improvements in the motion sensor–assisted rehabilitation and home-based exercise groups were compared, the motion sensor–assisted rehabilitation group had achieved better and faster meaningful changes than the home-based exercise group.

ⁱqDASH: Quick Disabilities of the Arm, Shoulder, and Hand questionnaire.

A comparison of the improvements in the motion sensor–assisted rehabilitation and home-based exercise groups over time revealed that, compared with patients in the home-based exercise group, those in the motion sensor–assisted rehabilitation group had significantly better pROM in shoulder abduction, flexion, extension, and external rotation; better aROM in shoulder extension and internal rotation; and a better qDASH score at the 3-month follow-up (Table 6). In addition,

the changes in shoulder ROM in most of the directions at different follow-up time points from baseline were correlated with improvements in qDASH score, inferring that the motion sensor device is a reliable tool for evaluating treatment efficacy in patients with AC (Multimedia Appendix 4). Table 7 shows that, compared with patients in the home-based exercise group, those in the motion sensor–assisted rehabilitation group had a significantly higher patient-reported exercise completion rate.

^aComparison of the participant-reported exercise completion rates between the motion sensor–assisted rehabilitation and home-based exercise groups.

Discussion

Principal Findings

This study revealed that wearable IMU-based sensors can measure shoulder ROM with acceptable reliability. When the wearable motion sensors were integrated with interactive mobile apps and telecommunication technology for the treatment of AC, patients could correctly perform daily home-based shoulder exercises under the remote supervision of a physician, as revealed by a 3-month ambulatory assessment. Consequently, compliance with the daily shoulder exercise regime was enhanced, thus improving the recovery of shoulder ROM and function among patients with shoulder AC using motion sensor device–assisted rehabilitation.

Measurement of shoulder ROM is an important component of related clinical assessments, providing information that is useful for guiding and evaluating interventions for patients with AC. Many methods can be used to measure ROM including a goniometer, 3-dimensional motion analysis (3DMA) systems, and IMU-based sensors. The goniometer is widely used but has variable reliability and tends to fail in assessing joint angles during dynamic movement [25]. The 3DMA system, which is regarded as the gold standard for evaluating lower limb kinematics [26], measures joint angles during dynamic movement with multiple degrees of freedom. However, the use of the system to measure shoulder ROM is technically challenging owing to the complexity of shoulder movement [27]. Moreover, the 3DMA system is typically immobile, difficult to access, and requires expertise to operate, preventing

its general clinical use. Wearable IMU-based sensors are becoming popular and have the potential to measure the joint angles of upper limbs with acceptable reliability [28]. Studies have already revealed that wearable IMU-based sensors can track shoulder movements with high accuracy [29]. In the present study, shoulder ROM measurement by IMU sensors yielded good to excellent interrater reliability with reports from well-experienced physicians who were using goniometers; it can therefore provide reliable angular information that physicians can use to monitor the progress of shoulder rehabilitation and facilitate the design of upper limb exercises that promote the rehabilitation of patients with AC.

An important aspect of the motion sensor device used in this study is the integration of a mobile phone-based system. Mobile phone apps for medical and rehabilitation purposes that are adaptable and easily accessible are being intensively researched [29,30]. Such apps may help in the development of a platform for delivering self-management interventions, thus improving the delivery of health care and outcomes [28]. Evidence has also revealed that app-based exercise instructions and tools can help patients to monitor their training compliance and progress with high acceptance and usability [29]. In this study, the mobile apps with the motion sensor device system provided an informative patient interface with comprehensible exercise instructions and simple progress monitoring; they support self-managed health care anywhere through the monitoring of rehabilitation exercise performance. Wireless telecommunication is used to synchronize with the Doctor App, send information regarding each patient's progress with home-based exercises, enable physicians to remotely supervise rehabilitation, and provide instant feedback to patients. Studies have established that the delivery of simple text message reminders to mobile phones increases the compliance of AC patients to a shoulder exercise regimen [31]. With the assistance of a mobile app that is used in conjunction with a motion sensor device for shoulder rehabilitation, physiotherapists or physicians can not only send text messages to remind patients to perform their daily exercises but also assign personal home-based exercises based on their training performance, thus increasing their motivation.

Overall, the positive results justify further work on motion sensor devices for treating AC. Further investigations of the usability of mobile apps and the development of auto-adjusted rehabilitation programs that are based on a user's personal performance are warranted before well-controlled research is conducted with large patient cohorts to demonstrate the viability of motion sensor devices in real-world environments. The motion sensor device-assisted rehabilitation model in this study can be applied in conjunction with telerehabilitation.

Telerehabilitation is the provision of rehabilitation services at a distance; it can be image-based or sensor-based and can be delivered using virtual environments or virtual reality [32]. A motion sensor device can support image-based and sensor-based telerehabilitation using an activity recognition model, an interactive 3D avatar in mobile phone apps, and a wireless telecommunicated network, supporting medical treatment for patients with AC. The future use of motion sensor devices in telerehabilitation for various muscle skeletal disorders is expected after its development reaches maturation.

Limitations

The main limitations of this study were the relatively small number of patients, short follow-up period, and consequent lack of information on the long-term effects of the intervention. The allocation of patients was not randomized, owing to their varying degrees of familiarity with mobile apps and motion sensor devices. Studies have found that new rehabilitation technology may be unlikely to be accepted by many elderly patients [33]. In this study, the targeted patients with AC were 40-70 years old. Within this population, younger and highly educated patients are generally accepting of motion sensor device-assisted rehabilitation and so were likely to be allocated to the motion sensor-assisted rehabilitation group. Researchers of future studies should consider a training program for motion sensor device usage before enrollment to prevent any potential selection bias. Finally, although this study revealed that the IMU-based sensors that were used to measure shoulder ROM were as reliable as goniometers used by two well-experienced physicians, the true accuracy of IMU-based sensors for shoulder ROM measurement is still unclear. Evidence has confirmed that the reliability of shoulder and elbow ROM measurement using the goniometer varies (interrater ICC, 0.36-0.91) [25]. Further assessment may be required to compare IMU-based sensors and the 3DMA system in the measurement of shoulder ROM with regard to accuracy and reliability.

Conclusions

Wearable IMU-based sensors can reliably record the angular motion of shoulders. Motion sensor device-assisted home-based rehabilitation can increase patient compliance with a daily self-exercise regime and facilitate the early stage of functional recovery for patients with shoulder AC. Collectively, motion sensor device-assisted home-based rehabilitation is a useful treatment model for AC with telerehabilitation to overcome obstacles to physiotherapy at home; it provides comprehensive and easily accessible exercise instructions, increases compliance, and enhances exercise correctness through progress monitoring.

Abstract

Background: Remote measurement technologies (RMT) can be used to collect data on a variety of bio-behavioral variables, which may improve the care of patients with central nervous system disorders. Although various studies have explored their potential, prior work has highlighted a knowledge gap in health care professionals' (HCPs) perceptions of the value of RMT in clinical practice.

Objective: This study aims to understand HCPs' perspectives on using RMT in health care practice for the care of patients with depression, epilepsy, or multiple sclerosis (MS).

Methods: Semistructured interviews were conducted with 26 multidisciplinary primary and secondary care HCPs who care for patients with epilepsy, depression, or MS. Interviews were transcribed verbatim and analyzed using thematic analysis.

Results: A total of 8 main themes emerged from the analysis: (1) potential clinical value of RMT data; (2) when to use RMT in care pathways; (3) roles of health care staff who may use RMT data; (4) presentation and accessibility of data; (5) obstacles to successful use of RMT; (6) limits to the role of RMT; (7) empowering patients; and (8) considerations around alert-based systems.

Conclusions: RMT could add value to the system of care for patients with central nervous system disorders by providing clinicians with graphic summaries of data in the patient record. Barriers of both technical and human nature should be considered when using these technologies, as should the limits to the benefits they can offer.

Introduction

Background

In a health care context, remote measurement technologies (RMT) can be used by health care professionals (HCPs) and clinical teams to collect data on a patient's health or behavior and use this to inform clinical decision making. The benefits of RMT have been explored in the management of patients with cardiac conditions [1-3], early stage dementia [4], neurological disease [5], and attention deficit hyperactivity disorder [6] as well as in behavior change [7] and monitoring for indicators of sepsis [8] among others.

The European Union H2020 Remote Assessment of Disease and Relapse-Central Nervous System (RADAR-CNS) project [9] explores the use of RMT in the care of patients with epilepsy, depression, or multiple sclerosis (MS). These conditions were chosen for this project as exemplars of central nervous system disorders that are under-researched in relation to RMT. As part of this project, RADAR-base, a cloud-based platform, is being developed to explore the potential to receive data from patients' RMT and to provide these data to HCPs with a view to informing clinical decision making [10]. This study is part of this project, aiming to understand the clinical utility of RMT in the care of patients with epilepsy, depression, or MS.

Previous literature has demonstrated the benefits of using RMT in health care practice. A 2013 literature review of the use of RMT in cardiology identified a number of studies demonstrating reduced hospital visits in terms of both emergency and routine appointments, as well as higher survival rates, in patients who were monitored using RMT [11]. Benefits were also found in patients' relations with the care team, quality of life, and compliance with treatments. However, no quality appraisal was conducted in this narrative review.

Some studies have challenged these findings, suggesting little or no evidence of an effect of RMT on key outcomes [12,13]. Other work has highlighted a number of barriers to implementing RMT in health care practice. Erdmier et al [14] described a lack of regulatory control over wearables as well as a number of barriers to progress in implementation, including technical capability, erratic user (patient) behavior, and a lack of transparency from manufacturers. A patient and HCP-led priority setting exercise in the field of digital mental health highlighted the need to explore the impact of removing face-to-face human interaction in care pathways for mental health conditions, and raised issues of safety, effectiveness, evaluation, and inequalities [15]. These issues apply equally to the use of RMT.

Objectives

Authors of prior work in the area of RMT highlighted a need for research to investigate the value to HCPs of implementing RMT [13]. Davis et al [16] conducted a systematic review of health care staffs' views on the use of RMT in clinical practice and included 15 relevant studies. They concluded that "there is a critical need to engage end-users in the development and implementation of RMT" and highlighted that the evidence base in this area is small. This paper seeks to address these points

by exploring HCPs' perspectives on the implementation of RMT in three central nervous system disorders.

Methods

Aim

This study aims to understand the perspectives of HCPs on the use of RMT in health care practice for the care of patients with depression, epilepsy, or MS.

Recruitment

We purposively recruited a sample of 26 HCPs, with the intention of covering multiple clinical roles (with representation from medical, nursing, and allied health professionals). Participants were all working in the National Health Service (NHS) in England in the care of patients with epilepsy, depression, or MS or a combination of these conditions. Participants were contacted through the professional networks of the research team members.

Procedure

A semistructured interview approach was used, with interviews lasting from 16 to 56 min (mean 30 min). An interview schedule was used to guide questioning, with ad hoc follow-up questions used to further explore salient points. Participants gave informed consent and were incentivized with a £15 (US \$18) charity donation.

A total of 23 interviews were conducted one to one, whereas one interview was conducted with three participants together. Moreover, 13 interviews were conducted by phone, whereas 11 were conducted in person. All interviews were recorded from start to finish using a voice recorder. The study was approved by the University of Nottingham School of Medicine research ethics committee (ref 277-1802).

Analysis

Interviews were transcribed verbatim and analyzed using thematic analysis [17]. Data were coded and themed (by JA) using NVivo 12 (QSR International). Initial codes and themes were discussed within the research team and were iteratively renamed and reformed throughout the analysis process. No new themes emerged when the last interview was coded, and so, it is considered that the sample reached data saturation.

Results

Participants

Participants were HCPs (medical doctors, nurses, clinical psychologists, physiotherapists, and dietitians) from 13 NHS trusts (health care organizations) within England. Of the 26 participants, 8 (31%) were female. A total of 12 participants specialized in the care of patients with epilepsy, 6 in depression, 6 in MS, and 2 were general practitioners working across all 3 conditions. Participants included both primary and secondary care clinicians. Moreover, 13 of the 26 interviewees had used RMT with their patients, and 14 of the 26 said that their patients had brought data to appointments. The health care roles of the participants are presented in Table 1 along with their specialization and gender.

Table 1. Job roles, genders, and specializations of interview participants.

Clinical specialization	Depression (n=6)	Epilepsy (n=12)	Multiple sclerosis (n=6)	Generalist (n=2)	Total (N=26)
Gender (female), n (%)	1 (17)	4 (33)	2 (33)	1 (50)	8 (30)
Job role					
Psychiatrist	4 (67)	0 (0)	0 (0)	0 (0)	4 (15)
Psychologist	1 (17)	0 (0)	2 (33)	0 (0)	3 (12)
Neurologist	0 (0)	6 (50)	3 (50)	0 (0)	9 (35)
Dietician	0 (0)	1 (8)	0 (0)	0 (0)	1 (4)
Specialist nurse	1 (17)	4 (33)	0 (0)	0 (0)	5 (19)
Physiotherapist	0 (0)	0 (0)	1 (17)	0 (0)	1 (4)
General practitioner	0 (0)	1 (8)	0 (0)	2 (100)	3 (12)

Thematic Analysis

Our analysis generated 8 main themes, each of which also featured a number of subthemes.

Theme 1: Potential Clinical Value of the Remote Measurement Data

The interviews explored the types of physiological, psychosocial, and lifestyle variables that could be targets for measurement using RMT. The HCPs described uses for certain variables they considered to be potentially useful in the care of patients with 1 of the 3 conditions. Variables considered by participants to hold potential are summarized in [Table 2](#).

Table 2. Target variables considered potentially useful to measure using remote measurement technology.

Condition	Variable
Epilepsy	Activity, anxiety, cognition, diet ^a , heart rate ^b , mood, quality of life, seizures (or proxies thereof), and sleep
Depression	Activity, anxiety, diet, mood, relapse signatures, sleep, and weight
Multiple sclerosis	Activity, anxiety, cognition, fatigue, mood, pain, quality of life, and visual acuity

^aOpposing views on the value of measuring diet were offered by different participants.

^bIt was noted that heart rate would be worth measuring in epilepsy only if proven to be a proxy measure of seizures.

Epilepsy

Participants stated that it would be useful to collect data from RMT that could indicate the occurrence of a seizure or number of seizures, especially in those who have many. However, participants thought that the current approaches to seizure detection (eg, Empatica and Embrace) were limited by lack of sensitivity to detect the full range of seizure types:

The limitations of this particular device is that it is designed for detecting repetitive movements which is of use for tonic clonic seizures, however, there are different types of seizures which definitely don't all involve movement but are still epileptic so they wouldn't be able to detect that [...] It would be ideal to have something where all types of seizures would be recorded. [P02]

Several types of RMT data were mentioned by participants as possible proxy measures of seizures. These were skin conductance, heart rate, accelerometry, pressure sensor readings, and electroencephalography. There were differing views on the usefulness of measuring heart rate and bed pressure as proxy measures for seizures, given the possibility of false positive signals (ie, lack of specificity).

Video and audio may be utilized remotely to assist with diagnosis and seizure identification, particularly through measurement of the sound and duration of a seizure:

I will sometimes tell people who struggle to video their loved one in a seizure for whatever reason, just to start the video going, put the phone down, and then it will both record the sound, and the duration of the seizure, which are probably the two most useful things we need, outside of seeing one. [P09]

Depression

Activity data, including movement and GPS, were thought to be useful in detecting whether a patient was “leaving the house” [P21] or “getting out and about” [P06], which in turn could be considered a potential “proxy marker of depression severity” [P16]. This was also thought to have the potential to indicate a patient’s global level of functioning. RMT data were also thought to offer a level of objectivity in the measurement of depression, which was otherwise lacking. Prospective mood monitoring using an electronic diary and measurement of sleep using wearables were also mentioned as potentially helpful in managing depression, where currently, systems such as Fitbits and mood diary apps could not collate this information together automatically.

Multiple Sclerosis

Participants saw potential in the use of RMT to measure fatigue, via a self-report app, and also cognition, given its association with relapse. However, some considered it difficult to pick one particular aspect of MS to measure using RMT because the symptoms experienced by patients vary:

I don't think you can have a particular tool that you would need to use for everyone. I think it is largely going to be dependent on the symptom profile. [P20]

Multiple participants mentioned visual acuity as an important indicator of relapse, which could be measured using RMT, although they were unsure if technology would be able to measure it when even well-trained humans struggled:

It would have to be really well designed to pick up those intricacies [...] sometimes it is really difficult even for the neurologist to say this person is having a relapse or they are not. [P19]

Theme 2: When to Use Remote Measurement Technology in the Care Pathway

Participants described different points in care pathways when data from RMT could usefully inform the care of their patients. Figures 1-3 demonstrate where participants indicated that it could be useful to receive data from RMT. Clinicians indicated that they would like data collected via RMT to be readily accessible in their electronic patient records (EPRs) when patients attended for appointments.

Figure 1. Participants' comments about the timing of the use of remote measurement technology in the epilepsy care pathway, including monitoring on a yearly basis once stable to allow assessment of follow-up and to create data for future research.

Epilepsy

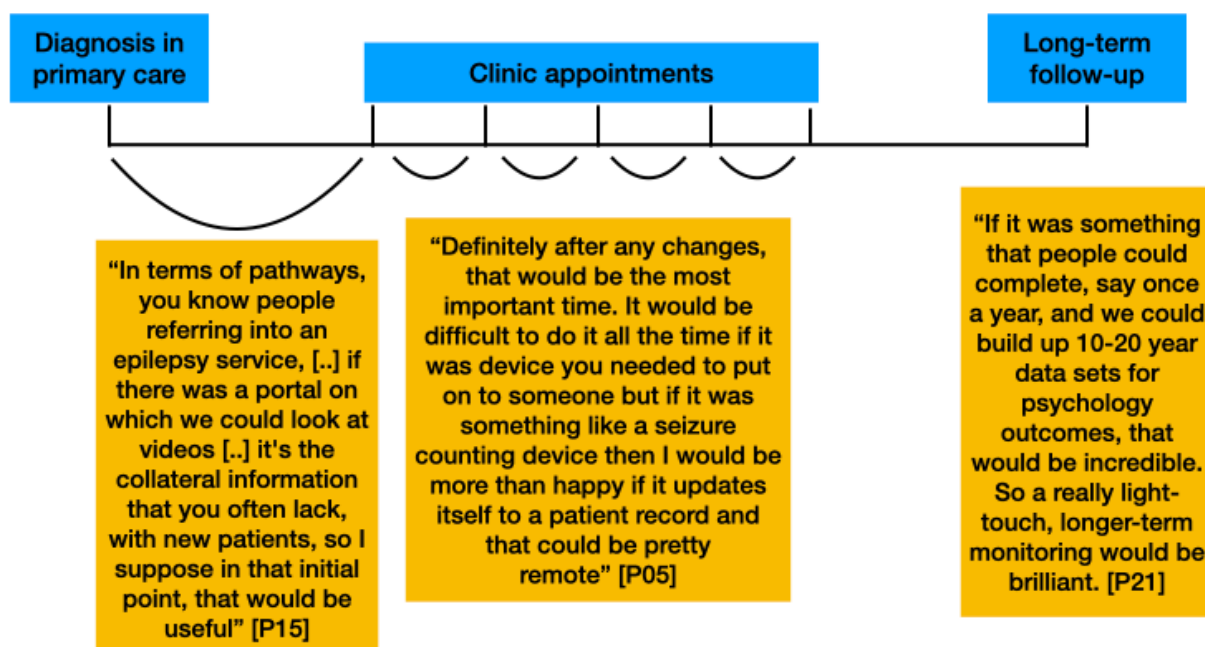

Figure 2. Participants' comments about the timing of the use of remote measurement technology in the depression care pathway, including monitoring during a change in treatment.

Depression

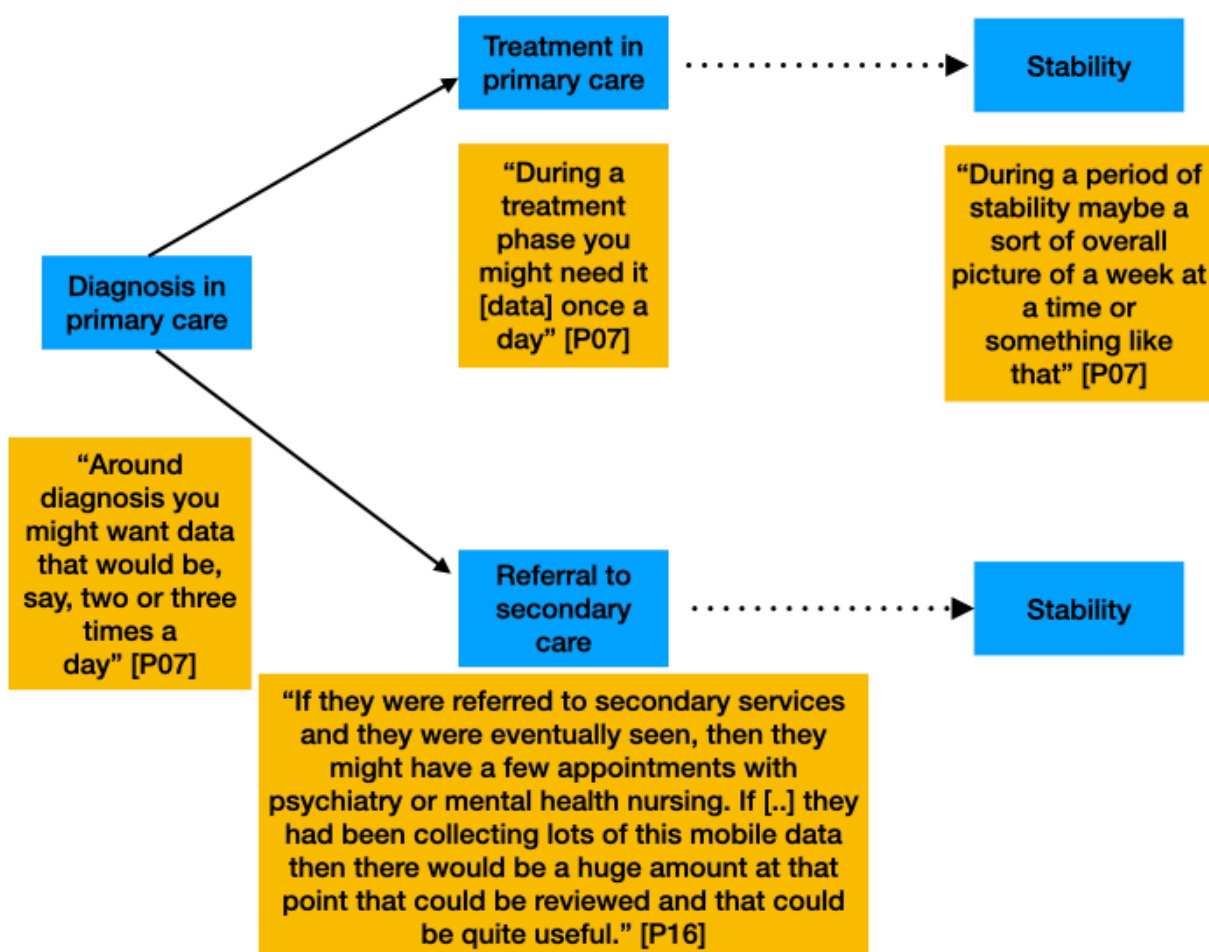

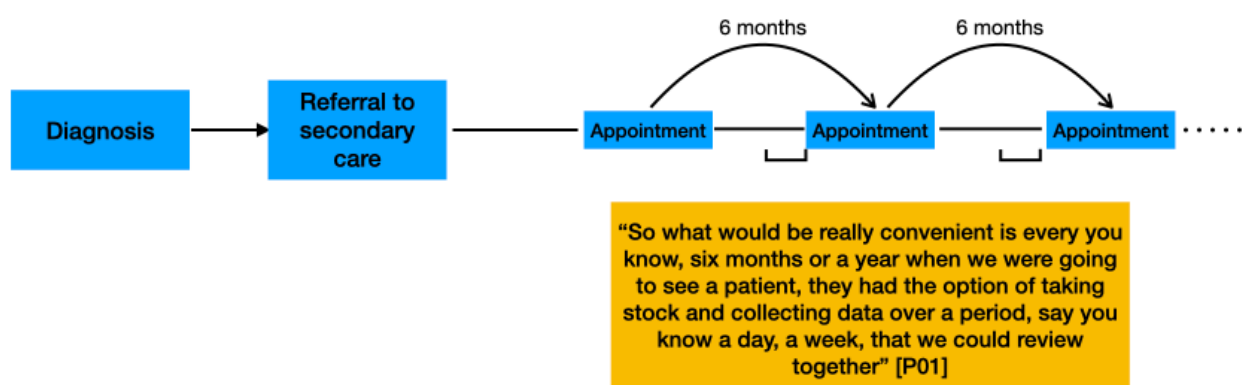

Figure 3. Participants' comments about the timing of the use of remote measurement technology in the multiple sclerosis care pathway, indicating the benefits of monitoring for a short period before an appointment.

Multiple sclerosis

It is acknowledged that not every patient's journey along a care pathway follows the same trajectory. These figures are for illustrative purposes only.

Theme 3: Roles of Health Care Staff Who May Use Remote Measurement Technology Data.

Participants discussed the roles of health care staff who should be involved in using any RMT data. Across all 3 conditions, participants suggested that primary care was a good place for data to be managed, given the systems available:

Primary care is certainly quite well set up with systems in place to action on things based through the electronic patient record. [P06]

In secondary care, specialist nurses were considered to have the closest relationships with patients among members of the care team, and thus, they were suggested to be the team member most likely to review data from RMT. For example, in epilepsy:

If it's sort of data that is being in some way downloaded in between clinics, then there would certainly be a role for something like an epilepsy nurse to look at that data. [P09]

Participants considered it important that all clinical, but not administrative, members of a team involved in the treatment of a patient should have access to RMT data when it is collected:

The discussions we've had are about, is it appropriate for admin staff to review that or actually does it have to be a clinician from a risk perspective [...] Your economic arguments come in about experienced clinicians are too expensive but I think making the wrong triage decision is also too expensive. [P21]

Theme 4: Presentation and Accessibility of the Remote Measurement Technology Data

Participants had a variety of views on the best way for data to be presented to them. Particular emphasis was placed on the importance of interoperability and the ability for any data from RMT to be accessible within an existing EPR system rather than requiring the opening of another window or program:

If [...] you want to have the information available to you at times other than when your patient is there, then it would be good if it could feed directly into your electronic patient record. [P07]

Across all 3 conditions, HCPs were keen to have data aggregated in a visual or graphical format. Some also recalled instances where they had used devices or software that presented information in graphs automatically and commented that this was useful for the patient as well as for the clinician:

For most of them [mood-reporting apps] you can do a graph function so they can show you the whole three months, in a fairly small chart, which helps us to think about if there have been any stresses or life events that have changed their mood or whether there's a pattern to the time of day, and so on. [P07]

The speed of access to information was also considered to be a priority. Participants spoke of particular situations in which the use of digital records could increase efficiency through time saving:

I certainly think if you can access the information quickly then it could be a focus point for the whole consultation and it could speed things up. [P16]

Uploading data to the EPR was considered preferable to reviewing data that patients brought to the clinic on their mobile phones:

It could be sent in and loaded up in the patients notes or some other big screen device otherwise you are

kind of stuck with little handheld mobiles and it's not really that helpful. [P13]

Theme 5: Obstacles to the Successful Use of Remote Measurement Technologies

Participants mentioned several aspects of the use of RMT, which they considered to be obstacles to their successful use and adoption in practice. These fitted into 2 broad categories of *technical issues* and *human issues*.

The most frequently mentioned technical issue was data accuracy ("I'm not sure they're accurate." [P03]). However, participants indicated that they would be happy to use devices even when they provided data that were not 100% accurate, so long as the clinician was aware of the margins of error that the data may contain:

So being as clear as possible what the potential pitfalls might be about all the data that we get back [...] I think as long as you know, kind of where it might go wrong, or how to be careful which bits to not over-interpret, then I think it's fine [P09]

There was also concern about the interoperability of any new system with existing ones, as clinicians are already required to use several different software packages to manage patients:

The main trouble currently is a lack of integration. [P01]

Data security was also discussed as an important issue to consider, although participants had differing views on the level of risk that providing data remotely may entail. Some had concerns:

Who has access to this data? Including if they have it on their phone, what if their phone goes missing, where does this data go? There's a big, data protection bit, there's a big big, patient safety bit. [P03]

Some advocated taking a pragmatic approach to reduce risk while continuing to use technology where it provided a benefit:

I think as long as appropriate safeguards are taken then that's fine, and I think sometimes this can be a barrier, an unnecessary barrier to introducing things that can be helpful. [P06]

Human issues considered obstacles to the use of RMT largely focused on 2 areas: patient anxiety and patient motivation. Participants discussed ways in which the use of RMT may cause patient anxiety through over focusing on their symptoms and how this in turn could be problematic for a health service:

We have had quite a few patients coming in that have used these monitoring devices and say my heart rate is really fast. For them it's another layer of education so it actually creates us more work. [P03]

However, others were less concerned, believing that RMT would not induce anxiety in patients who were not prone to it in the first place or that any anxiety would be manageable:

We've always found ways to react to that anxiety, this is just what it looks like in the current generation. [P21]

Participants suggested that patients with depression would have less motivation to engage with RMT as a result of their condition:

A lot of our patients may, especially if they're more severely depressed, not be very motivated to interact with the app [P16]

However, the use of RMT to generate more objective evidence of a patient's health state was considered by some to be useful in motivating engagement with their care:

So if you do your usual interview and you've got objective evidence to say, I think your depression is coming back or you haven't been exercising enough or you have way more seizures than you think, then of course, that might help motivating them to do certain things. [P22]

Theme 6: Limits to the Role of Remote Measurement Technology

Several of our participants mentioned elements of care in their specialism, which, in their view, should not be replaced by an RMT-enabled approach. In MS, the importance of face-to-face appointments was highlighted as essential for HCPs to identify subtle signs of worsening condition:

You really need to be physically examining the patient as well as hearing their perspective because there's subtle deficits that you can pick up on at examination that people won't notice day to day [...] you can pick up things like subtle signs like nystagmus, or problems with the balance or things like that, that people often won't notice. [P01]

In epilepsy too, HCPs reiterated the importance of seeing their patients face to face:

If their seizure frequency has increased you're there thinking I probably need to see you, what else is going on? Have they got a cold, a water infection? Is there something else going on in their life? Are they not taking their tablets? Sometimes some of those conversations need to be had. [P03]

A general practitioner mentioned the relational side of their work as important in the care of patients with depression:

The relationship element of it is very important, and obviously in primary care a lot of what I'm thinking is around depression [...] the human to human contact with someone who's struggling with mood, and the fact that you've got someone who can be empathic and rapport rather than just crunching data. [P06]

Theme 7: Empowering Patients

HCPs believed that RMT may benefit patients because it might empower them to take a leading role in their care. Some clinicians believe that patients should lead the use of technology and, therefore, have more control over their own care:

The way I see it is it's more about the patient using the data for themselves, the clinician is almost the passive recipient of the data who is working with the patient to try and interpret it and help them develop techniques to use the data themselves. [P07]

HCPs also spoke of how patients could be given full control of their own data collected using RMT and allow those data to be shared with a chosen clinician when they deemed it necessary:

Within the patient held database, [...] presumably a sort of secure log in, and that is, it's patient-controlled [...] and they could give out the ability to share. [P15]

Participants provided examples of how a patient could be empowered through the use of RMT, by determining when to arrange an appointment based on the outputs from the technology:

Through prospective mood monitoring you could capture periods where there had been a persistent lowering of mood over two weeks or more with associated other features or even shorter periods than that, that you'd agreed as part of a relapse signature. What people could do in those instances is potentially bring appointments forward. [P13]

However, in the case of depression, participants saw difficulties with patient motivation and thus thought it would be unlikely that patients would be able to take control of their own care:

[That] involves them taking a lot of responsibility for their own healthcare and I guess that may work better in some conditions, more than depression. [P16]

For some, it was a case of providing care on an individual basis:

I would tailor it to what they wanted, so you will have those who are very tech savvy who don't have any time and think this will really suit me, others are very much I really want to see you doctor [...] the key is to listen to them and individualise care rather than doing tick box medicine which we sometimes do. [P03]

Theme 8: Alert-Based Systems

There was debate across all 3 conditions in the interviews about the potential to use RMT to alert clinicians when a monitoring variable fell outside normative parameters, for example, if seizures increased in severity or frequency, if mood or activity were found to be particularly low, or if fatigue increased. The majority of participants considered such a system to be beneficial, so that interventions could be put in place as soon as possible:

It would be a system that had parameters set and triggered active alerts when those parameters were exceeded, I think would be the only way that I could see a lot of our consultant body engaging in it. [P01]

However, a small number of participants thought that such a system would be problematic, principally because alerts may create excessive demand for immediate processing, interpretation, and response (eg, outside of normal working

hours), and there would not be enough health care staff available to respond to the alerts produced:

Outside of fixed appointments the question would be who would actually have time and headspace to actually look at what was being flagged up. You would need to really carefully think about the staffing in the NHS and mental health services. [P13]

HCPs also perceived there to be a risk that alerts would go unnoticed in the system:

My worry is this data arrives and nobody looks at it for weeks, it's sitting somewhere in the ether. [P03]

Several participants suggested that it would be more useful if the technology alerted the patient to take action through their regular treatment pathways, rather than putting the onus on the clinician:

I would want it to prompt the patient to make contact with me. [P14]

Some saw a need for further research to determine the benefits of an alert-based system:

Unless you could do a good study and demonstrate that sending me alerts from an automated app would be helpful, then I would just want information that I could look back on when I next met with a patient face to face. [P14]

Discussion

Principal Findings

A total of 8 themes emerged from the analysis of our interviews. The first theme covered the potential clinical value of the remote measurement data. Where RMT are currently used in health care practice, HCPs find them to be largely inaccurate, particularly in the case of epilepsy, although efforts to develop more effective ways of monitoring epilepsy are welcomed. Participants were optimistic about the future use of activity data to monitor symptoms of depression and considered that using RMT to collect measures of fatigue and cognition in patients with MS would be useful.

In theme 2, key points in care pathways for the 3 conditions were identified as times where RMT data could provide most value. These included monitoring a short period before an appointment (MS), monitoring during a change in treatment (epilepsy), and monitoring on a regular basis once a patient was in a stable condition, to allow assessment of follow-up and to create data for future research (depression, epilepsy, and MS).

The third theme considered staff roles in the management of RMT use by patients. Participants suggested that all staff involved in a patient's care should have easy access to data generated by RMT via the patient record. Participants also made it clear that triage using data from RMT should be conducted by qualified HCPs rather than by administration staff. Primary care staff and specialist nurses in secondary care were thought to be well placed to manage incoming data from patients.

With regard to the presentation of data, in theme 4, HCPs described ease and speed of access to RMT data to be important

for their successful use and emphasized the importance of interoperability with the patient record. Presentation of data in graphs was mentioned as helpful for interpretation.

Theme 5 discussed obstacles to the successful use of RMT, and these included both *technical issues* such as data accuracy and data security (where views differed on the risks involved) and *human issues* such as anxiety created by monitoring (although not all participants agreed that this was an issue).

In theme 6 on the limits of RMT benefit, participants emphasized that RMT would never completely replace face-to-face appointments, particularly in depression where relationships were considered important.

The seventh theme concerned patient empowerment. HCPs expressed the value in providing patients access to their own data, enabling them to take an active role in their own care, for example, by advancing appointments where RMT data indicated it was necessary. However, there was some concern about patients with depression having the motivation to take responsibility for their own care.

Theme 8 was related to alert-based systems. Participants debated the value of such systems and highlighted the requirements for their successful use. Some thought alerts should be used to invite the patient to take action rather than alerting a clinician, due to workload concerns. The need for further research to determine the benefits of alert-based systems was also highlighted.

Comparison With Prior Work

Although prior work exploring RMT in health care has principally identified benefits and barriers to its implementation [11,14], this study has investigated HCPs' perceptions of the clinical value of implementing RMT, helping to address the knowledge gap identified by Vegesna et al [13] and Davis et al [16].

The themes emerging in this study add to findings from prior work in this area. Our findings support the work of Bruno et al [18], who highlighted that HCPs may view the management of data from digital devices as a burden. Goodrich et al [19], among others, have highlighted the importance of interoperability and a preference for data from mobile technologies to be automatically integrated into clinical records, similar to the views of our participants. Clinicians' concern about the need to respond to alert-based systems has also been raised previously [16,20].

Prior work has also emphasized the importance of face-to-face contact in the context of digital technology and mental health care [21]. A priority setting exercise for digital mental health [15] identified the need to explore the impact of removing such interactions from care pathways. Our data have shown that HCPs view face-to-face appointments as essential in the care of patients with these 3 conditions, even where RMT could provide them with detailed recent data on a patient's status. Our data show that HCPs imagine patients could be empowered to determine their own need for a clinical appointment based on data from RMT, helping to address questions around the impact of technology on access to services, which has also been identified as a research priority [15].

Davis' Technology Acceptance Model [22] describes perceived usefulness and perceived ease of use as key mediators to the successful uptake of a new technology. Our analysis highlights ways in which clinicians perceive RMT data could be useful (theme 1) as well as where there are limits or obstacles to this usefulness (themes 5 and 6). We have also identified how speed and ease of access to data are desirable for HCPs (theme 4), evidencing how perceived ease of use is applicable to this area. The analysis also raises the tailoring of care for patients using RMT (theme 7), where it was discussed that patients' perception of RMT should be that it is both useful and easy to use to motivate continued use.

Beyond the findings presented in previous work, our findings specify the types of RMT data that clinicians would value in the management of epilepsy, depression, and MS as well as the points in patient care at which these data would be of most use and the health care roles that would be best placed to manage these data.

Implications for Researchers and Developers

Findings from these themes will help to inform the development of the RADAR-CNS approach in the application of RMT for better care for epilepsy, MS, and depression. Researchers and companies developing monitoring technologies should ensure that the boundaries of accuracy of any new solution are well defined, such that clinicians can understand the level of confidence they should place in readings from such devices. As HCPs believe patients may benefit from the option to move or advance appointments based on their data, it would also be worthwhile for any mobile health solutions to link with appointment planning services, so that these can be easily accessed. In the United Kingdom, the NHS app is an example of such a system.

Strengths and Limitations

This study has several strengths. We recruited a multidisciplinary group of HCPs working in a variety of clinical staff roles in primary and secondary care. Therefore, the use of RMT was considered from multiple perspectives. The study was limited in its consideration of only three specific central nervous system disorders in one national health care system. However, the analysis has considered how insights gained from staff working in these three conditions might generalize and has permitted a deeper analysis of the three conditions mentioned. The ratio of male to female participants was high, with only 8 of 26 participants being female. Epilepsy staff were over-represented in comparison with depression and MS staff due to the convenience sampling method. However, staff were represented across most roles in the care team for each of the three conditions represented, with the exception of MS, where an MS nurse could not be recruited in the time available.

Future Directions

Although we have focused our consideration of the use of patient RMT data on an individual basis, further work could usefully explore the use of combined RMT data from groups of patients to assess risk or identify trends. The 2019 Topol Review

highlighted the potential of integrating predictive analytics into diagnosis and care pathways [23], and data from RMT could feed into these approaches.

Future work should also explore the views of health service managers, commissioners, and public health representatives to understand the value that the implementation of RMT could provide from a health care system payer and management perspective, for example, in its potential to increase efficiencies and improve outcomes for different patient populations.

Given the participants' views on the importance of nurses' roles in the management of patients' use of RMT, it would be useful to conduct further research to better understand nurses' views on subsuming associated responsibilities into their roles. Although some work has explored nurses' views on their roles in the use of technology in intensive care situations [24] and telehealth for diabetes [25], to our knowledge, no studies have explored views specifically relating to RMT in central nervous system disorders.

Further work should also be completed to understand how RMT might best facilitate increased patient autonomy (as advocated in the NHS Long Term Plan [26]) and situations where this may be less appropriate or successful. The remote assessment of disease and relapse-major depressive disorder study is recruiting 600 people with a major depressive disorder to use RMT over a period of 2 years, and this study may shed light in this area [27].

Conclusions

This paper has explored the views of HCPs on using RMT in managing central nervous system disorders, specifically epilepsy, MS, and depression. The results are as follows:

- target physiological variables for measurement that clinicians believe would be useful
- points in care pathways at which clinicians perceive benefit to patients using RMT
- roles of health care staff best placed to manage incoming data
- HCPs' preferred presentation of data
- obstacles to the successful implementation of RMT
- limits to the benefits that the RMT can provide
- ways in which patients may be empowered through the use of RMT
- considerations around alert-based systems.

Our findings show the importance of early engagement and co-design with HCPs when considering user requirements and potential use cases before using RMT in clinical care pathways. HCPs believe that RMT data can add value to the care of patients with these three conditions but are not sufficient for decisions about care to be made exclusively on the basis of these data. We have demonstrated that clinicians are pragmatic about the data security risks of using RMT data with patients. Further research is required to establish how RMT data could be used on a population level to benefit patients with central nervous system disorders.

Acknowledgments

The RADAR-CNS project [28] has received funding from the Innovative Medicines Initiative (IMI) 2 Joint Undertaking under grant agreement no 115902. This Joint Undertaking receives support from the European Union's Horizon 2020 research and innovation program and the European Federation of Pharmaceutical Industries and Associations (EFPIA; [29]). Abstract

Background: Health care delivery for cerebrovascular diseases is a complex process, which may be improved using telestroke networks.

Objective: The purpose of this work was to establish and implement a protocol for the management of patients with acute stroke symptoms according to the available treatment alternatives at the initial point of care and the transfer possibilities.

Methods: The review board of our institutions approved this work. The protocol was based on the latest guidelines of the American Heart Association and American Stroke Association. Stroke care requires human and technological resources, which may differ according to the patient's point of entry into the health care system. Three health care settings were identified to define the appropriate protocols: primary health care setting, intermediate health care setting, and advanced health care setting.

Results: A user-friendly web-based telestroke solution was developed. The predictors, scales, and scores implemented in this system allowed the assessment of the vascular insult severity and neurological status of the patient. The total number of possible pathways implemented was as follows: 10 in the primary health care setting, 39 in the intermediate health care setting, and 1162 in the advanced health care setting.

Conclusions: The developed comprehensive telestroke platform is the first stage in optimizing health care delivery for patients with stroke symptoms, regardless of the entry point into the emergency network, in both urban and rural regions. This system supports health care personnel by providing adequate inpatient stroke care and facilitating the prompt transfer of patients to a more appropriate health care setting if necessary, especially for patients with acute ischemic stroke within the therapeutic window who are candidates for reperfusion therapies, ultimately contributing to mitigating the mortality and morbidity associated with stroke.

Introduction

Stroke is a major source of disability and death in both developed and developing countries [1-4]. The adequate delivery of care for patients with acute stroke symptoms requires the expertise of neurologists and radiologists for timely diagnosis and treatment. Whereas hemorrhagic stroke often requires urgent surgical intervention, ischemic stroke is managed with reperfusion therapies such as thrombolysis with intravenous recombinant tissue plasminogen activator (IV rtPA) as well as early endovascular thrombectomy in the case of large vessel occlusions. These approaches have significantly improved the long-term outcomes of patients with ischemic stroke [5]. Nevertheless, patients frequently do not receive the appropriate treatment either due to the lack of available specialists to perform appropriate clinical assessments or the long distances and prolonged transfer times to stroke care centers [5]. This situation can also occur for patients located in urban areas due to delays in the referral process to health care facilities with the required stroke handling capabilities.

We have developed several strategies to improve the quality of care and speed up the transfer of patients with acute stroke symptoms from urban and rural areas to our hospital, a certified primary stroke center with thrombectomy capabilities. Our experience has shown that, by necessity, robust stroke systems should be able to assist health care providers in real-time scenarios, thus resulting in adequate transfer processes between any level of complexity in a specific health care setting.

The purpose of this work was to establish a protocol for the management of patients with acute stroke symptoms according to the available treatment alternatives at the initial point of care. This protocol was implemented as a web-based telestroke solution and is based on the guidelines from the American Heart Association and American Stroke Association (AHA/ASA) [6] for any patient with acute stroke symptoms (ie, hemorrhagic stroke, acute or chronic ischemic stroke, transient ischemic attack [TIA], stroke mimics, and large vessel occlusions). The authors considered that a detailed description of the workflow

protocols, pathways, and clinical and radiological scales used in the design of our telestroke network will help other maturing countries in the development of early-stage health systems assisting patients with acute stroke symptoms.

Methods

The work presented here is part of a larger project with the following objectives: evaluation of mobile systems for head computed tomography (CT) interpretation in acute stroke patients, evaluation of the quality of stroke care in our country from a public health standpoint, and development of a telestroke network system (the subject of this article). This initiative was approved by the Institutional Review Board of our hospital and university.

The latest diagnostic and therapeutic recommendation guidelines from the American Heart Association [6], in addition to several predictors, scales, and scores that allow the assessment of the vascular insult severity and neurological status of the patient (Table 1), were evaluated in order to define the protocols of this system.

Stroke care requires human resources (eg, neurologists, radiologists, or neuroradiologists) to evaluate the risk and eligibility of patients to receive reperfusion therapies (intravenous thrombolysis or endovascular thrombectomy) and to perform invasive treatments when indicated. In addition, technological resources, such as CT, computed tomography angiography (CTA), magnetic resonance imaging (MRI), magnetic resonance angiography (MRA), and the necessary medical supplies and equipment, are needed to administer reperfusion therapies. Different human and technological resources may be available according to a patient's point of entry into the health care system. Therefore, several possible health care settings were evaluated to define the protocols and algorithms of this system. The algorithms for the clinical workflow of the three health care settings were defined and reviewed by a group of experts in our hospital: a stroke neurologist, a general neurologist, a neuroradiologist, and two physicians from our stroke center.

Table 1. Neurological and radiological scales used in the stroke treatment processes.

Matrix or scale	Description
Glasgow Coma Scale [7,8]	Assesses the level of consciousness
National Institutes of Health Stroke Scale (NIHSS) [9-12]	Quantifies the clinical severity of ischemic stroke
Posterior circulation predictor [13]	Predicts posterior circulation involvement
ABCD2 score [14,15]	Predicts subsequent risk of stroke in patients with TIA ^a diagnosed by emergency physicians
Field Assessment Stroke Triage for Emergency Destination (FAST-ED) [16]	Determines the probability of large-vessel occlusion
Intracerebral hemorrhage (ICH) score [17-19]	Grades early hemorrhage growth in patients with intracerebral hemorrhage
Fisher scale [20]	Grades the severity of the subarachnoid hemorrhage
Modified World Federation of Neurosurgical Societies (WFNS) [21]	Grades the severity of subarachnoid hemorrhage based on the Glasgow Coma Scale
BE-FAST score [22]	Evaluate potential stroke before physician evaluation to activate the stroke code
Alberta Stroke Program Early CT Score (ASPECTS) [23]	Can estimate the infarction size of the middle cerebral artery territory
Reperfusion Therapy Risk Mitigation [24]	Assesses the absolute and relative risks of thrombolysis or thrombectomy
Thrombolysis in Cerebral Infarction (TICI) score [25]	Addresses the extent of tissue reperfusion

^aTIA: transient ischemic attack.

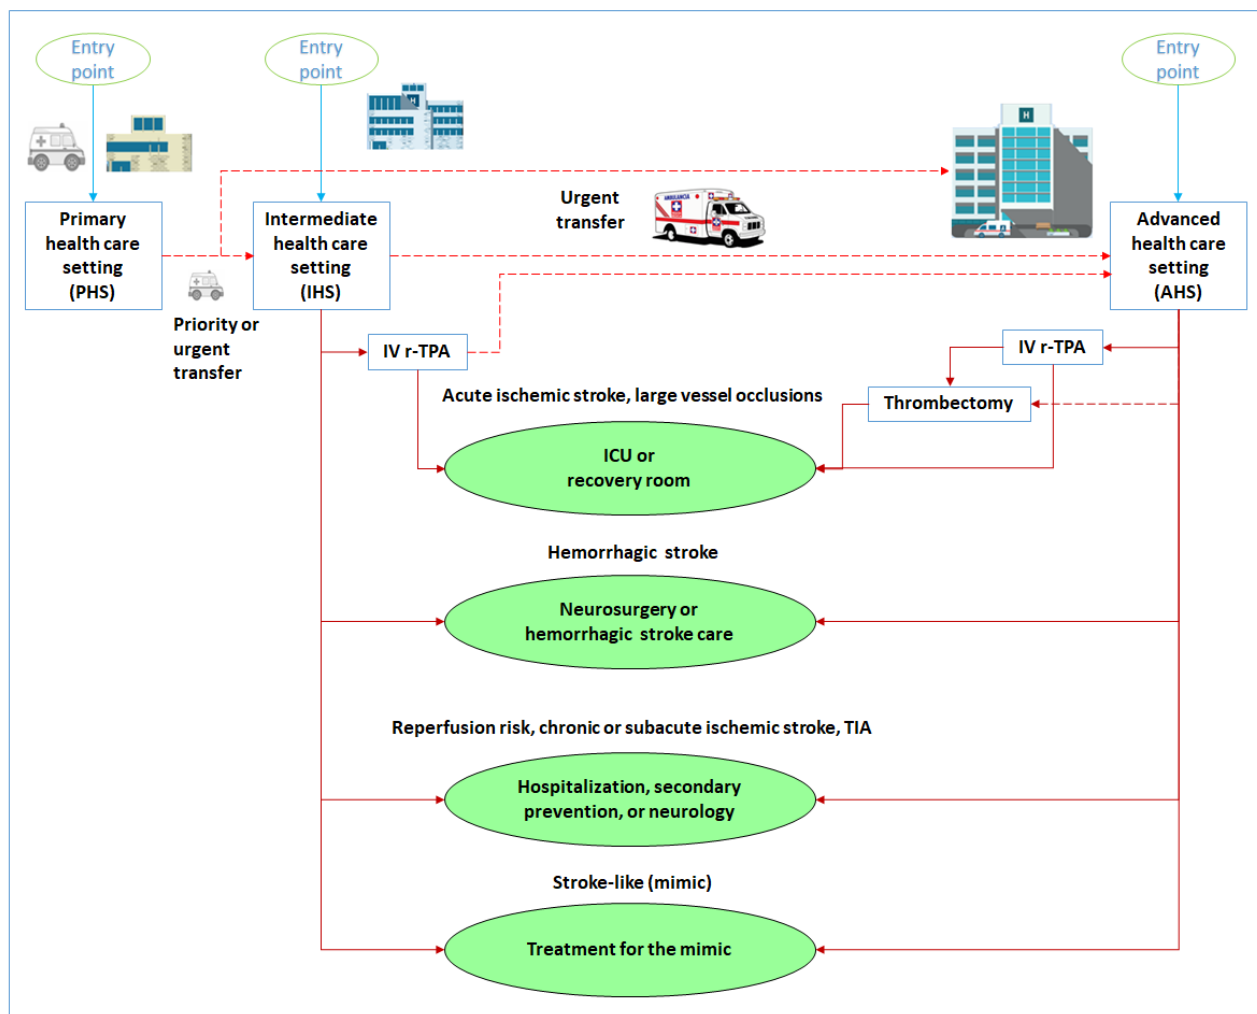

Results

The following health care settings were identified: primary health care setting, intermediate health care setting, and advanced health care setting. The interaction between these three settings is shown in [Figure 1](#), which also shows the optimal health care settings according to a specific patient diagnosis (eg, intensive care unit [ICU], recovery room, facility with neurology or neurosurgery capabilities, regular hospitalization, or ambulatory care). IV rtPA administration can be provided in the intermediate health care setting or advanced health care setting, while thrombectomy is performed only in the advanced health care setting. In both cases, a judicious risk assessment is needed before the administration of any treatment modality [6].

In all settings, the first step is the acquisition of demographic data followed by a clinical background update, blood glucose

registry, physical exam, assessment of the level of consciousness using the Glasgow Coma Scale [7], and assessment of the clinical severity of the ischemic stroke using the National Institutes of Health Stroke Scale (NIHSS) [9]. The next step is to determine the onset time to calculate the therapeutic window time (ie, the time between neurological symptom onset and patient arrival to the emergency room). In some cases, the event may be classified as wake-up or unwitnessed stroke. The therapeutic window time may be “within window” (<6 hours) or “out of window” with two possible ranges (6-24 hours or >24 hours) that determine the differences in patient management. The combination of the NIHSS and Glasgow scores as well as the time from onset to care delivery are critical breakpoints for the decision-making process performed at each of the three health care settings.

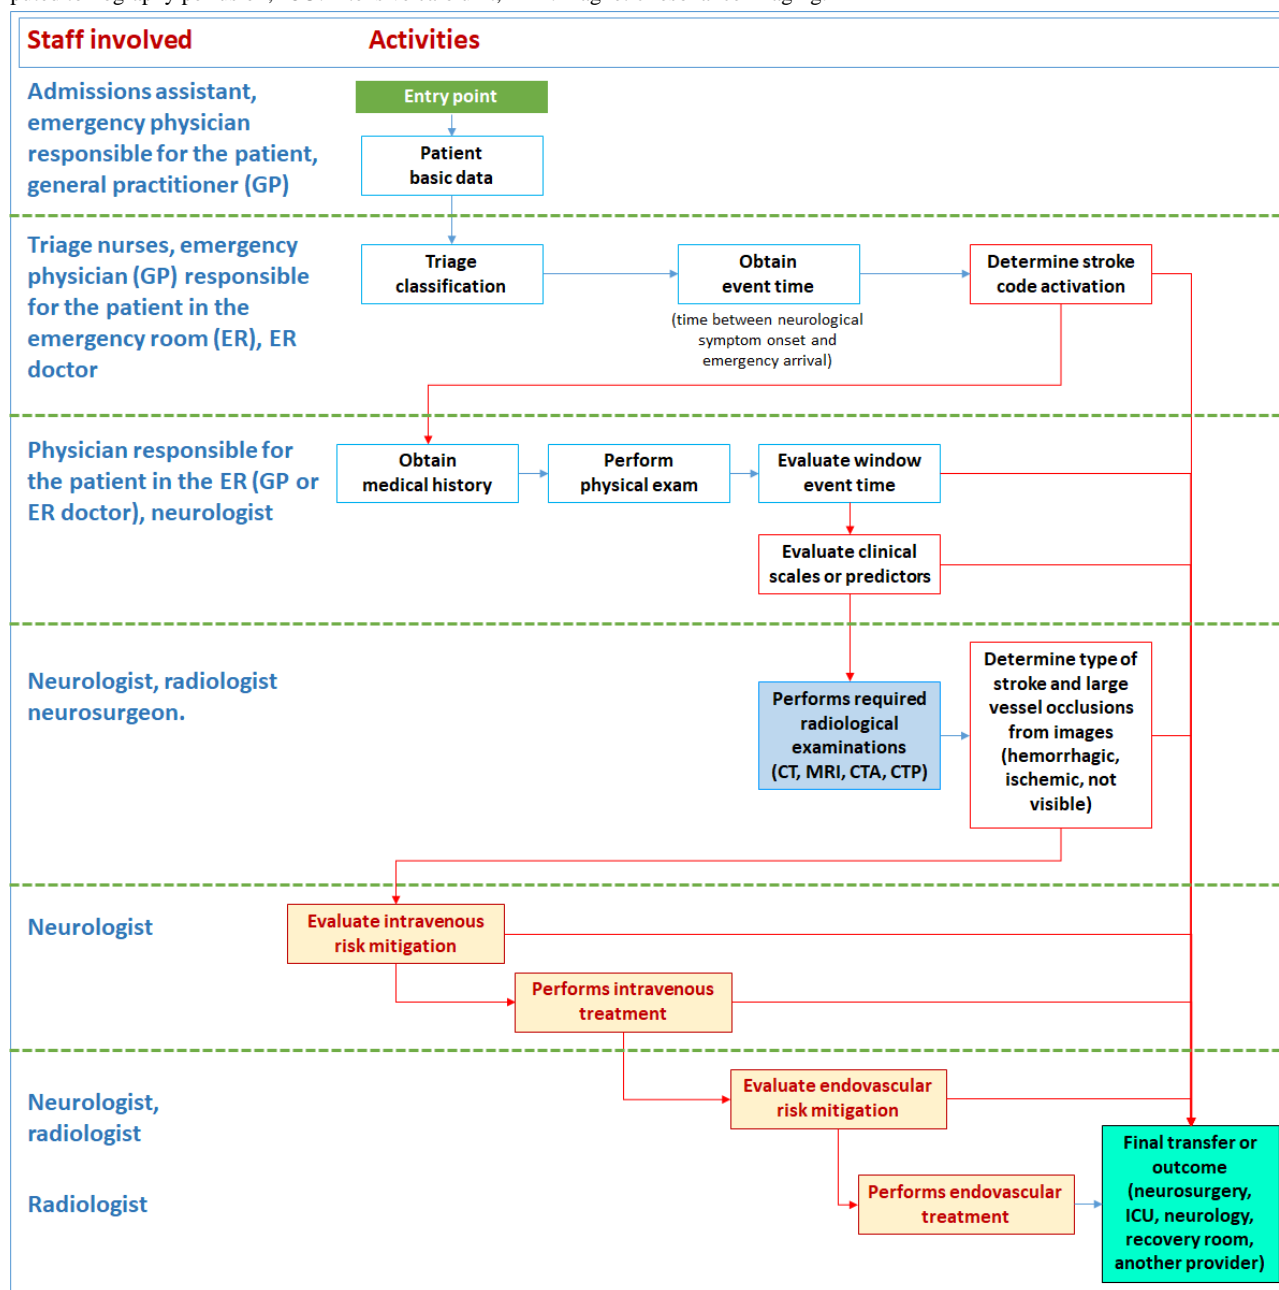

Figure 1. Interaction between the three health care settings and final possible diagnosis and referrals. ICU: intensive care unit; IV rtPA: intravenous recombinant tissue plasminogen activator; TIA: transient ischemic attack.

Health Care Settings

The general diagnostic and treatments steps, within each health care setting, are presented in a simplified workflow shown in Figure 2.

Figure 2. General simplified workflow for the three health care settings. CT: computed tomography; CTA: computed tomography angiography; CTP: computed tomography perfusion; ICU: intensive care unit; MRI: magnetic resonance imaging.

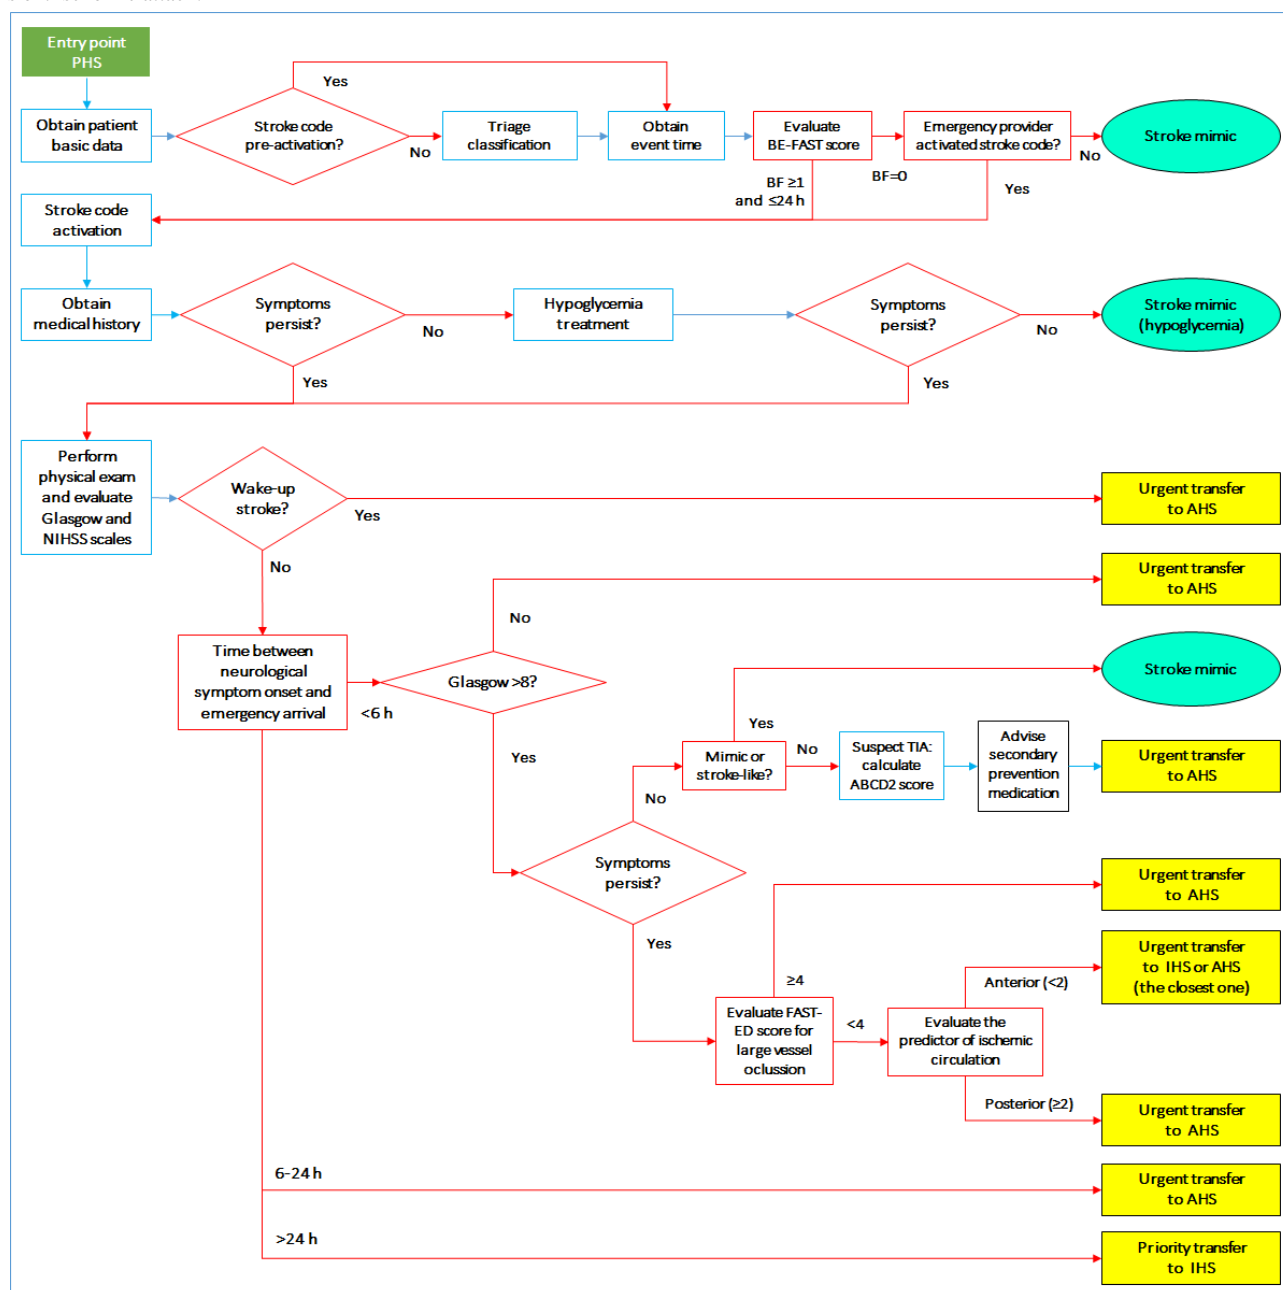

Primary Health Care Setting

In this setting, diagnostic tools are limited to the physical exam performed by a primary care physician as well as basic blood tests (eg, blood glucose). This setting may include ambulances, which may be a possible entry point to the health care system. The purpose of this setting is to provide an initial clinical assessment and determine the patient's transfers to a health care center with reperfusion capabilities, according to possible TIA, large vessel occlusion, or ischemic stroke in the anterior or posterior circulation. In this scenario, there are neither imaging facilities (CT or MRI) nor specialized health care personnel. Therefore, different clinical scales are used to assess the

patient's risk at multiple levels and to predict final patient outcomes. For example, patients with possible compromised posterior circulation will be transferred to an advanced health care setting, while those with anterior circulation may be transferred to any intermediate or advanced health care site; this estimation is achieved using ischemic stroke circulation predictors [13,26]. The ABCD2 score [14] is a powerful tool that predicts the subsequent risk of stroke after a TIA, and the Field Assessment Stroke Triage for Emergency Destination score is used to determine the probability of a large-vessel occlusion [16]. The detailed workflow for this setting is shown in Figure 3.

Figure 3. Workflow for the primary health care setting (PHS). AHS: advanced health care setting; Glasgow: Glasgow Coma Scale; FAST-ED: Field Assessment Stroke Triage for Emergency Destination; IHS: intermediate health care setting; NIHSS: National Institutes of Health Stroke Scale; TIA: transient ischemic attack.

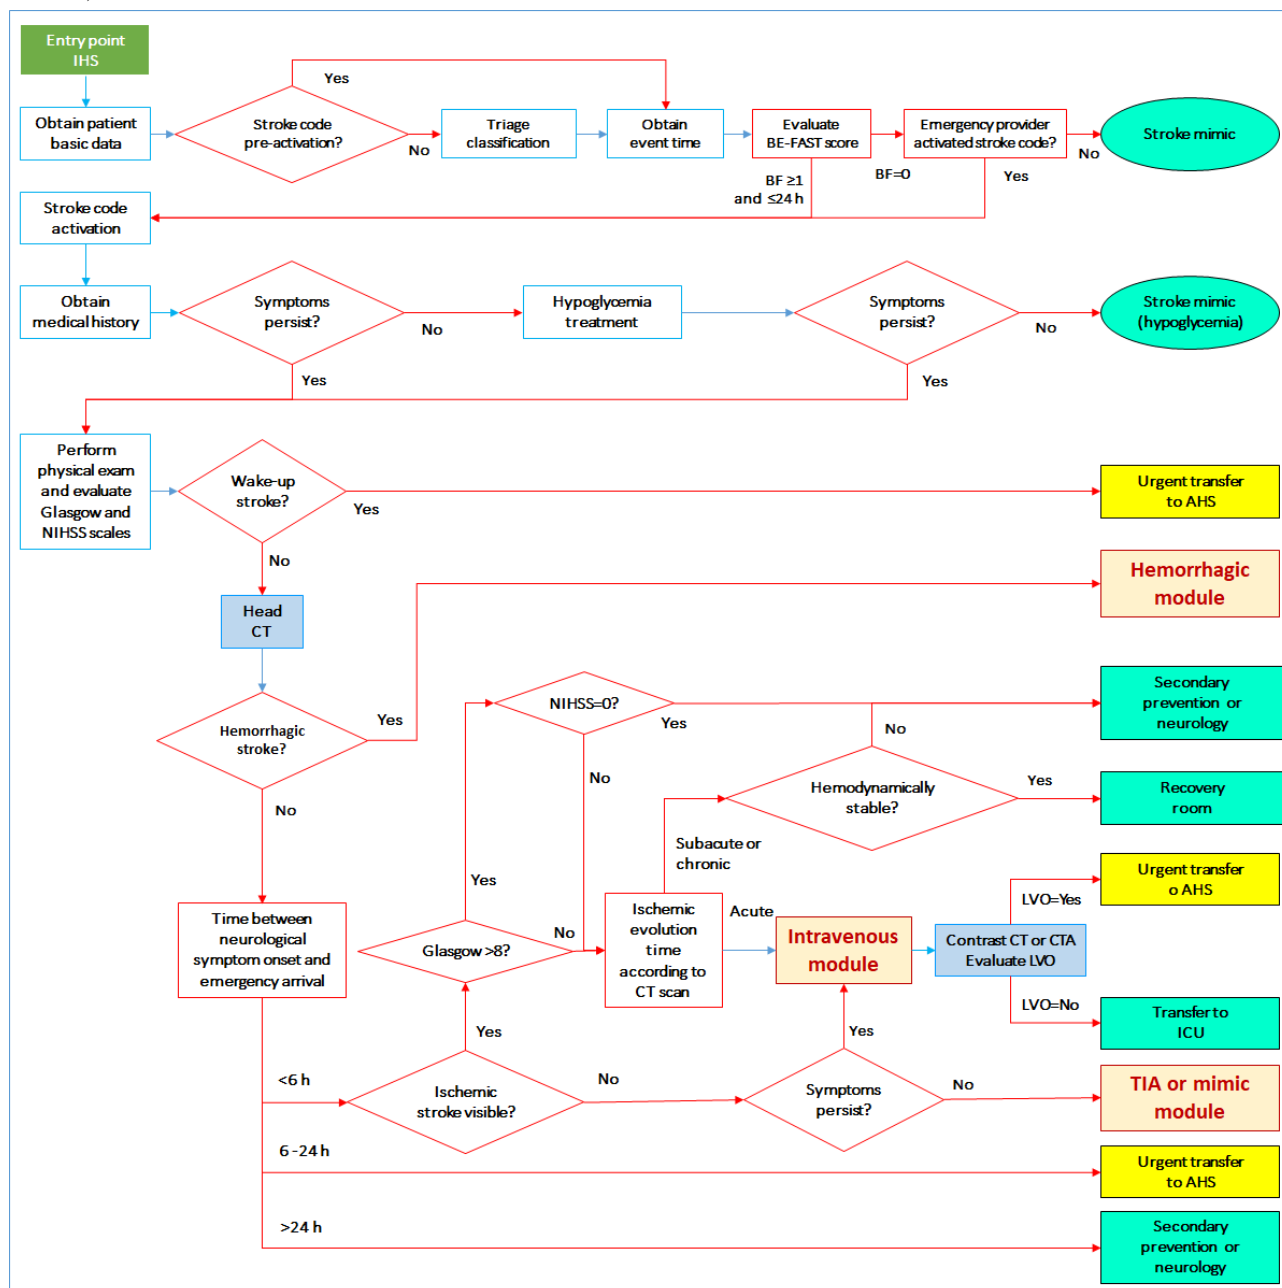

Intermediate Health Care Setting

At this level of health care facility, head CT must be available to detect hemorrhagic or ischemic stroke; intravenous thrombolysis capabilities are also required at this level.

To diagnose a potential large vessel occlusion and determine if further transfer to the advanced health care setting is necessary, CTA must be available (or contrast head CT if CTA is not available). At the intermediate health care setting, both neurologists and radiologists may be available, but not fulltime.

This setting works as a mothership for urgent and priority transfers from the primary health care setting. Possible outcomes include priority transfer to an advanced health care setting for thrombectomy purposes, emergent assessment by the neurology or neurosurgery teams, IV r-TPA administration, or ambulatory care. In this setting, if a patient is eligible for IV r-TPA administration, this is done in situ, to enable early treatment, even if the patient will be transferred to the advanced health care setting. The detailed workflow for this setting is shown in Figure 4.

Figure 4. Workflow for the intermediate health care setting (IHS). AHS: advanced health care setting; CT: computed tomography; CTA: computed tomography angiography; Glasgow: Glasgow Coma Scale; ICU: intensive care unit; LVO: large vessel occlusion; NIHSS: National Institutes of Health Stroke Scale; TIA: transient ischemic attack.

Advanced Health Care Setting

In this health care setting, specialized human and technological resources, such as stroke neurologists, neuroradiologists, CT, CTA, MRI, MRA, and the capacity for thrombolysis and mechanical thrombectomy, are available fulltime. Therefore, interfacility transfers are not necessary. In this setting, CT perfusion images are required for patients with wake-up stroke for which MRI is contraindicated. This setting receives transfers from primary health care settings and intermediate health care

settings. The possible outcomes are shown in Figure 5. The workflow in the advanced health care setting for patients within the window for thrombolysis (ie, <6 hours) is shown in Figure 6. To simplify the workflow figures and render each figure on a single page, several common procedures in the intermediate and advanced health care settings were arranged in modules presented in Figures 7-10 (ie, hemorrhagic module, TIA or mimic module, intravenous thrombolysis module, endovascular treatment module, and ischemic stroke out of window module).

Figure 5. Workflow for the advanced health care setting (AHS). CT: computed tomography; CTA: computed tomography angiography; CTP: computed tomography perfusion; Glasgow: Glasgow Coma Scale; MR: magnetic resonance; MRA: magnetic resonance angiography; MRI: magnetic resonance imaging; NIHSS: National Institutes of Health Stroke Scale; TIA: transient ischemic attack.

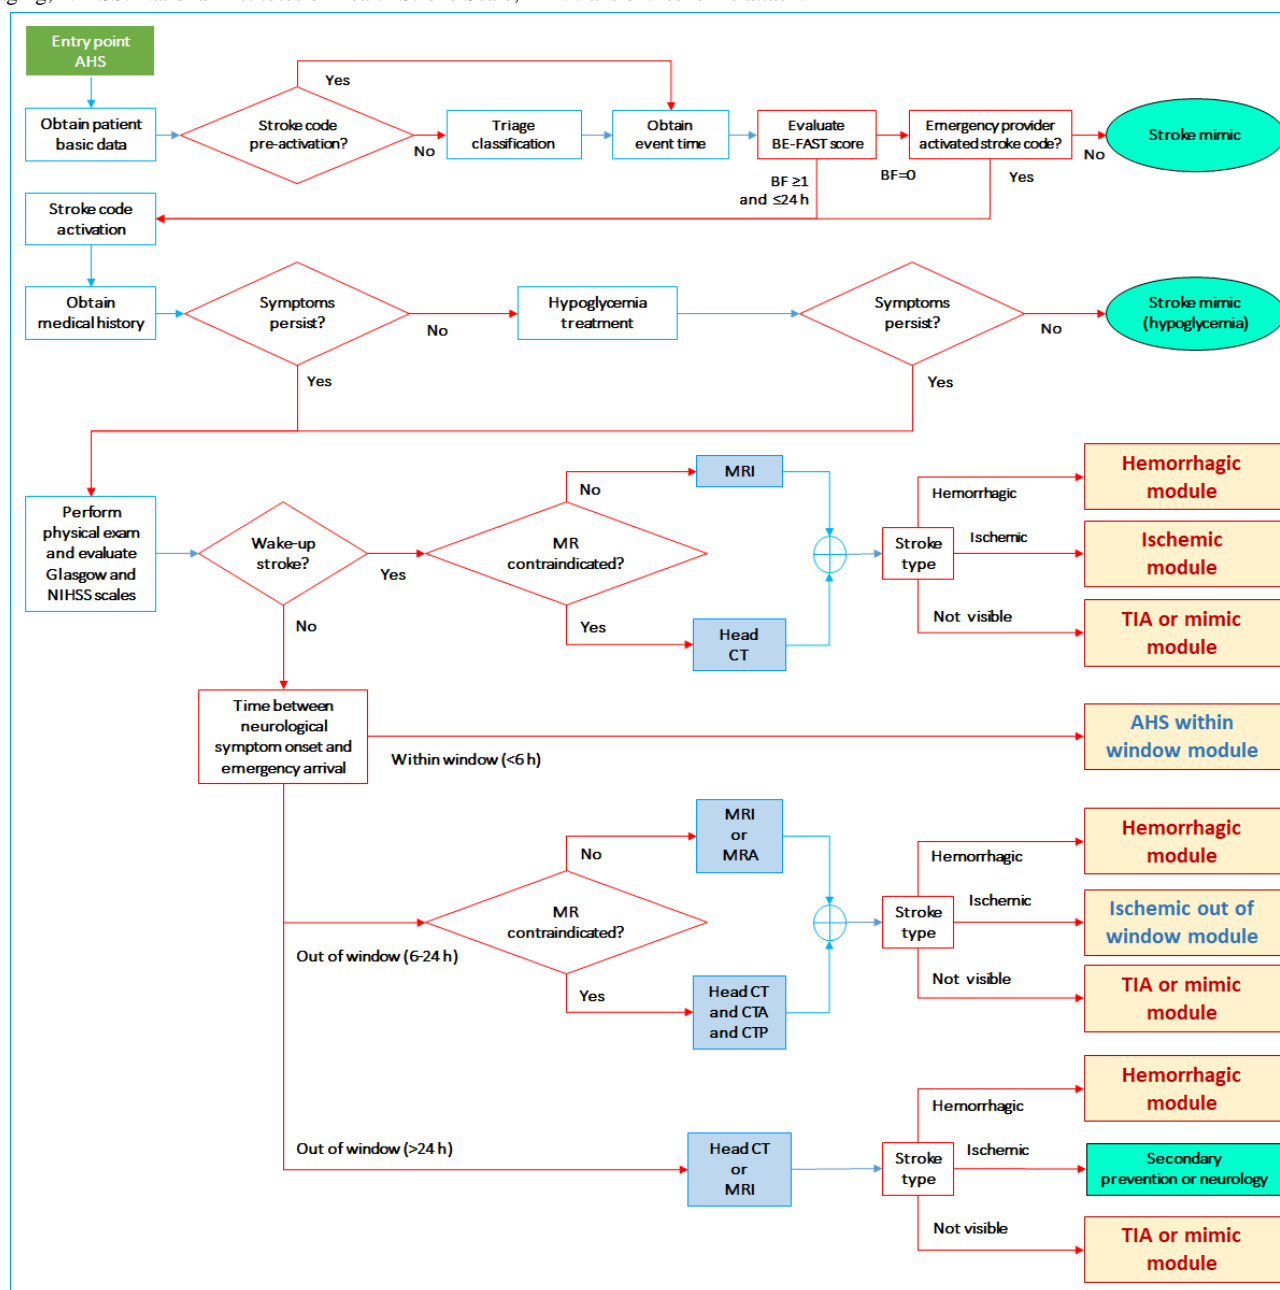

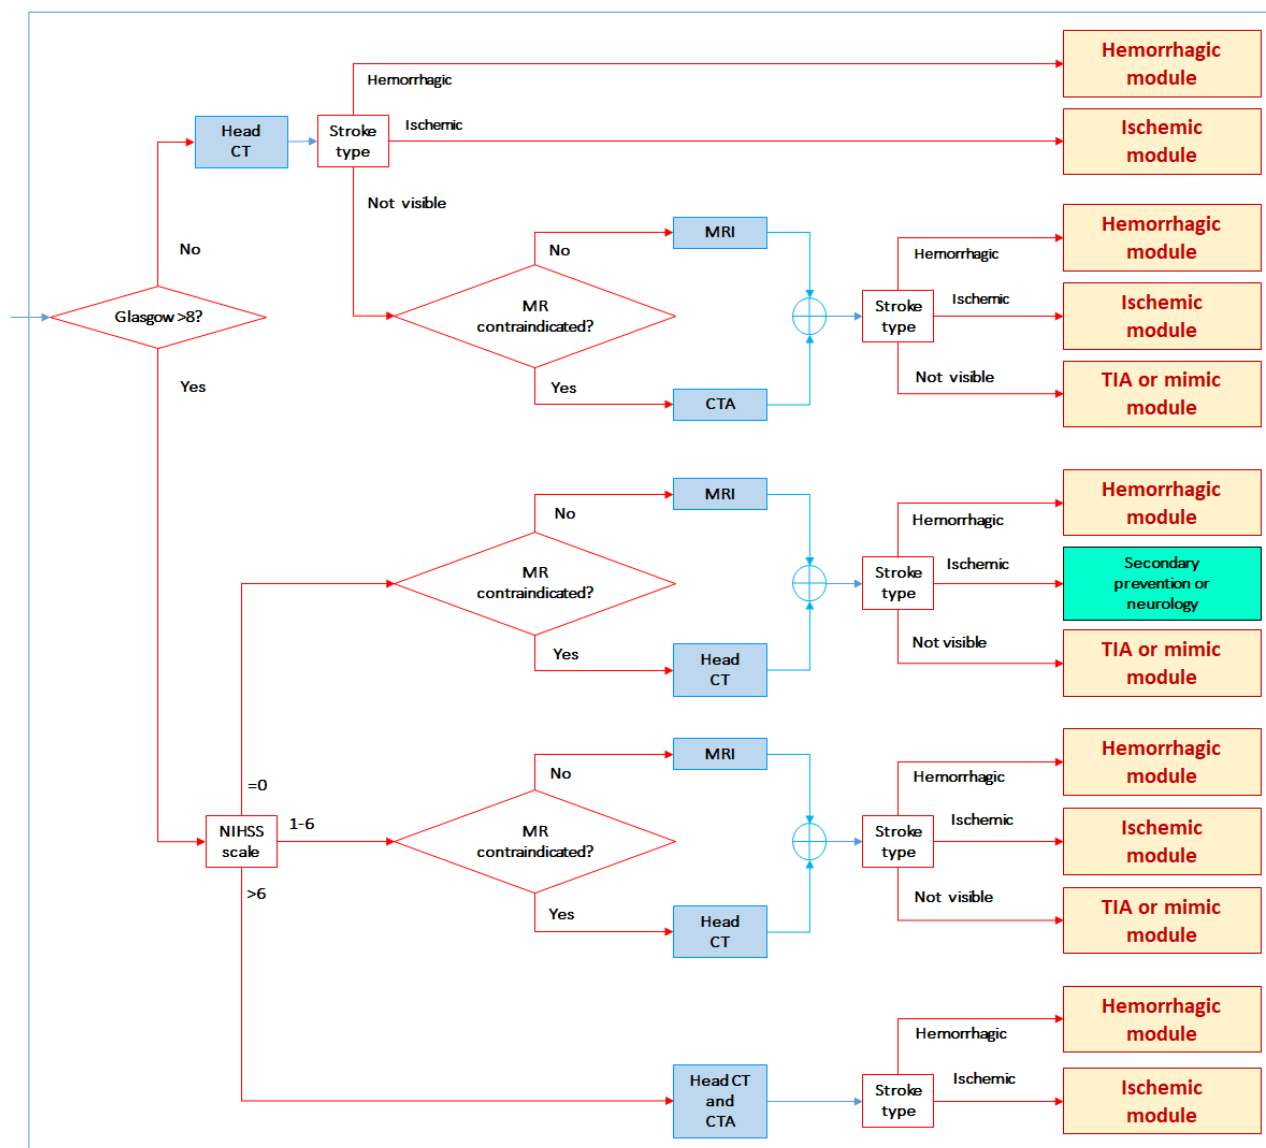

Figure 6. Within window module for the advanced health care setting. CT: computed tomography; CTA: computed tomography angiography; Glasgow: Glasgow Coma Scale; MR: magnetic resonance; MRI: magnetic resonance imaging; NIHSS: National Institutes of Health Stroke Scale; TIA: transient ischemic attack.

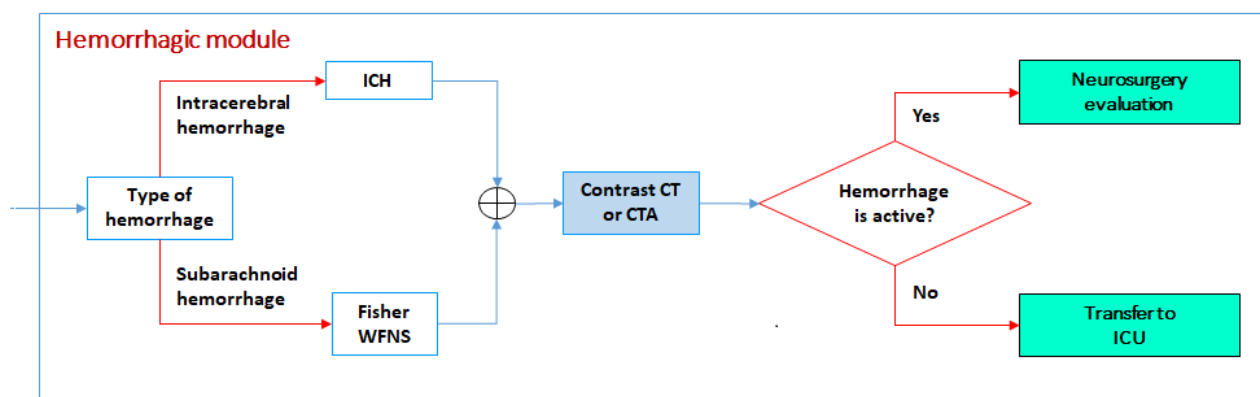

Common Modules

Hemorrhagic Module

If the imaging examination shows a hemorrhagic stroke, the Fisher scale [20] and modified World Federation of Neurosurgical Societies scale [21] are used to evaluate the

severity of the subarachnoid hemorrhage. To predict mortality in patients with intracerebral hemorrhage, the intracerebral hemorrhage score [17-19] is used. CT or CTA may reveal active intracranial bleeding; in this case, the patient is referred to the neurosurgery team for urgent care. Otherwise, the patient can be stabilized and treated in the ICU (Figure 7).

Figure 7. Hemorrhagic module. CT: computed tomography; CTA: computed tomography angiography; ICH: intracerebral hemorrhage score; ICU: intensive care unit; WFNS: Modified World Federation of Neurosurgical Societies.

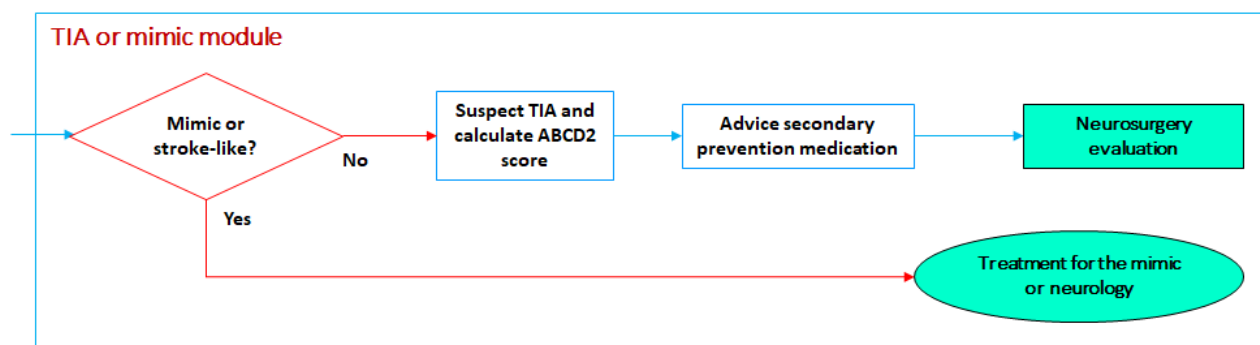

TIA or Mimic Module

If the symptoms are gone or are not consistent with a vascular territory and imaging examination reveals neither a hemorrhagic stroke nor an ischemic stroke, there are two possibilities: the

patient is presenting with a stroke mimic or having a TIA. In the later, the ABCD2 score [14] is calculated to evaluate the actual stroke risk. Secondary prevention using statins and antiaggregant therapy is initiated, and the patient is discharged for neurologic outpatient care (Figure 8).

Figure 8. Transient ischemic attack (TIA) or mimic module.

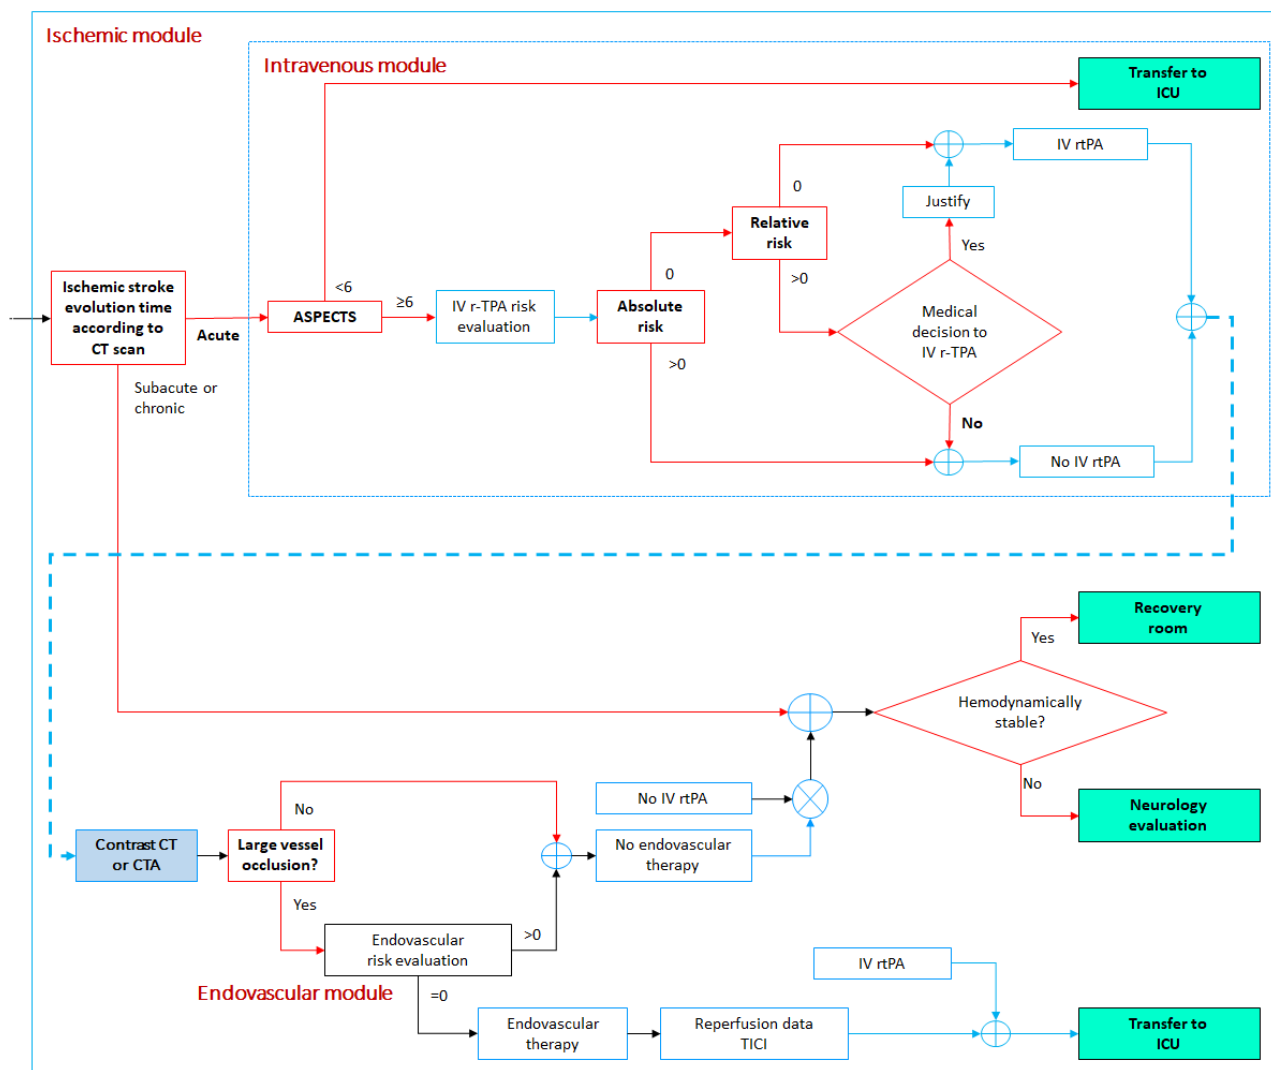

Ischemic Module

This module consists of two submodules: intravenous thrombolysis module for IV rtPA administration and

endovascular treatment module, to evaluate thrombectomy treatment (Figure 9).

Figure 9. Ischemic module. ASPECTS: Alberta Stroke Program Early Computed Tomography Scan; CT: computed tomography; CTA: computed tomography angiography; ICU: intensive care unit; IV rtPA: intravenous recombinant tissue plasminogen activator; TICI: Thrombolysis in Cerebral Infarction scale.

Intravenous Thrombolysis Module

If the initial imaging examination reveals an ischemic stroke, an imaging vascular evaluation of the anterior and posterior circulation is performed according to the onset time of the ischemic insult (acute, subacute, or chronic). Patients with subacute or chronic lesions are referred to the recovery room if hemodynamically stable; otherwise, they are hospitalized for neurology assessment. For patients with acute lesions in the middle cerebral artery territory, the Alberta Stroke Program

Early CT Scan (ASPECTS) is calculated; patients with ASPECTS <6 are referred to the ICU, whereas patients with ASPECTS ≥6 are evaluated in terms of the absolute and relative contraindications for IV rtPA administration (Table 2) [24]. Next, if there is no risk or only a relative risk after judicious medical assessment, intravenous thrombolysis is performed. At the same time, the patient is evaluated for the presence of large vessel occlusions and possible thrombectomy, as indicated in the endovascular treatment module (Figure 9).

Table 2. Risk mitigation matrices for reperfusion therapies.

Risk mitigation treatment	Contraindications
Intravenous thrombolysis – absolute criteria	
Clinical history	Previous ischemic stroke within 3 months; previous intracranial hemorrhage (excluded hemorrhagic transformation of a stroke); intra-axial neoplasm at this time; craniocerebral trauma or spinal within the inpatient acute period or within the 3 previous months; intracranial or spinal surgery in the last 3 months; infectious endocarditis or actual aortic dissection; extra-axial neoplasia, arteriovenous malformation, or aneurysm not excluded; arterial puncture in noncompressible location not in the last 7 days
Incoming clinical parameters	Suggestive symptoms of subarachnoid hemorrhage; blood pressure $\geq 185/110$ mm Hg, despite management according to the protocol; blood glucose levels <50 mg/dL; active internal bleeding or active hemorrhagic diathesis
Hematologic	Platelet count $<100,000/\text{mm}^3$; INR ^a >1.7 and PT ^b >15 seconds or PTT ^c >40 seconds; heparin (last 48 hours with an abnormal PTT), heparin of low molecular weight in therapeutic doses (last 48 hours); inhibitors of thrombin/Xa factor in the last 48 hours
Diagnostic imaging	Evidence of acute intracranial hemorrhage, infarction size of the middle cerebral artery territory hemisphere $\geq 1/3$ (ie, ASPECTS ^d <6)
Special cases	Start of pregnancy until 14 days postpartum; window 3-4.5 hours, ≥ 80 years old, diabetes, previous stroke, use of oral anticoagulant
Intravenous thrombolysis – relative criteria	
Clinical history	Surgery or major trauma in the last 14 days; gastrointestinal tract or urinary tract hemorrhage in the last 21 days; acute myocardial infarction, especially with segment ST elevation or pericarditis in the last 3 months
Incoming clinic parameters	NIHSS ^e <4 or NIHSS ≥ 25
Thrombectomy – absolute criteria	
Physical exam	NIHSS >29
Hematologic	INR >3 , PTT >2 , thrombocytopenia $<30,000/\text{mm}^3$
Diagnostic imaging	ASPECTS <6 , infarction size (on DWI ^f) >70 mL, active hemorrhage

^aINR: international normalized ratio.^bPT: prothrombin time.^cPTT: partial thromboplastin time.^dASPECTS: Alberta Stroke Program Early Computed Tomography Scan.^eNIHSS: National Institutes of Health Stroke Scale.^fDWI: diffusion-weighted magnetic resonance imaging.

Endovascular Treatment Module

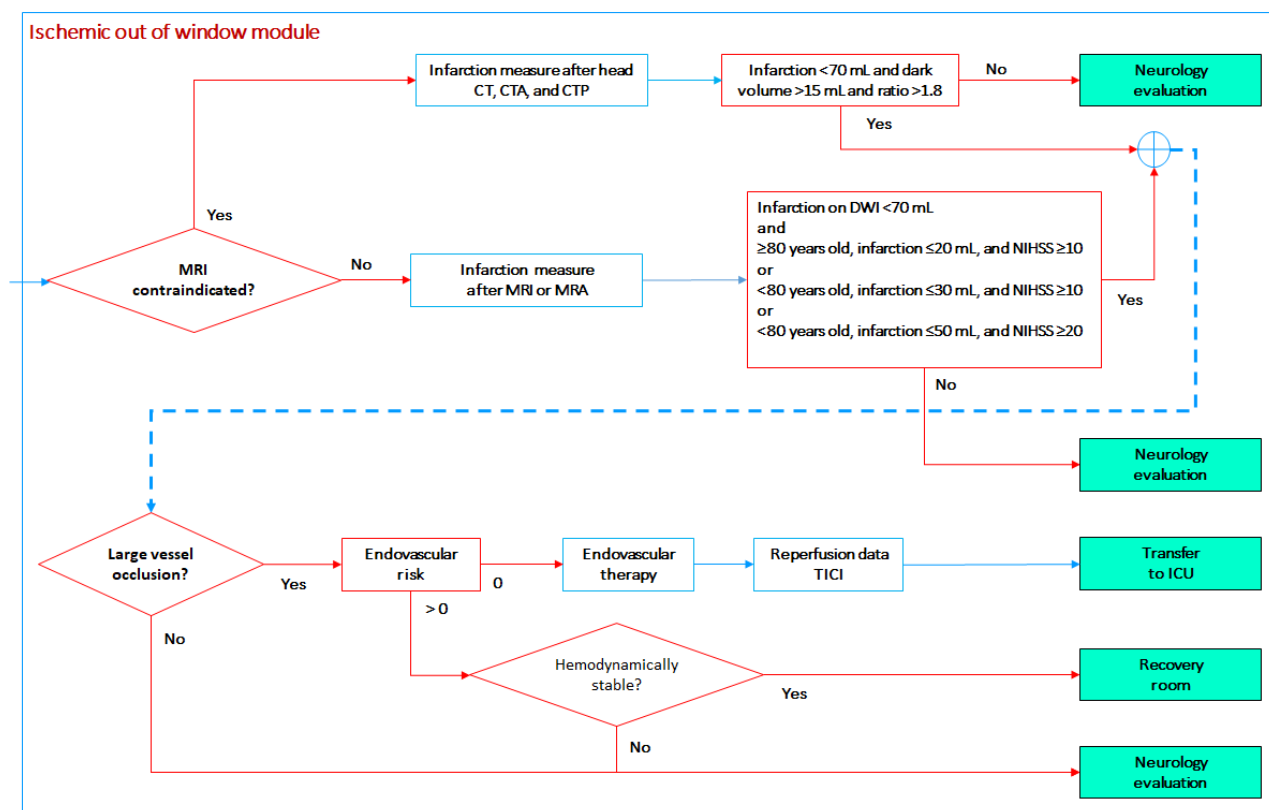

Large vessel occlusions are evaluated using contrast CT or CTA. If there are no occlusions, the patient is referred to the recovery room if hemodynamically stable; otherwise, they are hospitalized for continuous neurologic assessment. If a large vessel occlusion is confirmed, a comprehensive risk evaluation should be performed before thrombectomy [24]. Then, if no risks are identified, thrombectomy should be performed as soon as possible. After thrombectomy is performed, the degree of reperfusion is measured by means of the Thrombolysis in

Cerebral Infarction score [25], and the patient is referred to the ICU (Figure 9).

Ischemic Stroke Out of Window Module

Patients arriving to an advanced health care setting after a wake-up stroke, unwitnessed stroke, or “out of window” stroke with symptom onset 6-24 hours before first medical contact may benefit from reperfusion therapies only if certain conditions are met (Figure 10). These conditions rely on the infarct volume as quantified by diffusion-weighted MRI or CT perfusion (if MRI is contraindicated), patient age, and stroke severity (NIHSS score).

Figure 10. Ischemic stroke out of window module. CT: computed tomography; CTA: computed tomography angiography; CTP: computed tomography perfusion; DWI: diffusion-weighted magnetic resonance imaging; ICU: intensive care unit; MRA: magnetic resonance angiography; MRI: magnetic resonance imaging; NIHSS: National Institutes of Health Stroke Scale; TICl: Thrombolysis in Cerebral Infarction scale.

Design of Algorithms

The three algorithms work as a handy framework for the most critical steps in the care of patients with ischemic or hemorrhagic stroke. These algorithms were based on decision trees that represent the clinical requirements and specifications of the system and consist of checklists and questionnaires [27] evaluating common physiological variables, the patient's clinical background, different predictors and scales, and specific laboratory tests according to each algorithm stage. The responses to these questionnaires determine the next step to be performed.

The predictors, scales, and scores implemented in this system allow the assessment of the vascular insult severity and neurological status of the patient. Other factors that determine patient management, either in situ or in a distant health care setting, are shown in Table 1. The clinical background, physical exam, stroke severity, and radiological findings were stored in basic modules within the clinical algorithms. These modules, as implemented in our telestroke system, are shown in Table 3. The software outputs corresponding to specific diagnoses, clinical scenarios, and transfer decisions are shown in Table 4. The checklists for risk assessment before the administration of reperfusion therapies [24] are detailed in Table 2.

Table 3. Input information modules implemented in the telestroke system.

Input data	Examples of possible data
Identification data	Name, age, sex, identification number, date of birth
Triage module	
Short physical exam	Heart rate, blood pressure, respiratory rate, weight
Triage level	1 or 2
Incoming patient medium	By their own means, referral from another service, ambulance transfer
Cincinnati scale	0-3
Stroke code activation?	Yes/no
Clinical history module	
Neurological exam	Dysarthria, hemiparesis, hemiplegia, agnosia, aphasia, dysphagia, paresthesia, mutism, headache, delirium, loss of touch, facial weakness sparing the forehead
Past relevant illnesses	Previous stroke, diabetes mellitus, dyslipidemia, coronary disease, chronic kidney disease, atrial fibrillation, high blood pressure, sleep apnea or hypopnea syndrome, smoking, thrombophilia
Relevant findings	Patient found unconscious; patient woke with loss of sensation in the one side of her body
Use of anticoagulant?	Yes/no; if yes, which one: apixaban, dabigatran, rivaroxaban, enoxaparin, warfarin, edoxaban
Laboratory	Blood glucose levels, clotting times (PT ^a and aPTT ^b), platelet count, INR ^c , blood count
Physical exam module	
Cardiopulmonary resuscitation?	Yes/no
Intubation?	Yes/no
Glasgow Coma Scale	3-15
NIHSS ^d	0-37
Event time	
Time of onset of symptoms	Observed date and time or wake-up or unwitnessed stroke
Time of arrival at emergency door	YYYY/MM/DD hh:mm
Evolution time (hours)	Calculated from the previous times or typed directly
Therapeutic window type	Within therapeutic window (<6 hours), out of therapeutic window (>6 hours) or (6-24 hours; >24 hours), or wake-up or unwitnessed stroke
ABCD2 score; stroke risk after a TIA ^e	0-7; percentage (%) at 2, 7, and 90 days
Imaging evaluation (CT ^f , CT perfusion, CTA ^g , MRI ^h)	Compromised cerebral territory, ischemic event dating (acute, subacute, chronic), ASPECTS ⁱ , large vessel occlusions, or infarct volume, dark volume
Risk evaluation ^j	Absolute and relative evaluation for thrombolysis, risk evaluation for thrombectomy
Interventional procedure times	Door to needle time, door to inguinal puncture time
Thrombectomy	Date and time of inguinal puncture or stent implant or reperfusion; TIC ^k scale, thrombolysis reperfusion

^aPT: prothrombin time.^baPTT: activated partial thromboplastin time.^cINR: international normalized ratio.^dNIHSS: National Institutes of Health Stroke Scale.^eTIA: transient ischemic attack.^fCT: computed tomography.^gCTA: computed tomography angiography.^hMRI=magnetic resonance imaging.ⁱASPECTS=Alberta Stroke Program Early CT Scan.^jSee details for risk mitigation in Table 4.^kTICI: Thrombolysis in Cerebral Infarction.

Table 4. Output information in the telestroke system.

Module	Value suggested by the system
Diagnoses	Hemorrhagic stroke; acute, subacute, or chronic ischemic stroke; large vessel occlusions; TIA ^a ; stroke mimic
Outcomes	Neurosurgery; hemorrhagic care; hospitalization or neurology (if reperfusion risk, chronic or subacute ischemic stroke, TIA); recovery room (if hemodynamic stable); ICU ^b , after thrombolysis and/or thrombectomy; ambulatory care (with secondary prevention using statins or anticoagulants)
Transfer	Transfer from PHS ^c to IHS ^d or AHS ^e , transfer from IHS to AHS

^aTIA: transient ischemic attack.

^bICU: intensive care unit.

^cPHS: primary health care setting.

^dIHS: intermediate health care setting.

^eAHS: advanced health care setting.

Software Development and Validation

The algorithms included in the three health care settings were incorporated into web-based software. Individual user profiles were created for the administrative staff and health care providers, who were assigned specific privileges.

A user-friendly interface reduces human error and assures the completeness and integrity of the information. The questionnaires implemented were straightforward and only required single-click selections instead of free-text typing for easy and rapid data input. The software was developed using the Hypertext Preprocessor and JavaScript languages and could be executed in any web browser on a laptop, tablet, or smartphone.

For data storage, a MySQL 5.1.40 database (Oracle Corporation, Redwood City, CA) was used, wherein sensitive data were encrypted (ie, patient identification). Data were stored in a structured relational database, allowing future evaluation of the system performance as well as a strong foundation for public health policies. The database included the administrative information of each facility in the telestroke network and the possible referral facilities (ie, those that have a given facility that was contracted to receive patients when a transfer is required). This information allowed the rapid selection of the most suitable stroke center according to the patient's needs after a judicious assessment of the clinical requirements and transfer times. Given that "time is brain," potential administrative pitfalls between primary health care settings and advanced health care settings also had to be considered for a quick and effective transfer. In our country, patients may be transported to various emergency departments until they are accepted in one of them, producing a critical delay in the required care known as "the death ride."

Since a patient can arrive at any given hospital and may be transferred across several health care settings without receiving adequate stroke care, a "case" starting point was defined as the time when the first medical contact was documented in the last visited hospital until the final patient outcome was reported before the patient's discharge. Therefore, when a patient is transferred to a second health care setting, all the information for the case is available in the receiving facility given that all data are stored in a server database and shared with all the

facilities. This design decision allows common access to the patient's health condition at any moment from any health care setting while also avoiding the entry of redundant information. Hence, past medical history, current clinical condition, blood test results, imaging evaluations, and procedures are available in real-time for all health care facilities across the whole spectrum of stroke patient care. In addition, this allows transfer reporting to the referral facilities ahead of the patient's arrival, avoiding prolonged waiting times at emergency departments.

Software validation was performed in different phases. The first phase consisted of a simulation of the test scripts on all possible workflow pathways for each of the health care settings, which was performed to validate adequate software representation of each the algorithms. To validate the software implementation, more than 1211 test scripts were performed covering all possible pathways in each of the predefined health care settings. The second phase consisted of a retrospective registry of cases from our stroke database (nearly 600 patients in the last 5 years). The third phase was the validation of the software by neurology residents, who utilized the software while also performing a usual clinical assessment with printed forms. The final phase is to be performed between different health care facilities to test the performance of our telestroke network with real-life cases and transfers based on the information broadcast. The total number of possible pathways documented after this initial experience was as follows: 10 in the primary health care setting, 39 in the intermediate health care setting, and 1162 in the advanced health care setting.

The final system was named Telestroke-RU (copyright 13-70-240, 03/12/2018 from the National Copyright Office, Colombia) and is available for authorized users [28]. This system is not a product intended for commercial or profit uses and may be used for educational purposes.

Discussion

Principal Findings

The comprehensive telestroke platform developed in this work is the first stage to optimizing health care delivery for patients with stroke symptoms regardless of the entry point into our local emergency network in both urban and rural regions.

This system supports health care personnel by providing adequate stroke care and facilitating the prompt transfer of patients to a more appropriate health care setting according to the specific cerebrovascular disease at presentation. This system facilitates stroke care delivery for patients with acute ischemic stroke within the therapeutic window who are candidates for reperfusion therapies. Therefore, the system will contribute to mitigating the well-known mortality and morbidity associated with stroke.

Further evaluations will be performed to assess the true impact of this tool in terms of reductions in critical time windows, such as the time between symptom onset and reperfusion, door to needle time, primary health care setting to advanced health care setting transfer times, discharge clinical outcomes, accuracy of the final diagnosis, and the clinical outcomes of patients at 30 and 90 days using the modified Rankin scale [29].

Comparison With Prior Work

To the best of our knowledge, in our country, there are no software tools for the assessment and management of patients with stroke symptoms. Worldwide, smartphone apps and web-based tools are available [30-34]. These solutions were designed for acute ischemic stroke care, for triage protocols, and as an aid for transfers when reperfusion therapies are needed (eg, Field Assessment Stroke Triage for Emergency Destination score) [30] as well as the delivery of efficient inpatient or ambulatory stroke care [32,34]. Other tools have been developed with the purpose of the evaluation of specific clinical scales or radiological scores [33]; these tools use the same algorithm independent of the level of resources available at the entry point to the health care system. In contrast, our system integrates 12 clinical and radiological scales, scores, and predictors according to the specific health care setting or the referral facility to provide a specific diagnosis (hemorrhagic stroke; acute, subacute, or chronic ischemic stroke; TIA; stroke mimic). Our

system allows either immediate treatment or further transfer to the appropriate health care setting. Since our solution is not integrated with the hospital electronic health record (EHR) system, it can be used in all health care services, independent of the EHR system used at each facility. It is worth mentioning that, in our country, EHR systems are not available at several rural primary health care settings.

Limitations

The continuous improvement of evidence-based stroke care guidelines motivates the continuous review of health care setting algorithms and, therefore, software updates. Further work includes the use of GPS and traffic applications to calculate the actual duration of real-time patient transfers and adequate selection of the referral facility with the shorter transfer time. In the short-term, this system will be migrated to a smartphone app to allow for a greater number of system users in a friendlier interface.

Conclusions

The implementation of this system in a telestroke network contributes to the fulfillment of and adherence to recently published stroke care guidelines, providing evidence-based practice, improving patient outcomes, and supporting the achievement of several requirements to achieve and maintain primary stroke center certification.

This telestroke system allows the assessment of different therapeutic alternatives according to the specific patient's clinical condition, thus improving efficiency and providing high-quality delivery of care. Finally, the epidemiological information stored in the database will inform public health care policies to design and implement better national policies for remote regions with significant underreporting of acute cerebrovascular diseases.

Acknowledgments

We thank our institutions and the National Department of Science, Technology and Innovation of Colombia for funding this study (Grant 1204-744-55680).

Abstract

Background: The internet hospital is an innovative organizational form and service mode under the tide of internet plus in the Chinese medical industry. It is the product of the interaction between consumer health needs and supply-side reform. However, there has still been no systematic summary of its establishment and definition, nor has there been an analysis of its service content.

Objective: The primary purpose of this study was to understand the definition, establishment, and development status of internet hospitals.

Methods: Data on internet hospitals were obtained via the Baidu search engine for results up until January 1, 2019. Based on the results of the search, we obtained more detailed information from the official websites and apps of 130 online hospitals and formed a database for descriptive analysis.

Results: By January 2019, the number of registered internet hospitals had expanded to approximately 130 in 25 provinces, accounting for 73.5% of all provinces or province-level municipalities in China. Internet hospitals, as a new telehealth model, are distinct but overlap with online health, telemedicine, and mobile medical. They offer four kinds of services—convenience services, online medical services, telemedicine, and related industries. In general, there is an underlying common treatment flowchart of care in ordinary and internet hospitals. There are three different sponsors—government-led integration, hospital-led, and enterprise-led internet hospitals—for which stakeholders have different supporting content and responsibilities.

Conclusions: Internet hospitals are booming in China, and it is the joint effort of the government and the market to alleviate the coexistence of shortages of medical resources and wasted medical supplies. The origin of internet hospitals in the eastern and western regions, the purpose of the establishment initiator, and the content of online and offline services are different. Only further standardized management and reasonable industry freedom can realize the original intention of the internet hospital of meeting various health needs.

Introduction

During the past five years, China has been committed to promoting the use of the internet to provide medical services, although it is still in the exploratory stage [1]. Internet connections, in general, have brought about a significant change

to the Chinese economy, and there is no doubt that it can improve the quality of service and provide convenience for people. As a supplement to offline health services, online health services are of great significance in alleviating the relative shortage of medical resources in China [2]. With the development of technology, online health service levels have

continually improved, which has led traditional medical resources to gradually become networked.

China has 904 million internet users, with an internet penetration rate of 64.5%, according to the China Internet Network Information Center in April 2020 [3]. The vast number of internet users constitute China's booming consumer market. Mobile payment is becoming more and more popular in daily life, and user habits of paying for online medical services based on knowledge are also becoming established [4]. From April 2018 to April 2019, China's internet medical users grew from 28 million to 45 million, a year-on-year increase of 59.9% [5]. Ping An Good Doctor, one of the representative internet hospitals, had 300 million registered users as of October 2019, equivalent to 1 in every 3 Chinese netizens having used it [6], and the number of visitors exceeded 1.11 billion from January to April 2020 during the COVID-19 pandemic [7]. The age range of internet hospital users is wide, and the number of middle-aged and elderly users is increasing [8].

Internet hospitals is a term with a somewhat vague meaning. In general, it is an internet medical platform combining online and offline access for medical institutions to provide a variety of telehealth services directly to patients. It extends medical resources from the hospital to the internet by using information technology, and it develops online medical services and health services [9]. It can be as simple as using the internet to make and manage appointments or renew prescriptions; however, it can also be a means for Chinese citizens to communicate face-to-face with doctors via internet pages or public therapeutic platforms in apps such as WeChat (mobile social media apps) [10]. Internet hospitals are online platforms but need to be based in existing institutions with consistent online and offline service supervision. They include both medical and nonclinical services but can only use internet technology to provide safe and appropriate medical services for the follow-up of common and chronic diseases online [11]. Doctors are allowed to prescribe treatment for related diseases online after accessing the patient's medical records [11].

Telehealth is a medical service model similar to internet hospitals in China and is used in settings throughout the world [12,13]. It commonly describes a wide range of diagnostic and management modalities, education, and other related activities within health care [14]. It is expanding beyond telemedicine to cover nonclinical events such as appointment scheduling, continuing medical education, and physician training [14].

In the United States, telehealth or telemedicine has been defined in all states, and some of these services by video can be reimbursed [15,16]. Many states consider online services inadequate for building doctor-patient relationships and prescribing treatments, so some allow online diagnosis and prescription of drugs while others restrict them [15]. A growing number of states are passing legislation to guide health care professional boards to adopt standards of practice for providers using telehealth [15]. One US telehealth platform, Amwell, an internet-based health care giant, has more than 150 million insured users, serving over 55 health plans, more than 240 medical groups, and more than 2,000 hospitals [17]. In terms of strategy and governance, studies have shown that only 2

countries in the European Union are in the management stage of policy supervision, and 16 countries are considered to be in the initial and temporary stage, meaning that most countries in the EU have no formal definition of telemedicine services or only small short-term and independent pilot developments [18]. Meanwhile, in Japan, access to telehealth clinical functions was restricted to health consultations, and only during the COVID-19 pandemic did the government allow patients to receive medical care and receive prescription via the internet rather than by going to a physical hospital [19,20].

However, in China, the current situation developed after an initial period of growth in internet hospital services when Chinese health authorities ordered a temporary halt in the development in order to develop a more appropriate set of regulations [21]. The first internet hospital in China was established in Guangdong Province in 2014 [22]. Then, China began to promote this new model of online health care to develop internet health services actively, to provide convenience services through the mobile internet, to encourage internet enterprises to cooperate with medical institutions, and to establish a medical network information platform. Thus, internet hospitals began to appear in some areas, gradually. In 2016, the First Affiliated Hospital of Zhejiang University established Zhejiang First internet hospital and was headed by the tertiary hospital [23]. However, by 2017, the government re-examined and approved the abolition of internet hospitals, cloud hospitals, and network hospitals [21]. By 2018, the state again encouraged medical institutions to use information technology such as the internet to expand the space and content of medical services and to build a comprehensive online and offline medical service model covering prognosis, diagnosis, and postdiagnosis [11]. Medical institutions were again allowed to develop internet hospitals and to provide safe and appropriate medical services using internet technology [11]. In 2018, the government formulated specific regulations on internet hospital management, including diagnosis and treatment, telemedicine, and other online aspects. This marked the beginning of the standardized development of internet hospitals [11].

Three documents were issued on July 17, 2018 by the National Health Commission of the People's Republic of China and National Administration of Traditional Chinese Medicine: Internet Diagnosis and Treatment Management Measures (trial implementation), Internet Hospital Management Measures (trial implementation), and Telemedicine Service Management Standards (trial implementation) [11]. It was the first time that China put forward detailed regulations on internet hospitals, signifying that internet hospitals had entered the stage of standardized development [11]. Chinese internet hospitals have experienced ups and downs, after twists and turns of the embryonic stage, and are now entering the rapid development stage of standardization.

In order to capture the current state of development of internet hospitals in China, we carried out a study covering internet hospitals (up to the beginning of 2019) to analyze the construction mode and content of internet hospitals and provide corresponding suggestions for construction.

Methods

This study obtained data on internet hospitals through the Baidu search engine and Apple and Android app stores, manually. Baidu's dominant role in internet searching in China is comparable to the role of Google in Western countries, on both desktop and mobile devices, with approximately 70% to 80% market share. People can search for queries by entering keywords.

First, we searched for the official internet hospital name from April 6, 2019 to April 12, 2019. Before searching in Baidu, we sorted and analyzed policies of internet hospitals at the national level on the Website of the State Council. Internet Hospital Management Regulations stressed that internet hospitals should use the name of the hospital with the addition of the term *internet hospital* [11]. Some hospitals use the name of *cloud hospital* or *web hospital* as an auxiliary reference. So, we searched according to the internet hospital naming rules, following the Baidu Robots Protocol. Our inclusion criteria were internet hospitals established before January 1, 2019, and we included direct and indirect search results (direct: web items; indirect: government announcements and page content under web item). This resulted in a list of 130 internet hospital names in our Excel (Microsoft Inc) database.

Second, we queried the relevant information about the internet hospital name in Baidu, inquired from the internet hospital official website, and downloaded the internet hospital app from the app store to obtain the following variables to build a database used in the statistical analysis: establishment time (precise to the month), establishment location, service content provided by technical cooperation parties, and media (pages, public medical platforms, or apps) in contact with people. The study focused on the overall development of the internet hospital industry, so we did not collect the number of patients and doctors in each hospital.

Finally, the data obtained from the 130 internet hospitals were entered into the Excel database and analyzed.

Results

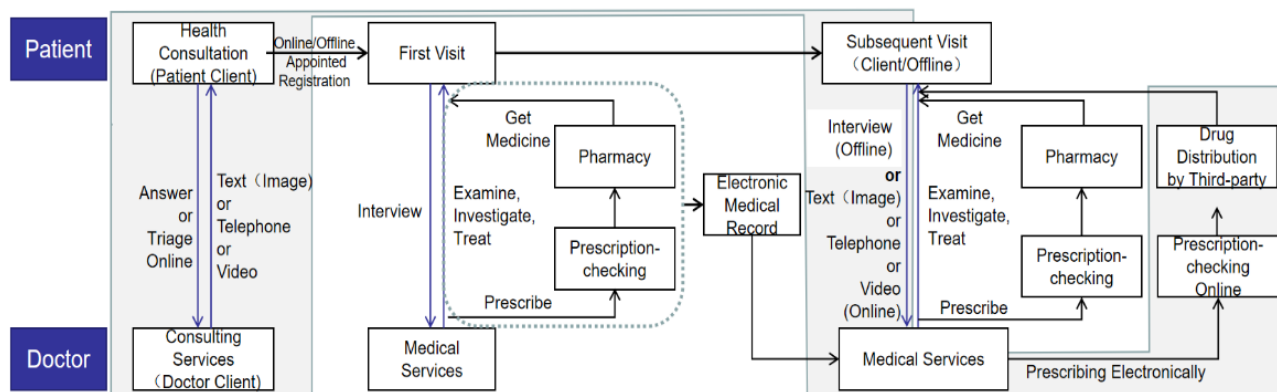

The Structure of Internet Hospitals

Our study of the available information about internet hospitals revealed that the term is used for a number of different types of activities. Telemedicine was launched first, and then mobile medicine and online medicine became popular. Generally speaking, online medicine, mobile medicine, and telemedicine are all covered by the concept of internet hospital. In Table 1, we have summarized the relationships between the various uses of the term internet hospital.

Based on the data we obtained, we constructed a flowchart between offline hospitals and online hospitals by summarizing the treatment process of existing internet hospitals based on doctor-patient interaction (Figure 1). Patients can consult online before going to the offline hospital to collect relevant professional health information and understand their current situation. If they need to go to a hospital, there can be a more extensive and reliable consultation that can assist the hospital in triaging. Next, patients can choose to register online or go to a hospital for a preliminary examination. After the first visit, patients can choose between online or offline ways to check the disease prognosis, treatment effects, and further treatment. Moreover, sometimes subsequent visits that require examination and testing need to be done offline. Therefore, the two areas are divided into white and gray, indicating that they may be online or offline (Figure 1). Then, pharmacists check the electronic prescriptions, and drugs can be delivered by a third-party logistics enterprise cooperating with the hospital or can be picked up at a nearby pharmacy. Patients can also accept door-to-door diagnosis and treatment out of the hospital.

Table 1. The relationship and difference between others with internet hospitals.

Noun	Definition	Relationship and difference with internet hospitals
Online health	The use of internet technology to provide patients and the public with disease diagnosis, treatment programs, prescriptions, and other services [21].	It is one of the services provided by internet hospitals.
Mobile medicine	Emerging mobile communications and network technologies for health care systems [24]. It is via mobile and wireless devices, and the sharing of that information between patients and providers such as personal digital assistants, mobile phones, and satellite communications.	Internet hospitals have a variety of digital media, such as portals, public medical platforms, and apps.
Telemedicine	Use of telecommunications technologies to provide medical information and services [25].	Internet hospitals are a platform to provide technical support for remote diagnosis and treatment.

Figure 1. Hospital treatment flowchart.

Status Analysis of Internet Hospitals

As of January 2019, 25 of the 34 provinces or municipalities (73.5%) had registered a total of 130 internet hospitals in China, ranging from 0 to 29 per administrative region (Figure 2). There has been a growth trend from the establishment of internet hospitals up to the beginning of 2019. In the years from 2014 to 2018, 1 (0.8%), 5 (3.8%), 42 (32.3%), 65 (50.0%), and 17 (13.1%) hospitals were launched, respectively. The top 11 provinces and cities accounted for 100/130 (76.9%) internet hospitals. We can conclude that the number of internet hospitals grew very slowly between the end of 2017, when the establishment of internet hospitals was discouraged, and the end of 2018, when policies for comprehensive regulation were introduced.

Based on the general classification of internet hospital services and based on our data and the national policy documents,

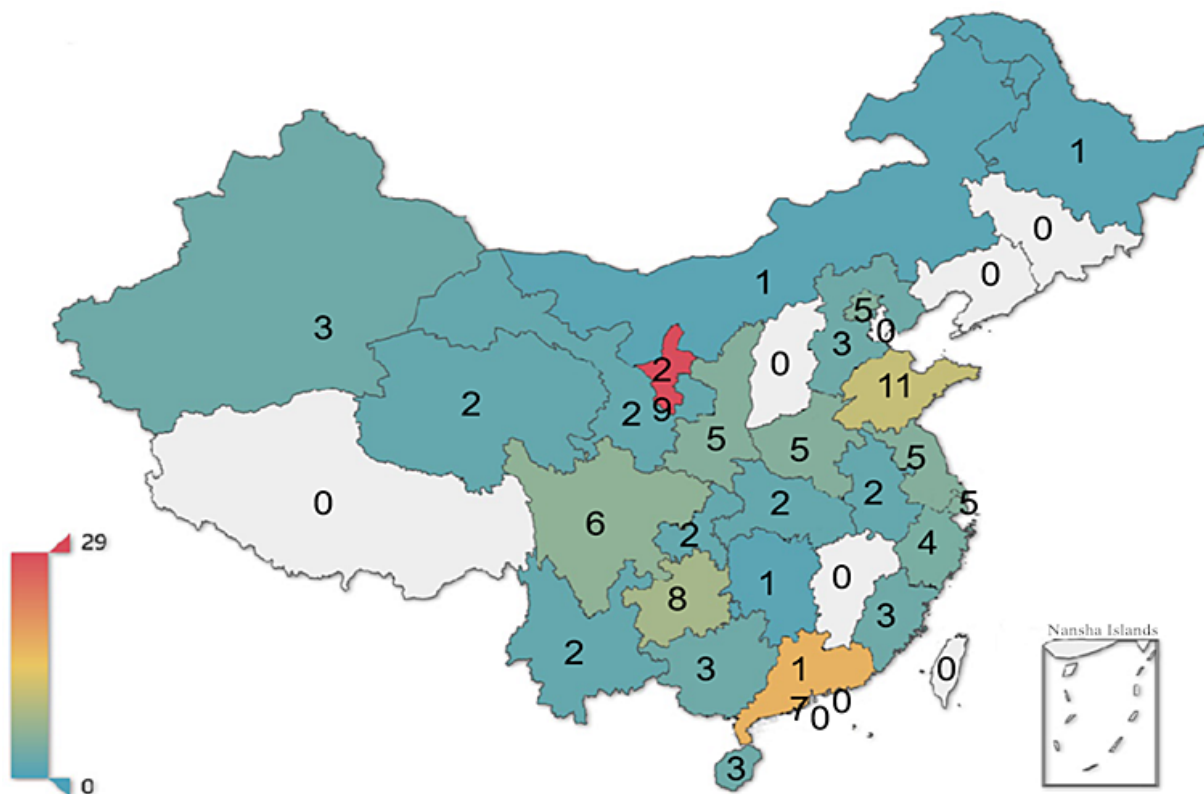

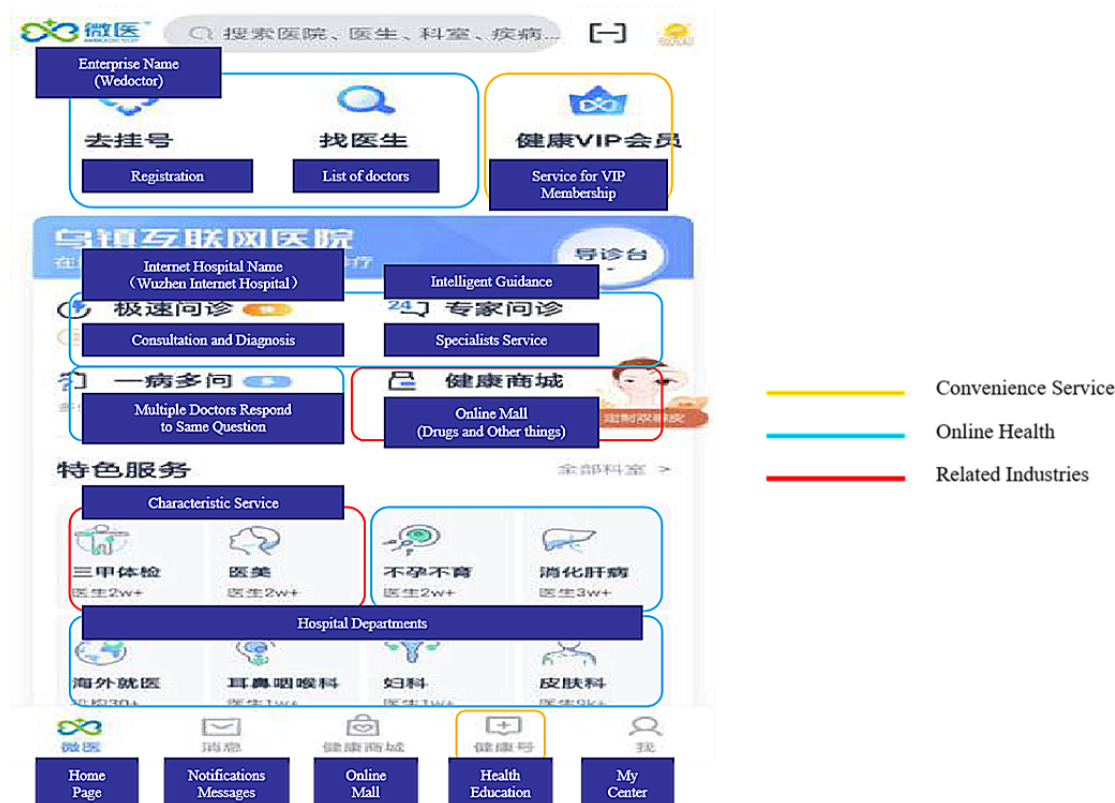

Figure 2. Heat map of number of internet hospitals in Chinese provinces.

Table 2. Internet hospital service classification.

Classification	Content
Convenience services	Intelligent guidance, registration, guidance, mobile payment, inspection report query, cost query [26], medical feedback, health education
Online health	Health consultation and follow-up for common and chronic diseases
Telemedicine (institution)	Providing on-line medical services initiated by institutions
Related industries	Drug order, drug distribution, health records

Figure 3. Example of internet hospital app interface.

Every internet hospital contains specific content in the introduction, such as a booking service (online booking of a medical expert appointment within the medical facilities), but also health education (the hospital provides a wide range of medical knowledge about drugs, chronic disease knowledge lectures, information about national health policy, and so forth). Through internet portals, the patient can query to book appointments and can check reports. Doctors, via the outpatient internet service, can provide electronic prescription service to patients, including online prescriptions and online payment records. The network outpatient service for patients offers electronic prescription services, including online prescription, online payment dispensing, and others.

Based on our data, internet hospitals can be divided into three categories, and each has relatively successful typical cases. In the first category, the government is the initiator whose primary purpose is to achieve a unified standard of regional population health management, such as the Sichuan Province internet hospital, or the Zhejiang Province internet hospital. The second category is initiated by hospitals whose primary purpose is to expand the scope and intensity of hospital services so that people can continue to see their doctors. For example, the First

Affiliated Hospital of Zhejiang University, a well-known tertiary hospital in China, opened their internet hospital to provide a platform for their doctors to provide services online. The third category is initiated by enterprises whose purpose is to connect patients with practicing doctors who, through these efforts, can increase the number of patients, and thereby, gain benefits. Also, they can improve the accessibility of health services for patients, and the increase in patients can improve doctors' income and skills. This category includes some enterprises such as Haodf (Yinchuan Intelligent internet hospital), Ping An Good Doctor (Ping An Good Doctor internet hospital), Wedoctor (Wuzhen internet hospital). These were the first to utilize internet plus in the medical industry to carry out the sales of light drug consultations, health management, and other services. Even though these three categories can be separate, the effective delivery of medical services requires the cooperation of doctors, patients, hospitals, governments, and enterprises. Based on our database of internet hospitals, 38/130 (29.2%) were initiated by the government and hospital, and 92/130 (70.8%) were initiated by enterprises; we can see that each of them undertakes different roles from the perspective of stakeholders. The sources of doctors and patients are also different (Table 3).

Table 3. Relevant parties of internet hospital model.

Initiator	Integration of government services for guidance	Longitudinal hospital-led service	Horizontal enterprise-led service
Government	Establishment of internet medical platform at administrative level	The government is responsible for examination, approval and supervision	The government is responsible for examination, approval and supervision
Hospital	Establishment of online hospital districts in local medical institutions	Transfer offline services to online	Conditions and requirements on which services must provide and carry out entity-based
Enterprise	Contractor provides technical and medical resources support	Contractor provides technical support	Invest in construction for profit
Doctor	The contractor platform registered physicians and physicians from regional medical institutions provide services.	Doctors belonging to the hospital	Multipoint practicing doctor
Patient	Patients in administrative areas	Hospital service area mainly for patients, supplemented by network patients	Internet patients

Discussion

Principal Findings

The most striking finding in our study is the level of integration of ordinary hospital services with the internet hospital. While enterprises have initiated most internet hospitals (92/130, 70.8%), the dominant model is an integration of the internet platform with existing hospital and government services. The construction of the internet hospitals in China is a two-way force, to a certain extent, as a joint effort by the government and the market to alleviate the coexistence of a shortage of medical resources and wasted medical supplies.

On the one hand, health resources are abundant in the east, while they are relatively few in the midwest regions [27]. In rural areas with scarce medical resources, the government and hospitals hope to optimize resources through telehealth, so that patients can contact other remote doctors to solve medical problems, and promote high-quality medical resources in the east to meet the needs of patients in the midwest; therefore, there are many internet hospitals in the central and western regions of China. The internet enables people to overcome geographic barriers to access health care services.

On the other hand, the e-commerce giants (such as Taobao or Jingdong) have been involved with the pharmaceutical industry, providing online drug shopping and health consulting for consumers, but they cannot directly sell prescription drugs [28]. The enterprises follow China's internet medical regulation policies to create offline hospitals or cooperate with the existing medical institutions in building internet hospitals to ensure that they have implemented the whole process by the closed loop (doctor-patient-hospital medical services). With the rise of the industry, many regions with developed internet technologies took the initiative to enter the internet medical field and set up internet hospitals in developed cities to serve more patients.

Internet Hospital Service Depends on the Integration of Online and Offline Services

The development of online medical services and health services in the new integrated model has several clear benefits. Patients can use the portal and medical information systems to improve communication with health care providers. They can take

advantage of internet technology, reduce registration time, and reduce treatment times [29]. The richness of internet medical treatment can meet the diversified health needs of patients, to a certain extent, and also help to realize the continuity of medical services for patients [30,31].

Despite these advantages, it is also clear that internet hospitals cannot replace many of the core functions of physical hospitals. The internet hospital Management Measures stipulates two situations for the use of internet medical treatment in practice. In the first case, when a patient visits a physical medical institution and the institution initiates contact with other doctors to consult through an internet hospital, the physician can provide diagnostic advice and prescriptions. In the other case, patients do not consult with physical medical institutions. Doctors can then only offer follow-up to patients for common and chronic diseases through the internet hospital. The internet hospital includes many internet-based medical services, but it does not have many necessary medical resources and physical infrastructure online such as sickbeds, diagnostic equipment, and operating conditions for medical services. Therefore, the reality is that most internet hospital online services still only offer a supplement to the traditional nonclinical parts such as booking, registration, guidance, payment, and other convenience services [32].

Moreover, internet hospitals cannot provide the first diagnosis and complex disease follow-up after a diagnosis, so they cannot be involved in some of the core business of medical care, limiting the utilization rate [11,33]. For example, dermatology mainly relies on visual data to make a diagnosis. Usually, doctors with rich clinical experience can make a clear judgment after seeing the skin photos, while some departments rely more on examination and monitoring for diagnosis [34]. Meanwhile, in health consultation, doctors can conduct triage based on patient descriptions or video images, and doctors need to master additional characteristics of the patient's integrated circumstance and ensure that they provide valid information for the medical records on the internet to provide online follow-up. Some medical services (first visit and severe illness) must be provided by offline hospitals, while others (nonclinical, health consultation, and follow-up diagnosis) can conveniently be realized online. Internet hospitals have stimulated the advantages of online and offline services to meet the medical needs of

patients better and release high-quality medical resources (health workforce, equipment, etc) for offline hospitals [35].

Different Initiators of Internet Hospitals May Have Different Development Directions

The government, hospitals, and enterprises are the initiators of the three ways of building internet hospitals, and they are also relevant stakeholders. The government is the policymaker, the main body of industry supervision, and plays an irreplaceable role [36]. The primary purpose of the government as the initiator is to integrate medical resource information and population health information in the region to form a database of population information, electronic health records, electronic medical records, and other data in the entire region [37,38]. As the foundation for the construction of internet hospitals, hospitals are providers of offline medical services. The primary purpose of an internet hospital with a physical hospital as the initiator is to extend the hospital's service process to the internet, extend the medical service capabilities of the physical hospital to the patient's home, and provide remote follow-up services for patients [39]. The enterprise is the technical support built by the internet hospital and maintains the regular operation of the platform. When enterprises are the main initiators of the internet hospital, their focus is on increasing operating income and achieving profitability. From the perspective of doctors and patients in internet hospitals, the source of doctors and patients for internet hospitals initiated by enterprises is significantly different from the source of doctors and patients when initiated by the government and hospitals. The doctors provided by internet hospitals built by the government and hospitals are qualified doctors within the administrative area, and the scope of their service is still local patients with a small number of cross-province patients. The service scope of the internet hospital built by enterprises is registered doctors and patients nationwide. Nevertheless, at least for the time being, enterprise-initiated internet hospitals still have to rely on existing physical infrastructure. If that should change and such hospitals can operate more independently, it would present a significant challenge for government regulation and supervision.

Limitations

This study has several limitations. First, although this study attempts to describe the current situation of all internet hospitals in China, there may be missing items because data collection relied upon web-based search engines. Second, this research sample only included internet hospitals up to the beginning of 2019, which is the initial stage of the internet hospital industry (from its initiation and growth from very few to a substantial number), but it did not include the continuous replication of the internet hospital model in 2019. We will include these data in future studies to further analyze the relationship between the number of internet hospitals and the amount of services they provide. Third, this study did not investigate the actual online-offline conversion rate of internet hospitals to evaluate the service capacity of the hospitals. It is necessary to conduct research from the perspective of doctors, patients, and managers to further study stakeholders' views on internet hospitals and to analyze the influencing factors of internet hospital usage in the current situation.

Conclusions

Internet hospitals redefined the concept of medical service provision through telecommunications technology and began to revolutionize the health sector [40]. It is praiseworthy that China innovates the internet hospital model in the field of internet health care so that more people can receive medical resources to which they did not previously have access. The most significant value of the internet lies in the realization of the transfer of medical centers, from traditional hospitals as the main body to a more patient-oriented model where people can receive medical services and health care without leaving home. Currently, although the government has put forward management measures, they are still unable to achieve an internet hospital that provides the core functions of medical service. The government still needs to develop more suitable content to form a systematic internet medical model and to explore the regulatory scope to provide more development freedom for the internet hospital industry. It is essential to realize the central idea of the internet hospital—hospitals have more space to treat diseases, and patients save time [41].

Abstract

Background: Chronic obstructive pulmonary disease (COPD) is a leading cause of mortality and leads to frequent hospital admissions and emergency department (ED) visits. COPD exacerbations are an important patient outcome, and reducing their frequency would result in significant cost savings. Remote monitoring and self-monitoring could both help patients manage their symptoms and reduce the frequency of exacerbations, but they have different resource implications and have not been directly compared.

Objective: This study aims to compare the effectiveness of implementing a technology-enabled self-monitoring program versus a technology-enabled remote monitoring program in patients with COPD compared with a standard care group.

Methods: We conducted a 3-arm randomized controlled trial evaluating the effectiveness of a remote monitoring and a self-monitoring program relative to standard care. Patients with COPD were recruited from outpatient clinics and a pulmonary rehabilitation program. Patients in both interventions used a Bluetooth-enabled device kit to monitor oxygen saturation, blood pressure, temperature, weight, and symptoms, but only patients in the remote monitoring group were monitored by a respiratory therapist. All patients were assessed at baseline and at 3 and 6 months after program initiation. Outcomes included self-management skills, as measured by the Partners in Health (PIH) Scale; patient symptoms measured with the St George's Respiratory Questionnaire (SGRQ); and the Bristol COPD Knowledge Questionnaire (BCKQ). Patients were also asked to self-report on health system use, and data on health use were collected from the hospital.

Results: A total of 122 patients participated in the study: 40 in the standard care, 41 in the self-monitoring, and 41 in the remote monitoring groups. Although all 3 groups improved in PIH scores, BCKQ scores, and SGRQ impact scores, there were no

significant differences among any of the groups. No effects were observed on the SGRQ activity or symptom scores or on hospitalizations, ED visits, or clinic visits.

Conclusions: Despite regular use of the technology, patients with COPD assigned to remote monitoring or self-monitoring did not have any improvement in patient outcomes such as self-management skills, knowledge, or symptoms, or in health care use compared with each other or with a standard care group. This may be owing to low health care use at baseline, the lack of structured educational components in the intervention groups, and the lack of integration of the action plan with the technology.

Introduction

Background

Chronic obstructive pulmonary disease (COPD) is the third leading cause of mortality worldwide [1], with 65 million people having moderate to severe COPD worldwide [2]. In Ontario, Canada, COPD accounts for 24% of hospital admissions and 24% of emergency department (ED) visits and is responsible for the highest percentage (18.8%) of 30-day ED readmissions [3]. Reducing the frequency of COPD exacerbations is an important patient outcome and could result in significant cost savings.

One approach to reducing exacerbations is to provide regular remote monitoring of patients from their homes. Remote monitoring requires patients to take measurements of their vital signs (oxygen, blood pressure, and symptoms) and to record them manually on paper [4] or to transmit them with devices using a phone or an internet line [5-7]. Recent developments such as Bluetooth technology, cloud-based storage, and Wi-Fi-enabled tablets have allowed data from remote devices to be uploaded automatically to a database accessible to patients, caregivers, and health care providers, either periodically or on an *as-needed* basis [8-10]. Remote monitoring programs are always monitored by a health care provider, even though they are sometimes referred to as *self-management* programs, as the recordings are taken by the patients [10]. Some remote monitoring programs also often have an educational component [11,12] such as coaching sessions to support self-management. COPD self-management behaviors include self-recognition and self-treatment of exacerbations (eg, taking medications); coping with breathlessness; and lifestyle changes such as quitting smoking, eating healthy, and exercising [13]. Self-management COPD interventions have generally been shown to be effective in improving quality of life measures [13,14], but a recent meta-analysis failed to show significant improvements in quality of life [15].

There is a large body of literature on COPD reporting on the effects of remote monitoring on patient outcomes and health care utilization, and several recent reviews have summarized these findings [16-18]. For example, Kruse et al [16] reported that the number of articles stating that patient outcomes improved overall with telemonitoring was approximately equal to that showing no improvement. Another review [17] reported that remote monitoring decreased ED admissions and

hospitalizations but failed to impact other patient outcomes (mortality, outpatient visits, and length of stay). Hong and Lee [17] suggested that *integrated remote monitoring* programs (those that have educational components) may be more effective, especially when they target patients with more advanced diseases.

Educational components come at an additional cost to these programs [19] and even the simple act of monitoring patients remotely and connecting with them only when alerts are received requires dedicated staff. Few studies have looked at the effectiveness of *self-monitoring* programs. Self-monitoring programs ask patients to take their readings and receive automated feedback based on these readings without being actively monitored by a health provider [4,20]. Results from the few studies available in the literature have shown some promise in improving patient outcomes but they were feasibility trials that required larger samples and control group designs. A self-monitoring program, if noninferior to a remote monitoring program, would provide the opportunity for significant cost savings without compromising on patient outcomes. To our knowledge, no studies to date have directly compared a remote monitoring program with a self-monitoring program for patients with COPD.

Objectives

The objective of our study was to compare the effectiveness of implementing a technology-enabled self-monitoring program versus a technology-enabled self- and remote-monitoring program (or simply remote monitoring) in a population of patients with COPD, compared with a standard care group. We hypothesized that both intervention programs would lead to improvements in self-management skills and respiratory symptoms relative to the standard care program. In addition, the technology-enabled remote monitoring programs may be more effective at increasing COPD knowledge than self-monitoring alone.

Methods

Study Setting

The study was conducted at a 309-bed community-based hospital in Ontario. Recruitment took place in a hospital-based outpatient COPD clinic, from the private practice of respirologists affiliated with the hospital, and from an outpatient COPD rehabilitation program.

Trial Design

We conducted an open-label randomized controlled trial (RCT) comparing 2 technology-enabled interventions, a self-monitoring group and a remote monitoring group, relative to standard care. Patients were randomized in a 1:1:1 ratio to 1 of the 3 groups. The study recruitment started in April 2018 and was completed in September 2019. A full description of the protocol has been published [21]. We report here only on the quantitative portion of the evaluation. The qualitative results are published separately [22].

Participants

Eligibility Criteria

Patients were included if they were aged 18 years or older and had an established clinical diagnosis of COPD by a respirologist, according to clinical guidelines [23]. Exclusion criteria included a diagnosis of other significant lung diseases (eg, interstitial lung disease), patients without Wi-Fi internet access in their homes, inability to read English (required for filling out the questionnaires), participation in other remote monitoring programs, or inability to use the technology because of physical or cognitive impairment.

Recruitment Process

The main site of recruitment was the hospital-based outpatient clinic, where all eligible patients seen within the past year were contacted for participation. Patients could also be referred to the study from outside the clinic, through the private practice of hospital-affiliated respirologists or through an outpatient COPD rehabilitation program. Patients were contacted by phone, directly approached at an appointment, or approached at the hospital's exercise rehabilitation program by a clinical staff member (respirologist or respiratory therapist [RT]). Those who were interested were referred to the clinical project specialist and scheduled for a baseline evaluation, at which time informed consent was obtained, group allocation was revealed, and the kit was provided (if in the self-monitoring or remote monitoring group).

Allocation

We used a web-based random number generator [24] to allocate patients to groups, as described in the trial protocol [21]. Sequential patient group allocation was placed in a sealed envelope and revealed to the patient by the clinical project specialist after consent was obtained.

Intervention

Technology

The *Cloud DX Connected Health Kit* (Cloud DX Inc) [25] (Multimedia Appendix 1) was used in the 2 intervention groups. It was selected as it was made by a local Ontario company (a requirement from the granting agency), was fully developed, was on the market at the time of the study, and was capable of monitoring oxygen saturation. The kit comprised the following Bluetooth devices: a custom tablet computer, a Pulsewave wrist cuff monitor (which measures blood pressure), an oximeter, a weighing scale, and a thermometer. The devices were approved by the US Food and Drug Administration and Health Canada.

A digital version of the COPD Assessment Test (CAT) [26] and the modified Medical Research Council (MRC) Scale [27] were also embedded in the technology. The data from all devices were transmitted to a database, and patients and health care providers interacted with it through a web-based portal. Regular bug fixes were occurring throughout the trial, and no major revisions of the content of the platform were done. Throughout the trial, there were 3 releases and 1 service pack installed in the platform and 2 releases, 5 hotfixes, and 1 service pack released for the companion app (see Multimedia Appendix 2 for details).

Intervention Procedures

The intervention lasted for 6 months. Patients in the intervention groups were asked to record their vitals (oximetry and blood pressure were required, whereas temperature and weight were optional) and symptoms (CAT and MRC) with the Cloud DX platform every day. They were also provided with a written version of a personalized COPD action plan that instructed patients on what to do if their readings fell outside predetermined thresholds (Multimedia Appendix 1). Individual patient thresholds were determined by the clinical project specialist (who was an RT), in consultation with the patient's respirologist. Patients in the self-monitoring and remote monitoring groups were additionally contacted by the clinical project specialist 2 weeks after receiving their kit to reassess the appropriateness of the thresholds. In addition, all patients had the option to email or call the clinic with any nonemergency questions they may have. All patients were advised to go to the ED if necessary, at any point in the study. Patients were also informed that data were not monitored 24 hours, 7 days a week and to respond to their clinical needs as they would normally do outside of the study.

When a patient's readings fell outside the predetermined thresholds, a notification was sent to both the clinical project specialist and the patient through email. The clinical project specialist reviewed the readings and responded when clinically indicated only for the remote monitoring group. Follow-up calls were made only when the readings exceeded thresholds twice or more within 2 days and were made only on weekdays. An attempt to complete the follow-up call was performed within 24 hours of receiving the notification. If the patient was unavailable, a message was left to return the call. In addition, the RT called the patients in the remote monitoring group once a week, irrespective of the values of the vitals. The purpose of the call was to check the patients, prompt action plan usage as needed, and provide education to the patients about their COPD as needed. The clinical project specialist received the readings for the self-monitoring group, but they were not actively monitored, and no follow-up calls were made in this group. Patients in the self-monitoring group were informed that their data were not actively monitored by the clinic. Patients in both intervention groups had secondary threshold levels (extreme measures) preset by the site investigator. Cloud DX staff monitored these levels and contacted the patients when necessary. For details, please refer to the protocol [21].

Patients in the standard care group were not provided with a technology or an action plan. This group received otherwise

standard care from the respiratory clinic, including routine in-person follow-up appointments and access to a certified respiratory educator. Patients in the standard care group were told that they would receive the equipment at the end of the trial to incentivize them to stay in the trial and to ensure that all participants had equal access.

Outcomes

All patients completed 3 assessments, at baseline, at 3 months, and at 6 months, on a series of questionnaires. Visit 1 (baseline) was in person, whereas visits 2 (3 months) and 3 (6 months) could be done in person or remotely (online through REDCap [28,29] or over the phone).

Primary Outcome

The primary outcome for the trial was self-management as assessed using the Partners in Health (PIH) Scale [30], a validated scale measuring the current status of self-management, with items on the knowledge of the condition and skills to monitor and respond to symptoms. This scale was selected to measure the primary outcome as we believed that both interventions could lead to self-management improvement.

Secondary Outcomes

The secondary outcomes included measures of COPD severity and COPD knowledge and were measured with the St George's Respiratory Questionnaire (SGRQ) [31] and the Bristol COPD Knowledge Questionnaire (BCKQ) [32]. The SGRQ contains subsections on respiratory symptoms, activities that are limited because of breathlessness, and impacts on daily life. The BCKQ [32] is a measurement of the level of knowledge of the disease in patients with COPD. Patients were also asked to self-report at baseline, 3 months, and 6 months on their COPD-related ED presentations, hospital admissions, length of hospital stays, number of exacerbations (episodes in which antibiotics or steroids were prescribed or hospital/clinic visits because of a respiratory issue), number of COPD-related visits to a family doctor, number of COPD-related nurse contacts, self-reported use of medication, and self-reported smoking cessation. The number of contacts/calls to the outpatient clinic and deaths were tracked and reported by the clinical project specialist. In addition, hospital admission data and ED usage from the local hospital were also obtained.

Vendor-recorded use data were also documented and sent for analysis at the end of the trial. This included the frequency of recordings for oxygen, blood pressure, temperature, weight, MRC and CAT scores, and the number of times thresholds were exceeded.

Statistical Analysis

Patient characteristics were summarized using descriptive statistics, including mean and SD for continuous variables (if normally distributed) or median, median absolute deviation, and absolute numbers for categorical variables.

All quantitative continuous data were analyzed by conducting a between-group repeated measures analysis of variance (ANOVA) comparing the scores at baseline versus 3-month follow-up and baseline versus 6-month follow-up assessments. This deviation from the original protocol (where we had planned

to include all 3 time points in each analysis) was done to maximize the data and avoid excluding participants who did not have data on all 3 time points. Kruskal-Wallis tests were used where data were not normally distributed or group variances were heterogeneous.

Ethics and Dissemination

The study was approved by the research ethics boards of the Markham Stouffville Hospital and Women's College Hospital, Ontario, Canada (protocol version 1.8, December 7, 2018). The study was also retrospectively registered with ClinicalTrials.gov (NCT03741855).

Patient and Public Involvement

During the initial planning stages of the study, we used a co-design approach in the development of the intervention. Patients were given access to the technology for 2 weeks and were subsequently interviewed about their experiences. Health care providers were also interviewed about their current models of care and their experience with the technology. The goal of this process was to establish whether the technology met the needs of its users (patients and health care providers) and to determine whether any modifications to the technology and the service it provided were needed. Modifications to both service and technology were done in response to this feedback. Some of this feedback was also used to inform the decisions about primary and secondary outcome selection.

Patient advisers were not involved directly in the development of the research question and outcome measures or recruitment. The burden of the intervention was assessed by the research ethics boards who had public member representatives. Any participants interested in receiving information about the results of the study will be provided with a summary once the results are available.

Results

Study Participants

A total of 122 patients participated in the study: 40 in the standard care, 41 in the self-monitoring, and 41 in the remote monitoring groups. Of these patients, 7 in the standard care, 5 in the self-monitoring, and 6 in the remote monitoring group did not complete the study (8 patients withdrew from the trial for various reasons; 6 patients were noncompliant with their readings; 4 patients died: 1 from a COPD exacerbation, 1 from complications of comorbid conditions, 1 from cardiac arrest, and 1 from unknown causes; and 1 patient dropped out because of difficulty using the technology; Figure 1). There were no significant differences in the rates of study completion among the groups ($P=.80$). Patients were excluded from individual analyses, if they had missing data.

The baseline characteristics of the patients are described in Table 1. Comparisons among groups were made with ANOVA for normally distributed variables, Kruskal-Wallis tests for variables that were not normally distributed, and chi-square tests for categorical data. Patients matched at baseline on all characteristics, except for the CAT baseline scores, where the

self-monitoring group had significantly lower scores than the standard care group ($P=.02$).

All patients were able to speak and read English, except for 3 patients in the remote monitoring group who were included as they had support from caregivers in completing the questionnaires. There was an equal distribution of education level across the 3 groups ($P=.64$; [Multimedia Appendix 1](#)). Patients from all 3 groups were present in all income brackets,

except for the highest income bracket, where there were no self-monitoring patients ($P=.01$; [Multimedia Appendix 1](#)). Patients in all 3 groups were also matched on a series of medical conditions at baseline ([Multimedia Appendix 1](#)), except for osteoporosis, for which the rates were lower in the remote monitoring group ($P=.02$), and pulmonary hypertension, which was reported only in 3 cases, all in the standard care group ($P=.04$).

Figure 1. Patient flow through the study. Patient flow through each arm of the study. A total of approximately 800 patients were screened for eligibility in order to obtain the final sample of 122 participants.

^dFEV1: forced expiratory volume in 1 second.

^eFVC: forced vital capacity.

Readings and Notifications

There were no significant differences in the number of readings completed by each intervention group on any of the measures. There were also no significant differences in the number of notifications received on any of the measures. Patients took their readings almost daily, with a median number of 160 readings in the self-monitoring group and 162 readings in the remote monitoring group over a 182-day period ([Multimedia Appendix 1](#)).

Incoming Calls

There were differences among the groups in the number of incoming calls completed during the intervention ($P<.001$). Post

hoc comparisons showed that the standard care group made significantly fewer calls (mean 0.13, SD 0.40) than the self-monitoring (mean 4.17, SD 4.17; $P<.001$) and the remote monitoring groups (mean 3.27, SD 4.29; $P<.001$). There was no difference between the number of calls made by the self-monitoring and remote monitoring groups ($P=.11$).

Primary and Secondary Outcomes

A repeated measures ANOVA showed a significant improvement in PIH scores from baseline to 3 months ($P=.001$) and from baseline to 6 months ($P=.008$) but no group effects or interactions, suggesting that there was no differential effect among the groups ([Figure 2](#)).

Figure 2. PIH at baseline and 3 months and baseline and 6 months for each group. Significant improvement in PIH scores from baseline to 3 months ($P=.001$) and from baseline to 6 months ($P=.008$) were observed, but no group effects or interactions, suggesting no differential effect among the groups. PIH: Partners in Health; RM: remote monitoring SC: standard care; SM: self-monitoring.

A repeated measures ANOVA showed a significant improvement in BCKQ scores from baseline to 3 months ($P<.001$) and from baseline to 6 months ($P<.001$; [Multimedia Appendix 1](#)). Steeper gains were observed in the remote monitoring group compared with the self-monitoring and standard care groups, both from baseline to 3 months and from baseline to 6 months, but the interaction effect did not reach statistical significance ($P=.13$ and $P=.07$, respectively). The gains in accuracy were less than 10%, and all groups had initial scores of just above 30% accuracy, which is lower than the average of 54% accuracy reported by the original BCKQ study [32]. No group main effects were observed.

A repeated measures ANOVA showed no changes in SGRQ activity scores ([Multimedia Appendix 1](#)) from baseline to 3 months ($P=.49$) or from baseline to 6 months ($P=.76$) and no group effects or interactions.

A repeated measures ANOVA showed a significant improvement in SGRQ impact scores ([Multimedia Appendix 1](#)) from baseline to 3 months ($P=.047$), but no significant group effect or interaction, suggesting that there was no differential effect among the groups. When comparing baseline to 6 months, a repeated measures ANOVA showed a significant effect of time ($P=.006$) and a significant interaction effect ($P=.005$). Separate pairwise comparison analyses were performed to examine the interaction effect. The standard care group improved from baseline to 6 months, whereas the remote monitoring group scores deteriorated (higher score) as demonstrated by a significant interaction effect ($P=.02$). A significant interaction effect ($P=.003$) was also observed when the self-monitoring and remote monitoring groups were analyzed separately, showing that the self-monitoring group improved, whereas the remote monitoring group worsened. Both standard care and self-monitoring groups improved significantly with time in their SGRQ impact scores ($P=.002$), and there was no interaction or group effect.

A repeated measures ANOVA showed no changes in SGRQ symptom scores from baseline to 3 months ($P=.56$) or from baseline to 6 months ($P=.62$) and no group effects or interactions ([Multimedia Appendix 1](#)).

Finally, for the remote monitoring and self-monitoring groups, a repeated measures ANOVA comparing the second CAT readings to their previous CAT reading, with time as a within-subject variable and group as a between-subject variable, showed no significant main effects or interactions. The same was observed with the MRC scores. Therefore, there were no changes in the CAT and MRC scores from the beginning of the intervention until the end.

Correlation Between Changes in Partners in Health Scores and the Number of Readings

We ran a series of Pearson correlations between the number of readings (CAT, MRC, and oxygen saturation) and the change in score from baseline to 6 months for the participants in the self-monitoring and remote monitoring groups. No correlations were observed in any of these analyses.

Health Care Use

In comparing baseline to 3 months, there were no significant effects of time, group, or interaction on any of the measures, except for a decrease in primary care COPD-related visits ($P=.04$). This reduction was most evident in the standard care and remote monitoring groups. In comparing baseline to 6 months, there were no effects of time, group, or interaction on any of the measures. The incidence of any of the above events was quite low ([Multimedia Appendix 1](#)).

In addition to the self-reported measures, the hospital charts of patients were reviewed to estimate the number of ED visits and hospitalizations that had occurred at the hospital during the 6 months preceding their enrollment and during their participation in the trial. The charts were also reviewed to assess the total number of clinic visits that the patients had completed during these periods (clinic visits could be ascertained only for patients who were seeing a physician at the COPD clinic). Nonparametric comparisons were run to estimate the effect of time, group, and time \times group interaction. No significant main effects or interactions were observed.

Separate data analyses were performed to compare only COPD-related ED visits and hospitalizations. These analyses showed a significant decrease in COPD-related ED visits during the 6 months before trial enrollment to the 6 months during trial

enrollment ($P=.007$); however, there was no group effect or interaction, suggesting that there was a general decline in visits across groups. For COPD-related hospital admissions, there

was a decrease but not a statistically significant effect across the 3 groups ($P=.07$; Table 2).

Discussion

Principal Findings

This study compared the effectiveness of a technology-enabled self-monitoring program to a remote monitoring program and standard care in a population of patients with COPD. Despite high adherence to the intervention and a low dropout rate, the study found no difference in self-efficacy or disease knowledge and disease severity measures among the groups. All 3 groups, including the standard care group, improved self-efficacy and disease knowledge measures. These changes were significant over time and were evident at both 3- and 6-month evaluations. The standard care and self-monitoring groups, but not the remote monitoring group, also reported a lower impact of COPD on their lives when comparing baseline to 6-month evaluations. There were no changes in symptoms or activity scores in any

of the groups. There were also no differences (increases or decreases) in patient health care utilization, including ED visits, hospital admissions, primary care visits, or nursing visits, during participants' participation in the trial relative to the 6 months preceding the trial, although these were secondary outcomes that the study was not powered for.

The lack of effect in this study is not unique, as current studies and reviews on the effects of remote monitoring on patient outcomes and health utilization have shown mixed results [16-18]. Some studies have reported positive results on some quality of life measures and symptoms [10,33-35], but many have reported no effects [8,12,36-39]. With respect to health care utilization, the effects are also mixed, with some reporting reductions in hospitalizations [5,7,33,40-42], length of stay [7,33,40,43], and ED visits [33,40], but many failing to find significant effects [6,10,34,36-38]. A recent systematic review concluded that the evidence on the effectiveness of remote

monitoring is mixed [16], although some meta-analyses have reported significant reductions in hospitalizations and ED visits [17,44]. Hong and Lee [17] took their meta-analysis one step further and examined the effects of patient severity and intervention type (interventions with or without an educational component). They concluded that interventions with an educational component (such as those seen in self-management programs) and those targeting patients with more severe diseases had the greatest effects, especially on health care utilization (hospitalizations and ED visits). Our intervention lacked both these components.

First, although spirometry readings on an average suggested moderate to severe disease, there was a large variability among patients, with many patients having milder symptoms. Most patients had no hospital or ED admissions in the 12 months before joining the intervention, which also suggested that even those with moderate to severe disease had enough clinical support to avoid hospitalizations. However, we know that there was room for improvement as all 3 groups improved on several patient outcomes, including self-efficacy and disease knowledge measures. This may mean that the standard care delivered at the local clinic may already have been quite effective in improving patient outcomes, which would have made it harder for us to detect any additional effect of remote monitoring or self-monitoring over those provided in standard care during the same period. If future studies exclude milder patients from similar interventions and find effects, it may provide evidence that remote monitoring and self-monitoring monitoring programs are better suited for moderate to severe patients. This may also make such programs more affordable for health care systems as only a subset of patients will have to be monitored. If the primary goal is to examine the impact on health care utilization (which was not our focus in this study), we recommend focusing on patients with at least one ED or hospital admission, using administrative data sets and examining longer intervention periods.

Second, our intervention did not have a formal educational component. Although the clinical project specialist was making regular calls to patients in the remote monitoring group and providing them with guidance and education when needed, there was no structured educational component in the form of coaching sessions. Some education was also already delivered as part of standard care in the clinic, which may also explain why patients with moderate to severe disease had relatively few hospitalizations. Future studies should include structured coaching sessions, covering topics on self-recognition and self-treatment of exacerbations (eg, taking medications), coping with breathlessness, and lifestyle changes [13] to make the intervention groups more distinct from standard care. More personalized educational components can be delivered by a health care professional in a remote monitoring program, whereas more standardized education modules can be delivered directly through the device in response to readings.

In this intervention, we provided patients with action plans that were not integrated with the devices. Evidence suggests that action plans can be effective in reducing the effects of exacerbations when they are followed, but few patients follow written action plans [45]. The integration of action plans within the platform, with patients receiving feedback directly from the device, may improve their use, although a recent study found no additional benefits when action plans were embedded within a self-monitoring mobile app over those provided by a written action plan [38]. Further developments in trend analyses and predictive analytics of remote monitoring data [46] may allow for early detection of exacerbations as relative changes in vital signs may be more important than detecting vitals reaching absolute thresholds.

Strengths and Limitations

With regard to strengths, this is the first study to directly compare remote monitoring relative to self-monitoring and standard care, and the comparison was conducted through an RCT, which offers strong internal validity for the findings. There was a high adherence rate from both intervention groups with hundreds of oximeter recordings, subjective symptom scores, and blood pressure measurements taken from patients. Furthermore, follow-up was very good, with only 7% of the participants withdrawing, 7% being noncompliant, and only one patient finding the technology to be too difficult to use. Despite this, our design suffered from drawbacks such as a relatively short intervention period (6 months) and inclusion criteria that allowed any patients with a diagnosis of COPD, irrespective of disease severity, to participate. Some of these decisions were made because of time constraints surrounding the trial funding and associated recruitment challenges. Many studies in the literature had disease severity inclusion criteria that often required patients to be admitted at least once and often twice in the previous year [8,42,47]. With respect to intervention duration, a full-year intervention seems to be the most common, but we noted interventions ranging from 3 to 24 months. Although our intervention was only 6 months, it is worth noting that some 6-month interventions have shown positive effects [7,34,35].

Conclusions

Our 6-month intervention comparing technology-enabled remote monitoring and self-monitoring programs showed no intervention specific improvements in self-efficacy, disease knowledge, or quality of life. No effects were observed in health care utilization, including hospital admissions and ED visits. Future studies should focus on patients with higher health care system use and moderate to severe disease. We also recommend including structured educational components (potentially both in remote monitoring and self-monitoring programs) and predictive analytics of vitals data that detect relative rather than absolute changes in vitals.

Abstract

Background: Utilizing the traditional centers of excellence approach to conduct clinical trials involving rare diseases remains challenging. Patient-based registries have been shown to be both feasible and valid in several other diseases.

Objective: This report outlines the clinical characteristics of a large internet registry cohort of participants with a self-reported diagnosis of granulomatosis with polyangiitis or microscopic polyangiitis.

Methods: Patients with a self-reported diagnosis of granulomatosis with polyangiitis or microscopic polyangiitis in an internet-based prospective longitudinal cohort (from the Vasculitis Patient-Powered Research Network) were included. Data on symptoms, diagnostic testing, and treatment were collected using standardized questionnaires.

Results: The study compared patients with granulomatosis with polyangiitis (n=762) and patients with microscopic polyangiitis (n=164). Of the cohort, 97.7% (904/925) reported the diagnosis had been confirmed by a physician. Compared to microscopic polyangiitis, patients with granulomatosis with polyangiitis reported significantly more ear, nose, and throat manifestations (granulomatosis with polyangiitis: 641/723, 88.7%; microscopic polyangiitis: 89/164, 54.3%; $z=10.42$, $P<.001$), fevers (granulomatosis with polyangiitis: 325/588, 55.3%; microscopic polyangiitis: 64/139, 46.0%; $z=1.96$, $P=.05$), joint involvement (granulomatosis with polyangiitis: 549/688, 79.8%; microscopic polyangiitis: 106/154, 68.8%; $z=2.96$, $P=.003$), and pulmonary involvement (granulomatosis with polyangiitis: 523/734, 71.3%; microscopic polyangiitis: 90/154, 58.4%; $z=3.13$, $P=.002$). Compared to microscopic polyangiitis, patients with granulomatosis with polyangiitis reported significantly less renal involvement (granulomatosis with polyangiitis: 457/743, 61.5%; microscopic polyangiitis: 135/163, 82.8%; $z=-5.18$, $P<.001$) and renal transplantation (granulomatosis with polyangiitis: 10/721, 1.4%; microscopic polyangiitis: 7/164, 4.3%; $z=-2.43$, $P=.02$). Antineutrophil cytoplasmic antibody positivity was reported in 94.2% (652/692) of patients with granulomatosis with polyangiitis and 96.1% (147/153) of patients with microscopic polyangiitis. A biopsy showing vasculitis was reported in 77.0% (562/730) of patients with granulomatosis with polyangiitis and 81.9% (131/160) of patients with microscopic polyangiitis.

Conclusions: In this large, internet-based cohort of patients with a self-reported diagnosis of granulomatosis with polyangiitis or microscopic polyangiitis, disease manifestations were consistent with expectations for each type of vasculitis. Given the rarity

of these and other vasculitides, conducting some types of research through internet-based registries may provide an efficient alternative to inperson, center-of-excellence clinical trials.

KEYWORDS

granulomatosis with polyangiitis; microscopic polyangiitis; vasculitis; patient-reported outcomes; patient registry; electronic health records; questionnaire; online cohort

Introduction

Granulomatosis with polyangiitis and microscopic polyangiitis are forms of antineutrophil cytoplasmic antibody–associated vasculitis that primarily target small arteries. These are rare diseases, with annual prevalence of granulomatosis with polyangiitis estimated from 24 to 160 per 1,000,000 and annual prevalence of microscopic polyangiitis estimated from 39 to 94 per 1,000,000 [1]. There are several challenges in conducting clinical trials involving rare diseases, including the need to involve multiple centers, high costs, and other logistical challenges. Novel methods for obtaining both meaningful and reliable data are needed. Multiple studies [2–6] of other diseases have proven the validity of patient-reported diagnoses and outcomes. The aims of this study were to describe the self-reported clinical features of patients with granulomatosis with polyangiitis and microscopic polyangiitis who participated in the Vasculitis Patient-Powered Research Network and to establish to what extent this internet-based cohort is representative of the general population of patients with these forms of antineutrophil cytoplasmic antibody–associated vasculitis.

Methods

Established in 2014, the Vasculitis Patient-Powered Research Network is an international, internet-based prospective longitudinal registry of patient- or caregiver-reported information. The Vasculitis Patient-Powered Research Network was established as a partnership between the Vasculitis Clinical Research Network (a vasculitis research network) and the Vasculitis Foundation (the largest patient advocacy group for vasculitis). The network represents a collaboration among a variety of vasculitis stakeholders including patients, patient advocacy organizations, academic clinical investigators, expert clinicians, biomedical informaticians, methodologists, and funding organizations. Patient-partners are an integral part of team and are involved in strategically planning, developing, reviewing, and approving research studies. Patient-partners receive training in patient participation in research.

The Vasculitis Patient-Powered Research Network is the largest patient-based registry for primary systemic vasculitis with over 3000 patients enrolled to date; patients (or caregivers) consent to participate in studies and provide self-reported information longitudinally using the internet-based platform [7]. For this study, advertisement for recruitment was done via social media, the Vasculitis Foundation website, and flyers at national and regional vasculitis conferences.

Only patients with a self-reported diagnosis of granulomatosis with polyangiitis and microscopic polyangiitis were included in this study. Patients provided consent online and were enrolled between November 2014 and May 2019. The data were obtained via convenience (or opportunity) sampling methods. Using the internet-based patient portal, participants filled out standardized questionnaires (open survey, [Multimedia Appendix 1](#)) in English which requested information such as demographics (age, gender, ethnicity), signs and symptoms of vasculitis at the time of diagnosis, results of diagnostic studies performed (ie, laboratory testing, biopsies, imaging, etc), prescribed treatments, and outcomes. For each item, respondents could select *yes*, *no*, or *I don't know* and were able to review or change previously answered questions. Responses that were left blank or where the answer was not known were excluded from the analysis. Patient participation was encouraged by sending email reminders to participants; however, no incentives were offered for completion of the questionnaires. Multiple entries by the same individual were prevented through the use of password-protected user log-ins.

This study was approved by the institutional review board of the University of South Florida. To address data completeness and compliance, the Vasculitis Patient-Powered Research Network operates a comprehensive data compliance strategy using a variety of tools and approaches. The data compliance reports are regularly monitored by the network and data managers of the Vasculitis Patient-Powered Research Network to identify emerging trends. If a participant has not completed all forms, a series of automated email reminders to the participant are triggered. After an initial, generic reminder email message has been sent, a form-specific email reminder is sent. This message specifies which forms are incomplete and also describes the scientific significance and need for the information requested by each form.

Data were analyzed to compare clinical manifestations and diagnostic testing of patients with granulomatosis with polyangiitis to those of patients with microscopic polyangiitis. Two-tailed *z* scores were performed for comparisons of proportions. Two-tailed independent *t* tests were used for comparisons of means and medians. *P* values $\leq .05$ were considered significant.

Results

Participant Characteristics

Granulomatosis With Polyangiitis

A total of 762 participants reported a diagnosis of granulomatosis with polyangiitis; 518 (68.0%) were female and

244 (32.0%) were male. The median age of patients at the onset of symptoms was 45 (IQR 31-57) for 619 respondents, and the median age at diagnosis was 48 (IQR 35-57) for 683 respondents. Out of 761 respondents, 248 (32.6%) reported their disease as active, 465 (61.1%) reported their disease as being in remission, and 48 (6.3%) reported they were unsure. Respondents (648/727, 89.1%) reported seeing one or more of the following specialists: rheumatologist (528/727, 72.6%), nephrologist (202/727, 27.8%), pulmonologist (139/727, 19.1%), otolaryngologist (135/727, 18.6%), neurologist (29/727, 4.0%),

immunologist (9/727, 1.2%), dermatologist (3/727, 0.4%). Respondents (720/762, 94.5%) reported their country of origin as the United States (572/720, 79.4%, of which state unreported: 72/572 and state reported: 500/572; northeastern states: 102/500, 20.4%; midwestern states: 132/500, 26.4%; southern states: 164/500, 32.8%; western states: 102/500, 20.4%), Canada (62/720, 8.6%), United Kingdom (36/720, 5.0%), Australia (18/720, 2.5%), or other (32/720, 4.4%) (Figure 1 and Figure 2).

Figure 1. Heat maps showing geographic distribution of participants with granulomatosis with polyangiitis and microscopic polyangiitis internationally.

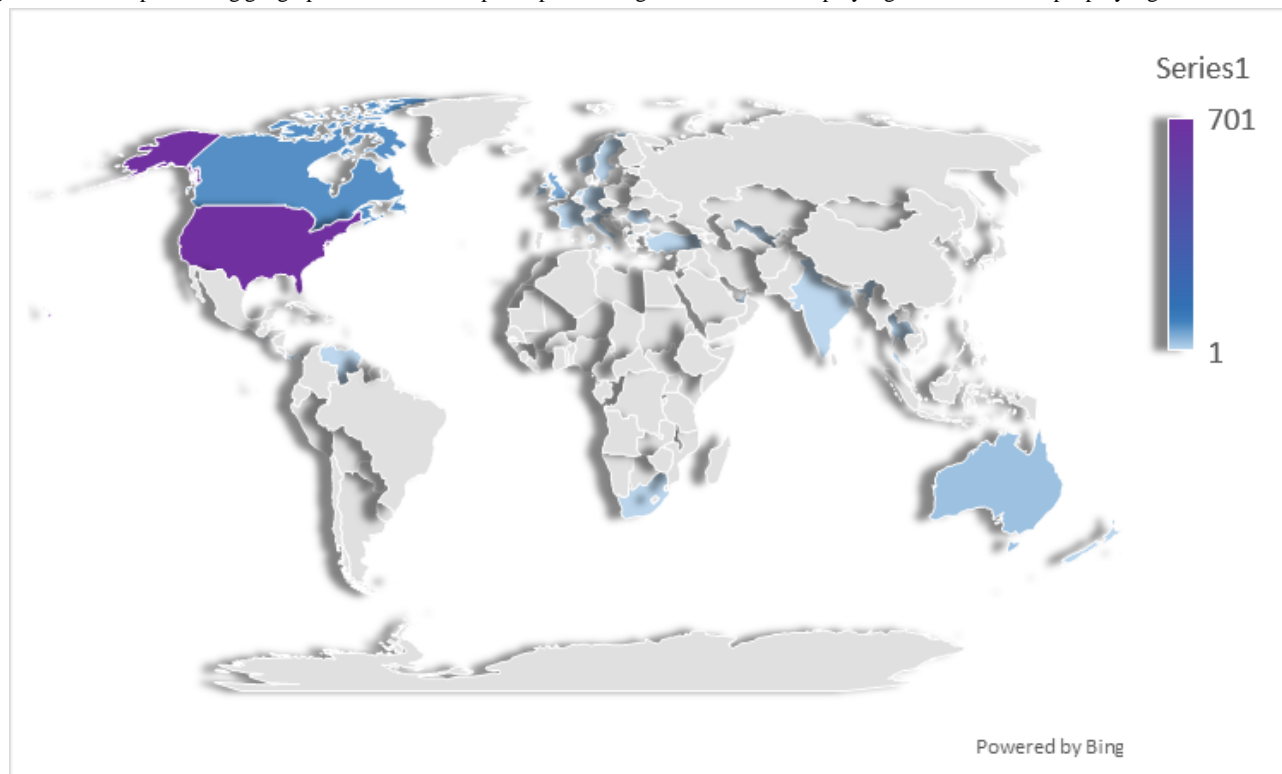

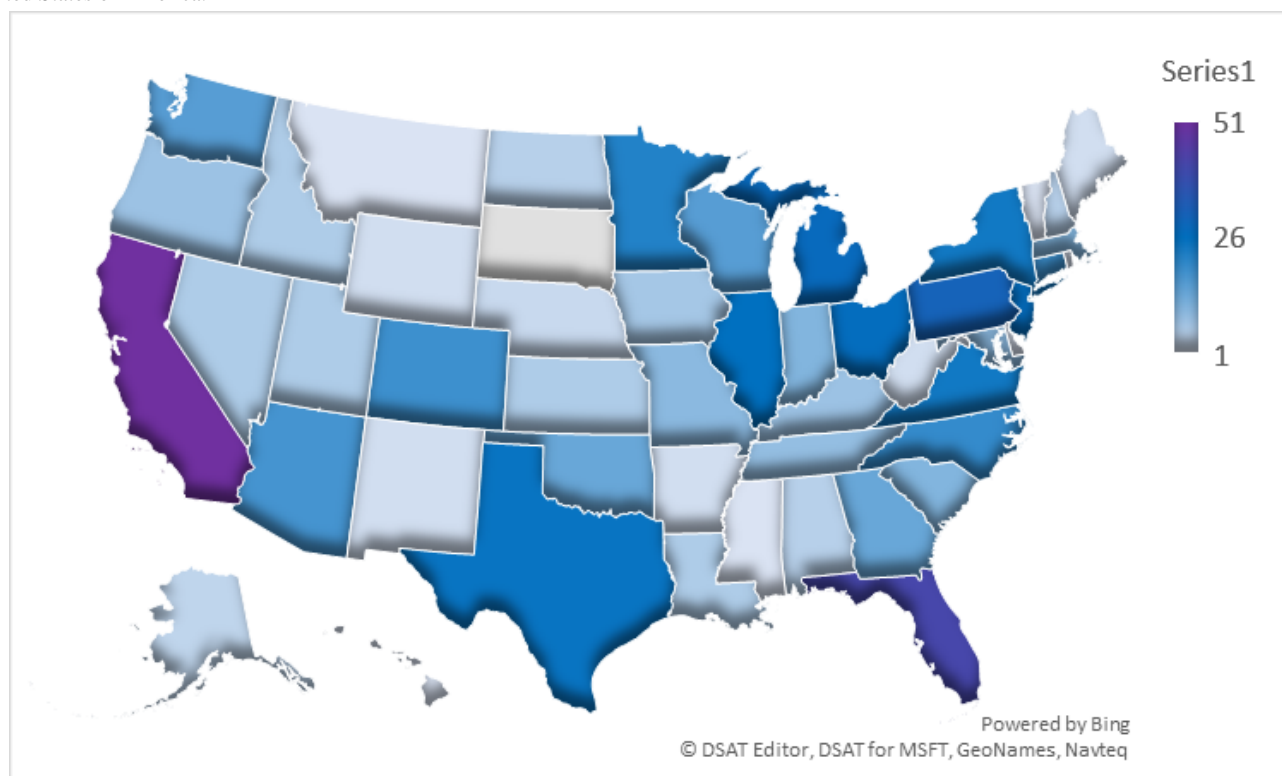

Figure 2. Heat maps showing geographic distribution of participants with granulomatosis with polyangiitis and microscopic polyangiitis within the United States of America.

Microscopic Polyangiitis

A total of 164 participants reported a diagnosis of microscopic polyangiitis; 133 (81.1%) were female and 31 (18.9%) were male. The median age of patients at the onset of symptoms was 52 (IQR 36-61) for 129 respondents, and the median age at diagnosis was 53 (IQR 41-62) for 158 respondents. Out of 160 respondents, 55 (34.4%) reported their disease as active, 96 (60.0%) reported their disease as being in remission, and 13 (8.1%) reported they were unsure. Respondents (141/160, 88.1%) reported seeing one or more of the following specialists: rheumatologist (95/160, 59.4%), nephrologist (85/160, 53.1%), pulmonologist (28/160, 17.5%), neurologist (6/160, 3.8%), immunologist (3/160, 1.9%), dermatologist (2/160, 1.2%) and otolaryngologist (1/160, 0.6%). Respondents (150/164, 91.5%) reported their country of origin as the United States (121/150, 80.6%, of which state unreported: 12/121 and state reported: 109/121; northeastern states: 15/109, 13.8%; midwestern states: 30/109, 27.6%; southern states: 31/109, 28.4%; western states: 33/109, 30.3%), Canada (10/150, 6.6%), United Kingdom (8/150, 5.3%), Australia (5/150, 3.3%), or other (6/150, 4.0%).

Self-Reported Manifestations

In patients with granulomatosis with polyangiitis, the most common self-reported manifestations were nasal or sinus in 82.9% (600/723), joint pain in 79.8% (549/688), pulmonary in 71.3% (523/734), peripheral nerve in 62.8% (411/654), and renal in 61.5% (457/743) of respondents. Pulmonary-renal syndrome (diffuse alveolar hemorrhage in combination with renal disease) was reported by 26.9% (184/684) of participants. Venous thromboembolisms were reported by 13.7% (96/701) of respondents.

In patients with microscopic polyangiitis, the most common self-reported manifestations were renal in 82.8% (135/163), joint pain in 68.8% (106/154), peripheral nerve in 64.6% (95/147), nasal or sinus in 61.0% (89/146), rash in 59.6% (93/156), and pulmonary in 58% (90/154) of respondents. Pulmonary-renal syndrome was reported by 29% (47/161). Venous thromboembolism was reported in 13.6% (21/154) of respondents. Patients also reported isolated renal manifestations without other organ manifestations (14/164, 8.5%), although constitutional symptoms such as myalgia (1/164, 0.6%), fever (2/164, 1.2%), and weight loss (6/164, 3.7%) were reported.

Diagnostic Testing

Confirmation of diagnosis by a physician was reported by 97.5% (742/761) of respondents with granulomatosis with polyangiitis. Patients with granulomatosis with polyangiitis underwent antineutrophil cytoplasmic antibody testing (652/692, 94.2%), laboratory testing (566/762, 74.3%), biopsy (475/762, 62.3%), and imaging (292/762, 38.3%) for diagnosis; symptom-based diagnosis was also reported (533/762, 69.9%). Out of 730 respondents, 562 (77.0%) reported having a biopsy showing vasculitis at some point, of which the biopsy sites included kidney (283/562, 50.4%), lung (192/562, 34.2%), nasal or sinus (146/562, 26.0%), skin (70/562, 12.5%), nerve (10/562, 1.8%), artery (7/562, 1.2%), and other sites (36/562, 6.4%).

Confirmation of diagnosis by a physician was reported by 98.8% (162/164) of respondents with microscopic polyangiitis. Patients with microscopic polyangiitis underwent antineutrophil cytoplasmic antibody testing (147/153, 96.1%), laboratory testing (129/164, 78.7%), biopsy (126/164, 76.8%), and imaging (69/164, 42.1%) for diagnosis; symptom-based diagnosis was also reported (110/164, 67.1%). Of 160 respondents, 131

(81.9%) reported having a biopsy showing vasculitis at some point, of which the biopsy sites included kidney (103/160, 78.6%), lung (20/160, 15.3%), skin (15/160, 11.5%), nerve (6/160, 4.6%), nasal or sinus (4/160, 3.1%), artery (3/160, 2.3%), and other sites (2/160, 1.5%). Additional diagnostic testing information can be found in [Multimedia Appendix 2](#).

Medications

For respondents with granulomatosis, the most commonly used medications included glucocorticoids (707/762, 92.8%), cyclophosphamide (total: 439/762, 57.6%; oral: 313/762, 41.1%; intravenous: 226/762, 29.7%), sulfamethoxazole and trimethoprim (418/762, 54.9%), rituximab (396/762, 52.0%), methotrexate (354/762, 46.5%), azathioprine (311/762, 40.8%), mycophenolate (140/762, 18.4%), and intravenous immunoglobulin (38/762, 5.0%); 8.4% (64/762) reported receiving plasma exchange at some point. For respondents with microscopic granulomatosis, the most commonly used medications included glucocorticoids (151/161, 93.8%), rituximab (89/161, 55.3%), cyclophosphamide (total: 79/161, 49.1%; oral: 44/161, 27.3%; intravenous: 49/161, 30.4%), azathioprine (79/161, 49.1%), sulfamethoxazole and trimethoprim (53/161, 32.9%), mycophenolate (39/161, 24.2%), methotrexate (34/161, 21.1%), and intravenous immunoglobulin (9/161, 5.6%); 9.9% (16/161) reported receiving plasma exchange at some point. Additional data on the medications used by patients with granulomatosis with polyangiitis and by patients with microscopic polyangiitis to treat their vasculitis can be found in [Multimedia Appendix 3](#).

Granulomatosis With Polyangiitis Versus Microscopic Polyangiitis

Compared to those with a self-reported diagnosis of microscopic polyangiitis, those with a self-reported diagnosis of granulomatosis with polyangiitis were younger at both onset of symptoms (45 years of age versus 52 years of age, $t_{746}=-2.46$,

$P=.01$) and diagnosis (48 years of age versus 53 years of age, $t_{839}=-2.60$, $P=.01$). Patients with granulomatosis with polyangiitis reported more sinonasal disease (83.0% versus 61.0%, $z=5.99$, $P<.001$), hearing loss (48.3% versus 15.3%, $z=7.28$, $P<.001$), tracheal involvement (30.0% versus 9.8%, $z=4.80$, $P<.001$), pulmonary involvement (71.3% versus 58.4%, $z=3.13$, $P=.002$), eye involvement (54.2% versus 33.8%, $z=3.14$, $P=.002$), joint involvement (79.8% versus 68.8%, $z=2.96$, $P=.003$) and fevers (55.3% versus 46.0%, $z=1.96$, $P=.050$) than patients with microscopic polyangiitis; whereas, those with microscopic polyangiitis reported more renal involvement (82.8% versus 61.5%, $z=-5.18$, $P<.001$) and were more likely to have undergone a renal transplant (4.3% versus 1.4%, $z=-2.43$, $P=.02$) than patients with granulomatosis with polyangiitis ([Table 1](#)). There was no difference in the proportion of venous thromboembolism (13.7% versus 13.6%, $z=0.02$, $P=.99$), no difference in the percentage of patients reporting a positive antineutrophil cytoplasmic antibody test (94.2% versus 96.1%, $z=-0.92$, $P=.36$), and no difference in the percentage of patients reporting a diagnosis based on biopsy (77.0% versus 81.9%, $z=-1.35$, $P=.18$). There were more diagnoses from lung (34.2% versus 15.3%, $z=4.23$, $P<.001$) and nasal or sinus biopsies (26.0% versus 3.1%, $z=5.74$, $P<.001$) in participants with granulomatosis with polyangiitis than those in participants with microscopic polyangiitis. Conversely, there were more diagnoses from kidney biopsy in participants with microscopic polyangiitis (78.6% versus 50.4%, $z=-5.87$, $P<.001$) than those in participants with granulomatosis with polyangiitis. A biopsy was more likely to have been performed in participants with microscopic polyangiitis than in those with granulomatosis with polyangiitis (76.8% versus 62.3%, $z=-3.53$, $P<.001$). Oral cyclophosphamide ($z=3.25$, $P=.001$), methotrexate ($z=5.92$, $P<.001$), and sulfamethoxazole and trimethoprim ($z=5.06$, $P<.001$) were more commonly used by patients with granulomatosis with polyangiitis than by those with microscopic polyangiitis ([Multimedia Appendix 3](#)).

Table 1. Self-reported clinical manifestations.

Clinical Manifestation	Granulomatosis with polyangiitis		Microscopic polyangiitis		Z score	P value
	N ^a	n (%)	N ^a	n (%)		
Rash	698	401 (57.4)	156	93 (59.6)	−0.50	.62
Weight loss	690	400 (58.0)	151	86 (57.0)	0.23	.82
Fever	588	325 (55.3)	139	64 (46.0)	1.96	.05

Discussion

Principal Findings

This study was conducted using exclusively patient-reported information. It is important to understand how patient-derived data may differ from those obtained through traditional physician reports used in observational cohorts and clinical trials. This is the first large, prospective cohort of patients with a self-reported diagnosis of granulomatosis with polyangiitis or microscopic polyangiitis that included detailed information from standardized forms to evaluate clinical manifestations, the results of diagnostic testing, and types of treatment. The participants were from across the United States, Canada, and from multiple other countries. An analysis [8] of this cohort found that more than 90% of patients met the 1990 American College of Rheumatology classification criteria for granulomatosis with polyangiitis and the Chapel Hill Consensus Conference definition of microscopic polyangiitis.

The type and distribution of clinical manifestations among patients in this cohort were similar to those reported for observational cohorts and in clinical trials [9–11]. Ear, nose, and throat; pulmonary; and renal manifestations were common

in granulomatosis with polyangiitis, as expected, while renal and lung involvement were common in microscopic polyangiitis. The proportions of positive antineutrophil cytoplasmic antibody tests (94.2% and 96.1%) were similar to what would be expected and to what has been in the literature [12]. It has been recognized that there is a high risk of venous thromboembolism in antineutrophil cytoplasmic antibody-associated vasculitis, especially during active disease. There was a 14% prevalence of venous thromboembolism in the combined cohort which was similar to that reported in the literature [13,14].

The most common means of diagnosis reported by participants (symptom-based, laboratory testing, biopsy, and imaging) closely reflected what was emphasized by the 1990 American College of Rheumatology classification criteria for granulomatosis with polyangiitis and the Chapel Hill Consensus Conference definition of microscopic polyangiitis. Only 1% of participants were not sure of the means of their diagnosis, reflecting good insight and recall of participants regarding the basis for their original diagnosis.

There were also important differences between this cohort and center-based cohorts. First, there was a higher than expected prevalence of skin (57.4% and 59.6%) and peripheral nerve

involvement (62.8% and 64.6%). This could reflect the nonspecificity of the queries where patients were asked to attribute manifestations to vasculitis. Patients may have had difficulty adjudicating whether their symptoms were caused by vasculitis or as a result of complications of therapy.

Ear, nose, and throat manifestations are a hallmark manifestation for granulomatosis with polyangiitis distinguishing it from microscopic polyangiitis. In a study [15] comparing physician-reported clinical characteristics of granulomatosis with polyangiitis and microscopic polyangiitis in observational cohorts versus randomized controlled trials, 19% patients with microscopic polyangiitis had ear, nose, and throat manifestations compared to 76% patients with granulomatosis with polyangiitis. In this study cohort, there was a statistically higher ($z=10.42$, $P<.001$) prevalence of these manifestations in granulomatosis with polyangiitis as expected, but there was also a higher than expected prevalence in microscopic polyangiitis with nasal-sinus manifestations being reported in 54.3% of patients. This may represent the nonspecificity of queries which included asking patients to attribute manifestations to vasculitis. Alternatively, it may in part also reflect misclassification in the medical community in which patients who test positive for myeloperoxidase antineutrophil cytoplasmic antibodies are classified as having microscopic polyangiitis; and only patients who test positive for proteinase 3 antineutrophil cytoplasmic antibodies are classified as having granulomatosis with polyangiitis.

As expected, patients with microscopic polyangiitis were significantly more likely ($z=-5.18$, $P<.001$) to have had renal involvement than patients with granulomatosis with polyangiitis. In the microscopic polyangiitis group, 8.5% patients had isolated renal manifestations (renal-limited vasculitis). Overall, the proportion of renal involvement was similar to that reported in the literature [12]; however, in earlier reports, up to one-third of those with antineutrophil cytoplasmic antibody-associated vasculitis with renal involvement went on to develop end-stage renal disease [16] which was higher than what was found in this study (granulomatosis with polyangiitis: 73/457, 16.0%; microscopic polyangiitis: 18/135, 13.3%). This could be related to the improvement of renal outcomes in granulomatosis with polyangiitis and microscopic polyangiitis patients over time reflecting the changes in diagnosis and management [16,17]. This could also reflect the fact that there was a possible bias as a result of less morbidity in participants from the online portal. Furthermore, this study enrolled patients with a clinical diagnosis of granulomatosis with polyangiitis or microscopic polyangiitis; patients who had isolated renal manifestations and part of the spectrum of antineutrophil cytoplasmic antibody-associated vasculitis could have been underrepresented, especially if they had not been clinically diagnosed with granulomatosis with polyangiitis or microscopic polyangiitis by their physicians. Patients with renal-limited disease who have end-stage renal disease may also no longer be followed or monitored for vasculitis, and therefore, may not have enrolled in the study.

Strengths and Limitations

This study had several strengths. First, the study cohort is large for such rare diseases, and is geographically diverse. The data elements of interest were selected and designed by highly experienced investigators in this field and collected using standardized forms. Patient input was obtained at each stage of the process, especially on the design of the user interface for the Vasculitis Patient-Powered Research Network website.

This study had several limitations. First, direct physician confirmation of the diagnosis was not obtained as part of this study; however, based on the patient information that was provided, more than 90% of patients with granulomatosis with polyangiitis and microscopic polyangiitis met either the 1990 American College of Rheumatology Classification Criteria for granulomatosis with polyangiitis or the Chapel Hill Consensus Conference definition for microscopic polyangiitis [8]. Almost all of the participants reported physician confirmation of the diagnosis. In addition, the manifestations described by patients were similar to those reported in the literature. Second, questions that were left blank or for which the participant answered, “I don’t know” were not included in the analysis. This may represent a response bias that is common among studies using self-reported data; however, for most questions this represented a small percentage of responses. Third, bias sampling may have led to an overrepresentation of certain subgroups. For instance, there were more women than men (2:1 for granulomatosis with polyangiitis and 4:3 for microscopic polyangiitis), despite the sex ratio in the general population being close to 1 for both diseases [1]. Internet-based participation in many surveys and studies is more common among women [18–20]. Age may also have been a factor in participation in this internet-based cohort. This appears to be less of an issue in this study which includes patients from across the age spectrum, including individuals older than 70 years. Fourth, the mode of survey response (internet) may have prevented some patients who lack access or higher education and since many of the participants were recruited through the Vasculitis Foundation, and it may also represent a bias toward participants who are savvier about their disease.

Conclusions

Granulomatosis with polyangiitis and microscopic polyangiitis are both rare (also known as orphan diseases), which makes clinical research for these disorders difficult and requires the use of multiple centers which can be financially and logistically challenging. Patient registries offer an alternative to the centers of excellence approach to conducting clinical research. The data reported herein for an internet-based cohort demonstrated the feasibility of such registries across broad geographic regions and the high level of comparability between an internet-based and traditional academic center-based participant populations. These data provide investigators and patients with confidence that internet-based patient-reported data are reliable and can be used to conduct novel, cost-efficient medical research. Such internet-based registries offer an advantage in capturing participant data from those who would not otherwise be able to participate in studies.

Acknowledgments

The Vasculitis Patient-Powered Research Network has received support from the Patient-Centered Research Institute (PCORI award PPRN-1306-04758) and through the Vasculitis Clinical Research Consortium. The Vasculitis Clinical Research Consortium is part of the Rare Diseases Clinical Research Network, an initiative of the Office of Rare Diseases Research, National Center for Advancing Translational Science. The Vasculitis Clinical Research Consortium is funded through a collaboration between National Center for Advancing Translational Science and the National Institute of Arthritis and Musculoskeletal and Skin Diseases (U54 AR057319).

Conflicts of Interest

Abstract

Background: In addition to the aging process, risk factors for hearing loss in adults include, among others, exposure to noise, use of ototoxic drugs, genetics, and limited access to medical care. Differences in exposure to these factors are bound to be reflected in the prevalence of hearing loss. Assessment of hearing loss can easily be carried out on a large scale and at low cost using mobile apps.

Objective: This study aimed to conduct a worldwide assessment of the differences in hearing loss prevalence between countries in a group of mobile device users.

Methods: Hearing tests were conducted using the open-access Android-based mobile app Hearing Test. The app is available free of charge in the Google Play store, provided that consent to the use of the results for scientific purposes is given. This study included hearing tests carried out on device models supported by the app with bundled headphones in the set. Calibration factors for supported models were determined using the biological method. The tests consisted of self-determining the quietest audible tone in the frequency range from 250 Hz to 8 kHz by adjusting its intensity using the buttons. The ambient noise level was optionally monitored using a built-in microphone. Following the test, the user could compare his hearing threshold against age norms by providing his or her age. The user's location was identified based on the phone's IP address.

Results: From November 23, 2016 to November 22, 2019, 733,716 hearing tests were conducted on 236,716 mobile devices across 212 countries. After rejecting the tests that were incomplete, performed with disconnected headphones, not meeting the time criterion, repeated by the same user, or carried out regularly on one device, 116,733 of 733,716 tests (15.9%) were qualified for further analysis. The prevalence of hearing loss, defined as the average threshold at frequencies 0.5 kHz, 1 kHz, 2 kHz, and 4 kHz above 25 dB HL in the better ear, was calculated at 15.6% (95% CI 15.4-15.8). Statistically significant differences were found between countries ($P < .001$), with the highest prevalences for Bangladesh, Pakistan, and India (>28%) and the lowest prevalences for Taiwan, Finland, and South Korea (<11%).

Conclusions: Hearing thresholds measured by means of mobile devices were congruent with the literature data on worldwide hearing loss prevalence. Uniform recruitment criteria simplify the comparison of the hearing loss prevalence across countries. Hearing testing on mobile devices may be a valid tool in epidemiological studies carried out on a large scale.

KEYWORDS

hearing loss; epidemiology; mobile-based; hearing test; pure-tone audiometry

Introduction

The worldwide prevalence of hearing loss is estimated to be between 4.0% and 18.1% [1-5], depending on the methodology, in particular the degree of hearing impairment used in the definition of hearing loss. Methodological differences also include the selection of data sources and calculation methods. Despite the uncertainty of the estimation, the scale of the burden is significant. Hearing loss is also an important problem because of its side effects. Due to communication disorders, hearing loss leads to decreased social activity, lower self-esteem, and consequently, stigmatization, social exclusion, and depression [6,7].

Apart from age, risk factors for hearing loss in adults include, but are not limited to, exposure to noise, use of ototoxic drugs, genetic conditions, infectious diseases, and limited access to medical care [5,8-12]. In view of increasing exposure to risk factors for hearing loss, in particular the aging population and increased exposure to noise in developing countries, the number of people with hearing loss has increased over the years [4,5,12].

Epidemiological analysis of hearing loss allows the identification of causes and planning of remedies [4,12]. Activities in the field of prevention and treatment of hearing loss are highly recommended, as it is estimated that 50% of hearing loss cases can be prevented and a significant portion of the remaining cases can be treated [4].

Worldwide geo-epidemiological investigations of hearing loss have been conducted in the form of meta-analyses of available data from different studies as a consequence of political, financial, cultural, and geographical limitations in the planning of uniform research on such a large scale [1-3,13]. Owing to the differences in study settings, in particular the differences in the definition of hearing loss, age groups, and method of participant recruitment, direct comparison of results is not possible, whereas indirect comparison is burdened with uncertainty resulting from sparse data adjustment [1-3,13].

Self-performed hearing tests on mobile devices can be easily carried out on a large scale and at low cost while maintaining a uniform qualification criterion. They are broadly accessible due to widespread use of smartphones, and they do not require engaging qualified personnel, while their results are comparable to pure-tone audiometry [14-23]. The difference in hearing threshold between the self-test in the Hearing Test app and pure-tone audiometry is estimated at 2.6 dB (SD 8.3 dB) [24], and the absolute difference is estimated at 8.8 dB [17].

The aim of this study was to assess the worldwide prevalence of hearing loss among Android users by means of the Hearing Test app [24,25] and compare the prevalence across countries.

Methods

Ethical Concerns

This was a cross-sectional study of hearing loss prevalence carried out by means of the open-access, mobile-based Hearing Test app [26]. Subject consent to use the results for scientific purposes was required the first time the app was started. The

consent to research was issued by the Bioethics Committee at the Medical University in Wrocław. Evaluation of the app, rationale behind the app, and comparison with other studies concerning mobile and web-based pure-tone hearing screening have been presented in prior articles [24,25,27,28].

Recruitment

The participants were recruited via the Hearing Test app that runs on Android systems. The app is offered free of charge in the Google Play store, where the user can become familiar with the app's features and download it to a phone or tablet. Thus, eligibility criteria for participants only included access to an Android device that is supported by the app. The test could be carried out by the phone owner or with his or her assistance.

Device Calibration

The study included tests carried out on mobile devices that supported the Hearing Test app for which calibration coefficients had been determined. All the tests in the study were carried out on bundled headphones that were supplied by the manufacturer in a set with the device. Devices of the same model used common calibration coefficients that were determined by the biological method [27,28] on the basis of at least 16 measurements carried out by subjects with normal hearing on different devices of the model [25]. This method is characterized by the standard error of determining the calibration coefficients below 5 dB and within-model variability at 4 dB [25]. The headphone connection status was monitored by the app, whereas the usage of bundled headphones was confirmed by the user. Tests taken using headphones other than bundled headphones were not taken into account.

Hearing Threshold

The hearing test consisted of self-determining the quietest audible sound by adjusting its intensity using the "I can hear" and "I can't hear" buttons. The intensity of a test tone could be changed many times. The quietest audible sound was confirmed with the "Barely audible" button. A modulated test tone was used, with a 100% modulation depth, 2 Hz modulation frequency, and an intensity changed in steps of 5 dB. When the intensity of the tone exceeded a 40 dB hearing level (HL), a narrowband masking noise was generated contralaterally at an intensity of 40 dB HL. For test tones above 60 dB HL, the intensity of the masking noise was increased to 60 dB HL. By default, the tests were carried out for frequencies from 250 Hz to 8 kHz; however, this range could be changed in the settings. The time to determine the hearing threshold was measured separately for each frequency. The hearing threshold determined in this way has been compared in previous works with pure-tone audiometry. A difference was found at the level of 2.6 dB (SD 8.3) [24], and the absolute difference was found at 8.8 dB [17].

Ambient Noise

Ambient noise was monitored during the measurement after obtaining the user's consent to access the microphone resources. An equivalent continuous A-weighted sound pressure level LAeq was registered in accordance with the Android specification [29] that sets a reference point at 90 dB SPL.

Age

At the end of the test, the users could optionally enter their age to compare the obtained hearing threshold against the age-based norm. By design, the app was developed for adults. Therefore, the user chose his or her age by selecting a value from 18-90 years. Providing the age was not obligatory for this study, to minimize the amount of potentially incorrect data. All the entered age values were recorded in the database to eliminate tests for which several different values were given. The age was also determined from the note, where it could optionally be given. User gender was not collected.

Geolocalization

The user's country was determined using the geoPlugin service [30] on the basis of the IP address.

Statistical Analysis

Power

Comparison of hearing loss prevalence between countries was conducted by adopting the definition of hearing loss as the average hearing threshold at frequencies 0.5 kHz, 1 kHz, 2 kHz, and 4 kHz above 25 dB HL in the better ear. The minimum number of tests for the country to be included in the analysis was calculated based on the standard deviation of the average hearing threshold determined in preliminary measurements at 17 dB. Assuming a level of statistical significance of .05, test power of .8, and an effect size of 5.0 dB, a sample size of 90 tests was obtained.

Data Exclusion

The tests in this study were unsupervised. Therefore, prior to analysis, they were verified for duration. A very short duration suggests unreliable results that can be manifested by an increased measurement error. To eliminate these tests, the standard deviation of the hearing threshold grand average was analyzed in relation to the test duration. Time threshold was set at the level at which stabilization of the standard deviation was observed. Incomplete tests, test carried out without headphones connected, and tests repeated on the same device were excluded as well.

Data Analysis

Both the subject's age and level of ambient noise during the test belong to data for which acquisition required additional action on the part of the user. Preliminary analyses have shown that these are sparse data compared to the hearing threshold,

geolocation, and device model. Therefore, the country-specific hearing loss prevalence was calculated based on all the tests, whereas the bias was estimated and discussed basing on subgroup analysis. The tests with age were used to characterize the population and analyze an age-related hearing threshold, while tests with noise were used to calculate the ambient noise effect. Distributions of hearing thresholds in the subgroups were tested for equivalence using the Kolmogorov-Smirnov test. Confidence intervals for the hearing threshold median and the hearing loss prevalence were determined by means of bootstrapping.

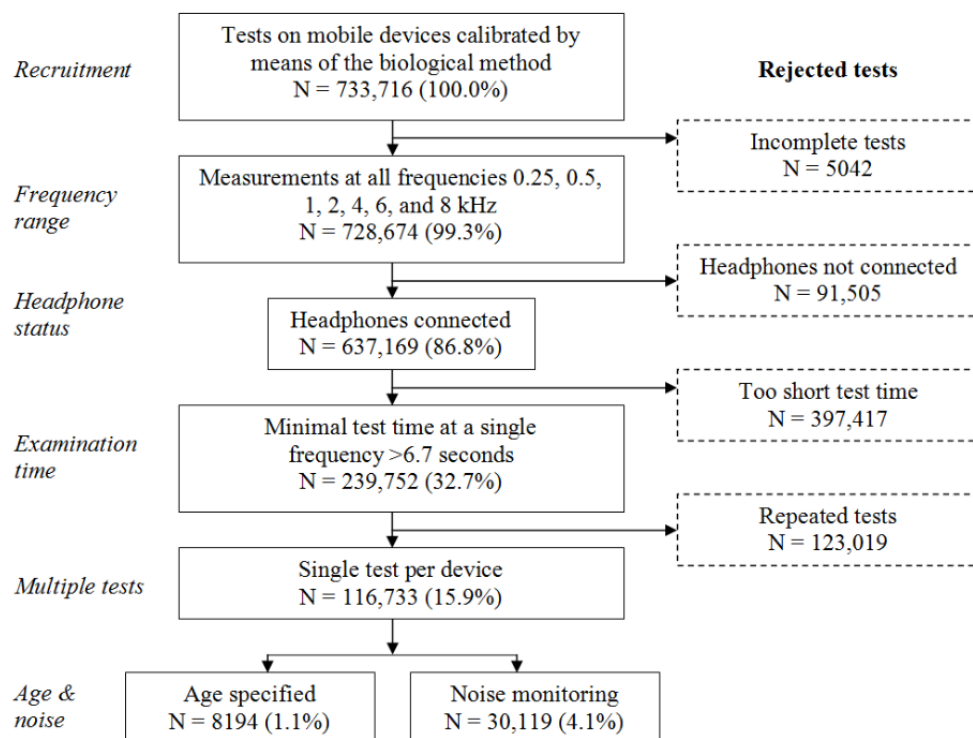

Results

Data Collection and Exclusion

In the period from November 23, 2016 to November 22, 2019, 733,716 tests were carried out on 236,716 devices in 212 countries. The hearing threshold measurement at the fundamental frequencies 0.25 kHz, 0.5 kHz, 1 kHz, 2 kHz, 4 kHz, 6 kHz, and 8 kHz was performed in 728,674 of 733,716 (99.3%) tests. After examining headphone connection status and rejecting the tests carried out with disconnected headphones, 637,169 of 733,716 (86.8%) tests were obtained (Figure 1).

Time limits were introduced to discard tests with a duration that actually prevented a correct measurement. The grand standard deviation of the hearing threshold in relation to the duration of the measurement at a single frequency is presented in Figure 2. Stabilization of the deviation is observed at longer durations. It has been assumed that tests in which the measurement at any frequency was carried out quicker than 6.7 seconds are subject to significant error. This threshold was set heuristically by fitting the data with a lognormal distribution and assuming its value at a cumulative probability density level of 0.99 (Figure 2). The time requirements were met by 239,752 of 733,716 (32.6%) tests.

Many devices were used for more than one test. To eliminate tests repeated by the same person or carried out in bulk (eg, in outpatient clinics or as part of screening programs) only one test from each device was qualified for the analysis. The last test was selected, at first considering the test with an age provided. Finally, 116,733 of 733,716 (15.9%) tests were obtained for the analysis. Age was provided for 8194 of 116,733 (7.0%) tests, and monitoring for ambient noise was present in 30,119 of 116,733 (25.8%) tests, whereas only 2556 of 116,733 (2.2%) tests included both age and noise data.

Figure 1. Flow diagram.**Figure 2.** Grand standard deviation of the hearing threshold in relation to the duration of the measurement at a single frequency.

Age

The subject's age was provided for 8194 of 116,733 (7.0%) tests that qualified for the analysis. The age characteristics of the research group is shown in Table 1. The age group with the highest number of tests was 30-39 years, while the fewest subjects were in the oldest groups (80-89 years and >89 years).

The median age was 39 years, and the average age was 40.0 years.

Tests with age provided were compared with those without age provided to estimate the bias resulting from the generalization of the results for the whole group. There were no statistically significant differences between the distributions of the hearing thresholds at the level of $P=.05$.

Table 1. Ages of the participants (n=8194).

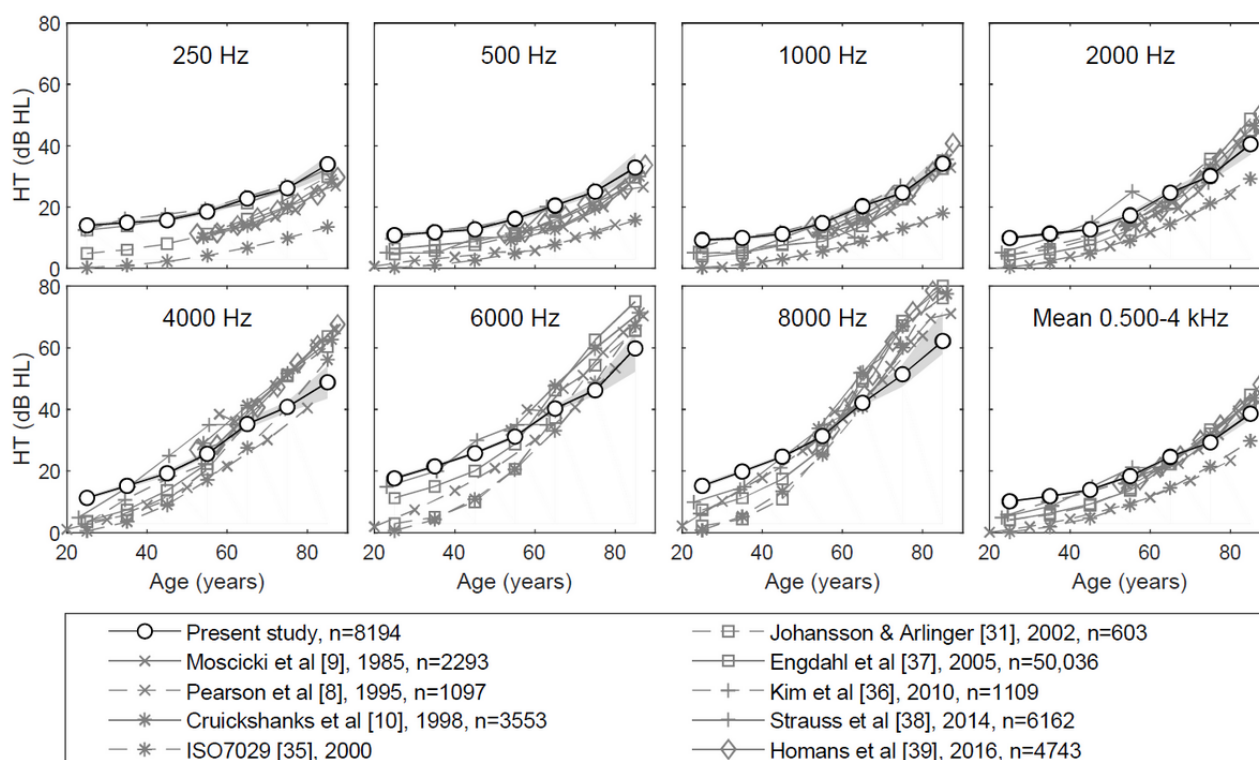

Age characteristics	Participant values
Age (years), mean (SD)	40.0 (15.1)
Age (years), median	39
Age (years), n (%)	
<20	842 (10.3)
20-29	1597 (19.5)
30-39	1813 (22.1)
40-49	1725 (21.1)
50-59	1227 (15.0)
60-69	655 (8.0)
70-79	253 (3.1)
80-89	62 (0.8)
>89	20 (0.2)

Hearing Threshold

Hearing threshold in relation to age was analyzed based on all 7332 of 116,733 (6.3%) tests for which the age provided was within the range of 20 to 89 years. Tests completed by subjects aged 18, 19, or 90 years were omitted from the analysis to obtain equal age ranges (20-29 to 80-89 years). Moreover, the ages of 18 and 90 years were characterized by a higher number of tests

in comparison with the adjacent age groups, suggesting the presence of additional data, such as results for subjects younger than 18 years or older than 90 years, or with incorrectly provided data. The median thresholds by age group and frequency are given in [Figure 3](#) and in [Multimedia Appendix 1](#). A comparison with the prior work presented in [Figure 3](#) is provided in the Discussion section.

Figure 3. Hearing threshold by age group and frequency. Dashed lines indicate screening studies including screening only for noise exposure [31], and continuous lines show studies without screening. The grey area illustrates the 99% CI.

Country Prevalence of Hearing Loss

The prevalence of hearing loss was determined based on 733,716 tests conducted in 212 countries. The required sample size of

90 tests was reached for 74 countries. The prevalence of hearing loss, defined as a mean hearing threshold >25 dB HL in the better ear at 0.5-4 kHz, is presented in [Figure 4](#), [Figure 5](#), and

Multimedia Appendix 2. The highest prevalences were obtained for Pakistan, Bangladesh, and India at 37.8% (95% CI 31.4-44.2), 32.2% (95% CI 23.6-40.8), and 28.5% (95% CI 27.1-29.9), respectively, whereas the lowest prevalences were

obtained for Taiwan, Finland, and South Korea at 9.6% (95% CI 7.2-12.1), 9.8% (95% CI 5.7-13.9), and 10.2% (95% CI 9.5-10.9), respectively. The global prevalence of hearing loss was calculated at 15.6% (95% CI 15.4-15.8).

Figure 4. The prevalence of hearing loss by country. Hearing loss was defined as an average hearing threshold >25 dB hearing level (HL) in the better ear at frequencies of 0.5 kHz, 1 kHz, 2 kHz, and 4 kHz. Whiskers indicate 95% CI. Countries with >1000 tests or with boundary values of hearing loss prevalence are included. The full list is available in [Multimedia Appendix 2](#). ppm: number of individuals per million people in the population.

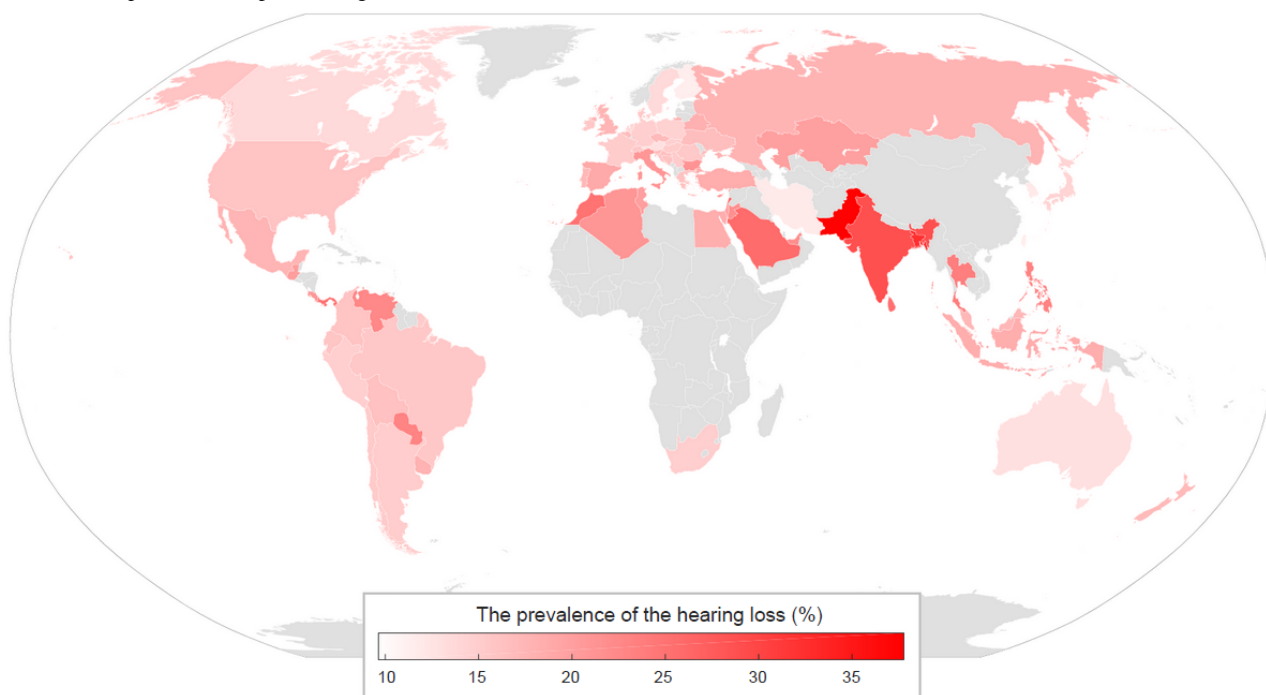

Figure 5. Global prevalence map of hearing loss.

Effect of Ambient Noise

The effect of ambient noise was estimated based on 30,119 of 116,733 (25.8%) tests conducted with ambient noise monitoring. The difference in the hearing threshold in relation to the ambient

noise level is presented in [Figure 6](#). Hearing thresholds were adjusted for ambient noise by assuming the reference level LAeq=35 dB(A) [32]. The average decrease in the hearing threshold was obtained at a level of 2.53 dB (SD 0.74 dB). Additionally, the distributions of the hearing threshold in the

groups with and without ambient noise monitoring turned out to be significantly different at the level of $P<.001$, with the monitoring group having a hearing threshold that was lower by 1.25 dB (SD 0.12 dB). This produces an overall effect of ambient noise of 3.78 dB (SD 0.75 dB), which corresponds to a 4.16% (SD 1.46%) reduction in the country-specific prevalence.

The highest ambient noise levels were found in Pakistan, Bangladesh, and India, which corresponded to 10.7%, 8.6%, and 6.2% decreases, respectively, in the prevalences of hearing loss. Nevertheless, these countries still had the highest prevalences of hearing loss.

Figure 6. The difference in hearing threshold in relation to ambient noise level.

Effect of the Device Model

Differences in hearing thresholds between device models were found to be significant at the level of $P=.01$. These differences result directly from the biological calibration method that is based on determination of the reference sound level in relation to subjects with normal hearing. The standard error of the biological calibration estimated at 4.2 dB for 16 independent measurements [25] justifies the discrepancies. After adjusting for the device model, the mean hearing threshold by country changed by a mere -0.07 dB (SD 0.96 dB).

Discussion

Principal Findings

This paper presents the prevalence of hearing loss worldwide based on the 116,733 hearing tests conducted by Android users on mobile devices. The global prevalence of hearing loss was 15.6% (95% CI 15.4-15.8). Statistically significant differences were found across countries ($P<.001$). Of the 212 countries, 74 countries exceeded the number of tests required for the assumed sample size. Amongst these countries, the highest prevalences were found in Pakistan, Bangladesh, and India at 37.8% (95% CI 31.4-44.2), 32.2% (95% CI 23.6-40.8), and 28.5% (95% CI 27.1-29.9), respectively, whereas the lowest prevalences were found in Taiwan, Finland, and South Korea at 9.6% (95% CI 7.2-12.1), 9.8% (95% CI 5.7-13.9), and 10.2% (95% CI 9.5-10.9), respectively. The risk of hearing loss in Pakistan was

74.6% (95% CI 38.2-110.7) higher than in Taiwan. The absolute difference was 28.2% (95% CI 14.4-41.8).

Of the 733,716 tests, 116,733 (15.9%) were selected for the analysis. The number of tests rejected due to incompleteness, short duration, lack of headphones, or repetitions on a single device seems reasonable, especially as prior to performing a proper test, users often become familiar with the app by conducting a trial test.

In addition to Finland, relatively low hearing loss values were obtained for the other two Scandinavian countries, Sweden and Norway, at 12.1% (95% CI 8.4-15.9) and 12.7% (95% CI 8.1-17.4), respectively. The prevalences of hearing loss for the other two Asian Tigers (ie, Singapore and Hong Kong) were slightly higher, at 14.6% (95% CI 10.0-19.2) and 15.3% (95% CI 10.3-20.4), respectively. The high prevalence of hearing loss in India, which, along with Pakistan and Bangladesh, is one of the most populated countries in the world, is supported by the findings of Garg et al [33]. Similar hearing loss prevalences were found in most Western and Central European countries, which were slightly higher than Australia (11.4%, 95% CI 9.8-13.0) and Canada (12.2%, 95% CI 10.4-13.9) but lower than that in the United States (14.6%, 95% CI 13.9-15.4). Similar prevalences of hearing loss were obtained among the countries of the former Soviet Union (ie, Russia, Belarus, Ukraine, and Kazakhstan), at levels between 15.4% (95% CI 12.9-17.9) for Ukraine and 18.9% (95% CI 14.3-23.6) for Kazakhstan.

In Italy, 20.0% (95% CI 19.3-20.7) of the subjects had hearing loss, and this value was definitely higher than in the other Western and Central European countries. The credibility of this result is questionable due to the much higher use of apps in this country, being the highest in the world and reaching 222.3 people per million population (Multimedia Appendix 2). Attention should also be paid to the low Iranian result of 10.3% (95% CI 7.8-12.7), which significantly differs from other countries of North Africa and the Middle East. On the other hand, according to a study by the World Health Organization [5] in the region of North Africa and the Middle East, the prevalence of hearing loss is lower than in developed countries.

The required sample size was not reached in a significant number of African countries. In the poorest countries, the limiting factor is access to mobile devices and the internet. The same situation may also occur in countries with significant social stratification, contributing to the lower prevalences of hearing loss resulting from a lack of data from the poorer part of the population. The lack of data from China is related to the lack of active Google Play service in this country.

The prevalence of hearing loss in countries has been correlated with the infant mortality rate [34], which is often used as an indicator of the health status in a country. A Cronbach alpha coefficient of 0.76 (95% CI 0.52-0.90) has been obtained.

Comparison With Prior Work

Age-Related Hearing Loss

Age related hearing loss assessed by means of the mobile app was compared with the results from other studies [8-10,31,35-39] (Figure 3). The hearing threshold in subjects screened negatively for noise exposure [8,31,35-37], otologic disorders [8,35-37], ototoxic drugs [8,36], and asymmetric hearing [8,36,37] tends to be lower than that obtained in this study and prior unscreened studies [9,10,37-39]. However,

substantial differences have been found between studies; although the threshold in the study by Kim et al [36] was higher than those in the studies by Engdahl et al [37] and Homans et al [39], it should have actually been lower because Kim et al conducted screening, while the other 2 studies did not [37,39]. In this study, for younger age groups (20-49 years), especially at low frequencies (250 Hz, 500 Hz), hearing thresholds were higher than in most previous studies. The results obtained at 250 Hz are consistent with those found by Kim et al [36] and Engdahl et al [37], while at 500 Hz, the results were consistent only with those found by Kim et al [36]. At frequencies above 4 kHz for older age groups (>70 years), the thresholds were lower than the values reported in the literature. Apart from the two youngest age groups (20-39 years) and the oldest age group (80-89 years), agreement with most studies was achieved for the average hearing threshold at the frequency range 0.5-4 kHz.

Increased hearing thresholds in younger age groups may be associated with a tendency for hearing-impaired subjects to take a test more willingly than people with normal hearing as well as with increased ambient noise, which mainly affects soft sounds. Lower values for the oldest groups might be related to an incorrect reaction to the masking noise. The effect of ambient noise and the masking noise is discussed in the Limitations section.

Hearing Loss in the World

The prevalence of hearing loss among users of the Hearing Test app may differ from population values, at least as regards the age structure. However, the value was compared with worldwide estimates. Figure 7 presents the worldwide prevalence of hearing loss with respect to the criterion based on the average hearing threshold in the better ear at frequencies 0.5-4 kHz. Despite statistically significant differences between the obtained results and other studies [1,2,4,5], the data are consistent.

Figure 7. Worldwide prevalence of hearing loss with respect to the criterion based on the average hearing threshold in the better ear at frequencies 0.5-4 kHz. Separate thresholds for adults (40 dB hearing level [HL]) and children (30 dB HL) in the study by the World Health Organization [5].

Country-Specific Studies

The prevalence of hearing loss was also compared with other studies. Calculations were performed by adopting the criteria for hearing loss and matching age ranges ([Multimedia Appendix 3](#)). The prevalence of hearing loss was lower in previous studies [11,16,40-45], pursuant to at least one criterion in research [9,10,46,47], and was higher in other articles [39,48-52]. There is large variation within the data presented in the literature, which may result not only from age structure differences and heterogeneous hearing loss definitions but also from research methodology, especially trial-specific recruitment methods or exclusion criteria. Therefore, drawing conclusions regarding country differences in the prevalence of hearing loss by means of literature data is challenging, as it requires the use of estimation methods in the presence of sparse data [2,3,13]. In this aspect, for country comparison, mobile data seem more valuable than a meta-analysis, although other confounding factors such as cultural background, propensity to new technologies, economic status, or app promotion should be underlined here as well.

Limitations

Masking Noise

Hearing thresholds for older groups at a frequency ≥ 4 kHz are lower than those reported in the literature ([Figure 3](#)). A histogram for these groups reveals an increased number of hearing thresholds at intensities of 40 dB HL and 45 dB HL ([Figure 8](#)). This bias could be related to the masking noise. Contralateral masking noise was switched on when the signal level exceeded 40 dB HL. Thus, some of the subjects could react incorrectly to the masking noise instead of the test signal. The higher the mean threshold in a group at a given frequency, the more subjects might react incorrectly to the masking noise, thus leading to an understatement of the threshold. The lapses are rare for a low mean, and the bias is not detectable until the mean threshold reaches 40 dB. Therefore, the bias is observable in a limited range at 4 kHz (older groups only) and is unnoticeable at lower frequencies. Consequently, its impact on the average hearing threshold at 0.5-4 kHz is negligible, and the prevalence of hearing loss largely coincides with data reported in the literature. Nonetheless, in the future, changes should be introduced to the app that will prevent improper reaction to the masking noise.

Figure 8. Hearing thresholds for subjects ≥ 60 years old at frequencies ≥ 4 kHz. The striped areas indicate the bias related to the masking noise that was enabled for stimuli >40 dB hearing level (HL). A lognormal distribution was assumed.

Ambient Noise

Ambient noise was recorded using a built-in microphone with a working range of 72-102 dB SPL, as guaranteed by the Android specification [29]. Since the measurements were carried out outside this range, they should be treated as approximate. Nevertheless, the results obtained are comparable with data reported in the literature. Elevation of the hearing threshold as a result of an increase in ambient noise from 35 dB LAeq to 60 dB LAeq was estimated at 8.0 dB ([Figure 6](#)), which agrees with the elevation of about 7.5 dB presented by Na et al [53].

A relatively low elevation of the hearing threshold related to a considerable increase in ambient noise may be associated with the measurement method applied in this study and in the study by Na et al [53]. Instead of being ready for the test signal during the whole test, the subject decides for herself or himself about the duration of the test signal presentation and can extend it during an event of louder noise. Subjects who spent sufficient time performing the test were able to assess the quietest signals during a temporary decrease in ambient noise.

The effect of ambient noise on hearing test results was determined assuming that the increase in hearing threshold caused by ambient noise is conditioned by the masking of the

test signal by the noise. However, for significant hearing losses, ambient noise values above the normative level need not mask the loud test signal. Therefore, it must be assumed that the effect is present only for soft test signals and the estimated level for the effect of 3.78 dB (SD 0.75 dB) found in the present study should actually be treated as its upper limit. For these reasons, the results broadly correspond to pure-tone audiometry (Figure 3) despite ambient noise often exceeding the normative value for the audiometry.

Calibration

Mobile devices were calibrated using the biological method (ie, in relation to subjects with normal hearing). This method is less accurate than laboratory calibration. However, it enables semi-automatic calibration, which is crucial for as many as 1336 models. Because the tests were conducted on diverse device

models in each country, the error associated with calibration has limited impact on differences between country-specific hearing loss prevalences.

Conclusions

This paper presents global country-specific prevalences of hearing loss based on self-tests carried out by Android users. Unsupervised self-tests require additional quality control based on the test duration and connection status of the headphones. Moreover, ambient noise and calibration method introduce additional bias. Despite this, hearing thresholds measured by means of mobile devices were congruent with data reported in the literature, whereas uniform recruitment criteria facilitate the comparison between countries. Hearing tests on mobile devices may be a valid tool in epidemiological studies carried out on a large scale.

Abstract

Background: The number of online services in health care is increasing rapidly in developed countries. Users are expected to take a more skilled and active role in taking care of their health and prevention of ill health. This induces risks that users (especially those who need the services the most) will drop out of digital services, resulting in a digital divide or exclusion. To ensure wide and equal use of online services, all users must experience them as beneficial.

Objective: This study aimed to examine associations of (1) demographics (age, gender, and degree of urbanization), (2) self-rated health, (3) socioeconomic position (education, experienced financial hardship, labor market position, and living alone), (4) social participation (voting, satisfaction with relationships, and keeping in touch with friends and family members), and (5) access, skills, and extent of use of information and communication technologies (ICT) with perceived benefits of online health care and social welfare services. Associations were examined separately for perceived health, economic, and collaboration benefits.

Methods: We used a large random sample representative of the Finnish population including 4495 (56.77% women) respondents aged between 20 and 97 years. Analyses of covariance were used to examine the associations of independent variables with perceived benefits.

Results: Access to online services, ICT skills, and extent of use were associated with all examined benefits of online services. ICT skills seemed to be the most important factor. Poor self-rated health was also consistently associated with lower levels of perceived benefits. Similarly, those who were keeping in touch with their friends and relatives at least once a week perceived online services more often beneficial in all the examined dimensions. Those who had experienced financial hardship perceived fewer health and economic benefits than others. Those who were satisfied with their relationships reported higher levels of health and collaboration benefits compared with their counterparts. Also age, education, and degree of urbanization had some statistically significant associations with benefits but they seemed to be at least partly explained by differences in access, skills, and extent of use of online services.

Conclusions: According to our results, providing health care services online has the potential to reinforce existing social and health inequalities. Our findings suggest that access to online services, skills to use them, and extent of use play crucial roles in perceiving them as beneficial. Moreover, there is a risk of digital exclusion among those who are socioeconomically disadvantaged, in poor health, or socially isolated. In times when health and social services are increasingly offered online, this digital divide may predispose people with high needs for services to exclusion from them.

Introduction

Background

The number of online services in health care is increasing rapidly in Finland and other developed countries. The new online services are implemented and adopted to support self-management and self-service, and thus users are expected to take a more skilled and active role in maintaining their well-being, health, and especially long-term illnesses. To ensure that users increase participation in online services, it is important that they find that online services are beneficial for them [1].

There are risks that users (especially those people who need the services most) will drop out of online services resulting in a digital divide or exclusion. The concept of digital divide has traditionally referred to the gap between persons who have and do not have access to new forms of information technology [2]. Limits to access can have motivational, physical, skills, or use grounds [3]. Nonuse of online digital services can have psychological (motivation, confidence, and experienced attractiveness of use), physical (opportunity to use), or practical (lack of skills) causes [4]. As the internet has diversified and diffused widely over the past 10 years, it is assumed that internet nonuse is, at present, far more common among vulnerable groups and that lack of access has become a less important reason for internet nonuse compared with lack of skills [5].

The digital divide or exclusion affects the poorest and most marginalized groups from the outset [6]. The internet reinforces existing social differences, and internet nonusers are reported to be older and less educated and more likely to be unemployed, disabled, and socially isolated [7]. Sociodemographic, economic, and geographical factors have been found to be key determinants of digital exclusion [8]. Among urban adults, the discriminating factors between computer users and nonusers include age, education, employment, and income, self-rated health status, hospital visits, organization membership, and participation in voluntary work [9].

A previous study from the Netherlands showed that the elderly benefit less from internet use than the young [5]. Moreover, those less educated and poorer gained fewer economic benefits from the internet than their counterparts, and single people gained fewer social benefits than those living with others [5]. A study from the United Kingdom found that more educated people benefit most from internet use [10]; surprisingly, the elderly benefited more than the young. In Germany, it was found that enabling and caring support through the internet was associated with job search benefits among the unemployed [11].

Social and digital exclusion are interlinked: differential access to technology contributes to socioeconomic stratification or inclusion and vice versa [12]. The debate has moved from a single digital divide to multiple digital divides that include not only global challenges but also local contextual problems in terms of availability of content, bandwidth, and skills, among other issues [13]. Helsper's [14] corresponding fields model suggests that digital and social exclusion influence one another and the resources a person has offline influence their ability to use digital online solutions. Consequently, client and patient

resources influence adoption and sustained use of new digital online health services. Therefore, socioeconomic factors, social participation, health status, and well-being have potential effects on digital divide or exclusion. Only by studying these together can we identify the separate and combined influences of different types of social exclusion on different types of digital exclusion. The model characterizes access and skills as important social impact mediators in this context. Without access, the internet or other information and communication technologies (ICT) cannot be used, which makes access the most basic mediator between offline and digital fields of exclusion. Similarly, certain skills on a basic technical and operational level are required for the use of ICT and the internet [14].

Aceto et al [15] have suggested that ICT in health care decreases costs, enables discovery, and improves patient outcomes. Moreover, ICT is proposed to extensively transform health care to being more proactive, preventive, and person-centered instead of being reactive and hospital-centered [15]. To fully take advantage of all the suggested benefits of ICT, patients must use online services and find them beneficial. We need to understand why people choose not to take advantage of the opportunities ICT offers for managing their health and define the characteristics of people who are most likely to benefit and those at risk of exclusion.

Research focus should shift from access to digital technology (first-level divide) to skills and use of technology (second-level divide) and who benefits the most or least from internet use (third-level divide) [16,17]. Third-level digital divide refers to gaps in capacity to translate individual internet access and use into favorable offline outcomes [5]. Research related to the third-level divide and its social determinants is scarce [17], and the role of access, skills, and extent of use in this context must be identified. Previous studies [4,7,8] have focused on general use of the internet, but information about determinants of using the internet for health care and social welfare services is lacking and must be identified because these vital services are increasingly moving online.

Objectives

This study aimed to examine direct associations of demographics (age, gender, degree of urbanization), self-rated health, socioeconomic position (education, experienced financial hardship, labor market position, and living alone) and social participation (voting, satisfaction with relationships, and keeping in touch with friends and family members) with perceived benefits of online health care and social welfare services (health, economic, and collaboration benefits). The study data are based on a large random sample representative of the Finnish population. Furthermore, we examined the effects of access, skills, and the extent of ICT use and whether these could account for those associations.

Methods

Sampling

The data collection and questionnaire formulation have been reported in more detail elsewhere [18]. A random sample of 10,000 people representative of the adult population (aged 20

years and older) living in Finland was collected from the Population Register Center of Finland. For those aged 75 years and older, double picking probability was used in order to guarantee sufficient group size. The questionnaire ([Multimedia Appendix 1](#)) was sent by postal mail to all sampled persons in 2017 with instructions on how to respond online. Reminders were sent 3 times to those who had not responded. The response rate was 44.95% (4495/10,000), with 56.77% (2552/4495) being women. The respondents were older, more often women, and had more education than the eligible population [18], and we addressed this by applying inverse probability weighting based on age, gender, marital status, education level, living region, and degree of urbanization of the residential municipality. This method has been used previously in many Finnish population studies, and it has been found to perform well in correcting possible effects of nonresponse on representativeness of the results [19].

Setting

Finland is among the leading countries in digitalization of health care and social welfare services. The country has launched nationwide integrated data services for health care and social welfare services, the Kanta services, in several steps from May 2010 onward [20,21]. Kanta services are targeted to citizens, health care and social welfare service providers and professionals, and community pharmacies. Kanta services include electronic prescribing (Prescription Centre), patient-accessible electronic health records (My Kanta Pages), health records (Patient Data Repository), and the client data archive for social welfare services. It is mandatory for all health care providers, public or private, to subscribe to and use the national Kanta services. Implementation and adoption of Kanta services for social welfare started in May 2018 and is currently ongoing. In addition to national comprehensive undertakings, at least two other nationwide digital service projects (Health Village 2.0 and Digisote [former ODA]) have been developed, implementing a large number of new online health and welfare services. In particular, these services have focused on supporting clients to self-manage their health and well-being online. Moreover, service providers such as hospital districts and primary health care centers provide regional and local electronic online services such as booking services, electronic consultations, and web-based question-answer services, etc [22].

Measurements

Dependent Variables

Benefits of online health and social care services were measured with 3 scales on perceived health, economic, and collaboration benefits. Health benefits were measured with 6 items such as “online services help citizens self-manage their health/well-being.” Cronbach alpha for this scale was $\alpha=.90$. Economic benefits included 4 items ($\alpha=.87$) such as “online services provide useful reminders (eg, the time of reception, laboratory tests, renewing prescriptions etc).” Collaboration benefits included 3 items ($\alpha=.86$) such as “online services support the collaboration and information flow between the patient/client and carer.” All items were rated on a 5-point Likert scale ranging from 1 (completely disagree) to 5 (completely agree), and the mean for each scale was calculated.

Independent Variables

Demographics included age in years, gender (male or female), and degree of urbanization of the residential municipality (urban, semiurban, or rural area). Health status was measured by asking how respondents would describe their state of health at present (with answer alternatives good, fairly good, average, fairly poor, poor). For analyses, it was coded 0 (above average health) or 1 (average health or poorer).

Indicators of socioeconomic position were education, classified into 3 categories (low, intermediate, or high) by setting the self-reported years of education in proportion to the tertiles of education years in each respondents' age and gender group (using 10-year age groups); financial hardship, assessed by asking whether respondent had been forced to bargain for food, medication, or physician visits due to shortage of money during the previous 12 months (none or yes to at least one of these); current labor market position (currently working, old age pension, disability pension, unemployed, student, or other); and living alone (no or yes).

Indicators of social participation were voted in last municipal elections (no or yes), satisfaction with one's social relationships (no or yes), and keeping in contact with friends and relatives outside the own household at least once a week (no or yes).

ICT-related variables included access to, skills to use, and extent of use related to online services in health and social care. Access to online services was measured by 7 items ($\alpha=.84$) asking availability of online services, access to computer and internet, quality of data connections, possibility of getting online services in their own language, accessibility of services despite obstacles (eg, disabilities), ease of finding online services, and possibility of taking care of things online on behalf of someone else. Skills to use online services were measured with 5 items ($\alpha=.86$) assessing technical skills to use online services, support received for using online services, possibility of receiving help when facing technical problems, experienced clearness and length of terms of use, and perceived ease of using online services. The response options for access and skills scales ranged between 1 (completely disagree) and 5 (completely agree), and the mean of the items was calculated for both scales. The extent of use of online services in health and social care was measured with 16 items asking whether the respondent had used described service/functionality during the past year (response options no, yes traditionally, or yes online). The functionalities/services were related to self-care (3 items assessing, for example, whether the respondent had used online symptom checkers or followed own personal health data online), use for collaboration (8 items such as whether respondent has viewed the patient data recorded by professionals about them, received laboratory results, renewed prescriptions, or asked advice from professionals), and seeking out services (5 items assessing, for example, whether the respondent had searched for information about available services, booked appointment, or compared quality of services). The sum of functionalities/services a respondent had used online was calculated, resulting in a range of 0 to 16 functionalities (extent of use).

Ethical Issues

Ethical approval for the study was received from the research ethics committee of the Finnish Institute for Health and Welfare. Data were collected with no direct identification information concerning the respondents, and therefore no individuals can be identified from the data.

Statistical Analysis

Associations of independent variables with outcome variables related to perceived benefits (health, economic, and collaboration) were examined using analysis of covariance (in separate analyses). Analyses were conducted in 3 steps. In the first step, analyses included demographics (age, gender, and degree of urbanization) and health status (model A). In the second step, variables related to socioeconomic position (education, experienced financial hardship, labor market position, living alone) and variables related to social participation (voting, satisfaction with relationships, and keeping in touch with friends and family members) were added to the model (model B). In model C, ICT-related variables concerning access, skills, and the extent of use were added. Skills and access were examined in separate analyses to avoid multicollinearity because they correlated with each other. Analyses were

conducted in these steps to examine the independent effect of each of the demographic and socioeconomic variables on each of the perceived benefits and whether ICT-related variables would partly account for possible associations of the independent variables from models A and B with outcome variables. Analyses were conducted using SPSS Statistics version 25 (IBM Corp). Methods suitable for weighted data were used (ie, complex samples general linear model for analyses of variance and complex samples descriptives and frequencies for descriptive statistics).

Results

Characteristics of Respondents

The characteristics of the study population are presented in [Table 1](#). The mean age of the respondents was 51.7 years, more than 70% (3201/4494, 71.23%) lived in urban regions, and about half (2160/4495, 48.08%) were employed. Those respondents having low education comprised the largest group. Approximately two-thirds (3054/4495, 67.94%) of the respondents had used at least one of the online health or social services and functionalities under study.

Table 1. The basic background characteristics of the weighted study sample (n=4495).

Characteristics	Value
Gender^a, n (%)

^dRange: 1-5.

^eRange: 0-16.

Perceived Health Benefits

Table 2 shows results regarding perceived health benefits. In model A, age and self-rated health were significantly associated with perceived health benefits. Older respondents and those with poor health perceived fewer health benefits from online services. The association of health to perceived benefits remained significant after all adjustments, whereas the association regarding age attenuated to nonsignificant after adjusting for ICT-related variables. In model B, education, financial hardship, satisfaction with relationships, and keeping in touch with friends and relatives were all significantly associated with health benefits. Compared with other

respondents, perceived health benefits were higher among those who were satisfied with their relationships and were keeping in touch with their friends and relatives, whereas health benefits were lower among those who had experienced financial hardship. Those having high education (estimated mean [EM] 3.64 [SE 0.04]) or intermediate education (EM 3.62 [SE 0.04]) perceived more health benefits compared with those having low education (EM 3.48 [SE 0.04]). Other associations persisted after adding the ICT-related variables, whereas education did not remain significant after that. In model C, higher levels of access, skills, and extent of use were all associated with higher levels of perceived health benefits. R^2 of model C was .16.

Table 2. Association of explanatory factors with perceived health benefits (analysis of covariance, n=4495).

Variable	Model A		Model B		Model C	
	<i>F</i> score (<i>df</i>)	<i>P</i> value	<i>F</i> score (<i>df</i>)	<i>P</i> value	<i>F</i> score (<i>df</i>)	<i>P</i> value
Gender	0.84 (1)	.36	1.06 (1)	.30	2.61 (1)	.11
Age	37.93 (1)	<.001	11.48 (1)	.001	1.70 (1)	.19
Urbanization	1.09 (2)	.34	1.11 (2)	.33	1.79 (2)	.17
Self-rated health	53.33 (1)	<.001	16.24 (1)	<.001	1.94 (1)	.001
Education	—	—	1.70 (2)	<.001	2.74 (2)	.07
Financial hardship	—	—	5.97 (1)	.02	6.17 (1)	.01
Labor market position	—	—	1.02 (5)	.40	0.77 (5)	.57
Living alone	—	—	0.00 (1)	.97	0.37 (1)	.54
Voting	—	—	3.06 (1)	.08	8.15 (1)	.004
Relationships	—	—	8.52 (1)	.004	6.75 (1)	.009
Keeping in touch	—	—	17.91 (1)	<.001	9.27 (1)	.002
Access	—	—	—	—	51.43 (1)	<.001
Skills	—	—	—	—	109.76 (1)	<.001
Extent of use	—	—	—	—	43.02 (1)	<.001

Perceived Economic Benefits

Table 3 shows the results regarding perceived economic benefits. In model A, age, degree of urbanization, and health status were significantly associated with perceived economic benefits. Older respondents and those with poor health perceived fewer economic benefits compared with their counterparts. Those living in urban areas perceived more economic benefits (EM 4.1 [SE 0.02]) than those living in semiurban (EM 3.9 [SE 0.04]) or rural areas (EM 4.0 [SE 0.04]). The association of benefits with health remained significant after all adjustments, whereas the association with age attenuated to nonsignificant after model B adjustments and with urbanization after adding ICT-related variables. In model B, education, financial hardship, and keeping touch with friends and relatives were all significantly associated

with perceived economic benefits. Those having high (EM 3.94 [SE 0.05]) or intermediate (EM 3.96 [SE 0.04]) education perceived more economic benefits compared with those having low education (EM 3.83 [SE 0.04]). Perceived economic benefits were higher among those who were keeping in touch with their friends and relatives and lower among those who had experienced financial hardship. The associations of economic benefits with financial hardship and keeping in touch with friends and relatives remained significant in all analyses, whereas the association with education attenuated to nonsignificant after adjusting for ICT-related variables. In model C, higher levels of access, skills, and extent of use were all associated with higher levels of perceived economic benefits. R^2 of model C was .14.

Table 3. The association of explanatory factors with perceived economic benefits (analysis of covariance, n=4495).

Skills	—	—	—	—	93.14 (1)	<.001
Extent of use	—	—	—	—	54.10 (1)	<.001

Perceived Collaboration Benefits

Table 4 shows the results regarding perceived collaboration benefits. In model A, age and health status were significantly associated with collaboration benefits. Older respondents and those with poor self-rated health perceived fewer collaboration benefits. The association between health and perceived collaboration benefits remained significant after all adjustments, whereas the association with age attenuated to nonsignificant after adjusting for ICT-related variables. In model B, satisfaction

with relationships and keeping in touch with friends and relatives were both significantly associated with collaboration benefits. Perceived collaboration benefits were higher among those who were satisfied with their relationships and those who were keeping in touch with their friends and relatives. These associations remained significant even after adjusting for ICT-related variables. In model C, higher levels of access, skills, and extent of use were all associated with higher levels of perceived collaboration benefits. R^2 of model C was .15.

Table 4. The association of explanatory factors with perceived collaboration benefits (analysis of covariance, n=4495).

Variable	Model A		Model B		Model C	
	<i>F</i> score (<i>df</i>)	<i>P</i> value	<i>F</i> score (<i>df</i>)	<i>P</i> value	<i>F</i> score (<i>df</i>)	<i>P</i> value
Gender	0.20 (1)	.65	0.00 (1)	.99	0.38 (1)	.54
Age	24.46 (1)	<.001	4.55 (1)	.03	0.00 (1)	.99

Access	—	—	—	—	56.14 (1)	<.001
Skills	—	—	—	—	111.77 (1)	<.001
Extent of use	—	—	—	—	38.90 (1)	<.001

Additional Analyses

Given that ICT-related variables attenuated the association of age, education, and urbanization to nonsignificant, we additionally examined the associations between these variables and access, skills, and extent of use in separate analyses of variance. All associations were statistically highly significant. Older respondents reported lower levels of access ($F_1=842.8$, $P<.001$), skills ($F_1=1069.5$, $P<.001$), and extent of use ($F_1=266.2$, $P<.001$) compared with younger respondents. Those who were living in urban areas reported higher levels of access ($F_2=37.2$, $P<.001$), skills ($F_2=35.7$, $P<.001$), and extent of use ($F_2=29.9$, $P<.001$) compared with those living in semiurban or rural areas. Those with a low education level reported lower levels of access ($F_2=47.5$, $P<.001$), skills ($F_2=39.4$, $P<.001$), and extent of use ($F_2=36.1$, $P<.001$) compared with those having intermediate or high education.

Discussion

Principal Findings

This study examined the associations of demographics, health, socioeconomic position, social participation, and ICT variables with perceived benefits of using online services. We found that access to online services, ICT skills, and extent of use were consistent factors associated with all examined benefits (ie, with perceived health, economic, and collaboration benefits). ICT skills seemed to be the most important factor. Moreover, self-rated poor health was consistently associated with lower levels of perceptions of each of the benefits examined. Experienced financial hardship seemed to be the most important indicator of socioeconomic position, given that poor people who reported having been forced to bargain for basic needs such as food, medication, or physician visits due to financial constraints perceived fewer health and economic benefits from online services. Dimensions of social participation were also highly relevant to perceived benefits. Those who were keeping in touch with their friends and relatives at least once a week perceived online services beneficial regarding all dimensions examined. Those who were satisfied with their relationships reported higher levels of health and collaboration benefits compared with other respondents.

Older respondents perceived less of each of the benefits examined, but this seemed to be at least partly explained by their lower access to online services, poorer skills when using these services, and lower extent of use. Those living in urban areas perceived more economic benefits than others, but this seemed to be at least partly explained by their higher access, skills, and use. Gender was unrelated to perceived benefits.

In addition to experienced financial hardship, there were also significant associations of other dimensions of socioeconomic position with the examined benefits. Those with a low level of education perceived lower levels of health and economic benefits. However, these significant associations also attenuated to nonsignificant after adjusting for ICT variables suggesting that the effects of education on perceived benefits from online services may also be largely explained by low access, poor skills, and low use among those with a lower level of education.

Comparison With Previous Results

This study showed the importance of ICT access, skills, and the extent of use for perceived benefits of online services. Previous studies have mainly focused on the determinants of these variables but not on their role for the outcomes such as perceived benefits [9,23]. Access and digital skills have been identified as being vital for the success of personal health record use and for ensuring that the records will not become limited to those who are already linked to the internet with high levels of health literacy and computer skills [24]. Internet use has previously been associated with economic, social, and institutional benefits [5]. Access and skills have also been associated with the adoption, engagement, and sustained use of patient portals [25-27].

Our findings suggest that people with economic disadvantage, poor health, and a low level of participation see fewer benefits from online services even when differences in access, skills, and use are accounted for. This corresponds to a previous finding showing that those with below-average earnings gained fewer economic benefits from the internet use than those with average earnings [5]. It is possible that people from these disadvantaged groups need more personal and individually tailored health and social services, which evokes an urge for getting services provided in an interpersonal encounter. Online services may be more suited for providing care for uncomplicated problems in a standardized manner and prevention of health or welfare problems. The health and welfare problems of disadvantaged groups may tend to be more complex, including multimorbidity, and potentially include social problems. Thus, they may require multisectoral and multidisciplinary services and simultaneous, coordinated action of different professionals.

Our results suggest that older people experience fewer benefits from online services, but this association is partly due to their lower levels of access, poorer skills, and lower use of online services. Previous studies have mainly focused on use and found mixed results [8,9]. One finding suggests that the young benefit more from internet use than older people [5], but another study had opposite findings [10]. Skills and access were not adjusted for in these studies, however, and our results suggest that they are of importance. For example, in Italy researchers found that a substantial proportion of those aged 50 years or older were not digitally skilled [28]. Because skills seem to be crucial for older people to benefit from online services, training should be provided for them [29]. A study found that older people were satisfied with ICT training that included working in couples, practicing with the device, choosing what to learn, and practicing material that facilitates communication and learning [30].

Differences in education level could be partly explained by differential access, skills, and use. Previously, lower education has been found to be associated with fewer benefits from internet use [5,10] and lower use of governmental e-services [8]. Computer nonusers have been found to have less education, higher unemployment, lower annual income, and poorer health and be less likely to have memberships in community organizations or perform volunteer work than their counterparts [9].

Previous studies have found mixed results regarding findings related to urbanization level. Rural participants are less likely to have regular access to the internet or manage personal health information online and email health care providers in the United States [31]. However, it has been found that rural patients engage digital rehabilitation means more than urban patients [32]. In Sweden, primary care choice reform in 2010 seemed to have negative effects on geographic equity; the effects do not appear to be very large but they concern some indicators of socioeconomically less advantaged areas [33]. The introduction of electronic online services may face special challenges in rural areas [34]. It has been suggested that rural online service implementation only leads to sustainable adoption (ie, it sticks) when the implementation carefully considers and aligns the content (the clicks), the preexisting structures in the context (the bricks), and the interventions in the implementation process (the tricks) [35].

Our findings that gender was unrelated to experienced benefits are supported by an earlier study from the Netherlands, where there were no gender differences related to who benefits from internet use [5]. Correspondingly, in Finland there were no gender differences in the use of governmental online services [8].

Deursen and Helsper [5] suggested that economic benefits of digital services are related to economic resources such as education, whereas social benefits are more related to social resources. Our findings give only partial support to this, given that satisfaction with relationships and keeping in touch with friends and relatives were associated with perceived collaboration benefits but also associated with other forms of benefits. Correspondingly, education was associated with economic benefits but also with health benefits and did not remain significant after adjusting for ICT variables. A previous study has found support for this idea showing that differences in economic outcomes were related to economic resources such as education and income, whereas differences in social outcomes were related to social resources such as marital status [5].

Strengths and Limitations

Previous studies have mainly focused on first-level digital divide or exclusion showing that demographics, health, socioeconomic position, and social participation are associated with the use of internet and online services. However, it has been suggested that shifting research focus from the first-level divide to the third-level divide and examining the benefits from online services and the inequalities in these outcomes is important [16,17]. Research related to social determinants of benefits is especially lacking [17]. Focusing on aspects of the third-level divide or exclusion and factors related to them is a strength of this study.

This study used a large random sample representative of the Finnish population. However, it relied on self-reported measures, which may lead to problems associated with an inflation of the strengths of associations and with common method variance. To minimize problems with self-reports, we used measures that showed good reliability. Our study was cross-sectional, thus we cannot draw any conclusions about causality. Moreover, although we controlled for many factors, we cannot rule out the

possibility of residual confounding. In addition, there are many possible determinants affecting the use and benefits of online services that we did not examine. For example, we did not examine attitudes toward ICT and motivation to use it, satisfaction with care provider, or personality. Future studies should examine these factors and the different types of health internet users (ie, a recent study found 6 different types: learners, pragmatists, skeptics, worriers, delegators, and adigitals [36]).

Finland is among the forerunners in the digitalization of health care and social welfare services [33]: the national digital Kanta services are unique in the world, and tax-financed universal health care is provided for all residents. Therefore, generalizing our findings to countries with other types of health care systems or online services should be done with caution.

In our sample the respondents were older, had more education, and were more often women than the eligible population [18]. One reason for this was that we used double picking probability for those 75 years of age or older to guarantee a sufficient group size for older people, given that they are an important group suggested to be at risk of digital divide and exclusion. To tackle possibly biased results, we used inverse probability weighting based on age, gender, marital status, education level, living region, and degree of urbanization of the residential municipality.

Conclusions

Our findings suggest that access to electronic online services, skills to use them, and the extent of use play crucial roles in perceiving benefits from these services. Skills seem to be the most central element. Moreover, health, financial hardship, and participation-related variables seem to be important as well. Thus, it seems that there is a significant risk of digital exclusion among economically disadvantaged people, those with poor health, and those who are socially isolated. In times when services are increasingly provided by electronic means, this digital divide may predispose people who do not perceive benefit from online services to be excluded from those services.

To ensure that the population, particularly those who are older, in poor health, socially isolated, or of low socioeconomic position, can equally benefit from online health services, access, skills, and possibilities to use these services must be provided. These groups are at the highest risk of digital exclusion and have the highest need for health and social welfare services. Promoting use would also increase benefits for organizations by enabling more users for online services.

Providing services online has the potential to widen social and health inequalities among the population. Widespread expansion calls for rigorous consideration of interventions aimed at tackling the negative effects that can arise from providing health and social care services online and promoting equal opportunities and capabilities among the population [37]. In accordance with Öberg et al [38], targeting training toward vulnerable groups such as senior citizens and people with poor health, lower levels of education, or social isolation may help to ensure that online health services are accessible and can reach a wide population and improve client involvement in their own care. Moreover, organizations should consider offering

instruction and support services to improve patient engagement [29].

Abstract

Background: No study has comprehensively investigated the association between the usage of typical screen-based electronic media devices and sleep quality in a Chinese population with individuals in a wide range of ages.

Objective: This study aimed to understand the characteristics of television (TV) viewing, computer usage, and mobile phone usage in a representative Chinese population in Macau and to examine their roles in predicting the variations in sleep quality.

Methods: This cross-sectional study was an analysis of 1500 Macau residents aged 15 to 90 years based on a community-based health needs assessment study entitled, “Healthy Living, Longer Lives.” Data collection was conducted in 7 districts of Macau from 2017 to 2018 through face-to-face interviews. The durations of daily TV viewing, computer usage, and mobile phone usage were recorded in a self-administered questionnaire. The Chinese version of the Pittsburgh Sleep Quality Index (PSQI) was used to assess the sleep quality.

Results: The prevalence of TV, computer, and mobile phone usage was 78.4% (1176/1500), 51.6% (769/1490), and 85.5% (1276/1492), respectively. The average daily hours of usage were 1.75 (1.62), 1.53 (2.26), and 2.85 (2.47) hours, respectively. Females spent more time watching TV ($P=.03$) and using mobile phones ($P=.02$) and less time on the computer ($P=.04$) as compared to males. Older adults were more likely to watch TV while young people spent more time using the computer and mobile phones (P for all trends $<.001$). The mean PSQI global score was 4.79 (2.80) among the participants. Females exhibited significantly higher PSQI scores than males (5.04 vs 4.49, respectively; $P<.001$). No linear association was observed between the PSQI score and the amount of time spent on the 3 electronic devices ($P=.58$ for PSQI-TV, $P=.05$ for PSQI-computer, and $P=.52$ for PSQI-mobile phone). Curve estimation showed significant quadratic curvilinear associations in PSQI-TV ($P=.003$) and PSQI-computer ($P<.001$) among all the participants and in PSQI-mobile phone among youths (age, 15-24 years; $P=.04$). After adjustment of the gender, age, body mass index, demographics, and lifestyle factors, more than 3 hours of TV viewing and 4 hours of computer usage or mobile phone usage was associated with 85% (95% CI 1.04-1.87; $P=.008$), 72% (95% CI 1.01-2.92; $P=.045$), and 53% (95% CI 1.06-2.22; $P=.03$) greater odds of having poor sleep quality (PSQI score >5), respectively.

Conclusions: The mobile phone was the most popular screen-based electronic device used in the Macau population, especially among young people. “J” shape associations were observed between sleep quality and the duration of TV viewing, computer usage, and mobile phone usage, indicating that the extreme use of screen-based electronic devices predicted poorer sleep status, whereas moderate use would be acceptable.

KEYWORDS

electronic device; screen-based; sleep; Chinese; digital; mobile phone

Introduction

The use of screen-based electronic media devices such as computers, televisions (TVs), mobile phones, video games, and other screen-based products have become an integral part of our lives and has continued to increase sharply in the past decade [1,2]. For example, about 80% of the population use smartphones and about 90% of the population watch TV in the United States of America, the United Kingdom, Mainland China, and Hong Kong [2]. However, the pervasive use of screen-based electronic media devices is a likely contributor to widespread sleep problems [3].

Numerous studies across the countries have suggested that prolonged daily use of screen-based electronic devices lead to negative sleep outcomes, including decreased sleep duration, reduced sleep efficiency, increased daytime sleepiness, and sleep disturbances [1,4,5]. A recent systematic review showed that in over 90% of the studies, increased screen-based media consumption by children and adolescents (age, 5-17 years) was associated with a reduction in total sleep duration [3]. Another systematic review of 67 studies in school-aged youth and teenagers found that screen time was associated adversely with sleep health through delayed bedtimes and reduced sleep duration [6]. Regarding the Chinese population, a cross-sectional study on adolescents in Hong Kong showed that prolonged mobile phone use was significantly related to daytime sleepiness, decreased sleep duration, and poor sleep quality [7]. Similar sleep problems were reported among the residents of Macau, which is another special administrative region of China. Nearly 40% of the adults in Macau reported at least one type of sleep disturbance [8]. We believe that most residents of Macau use electronic media devices because the cultural customs and lifestyle of Macau are similar to those of Hong Kong. However, no study has examined the role of screen-based electronic device usage in the development of sleep problems in Macau.

The majority of the previous studies focused on a special age group—in particular, the age groups of children and adolescents [1,3,9-12]. Very few studies have targeted a population of a wide age range. Youths are not the only age group that use screen-based electronic devices. The different pattern of use in adulthood may reflect a different sleep health profile. For example, adults may seek compensatory sleep when spending too much time on screen-based media devices, and thus, media use is associated with sleep onset latency but not tiredness [13]. Many of the previous studies focused only on 1 or 2 screen-based electronic devices [3,10,14,15]. It is also not known whether the same pattern of sleep problems occurs with the usage of different screen-based electronic media devices [1]. In fact, the trend in the modern society is the simultaneous use of multiple screen-based electronic devices and thus, a comprehensive investigation of several screen-based electronic media devices may help us to better understand the overall situation [6].

We conducted this study with the following aims: (1) describe the usage of 3 major screen-based electronic media devices (TV, computer, and mobile phone) and the sleep quality in a representative Chinese population in Macau, (2) examine the patterns of the associations between electronic device usage and sleep quality, and (3) explore how the usage of electronic devices predicts poor sleep status.

Methods

Data Source and Study Design

This study is a report of the partial data from a project named “Healthy life, longer lives (HLLL),” which was conducted from 2017 to 2018 in Macau. HLLL is a health needs assessment study of the Macau civilian, noninstitutionalized population. It was designed to assess the lifestyle behaviors of Macau residents in terms of their dietary habits, sleep patterns, physical activity, electronic device usage, smoking habits, drinking habits, and health information seeking behaviors, and to identify the barriers for a healthy lifestyle in vulnerable groups. The ethical approval for the study was obtained from the Human Research Committee of Hong Kong Polytechnic University (HSEARS20180516001), the Macau Polytechnic Institution (07/PSC/ESS/2017), and the Kiang Wu Nursing College of Macau (REC-2017.3). All participants signed informed consent forms.

Participants and Sampling Method

The inclusion criteria of the participants were (1) aged 15 years or above, (2) can read and write Chinese and speak Cantonese or Putonghua, which are the dialects commonly used in the city, and (3) residing in one of the 7 parishes in Macau. The exclusion criteria were (1) nonpermanent residents, (2) unable to communicate owing to psychological or physical illness, and (3) cannot provide written informed consent.

A multiple-stage sampling frame according to gender and age was adopted to recruit the participants. First, the number of the needed participants in each age group (age [years]: 15-17, 18-24, 25-34, 35-44, 45-54, 55-64, and 65+) was determined by referring to the distribution of age and gender in the census data of the Macau population [16]. Second, several recruitment strategies were adopted to approach potential participants in each age group. Thirty baccalaureate nursing students from 2 tertiary education institutions in Macau and living in different parishes of Macau were trained for recruitment and data collection. They went to their living districts and the nearby housing districts to recruit participants. They were also asked to invite 1-3 friends or relatives that belonged to the same age groups but with different education levels to participate in the study. To recruit enough adolescents (age, 15-17 years) and older adults (aged 65 years or above), the trained students also went to the public-funded health care and social service centers for adolescents and older adults for recruitment. To ensure the representativeness of the sample, only 1 eligible person in 1 household was considered as a valid participant. To avoid

duplication, we asked the participants to provide the last 3 numbers of their Macau national identification numbers. These Macau identification numbers were stored in a separate data set and the numbers were checked thoroughly, and we did not find any duplicate cases. Upon successful contact with the target person and after obtaining written informed consent, the self-administered questionnaire was given to the participants to complete. If he/she could not read the questionnaire (eg, older adults), the student assistants conducted a face-to-face interview thereafter. According to the feedback from the student assistants, only a small number of older persons aged 75 years and above completed the questionnaires by interview, accounting to less than 1% of the whole sample.

Measures

Screen-Based Electronic Media Device Usage

The screen-based electronic devices analyzed in this study were the TV, computer, and mobile phone, as these are the 3 most frequently used screen-based electronic media devices. Respondents were asked how many days they spent watching TV or using a computer and mobile phone in 1 week and the duration they spent on TV viewing and computer and mobile phone usage on a typical day (minutes or hours/day). Minutes were converted to hours and recorded to the nearest 0.1 hours. The upper bounds of the duration of each electronic device usage was set as 16 hours, because we considered that one person might spend 8 hours for sleep and for other things in a day. The total number of hours spent on the 3 electronic devices in 1 day should not be beyond 24 hours. The student assistants corrected the answers with the participants after receiving the questionnaires to avoid any unreasonable value. The average time reported for using each electronic device every day was calculated by dividing the sum of the hours spent on these devices in 1 week divided by 7 (ie, 7 days in a week).

Sleep Quality

The Chinese version of the Pittsburgh Sleep Quality Index (PSQI) [17,18] was used to measure the sleep quality. The PSQI has 7 components, namely, (1) sleep duration, (2) sleep disturbance, (3) sleep latency, (4) daytime dysfunction due to sleepiness, (5) sleep efficiency, (6) overall sleep quality, and (7) sleep medication. The scale consists of 19 items, and each item is scored from 0 to 3. The PSQI global score was calculated from the 7 component scores. The score ranges from 0 to 21. Higher PSQI global score indicates poorer subjective sleep quality. The Chinese version of PSQI has been identified with good reliability ($r=0.82-0.83$) [17]. A global PSQI score >5 is considered as poor sleep quality with a sensitivity of 98% and a specificity of 55% [17], indicating good performance when the PSQI is used in the Chinese population.

Demographics and Anthropometric Measures

Information on the following demographic characteristics were solicited: gender (male or female), age (years), and age groups (age [years]: 15-17, 18-24, 25-34, 35-44, 45-54, 55-64, and 65+), living region (7 parishes of Macau), employment status (ie, employed, retired, student, housewife, unable to work, unemployed), marital status (ie, never married, married, divorced, widowed, others), education level (ie, primary or

below, secondary, tertiary or above), and monthly household income (in MOP, conversion rate: 1MOP=US \$0.125). Participants reported their weights and heights by kilogram and centimeters, respectively. Body mass index (BMI) was calculated as weight in kilograms divided by the square of height in meters. Participants were categorized as underweight ($BMI < 18.5 \text{ kg/m}^2$), normal weight ($18.5 \text{ kg/m}^2 \leq BMI < 23.0 \text{ kg/m}^2$), overweight ($23.0 \text{ kg/m}^2 \leq BMI < 25.0 \text{ kg/m}^2$), and obese ($BMI \geq 25.0 \text{ kg/m}^2$) according to the World Health Organization (WHO) standard for Asian populations [19]. The former 3 categories were designated as nonobese ($BMI < 25.0 \text{ kg/m}^2$) in some analyses to compare with the obese group ($BMI \geq 25.0 \text{ kg/m}^2$).

Other Covariates

The following lifestyle factors were considered as potential covariates and measured in the questionnaire: physical activity (insufficient/sufficient according to WHO standards), smoking (currently smoking or not), drinking (currently drinking or not), and unhealthy eating habits in terms of remaining hungry (eg, delaying or skipping meal), dieting (eg, weight losing, fasting), and overeating. The eating habits were measured using the 5-point Likert scale ranging from Never (1), Occasionally (2), Sometimes (3), Frequently (4), to Always (5).

Statistical Analysis

The basic characteristics of the participants were described by the mean and SD for the continuous variables and by count and percentage for the categorical variables. To describe the usage of the device and the sleep quality, the duration of usage (hours), status of usage (yes/no), global score of the PSQI, and poor sleep status were presented by mean (SD) or frequency (n [%]) where appropriate. The device usage and sleep quality according to the different demographical groups were analyzed using one-way analysis of variance (ANOVA) or independent t -test for the continuous variables and chi-square test for the categorical variables. The mean sleep duration (hours) and the average 7 component scores of the PSQI were presented and compared with gender and age groups by ANOVA. To examine the association between screen-based electronic device usage and sleep quality, the average number of hours spent in using electronic devices were categorized into different strata and ANOVA was used to compare the differences in the PSQI scores among the groups. Both linear and curve estimation models were performed to demonstrate the nature of the association between using electronic devices and sleep quality. Binary logistic regression analysis was adopted to determine the predictive role of the electronic device usage on poor sleep status. The dependent variable was poor sleep quality (PSQI score >5). Odds ratios (ORs) and 95% CIs for having poor sleep quality according to different durations of using the computer, mobile phone, and TV were calculated accordingly. SPSS 25.0 software (IBM Corp) was used in all data analyses and the significance level was considered as .05.

Results

General Characteristics of the Participants

A total of 1500 participants were recruited between 2017 and 2018. The mean age of the females was 39.1 years and that of males was 39.3 years. The 4 age groups were as follows: youth (15-24 years), young adults (25-44 years), middle-aged adults (45-64 years), and older adults (65 or above). The proportions of the 4 age groups were as follows: youth, 14.1% (212/1500); young adults, 35.4% (531/1500); middle-aged adults, 37.4% (561/1500); and older adults, 13.1% (196/1500). The majority of the participants were employed (1030/1473, 70.0%), had secondary or above education level (1206/1489, 81.0%), and were married or they had a partner (899/1487, 60.5%). Females had lower monthly household income than males ($P<.001$). Males were more likely to be overweight or obese than females

(289/667, 43.3% vs 269/805, 33.4% respectively; $P<.001$). The mean BMIs of the males and females were 22.8 kg/m² and 22.0 kg/m², respectively ($P<.001$). Most participants did not have drinking and smoking habits, but the number of male drinkers was higher than that of female drinkers (221/675, 32.7% vs 152/821, 18.5%, respectively; $P<.001$). The number of male smokers was higher than that of the female smokers (97/673, 14.4% vs 23/821, 2.8%, respectively; $P<.001$). Around half of the male population (332/669, 49.6%) had enough physical activity while only 35.7% (286/801) of the female population was involved in any physical activity. Over half of the participants reported that they had at least one unhealthy eating habit, and males showed a higher percentage of unhealthy eating habits than females (401/669, 59.9% vs 420/819, 51.3%, respectively; $P<.001$). The basic characteristics of the participants according to gender are shown in [Table 1](#).

Table 1. Characteristics of the participants (N=1500).

Characteristics	Males	Females
Age (years), mean (SD)	39.3 (17.5)	39.1 (16.8)
Length of stay in Macau (years), mean (SD) ^a	36.4 (15.8)	33.1 (15.2)

minutes of vigorous-intensity aerobic physical activity throughout the week; $P=.001$.

^cUnhealthy eating habit means remaining hungry (eg, delaying or skipping meal), dieting (eg, weight losing, fasting), or overeating.

Screen-Based Electronic Media Device Usage Among Participants

Among the 1500 participants, the prevalence of watching TV and using computer and mobile phones was 78.4% (1176/1500), 51.6% (769/1490), and 85.5% (1276/1492), respectively. [Multimedia Appendix 1](#) shows the duration of screen-based electronic device usage and sleep quality according to the demographics and lifestyle factors of the participants. The average number of daily hours of watching TV, using a computer, and using a mobile phone was 1.75 (1.62) hours, 1.53 (2.26) hours, and 2.85 (2.47) hours, respectively. Females spent more time watching TV ($P=.03$) and using mobile phones ($P=.02$) and less time on computers ($P=.04$) than men. The use of the 3 electronic devices showed trends according to age, with older adults being more likely to watch TV and young people spending more time using computers and mobile phones (P for all trends $<.001$). The youth spent the longest time on computers and mobile phones at 2.7 hours and 4.4 hours, respectively. Participants who were couples, had lower educational level, were retired or unemployed, and had lower monthly household income had longer TV viewing times, whereas participants who were single, had a higher education level, who were students, and who were employed reported longer computer and mobile phone usage ($P<.001$). Significant differences were also observed across the different BMI groups. Obese people had longer TV viewing time ($P=.04$) but shorter computer usage ($P=.008$) and mobile phone usage ($P<.001$) as compared to the nonobese people. Regarding the common lifestyle factors, participants with enough physical activity ($P=.01$) and drinking habits ($P=.003$) spent shorter durations on TV viewing, while those who had unhealthy eating habits spent a longer time on TV viewing ($P<.001$) and shorter time on computer ($P=.001$) and mobile phone ($P<.001$) usage. The number and percentage of the users of the 3 electronic devices according to demographics and lifestyle factors is shown in [Multimedia Appendix 2](#).

Sleep Quality of the Participants

The mean (SD) of the PSQI global score was 4.79 (2.80). Females had a significantly higher PSQI global score than males (5.04 vs 4.49; respectively; $P<.001$). The prevalence of poor sleeping quality in females was around 10% higher than that in males (308/794, 38.8% vs 181/642, 28.2%, respectively; $P<.001$). No statistically significant differences in the PSQI global scores were detected according to the age groups ($P=.55$), marital status ($P=.22$), education level ($P=.07$), and employment status ($P=.06$). The highest average PSQI global score was found in obese participants (5.36 (2.96); $P<.001$); 40.4% had poor sleep quality ($P=.009$). Those with unhealthy eating habits ($P<.001$), that is, remaining hungry, dieting, or overeating and smokers ($P=.002$) were more likely to have higher PSQI global scores. However, participants with different physical activity levels ($P=.97$) and drinking habits ($P=.72$) showed no significant

difference in sleep quality ([Multimedia Appendix 1](#)). The sleep duration (hours) and the 7 component scores of the PSQI by gender and age groups are shown in [Multimedia Appendix 3](#). Males had better subjective sleep quality ($P=.007$) and lower sleep disturbances ($P=.01$) and sleep latency ($P<.001$) than females. Youths had higher daytime dysfunction ($P=.01$) and sleep latency ($P=.04$) but lower sleep disturbances ($P=.004$) than older adults.

Associations Between Screen-Based Electronic Device Usage and PSQI Scores

The associations between electronic device usage and sleep quality were examined by first comparing the mean global scores of PSQI with the stratified duration of electronic device usage. The results are shown in [Table 2](#). Significant differences were found among TV viewing strata and computer usage strata. Those with 1.5-2.5 hours of viewing (PSQI: 4.37; $P<.001$) and 2.0-2.4 hours computer usage (PSQI: 4.25; $P=.009$) had the lowest PSQI scores. However, no significant difference was observed between PSQI scores among the different age groups of mobile phone users ($P=.23$). No linear association was found between sleep quality and the duration of usage of all 3 electronic devices ($P=.58$ for PSQI-TV, $P=.05$ for PSQI-computer, and $P=.52$ for PSQI-mobile phone). Thus, we conducted the curve estimation and observed significant quadratic curvilinear associations of sleep quality with the durations of using TV ($P=.003$) and computer ($P<.001$) but not the mobile phone ($P=.12$). We further analyzed the association in each age group for the mobile phone usage and found a significant quadratic association between mobile phone use time and sleep quality among youths ($P=.04$). We further examined the model fitting through the scatterplot of residuals by fit values for the linear model and quadratic model, respectively. We found that these linear models would be inadequate because their coefficients did not make practical sense, and residuals were not independent of the fit values. The quadratic models did not have these problems, and hence we considered the quadratic models to be the more reasonable models that appropriately described the associations of sleep quality with TV viewing, computer usage, and mobile phone usage. The quadratic associations could be demonstrated using the following equations:

$$PSQI \text{ global score} = 5.033 - 0.268 * \text{duration of TV viewing} + 0.040 * \text{duration of TV viewing}^2$$

$$PSQI \text{ global score} = 5.044 - 0.336 * \text{duration of computer usage} + 0.036 * \text{duration of computer usage}^2$$

$$PSQI \text{ global score} = 4.644 - 0.013 * \text{duration of smartphone usage} + 0.011 * \text{duration of smartphone usage}^2 \text{ (age group 15-24 years)}$$

The association looks like a “J” shape. Both the shorter and longer use of TV, computer, and mobile phone were associated with increased PSQI scores ([Figure 1-3](#)).

Table 2. Univariate analysis of the duration of electronic media device usage with sleep quality (PSQI^a global score).

Duration of device usage	Total (n)	PSQI global scores, mean (SD)	P value
Television^b			<.001

Role of Screen-Based Electronic Device Usage in Predicting Poor Sleep Quality

According to the stratified analyses and curve estimations, the lowest PSQI score occurred in the participants with a moderate duration of using electronic devices. We thereby used 1.5-3 hours of TV viewing and 2-4 hours of computer and mobile phone usage as the reference groups. We conducted binary logistic regression for analyzing the association of poor sleep status with electronic device usage. As shown in Table 3, except for those using mobile phones less than 2 hours, all other groups showed statistically significant associations. The crude ORs

ranged from 1.43 to 1.78. After adjustment for gender, age, BMI, demographics, and lifestyle factors, the strength of the associations was slightly changed but they still showed statistical significance. The OR of poor sleep quality was 38% (95% CI 1.03-1.84; $P=.03$) and 85% (95% CI 1.18-2.91; $P=.008$) in the <1.5-hours and >3-hours TV viewing groups, respectively. In the computer usage groups, the OR was 71% (95% CI 1.10-2.64; $P=.02$) higher for <2-hours group and 72% (95% CI 1.01-2.92; $P=.04$) higher for the >4-hours group. As for the mobile phone usage, the adjusted OR was 1.53 (95% CI 1.06-2.22; $P=.02$) for the group with daily mobile phone use longer than 4 hours.

Discussion

Principal Findings

Mobile phone and TV were the most popular electronic media devices in our study population, but the usage was polarized by the age groups. Almost all the youth and young adults had mobile phones, while nearly two-thirds of the older adults did not use a mobile phone. On the contrary, over 90% of the older population treated TV viewing as a pastime, while relatively fewer young people watched TV. Another typical finding was that, unlike most previous studies, we found a quadratic curvilinear association between sleep quality and electronic device usage time; this J-shape occurred among all the participants for TV viewing and computer usage and among the youths for mobile phone usage.

Our study found that the prevalence of TV viewing in Macau was approximately 10% lower than that reported in some other countries and regions, such as the United States, the United Kingdom, Japan, Mainland China, and Hong Kong [2]. About

half of the participants used computers daily, which was consistent with that reported in other Chinese populations in Mainland China and Hong Kong [2]. Regarding mobile phone usage, our study population exhibited a slightly higher prevalence than that reported in other countries and regions [2]. In our study, the longest number of hours was spent daily on mobile phone use, followed by TV viewing and computer use. Internet access is the key for people choosing electronic media devices. A smartphone can facilitate access to the internet rapidly and conveniently, which might be the reason for most participants to spend more time on the mobile phones instead of the traditional TV [20]. The percentage of users and viewing time of mobile phones and computers decreased with increasing age, which was consistent with that reported in previous studies in other countries [6,21]. Although the older population spent lesser time on mobile phones and computers, an increasing trend in using these devices was reported in a Chinese population [7].

The sleep duration in our study population was similar to that reported in previous studies conducted in Macau, Hong Kong, and Mainland China [7,22,23], which was around 7.3-7.8 hours.

Females had poorer sleep quality than males, and they reported that they took a long time to fall asleep and were more likely to experience sleep disturbances. These findings were similar to that reported in a local study conducted among adolescents in 2012 [24] and that reported in a study on older adults in 2016 [8]. We found that sleep latency increased with age, which is consistent with the findings from a large cross-cultural study [25] conducted in China, Ghana, India, Mexico, and Russia, as well as in many other studies [26-28]. A recent study conducted among 0.5 million Chinese individuals suggested that increased sleep problems were associated with the growing use of TV, internet, mobile phones, and social media in the nighttime, which results in reduced sleep duration and increased prevalence of insomnia [22].

Most previous studies suggested an inverse linear relationship between electronic device usage and sleep problems [1]. However, our study found a significant quadratic curvilinear association, which was a “J” shape pattern in all 3 types of electronic device usage. The higher PSQI global score increased towards the end of the longer and shorter durations of electronic device usage. This pattern also appeared in the logistic regression analysis for poor sleep quality, in which people with a moderate duration of usage had the lowest odds to have a poor sleep status. Several mechanisms can be highlighted as the reasons for longer electronic device usage leading to poorer sleep quality. The electronic devices might affect sleep quality directly through reduced sleep duration and persistent electromagnetic radiation [29]. Bright light exposure from the electronic devices might suppress the release of melatonin and disrupt the circadian rhythm [10,29,30]. Long-time use of electronic devices may lead to physical discomforts such as muscular pain and headache, which could result in sleep problems [31]. All these reasons could explain how sleep quality was affected by long-time usage of screen-based electronic devices. Our study also found that moderate use of screen-based electronic devices resulted in the best sleep quality; the J-shape pattern indicating the mild use of these devices was better than that of nonusers or of those who used these devices for very short durations. A study conducted in the United Kingdom suggested that a moderate amount of digital-screen engagement such as watching TV, using a computer, or using a smartphone could help maintain the mental well-being and increase mood regulation and relaxation, which could improve sleep quality [32]. These screen-based electronic devices are widely used in modern society for recreation and relaxation. A study in Belgium showed that 36.7% of the adolescents considered TV viewing as a sleep aid for relaxation [33]. Another study in a Chinese population identified that watching TV and surfing the internet could improve happiness [34]. Some studies indicated that moderate use of smartphones could be considered as a coping strategy that diverts attention from stressful situations, which helps to regulate the individuals’ negative emotions [35,36]. Negative emotions and stressful situations can increase sleep

fragmentation and decrease sleep duration, thereby resulting in a poor sleep status [37]. Based on our findings and the evidence from these previous studies, we suggest that moderate and appropriate use of screen-based electronic devices could be helpful in emotion regulation and stress relief, which enhances sleep quality thereafter.

Limitations of Our Study

Our study has several limitations. First, the measurement of the electronic device usage did not specify the times, places, and contents watched. Moreover, the usage of other portable or screen-based devices such as video game machines were not evaluated in our study. Further, we did not measure the details of the smartphone usage pattern, for example, the time spent on making traditional phone calls and that spent on using apps based on interactive operations. Nor did we measure the details about when the phone calls were made (day or night), the frequency of the phone calls, and the content of the phone calls. Such information would have allowed for a more comprehensive and insightful investigation into the relationship between electronic device usage and sleep quality. Second, underestimation or overestimation might occur from self-reporting. The participants could tend to report a shorter or longer screening time for social desirability, which might affect the strength of the associations. However, we believe that this would not overturn the nature of the associations that we found because the biases in the responses were random. The large sample size would alleviate the effects of the self-reporting bias on the results.

Future Research and Conclusions

Our study was the first to conduct a comprehensive investigation of the usage of 3 typically used screen-based electronic media devices, namely, TV, computer, and mobile phones and its relationships with sleep quality in a representative Chinese population with a wide range of ages. Most young people use mobile phones frequently in their daily lives, indicating that digital life is an integral part of the modern society. The most interesting finding in our study is that a typical “J” shape association was observed between sleep quality and TV viewing, computer usage, and mobile phone usage. The extreme use of screen-based electronic devices predicted poor sleep status, whereas moderate use was acceptable. These findings can be used to raise awareness among the general public on how to maintain the healthy use of screen-based electronic devices. As a public health issue, making age-specific guidelines for screen-based electronic device usage with regard to quantity and timing should be developed [29]. Future experimental and observational studies that elucidate how the pattern (frequency, duration, contents, location, time of the day, etc) of electronic device usage alters sleep and circadian rhythms across the life course and leads to poor health outcomes are needed. These studies could provide evidence for tailor-made primary prevention strategies in the future.

Acknowledgments

This study was supported by the Macau Galaxy Entertainment Foundation. The authors wish to acknowledge the invaluable contribution of the participants in the study. We would like to specially thank Lee Sara, Lau Kwong Lok, Ng Wai Lok, Sit Chi Hin, Suen Lai Ngan, To Sze Pan, Wong Kin Woon, Yeung Sin Yu Eunice, Yim Cheuk Hin, and students from the Macau Polytechnic Institution and Kiang Wu Nursing College for their support and assistance in data collection, data cleaning, and preliminary data analysis.

Authors' Contributions

YJX conceived and designed the study; YJX, DC, and BLN provided administrative, technical, or material support to the study; AYL, BLN, KML, CL, AYML, and ASMT helped in data collection; YJX analyzed the data and drafted the manuscript; and YJX, AM, DC, AYL, and AYML made critical revisions to the manuscript. All authors read and approved the final manuscript.

Abstract

Background: There is uncertainty about the impact of internet use on mental health in older adults. Moreover, there is very little known specifically about the impact of particular purposes of internet use.

Objective: This study aims to investigate the longitudinal relationship between two distinct concepts of mental health with the frequency of internet use among older adults: the moderating role of socioeconomic position (SEP) and the association between specific purposes of internet use.

Methods: Longitudinal fixed and random effects (27,507 person-years) models were fitted using waves 6-8 of the English Longitudinal Study of Ageing to examine the relationship between different aspects of internet use (frequency and purpose) and two mental health outcomes (depression and life satisfaction). The potential moderating effect of SEP on these associations was tested using interaction terms.

Results: Infrequent internet use (monthly or less vs daily) was predictive of deteriorating life satisfaction ($\beta=-0.512$; $P=.02$) but not depression. Education and occupational class had a moderating effect on the association between frequency of internet use and mental health. The associations were stronger in the highest educational group in both depression ($P=.09$) and life satisfaction ($P=.02$), and in the highest occupational group in life satisfaction ($P=.05$) only. Using the internet for communication was associated with lower depression ($\beta=-0.24$; $P=.002$) and better life satisfaction ($\beta=.97$; $P<.001$), whereas those using the internet for information access had worse life satisfaction ($\beta=-0.86$; $P<.001$) compared with those who did not.

Conclusions: Policies to improve mental health in older adults should encourage internet use, especially as a tool to aid communication.

KEYWORDS

internet; socioeconomic factors; mental health; life satisfaction; depression; effect modifier

Introduction

As population aging brings major challenges for society and health care services, promoting healthy aging is important to prevent the burden and financial costs related to aging-associated diseases. Mental health is a crucial component of healthy aging. Poor mental health can profoundly affect the quality of life of older adults and is associated with an increased risk of mortality and morbidity [1,2].

Risk factors for poor mental health in older adults could be potentially impacted by internet use; maintaining and building social relationships through email or social networking sites may increase feelings of social support and connectedness and relieve feelings of isolation and loneliness [3-7]. The internet is used at least once every 3 months by an increasing proportion of the English population aged 50 years and older (63% and 51% of men and women, respectively, in 2010 compared with 84% and 78% of men and women, respectively, in 2016) [8].

However, internet use remains lower in older adults than in younger adults [9].

Evidence is mixed on the impact of internet use on mental health in older adults. Forsman and Nordmyr [10] reported a balanced positive association in a review of 18 quantitative and 14 qualitative studies but found that 40% of the outcomes they reviewed showed no association. Claims for positive impacts according to some researchers are often exaggerated because of training effects, inappropriate generalization of results, and misattribution of causality [11]. Training effects and limited generalizability are typically leveled in experimental studies where a small intervention group of selective participants is given support such as training to use the internet [12-14]. However, recent evidence suggests that internet use can improve mental health. Using data from the US Health and Retirement Study (HRS) over a 6-year period, Cotten et al [15] found that prior internet usage reduced the probability of depression by one-third between 2002 and 2008 in a sample of 3000 retired adults aged 50 years and older. Using data over a 10-year period, Lissitsa and Chachashvili-Bolotin [16] found that internet adoption among an Israeli sample of adults aged 65 years and older was associated with increased life satisfaction, with the strength of the estimated association being as strong as that found for being married.

To our knowledge, no literature has longitudinally examined the associations between internet usage and multiple subdimensions of mental health in the same sample. The dimensions of mental health include hedonic and eudemonic well-being [17]. According to Vanhoutte [18], hedonic well-being refers to pleasure maximization and suffering minimization, with the cognitive and affective aspects of well-being forming subdimensions of hedonic well-being. Cognitive well-being is an evaluative process in which an individual assesses the quality of their life; in contrast, affective well-being refers to positive and negative moods and emotions that are not simply the opposite of one another [18,19]. Eudemonic well-being is conceptually distinctive in that it refers to a sense of purpose or control [20]. Separating these dimensions is important (through, eg, separate measurement scales for life satisfaction, depression, and quality of life) because they capture varied aspects of mental health; these could, theoretically, be influenced by internet use in different ways. For example, Matthews and Nazroo [21] explored the cross-sectional relationship between internet use and several dimensions of mental health using data from persons aged 50 years and older in the 2012-2013 English Longitudinal Study of Ageing (ELSA). Frequent internet usage was found to be associated with lower levels of depression (affective well-being) and better quality of life (eudemonic well-being), but no association was found with life satisfaction (hedonic well-being) [21]. In contrast, Heo et al [22] found that more frequent internet use was associated with better life satisfaction and greater psychological well-being among HRS participants aged 65 years and older.

The current literature is limited on the purposes of internet use which have a positive (or negative) influence on mental health in older adults. The internet has myriad uses, for example, using the internet for communication purposes may improve mental

health among older adults because it enables them to stay in touch with family and friends who previous generations may have lost contact with [23,24]. On the other hand, certain types of information access may undermine mental health. For example, using the internet for job searching was associated with more depressive symptoms, lower quality of life, and lower life satisfaction among ELSA participants [21]. Using the internet for finding new people and for entertainment was associated with decreased well-being among older Australians [25].

A possible confounder or moderator of the internet use and mental health association is socioeconomic position (SEP). Internet use is more prevalent in higher SEP groups [26-28], with use for information access and for entertainment being higher for persons with higher and lower SEP, respectively. SEP could also moderate this association; however, this has not been investigated in the literature to date. It could be the case that in groups with the highest levels of internet use (eg, the wealthiest and better educated), nonusers are at a greater disadvantage in terms of their mental health.

This study aimed to further the debate by using a longitudinal sample, analyzing the associations between internet usage and the hedonic dimension of well-being (life satisfaction) and the affective dimension of wellbeing (depression) over a 4-year period, analyzing different purposes of internet usage (eg, communication, entertainment, and information access), and examining whether SEP moderates these relationships. This study hypothesized that (1) more frequent internet use predicts better mental health longitudinally; (2) the association is moderated by SEP, being stronger in the higher SEP groups; and (3) mental health is most strongly associated with internet use for the purposes of communication (positively) and information access (negatively). Our findings will have implications for understanding the importance of internet use and its impact on mental health, which can inform policies to encourage wider and more frequent internet use in older adults to improve mental health.

Methods

Data and Sample

The ELSA is a nationally representative sample of the English population aged 50 years and older. Established in 2002, the sample has been followed up every 2 years [29]. Data were collected through computer-assisted personal interviews, self-completion questionnaires, and nurse assessments (every 4 years) [29]. The original sample was selected from the Health Survey for England (1998, 1999, and 2001) [30]. This analysis used data from waves 6 (2012-2013), 7 (2014-2015), and 8 (2016-2017). The analytical sample ($n=9169$ persons aged 50 years and older at wave 6, with 27,507 person-years of follow-up between waves 6 and 8) comprised sample members first recruited at waves 1 ($n=5659$), 3 ($n=888$), 4 ($n=1796$), and 6 ($n=826$). ELSA participants provided signed consent, and the London Multicentre Research Ethics Committee (MREC 01/2/91) granted ethical approval for the study.

Time-Varying Outcomes

As an aspect of the affective dimension of hedonic well-being, mental health was measured using the validated 8-item version of the Center for Epidemiologic Studies Depression Scale (CES-D) [31]. Items were answered using a dichotomous response (*yes* or *no*), which were summed to result in a total score ranging from 0 to 8, where a score of 0 indicates no depressive symptoms. As an aspect of the cognitive dimension of hedonic well-being, life satisfaction was measured using the Satisfaction with Life Scale [32,33], which has been explicitly tested on older persons and consists of 5 items. The individual item responses ranged from *strongly agree* to *strongly disagree* on a 7-point Likert scale, which was summed to result in a total score ranging from 5 (lowest satisfaction) to 35 (highest satisfaction).

Time-Varying Exposure

Data on the frequency of internet use were collected through self-completion questionnaires. The responses were recoded as *daily*, *weekly*, *monthly or less*, or *never*.

Time-Constant Exposure

The purposes of internet use were assessed only for participants who reported using the internet at least once every 3 months. For this study, 12 purposes of internet use at wave 6 were grouped into 6 as follows: (1) communication (sending or receiving emails; use of social networking sites; and creating, uploading, or sharing content), (2) entertainment (news, newspaper or blog websites, streaming or downloading live or on demand television or radio, music, electronic books, and games), (3) information access (finding information about goods and services; searching for information for learning, research, and fact finding; and looking for a job or sending a job application), (4) managing finances, (5) electronic commerce (shopping and buying goods or services over the internet or selling goods or services over the internet), and (6) other. The questions on the purposes of internet use changed in waves 6, 7, and 8; therefore, we could not use it as a time-varying variable in the modeling. Our analyses focused on the 5 categories mentioned earlier.

Time-Varying Covariates

Participants' age was measured in a single year (coded to 99 to indicate those aged 91 years or older, whose individual age was not released). We tested nonlinear age and mental health associations using second-order polynomial terms. Couple status was measured according to whether a participant was cohabiting (married or unmarried) or not. Working status (currently working) was derived from economic activity status by dichotomizing those who were employees or self-employed from those who were seeking work, sick and not seeking work, retired, or unoccupied. Health status (presence of a limiting long-term illness) was measured through whether a participant self-reported an illness or disability that limited their activities in any way.

Time-Invariant Covariates

SEP at wave 6 was measured using 3 different domains [34]: occupational class, wealth, and education. On the basis of degree

of control and autonomy, occupational class (based on the household reference person's last occupation) was measured using the 3-category version of the National Statistics Socio-Economic Classification: managerial and professional, intermediate, and routine and manual occupations [35]. Wealth was measured using quintiles of total net nonpension household wealth, a summary measure of the value of financial, physical, and housing wealth minus any debt [35]. It represents the permanent economic status of older adults [36], as most participants in aging cohort studies are retired. The highest educational qualification was grouped into 3 categories: degree level, below degree level, and no qualifications. Education among the ELSA cohort members is generally determined earlier in the life course, whereas wealth and occupational class are more likely to change during mid to later life.

Statistical Analysis

To examine the longitudinal association between internet use and mental health, we used a series of fixed and random effects linear models. A nonlinear model for depression did not satisfy the condition of the fixed effects model, and the results from the random effects logistic regression model were substantively similar (not shown here). Therefore, the CES-D score was treated as a continuous dependent variable in both the fixed and random effects models. The fixed effects models control for all measured and unmeasured time-invariant characteristics by using each participant as their own control over survey waves. We adjusted for time-varying age, age squared, working status, couple status, and health status to address our first hypothesis.

H1: More frequent internet use predicts better mental health longitudinally.

Internet use was entered into the models as a four-category independent variable, with daily use as the reference. Random effects models do not control for the correlation between measured and unmeasured characteristics and, therefore, analyze both within- and between-participant variance. We adjusted for the same time-varying variables as for the fixed effects model and additionally adjusted for time-invariant SEP and sex to address our second hypothesis.

H2: SEP moderates the association between internet use and mental health.

An assessment of moderation was performed by including an interaction term between the frequency of internet usage and each marker of SEP; these were retained if statistically significant (likelihood ratio test, $P < .10$). Separate random effect models tested the association between the purpose of internet use and mental health to address our final hypothesis.

H3: There is a positive association between communication internet use and mental health and a negative association between information internet use and mental health.

The analysis not presented here showed similar results when limiting the analytical sample to those who used the internet compared with the results for all participants presented here.

To address attrition from wave 6 onward and item nonresponse within a survey wave, we fitted multiple imputation models by chained equations on all variables (outcomes, exposures, and

covariates) with missing values. The purpose of internet use was imputed conditionally on whether a participant reported internet usage at wave 6. All statistical analyses were conducted using cross-sectional survey weights to minimize bias arising from sample attrition from the beginning of the ELSA study to participation in wave 6. The use of imputation and survey weights did not substantively alter the main findings.

Results

Descriptive Results

Table 1 presents the means, SDs, or percentages across person-waves for the key variables by frequency of internet usage. Overall, 56% of older adults used the internet daily, 12%

weekly, 6% monthly or less, and 26% had never used the internet. The most common purpose was information access (68%), followed by communication (66%), electronic commerce (52%), entertainment (45%), and managing finances (39%). Those who used the internet more frequently had better life satisfaction scores; lower depression scores; and were more likely to be younger, currently working, be in a couple, have no limiting long-term illness, male, have a degree, be in managerial and professional occupations, and be in the wealthiest quintile compared with those who used the internet less frequently or not at all. For example, the mean age of a daily internet user was 66 (SD 7.64) years, whereas the mean age of a participant who had never used the internet was 75 (SD 9.30) years. Overall, 49% of daily users were male, compared with 38% of those who had never used the internet.

^aDescriptive statistics for time-varying variables calculated using data from waves 6-8.

^bDescriptive statistics for time-invariant variables calculated at wave 6 only.

Frequency of Internet Use and Mental Health (Fixed Effects Models for Within-Person Change)

Table 2 presents the fixed effects panel modeling estimates for the frequency of internet usage on depression and life satisfaction. The model estimates from the full models are shown in Multimedia Appendix 1. The coefficients represent estimates of change within participants between waves 6 and 8, and therefore positive estimates represent an increase in the depression score (a poorer health outcome) and an increase in the life satisfaction score (a positive health outcome). The frequency of internet use was not predictive of within-person

change in depression when taking into account time-varying age, working, being in a couple, and health status. Daily internet usage did predict better life satisfaction over time compared with using the internet on, at most, a monthly basis when controlling for the same time-varying variables (β for monthly or less = -0.512 ; $P = .02$). On the basis of model estimates, Figure 1 shows that those using the internet daily were predicted to have more than a half-point increase in life satisfaction scores between waves 6 and 8. There was no significant within-person change in life satisfaction for weekly or never users (vs daily users).

Table 2. Fixed effects model coefficients for frequency of internet use on mental health outcomes.

Frequency of internet use ^a	Depression ^b		Life satisfaction ^c	
	Coefficient (95% CI)	P value	Coefficient (95% CI)	P value
Daily	Reference	N/A ^d	Reference	N/A
Weekly	0.030 (−0.822 to 0.143)	.59	−0.230 (−0.495 to 0.034)	.09
Monthly or less	0.111 (−0.060 to 0.281)	.20	−0.512 (−0.956 to −0.067)	.02
Never	0.096 (−0.101 to 0.293)	.33	−0.472 (−0.955 to 0.012)	.06

^aModels adjusted for time-varying age, age squared, working status, couple status, and health status.

^bHigher scores represent deteriorating depression within participants.

^cHigher scores represent improving life satisfaction within participants.

^dNot applicable.

Figure 1. Predicted life satisfaction score by wave of study and frequency of internet usage from fixed effects model. Model adjusted for time-varying frequency of internet use, age, age square, working status, couple status, and health status.

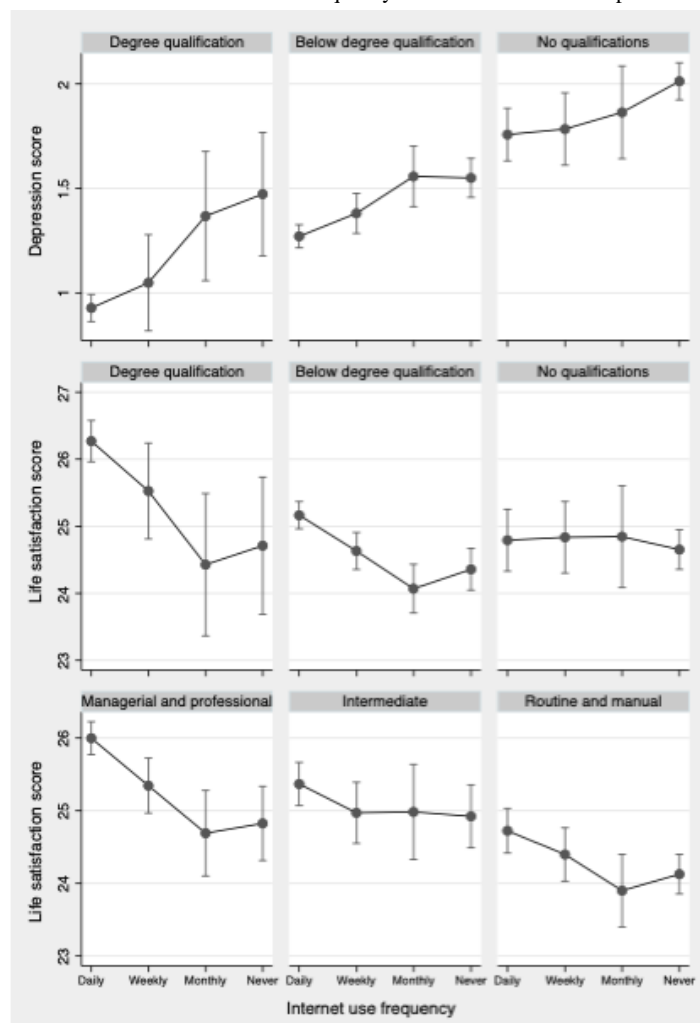

Socioeconomic Position as a Moderator of the Association Between Internet Use and Mental Health (Random Effects Models)

Figure 2 graphically illustrates the predictions from the random effects modeling, which showed that education and occupational class significantly moderated the longitudinal association between internet use frequency and mental health (likelihood ratio test $P < .10$ for interaction terms). The model estimates from the full models are presented in Multimedia Appendix 2. The differences in the predicted scores of depression ($P = .09$) and

life satisfaction ($P = .02$) by internet use were steeper for those with a degree. For example, the predicted life satisfaction score for those who had no formal educational qualifications was almost 25 irrespective of internet use frequency, whereas the predicted score for those with a degree was over 1 unit higher for daily users compared with monthly or never users. Similarly, the models suggested that occupational class moderated the association between internet use frequency and life satisfaction ($P = .05$) but not depression. There was no evidence to suggest that wealth moderated the associations.

Figure 2. Predicted mental health score by socioeconomic position and frequency of internet usage from random effects model. Model adjusted for time-varying frequency of internet use, age, age square, working status, couple status, and health status and for time-invariant education, occupational class, wealth, and sex, including interaction terms for education and frequency of internet use and occupational class and frequency of internet use.

Association Between Purpose of Internet Use and Mental Health (Random Effects Models)

Table 3 presents the estimates from the random effects model for mutually adjusted purposes of internet usage on mental health (full estimates are presented in Multimedia Appendix 3). Compared with those not using the internet for this stated

purpose, using the internet for communication purposes was associated with a lower depression score between waves 6 and 8 ($\beta = -0.24$; $P = .002$) and a higher life satisfaction score ($\beta = .97$; $P < .001$) when controlling for time-varying and time-invariant variables. In contrast, using the internet for information access was associated with a worse life satisfaction score ($\beta = -0.86$; $P = .001$).

Table 3. Random effects model coefficients for the purpose of internet use on mental health outcomes.

Purpose of internet use ^{a,b}	Depression (95% CI) ^c		Life satisfaction (95% CI) ^d	
	Coefficient (95% CI)	P value	Log odds (95% CI)	P value
Entertainment	0.047 (–0.027 to 0.121)	.21	0.093 (–0.023 to 0.412)	.56
Communication	–0.242 (–0.391 to –0.092)	.002	0.968 (0.509–1.428) ^e	<.001
Information access	–0.034 (–1.344 to 0.105)	.62	–0.858 (–1.344 to –0.372) ^e	.001
Electronic commerce	–0.098 (–0.199 to 0.004)	.06	0.322 (–0.035 to 0.678)	.08
Finance	–0.073 (–0.153 to 0.007)	.07	0.210 (–0.110 to 0.531)	.19

^aModels adjust for time-varying age, age squared, working status, couple status, and health status and for time-invariant socioeconomic position and sex.

^bReference category was not using the internet for each purpose.

^cHigher scores represent deteriorating depression.

^dHigher scores represent improving life satisfaction.

Analysis of more specific purposes ([Multimedia Appendix 4](#)) showed that using the internet for email was the only communication purpose associated with better mental health longitudinally and that using the internet for job searching was the only information access purpose associated with deteriorating mental health. Adjustment for more detailed working status categories did not change our findings, suggesting that using the internet for job searching was associated with lower life satisfaction longitudinally over and above being unemployed or out of work.

Discussion

Principal Findings

This study partially confirmed our first hypothesis (H1) that more frequent internet use improves mental health. After adjustment for time-varying confounding factors, there was a positive longitudinal effect of using the internet daily compared with monthly or less on life satisfaction. Internet use frequency was not associated longitudinally with depression. The second hypothesis (H2) that SEP moderates the association between internet usage frequency and mental health was confirmed. This association was stronger for those with an educational degree. There was also a stronger association in those in managerial occupations and professional occupations in life satisfaction. We confirmed our third hypothesis (H3) that using the internet for communication purposes (specifically use of email) was associated with better mental health and that using the internet for information access (specifically for job searching) was associated with worse mental health.

Existing studies have found mixed results regarding the association between internet use and mental health. Notwithstanding methodological differences, our findings are consistent with studies that found that frequent internet use can have benefits for older adults' depression and life satisfaction [13,15,21,34]. The discrepancy between the findings could be because of methodological issues, such as measurement of mental health [18], and varying sample characteristics, sizes, and context [37]. Very few previous studies have been able to analyze internet use frequency and its relationship with mental

health longitudinally. Our findings are consistent with the limited literature available [15,16].

This is the first study to our knowledge that explores SEP as a potential moderator of longitudinal associations between internet use and mental health among older adults. Several studies draw conclusions from sample sizes of fewer than 300 respondents and are not generalizable to middle- and older-aged adults. In contrast, the results of this study come from a large and nationally representative sample of persons aged 50 years and older. Furthermore, the range of questions on internet use allowed us to extend knowledge on the impact of different purposes of internet use on mental health.

Evidence from this study suggests that markers of SEP moderate the association between internet use and mental health; frequent usage in the highest educational and occupational groups had a larger positive impact on mental health than frequent use among those in the lowest groups. This might suggest that low usage in higher SEP groups through digital exclusion, for example, may be particularly problematic for mental health. Our findings, however, need to be viewed in light of our mental health outcomes. The measure of mental health used in our study is determined solely on the affective (depression) and cognitive (life satisfaction) aspects of hedonic well-being, which may not be fully indicative of overall mental health, which also includes eudemonic aspects such as a sense of purpose or control. We cannot rule out the possibility that internet use fulfills eudemonic needs among older adults in disadvantaged SEP groups. Future studies should use a broader measure of mental health to assess whether the longitudinal association between internet use and mental health varies significantly across SEP groups. Further work could also explore whether the relationship between internet use frequency and mental health is moderated by SEP in younger samples in whom almost all use the internet. One might posit that our finding is a cohort effect because later-born generations are expected to enter older age with a much higher prevalence of internet usage.

Our findings highlight heterogeneity among different purposes of internet use. Using the internet for communication through email was associated with better mental health. This provides empirical support for the importance of communication for

positive mental health, as it allows individuals to maintain strong social ties and contacts, thereby reducing the negative impacts of social isolation and loneliness on mental health [7,15,38,39]. In contrast, using the internet for job searching was associated with higher depression and worse life satisfaction over time. This is comparable with previous analyses of ELSA data. This finding may indicate dissatisfaction with one's current job or economic activity status rather than a direct effect of using the internet for this purpose [21]. Our results emphasize the importance of disaggregating different internet usage purposes, as internet use among older adults is not homogenous [40] and impacts different aspects of mental health in different ways.

Policy Recommendations

Our findings point to clear policy implications, the most pressing of which is the need for interventions to encourage older adults to use the internet, so as to build and maintain strong social ties, thereby avoiding the damaging impacts of social isolation and loneliness on mental health. Strategies to promote and increase internet usage among older adults could include setting up public Wi-Fi in places frequently visited by older people and where usage might be low because of barriers to access and digital exclusion. Design of policy interventions to increase internet usage should consider the fact that nonusers of the internet in older age are not homogenous entities but are heterogeneous with respect to gender, age, SEP, household composition, and attitudes toward the internet [41]. It is also important to recognize that for many older people, intrinsic training in how to use the internet did not take place during their formal education or working life, and therefore, the barriers to access can be much more than about availability. Therefore, modifying any psychological barriers to active engagement with the internet is also important. More specifically, to promote internet use for communication, public policy makers should encourage private providers of social networking tools to create age-friendly interfaces. Hardware also needs to be appropriate for novice users and users with impairments such as poor eyesight. This requires manufacturers to be sensitive to these needs when designing products and making the accessibility settings easy to navigate to change the text size, for example.

Limitations

Several limitations of this study need to be acknowledged. The 8-item CES-D administered in ELSA does not measure depression, rather symptomology, and its association with internet usage may be confounded by omitted variables not included or imperfectly measured in this study. These might include the diagnosis of mental health problems and access to mental health services. Further research should theorize the possible pathways between internet usage and mental health to minimize potential confounding. The measurement of our main exposure is also imperfect, as we were unable to disaggregate daily use of the internet (almost half of the sample) by the number of hours spent on the internet on a typical day. Evidence from other studies suggests that spending an excessive amount of time on the internet correlates with negative mental health in younger age samples [42]. We are not aware of any evidence of the relationship between very frequent internet usage and mental health in older age. A further limitation is the limited 4 years of follow-up. More data points are necessary to explore in detail how any change in the frequency and purposes for internet usage impact mental health trajectories.

A final limitation of our study is the potential bias in our estimates because of the selective nature of participation in aging cohort studies, such as ELSA. Our study sample included participants from the refreshment samples added at waves 3, 4, and 6 to ensure a nationally representative sample of persons aged 50 years and older living in private households at the time of wave 6 (2012-2013). Although our analyses used the appropriate weights available for use with the ELSA study and used multiple imputed data to reduce (wave and item) nonresponse bias, the healthier nature of surviving participants could have inevitably led to an underestimation of the internet use and mental health associations.

Conclusions

In summary, internet use can serve as a channel for improving the mental health of older adults. With population aging and increases in the prevalence of poor mental health, promotion of (affordable) internet use and minimization of psychological barriers to digital engagement could potentially help to promote healthy living in older age.

Abstract

Background: Medical crowdfunding has emerged as a growing field for fundraising opportunities. Some environmental trends have driven the emergence of campaigns to raise funds for medical care. These trends include lack of medical insurance, economic backlash following the 2008 financial collapse, and shortcomings of health care regulations.

Objective: Research regarding crowdfunding campaign use, reasons, and effects on the provision of medical care and individual relationships in health systems is limited. This study aimed to explore the nature and dimensions of the phenomenon of medical crowdfunding using a visual analytics approach and data crawled from the GoFundMe crowdfunding platform in 2019. We aimed to explore and identify the factors that contribute to a successful campaign.

Methods: This data-driven study used a visual analytics approach. It focused on descriptive analytics to obtain a panoramic insight into medical projects funded through the GoFundMe crowdfunding platform.

Results: This study highlighted the relevance of positioning the campaign for fundraising. In terms of motivating donors, it appears that people are typically more generous in contributing to campaigns for children rather than those for adults. The results emphasized the differing dynamics that a picture posted in the campaign brings to the potential for medical crowdfunding. In terms of donor's motivation, the results show that a picture depicting the pediatric patient by himself or herself is the most effective. In addition, a picture depicting the current medical condition of the patient as severe is more effective than one depicting relative normalcy in the condition. This study also drew attention to the optimum length of the title. Finally, an interesting trend in the trajectory of donations is that the average amount of a donation decreases with an increase in the number of donors. This indicates that the first donors tend to be the most generous.

Conclusions: This study examines the relationship between social media, the characteristics of a campaign, and the potential for fundraising. Its analysis of medical crowdfunding campaigns across the states offers a window into the status of the country's health care affordability. This study shows the nurturing role that social media can play in the domain of medical crowdfunding. In addition, it discusses the drivers of a successful fundraising campaign with respect to the GoFundMe platform.

KEYWORDS

crowdfunding; medical crowdfunding; GoFundMe; fundraising; health care; health care affordability; patient; Facebook; fundraiser

Introduction

The crowdfunding phenomenon extends the traditional idea of fundraising into a contemporary internet platform-based funding

vehicle [1-3]. In this exploratory study, we applied visual analytics to study medical crowdfunding, in which individuals raise funds for their medical treatment or for research projects via digital platforms such as GoFundMe [4-8].

Crowdfunding is an old phenomenon. Its earliest form, designed by Joseph Pulitzer, channeled Pulitzer's newspaper to raise funds for the pedestal of the Statue of Liberty [1,9]. Similarly, this avenue has been used by artists, composers, and inventors to procure funding from backers willing to invest in their projects [10].

Crowdfunding has evolved into a powerful alternative to other traditional investment forms, such as venture capital, initial public offerings, and angel investments [1]. This trend has been facilitated by the ubiquity of digital media, including the internet, social media, e-commerce, and web-based advertising [11,12]. These platforms bestow comfort and ease in web-based transactions [1].

In the United States, the entrepreneurial culture has increased public awareness and the desire to support entrepreneurs [1,13]. As an alternative form of investment, crowdfunding offers opportunities for entrepreneurs to access various forms of funding [14]. As an example, Formlabs, a 3D printing startup, raised US \$2 million in seed funding. The business used the Kickstarter crowdfunding platform to raise an additional US \$2.9 million in the first year and US \$19 million in the following year [1]. Kickstarter was initially used to raise small amounts of capital. However, its funding potential has progressively increased [15]. It is projected that the platform will generate more than US \$300 million in funding by 2025 [16].

The process of crowdfunding begins with the entrepreneur's pitch (or narrative) on details such as their background, funding-reward structure, and overview of the project or product for which funding is needed. This stage is intended for prospective backers [1]. The narrative is used throughout the funding period such that potential funders can evaluate the venture or the entrepreneur can make a funding decision. Owing to its potential, the phenomenon of crowdfunding is deployed in various domains, including law and medicine [6,17-20].

This study aimed to explore the nature and dimensions of the phenomenon of medical crowdfunding. It used a visual analytics approach and data crawled from the popular GoFundMe platform. This type of exploration sheds light on the characteristics and magnitude of the phenomenon, offering ethical, health, and social policy implications and recommendations [4-8]. This exploratory study addressed the following questions:

1. What are the dimensions of medical crowdfunding?
2. What factors create a successful medical crowdfunding campaign?

The next section provides the background information on crowdfunding, particularly medical crowdfunding. Following this is the outline of the methodology. Next, the results of visual analytics are presented, along with the scope and limitations of the study. Finally, the implications and future research are covered, along with the conclusions.

Background

The success of crowdfunding in raising financial resources for new ventures has attracted the attention of entrepreneurs who explore this avenue for sourcing new ideas and projects

[12,21-24]. In particular, crowdfunding facilitates entrepreneurs who are in the formative stages of gathering financial resources to turn raw ideas into real business [21,23,25,26]. As this field grows, its conceptualization also evolves [12,15,21,23,27-30].

Research has identified key factors and definitions related to this phenomenon, including crowd, project creator (funding requester or fundraiser), and platform [21,27,28,30-35]. Some researchers suggest that a comprehensive definition of crowdfunding should include these elements as well as how each relates to or impacts others [21,34].

Microfinancing and crowdsourcing definitions have adopted a general conceptualization of crowdfunding [21,26,29,32,33,36-39]. The scope extends to both commercial and noncommercial forms of crowdfunding [14,21,27,35,40]. For example, Paschen [26] defined crowdfunding as "the outsourcing of an organizational function, through information technology, to a strategically defined network of actors (ie, the crowd) in the form of an open call specifically, requesting monetary contributions toward a commercial or social business goal." The objective of crowdfunding is that a crowd provides the "financial resources either in form of donation or in exchange for some form of reward and/or voting rights to support initiatives for specific purposes" [41]. In the context of new ventures and entrepreneurial financing, crowdfunding is defined as "the efforts by entrepreneurial individuals and groups—cultural, social, and for-profit—to fund their ventures by drawing on relatively small contributions from a relatively large number of individuals using the internet, without standard financial intermediaries" [29]. Other crowdfunding definitions, which focus on backers, are based on the contributions of an interested crowd of people in a specific phenomenon [42].

Using the context-specific approach, scholars have classified crowdfunding into several types [27,29,43-45]. Typically, 4 models can be broadly identified.

Donation

In this type of crowdfunding, funders support charity projects [46-49]. JustGiving, based in the United Kingdom, focuses on donation crowdfunding. Donors can be grouped based on the expectation of receiving rewards [26]. The first group (pure donors) financially supports crowdfunding projects without either monetary or nonmonetary returns [26]. The second group does not receive monetary rewards. Instead, it receives nontangible rewards such as recognition or tokens [21,50].

Investment (Equity)

This crowdfunding option allows funders to invest in a project or business and acquire equity in return. SoMoLend in the United States and Crowdcube in the United Kingdom are examples of this model [46].

Lending (Debt)

This type of crowdfunding is when funders lend money to a project or business and expect repayment with or without interest. Kiva is a well-known example of lending.

Rewards

In this system, funders receive tangible or intangible items as rewards [46]. Fundraisers can select individual reward schemes for their contributions. This is a popular form of crowdfunding [14,27,35,40,44,46,51-55]. Examples include GoFundMe, Indiegogo, and Kickstarter.

Among platforms, GoFundMe, Indiegogo, and Kickstarter were the top crowdfunding websites in 2019 in terms of both fundraising and volume [56]. Other crowdfunding platforms include Fundly, JustGiving, Crowdrise, Indiegogo, Teespring, Patreon, YouCaring [50], Chuffed, ArtistShare, MightyCause, InKind, Crowdfunder, Kiva, and GiveWP. Fundraisers can find support for novel projects through crowdfunding, which would have been difficult through traditional funding sources. In addition, fundraisers have a choice in selecting platforms in which they do not have to pay commissions unless the effort is a success. For example, Kickstarter collects a 5% commission only if a project reaches its funding goal [50].

The number of crowdfunding platforms has grown in the past few years. Platforms such as Kickstarter, GoFundMe, and Indiegogo have shown increasing trends in fundraising [22]. According to AP News, the global crowdfunding market is expected to exceed US \$28.77 billion by 2025 [57]. The potential for crowdfunding has urged regulatory efforts in the domain, such as the Jumpstart Our Business Startups Act [22]. In addition, many nonprofit businesses and governments are considering crowdfunding as a source for financing community programs aimed at serving the public [58]. In this regard, crowdfunding analytic tools can offer insights into the design of a successful fundraising campaign [22].

Next, this study focuses on the object of its research, that is, medical crowdfunding.

Medical Crowdfunding

In general, crowdfunding is being used for the development of community or social projects [6,29,58,59]. Health care can be considered both a community and social project because it incorporates programs such as poverty reduction and child education [6,29,59,60]. In this context, medical crowdfunding has emerged as a growing area of opportunity for crowdfunding [5,20,61-65].

What is the niche for medical crowdfunding? In recent years, crowdfunding has been adopted for entrepreneurial finance and litigation. More recently, individuals have deployed it for health issues and costs [6]. The increased need for funding health initiatives—the development of vaccines for public health or improving research protocols and systems—makes it a viable channel for deployment in the medical domain [5,6,66].

There are some renowned cases of medical crowdfunding [5]. For example, a campaign on RocketHub developed an affordable cost genome drug analysis test for patients [6,67]. This successful fundraising campaign spurred other campaigns like a rare genomic project for helping children with rare genetic diseases [68]. A campaign on Indiegogo analyzed microorganisms found on common public surfaces. The research aimed to prevent the spread of contagious diseases through

mobile alerts [6,8]. These, and other similar projects, motivated contributions by creating donor awareness about the potential for medical research [6,69,70].

Some US-based websites are exclusively devoted to helping patients. These include GiveForward, GoFundMe, and YouCaring [6,20,61,62,66]. People who are ill or with disabilities resort to crowdfunding as a means to raise funds for meeting health care costs [4,20,61,66]. Environmental trends drive patients and caregivers to these platforms to raise funds for medical care. Factors include lack of medical insurance; aftereffects of the financial downturn in 2008; and lack of health care regulations, such as the Affordable Care Act [4,6-8,68]. Although crowdfunding can be used for many forms of medical needs, campaigns for acute and exceptional medical needs are more likely to be funded than those for chronic needs [63]. Medical crowdfunding campaigns can include raising funds for a variety of reasons, such as treatment of diseases in adults or children, hospital expenses, postoperative care, homecare needs, and general support in terms of drugs and postdiagnosis protocols, among others.

There are some dedicated medical crowdfunding websites. YouCaring had 15,880 active medical campaigns in 2016. FundRazr had 5326 campaigns [8]. GoFundMe reported an increase from 8000 campaigns (raising US \$1.6 million) in 2011 to over 600,000 (raising nearly US \$150 million) in 2014 [5]. GiveForward reported that medical-related needs are its most popular form of crowdfunding campaign [63]. These websites are expected to grow annually at a rate of 25% [71].

Despite this trend, little attention has been given to medical crowdfunding campaigns in terms of exploring reasons for use, impact on the provision of medical care, and individual relationships to health systems [4,8,17,66]. This exploratory study was conducted to address the paucity and obtain a panoramic view of the current state of medical crowdfunding. It explored the dimensions of medical crowdfunding as well as the factors of a successful campaign.

Methods

Visual Analytics Approach

This data-driven study used a visual analytics approach with primarily descriptive analytics [72,73] to obtain a panoramic insight into medical projects funded through GoFundMe. Visual analytics provides researchers and policy makers with effective ways to comprehend and analyze large datasets while acting on the findings in real time [74]. By integrating the computer's capabilities with that of humans, visual analytics allows for the discovery of unexpected patterns and insights, which can lead to innovative and novel solutions [75,76]. It can address the challenge of information overload by translating information into viable opportunities, allowing researchers to examine results and the processes leading to those results [74,77,78]. The goal is to tell a compelling story through information visualization and the pillars of visualization, statistics, and data mining [75,77].

Descriptive analytics is based on the idea of describing data *as is* (without a preconceived assumption). Descriptive analytics

is more data driven than other models; it allows for the understanding of past and current patterns and data trends, using the insight for informed decision making [72,79]. Through categorization, characterization, and aggregation or classification of data, information is presented visually in the form of meaningful charts and reports for analyzing business decisions [72,79].

In the current context of medical crowdfunding, we deployed visualization with descriptive analytics to address insightful questions such as the following. Drawing from the literature on medical crowdfunding and from general insights in the domain of crowdfunding, particularly in the context of web-based platforms, we explored the following in our study:

1. What factors lead to the success of a medical crowdfunding campaign?
2. Is there an optimum length for a fundraising campaign to be successful?
3. Do gender and age of fundraisers play a role in the amount of funds that can be raised?
4. Do pictures posted by fundraisers impact the success of the campaign?
5. What role does social media play in crowdfunding, particularly medical crowdfunding?
6. How does an analysis of medical crowdfunding campaigns across the states offer a window into the status of health care affordability in the country?

The Platform: GoFundMe

The data source for this study is the GoFundMe crowdfunding platform, founded in 2010. It is the world's largest crowdfunding platform in terms of the total funding amount raised and the

total number of active campaigns [80]. GoFundMe campaigns include fundraising for several categories such as medical, memorials, emergency situations, and charitable causes.

In this study, we extracted data between June 19 and June 25, 2019, from the medical category of GoFundMe. We used the Selenium and BeautifulSoup packages in Python to crawl data from the medical category. Although it is possible that medical campaigns may exist in other categories, the medical category exclusively holds the bulk of these campaigns [7]. Therefore, we consider this to be an appropriate repository for medical crowdfunding campaigns. In addition, to ensure that only medical campaigns were included from this category in our data, we performed a manual perusal of the project descriptions upon extraction. Textbox 1 outlines the methodology used.

Table 1 describes the entities in the study and the variables for each entity. The entities in the crowdfunding study include the *fundraiser* (the person who is running the campaign and raising medical funds for himself or herself or another), the *campaign*, and the *donor*. We also show the source of each variable in terms of whether the code was directly downloaded from the data source or had to be coded after a manual perusal of the data. The variables are described in further detail in the context of the data analyses and results.

Using the web crawler, we collected data on 1000 medical crowdfunding campaigns. Three campaigns were eliminated for lack of data, resulting in a sample size of 997 fundraising campaigns. The raw data were extracted in a comma-separated value format and loaded into Tableau (Tableau Software Inc), a visual analytics tool. The following section discusses the results of the analyses.

Textbox 1. Methodology.

Data collection

- GoFundMe

Data preparation

- Data crawled from GoFundMe, extracted in a comma-separated values format, and prepared for an analytic tool

Platform selection and implementation

- Tableau 2019.2

Table 1. Variables in the research.

Entity and variable	Description	Source of variable code
Patient (for whom funds are being raised in the campaign)		
Gender	Gender refers to the gender of the patient for whom the campaign is developed (M: male, F: female)	Directly from the data source
Age	Age refers to the age of the patient for whom the campaign is developed. People below the age of 18 years are considered children, while others are considered adults (C: children, A: adult)	Directly from the data source
Campaign		
Group picture	Represents a picture that is posted in the campaign. If there is a single person in the picture, it is deemed to be a single picture. All other pictures are categorized as a group picture (G: group picture; S: single picture)	Manual review of data
Status	Status provides details regarding the picture of the patient (P: picture in which the patient appears healthy and not in a medical setting; N: picture in which the patient appears ill and in a medical setting)	Manual review of data
Position	Websites have multiple pages. Therefore, campaigns on the homepage are marked as <i>position 0</i> . Those on successive pages are marked with successive numbers (0-333)	Manual review of data
Location	The geographical location of the fundraiser (city)	Directly from the data source
Goal	The dollar amount that is sought through the campaign (US\$)	Directly from the data source
Length of fundraising	The time period for which the campaign has been active (months)	Directly from the data source
Amount raised	Amount raised denotes the total dollar amount that the campaign generated (US\$)	Directly from the data source
Facebook shares	Number of people who shared the campaign link on their Facebook page (#)	Directly from the data source
Favorite hearts	The number of people who liked the campaign on GoFundMe. This shows support toward the campaign (#)	Directly from the data source
Donor		
Number of donors	Number of people who donated to a campaign (#)	Directly from the data source

Results

Distribution of Campaigns

We first explored the geographic distribution of the number of medical fundraising campaigns across various states in the United States ([Figure 1](#)). In addition to the geographical distribution, the figure depicts the distribution by gender.

[Figure 1](#) shows that California has the highest number of fundraising campaigns (n=163), whereas the average number of campaigns for most states is approximately 20. This is followed by New York with 90, Texas with 65, New Jersey with 64, and Florida with 58 campaigns. We can only speculate on the distribution of fundraising amounts by state. For one,

according to the 2019 US Census, these are also the states with a population of over 10 million [81]. It is also suggested that platforms such as GoFundMe, Fundly, and JustGiving are gaining popularity as people struggle to meet rising health care costs [82]. On the basis of this information, our results suggest the need for further empirical exploration on whether the high number of campaigns in these states is, in some way, a reflection of the high population that naturally entails a higher usage of the platform, or more people using the crowdfunding platform to cope with rising health care costs [81,82]. [Figure 1](#) also reveals the analysis for gender. It shows that there are more campaigns by male patients 59.2% (59.2/100) compared with female patients 39.4% (39.4/100). In terms of age, our data show that most patients are primarily adults 80.9% (80.9/100).

Figure 1. Distribution of fundraising campaigns by state.

Factors Driving the Success of Campaigns in Terms of Amount Raised

We then explored factors that can drive the success of a campaign. For one, if the position of the campaign posting on the website and the length of time that the fundraising campaign was active had any influence on the amount of funds raised (Figure 2). In Figure 2, the x-axis shows the duration of the campaign in months, and the y-axis shows the total amount raised. The position is represented by the size of the band for each campaign within each bar. The position of the campaign is the page on the website on which the campaign appears. The smallest bar represents a campaign positioned on the first page of the website (0). The size of the bar increases with the change in position on successive pages. The positioning of the campaign can play a major role in raising funds. Per the rationale, campaigns on the front pages receive higher visibility with donors. Thus, these campaigns have a higher chance of funding.

The results in Figure 2 show a positive correlation between the position of the campaign and the amount raised. Campaigns

posted in the first few pages of the website do have a higher amount raised. With respect to the length of the campaigns, we found that campaigns that ran for 2 to 5 months received better funding and had a higher chance of meeting their goals. This shows that there is an optimal period for a campaign to remain active, beyond which the potential for increasing returns is questionable. Although this is an interesting finding, there is no prior research or literature to substantiate the reasons for the lack of an incremental effect on the amount raised after 5 months. We can only speculate on a few. For one, because of the increasing number of campaigns, after a period of time, donor attention may be diverted to other newer campaigns on the platform. Second, in medical crowdfunding, since the cause for funding is medical, this may have an effect on the perception of the sense of urgency of the need. A campaign that is open for a longer period may not convey an imminent sense of urgency as another that is open for a shorter term. However, further studies are needed to explore this in greater detail, incorporating more sophisticated techniques.

Figure 2. Impact of positioning and length of fundraising.

Factors in Closing the Gap Between the Goal and the Actual Amount Raised

In the context of fundraising, it is important to identify which features of the campaign have a favorable influence in terms of closing the gap between the goal amount and the amount raised. The aim is to ensure that the difference is reduced and that the goal is reached.

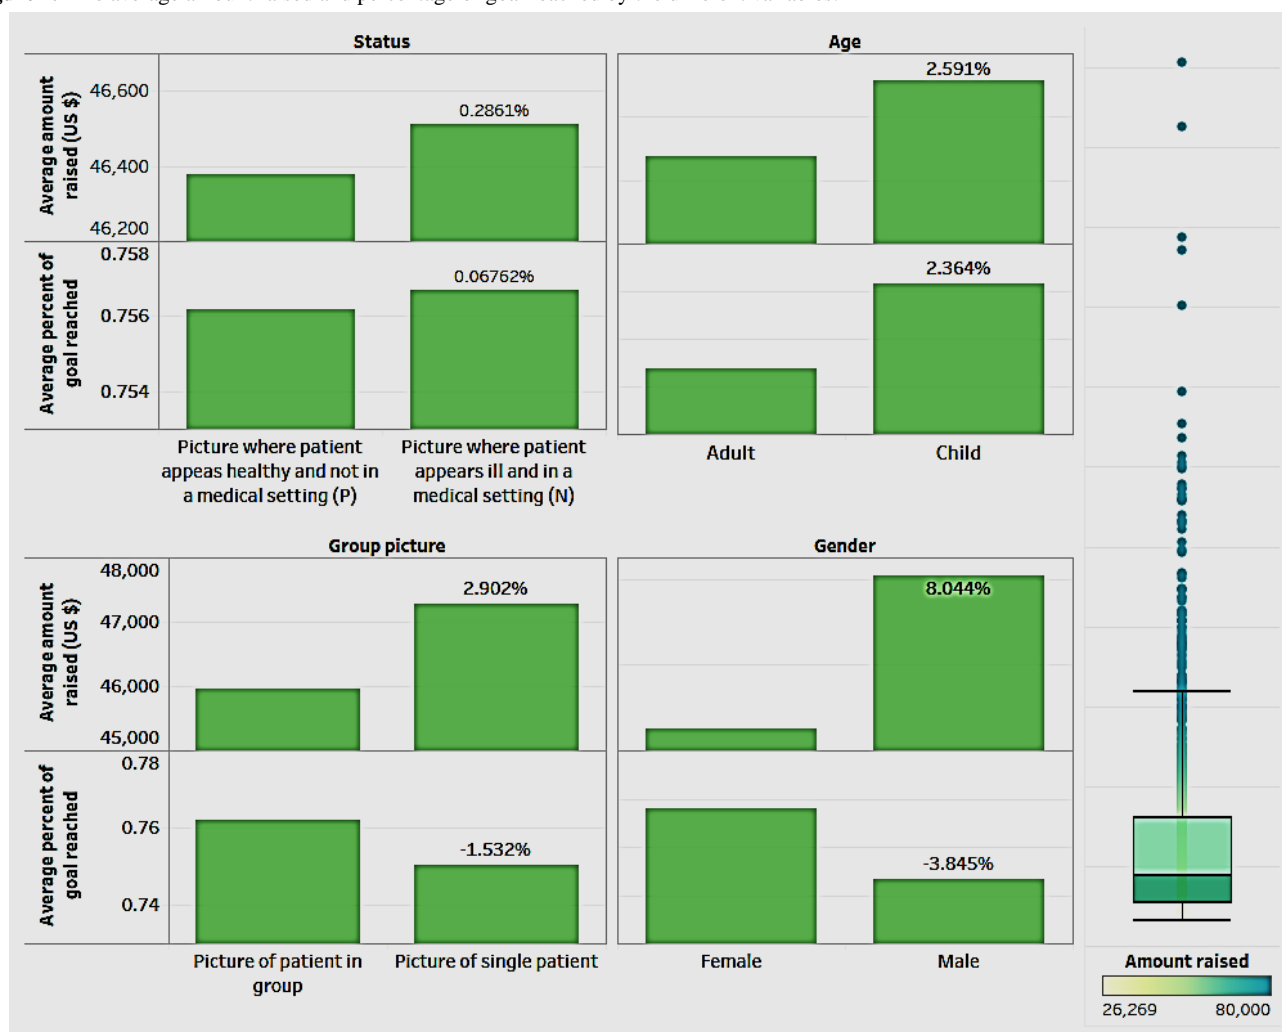

In this regard, we studied the role of the campaign length in influencing the gap between the goal and the amount raised. Figure 3 shows a combination line chart and a bar-in-bar chart. The blue bar shows the average goal of the fundraising campaign, the orange bar shows the average amount raised, and the yellow line chart shows the difference between the goal and the actual amount raised. These are depicted in the context of the length of fundraising (the x-axis).

According to Figure 3, as the length of the fundraising period (in months) increases, the difference between the goal and the actual amount raised decreases. The decrease lasts up to a period of 5 months. After that, the difference increases. This trend indicates that the optimal fundraising period to meet a goal is between 2 and 5 months.

Next, we explored the role of other variables related to the patient (such as gender and age) and the picture (status and

group picture) posted in the campaign (Figure 4). Gender refers to whether the patient is male (M) or female (F); age refers to whether the patient is a child (C) or an adult (A); status refers to the depiction of the status of the patient as reflected in the campaign picture—whether the patient appears healthy and not in a medical setting (P) or the patient appears ill and in a medical setting (N); and a group picture denotes whether it is a single picture (S) portraying only the patient or a group picture (G). Figure 4 uses a combination chart to show the average percentage of the goal reached and the average amount raised by each of the 4 variables.

In Figure 4, analysis by the status of the picture shows that campaigns with the picture of a patient appearing ill and in a medical setting (N) had a higher average amount raised and a higher average percentage of goal compared with campaigns with pictures where the patient appears healthy and not in a medical setting (P). On analyzing by gender, campaigns for male patients raised more funds (approximately 8%) on average than those for female patients; when comparing the average percentage of goal reached, campaigns for male groups lagged (by about 4%). When considering both the criteria of the average amount raised and the percentage of goal reached, campaigns for children raised more funds (about 2.5%) than those for adults.

Figure 3. Role of the length of fundraising in closing the gap between the goal and the amount raised.**Figure 4.** The average amount raised and percentage of goal reached by the different variables.

While the above analysis revealed the separate influence of age and picture on the average amount raised, we now analyzed their combined influence on the average amount raised. Figure 5 depicts the amount raised for adult and pediatric patients, differentiated by the type of picture in the campaign (single: S or group: G).

Figure 5 depicts the amount raised for adult and pediatric patients differentiated by the type of picture in the campaign. Some campaigns use a picture showing a single patient while others show the patient in a group. Our findings from the figure

show that for adult patients, the average amount raised with the picture of a single patient is slightly lower than that raised using a group picture. However, in the case of children, the trend is reversed, with a higher amount being raised with the picture of a single patient. Therefore, for adults, the difference is in the opposite direction and much less visible than for children. This holds interesting prospects for future research to further analyze the factors behind the differential effect being more pronounced for children. In addition, campaign developers can design campaigns with this differential in mind.

Figure 5. Influence of age and type of picture on the average amount raised.

Association of Popularity Measures of the Campaign With Amount Raised

Campaigns have several measures that denote their popularity. In our study sample from GoFundMe, these include favorite hearts and Facebook shares. Favorite hearts denote the number of people who liked the campaign on GoFundMe. Facebook shares denote the number of people who shared the campaign on their social media platform, Facebook. In addition to these 2 measures, we also analyzed the influence of the goal and number of donors on the amount raised. We further showed the percentage of goals reached in the scatterplots (Figure 6). The dashboard in Figure 6 shows the associations for each of the 4 variables.

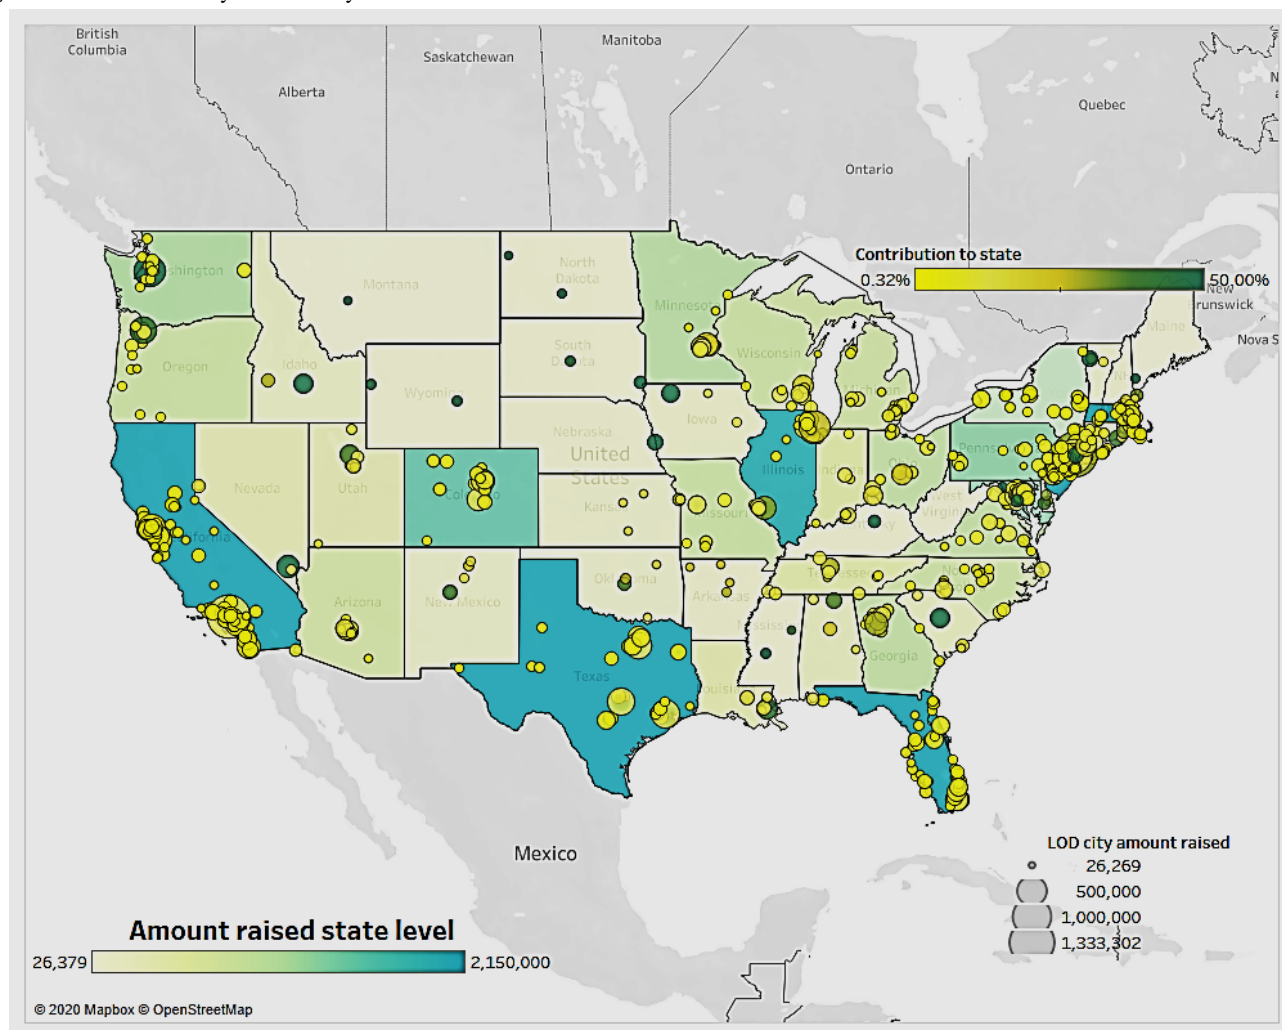

Figure 6 shows that favorite hearts have a significant and positive correlation ($P<.001$; $R^2=0.26$) with the amount raised.

Facebook shares did not have a significant correlation with the amount raised ($P=.06$). There was a significant positive correlation between funding goals and the amount raised for a campaign ($P<.001$; $R^2=0.30$). Therefore, the higher the goal, the higher the amount raised. Finally, the number of donors had a significant positive correlation with the amount raised ($P<.001$; $R^2=0.47$), which indicates that the higher the number of donors the higher is the amount raised. Keeping in mind that the average donation amount tends to be the same, the higher the number of donors correlates with the higher probability of raising a larger amount. From the analyses, we can see that in the association of goal with the amount raised, the colored bubbles show that the higher the goal amount, the higher the possibility of the percentage of the goal being achieved.

Figure 6. Association of amount raised with campaign popularity measures.

Figure 7 illustrates the state- and city-level distribution of the amounts raised. This includes 3 characteristics: the intensity of color inside the states denotes the amount raised by the state, such that the darker colors show larger amounts raised; the bubbles inside each state represent the amount raised at the city level; and the bubble color indicates the contribution of the city-level amount raised to the state's overall campaign amounts raised.

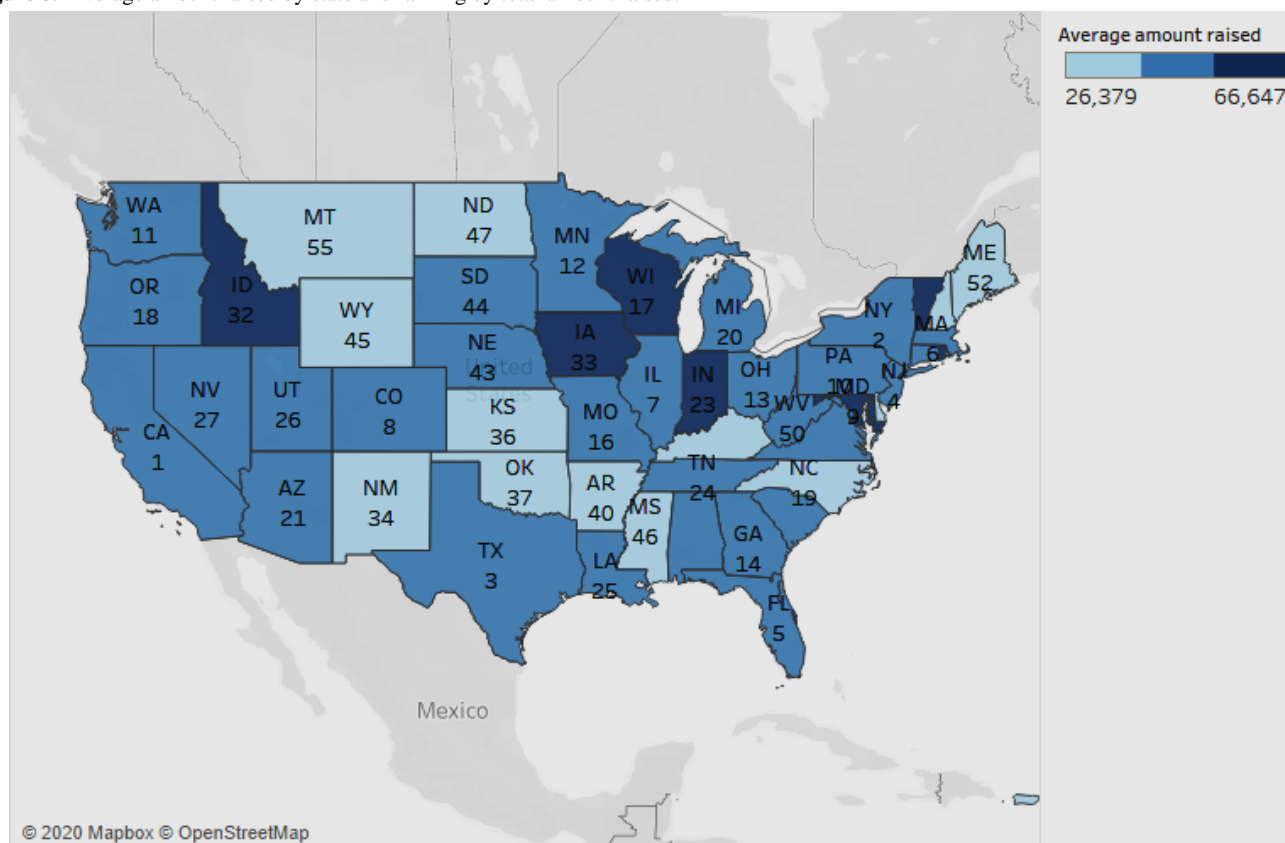

Figure 7 shows that California, New York, Texas, and Illinois have the highest amount raised compared with the other states. It also depicts clusters in the above states. These represent the locations of most of the crowdfunding campaigns. For example, areas around New York City and Los Angeles are the most concentrated in terms of campaigns created as well as amounts raised.

Figure 7. Amount raised by state and city.

Along the lines of state-level distribution, we performed a state-level comparison of the average amount raised and the total amount raised (Figure 8).

In Figure 8, in addition to the average amount raised in each state (denoted by the color), the ranking in terms of the total amount raised is indicated as a label. The figure shows Iowa, Indiana, Wisconsin, and Idaho as the states with the highest

average amount raised. However, in terms of the total amount raised, these states are ranked as 33rd, 23rd, 17th, and 32nd, respectively. In terms of the total amount raised, California ranks first, followed by New York, Texas, New Jersey, and Florida. These results highlight the potential for platforms such as GoFundMe to customize their campaign strategies based on the funding performance of the different states.

Figure 8. Average amount raised by state and ranking by total amount raised.

Association of the Amount Raised With Relevant Campaign and Fundraiser Variables

The box plot in Figure 9 shows the association of the amount raised with the age of the patients (child or adult) for whom the fundraising campaigns were developed.

Figure 9 shows that campaigns for adult and child patients have a similar median (approximately US \$30,000 to US \$40,000). However, the adult group has a higher biased distribution with more outliers. We propose that crowdfunding platforms pay special attention to these outliers because they may represent unique circumstances requiring specialized assistance and strategies for funding.

Figure 9. The median amount raised by age.

We compared the amount raised with the number of updates and the length of the fundraising campaign (Figure 10). In the figure, the intensity of the color denotes the average amount raised, with the darker color representing higher amounts. The 2 labels inside the boxes represent the number of updates (top label) and the length of the fundraising campaign in months (bottom label). The updates represent those posted to the campaign regarding health and treatment.

Figure 10 shows that campaigns with an average of 30 to 40 updates can raise much higher amounts in a 2- to 3-month period. The highest average amount raised is for a fundraiser with more than 40 updates and a period of 3 months. It should be noted that these are average values. In calculating these averages, we did not consider the position or the goal of the campaign. They were assumed to be the same across campaigns. These results indicate that we can focus on the length and the number of updates as relevant criteria to achieve a fundraising goal.

Figure 10. The average amount raised, number of updates, and length of campaigns.

Trajectory of Donations and Influence of Favorite Hearts and Updates

Next, we looked for patterns in donations over time based on the number of updates or the number of favorite hearts in a campaign (Figure 11).

Figure 11 shows the relationship between the average number of donors with favorite hearts and the average number of updates in a campaign. The size of the bubbles in the scatterplots

indicates the average amount raised. In Figure 11, we can see that the number of favorite hearts shows a significant positive association ($P=.04$) with the number of donors. Favorite hearts represent the number of people who liked the campaign on the GoFundMe website. It appears that people are more motivated to contribute if they see others endorsing a campaign in some manner. However, considering the lack of significance ($P=.06$) about the number of updates, it appears that donors focus on the initial story without following successive updates.

Figure 11. The average number of donors, favorite hearts, and updates.

Role of the Title and Description of the Campaign on Donations

The title of the campaign was important. Therefore, we wanted to explore whether it influenced the average number of donors and the average amount raised (Figure 12). Figure 12 shows the two-line charts. The green line indicates the average amount raised, and the blue line indicates the number of donors.

Figure 12 shows that campaigns with titles having a length of 6, 7, and 9 words had a higher average number of donors. Titles with 10 or 11 words had a higher average amount raised. It can be inferred that the title plays an important role. An interesting title with 6 to 11 words can have a strong association with raising funds. The figure shows that most campaigns use 2- to 7-word titles. Future studies can explore the content of titles in addition to the length of in-depth associations.

Multimedia Appendix 1 depicts a word cloud for keywords that appear more than 500 times in the textual descriptions of campaigns.

A word cloud is a visual representation of the frequency and value of a word. It is used to highlight popular or trending terms based on the frequency of use and prominence in a corpus of text. The more times a keyword is present in a dataset, the bigger and bolder the keyword appears. Multimedia Appendix 1 shows that frequently occurring words include help, family, cancer, support, medical, treatment, time, and hospital. These represent the most discussed topics as well as the key factors in medical crowdfunding campaigns. The word cloud analysis shows that a large number of campaigns were designed to help with costs related to cancer treatment.

Figure 12. Influence of title length.

Discussion

Principal Findings

The visual analysis provides key insights that can help in developing successful medical crowdsourcing campaigns. States such as California and New York show the highest number of campaigns in the country. This indicates the need for further empirical investigation into a few possibilities: whether the high population in these states [81] naturally suggests higher platform usage or being that the objective of medical crowdfunding is primarily to meet medical costs [82], whether high platform usage actually reflects people reaching out for health care needs [81,82]. This study showed that some factors influence the amount raised in a medical crowdfunding campaign. For example, the positioning of a campaign is crucial. Posting a campaign within the first 10 pages of the website enhances its visibility to donors.

In terms of donor motivation, people are typically more generous in contributing to campaigns for children. It is also interesting to note the dynamics that a picture brings to the fundraising potential of a medical campaign. This study showed that a single patient picture is more effective for children. A group picture is more effective when fundraising for adults. A picture depicting the current medical condition of the patient (as severe) is more effective in motivating donations than one that depicts normalcy in the patient's condition.

We draw attention to the importance and effectiveness of the title in a medical crowdfunding campaign. In this regard, an optimum length contains 6 to 11 words. Regarding the role of gender and age of patients for whom the campaigns are developed, it appears that campaigns for female children are more successful, raising up to 78% of the goal amount.

Finally, an interesting trend in the trajectory of donations is that the average donation decreases with an increase in the number of donors. This indicates that the first donors tend to be the most generous. These initial donations are typically substantive, suggesting that they may be from the family or friends of the fundraiser. The public at large seems to donate marginally less than the initial donors.

Scope and Limitations

This study has some limitations. We crawled the data during a specific time period, that is, 2019. Therefore, it provides a snapshot of crowdfunding activity. Future studies should span a longitudinal timeframe and a more expansive set of variables. In addition, although we used a visual analytics method, alternative techniques such as data mining (ie, clustering, association) can be deployed. Although visual analytics, as a methodology, offers descriptive analysis, further empirical investigation is needed to draw quantitative conclusions. Furthermore, although the research focuses on the amount raised, goal, and position of the campaign, information on the fundraiser's background is not included. Access to fundraiser information would help ascertain whether certain profiles are more successful in attracting donations. Including specific information about the donors may also enable researchers to conclude whether the donor knew the patient or how many

people donated to an unknown cause. Future studies can analyze differences in the type of patients for whom funds are raised (eg, medical expenses for a patient or pet). In addition, future studies can incorporate details on the insurance coverage of fundraisers. This might help ascertain their actual medical requirements. It will also be interesting to determine the current situation of fundraisers with regard to whether the treatment is completed or ongoing.

Implications

Despite these limitations, this research presents numerous contributions to the literature on medical crowdfunding and health care. This research highlights factors that are key to the success of a medical crowdfunding campaign. It also demonstrates the critical role of social media in the domain of health care. For example, research shows that campaigns with photos, frequent updates, and descriptions get more hearts (likes) and Facebook shares.

Through this research, we show how data-driven analytics can help donors make educated, fact-based contribution decisions in medical crowdfunding. The visual analytics methodology offers a holistic perspective on the phenomenon, including insight for policymaking in the arena of medical crowdfunding. Furthermore, this study offers insight into the geographic distribution of crowdfunding campaigns. This highlights the need for advanced analytics to empirically explore the contributing factors for differentials in platform use and fundraising success by state.

Conclusions and Future Research

This study focused on the dimensions and factors of a medical crowdfunding campaign using the most popular platform, GoFundMe. We examined the relationship between the use of social media, the characteristics of a campaign, and the potential for fundraising. The analysis of medical crowdfunding campaigns across the states offers a window into the status of health care affordability in the United States. The research shows the nurturing role that social media can play in the domain of medical crowdfunding. We also add to the drivers of a successful fundraising campaign with respect to the GoFundMe platform.

This research is significant because the topic of medical crowdfunding has been gaining public attention. Ethical concerns have been raised in relation to these kinds of campaigns. Most of these concerns focus on issues relating to both fundraisers and donors, such as exposure to fraudulent campaigns, loss of privacy, and fairness in fund distribution [6,8,65]. There is also a debate on whether campaigns can be designed to raise funds for medical treatment or conditions related to pets.

In the meantime, systematic efforts to comprehend the scope of these ethical concerns are lacking. For example, a search on Google Scholar using the terms *medical* and *crowdfunding* returned only 3 results focusing on crowdfunding specifically for covering medical expenses rather than for research [6,8,68]. Researchers and academicians can add insight into the phenomenon of medical crowdfunding given the interest in the social dimensions of health care combined with the ability to deploy a variety of methods from different disciplines [6,8,65].

For instance, health geographers can offer insight into the spatial dimensions of campaigns, such as the extent of the donor network from an ethics of care approach [6,8,68]. Health economists can explore the regulatory aspects related to the possible competing interests of parties in medical crowdfunding. Health informatics experts can incorporate leading-edge technology such as text analytics or sentiment analysis to analyze whether the severity of the medical condition influences the funds raised for medical crowdfunding campaigns.

Drawing from our research and the related literature, we propose ethical and social considerations for future medical crowdfunding research. First, it is important to explore how medical crowdfunding impacts the national phenomenon of health care, specifically affordability and cost of care. The exploration of whether the age group of patients has a

differential impact on fundraising potential is also important. Second, crowdfunding platforms are all technology based. Therefore, research needs to explore fundraiser information privacy and security [6,8,65]. Third, the associated aspect of regulating misuse of platforms for fraudulent campaigns, including misrepresenting the severity of illness for securing funds or misappropriating funds, needs to be investigated [8,62]. Fourth, the results of the study emphasize the role of social media endorsements for crowdfunding campaigns, such as Facebook shares. It also questions whether social media companies should regulate the authenticity of endorsements as well as their role in influencing potential donors. At this stage, more social, political, and economic issues will continue to be explored as the prevalence and popularity of crowdfunding technology platforms rise.

Abstract

Background: People from underserved communities such as those from lower socioeconomic positions or racial and ethnic minority groups are often disproportionately targeted by the tobacco industry, through the relatively high levels of tobacco retail outlets (TROs) located in their neighborhood or protobacco marketing and promotional strategies. It is difficult to capture the smoking behaviors of individuals in actual locations as well as the extent of exposure to tobacco promotional efforts. With the high ownership of smartphones in the United States—when used alongside data sources on TRO locations—apps could potentially improve tobacco control efforts. Health apps could be used to assess individual-level exposure to tobacco marketing, particularly in relation to the locations of TROs as well as locations where they were most likely to smoke. To date, it remains unclear how health apps could be used practically by health promotion organizations to better reach underserved communities in their tobacco control efforts.

Objective: This study aimed to demonstrate how smartphone apps could augment existing data on locations of TROs within underserved communities in Massachusetts and Texas to help inform tobacco control efforts.

Methods: Data for this study were collected from 2 sources: (1) geolocations of TROs from the North American Industry Classification System 2016 and (2) 95 participants (aged 18 to 34 years) from underserved communities who resided in Massachusetts and Texas and took part in an 8-week study using location tracking on their smartphones. We analyzed the data using spatial autocorrelation, optimized hot spot analysis, and fitted power-law distribution to identify the TROs that attracted the most human traffic using mobility data.

Results: Participants reported encountering protobacco messages mostly from store signs and displays and antitobacco messages predominantly through television. In Massachusetts, clusters of TROs (Dorchester Center and Jamaica Plain) and reported smoking behaviors (Dorchester Center, Roxbury Crossing, Lawrence) were found in economically disadvantaged neighborhoods. Despite the widespread distribution of TROs throughout the communities, participants overwhelmingly visited a relatively small number of TROs in Roxbury and Methuen. In Texas, clusters of TROs (Spring, Jersey Village, Bunker Hill Village, Sugar Land, and

Missouri City) were found primarily in Houston, whereas clusters of reported smoking behaviors were concentrated in West University Place, Aldine, Jersey Village, Spring, and Baytown.

Conclusions: Smartphone apps could be used to pair geolocation data with self-reported smoking behavior in order to gain a better understanding of how tobacco product marketing and promotion influence smoking behavior within vulnerable communities. Public health officials could take advantage of smartphone data collection capabilities to implement targeted tobacco control efforts in these strategic locations to reach underserved communities in their built environment.

Introduction

Background

Tobacco use is a major risk factor for lung cancer and premature morbidity [1] and also one of the leading preventable causes of death in the United States [2,3]. Approximately 480,000 deaths (1 in 5 deaths) in the United States annually could be attributed to smoking or tobacco consumption [4]. Although tobacco use is a prevalent public health problem in the United States, research has shown that the health and economic burden of tobacco use disproportionately affect underserved communities and that these communities have not benefitted from tobacco control efforts as much as others [5]. Research has also shown that the density of tobacco retail outlets (TROs) is higher in low-income neighborhoods [6] as well as in communities with higher percentages of ethnic minorities [7,8]. In addition, people from lower socioeconomic positions (SEPs) are often the target of the tobacco industry's advertising, including the places of their residence [9]. The presence of TROs, together with a disproportionate exposure to protobacco messages, is associated with smoking behaviors and may attenuate the attempts of smokers to quit by allowing easy access to tobacco products as well as encouraging impulse purchases by providing environmental cues for smoking [10].

Although many studies have examined how factors such as the proximity of a residence to TROs and exposure to protobacco messages are related to smoking attitudes and initiation, smoking prevalence, and even hospital admissions [3,11-14], few studies have investigated the exposure and awareness of antitobacco messaging within underserved communities, particularly in relation to TROs and across media platforms. For instance, what are the media platforms where underserved communities are exposed to anti- or protobacco messages? Are people strategically exposed to antitobacco messages near locations such as TROs or places they are most likely to smoke or other places? To date, research on the extent of such antitobacco and protobacco message exposure is limited by its reliance on aggregated cross-sectional self-reported survey data.

The Potential of Smartphone Apps in Informing Protobacco and Antitobacco Messaging Efforts

With the ubiquity of smartphone ownership, particularly within vulnerable communities, data from smartphone apps provide a potential data collection mechanism for informing health policy makers where to focus antitobacco messaging efforts [15,16], especially when they are used to complement traditional data

sources such as the location of TROs. After all, smartphone penetration in the United States is high, with about 81% of the population owning a smartphone; the smartphone ownership figures are also high for underserved communities, such as people living in rural areas (71%), those making less than US \$30,000 annually (71%), and in minority communities (approximately 79% to 80%) [17]. Health promotion organizations and policy makers could take advantage of the contextual information provided by smartphones to identify strategic areas to help ensure adequate exposure to antitobacco messages [18].

Smartphones enable researchers to *passively* engage in data collection at-scale within people's naturalistic environments. For instance, by enabling geolocation tracking with the explicit consent of users, smartphone apps can collect temporally ordered information on the precise locations they visited or the paths they have taken, without being intrusive. The ability to track the behaviors of those in underserved communities in situ is a huge advantage over traditional survey methods that rely on self-reported recall [19]. Methods based on recall are limited in that participants may not remember all locations they have visited accurately, or they may omit details for the sake of social desirability (eg, underreporting of places they may perceive as undesirable). Geolocation tracking can provide valuable information for health organizations in helping to strategically target antitobacco messaging efforts by accurately identifying where protobacco messaging is being encountered. For example, the mobility or path data that outline how individuals move through their communities would be useful for identifying the most popular TROs and other place-based platforms where messages are being aired.

This type of smartphone data collection might also provide opportunities for health organizations to partner with underserved communities for *participatory science* efforts [20]. Although collecting data from the underserved communities can be extremely difficult [21], the use of smartphones could circumvent this problem as it adds a minimum logistical burden given the role of smartphones in their lives. The data collection could employ ecological momentary assessment (EMA) techniques, which assess particular events in the lives of subjects at periodic intervals, such as smoking behavior or exposure to specific types of messages, which are automatically prompted. These data, together with geolocation of smoking-related behaviors, could be used to map smoking *hot spots* [22]—defined as locations where there are non-random observed patterns of clustering—which are areas where there is a

statistically significant clustering of respondents who report smoking in the same area.

These types of data collection efforts can facilitate the proactive reporting of exposure to tobacco messages that have high temporal specificity and are capable of capturing details of even ephemeral exposures (eg, a photo of an advertisement on a rotating billboard or as part of a video at a gas station and radio advertisements). Insights into where and how anti- and protobacco messages are reaching those in underserved communities can assist tobacco control practitioners and policy makers in helping reduce the disproportionate burden of tobacco use within vulnerable communities.

Objectives of the Study

This study aimed to examine how smartphone app data collection could complement existing data sources to help inform tobacco control efforts for underserved communities. There are three specific objectives of this paper. First, we sought to identify if there were concentrations of TROs in Massachusetts and Texas. Second, using both passive (ie, geolocations) and active (ie, self-reports) data, we aimed to identify (1) the most popular TROs, denoted by a small number of TROs that attracted the most human traffic; (2) the areas in which participants were most likely to smoke; and (3) the locations where the participants reported exposure to tobacco messages and where the concentrations of pro- and antitobacco messages were. Third, we drew suggestions for tobacco control based on our results.

Methods

Study Design and Recruitment

To address the objectives of our study, we conducted a small-scale feasibility test using a smartphone app in underserved communities in Massachusetts and Texas. We have chosen to conduct the study in these 2 states, given the diversity in tobacco control policy implementation, where Massachusetts had stricter tobacco laws as compared with Texas [23,24]. Ethics approval was obtained from the respective institutional review boards (IRBs) of Harvard University, Baylor College of Medicine, and the University of Saskatchewan after extensive review, which ensured that adequate layers of protection were in place for our participants. Upon receiving the IRB approvals, we recruited 95 participants (smokers and nonsmokers) aged 18 to 34 years who resided in different cities within Massachusetts and Texas to participate in our 8-week smartphone tobacco tracking study.

Participants were required to meet the following criteria: (1) existing Android smartphone users with a data plan (although we covered the costs of their plan for the duration of the study) or would be willing to change their primary phone to a study-compatible phone, (2) consented to download a location-tracking smartphone app called *Ethica* and to keep their location-tracking feature switched on for the duration of the study, and (3) were willing to complete a pretest at the start of the study and a posttest at the end of the study as well as respond to EMAs that would be pushed to them. *Ethica* is a smartphone app designed to collect sensor-based data (eg,

geolocations, accelerometry, and electrodermal activity) as well as contextual self-reports (eg, EMAs).

Once the participants downloaded *Ethica* (assisted by study staff) and registered using their email and a password, the study staff helped ensure that the location-tracking feature on their phones was enabled. The participants were then asked to complete the pretest via the app on their smartphone. This pretest contained questions pertaining to demographics, smoking status, number of cigarettes smoked in the past 30 days, and other related smoking attitudinal and behavioral questions. The location-tracking app began collecting geolocation data once registration was complete. At the end of the study, the participants completed a similar posttest.

Profile of Participants

Among the 95 participants (49 females, 42 males, 4 nonresponse), 51 were from Massachusetts and 43 were from Texas, with 1 nonresponse. Of all the 95 participants, when asked if they were of Hispanic, Latino, or Spanish origin, 54 (57%) reported they were “not of Hispanic, Latino, or Spanish origin”; 7 (7%) were “Mexican, Mexican American, Chicano”; 10 (11%) were “Puerto Rican”; 12 (13%) were “Dominican”; 1 (1%) was “Cuban”; 6 (6%) were “another Hispanic, Latino, or Spanish origin (eg, Guatemalan, Salvadoran, Honduran, Nicaraguan, Panamanian, Colombian, Venezuelan, Peruvian)”; and 5 (5%) with no response. In terms of race, 37/95 (39%) of our participants identified as “Black or African American”, 33/95 (35%) as “White”, and the rest identified themselves as a combination of different ethnic groups (eg, “American Indian or Alaska Native”, “Asian”, “Native Hawaiian”, or “other Pacific Islander”).

The median total combined household income was between US \$20,000 and US \$29,000 (from 1 [US \$10,000] to 9 [≥US \$75,000]; median 3.00 [US \$20,000 and US \$29,000]; SD 2.11), and the median education status was having *some college* (1 [completed grade school or less] to 8 [completed graduate or professional school after college]; median 5.00 [some college]; SD 1.32). In total, 53 participants self-identified as smokers, whereas 41 were nonsmokers, with 1 nonresponse. The participants were also asked to report the total number of cigarettes they smoked in the past 30 days (mean 11.3, SD 13.4).

Data Management and Processing

Geolocations of Tobacco Retail Outlets

The geolocations of TROs were obtained from the North American Industry Classification System (NAICS). Developed by the Office of Management and Budget, NAICS is the federal standard business classification system based on the primary activities of businesses. We identified and extracted records for 252 TROs in Massachusetts and 1422 in Texas, based on the NAICS classification of *Tobacco Stores*. For this study, we chose to focus our analysis on TROs that were solely cigars, cigarettes, and tobacco dealers and retailers or smoke shops (NAICS8 code: Tobacco Stores) and excluded retailers whose primary descriptions were not in the area of tobacco sales (eg, beer, wine, and liquor stores; convenience stores; and gasoline stations with convenience stores), even though they might sell tobacco products. The reason for excluding these stores was

that people might pass by or linger at these places because of reasons (eg, when shopping for groceries) other than tobacco purchase and consumption.

Participants' Geolocations

Ethica collected approximately 31 million time-stamped geolocations from all the participants recorded in millisecond intervals. To increase the reliability of the data (eg, as there were multiple geolocations of individuals recorded when they were stationary), we collapsed participants' geolocations into multiple 10-min time intervals and extracted the most accurate and representative longitude and latitude locations for each interval. In total, there were 279,840 geolocations of participants from Massachusetts and 227,991 geolocations for participants in Texas.

Geolocations of Smoking Behaviors

Questions regarding smoking behaviors were randomly administered 4 times a day to smokers via Ethica (between 8 AM and 9 PM on weekdays and between 10 AM and 9 PM on weekends). The geolocations of participants when they were smoking were captured from their responses to the question "Have you smoked in the past hour," in which they were asked to select from the following responses: (1) I smoked a cigarette in the past hour, (2) I smoked an electronic cigarette (e-cigarette) in the past hour, (3) I used another tobacco product in the past hour, (4) I am smoking a cigarette right now, (5) I am smoking an e-cigarette right now, (6) I am using another tobacco product right now, and (7) I have not smoked. To obtain the geolocations of the participants when they were smoking, we extracted the longitude and latitude of smokers at the time if they indicated that they were smoking a cigarette or an e-cigarette or using another tobacco product *right now*. A total of 10,393 smoking geolocations in Massachusetts and 10,187 in Texas were recorded.

Geolocations of Tobacco Message Exposure

Through Ethica, participants were able to take or upload photos of tobacco messages and advertisements they came across in their communities (eg, billboards, TROs) or on the internet. After this, they were prompted to answer an EMA survey where the participants were given the options to identify the messages as either antitobacco or protobacco and to report when they saw the message (where 1=I see it right now; 2=in the past hour; 3=in the past 1-5 hours; 4=more than 5 hours ago). The latitude and longitude of the photos and EMA surveys were logged using Ethica.

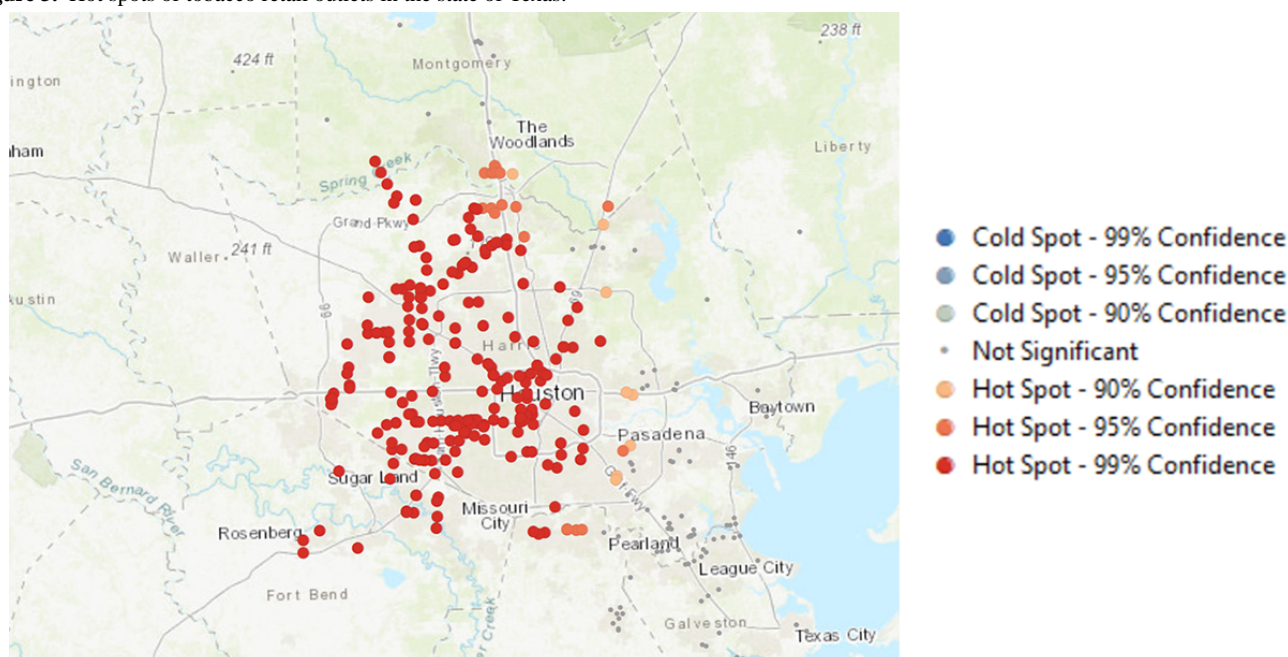

Statistical Analysis

Data were imported into ArcMap 10.6.1 for mapping and statistical analyses, where we conducted *spatial autocorrelation* and *optimized hot spot analysis* as well as *power-law analysis* in R studio (version 1.8383) to address all the study objectives. The global spatial autocorrelation was used to test for the presence of spatial variation in a given dataset [25], specifically in examining the correlation among data points that are close to one another and to determine if there is a nonrandom spatial clustering among data points that were in close proximity [26]. The global Moran index is a statistic that indicates the presence of statistically significant spatial clustering, which produces a number between -1 and $+1$. A negative value indicates the presence of negative spatial autocorrelation, which is the tendency for dissimilar values to be located together. On the other hand, positive values indicate the presence of positive spatial autocorrelation, where data points with similar values are clustered together [25]. If the presence of spatial clustering was detected, we then conducted the optimized hot spot analysis to examine the locations of the *hot spots* and *cold spots* of TROs, smoking, and antitobacco messages.

The power-law analysis aimed to test if there was an observable power-law distribution in the data. A power-law distribution is also known as a heavy tail distribution, where smaller values on the x -axis correspond to large values in the y -axis. In other words, in the context of this study, if a power-law distribution is observable, a small number of TROs would attract the most human traffic. This may suggest that certain TROs are more popular, or centrally located, such that people are more likely to pass by as compared with TROs located in obscure locations.

Results

Our first objective was to identify if there were concentrations of TROs (ie, TRO hot spots) in Massachusetts and Texas (see Figures 1-3). To do so, we conducted spatial autocorrelation on the geolocations of TROs and determined if there was a statistically significant spatial clustering of TROs. The results suggest that there was evidence of clustering of TROs in both Massachusetts (global Moran index=0.79; $z=8.04$; $P<.001$) and Texas (global Moran index=0.69; $z=5.85$; $P<.001$). Next, optimized hot spot analysis in ArcMap showed that there was a statistically significant clustering of TROs in the city of Boston, with the most significant clusters found in Dorchester Center, Jamaica Plain, and Hyde Park ($z\geq 3.50$; $P<.001$). The TRO hot spots in Texas were found in Houston, and they were in places such as Spring, Jersey Village, Bunker Hill Village, Sugar Land, and Missouri City.

Figure 1. Hot spots of tobacco retail outlets in the state of Massachusetts.**Figure 2.** Zoomed-in view of the most significant hot spots in the city of Boston.**Figure 3.** Hot spots of tobacco retail outlets in the state of Texas.

Our second objective was to draw upon both passive (ie, geolocations) and active (ie, self-reports) data to identify (1) the most popular TROs, (2) the areas in which participants were most likely to smoke, and (3) the locations where participants reported being exposed to tobacco messages and where these concentrations of protobacco and antitobacco messages were.

To examine which were the most popular TROs—if a small number of TROs attracted the most traffic—we tested if a power-law distribution was observable by analyzing geolocations of participants near the TROs. To do so, we created a 100-m buffer around all the TROs in our dataset and performed a spatial join with all the geolocations that intersected within the buffer. The selection of a 100-m buffer was consistent with previous research [27]. We then exported the data to R studio to fit a power-law distribution in accordance with the steps recommended by Clauset et al [28]: (1) construct a discrete power-law distribution object, (2) estimate the x_{\min} and exponent α of the power law and assign them to the power-law object, and (3) bootstrap to obtain the P value for the hypothesis test of if the data followed a power-law distribution. In the Kolmogorov-Smirnov test, the null hypothesis is that observations will follow a specific distribution, whereas the alternative hypothesis specifies that a set of distribution does not follow a specific distribution. As such, to claim that observations follow a power law distribution, the P value would have to be equal or more than .05 for the null hypothesis to be accepted, thereby indicating the presence of a power-law distribution. The analysis found marginal support for the power-law distribution ($D=0.12$; $P=.05$) for TROs in Massachusetts (Figure 4) but not for Texas. The top TROs that attracted the most human traffic from our sample were in the neighborhood of Roxbury in the city of Boston and Methuen, a city close to Boston.

Next, to identify the areas where participants were most likely to smoke (ie, smoking hot spots), we conducted spatial autocorrelation on geolocations where the participants reported their smoking behavior through the EMAs and determined if there was a statistically significant spatial clustering of smokers who reported smoking (Figure 5). The results suggest that there was significant clustering in both Massachusetts (global Moran index=0.29; $z=34$; $P<.001$) and Texas (global Moran

index=0.25; $z=63.5$; $P<.001$). Next, we conducted optimized hot spot analysis, and the results showed that in Massachusetts, the heaviest smokers (based on the number of cigarettes smoked in the past 30 days) tended to report that they smoked in Dorchester Center, Roxbury Crossing, Lawrence, and Peabody ($z\geq 2.84$; $P<.001$). In Texas, the heaviest smokers tended to report smoking in West University Place, Aldine, Jersey Village, Spring, and Baytown ($z\geq 2.67$; $P<.001$).

To identify the locations where the participants reported being exposed to antitobacco and protobacco messages, we examined the photos taken by the participants through the app where they rated if the messages were either antitobacco or protobacco. In Massachusetts, there were 41 antitobacco and 48 protobacco messages reported (see Multimedia Appendix 1). The top 3 most frequent platforms for exposure to antitobacco messages in Massachusetts were on (1) television and others (19.5% each, 8/41 for television and 8/41 for others), (2) store sign or display (7/41, 17.1%), and (3) billboard/bus/train stop advertisements (6/41, 14.6%). The top 3 highest exposures to protobacco messages were on (1) store sign or display (27/48, 56.3%), (2) newspaper or magazine (7/48, 14.6%), and (3) website (5/48, 10.4%).

In Texas, there were 63 antitobacco and 43 protobacco messages (Multimedia Appendix 1). The top three highest exposures to antitobacco messages in Texas were (1) others (21/63, 33.3%), (2) television (14/63, 22.2%), and (3) store sign or display (7/63, 11.1%). The top 3 highest exposures to protobacco messages were on (1) store sign or display (25/43, 58.1%), (2) others (7/43, 16.3%), and (3) television (4/43, 9.3%).

Finally, we aimed to examine if there were spatial clustering of tobacco messages and if such clusters were located near TROs or smoking hot spots. We analyzed the data using spatial autocorrelation, and the results suggested that there was evidence of antitobacco message clustering in Massachusetts (global Moran index=0.28; $z=1.89$; $P=.06$) but not in Texas (global Moran index=-0.12; $z=0.73$; $P=.07$). We then conducted an optimized hot spot analysis for antitobacco messages in Massachusetts, and the results showed that the clustering of antitobacco messages ($z=3.85$; $P<.001$) only occurred in Lawrence in Massachusetts (Figure 6). There was no evidence of protobacco message clusters.

Discussion

This study showcases how data from smartphone apps could significantly inform tobacco control communication efforts when used to complement existing data sources, such as the geolocations of TROs in our study obtained from NAICS [29]. Using these methods, we were able to identify the locations where our participants were exposed to tobacco messages (anti- and pro-), the specific TROs that attract the highest level of patrons, as well as areas where individuals were most likely to smoke. There are several notable findings from our results. The data showed that physical locations still matter more than online tobacco messages when considering where people were most likely to encounter external cues for tobacco use, such as locations of TROs and areas where protobacco messaging were reported. From NAICS data, there was a concentration of TROs in economically disadvantaged areas within Boston, such as the Dorchester Center and Jamaica Plain [30]. In Texas, our data showed that there was a high concentration of TROs across Houston.

The data from smartphones complement traditional tobacco surveillance data, such as population health surveys [31], in that smartphone data provide context to how access to tobacco products and exposure to marketing and promotional efforts may influence tobacco use behavior within underserved

communities. For example, we found that in both Massachusetts and Texas, participants reported that they predominantly encountered protobacco messages at store signs or displays as compared with web-based sources. This is somewhat surprising considering the increasing concern about the influence of social media posts in the promotion of tobacco, either through user-generated content on social media or through targeted industry web-based advertising efforts [32,33]. In contrast, although our participants reported encountering antitobacco messages through web-based and offline sources, they were most likely to come across antitobacco messages on television. In addition to airing messages on mainstream media, public health officials should consider boosting efforts in placing antitobacco messages around TROs.

Another finding is that in both Massachusetts and Texas, participants reported encountering fewer antitobacco messages in newspapers or magazines as compared with protobacco messages. This is consistent with the findings from a recent study [34], which aimed to determine the extent of exposure to federal court-ordered antismoking advertisements—where tobacco companies were required to pay for these advertisements to correct smoking misinformation [35]—among a nationally representative sample of the adult population in the United States in 2018. The study found that the overall estimated exposure to antismoking advertisements was generally low

(40.6%), with the lowest exposure rates found among people aged 18 to 34 years (37.4%), those who had high school education or less (34.5%), those who earned less than US \$35,000 annually (37.5%), and Hispanic smokers (42.2%). Although it was difficult to definitively pinpoint why our participants reported low exposure to antitobacco advertisements in newspapers, one plausible reason was that young people such as those in our sample may not be using print newspapers and magazines as much as the internet and social media [36,37], and thus, they would be less likely to come across antitobacco messages across traditional media platforms. In addition, research has documented that people from underserved communities were less likely to use newspapers as their primary news sources as compared with individuals from higher SEPs [38].

Second, this type of smartphone data collection allows one to target strategic areas for antitobacco message placement. For instance, in the state of Massachusetts, there was evidence of antitobacco messages only in Lawrence, which traditionally has a higher percentage of adult smokers and TROs per 1000 adults as compared with other parts of Massachusetts [39]. Although this was a positive step, there was a need for broader dissemination of antitobacco messages to reach other areas where popular TRO hot spots were found (Dorchester Center, Jamaica Plain, and Hyde Park), specific TROs (Roxbury and Methuen) with highest human traffic, as well as areas where smoking was concentrated (Dorchester Center, Roxbury Crossing, and Peabody).

Third, it is evident that the use of smartphone data to inform antitobacco messaging efforts for underserved communities is not a magic pill solution, as it would need concurrent *supply side* tobacco control regulations to be most effective. In Houston, the widespread prevalence of TROs remained problematic for targeted antitobacco messaging to be efficacious. In other words, effective and targeted antitobacco messaging in Texas would need to be accompanied by concurrent supply side solutions, such as restricting the number of TROs or increasing tobacco taxes.

Despite the study's significant strengths, there are limitations. First, we relied on a small sample of individuals from underserved communities, and the results would not be generalizable to the overall population. For example, the locations of popular smoking areas could be heavily influenced by the characteristics of our sample. Second, as in all studies that employ smartphone apps, the geolocations were only captured when the smartphones were operational. Third, this

methodology does not guarantee that exposure to all antitobacco messages is captured. Participants might not be able to snap a picture of the antitobacco message on a billboard in time if they were driving or traveling in a car. Finally, we recognized that, similar to many smartphone tracking studies, there are issues pertaining to privacy because of the amount of data collected that may not relate directly to the study's objectives. Considering that we were working with underserved communities that were arguably more vulnerable than the general population, we prioritized the privacy protection of participants from the beginning of this study and took significant steps in communicating with our participants the privacy protection measures we have implemented.

At the policy and system architecture level, Ethica was built to be compliant with the General Data Protection Regulation requirements, which extended data protection for different types of health data collected from individuals [18,40]. In other words, our participants had the right to access and delete their own data. If the participants did not have the technical skills to do so, Ethica would provide technical support as needed. In addition, Ethica allowed the participants to request a copy of their data, and the support staff would provide them with a machine-readable file containing all the data collected about them. On a practical level, Ethica was designed in such a way that participants could snooze their study participation for some time. For instance, there was an incognito function where participants could pause data collection (eg, tracking of their geolocations) at any time they wanted.

Despite these limitations, this study presents a novel way of integrating passive and active data from smartphones with traditional tobacco surveillance information to help inform tobacco control efforts within underserved communities. We recommend that public health researchers continue to explore how to capitalize on big data from smartphones for tobacco control. For instance, future studies could extend our study by recruiting a larger sample of participants from different states and examining how fluctuations in emotions (captured by the EMA) could play a role in influencing tobacco use. Future research could also design smartphone-based interventions examining the optimal locations and time to administer antitobacco messages to people from underserved communities. In conclusion, smartphone data can inform tobacco control efforts in a powerful way, and health organizations and public health researchers should take advantage of this data revolution to strengthen tobacco control efforts to benefit the health of underserved communities [20].

Acknowledgments

This work was funded by the *Truth Initiative* (KV, principal investigator). The authors would like to thank the study coordinators from both Massachusetts (Carmenza Bruff) and Texas (Amanda Zhao and Anna Kimutis) for their efforts in recruitment and data collection as well as Mohammad Hashemian from *Ethica* for app-related technical assistance. In addition, the authors would like to acknowledge Dr Jill Kelly and Dr Matthew Wilson for providing technical guidance on ArcMap through the annual Geographical Information Systems Summer Institute 2019 organized by the Center for Geographic Analysis at Harvard University.

Conflicts of Interest

None declared.

Abstract

Background: The number of patients with neurological diseases is currently increasing annually, which presents tremendous challenges for both patients and doctors. With the advent of advanced information technology, digital medical care is gradually changing the medical ecology. Numerous people are exploring new ways to receive a consultation, track their diseases, and receive rehabilitation training in more convenient and efficient ways. In this paper, we explore the use of facial expression recognition via artificial intelligence to diagnose a typical neurological system disease, Parkinson disease (PD).

Objective: This study proposes methods to diagnose PD through facial expression recognition.

Methods: We collected videos of facial expressions of people with PD and matched controls. We used relative coordinates and positional jitter to extract facial expression features (facial expression amplitude and shaking of small facial muscle groups) from the key points returned by Face++. Algorithms from traditional machine learning and advanced deep learning were utilized to diagnose PD.

Results: The experimental results showed our models can achieve outstanding facial expression recognition ability for PD diagnosis. Applying a long short-term model neural network to the positions of the key features, precision and F1 values of 86% and 75%, respectively, can be reached. Further, utilizing a support vector machine algorithm for the facial expression amplitude features and shaking of the small facial muscle groups, an F1 value of 99% can be achieved.

Conclusions: This study contributes to the digital diagnosis of PD based on facial expression recognition. The disease diagnosis model was validated through our experiment. The results can help doctors understand the real-time dynamics of the disease and even conduct remote diagnosis.

Parkinson disease; face landmarks; machine learning; artificial intelligence

Introduction

The population overall is currently aging. While an aging population represents the triumph of medical and social advances over disease, it also presents daunting challenges. Age is a crucial parameter for the occurrence, development, and diagnosis of diseases. As age increases, the central nervous system's morphology, metabolism, and function undergo different degrees of decline, which results in certain neurological

diseases [1]. One typical example is Parkinson disease (PD), which is caused by a decrease in dopamine secretion. PD, also known as tremor palsy, is a common neurodegenerative disease; the manifestations are mainly bradykinesia, myotonia, resting tremors, and unstable posture [2]. Clinical symptoms may also include nonmotor symptoms such as olfactory function decline, constipation, and depression. As a progressive disease, the various symptoms, both motor and nonmotor, become more serious as the disease course develops, and various

complications, such as the “on-off” phenomenon, dyskinesia, and decline in drug efficacy, often occur in the later stages. Patients with serious illness may be plagued by balance disorders, frozen gait, falls, and speech disorders, resulting in an inability to take care of themselves and a decrease in quality of life [3]. Famous people like Xiaoping Deng, Jingrun Chen, Jin Ba, and Muhammad Ali have all been deeply affected by PD. Hence, an accurate diagnosis and medication that works immediately are important.

In recent years, with the development of computer vision technology, facial image recognition has been used for disease diagnosis. In 2017, the National Human Genome Research Institute developed facial diagnosis software to identify whether a child has DiGeorge syndrome [4]. It is a very rare disease, with a pediatric incidence rate ranging from 1/6000 to 1/3000 worldwide. With such a wide range of morbidity, disease diagnosis can be difficult. However, all children with DiGeorge syndrome have clinically obvious facial features, which were utilized by the National Human Genome Research Institute for disease diagnosis. In 2016, FDNA Inc developed the Face2Gene system, which can help doctors diagnose genetic diseases via facial recognition [5]. Some relatively rare genetic diseases can even be discovered by comparing photos of patients with healthy people. This helps patients detect their disease and obtain treatment in a relatively short time.

For PD, the disease-specific facial expressions of patients have attracted researchers' attention. In the 1860s, Charcot first described the characteristics of “masked face” in patients with PD [6]. Based on years of research, “masked face” is considered one of the common symptoms of PD. Its symptoms involve a faceless and binocular gaze [7]. Facial expressions in humans are expressed by the superficial muscles of the face. These muscles are called the “facial muscles” or “expression muscles.” Smiles and other facial expressions of patients with PD often appear to be unresponsive and have significantly smaller amplitude. The time it takes to form an expression is also extended. To many patients' families, the “masked face” symptom causes issues because it is an expression of sullenness. Therefore, exploring a diagnostic method using facial feature point recognition is promising. Note that detection of a speech disorder in patients with PD, which is also a noninvasive diagnostic method, has been shown to be effective [8,9]. Hence, facial expression recognition can be combined with speech disorder recognition to obtain a more comprehensive, multidirectional, noninvasive, remote diagnosis.

Several researchers have utilized machine learning and computer vision technology to explore the inner relationship in the “masked face.” Bandini et al [10] proposed an automatic method in 2017 to analyze videos of facial expressions in patients with PD. They

extracted the average distances between facial key points using face tracing. Then, they found that patients with PD have much smaller distances of facial movement. In contrast to video-based research, Rajnoha et al [11] designed an automatic detection method based on static facial images using convolutional neural network models. However, the best achieved accuracy was only 67.33%. In 2019, Langevin et al [12] designed the Parkinson's Analysis with Remote Kinetic-tasks framework to analyze PD characteristics, finding that facial features and motion features in the Movement Disorder Society Unified Parkinson's Disease Rating Scale (MDS-UPDRS) could be extracted from videos.

In order to explore facial expressions in humans and test whether they are accompanied by tremors, we need to extract the key points of the face. In this paper, we investigated the ability to diagnose PD by recognizing changes in key points of the face in a short video. At present, to the best of our knowledge, we are the first to utilize sequential changes in key points of the face to diagnose PD.

Methods

Data Collection

People with PD usually suffer from loss of facial expression on both sides of the face. Moreover, their eye movement is reduced, like wearing a mask. This symptom is usually called the “masked face” [13]. Motion retardation is one of the main symptoms of PD. When facial symptoms appear, movement in facial expressions is significantly reduced, accompanied by local tremor symptoms of the small tendon group. When patients with PD try to smile or form other expressions, the facial muscles move slowly and often show excessive expressions. Based on the main facial expression symptoms of patients with PD, we recorded the smiles of patients with PD. Each video was 5 seconds long, and we recorded 2-3 videos per patient. The expression of a smile can be used to distinguish a patient with PD from someone without PD by comparing the magnitude of the expression and trembling of the small muscles of the face.

Patients with PD at the First Affiliated Hospital of Dalian Medical University were recruited and provided video data. Patients provided written informed consent before collecting data. Data for the control group, or people without PD, were randomly collected from senior people who liked to exercise frequently. Finally, we collected data from 64 senior citizens, including 33 people with PD. Each person recorded a smile expression 3 times. The length of every video was 5 seconds. After filtering out the videos that could not be used, we finally collected 176 records. The label is the subject status (ie, whether he or she had PD), as shown in Figure 1.

Figure 1. Smiles of a patient with Parkinson disease (left) and person without Parkinson disease (right).

Acquisition Equipment

In order to make the captured video clear enough and not affect the experimental results due to human jitter, the videos were captured using a Canon 700D camera placed on a standard tripod.

Collection Plan

In the process of recording facial expressions, we showed emoticons, which were printed on photos, to the patients with PD and asked them to imitate the emoticons. This data collection process aimed to explore the vibration of the small muscle groups of the face to distinguish patients with PD from people without PD. The underlying reason for asking the participants to imitate an emoticon in a photo was to prevent the subjective

emotions of the patients with PD from affecting the data collection. At the same time, it guaranteed consistency of data collection and ensured that each patient's understanding of a smile or anger was identical. The data collection process was as follows. First, we recorded the participant's gender, age, and history of other neurological diseases. Then, the subjects filled out the video data collection registration form, with full awareness of the PD detection research project. Table 1 displays an example of the information collected via the registration form. Third, the emoticon photos were given to the subjects, and they were asked to imitate them. We collected 3 videos of smiling facial expressions, each of which lasted for 5 seconds. After all the recordings were completed, the videos were classified into 2 classes: patients with PD and people without PD. Different folders were sorted according to the patient ID.

Table 1. Example data collected using the registration form to collect data via video of patients with Parkinson disease.

Patient Number	Age (years)	Gender	Confirmed	Other neurological disease	Length of disease (month)	Date of collection
1	60	Male	Yes	No	10	11/13/2017
2	55	Male	Yes	No	24	11/13/2017
3	60	Male	Yes	No	10	11/13/2017
4	63	Female	Yes	No	14	11/13/2017

Converting Video to Images

To obtain the participant's facial information, we split the recorded video into individual frames that were extracted directly from the video every 0.1 seconds. In this experiment, we used ffmpeg to implement this function. ffmpeg is a set of open source computer programs that convert digital audio and video into streams [14]. In practice, processing multiple videos in multiple folders involves the files' operation commands. We leveraged a subprocess module in the python programming environment that encapsulates the running terminal commands, which perfectly met our needs. The subprocess package mainly executes external commands and programs and uses the function `subprocess.call()` to call external commands. The video was converted into several images according to a preset time interval and stored in the specified folder for analysis.

Data Preprocessing

Face++ is a well-known service for face recognition and facial landmark detection. There are many interesting applications for

using Face++, such as inferring the demographics of social media users from profile pictures [15]. We chose Face++ because of its outstanding ability to localize facial landmarks. Based on previous literature and market research on key points of faces, we found that the Face++ interface can provide 106 coordinate points to create very accurate faces at this stage.

Users simply log in to the Face++ official website and apply for an API key. By calling the "Detect API" interface while using the "POST" method and setting the `return_landmark` parameter value to 2, the system will return 106 key points of the human face, as shown in Figure 2. These 106 points cover most of the key points of a human's face, including the facial contour, eyebrows, eyes, nose, and mouth that can describe almost all facial expressions. The returned coordinates are numbers using pixels as the unit. The top left corner of the image is used as the origin point.

Figure 2. Face key points (n=106) returned by the Face++ interface.

The facial muscles of patients with PD tend to be more rigid than those of people without PD, which causes a smaller facial expression range. We obtained the magnitude of the patient's expression by calculating the coordinate positions' range. However, during the video recording process, we found that although the video equipment is stable, it is difficult to ensure the participant, especially a patient with PD, does not move. To capture a relatively accurate magnitude of the facial expression, we converted the absolute coordinates into relative coordinates. Through the variation of the relative coordinates, the magnitude of the change in the facial expression of the patient can be reflected, and the error caused by postural changes of the body can be avoided.

To transform absolute coordinates into relative coordinates, we used the midpoint between the inside corners of the eyes as the origin of the coordinate (0,0). Then, we set the line connecting

the inside corners of the eye as the x axis and the line connecting the nose and the origin as the y axis. A non-Cartesian coordinate system could then be created. As for the units, the coordinates of the inside corners of both eyes were quantized as $(-1,0)$ and $(1,0)$, and the coordinates of the nose were quantized as $(0,-1)$, as shown in Figure 3. The black coordinate system was used to record the position of the pixels in the image, so we called this the absolute coordinate system. The blue coordinate system represents the relative coordinate system.

Assuming that the unit vector along the x axis in the relative coordinate system is vector a (a_1, a_2) and the unit vector along the y axis direction is vector b (b_1, b_2), we only need to compute (x,y) , as shown in Figure 4. In Figure 4, the absolute coordinates (m_1, n_1) , (m_2, n_2) , (a_1, a_2) , (b_1, b_2) can be converted to the relative coordinates $(0, 0)$, (x, y) , $(1, 0)$, $(0, 1)$, respectively.

Figure 3. Relative face coordinate system, where the Cartesian, or absolute, coordinate system is represented by the black coordinate system, which was used to record the position of pixels in the image, and the non-Cartesian, or relative, coordinate system is represented by the blue coordinate system, which was used to record the relative position of key points on the face.

Figure 4. Coordinate system conversion, where the absolute coordinates (m_1, n_1) , (m_2, n_2) , (a_1, a_2) , and (b_1, b_2) can be converted to the relative coordinates $(0,0)$, (x,y) , $(1,0)$, and $(0,1)$, respectively.

The following relationships were satisfied between vectors:

After calculation, the converted relative coordinates (x, y) were:

At this time, the value of (x, y) was the coordinate position in the relative coordinate system, which was converted by (m_2, n_2) in the absolute coordinate system.

Key Facial Feature Extraction

Based on the facial expressions and tremors in patients with PD, we evaluated and extracted features from two main dimensions. One was the amplitude magnitude of the patient's facial expression, which can be used to detect whether there is "mask face." The other was judging the patient's facial tremor through the face's key points. When the tremor effects of some patients are obvious, head and elbow vibration will drive the head to perform regular tremors. For the 106 key points on the face, they were divided into two main parts, which were amplitude features of the facial expression and shaking features of the facial small muscle group.

Extraction of the Features of Facial Expression Amplitude

We defined a key point z 's position at the i th frame with a vector: $\mathbf{p}_{i,z}=(x_{i,z}, y_{i,z})$, in which $x_{i,z}$ and $y_{i,z}$ are the relative position's horizontal coordinate and vertical coordinate, respectively. It is called the \mathbf{p} 's vector position.

For range R_{\max} , we defined the key point z 's range in the x-axis direction as R_x , then:

$$R_{x_{\max}} = x_{z_{\max}} - x_{z_{\min}} \quad (3)$$

Similarly, the key point's range in the y-axis direction was:

$$R_{y_{\max}} = x_{z_{\max}} - x_{z_{\min}} \quad (4)$$

Intuitively, covariance, $\text{Cov}(X, Y)$, represents the expectation of the overall error of two variables, which can reflect the correlation of the patient's expression amplitude changes in two directions, and it is calculated as follows:

$$\text{Cov}(X, Y) = E(XY) - E(X)E(Y) \quad (5)$$

where $E(X)$ and $E(Y)$ are the expected values of x and y , respectively.

For absolute covariance, $\text{Cov}(X_{\text{abs}}, Y_{\text{abs}})$, we also calculated the covariance between the absolute coordinate $X_{\text{abs}}, Y_{\text{abs}}$. To some extent, it reflects the shaking of the human head.

Feature Extraction of the Tremor at Facial Key Points

Because patients with Parkinson disease patients cannot control their muscles like people without PD, the key points will tremble when they are trying to maintain facial expressions. To obtain the extent of tremor, we adopted absolute coordinates to measure the patient's vibration. More specifically, we used $\mathbf{p}_{i,x} = (x_{i,z}, y_{i,z})$ to denote the position of the key point z at the i th frame. The Euclidean distance between the two locations was defined as:

Moreover, when there were many position vectors, the set \mathbf{P} was defined as:

$$\mathbf{P} = \{\mathbf{p}_{a(1,1)}, \mathbf{p}_{a(1,2)}, \mathbf{p}_{a(2,1)}, \mathbf{p}_{a(2,2)}, \dots, \mathbf{p}_{a(N,1)}, \mathbf{p}_{a(N,2)}\} \quad (7)$$

in which there exists N position vectors. Then, the average position of the set \mathbf{P} was defined as:

Jitter is a good measure of tremor [16]. However, it was created to calculate the tremor of a single signal. If we want to evaluate the positional Jitter of organ z , we take N frames of the organ, and the average position of the N frames is $\mathbf{p}_{\text{ave}}(\mathbf{P}_z)$. Then, positional jitter can be defined.

Jitter_abs is the relative Jitter of the key points (ie, the average absolute value of the positional distance between two adjacent frames).

Jitter_PPQ5 represents the adjacent 5 points of Jitter at the key point (ie, the average absolute value of the difference between the position of a certain frame and the average position of the adjacent 5 frames).

where $\mathbf{P}_{z,i,5} = \{\mathbf{p}_{i-2,z}, \mathbf{p}_{i-1,z}, \mathbf{p}_{i,z}, \mathbf{p}_{i+1,z}, \mathbf{p}_{i+2,z}\}$ denotes the average position of 5 adjacent frames (including the i -th frame) before and after the i -th frame of the key point z .

Jitter_rap represents the adjacent 3 points of jitter at the key point (ie, the average absolute value of the difference between the position of a certain frame and the average position of the adjacent 3 frames).

where $\mathbf{P}_{z,i,3} = \{\mathbf{p}_{i-1,z}, \mathbf{p}_{i,z}, \mathbf{p}_{i+1,z}\}$ is the average position of 3 frames (including the i th frame) before and after the i th frame of the key point z .

Jitter_ddp represents the difference between the adjacent 3 points of the key points' jitter (ie, the difference between the distances of each adjacent 2 frames in the adjacent 3 frames). Then, the average absolute value was calculated as:

When we analyzed each patient's key points, statistical analysis was performed on 106 key points. There were 8 features extracted for each key point, including 4 facial expression change amplitude features ($R_{x_{\max}}, R_{y_{\max}}, \text{Cov}(X, Y), \text{Cov}(X_{\text{abs}}, Y_{\text{abs}})$) and 4 facial tremor features (Jitter, Jitter_PPQ5, Jitter_rap, Jitter_ddp). Since the collected data were not evaluated by a professional doctor using the UPDRS and we only knew whether the person had PD, we performed a diagnostic (classification) experiment. The final data statistics used in our experiment are shown in Table 2.

Table 2. Video data statistics.

Data statistics	Video data
Creation date	3/15/2018
Number of patients with Parkinson disease	33
Number of people without Parkinson disease	31
Number of records	176
Number of features	848
Task	Classification

Results

In this paper, we performed a categorization task for facial expressions using widely used machine learning algorithms

such as logistic regression (LR) [17], support vector machine (SVM) [18], decision tree [19], and random forest (RF) [20]. Table 3 shows that the methods based on facial key points can distinguish patients with PD from people without PD. The diagnostic result is relatively good.

Table 3. Experimental results of common machine learning algorithms.

Algorithm	Precision	Recall	F1 value
LR ^a	0.98	0.98	0.98
SVM ^b	0.99	0.99	0.99
DT ^c	0.93	0.93	0.93
RF ^d	0.98	0.98	0.98

^aLR: logistic regression.

^bSVM: support vector machine.

^cDT: decision tree.

^dRF: random forest.

In order to verify the significance of original features, we conducted hypothesis testing. In this experiment, the threshold value α , which is referred to as the level of significance, was set to .05 and .005 separately.

Table 4 shows the number of key points that reached significance for each of the 8 features types. At a P value $<.05$,

all 106 key points were significant for all 4 tremor features at facial key points. At a P value $<.005$, all key points were significant for only 3 tremor features at facial key points. Therefore, we found that tremor features at facial key points may be more important than facial expression amplitude features.

Table 4. Number of points that reached significance for each feature type.

Feature name	Number of key points that reached significance	
	P value $<.05$	P value $<.005$
R_{x_max}	83	69
R_{y_max}	56	45
Cov(X, Y)	97	87
Cov(X_abs, Y_abs)	13	12
Jitter	106	106
Jitter_PPQ5	106	106
Jitter_rap	106	90
Jitter_ddp	106	106
Total	673	621

The least absolute shrinkage and selection operator (LASSO) is a linear regression method using L1 regularization [21]. LASSO can make part of the learned feature weights be 0, so

it achieves the function of sparseness and feature selection simultaneously. In this experiment, we used LASSO to compress the features.

If a feature weight is nonzero in LASSO, this feature will be left; otherwise, this feature will be abandoned. The red line in Figure 5 shows that, as the coefficient α in LASSO increases, the number of features after compression decreases gradually. Then, we used the compressed features to perform the final classification task. As the number of features used in the training model decreases, the accuracy of the training set of the LR and

SVM models changes (as shown by the gray and yellow lines, respectively). At an α value of .004, the two models (LR and SVM) had the highest prediction accuracy. However, as the original features were gradually reduced, the accuracy did not decrease linearly, which can prove the remaining features are more important than the discarded features.

Figure 5. The effects of least absolute shrinkage and selection operator (LASSO) feature compression on logistic regression (LR) and support vector machine (SVM) models.

Then, we used LASSO with the best hyperparameters to obtain the most relevant features to the target (PD or not). At the same time, RF was used to sort out the importance of the features. These points are near the corner of the right eye and the lips on

a human. In Figure 6, the features chosen by LASSO are marked with red circles, and the features chosen by RF are marked with blue ovals.

Figure 6. The key points that have a large influence on the classification result.

In this paper, we also utilized the advanced deep learning technique long short-term memory (LSTM) [22] to perform the classification. We converted the position changes of the key points in the x axis and y axis with time into time-series data. Then, we applied an order difference to the time series, that is, $\Delta x_i = x_{i-1} - x_i$, $\Delta y_i = y_{i-1} - y_i$. LSTM utilized these new time series

in the model training. The results are shown in Table 5. The experimental results are relatively good too. Compared with the pure recurrent neural network technique [23], which has no effect on the classification, LSTM demonstrated it is more practical when dealing with sequential video data. Note that the facial video data used in this paper are limited. LSTM should be able to achieve better results if more data can be acquired.

Table 5. Experimental results of neural network models.

Algorithm	Precision	Recall	F1 value
LSTM ^a	0.86	0.66	0.75
RNN ^b	0.48	0.46	0.47

^aLSTM: long short-term memory.

^bRNN: recurrent neural network.

Discussion

Limitations

The amount of data that we collected was not sufficient. We hope to collect more data not only from patients with PD and people without PD but also from patients with other neurological diseases.

Comparison With Prior Work

In the case of PD, to the best of our knowledge, there have only been a few software options, similar to ours, providing patients a convincing diagnosis using the facial recognition technique. These are compared to our work in Table 6.

Table 6. Comparison with a selection of prior work.

Work	Target and result	Data	Feature	Technology
Bandini et al [10]	Found PD ^a patients have lower average facial expression movement distance; facial expression recognition for PD	17 PD patients, 17 healthy control subjects	Average distance of 49 facial key points in the facial expression movement	Face tracing, SVM ^b
Rajnoha et al [11]	Identified PD hypomimia by analyzing static facial images; less accurate compared with video-recording processing method.	50 PD patients, 50 healthy control subjects	128 facial measures (embedding) by CNN ^c	Face detector-based (HOG ^d), CNN, traditional classifiers (eg, random forests, XGBoost)
PARK ^e framework by Langevin et al [12]	PARK instructs and guides users through 6 motor tasks and 1 audio task selected from MDS-UPDRS ^f and records their performance by videos	127 PD patients, 127 healthy control subjects	Facial features: facial action units (AUs); motion features: motion magnitude metric of fingers and hands based on FFT ^g	OpenFace tool version 2, FFT
Our method	Proposed facial landmark features from videos to diagnose PD using facial expressions and achieved outstanding performance	33 PD patients, 31 healthy control subjects, 176 records	848 facial expression amplitude features and tremor features of facial key points; 65 features were left after feature compression	Face ++, traditional classifiers (LR ^h , SVM, DT ⁱ , RF ^j), LSTM ^k , LASSO ^l

^aPD: Parkinson disease.

^bSVM: support vector machine.

^cCNN: convolutional neural network.

^dHOG: histogram of oriented gradients.

^ePARK: Parkinson's Analysis with Remote Kinetic-tasks.

^fMDS-UPDRS: Movement Disorder Society Unified Parkinson Disease Rating Scale.

^gFFT: fast fourier transform.

^hLR: logistic regression.

ⁱDT: decision tree.

^jRF: random forest.

^kLSTM: long short-term memory.

^lLASSO: least absolute shrinkage and selection operator.

Conclusions

In this paper, we established a diagnostic model for PD based on facial expressions. In the model, we formulated the diagnostic task into a classification problem. Then, we solved it by using algorithms from the area of traditional machine learning and the LSTM model from the field of deep learning research. When constructing video features, we conducted feature extraction according to the expression amplitude and degree of tremor. Using a fixed time interval and conversion of the coordinate system, the image was intercepted. This method converted the video into frame data. Further, the LSTM model was applied to the diagnosis of PD based on the generated time series data.

Experimental results proved our model is effective and can be used as an efficient tool in PD diagnosis.

This article is a preliminary exploration of neurological diseases in the context of machine learning. The proposed method is designed to help patients get more comprehensive treatment and help doctors to understand the real-time dynamics of the disease. At the same time, it also aimed to relieve the problem of registering patients who have difficulty moving and to relieve the pressure on repeated patient diagnoses by doctors. With the development of science and technology, the introduction and application of artificial intelligence will bring more convenient and rapid diagnostic and treatment technologies.

Acknowledgments

We are deeply indebted to people from the Department of Neurology, the First Affiliated Hospital of Dalian Medical University, who supported us in data collection and provided considerable professional advice. In addition, we owe our thanks to all the volunteers, who allowed us to collect their video data. This study was supported by the Program of National Key R&D Program of China (2018YFC0116800), National Natural Science Foundation of China (No. 61772110), CERNET Innovation Project (NGII20170711), and Introducing Talents of Discipline to Universities (Plan 111) (No. B20070).

Authors' Contributions

YQ developed the conceptual framework and research protocol for the study. BJ and LZ conducted the publications review, data collection, and analysis. ZG interpreted the data. BJ drafted the manuscript, and LZ made major revisions. All authors approved the final version of the manuscript.

Abstract

Background: To date, the evaluation of diet has mostly been based on questionnaires and diaries that have their limitations in terms of being time and resource intensive, and a tendency toward social desirability. Loyalty card data obtained in retailing provides timely and objective information on diet-related behaviors. In Finland, the market is highly concentrated, which provides a unique opportunity to investigate diet through grocery purchases.

Objective: The aims of this study were as follows: (1) to investigate and quantify the selection bias in large-scale (n=47,066) loyalty card (LoCard) data and correct the bias by developing weighting schemes and (2) to investigate how the degree of loyalty relates to food purchases.

Methods: Members of a loyalty card program from a large retailer in Finland were contacted via email and invited to take part in the study, which involved consenting to the release of their grocery purchase data for research purposes. Participants' sociodemographic background was obtained through a web-based questionnaire and was compared to that of the general Finnish adult population obtained via Statistics Finland. To match the distributions of sociodemographic variables, poststratification weights were constructed by using the raking method. The degree of loyalty was self-estimated on a 5-point rating scale.

Results: On comparing our study sample with the general Finnish adult population, in our sample, there were more women (65.25%, 30,696/47,045 vs 51.12%, 2,273,139/4,446,869), individuals with higher education (56.91%, 20,684/36,348 vs 32.21%, 1,432,276/4,446,869), and employed individuals (60.53%, 22,086/36,487 vs 52.35%, 2,327,730/4,446,869). Additionally, in our sample, there was underrepresentation of individuals aged under 30 years (14.44%, 6,791/47,045 vs 18.04%, 802,295/4,446,869) and over 70 years (7.94%, 3,735/47,045 vs 18.20%, 809,317/4,446,869), as well as retired individuals (23.51%, 8,578/36,487 vs 31.82%, 1,414,785/4,446,869). Food purchases differed by the degree of loyalty, with higher shares of vegetable, red meat & processed meat, and fat spread purchases in the higher loyalty groups.

Conclusions: Individuals who consented to the use of their loyalty card data for research purposes tended to diverge from the general Finnish adult population. However, the high volume of data enabled the inclusion of sociodemographically diverse subgroups and successful correction of the differences found in the distributions of sociodemographic variables. In addition, it seems that food purchases differ according to the degree of loyalty, which should be taken into account when researching loyalty

card data. Despite the limitations, loyalty card data provide a cost-effective approach to reach large groups of people, including hard-to-reach population subgroups.

loyalty card data; diet; selection bias; weighting; raking; food

Introduction

Diet has a substantial impact on human health. Poor dietary habits are associated with obesity and a wide range of chronic diseases, including type 2 diabetes, cancer, and cardiovascular diseases [1,2]. Suboptimal diet is responsible for more deaths than any other risk factor globally [3]. It is therefore imperative to collect timely and valid information on diet and individual risk factors.

To date, the evaluation of diet has mostly been based on questionnaires and diaries [4]. Although valuable in research, data collection with such instruments, particularly food diaries, is time and resource intensive, and the information is gained with a considerable delay. They also suffer from participant tendency toward social desirability [5,6]. Moreover, the information gained through questionnaires is subject to recall bias with participants not reporting all foods consumed [4]. Another limitation with dietary surveys as well as health surveys in general is selection bias, which manifests as healthy, socioeconomically advantaged, middle-aged women being the most likely to enroll in these studies [7-9].

The continued development of innovative digital tools and digital data repositories provides novel opportunities for epidemiological research [10-13]. Web-based data collection instruments [13,14] and consumer-generated data are increasingly being used for health research purposes [15-19]. While such novel data collection methods and tools may overcome some of the problems faced with traditional methods, some of the limitations remain, of which selection bias is a major concern [13,20]. Namely, those who generate the data are frequently highly selected and likely to differ from the general population representing wealthy and healthy individuals. For instance, smartphone users, and subsequently mobile health app and social media users, are younger, better educated, and represent wealthier individuals than those in the general population [21-23]. However, automated data collection, which is a typical feature for these instruments and tools, provides objective measures on individuals' health behaviors and thus decreases information bias.

Food purchase data have invoked interest as a novel approach to enrich diet and nutrition research efforts [24-26]. So far, most of the published studies have used panel-based data, with all grocery purchase receipts scanned at home [26]. While such studies are frequently large and may include data from multiple sources, they are limited by recording discrepancies [27]. In addition, receipt scanning requires consistent efforts and long-term engagement from the participants [28,29]. In this study, we used loyalty card data (ie, individual-level grocery transaction data generated by retail food chains). Importantly,

loyalty card data contain information about what, where, when, and who has bought, thus enabling longitudinal tracking of the purchase behaviors of a single customer or a household over time. Objective measures of food purchases have been shown to correlate with one's food intake and overall diet quality [28]. Loyalty card data also accumulates automatically in retailers' information technology systems, producing objective and up-to-date information in a cost-effective manner. However, loyalty card data have shortfalls that could impede the usefulness for research. First, consumers may distribute their purchases among different retailers. Therefore, loyalty card data from a single retailer most likely does not include all food purchases conducted by consumers. However, in Finland, the market is highly centralized with the three biggest market chains claiming over 90% of the market share, and the largest operator having a market share as high as 47% [30]. Such centralization provides a unique opportunity to investigate heterogeneous populations through a single retailer.

The aims of this study were as follows: (1) to investigate and quantify selection bias in Finnish large-scale loyalty card (LoCard) data and further develop a means to correct this bias by characterizing the loyalty card data consenters and comparing their sociodemographic background to that of the general Finnish adult population and (2) to assess how the degree of loyalty relates to food purchases by investigating the self-perceived degree of loyalty (share of total grocery purchases in retailers' shops and supermarkets) and its association with food purchases. The overall purpose of this research was to increase the understanding of how loyalty card data should be understood and subsequently analyzed in dietary and health research.

Methods

Study Design and Participation

The LoCard data used in this study were obtained from S Group, which is the largest commercial operator of retail grocery stores in Finland. According to S Group, their full coverage is 2.4 million households, meaning that 88% of households in Finland have registered purchases in their databases. The members of S Group's loyalty card program are provided with an electronic customer card to be used when making purchases, and customers are rewarded for their purchases by getting a maximum 5% financial bonus that is refunded to them on a monthly basis. Individuals of the same household may link their purchases to the same loyalty account. In this study, only purchases of the household's main cardholder were used.

Members of S Group's loyalty card program (primary cardholders) across Finland were contacted via email and were invited to take part in the study, which involved consenting to

the release of their grocery purchase data to be used for research purposes and voluntarily responding to the study questionnaire. Members who did not have an email address declared or who had prohibited the retailer from contact them with any marketing or research-related material were excluded. Cardholders under 18 years of age were also excluded. All invitations were sent by S Group as they had customers' contact information.

The grocery purchase data used in this study covered the period from January 1, 2017, to December 31, 2018. Each purchase was associated with item description, time stamp, quantity (ie, weight, volume, or number of packages), and expenditure on the item.

Background Variables

All consenting participants were asked to fill out a web-based background questionnaire that included the following sociodemographic variables: education, marital status, size of the household, number and age of children, occupational status, income, and perceived health. The background data were complemented with information on participant sex, age, and postal code obtained from the retailer's electronic database.

Degree of Loyalty

As part of the baseline questionnaire, all participants were asked to estimate their degree of loyalty as a share of purchases made in the retailer's shops and supermarkets on a five-item ordinal scale. The response categories were as follows: "0%-20%," "21%-40%," "41%-60%," "61%-80%," and "81%-100%."

Food Variables and Food Groups

The LoCard grocery purchase data required preprocessing to be usable in further analyses. First, we identified food groups from all the grocery product groups. Second, we regrouped the identified food groups into new groups that were formed on the basis of the commonly used food groupings in nutritional studies [31] and earlier findings on the associations between dietary components and health [32,33]. For instance, skimmed liquid milk and buttermilk were aggregated into "skimmed milk & sour milk" and foods and mixed dishes with red or processed meat as the main ingredient were aggregated into "red meat & processed meat."

Out of 4234 grocery product groups, 865 (20.4%) were assigned into one of the new food groups used in this study. In addition, 42 food groups were left out as they involved either (1) a mixed dish or food group with no definite primary ingredient or (2) a rarely purchased product. The food groups used in this study included "vegetables," "skimmed milk & sour milk," "sugar-sweetened beverages," "rye bread," "red meat & processed meat," "fat spreads," and "sweets & chocolate." These groups were used as indicators for evaluating the nutritional quality of household food purchases. A detailed description about the grouping of the food purchase data is included in [Multimedia Appendix 1](#).

Reference Material

Population statistics on the general adult population were obtained from Statistics Finland using StatFin databases that can be freely accessed [34]. The databases include tabulated data on Finnish citizens and Finland in general that are collected

on a yearly basis. Data from 2017 were used because of the availability of the latest data tables for all sociodemographic variables used in the analyses. For this study, individuals aged at least 18 years were included.

The FinHealth survey is a national population health study on Finnish citizens. The study encompasses a series of cross-sectional population surveys carried out every 5 years in Finland. The latest FinHealth survey was carried out at 50 localities in 2017, with a participation rate of 71% among those invited for the study [35]. The purpose of the FinHealth study is to collect up-to-date information about the health and well-being of adults residing in Finland and on the factors influencing their health and well-being. Each survey invites 10,000 randomly selected individuals aged over 18 years. The study consists of physical examinations and study questionnaires. The latest report (values used in this study) is restricted to adults aged 30 years or older to make the results comparable with earlier FinHealth studies. A subgroup of the participants was also invited to undergo a nutrition review; the FinDiet survey is a substudy (n=1655) of the FinHealth survey, which monitors the nutrition and dietary habits of the Finnish population [36].

Statistical Methods

Analysis of and Correction for Selection Bias

The sociodemographic characteristics of the LoCard study participants were first compared with the characteristics of the Finnish adult population and participants of the FinHealth study to identify traits in LoCard participants that deviated from traits in the general Finnish adult population.

Second, we constructed poststratification weights for the LoCard participants to match their sociodemographic distributions with the adult Finnish population distributions as closely as possible. The individual weights were calculated using the raking function available in the *survey* package in R [37]. The raking function uses iterative proportional fitting (IPF), which is a technique that can be used to adjust a distribution reported in one dataset by totals reported in another. For a given two-way contingency table, the IPF proportionally adjusts each row of the sample distribution in the two-way contingency table to have its total equal the reference population row distribution and adjusts each column of the sample distribution to have its total equal the column total in the reference table [38].

The advantage of the raking function is that the algorithm allows multiple two-dimensional (or higher dimensional) tables to be matched simultaneously [37]. For example, instead of matching age, sex, and education univariate distributions separately, we can match all bivariate distributions (ie, age and education, sex and education, and sex and age) simultaneously. The adjustment process is repeated iteratively until the weights converge for each table used in the analysis. The raking function requires that the two contingency tables have the same classes for the row and column variables and no zero values in any of the cells.

The following two-way tables were available for both the LoCard data and the Finnish adult population: sex and age, sex and education, sex and marital status, sex and occupational status, age and education, age and marital status, age and

occupational status, and education and occupational status. All tables were subsequently used to construct the poststratification weights. In addition, the distribution of children aged under 18 years living in the household was used alone because corresponding two-dimensional tables with any of the background variables were not available in Statistics Finland. In total, eight two-way tables and a single one-way table were used in the construction of the weights. Finally, the obtained weights were trimmed to avoid extreme values and instability by setting a minimum value of 0.1 and a maximum value of 10. Without trimming, the poststratification weights ranged from 0.04 to 32.7, and there was a single extremely high weight of 82.4.

Owing to missing data, the poststratification weights were constructed in two phases. First, the weights were calculated as described above for participants for whom all baseline characteristics used in the matching were available. These data were available for 36,094 individuals. Participants with missing data for any of these variables ($n=10,972$) obtained their weights in the second phase, where the poststratification weights were calculated for the whole LoCard sample using sex and age variables only. This information was available for 47,045 participants. Finally, the combined weights were rescaled to add up to 47,045. Twenty-one participants without data on sex and/or age remained without weights.

The selected food group variables were analyzed to describe the volume and money (€) spent on their purchases over the 2-year period (2017-2018). For descriptive purposes, median values and IQRs were reported for each variable because the distributions were strongly skewed to the right, and there was an excess number of zero values in some of the food variables. The same variables were used to demonstrate how the poststratification weights affected the results.

Degree of Loyalty

To validate the self-assessed degree of loyalty, we conducted the recency, frequency, and monetary (RFM) value analysis using the transaction data of all participants and compared the RFM scores across the five degree of loyalty groups. RFM analysis is a behavior-based technique used to segment customers by examining their transaction history from three dimensions (how recently a customer made purchases, how

often they purchased, and how much they purchased). RFM analysis is also widely used in customer relationship management. Based on these three dimensions, the RFM score is generated for each individual, with a higher score indicating higher loyalty. The analysis was conducted using the *rfm* package in R [39]. In addition, total volume and total money (€) spent on food purchases were calculated for each degree of loyalty group to investigate how closely the self-reported degree of loyalty relates to volume and money spent on the purchases.

To assess the impact of the degree of loyalty on food purchasing profiles, the selected food group variables were compared among the five degree of loyalty groups. The Kruskal-Wallis test was applied for differences across the groups.

The association between the degree of loyalty and background characteristics was analyzed by comparing the distribution of each sociodemographic variable among the five degree of loyalty groups. The differences across the groups were tested using the chi-square test.

Ethical Aspects

The study was approved by the University of Helsinki Review Board in the Humanities and Social and Behavioral Sciences (Statement 21/2018). Informed consent was electronically obtained from all participants included in the study when they were invited via email to release their loyalty card data and fill out the background questionnaire. The data were pseudonymized by S Group before the researchers could obtain the data.

Results

Recruitment

S Group had approximately 2.4 million primary loyalty card owners, and all of them were assessed for eligibility (Figure 1). Approximately half (1,214,663, 51%) of the loyalty card owners were contacted, and of these, 47,066 (4%) consented to participate. We did not have information on the number of valid email addresses or what proportion of emails reached the card owners (eg, by passing through trash email filters). Among the participants, 36,621 (78%) responded to the background questionnaire. Nearly all participants (46,825, 99.5%) purchased at least one grocery item from 2017 to 2018.

Figure 1. Participant recruitment and eligibility flow chart.

Participant Characteristics

Table 1 shows the participant characteristics compared with those of the Finnish adult population and the FinHealth study participants. Discrepancies were found in sex, age, education, and occupational status when compared with the general Finnish adult population. Namely, there were more women, more individuals with a higher education, and more employed individuals in the LoCard sample. On the contrary, individuals aged under 30 years and over 70 years (correspondingly, retired individuals) were underrepresented in the LoCard sample. Selectivity associated with education was strong in the LoCard sample. The proportion of individuals having a basic education level was clearly lower in the LoCard sample (6% of participants had basic education) than in the Finnish adult population (25% had basic education). There were no major differences in the distribution of marital status. However, there were fewer individuals living in a household with children aged under 18 years in the LoCard sample. The LoCard sample was widely

distributed across Finland and comparable to the geographical distribution of Finnish citizens (Multimedia Appendix 2 and Multimedia Appendix 3).

On comparing the LoCard sample to the FinHealth study participants, there were differences in sex, education, and marital status distributions, with more women and individuals with higher education and fewer married individuals in the LoCard sample. The age distributions were not comparable owing to the fact that the FinHealth study included only individuals aged at least 30 years. Distortion in the distribution of occupational status was similar in the two studies compared with the Finnish adult population.

The reweighted distributions of the sociodemographic variables demonstrated that the constructed poststratification weights corrected the deviations successfully, and thereafter, the sociodemographic distributions of the LoCard sample matched well with the Finnish adult population.

^aFinHealth study included individuals aged ≥ 30 years, which makes the age distribution not comparable to other data listed in the table.

^bData for the following numbers of participants were missing in the LoCard sample: sex, 21; age, 21; marital status, 10,635; household, 10,689; children aged under 18 years, 10,576; education, 10,718; occupational status, 10,579; degree of loyalty, 10,540.

^cWeighted LoCard sample refers to the descriptive statistics calculated using the poststratification weights of the LoCard participants.

^dNot available.

^eN/A: not applicable.

^fCohabiting included in this category.

^gHouseholds with three or more persons.

^hBachelor's degree or higher.

ⁱParental leave included.

Food Purchase

Table 2 shows the purchases of selected food groups in the original LoCard sample and in the weighted LoCard sample. Over 95% of the participants had purchased at least one food product in all food groups, except skimmed milk & sour milk. Skimmed milk & sour milk had been purchased by 74% of the participants. Among them, the median expenditure and the median weight were €23.0 (€1=US \$1.13 in 2017) and 23.5 kg, respectively, during the 2-year follow-up.

After applying the poststratification weights, there was an increase in the purchase of red meat & processed meat and small increases in sugar-sweetened beverages and fat spreads. The purchase of vegetables and sweets & chocolate decreased as a result of reweighting. The largest change was seen in red meat & processed meat; the weighted amount of purchase increased from €387 to €417 (cost) and from 48 kg to 54 kg (weight), corresponding to relative percentage increases of 7.8% and 12.6%, respectively.

Table 2. Purchase of selected food groups (measured in € and kg) in the original LoCard sample and in the weighted LoCard sample.

Food group	Original LoCard sample ^a (N=47,066)				Weighted LoCard sample ^a (N=47,045)			
	€ median [IQR]	€(%) ^b , median [IQR]	kg, median [IQR]	kg (%) ^c , median [IQR]	€ median [IQR]	€(%) ^b , median [IQR]	kg, median [IQR]	kg (%) ^c , median [IQR]
Vegetables	284.3 [124.9-520.1]	7.7 [5.4-10.5]	76.6 [33.2-144.4]	8.2 [5.4-11.7]	263.7 [107.3-487.6]	7.2 [4.8-9.9]	73.4 [29.6-139.6]	7.6 [4.8-11.0]

^aPurchases are aggregated over a 2-year period from January 1, 2017, to December 31, 2018 (€=US \$1.13 in 2017).

^bShare of the food group purchase among all grocery purchases measured in euros.

^cShare of the food group purchase among all grocery purchases measured in kilograms.

Degree of Loyalty

Table 1 shows the self-assessed degree of loyalty. Almost 40% (14,194/36,526) of the participants reported that they made 80% or more of their food purchases at S Group shops and supermarkets, and 64% (23,418/36,526) reported making at least 60% of their purchases at the retailer's shops and supermarkets.

The RFM scores were significantly different among the five degree of loyalty groups, with the lowest scores in the lowest degree of loyalty group and a steady increasing trend toward

the highest degree of loyalty group ($F_4=4625.5$, $P<.001$). The poststratification weights also differed significantly across the five groups ($F_4=24.1$, $P<.001$), indicating that the degree of loyalty was associated with individuals' sociodemographic characteristics. However, the observed differences were rather small, with a maximum difference of six percentage points between the groups (Table 3). In the highest degree of loyalty group, there were slightly more young and married participants, and the percentage of households with children was higher, whereas the percentage of divorced or separated participants and those with a master's degree declined with the degree of loyalty.

Table 3. LoCard participant characteristics and RFM scores across the five degree of loyalty groups.

^aRFM: recency, frequency, and monetary.

Table 4 shows food purchases in the degree of loyalty groups, and all showed significant associations ($P<.001$ for all food groups, except sweets & chocolate [$P=.007$]). The result was expected owing to the large sample size. The shares of vegetable, red meat & processed meat, and fat spread purchases increased as the degree of loyalty increased. In the other food

groups, there were no major differences across the degree of loyalty groups.

Additionally, Table 4 shows that the quantity and expenditure regarding food groups increased steadily with the self-assessed degree of loyalty, suggesting that the self-assessment can be relied upon.

Table 4. Purchases (in € and kg) of selected food groups across the five degree of loyalty groups.

Discussion

Principal Findings

The findings of this study showed that individuals who consented to the release of their loyalty card data for research purposes tended to diverge from the general Finnish adult population. Similar to many other health and nutrition studies, including those encompassing electronic data collection tools [7,13,35,40,41], the LoCard participants manifested volunteer bias, with employed individuals, middle-aged individuals, women, and individuals with higher education being overrepresented in the sample. The LoCard sample included fewer retired individuals, fewer individuals with basic education, and fewer individuals who had children aged under 18 years living in the household. Compared with the Finnish national FinHealth and FinDiet studies, the selection mechanism appeared to be somewhat different in the LoCard sample. While employed individuals were overrepresented in all these three studies, the gender and education biases were stronger in the LoCard sample. Moreover, the LoCard sample had a rather similar distribution of marital status as among Finnish adults, whereas in the FinHealth study, married individuals were overrepresented [35,36,42].

However, the size (n=47,066) and heterogeneity of the LoCard sample enabled a successful correction of the differences seen

in the sociodemographic variables. We developed the poststratification weights using all sociodemographic background variables available with the two-way joint distributions to correct the background distributions of the LoCard participants to make them closer to the Finnish adult population. The large sample size provided a sufficient number of participants for hard-to-reach population subgroups, and thus, it was possible to construct the poststratification weights for them as well. The highest weights were seen for unmarried men aged under 30 years, who indeed are often underrepresented or not enrolled in health studies [41].

Of the 1.1 million loyalty card holders contacted, approximately 4% (n=47,066) took part in the LoCard study. Although low, the participation rate was similar to that for other massive data collection methods [7]. The advantage of the use of digital tools is that they reach a large number of potential study participants with relatively low effort in data collection. After all, we reached substantially more individuals than in the majority of dietary studies using traditional data collection methods with minimum human involvement in data collection. A likely reason for the low participation rate was that the participants were contacted via email, which may not have reached them (invalid email address or contact email classified as “junk email”) or may have limited their participation and induced selection bias. Although 88% of households in Finland have an internet connection and 83% use email [43], email use varies according to

sociodemographic profiles and is relatively low at 62% among individuals aged over 65 years and among individuals with basic education [44]. This may partly explain the baseline characteristics of the LoCard sample. However, it has been shown that the use of digital tools in recruitment and data collection does not increase the selection bias, but the traits of participants in health studies are rather similar regardless of the recruitment method used [13,40]. Moreover, it is likely that many simply ignored an email coming from a commercial party.

Important aspects are whether and when informed consent from loyalty card owners is needed. Recently, Aiello et al [45] published an interesting ecological study on the associations between loyalty card food purchase data and prescription records that were used as a proxy for real disease profiles in London. Their dataset included 1.6 million loyalty card users, and they used the anonymized data without the consent of the individuals. In our study, consent and a positive reply were required for two reasons. First, transparent use of loyalty card data on customers for a common good builds trust among them, researchers, and the company, and reduces the likelihood of negative publicity. Second, contact was needed to obtain information about participants' background characteristics for use in further analyses. A future scenario could involve a consent request when the customer becomes a member of the loyalty card program. This would create an ethically sound and transparent research protocol for the use of customer data.

Poststratification weights were further applied in evaluating the purchases of the main food groups. The corrections demonstrated small changes in some food groups; the purchase of vegetables and sweets & chocolate decreased after the correction, whereas the purchase of red meat & processed meat, sugar-sweetened beverages, and fat spreads increased. The sociodemographic profiles of the LoCard participants and bias related to them might, at least partly, explain these results. The FinDiet study showed that women, who were overrepresented in the LoCard sample and thus had smaller weights, tended to consume more fruits and vegetables than men [36]. In line with this, after applying the poststratification weights, the purchase of vegetables decreased. It has also been shown that socioeconomically advantaged individuals, who likewise were overrepresented in the LoCard sample, consumed healthy foods, such as fruits and vegetables and low-fat dairy products, more frequently [46]. Moreover, the increased amount of red meat & processed meat purchase is likely related to male participants who tend to consume more meat [36,47]. In line with the overall findings of this study, the NutriNet-Santé study showed that the consumption of fruits and vegetables was higher and the consumption of meat was lower in the cohort than in the general population in France [13].

The degree of loyalty was fairly high in the LoCard sample with 64% (23,418/36,526) of the participants reporting making over 60% of their grocery purchases at the retailer's shops and supermarkets. The food purchases were rather similar in the higher loyalty group (60% or higher), whereas individuals making less purchases in the retailer's grocery stores showed some differences. In particular, individuals reporting the lowest degree of loyalty tended to buy fewer vegetables and fat spreads and fewer red meat & processed meat products. Although some

variation was seen, the differences across the loyalty groups were smaller than expected. One reason could be the food groups selected for the current analyses. There could be other products, such as alcohol and tobacco, that are differently purchased. These results, together with the differences seen in the sociodemographic variables between the loyalty groups, underline the importance of estimating and accounting for the degree of loyalty in future studies using loyalty card data. A direct way to address the problem of coincidental purchases is to focus on a subsample with at least 60% loyalty. It is also important to note that loyalty card data can enable research on longitudinal trends in food purchases, which can be performed regardless of the degree of loyalty.

Limitations

Although we used a large set of matching variables for developing the poststratification weights, some limitations concerning these remain. First, we were not able to compare or account for possible differences in income, as there was no comparable reference data available in Statistics Finland. Therefore, it remains unclear whether the LoCard sample was representative in terms of income, which is an important contributor to food purchase. The higher education level of the LoCard participants and the lower prevalence of young and retired individuals clearly suggest that the income levels might be overestimated in our sample. Second, although we matched families with children, the number of children and their ages, which can clearly affect a household's food purchases, were not used in weighting. Importantly, we were able to correct the differences only in the observed sociodemographic variables, and thus, unidentifiable selection bias cannot be ruled out. This may include factors that would be associated with willingness to participate, such as special dietary restrictions and socially excluded people. In particular, among those participants who did not have complete background information and whose poststratification weights were thus based on sex and age only, the risk for unidentifiable selection bias could be even higher.

It is important to note that grocery purchases reflect consumption on a household level, which may consist of more than one person, and not everybody might eat the same foods. Thus, accuracy of loyalty card data in investigating individual diet may not be as high as that obtained with traditional data collection methods. However, good compatibility between respondent-collected household-level food purchase data and individual-level dietary data has been demonstrated [28,48]. Moreover, foods purchased from stores do not necessarily indicate foods consumed owing to many different reasons. These include, for example, foods that are not included in loyalty card data, such as dinner foods at restaurants or lunch foods at work. Cardholders may also buy foods that are consumed by others, for example, grandchildren, other relatives or close friends invited for dinner, and pets. Some foods are not consumed at all, resulting in food wastage [49,50].

Finally, the degree of loyalty remains a challenge. In this study, the degree of loyalty was self-estimated, and it is difficult to estimate possible bias related to this self-report. However, we showed that the RFM scores increased steadily with the groups of loyalty, indicating that higher frequency, higher engagement,

and more money spent on grocery purchases were associated with a higher degree of loyalty. Moreover, a positive correlation was found between the proportional increases in money spent (€) and weight (kg) regarding food purchases and the degree of loyalty. These results suggest that this self-assessment seemed to provide a feasible estimate of the true values. In another study, the researchers defined loyalty through the frequency of purchases made in the supermarket combined with the amount of money spent on purchases. However, in this study, the degree of loyalty was not specifically defined [51].

Despite its limitations, we see real potential in the use of these automatically collected longitudinal food purchase data in the population-based assessment of dietary patterns, which are important determinants of health and carbon footprint [52]. Loyalty card data provide a cost-effective tool to reach large groups of individuals with minimum data collection efforts and to investigate diet-related behaviors with less information bias. Linking these data with other health data (such as electronic health records and health registers) would provide new opportunities to understand diet and related outcomes. However, such research settings include privacy concerns that need to be carefully addressed to guarantee individual anonymity and consent. In addition, loyalty card data enable the monitoring of longitudinal trends in food purchases including timely

monitoring and evaluation of the impact of population-level steering instruments such as taxation.

Conclusions

Individuals who consented to the use of their loyalty card data for research purposes tended to differ from individuals in the general Finnish adult population. The sociodemographic distributions were toward similar characteristics, as is frequently seen in health and nutrition studies. However, the high volume of data enabled the inclusion of sociodemographically heterogeneous subgroups, potentially including hard-to-reach subgroups, and further correction of the differences so that distributions matched well with those of the general Finnish adult population. A potential confounder in studies using loyalty card data is the degree of loyalty, which in this study, was associated with food-purchasing profiles and also the participants' background characteristics. This underlines the importance of obtaining sufficient background information when using loyalty card data for health research.

Despite the limitations, loyalty card data provide a cost-effective approach for large groups of individuals with minimum data collection effort and for the investigation of diet-related behaviors on a large scale with less information bias. Importantly, loyalty card data enable the monitoring of longitudinal trends in grocery purchases.

Acknowledgments

We thank S Group for collaboration. We are also grateful to the loyalty card holders who provided consent for the use of their loyalty card data in this research project. This work was funded by Tampere University, the University of Helsinki, the Finnish Foundation for Alcohol Studies, and EIT Food ("Towards a smarter shopping list" #20041). EIT Food is the Innovation Community on Food of the European Innovation and Technology (EIT), a body of the EU, under Horizon 2020, the EU Framework Programme for Research and Innovation.

Authors' Contributions

ME, JN, HS, LU, and MF participated in data collection and transfer. All authors participated in the design of the study. TN, ME, SK, and JN performed data management. A-LV and JN planned the data analyses, which A-LV conducted. A-LV wrote the original draft. All authors participated in reviewing and writing the drafts, including approval of the final version of the manuscript.

Abstract

Background: Licensed drugs may cause unexpected adverse reactions in patients, resulting in morbidity, risk of mortality, therapy disruptions, and prolonged hospital stays. Officially approved drug package inserts list the adverse reactions identified from randomized controlled clinical trials with high evidence levels and worldwide postmarketing surveillance. Formal representation of the adverse drug reaction (ADR) enclosed in semistructured package inserts will enable deep recognition of side effects and rational drug use, substantially reduce morbidity, and decrease societal costs.

Objective: This paper aims to present an ontological organization of traceable ADR information extracted from licensed package inserts. In addition, it will provide machine-understandable knowledge for bioinformatics analysis, semantic retrieval, and intelligent clinical applications.

Methods: Based on the essential content of package inserts, a generic ADR ontology model is proposed from two dimensions (and nine subdimensions), covering the ADR information and medication instructions. This is followed by a customized natural language processing method programmed with Python to retrieve the relevant information enclosed in package inserts. After the biocuration and identification of retrieved data from the package insert, an ADR ontology is automatically built for further bioinformatic analysis.

Results: We collected 165 package inserts of quinolone drugs from the National Medical Products Administration and other drug databases in China, and built a specialized ADR ontology containing 2879 classes and 15,711 semantic relations. For each quinolone drug, the reported ADR information and medication instructions have been logically represented and formally organized in an ADR ontology. To demonstrate its usage, the source data were further bioinformatically analyzed. For example, the number of drug-ADR triples and major ADRs associated with each active ingredient were recorded. The 10 ADRs most frequently observed among quinolones were identified and categorized based on the 18 categories defined in the proposal. The occurrence frequency, severity, and ADR mitigation method explicitly stated in package inserts were also analyzed, as well as the top 5 specific populations with contraindications for quinolone drugs.

Conclusions: Ontological representation and organization using officially approved information from drug package inserts enables the identification and bioinformatic analysis of adverse reactions caused by a specific drug with regard to predefined ADR ontology classes and semantic relations. The resulting ontology-based ADR knowledge source classifies drug-specific adverse reactions, and supports a better understanding of ADRs and safer prescription of medications.

Introduction

Overview

Chemicals and drugs have made a great contribution to human health care. At the same time, they are rarely free from occasional adverse drug reactions (ADRs) [1], which are defined by the World Health Organization (WHO) as any noxious, unintended, and undesired effects of a drug that occur at doses used for the prevention, diagnosis, and treatment of a disorder. A significant number of ADRs occur each year. ADRs are the sixth leading cause of death worldwide, and the fourth primary cause of death in the United States and Canada, behind cardiovascular disease, malignant neoplasm, and stroke [2]. Although the actual incidence of ADRs is difficult to access precisely, it is known that ADRs have a considerable impact upon both health care and pharmaceutical manufacturers.

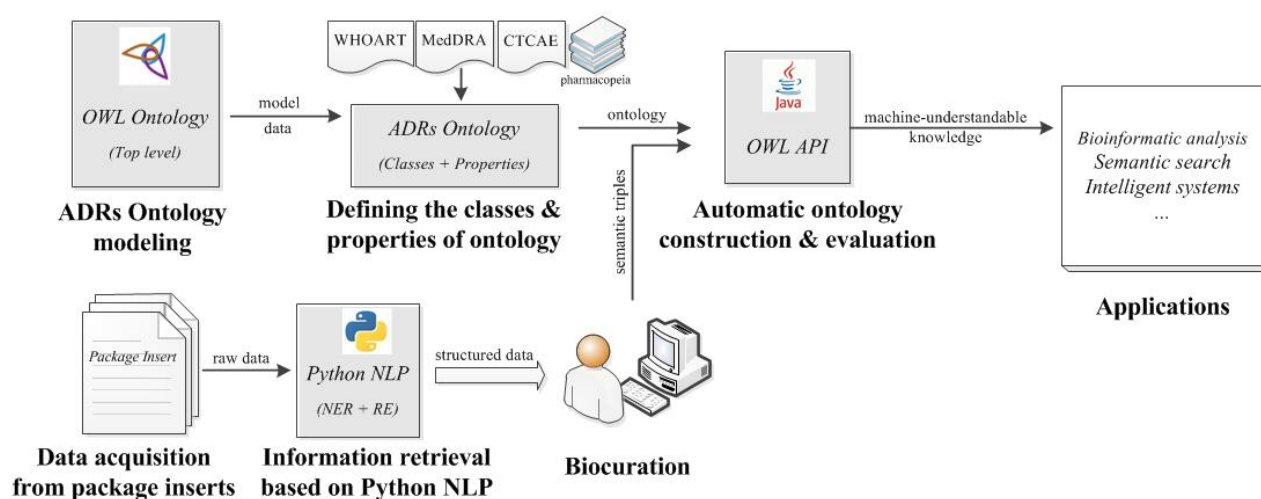

Package inserts (sometimes called patient information leaflets) are the primary official papers which accompany most prescribed drugs and over-the-counter medications. Although different countries have diverse requirements for the obligatory contents, the package inserts serve at least two main purposes. They contain informative details regarding the generic names of drugs, active ingredients, indication for use, instructions for use, special warnings, contraindications, and statistical values from clinical trials, including the percentage of people who had side effects, the types of side effects, and additional precautions. Furthermore, the package insert is an easy reference for physicians when prescribing medications, and can help them avoid prescribing drugs that may be contraindicated. The inserts also serve as an easy reference for patients. However, the informative package inserts are generally semistructured and cannot be understood easily by machines. As the number of newly licensed drugs increases, the demand for automatic

technology for semantic integration and linkages, as well as bioinformatic analysis of the information (including ADRs) enclosed in package inserts, has become an urgent issue both in biomedical research and the pharmaceutical industry.

In information science, an ontology is the formal, explicit specification of a shared conceptualization of a domain [3]. Generally, biomedical ontologies not only represent the essential properties of biomedical entities and their correlations to other biomedical concepts, but also provide a standardized vocabulary and formalized knowledge source for the biomedical community. Hundreds of biomedical ontologies have been elaborately built to support scientific discovery and the analysis of biomedical data [4-8]. Moreover, systematically evaluated ontology is one of the two fundamental sources of background knowledge for artificial intelligence algorithms in biomedicine (the other is the knowledge graph).

In this paper, we propose an ontological organization of traceable ADR information extracted from licensed package inserts, which aims to provide machine-understandable knowledge for bioinformatics analysis, semantic retrieval, and intelligent clinical applications (Figure 1). This entails the following: (1) Present a generic ADR ontology model from two dimensions (and nine subdimensions) covering the essential ADR information and medication instructions. (2) Customize a Python natural language processing (NLP) method to automatically retrieve the identified information enclosed in package inserts. (3) Collect the approved package inserts of quinolone drugs and build a specialized ontology for algorithm verification and validation. (4) Bioinformatically analyze the adverse reactions caused by quinolones based on the obtained ADR ontology, and discuss potential applications including semantic retrieval and a clinical decision-making system.

Related Works

Identification of ADRs

In recent decades, many studies have identified ADRs through diverse channels of information, including patient reports [9-14], electronic health records [15-18], PubMed literature [19,20], and social media [21-26]. Briefly, a patient report is a traditional source of information, where the users of a drug spontaneously report medication side effects to health authorities; electronic health records contain comprehensive medications and procedures as recorded by physicians; PubMed collects rich and up-to-date published clinical trials and other types of biomedical publications concerning drugs' adverse reactions; and social media represents a new data source of patient experiences with drugs and could be characterized by its high volume and quick availability. Although patients, health professionals, research scientists, and even the public have increasingly contributed to ADR reporting, the role of pharmaceutical companies in reporting ADRs cannot be neglected; package inserts play a significant part in medication safety.

Ontologies of ADRs

Several studies about building ontologies for ADRs for different applications have already been carried out. For instance, the Adverse Drug Reaction Classification System (ADReCS) was developed as a comprehensive ADR ontology database, which enabled standardization and provided hierarchical classification of ADR terms for a molecular understanding of drug safety in the laboratory, and use in bioinformatics and systems biology for toxicological research [27]. Additionally, an ontology of ADRs (OADRs) was built to describe the semantics of ADR terms for automated signal generation in pharmacovigilance [28].

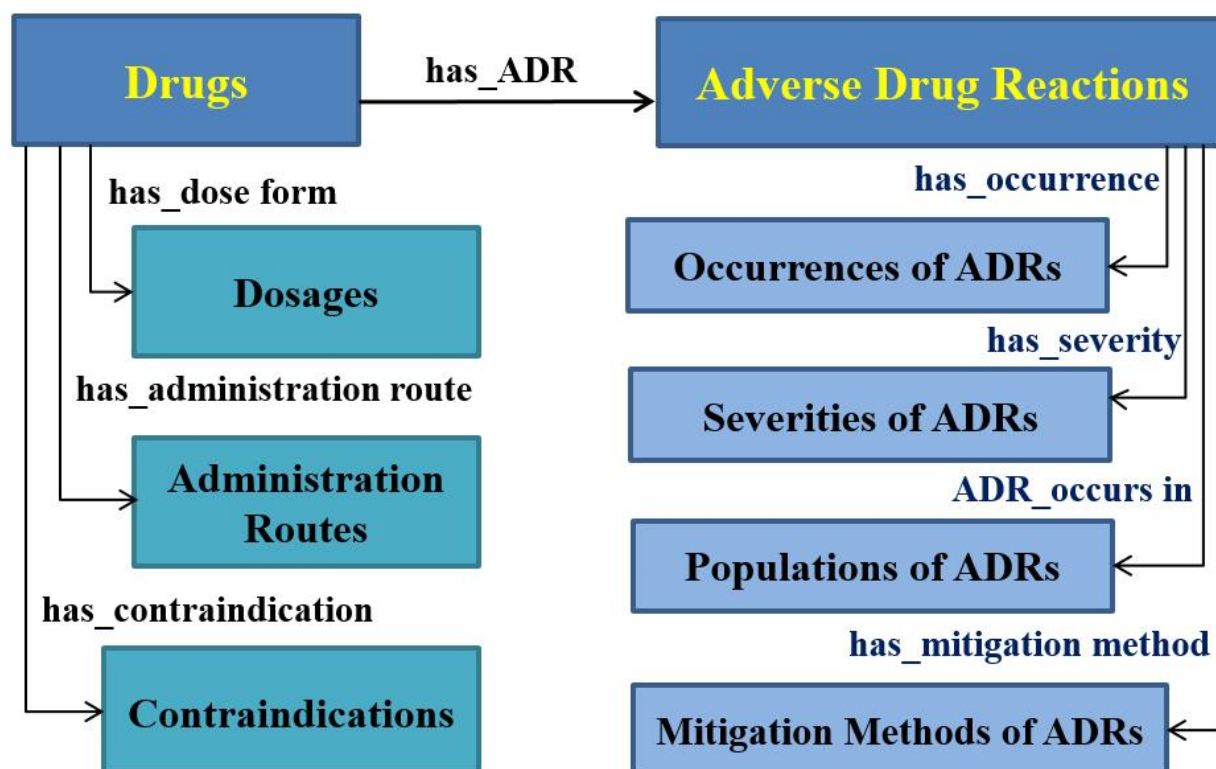

Adverse drug events (ADEs) refer to the injuries resulting from medical interventions related to drugs [1], which include medication errors, ADRs, allergic reactions, overdoses, and other events associated with the prescription, preparation, dispensation, or administration of medications. Therefore, research efforts concentrated on ontology-based representation and analysis of ADEs indirectly related to our work. Among them, the Ontology of Adverse Events (OAE) has recently garnered research attention; it represents numerous adverse events related to medical intervention, time at medical

intervention, pathological bodily process, patient information (especially patient age), and other adverse event-related terms imported from existing ontologies, as well as clinical adverse event reports [29]. To better analyze adverse events related to vaccines and support safety studies of vaccines, the authors further expanded OAE and developed the Ontology of Vaccine Adverse Events (OVAE) by analyzing the adverse events recorded in the official packet inserts of licensed vaccines [30]. All the ontologies mentioned above provide a fundamental basis on which to conduct our study and will be compared with the proposed ADR ontology from several perspectives.

Methods

Ontology Modeling

We built the ADR ontology using two dimensions: ADR information and drug-related medication instructions, which were further separated into nine subdimensions. The former covers the following: (1) adverse drug reactions, presenting diverse types of ADRs; (2) the occurrence of ADRs, describing the frequencies of ADRs after the administration of a drug in a population; (3) the severity of ADRs, describing a general measure of the subsequent risks of potential ADRs; (4) populations affected by specific ADRs, noting the individual human patients associated with an adverse reaction after the administration of a drug; and (5) the mitigation methods of ADRs, referring to any measure that shortens the duration of an adverse reaction or reduces its severity. The drug-related medication instructions contain generic information about rational drug use: (6) drug names, describing different pharmaceutical agents; (7) dosage forms of drugs, collecting the complete form of the pharmaceutical preparation used to administer the prescribed dose of medication; (8) administration routes of drugs, consisting of the various ways of administering a drug to a patient to allow the chemical to be absorbed into the blood and delivered to the target tissue; and (9) contraindications of drugs, predefining a condition or factor associated with a recipient that makes the use of a specific drug improper or inadvisable. These nine branches determine the fundamental concepts and classes of our ontology. Figure 2 demonstrates the nine classes of proposed ADR ontology as well as the eight semantic relations among them. The generic model will help to generate specialized ADR ontologies on request as illustrated in the next section.

Figure 2. The generic model of ADRs ontology. ADRs: adverse drug reactions.

Classes of Ontology and Their Hierarchy and Properties

The biomedical terms denoting nine classes within the ADR ontology are much more comprehensive than shown in Figure 1. With reference to controlled biomedical vocabularies and well-developed pharmacopeia, we integrated many synonymous terms (both in English and Chinese) into various concepts and organized them in a hierarchical way. Generally, the WHO Adverse Reactions Terminology (WHOART) is reused to generate the ADR class and its hierarchy in four levels: system/organ classes (SOC), high level terms (HLT), preferred terms (PT), and included terms (IT). Among them, SOC and HLT consist of broad grouping terms, while PT represents more specific adverse reactions and IT are entry terms (synonyms) for PT. The large number of PT and IT as well as their synonyms from the Medical Dictionary for Regulatory Activities (MedDRA) will become the essential vocabulary to recognize the named entities of ADRs in package inserts. Furthermore, the Council for International Organization of Medical Science (CIMOS) has recommended five terms derived from different percentages to classify the occurrences of ADRs: Very Rare ($<0.01\%$), Rare ($\geq 0.01\%$, $<0.1\%$), Uncommon ($\geq 0.1\%$, $<1\%$), Common ($\geq 1\%$, $<10\%$), and Very Common ($\geq 10\%$). This forms the basis for the classification of ADR frequencies in our work. The Common Terminology Criteria for Adverse Events (CTCAE) is a standard classification and severity grading scale for adverse events in clinical trials and oncology settings. We adopted CTCAE for labeling the severities of ADRs with five levels: Grade 1 (mild), Grade 2 (moderate), Grade 3 (severe but not immediately life-threatening), Grade 4 (life-threatening) and Grade 5 (death caused by ADRs). The other classes that

are closely related to the pharmaceutical agents and their medication instructions will be acquired and represented according to the classic pharmacopeia for ease of use.

In addition, two kinds of data properties will be incorporated into the ADR ontology, including a general description of the drugs (such as the active ingredient, injection excipients, drug specifications, antibacterial mechanism, interaction drugs); the key codes and definitions from referenced vocabularies containing ARecNO (the PT code) and the SOC code from WHOART, the MedDRA code, the NCI code; and definitions from CTCAE. Furthermore, the origin of the package inserts will be recorded in the ontology's annotation property for ontology data identification and traceability.

Information Retrieval From Package Inserts

From the viewpoint of ontology construction, the ADR information and medication instructions extracted from package inserts will become the instances of object properties within the ADR ontology. Due to the large amount of data enclosed in package inserts, manual extraction would be a labor-intensive process. We developed a Python NLP-based algorithm to automatically retrieve ADRs and drug-related information, which consists of two steps: named entity recognition (NER) and relation extraction (RE).

Briefly, NER will recognize a string of text as an entity (eg, an adverse reaction) that is already defined in our ADR ontology. The Jieba word segmentation model implemented in Python is adopted to segment the words enclosed in package inserts, while the names of classes and their synonyms from the proposed ontology will function as a domain vocabulary to improve performance. RE is a process that determines whether two

entities have a specific relationship (eg, the “has_ADR” causality between a particular drug and an adverse reaction). Since formal package inserts have already been separated into several titled sections, these titles will be used to implement the RE task. Specifically, the titles “ADVERSE REACTIONS” and “WARNINGS AND PRECAUTIONS” are converted into semantic relations about ADR information, while the medication instructions for a particular drug would be extracted from the sections titled “DOSAGE AND ADMINISTRATION,” “CONTRAINDICATIONS,” and “USE IN SPECIFIC POPULATIONS.”

The information automatically retrieved from package inserts will be passed to downstream biocuration for data identification. The major criteria of the manual review process emphasize the following two points: (1) whether the medication instructions and information about ADRs caused by a specific drug was accurate and complete, without missing data or mistakes; and (2) the frequency and severity of a drug-ADR triple must be explicit; vague descriptions were not recorded. Eventually, the human biocurated semantic information is used to build the ADR ontology.

Automated Ontology Construction and Evaluation

The Ontology Web Language (OWL) is a widely used programming language for defining and instantiating web-based ontologies. It provides a machine-understandable schema to describe classes and their semantic relations in a specific domain. In this work, the OWL application programming interface, a Java interface and implementation for OWL, is used to build the ADR ontology automatically based on content data primarily obtained from package inserts and well-established vocabularies (eg, WHOART, MedDRA, CTCAE). Moreover, to ensure high-quality results, the ADR ontology will be evaluated and validated by checking the clarity, coherence, extendibility, minimal encoding bias, and minimal ontological commitment, which are the fundamental principles of building a domain ontology [31].

Results

Data Collection and Ontology Construction

Quinolone drugs have become commonly used antibacterial agents due to their strong and broad-spectrum antibacterial activity, as well as their rapid and complete absorption in humans. As quinolone usage increases, the risk of ADRs increases proportionally. According to the Annual Report of National ADR Monitoring in China, the number of adverse reactions and events from quinolones has continuously been the second-highest among antibacterial drugs. Therefore, the safe administration of quinolones is a serious matter that requires more attention.

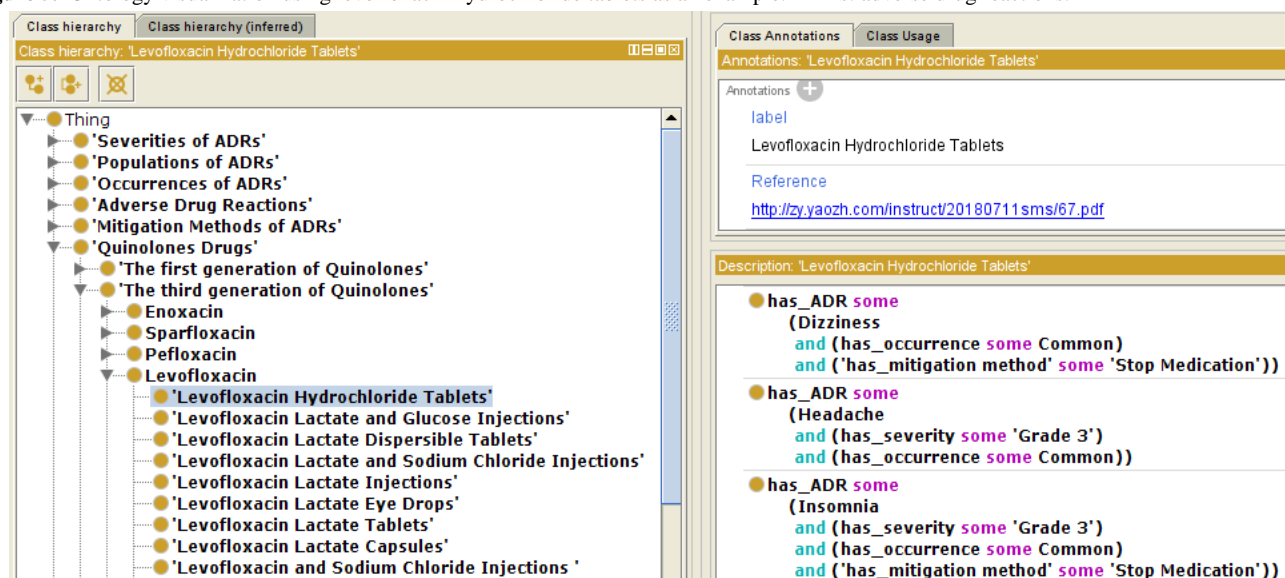

After half a century of development, quinolones have evolved from the first generation to the fourth generation. We collected 165 specific drug names of quinolones from the China Pharmaceutical Reference and the National Essential Drugs List in China, and further organized them based on their generation.

The electronic package inserts of these drugs were then downloaded from the National Medical Products Administration and Yaozhi drug database in China. Although these package inserts were written in Chinese, the Chinese and English synonyms of the class names defined in the proposed ADR ontology will enable information extraction based on a customized Python program. Finally, an ADR ontology for quinolones was automatically built and evaluated for further analysis.

Ontology Statistics and Visualization

Currently, the specialized ADR ontology covers a total of 2879 classes grouped into nine categories: ADRs and their occurrence, severity, population, and mitigation methods, as well as 165 drugs and their dosages, administration routes, and contraindications (Figure 3A). These classes were deeply divided into subclasses on the basis of biomedical concepts and arrayed hierarchically from most general to most specific in up to 4 levels, with the abovementioned nine categories at the top (Level 1) of the ontology hierarchy (Figure 3B). Furthermore, the obtained ADR ontology also includes eight types and 15,711 nonredundant semantic triples (Figure 4A) extracted from package inserts, where the causalities between ADRs and quinolones (with the type label “has_ADR”) account for a large proportion ($n=7725$, 49.17%). Among the 7725 identified drug-ADR triples, 4043 (52.34%) and 716 (9.27%) explicitly stated the frequency and severity, respectively. The statistics of drug-ADR triples by frequency and severity suggest that most ADRs caused by quinolones ($n=4037$, 52.26%) occur at a low frequency ($<10\%$), and none of them are life-threatening (Figure 4B).

Figure 5 demonstrates how the proposed ontology organized the ADR information enclosed in the package insert, using the Protégé OWL editor for ontology visualization. Briefly, levofloxacin hydrochloride tablets have been reported to account for different types of ADRs (including dizziness, headache, and insomnia) that have already been defined in our ontology. For each adverse reaction, it is likely that the frequency, severity, and mitigation method are informed by the patient population. Therefore, we used four semantic relation types (“has_occurrence,” “has_severity,” “has_mitigation method,” and “has_population”) to link information associated with a particular adverse reaction caused by a specific drug (the lower right section of Figure 5). The “AND” clause is adopted to combine multiple semantic triples into a composite knowledge unit. It is worth mentioning that we extracted ADR information from the explicitly stated content in package inserts; thus, some of the four types linked to a given drug-ADR triple may not be obtained due to a missed or implicit description. To enable knowledge tracing, the package insert citation was recorded as a referenced annotation property (the upper right section of Figure 5). In addition, the Internationalized Resource Identifier (IRI) [32], which is the unique identifier for ontology sharing and reuse around the world, was customized as “ADR+six numbers” within the proposed ADR ontology. For instance, the IRI for the levofloxacin hydrochloride tablets used in the example is ADR000572.

Figure 3. Statistics of the classes in ADRs ontology. ADRs: adverse drug reactions.**Figure 4.** Statistics of the semantic relations in ADRs ontology. ADRs: adverse drug reactions.**Figure 5.** Ontology visualization using levofloxacin hydrochloride tablets as an example. ADRs: adverse drug reactions.

Comparison With Existing Ontologies

We compared our work with four other ontologies (described in the Introduction) in terms of the semantic relations defined in the proposed ADR ontology (Table 1), since they are the essential knowledge unit for the wide utility of an ontology. The proposed ontology represents a complete set of information

pertaining to ADRs containing drug-ADR triples and the associated frequency, severity, and mitigation methods. Moreover, the explicit medication instructions (eg, the dosage form, route, and contraindication) extracted from the package insert of a particular drug support physicians in guiding patients in the safe, effective, and rational use of drugs, as an adverse reaction can occur when using the prescribed dosage.

Table 1. Comparison with existing ontologies.

Semantic relations of the proposed ADR ^a ontology	Definition	Adverse Drug Reaction Classification System	Ontology of ADRs	Ontology of Adverse Events	Ontology of Vaccine Adverse Events
has_ADR	The adverse reaction caused by a specific drug.	Yes	Yes	Yes	Yes
has_occurrence	The occurrence frequency of an adverse reaction caused by a specific drug.	Yes	No	Yes	Yes
has_severity	The severity of an adverse reaction caused by a specific drug.	Yes	No	Yes	Yes
ADR_occurs in	The population in which an adverse reaction occurs.	No	No	Yes	Yes
has_mitigation method	Any measure that shortens the duration of an adverse reaction or reduces its severity.	No	No	No	No
has_dose form	The form of a dosage of a specific drug.	No	No	No	No
has_administration route	The prescribed way of administering a drug to a patient.	No	No	No	Yes
has_contraindication	A predefined condition or factor associated with a recipient that makes the use of a specific drug improper or inadvisable.	No	No	No	No

^aADR: adverse drug reaction.

Bioinformatic Analysis of the Identified ADRs Caused by Quinolones

The ontology of ADRs caused by quinolones consists of 7725 drug-ADR triples retrieved from 165 package inserts. After duplicate removal, 331 ADRs were identified to be caused by quinolones. Table 2 lists the major ADRs from two dimensions: the quinolone generation and active ingredient. Since topical drugs have fewer ADRs than oral and intravenous ones due to their administration route, we concentrated on the comparison of quinolone drugs that are only administered by the oral and intravenous routes. After bioinformatic analysis, there were

three important points that could be summarized as follows: (1) Levofloxacin (third generation) and gatifloxacin (fourth generation) induce a significant number of ADRs ($n=139$, 43.57% and $n=122$, 38.24%, respectively), and many drugs are made from these ingredients ($n=21$, 17.21% and $n=20$, 16.39%, respectively). (2) The highest numbers of ADRs are caused by ciprofloxacin ($n=221$, 69.28%) and enoxacin ($n=156$, 48.90%), respectively. (3) There are relatively few ADRs associated with nalidixic acid ($n=21$, 6.56%) and pipemidic acid ($n=11$, 3.45%), which implies that they are comparatively safe in terms of known adverse effects. In future work, we will investigate the ADR differences related to drug dosages.

Table 2. Identified adverse drug reactions of quinolones, excluding topical drugs (N=122).

Quinolone generation and ingredient	Drugs, n (%)	Drug-ADRs ^a (n=7563), n (%)	ADRs (n=319), n (%)	Major ADRs	Typical dosage form(s)	Major routes
First generation						
Nalidixic acid	1 (0.82)	21 (0.28)	21 (6.56)	Nausea, vomiting, diarrhea, abdominal pain	Tablet	Oral
Second generation						
Pipemidic acid	3 (2.46)	33 (0.44)	11 (3.45)	Nausea, eructation, abdominal pain	Granules, capsule, tablet	Oral
Third generation						
Enoxacin	6 (4.92)	335 (4.43)	156 (48.90)	Skin rash, dizziness, abdominal pain	Tablet, capsule, injectable	Oral, intravenous
Sparfloxacin	5 (4.10)	235 (3.11)	47 (14.73)	Headache, dizziness, insomnia, anemia	Tablet, capsule, granules	Oral
Pefloxacin	5 (4.10)	150 (1.98)	35 (10.97)	Anaphylaxis, convulsion, tremor	Tablet, capsule, injectable	Oral, intravenous
Levofloxacin	21 (17.21)	1592 (21.05)	139 (43.57)	Anaphylaxis, insomnia, dizziness	Tablet, capsule, injectable	Oral, intravenous
Tofloxacin	1 (0.82)	26 (0.34)	26 (8.15)	Fatigue, anorexia, erythematous rash	Capsule	Oral
Fleroxacin	8 (6.56)	210 (2.78)	47 (14.73)	Nausea, vomiting, headache, dizziness	Tablet, capsule, injectable	Oral, intravenous
Ofloxacin	9 (7.38)	303 (4.01)	87 (27.27)	Anaphylaxis, itching, skin rash	Tablet, capsule, injectable	Oral, intravenous
Lomefloxacin	12 (9.84)	474 (6.27)	85 (26.65)	Itching, skin rash, headache, nausea	Tablet, capsule, injectable	Oral, intravenous
Ciprofloxacin	8 (6.56)	684 (9.04)	221 (69.28)	Skin rash, itching, diarrhea, hematuria	Tablet, capsule, injectable	Oral, intravenous
Rufloxacin	2 (1.64)	68 (0.90)	34 (10.66)	Skin rash, insomnia, lethargy, convulsion	Tablet, capsule	Oral
Norfloxacin	9 (7.38)	199 (2.63)	35 (10.97)	Itching, skin rash, abdominal pain	Tablet, capsule, injectable	Oral, intravenous
Fourth generation						
Gatifloxacin	20 (16.39)	2270 (30.01)	122 (38.24)	Headache, vision disorder, dysgeusia	Tablet, capsule, injectable	Oral, intravenous
Gemifloxacin	1 (0.82)	106 (1.40)	106 (33.22)	Skin rash, nausea, urticaria, diarrhea	Tablet	Oral
Balofloxacin	2 (1.64)	66 (0.87)	33 (10.34)	Itching, thirst, hypesthesia, headache	Tablet, capsule	Oral
Pazufloxacin	3 (2.46)	180 (2.38)	60 (18.81)	Skin rash, jaundice, myalgia, diarrhea	Injectable	Intravenous
Prulifloxacin	3 (2.46)	189 (2.50)	63 (19.75)	Eructation, dyspnea, hypotension	Tablet, capsule	Oral
Moxifloxacin	3 (2.46)	420 (5.55)	141 (44.20)	Fatigue, constipation, rupture of tendon	Tablet, injectable	Oral, intravenous

^aADR: adverse drug reaction.

The 331 ADRs could be further classified into 18 categories that we defined in the ontology (Table 3). Most organs are involved in ADRs. Skin reactions (eg, itching, skin rash) are the most common reactions and are linked to 141 drugs (85.45%), followed by nervous system reactions (eg, headache,

hypertonia), which are associated with 127 agents (76.97%). Moreover, the least frequently reported adverse reactions are those of genital organs and the application site. This may be due to the difficulty in detecting genital organ diseases and the minor impact of injection site reactions.

Table 3. Categorized adverse drug reactions of quinolones (N=165).

Category of adverse drug reaction	Associated drugs, n (%)	Possible adverse drug reactions
Skin reactions	141 (85.5)	Itching, skin rash, photosensitive reaction, erythema multiforme, increased sweating
Nervous system reactions	127 (77.0)	Headache, hypertonia, convulsion, coma, paresthesia, vertigo, tremor
Immune reactions and infections	123 (74.6)	Candidiasis, anaphylaxis, angioneurotic edemas, anaphylactic shock, facial edema
Gastrointestinal reactions	122 (73.9)	Nausea, vomiting, abdominal pain, diarrhea, stomatitis, constipation, xerostomia
Generalized reactions	120 (72.7)	Fever, fatigue, syncope, chest pain, shivering, edema, oral edema, discomfort
Mental disorders	119 (72.1)	Sleeplessness, personality disorders, hallucinations, depression, agitation, anxiety
Liver and gallbladder diseases	117 (70.9)	Alanine transaminase (ALT) elevation, jaundice, alkaline phosphatase increased, liver failure, bilirubinemia
Urinary diseases	111 (67.3)	Hematuria, urinary incontinence, dysuria, crystalluria, interstitial nephritis
Musculoskeletal diseases	105 (63.6)	Arthritis, arthralgia, muscle weakness, myalgia, rupture of tendon, bone pain
Hematological diseases	103 (62.4)	Eosinophilia, leukopenia, granulocytopenia, pancytopenia, lymphadenopathy
Vascular, hemorrhagic, and coagulation diseases	102 (61.8)	Elevated international normalized ratio (INR) value, purpura, phlebitis, vasculitis, vasodilatation, flushing, thrombocytosis
Cardiovascular diseases	80 (48.5)	Prolonged QT interval, hypotension, ventricular tachycardia, palpitation, bradycardia
Respiratory system diseases	71 (43.0)	Pulmonary infiltration, bronchial spasm, asthma, laryngeal edema, dyspnea
Metabolic and nutrition diseases	63 (38.2)	Hypoglycemia, electrolytes abnormality, diabetes mellitus, hyperglycemia
Vision diseases	62 (37.6)	Xerophthalmia, eye pain, conjunctivitis, diplopia, photophobia, abnormal vision
Auditory, vestibular, and sensory diseases	62 (37.6)	Tinnitus, hypoacusis, deafness, taste disorders, parosmia, earache, ageusia
Genital organ diseases	48 (29.1)	Vaginitis, epididymitis, orchitis, dysmenorrhea, uterine hemorrhage
Application site reactions	19 (11.5)	Injection site reaction, injection site itching, infusion site reaction, injection site pain

Table 4 lists the top 10 ADRs caused by quinolones and shows that itching and skin rash are listed in nearly 80% of currently licensed quinolone package inserts in China. Although alanine transaminase (ALT) elevation and phlebitis frequently occur after the administration of 3 drugs made of pazufloxacin mesylate, other adverse reactions caused by quinolones are usually infrequent (<10%). All of the reported ADRs have a severity of Grade 1 (mid) to Grade 3 (severe but not immediately

life-threatening), and stopping medication is generally recommended as the mitigation method after the detection of an adverse reaction. Additionally, quinolone drugs are administered to patients at various dosages and through different routes (**Table 2**). Finally, analysis of contraindication data found that the top 5 specific populations are those who are allergic to quinolones, pregnant women, teenagers, infants, and patients with central nervous system diseases.

Table 4. The 10 most commonly reported adverse drug reactions of quinolones (N=165).

Adverse drug reaction	Related drugs, n (%)	Category of adverse drug reaction
Itching	132 (80.0)	Skin diseases
Skin rash	131 (79.4)	Skin diseases
Headache	126 (76.4)	Nervous system diseases
Nausea	119 (72.1)	Gastrointestinal diseases
Abdominal pain	117 (70.9)	Gastrointestinal diseases
Vomiting	116 (70.3)	Gastrointestinal diseases
Diarrhea	114 (69.1)	Gastrointestinal diseases
Insomnia	110 (66.7)	Mental disorders
Fever	104 (63.0)	Generalized diseases
Photosensitive reaction	100 (60.6)	Skin diseases

Discussion

Major Applications of ADR Ontology

The ADR ontology proposed in this study has two major applications. The first is the semantic retrieval system that can use the ADR knowledge to integrate various external sources of information. Since the primary ADR terms and their key codes were reused from WHOART and MedDRA, it should be straightforward to integrate our ontology with these controlled vocabularies, as well as other medical terminologies (eg, Logical Observation Identifiers Names and Codes [LOINC], Systematized Nomenclature of Medicine-Clinical Terms [SNOMED CT]), for semantic knowledge retrieval by providing formally represented ADR information. Another major application is intelligent clinical decision-making support. The proposed ADR ontology provides machine-understandable knowledge, which could be used by artificial intelligence algorithms in biomedicine. To pursue clinical and therapeutic approaches to optimal disease management and rational drug use, it is useful for a physician treating a specific disorder to know all the identified adverse reactions induced by the drugs prescribed for patients with that condition. Manually reading the package inserts to find the ADR information and medication

instructions is laborious and time-consuming, as the number of newly approved drugs and reported ADRs increases every year. Conversely, our ontology will aid in the development of an intelligent clinical decision-making system, which would positively affect the drug prescribing patterns of physicians and potentially have a significant socioeconomic impact.

Conclusions

We have shown that the ADR ontology can be used to formally represent and organize the ADR information and medication instructions enclosed in official drug packages. In addition, it can provide machine-understandable knowledge for bioinformatic analysis. By collecting 165 package inserts of quinolone drugs, a specialized ADR ontology was built to classify various identified ADRs caused by quinolones. Systematic analysis of the obtained ontology data improves the deep recognition of drug-specific ADRs, making it possible to intelligently guide safe drug use and benefit human health.

The proposed ADR ontology can be generalized to organize the ADR information from other channels, not just package inserts. Electronic health records, in which the ADR data are frequently reported, will be acquired for the enrichment of the ADR ontology in the near future.

Acknowledgments

This work was funded by the Chinese Academy of Medical Sciences Innovation Fund for Medical Sciences, grant number 2017-I2M-3-014.

Authors' Contributions

XYL prepared the initial draft of the manuscript and finished building the ontology. XL proposed the ontology model and analyzed the experimental results. HLR was in charge of the project and administered the project. JJG sampled data and investigated the application of ontology for semantic retrieval. All authors provided contributions to the final version of the paper and approved it.

Abstract

Background: Home blood pressure monitoring has many benefits, even more so, in populations prone to high blood pressure, such as persons with diabetes.

Objective: The purpose of this research was to validate the QardioArm mobile device in a sample of individuals with noninsulin-dependent type 2 diabetes in accordance with the guidelines of the second International Protocol of the European Society of Hypertension.

Methods: The sample consisted of 33 patients with type 2 diabetes. To evaluate the validity of QardioArm by comparing its data with that obtained with a digital sphygmomanometer (Omron M3 Intellisense), two nurses collected diastolic blood pressure, systolic blood pressure, and heart rate with both devices.

Results: The analysis indicated that the test device QardioArm met all the validation requirements using a sample population with type 2 diabetes.

Conclusions: This paper reports the first validation of QardioArm in a population of individuals with noninsulin-dependent type 2 diabetes. QardioArm for home monitoring of blood pressure and heart rate met the requirements of the second International Protocol of the European Society of Hypertension.

Introduction

Ultimately, devices that automatically measure blood pressure have gradually evolved to replace the standard mercury sphygmomanometer, as the risk of mercury toxicity outweighed any potential benefits of its use. Today there are a wide variety

of devices capable of measuring blood pressure both in and outside of clinical environments [1-7].

Among the advantages of home blood pressure monitoring are that it helps to detect white coat and masked hypertension; it is highly available at a low price; blood pressure measurements at home are taken in a more natural, relaxed, and domestic

environment than when taken in the doctor's office; patient convenience in blood pressure measurement ensures more commitment; repeated measurements can be easily taken, and it can be used over longer periods to assess the daily variability of blood pressure [8].

But logically, it is a necessary requirement that these devices have been validated by standardized protocols, such as the European Society of Hypertension-International Protocol 2 (ESH-IP2) [9], the British Hypertension Society protocol [10], or the protocol of the Association for the Advancement of Medical Instrumentation [11].

If this validation is essential in the general population, it is even more important in at-risk populations, such as patients with diabetes, where reliability and accurate blood pressure measurement are essential to avoid the disease's progression. Type 2 diabetes is a prevalent disease and represents a very serious social health problem; it has been seen to occur to a greater extent in older adults [12,13]. The main complication of type 2 diabetes is atherosclerotic disease [14,15].

This atherosclerotic disease is the main cause of morbidity and mortality in people with diabetes, and the one that contributes the most to the direct and indirect costs of diabetes [16,17]. In addition, atherosclerosis reduces arterial elasticity, and therefore, causes arterial stiffness. This arterial wall stiffening produces a high risk of mortality [14-18]. Furthermore, the occurrence of stiffened arteries increases with diabetes [19] and hypertension; therefore, it is common that patients with diabetes are also hypertensive [18,20,21]. In fact, it is estimated that more than two-thirds of patients with type 2 diabetes are also hypertensive [22]. It has also been shown that arterial stiffness is more critical in individuals with both hypertension and type 2 diabetes than in those without hypertension [23,24]. This is a major health problem.

For all these reasons, correctly and validly measuring blood pressure in a person with diabetes is crucial. On one hand, blood pressure control has been shown to decrease the risk of diabetes-related complications such as microvascular and microvascular pathology [16,22-25]. On the other hand, the increase in arterial stiffness can affect the accuracy of automatic blood pressure measurements that are essential for diagnosis and administration [26,27]. And, more importantly, measuring blood pressure accurately facilitates the establishment of a threshold above which antihypertensive treatment may be recommended, especially in patients with type 2 diabetes who are very likely to develop complications such as peripheral arterial disease, stroke, heart attack, sudden death from heart failure, or renal pathologies, if not treated [28,29].

In that regard, it has been proven that blood pressure control and the prevention of morbidity and related mortality could be improved in persons with diabetes [3,8,16]. However, knowledge, treatment, and control of hypertension are persistently low worldwide [30,31].

One of the great challenges is to avoid therapeutic inertia, as this would result in an unacceptable burden in terms of human lives, sequelae, and socioeconomic costs [16,32].

Therefore, we consider it highly relevant to evaluate the validity of automatic blood pressure measurements in persons with diabetes because of the high prevalence of hypertension in this specific population and its significant morbidity and mortality rate.

The main goal of this study was to test the validity of the measurements of the QardioArm blood pressure monitoring device in individuals with noninsulin-dependent type 2 diabetes persons, in accordance with ESH-IP2 [9]. We hypothesized that the QardioArm for home blood pressure monitoring measurements of blood pressure and heart rate in individuals with noninsulin-dependent type 2 diabetes would be equivalent to those from a gold standard device within the requirements of ESH-IP2.

Methods

Study Design

We performed an observational concordance study to validate the QardioArm device for measurement of heart rate, diastolic blood pressure, and systolic blood pressure, in individuals with noninsulin-dependent type 2 diabetes according to ESH-IP2 [9] and STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) criteria [33]. The study was conducted between September 2019 to January 2020.

Ethics

This research study received ethical approval (number 173/2019). This study respected the Helsinki Declaration [34]. All participants signed an informed consent form prior to being included in the study.

Devices

Omron M3 Intellisense

The Omron M3 Intellisense (Omron Healthcare Co Ltd) was used as the gold standard instead of a mercury sphygmomanometer, in this study, because it has been validated in the general population according to ESH-IP2 [35].

The Omron M3 Intellisense device records heart rate in the range of 40 to 180 bpm and brachial blood pressure in the range of 0 to 299 mmHg using the oscillometric method; systolic blood pressure, diastolic blood pressure, and heart rate are shown on screen. The inflation system does not require pressure presetting or reinflation because of its technology, and deflation is automatically released by a pressure valve. It weighs approximately 340 g without batteries. The standard cuff fits arm circumferences ranging from 22 to 32 cm; it is also available in a large cuff to fit arm circumferences from 32 to 42 cm.

QardioArm

The QardioArm (Atten Electronic Co) is an automatic home blood pressure measurement monitoring device. QardioArm is a blood pressure measurement system intended to assess heart rate, diastolic blood pressure, and systolic blood pressure in an adult population, for pulse rates in the range of 40 to 200 bpm and blood pressure in the range of 40 to 250 mmHg.

This device utilizes an inflatable cuff that is wrapped around the upper arm, with circumferences ranging from 22 to 37 cm. The weight of unit is 310 g with batteries and its dimensions, when closed, are 140 mm×68 mm×38 mm. There is a freely downloadable app on the company's website, Google Play, or the Apple App Store. A smart device with Android 4.4 (KitKat) or later, or Bluetooth 4.0 and iOS 7.0 or later, is required, being compatible with iPhone, iPod, iPad, Apple Watch, tablets, and smartphones. QardioArm also provides graphics to facilitate visual data interpretation on screen. This app may be configured by warnings and reminders, also measurements and progress may be shared in real time with clinicians and other users.

Patients and Recruitment

All patients were recruited from Fresenius Medical facilities in Plasencia-Extremadura, Spain. The inclusion criteria were age greater than 25 years, gender (at least 10 men and 10 women), and recruitment blood pressure requirements according to the guidelines [9]: 33 participants diagnosed with noninsulin-dependent type 2 diabetes were included.

The exclusion criteria were having an arrhythmia or using insulin as treatment at the time of the study.

Study Protocol

Two nurses with experience in blood pressure measurement performed all assessments. The assessment room was a comfortable temperature without noise, distractions, or any factors that could have influenced the measurements [9].

Birth date, gender, weight, and height of each participant were recorded, and the arm circumference was measured in order to ensure an adequate cuff size. Body mass index was calculated using the Quetelet index.

The same assessment room was used for all participants. Each participant was seated in the assessment room, and the measurements were assessed after a period of 10 to 15 minutes of rest. Measurements by both units were taken on the left arm supported at the heart level, and a total of 9 consecutive measurements (systolic blood pressure, diastolic blood pressure and heart rate) were carried out alternating the Omron M3 Intellisense and the QardioArm in the following order: blood pressure A—entry blood pressure using the Omron M3 as standard device; blood pressure B—entry blood pressure using the Omron M3 as test device; blood pressure 1 by Omron M3; blood pressure 2 by QardioArm; blood pressure 3 by Omron M3; blood pressure 4 by QardioArm; blood pressure 5 by Omron M3; blood pressure 6 by QardioArm; and blood pressure 7 by Omron M3.

During measurement, the patient remained quiet and calm, sitting placing the back straight maintaining the feet over the floor in parallel position without crossing their legs as well as resting the arm over a flat surface, with the hand palm upwards and the elbow in a slightly flexed position in order to place his fist at the height of its heart. The interval between one measurement and the next was 30 or 60 seconds [9].

Data Analysis

Results are described as mean and standard deviation with range. Sociodemographic variables were examined using the Kolmogorov–Smirnov test to assess normality, and data were considered normally distribution if $P>.05$. Two-tailed independent t tests or Mann–Whitney U tests were used for parametric or nonparametric variables, respectively.

Device accuracy, following the ESH-IP2 [9], is based on a comparison between the device and reference measurements. Part 1 of the protocol refers to the number of differences within the required ranges for individual measurements (99 measurements), and part 2 of the protocol refers to the number of differences within the required ranges for each individual ($n=33$).

For each patient, systolic blood pressure measurements obtained from the QardioArm device (blood pressure measurements 2, 4, and 6) were compared with the systolic blood pressure measurements from the Omron device (blood pressure measurements 1, 3, and 5, respectively, or with blood pressure measurements 3, 5, and 7, respectively); the comparisons which were favorable to the device were utilized. The same procedure was followed with diastolic blood pressure and heart rate measurements.

Differences were separately classified for diastolic blood pressure and systolic blood pressure, depending on whether the difference was within 5, 10, or 15 mmHg [9] as well as for heart rate depending on whether the difference was within 3, 5, or 8 bpm.

Results were analyzed and detailed according to ESH-IP2 requirements in order to determine if the device passed the validation protocol. Accuracy was determined by the number differences in these ranges for both individual measurements (part 1) and individuals (part 2). To pass, a device must meet the minimum pass requirements.

Furthermore, Bland–Altman plots were utilized to quantify agreement between such systolic blood pressure, diastolic blood pressure, and heart rate by constructing limits of agreement (a graphical method in which the differences between both devices are used to compare two measurements of the same variable).

All analyses were carried out with SPSS statistical software (version 19.0; IBM Corp). In all analyses, the threshold for statistical significance was $P=.05$ with a 95% confidence interval.

Results

Participants

All the sociodemographic variables showed a normal distribution ($P>.05$, Table 1). A sample of 37 participants diagnosed with noninsulin-dependent type 2 diabetes were recruited; 4 were excluded due to device failure ($n=2$), arrhythmias ($n=1$), and cuff size unavailability ($n=1$), therefore, there were 33 participants (17 men and 16 women) who met the ESH-IP2 inclusion criteria. Table 1 shows participant demographic characteristics.

Table 1. Demographic characteristics and descriptive data of the participants.

Participant characteristics (N=33)	Value, mean (SD)	Value, range ^a	P value
Age (years)	65.9 (9.8)	39.0-85.0	.73
Men (n=17)	66.4 (12.3)	39.0-85.0	
Women (n=16)	72.6 (6.7)	65.0-84.0	
Weight (kg)	74.8 (12.6)	48.0-101.0	.42
Men (n=17)	76.5 (12.5)	48.0-100.0	
Women (n=16)	72.9 (12.9)	57.0-101.0	
Height (cm)	164.9 (7.3)	147.0-180.0	.17
Men (n=17)	166.6 (5.3)	160.0-180.0	
Women (n=16)	163.1 (8.8)	147.0-175.0	
BMI (kg/m²)	27.6 (5.2)	18.1-43.7	.90
Men (n=17)	27.5 (3.7)	18.1-34.1	
Women (n=16)	27.7 (6.5)	20.3-43.7	
Arm circumference (mm)	286.4 (32.7)	220.0-360.0	.19
Men (n=17)	279.1 (26.8)	220.0-320.0	
Women (n=16)	294.1 (37.3)	243.0-360.0	

^aminimum to maximum

Blood Pressure Outcome Measurements

Parts 1 and 2 of the validation according to the ESH-IP2 for the QardioArm blood pressure are presented in Table 2; the number of differences between the device and reference for systolic blood pressure and diastolic blood pressure classified within 5, 10, or 15 mmHg are detailed.

Mean differences between the QardioArm and Omron M3 were 3.37 (SD 3.19) mmHg for diastolic blood pressure and 3.15 (SD 4.67) mmHg for systolic blood pressure.

A total of 87/99 differences (89%) for systolic blood pressure and a total of 88/99 differences (89%) for diastolic blood pressure showed an absolute difference within 5 mmHg (ESH-IP2 criteria: at least 65 for diastolic blood pressure and at least 73 for systolic blood pressure). Furthermore, a total of 95/99 comparisons (96%) for systolic blood pressure and a total of 96/99 (97%) for diastolic blood pressure showed an absolute difference within 10 mmHg (ESH-IP2 criteria: at least 81 for diastolic blood pressure and at least 87 for systolic blood pressure). A total of 98/99 differences (99%) for systolic blood pressure and a total of 99/99 differences (100%) for diastolic

blood pressure exhibited an absolute difference within 15 mmHg (ESH-IP2 criteria: at least 93 for diastolic blood pressure and at least 96 for systolic blood pressure). Part 1 of the validation was successfully completed since 2 or more of the 3 absolute difference ranges (within 5, 10, or 15 mmHg) for systolic blood pressure met the minimum requirements, and 3 out of 3 absolute difference ranges for diastolic blood pressure met the minimum requirements.

A total of 32/33 patients (97%) for systolic blood pressure and a total of 29/33 patients (88%) for diastolic blood pressure showed a minimum of 2 out of 3 differences within 5 mmHg (ESH-IP2 criteria: at least 24 out of 33 patients for systolic blood pressure and at least 24 out of 33 patients for diastolic blood pressure). Nevertheless, 1/33 patients (3%) had 3 differences outside 5 mmHg for systolic blood pressure, though 0/33 patients (0%) had 3 differences outside 5 mmHg for diastolic blood pressure (ESH-IP2 criteria: a maximum of 3 patients for diastolic blood pressure and systolic blood pressure according to the ESH-IP2 criteria. Part 2 of the device validation was successfully completed; therefore, part 3 of the QardioArm device validation was passed, since parts 1 and 2 were both passed for diastolic blood pressure and systolic blood pressure.

Table 2. Number of measurement differences in each range.

Measurement type and range	ESH-IP2 requirement, n		Achieved (N=99), n	Difference (mmHg), mean (SD)
	For 2 of 3 ranges	For all 3 ranges		
Part 1				
Systolic blood pressure				3.37 (3.19)
≤5 mmHg	73	65	87	
≤10 mmHg	87	81	95	
≤15 mmHg	96	93	98	
Diastolic blood pressure				3.15 (SD 4.67)
≤5 mmHg	73	65	88	
≤10 mmHg	87	81	96	
≤15 mmHg	96	93	99	
Heart rate				1.65 (2.91)
≤3 bpm	73	65	91	
≤5 bpm	87	81	96	
≤8 bpm	96	93	99	

Heart Rate Outcome Measurements

Parts 1 and 2 of the validation according to the ESH-IP2 for heart rate are also shown in [Table 2](#) and [Table 3](#); the number of differences between QardioArm and the standard device, Omron M3, within 3, 5, and 8 bpm are detailed. The mean difference between the tested device and standard was 1.65 (SD 2.91) bpm.

A total of 91/99 differences (92%) showed an absolute difference within 3 bpm, a total of 96/99 comparisons (97%) showed an absolute difference within 5 bpm, and a total of 99/99 differences (100%) showed an absolute difference within 8 bpm. Thus, part 1 of the device validation was successfully completed for the heart rate.

Table 3. Within-participant measurement differences.

Measurement type and range	2 of 3 measurements		0 of 3 measurements	
	ESH-IP2 requirement, n	Achieved (N=33), n	ESH-IP2 requirement, n	Achieved (N=33), n
Part 2				
Systolic blood pressure				
≤5 mmHg	≥24	32	≤3	1
Diastolic blood pressure				
≤5 mmHg	≥24	29	≤3	0
Heart rate				
≤3 bpm	≥24	31	≤3	1

A total of 31/33 participants (94%) had a minimum of 2 of 3 comparisons within 3 bpm difference for heart rate. Nevertheless, a total of 1/33 participants (3%) had 3 differences greater than 3 bpm; therefore, part 2 of the device validation was successfully completed for heart rate, and consequently, part 3 of the QardioArm device validation was passed.

Indeed, the QardioArm device met the validation criteria of the ESH-IP2 for heart rate, systolic blood pressure, and diastolic

blood pressure for this sample of 33 individuals with noninsulin-dependent type 2 diabetes.

The Bland-Altman plots show the differences between QardioArm and Omron M3 measurements for systolic blood pressure ([Figure 1](#)), diastolic blood pressure ([Figure 2](#)), and heart rate ([Figure 3](#)).

Figure 1. Bland-Altman plot showing differences between QardioArm and Omron M3 measurements for systolic blood pressure.**Figure 2.** Bland-Altman plot showing differences between QardioArm and Omron M3 measurements for diastolic blood pressure.

Figure 3. Bland-Altman plot showing differences between QardioArm and Omron M3 measurements for heart rate.

Discussion

As far as we know, this is the first study to validate an upper arm oscillometric wireless device connected to an app to measure heart rate and blood pressure in a population with noninsulin-dependent type 2 diabetes. QardioArm was validated in 2017 [36,37] in the general population. Furthermore, QardioArm has also been validated in a population of obese individuals in 2018 [38], and recently, in a population of individuals with chronic kidney disease [39].

The results of this study have shown that QardioArm device passed both parts of the validation [9] in patients diagnosed with noninsulin-dependent type 2 diabetes as hypothesized. This validation has been carried out following the ESH-IP2 guidelines, although a validated noninvasive oscillometric upper arm device was used as a reference instead a mercury sphygmomanometer [3-6]. Our findings, however, should not be extrapolated to other populations with other diseases.

We have already seen the enormous advantages of home blood pressure monitoring, especially in specific populations prone to hypertension, such as persons with diabetes. Chronic diseases such as diabetes are one of the most common pathologies and have significant physical, psychological, social, and economic impacts [3,8,16,17,19-25,28,29,32]. mHealth and apps that assess blood pressure are progressively gaining a fundamental role in the management of hypertension with the potential to improve the quality of managed care by offering additional advantages, especially when it comes to blood pressure self-measurement. Advantages could include assisting in lowering blood pressure [3,40,41]; enabling individuals to have 24-hour access to detailed and personalized blood pressure information [40,42]; improving adherence to treatment [3,43];

providing information to facilitate diagnostic and therapeutic decisions [40,41,43,44]; improving patient knowledge of blood pressure, lifestyle, and risk factors that may accompany hypertension [40,42,43]; more effectively preventing cardiovascular complications [43]; or health cost savings by avoiding unnecessary hypertensive treatment and reducing the number of visits to the clinic [3,42].

Nevertheless, we found very few studies analyzing the validity of automatic blood pressure monitors in a population with noninsulin-dependent type 2 diabetes, [37,45-48], and furthermore, most of these validations did not follow specific protocols such as ESH-IP2 [9-11].

Only one study by Chahine et al [37] was found that followed the same recommendations as those of the ESH-IP2 [9]. They validated Omron M6 IT Comfort using a mercury sphygmomanometer as the standard. If we compare our results with their results [37], the number of differences for each category (5, 10, and 15 mmHg) for the systolic blood pressure and the diastolic blood pressure were similar in the two validations, and parts 1 and 2 were passed in both. QardioArm achieved better results in part 1 of the protocol, especially for diastolic blood pressure with a number of higher differences in the 3 categories. Within part 2, QardioArm and Omron M6 differed in 3 individuals for the first criterion (2 of 3 comparisons within 5 mmHg difference) for both systolic and diastolic pressure, in favor of QardioArm. The results of the second criterion (3 differences outside 5 mmHg) were almost identical for both devices. On the other hand, the data obtained for heart rate cannot be compared because Chahine and company [37] did not assess this variable.

Another important fact is that measurements of people with type 2 diabetes involve stiffer arteries; however, in our study

this was not assessed, since it was not the main aim of this research.

Finally, for future studies, consecutive sampling bias should be considered; a simple random sampling process might be more appropriate.

Moreover, we consider that further validations are needed for devices that measure blood pressure in patients with noninsulin-dependent type 2 diabetes. In fact, a future line of research could be to specifically investigate the validation of this QardioArm device in patients with type 2 diabetes who

have microarteriopathy as diabetic retinopathy, patients with type 1 diabetes as well as other populations with specific diseases such as pregnant women.

QardioArm for home blood pressure monitoring showed validated measures of blood pressure and heart rate in individuals with noninsulin-dependent type 2 diabetes meeting the requirements of ESH-IP2. The findings of the study may be relevant since it is the first validation showing that a device linked to an app to measure blood pressure and heart rate met the requirements of the ESH-IP2 in noninsulin-dependent type 2 diabetes population.

Abstract

Background: A long-acting implant for HIV pre-exposure prophylaxis (PrEP) is in development in the Sustained Long-Action Prevention Against HIV (SLAP-HIV) trial. This could provide an alternative to oral PrEP.

Objective: Our mixed methods study aimed to understand (1) users' experiences with a similar subdermal implant for contraception and (2) factors influencing the likelihood that gay and bisexual men (GBM) would use a proposed PrEP implant.

Methods: Work was completed in 4 stages. In stage 1, we conducted a scientific literature review on existing subdermal implants, focusing on users' experiences with implant devices. In stage 2, we reviewed videos on YouTube, focusing on the experiences of current or former contraceptive implant users (as these implants are similar to those in development in SLAP-HIV). In stage 3, individuals who indicated use of a subdermal implant for contraception in the last 5 years were recruited via a web-based questionnaire. Eligible participants (n=12 individuals who liked implants a lot and n=12 individuals who disliked implants a lot) completed in-depth phone interviews (IDIs) about their experiences. In stage 4, results from IDIs were used to develop a web-based survey for HIV-negative GBM to rate their likelihood of using a PrEP implant on a scale (1=very unlikely and 5=very likely) based on likely device characteristics and implant concerns identified in the IDIs.

Results: In the scientific literature review (stage 1), concerns about contraceptive implants that could apply to the PrEP implants in development included potential side effects (eg, headache), anticipated high cost of the device, misconceptions about PrEP implants (eg, specific contraindications), and difficulty accessing PrEP implants. In the stage 2 YouTube review, individuals who had used contraceptive implants reported mild side effects related to their device. In stage 3, implant users reported that devices were comfortable, unintrusive, and presented only minor discomfort (eg, bruising) before or after insertion and removal. They mainly reported removing or disliking the device due to contraceptive-related side effects (eg, prolonged menstruation). Participants in the stage 4 quantitative survey (N=304) were mainly gay (204/238, 85.7%), white (125/238, 52.5%), cisgender men (231/238, 97.1%), and 42.0% (73/174) of them were on oral PrEP. Not having to take a daily pill increased the likelihood of using PrEP implants (mean 4.13). Requiring >1 device to achieve 1 year of protection (mean range 1.79-2.94) mildly discouraged PrEP implant use. Participants did not mind moderate bruising, a small scar, tenderness, or bleeding after insertion or removal, and an implant with a size slightly larger than a matchstick (mean ratings 3.18-3.69).

Conclusions: PrEP implants are promising among GBM. Implant features and insertion or removal-related concerns do not seem to discourage potential users. To ensure acceptability, PrEP implants should require the fewest possible implants for the greatest protection duration.

KEYWORDS

PrEP implant; YouTube; acceptability; long-acting PrEP; systemic PrEP; human-centered design; HIV prevention; removable implant; long-acting HIV prevention; gay and bisexual men

Introduction

Subdermal implants represent a promising, long-acting biomedical HIV prevention innovation in the development pipeline. A total of two trials are currently investigating subdermal implants for HIV pre-exposure prophylaxis (PrEP): (1) the Sustained Long-Acting Prevention against HIV (SLAP-HIV) trial (preclinical phases) [1,2] and (2) Centre for the AIDS Programme of Research in South Africa-018 (phase I or II) [3]. Little is known about whether such HIV prevention devices would be acceptable or feasible for end users [4]. This is a concern given that uptake of existing PrEP products (eg, oral PrEP) is suboptimal in some key populations who are disproportionately affected by the HIV epidemic. For example, in a 2017 cohort study of 995 gay and bisexual men (GBM) across the United States, only 4% of participants reported currently using oral PrEP [5]. The reasons for this limited uptake are continually emerging [6-9]. Involving potential consumers in the initial stages of product development could help mitigate later issues with method use. Specifically, early consumer involvement could help researchers understand end users' anticipated challenges with uptake and adherence, allowing them to address and potentially limit these problems in the design of clinical tools [10].

SLAP-HIV is an interdisciplinary research project that aims to identify, develop, and test a long-acting PrEP implant. A proposed version of this product could be inserted under the skin of a user's upper arm. This device is conceptualized to slowly dispense a single HIV prevention medication (such as tenofovir alafenamide or cabotegravir) over a period (eg, 2-12 months). Similar devices are currently used by cisgender women (ie, individuals who were assigned female at birth and identify as women) to dispense contraceptive medication (eg, Nexplanon) [11]. Thus, it is possible to learn from the experiences of current and past users of an implant similar to the one in development to understand their likes and dislikes about this mode of drug delivery.

This study was undertaken as part of SLAP-HIV. We aimed to identify barriers and facilitators anticipated by GBM who might use PrEP implants in the future. Although the end goal of this work focused on the opinions of GBM, we focused on cisgender women during the initial stages, as the contraceptive implant is the product most similar to the one in development by SLAP-HIV.

Methods

This work was completed in 4 stages, which are summarized below.

Stage 1: Scientific Literature Review

We conducted a review of the scientific literature on publicly available (eg, Google Scholar and PubMed) and university-specific (eg, Columbia University libraries) databases to identify barriers and facilitators of contraceptive implant use among cisgender women. We focused our review on contraceptive implants, as this device is most similar to the one in development by SLAP-HIV. Furthermore, there is extremely limited data on cisgender men's experiences with implants to deliver gender-specific medications (eg, the Testopel testosterone implant); these implants also operate differently than those under study in SLAP-HIV (eg, Testopel is a nonremoveable biodegradable pellet implant) [12]. We limited our search to studies published in the last 10 years (January 1998 to July 2017). Search terms included "contraceptive implant barriers," "contraceptive implant removal," "contraceptive implant facilitators," "contraceptive implant experiences," and "contraceptive implant continuation." We limited the search to studies published about US populations and manuscripts on arm-implant contraceptives (eg, studies focused only on intrauterine devices [IUDs] were excluded).

The primary author (CR) and a research assistant (CL) abstracted relevant studies and independently reviewed their full content to determine their applicability to the topic under study (eg, device-related barriers and facilitators to contraceptive implants). CR and CL met in person to discuss the results of the independent reviews, resolve a disagreement about study relevance in concert, and identify studies to move forward with. After the studies to be included in the final review were identified, CR tallied the specific mention of device-related and contraceptive medication-related barriers and facilitators in a word document. There was very little mention in the scientific literature about the device-related effects of contraceptive implants. Thus, stage 2 (summarized below) intended to learn more about users' device-related subdermal implant experiences, as this will be important for our target population, GBM (stage 4).

Stage 2: Review of YouTube Videos

A total of 2 members of the research team identified a collection of potentially relevant YouTube videos through a manual search. Search terms included lay and commercial names of contraceptives: "Nexplanon," "Nexplanon insertion," "Jadelle," "Jadelle implant," "Nexplanon birth control," "Norplant,"

“Implanon,” “Implanon birth control review,” and “Arm bar birth control.” We excluded sponsored testimonials, insertion or removal footage that included no assessment of the patient’s experience, clinical videos (ie, procedural videos on how to insert or remove implants), promotional or educational videos (ie, videos explaining what contraceptive implants are or how they work), and advertisements for any product. Then, spoken word transcripts of potentially relevant videos were automatically generated using YouTube’s state-of-the-art speech recognition algorithms [13].

To identify biomedical terms in YouTube transcripts, we used a publicly available natural language processing system called National Center for Biomedical Ontology Annotator, maintained by the National Library of Medicine [14]. The system recognizes sets of words and phrases using string matching and regular expressions that operate directly on text without preprocessing, such as spelling correction, part-of-speech tagging, and word sense disambiguation [15]. To identify the various side effects associated with subdermal implants, we utilized Systemized Nomenclature of Medicine (SNOMED) [16], a comprehensive terminology that provided term-to-concept mapping for a vast array of conditions, symptoms, and clinical findings.

We restricted our search to several types of concepts or *semantic types*. We identified relevant semantic types by using SNOMED to annotate a string of words typically associated with unpleasant experiences with drug delivery implants. We then reported the frequency of the specific terms describing these unpleasant experiences (eg, contusion and pain). Terms were paired to ensure clarity in the themes to which they were intended to refer (eg, bleeding, menstrual spotting). We then quantified the frequency (eg, number of videos) with which they appeared.

Stage 3: In-Depth Interviews With Contraceptive Implant Users

In stage 3, we recruited potential participants using paid Facebook advertisements and posts on contraceptive implant-themed Facebook pages (eg, *Nexplanon* and *Implanon*) and other female-centered Facebook groups (eg, *Girls Love Travel*), with permission from page moderators. We exclusively sampled cisgender women in this stage because we wanted to ensure that the implant participants had used a design that was consistent with those of the PrEP implants in the development pipeline. Subdermal implants commonly available to men (eg, Testopel testosterone pellets, which are a nonremovable pellet implant, placed in the gluteal region) have a much different design [12,17]. This sampling approach had 2 purposes as it would allow (1) PrEP implant developers to incorporate feedback from past or current users of a similar implant into their device design and (2) the research team to be more precise about the questions asked to potential future PrEP implant users in the stage 4 web-based survey.

Participants were invited to click on a link that took them to a brief screening questionnaire to assess eligibility for telephone interviews about their experiences with implants. Eligible participants were at least 18 years old, identified as cisgender women, and had used an implant for contraception in the last 5 years. To sample a wide range of users’ experiences, we selected those who reported that they *liked very much* or *disliked*

very much their implant on a 4-point Likert scale (1=disliked very much, 2=disliked a little, 3=liked a little, and 4=liked very much). In all, 24 participants were selected for interviews on a *first come first serve* basis, 12 who *liked very much* and 12 who *disliked very much* their implants and could be reached using the telephone numbers they provided.

Telephone interviews were audio-recorded and guided by findings from the YouTube analysis and scientific literature review. Specifically, we focused on the in-depth phone interview (IDI) guide on themes from the scientific literature and those YouTube users referenced frequently (identified using SNOMED). We categorized these themes into 6 broad categories: (1) general questions about participants’ experiences with subdermal implants, (2) decision making around the use of an implant, (3) acceptability of the implant, (4) the implantation process, (5) the removal process, and (6) recommendations for researchers working on a future PrEP implant. Participants were also asked about their reasons for removing the contraceptive implant. Upon completing the interviews, participants were compensated with US \$50 Amazon gift cards.

Next, audio-recordings of the interviews were transcribed and cleaned for accuracy. To analyze the data, a codebook was developed jointly by the principal investigator of the project and a research assistant. It incorporated categories and themes from the interview guide and included definitions, inclusion and exclusion criteria, and examples of passages for inclusion. To validate and finalize the codebook, 2 researchers coded 2 transcripts independently, met to reconcile discrepant codes, and modified the codebook as needed to ensure that all themes of interest were being accurately captured. Researchers, then, proceeded to code the remainder of the transcripts in pairs, meeting after every 11 transcripts (half of the remaining data) were coded to reconcile discrepant codes. The finalized codes were analyzed using content analysis [18] to identify prevalent themes, illustrative examples of each theme, and knowledge gaps.

Stage 4: Web-Based Surveys With Gay and Bisexual Men

Findings from the IDIs among cisgender women in stage 3 informed the development of a web-based quantitative assessment. This assessment took approximately 3 min to complete and aimed to determine how likely members of key HIV risk demographics (ie, GBM) would be to use an implant for HIV prevention. Specifically, we published text-based pop-up advertisements (known as broadcasts) on Grindr, a dating and *hookup* app for GBM. Logistically, these advertisements popped up the first time any Grindr user within a specified location opened the app; users who clicked on the advertisement were automatically rerouted to the quantitative assessment. For the purposes of this study, we published 2 broadcast advertisements (per city) in New York City, Baltimore, and Chicago. The quantitative assessment was open to anyone who wished to take it; eligible participants reported identifying as a gay man who was at least 18 years old. We focused our recruitment on GBM (rather than cisgender heterosexual cisgender women) because this population is at comparatively

higher risk for HIV exposure and is one of the planned target populations for future PrEP implant studies. To reduce the odds of receiving multiple entries from the same person, participants did not receive compensation for their time, and surveys that had identical Internet Protocol addresses were eliminated. Additionally, for the purposes of the analyses presented in this paper, only HIV-negative GBM who lived in the United States were included.

As the PrEP implant is still hypothetical, we posed a variety of device configurations to participants. Specifically, the quantitative assessment measured how willing participants would be to use a hypothetical HIV prevention implant given a number of different factors: varying lengths of effectiveness (eg, 12 months, 6-8 months, and 2-3 months), number of implantable devices required, potential physical side effects (eg, bruising and scarring) resulting from the implantation or removal processes, implant size, and the convenience of using an implant compared with taking a daily HIV prevention pill (PrEP). All responses were recorded using a 5-point Likert scale, ranging from 1 (*I am very unlikely to use it*) to 5 (*I am very likely to use it*). The value 3 on this scale represented a neutral response. Questions were presented in a different random order for each participant to minimize potential bias. Basic demographic, sexual risk, and injection drug use information were also collected using the web-based survey ([Multimedia Appendix 1](#)).

To give participants an idea of what a PrEP implant would entail, we embedded photos of the proposed implant next to a dime to help respondents estimate its size. Additionally, we embedded graphics interchange formats (GIFs: a lossless image file format that presents time-lapse video imagery) of the implant insertion and removal processes so that participants could gain an understanding of how they worked.

Results

Stage 1: Scientific Literature Review

In the scientific literature, all studies that were identified by the research team focused on cisgender women. Barriers to

contraceptive implant uptake and sustained use most frequently included some that do not apply to an HIV prevention implant (eg, irregular or unpredictable menstrual bleeding [19-21]) and others that do apply, such as potential nonmenstrual side effects (eg, headache) [20,21]; perceived or actual high cost of implants [22-29]; patient or provider misconceptions or lack of information about implants (eg, believing that implants are contraindicated for specific patient populations) [21,23,26-32]; and challenges with access to implants [25,27]. Few studies discuss facilitators of the use of contraceptive implants as a birth control method and instead mostly focus on facilitators of implementation of programs designed to encourage implant use [26,33]. However, the scant body of existing evidence on implant facilitators shows that these include low implant cost, same-day insertion [27], and the inherent privacy of implants (eg, you can use this contraceptive method with low risk of others finding out) [29]. We were unable to identify scientific studies focused on user preferences regarding specific implant attributes (eg, size) or device-related effects (eg, bruising and local pain). Consequently, we sought additional sources of information.

Stage 2: Self-Reported Side Effects Associated With Contraceptive Implants

Stage 2 summarizes our systematic review of YouTube videos. In July 2017, 272 videos about users' experiences with contraceptive implants (that did not meet the exclusion criteria specified in the Methods section) had been uploaded to YouTube. [Table 1](#) reports the frequency of videos in which the most often cited terms related to undesirable implant effects appear. These terms include the following: (1) pain, stinging, burning, or soreness and tenderness unrelated to menstruation (51 videos); (2) menstrual bleeding or spotting (33 videos); (3) contusion (32 videos); (4) scarring (25 videos); and (5) bleeding unrelated to menstruation (24 videos). We do not report demographic data as terms originated from videos posted on YouTube, and in the sample of videos accessed for the purposes of this study, posters rarely reported their demographic characteristics.

Table 1. Most frequently reported terms related to undesired implanted medication delivery device effects and the number of videos in which they are mentioned (stage 1; N=272 videos).

Term	Number of videos in which the term is referenced, n (%)
Pain, stinging, burning, or soreness and tenderness unrelated to menstrual bleeding or spotting	51 (18.8)
Menstrual bleeding or spotting	33 (12.1)
Contusion	32 (11.8)
Scarring	25 (9.2)
Bleeding unrelated to menstruation	24 (8.8)

Stage 3: Users' Reported Experiences With Contraceptive Implanted Medication Delivery Devices

Participants in IDIs were cisgender women who were aged, on average, 24 years and had used an implant for contraception in the last 5 years. Coders identified several themes within the

topics previously recognized using SNOMED and covered in the IDI guide. Topics included the following: (1) specific attributes of implant products that attracted participants to these devices; (2) concerns about the implant; (3) feelings about the insertion process; (4) participants' observed likes and dislikes

about the implant, once it was inserted; and (5) recommendations for future implant designs and placement.

Specific Attributes of Implant Products That Attracted Participants

A majority of participants (n=20) reported that they were motivated to use contraceptive implants because they were long lasting and did not require additional attention or maintenance once inserted:

...I was on the pill for a long time and then I tried the shot and I didn't like either of those options. So I kind of wanted something a little bit more permanent that I didn't really have to worry about, which is why I thought it was a good fit for me...Like I said, it's kind of more permanent, which I liked. You don't really have to worry about it... [Participant 52: age 26 years, liked implant very much]

I wanted something that I didn't have to worry about...Like trying to remember to take a pill every day and, you know, this, you know, you don't notice it's there. You know, I mean, you can feel it if you touch it, but you don't have to worry about anything. It's just there...You don't have to worry about taking a pill at the same time every day, or with the IUD, with it falling out, or something. I've heard stories of that. This you know is there. It's not going to come out, unless you get it taken out. [Participant 46: age 36 years, liked implant very much]

Almost half of the participants (n=10) reported that they chose implants because they believed that the side effect profile was favorable to other contraceptive medications on the market and even had some positive effects (eg, reduction in or stoppage of menstrual bleeding):

Well, it just seems less, like there'd be less side effects. Like, I have friends and stuff who've had the IUD and they say it causes really bad period cramps and I've never really heard of any bad stories with the Nexplanon, so that's why I opted to go with it rather than the IUD. [Participant 96: age 25 years, liked implant very much]

I liked the Nexplanon because there was a really high chance that I would not have a cycle, or I'd have a very light cycle because previous to that, I was having very heavy cycles, like painful, you know, just really couldn't even go sit in class all day, I was cramping so much, stuff like that. So, I was hoping I'd be in that percentage of like, lightening up a little bit, or not having a cycle at all... [Participant 119: age 20 years, disliked implant very much]

Concerns About the Subdermal Implant

Although many participants felt that the side effects of contraceptive implants were less problematic than those of other contraceptives, they still expressed some concerns (n=12):

And then some of the cons that I had heard were weight gain, depression, mood swings, stuff like that. But at the time -- you hear different things about

different birth controls and everybody's body's different so even though I had heard those few bad things I was still willing to give it a try. [Participant 37: age 20 years, disliked implant very much]

...I anticipated highly irregular periods. I also anticipated looking for any sort of hormonal imbalances or emotional imbalances based on hormone usage. Nexplanon is my first birth control, so since I didn't have any prior experience I was just wary of hormonal medication at all... [Participant 138: age 23 years, liked implant very much]

However, given that PrEP implants do not contain hormonal medications, these concerns would not apply.

Feelings About the Insertion Process

Many participants (n=15) felt that the insertion process was quick and straightforward:

it's very straightforward. It's really like a two-process insertion, which I thought was great, rather than them trying to feel around where to put it. They insert the little machine and click it in and that's it. So it's very simple... [Participant 56: age 26 years, liked implant very much]

...I mean, it was pretty easy for them to...get it in there with the -- I guess they use a needle after they numb you, and they make the incision -- I guess it's a needle, I don't really -- it's a big one, but it's pretty easy to put in there...I guess when they made that incision, and then used the little insert - that was pretty fast. Like, it -- when they put it in it goes really fast. It's just waiting to be numb that took the longest. [Participant 260: age 20 years, disliked implant very much]

Participants reported few dislikes about the insertion process, though a minority (n=5) felt intimidated by the size of the implant or applicator:

Yeah, like I mentioned, whenever you first see it -- and I'm not a big needle person, anyways, but whenever you first see it, it looks scary. The needle that they insert it with is pretty wide. [Participant 37: age 20 years, disliked implant very much]

After the device was inserted, the majority of participants (n=21) experienced localized pain related to device insertion. This pain was mostly mild and included bruising, soreness, and bleeding:

Immediately, the area was like kind of a little bit sore, but like I said, it just like bruised a little bit and then it was fine...It was kind of bruised like for a couple of days, but after that it was fine. [Participant 52: age 26 years, liked implant very much]

My arm bled for a little while after they got it in, so I had to keep the wrap on for three days and it was a really smooth transition putting it in...They recommended to keep it on for three days, but it was really, really tight, so it was a little rough to keep the wrap on for three days, and showering and moving around with a tight, brown wrap on your arm. So I

did end up taking it off, I think, after two. But by then, it was fine. [Participant 16: age 24 years, disliked implant very much]

Participants' Likes and Dislikes About the Implant After It Was Inserted

After the implant was inserted, participants continued to view the long-lasting properties of the device and its little need for user attention as a benefit (n=13):

I liked that I didn't have to take something every day, that it was just there...but pretty much I didn't have to remember to take anything and I knew I wasn't going to get pregnant because it had worked for so many other girls before. [Participant 64: age 27 years, liked implant very much]

...Overall, I feel it's been more beneficial to my life than the pill was. Because, once again, convenience. I don't have to forget anything. I've got the little card in my wallet that says, "OK, this is when you need to get it removed." It's in my arm, it's there, good to go... [Participant 98: age 19 years, liked implant very much]

Additionally, almost half of the participants (n=10) liked the implant's effectiveness in preventing pregnancy:

...I like the fact that I know that I could have unprotected sex with this, and I won't get pregnant. And I don't have to use condoms, because it's 100 percent active, like effective...I know I'm not going to get pregnant because I don't need that, especially after I just had a baby not too long ago... [Participant 235: age 30 years, disliked implant very much]

Participants liked the implant's small size (n=13):

It's small...So, if it would have been something a bigger size, I probably wouldn't have put it on, because I -- to have this thing stay in my arm, it would have been probably maybe uncomfortable, but the fact that it's small, it -- I can't feel it. It's not heavy. [Participant 86: age 28 years, liked implant very much]

...it was smaller. I wouldn't have to worry about anybody really noticing, or being able to associate anything with having birth control... It just made me feel more comfortable that it was smaller, and that I wouldn't have to worry about if it was large or thick, restraining any activity, or anything like that, that it might bend or break or anything. [Participant 201: age 20 years, disliked implant very much]

Furthermore, participants liked that they could not feel the device while they carried out their normal daily activities (n=14):

I think, also the fact that you could tell like it was flexible, my job that I had, I would have to pull out of boxes that were kind of almost about like chest height, and I -- there was one time I bent in, and I felt it hit against my arm, but because of it being flexible, it just kind of went with it instead of it had been more sturdy or like, more structured, I felt like it could have

possibly broken in that situation just because I had forgotten about it and didn't even think about reaching in like that. [Participant 68: age 24 years, disliked implant very much]

Although participants liked the small size of the device and that it was relatively unnoticeable during normal activities, some participants (n=8) also liked that the device was detectable if they searched for it. They found this reassuring, as they could ensure that the device was still in the correct spot and had not migrated:

You can't -- with an IUD, you can't check to see if it has moved, really. I mean, you kind of can, but not really. With this implant, you can feel where it is. If it feels like it's starting to, like, imbed further, I could go into the OB and have them check to make sure it hasn't moved. [Participant 67: age 23 years, liked implant very much]

...it doesn't bother me. I can poke it, and I can see it, but other than that it doesn't bother me. It's just there...It doesn't weird me out or anything. It's normal. I got used to it. It was kind of weird at first. But as long as I know it's there, and it's not like going further into my tissue, then it makes me a lot more comfortable knowing it's actually still there. Because I've heard the horror stories of having to get it taken out and having to have an actual surgery to get it out versus it just being pulled out. [Participant 211: age 24 years, disliked implant very much]

Some participants (n=8) reported that the implant felt uncomfortable when bumped:

...If I bump into anything on that arm where the implant is, it's uncomfortable, but it doesn't swell or anything like that...When I bump it it's just kind of a dull pain, like almost like a bruise feels. It's kind of weird to explain because it's internal pain, but it's -- I don't know, it's kind of weird. It's like when you bruise your foot and you keep bumping it, it feels like that for a short while. [Participant 98: age 19 years, liked implant very much]

It's a thin rod. If it was any bigger, I think they would probably bother people because if I put pressure on it -- you know, like, sometimes you turn around or something in the car -- not while you're driving, obviously, but I'll turn around in the passenger seat to check on my kids. And if you push your arm where the implant is up against something, it will start to hurt. It'll start to irritate me, so I try not to put pressure on the implant. [Participant 67: age 23 years, liked implant very much]

Recommendations for Future PrEP Implant Designs and Placement

Participants had suggestions for researchers regarding the design of the PrEP implant device. Specifically, some participants wanted the device to be designed in a way that would facilitate easier removal (n=7), be small in size, constructed from a flexible material (n=15), and be placed in an area of the arm that would not interfere with the device (n=9):

...Maybe make it easier to remove if there's any way to do that. I think that's the only thing that's really deterring people is that they're scared it's going to get stuck...I've seen pictures where they've cut people a couple of times, and they can't seem to get it out. So if there's any way to make sure that it's going to be easy to come out with this design you guys are making -- I don't know if there's a way to do that, but...I wish they could remove it like that with the needle instead of cutting your arm. [Participant 67: age 23 years, liked implant very much]

It's like a slim rod that's really lightweight and plastic so like you don't feel it, and it just comes -- so, it goes in easily, but yeah, if it was shorter, it probably would have been a little more appealing...I don't really have an opinion about the size. I mean, it was I think a couple inches long, which is kind of big, and I probably would have liked it to be a little smaller, but it still wasn't too bad. [Participant 66: age 21 years, liked implant very much]

I don't feel like it hit on anything; I don't feel like it would hit against like the underwire of my bra because of where it was placed. And so, it was very convenient because it was just out of the way...I'd say

keep the flexibleness of that, but just kind of, make sure it's like as in-invasive to somebody's day-to-day life as possible. So, placed in a spot that isn't going to affect people that have different lifestyles, or maybe even have different options based on people's lifestyles and what they do, that that could be a possibility too. [Participant 68: age 24 years, disliked implant very much]

Stage 4: Gay and Bisexual Men's Likelihood of Using a PrEP Implant

Participants (N=304) in the stage 4 web-based survey were aged, on average, 38 years and predominantly self-identified as gay or homosexual (204/238, 85.7%) cisgender men (231/238, 97.1%); about half (125/238, 52.5%) of them identified as white and a quarter (58/238, 24.4%) identified as Latino. Over two-thirds of the sample were college graduates (89/238, 37.4%) or had attended graduate school (77/238, 32.4%) and reported ever (101/174, 43.4%) or currently (73/174, 30.7%) using oral PrEP. Condomless sex with an HIV-positive or unknown status partner (104/126, 43.7%) was the most frequently reported HIV risk behavior in the past year (Table 2).

Table 2. Demographic information (stage 4; N=238).

Sample characteristics	Value, mean (SD)	Value, range	Value, n (valid %) ^a
Age (years; N=238)	36.44 (11.33)	18-71	N/A ^b
Race/ethnicity (N=238)			
White	N/A	N/A	125 (52.5)
Latino	N/A	N/A	58 (24.4)
African American	N/A	N/A	27 (11.3)
Asian or Pacific Islander	N/A	N/A	19 (8.0)
Other	N/A	N/A	9 (3.7)
Education (N=238)			
College graduate	N/A	N/A	89 (37.4)
Graduate school	N/A	N/A	77 (32.4)
Some college	N/A	N/A	40 (16.8)
Trade/Technical/Vocational	N/A	N/A	12 (5.0)
High school graduate/general education diploma	N/A	N/A	19 (8.0)
Less than high school	N/A	N/A	1 (0.4)
Gender identity (N=238)			
Man	N/A	N/A	231 (97.1)
Transgender, gender queer, nonbinary	N/A	N/A	7 (3.0)
Sexual orientation (N=237)			
Gay or homosexual	N/A	N/A	204 (86.1)
Bisexual	N/A	N/A	28 (11.8)
Straight or heterosexual	N/A	N/A	2 (0.8)
Other	N/A	N/A	3 (1.3)
Pre-exposure prophylaxis (N=174)			
Ever used	N/A	N/A	101 (58.0)
Currently using	N/A	N/A	73 (42.0)
HIV risk behaviors in past year (N=126)			
Condomless sex with HIV-positive or unknown status partner	N/A	N/A	104 (82.5)
Traded sex for money or other goods or services	N/A	N/A	16 (12.7)
Injected drugs	N/A	N/A	6 (4.8)

^aValid percent is the percent when missing data are excluded from the calculation.

^bN/A: not applicable.

Table 3 shows the participants' preferences related to specific PrEP implant characteristics. Of these characteristics, not having to take a daily pill increased the likelihood of PrEP implant use (mean 4.13). Requiring more than 1 device to achieve 1 year of protection (mean participant rating range:1.79-2.94) mildly

discouraged implant use. Participants did not mind the following: moderate bruising, a small scar, tenderness, or bleeding after insertion or removal, or having an implant slightly longer or fatter than a matchstick.

Table 3. Participants' likelihood of using pre-exposure prophylaxis implants based on their specific potential attributes (stage 4; N=304).

Implant characteristic	Likelihood of use ^a
Duration of protection, mean (SD)	
Protection lasts up to 12 months	3.6 (1.5)
Protection lasts up to 6-8 months	3.3 (1.5)
Protection lasts up to 2-3 months	2.7 (1.6)
Number of implants needed, mean (SD)	
2 implants needed	2.9 (1.6)
3 implants needed	2.2 (1.4)
4 implants needed	1.8 (1.3)
Potential application site related-side effects, mean (SD)	
Moderate bruising	3.7 (1.4)
Small scar	3.5 (1.5)
Implant can be felt	3.5 (1.5)
Some pain	3.6 (1.4)
Bleeding	3.6 (1.4)
Tenderness	3.5 (1.4)
Other PrEP^b implant device-related characteristics, mean (SD)	
No daily oral PrEP	4.1 (1.3)
Trocar is used to insert implant	3.7 (1.4)
Must go to the doctor's office for removal	3.9 (1.4)
Implant longer than a matchstick	3.5 (1.4)
Implant fatter than a matchstick	3.2 (1.4)

^aValues presented are descriptive statistics only; value of 3 on the Likert scale indicates a neutral rating.

^bPrEP: pre-exposure prophylaxis.

Discussion

The scientific literature review conducted in stage 1 did not yield data on specific implant *device-related* barriers or facilitators. However, the existing literature did show that many of the problems associated with *general* contraceptive implant use are similar to those observed in relation to oral PrEP use. For example, several studies identified patient or provider misconceptions or lack of information about implants as a barrier to their uptake. Specifically, patients who have providers who harbor misconceptions about PrEP (eg, PrEP is only moderately effective) are less likely to obtain a prescription for this medication from their provider [34]. Additionally, concerns about contraceptive implants' side effect profiles and potential high cost deterred use; these same barriers also affected oral PrEP use [35]. Finally, access to contraceptive implants or oral PrEP was a challenge to use for each of these products [36]. All these concerns are likely to translate to PrEP implants. Suggestions from the contraceptive and oral PrEP studies on how to overcome these issues may be helpful. For instance, concerted efforts (eg, trainings) to ensure that providers have accurate information about PrEP [37,38] implants (including information on insertion and removal techniques) and effective tools to identify PrEP implant candidates could be helpful.

Same-day access to PrEP implant insertion could also boost uptake [39]; offering PrEP implants in emergency department settings could also boost implant uptake.

Potential device side effects were a concern, as expressed by participants in stages 2, 3, and 4. Specifically, in stage 2, YouTube videos identified a number of potential side effects related to contraceptive implant use that could potentially be concerns for PrEP implant users, including pain, stinging, burning, soreness or tenderness, contusion, scarring, and bleeding. Participants in stage 3 also reported these effects after contraceptive implants were inserted or removed, although this was typically mild. Results from stage 4 showed that the possibility of experiencing these effects (eg, moderate bruising, small scar, some pain, bleeding, and tenderness) did not impact GBM participants' likelihood of using PrEP implants. Although these outcomes may not present a barrier to use for these men, this is not the case for all potential users. For example, other studies have shown that some transgender women were concerned that mild scarring and other skin-related reactions related to potential future PrEP implants could become serious [40,41]. Thus, it may be necessary to engage novel strategies to communicate actual risk [41], as some populations may overestimate this. Icon arrays, which communicate risk using graphical representations of icons symbolizing people affected

by a given outcome (eg, circles), may be one such strategy [42]. Icon arrays are shown to be better at communicating risk for low-risk procedures and may be especially effective for populations that have variability in numeracy skills [43].

Stage 2 YouTube videos reported menstrual complaints related to contraceptive implants. Stage 3 interviews also revealed that contraceptive implants had a negative effect on menstruation for some users. Specifically, over half of the participants endorsed this idea, complaining of prolonged or unpredictable cycles. It is highly unlikely that the menstrual or hormonal issues identified in stages 2 and 3 would be problematic for PrEP implant users, as these effects are associated with the use of hormonal medications, not antiretrovirals. However, given that this is such a pervasive issue among contraceptive implant users, it is paramount to ensure that potential PrEP implant users do not attribute these effects to implants in general. Rather, we must clarify that implants are a method to distribute a variety of medications. They are not a medication themselves. Potential PrEP implant users must be made aware that hormonal medications used in contraceptive implants, and antiretroviral medications used in PrEP implants will have completely different effects from one another. Communicating this will be particularly important for cisgender and transgender women users, as they may have greater familiarity with contraceptive implants and may be more concerned about how PrEP implants would interact with female hormones. Stage 4 participants were not asked about this theme because (1) this concern would not apply to male users and (2) medications contained in PrEP implants are not anticipated to interfere with male hormones.

Although negative side effects can deter implant use, other side effects may be seen as positive. Nearly half of the participants in stage 3 revealed that they chose the contraceptive implant because they believed that it had a more favorable side effect profile than other available options. Although specific side effects of the antiretroviral drug that would be delivered via implant are still under study (eg, these side effects may be different, and data show that these drugs are well tolerated [44,45]), it is critical to consider their side effects parallel to the HIV prevention effects of these medications. Users' experiences with oral PrEP show that this is the case; fear or experience with unfavorable short- (eg, gastrointestinal effects) or long-term side effects (eg, renal toxicity) are factors for drug discontinuation in 9.2%-33.0% of GBM who stop taking PrEP [46-48]. Implants that distribute PrEP medications that have side effect profiles perceived as too intolerable may have limited uptake and continued use.

Conversely, if they seem to have fewer or beneficial side effects due to the delivery method, this could be viewed as positive. For instance, some stage 3 participants reported using contraceptive implants because they have the potential to have the beneficial side effect of lessened menstruation. Although it is highly unlikely that PrEP implants would have a similar effect, it is important to note the appeal of beneficial side effects. This is particularly important for those beneficial side effects that produce a notable enhancement in the life or appearance of the user, since these enhancements could potentially facilitate improved uptake or sustained use. Beneficial side effects have been noted in other medications, including finasteride (hair

regrowth in men experiencing male pattern baldness [49] and initially used to treat benign prostatic hyperplasia [50]) or oral contraceptives (facial acne reduction and initially used to prevent pregnancy [51]). If and when beneficial side effects are identified in drugs contained in PrEP implants, this could play a role in future messaging and uptake campaigns.

The effectiveness and duration of products as well as the amount of maintenance they would require were important to participants in stages 2-4. Specifically, participants in stage 3 liked that the contraceptive implant was effective at preventing pregnancy and lasted for a prolonged period, during which little maintenance was required on their behalf (eg, they did not have to perform a routine activity, such as taking a daily pill). Participants in stage 4 shared this sentiment, and not having to take a daily pill increased the likelihood of using the PrEP implant. Additionally, in stage 4, protection against HIV lasting 6 months or more modestly increased potential users' likelihood of implant use; protection lasting 2-3 months modestly decreased the likelihood of use. Given this, it is critical in development phases to prioritize the amount of time that the implant will last and the amount of maintenance it requires.

The size and number of devices were also important. For example, in stage 3, participants found the small size and unintrusiveness (eg, most participants could not feel the implant during daily activities) of the contraceptive implant to be positive attributes. In stage 4, participants found the potential implant size (slightly longer and fatter than a matchstick) neither motivated nor dissuaded the likelihood of use. This may mean that the current size is acceptable. However, reducing the size of the implant could have a positive impact on potential users' perceptions of it. Related to this, stage 4 participants also reported that as the number of implants necessary to provide protection against HIV increases, the likelihood of use of this prevention strategy decreases. Taken together, this means that implant size and the number of implants necessary to achieve HIV protection are also critical factors for potential user uptake. The trajectory of contraceptive implant development shows that although it may not be possible to devise a small, 1-device implant in the first product iteration, it is possible to reduce implant size and number over time [11,52]. Thus, developers of PrEP implants should aim to reduce the size and number of devices, even if this is not immediately possible.

Participants in stage 3 (all cisgender women) reported that the insertion and removal procedures for contraceptive implants were quick and straightforward, with minimal pain. There was no mention of discomfort related to having this procedure done in a health care provider's office. However, a minority of participants reported feeling intimidated by the size of the trocar used to insert the contraceptive implant. This was not the case in stage 4. Stage 4 participants (all GBM) did not find the potential trocar planned for use in clinical research to implant the PrEP implant to be a barrier to uptake. It is important to note that no participants in stage 4 had ever undergone this procedure, although stage 3 participants had. This could have contributed to differences in participants' level of comfort with trocar insertion.

Furthermore, having the implant removed by a health care provider appeared to mildly improve the likelihood of use among stage 4 participants. Thus, it appears that users of contraceptive implants and potential users of PrEP implants are mostly comfortable with the proposed model for device application and removal. However, although we can only speculate, it may be that this level of comfort is based on the proposed length of time that the implant could be used. That is, potential users may be less likely to undergo these insertion and removal processes if the implant does not last for very long. This again highlights the importance of the device duration.

Limitations

In stage 2, we may have missed some references to specific participant experiences if participants used descriptive words not contained in SNOMED's database. The interviews we conducted as part of stage 3 were partially meant to address this potential gap by more fully fleshing out users' experiences with contraceptive implants. As is the case with all research on acceptability and feasibility of hypothetical clinical products, it is difficult to estimate the gap between participants' perceived likelihood of use and actual use of implants for PrEP. However, data from past and current users of similar implants for contraception in stages 2 and 3 help to mediate this issue.

Additionally, because we were concerned with ensuring that users' experiences with existing implants were as similar as possible to potential future PrEP implants, we sampled only women in stage 3. In stage 4, we targeted only GBM (as they have a higher risk for HIV exposure compared with heterosexual cisgender women) with web-based surveys on their preferences

for PrEP implants. Given the lack of formative work specific to GBM, there may be a gap in the preferences and perceptions of this implant product between these 2 groups. Future studies should conduct qualitative interviews with GBM on their preferences around PrEP implant products to limit this shortcoming. Despite these limitations, given the dearth of research on this topic, this work makes an important and unique contribution to the literature on implants for PrEP.

Conclusions

In all stages of research, participants reported experiencing (stages 2 and 3) or anticipating (stage 4) implant-related side effects. These effects were related to the device itself (bleeding, bruising, and pain after insertion) or, among contraceptive implant users, medication-related side effects (menstrual changes, weight gain, and acne). Although it is highly unlikely that PrEP implant users will experience similar hormonal side effects to contraceptive implant users, it is critical to point out the difference between these 2 products to potential PrEP users. Icon arrays could be a useful way to communicate serious risks related to implant devices. Future studies should monitor for the presence of beneficial side effects related to implant medication, as this has been evidenced with other medications and may improve uptake and sustained use. Furthermore, small implants need only 1 device, last for at least six months, are unintrusive, and require little to no user effort to optimize uptake. Current and potential future users appear comfortable with the currently used procedures for implant insertion and removal. Finally, future work should include more formative work specific to GBM, as this will allow researchers to address their concerns with greater precision.

Conflicts of Interest

None declared.

Multimedia Appendix 1

Web-based survey.

Abstract

Background: Patients with multiple sclerosis (MS) face several challenges in accessing clinical tools to help them monitor, understand, and make meaningful decisions about their disease course. The University of California San Francisco MS BioScreen is a web-based precision medicine tool initially designed to be clinician facing. We aimed to design a second, openly available tool, Open MS BioScreen, that would be accessible, understandable, and actionable by people with MS.

Objective: This study aimed to describe the human-centered design and development approach (inspiration, ideation, and implementation) for creating the Open MS BioScreen platform.

Methods: We planned an iterative and cyclical development process that included stakeholder engagement and iterative feedback from users. Stakeholders included patients with MS along with their caregivers and family members, MS experts, generalist clinicians, industry representatives, and advocacy experts. Users consisted of anyone who wants to track MS measurements over time and access openly available tools for people with MS. Phase I (inspiration) consisted of empathizing with users and defining the problem. We sought to understand the main challenges faced by patients and clinicians and what they would want to see in a web-based app. In phase II (ideation), our multidisciplinary team discussed approaches to capture, display, and make sense of user data. Then, we prototyped a series of mock-ups to solicit feedback from clinicians and people with MS. In phase III (implementation), we incorporated all concepts to test and iterate a minimally viable product. We then gathered feedback through an agile development process. The design and development were cyclical—many times throughout the process, we went back to the drawing board.

Results: This human-centered approach generated an openly available, web-based app through which patients with MS, their clinicians, and their caregivers can access the site and create an account. Users can enter information about their MS (basic level as well as more advanced concepts), visualize their data longitudinally, access a series of algorithms designed to empower them to make decisions about their treatments, and enter data from wearable devices to encourage realistic goal setting about their ambulatory activity. Agile development will allow us to continue to incorporate precision medicine tools, as these are validated in the clinical research arena.

Conclusions: After engaging intended users into the iterative human-centered design of the Open MS BioScreen, we will now monitor the adaptation and dissemination of the tool as we expand its functionality and reach. The insights generated from this

approach can be applied to the development of a number of self-tracking, self-management, and user engagement tools for patients with chronic conditions.

Introduction

Background

Delivering actionable clinical tools into the hands of patients and clinicians represents a major unmet need for the delivery of precision medicine for complex diseases such as multiple sclerosis (MS). MS is a chronic, inflammatory, and neurodegenerative disease characterized by onset typically during young adulthood, a protracted and heterogeneous course, variable impairments across multiple functional domains, and variable response to medications [1]. Digital tools help to track this heterogeneity and inform decision making [2]. These include digital tools that create research cohorts and registries (eg, iConquerMS [3] and The North American Research Committee on Multiple Sclerosis [4]) and help patients connect with one another and collect and share information (eg, PatientsLikeMe [5], SmartPatients [6], and Facebook groups [7]). In health care settings without a single-payer system or a national electronic health record (EHR), there is a further need for a data collection system to allow patients to collect essential information about their MS course as they navigate multiple providers and EHRs over time. Within this landscape, we aimed to create a freely available platform through which patients can enter basic MS measurements, visualize their course, and access actionable research tools curated by clinicians to inform their decision making.

Open MS BioScreen

In 2013, the University of California, San Francisco (UCSF) Multiple Sclerosis Group announced the *UCSF Multiple Sclerosis BioScreen* [8]. The MS BioScreen is a *data infrastructure platform* that gathers all relevant MS data from different sources, including clinical, imaging, and biomarker information; visually represents the disease course of an individual with MS from a front-end interface; and frames this course within the context of a large cohort of patients treated according to contemporary standards. The goal is to inform more precise clinical decisions and by providing clear information and decision aids, to empower patients to participate more actively in their clinical care. This work received key support from the Patient-Centered Outcomes Research Institute and the Conrad N. Hilton Foundation. However, this first prototype was developed as a clinician-facing, tablet-based tool and hence was not accessible beyond the limited group of patients followed at UCSF. Due to the limitations of tablet storage and connectivity, the MS BioScreen was not used after the pilot phase.

To expand the reach of our precision medicine solution, we aimed to develop the Open MS BioScreen [9]: a publicly available web-based app, free of commercial interest, that allows users within or beyond highly specialized academic care settings the opportunity to enter data on their condition; obtain a richly contextualized, digestible, and actionable predictive output; and participate in a shared decision-making process. We included *open* in the title as a key concept because the platform is freely available for anyone in any location to create a profile and enter their MS measurements, without requiring a fee or any user validation process.

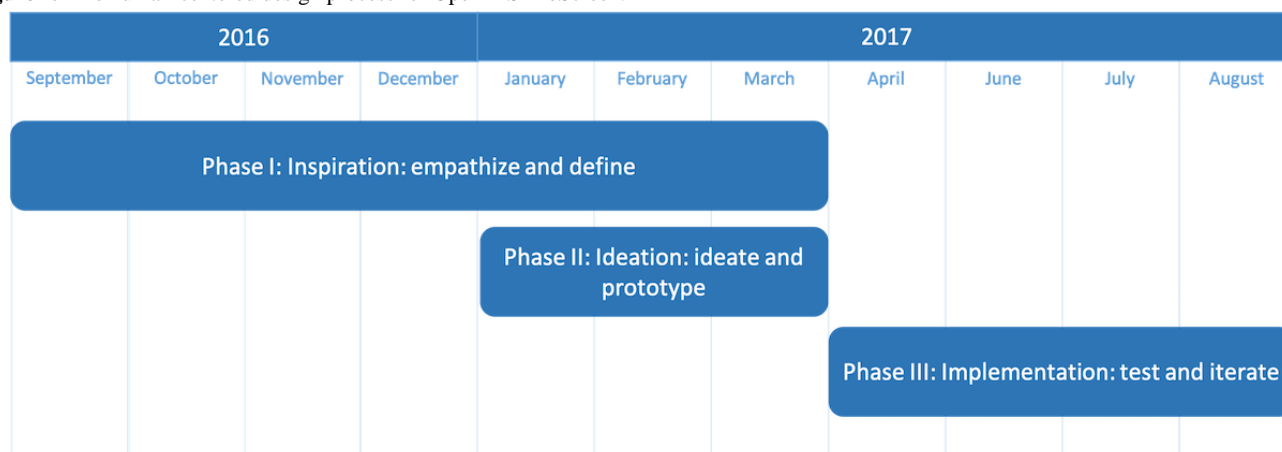

Here, we describe the human-centered design approach that we applied throughout the development process, an approach that focuses on the usability and needs of those the tool is meant to serve in addition to the specific theoretical framework that was applied as an underpinning to the platform content.

Methods

Human-Centered Design Approach

App development of the Open MS BioScreen began in March 2017 and is ongoing. We applied the concept of human-centered design [10,11], an approach that focuses on the usability and needs of those the tool is meant to serve. We included a variety of key stakeholders: individual patients, patient support groups, clinicians, technology consultants, and institutional groups, and we integrated their feedback continuously throughout the development of the app. In the context of chronic disease, the application of human-centered design represents an opportunity to address key underlying provider and patient gaps that obstruct improved health outcomes. As previously described [11], to bridge the knowing and doing gap between evidence-based provider recommendations and patient implementation, solutions must wield individualized and actionable goals that can be addressed within real-world limitations. Without involving key stakeholders in the development, promising technology-leveraged management platforms have difficulty achieving clinical improvement (eg, type 2 diabetes [12] and cardiac rehabilitation [13]). In contrast, tools incorporating human-centered design demonstrate positive effects for specified outcomes across diverse populations [14], including caregivers of patients with Alzheimer disease [15], patients managing chronic obstructive pulmonary disease [16], and in pain management [17].

As outlined in [Figure 1](#), we applied the three phases of human-centered design [11]: (1) inspiration (empathize and define), (2) ideation (ideate and prototype), and (3) implementation (test and iterate).

Figure 1. The human-centered design process for Open MS BioScreen.

Team and Stakeholders

The *Open MS Bioscreen* team at UCSF includes a clinical lead (RB), developer (ES), back-end data consultants (AS and AR), technical consultant (AL), radiology consultant (RH), compliance and logistical assistant (WR), designer (AB), students, and research assistants. This group leveraged the expertise of the broader group of UCSF-based MS researchers (the UCSF Expression, Proteomics, Imaging, Clinical [EPIC] longitudinal study [18,19]) as well as team experience with other tools developed through the UCSF MS BioScreen project, namely, Sutter Health MS Share [8] and UCSF BRIDGE [20].

Health Literacy Expert

A health literacy consultant with expertise in chronic conditions, including MS, was engaged to provide individual feedback on solution design and patient interview protocols as well as guide content creation using input gleaned from patient focus groups.

Key Stakeholders

Patients With Multiple Sclerosis

Through convenience sampling, we identified 50 adults with MS who participated either in individual interviews with patients identified by participating clinicians or approached by the study team in the clinic waiting room and at an MS fundraising walk ($n=15$, often accompanied with a partner, friend, or caregiver) and focus groups (3 groups comprising 6, 8, and 21 people; 2 community-based [National Multiple Sclerosis Society, NMSS, support groups] and 1 UCSF-based). An additional 24 participated in the validation of patient-reported MS duration and treatment and provided individual feedback.

Clinicians

Through convenience sampling, we identified 6 UCSF-based MS consultants, as well as 2 external neurologists (1 MS and 1 general), who were included through phases I and II.

Advocacy Group

Representatives from the NMSS, a primary organization for MS advocacy and research in the United States, were consulted in phase 1 ($N=1$) and phase 3 ($N=3$) to advise on the overall goals of the Open MS BioScreen, clarity and relevance of the content to MS patients, and any ethical or other considerations anticipated.

Industry Representatives

This convenience sample of representatives who had approached the MS BioScreen team during the development phases included representatives from 2 biotech companies seeking to develop patient-facing technical solutions for the delivery of MS precision medicine (1 pharmaceutical and 1 biotechnological) as well as 3 experts in the delivery of advanced magnetic resonance imaging (MRI) solutions to patients. The role of input from these representatives was to better delineate the value proposition of an openly accessible, freely available platform within the context of current digital health efforts; however, the platform was not designed to collect data of commercial relevance.

Theoretical Underpinning

Although the design process was iterative and human-centered, we identified a priori several key underpinnings of the platform, namely, Open MS BioScreen should comprise 5 features: (I) profile, (II) measures, (III) patient-reported expanded disability status scale (prEDSS), (IV) course, and (V) decision aids, as outlined in Figure 2. Finally, the user can represent a patient, a patient's proxy (friend, spouse, partner, child, and caregiver), or a clinician [21].

Feature I allows a user to create a profile about themselves. The profile contains required information: month and year of birth and age of onset of MS. In addition, users can add optional information: gender, MS type, city, country, education, employment, race, smoking history, and spinal tap results.

Feature II is used for patient-reported basic MS measures. Users can enter in their standard disability scores (expanded disability status scale, EDSS) [22] results and date of results. Relapse dates can be reported and stored. Additionally, users can enter their MS medication types and dates.

Feature III focuses on 1 specific measure, the prEDSS questionnaire. The prEDSS feature allows a user to answer a series of questions to generate a prEDSS score and visualization and can be used when patients do not have access to a clinician's objective EDSS score.

Feature IV is a data visualization component that brings in data from features I-III. The patient course is plotted in a single interactive view, allowing the user to see all their MS

measurements plotted along with their prEDSS scores. Users can optionally display their course in context with our contextualization cohort to see how their MS course compares.

Feature V is a set of many evolving features. Here, we take relevant and new MS research findings and translate them into

interactive and actionable features that serve as decision aids regarding if and when to start MS therapies and how to balance the risks and benefits of treatment approaches. We also link it to other tools that could be useful.

Figure 2. Open MS BioScreen features. EDSS: expanded disability status scale; prEDSS: patient-reported expanded disability status scale.

Phase I—Inspiration: Empathize and Define

The goal of this phase was to define the problem we were trying to solve. To accomplish this, between September 2016 and March 2017, one-on-one in-depth in-person interviews were conducted with clinicians, MS patients (and their friends, families, and caregivers), and industry and advocacy experts. Interview transcripts and questionnaire responses were then reviewed and parsed into key *insights* (Tables 1 and 2).

We gathered information from clinicians, patients, partners and through market research.

1. Clinician interviews: We interviewed 1 MS expert (2 hours) and shadowed 5 others in the clinic (one 4-5 hour session each) to observe the interaction and document the information provided. As part of the observation, we talked with the patients to develop an understanding of them, their MS, and how they stay informed. Following the clinical observations, all interviews focused on the tools available to clinicians to monitor their patients (eg, what types of patient-centered data were missing from the clinical EHR?), decision support tools available to them in routine clinical encounters (eg, contextualization or predictive algorithms readily available and would they be useful), and unmet needs (eg, what types of visualizations would help them communicate risk with patients?).
2. Patient interviews: In total, 12 individual patients were interviewed using semistructured questionnaires, developed with input from the health literacy expert. Interviews lasted 30-60 min and asked patients general questions about their MS and their use of tools to understand and track their condition outside of clinical encounters ([Multimedia Appendices 1 and 2](#)).
3. Interviews with technology and advocacy partners: These general interviews lasted 30-120 min and were related to the availability of other tools on the market, relative strengths, and unmet needs.
4. Comparative analysis of existing technological solutions: Here, our team researched other technical solutions available to patients with MS and their clinicians to track their own course and access relevant algorithms and visualizations that empowered them to participate in their own care. To accomplish this, we used the Google search engine, the iOS App Store, and the Google Play Store and used the search terms “multiple sclerosis” or “MS” and the terms “symptom tracker,” “monitor,” “tracker,” and “algorithm.” From these results, rather than reporting an exhaustive list, we selected tools intended to highlight desired features, possible redundancies/overlap, as well as technological or other pitfalls of existing tools.

Table 1. Patient interview insights.

Insight	Patient input
Clarity	<ul style="list-style-type: none"> • Does not want to be inundated with information • Wants to reclaim control of their disease—too little clarity, not enough power in their hands • Currently feels like there are no clear answers given, feels alone in trying to understand • Wants information that is easy to understand and translate between centers • Can be medically illiterate at times—feels they have a lot of misconceptions
Data collection and visualization	<ul style="list-style-type: none"> • Tracks in everything in a notebook—filled with other information • Wants to see scores
Personalized	<ul style="list-style-type: none"> • Tracking their own progress and treatment efficacy, balanced with their own preferences and needs
Trajectory	<ul style="list-style-type: none"> • Wants to know if they are getting better or worse • Wants to know 5-year outlook • Constantly playing mind games to stay positive
Comparison	<ul style="list-style-type: none"> • Would like to see other patient data without communicating with them • Wants to meet other people with the same progression • Wants to gain more perspective about other people with MS^a
Treatment	<ul style="list-style-type: none"> • Wants to know that the treatments they are getting are useful or the best for their disease
Resources	<ul style="list-style-type: none"> • Wants more information about specific areas of interest—genetics, therapies, and education about MS • Wants lots of educated opinions
Time with specialist	<ul style="list-style-type: none"> • Prefers time spent with doctor to time spent researching on their own • Does not know what to contact their neurologist about • Will not go to the doctor until it is unbearable • Wants a printout from every visit

^aMS: multiple sclerosis.

Phase II—Ideation: Ideate and Prototype

At the completion of phase I, in January 2017, and as detailed below in the *Results* section, we defined the problem that we wanted to solve as: “People with MS are faced with a lot of variables, numbers, and changes, and it is hard to keep track of everything.” In phase II, our goal was to develop mock-ups. Therefore, we began to come up with solutions to this problem: how best to allow users to enter and visualize all their data and incorporate research findings and additional resources together in a cohesive and actionable way, using tools that are sustainable, low cost, and would not require payment on the part of patients. We met weekly to discuss how best to collect and visualize patient data. Phase II meetings lasted for an hour and focused on determining the user interface for data collection and visualization. Methods for idea generation included brainstorming options, whiteboarding, and searching for ways other people visualized similar problems. Phase II meetings started in January 2017 and lasted until March 2017.

The most promising ideas were moved to the prototype, using tools including Balsamiq [23] for creating wireframes and

Invision [24] for creating click-through mock-ups. These wireframes and mock-ups were then shown, in a second round of interviews, to clinicians and patients with MS for further feedback. At this stage, the health literacy expert was re-engaged to specifically explore the pros and cons of various components of the prototype (eg, color range, explanation of disability, and degree of precision regarding predictive models).

These were shown both to individual patients after their clinical appointment (n=4) as well as to an MS support group (n=11) and patients participating in an MS fundraising walk (n=6). Demographic information was not always collected, but the cohort included both ambulatory and nonambulatory patients, patients seen both within our academic institution and from the broader Northern California community of people living with MS, and also explicitly included patients who self-identified as racial and ethnic minorities. We used the same initial questions as in [Textboxes 1](#) and [2](#) as well as additional questions from [Table 1](#). After each set of interviews, we incorporated patient feedback into the mock-ups.

Textbox 1. Clinician interview insights to include in the app.

Include in the app

- How patients compare with those of similar demographics
- Potential treatments
- Data as a function of time
- Better metrics of progression
- Simple visualizations
- Tool to promote communication
- Clarity about the design process

Textbox 2. Clinician interview insights to exclude from the app.

Exclude from the app

- Information above a high-school level
- Too many numbers or laboratory test data
- Physician feelings and analyses
- Default contextualization (patients should have an option to view how they are doing compared with others)
- Unfiltered scores that patients can misunderstand
- Overly specific information, such as specific risk scores, given the imprecision in data used to generate algorithms

Phase III—Implementation: Test and Iterate

Our goal in phase III was to develop a minimally viable product (MVP). Therefore, once our phase II mock-ups were refined based on user input; we went through an agile development process to build Open MS BioScreen. We met weekly to review progress of the app and determine how to keep in line with feedback from patients and providers. Phase III meetings were conducted from March 2017 to July 2017. Meetings lasted for 1 hour and focused on app demos and feedback. Open MS BioScreen was built in Ruby [25], a programming language, using a Ruby on Rails development framework, jQuery, and d3.js for the front end. In this phase, the tool itself was submitted for approval by the UCSF institutional review board (IRB), an Information Technology security risk assessment, and privacy legal and risk review. Once we had a final product, we again brought the app to an MS support group, to 15 individual patients, and to advocacy group consultants, to gather and incorporate feedback into the app.

To evaluate the accuracy of basic data entered by participants, in pilot testing, we asked 24 patients who were long-time participants in the UCSF EPIC study [18,19] to enroll in Open MS BioScreen and create a basic profile. After signing a written informed consent for an IRB-approved research protocol, participants enrolled and entered their MS duration, data, and treatments. We then compared these entries to study clinician-entered data available in the EPIC study.

Ethics Approvals

Funding for this project was provided by the Conrad N. Hilton Foundation. All procedures performed in studies involving human participants were in accordance with the ethical standards of the UCSF IRB and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. Electronic, implied informed consent was obtained from all individual participants included in the study under UCSF IRB no. 17-22732.

Results

Phase I—Inspiration: Empathize and Define

Clinician Interviews

Clinicians provided a range of responses regarding key features that would be provided in a tool that engaged patients with MS, allowed them to track their condition in a manner useful to them, share what they track with clinicians, and use visualizations to become more informed participants in their care process (Textboxes 1 and 2). To summarize clinicians' insights, patient data had to be presented in an understandable format, without excessive details or over-reliance on specific risk ratios or numbers, given the limitations in the data used to generate risk, and the need for visualizations to be inherently meaningful to patients *without* clinician interpretation or input.

Patient Interviews

During this phase, 12 patients were interviewed. To summarize their responses, they articulated a need for clarity, simple

tracking and display of key MS data, ability to personalize how they viewed their MS course and what factors went into the contextualization algorithm, and positive emphasis on their trajectory and algorithms. For example, if the contextualization algorithm showed that their MS was worsening at a faster rate than others, then a pop-up might encourage them to return to their physical therapist or discuss their optimal MS management with their clinician. These are detailed in Table 1.

Comparative Analysis of Existing Patient-Facing Tools

The comparative analysis approach allowed us to identify a number of tools with rich information (illustrative examples given in Table 2) and to use their relative strengths and limitations to inform our own subsequent ideation process. Some of these tools evolved since our original phase I in 2016 and have since been summarized elsewhere [2,26].

On the basis of this analysis, we were able to define several key features for our own ideal platform, namely: (1) web-based and platform-agnostic, that is, not dependent on the life cycle of any other individual technology piece; (2) limited imprint from the pharmaceutical industry; (3) reliable over time without requiring daily input; and (4) clinician-derived informational modules.

Phase II—Ideation: Ideate and Prototype

Mock-Ups

The priorities identified in the empathize and define phase were used to develop an initial series of mock-ups and click-through presentations of the app (Figure 3). The longitudinal view of the patient course (middle panel, left image) was designed based on the longitudinal view of the original tablet-based MS BioScreen, whereas other features were new. This prototype was then presented to users for feedback on the design and usability of the Open MS BioScreen.

The upper panel demonstrates various iterations of the landing page, which were designed to allow the user to navigate the site with clarity. The middle panel demonstrates a series of iterations of the longitudinal disease contextualization, which was designed to allow the patient to visualize and interpret their clinical course while minimizing the potential for distress. The bottom panel demonstrates iterations of the patient's global neurological functioning, which was designed to allow patients to enter information about the various functional domains affected by MS (eg, vision, cognition, and walking) and their severity (mild, moderate, or severe), and to visualize these globally. We initially anticipated that patients would want to see their functional domains represented as a sort of avatar, but patients reported that they preferred to have their functional representation alongside, rather than showing their symptoms on a figure. The questions comprising the tool were derived from the prEDSS initially developed by Goodin et al [33], expanded to enable greater sensitivity to changes in cognition and upper limb function over time, and iteratively tested and refined through a series of validation studies (reported separately, manuscript under review). Here, as part of our design work, we specifically iterated visualization of the final prEDSS score but not the questions or scoring.

Figure 3. Phase II: Ideation. Evolution of Open MS BioScreen mock-ups. Top panel: landing page. Middle panel: longitudinal disease course visualization and contextualization tool. Bottom panel: assessment and representation of global neurological function.

Patient Interviews

With the prototypes, we interviewed another 21 patients. Targeted interviews lasted approximately 15 min each and asked patients to reflect on the clarity of the information, impact (educational or emotional) of the information and visualizations provided, ease of navigation and of data entry when appropriate, and missing aspects of the tool. We recorded all feedback, and then, we developed codes for the responses using a grounded theory approach [34]. The authors (RB and JP) read through all transcripts and identified open codes based on line-by-line analysis of emerging themes. The authors then discussed relationships among open codes and created selective codes, or themes, of larger concepts.

Patient insights were primarily clustered around 6 themes:

1. Information: not knowing which information is important
2. Education: feeling like their doctors are not telling them the whole story

3. Data: wanting more tracking options and the ability to see their own data
4. Emotion: expressions of fear and discretion
5. Clarity: wanting clearer labels and explanations of the tool
6. Perception: wanting the tool to present an action-oriented rather than a pessimistic view of MS progression

Phase III—Implementation: Test and Iterate

Once phase II was complete, app development of the MVP occurred between March 2017 and September 2017, incorporating insights from phases I and II (Table 3) and turning these into a web-based prototype (Figure 4). We then conducted an additional round of interviews with our 4 stakeholder groups: patients, clinicians, advocacy, and industry representatives. We compiled all the interviews into actionable insights that we incorporated into the MVP (Table 4). This MVP was launched in February 2018 [9].

Table 3. Insights derived from 21 patients who viewed mock-ups.

Insight	Examples	Quotes
Information: Patients do not know which information is important (18/21, 86%)	<ul style="list-style-type: none"> Sharing information across specialties Understanding their course 	<ul style="list-style-type: none"> "If I talk to any other doctor, they don't know about my specific clinical trial." "We don't know which level we're at—so it's important that now that we know how to treat it, now that we have the chance to take better drugs, it's very lucky."
Education: Patients feel like their doctors are not telling them the whole story (12/21, 57%)	<ul style="list-style-type: none"> Knowing when their diagnosis changed Understanding the landscape 	<ul style="list-style-type: none"> "I didn't know I was secondary progressive until I decided to read all of the informational packets they give you at the appointment. I said 'Wait, when did that happen? Nobody told me!'" "The judgements about who is getting better and who is getting worse, and which drugs are working—because there's no way to truly compare."
Data: Patients want more tracking options and ability to see their own data (19/21, 91%)	<ul style="list-style-type: none"> Tracking things that are relevant Comparing their data with other relevant data 	<ul style="list-style-type: none"> "I want a tool that will benefit real people" "There's so many aspects—travel, activity, medicines. I want to see that." "I'm not curious about other people—usually the information is not relevant because it's so so different for everyone. But this [support group] is a great group, I just wish we were larger."
Emotion: Patients express fear and discretion (9/21, 43%)	<ul style="list-style-type: none"> Wanting to not progress or hear about progression 	<ul style="list-style-type: none"> "I don't want to know if it's getting worse." "Sometimes I don't want to know—because I grew up with my father, watching his stages." "Loved to read, prayed that her vision wouldn't go even if she would be in a wheelchair" and the lord granted my wish, I'm in a wheelchair, I can read, but I don't read, really anymore. I lost the concentration of what I was reading—I can't remember it."
Clarity: Patients want clearer labels and explanations of the tool (6/21, 29%)	<ul style="list-style-type: none"> Understanding the parts of the graph Clarifying the content and labels of the graph 	<ul style="list-style-type: none"> "How is this graph made?" "What is this plotting?" "What do these terms mean?" "It's unclear because there's a chance I'm in one part of the graph, and a chance I'm in another." "Lack of experience, makes it hard to know where to go."
Perception: Patients want the tool to present a positive view of multiple sclerosis progression (13/21, 62%)	<ul style="list-style-type: none"> Tracking full course Understanding treatments and options 	<ul style="list-style-type: none"> "I am living with it, I am not suffering." "Then they say 'so and so died from MS,' and it's like 'Yeah, it's not the MS that kills us, it's the different things that the MS is affecting, but that's only if we sit on our butt and don't do anything.'" "'You'll never be normal' But I persevered, and it was important to be able to track all my shots, my own things to look out for—I'll know what the things are that I need to do, so I don't fall off the wagon." "We don't know which level we're at—so it's important that now that we know how to treat it, now that we have the chance to take better drugs, it's very lucky." "I haven't been seeing anything progressing—but getting better."

Figure 4. Phase III: Implementation screenshots of Open MS BioScreen's initial minimally viable product. Top panel: landing page and initial data entry tools. Middle panel: the longitudinal multiple sclerosis course visualization tool, without a contextualization tool. Bottom panel: the patient-reported expanded disability status scale tool, whose development occurred as part of Open MS BioScreen and whose formal clinical validation is reported separately (manuscript under review).

Table 4. Examples of actions taken during phase III (implementation) based on patient insights generated in phase 2.

Comparison of Basic Clinical Data Collected Through Open MS BioScreen Against Study Clinician-Entered Data

In our pilot testing of 24 patients who were EPIC study participants (median EDSS 2, IQR1-4), we compared patient- and study clinician-entered responses for 3 basic clinical data: MS duration, MS type, and MS disease-modifying therapy (DMT). We found that the mean difference between the patient-reported and study-recorded year of MS onset was -0.29 years (SD 3.16). The MS type included 16 relapsing-remitting (RR), 4 secondary progressive (SP), 2 primary progressive, 2 clinically isolated syndrome (CIS); 83% (20/24) agreed on MS type, with EPIC patient-reported mismatches as follows: SP-RR, SP-RR, RR-SP, and CIS-RR. There was also 83% (20/24) concordance on the most recent DMT; in all residual cases, the patient indicated a newer approved DMT relative to the self-injectable recorded in the database.

Focus on Accessibility

We prioritized accessibility in a number of ways. We included *open* in the title as a key concept because the platform is freely available for anyone in any location to create a profile and enter their MS measurements, without requiring a fee or any user validation process. Throughout the design process, we worked with end users to make Open MS BioScreen easy to use for different technical skill levels. Open MS BioScreen is currently an English language app, but users could use a web-based translation to view the site in another language, and patients with cognitive or physical limitations can request assistance from a proxy user.

Added Functionalities

In addition to incorporating user feedback into the MVP, we also built Open MS BioScreen in such a way that we could

easily edit existing functionality or add new features. We focused on three initial types of tools, as illustrated in [Figure 5](#).

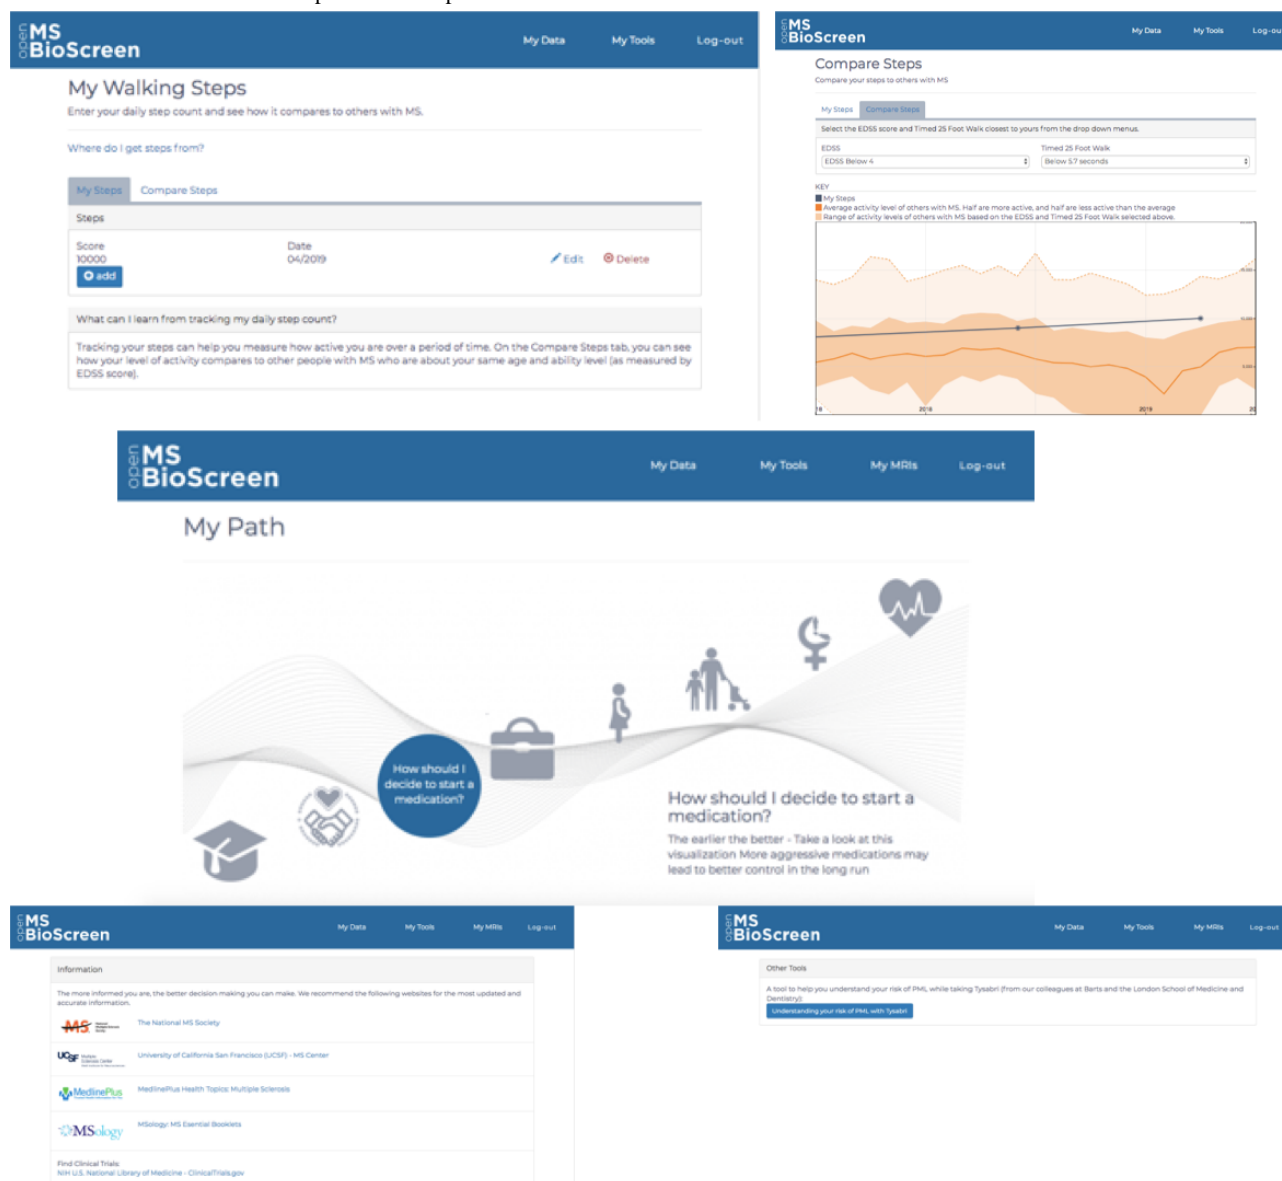

As an example of a tool that allows patients to record and track their wearable device data in an effort to address the known limitations of existing tools such as the EDSS [36], we built a tool that allows users to manually enter their step count (as reported by any commercially available wearable device) and to compare their count with disability level- and walking speed-matched patients from a research cohort of 100 UCSF patients with MS followed for over 1 year [13,14,35]. Aside from the data type check, there is no data validation done on the Open MS BioScreen side.

As an example of a tool designed to provide personalized guidance to patients with MS at various points over their life course, we built My MS Paths, a visualization narrating specific decisions and challenges that patients may encounter.

As an example of a clinical decision support tool developed and validated by other investigators but felt to provide significant value to patients with MS, we created a series of links on Open MS BioScreen to sites that allowed patients to calculate their risk, for example, of developing a fatal brain infection, progressive multifocal leukoencephalopathy, while on natalizumab treatment [37].

Again, we worked with end users and our development team to design and build these features. Due to our flexible platform and agile development process, we were able to go live with features as soon as the research was published; this allows patients to have access to actionable research immediately. At the time of manuscript submission, additional features are in development.

Figure 5. Additional features developed after the Open MS BioScreen live data. The top panel depicts the step count comparison tool that allows patients to enter their daily step count and compare this with others from a cohort of patients with multiple sclerosis (MS) at their phase of the disease [35]. The middle panel depicts My MS Paths, a visualization narrating specific decisions and challenges that patients may face over their lifetime living with MS. The bottom panel shows links to algorithms and clinical decision support tools developed by other investigators that provided complementary information and for which links were provided on Open MS BioScreen.

Discussion

Strengths and Limitations

We detail a human-centered approach undertaken to engage stakeholders in the iterative development of an on-demand tool designed to expand patient access to clinically actionable research insights generated by MS researchers and academics. A major limitation of the original MS BioScreen tablet-based app was that it did not take into account many of these principles, and as a result, it was not accessible, agile, or designed with user (patient and clinician) experience in mind. Here, we prioritized the patient and clinician's experience, carefully assessing for similar tools that might be available commercially or not-for-profit, and returned to stakeholders at each step of the development process to ensure that the end result was understandable and actionable. We were able to

achieve the 4 main features articulated during our ideation process, features that to our knowledge were not all present in any existing tool reviewed: (1) web-based and platform-agnostic, that is, not dependent on the life cycle of any other individual technology piece; (2) limited imprint from the pharmaceutical industry; (3) reliable over time without requiring daily input; and (4) clinician-derived informational modules.

The current platform provides a number of benefits to patient users. It allows patients to enter and track regular changes in their MS course, including important treatment changes, relapses, and changes in clinical function. As these data are available live in Open MS BioScreen, as opposed to a health system's electronic medical record, patients can easily maintain continuity over time, across providers and health systems. This is beneficial in health care settings such as the United States, where, in contrast to countries such as Sweden that benefit from a central, integrated MS registry [29], patients must navigate a

number of platforms and systems—with the potential for data loss, data duplication, and burdensome navigation of EHRs to synthesize the relevant MS-related information as patients transition between specialists and care settings. Of note, within UCSF, we have built a platform, BRIDGE, that launches directly from the EHR (bridge.ucsf.edu). Open MS BioScreen also allows patients to access narrative visualizations through which they can explore current and next phases in their clinical trajectory with MS, such as how to select an initial DMT, how to interpret and respond to a diagnosis of clinical progression, and how to approach upcoming life transitions (eg, pregnancy, menopause, or healthy aging). It also allows them to develop personalized action plans based on other patients living with MS (rather than the general population), taking into account realistic goal setting for their daily activity levels. The next phase of development is to measure and monitor the uptake of the tool in response to planned dissemination efforts and to continue to fine tune features based on user input.

The current platform also prioritizes certain clinician and researcher needs. First, Clinicians meeting a patient with long-standing MS must often spend valuable encounter time reviewing copious historical and administrative records to extract key MS-related clinical information. Second, Neurologists who are not MS experts also benefit from benchmarking a given patient's current function against the UCSF MS research cohort, a form of *virtual cohort* to inform expectations about patient course. Third, patients who are more informed about treatment decisions, such as weighing risks and benefits of therapies or what to expect at various life stages, are better able to participate in the clinical decision-making process. Over time, the research community will benefit from these data (which patients explicitly consent to be shared in a deidentified manner), to monitor trends in patient-related function, information-seeking, adaptation, and interpretation of data from wearable technology, and eventually MRI analytics. One obvious limitation, for both clinicians and researchers, is that there is no formal validation process for user-entered data, although our pilot testing for 24 participants suggests reasonable agreement between patients and clinicians regarding key MS metrics.

Conclusions

A major recommendation from patients, industry, and advocacy stakeholders was the need to incorporate a greater number of patient-generated data, such as ambulatory activity and MRIs. Unfortunately, the field of commercially available wearable devices is rapidly evolving in terms of both device engineering as well as regulations surrounding devices and data use. Given

this landscape, rather than invest substantially in developing Application Programming Interfaces with selected vendors and industry partners (who may or may not retain market share) to synchronize data from wearables, we focused instead on a simpler, more agile MVP. We, therefore, designed a simple, device-agnostic solution that enables patients with MS to enter data about their daily step count obtained from any number of commercial activity trackers and to obtain contextualizations of their ambulatory activity according to their own age and ability level. Our initial platform will allow for agile and responsive development and flexible adaptation of clinically actionable algorithms and tools developed by other research groups. This will be instrumental in ensuring that Open MS BioScreen allows patients to monitor their own course and make informed decisions based on current advances in clinical research.

As with any digital tool, there are a number of sustainability concerns that will be navigated, for which we have created a dissemination and sustainability roadmap. Dissemination and adaptation of digital tools represent a significant next phase in Open MS BioScreen development. Planned analysis of this dissemination plan includes a 2-year analysis of Google Analytics user activity data to track the dissemination and adaptation of this platform by patients living outside the UCSF research space. We will also include direct user feedback through the platform itself as well as through an additional cycle of interviews with users after the completion of the next modules (MRI data). These planned sources of feedback will allow us to expand within the inevitable biases of any specific academic, clinical, or geographic setting. Although we took care throughout our design process to interview a range of patients and clinicians both within and outside the UCSF MS group, there are likely residual biases that will be addressed through this planned feedback process. Financially, beyond the current philanthropy (Conrad N. Hilton Foundation) funding cycle, the dissemination results will allow us to determine if the platform is best maintained within an academic setting or would benefit from the adaptation by a nonprofit partner.

To date, there have been limited descriptions of human-centered design in MS care [2,38-42]. The insights gained from our extensive human-centered design process described here can inform approaches for developing a number of tools that enable tracking, communicating, and eventually improving function in patients with chronic conditions characterized by variable course, functional impairments, and a strong focus on quality of life.

Acknowledgments

This project was generously supported by the Conrad N. Hilton Foundation. The authors would like to thank the patients and UCSF MS and Neuroinflammation Center clinicians who participated in research interviews as well as participants in various Northern California MS support groups and fundraising activities, the entire UCSF EPIC research team, and the 2016-2017 UCSF-University of California, Berkeley Masters in Translational Medicine students who contributed to the Open MS BioScreen design as part of their Capstone Project: Christine Joseph, Zian Liu, Stephanie Nemec, and Arash Nourian.

Conflicts of Interest

JG reports consulting fees from Biogen and Alexion, research support (to UCSF) from Genentech, service contract support (to UCSF) from MedDay, honoraria for editorial work from Dynamed Plus, and personal compensation for medical-legal consulting. RH reports research grants from Roche and MedDay and consulting fees from Roche, Novartis, and Sanofi. SH serves on the board of trustees for Neurona and on scientific advisory boards for Alector, Annexon, Bionure, Molecular Stethoscope, and Symbiotix and has received travel reimbursement and writing assistance from F Hoffmann-La Roche Ltd for CD20-related meetings and presentations. RB has received research support from the National Multiple Sclerosis Society, the Conrad N. Hilton Foundation, the California Initiative to Advance Precision Medicine, the Sherak Foundation, and Akili Interactive. RB has also received personal compensation for consulting from Novartis, Sanofi Genzyme, Roche Genentech, and Pear Therapeutics. All other authors have no conflicts of interest to declare.

Abstract

Background: Patients play a critical role in managing their health, especially in the context of chronic conditions like diabetes. Electronic patient portals have been identified as a potential means to improve patient engagement; that is, patients' involvement in their care. However, little is known about the pathways through which portals may help patients engage in their care.

Objective: Our objective is to understand how an electronic patient portal facilitates patient engagement among individuals with diabetes.

Methods: This qualitative study employed semistructured telephone interviews of 40 patients living with diabetes since at least 2011, who had experienced uncontrolled diabetes, and had used secure messaging through a portal at least 4 times over 18 months. The interviews were recorded, transcribed, coded, and analyzed using primarily an inductive approach to identify how patients living with diabetes use an online health portal to support diabetes self-management.

Results: Overall, patients who used the portal reported feeling engaged in their health care. We identified four pathways by which the portal facilitates patient engagement and some challenges. The portal provides a platform that patients use to (1) better understand their health by asking questions about new symptoms, notes, or labs, (2) prepare for medical appointments by reviewing labs and notes, (3) coordinate care between VA (Veterans Affairs) and non-VA health care teams, and (4) reach out to providers to request help between visits. Several patients reported that the portal helped improve the patient-provider relationship; however, aspects of the portal design may hinder engagement for others. Patients reported challenges with both secure messaging and access to medical records that had negative impacts on their engagement. Benefits for patient engagement were described by many types of portal users with varying degrees of diabetes control.

Conclusions: Patient portals support engagement by facilitating patient access to their health information and by facilitating patient-provider communication. Portals can help a wide range of users engage with their care.

KEYWORDS

patient engagement; patient portal; chronic disease; diabetes; secure messaging; veterans

Introduction

Patients play a crucial role in managing their health, and that role is even more central in the context of chronic conditions that require ongoing coping skills and self-management efforts [1,2]. Broadly, the term “patient engagement” refers to patients taking part in or actively participating in their care [3], including how patients work with health care providers and systems to manage and improve their health. Hibbard [4] conceptualized patient engagement as degrees of active involvement in their care, termed patient activation. Patient engagement can operate at multiple levels and exists on a continuum [5]. We focus primarily on the level of direct patient care where engagement can range from patients receiving information about a diagnosis to patients participating in treatment plan decisions [5]. Although it has been characterized in a variety of ways, a common thread is that patient engagement is a multi-faceted concept incorporating actions on multiple levels to promote patient-centered care and self-management.

Patient-facing eHealth technologies are often described as a means to improve patient engagement [6,7]. Online patient portals have received particular attention since their features often support healthcare system transactions (eg, prescription refills, scheduling), healthcare team communication, access to patient medical records, and the delivery of health education resources [7,8]. Previous studies of patients living with diabetes, for example, suggest that individuals who use online patient portals are more likely to achieve desirable outcomes, including improved glycemic control [9-12].

Few studies have attempted to specify how engagement may be realized through patient portals or the pathways through which portals may help patients engage in their care and self-management. One study of direct-release of test results via patient portals found that this access to information improved engagement by helping patients to monitor results over time and prepare before communicating with their provider [13]. However, a greater understanding of pathways through which a range of portal features support engagement is needed.

A framework for patient engagement by Barello and colleagues may help us understand the different ways in which a patient portal may support patient engagement [14]. This framework incorporates patients’ actions, thoughts, and feelings and considers patient engagement within three dimensions: emotional, cognitive, and behavioral [14]. In this model, the emotional dimension of engagement encompasses the patients’ emotional state and feelings about their care. The cognitive dimension captures patients’ understanding of their disease and treatment. The behavioral dimension of engagement captures patients’ actions to address their health.

In this paper, we examine whether and how an online patient portal supports patient engagement for individuals living with diabetes. We take a qualitative approach to this by reviewing patient portal experiences among veterans living with diabetes and describe several ways in which an electronic patient portal facilitates patient engagement.

Methods

Data were collected in a more extensive study examining the role of patient portals in diabetes management, described previously [15]. Briefly, from November 2017 to January 2018, 1200 patients living with diabetes were invited to participate in a mailed survey about their diabetes self-management and use of the United States Department of Veterans Affairs (VA) online patient portal, My HealtheVet [16]. The My HealtheVet portal offers several features to help patients manage their care. Patients can request medication refills, schedule appointments, receive appointment reminders, communicate electronically with providers through secure messaging, and use the Blue Button feature to access portions of their medical records including labs and clinical notes [17].

All 1200 patients had a diabetes diagnosis in their record since at least 2011, had experienced uncontrolled diabetes in 2012 (mean $HbA_{1c} > 8.0\%$ and less than 25% of the year with an $HbA_{1c} < 8.0\%$) and were actively engaged patient portal users who used secure messaging at least four times between January 2016 and June 2017. Since 2012, half had achieved glycemic control, defined as having mean $HbA_{1c} < 8\%$ in 2016 and $HbA_{1c} < 8\%$ for at least 75% of 2016, and half had not. We stratified each group based on urban/rural residence, according to the Rural-Urban Commuting Areas [18], and the presence of comorbid mental health diagnoses. Individuals were considered to have a comorbid mental health diagnosis if they had two outpatient diagnoses or one inpatient diagnosis within each diagnostic group. The diagnostic groups selected using International Classification of Diseases (ICD), 9th and 10th Revision (ICD-9 and ICD-10) codes were anxiety, bipolar, depression, personality disorder, post-traumatic stress disorder, schizophrenia, and substance use disorders. We received 449 completed surveys, of which 350 patients responded that they would be interested in participating in an interview about how they managed their diabetes. This study was approved by the Edith Nourse Rogers Memorial Veterans Hospital Institutional Review Board.

Purposeful sampling was used to identify and select patient portal users for telephone interviews. In total, 160 respondents provided positive responses to an open-ended survey question, “Can you tell us about an ‘A-Ha!’ moment when you realized you could use the My HealtheVet portal to better manage your

diabetes?" We selected interviewees to represent a variety of responses to this and other survey items about My HealtheVet use. Interviewees were selected to represent those who used a variety of My HealtheVet portal features, those with controlled and uncontrolled diabetes, urban and rural patients, and those with and without comorbid mental health diagnoses. Women and minority veterans were oversampled to broaden the representation of patient demographics.

Forty telephone interviews were completed between February and May of 2018. Each interview was conducted by two researchers and averaged 70 minutes long. The interview covered how the patient managed their diabetes, including their feelings about the efficacy of their self-management, how they gathered and used information, how portal features and other technologies supported their diabetes management, and their suggestions for improving the portal. Interviewers were intentionally blinded to the patient's glucose control at the time of the interview.

Participants

The demographic and health characteristics of our patient sample, obtained from the survey data and health records, are reported in Table 1. The mean age of participants was 65.9 years. The majority were white (85%) and male (80%); 60% had a mental health diagnosis. Participants' mean HbA_{1c} tested closest to the interview (recent HbA_{1c}) was 8.2% (SD 1.4%), over our threshold for diabetes control (<8.0).

Approach

All interviews were recorded, transcribed, and double-coded for multiple themes, using a coding scheme developed by the

team. Several coders collaborated to establish the list of codes using both deductive and inductive thematic coding [23]. Deductive coding was used initially to create a list of preliminary codes from the topic areas of our interview guide. These codes included the benefits and challenges of each specific portal feature. Inductive codes were developed as coders reviewed the narrative, and new themes emerged from the interview transcripts. Coders met regularly to discuss the codes and themes, and to ensure consensus on meaning was achieved. Coding discrepancies were resolved with discussion among three authors (MTS, SLS, TPH). Coders were blinded to the interviewee's glucose control status.

We selected eight codes related to portal use and patient engagement for in-depth analysis and reporting here. The following inductively developed codes were used to identify pathways for engagement: (1) patient-team relationship (portal use impact on the patient-healthcare team relationship); (2) empowerment (patients feeling empowered through portal use); (3) care collaboration (patients using the portal to coordinate care with their healthcare teams); (4) impact on care plan (how portal use changes patients' care plans between visits); (5) clarification (patient-initiated communication through the portal for explanations of information). The following deductively developed codes were used to identify challenges to patient engagement: (1) secure messaging challenges, (2) medication refill challenges, (3) BlueButton challenges. The interview text excerpts identified by these codes were analyzed, and themes around how the patient portal facilitates engagement were elicited and used to organize our results.

Table 1. Sample characteristics (N=40).

Characteristic	Value
Diabetes Self-Management Questionnaire (DSMQ) Score ^a , mean (SD)	8.0 (0.79)
Mean diabetes self-efficacy score (DSES) ^b , mean (SD)	7.4 (1.6)
Recent HbA _{1c} ^c , mean (SD)	8.2 (1.4)
Nosos risk score ^d , mean (SD)	2.4 (2.7)
Age (years), mean (SD)	65.9 (6.5)

\$25,000-\$49,000	10 (25)
\$50,000-\$149,000	15 (38)
>\$150,000	3 (8)
Income not reported	3 (8)

^aDiabetes Self-Management Questionnaire (DSMQ): a global measure of diabetes self-management comprised of 16 items to assess activities related to glycemic control in patients with diabetes. Scaled scores range from 0-10 and higher values indicate more effective self-management [19].

^bDiabetes Self-efficacy Scale (DSES): measures how confident patients are in their ability to do certain activities related to managing their diabetes. Scores range from 1-10 and higher values indicate higher self-efficacy [20].

^cHbA_{1c}: glycated hemoglobin.

^dNosos risk score: VA's modified version of Medicare's Hierarchical Condition Category. A measure of expected health care costs based on demographic, pharmacy, psychiatric and health care utilization data; mean for a population equals 1.0 and scores >1.0 indicate the patient is expected to have health care costs that much higher than the average VA patient [21].

^eHealth literacy: determined by the patient's response to the question, "How often do you have someone help you read hospital materials? [22]" Health literacy was considered inadequate when patients responded "Often" or "Always"; "Sometimes" was considered marginal health literacy; "Never" was considered adequate health literacy.

Results

Across all 40 patient interviews, 30 touched on concepts related to patient engagement through portal use. Overall, patients reported feeling engaged by their use of the portal. We describe this below, followed by illustrations of the four pathways of interaction with the portal that support patients' feelings of engagement. Finally, we share patient insight on how portal functionality may hinder engagement. To further contextualize our data, we describe select patient characteristics after each illustrative quote.

Feeling Engaged by Use of the Portal

Patients explained that the portal helped to support their engagement with their care and improve their health by having a provider available to give consistent feedback. One patient reported that interacting with providers through the portal improved their attitude and health:

The best thing I ever did was when I enrolled in (My HealtheVet). It helped me be in better control of my attitude, my depression, my diabetes. When I deviate a little bit left or right, there's always somebody on

the other end going, 'uh oh, you need to go down that straight and narrow path again.' It's a great program. (60-year-old Latino male, white, urban, mental health diagnosis, recent HbA_{1c} 7.3, in control)

Patients reported feeling that interacting with providers through the portal helped build patient-provider relationships and that these relationships were vital to receiving better care:

The more interest you show, the more interest they show in you. I think the secure messaging helps you establish that kind of relationship. Like, 'Oh here's a guy that's trying to take care of himself, let's help him. (82-year-old white male, rural, no mental health diagnosis, recent HbA_{1c} 7.5, in control)

How the Portal Supported Patient Feelings of Engagement

Our analysis identified four key pathways by which the portal supported patients' engagement in their care and some difficulties with the portal that may hinder engagement. The portal provides support for patients to (1) work to better understand their health, (2) prepare for medical appointments, (3) coordinate care and share health information between VA and non-VA health care teams, and (4) reach out to providers to request help between visits. These pathways are illustrated below.

Working to Better Understand Their Health

Reading clinical notes and test results helps patients understand their health information in their own time, gauge the seriousness of health issues they have, keep things in perspective, and make decisions about appropriate next steps. For example, patients reported that reviewing clinical notes using the Blue Button portal feature after an appointment helped them to understand what their provider was telling them. "It doesn't always sink in right away what they are telling you. So I've used the Blue Button notes." (69-year-old white male, rural, no mental health diagnosis, recent HbA_{1c} 7.5, in control)

Making test results available through the patient portal provides an opportunity for patients to be proactive based on test results:

I think that was the "A-ha" moment when I said, 'now I can see my results of 50 different tests'. And all at once and go over them and pick out the ones that are too high or too low. Then if I see something way off, I can make an appointment. (72-year-old black male, urban, no mental health diagnosis, recent HbA_{1c} 6.9, in control)

Sharing health information through patient portals can also cause some distress when patients do not understand the information. One participant described a situation like this, but said they use the secure messaging feature to obtain more information and reassurance from their provider:

I've had issues where I [view a test result] and it sounds really bad but the note says it's no big deal so I would send a secure message to my doctor and ask them why they're not concerned about this level being high, and she would explain it more to me. So

that's helped. (51-year-old black female, urban, mental health diagnosis, recent HbA_{1c} 9.2, not in control)

Patients reported finding the portal helpful because they could ask questions before they forget. The portal helps reduce the chance of a patient forgetting a health concern or inquiry by enabling them to send providers questions via secure messaging right when patients think of them:

Sometimes you can't get an appointment for a week or so and by then you've forgotten what question you have! So it's so much easier just writing it down in that secure message and sending it off before you forget what you want to ask. (61-year-old white female, urban, no mental health diagnosis, recent HbA_{1c} 7.0, in control)

Patients also used the information available through the portal together with information available from other sources to better understand their conditions:

There've been times when I look at my blood work and I see something I don't understand; medical jargon. I've been able to Google it and find out what it means. That's empowering. (51-year-old black female, urban, mental health diagnosis, recent HbA_{1c} 9.2, not in control)

Preparing for Medical Appointments

Patients described reviewing notes to prepare for their visit to be proactive about their care. One patient reported using the patient portal to prepare for their appointment so that they would be able to ask thoughtful and helpful questions:

I'm always checking on my lab results. I ask the doctor if something's high or low because I know the results before I go in and see her. That's what I like about [My HealtheVet], I know the lab results, I know what questions to ask. (72-year-old black male, urban, no mental health diagnosis, recent HbA_{1c} 6.9, in control)

Another patient described using the portal to review information and vocabulary to engage more meaningfully during appointments in the conversations with their provider:

It's easier to sit there and look at [My HealtheVet] and have an idea of what's going on before you talk to the people who know more about it than you do... So that I have an understanding of what terms that they're using. So that they aren't snowballing me or going over my head. (69-year-old white male, rural, no mental health diagnosis, recent HbA_{1c} 7.5, in control)

Coordinating Care and Sharing Health Information Between VA and Non-VA Health Providers

Having access to the patient portal puts control over health information into the hands of patients. When patients want to share information between providers, patients can send information themselves. Patients reported sharing lab results between VA and non-VA providers to avoid duplicate labs and

unnecessary testing. This access saves time and health care resources.

With the VA I usually get labs done every 2 months, give or take. Privately it's probably about the same, every 2-3 months. It goes back and forth. That's the nice thing about this. Go from private to the VA. VA to private. You can take that information and if the doctors need it or want it, you can transfer it to them. (71-year-old white male, rural, mental health diagnosis, recent HbA_{1c} 8.2, not in control)

Patients also reported using the portal to coordinate care between VA and non-VA providers because the providers do not coordinate themselves. When patients have to take on the care coordination role, having information in writing from each doctor supports accurate sharing of information between providers:

I have a VA doctor and I have one through Medicare, I've got to be very careful that I have both of them in agreement. So what I end up doing is if one of them recommends a different type of medication ... I can email both of them ... they don't seem to want to talk, for whatever reason they don't talk on the phone. So I will literally copy and send emails back and forth with the pros and cons ... I have something in writing that I can actually communicate back, rather than me trying to remember. (68-year-old white male, urban no mental health diagnosis, recent HbA_{1c} 7.8, in control)

Reaching Out to Providers to Request Help or Changes to Care Plan Between Visits

Close collaboration with providers may facilitate improved health and reduce the amount of in-person medical visits, which may be especially burdensome for rural patients. Patients reported using the portal to reach out to providers for information about how to address symptoms and manage their blood sugar levels. Patients described they found secure messaging supportive as a tool to reach out to their providers to understand why their blood sugar is too low or too high and facilitates their ability to receive guidance about what to do differently. Patients use secure messaging to help them as they work to manage their health and understand why they may have certain symptoms,

I sent a question to my care team [through secure messaging] asking about what I'm doing wrong because I'm ending up with morning [blood sugar] numbers that are too low...I like that because they're usually pretty prompt at getting back to me. (59-year-old white male, rural, no mental health diagnosis, recent HbA_{1c} 6.5, in control)

Variations of this comment were heard from many patients:

If I thought my [A_{1c}] was out of whack or ... that I think it's high, then I might say something. Especially when I don't understand why it's high. (72-year-old black male, urban, no mental health diagnosis, recent HbA_{1c} 6.9, in control)

Between visit communication between patients and providers through secure messaging affords an opportunity to more quickly address issues, including potentially changing medication management plans, to try to gain control over blood sugar:

I could send the readings via secure message and, then they'd say, 'Okay, well you can drop this dose or you need to add this dose. (60-year-old white female, rural, mental health diagnosis, recent HbA_{1c} 9.9, not in control).

Patients reported that they used portal interactions to advocate for themselves and be proactive about getting what they need, including asking about how to manage blood sugar better:

If I notice that my blood sugar stays high and I can't seem to regulate it, I use My HealtheVet to do the secure messaging and I'll send my care provider [a message]. I usually let it go for a couple of days so that I can see an average. And, then I'll contact them and maybe they'll contact me right back and say, 'Listen, I need you to increase it by two units. And let's see if we got you on track now.' (61-year-old black male, urban, mental health diagnosis, recent HbA_{1c} 7.7, in control)

Some patients also reported these interactions reduced the number of in-person visits required.

If I punched in high numbers into telehealth, [my doctor] would message me, find out what I was doing and tell me what I needed to adjust. I have to say that a lot of [my motivation to use My HealtheVet] had to do with being able to have more interaction directly with my doctor straight from my house. I almost don't even have to go to the VA anymore. (54-year-old white male, rural, mental health diagnosis, recent HbA_{1c} 7.2, in control)

Patients also found secure messaging to be an efficient way to ask about how to address medication side effects they were experiencing:

You know, I can ask her, 'This new medication is making me a little light-headed or whatever. What should I do.' And I get an answer the next day. (56-year-old white male, rural, mental health diagnosis, recent HbA_{1c} 9.7, not in control)

Portal Functionality Hinders Engagement

Patients identified some issues with portal features that may have dampened their engagement. First, multiple patients reported being unable to use secure messaging with all of their providers. Patients do not always understand that this is a portal design issue; some misinterpret this as a purposeful act on the part of their providers and may see it as a form of rejection:

On secure messaging I have 6 groups of different people including my primary doctor and my pharmacist. I used to have my hepatologist and somehow they took that off of there. I do a lot of work through my hepatologist and I can't secure message

him because he's not on my board anymore, which makes me very mad. (67 year old male, urban, mental health diagnosis, recent HbA_{1c} 6.1, in control)

Second, patients reported that they could not send secure messages to individual providers, but instead had to message the team and that their uncertainty about who might read the message made them uncomfortable.

They call it secure messaging but it doesn't go to the specific person, it just goes to the department and then it gets trickled down from there. So you don't really know who's going to be reading all that. I have to write to the purple team, not my primary doctor. (57-year-old American Indian/Alaska Native female, urban, no mental health diagnosis, recent HbA_{1c} 7.4, in control)

Finally, patients described challenges with the BlueButton feature that may hinder engagement, either by preventing access to information or generating frustration so that patients stop trying to engage. One patient said the information in BlueButton is not helpful and feels impersonal, "There is a lot of it that feels cookie-cutter, nothing new" (54-year-old white male, rural, no mental health diagnosis, recent HbA_{1c} 7.1, in control). Several patients reported the interface is difficult to navigate, and they expressed frustration with not knowing how to download their notes. Such challenges prevent them from obtaining information that may facilitate engagement. One reported, "finding medical record notes, that's been hard for me. I couldn't find that so I just said the heck with it." (72-year-old white male, urban, mental health diagnosis, recent HbA_{1c} 8.1, not in control)

Discussion

Through 40 interviews with patients with diabetes who used a patient portal, we engaged in a wide-ranging discussion regarding patient engagement and pathways by which portals may facilitate engagement. Access to detailed health information in the portal facilitates engagement by allowing patients to learn about their condition, remember information from provider visits that they otherwise may forget, and prepare for medical appointments. Tools to facilitate communication through the portal allow patients to partner with their providers to manage their health. Many patients found secure messaging and Blue Button features supportive of engagement; difficulties that patients reported with these features may, by extension, be barriers to patient engagement.

Patient narratives in this study align with Barello and colleagues' framework [14] of three engagement dimensions (emotional, cognitive, and behavioral) and highlight an interconnectedness between cognitive and behavioral engagement. In terms of emotional engagement, patients felt that interacting with providers via the portal improved the patient-provider relationship. Portal use cognitively engaged patients to understand their health by using portal tools such as secure messaging to ask questions and Blue Button to review clinical notes. Patient narratives revealed how cognitive engagement is translated into behavior. Access to information through the patient portal led patients to engage in behaviors to support their

health and self-management. Actions facilitated by the portal's information and communication platform included preparing for visits, coordinating care among providers, and making lifestyle or medication changes between visits.

There are concerns in the literature that eHealth initiatives may worsen disparities [24] or weaken patient-provider relationships [12]. Disparities could worsen if vulnerable groups have less access to technology that promotes engagement or if vulnerable populations are less likely to use patient portals [25]. Our data suggest varied backgrounds and degrees of glucose control among patients using the portal to enhance their engagement. Portal benefits for engagement seem to be experienced by all types of patients, including individuals in urban and rural settings, with and without mental health conditions, those with diabetes in control, and those with diabetes not in control. Furthermore, several patients who were not in control described activities related to engagement. A portal may offer further opportunities to work with these patients to improve diabetes control. However, engaging patients via portal use does not necessarily indicate they will have better outcomes. In this analysis, we do not measure whether engagement facilitated by the portal influenced diabetes outcomes or patient satisfaction scores or whether this varied based on additional patient characteristics. The interviews were overwhelmingly positive about the benefits of the portal and suggested patient satisfaction is improved among those who use it. Future research should explore whether portal engagement predicts health outcomes and patient satisfaction and whether the findings are consistent among patients with other chronic conditions.

Patient-provider relationships are essential for individuals with chronic conditions like diabetes. There is some concern that portals may hurt the patient-provider relationship if portal interactions replace face-to-face interactions [12,26]. However, in our study, patients described the portal interactions between patient and provider as a key factor that facilitated their engagement. Some patients reported feeling that their interactions with providers through the portal help strengthen their relationship with providers. A point of caution: we must recognize the unintended consequence that a portal's design may have on patient perceptions of their provider's willingness to communicate with them. In our analysis, most patients found the portal helpful, but the design of the secure messaging feature led some patients to feel their providers may not want to communicate with them. Employing human-centered design may be one strategy to help mitigate portal design issues by engaging patients and providers early in the design process. One patient also complained about the impersonal, "cookie-cutter" nature of some clinical notes, which could make patients feel like their providers didn't know them as individuals, or that the notes did not capture the essence of what was discussed during the clinical encounter. Future qualitative work should continue to explore patient and provider perspectives on how portals affect their relationships and could examine provider attitudes and approaches to the portal as a possible moderator of patient engagement.

This study has several limitations. The study population was limited to United States military veterans with diabetes who used the My HealtheVet patient portal. We found

overwhelmingly positive comments regarding the portal, perhaps because all interviewees were portal users. Our study was not designed to determine the prevalence of patient engagement, but our findings do reveal potential ways in which a portal may facilitate engagement.

In this study, patient narratives helped identify pathways by which a portal may facilitate patient engagement. Patients found the portal helped strengthen their relationship with providers

and helped the patient feel engaged. Patients reported finding the portal useful for receiving help in managing symptoms, coordinating their care, and learning about their health. Patient portal users included a variety of individuals who described the engagement benefits of the portal. The group included individuals living in urban and rural settings, those with and without mental health conditions, and those with controlled and uncontrolled diabetes. Thus, the portal may help a wide range of portal users engage with their care.

Abstract

Background: The use of patient portals for presenting health-related patient data, such as blood test results, is becoming increasingly important in health practices. Patient portals have the potential to enhance patient health engagement, but content might be misinterpreted.

Objective: This study aimed to discover whether the way of presenting blood test outcomes in an electronic patient portal is associated with patient health engagement and whether this varies across different blood test outcomes.

Methods: A 2x3 between-subjects experiment was conducted among members of the Nivel Dutch Health Care Consumer Panel. All participants read a scenario in which they were asked to imagine themselves receiving blood test results. These results differed in terms of the presented blood values (ie, normal vs partially abnormal vs all abnormal) as well as in terms of whether the results were accompanied with explanatory text and visualization. Patient health engagement was measured both before (T0) and after (T1) participants were exposed to their fictive blood test results.

Results: A total 487 of 900 invited members responded (response rate 54%), of whom 50.3% (245/487) were female. The average age of the participants was 52.82 years (SD 15.41 years). Patient health engagement saw either a significant decrease or a nonsignificant difference in the experimental groups after viewing the blood test results. The mean difference was smaller in the groups that received blood test results with additional text and visualization (mean_{T0} 5.33, SE 0.08; mean_{T1} 5.14, SE 0.09; mean difference 0.19, SE 0.08, $P=.02$) compared with groups that received blood test results without explanatory text and visualization (mean_{T0} 5.19, SE 0.08; mean_{T1} 4.55, SE 0.09; mean difference 0.64, SE 0.08, $P<.001$). Adding text and visualization, in particular, reduced the decline in patient health engagement in participants who received normal results or mixed results (ie, combination of normal and abnormal results).

Conclusions: Adding text and visualization features can attenuate the decrease in patient health engagement in participants who receive outcomes of a blood test via a patient portal, particularly when blood test results are (partly) normal. This suggests that explanatory text and visualization can be reassuring. Future research is warranted to determine whether these results can be generalized to a patient population who receive their actual blood test results.

KEYWORDS

online patient portals; patient health engagement; blood testing; blood test results; consumer panel, visualization; patient information

Introduction

Patient health engagement (PHE) can play an important role in personal health and can improve adherence and satisfaction with received care [1,2]. From a holistic perspective, PHE can be defined as a multidimensional process, including elements of cognition (thinking), emotion (feeling), and behavior (acting) of a patient towards his or her role in health management [3]. Patients' engagement in their health management is dependent on the stability of these dimensions. A lack of understanding of their position in health care can immobilize patients, making them indecisive or apathetic, while a better understanding makes them more active [3]. Engaged patients who want to be informed about and take an active role in their own health care are more likely to show healthy behaviors, have better self-management, and achieve better health-related outcomes [2,4]. Vice versa, lower PHE has been related to preventable deaths and unnecessary costs [5]. One stage where PHE is important is the stage of diagnosis [6]. When patients take an active role by asking questions and voicing their opinions, they enhance their role in their health management and increase their empowerment [7]. An important part of the stage of the diagnostic process is the information that becomes available from blood tests. However, this information can cause insecurity and uncertainty for the patient. This can negatively impact PHE as patients can become emotionally destabilized by the confusion or impact of the test results [7]. This risk is bigger when patients find the blood test values difficult to interpret [8].

Currently, electronic patient portals are increasingly offered by health professionals to communicate blood test results to the patient. Even though these portals are not optimally used yet [9], patient portals are becoming increasingly important in the health care sector and valued by both patients and practitioners [10]. Patient portals have been designed to encourage patient involvement. Yet, the way the content is presented in a portal and the way the patient interprets such content impact the overall usefulness of the information [10]. To prevent unnecessary anxiety, blood test results must be presented properly to patients [7] and needs to be done in such a way that it does not jeopardize PHE. In health practices, blood test results in a standard portal are usually communicated by giving the quantitative results (ie, the patient's value) plus reference values (ie, a range that expresses the normal values for that test). Added features such as text, symbols, or visuals to help interpret blood test results are usually not provided. However, problems have been reported about the usage of such a basic portal. For instance, the limited amount of information makes interpretation of results complex, which makes the blood test results only useful for patients with high health literacy [11]. Furthermore, misinterpretation has led to patients underestimating the severity of blood test outcomes [12].

One of the main problems is that patient portals often rely on numerals to purvey information. This is a concern for people with low numeracy skills (ie, people who lack the ability to use and draw meaning from numbers). People with low numeracy

skills have shown more difficulties with identifying out-of-range test results [13]. This is likely due to the unfamiliar abbreviations, unfamiliar units, and little guidance as to whether higher numbers represent more positive or negative outcomes. This problem increases when larger sets of values are displayed at once [13]. These findings raise concerns for patient safety. Arguments for keeping this type of portal can be that people, who searched online for information, found that websites often have too much information for them to comprehend [14]. Furthermore, detailed information was found to be overwhelming for certain patients [15]. Thus, a patient portal can be useful to provide patients with individualized information (in this case, blood test results) without irrelevant information. However, this information has to be presented in a comprehensible way.

There are good reasons to believe that textual explanations with explanatory visual aids can benefit patients [16], both online and offline. For example, visualization to communicate different levels of driving risks (ie, yellow, orange, and red bars) provided good insight into the risk level of driving while using a specific medicine [17]. When risk communication is done using well-designed visual aids, information through patient portals could be received with fewer problems and enhance consent to further treatment [18]. Infographics have also been shown to be of added value in delivering complex information [19], and graphs helped a third of patients with lower numerical skills in transferring risk information [20]. When people do not understand the information, they will often use their "gut" feeling to make decisions about uncertain situations [21]. This can be a problem for PHE, as this feeling can make a patient more passive in their health management. Little is known about how presenting blood test values in a patient portal can influence PHE. The aim of this study was to explore whether the way blood test outcomes are presented in a patient portal is associated with PHE and whether this varies across different blood test outcome combinations. Exploratory research can be a crucial step to further develop scientific knowledge by laying groundwork for research topics that do not yet have a strong basis for hypotheses [22]. An experiment was conducted to systematically test the effect of different blood test results presented in a basic patient portal as well as in a patient portal in which text and visualization was added to the standard way of presenting blood test results.

Methods

Portal

The basis of our study was the comparison of two portals. Both portals communicated blood test results accompanied by reference values (ie, the range that expresses the normal values for that test). These types of portals are most often used in Dutch clinical practice, which was the setting of our study. The first portal was a fictive basic portal only providing the patient's blood values with the corresponding reference categories. The second portal was based on a more sophisticated portal as

developed by Saltro, one of the largest diagnostic centers in the Netherlands. The Saltro portal adds two main features compared to the first portal: (1) textual understandable information explaining the test and its outcomes and the action the patient can take afterwards and (2) visual support by using traffic light colors to indicate whether the outcome is within the normal range. The content of this portal was cocreated with health care professionals, communication experts, and patients. The text was written to be understandable for the majority of people. The level of health literacy of the results information has been estimated at communication level 1B on the scales of the Common European Framework of Reference for Languages. Furthermore, the content is frequently evaluated by patients and adapted according to their recommendations.

Design and Procedure

A 2x3 between-subjects experimental design was employed to test the effects of the blood test results outcome and the addition of explanatory text and visualization on PHE. Participants were so-called analog or simulated patients (ie, people who imagine themselves being in a hypothetical health care situation) presented with a hypothetical case (see [Textbox 1](#)). We opted for analog patients for two reasons. First, since we manipulated the blood test outcomes, it was unethical to use “real” patients

receiving their own blood test results. Second, analog patients can be used in study designs such as ours, based on a meta-analysis that demonstrated the validity of using analog patients by showing insignificant discrepancies between the perceptions of analog patients and clinical patients [23]. The hypothetical case was identical for every participant ([Textbox 1](#)). Fatigue was chosen as a health problem as it is easy to relate to. In short, the case description stated that participants had to envision they have been tired for a couple of months now and it is not getting any better. We chose an excessive form of fatigue in order to arouse feelings of fear or worry in the participant. They went to a general practitioner who ordered some blood tests. The outcomes were to be communicated through a web portal.

We tested the two types of portals (ie, with vs without explanatory text and visualization), within which we distinguished three possible outcomes of the blood tests: all values within range (normal), partially deviating values (partially abnormal), and all deviating values (all abnormal). [Table 1](#) shows the 6 conditions that were tested. The outcomes per blood value group were identical. Participants were randomly assigned to 1 of the 6 experimental conditions without knowing about the other 5 conditions.

Textbox 1. Fictional case presented to each participant, translated from Dutch to English.

You have been tired for a couple of months now, and it does not get any better. No matter how much you sleep, you remain tired. You even fell asleep at work once. You do not feel tense or stressed. It does bother you that the tiredness does not go away. You decide to visit your general practitioner (GP) to describe your symptoms to better understand/get a grip on your situation. The GP asks if you have any thoughts on the cause of the tiredness. You have no clue. Your private life is fine, you have never been this tired before, your diet is healthy, and you do not smoke or use medication. You have become worried about the situation; what is going on? The GP suggests to first run some blood tests before making any decisions. The GP explains that she wants to measure 3 types of blood values: tests for an underactive thyroid (thyroid stimulating hormone), anemia (hemoglobin), and a deficit of vitamin D. In the morning, your blood gets drawn, and you are told that your results are available at your convenience on the website of your GP through a patient portal the same day.

Table 1. The 6 groups of the 2x3 design.

Portal type	All normal values	Partially abnormal values	All abnormal values
No features	“Green basic”	“Partial orange basic”	“Orange basic”
Added features ^a	“Green Saltro”	“Partial orange Saltro”	“Orange Saltro”

^aExplanatory text with added visuals (see [Figure 1](#)).

Figure 1. Basic portal (top) and Saltro portal (bottom), both displaying the same partially abnormal results. All text is in Dutch and is shown in a similar fashion for hemoglobin and thyroid stimulating hormone.

Stimulus Materials

The Saltro portal adds explanatory text that gives an explanation about which function the substance has in the body and what exactly is being measured, while showing a bar that presents the patient's blood value in an orange (abnormal) or green (normal) range. A marker shows where the patient's blood test result falls within the range (see Figure 1). The text also offers an explanation on why measuring this particular substance is important, what it could mean if a value is below or above the normal range, and an indication of possible causes for the abnormal result. The text encourages the patient to contact their physician for further questions. The text ends with a conclusion stating whether the blood test result of the patient is below, above, or within the normal value range. Participants were exposed to 3 blood tests: hemoglobin, thyroid stimulating hormone, and vitamin D. The total word counts of the explanatory text were 271 for hemoglobin, 175 for thyroid stimulating hormone, and 194 for vitamin D.

Participants

We approached a sample of 900 participants of the Dutch Health Care Consumer Panel to complete an online questionnaire. This panel aims to measure opinions on and knowledge of health

care as well as the expectations of and experiences with health care among a cross-section of the Dutch population [24]. The Dutch Health Care Consumer Panel is an access panel consisting of people who have agreed to answer questionnaires on a regular basis. Some sociodemographic details of the participants are known, such as age, gender, and highest level of education. In June 2018, the Consumer Panel consisted of about 12,000 people. To be included in the panel, a respondent has to be 18 years or older. All participants typically are asked to complete a questionnaire 3-4 times a year. Participants have complete liberty to decide whether to only answer certain questions or to participate at all. The technical functionality of the questionnaires is tested by the researcher before sending out the questionnaire. Resigning from the panel can be done at any time. People cannot sign up for the panel on their own initiative, and as such, we used a closed survey. The response rate for this study was stimulated by sending two electronic reminders to panel members who had not responded yet. The closing date of the questionnaire was at the end of May 2018. Panel members did not receive financial compensation.

Data were analyzed anonymously and processed according to the privacy policy of the Dutch Healthcare Consumer Panel, which complies with the General Data Protection Regulation. According to Dutch legislation, there is no legal requirement

to obtain informed consent nor approval by a medical ethics committee for conducting research through the panel [25]. Privacy regulation is available.

Measurements

We used the original 9-item version of the PHE scale as the starting point for our measurement [3]. The PHE scale defines patient health engagement as a multidimensional process, including elements of emotion (feeling), cognition (thinking), and behavior (acting) towards his or her role in health management. Of the 9 original items, 5 items were considered appropriate for this experiment. For 2 items, the answer categories were slightly adapted to make it more applicable to the case in our study. Of the original PHE scale, 4 items were considered irrelevant for this study, as they specified feelings about the illness itself and could not be used due to the fictional nature of the case study. Participants were asked to indicate the extent to which the 7-point semantic differential scales applied to them. The items were: “I feel in blackout” versus “I feel positive,” “I feel dazed” versus “I feel serene,” “I can’t understand what happened to me” versus “I understand what this situation means to me,” “I feel totally messed up” versus “I know what to do in this situation,” and “I let others take care of me” versus “I can autonomously manage my medical regime.” The participants filled out the 5-item version of the PHE scale both before (T0) and after (T1) exposure to the patient portal. All 5 items were averaged into one mean scale of PHE at T0 (Cronbach $\alpha=.90$) and T1 (Cronbach $\alpha=.92$). As individual items showed similar trends to those of the overall items, we did not analyze those separately. A higher score on the mean scale means a higher PHE. Because T0 was the baseline measurement (after exposure to the case scenario but before the patient portal with the blood test results), it could be expected that the health engagement score would not increase after exposure to the portal with the blood test results, but either remain the same or decrease, depending on the extent to which the blood test results would evoke elements of emotion, cognition, or behavior that could hinder patients’ health engagement. The reason for this is that when the results are abnormal, the level of PHE is expected to be lower after receiving the test. Also, for those who receive normal results, an increase is not obvious because it means that the cause for the long-term tiredness is not clear.

Statistical Analysis

For the randomization check, we examined whether participant characteristics were equally divided across experimental conditions using *F* tests and chi-square tests. For age, education,

and health status, we conducted 3 two-way analyses of variance with differences between “text/visualization added” and between “outcome of blood test results” as the between-subjects factors and age, education, and health status as the dependent variables. Health status was measured with a single question asking how the participants would rate their own health (1=excellent, 5=poor). For gender, we conducted a chi-square test with the combined experimental factors as one variable and gender as the other variable.

For the main analysis, a mixed analysis of variance was conducted with “text/visualization added” and “outcome of blood test results” as the between-subjects factors and “pretest measure of patient health engagement” versus “posttest measure of patient health engagement” as the within-subjects factor or repeated measure. Main effects of the between-subjects factors (ie, “text/visualization added” and “outcome of blood test results”) and within-subjects factor (ie, “pretest measure of patient health engagement” versus “posttest measure of patient health engagement”) were calculated. Furthermore, the interaction effect between the between-subjects factors (ie, “text/visualization added” \times “outcome of blood test results”), two-way interaction effects between the between-subjects and within-subjects factors (ie, “text/visualization added” \times “pretest vs posttest” and “outcome of blood test results” \times “pretest vs posttest”), and three-way interaction effect between factors (ie, “text/visualization added” \times “type of blood test results” \times “pretest vs posttest”) were assessed. Simple effects analyses were conducted in case of significant interactions between variables.

Results

Sample Characteristics

Of the 519 participants that started the survey, 487 had sufficiently complete data (ie, $\geq 60\%$ of the PHE measure completed). Table 2 shows the descriptive statistics of these 487 participants. Participants were, on average, 53 years old (mean 52.82 years, SD 15.41 years) and reported to be in good to very good health (mean 2.65, SD 0.87). About half of the participants were female (245/487, 50.3%), and most people had completed a middle level (219/487, 45.8%) or higher level (222/487, 46.4%) of education. The randomization check presented no significant differences between the 6 experimental conditions with respect to gender ($\chi^2_5=7.52$, $P=.19$), age, ($F_{2,472}=0.32$, $P=.73$, $\eta^2=.00$), education ($F_{2,472}=0.00$, $P=1.00$, $\eta^2=.00$), and health status ($F_{2,472}=0.13$, $P=.88$, $\eta^2=.00$). No control variables were included in the analyses.

Table 2. Sample characteristics (N=487).

Characteristics	Values
Age (years), mean (SD; range)	52.82 (15.41; 24-90)
Gender, n (%)	
Male	242 (49.7)
Female	245 (50.3)
Education^a, n (%)	
Low	37 (7.7)
Middle	219 (45.8)
High	222 (46.4)
Health status ^b , mean (SD; range)	2.65 (0.87; 1-5)

^aValues for education do not add up to 487 due to missing data.

^bSelf-reported health status (how would you rate your own health) ranges from 1 = excellent to 5 = poor.

Effects of the Outcome of the Blood Test Results

We found that the outcome of the blood test results, regardless of the portal design, impacted PHE after exposure to the blood test results ($F_{2,481}=6.65$, $P<.001$, $\eta_p^2=.03$). Receiving normal blood test results did not significantly decrease PHE (mean_{T0} 5.27, SE 0.10; mean_{T1} 5.10, SE 0.11; mean difference 0.17, SE 0.09, $P=.07$), but PHE significantly decreased after receiving abnormal blood test results (mean_{T0} 5.35, SE 0.10; mean_{T1} 4.69, SE 0.11; mean difference 0.66, SE 0.10, $P<.001$) or partially abnormal blood test results (mean_{T0} 5.16, SE 0.10; mean_{T1} 4.75, SE 0.11; mean difference 0.41, SE 0.10, $P<.001$).

Effect of Textual and Visual Explanation

Furthermore, adding text and visualization that explained the blood test results impacted PHE after exposure to blood test results ($F_{1,481}=16.83$, $P<.001$, $\eta_p^2=.03$). Although receiving blood test results with additional text and visualization significantly decreased PHE after receiving the results (mean_{T0} 5.33, SE 0.08; mean_{T1} 5.14, SE 0.09; mean difference 0.19, SE 0.08, $P=.02$), this decrease was significantly larger when blood test results were presented without explanatory text and visualization (mean_{T0} 5.19, SE 0.08; mean_{T1} 4.55, SE 0.09; mean difference 0.64, SE 0.08, $P<.001$).

Interaction Between the Type of Outcome of the Blood Test Result and Textual and Visual Explanation

A significant interaction effect between the outcome of the blood test results and the addition of explanatory text and visualization revealed a nuanced insight into how PHE develops after being exposed to blood test results. It showed that, for all outcomes of blood test results, a lack of explanatory text and visualization decreased PHE after being exposed to the results ($F_{2,481}=3.83$, $P=.02$, $\eta_p^2=.02$). More specifically, this decline occurred for normal blood test results (mean_{T0} 5.02, SE 0.14; mean_{T1} 4.73, SE 0.16; mean difference 0.29, SE 0.13, $P=.03$), abnormal blood test results (mean_{T0} 5.39, SE 0.14; mean_{T1} 4.61, SE 0.09; mean difference 0.77, SE 0.13, $P<.001$), and partially abnormal results (mean_{T0} 5.16, SE 0.15; mean_{T1} 4.31, SE 0.16; mean difference 0.85, SE 0.14, $P<.001$). However, when explanatory text and visualization were added to the blood test results, we found no significant decline in PHE for normal (mean_{T0} 5.51, SE 0.14; mean_{T1} 5.46, SE 0.16; mean difference 0.05, SE 0.13, $P=.71$) and partially abnormal (mean_{T0} 5.16, SE 0.14; mean_{T1} 5.19, SE 0.16; mean difference -0.03 , SE 0.13, $P=.81$) blood test results. Yet, in the case of abnormal blood test results, even with explanatory text and visualization, PHE significantly decreased after receiving the blood test results (mean_{T0} 5.31, SE 0.15; mean_{T1} 4.73, SE 0.17; mean difference 0.54, SE 0.14, $P<.001$). These findings are presented in [Table 3](#).

Table 3. Descriptive statistics for patient health engagement (PHE) before (T0) and after (T1) exposure to the patient portal across the experimental conditions (N=487).

Experimental conditions	n	PHE at T0, mean (SE)	PHE at T1, mean (SE)	P value
Normal blood test results				
Without text	83	5.02 (.14)	4.73 (.16)	.03
With text	82	5.51 (.14)	5.46 (.16)	.71
Partially abnormal blood test results				
Without text	87	5.16 (.15)	4.31 (.16)	<.001
With text	74	5.16 (.14)	5.19 (.16)	.81
Abnormal blood test results				
Without text	78	5.39 (.14)	4.61 (.09)	<.001
With text	83	5.31 (.15)	4.73 (.17)	<.001

Discussion

Principal Findings

The aim of this study was to discover whether the way in which blood test outcomes are presented in a patient portal is associated with PHE and whether this varies across different blood test outcomes. Adding textual and visual explanations to blood test results minimizes the decline in PHE when receiving blood test results in an electronic patient portal. When presenting blood test results through an existing patient portal, the group that received explanatory text and visualization in addition to their results experienced less of a decline in PHE than the group without these features. This was particularly true for patients who received normal and partially abnormal results (ie, combination of normal and abnormal results). For patients who received abnormal results for all three blood tests, health engagement significantly decreased independent of whether explanatory text and visualization were added. It can be concluded that adding text and visualization to a patient portal can attenuate PHE and therefore involve patients more in their health management, but only when blood test results are normal or partially abnormal.

Comparison With Prior Work

The focus of our study was to gain insight into how providing explanatory text and visualization, when presenting blood test results via a patient portal, influences PHE. While previous research has shown that patients are generally satisfied with the use of a patient portal to check their blood test results [16], there are also concerns with such portals.

One recurring concern with patient portals is the fear of the misinterpretation of results [9,10]. For example, in a study by Korngiebel et al [26], clinicians' main concern was that providing blood test results to patients without explanation could lead to confusion due to the sensitive and complicated nature of the test results. Especially divergent results would have to be carefully shown. Although our results cannot confirm if the nature of the feelings of our participants are due to confusion, it does show signs of fear, as lower PHE is associated with greater emotional immobilization. Participants who received normal or partially abnormal results in the "standard" way showed a significant decline in PHE, while health engagement

in patients who received explanatory information and visual support remained at the same level as at baseline.

In this study, we did not distinguish between the added value of explanatory text only and the added value of visualization only. Hence, we do not know which of these two features was the "active ingredient" or whether the combination of the features caused the effectiveness of the patient portal. In two previous studies, information provision in a patient portal was evaluated in isolation. In the first study, visual support using a color scheme to differentiate between normal results and divergent results was positively evaluated by elderly patients [27]. In the second study, veteran patients did not have extra text available but instead were given a search bar to find relevant health information themselves [28]. The veterans evaluated the search bar positively. Both these studies based the evaluation of the patient portal on opinions, whereas our study measured effectiveness in terms of PHE.

In addition, our study measured PHE using a questionnaire. Previous studies have used different ways to measure (patient) engagement. To illustrate, Phelps et al [29] defined engagement in terms of portal usage and measured it by monitoring the number of logins. They found an increase in logins, for instance shortly before meeting a physician, and results were therefore seen as positive. We used a different operationalization of engagement, including emotions and cognitions that test results can evoke, which resulted in a more nuanced picture of how people can respond upon being confronted with blood test results. The explanatory text and visualization had a positive influence on PHE, such that it reduced the decline in engagement after being exposed to blood test results. It did not improve PHE compared to the baseline measure. However, since we were studying how people react upon exposure to (potential) risk information, it seems to make sense to aim for a reduction of negative reactions rather than for an increase of positive reactions.

Strengths and Limitations

A strength of our study is that it systematically tested the impact of patient portal design on PHE in a highly controlled experimental setting. Although patient portal designs have been introduced to patients, these have not been studied yet in terms of how their design can impact PHE. In addition, our

measurement of PHE gave a broad depiction of PHE through patients' feelings, thoughts, and behaviors. Therefore, our study design gives this study a good foundation for its conclusions and implications.

There were also some limitations to our study. The first one is the potential bias in our sample. Although the sample was randomly selected from the Nivel Consumer Panel, which represented a relatively diverse group of patients, the participants of this panel are people who agreed to fill out questionnaires about health and health care. This means that there is good reason to believe that a majority of the people have, at least to some extent, affinity with their personal health (and health care). Furthermore, it can be assumed that the average panel user has a higher health literacy than normal. Health literacy entails the capability of obtaining, processing, and understanding information about health and health services [30]. If this assumption holds true, it is relevant to consider that affinity with health care might coincide with a better understanding and processing of health care information. Thus, extra information might not be as vital to them as to those with lower health literacy. In that sense, our sample resembled the target group of the portal with added text, as both our questionnaire and the portal require some level of functional literacy.

The necessity for participants to empathize with a fictional case was another limitation. Actual patients, for whom results might indeed have an impact on their life, might have reacted differently to the results of the blood test as they might be expected to be more emotionally involved. Based on the meta-analysis by Van Vliet et al [23], we do not expect that the results in actual patients will be weaker than in the current sample of analog patients, and they might even be stronger in actual involved patients. Thus, a replication of our study with actual patients would be of added value. Moreover, we used the original 9-item PHE scale [3] as the starting point for our measurement while rephrasing and shortening it for the purpose of our study, resulting in a scale with high internal consistency. The reason for doing this was that there is no scale available that is validated for the case in our study (tiredness).

Another possible limitation is the specific design of our portal. Our results could not cover all portal designs, so the scope of the study may be limited and not generalizable to other patient portals. For instance, the colors of our "complementary" portal design could have influenced the feelings of the participants. Research has shown that the color red can evoke feelings with patients [31]. The color orange might cause an unnecessary reaction as well, since it can be associated with danger or a sign for increased attention. It could therefore be that a participant who viewed a full or partially orange result were more anxious, although an abnormal result does not automatically mean a danger to your health or the need for immediate medical intervention. Future research can address the consequences by implementing more neutral colors. This way, a patient's anxiety can be ascribed to the conclusion of the blood test result and not stimulation by a bright color. Finally, as mentioned before, our existing portal had two features: additional text for explanation and added visualization for understanding the blood

levels. The downside of this is that a distinction cannot be made between the impact of the text and that of the visualization. If electronic patient portals are to be improved, it is necessary to understand if the limiting impact on the decline in PHE is due to either one of the features or perhaps the interaction between them.

Clinical and Research Implications

Our study has provided insight into how portal design can benefit PHE. Our results suggest that institutions that use a patient portal for blood test results might want to consider adding complementary information and visual support. Further testing of patient portal features is recommended, but institutions would do well to start adding visualization and textual support to their portals as this can benefit PHE. Adding text and visualization that explain the blood values and the implications of an abnormal result might support their patients in their health management. It might lead to patients who are more involved in their diagnosis and treatment, which could lead to, for instance, patients being more comfortable voicing concerns or asking questions. As mentioned, there is a possibility that our sample consisted of participants with an above-average health literacy. Therefore, future research could focus on patients with below-average health literacy who might need a different portal design. Yet, more research among actual patients is needed to test the portal with patients who are personally involved and therefore more concerned about the outcomes of blood test results. For example, in case a fictional study is chosen, this fictional case could include a disease with a higher emotional impact and familiarity, such as cancer. For such a disease, a more intense reaction could occur while viewing blood test results, such as relief or anxiety, which in turn could have a stronger effect on PHE. However, ethical considerations should be taken into account, as participants often do not know that they are being confronted with such an emotional case. A warning up front for the participant might be considered if the need for a more emotional investment is deemed necessary. Lastly, we used an adaptive version of the validated, original PHE scale. By deleting 4 items, it is possible that it did not cover the full domain of PHE (ie, did not measure the domains of feelings, thoughts, and behaviors as fully as the original scale).

Conclusion

Patient portals have been designed to improve patient involvement. When blood test results are communicated to patients, it can negatively affect their PHE and consequently their involvement in their health management. However, when these outcomes are supported by explanatory text and visualization to help interpret the outcomes, the decrease in PHE can be attenuated, especially when test results are partially normal. As receiving test results can cause feelings of uncertainty in patients, which can lead to lower PHE, our results suggest that explanatory text with visualization can cause feelings of relief in patients. Future research should focus on repeating the experiment with actual patients who receive their own blood test results to test whether the results hold in more ecologically valid settings.

Conflicts of Interest

BS, NB, JvW, AB, and LvD do not have conflicts of interest to declare. AG, ETK, and SvD are employees of Saltro, the organization that developed the portal that was tested in this experiment.

Abstract

Background: Patients within safety-net settings are less likely to access health information on patient portals, despite expressed interest. Family and friends are important resources to assist these patients (ie, Medicaid recipients, older patients, patients with limited English proficiency) in navigating health systems, and provider support of the use of patient portals among these groups may also facilitate caregivers' use of their patients' portal.

Objective: Because safety net providers work closely with caregivers to care for their patients, we used qualitative methods to explore safety net providers' perspectives on portal use among caregivers for their patients, especially as there is limited literature about caregivers' use of portals in the safety net.

Methods: We conducted 45- to 60-min semistructured telephone interviews with providers from three large California safety-net health systems. The interviews focused on providers' experiences with caregivers, caregiver roles, and how the portal could be leveraged as a tool to support caregivers in their responsibilities. A total of three coders analyzed the interview transcripts using both deductive and inductive approaches and established a consensus regarding major themes.

Results: Of the 16 participants interviewed, 4 specialized in geriatrics, and all held a leadership or administrative role. We described themes highlighting providers' recognition of potential benefits associated with caregiver portal use and specific challenges to caregiver engagement.

Conclusions: Providers recognized the potential for portals to improve information delivery and communication by helping caregivers assist socially and medically complex patients in the safety net. Providers in safety net sites also discussed a clear need for better ways to keep in touch with patients and connect with caregivers, yet security and privacy are perhaps of higher importance in these settings and may pose challenges to portal adoption. They noted that caregivers of patients in the safety net likely face similar communication barriers as patients, especially with respect to digital literacy, health literacy, and English proficiency. Further research is needed to assess and support caregivers' interest and ability to access portals across barriers in health and

digital literacy, and English proficiency. Portal platforms and health systems must also address specific strategies to uphold patient preferences while maintaining privacy and security.

KEYWORDS

patient portal; caregivers; vulnerable populations; digital divide; mobile phone

Introduction

Background

Growing evidence on the benefits of patient engagement has fueled health systems' focus on patient portals as a central access point for the future of primary care [1,2]. The financial incentives of the Meaningful Use Program, as part of the US health care reform in 2014, spurred a rapid uptake of patient portals across health systems nationwide [3-5]. Emerging national evidence in the last 5 years indicates that the digital divide is shrinking, as 80% of the US population owns internet-accessible smartphones, without differences by race or ethnicity and with few differences across income categories nationally, especially when it comes to mobile use [6,7].

Despite improved health information technology (IT) access, there is a large body of evidence demonstrating significantly lower use of digital health care tools among underserved populations, underscoring the need for more research to understand the contextual factors affecting their use [8,9]. Vulnerable patients within safety-net settings (eg, low socioeconomic status, under- or uninsured, limited English proficient [LEP], aging, and physically or mentally disabled) are interested in accessing their health information on patient portals but are less likely to actually do so. Numerous studies have shown that there is a high level of patient interest in portals, repeatedly documented among LEP populations, Medicaid/Medicare recipients, and older patients [10-14]. A 2014 survey of Spanish-speaking patients in a Los Angeles Federally Qualified Health Center found that the majority of patients had computer access (66%), internet access (78%), a current email account (78%), or a smartphone (71%) and that 75% of patients were interested in using a patient portal [10].

Family and friends are important resources to assist these underserved populations (especially those that are Medicaid recipients, older patients, or LEP) in navigating health systems, and provider support could facilitate their portal engagement. Caregiver engagement with a patient's portal may range from simply assisting the patient to log on and use the portal to logging onto a patient portal for the patient (unofficial patient *surrogate*) all the way to acting as a registered proxy for portal access (where caregivers are granted their own registered access to a patient's health information on the patient portal with the patient's permission) [15,16]. Older patients, especially those who are LEP, tend to navigate health system processes with family members or close friends who schedule and attend medical visits, coordinate care, manage medications, assist with self-care tasks, and facilitate transitions across care settings [15,16]. Patients with low health literacy similarly benefit from the involvement of trusted family or friends during medical visits [17,18]. Prior studies among older patients have confirmed

that family members facilitate patient access and use of the patient portal [19,20] and utilize the patient portal for the patient [21-25]. Given that these patients are interested in sharing electronic health information with family members or close friends [19,20,26,27], tailored strategies are needed to engage family members or friends in accessing health care digitally, especially in safety-net settings with a majority proportion of vulnerable patients and where caregivers play a key role in patient care.

The growing role of caregivers and caregiver/proxy portal use among vulnerable patients presents a potential well-aligned digital strategy for reducing racial/ethnic disparities in health that can be facilitated via already available health IT. However, buy-in from physicians and other health care providers will be important in promoting patient portals on this next level, especially in safety-net settings [28,29]. The aim of this qualitative study was to explore safety-net providers' perspectives on caregiver/proxy portal use.

Methods

Design and Study Setting

The study was approved by the University of California, San Francisco and University of California, Los Angeles institutional review boards. For this descriptive, qualitative study [30], we conducted individual telephone semistructured interviews with a purposive sample of physicians or providers (n=17), working in a California safety-net setting in Los Angeles, San Francisco, or Alameda County. Los Angeles participants were recruited from the Los Angeles County Department of Health Services (LAC DHS) system. LAC DHS forms the core of the health care safety-net for indigent populations in Los Angeles County, the largest, most ethnically diverse county in the United States. LAC DHS serves more than 10 million residents and provides over two and a half million ambulatory visits every year [31-33]. In northern California, providers were recruited from the San Francisco Health Network (SFHN) and the Alameda Health System (AHS). The AHS is the East Bay's (Oakland area) public health system with 5 hospitals and 4 primary care clinics, whereas SFHN is San Francisco City's and county's public health care system, providing primary care at 14 clinics, youth-focused care at 11 clinics, and care at a hospital serving over 1 million residents. The internet patient portals for the safety-net health systems included in the study allow patients to view clinical data (laboratories and radiology reports), refill medications, request/change appointments, message their health care teams, read about their prior and current diagnoses (links to educational content), and view/download their medical records.

Participants and Recruitment

From April to November 2018, we recruited and interviewed providers from the LAC DHS, SFHN, and AHS. Providers were sought if they had clinical activity in a safety-net health setting and/or held a leadership role in any safety-net clinical setting. Los Angeles participants were recruited via personal recommendations from the medical director of digital health services in LAC DHS. The SFHN and the AHS providers were recruited via recommendation from study coinvestigators. We conducted 45- to 60-min semistructured interviews with health providers from these 3 large California safety-net health systems. Participants were interviewed via telephone. AC, AGC, WS, and CL conducted the interviews on multiple days until at least three providers were interviewed from each of the 3 health systems. Participants were provided with a US \$25 gift card after completing their scheduled interviews.

Data Collection

The semistructured interviews focused on providers' experiences with caregivers, the roles caregivers play, and how the portal could be leveraged as a tool to support caregivers in their responsibilities. The discussion questions were modified from projects led by study investigators who examined barriers and facilitators to portal use to develop a randomized trial on patient portal training [34]. This prior research highlighted the limited knowledge and understanding of caregivers' use of the patient portal.

Discussion introductions included participants' self-describing clinical and administrative roles. Participants were then asked about their experiences with patient caregivers (definition, types of caregivers, and positive and challenging interactions). They were subsequently tasked to describe strategies that they have observed caregivers take on with patient health management. We asked participants about how the patient portal affects these caregiver strategies, what they thought was useful, and how they envisioned the portal could affect these patients' and caregivers' care. The discussions wrapped up with a

conversation about what the health system could do to help improve caregiver and patient engagement with the portal.

Analysis

Interview discussions were audio recorded and transcribed, reviewed for accuracy, and deidentified. AC and AGC independently read and summarized 6 transcripts over multiple theme meetings, applying inductive and deductive methods to identify the spectrum of themes encountered for each of the interviews with accompanying example quotations. AC and AGC then cross-referenced their independently developed list of themes. Through codebook discussions, they reached a consensus for a more final codebook. AC and AGC then coded 3 transcripts independently with this codebook for validity. The definition for each theme (code), with the final example quote, was developed by AC, with iterative feedback from the AGC and the entire group, until a clear consensus was achieved. Using the established codebook and definitions, a third coder (ML) analyzed the transcripts using Dedoose version 8.2.14. AC and AGC reviewed the analysis by ML and established a consensus regarding any other discrepancies in themes and corresponding quotes [35].

Results

Participant Characteristics and Theme Categories

Of the 16 participants interviewed, 4 specialized in geriatrics, and all held a leadership or administrative roles, as shown in Table 1. All the participants worked in primary care settings, including a speech language pathologist.

We described primary themes highlighting safety-net physicians' and providers' recognition of potential strong benefits associated with caregiver portal use and specific barriers to caregiver engagement. The 4 major themes are separated into 2 large categories: (1) positive aspects of portal use by caregivers (Table 2); and (2) challenges to address for portal use by caregivers (Table 3). These show major themes, subthemes, frequencies, and quotes.

Table 1. Safety-net provider participants' characteristics.

Clinical specialty	Safety-net role
Geriatrics	Physician, Medical Director
Geriatrics	Physician, Department Chief
Geriatrics	Physician, Director of Primary Care
Geriatrics	Physician, Outpatient Care Medical Director
Internal medicine	Physician, Clinical Lead
Internal medicine	Physician, Clinical Lead
Internal medicine	Physician, Health Care Executive
Internal medicine	Physician, Medical Director
Internal medicine	Physician, Medical Director
Internal medicine	Physician, Resident Preceptor
Internal medicine	Physician, Director of Outpatient Care
Internal medicine	Physician, Director of Primary Care Quality
Family medicine	Physician, Assistant Medical Director
Family medicine	Physician, Health Care Executive
Family medicine	Physician, Health Care Executive
Occupational therapy	Speech Pathologist, Health Care Executive

Table 2. Themes and subthemes on positive aspects of portal use with exemplar quotes.

Themes/subthemes	Quotes
Caregiver designation in the electronic health record (n=25)	
	<ul style="list-style-type: none"> “I record it in my notes...at the first part of workflow...registration staff is collecting information about emergency contacts and alternate contacts...depending on what the patient or their caregiver says at registration, there might be something entered into the chart in that capacity.” “Sometimes, because usually it would be because the note would say, ‘Accompanied by daughter’ or ‘Discussed with daughter’, ‘Discussed with son’, ‘Discussed with caregiver’, ‘Discussed with IHSS [in home support services] worker,’ but not all the time.” “I don’t think uniformly. You’ll see it (caregiver information) in the body of the note, not always in the, social history section. And to tell you the truth, our EHR doesn’t have a good section on caregiver information...in terms of like whose number should you call? Do they have a caregiver they can call?” “[I’m] trying my best to collect the information and actually put it in the EHR so I know who they are...oftentimes, after I did that, [with] a group of patients, I always follow up if they live in supportive housing, or they have a case manager and so that’s external, nonfamily caregiver visit their office, followed up by email to whoever their support people are in the community to make sure that they know what the next steps are.”
Caregiver use and potential use of the portal (n=55)	
Portal as a tool to assist caregivers with standard health care tasks (n=32)	<ul style="list-style-type: none"> “I think caregivers using the patient portal could co-manage patient’s health, could be a huge asset to the caregiver and the provider... it’s not infrequent that the patient or the patient and the caregiver show up to appointments saying they ran out of their meds two months ago.” “Usually there’s more than one caregiver, where there’s a network and may have varied involvement. Like with my sisters and me, we have this constant flow of information, and having a way to put it all in one place to share easily is really important.” “...they’re just rolling out this new scheduling tool that will allow internal schedulers to be able to search for ways of grouping their appointments. So, the [OT, PT,] speech could all happen on the same day. If that tool could be made available to a caregiver so they can say ‘Okay, I wanted to have doctor’s appointments at this and this and this all on the same day’, I think that would be really powerful.”
Portal as a tool to directly support the caregiver (n=7)	<ul style="list-style-type: none"> “Empowering the caretakers to be able to use technology decreases their stress level.” “I think respite is also a big thing, caregiver relief and caregiver fatigue is a big problem sometimes, and having access to joint behavioral health services, or like couple counseling, or parent-child counseling in the study of chronic disease, I think it’s something super underutilized. That could probably help a lot with the challenges.” “I know there’s a lot of groups that are working on this or have published. I know at UCLA in geriatrics, they’ve done an Internet caregiving education course, and I know at Stanford, they put together Caregiving Ed. And at the VA, there’s several well published evidence-based caregiving teaching programs, but our patients certainly don’t have—or a lot of my patients don’t have access to that.” “I would be really interested in the opportunity to do more training for caregivers. I think that’s a great business opportunity, because so many caregivers have no idea what they’re doing and would be happy to get trained. You can imagine the range of trainings, but our organization or your organization, or you know some private—any big county—I could imagine offered some form of training for caregivers. I think having a portal will help hopefully and I think having processing in place to clarify what can be shared and what can’t be shared with caregivers, if it’s documented well.”
Expanding portal functionality for caregiver use (n=18)	<ul style="list-style-type: none"> “For caregivers who have a homebound elder, to be able to, you know, put on their FaceTime and for me to see what’s going on that would be amazing.” “...allowing patients to search and contribute to the medical notes before the visit, the medical records, typing in their symptoms. I think there should be conversations of getting caregivers involved in the patient’s care.” “If people just keep track of hey, someone’s calling not for themselves and just kept a running list, and then you do active outreach for anyone who is calling not for themselves.”

Table 3. Themes and subthemes on challenges to portal use with exemplar quotes.

Themes/subthemes	Quotes
Portal privacy and security in the caregiver-provider-patient triad (n=38)	
Portal triad relationship (n=7)	<ul style="list-style-type: none"> • “The one downfall of caregivers having access is, is there any loss in translation or, if some plan is made on the portal, is that being followed through by the caregiver?” • “One of the few that I communicate with is a husband and wife patient and this is a challenge...because then I have to document it in her, in his chart, where her messages get documented in his chart... and it’s worked because she has direct access to me and then he has direct access too, but she uses her account to...manage his health... And, yeah, I thought it would be nice if she could switch back and forth.” • “If it’s something I can communicate to them immediately, then I send a message through the portal. Then, if there’s anything else that I might need to communicate with them, and I don’t need to call them, then I’ll do it through the portal. A lot of it is dependent on, ‘What can I communicate briefly in writing without creating [confusion] on their part or some more questions than answers?’” • “I’m observing body language, so on rare occasions, if I’m concerned that perhaps the person feels like they can’t ask the other person to leave the room, then I go ahead and...When I’m gonna be asking something sensitive in the interview around social history or any history, I’ll actually ask the other person to step out of the room and wait in the waiting room and I just normalize that and say, ‘You know, I always do this to respect confidentiality’. That’s in person, so what do you do when tech comes in?” • “If you build a system that is specifically asking, ‘Is this a proxy person?’ and kind of asking for that designation right up front and putting it in black and white, you do run the risk of—of having more scrutiny and I think it’s appropriate.” • “I think that what we’re doing right now is we are just in the infancy of using our portal for patient communication.” • “And when I get an odd message or a little crazy message, you know, or someone requesting whatever, I screenshot it and I send it to the site managers and I tell them to call them on the phone to get more information.”
Control of shared access (n=13)	<ul style="list-style-type: none"> • “When we see some research that suggests that some patients don’t want the entire portal revealed to their loved ones, but maybe part of it...and so patient privacy is—is a big concern. A husband may not want his wife to know that he was a prior IV-drug user from a different life.” • “I have mixed views because we try the different role for parents from the portal once the kid at 13. And sometimes they want to come for birth control and they didn’t want their moms to know. So, I don’t want the moms to see the kid’s the portal.” • “I mean just mostly with like the proxy access...they’ve just had a lot of questions and concerns around, ‘When is it okay? Do we need a legal document that states, “Yes, ma’am. They are my legal healthcare proxy,”’ or if they’re, on mild dementia, but they say, ‘No, let her do it’, is that sufficient?”
General portal security and technology concerns (n=11)	<ul style="list-style-type: none"> • “I do have some HIV patients who won’t join because they’re just afraid of the internet, in general...I think it’s a broader concern beyond just their HIV status but just that they don’t think it’s safe to have their information in the cloud basically, because it could be stolen or, or utilized in a way that’s negative.” • “How do you build a portal that respects patient privacy? You also wonder if adding a caregiver affects the security of the health data.”
Barriers to caregiver enrollment and use (n=46)	
	<ul style="list-style-type: none"> • “The number of people [caregivers] who don’t have access to either a smartphone or the internet...I think is just the reflection of the income level and kind of resource constraints of our patient population.” • “I’m guessing that there would be times when people are concerned by the results that look abnormal or don’t understand them because no one explained it to them...” • “A lot of our patients just don’t really use like electronic technology and they don’t speak English, or they don’t have an internet connection or a computer.”

Positive Aspects of Portal Use by Caregivers

Table 2 displays themes and subthemes for the category describing positive aspects of portal use. In the theme, *caregiver designation in the electronic health record*, participants described various potential pathways for identifying caregivers via the electronic health record (EHR) and how this would be useful. Some participants also described the challenges of not having a workflow to readily integrate current caregiver

information into the EHR and how having such information available would make it easier for physicians and other providers to engage the caregivers during and outside of the clinic encounter. This was important, as the participants in the study noted multiple *caregiver types*, which are present in different ways for patients within safety-net settings: relatives, friends, case managers, in-home supportive services, and social workers.

Participants also discussed *caregiver use and potential use of the portal*, detailing current uses of patient portals by caregivers and aspirational ideas about what the patient portals could potentially do for safety-net caregivers in terms of facilitating patient care. This theme was organized into 3 subthemes: for subtheme 1, *portal as a tool to assist caregivers with standard health care tasks*, participants mentioned ways that the current versions of their patient portal supported or eased the job of the caregiver by facilitating simple health care tasks for the patient via the portal (eg, obtaining medication refills or making appointments), making it easier for the caregiver to care for the patient (as they might have to spend less time on the phone making calls and possibly decreasing the need for face-to-face visits).

For subtheme 2, *portal as a tool to directly support the caregiver*, participants discussed how portals could provide well-being/resources specifically tailored for the caregiver. For example, they mentioned that patient portals could be a way to provide explicit support to caregivers (eg, preventing caregiver burnout) and connect caregivers directly to community resources (including information about self-care and programs that assist caregivers in the safety-net) that make the caregiving job more manageable. They also noted that such resources could include a tutorial on caregiver education/navigation. The portal could provide caregivers access to tools on how to care for patients and/or how to navigate a complicated safety-net health care and social service system.

For subtheme 3, *expanding portal functionality for caregiver use*, discussions centered on a wish list of what the portal could do in the future (Portal 2.0) for caregivers. Participants mentioned how technology could help paint a better picture of the patient and caregiver via telehealth (access to home context) and more frequent communication. Such modalities could facilitate the implementation of evidence-based initiatives such as advanced care planning in the safety-net.

Challenges to Portal Use by Caregivers

Table 3 displays themes and subthemes related to challenges to portal use by caregivers. The major theme, *portal privacy and security in the caregiver-provider-patient triad*, encompassed unresolved issues that these participants noted in communicating with the patient and caregiver through the portal. They raised several challenges that may have not been fully thought through yet as patient portals are being marketed to caregivers in the safety-net. These were summarized in 3 subthemes.

For subtheme 1, *portal triad relationship*, participants described the nuances of building or managing a relationship with the caregiver, as well as the patient, through the portal. For example, many times throughout these discussions, physicians cited the many nuanced ways in which they would validate caregiver reporting during clinic visits (talk to patient and caregiver separately), check for caregiver abuse of the patient by examining the patient or reading body language, and simply also assess how the caregiver was doing with the burden. They noted that this subtle art of relationship management and checking in with a caregiver, which are essential features of the triad relationship [24,36,37], would be very difficult to achieve

via digital communication and expressed concern that some of these needed in-person checks and balances would be lost via the current version of our patient portals.

For subtheme 2, *control of shared access*, participants mentioned concerns about proxy access. For example, what if a patient allows a caregiver to log in as a proxy into their patient portal, but the patient does not want the caregiver to see their entire medical record? Or what if the proxy sends messages to the provider on the portal as the *patient*, but the provider is not aware that they are communicating with someone that is not their patient? This is an important concern in a safety-net population where patients may have sensitive diagnoses (such as sexually transmitted infections, illicit drug use, addiction, or mental illness) that have not been disclosed to the caregiver or other close friends or family because they carry some social stigma. Sensitive information on the portal could also reveal risks to family caregivers that they may not have been made aware of (genetic diseases or genetic risk factors). Participants also noted the simple workflow barriers to creating proxy login for caregivers. Although most systems have the potential to do this, most clinical settings do not outright offer it and/or facilitate the registration process.

For subtheme 3, *general portal security and technology concerns*, safety-net physicians made general comments about security or privacy issues with technology in health care. Providers worried that their patients and caregivers would not use a portal secondary to fears about their private data being accessed by outside parties (be *hacked*).

In the last major theme, *barriers to caregiver enrollment and use*, participants noted the challenges to enrolling caregivers as proxies into their patient's portal. Many of the barriers noted paralleled the general challenges to portal use among patients in the safety-net: decreased access to and familiarity with technology (low digital health literacy), lack of easy access to the internet at home, being LEP (when most of the portal is in English), fear of signing up because of immigration documentation status, lack of awareness about a patient portal in the safety-net, or lack of understanding of what a patient portal can do.

Discussion

Principal Findings

Patient portals and caregiver engagement in primary care both represent clear ways to improve our communication processes with vulnerable patients by making care more convenient and coordinated. However, even in large integrated delivery systems with established track records of portal use, there is very little research on the role that caregivers can play in terms of digital communication via the EHR. Our study echoes some of the prior literature recognizing the clear need for better functionality of portals for caregivers (specific content for them and better ways for patients to designate what types of information or access to share) [22-24]. We also shed light on some specific needs in this population, such as the needed support for caregivers with communication or language barriers (which is of high importance in safety-net settings).

Beyond the health care setting, there is already a *team* around many of our patients—family members and friends who serve as caregivers and trusted confidants when making health decisions. Health leaders must recognize the need to make it easier to connect with these trusted team members, in addition to the patient, when creating care plans together, especially as systems focus on the patient portal as a primary health management tool moving forward. The next version of portals can potentially improve the integration of telehealth options into the interface and provide resources that are specific to assisting caregivers, such as local resources, to reduce or prevent caregiver burnout. These innovations may be important for patients and caregivers in safety-net settings.

Participants brought up many important privacy and communication issues to resolve and improve to make portals work for safety-net caregivers and patients. Although most safety-net EHRs have the technical capability to create proxy account functionality [38], limited information exists regarding the use of shared access. Available data indicate that health system implementation of shared access functionality has been variable [39], but national estimates are that up to 30% of portal users have used the portal as a proxy for someone else (with about 50% of them as a formal caregiver/proxy login) [40,41]. Prior studies have evaluated patients' experiences with accessing and using their own patient portal account [21] and preferences for sharing their electronic health information with others [27,42,43]. These studies suggest that some patients would like the option of selecting the *level* at which a proxy caregiver has access to their complete medical record. As such, we found that addressing the privacy and security nuances of building a digital relationship with a caregiver in the safety-net was a major barrier to physician and provider participants being completely supportive of proxy patient portal use. In the safety-net, physicians have reported the need to provide limited portal views of *sensitive* information (eg, HIV results and prior intravenous drug use history) for patients who rely on family or friends as informal or formal caregivers. Many times, the option to use the portal is foregone by patients because of this current *all-or-nothing* access approach to patient information via a proxy login. One solution to this dilemma is to allow patients the ability to choose the level of proxy access a caregiver or family member will have. EHR vendors should be incentivized via health information policy to innovate, and safety-net health systems should advocate for more

patient-centered options around *level of access* to health data via proxy relationships, especially when patient privacy and security remain a top level of concern among safety-net patients. This is a feature that should be available to all patients and will resonate with several groups, including adolescents, older adults, and patients with some sort of impairment or disability, in other health care settings.

Limitations and Strengths

Among the limitations of this formative study are the small sample size and generalizability to other safety-net health care systems, which are different from the California settings included in the study. However, the purpose of this qualitative study is to generate initial insights about provider buy-in regarding portal potential for caregivers in the safety-net.

This is one of the few studies to probe into provider perspectives around the role of caregivers in portal use within the safety-net. We found that providers recognized the potential for portals to improve information delivery and communication, benefiting caregivers who are assisting socially and medically complex patients in the safety-net. These safety-net health care providers and leaders focused on expanding the functionality of the portal, so that it does *more* for caregivers.

Conclusions

Overall, safety-net systems that seek to maximize the use of portals in their communities must develop specific strategies to uphold patient preferences and innovatively support caregivers while maintaining privacy and security. Further work is needed to assess and support diverse caregivers' access to portals by addressing pivotal barriers, such as health or digital literacy and English proficiency [44]. Safety-net health systems provide health care for our most medically and socially fragile patients: populations that include patients with multiple morbid conditions, limited English proficiency, cognitive impairment, physical and mental disabilities, low literacy, homelessness, substance use disorder, justice involvement, and immigrant and refugee status. As they serve the most vulnerable, safety-nets are the ideal places to develop and refine the next patient and caregiver-centered iterations of the EHR and the patient portal. However, to make this tool work for our most vulnerable patients, we must take intentional steps to ensure that the patient portal can be effectively and efficiently deployed by their caregivers in the systems that serve these high-risk patients.

Abstract

Background: Giving patients access to their health information is a provincial and national goal, and it is critical to the delivery of patient-centered care. With this shift, patient portals have become more prevalent. In Alberta, the Alberta Health Services piloted a portal (MyChart). There was a need to identify factors that promoted the use of this portal. Furthermore, it was imperative to understand why there was variability in uptake within the various clinics that participated in the pilot.

Objective: This study aims to identify potential factors that could improve the uptake of MyChart from the perspectives of both users and nonusers at pilot sites. We focused on factors that promoted the use of MyChart along with related benefits and barriers to its use, with the intention that this information could be incorporated into the plan for its province-wide implementation.

Methods: A qualitative comparative case study was conducted to determine the feasibility, acceptability, and initial perceptions of users and to identify ways to increase uptake. Semistructured interviews were conducted with 56 participants (27 patients, 21 providers, 4 nonmedical staff, and 4 clinic managers) from 5 clinics. Patients were asked about the impact of MyChart on their health and health care. Providers were asked about the impact on the patient-provider relationship and workflow. Managers were asked about barriers to implementation. The interviews were recorded, transcribed verbatim, and entered into NVivo. A thematic analysis was used to analyze the data.

Results: Results from a comparison of factors related to uptake of MyChart in 5 clinics (2 clinics with high uptake, 1 with moderate uptake, 1 with low uptake, and 1 with no uptake) are reported. Some theoretical constructs in our study, such as intention to use, perceived value, similarity (novelty) of the technology, and patient health needs, were similar to findings published by other research teams. We also identified some new factors associated with uptake, including satisfaction or dissatisfaction with the current status quo, performance expectancy, facilitating conditions, behavioral intentions, and use behavior. All these factors had an impact on the level of uptake in each setting and created different opportunities for end users.

Conclusions: There is limited research on factors that influence the uptake of patient portals. We identified some factors that were consistent with those reported by others but also several new factors that were associated with the uptake of MyChart, a new patient portal, in the clinics we studied. On the basis of our results, we posit that a shared understanding of the technology among patients, clinicians, and managers, along with dissatisfaction with nonportal-based communications, is foundational and must be addressed for patient portals to support improvements in care.

KEYWORDS

patient portals; information technology; adoption

Introduction**Background**

The rising costs of health care services and the increased prevalence of chronic conditions necessitate transformative changes in health care delivery. Deliberations on these changes have focused on access to information and the interconnectedness of health information systems [1]. Providing patients secure access to their health information is a provincial [2-5] and national goal in Canada [6,7], and it is considered critical to the delivery of patient- and family-centered care [2-4]. Surprisingly, many portals have underperformed expectations in Canada [8] and in other jurisdictions [9,10]. Although patients today have greater access to their medical information than ever before, there is a need to identify the best way to provide this information and to understand the impact of the provision of medical information to patients on the health care providers.

To address the issues mentioned above, the Alberta Health Services (AHS), a province-wide health delivery organization, piloted a patient portal called eCLINICIAN MyChart (an AHS branding of EpicCare Ambulatory from Epic Systems, 2014 version) between 2016 and 2019 [11]. The goals of the study were to determine whether MyChart would help patients and their families participate actively in the maintenance and monitoring of their health information and to provide information that could be used to scale up the use of MyChart by documenting factors that both hindered and promoted MyChart uptake.

Objectives

We aimed to accomplish this goal by collecting data from both users and nonusers at the pilot sites. We focused on factors that promoted the use of MyChart along with the related benefits and barriers to its use, with the intention that this information could be incorporated into the plan for its province-wide implementation. To the best of our knowledge, this is the first study that has considered the perspectives not only of patients and health care providers but also of clinic managers and nonmedical staff, such as receptionists, on the impact of patient portal uptake. The timing of data collection began before the introduction of the portal to identify expectations held by health care providers' practitioners and managers. This approach to data collection was used to identify previously unknown or unanticipated factors that could limit the potential of patient portals for health care systems, including previously obscure power dynamics among clinical leadership. Portals are likely to have systemic groups of nonusers for reasons that have not been previously articulated. In this study, we sought to clarify why portals can, at times, fail to achieve their transformative potential. In parallel with this work, a quantitative survey was conducted on patient views of the portal [12], and the views of the clinicians and managers presented here complement those findings.

Methods**Research Question**

The research question was as follows: *What factors impacted the differences in uptake of the patient portal MyChart and what elements were deemed crucial for uptake and access for all end users?*

This question was developed by incorporating the principles of *diffusion of innovation* by Rogers [13] and the *theory of technology acceptance* by Davis [14]. Roger's theory focuses on explaining how and why new ideas and technologies spread, whereas Davis's theory focuses on the perceived usefulness of a technology to enhance performance [13,14]. By incorporating these 2 frameworks, we were able to consider the various theoretical approaches relevant when considering the uptake of a patient portal within a publicly funded health care system.

Ethics Approval

This study received ethics approval from the Research Ethics Board at the University of Alberta (Study ID: MS6_Pro00084135) and operational approval for the clinics included in this study from AHS (OA43157, OA43158, OA43159, and OA43160).

Design

Using a qualitative comparative case study design [15-17], we performed 56 in-depth semistructured interviews with clinic managers, health care providers, nonmedical providers (receptionists), and patients from 5 clinics that participated in the pilot. Comparative case studies involve the analysis and synthesis of similarities, differences, and patterns across 2 or more cases that share a common focus or goal [15]. In this study, each of the 5 clinics constituted a case. A comparison of cases provided an opportunity to learn more about factors that played a role in the uptake during a real-time patient portal implementation from the standpoint of study participants rather than from existing frameworks.

Study Setting

Alberta, Canada, has a publicly funded and managed health care system based on the principles of universal access to medically necessary services. AHS [18] is the largest provider of health care services in Alberta, delivering care to more than 4 million people. In 2016, AHS introduced a patient portal called MyChart that was connected to the central electronic medical record system called eCLINICIAN. This was carried out through a pilot where several self-selected clinics decided to participate; however, individual health care providers within the clinics were free to participate or not. MyChart allowed patients to view appointments, medical test results, and medication therapies and to communicate with their health care providers through a computer or an app on a phone or tablet. It was developed by the Epic Systems Corporation (Epic) and customized to fit the needs of AHS. The pilot was led by the eCLINICIAN MyChart Working Group, comprising physicians

from both family medicine and various specialties, technology experts, policy makers, and health care administrators.

Following ethics approval, 5 clinics in the pilot were selected for this study based on the number of patients enrolled in MyChart per clinic and the length of time each clinic had been using it. These clinics were considered minimal and safe users of the nonportal functionalities of the Epic product (eg,

eCLINICIAN). Three of the clinics were specialist clinics, 1 clinic was a community-based family practice clinic, and 1 clinic was a family practice clinic hosted within an AHS facility. The AHS family practice clinic was selected because although in principle they agreed to participate, they never enrolled any patients. The key features of the cases are outlined in Table 1.

Table 1. Case study characteristics.

Details of the clinic	Type of setting	MyChart patient enrollment, n ^a
Clinic 1: medium user of MyChart	Specialty clinic in academic setting	357
Clinic 2: high user of MyChart	Specialty clinic in academic setting	875
Clinic 3: low user of MyChart	Specialty clinic in academic setting	172
Clinic 4: high user of MyChart	General practice clinic in community setting	965
Clinic 5: no users of MyChart	General practice clinic in academic setting	0

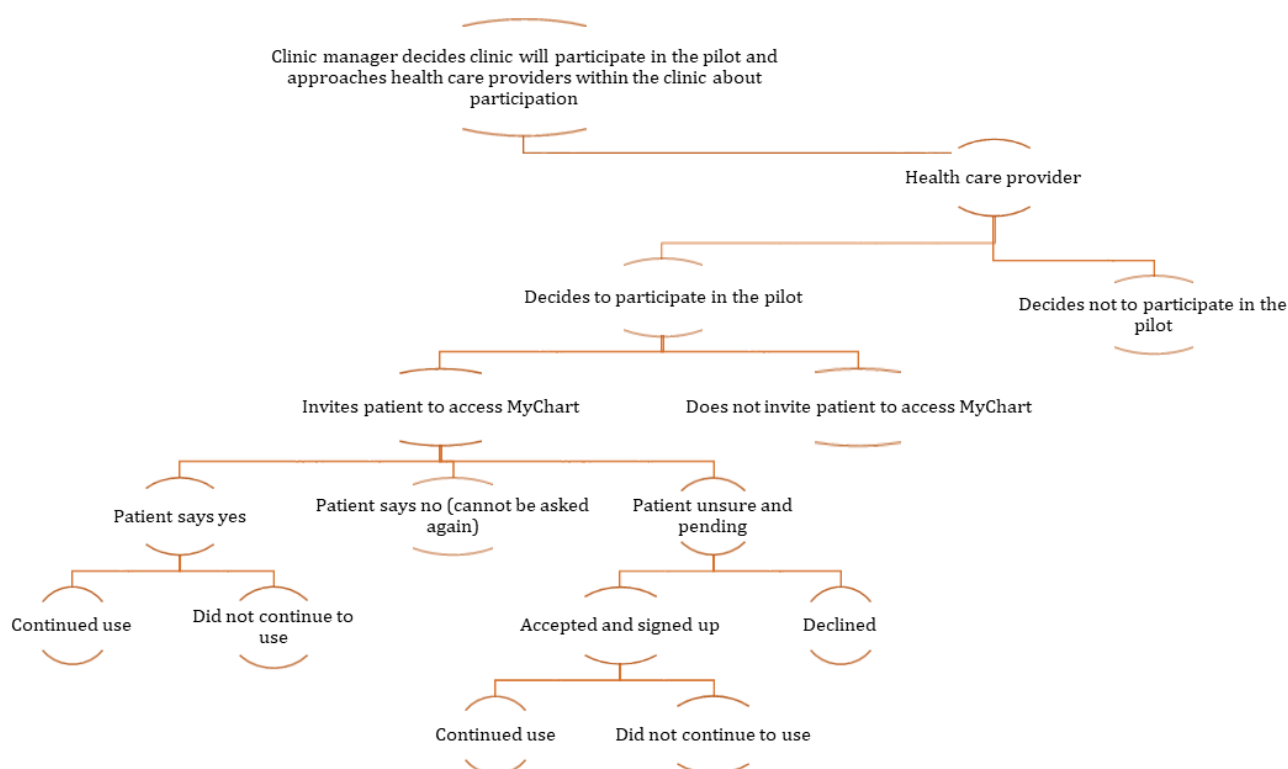

^aAs reported in April 2019.

Sample and Recruitment Strategy

Before deciding on the required study sample, the project team had discussions with the MyChart project team and the staff of

several clinics in the pilot to understand how its use evolved in each setting. On the basis of those conversations, MA developed a participant recruitment framework (Figure 1), which was reviewed by KO, TS, DM, and MB and then finalized.

Figure 1. Participant recruitment framework.

On the basis of this framework, we decided to recruit clinic managers and health care providers who did or did not participate in the pilot and patients who used or did not use MyChart, including proxy users. MyChart permits proxy access to family members who provide care to their loved ones.

Clinic managers and health care providers were recruited using a purposive sampling [19] approach. TG contacted each identified clinic, requested an introductory meeting with the

clinic manager, and responded to any follow-up concerns. The clinic managers invited health care providers (specialists, general practitioners, and/or nurses) to participate in these introductory meetings. MA developed the presentation and recruitment materials. DM and TS reviewed the materials. MA and MB attended these meetings, described the study, and discussed recruitment strategies for health care providers and patients within each clinic. After answering any questions, MA obtained

written consent from health care providers and other clinic staff who were willing to participate in the study. MA set up interviews with clinic managers and health care providers. During the interviews, we identified that only 1 clinic implemented the MyChart web-based booking and canceling appointments function, so all 4 receptionists (nonmedical providers) in that clinic were interviewed.

Patients were recruited using a recruitment card ([Multimedia Appendix 1](#)), which was handed out by health care providers at each clinic over a 2-week period. They had provided the card to all patients they saw during those 2 weeks. Patients contacted MA directly if they were interested in participating.

Data Collection

MA scheduled interviews and explained the study, answered questions, and obtained written consent from those who agreed to participate. The participants then completed a demographic information form and were assigned a deidentifying code used to maintain anonymity and track data. All recruited participants took part in an individual semistructured interview (conducted by MA face-to-face or by telephone) lasting between 30 and 45 min. Notes and reflections were written by MA immediately after each interview. The semistructured interview guides ([Multimedia Appendix 2](#)) were developed by MA, based on the research question, and then were reviewed by the other authors and revised based on feedback. To determine whether the interview guides required adjustments, MA evaluated the recordings of the first 2 interviews per group. No changes were made. All interviews were recorded digitally, transcribed verbatim, checked for accuracy, and then uploaded to NVivo 11 (QSR International) to facilitate analysis. Data collection and analysis occurred concurrently until no new dimensions of the participants' experiences were identified [20].

Data Analysis

The data collected guided the structure of the subsequent analyses, following the principles of inductive thematic analysis [21–23]. MA cleaned all transcripts and then read each transcript several times, coded transcripts for key ideas related to the research question, and grouped codes into preliminary categories. KO reviewed all codes and categories and discussed them with MA. Preliminary categories across cases and participant groups were organized according to recurring and emerging themes by MA and reviewed by KO and TS. As is common in qualitative research, the findings were built from the data [24]. The findings were then compared with those of other studies.

Several processes were undertaken to maintain the trustworthiness of the data [23], including establishing credibility by recruiting a diverse sample with different and sometimes opposing perspectives and maintaining a comprehensive audit trail in NVivo 11. To ensure transferability of the data, detailed descriptions of the sample and thick descriptions of findings were developed. Analytic rigor was enhanced through regular meetings of the research team to discuss emerging findings. As each interview was completed, all available interviews were reviewed collectively. Data saturation was reached after 25 patient and 20 health care provider interviews, but 2 more patients and 1 more provider were interviewed to ensure that important information was not missed. The demographic data were analyzed descriptively and added as case nodes in NVivo to explore factors associated with the adoption of MyChart.

Results

Demographic Characteristics

Our plan was to recruit patients who would fit one of the following categories: user (has access to MyChart and has used it at least once in the past 6 months), declined (offered but declined to sign up), did not continue to use (signed up but did not use), and proxy access user. We were able to recruit only 1 patient who declined and none who did not continue to use, as we had no means of obtaining information about discontinued usage.

We also recruited 1 caregiver who used MyChart under the proxy provisions and several caregivers who used the family member accounts. [Table 2](#) shows the patient respondents' demographics and reported conditions.

We were able to recruit several health care providers who were nonusers (1 provider elected not to participate in the pilot, 1 medical resident who was not aware that MyChart was part of the clinic where he or she was working, and 3 medical office assistants who were familiar with MyChart; however, as a result of the implementation process for MyChart in that particular clinic, they were not involved directly with MyChart). The specialty physicians were endocrinologists (n=3), neurologists (n=5), and gastroenterologists (n=5). [Table 3](#) shows the health care providers' and clinic managers' demographic information.

Overall, 56 participants were recruited ([Table 4](#); to see interview codes and the demographic characteristics per participant group, see [Multimedia Appendices 3 and 4](#)).

Themes

We coded each group of interviewees (clinic managers, health care providers, nonmedical staff, and patients) separately. As we were reviewing the transcripts and coding them, it became

evident that the concerns raised by nonusers were also raised by users of MyChart. Therefore, information collected from users and nonusers was aggregated. [Textbox 1](#) shows the identified themes.

Textbox 1. Themes per sample group.

<p>Patients</p> <ul style="list-style-type: none"> • Theme 1: My health, my responsibility, but I need the information to do that • Theme 2: Convenience, convenience, convenience • Theme 3: A few tweaks will do it • Theme 4: Do not take it away <p>Health care providers</p> <ul style="list-style-type: none"> • Theme 1: Of course we need it • Theme 2: Yes, it did some good things • Theme 3: Not all was great • Theme 4: Consider my needs <p>Clinic managers</p> <ul style="list-style-type: none"> • Theme 1: Time for some efficiency in communication • Theme 2: Heard great things about it • Theme 3: Heard about some issues as well • Theme 4: Change is needed <p>Nonmedical providers</p> <ul style="list-style-type: none"> • Theme 1: Great service for the patient • Theme 2: Needs some education • Theme 3: Need to maintain and expand

The themes from each sample group are described in more detail below, with direct quotations used to support the analysis.

Patients

A total of 27 patients from 4 clinics were interviewed. Four themes emerged from the interviews: (1) my health, my responsibility, but I need the information to do that; (2) convenience, convenience, convenience; (3) a few tweaks will do it; and (4) do not take it away.

Theme 1: My Health, My Responsibility, but I Need the Information To Do That

When initially offered, patients were unsure what to expect from a system that would give them access to their own health care information—information that had been difficult to obtain previously. Furthermore, participants noted that the introduction to MyChart was not as convincing as it might have been, thus they were unsure if there was any benefit for them. Patients decided to enroll and use MyChart based on their interest in being more proactive in their own health:

First, I am convinced that my health is MY responsibility, not the physician or treatment team. They are here to advise and instruct and carry out detailed procedure that I accept. I must be convinced of the efficacy of treatment options. I am not a blind follower of absolute directions from the all-knowing care-teams. I always try to enter into a meaningful dialogue about treatment options and expected results, and I expect the treatment teams to deal with me professionally and personally. [1PAT3]

Patients noted that seeing their medical results did not cause them to be anxious or call the doctor's office more, as had been expected by their health care providers. Patients were genuinely surprised that the system actually maintained records of their health information. Some were surprised to learn things that they were uninformed about previously.

This theme centered on the importance of having access to credible information that “helps me look after me” (3PAT1). Having access to the information allowed patients to make more informed choices. Empowerment and comfort were also considered important:

It has been empowering for me and that also feel that because of it, I am burdening the system a lot less. Fewer appointments, fewer phone calls...and also I feel not just burdening the system but I'm better able to take care of myself. [3PAT1]

Patients no longer accepted the modus operandi that *no news, is good news*. They wanted to know whether their results were good or bad. Having access to their medical records was seen as a necessity, as patients were already trying to collect and maintain it by requesting copies from their health care providers. Patients expressed frustration with the fact that patient portals exist elsewhere and regarded the process of implementation in Alberta to be slow. Overall, patients felt that they needed this information to be responsible for their own health.

Theme 2: Convenience, Convenience, Convenience

The term *convenience* was used to describe a missing element in health care and the contribution of MyChart to solving this problem. Regardless of where the patient was, they liked being able to connect with their health care team through MyChart. Just knowing that they could reach out to their health care provider was considered a safety net. Being able to contact their health care provider directly through an email system and receive prompt replies was appreciated. Patients indicated that, from their point of view, they did not abuse this system and they only sent messages when needed. Although patients did not understand all their test results, they saw the benefits of having the information and used it to frame more specific questions for their health care providers and to discuss treatment plans. Most of the time, the provided ranges of results were sufficient for patients to understand their results. Furthermore, some patients had been performing the same tests over the years, thus they were already aware of how to interpret their test results.:

I may not understand everything, in fact I understand very little but this information enables me to ask a smarter question. [4PAT2]

Patients wanted the same convenience in interactions with their health care provider as for other services such as banking and shopping. The ability to make and cancel appointments web-based was described as extremely convenient and valuable. One patient explained that “you should not have human resources doing the work that can be done with clicks” (4PAT2). Another patient described the ability to make appointments web-based as *freedom*. In addition, having the ability to fill out questionnaires before going to the appointment was seen as beneficial, as patients had the ability to take the time and carefully think about the answers. Caregivers used the information in MyChart to monitor the health of their family members.

Patients correlated the convenience of MyChart with cost saving, as patients were able to see their results without making unnecessary follow-up appointments, did not have to travel for a short appointment, did not have to take time off from work, and did not have to pay for parking and/or pay to get their results printed. They saw this not only as cost savings to them but also as cost savings to the health care system.

Although proxy access was one of the most challenging elements to set up within MyChart, patients noted that it was one of the most beneficial connections, especially when caring for a family member:

Now my father who is 90 is a different story and one of the very interesting and most important features of this is the availability we have to see dad's test results. So, I can access because you know my dad and I work together, and this is maybe kind of not how they thought this was going to work, but as a primary caregiver with my dad, I've got his user ID and password, which I set up for him anyway. [4PAT3]

Patients who had provided proxy access to their accounts were cognizant of the possible issues, but they found that the benefits outweighed the risks. Patients in our study did not seem to be greatly concerned about privacy and security. They felt that this system was as secure as any other system that had their personal information:

Well there's a concern every time I pull out my debit card or my visa. There is a concern every time I go on Instagram. There's a concern with every single thing we do and I could choose to be paralyzed by that and not have a credit card, and not go online, not do anything. But I choose to do all those things to enjoy the benefits, I guess. It's I suppose convenience and you use reasonable care, I think. And you kind of recognize that things can be hacked into and data can be lost. [4PAT4]

Theme 3: A Few Tweaks Will Do It

Although patients found MyChart very beneficial, they also described some of the barriers that they experienced with the system. Some patients expressed concerns about their ability to understand the results, as they did not find the descriptions in MyChart valuable at all times. Diagnostic reports were not accompanied with explanations; thus it was difficult for patients to interpret the findings. Some patients did not appreciate the fact that health care providers did not see them as sufficiently competent to understand the information:

But you know the medical professionals are God and everybody else bows before them and does whatever they say. You know they're the only ones that can interpret this stuff properly. [4PAT4]

Patients expressed dissatisfaction about the inability to see the entire medical record, including the doctor's notes.

No education or training on how to use MyChart was provided. As they did not know what their use of MyChart would entail, some patients decided not to sign up, noting that it might take "too much time to learn the things" (4PAT11 [NU]). Patients were frustrated about the lack of access to most MyChart functions. Patients in the clinics without the option to book web-based appointments defined this gap as a barrier:

I can book my flights, I can book my hotels, I can do it all on an app on my smartphone. I can book my lab, why can't I book my doctor's appointment. [4PAT4]

Patients also did not understand why all their family members could not be on the system.

The sign-up and the sign-in process were barriers to some patients. One person said, "I mean I understand that they need a certain security level, I totally understand that, but it was so delicate and so picky that it often didn't work" (4PAT1). Although MyChart was seen as a beneficial tool that enhanced the patient-provider relationship, some expressed concerns about health care being computerized and what that would mean for patients.

Theme 4: Do Not Take It Away

Many of the interviewed patients expressed concerns about the possibility that MyChart might not be continued after the pilot

and said it would be like going "back to the Stone Ages" (4PAT4). They said they were not being informed on regular bases about the future of MyChart. Furthermore, patients explained that if MyChart was removed, they would have to go back to playing phone tag with their providers:

In this world where we have access to so much information and can make choices and view and control things online. My expectation is that I should be able to do that with my healthcare. And my experience is it's probably giving me better healthcare more efficiently than the old way. [4PAT4]

Participants wanted to inform decision makers regarding the value of the patient portal and their wish for it to be maintained, and they had some suggestions for improvements (see [Multimedia Appendix 4](#) for additional quotes).

Health Care Providers

A total of 21 health care providers from 5 clinics were interviewed. Four themes emerged from the interviews: (1) of course we need it; (2) yes, it did some good things; (3) not all was great; and (4) consider my needs.

Theme 1: Of Course We Need It

We commenced the interviews with health care providers by soliciting opinions about their perceptions of MyChart and their experience of its implementation. Many expressed positive views as they saw it as a good vehicle for delivering information to patients:

I think it's the patient's information. And unless there's a really clear medical reason, like maybe they have severe anxiety, mental health issues, or something else that maybe they shouldn't have it. I don't see any reason why they shouldn't have that information based on pretty much real time unless there are a certain subset of things that possibly might qualify for that maybe it's a cancer diagnosis. [4HCP1]

One described MyChart as "a piece of our healthcare system that's been missing" (1HCP2). Furthermore, many providers agreed that patients had the right to their information and said portals were a great tool for that purpose. Providers thought MyChart had a positive impact on both themselves and their patients, "I can say fairly from my patients that experience is always been positive and been positive to me" (1HCP2).

Theme 2: Yes, It Did Some Good Things

Health care providers described several benefits from the MyChart for patients, "by learning about their health even and that sort of thing that they can click on into a health portal and learn about their condition or what comes up, or surgeries or whatever" (1HCP1). Providing patients with information improves patient visits. One provider said, "when you are armed with the results and armed with some of those values, it will make the patient interviews and patient visits a bit more meaningful" (4HCP2). MyChart was seen as a secure system where everything was recorded, as even a nonuser provider stated, "everything's documented so you don't have to worry" (4HCP4 [NU]).

Providers stated that MyChart was desirable as it reduced phone calls and provided an alternative means of communication. One of its novel functions was 2-way secure communication for nonemergency issues. This function required many modifications and decisions because it had not been tested before the pilot, and participating clinicians had expressed skepticism. It was also one of the main reasons many health care providers within the participating clinics decided not to participate in the pilot. Providers assumed that they would be inundated with a high number of messages, and there was no payment plan in place to remunerate them for the time required to answer these messages. As patients on MyChart started calling the clinic less frequently to get results, health care providers recognized the improvement in workflow, “instead of them calling us, they’re just sending us a message through MyChart, which is easier for us on our end” (2HCP4).

Although only 1 clinic during the pilot decided to implement the appointments function for their patients, it proved to be extremely valuable as patients could “do it at their convenience to save some calling back and forth” (4HCP1). Providing proxy access was seen as a much-needed innovation in delivering health care. It was a new function that was never offered in Alberta before the MyChart pilot. Providers were positive about the approach. The most common request for proxy was for a spouse or adults caring for their elderly parents. One provider said, “the wife is the one that like keeps track of all the health information or like the different results and medications and whatnot so they’re usually the ones that email about their husband’s symptoms or questions or whatnot” (2HCP1).

MyChart did not impact workflow negatively, as was originally expected. The major benefits in terms of workflow was that it improved communication between patients and providers and that it provided a means of accessing information quickly. The work itself did not change, but there was a change in the way the work was performed. The system allowed other team members to be informed about communication and decisions.

Theme 3: Not All Was Great

Although there were many benefits of having MyChart available to patients, providers expressed several concerns. Not all patients were deemed fit to have access to their health care information, as “too much information sometimes is not a great thing” (1HCP1). Another provider stated that “a lot of patients wouldn’t really want to know that; they’ll just want to know if they’re living or dying” (5HCP1 [NU]). Providers made decisions about which patients would be offered MyChart and stated that sometimes they did not offer it because there was no time to do so:

I offer it to all although I can tell you I'm not consistent. So, I mean to offer it all but there's plenty of times when I'm rushing around in a clinic, and/or if a person has a lot of other concerns it doesn't pop into your mind and so you're more focused on other things during your clinic visit. [2HCP3]

Health care providers did not want the additional work of educating and helping patients or providing technical support. One provider stated, “more physicians are annoyed with that; they’ll just stop offering that service” (1HCP3). This reluctance

was based on previous experiences that technologies tend to be implemented without proper technical support or education. Providers felt that they had to *wing it* in using the system. MyChart was perceived as potentially taking time away from medical consultations if providers had to do promotion and education. As another provider stated, “I do not have time in that time to introduce a concept that has to be done by somebody else” (3HCP5). Some providers described that they just forgot about MyChart and did not bother with enrolling patients:

It's kind of forgotten sometimes and it could be the nature of the clinic. It's a busy clinic and maybe it's just forgotten as a tool. There is one physician that does use it more so than others. [3HCP3 NU]

There were no clear guidelines and expectations, thus there was hesitancy about what was the right thing to do. Health care providers expressed apprehension because they were unclear what MyChart meant in terms of changes in charting practices.

Theme 4: Consider My Needs

When asked about the upcoming provincial-wide implementation, health care providers stated that if MyChart were continued, then it needed to reflect their needs and be established in a manner that would work within their busy schedules. It was stated that the system would need to be developed around some kind of incentives. No incentives would mean that “people won’t use it” (1HCP3) and patients would not receive the opportunity to be introduced to the portal. Policies and guidelines should be implemented about charting, proxy access, and 2-way communication. MyChart could be incorporated as long as it did not contribute to additional workload (see [Multimedia Appendix 4](#) for additional quotes).

Clinic Managers

A total of 4 clinic managers were interviewed, and 4 themes emerged from the interviews: (1) time for some efficiency, (2) heard great things about it, (3) heard about some issues as well, and (4) culture change is needed.

Theme 1: Time for Some Efficiency in Communication

When managers were asked why they decided to be part of the pilot, they stated that it was to eliminate paper and phone calls, try an innovation, and provide new ways for patients to manage complex chronic conditions. They had positive views about portals and how portals could impact practice in a positive way. This was an important finding, as clinic managers were involved in decisions about whether to have their clinic involved in the pilot:

I think that you know this is going to be the future. The question is how we get there. [4CM1]

They viewed MyChart as a way to connect team members and assist patients and providers. They thought that the system had the capacity to improve the communication processes currently broken in the health care system, as patients continue to complain that they are unable to reach their providers when needed.

Theme 2: Heard Great Things About It

Clinic managers stated that the impact of patients seeing their medical records was seen as a facilitator to better care. Patients already search for things on the web, and MyChart provided access to correct and legitimate information:

Our patients are different patients than what they were 20 or 30 years ago because they have Internet access already. They already research all. [2CM21]

It is important to note that clinic managers agreed that not all patients would use MyChart and that the system needed to accommodate this possibility. The MyChart 2-way communication function capacity was seen as a means of establishing new ways of communication and reducing reliance on phone calls.

Theme 3: Heard About Some Issues As Well

When the pilot started, only physicians were allowed to sign up patients to MyChart. This led to low enrollment numbers because physicians did not have enough time to explain MyChart to each patient. Furthermore, clinic managers described that many physicians did not participate in the pilot even though the clinic was part of the pilot. This was because of a lack of buy-in as physicians did not see MyChart as something beneficial. One clinic manager identified the issue of control as a drawback to the use of MyChart:

Physicians traditionally are so accustomed to kind of controlling everything that happens with that patient. And when the patient starts seeing the results of what they're trying to achieve. They're worried about it derailing the treatment progress and the relationship between the provider and the patient, when in fact I think the actual opposite occurs. [2CM21]

Clinic managers acknowledged that they heard from the health care providers about patients having issues with MyChart. The sign-up process was challenging and created grievances. Technical support was lacking, and health care providers had to figure out ways to help patients with the sign-up process. One of the barriers was that physicians did not take full responsibility for the 2-way communication.

Theme 4: Change Is Needed

Clinic managers stated that change is needed in the current provider-patient relationship. They agreed that all clinics should be able to provide it, so all patients would have the same opportunity to access their health care information:

It needs to be a normal part of the life or not, it needs to be a normal part of, more the norm than the exception. [1CM1]

Furthermore, clinic managers stated that physicians need to learn how to work with innovations such as MyChart and that

these changes might not be easy in the beginning but are needed (see [Multimedia Appendix 4](#) for additional quotes).

Nonmedical Staff

Only 1 clinic within the pilot opened the web-based appointment booking and canceling appointments function. For the scheduling function to be accessible, participating health care providers had to enter their availability in the system, which would allow patients to select from the available slots. Once a patient selects a slot, the clinic receives a message. If the booking was done incorrectly or the slot was changed, the office staff would call the patient and modify the booking. From these interviews, we identified 3 themes: (1) great service for the patients, (2) needs some education, and (3) need to maintain and expand.

Theme 1: Great Service for the Patient

The nonmedical staff described that participants “loved booking their own appointments especially because they know (if) something happens in the middle of the night, they can go on and book for the next day if there's openings” (4NON2). If there were any issues with the appointment, then the staff would call the patient and get it all sorted out; therefore, MyChart lightened the workload.

Theme 2: Needs Some Education

As not all health care providers participated in the pilot, some patients in a given clinic were able to make web-based appointments, whereas others could not do so. In addition, a challenge was with patients who would book many appointments, as “they can book a whole bunch of them on MyChart in one day” (04MANON00213DEC2018).

Theme 3: Need to Maintain and Expand

Staff indicated that they would like more information about MyChart so that they could assist patients better and said that they needed “more awareness and if they ask questions I can help as I can't help them much now” (4NON3; see [Multimedia Appendix 4](#) for additional quotes).

Summary of the Results

We report the uptake and adoption of an initial phase of a patient portal introduction among 5 health care clinics that were, at the outset of the introduction, judged to be clinics where high uptake would be found. In contrast, 2 clinics showed high uptake, 1 clinic showed moderate uptake, 1 clinic showed low uptake, and the last clinic was categorized as a clinic without use. We identified several factors related to the uptake of the patient portal, including satisfaction and/or dissatisfaction with the current communication tools, performance expectancy, facilitating conditions, behavioral intentions, and use behavior. All these factors had an impact on the level of uptake in each setting and created different opportunities for the end users. [Table 5](#) summarizes our findings about each clinic by considering our findings.

Table 5. Impact of the MyChart pilot on each case study.

Case study	Level of usage	Satisfaction or dissatisfaction with the current communication tools	Performance expectancy	Facilitating conditions	Behavioral intention	Use behavior
Clinic 4	High user; 965 enrolled patients	Clinic considered as an innovation hub clinic; first clinic to go live within the PoC ^a ; 2 family doctors and a registered nurse participated; 3 family doctors did not participate	MyChart described as the <i>most rewarding</i> initiative; offered the web-based booking and canceling appointment function. Only clinic to do so	The registered nurse acted as the MyChart support person	High enrollment as they offered it to almost all patients	The clinic maintained high enrollment and incorporated the frontline staff (office assistants) to be part of the process
Clinic 2	High user; 875 enrolled patients	It was described that the clinic had the <i>old way</i> and the <i>new way</i> processes	The participating providers used the technology to share medical results with their patients and decrease the number of phone calls to the clinic	Two specialists maintained the <i>old way</i> who did not participate in the PoC because of the assumption that it will increase their workload and patients will contact them all the time. Two specialists implemented the <i>new way</i>	This process was maintained for a while, until the nurses from the nonparticipating specialists decide to start enrolling patients on MyChart	After the nurses took on the initiative to sign up patients to MyChart, the enrollment increased
Clinic 1	Medium user; 357 enrolled patients	MyChart was brought in because of the potential for uploading forms and questionnaires that patients tend to do	The technology did not produce the identified needs as the forms on MyChart were found to be inappropriate by the clinic	Nurses took on the active role in enrolling patients	Only offered to certain patients (medium enrollment)	The implementation process was observed by 2 other specialty clinics that enrolled in the PoC and achieved a high enrollment (1047 and 667 patients)
Clinic 3	Low user; 172 enrolled patients	The participating specialist is the clinic manager that brought MyChart to the clinic with the intent to decrease the number of phone calls or unnecessary follow-up appointments	The portal was deemed needed because of the 2-way communication function. However, patient messages sent through MyChart were often unanswered because of staff changes	The nurses did not actively participate in the enrollment process; other staff did not see the benefit and were unwilling to participate because of the 2-way communications function	Low enrollment, although patients expressed interest (interviewed 1 patient from this clinic who did not have access but wanted it)	MyChart was described as an <i>afterthought</i>
Clinic 5	Nonuser; 0 enrolled patients	Although offered to participate, the staff at this academic setting family clinic decided not to	The technology was deemed difficult to incorporate in the clinic's flow	The clinic has patients with MyChart because of access provided at other clinics, but no provider from this clinic wanted to use or assist patients with the portal	The portal was not seen as something necessary in the delivery of health care services	No perceived value and thus no enrolment or usage

^aPoC: proof of concept.

Discussion

Principal Findings

In our study, dissatisfaction with current health care communication tools appeared to be the primary factor that drove patients' and providers' decisions to consider the use of MyChart. Once they had made this decision, uptake was dependent on performance expectancy, which included

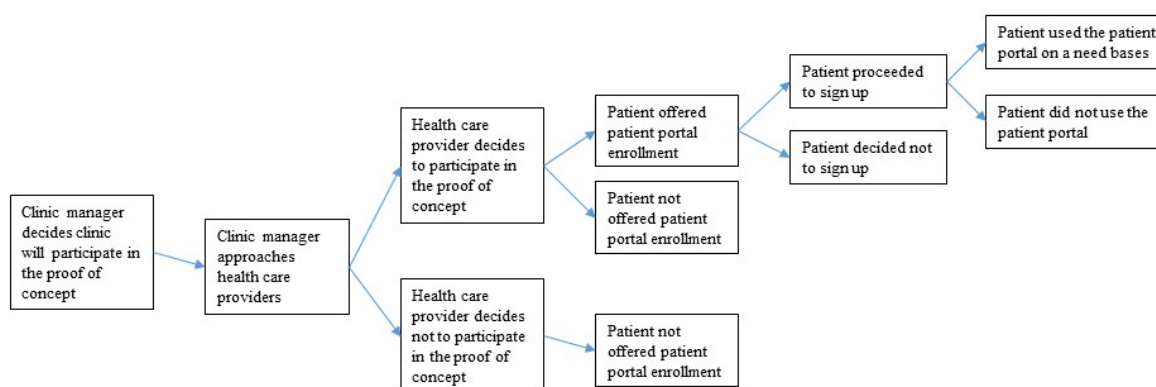

understanding how to use the technology and valuing the additional functionality that it offered. Furthermore, although the themes emerged from the interview data, they aligned with the *theory of technology acceptance* by Davis [14] and included *perceived usefulness*, *perceived ease of use*, *barriers to ease of use*, and *future usage* [14]. For example, theme 1 from the patient interviews was *my health, my responsibility, but I need the information to do that*, which correlated with *perceived usefulness* [14], as shown in [Textbox 2](#).

Textbox 2. Themes per sample group correlating with the theory of technology acceptance.

Patients <ul style="list-style-type: none"> Theme 1: My health, my responsibility, but I need the information to do that (perceived usefulness) Theme 2: Convenience, convenience, convenience (perceived ease of use) Theme 3: A few tweaks will do it (barriers to ease of use) Theme 4: Do not take it away (future usage)
Health care providers <ul style="list-style-type: none"> Theme 1: Of course we need it (perceived usefulness) Theme 2: Yes, it did some good things (perceived ease of use) Theme 3: Not all was great (barriers to ease of use) Theme 4: Consider my needs (future usage)
Clinic managers <ul style="list-style-type: none"> Theme 1: Time for some efficiency in communication (perceived usefulness) Theme 2: Heard great things about it (perceived ease of use) Theme 3: Heard about some issues as well (barriers to ease of use) Theme 4: Change is needed (future usage)
Nonmedical providers <ul style="list-style-type: none"> Theme 1: Great service for the patient (perceived usefulness) Theme 2: Needs some education (barriers to ease of use) Theme 3: Need to maintain and expand (future usage)

The conditions that facilitated understanding of the technology varied across clinics. Some clinics formally designated assistance with MyChart use to staff in their clinic. All clinics had high or medium uptake of MyChart. In other clinics, staff decided not to offer MyChart to some patients, which had an impact on the uptake of MyChart. Reasons are not entirely clear and require further investigation. Some patients who understood how to use the technology and valued it became *users*, whereas others did not. The main reason for discontinuing use appeared to be the lack of an immediate health care concern [25].

Clinic managers were foundational to the uptake of MyChart (Figure 2), a finding that has not been discussed in the literature to date. They made decisions about whether to present the technology to providers. Our data suggest that this decision was based on an informal assessment of satisfaction with the current communication tools. Clinic managers who declined participation in the pilot indicated that their clinic patients and providers would not be interested in trying the technology. Figure 2 summarizes the impact of the clinic managers on the uptake of MyChart.

Figure 2. Clinic managers as gatekeepers to uptake of MyChart.

The actions of the clinic managers could be observed through Roger's theory of diffusion, as they served as early adopters by assessing the advantages or disadvantages of the innovation. They determined the *perceived efficiencies*, its *compatibility*

with the existing system, the *complexity*, and, ultimately, the *benefits* and unintended *consequences* of the innovation [13].

Usage and enrollment depended on how patients were informed about the portal. Patients in this study reported variable

understanding of the portal following the introduction by clinic staff. Similar to the study by Kim et al [25], a quick introduction did not appear to be valuable to patients. In this study, participating health care providers reported not having sufficient time to explain the portal to patients. In clinics with higher uptake, a short introduction became incorporated into the clinic visit workflow, which allowed for more sufficient means in enticing patients to sign up.

Knowledge about the technology was another important component that led to increased or decreased usage. Ryan et al [26] found that patients and health care providers had positive views about patient portals but that older patients had less knowledge about patient portals. In this study, older participants reported that they took the time to learn and understand the system once they decided to enroll. We found that patients had to learn the system by *trial and error*. When patients were unable to navigate the sign up and authentication, the use of MyChart became impossible. When patients accessed medical information in MyChart, they reported becoming more active in the management of their health, which allowed them to see their health trends and identify opportunities for self-care. Patients came prepared with specific health questions because they could spend less time going over less valuable health information (eg, lab results) and making better use of scarce time with their care provider. This finding was similar to the results reported by Dendere et al [27].

Some research teams have reported a relationship between concerns regarding privacy and technology uptake [28-36]. In our study, participants did not report perceiving significant risks to having the confidentiality of their health information violated. Participants reported a sense that the health system would maintain appropriate controls and procedures to protect the security of their health information.

Although not all health care providers saw the *value* of patients having access to the same information, participants *championing* use of MyChart experienced more efficient ways to connect and communicate with their patients. This finding is in contrast to the findings reported by others who have studied patient portals [27,37-40] and reported that portals increased workload. For example, Koivunen et al [41] described the negative views of nurses about patient portals. Our findings are consistent with the work of other research teams who reported that nurses saw patient portals as an opportunity to improve communication with patients [42-44].

Furthermore, theories of how patient portals support health care system transformation may not draw upon crucial empirical data. The current findings emphasize that without a shared understanding of the purpose of patient portals and some dissatisfaction with existing communication methods, uptake lags. We posit that these aspects will be crucial as patient portals introduced in real-life care settings often accompany other technologies for clinicians and managers to navigate [44].

We agree with Wiljer et al [45], who described a need for a culture shift, where access to medical records is a fundamental right of every patient. A shift of this magnitude could only be accomplished with broad support from policy makers, health care providers, health administrators, and patients. Without adequate support for patients as complete partners in the management of their health, patients would be left to take actions based on incomplete and possibly inaccurate information from untrustworthy sources. Clinically useful uptake of patient portals is an essential enabler for patients as partners in managing their health and transforming the wider health system.

Limitations

There were several limitations to this study. Patient interviews were only conducted with patients who volunteered to participate and were attending an appointment with a health care provider who was also participating in the study. The information provided by participants may not have been recalled accurately by them. In addition, although all efforts were made, we were unable to identify and recruit participants who did not continue to use MyChart as we had no means to obtain information about discontinued usage. Finally, the findings should be generalized with caution to other health care systems and to settings that use other types of patient portals.

Conclusions

This work exposes a number of factors that have an impact on the uptake of MyChart. We found that dissatisfaction with nonportal-based communications was a foundational element that likely needs to be addressed before more advanced goals can be reached. We also found that clinical managers were key gatekeepers in the uptake process. Once a clinic manager decided that the clinic should use the portal, the designation of a staff member to help patients become more familiar with the portal appeared to increase uptake.

Acknowledgments

The authors would like to acknowledge and thank the clinic managers and clinic staff for their interest and participation in this study. Without their help, this research would not have been possible. The authors would also like to thank all patients who participated in this study and guided the research team toward a better understanding of their experiences when using the patient portal. Furthermore, the authors would like to thank the Canadian Institutes of Health Research's (CIHR's) Health System Impact Fellowship and the Alberta Innovates Graduate Student Scholarship programs for providing funding for this work. Financial support for this work was provided to MA through the CIHR's Health System Impact Fellowship and the Alberta Innovates Graduate Student Scholarship.

Abstract

Background: Technology-mediated obesity treatments are commonly affected by poor long-term adherence. Supportive Accountability Theory suggests that the provision of social support and oversight toward goals may help to maintain adherence in technology-mediated treatments. However, no tool exists to measure the construct of supportive accountability.

Objective: This study aimed to develop and psychometrically validate a supportive accountability measure (SAM) by examining its performance in technology-mediated obesity treatment.

Methods: Secondary data analyses were conducted in 2 obesity treatment studies to validate the SAM (20 items). Study 1 examined reliability, criterion validity, and construct validity using an exploratory factor analysis in individuals seeking obesity treatment. Study 2 examined the construct validity of SAM in technology-mediated interventions involving different self-monitoring tools and varying amounts of phone-based interventionist support. Participants received traditional self-monitoring tools (standard, in-home self-monitoring scale [SC group]), newer, technology-based self-monitoring tools (TECH group), or these newer technology tools plus additional phone-based support (TECH+PHONE group). Given that the TECH+PHONE group involves more interventionist support, we hypothesized that this group would have greater supportive accountability than the other 2 arms.

Results: In Study 1 (n=353), the SAM showed strong reliability (Cronbach $\alpha=.92$). A factor analysis revealed a 3-factor solution (representing Support for Healthy Eating Habits, Support for Exercise Habits, and Perceptions of Accountability) that explained 69% of the variance. Convergent validity was established using items from the motivation for weight loss scale, specifically the social regulation subscale ($r=0.33$; $P<.001$) and social pressure for weight loss subscale ($r=0.23$; $P<.001$). In Study 2 (n=80), the TECH+PHONE group reported significantly higher SAM scores at 6 months compared with the SC and TECH groups ($r^2=.45$; $P<.001$). Higher SAM scores were associated with higher adherence to weight management behaviors, including higher scores on subscales representing healthy dietary choices, the use of self-monitoring strategies, and positive psychological coping with weight management challenges. The association between total SAM scores and percent weight change was in the expected direction but not statistically significant ($r=-0.26$; $P=.06$).

Conclusions: The SAM has strong reliability and validity across the 2 studies. Future studies may consider using the SAM in technology-mediated weight loss treatment to better understand whether support and accountability are adequately represented and how supportive accountability impacts treatment adherence and outcomes.

Introduction

Background

Technology-mediated health behavior change interventions have become ubiquitous [1-4]. Adherence tends to drop off dramatically over time, such that few participants meet the program goals related to the use of technology-based intervention tools (eg, self-monitoring platforms) by the end of treatment [5-7]. Importantly, this poor adherence may lead to suboptimal treatment outcomes. Although technology-based interventions can lead to clinically significant weight loss in some participants [8], most of these programs demonstrate subpar outcomes in relation to in-person treatments [9,10]. For example, electronically delivered behavioral weight loss programs commonly achieve a weight loss of 3 kg to 5 kg within 3 to 6 months of treatment [11,12], whereas traditional in-person programs often produce a weight loss of 8 kg to 10 kg within the same time frame [11,13].

Given this challenge, research has focused on methods to improve adherence to technology-based behavioral interventions. To date, one of the most effective strategies has been the provision of additional support (eg, via telephone, email, text messages or via smartphone apps) from interventionists or lifestyle coaches [14-16]. Indeed, existing guidelines for the treatment of overweight and obesity specifically note that programs delivered electronically should provide personalized feedback from an interventionist and that primarily knowledge-based internet programs may be ineffective [11].

Consistent with these empirical findings, Mohr et al [17] recently proposed Supportive Accountability Theory, which posits that adherence to technology-based interventions may be improved through the provision of both social support (whether delivered in person or electronically and either synchronously or asynchronously) and accountability (the expectation that an individual would regularly have to explain their progress toward program goals). Despite the utility of Supportive Accountability Theory for identifying important potential mechanisms for improving adherence and, ultimately, program outcomes in technology-based interventions, there is no validated measure to assess supportive accountability.

Objectives

The objective of this study was to describe the development and validation of a measure for assessing supportive accountability within the context of technology-mediated programs for the treatment of adult obesity. Building off of the Social Support for Diet and Exercise Behaviors Scale by Sallis et al [18], a widely used measure of social support for healthy eating and activity, new items were added to represent the construct of accountability as described by Mohr et al [17]. The psychometric characteristics of this new measure (Supportive Accountability Measure [SAM]) were assessed using data collected from 2 weight loss trials. Baseline data from the first

trial (Study 1) aimed to examine reliability, conduct an exploratory factor analysis (EFA), and assess convergent validity. Data from the second trial (Study 2) aimed to further investigate the criterion validity of the new measure. Specifically, Study 2 examined the impact of newer self-monitoring technology and phone coaching on weight loss; thus, it was hypothesized that participants who were randomized to receive additional phone coaching, in addition to technology-based self-monitoring tools, would report higher supportive accountability compared with participants not provided with this additional coaching.

Methods

Supportive Accountability Measure Development

The SAM was developed by adding novel items representing the construct of accountability to items from the existing Social Support for Diet and Exercise Behaviors Scale developed by Sallis et al [18], a widely used social support measure in the weight management literature [15]. First, questions assessing accountability were developed by a senior author (TL), drawing on Mohr's description of Supportive Accountability Theory [17] and her expertise in the field of obesity treatment. Items were developed to assess accountability for typical behavioral intervention components, including goals related to weight loss, dietary intake, and physical activity. Participants respond to items on this scale using a 7-point Likert scale, with response options ranging from 1 (*not at all*) to 7 (*very much*). A total of 10 items were judged to fully capture all facets of this construct (supporting content validity) and were thus retained. [Multimedia Appendix 1](#) shows the final accountability items selected for the SAM.

To ensure balance in the number of items, 10 items were selected from the Sallis Social Support measure [17]. The original Sallis measure includes 43 items; some assess social support, whereas others assess sabotage, negative comments, and punishment. Overall, these subscales have demonstrated good internal consistency, criterion validity, and construct validity and acceptable test-retest reliability [18]; however, less support has been found for the utility of the negative subscales (Negative Comments, Sabotage, and Punishment) [18,19]. Given the lack of psychometric support for the negative subscales and that the questions focused on negative comments and sabotage did not align with the theoretical construct of supportive accountability, the 10 items that were retained from the Sallis measure were those that assessed positive support for healthy eating and exercise [18]. Participants were asked to rate support received from family, friends, and their weight loss coach on the 10 items using a 5-point Likert scale identical to that used in the original Sallis measure (1=*Never*, 2=*Rarely*, 3=*A few times*, 4=*Often*, 5=*Very often*, and 6=*Does not apply*, with scores of 6 being recoded as 1 before scoring).

A total score for the SAM was created using the 10 support items and 10 accountability items. The Social Support subscale involves summing all social support items. Since the

accountability items were measured on a 7-point scale and the social support items on a 5-point scale, the scores for the accountability measure involved summing all accountability items, multiplying the sum by 5, and then dividing by 7 to yield identical maximum scores for the 2 subscales. The total scores for social support and accountability were then summed to create an overall SAM score, with higher scores indicating higher levels of supportive accountability (possible range of total SAM scores 17.14-100). We then examined the psychometric characteristics of the SAM across 2 weight management trials (the study details are provided below under the Methods section for Study 1 and Study 2). Study procedures for Study 1 and Study 2 were approved by The Miriam Hospital Institutional Review Board, and secondary analyses of Study 2 data were approved by the University of Florida Institutional Review Board.

Study 1

Study 1 evaluated the psychometric characteristics of the SAM in adults with obesity enrolled in a behavioral weight management trial. Only baseline data from this trial were used, allowing for the evaluation of the SAM in the relevant population before any intervention or support.

Participants

Study 1 included 353 adults (aged 40-60 years) with obesity (BMI between 30 kg/m² and 40 kg/m²). Full eligibility criteria and recruitment procedures have been described elsewhere [20]. In brief, participants were recruited through mass mailings, newspaper/listerv ads, and direct referrals to an obesity treatment research center and were screened over the phone. Exclusion criteria were participation in another weight loss program, use of weight loss medication, history of bariatric surgery, weight loss of ≥5% in the last 6 months, pregnancy, lactation, less than 6 months postpartum, or plans to become pregnant during the study period, any health conditions that would contraindicate weight loss (eg, cancer, reported uncontrolled heart condition, inability to walk 2 blocks without stopping, and unexplained loss of consciousness), or inability to participate in an in-person, group program (eg, scheduling constraints). For individuals reporting joint problems, medication use, or other medical conditions that may limit the ability to exercise or need adjustment with weight loss, physicians' consent was obtained. Study 1 participants were excluded from the current analyses if they did not complete the SAM measure at baseline (n=3).

Measures

All measures were collected at baseline.

Demographics

Standard demographics (eg, sex, age, race/ethnicity) were collected via a survey.

Anthropometrics

Height and weight were objectively assessed, with participants wearing one layer of light indoor clothing and shoes removed.

Supportive Accountability

The SAM was used to assess supportive accountability (see the Supportive Accountability Measure Development section for details).

Social Motivation for Weight Loss

The Treatment Self-Regulation Questionnaire (TSRQ) was administered to assess its convergent validity with the SAM. Given that the SAM is expected to measure social accountability, we examined whether the social external regulation subscale of the TSRQ [21] was associated with the SAM; 6 items were included, ranging from 1=*Not true at all* to 7=*Very true* (eg, "I want to lose weight or control my weight because...my spouse, family, friends or doctor would be upset if I didn't"). Mean scores were calculated for this scale.

Social Pressure for Weight Loss

Social pressure was assessed using an item from the Motivating Factors for Weight Loss Scale, developed to assess motivation for weight loss among participants in the National Weight Control Registry [22]. Participants were asked how important social pressure was in their decision to lose weight or join a weight loss program. Response options ranged from 1=*Not at all important* to 5=*Extremely important*.

Statistical Analyses

Analyses were conducted using SPSS Statistics for Windows, version 25 (IBM Corp). The reliability of SAM items was assessed via the Cronbach alpha [23], and construct validity was assessed using an EFA using principal component analysis with Oblimin rotation (delta=0). A scree plot was used to assess the number of factors using the standard eigenvalue of 1 or greater. Convergent validity of the SAM was assessed by correlating total SAM scores with the total Social Motivation score and the Social Pressure item.

Study 2

Study 2 was a randomized weight management trial investigating the impact of newer self-monitoring technology (ie, a Bluetooth-enabled activity monitor, a smart scale, and a website/smartphone app that synced with both of these devices and allowed individuals to self-monitor caloric intake) and phone coaching on weight loss. It was hypothesized that participants who received interventionist support through phone coaching would report significantly higher supportive accountability, as assessed by the SAM, at a 6-month posttest because of the presence of additional support. Moreover, we hypothesized that higher supportive accountability at intervention posttest would be associated with greater intervention adherence. As an exploratory aim, we investigated whether higher supportive accountability at the posttest was associated with greater weight loss from baseline to posttest.

Participants

Study 2 participants were 80 adults (aged between 18 and 70 years) with overweight or obesity (BMI between 27 kg/m² and 40 kg/m²) who reported having access to a computer and Wi-Fi at home [24]. Exclusion criteria were similar to Study 1; full eligibility criteria and details regarding participant recruitment

and screening have been published previously [24]. Study 2 participants were excluded from the current analyses if they did not complete the SAM measure at the 6-month follow-up.

Intervention

Study 2 was a randomized trial that examined the impact of a 6-month weight loss intervention in which participants were randomized to 1 of 3 treatment groups, using traditional self-monitoring tools (a paper food record, a printed calorie reference book, a standard pedometer, and a standard in-home scale—SC group), newer, technology-based self-monitoring tools (Fitbit Zip, Fitbit Aria smart scale, and use of the Fitbit app/website to track dietary intake—TECH group), or these newer technology tools plus phone-based interventionist support (TECH+PHONE group). All participants received a one-time, group-based Weight Loss 101 session that provided information on how to accurately monitor calories, weight, and physical activity and weight management goals for calories, exercise, and weight loss. Participants were also taught how to use their assigned self-monitoring tools. Participants randomized to SC ($n=26$) and TECH ($n=27$) received self-monitoring tools only; they did not receive any interventionist support. Participants randomized to TECH+PHONE ($n=27$) received the additional phone-based intervention (8 weekly, 4 biweekly, and 2 monthly contacts; each lasted 10-15 min), delivered by trained interventionists (either a clinical psychologist or dietitian, both experienced in delivering behavioral weight management programs), using a manualized protocol.

Measures

Demographics

Standard demographics (eg, sex, age, race/ethnicity) were collected via a survey at baseline.

Anthropometrics

Height and weight were measured with participants wearing light indoor clothing and with shoes removed. Height was measured at baseline and weight was measured at baseline and at the 6-month posttest. Weight change was operationalized as percent weight loss from baseline to the posttest visit.

Supportive Accountability

Supportive accountability was assessed at the 6-month posttest using the SAM.

Use of Weight Management Strategies

Weight management strategies were assessed at the 6-month posttest using the Weight Control Strategies Scale (WCSS) [25]. This self-report measure assesses behaviors across 4 subscales: dietary choices, self-monitoring strategies, physical activity, and psychological coping. WCSS dietary choices and physical activity subscales have been shown to be associated with changes in caloric intake and physical activity during weight management interventions, and WCSS scores have been shown to correlate with weight loss during these programs.

Statistical Analyses

Analyses were conducted using SPSS. Reliability was reassessed in this sample using Cronbach alpha. Construct validity of the

SAM was assessed using a one-way analysis of variance, investigating differences in SAM scores by treatment group. We hypothesized that, at the 6-month posttest, the SAM score would be significantly higher in the TECH+PHONE condition than in the SC and TECH conditions, given that this condition was provided with additional interventionist support.

Results

Study 1

Study 1 included a total of 350 participants (Table 1). The mean SAM score was 48.63 (SD 16.33); mean support and accountability subscale scores were 22.71 (SD 7.80) and 36.28 (SD 17.28), respectively. There was an association between total SAM scores and baseline BMI ($r=0.13$; $P=.02$). In examining the subscales, accountability scores were positively associated with baseline BMI ($r=0.17$; $P=.002$), whereas support scores were not ($P=.96$). There were no associations between SAM scores and participant demographic characteristics ($P>.06$).

The overall reliability of the SAM was excellent, as demonstrated by the internal consistency (Cronbach $\alpha=.92$). The lowest item to total SAM correlation ($r=0.41$) was for the item, “My friends/family encouraged me to not eat unhealthy foods when I’m tempted to do so.” However, the total Cronbach alpha was not improved with this item removed; thus, the item was retained. Cronbach alpha for the support and accountability subscales were also strong (.88 and .95, respectively). Inter-item correlations for the SAM are provided in Multimedia Appendix 2. As expected, items reflecting social support (items 1-10) correlated more closely with each other and had lower correlations with accountability items (items 11-20).

Results from the EFA demonstrated that a three-factor solution provided the best fit (Figure 1), explaining 69.2% of the variance. Item loadings for the three-factor solution, representing Support for Healthy Eating Habits, Support for Exercise Habits, and Perceptions of Accountability, are presented in Table 2. Assumptions of EFA were verified using the Kaiser-Meyer-Olkin (KMO) statistic, which demonstrated sampling adequacy (KMO=0.88). Furthermore, the Bartlett test of sphericity demonstrated that items correlated satisfactorily ($\chi^2_{190}=6573.91$; $P<.001$).

Convergent and divergent validity analyses revealed statistically significant correlations between the SAM total score and TSRQ items representing external motivation for weight loss ($r=0.34$; $P<.001$) and the social pressure item ($r=0.23$; $P<.001$). In examining the subscales of SAM, there were significant correlations between the Support subscale and Social Motivation items ($r=0.19$; $P=.001$) and the Social Pressure item ($r=0.17$; $P=.002$). Similarly, there were significant correlations between the Perceptions of Accountability subscale and Social Motivation items ($r=0.33$; $P<.001$) and the Social Pressure item ($r=0.20$; $P<.001$).

Table 1. Baseline and demographic characteristics of participants in study 1

Characteristic	Study 1 (n=350)

Study 2

Of the 80 participants included in Study 2, 55 completed the SAM at the 6-month assessment and were thus included in these analyses. Table 3 provides participants' baseline characteristics by group. There were no significant differences between groups

in terms of age, baseline BMI, sex, education, or race/ethnicity, all *P* values were >.05.

At the 6-month follow-up, the mean SAM score was 47.86 (SD 20.88); scores ranged from 17.14 to 94.57 (highest possible score of 100). Replicating the analyses conducted in Study 1, the reliability analyses for 6-month SAM scores demonstrated strong internal consistency (Cronbach α =.95).

^aSC: standard in-home scale group.^bTECH: technology-based self-monitoring tools group.^cTECH+PHONE: technology-based self-monitoring tools plus phone-based support group.

As hypothesized, there were significant differences in the 6-month total SAM scores by treatment group ($F_{2,52}=20.9$; $r^2=0.45$; $P<.001$; Table 4). Bonferroni-adjusted posthoc analyses demonstrated significantly higher SAM scores in the TECH+PHONE group than the TECH group ($t_{54}=3.70$, $P<.001$; SC: $t_{54}=6.39$, $P<.001$). Moreover, the TECH group demonstrated significantly higher SAM scores compared with SC ($t_{54}=2.57$; $P=.04$).

Between-group differences in SAM subscales were also examined (Table 4). The Support for Healthy Eating subscale demonstrated a similar pattern to the overall SAM scores. There was a significant difference in Support for Healthy Eating subscale scores by group ($F_{2,52}=21.4$; $r^2=0.45$; $P<.001$), with the TECH+PHONE group demonstrating higher subscale scores than both TECH ($t_{54}=3.48$; $P<.001$) and SC ($t_{54}=6.51$; $P<.001$) groups, and the TECH group demonstrating significantly higher scores compared with the SC group ($t_{54}=2.88$; $P=.02$). Although an overall significant difference between groups was demonstrated on the Support for Exercise Habits subscale

($F_{2,52}=3.9$; $r^2=0.13$; $P=.03$), there were no significant group differences when conducting Bonferroni-corrected posthoc comparisons. Finally, there was a significant difference between groups in the Perceptions of Accountability subscale ($F_{2,52}=15.3$; $r^2=0.37$; $P<.001$), such that the TECH+PHONE group had higher scores on this subscale compared with both TECH ($t_{54}=3.96$; $P<.001$) and SC ($t_{54}=5.22$; $P<.001$) groups. There were no significant differences in Perceptions of Accountability subscale scores between TECH and SC ($P=.71$) groups.

Table 5 presents correlations between SAM scores and adherence to weight management behaviors and percent weight change during the intervention. Higher SAM scores were associated with higher adherence to weight management behaviors, including higher scores on subscales representing healthy dietary choices, the use of self-monitoring strategies, and positive psychological coping with weight management challenges. The association between total SAM scores and percent weight change was in the expected direction but not statistically significant ($r=-0.26$; $P=.06$).

Table 4. Six-month scores on supportive accountability measure (SAM) and each of the three SAM subscales by intervention group.

Scale	Value, mean (SE)

Discussion

Study 1

Study 1 evaluated the psychometric properties of the novel, theory-based SAM in a sample of adults interested in a behavioral weight management trial. EFA revealed a three-factor solution for the SAM, representing subscales for Support for Healthy Eating Habits, Support for Exercise Habits, and Perceptions of Accountability. All items were retained, leaving 10 items representing social support and 10 items representing accountability, which together form the theoretical basis for the

construct of supportive accountability [17]. Overall, the 20-item SAM demonstrated excellent internal consistency. Moreover, SAM total scores were significantly associated with measures of Social Motivation [21] and Social Pressure [22]. However, these correlations were small to moderate in magnitude, consistent with the idea that supportive accountability is a construct distinct from motivation related to fears of upsetting others or feelings of social pressure [17]. Examining the convergent validity of the SAM with other measures of social support with weight loss may yield higher correlations. Overall, SAM showed strong reliability and validity in adults with obesity seeking weight loss.

Study 2

Study 2 evaluated the criterion validity of the SAM. Consistent with the hypotheses, participants provided with additional phone support (TECH+PHONE) reported higher SAM scores at the end of a 6-month weight loss program compared with participants who did not receive phone support (TECH only or SC only). Interestingly, participants who did not receive phone support but were provided with newer, technology-based self-monitoring tools reported higher supportive accountability at the end of the intervention compared with participants randomized to self-monitoring using traditional tools (a standard pedometer, bathroom scale, a calorie reference book, and paper self-monitoring logs used to track physical activity, weight, and caloric intake). Subscale analyses revealed that this was likely driven by increased feelings of social support but not accountability. It may be that the brief, automated feedback provided by these tools gave participants a sense of support. Specifically, these tools provided immediate feedback to participants who met short- and long-term goals (such as notifications on the activity monitor and pushed smartphone notifications and *badges* displayed on the app homepage that functioned as visual reminders of goals that had been met) [24]. Similarly, tailored feedback related to intervention goals, even when provided by automated systems, has been demonstrated to improve weight loss outcomes [10]. Thus, there may be some *digital support* inherent in this feedback. Additionally, the availability of social/community features on the Fitbit platforms (eg, the ability to share step counts with friends, competitions among friends to achieve certain step goals) might have promoted feelings of social support. The parent study for Study 2 was conducted between 2013 and 2015 when there were only minimal social components to these tools. Future research should investigate whether newer, more comprehensive social/community features further lead to increased feelings of support.

Consistent with the Supportive Accountability Theory [10], the provision of additional phone-based support resulted in the highest SAM scores. Compared with the 2 groups that did not receive phone support (TECH and SC), participants provided with phone support demonstrated significantly higher SAM total scores and subscale scores for Support for Healthy Eating Habits and Perceptions of Accountability. This suggests that ongoing interventionist contact improves support for healthy eating and provides a sense of accountability toward weight management behaviors and weight loss goals. Although the overall test statistic demonstrated significant differences across groups in Support for Exercise Habits, there were no posthoc group differences between any of the groups after Bonferroni corrections. This may have been related to power (Bonferroni corrections represent the most conservative approach but can lead to type II errors, especially in small samples [25]). Moreover, it may be possible that the items on this subscale were influenced less by the type of intervention utilized in Study 2. It would not be expected that items asking about whether supportive individuals “exercised with me,” “offered to exercise with me,” and “changed their schedule so we could exercise together” would be rated higher in participants receiving additional phone-based interventionist support. Thus, future

research may investigate whether alternative item wording for exercise may better reflect the social support provided by intervention staff.

Finally, consistent with Mohr’s theory that supportive accountability could increase intervention adherence [16], the results demonstrated that higher SAM scores were associated with better adherence to weight management strategies. Interestingly, these associations appear to be driven by ratings of accountability versus support. The correlations between the Perceptions of Accountability subscale and report of adherence to weight management behaviors on the WCSS (both the WCSS total score and all subscale scores) were larger than associations between weight management adherence and the social support subscales (either Support for Healthy Eating Habits or Support for Exercise Habits). Although there was no statistically significant association between total SAM score and percent weight change during the intervention, the association was in the expected direction and represented a medium effect size. Similarly, the association between the SAM subscales (Support for Healthy Eating, Support for Exercise, and Perceptions of Accountability) and percent weight change was not statistically significant; however, it was in the expected direction.

Overall, data from 2 studies were used to examine the psychometric properties of the SAM, a new survey to assess supportive accountability for weight management behaviors. Across both studies, the SAM demonstrated excellent internal consistency and construct validity. This study has some limitations. Participants were predominantly female and non-Hispanic white, which limits the generalizability of the study results. Future research is needed to examine whether SAM demonstrates a similar factor structure, internal consistency, and validity in more diverse samples. The small sample size in Study 2, combined with the fact that participants in only 2 of the 3 groups were asked to use technology-based self-monitoring tools, precluded the investigation into whether the SAM was associated with objective engagement with the technology-based self-monitoring tools. This study also did not assess test-retest reliability or sensitivity to change over time. Future work in these areas would strengthen confidence in this measure for assessing the construct of supportive accountability and further provide important results that could inform future theory development. Finally, the scoring on this measure was complicated by the different scales used for scoring the accountability items (which used a 7-point scale) and the social support items (which used a 5-point scale). The accountability items were developed before the selection of social support items from the Sallis questionnaire, and a 7-point scale was chosen to optimize variability in responses. Future research should investigate whether this scale performs similarly when all items use the same scale (eg, either 5 or 7 response points).

This research also has notable strengths. The development of SAM was theory-based, relying on the Supportive Accountability Theory by Mohr [17]. The SAM included the use of a widely used validated measure of social support as a basis [18] and built upon this measure by adding psychometrically sound accountability items. Furthermore, reducing the items from the original social support scale makes this new tool a concise measure of support and accountability

that can be used in many technology-mediated interventions that would avoid scale fatigue and respondent burden. In Study 1, the sample size was large, which allowed for initial validation and an EFA. Furthermore, all weight data were objectively assessed. Moreover, in 2 separate samples, the SAM demonstrated both internal consistency and construct validity. Finally, the SAM was included in a randomized trial that involved interventions with and without phone support, which allowed for the examination of criterion validity. These methodologies allowed for a robust examination of the psychometric properties of a new measure of supportive accountability.

Supportive accountability was developed as a construct within the context of technology-mediated *electronic health* interventions [16]; however, this construct may have broader applicability. For example, it is theoretically plausible that supportive accountability may play a role in promoting adherence even in traditional face-to-face behavioral interventions. With the SAM, future studies will be able to investigate whether supportive accountability mediates outcomes

in face-to-face programs. This may be particularly important in interventions that rely heavily on social support.

Moreover, although the construct of supportive accountability suggests the importance of human support [16], the SAM would be useful for research focused on the development of technologically mediated support systems. For example, the SAM could be used to evaluate whether tools that integrate social components (eg, leaderboards, competitions among friend groups, or chat rooms/bulletin boards that allow contacts to provide support) increase feelings of supportive accountability and ultimately promote intervention adherence. The SAM could also be used to evaluate whether automated feedback provided via tailoring algorithms or artificial intelligence programs can impact feelings of supportive accountability.

Considering the ever-growing technological innovations, the SAM will help researchers better understand the factors that drive the effectiveness of technology-based treatments. This use of the SAM may thus guide the development of more effective interventions and help improve foundational knowledge regarding the mechanisms that drive treatment effects in technologically mediated treatment.

Abstract

Background: Massive open online courses (MOOCs), as originally conceived, promised to provide educational access to anyone with an internet connection. However, the expansiveness of MOOC education has been found to be somewhat limited. Nonetheless, leading universities continue to offer MOOCs, including many in the health sciences, on a number of private platforms. Therefore, research on online education must include thorough understanding of the role of MOOCs. To date, studies on MOOC participants have focused mainly on learners' assessment of the course. It is known that MOOCs are not reaching the universal audiences that were predicted, and much knowledge has been gained about learners' perceptions of MOOCs. However, there is little scholarship on what learners themselves gain from participating in MOOCs.

Objective: As MOOC development persists and expands, scholars and developers should be made aware of the role of MOOCs in education by examining what these courses do offer their participants. The objective of this qualitative synthesis of a set of MOOC evaluation studies was to explore outcomes for MOOC learners, that is, how the learners themselves benefit from participating in MOOCs.

Methods: To explore MOOC learners' outcomes, we conducted a qualitative synthesis in the form of a deductive thematic analysis, aggregating findings from 17 individual studies selected from an existing systematic review of MOOC evaluation methods. We structured our inquiry using the Kirkpatrick model, considering Kirkpatrick levels 2, 3, and 4 as potential themes in our analysis.

Results: Our analysis identified six types of Kirkpatrick outcomes in 17 studies. Five of these outcomes (learning/general knowledge, skills, attitudes, confidence, and commitment) fit into Kirkpatrick Level 2, while Kirkpatrick Level 3 outcomes concerning behavior/application were seen in four studies. Two additional themes were identified outside of the Kirkpatrick framework: culture and identity outcomes and affective/emotional outcomes. Kirkpatrick Level 4 was not represented among the outcomes we examined.

Conclusions: Our findings point to some gains from MOOCs. While we can expect MOOCs to persist, how learners benefit from the experience of participating in MOOCs remains unclear.

Introduction

When the first massive open online course (MOOC) was offered in 2008, the MOOC format—free, online, and open to anyone with an internet connection—was touted as revolutionary for its potential to democratize access to educational opportunities due to its theoretically universal availability [1-3]. The earliest MOOCs used a connectivist paradigm in which the course was built from networks of online resources and relied on openness and participation from learners. These so-called cMOOCs had the potential to allow learners to participate in their own education outside the traditional, face-to-face classroom setting and to connect with learners worldwide [4]. Extended MOOCs (xMOOCs) brought the MOOC format back to a more traditional structure, with instructors determining the content while still providing “open” availability to anyone with internet access. In practice, there are limits to what this expansive availability has accomplished [2,5]. However, as MOOCs persist, it is useful to explore their role in education by examining what they do offer their participants.

Learning is a complex phenomenon that can be described from different perspectives. Understanding learning is about understanding not only learning processes but also the conditions that influence—and are influenced by—the learning process [6]. In this paper, learning is understood from a constructivist and social-constructivist perspective in which reality and new understanding are constructed by learners on the basis of their previous knowledge, perceptions, and experiences. Learning thus consists of contextual aspects (ie, teachers present information in a way that enables learners to construct meaning on the basis of their own experiences, with a focus on situating learning in an authentic activity); cognitive aspects (ie, recognizing individuals’ perception, memory, and meaning-making); and social aspects (ie, converging on learning as a social activity that occurs through interactions between the learner and others) [7,8]. This conception of learning thus reintegrates the artificial and no longer useful distinction between cMOOCs and xMOOCs [9].

A number of systematic reviews have examined MOOCs [4,10-17]. These reviews indicate that much research on MOOCs focuses on evaluating noncompletion rates and retention vs attrition; learner motivation and engagement as well as other behavioral elements, and how these relate to retention and achievement; implications of the latter for MOOC design; and learners’ own assessments of the courses [3,4,10,12,16,18]. Research also points to a lack of studies on learners’ own experiences and outcomes [3,4,10]; however, there are some exceptions [14,19]. For example, in their review, Pilli and Admiraal [19] investigated MOOC learner outcomes with the intention of informing MOOC course design. Joksimovic et al [14] argued that outcomes and learner engagement are commonly differentiated in the MOOC literature; however, their systematic review proposes an approach that reconnects the two, especially for MOOCs that do not include assessments (eg, cMOOCs as originally conceived). Joksimović et al [14] built on a model by Reschly and co-workers [20] that conceives of learning outcomes as “proximal” or “distal,” with academic, social, and affective outcomes within each; they modified this

model for the “nonformal, digital educational settings” of MOOCs [14]. Despite their work on outcomes, Joksimovic and colleagues reiterated the finding that attempts to measure or evaluate the benefits to learners of participating in MOOCs have been mostly limited to date.

Another systematic review by Rowe et al [17] investigated the utility of open online courses (OOCs, including MOOCs) in health professions education. They evaluated the available research with a framework that included five “outcome” categories, including effectiveness (increase in learner knowledge), learner experiences, feasibility, pedagogy, and economics; they concluded that the available evidence neither unequivocally supports nor refutes the use of such courses. Their review was limited to the health professions; however, it highlighted the absence of rigorous research on MOOCs and the concurrent persistence of these courses. Their “effectiveness” category further highlighted the absence of research on benefits to MOOC learners, specifically in the health professions. They argued that the application of MOOCs in health professions education should be limited until a great deal more quality research is performed [17].

In their recent systematic review, Alturkistani et al [21] also added to the discourse on MOOC evaluation methods. Alturkistani et al identified three “evaluation-focused categories” among the studies they reviewed: learner-focused, teaching-focused, and MOOC-focused [21]. We approached this review as a jumping-off point to further synthesize understanding of MOOC learner outcomes. Here, we unpack the learner-focused category in [21] and, more specifically, the “learning outcomes and experience” subcategory to investigate the learner outcomes for the included MOOCs. In our study, “learner outcomes” are direct statements that describe the knowledge, skills, and attitudes that learners have demonstrated or are expected to reliably demonstrate when successfully completing a course. Learner outcomes is an understudied area that warrants further investigation, as MOOCs are a learning environment distinct from traditional classrooms and even other forms of e-learning, and they continue to be embraced as an educational modality [22].

Thus, despite their persistence, MOOCs have not lived up to the early expectation that they would allow widespread, nearly universal access to education. For example, there is consistent evidence that learners who use MOOCs, and indeed those who are more likely to complete them, are generally more educated and affluent [1,23,24]. There is also insufficient evidence that MOOCs are useful in areas such as health professions education [17]. MOOC learners are heterogeneous along numerous dimensions, including native language, prior training, age, economic status, and geographic location [24]. The heterogeneity of the expectations and goals of MOOC learners has also undoubtedly contributed to the difficulty of evaluating MOOCs and characterizing their benefits, a difficulty that is illustrated below in the heterogeneity of the studies reviewed. Thus, if MOOCs are not, in practice, democratizing education, and they have not lived up to traditional learning settings for at least some professional fields, what are they offering? In this study, we focus our attention on what learners do gain from participating in MOOCs, including but not limited to

performance measures; that is, we explore how learners benefit from the experience of participating in MOOCs, including and beyond outcomes directly related to learning.

Methods

We conducted a qualitative synthesis in the form of a deductive thematic analysis, aggregating findings from individual studies, to explore MOOC learners' outcomes. The datasets used and analyzed during the current study are available from the first author on reasonable request. To structure our inquiry, we relied on a commonly used framework for evaluating learning with applications in multiple learning and training settings: the Kirkpatrick model [25]. This model frames training on four levels: (1) *reaction*, (2) *learning*, (3) *behavior*, and (4) *results*. A more recent version [26] updates and clarifies the model, proposing that *reaction* includes customer satisfaction, engagement, and relevance; *learning* includes knowledge, skills, attitude, confidence, and commitment; and *behavior* refers to how the learner applies the learning "on the job." The more recent version of the behavior level adds "processes and systems that reinforce, encourage, and reward performance of critical behaviors on the job" [26], which can be seen as catalysts for applying what has been learned. These processes and systems, which include job aids, coaching, work review, and incentive systems, are referred to in [26] as "required drivers" or factors that increase the likelihood that people will retain and apply what they have learned in a given setting, referred to as "required drivers". *Results* are the targeted outcomes of the training, such as whether the results of the training are seen within an organization; the more recent version adds "leading indicators" (short-term measures that can indicate whether the results are likely to occur) [26].

The studies in the current synthesis derive from Alturkistani et al's systematic review of MOOC evaluation methods [21]. Their review included studies from 2008 to 2018 that focused primarily on MOOC evaluation and studies that reviewed or applied MOOC evaluation methods. Both quantitative and qualitative studies were included, after a careful assessment of their methodological quality, as well as grey literature. During the last few years, the contribution of qualitative evidence has been acknowledged within research [27]. This is in line with the epistemological stance of this review. The complete search strategy and further details of the source review [21] can be found in [18]. Alturkistani et al [21] identified 3275 records; after a review procedure, the final review included 33 studies.

Specifically, Alturkistani et al's "learning outcomes and experiences" subcategory was the basis for the current synthesis, as we looked at what learners gain from the experience of participating in MOOCs. This subcategory included 21 studies. We reviewed each paper in this category for findings that included learners' outcomes. Each study was examined for outcomes specific to the learners themselves. We did not include measures of engagement, motivation, completion, or attrition in our analysis unless they were clearly tied to the outcomes for learners. In an additional step intended to capture all learner outcomes, we examined Multimedia Appendix 3 in Alturkistani et al's review [21], which included all 33 studies. As a result of this review, we excluded 12 studies that did not include clear outcomes for learners (Figure 1), which left 21 studies for our analysis. As the analysis proceeded, we determined that the outcomes in 6 of these 21 studies were not clear enough to include. Notably, we did include one study [28] that was not included in Alturkistani et al's "learner outcomes and experience" category. Of the resulting 16 studies for analysis, 4 had more than one outcome. Multimedia Appendix 1 describes this procedure in detail.

More specifically, in this qualitative synthesis, we performed a deductive thematic analysis [29] where the starting themes were the four Kirkpatrick levels. We extracted all outcomes from the 16 studies; we then placed these in Kirkpatrick level 2, 3, or 4. After this first coding, which was conducted by ERB, TS and PJP reviewed the results. Second, ERB further analyzed the findings in each category according to the subthemes within each Kirkpatrick level. Subsequently, the findings were discussed and subjected to adjustments until consensus among all investigators was reached. Although the aforementioned steps appear to be consecutively ordered, the process of analysis and search for patterns was in no way linear; rather, it was iterative and recursive. No software program was used to aid the analysis. The structure of our analysis allows for the possibility that the same study will have multiple outcomes and thus will appear under more than one level. Level 1 (*reaction*) in the Kirkpatrick model was not of interest to our investigation, as there is a great deal of existing research on learners' assessment of MOOCs.

Outcomes that could not be matched with the Kirkpatrick levels were set aside for a separate inductive thematic analysis, which is presented as "Outcomes beyond Kirkpatrick."

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow diagram: systematic review (A) for a synthesis paper on MOOC learning outcomes (B). Modified from Alturkistani et al [21].

Results

Our analysis resulted in six types of outcomes. These are summarized in Table 1 as framed by the levels in the Kirkpatrick model.

Kirkpatrick Level 2: Learning

Our deductive analysis showed that 15/16 (94%) of the examined studies included one or more outcomes corresponding to Kirkpatrick Level 2. Thus, the Learning theme here incorporates concepts such as knowledge, skill, attitude, confidence, and commitment. Each subtheme is presented using the identified data and illustrated with supporting quotations.

Subtheme: Knowledge

Most of the Level 2 outcomes we identified were scores or survey items that assessed knowledge in some form. For example, in their MOOC on new media in teaching and learning, Chen et al [30] reported "learning performance" via quiz scores and a final paper, for which the participants could earn

"Excellence Awards." Four studies in our sample took a longitudinal view of learning outcomes via a pretest/posttest design. For example, Konstan et al [31] used a longitudinal design to test knowledge of technology that predicts preferences based on previous behavior (recommender systems technology); based on precourse and postcourse test scores within their MOOC, the gains in knowledge measured at the end of the course persisted at a 5-month follow-up in most cases. Further, in a MOOC designed to prepare medical students for global health experiences, Jacquet and colleagues [32] found an increase in post-MOOC compared to pre-MOOC test scores. Next, using average quiz and homework scores, Liang et al [33] reported an increase in quiz and homework scores enhanced by participation in online activities. Cross [34] used preassessments and postassessments to track changes in knowledge on a scale from "novice" to "expert," while Colvin et al [35] reported improved scores on postcourse versus precourse tests in introductory physics, and Mackay et al [36] saw a postcourse increase in scores on their assessment of participants' knowledge about animal welfare.

Table 1. Outcomes of MOOC studies framed by Kirkpatrick Level 2 or Level 3.

Kirkpatrick level, subtheme, and study	Data collection	Data analysis	Outcome variables	Outcome findings
Level 2: Learning				
1. General learning/change in knowledge				
Chen et al (2015) [30]	Scores on quizzes and final paper	Inferential statistics	Possible “Excellent Paper,” “Excellent Participation,” and “Excellent Group Member” awards	Learners received these awards if they fulfilled the criteria
Konstan et al (2015) [31]	Three-part longitudinal design: precourse, post-course, and 5-month follow-up “knowledge tests” and surveys	Inferential statistics; qualitative analysis	Assessed knowledge of recommender systems ^a	Gains in knowledge and 5-month retention of acquired knowledge
Jacquet et al (2018) [32]	LMS ^b data; pre-MOOC and post-MOOC knowledge tests	Inferential statistics	Score on knowledge test	Increased knowledge score from pretest to posttest
Liang et al (2014) [33]	Assessments: quizzes and homework	Inferential statistics	Average assessment score	Increase in assessment score related to degree of participation
Cross (2013) [34]	Precourse and postcourse surveys; LMS	Descriptive statistics	Knowledge: “novice” to “expert” ^a	Increase in knowledge
Colvin et al (2014) [35]	Normalized gain between pretests and posttests in introductory physics; “ability” based on test items attempted, analyzed with Item Response Theory (IRT)	Inferential statistics	Comparison of pre-MOOC and post-MOOC physics knowledge and “ability”	Learning (measured via posttest score) across several cohorts identified using IRT
MacKay et al (2016)[36]	Precourse and postcourse assessments of animal welfare knowledge	Inferential statistics	Scores on animal welfare knowledge assessment	Increased scores
2. Skill				
Brunton et al (2017)[37]	Weekly Likert scale quizzes during the MOOC: “individual digital readiness tools” and postcourse quiz	Descriptive statistics	Preparedness for online learning ^a	Self-assessed changes in preparedness for online learning
Rubio (2015)[38]	Precourse and postcourse comprehensibility ratings	Inferential statistics	Spanish comprehensibility (language pronunciation)	Increased comprehensibility in postcourse ratings
Stephens and Jones (2014) [39]	Precourse and postcourse surveys with mostly open-ended items	Content analysis	Skills discovery ^a	Technological skills
Liu et al (2014) [40]	End-of-course surveys (Likert scale and open-ended); email interviews	Descriptive and thematic analysis (focused coding)	Three things students learned ^a	Skills in data visualization, critiquing, and creating infographics
3. Commitment				
Alturkistani et al (2018) [41]	Case studies; interviews	Thematic analysis	Learning achievement; use of information in the workplace ^a	Intention to apply knowledge
4. Attitude				
MacKay et al (2016) [36]	Multiple-choice quizzes; confidence and attitude surveys (mostly Likert scale)	Inferential statistics	Change in attitudes; certificate of achievement for completion ^a	Change in attitude
5. Confidence				

Kirkpatrick level, subtheme, and study	Data collection	Data analysis	Outcome variables	Outcome findings
Hossain et al (2015) [28]	Ten-point scale; confidence-to-treat	Inferential statistics	Confidence to treat spinal cord injury ^a	Gains in confidence
Cross (2013) [34]	Precourse/postcourse survey; LMS	Descriptive statistics	Confidence to apply learning ^a	Gains in confidence
Mackness et al (2013) [42]	Interviews (face-to-face and email) and focus groups; assessment of microteaching	Qualitative case study approach	Confidence to participate in social learning environments ^a	Gains in confidence
Lei et al (2015) [43]	Pre-MOOC and post-MOOC surveys; forum threads	Sentiment analysis	Identity and confidence ^a	Confidence in work; confidence to inspire
Milligan and Littlejohn (2014) [44]	Interviews mid-MOOC	Qualitative analysis	Changes in practice ^a	Confidence about practices on the job
Level 3: Behavior				
Behavior/Application				
Milligan and Littlejohn (2014) [44]	Survey and interview	Qualitative analysis	Application of learning in professional practice ^a	Integrating new understanding in practice
Lei et al (2015) [43]	pre-MOOC and post-MOOC surveys; forum threads	Sentiment analysis	Effects on learners and community ^a	Bringing knowledge back to community
Cross (2013) [34]	Precourse/postcourse survey; LMS	Descriptive statistics	Changes in practice ^a	Implementation of tools in course design
Konstan et al (2015) [31]	Follow-up interview and survey	Inferential statistics	Application of new recommender system skills ^a	Application of systems at work, school, business

^aIncludes a self-report.

^bLMS: learning management system.

Subtheme: Skill

We found several examples of skill outcomes, including self-assessed preparedness (readiness for online education) [37] and improvement in Spanish language pronunciation and comprehensibility measured by pre-MOOC and post-MOOC assessments [38]. Further, participants in a library and information science MOOC were asked “What did you gain most from taking part in the MOOC?” Their responses included “Students gained new technological skills through their learning experience” [39]. Liu et al [40] found that learners gained skill through learning to “visualize data and critique infographics (and) learning visualization concepts and...tool use”; these were the most frequently cited “three things [students] had learned” in a journalism MOOC.

Subthemes: Commitment, Attitude, and Confidence

Other Level 2 outcomes were commitment, as shown through intention to apply knowledge [41]; attitude about animal welfare [36]; and confidence to treat patients, as measured in a randomized control trial study comparing a MOOC with a self-directed online learning module [28]. Additionally, Cross [34] reported that learners gained confidence with regard to applying what they had learned, and Mackness et al [42] also reported confidence to participate in various interactive learning activities:

They also gain the confidence to attend and contribute to live synchronous sessions, to openly share their work and ideas, and to cooperate and/or collaborate in social networking environments. “They shift from being consumers to producers.”

In their MOOC on Asian vernacular architecture, Lei et al [43] used a case study design to investigate learners’ postlearning experiences, asking, “How has the course influenced learners and their surrounding community?” This influence is reflected in the following learner’s experience:

It is through learning that I have gained the most confidence, in my identity and in my work. And I hope that this course would be the one of many stepping stones towards me being able to help inspire and nurture future generations....

Using a clinical trials MOOC, Milligan and Littlejohn [44] asked learners halfway through the course “to reflect on how their practice had changed as a result of the course.” Some learners had already seen an effect on their confidence and perspective: “These respondents reported a range of general benefits: that the course had given them a new perspective, had made them assured, or had helped them bring a greater criticality to their practice.” One participant stated, “I know why and why not...you have an overview, I cannot say I apply everything in my day to day work, but the fact that you feel more confident,

for me, it helps a lot.” This outcome in turn intersects with Kirkpatrick Level 3, as discussed in the next section.

Kirkpatrick Level 3: Behavior: Application

Our analysis found 4/21 studies (19%) with evidence of Level 3 outcomes. Level 3 includes application via critical behaviors plus the presence of outcomes that make it more likely that people will retain and apply what they have learned in a given setting (the abovementioned catalysts for application or “required drivers”).

In addition to effects on confidence (Level 2), Milligan and Littlejohn [44] found evidence of Level 3 outcomes from their clinical trials MOOC; in answer to the same question as above (how their practice changed as a result of the course), most learners reported having already incorporated their learning. For example, the respondent quoted above also reported immediate effects: “Well, it gives me a better understanding of why I do what I do...I understand why I have to submit my protocol or a complete or total submission to authorities, how a protocol has been developed.” [44] Another respondent said, “It is much, much better, I could address all of the challenges much better and make better decisions, and actually I participate with this CRO in developing the protocol and the study documents and everything.”

Lei and colleagues [43] described effects on how the learners brought their experience back to their communities, a behavioral application which reflects Kirkpatrick Level 3. For example, one participant from an area damaged by earthquakes reflected:

This course helped me to see the significance of the collapsed houses, temples, shrines, monuments and courtyards in a different angle which otherwise I would not have been able to see...I have already started contributing my knowledge with the local community as we come together to rebuild what has been destroyed.

Cross [28] described learners’ goals, including plans to implement tools from the MOOC in their course design; some learners reported having already done so, which is another example of application of the MOOC experience. Employing a longitudinal study design, Konstan et al [31] investigated MOOC learners’ application of course content (recommender systems technology). Kirkpatrick Level 3 behaviors are evident in the participants’ reports of incorporating the systems at work, school, or in entrepreneurial settings, and some also applied the underlying algorithms in other contexts.

Kirkpatrick Level 4

In this qualitative synthesis, we did not find any data congruent with Kirkpatrick Level 4, which includes outcomes and “leading indicators.”

Outcomes Beyond Kirkpatrick

Not all of the outcomes described in the studies are congruent or align well with the Kirkpatrick framework; hence, we present these outcomes separately here. After our inductive thematic analysis, we identified two themes among these outcomes: “culture and identity” outcomes and “affective/emotional” outcomes. Culture and identity outcomes included “insights

about themselves through personal reflection about their learning styles, professional practices, and the ways they view the world” [39], as well as connection to a community, whether of fellow educators [39,42] or those with a shared cultural heritage [43]. Affective outcomes such as “excitement” and “inspiration” are evident in [39], where learners gained “inspiration, energy, and excitement about the field.”

Discussion

Principal Results

In this qualitative analysis, we explored the benefits that MOOCs in a broad range of subjects offer their participants. We synthesized the types of outcomes reported in a set of MOOC studies, including but not limited to outcomes that assess learning in some way. Using the Kirkpatrick model as a framework, the most prominent findings were that most of the MOOCs described in the included studies only had outcomes that could be categorized as Kirkpatrick Level 2. Kirkpatrick Level 3 outcomes were also represented, although these were not as common as Level 2 outcomes. We did not observe any Kirkpatrick Level 4 outcomes in the data we analyzed. If a MOOC were to aim for or result in Level 4 outcomes, we would expect to see changes at the organizational level. This might reveal itself in the form of implemented changes in policy in a health care setting after a group of managers participated in a policy MOOC, or in the case of higher education, a change in pedagogical training for educators after a MOOC was attended by several faculty members. Our complementary analysis of outcomes that did not align with Kirkpatrick yielded two additional themes.

Previous Research

Previous research has shown that students generally perform better in face-to-face courses than in online courses [45], and several of the studies in our review used comparisons between MOOC and non-MOOC learning contexts. The studies analyzed in this study did not report outcomes that were unique to MOOCs; however, they did provide insight into what MOOCs do and do not offer to participants. For example, in a randomized control trial by Hossain et al [28] comparing a self-paced online course with an online course with MOOC-based guidance and study tips, improvement in knowledge of spinal cord injury treatment as well as gains in confidence to treat were observed after both courses; however, there was no advantage in the MOOC group. Additionally, Chen and coworkers [30] found no difference in scores on assignments between an online and an onsite version of a digital media course. Colvin et al [35] compared learning gains measured in their MOOC with learning gains in traditional settings; they found evidence of learning in the MOOC, in which scores were slightly higher than typical for a comparable lecture-based course but significantly lower than those seen in other courses with an “interactive engagement” component. In a finding that appears counter to the above, Rubio [38] found that improvement in language comprehensibility was greater in a MOOC compared to a face-to-face course. Finally, in their review, Rowe et al [17] looked specifically at the effectiveness of MOOCs in health professions education; they concluded that it cannot be said that

MOOCs “enhance student learning” despite the proliferation of MOOCs and the “hype” about their potential. These contradictory findings suggest that when comparing MOOCs to other learning formats, the benefits of MOOCs remain unclear.

MOOCs were also expected to foster and build social networks. However, in reality, the amount of interaction among MOOC participants is often limited, and a small proportion of learners are usually responsible for most of this interaction. This finding was reinforced by the studies we examined [42,43,45]. However, there are social elements to MOOC participation, as discussed in the Outcomes Beyond Kirkpatrick section above. Joksimović and colleagues [14] proposed a model that may be a useful framework for illuminating some of the outcomes that do not readily fit with the Kirkpatrick framework. Their model considers social outcomes (along with academic and affective outcomes) in “immediate,” “course-level,” and “postcourse” settings. Since affective and social outcomes are evident in the studies critically analyzed here, it is worthwhile to consider them as benefits to MOOC participation, which may warrant additional research in its own right; the model proposed by Joksimović and colleagues [14] may be a useful starting point.

Methodological Considerations

Using a well-known model to frame and lens our findings, in this study, we explored one understudied aspect of MOOCs that provides a view of what learners can gain from MOOCs. The richness of data using an in-depth secondary analysis of a small number of studies from a systematic review with broad subject matter, combined with frequent debriefing sessions and investigator triangulation, enhanced the credibility of the findings. We argue that qualitatively synthesizing existing data in an attempt to make sense of contextually and methodologically diverse findings is an important contribution to the scholarly literature. There are also some limitations to this study. Synthesizing both quantitative and qualitative data is a daunting task, as these data derive from very different paradigms. Thus, an important factor limiting the applicability of our findings is the problem with extracting results from eclectic and dissimilar studies, including qualitative and quantitative methods and grey literature, and attempting to contrast and compare them. The findings should thus be interpreted with due caution in light of this fact. Further, as our work builds on a previous review, we included only studies that were included therein. This may leave out some relevant studies, despite the rigorous inclusion criteria of the previous review. Finally, despite the frequent scholarly use of the Kirkpatrick framework, there are some inherent limitations to the model that also have implications for this work. It has been argued that the four-level model depicts an oversimplified view of learning and training effectiveness that does not take individual or contextual influences into account in the evaluation of the learning that occurs [46]. Thus, using the Kirkpatrick framework deductively as in this study and assorting “contextual” data into predefined themes was challenging. Further, Kirkpatrick’s model assumes that the four levels denote a causal chain in which

positive reactions lead to greater learning and training, yielding greater transfer and, consequently, more positive results. While the Kirkpatrick model is vague about the causal relationships between level outcomes, it does imply that a simple causal relationship exists between the levels in the model [47]. Finally, in this study, we examined data that were not congruent with the framework but which are nonetheless important to the discussion of MOOC outcomes. For example, when considering the outcomes reported in the studies we reviewed, we chose not to include outcomes we viewed as belonging to Kirkpatrick Level 1, Reaction. This level is usually reserved for outcomes that reflect a participant’s reaction to a particular program or training. Since this may include how the participants “feel” about the program in question, Level 1 outcomes can certainly include an affective state in relation to the training. We found some outcomes that we described as “affective,” which included “feelings” such as excitement and inspiration. However, these feelings did not refer to the MOOC (training) itself. Instead, the “excitement” and “inspiration” were feelings about the subject of the MOOC as a result of the MOOC, which does not seem to us to fall clearly within Kirkpatrick Level 1. We believe that these feelings may even fall under Kirkpatrick Level 2 in the “Attitude” category; however, we made the conservative decision to separate them. Whether these feelings are part of a Kirkpatrick framework would be an interesting topic for further inquiry.

Conclusions

Our findings point to some gains from MOOCs, and while we can expect MOOCs to persist, how learners benefit from the experience of participating in these courses remains unclear. This is especially true when comparing MOOCs to other learning modes, as evidenced by the comparative studies included in our sample. In our study, we looked for gains or benefits to MOOC learners in all subject areas, and we used the Kirkpatrick framework to explore what learners might gain. From a diverse set of studies, we found outcomes that included changes in knowledge, skills, attitude, and confidence as well as changes in behavior, increased excitement about a subject, and effects on cultural identity as a result of MOOC participation. Thus, beyond outcomes that can be classified as “learning,” such as increased knowledge or skill, it does appear that MOOCs provide some value for participants via the gains described above.

In contrast to systematic reviews of MOOC research, we carried out a deeper qualitative analysis of a set of studies from one systematic review that looked only at MOOC evaluation methods. Thus, as an extension of Alturkistani et al [21], we sought to identify MOOC outcomes that benefit the learner. With a qualitative investigation of a subset of studies on MOOC evaluation methods, we were able to apply the Kirkpatrick framework to identify a number of types of learner outcomes. However, as others have pointed out, the absence of systematic ways of measuring the benefits to learners is evident in our synthesis, and work remains to be done to determine the role of MOOCs and what they offer to participants and to the world.

Acknowledgments

We would like to thank Abrar Alturkistani, MPH and Edward Meinart, PhD for collaboration on the EIT Health project that inspired this paper. We also thank Hanna Augustsson, PhD for her expert review of our application of the Kirkpatrick model. All conclusions are the authors' own. This work was partially funded by EIT Health (Grant 18654).

Authors' Contributions

ERB, TS, and PJP contributed to the conception, study design, data collection, analysis and interpretation, and drafting and critical revision of the manuscript. All authors approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Simulation in virtual environments has become a new paradigm for surgeon training in minimally invasive surgery (MIS). However, this technology is expensive and difficult to access.

Objective: This study aims first to describe the development of a new gesture-based simulator for learning skills in MIS and, second, to establish its fidelity to the criterion and sources of content-related validity evidence.

Methods: For the development of the gesture-mediated simulator for MIS using virtual reality (SIMISGEST-VR), a design-based research (DBR) paradigm was adopted. For the second objective, 30 participants completed a questionnaire, with responses scored on a 5-point Likert scale. A literature review on the validity of the MIS training-VR (MIST-VR) was conducted. The study of fidelity to the criterion was rated using a 10-item questionnaire, while the sources of content-related validity evidence were assessed using 10 questions about the simulator training capacity and 6 questions about MIS tasks, and an iterative process of instrument pilot testing was performed.

Results: A *good enough* prototype of a gesture-based simulator was developed with metrics and feedback for learning psychomotor skills in MIS. As per the survey conducted to assess the fidelity to the criterion, all 30 participants felt that most aspects of the simulator were adequately realistic and that it could be used as a tool for teaching basic psychomotor skills in laparoscopic surgery (Likert score: 4.07-4.73). The sources of content-related validity evidence showed that this study's simulator is a reliable training tool and that the exercises enable learning of the basic psychomotor skills required in MIS (Likert score: 4.28-4.67).

Conclusions: The development of gesture-based 3D virtual environments for training and learning basic psychomotor skills in MIS opens up a new approach to low-cost, portable simulation that allows ubiquitous learning and preoperative warm-up. Fidelity to the criterion was duly evaluated, which allowed a good enough prototype to be achieved. Content-related validity evidence for SIMISGEST-VR was also obtained.

Introduction

Background

The emergence of minimally invasive surgery (MIS) in the mid-1980s [1] led to an increase in the number of iatrogenic bile duct injuries, as many surgeons worldwide switched from the paradigm of open surgery to these procedures with no previous training [2,3]. In the wake of these developments, simulation became valuable as a tool for learning psychomotor skills in MIS and numerous studies have demonstrated its usefulness [4,5].

Simulators for skill learning in MIS can be classified into 3 large groups: (1) traditional box trainers, (2) augmented reality simulators (hybrids), and (3) virtual reality (VR) simulators [6,7]. The last two are expensive and are unavailable in most universities or hospitals in developing countries [8]. The first VR simulator for MIS training was MIS training-VR (MIST-VR) [9]. In 1998, evidence for the construct validity of the device was established [10]. Later, in 2002, the evidence for prediction validity was added [4,11]. Finally, from 2002 onward, the evidence for concurrent validity was also demonstrated [12,13]. Recent years have seen the development of low-cost, gesture-based touchless devices that can interact with 3D virtual environments, such as the Microsoft Kinect (MS Kinect, Microsoft Corp), Leap Motion Controller (LMC; Leap Motion Inc), and the Myo armband (Thalmic Labs, Kitchener) [14].

For the development of the simulator used in this study, the researchers adopted the design-based research (DBR) paradigm, also known as *design research*. DBR seeks the creation and validation of useful artifacts that do not exist in nature [15] and is described by Manson [16] as “a process of using knowledge to design and create useful artefacts, and then using various rigorous methods to analyze why, or why not, a particular artefact is effective. The understanding gained during the analysis phase feeds back into and builds the body of knowledge of the discipline.” DBR is a solution-oriented process that focuses on solving practical and complex real-world problems [17]. The artifacts created can be constructs (vocabulary and symbols), models (abstractions and representations), methods (algorithms and practices), *instantiations* (implemented and prototype systems), and better design theories [18,19]. To develop the simulator, the study followed the method proposed by Manson [16,20,21], in which using processes of abduction and deduction that detect errors in the design or function of the prototype, supports the development of improved versions until a sufficiently *good enough* functional product is obtained that can be subjected to validation studies [16,20-22]. These *good enough* devices are rarely complete and are functional systems ready to be used in practice; rather, they are innovations that define the ideas, practices, technical capabilities, and products using which systems analysis, design, implementation, and use are achieved effectively and efficiently [17].

Objectives

The first aim of this study was to describe the development of a web-based 3D VR simulator mediated by a gesture interface device (LMC) for learning basic psychomotor skills in MIS,

called gesture-mediated simulator for MIS-VR (SIMISGEST-VR). The device is characterized by its portability and low cost, as well as the possibility of learning and training at any time and place (ubiquitous learning). The second aim of this study was to evaluate fidelity to the criterion and to find sources of content-related validity evidence for SIMISGEST-VR.

Methods

Overview

This is a descriptive report of the development, using a DBR paradigm, of a gesture-mediated simulator for learning basic psychomotor skills and of the prospective evaluation of the data obtained from Likert scale surveys to evaluate fidelity to the criterion and the sources of content-related evidence. To this end, the study participants rated fidelity to the criterion using a 10-item questionnaire about its ease of use, relevance as a tool for simulation in MIS, degree of correspondence between the movements of the forceps and their representation in the virtual space, and feedback. The sources of content-related validity evidence were (1) a literature review on a previously validated tool, the MIST-VR, and (2) an expert panel that answered 10 questions about the training capacity and 6 questions about each proposed task, with responses scored on a 5-point Likert scale that rated the extent to which the test content represented the domain evaluated. An iterative process of simulator development was performed using pilot testing by surgeons, engineers, and education experts until a *good enough* prototype was achieved.

The hypotheses were as follows:

- It is possible to develop a portable, low-cost, gesture-mediated simulator using the LMC for training and learning basic psychomotor skills in MIS.
- The 3D virtual environment and the proposed tasks showed fidelity to the criterion.
- It is possible to demonstrate sources of evidence for the content validity of the test items.

The first step of the validation process was to define the construct and proposed interpretation. In this study, the general construct is psychomotor skills in surgery, specifically basic psychomotor skills in MIS. The assumptions and proposed interpretations are that the 3D virtual environment is faithful to the criterion and the tasks adapted from the MIST-VR represent the construct that is intended to be measured. The instrument under investigation is a contactless, gesture-mediated simulator that uses the LMC (construct context). To determine the current use of gesture-mediated interfaces in surgery, especially in the field of surgical simulation, a systematic literature review was conducted [14]. Finally, as content-related validity evidence was collected, the goal was to identify whether there were any areas of construct underrepresentation or construct irrelevance.

Phase 1: Initial Development of the Gesture-Mediated Simulator for Minimally Invasive Surgery-Virtual Reality

To develop a new type of web-based 3D VR simulator mediated by a gesture interface device (LMC) for learning basic

psychomotor skills in MIS, a group consisting of a pediatric surgeon, systems engineer, industrial designer, and specialists in education was formed. The following technical elements were assembled: an electronic device (LMC), a computer program for the development of the 3D environment, a computer, hardware devices with no electronic components, and a database administrator.

Electronic Device: Leap Motion Controller

In May 2012, a sensor was launched based on the principle of infrared optical tracking, which detects the positions of fine objects such as fingertips or pen tips in a Cartesian plane. Its interaction zone is an inverted cone of approximately 0.23 m³, and it has a motion detection range that fluctuates between 20 mm and 600 mm [23,24]. This sensor measures 76 mm × 30 mm × 13 mm and weighs 45 g. It has 3 infrared emitters and 2 infrared cameras that capture the movements generated within the interaction zone [25,26]. The manufacturer reports an accuracy of 0.01 mm for fingertip detection, although one independent study showed an accuracy of 0.7 mm [27]. Although the LMC is designed mainly to detect the motion of the hands, it can track objects such as pencils and laparoscopic surgical forceps [28,29].

The LMC has been used as a tool to manipulate medical images in the fields of interventional radiology and image-guided surgery or when there is a risk of contamination through contact (eg, autopsy rooms). It has also been used for touchless control of operating lights and tables and simulation in MIS and robotic surgery using physical or VR simulators [14,28].

Unity3D and Development of the Web-Based Virtual Environment Based on Minimally Invasive Surgery Training–Virtual Reality Tasks

The 3D virtual environment with MIS tasks was created using a tool for developing games, Unity3D, which allows apps to be developed that are independent of the operating system or device [30].

The basis for the development of this environment was the MIST-VR, presented in 1997. This device is a low-cost, nonprocedural simulator that provides a large variety of metric data for analysis [31] and generates simple and abstract images that allow the training and learning of basic psychomotor maneuvers that cross many surgical disciplines [9,32,33]. The simple images allow novice learners to progress rapidly in the early phase of the basic psychomotor skills learning curve [34–36], although detailed performance analysis and feedback allow them to train alone, with no need for specialized instructors [37].

The basic psychomotor skills in MIS that can be learned using the MIST-VR are navigation-coordination, touching, grasping, stretching-traction, translocation, and electrocautery [38].

Computer

The computer displays the 3D virtual environment, records the metrics, stores them on a database, and provides feedback using graphs that show the score obtained after each exercise. The virtual environment developed runs on both PC and iOS operating systems.

Hardware Devices

The mechanical devices are represented by 2 MIS forceps that do not need to be functional, 2 support devices for the forceps with an entry trocar simulator, 1 support device for the LMC, and 1 pad for mounting the support devices.

During the development of the virtual environment, the types of specificity recommended by Bowman et al [39] were applied:

- *Application:* To design a web-based 3D virtual environment for basic psychomotor skills training in MIS
- *Domain:* Basic psychomotor skills in MIS
- *Tasks:* 6 tasks described in the MIST-VR were adopted
- *Device:* LMC, LEAP
- *Users:* Surgeons in training for learning basic psychomotor skills in MIS

Phase 2: Evaluation of Fidelity to Criterion, Content-Related Validity Evidence

Subjects

The study was performed over a period of 3 months at different locations: XXXIV Brazilian Congress of Paediatric Surgery (Campo Grande, Brazil); Hospital Vall d'Hebron (Barcelona, Spain); and Hospital Infantil de la Cruz Roja (Manizales, Colombia). A total of 22 experienced surgeons (performed more than 100 MIS procedures) and 8 pediatric and general surgery residents (referent group, performed less than 100 MIS procedures) assisted in an informative session on the characteristics of the project, watched a demonstration video of the different tasks supported by the simulator, and had 2 opportunities to perform each of the tasks on the simulator. The performance metrics were not taken into account during this study, as the emphasis was placed on the assessment of the tool by those surveyed.

Content-Related Validity Evidence for a Previously Validated Tool

The first source of content validity for the SIMISGEST-VR sought to identify the main sources of validity evidence for the MIST-VR, as well as the studies that have demonstrated such validity.

Questionnaire

First, a demographic survey was administered that included questions on the level of training as a surgeon and level of experience in MIS, as well as experience with video games. The different factors in the evaluation of fidelity to the criterion and content validity study were assessed using a Likert scale, where 1=strongly disagree, 2=disagree, 3=neither agree nor disagree, 4=agree, and 5=strongly agree [40].

The questionnaire to assess fidelity to the criterion evaluated 10 aspects, while the content validity rated the training capacity and the tasks. In terms of the training capacity, 6 aspects were evaluated, and each of the 6 tasks (Table 1) was assessed based on whether or not it represented a specific surgical maneuver (Multimedia Appendix 1).

Simulator, Hardware, and Software

This study used SIMISGEST-VR with 6 tasks and their respective metrics and feedback. The hardware and software components of the simulator are described in phase 1: Development of SIMISGEST-VR of this paper.

Statistics

Normality was tested using the Shapiro-Wilk test. The distribution of the variables was not normal. The Likert scale median and interquartile range differences between the levels of education and experience were compared using the Kruskal-Wallis test. A statistically significant level <0.05 was established. The analysis was performed using Stata version 15.0 (StataCorp).

Results

Phase 1: Development of Gesture-Mediated Simulator for Minimally Invasive Surgery–Virtual Reality

The Virtual Environment

The virtual environment consists of the following modules:

- *Registration*: Collects the user's demographic information and stores it in the database
- *Tutorial*: Presents demonstration videos of the exercises
- *Test (tasks)*: Supports 6 tasks, each of which corresponds to a surgical equivalent (Table 1) [9,41]
- *Performance graphs*: When an exercise is completed, the platform displays the results of the metrics in terms of the time taken to perform the exercise, precision of movement, and presence or absence of errors (immediate feedback; Figure 1). In this module, the student can look up the score obtained after each exercise and check whether or not their performance has improved (terminal feedback; Figure 2).

Except for Task 3, all tasks have the option of configuring the dominant hand during the exercise. Task 3 requires the simultaneous use of both hands and therefore both play a dominant function.

The web-based virtual environment runs on PC and iOS platforms.

These exercises are based on the instructional strategy known as *drill and practice*, which promotes the acquisition of knowledge or skill through repetitive practice [42].

Table 1. Description of the tasks and their surgical equivalents.

Task ^a	Description	Surgical equivalent
Task 1: Grip and placement	Take the sphere with one hand and move it to a new location within the workspace	Gripping and retraction of a tissue to a given position, placement of clips and hemostasis, and use of extractor bags
Task 2: Transfer and placement of an object	Take the sphere, transfer it to another instrument, and place it inside a hollow cylinder	Transfer of a needle between a clamp and a needle holder
Task 3: Cross	Instruments travel along a surface in a 3D cylinder	Small intestine exploration
Task 4: Removal and reinsertion of instruments	Removal of the instruments from the operative site and reinsertion	One instrument stabilizes one organ while the other is removed from the field and reintroduced
Task 5: Diathermy	Cauterize a series of targets located in a fixed sphere	Cauterize a bleeding blood vessel
Task 6: Target manipulation and diathermy	Take the sphere with the instrument and place it inside a virtual space represented by a cube. Cauterize a series of targets with the other hand	Present and set a target to cauterize

^aAdapted from [9].

Figure 1. Immediate feedback.**Figure 2.** Performance history and terminal feedback curve.

Metrics

The metrics were established using 5 parameters:

1. *Time*: Time taken from starting the task until completion. The time is measured only for each individual task.
2. *Efficiency of movement for the right and left hand*: This is the time during which the tip of the forceps is outside the ideal path, that is, the difference between the actual and the ideal path length [10,43].
3. *Economy of diathermy*: If contact occurs with the target for more than 2 sec during the diathermy, it is considered excess burn time and is penalized as a specific error.
4. *Error*: The following were defined as errors [43,44]: contact of the target with a part of the forceps other than the tip: all exercises; contact of the instrument with the limits of the virtual working space: all exercises; number of contacts of the instrument with the target sphere: exercises 1 and 2; number of contacts of the instrument or the sphere with the container margins: exercises 1 and 2; number of times that the instruments made undue contact between them: exercises 3 and 4; number of times that the instruments exceeded the number of contacts permitted with the oval: exercise 4; time during which the tip of the instrument remained outside the ideal path for the exercise: exercises 1, 2, 4, and 6; diathermy of the sphere outside the stated objectives: exercises 5 and 6; excess burn time: exercises 5 and 6.
5. *Final score*: The final score is obtained from the sum of the results of the efficiency of movement for each hand plus the economy of diathermy and from the errors generated in each exercise. Each exercise generates different types of errors, and each error is assigned a value between 1 and 5, where 1 is the least important and 5 is the most important. For example, diathermy outside the assigned targets means an error with an assigned score of 5. The number of errors committed in each of the exercises is then counted, and this figure is multiplied by the value assigned to each error. Finally, all the figures obtained in each of the errors are added, and the final score results from subtracting the sum obtained from 100. This is expressed in the following formula: $100 - \sum(\text{error} \times \text{value})$. Thus, a higher score indicates better performance.

Feedback

The haptic sensation and the concurrent feedback are simulated using sound signals, color changes in the objects, and movement of the object when an undue collision occurs between the different components of the environment or when an error occurs during the exercise. At the end of each task, the system provides information on the presence or absence of errors, the efficacy and efficiency, and the time required (immediate feedback). At the end of each training session, the system provides a series of graphs and tables that show the performance over time; this is the terminal feedback (Figures 1 and 2).

SQLite Database Engine

The data generated by the program were initially stored on an independent Structured Query Language database engine. However, during the development, this database was integrated into the virtual environment, which facilitated the acquisition of the users' demographic data, registration of all the data provided by the metrics, and generation of reports of the users' demographic and performance data. This information is stored on the computer on which the tests are performed.

Hardware

Two laparoscopic forceps were used. These MIS forceps did not need to be functional.

In the initial phase of development, the researchers used a prototype that did not have support devices (Figure 3), but it soon became evident that the fulcrum effect was not being reproduced. For this reason, they designed support devices for the forceps, which simulate the entry portal to the abdomen (Figure 4). These devices, while generating friction when inserting and removing the forceps, limit the moment of the arms, as occurs in real surgical procedures. During the process of designing these devices, principles were prioritized, such as noninterference with the forceps reading by the LMC, portability, and low cost. A pad for mounting the support devices and the LMC was also designed, which had a 45-degree tilt on a horizontal plane.

The final artifact with all its components assembled is shown in Figure 5. It shows the fixing pad (1) for the LMC and the mounting support devices (3) for the MIS laparoscopic forceps (2), which allow simulation of the fulcrum effect; the LMC (4), responsible for detecting the movements of the instruments;

and the computer, which using the software programs administers the virtual environment and the metrics and provides feedback and the final performance score on the screen (5), where the 3D virtual environment is displayed.

In Figure 4, the LMC has a 45-degree tilt toward the screen with respect to the horizontal plane. This arrangement was the result of a process of trial and error, which showed that setting the LMC at this angle with respect to the horizontal plane ostensibly improved the detection of the forceps. Another significant change during the design was that the original black color of the shaft of the forceps did not facilitate reading by the LMC [45]; therefore, they were painted white in the final prototype (Figure 4).

Figures 6-8 show various stages in the development of the prototype for the 3D virtual environment. As in the development of the hardware elements, the 3D virtual environment design process was iterative, so that each new version of the 3D virtual environment became increasingly closer to the version considered *good enough* in terms of the design and function.

Figure 6 shows the initial attempt at the interaction between the forceps and the basic 3D virtual environment. At this stage of the design, the researchers achieved *capture* of the virtual objects by the tip of the instruments and their transfer to a virtual container (Figure 6). The second stage of development accomplished the development of the 5 tasks in a 3D virtual environment characterized by rectangular geometric shapes (Figure 7). Although the researchers did have concurrent feedback based on sounds, color changes, and a sensation of collision, at that time, the metrics had not been developed. Figure 8 shows the final *good enough* result of the 3D virtual environment. On the basis of the feedback provided by the expert surgeons, the environment was redesigned without rectangular geometric shapes, although with abstract circular shapes that were closer to the view of the body cavities during the MIS procedure.

The changes shown in Table 2 reflect the steps in the process described by Manson [16,20], where during the development of the artifact, through iterative processes of deduction and circumscription, errors were recognized in the design or function of the prototype that required further versions to be developed until the study achieved one that was considered *good enough* [16,17] and functional.

Phase 2: Evaluation of Fidelity to the Criterion and Subjective Validation of SIMISGEST-VR (Content Validity)

The next step in the process was the evaluation of fidelity to the criterion and the process of subjective content validity. The results are described below.

Demographics

A total of 30 people with an average age of 42 years (SD 2.2) participated in the study; 53% (n=16/30) were men. Those surveyed came from Colombia (n=14), Spain (n=8), Argentina (n=3), Brazil (n=2), Uruguay (n=2), and France (n=1).

Table 3 summarizes the participants' profiles according to the level of training and experience. The residents belonged to training programs in general and pediatric surgery; one of the participants was a biomedical engineer with extensive experience in the design of devices and simulators in MIS. The vast majority (n=28/30, 93%) of participants were right-handed, 1 was left-handed (n=9/30, 3%), and the other, ambidextrous (n=9/30, 3%).

In terms of the use of video games, most (n=22/30, 73%) of those surveyed had no experience with these app; 62% (n=5/8)

of those who used video games were women. Of those with experience in video games (n=8), only 1 played them weekly, while the rest played them once a month (n=3) or occasionally (n=4). The mean age of those with no experience in video games was 44 years (SD 2.7), compared with 37 years (SD 3.5) for those with experience ($P=.16$).

Only 33% (n=10/30) of the participants had experience with VR devices, and only one-third used them occasionally.

Most of the surveyed participants had previous experience with simulators. In terms of the level of operating experience, 54% (n=14/26) of the respondents with experience with simulators had an intermediate or advanced operating level, followed by those with a basic operating level (n=10/26, 38%). Among participants who had experience with simulators [26], 62% (n=16/26) had used physical simulators, 23% (n=6/26) had used hybrid simulators, and only 15% (n=4/26) had used VR simulators. The average age of those who had no experience with simulators was 40 years (SD 6.7), compared with 42 years (SD 2.4) for those with previous experience ($P=.83$).

The demographic profile questionnaire can be found in Multimedia Appendix 1.

Table 3. Demographic profile according to the level of experience and training (N=30).

Demographic variable	Level of experience				Level of training		
	Basic manipulation (n=3) ^a	Basic operating level (n=11) ^b	Intermediate operating level (n=8) ^c	Advanced operating level (n=8) ^d	Practicing surgeon (n=21)	Resident (n=8)	Other (n=1) ^e
Age (years), mean (SD)	26 (0.6)	40 (4.3)	43 (3.3)	49 (2.9)	47 (2.2)	27 (0.6)	49 (—) ^f

Evaluation of Fidelity to Criterion

Tables 4 and 5 show that there were no significant differences in the different ratings when the level of training (Table 4) or experience (Table 5) was considered.

In terms of the fidelity to the criterion, none of the respondents strongly disagreed with any of the items asked. The rating of *disagree* was given by one participant to the question about relevance, by another to the assessment of how the movements of the physical instruments were represented in the virtual environment, and 3 assigned this score when rating the fulcrum effect.

In terms of ease of use, 73% (n=22/30) and 27% (n=8/30) assigned a rating of 5 and 4, respectively. The same results were obtained when the navigation menu was assessed. With regard to the relevance of the tool as a simulator, 73% (n=22/30) assigned a score of 5 and 20% (n=6/30) assigned a score of 4.

When assessing the capacity of the physical devices to simulate the fulcrum effect, 73% (22/30) assigned a score between 4 and 5, 17% (n=5/30) assigned a score of 3, and 10% (n=3/30) assigned a score of 2. For this last rating, in terms of the level

of training, 2 were practicing surgeons and 1 was a resident, whereas in terms of the level of experience, one corresponded to basic manipulation, one to intermediate operating level, and another to advanced level.

In terms of how the movements of the forceps were represented in the virtual environment, 73% (n=22/30) rated this as 4 or 5, 23% (n=7/30) assigned a score of 3, and only one of the participants (n=9/30, 3%) assigned a score of 2 (level of training=practicing surgeon and level of experience=intermediate).

When assessing how appropriately the tool simulates the movements of MIS, 83% (n=25/30) rated the question as 4 or 5. All respondents (n=30/30, 100%) rated the design as attractive, with scores of 4 or 5. Almost all surveyed respondents (n=29/30, 97%) assigned ratings of 4 or 5 to the innovation factor, the capacity to provide feedback, and to the question of whether the latter was adequate.

The fidelity to the criterion study questions can be found in Multimedia Appendix 1. The fidelity to the criterion study result tables can be found in Multimedia Appendix 2.

Content Validity

[Table 6](#) summarizes the sources of validity evidence for the MIST-VR and the studies that have demonstrated such validity.

With regard to content validity, none of the items evaluated for the training capacity were rated as 1, although, in the case of hand-eye coordination by a practicing surgeon with an advanced operating level and the depth perception by a practicing surgeon with an intermediate operating level, the hand-eye coordination and depth perception were rated as 2. Almost all of those surveyed (n=28/30, 93%) rated the hand-eye coordination as 4 or 5, while 87% (n=26/30) gave this score for depth perception.

The highest-rated item was the one that considered that the prototype could be a solution for ubiquitous learning in MIS: 100% (n=30/30) of those surveyed rated it as 4 or 5. With regard to the evaluation of the metrics, 17% (n=5/30) of those surveyed rated them as 3, while the remaining participants (n=25/30) rated them as 4 or 5.

Almost all respondents (n=29/30, 97%) considered that the SIMISGEST-VR enables learning of basic psychomotor skills in MIS, with ratings of 4 and 5; whereas, 93% (n=28/30) agreed that the tasks reflect the basic steps of a minimally invasive procedure, with ratings of 4 and 5.

An analysis of the evaluation of the tasks, in general, showed that the following were rated between 4 and 5: Task 1 received this rating from 70% (n=21/30) of those interviewed; Task 2 from 77% (n=23/30); Task 3 from 73% (n=22/30); Task 4 from 77% (n=23/30); and Task 5 and Task 6 from 90% (n=27/30) of the participants.

For Task 6 (Table 4), a lower score was assigned by individuals with lower levels of training ($P=.02$).

The content validity study questions can be found in Multimedia Appendix 1. The tables of results of the content validity study can be found in Multimedia Appendix 3.

Discussion

Principal Findings

Simulation as a tool for learning psychomotor skills in MIS has become a new model for education in surgery. The use of human or animal cadavers is becoming increasingly controversial for learning surgical maneuvers [124,125], resulting in an immense growth of simulation using virtual environments as a tool for learning psychomotor skills in MIS and for the simulation of full surgical procedures [5,126].

Simulators for psychomotor skills learning in MIS are classified into mechanical, hybrid/augmented reality, or VR [6,7]. Devices for gesture-based human-computer interaction are a new way of interacting with virtual environments. This study's simulator presents a new form of gesture-based simulation that is portable, low-cost, and enables ubiquitous learning and preoperative warm-up [14,127,128].

Development of Gesture-Mediated Simulator for Minimally Invasive Surgery—Virtual Reality

The development of SIMISGEST-VR was based on DBR principles. It was a *pragmatic* process because the researchers tried to resolve the problems of portability and the high cost of simulators for learning psychomotor skills in MIS. It was *grounded* in both theory and the real-world context, as we designed a functional simulator based on theories on simulation-based surgical skills training. It was *interactive*, in that during the simulator design stage, a *good enough* prototype was obtained through the participation of an interdisciplinary team (pediatric surgery, systems engineering, graphic design, and experts in education and psychology), as well as the comments and feedback provided by experts in MIS during the subjective validation study. Finally, the process was *iterative*, in that a process of analysis, design, evaluation, and redesign was applied (Table 1) until a *good enough* protocol was obtained that could be subjected to validation studies [129].

To develop this study's 3D virtual environment, the researchers adopted the principle of low fidelity, given that the model is envisaged for basic psychomotor skills learning. The term fidelity refers to the extent to which a simulation imitates reality (in the case of surgical simulation, the anatomy) and is considered a critical variable in the design of simulators.

However, this statement is not necessarily completely true, as for novice learners, low-fidelity models that reproduce the essential constructs of a procedure allow a faster and more cost-effective learning curve to be achieved [35,130]. Thus, in the field of simulation in aviation, simple images reduce the learner's confusion when learning basic skills [131], while experts benefit from higher fidelity simulations [33,132].

The tasks were adapted from the MIST-VR, which is the only laparoscopic VR trainer that can act as a standard because it is the sole surgical VR system that has been reasonably validated [4,11,65,133]. MIST-VR has been shown to allow the learning of basic skills that can be transferred to the surgical environment at a more reasonable cost [4,11,52,73,134].

Metrics

Performance evaluation is a fundamental part of the learning process and is essential for certification. To obtain an objective evaluation of performance, the simulator should define metrics that must be valid, accurate, and relevant in terms of the procedure that is being taught. Evaluation using metrics and effective feedback are the most important elements of effective learning in a simulation environment [7]. Metrics allow an objective measure of motor performance to be obtained and enable the learning progress to be compared and tracked [10,43,44]. Accordingly, if the metrics lack sensitivity and validity, training on simulators will not be optimal and the learning will be affected [135]. In SIMISGEST-VR, the metrics were determined by time, the efficiency of movement, economy of diathermy, and error. This was an iterative process involving several pilot studies and modifications to the tasks and their metrics based on feedback provided by surgeons and education experts.

Feedback

Feedback is essential [136,137]. Training on a simulator should have 3 purposes: (1) to improve performance; (2) to make the performance consistent; and (3) to reduce the number of errors [57]. The metrics and feedback are essential for achieving these objectives. On the SIMISGEST-VR, the study adopted 3 types of feedback: (1) concurrent, which is provided while the task is being performed; (2) immediate, when the exercise is finished; and (3) terminal, which shows the final score when all the tasks have been completed [136,138-140].

Hardware

The design of the hardware components aimed to simulate the movements made by the surgeon during MIS. These movements are defined by the physical characteristics of the devices and, therefore, require the design of mechanical support devices that simulate the fulcrum effect (entry portals), add friction to the movements of the forceps, and limit arm movement during the performance of the tasks without interfering with the reading of the instrument movements by the LMC [141,142]. The portability and low cost were also taken into account.

Cost of Gesture-Mediated Simulator for Minimally Invasive Surgery-Virtual Reality

The VR or augmented VR simulators currently available in the market are not portable, and their cost ranges from US \$2000 to US \$100,000 (with annual maintenance costs of US \$25,000) for a haptic VR simulator. The LMC costs approximately US \$130, plus a further US \$70 for the hardware elements, adding up to a total cost of approximately US \$200 for the SIMISGEST-VR, software costs excluded.

Subjective Validation of Gesture-Mediated Simulator for Minimally Invasive Surgery-Virtual Reality

The second aim of this study was to evaluate fidelity to the criterion and a content validity study. Validity refers to the quality of the inferences, claims, or decisions taken from the scores given by an instrument, not the instrument itself. Validation for its part is a process through which the evidence that supports the quality, significance, and utility of the decisions and inferences that can be made from the scores provided by the instrument is drawn together and evaluated [143]. Validity is not an all-or-nothing statement, as it reflects a gradual appraisal that depends on the purpose of the measurement and the proper interpretation of the results. Validity is also not in itself a characteristic of the system, but the appropriate interpretation and use of the measurement results of the system. A single instrument may be used for many different purposes, and the resulting scores may be more valid for one purpose than for another [133].

Study of Fidelity to Criterion

Although it has been deemed that *face validity* should no longer be considered a type of validity or used as a term in validation studies [144,145], its assessment is extremely important during the design phase of any evaluation device [146,147]. Therefore, the use of an alternative term to denominate this type of evaluation has been suggested: *fidelity to the criterion* [148]. Despite such warnings, it is very striking to find that the term *face validity* is still being used in published literature on simulation in surgery [149,150].

Fidelity to the criterion evaluates to what point the test reflects the real-life situation, whether the simulator represents what it is supposed to represent (the realism of the simulator) or the extent to which a questionnaire or other measurement reflects the variable to be measured [125,151,152]. In the case of DBR, it is used in the initial phase of the construction of the test. The surveys that assess fidelity to the criterion feedback into the iterative design process, which allows the *good enough*

prototype to be obtained [153]. Fidelity to the criterion is evaluated by experts and novices called referents [154,155].

In this study, the evaluation of fidelity to the criterion provided feedback on the initial design, and this was how the 3D virtual environment was redesigned until a *good enough* prototype was obtained. The quality of this evaluation is improved systematically when structured questionnaires and Likert scales are applied [154].

In all the items evaluated for fidelity to the criterion, most of those surveyed assigned scores of 4 or 5. There were no significant differences between the expert and referent groups (level of training) when rating fidelity to the criterion. The lowest scores were obtained for the item about the relevance (n=9/30, 3% of participants), the representation of the movements of the physical forceps in the virtual environment (n=9/30, 3%), and for the fulcrum effect (n=3/30, 10%).

Evidence Based on Test Content

The latest standards on validity and validation refer to sources of validity evidence, rather than distinct types of validity. Validity therefore refers to the degree to which the evidence and theory support the interpretations of test scores for the proposed uses of tests [156,157].

Evidence based on test content is an issue of representation and may be obtained from an analysis of the relationship between test content and the construct that is intended to be measured. In this study, the test content refers to the simulator's 6 specific tasks. Evidence can be obtained from logical or empirical analyses of how test content represents domain content and of the relevance of domain content to the proposed interpretation of test scores. Evidence may also come from experts' opinions on the relationship between the different test items and the construct when assessing whether the test contains the meaningful steps, skills, and materials used in the actual procedure [158] and determines whether the simulator can realistically teach what it is supposed to represent [159].

The question is, does the simulator realistically teach what it should teach? In other words, does the instrument represent all the ways in which it can be used to measure the content of a given construct? [160]. In summary, evidence based on test content judges the appropriateness of the simulator as a teaching modality or as a training tool within the domain that it seeks to measure [31,151,152].

This type of validation is highly recommended in the practice of DBR during the design phase of the *good enough* prototype. Content validity can be obtained from a literature review, an expert review, using content validity rates, and *Q sorting* [161].

The tasks within the surgical simulation should fulfill 3 criteria: objectivity, clarity, and completeness. To be objective, the definition of the task should refer to observable characteristics of the behavior; for it to be clear, the task should be unambiguous so that it can be read, understood, and reproduced equally by different observers; and finally, to meet the criterion of completeness, the definition of the task should delineate its start and end and make it clear when it was completed [162].

In this study, the 6 skill tasks were chosen for two main reasons: (1) these tasks are well-validated in many clinical studies [4,10,82,117] using the MIST-VR (Table 6); and (2) they contain laparoscopic skills and techniques that are usually present in many laparoscopic procedures (Table 1).

The vast majority of study participants considered that the SIMISGEST-VR was a useful tool for the development of hand-eye coordination and depth perception, with ratings of 4 and 5 on the Likert scale. Similarly, there was consensus about the capacity of the simulator to teach basic psychomotor skills and to reflect the basic steps in MIS. All the respondents considered the metrics to be adequate and envisaged that the simulator could become a solution to achieve ubiquitous learning of basic psychomotor skills in MIS.

In terms of the specific rating for each of the 6 tasks, this varied between 3.97 and 4.53. The participants considered all the items of the SIMISGEST-VR training system as good to excellent.

Finally, the study of fidelity to the criterion and content validity must be proven in the design stage of the artifact, before the criterion (concurrent and predictive) and construct validity (convergent and discriminative) can be confirmed. The evaluation of fidelity to the criterion, although somewhat subjective, is a necessary assessment during the initial phase of any high-stakes test construction and in this study, within the context of DBR, in the design phase of prototypes that will give a *good enough* prototype as a result [154,158,163]. In conclusion, the results of the study of fidelity to the criterion and content-related validity evidence showed overall positive scores.

Threats to Validity

The *Hawthorne effect* occurs when the opinion may be influenced by the attention paid to the respondent during his or her performance with the simulator, which may contribute to the occurrence of favorable responses or scores. This effect can be ameliorated by paying equal attention to each respondent. In addition, the *Pygmalion effect* occurs when the enthusiasm shown by the developers or because the novelty of the artifact affects the opinion of the respondent; the referent group is more prone to this latter effect [154,164]. In this study, the SIMISGEST-VR developer conducted the interviews and applied the Likert scale questionnaires; this may have influenced the ratings assigned by the participants (*Hawthorne effect*).

Regarding the representation of the construct, in this study there was an underrepresentation—when compared with the learning models based on training boxes—referring to the *cut* skill of the *basic psychomotor skills* construct, which was because of technical reasons associated with the LMC (construct context). There was no overrepresentation of the construct [165].

Limitations

There are, however, limitations to this study. The sample size of this study was one of availability and, for the simulator to be

portable and allow ubiquitous learning, the researchers disregarded some ergonomic principles applied to MIS [166,167]. Further research will be conducted using new motion metrics, new skill tasks, and the development of the web-based virtual environment for download as an app. In addition, the researchers of this study are working on the development of different difficulty levels for each exercise.

Future Work

The researchers of this study are currently conducting another study to show validity evidence for the *good enough* prototype described in this paper, using the new framework for validation in education [168,169]. This new study is expected to verify the sources of validity evidence for the internal structure, relationships between variables, and test consequences.

Once the metrics and the results of the performance scores have been validated as a useful tool for learning basic psychomotor skills in MIS, a model will be obtained to enable ubiquitous learning in MIS and preoperative warm-up by using the 3D reconstruction of patient images [14]. Studies conducted in this area have demonstrated that, generally speaking, preoperative warm-up exercises performed for at least 15 min before the procedure improve the surgeon's handling of soft tissue during cholecystectomy [170], bimanual skill, efficiency and smoothness of movement, and depth perception, at the same time as mistakes and operating time are reduced [171-177].

The large size and elevated costs of VR simulators currently available in the market prohibit their use in the operating theater. A portable, low-cost simulation solution, such as the SIMISGEST-VR, would allow surgeons to perform preoperative warm-up exercises anytime, anywhere (ubiquitous learning). In addition, the researchers aim to enable a surgeon to perform warm-up exercises based on 3D reconstructions of preoperative images of a specific patient, thus, practicing the procedure before performing the actual surgery. This could take place the night before in the surgeon's home or the operating theater on the day of the surgery [178-183].

Conclusions

This study demonstrated the feasibility of a portable, low-cost, gesture-based, functional simulator (SIMISGEST-VR) for learning basic psychomotor skills in MIS.

The results of the evaluation of fidelity to the criterion and content validity showed overall positive scores, which indicates that the SIMISGEST-VR would be acceptable to both the expert group and referent group as a training and learning device (including at home) to achieve ubiquitous learning in MIS.

The participants in the study agreed that content validity was acceptable, accurate, and representative in the field of basic psychomotor skills learning in MIS.

Authors' Contributions

All the authors contributed substantially to the study conception and design, data analysis, and interpretation of the findings and manuscript drafting. Fernando Álvarez López participated in the collection and assembly of data. Francesc Saigí-Rubió is the guarantor of the paper. All the authors have read, revised, and approved the final manuscript.

Abstract

Background: Over the course of a year, we developed and tested a 6-week massive open online course (MOOC) on multiple sclerosis (MS) in consultation with the MS community. The course targeted the MS community and interested laypeople and was titled *Understanding MS*. The primary purpose of the course was to improve MS knowledge, health literacy, and resilience among participants. The final version of the MOOC made available for open enrollment was ranked first among all MOOCs released in 2019 (n>2400) based on participant reviews.

Objective: The aim of this study was to present a detailed description and assessment of the development process of the *Understanding MS* MOOC.

Methods: The development process included a course development focus group; the creation of more than 50 content videos and related text, quizzes, activities, and discussion prompts; the creation of original images and animations; a pilot study; and collaborations with people living with MS, MS nurses, allied health care practitioners, and neurologists and researchers from 4 universities.

Results: Overall, the process was efficient and effective. With a few small changes, we recommend this approach to those seeking to develop a similar course. This process led to the development of a highly reviewed MOOC with excellent user satisfaction.

Conclusions: We identified 5 key lessons from this process: (1) community support is essential, (2) stakeholder involvement improves content quality, (3) plan for research from the beginning, (4) coordination between the academic lead and project manager team ensures a consistent voice, and (5) a network of collaborators is a key resource.

Introduction

Background

Massive open online courses (MOOCs) have the potential to extend the classroom to people who cannot access traditional learning environments by capitalizing on the widespread availability of the internet [1]. The defining characteristics of MOOCs are that they are freely available and have virtually

unlimited enrollment capacity. These features make MOOCs versatile; they can be used to present information on a range of topics to an array of different audience.

Over the past decade, there has been a rapid increase in the development of MOOCs. Class Central, the leading MOOC aggregator site, currently lists more than 13,000 MOOCs from more than 900 universities [2]. However, there are significant challenges in MOOC development and implementation,

including the cost and time involved [3,4], with universities spending US \$200,000 or more per course [4]. These challenges suggest that it is worth evaluating the approaches used to create MOOCs to identify strategies that are cost-effective and result in successful courses.

Furthermore, little is known about the impact of MOOCs on learning outcomes. Addressing this knowledge gap requires meaningful comparisons of many courses [5]. These comparisons require an understanding of the similarities and differences in course development and content. However, little research has been done describing the process of developing an MOOC in detail [6,7]. Here, we present a detailed description and assessment of our work—developing an MOOC on multiple sclerosis (MS) for the MS community and interested laypeople—including all tools and materials that we used or produced, in the hope that it assists others in the creation of similar content and allows for more meaningful comparisons between courses.

MS is a disease of the central nervous system that affects approximately 2.3 million people worldwide [8]. People living with MS often experience mobility and fatigue-related symptoms that can interfere with their ability to access health care [9]. Consequently, several digital and remote communication disease management technologies have been developed for people living with MS [10]. MS symptoms may also impede the ability of people living with MS to access traditional educational offerings (eg, in-person courses), making it difficult for them to travel to a particular meeting place or maintain active participation over long sessions. Therefore, an MOOC may be a more appropriate vehicle for knowledge translation for people living with MS and other members of the MS community (eg, family and friends, caregivers, and health care providers), particularly for those who may feel isolated by living with a rare condition.

Objectives

Here, we describe and assess our experience in developing a successful 6-week English-language MOOC about MS. The first enrollment ran from April to June 2019 and the second ran from September to November 2019, with more than 8000 people enrolling and an average completion rate of 47% (SB Claflin, unpublished data, 2019), far exceeding the average for MOOCs, which fluctuates between 5% and 15% [11,12]. On the basis of participant reviews from these 2 enrollments, the course was ranked first among more than 2400 MOOCs released in 2019 and third among all health and medicine MOOCs globally by the leading online course aggregator site, Class Central [13,14]. In this paper, we described the process we used to develop the *Understanding MS* MOOC in detail, highlighting the strengths and weaknesses of our approach and making recommendations for the development of similar interventions.

Methods

Ethics

The work conducted for this project was approved by the Social Science Human Research Ethics Committee at the University of Tasmania (UTAS), including the focus group (H0017241) and a pilot study (H0017778).

Funding and Costs

The *Understanding MS* MOOC was collaboratively developed by the MS Flagship at the Menzies Institute for Medical Research (Menzies) at UTAS and Multiple Sclerosis Limited, a service organization providing resources to the MS communities of New South Wales, Victoria, Tasmania, and the Australian Capital Territory. These organizations cofunded the project, resulting in a total budget of approximately AUD \$200,000 (US \$139,000). The majority of these funds were used to pay the salary of a full-time postdoctoral research fellow who served as the academic lead of the project (SC) and the secondment of a MOOC project manager (RG) from the Wicking Center for Dementia Research and Education (WDREC). A small amount of funding was used to develop some of the course animations and to pay for travel costs and video transcription.

The remainder of the costs related to course development were in-kind, provided in either time or materials. The area experts who presented the course videos did it for free. The UTAS employs a videographer who filmed all but a few of the videos. These videos were primarily shot in studios that were generously offered at no cost by the local Australian Broadcasting Corporation and the University of Melbourne. All video editing was performed by the UTAS staff. All images were reproduced for free with permission from the original source or developed by the UTAS staff. A few animations were also produced in-house. Finally, the course was hosted on a custom UTAS-built MOOC platform, which was originally constructed to host MOOCs produced by the WDREC [5].

Management Structure

The development of the MOOC was primarily overseen by 2 full-time employees: the academic lead and the project manager. The academic lead was responsible for the development of course content, including syllabus, video outlines, text, quizzes, discussion prompts, and activities. The academic lead was also responsible for video presentations, both presenting by herself and liaising with other area experts. In addition, she was responsible for developing the research projects surrounding the MOOC and leading the focus group, pilot study, and development of the MS Knowledge Assessment Scale. The project manager was responsible for coordinating and overseeing video production (including editing and transcription; scheduling filming; and liaising with external contractors, such as the video animator), establishing branding and style guidelines for the course, liaising on technical requirements for the web-based learning management system, coordinating digital marketing strategies for the course, coordinating and implementing communication processes for participant engagement and retention, and general project planning and administration tasks. The academic lead and project manager worked closely together, usually meeting for the project several times per week and sometimes as often as several times per day.

The project was also overseen by an advisory group that met fortnightly throughout the project. The group included a clinician-researcher who served as the academic lead's direct supervisor (BT); Menzies MS Flagship project manager; Menzies MS Flagship communications officer; Menzies business

manager; MS researchers, including an epidemiologist, a neuroscientist, and a health economist; a web-based learning and systems support manager; and a liaison from Multiple Sclerosis Limited (MSL). The group contained a wide range of MS community expertise, from the lived experience of people living with MS to the clinical expertise of a neurologist and an MS nurse. This group provided feedback on course content and study design, contributed their expertise to course videos, and recruited other area experts. All the members of the advisory group were asked to provide their feedback in preparation for this assessment.

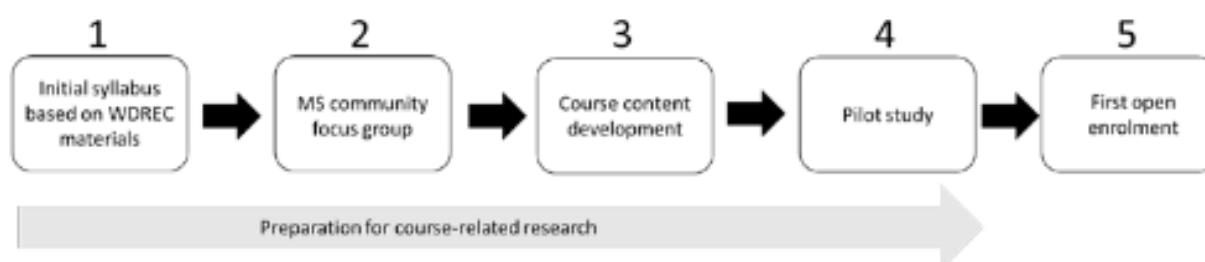

Core Principles and Development Outline

The advisory group developed 3 core principles that guided our work:

1. *Do no harm.* The course should not frighten participants and should be sensitive to participant anxiety.
2. *Keep it positive.* We used positive language in the course and course-related materials.
3. *Share the journey.* We wanted the course to be inclusive in design, content, and presentation and involve a diverse group of MS community members in all stages of development.

Course development included 4 distinct steps leading to the implementation of the course (initial syllabus development, focus group, content development, and pilot study) in the first open enrollment. Alongside this work, we carried out preparations for course-related research. The steps of the development process are illustrated in [Figure 1](#).

Figure 1. Course development flowchart. MS: multiple sclerosis; WDREC: Wicking Center for Dementia Research and Education.

Initial Course Syllabus Development

The initial course syllabus was modeled on the work of the WDREC. WDREC previously developed 2 extremely successful MOOCs, *Understanding Dementia* and *Preventing Dementia* [15]. The syllabuses for these courses were used as an initial template for the *Understanding MS* course syllabus. This template was then adapted to fit the MS context. This included adjusting the content to ensure its relevance to people living with MS, as the WDREC courses are primarily taken by caregivers rather than people living with dementia. The initial course syllabus is available in the supplementary materials ([Multimedia Appendix 1](#)).

Focus Group

The main purpose of the focus group was to determine the content and modes of delivery that were most important and/or acceptable to the MS community, particularly people living with MS. The focus group participants were purposefully recruited through existing relationships with Multiple Sclerosis Limited to ensure that the focus group was broadly representative of the larger MS community (eg, representation of multiple MS phenotypes, male and female representation, and a variety of MS community roles). Before participation in the focus group, small group facilitators were given a 1.5-hour facilitator training by an experienced facilitator and a translational researcher. This training covered the protocol of the focus group and facilitation approaches and techniques.

The focus group followed a modified World Café [16] approach:

- **Introduction:** small group facilitators and MS MOOC team members greeted participants, and the academic lead gave a brief introduction presentation, including an agenda for

the day, context and background for the discussion, rationale for developing an online course, and examples of the various modes of delivery available to the team (eg, video types, etc). This was followed by an introduction exercise and a large group discussion of ways of working to establish rules for the small group discussions. After this discussion, a catered morning tea was provided.

- **Small group discussions:** small group discussions followed the World Café format, except that, because of mobility issues, the participants remained at the same table throughout, and the facilitators moved between tables. Small groups discussed 4 questions, and each question was discussed for 15 to 20 min. Discussion questions are available in the supplementary materials ([Multimedia Appendix 2](#)). Discussions were followed by a catered lunch.
- **Large group discussion and *dotocracy*:** the small group facilitators summarized the main points of the discussions into bullet points, which were posted on a whiteboard and presented to the large group after lunch. Each participant was given a strip of 12 red dot stickers (3 per discussion question). They were told to place the stickers next to the summarized statements that they felt were most important for inclusion in the course. They were allowed to place more than one dot next to a given statement.
- **Wrap-up:** after voting, the participants were thanked and invited to participate in the course pilot study. The small group facilitators were asked to submit their feedback on the process within a week of the event.

The results of the focus group were analyzed quantitatively using summary statistics and qualitatively using textual analysis. Each group discussion was considered a data item ($n=16$). All discussion notes were transcribed and assessed using thematic

analysis. Any topic mentioned at least twice throughout the data set was considered to be a theme. Any theme mentioned by all 4 groups was considered a key theme. The data collected from the focus group were used to amend the initial syllabus and create the initial course outline, which served as the blueprint for the core course content. The results also informed the style and mode of delivery decisions for course materials.

Development of Course Materials

The course materials were designed in accordance with our core principles and integrated with the feedback of the focus group participants and the advisory group. The academic lead wrote the first draft of the core course content by elaborating on the course outline, breaking down larger topics into their component pieces, and giving greater detail on each one. The course was structured into 6 modules, with each module comprising several sections. The course outline was adapted into video scripts, with nearly every section containing at least one video, and was distributed to the area expert presenting the information. The area experts were given the opportunity to refine the content of

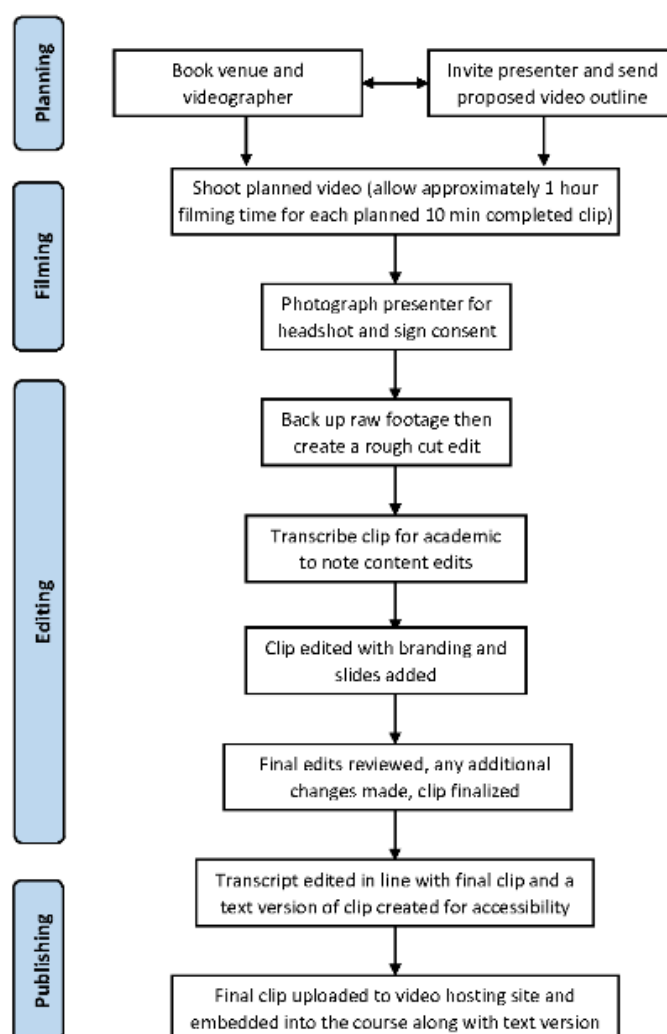

the video with the academic lead before and during filming. These academic videos formed the core content of the course and served as the basis for the rest of the course material.

The academic videos were filmed in 3 formats:

1. Interview: the academic lead sat off-camera interviewing the area expert who was on camera. In the final version, tiles with the interview questions appear between the responses of the expert.
2. Conversational: The area expert and the academic lead were on the camera together, side-by-side. The academic lead interviewed the area expert.
3. Direct-to-camera: the academic lead presented a short (<5 min) scripted lecture on a topic. These videos were later animated.

After the videos were shot, they were edited and transcribed so that a text version of all videos could be made available to the course participants. Some videos were animated to illustrate the concepts that they covered. Figure 2 demonstrates the process used to develop video content.

Figure 2. Video production flowchart.

Text was written to reinforce the main messages of the videos and to add a greater context. The main messages were presented as headers, with more details given in the supporting text. The

goal was to ensure that if a participant only read the headers, they would come away with the main points of the section. The text was pitched at a general audience and assumed participants

had completed a secondary school science education. [Figure 3](#) shows a screen capture of one of the course pages.

Figure 3. Screen capture showing the layout of a single page of the course.

Activities were developed to encourage participant resilience (eg, goal setting) and develop their disease management skillset (eg, symptom tracking). Discussion prompts aimed to inspire reflection about the course content and gather feedback about the activities. End-of-module quizzes aimed to cover the main content of each module, aligning with the module learning objectives. Each quiz was made up of 10 questions, and all

questions were multiple choice. Participants had to achieve a score of 70% or higher to move on to the next module, but they could take each quiz as many times as they liked. The correct answers to the quizzes were presented at the beginning of the following module.

In addition, 2 other video series were included in the course: the *community insights* series and *MS perspectives* series. The

MS perspective series included interviews with people living with MS recruited through pre-existing relationships with Multiple Sclerosis Limited and Menzies. Both were filmed in an interview format. They were each asked the same series of questions, which were related to the core content of the course. The interviews were then spliced together so that the final set of 5 videos showed the experience of multiple people living with MS on a particular subject. The *community insights* series included interviews with other members of the MS community, such as a caregiver and an MS nurse, about their experience working with and/or caring for people living with MS. These videos were placed in the course alongside the core content related to them.

Each module opened with a summary paragraph describing the content, a list of learning objectives, and a list of possible applications for the information presented in the module. The module sections usually began with a video under the section heading, followed by the supporting text. There were 1 to 2 discussion prompts and 1 activity in each module. The final section included a summary paragraph and downloadable summary PDF file, as well as a list of additional resources (mostly links to external websites) and the end-of-module quiz. An example quiz, a list of module activities and discussion prompts, and the finalized course outline are available in the supplementary materials ([Multimedia Appendices 3-5](#)). To minimize the burden on course participants, we aimed to keep the time required to complete each module under 2 hours. Due to this, the length of most of our videos was 7 min.

Pilot Study

The purpose of the pilot study was to gauge MS community members' satisfaction with the course and to test its technical components. The pilot study was advertised to MS community members via Menzies and Multiple Sclerosis Limited newsletters. People interested in taking part could register their interest on the course's landing webpage. People who indicated interest were contacted via email and invited to enroll in the pilot study, which began on January 21, 2019. Participants were given access to the course materials in the same fashion as course participants during regular enrollments, with 1 module opening each week accompanied by a reminder email.

Participants were given the option of providing feedback via a web survey at the end of each module and on the overall course. In these surveys, participants were asked to provide quantitative (eg, rating) and qualitative (eg, free text) feedback. Participants rated their satisfaction with each course component (videos, text, images and animations, discussions, quizzes, and technical aspects) on a 5-point Likert scale from very dissatisfied to very satisfied. They were also asked to provide their level of agreement with statements about each course component. The results were analyzed quantitatively using summary statistics (eg, percentage satisfied or in agreement with a given statement) and qualitatively using thematic analysis. An example evaluation survey is available in [Multimedia Appendix 6](#). The results of this study were used to refine the course before the first public iteration, which opened on April 29, 2019.

Preparation for Course-Related Research

Along with providing community education, research is one of the primary purposes of the Understanding MS MOOC. To prepare for research projects around the first enrollment of the course, the academic lead prepared an implementation evaluation tool and an outcomes evaluation tool, led the development of the MS Knowledge Assessment Scale, and submitted ethics applications for course-related projects. These tools and related research will be described in more detail in future publications.

Results

In this section, we will assess the methodology we used to develop the Understanding MS MOOC by discussing the strengths and weaknesses of each step in the process.

Advisory Group and Massive Open Online Course Management Structure

The members of the advisory group reported that the group was effective. As the group contained a cross-section of expertise from all areas of the project (technical, academic, managerial, and clinical) and project stakeholders, as well as key decision makers, decisions were well informed and could be made swiftly. The group was inclusive and respectful of the members' time. There was an action item list for each meeting, and meetings were not held if there was nothing to discuss. The regular meeting time and buy-in from all members contributed to the group's success.

Group members reported one notable weakness: the function of the group could be improved by greater budget transparency, which would simplify decision making and purchase approvals.

Initial Course Syllabus Development

As discussed earlier, access to WDREC materials was a significant advantage when combined with our initial syllabus, as we were able to emulate the structure of successful MOOCs. The only substantial discussion around the initial syllabus was about the module order, particularly the placement of the biology and pathology module. This module is the most technical, and there was a concern that placing it first might discourage participants from completing the course. However, we concluded that placing it first made the most sense, as it provides information that underpins the following modules.

Focus Group

The small group facilitators agreed that the focus group was a success. They reported that the atmosphere was positive and that the participants enjoyed the process. The focus group had a 100% attendance rate; 21 people were invited and agreed to attend (the demographics of the attendees are provided in [Table 1](#)). This was the result of long-standing relationships with the MS flagship business manager, who acted as a community liaison. Furthermore, her initial contact with attendees set a casual and collegial tone for the focus group, which resulted in people arriving relaxed and open. This contributed significantly to the success of the event.

Table 1. Demographics of the focus group (n=21). Participants were able to select more than one multiple sclerosis (MS) community role and MS disease course.

Our method allowed us to identify the key themes from the small group discussions, such as accessibility, style, and exportable resources, and to compare these themes with the discussion summary statements that were most commonly voted as important by focus group participants (Table 2).

There were 2 main weaknesses in our focus group method. First, the small group facilitators reported some concern about fatigue. One facilitator suggested shortening the day by reducing the

amount of time for questions at the end, whereas another suggested shortening the small group discussion periods from 15 to 10 min. Second, our selection of example videos was poor (ie, did not illustrate stylistic differences well), and we suggest that future projects choose videos more carefully to clearly show the differences in style. This might be accomplished by creating a few videos about the same subject in different styles, specifically for use in the focus group.

Table 2. The most important small group discussion summary statements (≥ 6 votes), as voted by focus group participants. The focus group participants were able to vote for the same statement multiple times.

Question	Votes, n
What topics/subjects would you like to see covered in an online course about MS^a?	
Tips, management tools/activities to make living with MS easier, positive, and enhance quality of life	8
What to expect for certain scenarios (ie, lesion location)	7
Support and where to find it	7
Guides for partners, children, public personnel, establishments, and health care providers (eg, general practitioner and allied health)	6
Support services, events in local area	6
Guides for types, symptoms	6
What modes of delivery do you prefer?	
Video lecture (facing the audience)	12
Keep it simple	11
Link to other resources	6
What would make an online course about MS useful to you?	
Interview people with MS	13
Know more about MS	8
Cater for a variety of learning styles	6
What would make the course engaging for you?	
Plain English, simple language	14
Consider different learning styles, for example, visual and reading—either options or a mix of presentation styles	10
Speakers—engaging, warmth, humor, lived experience	9
Speakers must be engaging. Academics in chairs speaking to each other= boring	7

^aMS: multiple sclerosis.

Development of Course Materials

In total, we created 53 videos, including 6 *MS perspectives* videos and 4 *community insights* videos, totaling 5 hours, 40 min, and 32 seconds of film. Only 4 used green screen animations. There were a total of 62 pages from the introduction through the completion of modules. On average, participants in the pilot study took approximately 2 hours to complete each module (Table 3), equating to 12 hours of total course content.

Our content development process had 4 main strengths. First, our core principles effectively shaped the tone of the course. We translated them into course-related materials in a variety of ways, including the following examples:

1. *Do no harm.* This influenced both the tone and the structure of the course. For example, while the content about MS symptoms, in general, was mandatory, videos detailing specific MS symptoms were made optional. This allowed participants to avoid exposure to information that might increase their symptom-related anxiety.
2. *Keep it positive.* In the feedback survey, instead of asking what was wrong with the course, we asked what could be improved.
3. *Share the journey.* Throughout the course, we choose to use the pronoun *we* instead of *you* to emphasize a sense of community. In addition, we individually greeted each participant who posted on the introduction discussion board

in the first week of the open enrollments, thanking them for their participation and welcoming them to the course.

Second, having a single academic lead who oversaw all course content development was a very effective strategy, and we would recommend this approach to others. We found that it reduced duplication and contradiction and increased the continuity between sections. As all the written material (eg, text, quizzes, summaries, etc) had a single author, the course had a consistent style and pitch.

Third, we used a variety of different video styles. Not only is it more visually interesting but each video format also has particular advantages. The interview style is very flexible and allows for filming to be stopped between questions, which provides time for the academic lead and the presenter to workshop the upcoming question and response. Frequent pauses also mean that it is easy to reshoot the responses and only requires the presenter to remember their response to one question at a time. The conversational style allows for in-the-moment redirection of the presenter and follow-up questions by the academic lead. The conversational and interview styles require minimal upfront time investment by the presenters, which reduces the burden placed on them and may make them more likely to participate and enjoy participating. The direct-to-camera style allows for the concise delivery of information. However, it requires more upfront preparation,

including memorization of a script. For this reason, this style of video was only presented by the academic lead.

Fourth, strong selection of video presenters from across the MS community (eg, people living with MS, caregivers, researchers, neurologists, etc). We found that the area experts made the best presenters, as they were comfortable speaking about their area of expertise. Inviting the presenters to workshop the script ahead of shooting increased their involvement and preparation and made them more comfortable when filming. We found that filming was improved by keeping things casual. This made

presenters more comfortable, which both improved their performance and made them more likely to enjoy themselves.

The largest weakness of our content development was our ambitious timetable, which allowed approximately 10 months leading up to the first open enrollment. Given the amount of content needed, this rushed the process. In addition, because of financial and logistical constraints, the course materials were only made available in English. This limited the accessibility of the course.

Table 3. Demographics of the pilot study participants who completed the feedback surveys.

Demographics	Module 1 (n=51)	Module 2 (n=44)	Module 3 (n=41)	Module 4 (n=41)	Module 5 (n=36)	Module 6 (n=39)	Overall (n=29)

^aMS: multiple sclerosis.

Pilot Study

A total of 97 people enrolled in the course of the pilot study. Of those, 51 provided feedback on at least one section of the course. Across all surveys, a minimum of 90% (26/29) of the respondents were female, and a minimum of 59% (17/29) were people living with MS. The pilot study participant demographics are presented in [Table 3](#).

The pilot study had 2 main strengths. First, the group was reasonably representative of the MS community, with a variety of MS community roles represented and a range of MS phenotypes. Second, we were able to pinpoint areas for improvement because we surveyed participants about each module and the overall course, which provided fine-grained data (shown in [Multimedia Appendix 7](#)). If we had simply asked about overall satisfaction, our ability to target underperforming areas would have been lost (compare part A of [Multimedia Appendix 7](#) with part B of [Multimedia Appendix 7](#)).

The main weakness of the pilot study was the relative paucity of data. This was a fairly small study, and we did not make providing feedback a mandatory part of participating in the pilot. Therefore, we did not collect as much data as we could have. More data may have provided a more detailed or nuanced view of the course materials.

Discussion

Principal Findings

Overall, our process was effective and efficient. This resulted in the production of a successful health and medicine MOOC aimed at the MS community and interested laypeople with high participant satisfaction, retention, and recruitment and with no major technical errors. We believe that this project was a good value for money and that the funds were well spent. We estimate that without extensive in-kind support, the project costs would have exceeded AUD \$500,000. The generosity of our project partners was essential to its success and to illustrate the community support for this work. We have identified 5 key lessons learned from our experience.

Community Support is Essential

The support that this project received from the community, UTAS, and Multiple Sclerosis Limited was critical. Without it, this project would not have been possible. UTAS' institutional support was particularly extensive. We were able to leverage the expertise, experience, and resources (particularly the custom online course platform) of the WDREC to achieve high cost-effectiveness. This was a sizable advantage; without it, the project would have been significantly more expensive, challenging, and time-consuming. Community buy-in and support also performed several other essential functions for the project. This allowed us to integrate the community from the outset. This led to collaboration, co-design, and engagement and allowed us to identify, understand, and tailor course content for our audience early on.

Stakeholder Involvement Improves Content Quality

There are many reasons to engage with stakeholders, including social justice and utilitarian motivations [17]. From a social

justice perspective, there are compelling ethical reasons to involve stakeholders in the process early and often. From a utilitarian perspective, we found that early stakeholder involvement allowed us to identify the preferences of our target audience at the beginning of the process and helped to ensure that the content we created was appropriate. For example, we were surprised by the importance placed by focus group participants on the tone of the course. They indicated that they wanted a warm, good-natured tone. We incorporated this into the course content. This was a significant benefit to our project.

Plan for Research From the Beginning

We found that the best time to integrate research into an MOOC is at the beginning, while design and development are underway. This makes it possible to incorporate research tools directly into the course. It also allows sufficient time to produce tools that may be missing and require development. Early preparation also allowed the pilot study to function as a test of the course evaluation survey, which is now available for all course completers to provide feedback.

The Academic Lead and Project Management Team Ensure a Consistent Voice

A dedicated academic lead and project management team ensured that there was a consistent voice and style throughout the course content, accelerated course development, and minimized discrepancies in the course material. As this was their primary project throughout the year, they ensured that our ambitious timeline was met. They worked together to establish the textual, visual, and tonal styles of the course.

A Network of Collaborators Is a Key Resource

Our network of collaborators provided area experts from across the MS community, provided input on the course material, and, in the case of the WDREC, allowed us the immense benefit of their experience. Their generosity with their time made this project possible within the time and budget constraints presented above. Furthermore, collaborating at every level of this project has ensured that the community is involved and that stakeholders are represented, including in the authorship of this manuscript.

Strengths and Limitations

The main strength of this research was the diverse group of MS community members involved in all aspects of course development. The main limitations of this work were that it primarily involved Australian participants and was limited to those fluent in English. The web-based components further required the ability to access and use digital platforms.

Conclusions

The process behind the development of the Understanding MS MOOC was extensive, but each component contributed to a successful outcome. However, although this process was successful for us, it is important to recognize that this is a single project. We hope that by providing our material here, we will encourage others to use them in future work, allowing for meaningful comparisons in course development methodology and outcomes.

Acknowledgments

The authors would like to thank all of the people who contributed to the development of the Understanding MS MOOC. The authors would particularly like to thank the MS community members, who generously gave up their time to take part in the focus group, the course videos, and the pilot study; the course cosponsor; Multiple Sclerosis Limited; and the WDREC, whose technical expertise and substantial MOOC experience were invaluable.

Abstract

Background: Although smartphone-based emergency care training is more affordable than traditional avenues of training, it is still in its infancy, remains poorly implemented, and its current implementation modes tend to be invariant to the evolving learning needs of the intended users. In resource-limited settings, the use of such platforms coupled with gamified approaches remains largely unexplored, despite the lack of traditional training opportunities, and high mortality rates in these settings.

Objective: The primary aim of this randomized experiment is to determine the effectiveness of offering adaptive versus standard feedback, on the learning gains of clinicians, through the use of a smartphone-based game that assessed their management of a simulated medical emergency. A secondary aim is to examine the effects of learner characteristics and learning spacing with repeated use of the game on the secondary outcome of individualized normalized learning gain.

Methods: The experiment is aimed at clinicians who provide bedside neonatal care in low-income settings. Data were captured through an Android app installed on the study participants' personal phones. The intervention, which was based on successful attempts at a learning task, included adaptive feedback provided within the app to the experimental arm, whereas the control arm received standardized feedback. The primary end point was completion of the second learning session. Of the 572 participants enrolled between February 2019 and July 2019, 247 (43.2%) reached the primary end point. The primary outcome was standardized relative change in learning gains between the study arms as measured by the Morris G effect size. The secondary outcomes were the participants individualized normalized learning gains.

Results: The effect of adaptive feedback on care providers' learning gain was found to be $g=0.09$ (95% CI -0.31 to 0.46 ; $P=.47$). In exploratory analysis, using normalized learning gains, when subject-treatment interaction and differential time effect was controlled for, this effect increased significantly to 0.644 (95% CI 0.35 to 0.94 ; $P<.001$) with immediate repetition, which is a moderate learning effect, but reduced significantly by 0.28 after a week. The overall learning change from the app use in both arms was large and may have obscured a direct effect of feedback.

Conclusions: There is a considerable learning gain between the first two rounds of learning with both forms of feedback and a small added benefit of adaptive feedback after controlling for learner differences. We suggest that linking the adaptive feedback provided to care providers to how they space their repeat learning session(s) may yield higher learning gains. Future work might

explore in more depth the feedback content, in particular whether or not explanatory feedback (why answers were wrong) enhances learning more than reflective feedback (information about what the right answers are).

KEYWORDS

neonatal mortality; education; emergency medical services; global health; smartphone; feedback; health workforce; developing countries; mobile phone

Introduction

Background

In low-income regions such as sub-Saharan Africa (SSA), the need for health workers to provide care by themselves is more frequent than in middle- and high-income settings, and it can be associated with negative neonatal outcomes [1]. Of the estimated 2.9 million neonatal deaths each year globally, SSA has the highest overall risk of death within the first 24 hours of life, accounting for 37% of global neonatal deaths [1]. Severe workforce shortages, coupled with the skill imbalance and maldistribution of the health workforce, and a lack of training opportunities [1,2] are likely to be key contributors to this high mortality rate. Additional training is needed to better prepare health care providers in these regions to provide effective emergency pediatric and neonatal care [3,4]. However, face-to-face training costs between US \$80 and US \$300 per person per day and is difficult to deliver at scale [5]. Only a small fraction of trained health providers with the basic requisite skills training for new-born resuscitation are usually found in these regions [6,7]. Therefore, new strategies are required to improve training access for over 1 million health providers across SSA. Any such approach needs to be updated efficiently in real-time as guidelines change in light of new evidence and (ideally) capture data on the number of health workers that are able to train within a certain time period [8,9].

There is little evidence about the implementation of digital learning interventions that are relevant to the context of low-income settings, that take into account health workers' initial and continuing clinical training needs, and that adapt learning content in the light of skill mastery and performance as learners continue to develop knowledge [9-15]. In nonclinical, high-resource contexts, adaptive instructional support has been shown to significantly outperform trainer-led large-group instruction, nonadaptive computer-based instruction, and paper-based instruction in producing learning gains [4,10,16,17]. Within low-resource contexts, investigation of learner models (cognitive models that try to model observed student learning behaviors) needed to support such tailored instructional approaches in clinical training settings is justified [10,11].

Health care training apps that have been developed to date and the approaches used can broadly be divided into two categories: those that simply replicate existing teaching strategies “on a screen,” for example, by providing questions and answers for exam practice or displaying textbook graphics, that is, the

“drill-and-practice” pedagogical approach, and others, that take advantage of features specific to digital devices, examples of which include the ability to respond with different pathways to user choices or the use of animations with which the user can interact, that is, a more learner-centered pedagogical approach [9]. Serious games, which are games with a specific, applied purpose (other than entertainment) that can be played on mobile phones, are one such way of providing training with the potential to affect health outcomes [18]. The rationale for using serious games is that, in a similar way to “first-person” computer games, emergency care training should enable health workers to follow highly structured pathways (such as clinical care algorithms) with pieces of information (cues) sought at each step that determine the correct actions to perform. With both clinical training and performance in computer games, executing cue-response sequences perfectly, rapidly, and automatically, with minimal help (eg, from corrective feedback and hints), demonstrates mastery. This type of mastery has been shown to support effective clinical care delivery, but the required frequency of rehearsal in this approach is difficult and expensive to maintain for face-to-face training [19]. By using a serious gaming approach, users may be more motivated to repeatedly play the serious game, using incentives such as rewards, increasing difficulty, and scores—techniques that have been successfully used to encourage repeated gameplay in nonserious computer games. There is a scarcity of evidence from the evaluation and assessment of serious gaming approaches in smartphones for health care training in low-income settings. Addressing this need was highlighted in the most recent systematic review in this area [15,20].

The Life-Saving Instruction for Emergencies (LIFE) project uses a smartphone-based serious game approach initially to provide training in the care of very sick newborns and children. The app extends the scenario-based Emergency Triage, Assessment, and Treatment Plus admission care training (ETAT+) training model [21,22] by incorporating more learner-centric intervention approaches. The aim of ETAT+ is to familiarize health care providers with clinical guidelines and the necessary knowledge and skills for triaging all sick children when they arrive at a health facility into those with emergency signs, with priority signs, or nonurgent cases and provide emergency treatment for those with life-threatening conditions [23]. The ETAT+ teaching model uses a face-to-face model to train health care workers in Africa and Southeast Asia and is explained in detail elsewhere [21-25].

Given the contextual challenges of enhancing health care providers' learning settings, such as SSA, LIFE is designed to develop health care providers' self-regulating learning (SRL) of ETAT+ content independent of any classroom or face-to-face tutoring facilitation. The potential for utilizing the digital and reusable nature of interventions such as LIFE to adapt the way health care professionals learn and receive feedback on their performance remains underexplored in SSA. Such personalization of learning could be used to maximize learning outcomes and to develop learners' skills [14,15]. The ubiquitous nature of smartphones as experimental tools offers access to a wider pool of study participants [26] and can minimize the cost of implementing, evaluating, and scaling educational platforms such as LIFE in a resource-constrained context [9]. Smartphones have also been shown to raise learners' interest in learning interventions [27].

SRL is a weakly recursively process that is facilitated by feedback at each stage [28-30] supporting learners' metacognitive regulation of learning strategies to help them regulate resources and emotions while learning [29]. In addition to regulation, metacognition consists of declarative knowledge and deals with the interplay between knowledge of one's abilities to perform tasks, the nature of the learning task, and the strategies one can employ to successfully perform the task [29]. It is theorized to have a limited capacity that renders the learners prone to making errors in complex or time-limited learning tasks (eg, delivery of emergency care in newborns) [31]. In the presence of such performance errors (eg, slipping or guessing) due to cognition's limited capacity [32], to guide SRL, a key objective is to infer the knowledge of the learning task being tutored. Feedback is posited to enhance learning when "...it provides further information to correct or modify action through the construction and activation of more appropriate [action sequences] ..." [33]. The information provided ought to move the learner to a deeper understanding of the learning task [34]. However, more feedback does not always equate to better learning: "...The amount of information given to the student must be what the student can use, rather than the amount the [tutor] may wish to give..." especially in light of the limited capacity of cognition [32,34-36]. Feedback that is too elaborate is more likely to produce cognitive overload. On the other hand, if it has low specificity, it is more likely to be perceived by learners as useless [32,37]. Effective feedback is posited to be specific but not too elaborate and presented in manageable units [37,38]. Its timing, specificity, frequency, and type have varying effects in enhancing learning [36]. In the absence of flexibility in determining the instruction challenge level or stratifying learning pathways within the LIFE project (due to the efforts to standardize delivery of clinical guidelines training content), feedback remains the most promising intervenable theory-aligned concept for enhancing SRL using smartphones in settings such as SSA.

Objectives

The primary objective of this randomized experiment was to investigate whether adaptive individualized feedback is superior to standardized feedback in mobile smartphone-based emergency neonatal care training. We hypothesized that health care providers randomized to receive adaptive feedback would

have significantly higher learning gains than those randomized to receive standardized feedback. The secondary objective was to investigate learning gain in general and how learning gains when using LIFE are modified by health care providers' characteristics and how they space their learning.

Methods

Ethical Approval

The breakdown of the methods and analysis plan for this experiment are described in the published protocol for this study [39] and was approved by the Kenya Medical Research Institute's (KEMRI) Scientific and Ethical Review Committee (#3444) and the Central University Research and Ethics Committee of Oxford University (#ED-CIA-18-106). It follows the Consolidated Standards of Reporting Trials guidelines for reporting randomized experiments [40].

Study Design

The study was a parallel-group, double-blinded, randomized experimental design with an allocation ratio of 1:1. The participants were randomized to receive the intervention or to be in the control group when they launched the training app for the first time on their individual smartphone devices.

Eligibility Criteria

The participants were health care providers from any professional cadre involved in providing bedside patient care, who were either undergoing training (eg, students), or actively providing nursing, clinical or medical care. Health care providers who had retired from clinical practice, who practiced in high-income settings, or participants who were not health care providers were excluded from the study.

Study Setting and Recruitment

This study was confined to participants from low-income countries who stand to benefit from training in the management of pediatric emergencies (Multimedia Appendix 1). The distribution of the LIFE smartphone app was through the Google Play Store, with initial efforts directed toward face-to-face recruitment of participants in Kenya (more details are provided in the study protocol [39]). The recruitment of study participants endeavored to promote voluntary self-enrolment and used snowballing and purposive sampling strategy [41], which have been explained in detail in the study protocol [39].

The Intervention

The intervention in this study was the adaptive differentiated immediate feedback provided while learning through a smartphone-based serious gaming app. The content to be learnt was based on a neonatal resuscitation guideline course that is already offered in nine low-income countries [21,22,24]. The smartphone-based app was publicly available on the Google Play Store, where it was downloadable and installable to compatible Android-based smartphones. All study participants received a link to the mobile app hosted on the Google Play Store. The LIFE app was designed to target Android's SDK19 as the minimum version of Android supported as at February 2019 (which targets 100% of Android devices) [42]. The

smartphone app had already undergone alpha and beta testing on a pilot cohort of health care providers' smartphones from Kenya since October 2017 to ensure stability and reliability of its functioning on different mobile phones. More details of the intervention are provided in the [Multimedia Appendix 2](#) [43-45].

The number of standardized feedback levels was determined by global health academics and expert medical trainers involved in ETAT+ training in SSA in consultations with the relevant medical professional bodies accrediting continuous professional development. The adaptive immediate feedback provided to the experimental group participants was designed to arouse meaningful reflective learning from continuous interaction between the learners and the smartphone-based training [46,47]. As didactic-procedural form of feedback [48] aligned to our theoretical framing, it was designed to force the health care provider to contemplate over the incorrect care provision choices they provided in their failed attempt (eg, "Some of the selected actions are not *appropriate* at this *stage*" focuses on the number of wrong choices and their placement within the clinical care-giving pathway and is meant to force reflection as to which stage they are most appropriate). This feedback was provided to the experimental arm after each incorrect attempt at a learning task with three cascading detail levels based on the predicted probability that the learner's next attempt was going to be correct. The modeling approach to support the data collected from 187 health care providers during the beta testing phase and is briefly described in the [Multimedia Appendix 2](#) and explained in detail elsewhere [49]. The wording of the feedback provided was dependent on the number of incorrect choices the learner had selected and the actual incorrect choices themselves. This is illustrated in [Multimedia Appendices 3-6](#). The control group study participants received standardized nonadapted immediate feedback after each incorrect attempt at a learning task, with the feedback on the first incorrect attempt asking the learner to retry (level 0, [Multimedia Appendix 6](#)) and the feedback on the second attempt giving a detailed explanation of the correct choices to select (level 2, [Multimedia Appendix 6](#)). Using multidimensional model of personalization by Holmes et al [50], in this experiment, the adaptive mechanism targets the personalization of how feedback is to be presented and when it is to be introduced.

The LIFE app was both the learning and the measurement tool. The learning task is synonymous with the quiz as learning is designed to be embedded in the formative evaluation. At the end of a successful completion of a learning session, the platform provided a performance score based on whether each learner's response to the learning tasks was correct on the first attempt. For this study, a learning session was conceptualized as every unique initiation (ie, iteration) of the neonatal resuscitation learning scenario training round on the LIFE smartphone app (illustrated in Scenario A in [Multimedia Appendix 7](#)).

Outcomes

The primary end point for both arms of the experiment was the completion of two learning sessions using LIFE, the first session being treated as pretest and the second session being treated as posttest. Both scores were converted into percentages. From

the pre-post scores, the study's main comparative outcome was the learning effect size (g) [51], with the formula for its calculation provided in this study's protocol [39] and provided in the [Multimedia Appendix 2](#). This effect size, also referred to as *Morris G* [51], represents the mean difference between the relative change within the study arms. From education literature [16,52,53], effect sizes of approximately 0.2, 0.5, and 0.8 are considered as small, moderate, and large effect sizes, respectively. These thresholds represent the magnitude of the effect and reflect our assumption that a statistically significant result is not necessarily important or meaningful. For example, for an effect size of approximately 0.2, the difference between the study groups is trivial even if it is statistically significant [52,54].

In addition to randomization, which eliminates or at least dramatically reduces biases influencing this study's primary outcome, the calculation of this study's primary outcome (1) is robust in managing preexisting knowledge differences among learners, (2) allows for the estimation of the intervention effect even when experimental and control groups are nonequivalent, and (3) considers the variances of both pretest and posttest scores. This contrasts with other forms of effect size calculation such as Hedges G and Becker D, which only use pretest or pooled variances [51]. In this model, the pretest and posttest variances were assumed to be homogeneous. The secondary outcome considered was the individualized learning gain of the study participants, defined as the relative change in performance score of health care providers divided by the maximum score they could have improved upon [55]. This was calculated from the performance scores from learning sessions following each other, with the performance from the first session treated as pretest score and the one from the last session treated as a posttest score. The formula for this calculation is provided in this study's protocol [39].

Participant Timeline

Enrolment of study participants began on February 1, 2019, and continued up to July 31, 2019. This study's rollout of LIFE's intervention was based on implementation study principles and outcomes [56] and was informed by self-regulated, self-directed learning [28,31,57]. It sought to understand and work within real-world conditions, rather than trying to control for adoption, acceptability, coverage, and sustainability conditions or to remove their influence on the study outcome [56]. Subsequently, no training sessions were planned for the study participants. Although LIFE is designed for low-income contexts, there was no limit set by geographical coverage for health care providers who might be interested in undertaking this self-directed training; anyone could download the app. However, we only analyzed health care providers from low-income countries. Participants without any geographic location data (due to refusing to grant the LIFE app the required Android permissions) were assumed to be from developing countries, given that our recruitment efforts were directed toward professional groups in these countries.

Sample Size Calculation

Similar interventions in other subject domains have been found to have a mean effect size of between 0.22 (95% CI 0.16 to

0.27) to 0.70 (95% CI -0.08 to 1.49) [16,58]. Drawing from these studies, to detect an effect size of 0.22 with a two-sided 5% significance level and a power of 80%, a sample size of 83 participants per group who reach the primary end point of the study was necessary. A sample size calculation for a one-way analysis of variance, together with one-sample and paired-sample *t* test analysis using the same effect, power, and significance parameters produced the same required sample size of 166 participants. The sample size calculation formula is provided in this study's protocol [39].

On the basis of the alpha tests of the LIFE smartphone app, we assumed a 50% dropout rate of study participants, with dropout defined as the incomplete or single use of the LIFE smartphone app, and planned to recruit at least 332 participants to account for this dropout rate. To encourage repeated usage of LIFE, all participants received email reminders from the time they were enrolled in the study once every 2 weeks, and this was suspended after they had received three reminders. From interviews of the study participants in the alpha and beta phases of the LIFE app development, those from lower clinical cadres tended to characterize the cost of phone data charge necessary for downloading the 231 MB smartphone app as too high. To mitigate the burden of saddling participants with this extra cost to their personal finances due to participating in the study, they could request for reimbursement of costs within a few weeks of using the LIFE smartphone app.

Demographic data was collected within the app in its initial use by study participants at the end of the first learning session if they consented. This was because demographic data were deemed more sensitive than trace play data and therefore required additional consent as per the ethical approval. This meant that for learners who dropped out before completing the first session, or chose not to fill-in those data, no demographic data were collected. From these data, statistical analyses were conducted to evaluate whether there was any systematic bias in the attrition of study participants. Study variables used in this analysis were study groups, exposure to previous neonatal training, clinical cadre, age, and level of experience. This was because given the differences in training pathways for clinical cadres and length of practice, level of expertise might produce differences in the effectiveness of the learning intervention [59]. In addition, age was included to evaluate whether it was associated with the pattern and effectiveness of smartphone-based learning given its novel nature requiring digital acuity [60]. We judged sex not to be theoretically influenced by the socio-cognitive framing of this experiment's research questions.

Randomization

For allocation of the participants, an in-app algorithm randomly generated a value between 0 and 3 when the smartphone app was launched for the first time. If the value was either 0 or 1, it was recoded to 0, otherwise recoded as 1. This algorithm was implemented using a randomization routine provided by the game engine for development reasons, which we assumed to be reliable [61]. The algorithm determined whether a participant was allocated to the control (if the recoded value was 0) or the experimental group (if the recoded value was 1). It also blinded

both the study participants and staff to the allocation of participants to groups during the experiment, but not at the analysis stage. Sequence generation for random allocation was a computerized procedure pegged on a single instance (ie, smartphone app installation instance) that mimicked a coin-tossing procedure. Therefore, using permuted blocks of random sizes to assign participants to either the control or experimental group was not possible and therefore not implemented.

Statistical Methods and Analyses

For the primary end point, we used the Morris G effect size to analyze the differences between study arms of relative change in scores within the arm, as described in detail in the study protocol [39]. This was assessed after the second round of completing the training scenario through the smartphone app, with each round's performance score recorded. Secondary analysis was conducted using regression analysis, with the dependent variable being the normalized learning gain and the independent variables being health care providers' demographic characteristics and the game play characteristics (eg, spacing of repeat learning session, amount of time spent on learning task, and previous exposure to neonatal training), to evaluate their effect on learning gains.

The primary learning outcome used in this study could not be computed for study participants whose dropout was characterized by a lack of at least two complete learning sessions. Without a postbaseline assessment, "intention-to-treat" analysis could not be performed unless we imputed outcomes, which tends to produce biased estimates [62]. Therefore, we did not conduct an intention-to-treat analysis. However, dropout numbers are reported in relation to those who reached the study's primary end point, with their implications discussed considering self-regulated, self-directed learning [28,31,57].

Qualitative interviews were conducted in parallel to the experiment from a small sample (N=19) of the health care providers who participated in the study, regardless of whether they reached the primary end point or not. These interviews were used to explore health care providers' perceptions of self-regulated learning that affected the contextual use of the smartphone-based learning platform. They provided a context for interpreting the observed learning outcomes from this study and will be reported separately.

Data Management

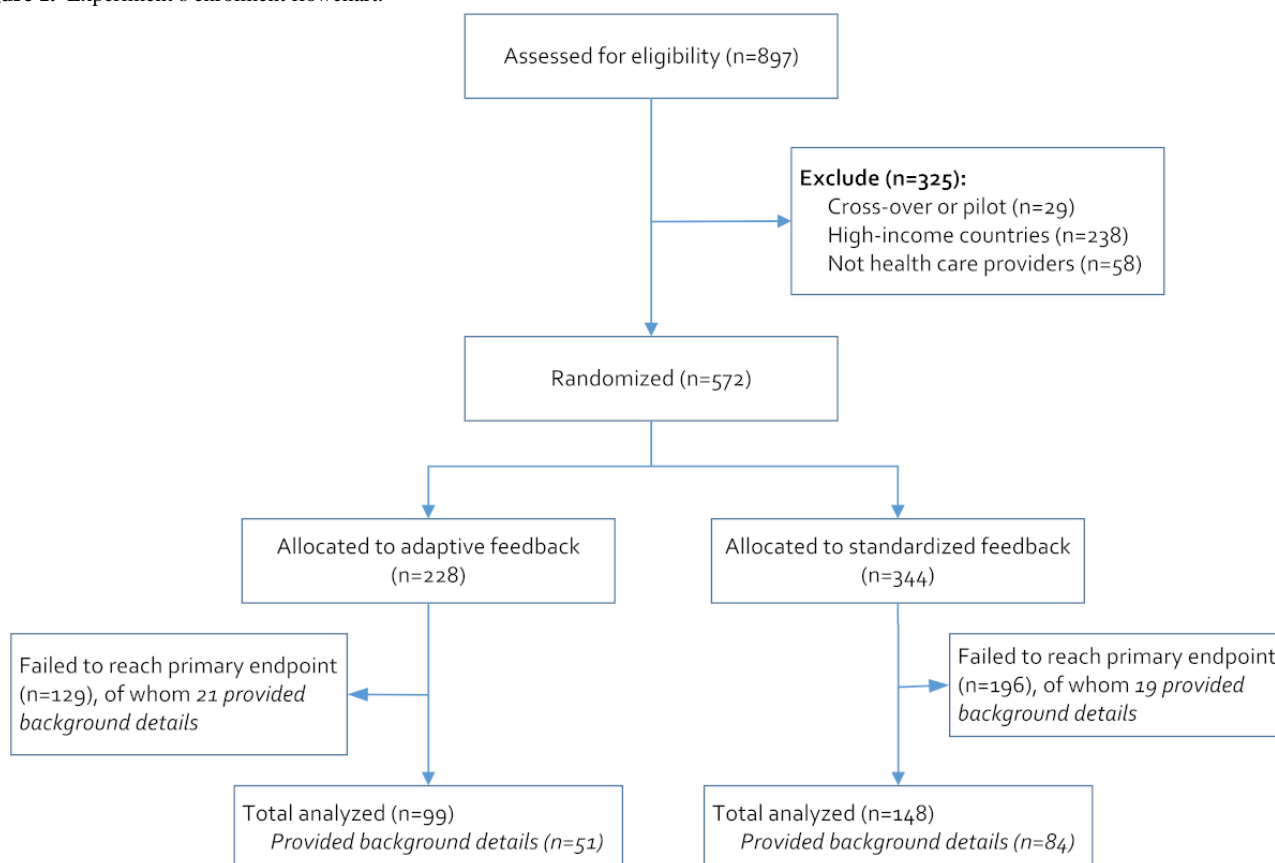

The primary data collected from the study participants' Android smartphone app are held on their devices with a back-up copy synchronized to *Google Firebase*, a secure distributed cloud-based database server, after being transmitted in an encrypted format. Data collected after the experiment were stored on encrypted password-protected USB devices and transferred to secure password-protected servers in Kenya and Oxford. Deidentified data were shared with study staff based at the research institutions listed on the ethical approval forms.

Informed Consent

Individual participant consent was elicited from within the mobile app before collection of any demographic data, in

addition to using explicit Android permission requests for collecting trace anonymized learning data from the app. This approach of informed consent in an app is not uncommon in medical research; it has been described in detail in a systematic review [63] as well as specifically for mobile app-based research [64]. The informed consent process also included information on the credentials and affiliations of the researchers and developers of the LIFE platform. Participants had no way of knowing whether they were receiving the “intervention of interest.”

Figure 1. Experiment’s enrolment flowchart.

It was challenging to enforce the allocation ratio because the algorithm used for randomization was not centralized and therefore unable to implement a blocking mechanism in participant to group allocation. Randomization was happening on the individual health care provider’s personal smartphone independent of how other participants were allocated and is illustrated in detail in [Multimedia Appendix 8](#). In addition to the lack of an enforceable blocking mechanism, the software library used for the random generator function (C++ rand function) is most likely to have caused an unequal allocation ratio because it has varied efficiency across multiple smartphone devices that remain largely unknown ([Multimedia Appendix 9](#)) [61,65]. It is highly likely that this was what contributed to the observed disparity in allocation ratio. However, this did not

Results

Study Sample

At the end of the data collection period, 572 of the enrolled 897 participants were eligible for the study and 247 (43.2%) ended up reaching the study’s primary end point ([Figure 1](#)), as expected in our published protocol [39].

render the allocation of study participants to the study arms nonrandom, as detailed below.

A total of 30.6% (175/572) of the enrolled participants provided their background information, and of these, 135 reached the experiment’s primary end point ([Figure 1](#)). From the difference in means test and difference in proportions test, there was no significant difference between the experimental and control groups of both those who dropped out and those who reached the study’s end point by LIFE use characteristics ([Multimedia Appendix 10](#)) or demographic characteristics ([Table 1](#)). However, the dropout rate was significant in health care providers in clinical officer cadres and those who had specialized training ([Multimedia Appendix 11](#)).

The effects of attrition bias appear to be minimal, as reported in [Table 1](#) and [Multimedia Appendix 10](#). There is good reason to infer that the randomization generally achieved its purposes of balancing participants from different backgrounds between the intervention arms while also mitigating against selection bias despite the unexpected allocation ratio.

Effect of Adaptive Feedback on Learning Gains Across Study Arms

The performance of the learners showed a substantive improvement of about 30% above pretest scores in both the control and experimental arms ([Table 2](#)). As the overall learning change from LIFE use was large, this may obscure a direct effect from the adaptive feedback. From Levene's test, the assumption that the variance of the performance scores was homogenous holds true [66].

Table 2. Performance of learners within study arms.

^aEffect size based on intra-individual changes in test scores accounting for correlation between the scores in a single-group pretest posttest design [51].

^bPearson R correlation between the scores within the study arm.

The main outcome of interest, which was the effect of adaptive feedback on learning gain, was calculated after the second round of the completed learning scenario, and its calculation is explained in detail elsewhere [39]. Adaptive feedback had an intervention effect of 0.09 (95% CI -0.31 to 0.46; $P=.47$), which is both statistically and substantively insignificant. It is noteworthy that the calculation for the effect size computed here does not treat the scores as repeated measures but as

independent data. It also assumes that pretest and posttest variances are homogeneous. To minimize this bias, a correction adjustment factor of 0.998 was applied to the effect size and is explained in the protocol [39,51]. This suggests that the degree of bias in the effect size calculation was minimal given that it is a very small adjustment. The number of feedback messages provided in the experiment over the learning sessions is illustrated in [Table 3](#).

Effect of Adaptive Feedback on Individual Learning Gains

The primary outcome analysis results are likely to suffer from two forms of detection bias: subject-treatment interaction bias and differential time-effect bias [67], as illustrated in [Multimedia Appendix 12](#). To mitigate against these biases and explore how LIFE use and learner background characteristics might affect learning gains, we conducted a secondary analysis using normalized learning gain at the individual level. This was consistent with the published protocol [39]. Details of our calculation of the normalized gain are explained elsewhere [39,55].

When considering differences in LIFE use at the individual health care provider level, learners who had a space of more than a week between subsequent use of LIFE had significantly lower normalized gains by -0.395 (95% CI -0.557 to -0.232 ; $P<.001$) than those who had spaced their learning to an hour or less. Any variation in spacing the self-directed use of LIFE, which was a week or less, did not produce significant changes to the normalized gains. The adaptive feedback mechanism had a significant effect on health care providers' normalized learning gains of 0.523 (95% CI 0.345 - 0.702 ; $P<.001$). Longer time spent on learning tasks and ratio of feedback hints provided per attempt at a learning task were significantly associated with lower normalized student learning gains. Health care providers' previous face-to-face training in ETAT+ content had no positive significant effect on their learning gain. This is illustrated in [Table 4](#), model A.

When considering the demographic and background characteristics of the health care providers, their clinical cadre and level of practice/training had no significant effect on their learning gains, except for doctors whose learning gains were significantly higher by 0.14 (95% CI 0.016 - 0.265 ; $P=.027$). This is illustrated in model B of [Table 4](#). Controlling for health care providers' background characteristics significantly increased the effect of adaptive feedback on individualized normalized learning gains to 0.644 (95% CI 0.347 - 0.941 ; $P<.001$). It also improved the proportion of variance for average student normalized gain, which was explained by the independent variables in the regression model A by 18.3% ([Table 4](#)). Overall, independent variables had low multicollinearity in both variants of the regression model in [Table 4](#), as illustrated in [Multimedia Appendix 13](#). Both models explained 34.4%-40.7% of the variance in the normalized learning gains of the health care providers using the LIFE smartphone app to train on neonatal emergency care. However, only model B in [Table 4](#) satisfied all the statistical modeling assumptions.

A fraction of the learners had more than two rounds of play, as illustrated in [Multimedia Appendices 14-16](#). However, with each round of play, the numbers of health care providers dropped by around 40%-60%. This meant that fitting a longitudinal model was not feasible because the variances of more than one linear combination of time effects were close to zero (ie, singular), indicating that the model would be overfitting [68]. Furthermore, health care providers' spacing of their learning was not standardized, and the learning iteration variable violated the sphericity assumption necessary for conducting a repeated measures analysis of variance test [69].

Discussion

Summary of Findings

This study was used to explore the effectiveness of adaptive feedback for smartphone-based training of health care workers in low-income settings, which is a largely unexplored topic of medical education in this context. We found that although there was considerable learning gain with both forms of feedback (Table 2), adaptive feedback had a weak effect of 0.09 (95% CI -0.31 to 0.46; $P=.47$), which was not statistically significant. However, when considering the background characteristics of health care providers and the various self-directed spaced learning options, and using learning gains analyzed at the individual level as opposed to the group level, adaptive feedback had an effect size of 0.644 (95% CI 0.347-0.941; $P<.001$) on

student normalized learning gains with immediate repetition. Spaced learning of a week or more was associated with a significant reduction in normalized gains by 0.28. Differences in clinical cadre, level of practice/training, and previous exposure to neonatal emergency care training had no significant effect on the individual health care providers' learning gains.

Relation to Other Studies

This experiment differs from previous similar studies in digital education for clinical practice in that it (1) used mobile devices for delivery of digital education interventions, (2) evaluated novel educational modalities enabling simulated learning such as adaptive feedback, (3) provided essential methodological information necessary for comparability purposes, (4) reported relative learning gains as done in this study except one (rather they tended to report differences of postintervention scores in

the study arms), and (5) were from low-income settings such as SSA or South-East Asia [11]. In the three studies that dealt with resuscitation identified by the systematic review by Car et al [11], only one study reported relative mean change but found no significant effect of different formulations of online content on learning gain [70], which is similar to our findings, although our primary outcome is calculated differently from theirs. In that study, a variant of individual students' normalized gain was used, such as the secondary outcome we used in this study where we found the effect on individual student learning gains was 0.644 (95% CI 0.347-0.941; $P < .001$) when considering individual learner characteristics.

This study has addressed some of the recommendations from a recent evidence review into gamified education in health, which proposed future studies to employ the use of a rigorous experimental design to evaluate learning interventions, and include more studies from low- and middle-income countries, two underrepresented aspects of the current evidence base [15]. Even when considering interventions looking into adaptive feedback in digital education, none that we know of are in the health domain [71], making this study unique. Given that the implementation of the learning intervention was available to all clinical cadres involved with bedside care provision, who had varying levels of experience (from students to consultants), from multiple low-income countries, representing a varied mix of geographical and resource settings, the diverse population of the clinical taskforce in this experiment ensures that those who would most benefit from using the presented learning tool for training in emergency care delivery are well represented. Furthermore, as the overall learning gain from LIFE use in both study arms was large, given that the learning platform minimized elements that would not be typically available in routine app settings [56], this experiment's findings are generalizable to emergency care training of the health care provider population from low-income countries using smartphone-based platforms.

Implications of Findings

At the group level, the effect of adaptive feedback on health care provider learning gains was not significant, but the opposite is true when evaluated at an individual level. This might imply that the intervention effect is strongly mediated by other factors (which were external to the smartphone app), chief among them being health care providers' individualized spacing of learning repetition. Together, with the inclusion of demographic characteristics, this increased the explainable variance of adaptive feedback on individual learning gains by 18.31%. Linking the level of adaptive feedback provided to health care providers' individualized learning repetitions conditioned on their level of experience and clinical role might explain the stronger intervention effect at the individual learner level.

This difference between the group and individual learning gain might also imply that the decision of when to collect postintervention or repeated measures is a significant factor in determining what is effective learning intervention. Considering spaced learning, intuitively, the intervention effect becomes more reflective of a mechanism that works on optimizing the recall rate as opposed to the level of internalizing/understanding content. Despite efforts to encourage the latter mechanism by

using reflective cues (Multimedia Appendix 6), from early findings of an ongoing qualitative evaluation for this study, an alternative model using elaborative cues on why the choices of the health care providers were wrong would arguably enhance internalization of the learning content.

The high drop-off rate with each subsequent round of play despite a lack of maximization of the learning gains (Multimedia Appendices 14-16) was disconcerting and limited the assessment of learners' skill mastery over time. The high drop-off rate might imply that (1) effort regulation and motivation for self-directed learning using LIFE is very low, (2) health care providers self-assessed learning needs lead them to believe that they have attained content mastery and thus are no longer in need of this training, or (3) other factors that are external to this experiment affect the use of the LIFE app (eg, uninstalling the LIFE app to make more space for other apps on the learner's smartphone). Qualitative interviews will be used to explore whether any of these explanations are plausible and how they can be leveraged to encourage low drop-off rates.

From our findings, a gamified smartphone-based alternative to the low-dose-high-frequency clinical training approach commonly used in low-income settings that employs a self-regulated learning approach offers significant learning gains. This is useful where face-to-face training is not possible, costs of training are a concern, and learners prefer flexible learning schedules. In addition, the spaced repetition of such a learning approach can be encouraged after a week has passed, with the encouragement differentiated based on a knowledge tracing approach that is informed by the clinical role and experience in addition to learner progression. This can be explored in future research.

Study Limitations

In this randomized experiment, we used the standard Bayesian Knowledge Tracing (BKT) modeling approach, which is explained in detail in the Multimedia Appendix 2 and elsewhere [49], to determine the adaptive feedback threshold cutoffs. However, BKT has a set of problematic assumptions: it assumes that forgetting does not occur, the knowledge components (ie, quizzes in our case) are treated as being mutually independent, its typical implementation does not allow learners to have different learning rates, it assumes that all students have the same probability of knowing a particular skill at their first opportunity (Multimedia Appendix 4), and it suffers from the problem of multiple global maxima when trying to estimate model parameters [49,72]. In addition, we used learning data from 187 health care providers from the beta phase to train the model, which is a relatively small number. Together with the moderate predictive accuracy of the health care provider's knowledge (Multimedia Appendix 2), it is highly probable that the prescription of the level of feedback might have been biased, thereby underestimating the effect of the intervention. However, this modeling approach was used because it is more easily embedded within the smartphone app and was able to function offline compared with other common alternatives [49,73].

From interviews of the physically accessible study participants, those who were from lower clinical cadres found the one-off phone data cost necessary for downloading the smartphone app

as being too high. To mitigate against burdening participants with this extra personal cost due to participating in the study, they could request for reimbursement within a few weeks of using the smartphone app. This skewed the study participants numbers toward a specific country where the reimbursements were made available (Multimedia Appendix 1). Within these resource contexts, such costs play a role in generating study participants who might not be representative of those with the intention to participate, rather representing those with the “economic” ability to participate, which is difficult to mitigate against in a multicountry study. It is challenging to determine if the reimbursement favored any study arm because of the blinded participant allocation to the study arms coupled with a lack of linking participants (whose data were collected as anonymous at source) to reimbursement.

The risk of performance bias across arms was moderate given that allowing for the “real-world” use of the smartphone app in a self-directed manner would also make it difficult to comprehensively control for exposure to factors outside the intervention of interest. This is especially true where some of the participants were in the same peer groups, hospitals, or social circles and might have collaboratively used the smartphone app.

Although randomization allocation did not result in an equal number of participants in the study arms, from our post-hoc analysis (Table 1; Multimedia Appendices 10 and 11), we do not believe that this biased this experiment’s findings.

Conclusions

This study set out to evaluate the effect of adaptive feedback within a smartphone-based serious game on the learning gains of health care providers from low-income countries. From 247 health care providers, the effect on learning gain was found to be $g=0.09$ (95% CI -0.31 to 0.46 ; $P=.47$). When subject-treatment interaction and differential time effect were controlled for, the effect of the adaptive feedback on learning gains increased significantly to 0.644 (95% CI 0.347 to 0.941 ; $P<.001$). From our findings, we suggest that linking the level of adaptive feedback provided to health care providers to how they space their learning and their clinical level might yield a larger intervention effect at both the group and individual learner levels. For the feedback content itself, as an alternative to using reflective hints on what the right answers might be, elaborating why the health care providers’ responses were wrong might enhance understanding of the learning content.

Acknowledgments

The authors would like to thank Jakob Rossner, the lead developer of LIFE, and the beta-testers based in Kenya, who continue to be instrumental in the development and scale-up of the LIFE platform. Funds from the *Economic and Social Research Council* (ESRC), Award Number: 1926841 awarded to TT as a DPhil fellowship supported this work. Snapshots of the Life-Saving Instructions for Emergencies smartphone app.

[[PNG File , 693 KB](#) - [jmir_v22i7e17100_app7.png](#)]

Multimedia Appendix 8

Random allocation procedure.

[[PNG File , 160 KB](#) - [jmir_v22i7e17100_app8.png](#)]

Multimedia Appendix 9

Random allocation ratio based on time of day (the seed used for the generator).

[[PNG File , 119 KB](#) - [jmir_v22i7e17100_app9.png](#)]

Multimedia Appendix 10

Tests of whether differences in allocation rate between study arms resulted in non-equivalent Life-Saving Instructions for Emergencies app use for all study participants included.

[[DOCX File , 15 KB](#) - [jmir_v22i7e17100_app10.docx](#)]

Multimedia Appendix 11

Tests of whether dropout rate is different between study arms using baseline characteristics of study participants where demographic data are available.

[[DOCX File , 18 KB](#) - [jmir_v22i7e17100_app11.docx](#)]

Multimedia Appendix 12

Learning spacing between first two sessions, n (%).

[[DOCX File , 14 KB](#) - [jmir_v22i7e17100_app12.docx](#)]

Multimedia Appendix 13

Multicollinearity tests for the learning gain outcome.

[[DOCX File , 13 KB](#) - [jmir_v22i7e17100_app13.docx](#)]

Multimedia Appendix 14

Learners in each study arm at each learning iteration.

[[DOCX File , 14 KB](#) - [jmir_v22i7e17100_app14.docx](#)]

Multimedia Appendix 15

Change of student learning gains over learning sessions by study arm.

[[PNG File , 56 KB](#) - [jmir_v22i7e17100_app15.png](#)]

Multimedia Appendix 16

Change of student learning gains over successive learning sessions by spacing options.

[[PNG File , 52 KB](#) - [jmir_v22i7e17100_app16.png](#)]

Multimedia Appendix 17

CONSORT-EHEALTH checklist (V 1.6.1).

[[PDF File \(Adobe PDF File\), 1002 KB](#) - [jmir_v22i7e17100_app17.pdf](#)]

Abstract

Background: Recently, internet-based cognitive behavioral therapy (ICBT) and serious gaming interventions have been suggested to enhance accessibility to interventions and engagement in psychological interventions that aim to promote health outcomes. Few studies, however, have investigated their effectiveness in the context of simulated real-life challenges.

Objective: We aimed to examine the effectivity of a guided ICBT combined with a serious gaming intervention in improving self-reported psychophysiological and immunological health endpoints in response to psychophysiological and immune-related challenges.

Methods: Sixty-nine healthy men were randomly assigned to the intervention condition, receiving ICBT combined with serious gaming for 6 weeks, or the control condition, receiving no intervention. Self-reported vitality was the primary endpoint. Other self-reported psychophysiological and immunological endpoints were assessed following various challenges, including a bacillus Calmette-Guérin vaccination evoking pro-inflammatory responses, 1 and 4 weeks after the intervention period.

Results: Although the intervention did not affect vitality-associated parameters, self-reported sleep problems ($P=.027$) and bodily sensations ($P=.042$) were lower directly after the intervention compared with controls. Furthermore, wellbeing ($P=.024$) was higher in the intervention group after the psychophysiological challenges. Although no significant group differences were found for the psychophysiological and immunological endpoints, the data provided preliminary support for increased immunoglobulin antibody responses at the follow-up time points ($P<.05$). Differential chemokine endpoints between conditions were observed at the end of the test day.

Conclusions: The present study provides some support for improving health endpoints with an innovative ICBT intervention. Future research should replicate and further extend the present findings by consistently including challenges and a wide range of immune parameters into the study design.

Introduction

Psychological interventions have been shown to be effective in improving self-reported health outcomes [1,2] and immune status [3-5]. Two meta-analytic reviews found modest support for improved immune function after psychological interventions [6,7]. However, it is difficult to draw conclusive findings from these studies due to the large heterogeneity in the incorporated interventions (ie, various types of relaxation, conditioning, disclosure, and stress management interventions) and immunological outcomes (ie, quantitative and qualitative). Moreover, novel developments in psychological treatments may potentially further enhance the effectiveness of psychological interventions in improving self-reported and immunological health outcomes [7]. A rather novel development focuses on providing psychological interventions based on cognitive behavioral therapy (CBT) via the internet (ICBT). CBT focuses on enhancing coping and problem-solving skills and therefore can be applied to improve health management strategies [8]. Furthermore, cognitive behavioral strategies can adjust standards of health and in turn improve quality of life [8]. A meta-analysis showed that the effectiveness of guided ICBT interventions is comparable to face-to-face interventions in patients with chronic somatic conditions [9]. Advantages of ICBT over face-to-face interventions are the increased convenience in use and enhanced flexibility of the specific location and time for users regarding where the intervention sessions are completed [10]. However, adherence rates in ICBT are lower compared to face-to-face interventions; therefore, engagement should be taken into account [11,12].

Engagement can possibly be enhanced by applying persuasive internet-based technologies, such as serious gaming. Serious gaming aims to provide education in an entertaining manner and can therefore be intrinsically motivating [13,14]. A meta-analysis showed evidence for the effectiveness of serious gaming in promoting a healthy lifestyle [15]. Serious games are able to tap into multiple learning processes such as explicit behavior change strategies (eg, goalsetting and transferring knowledge [16]), but also imply more implicit behavior change strategies (eg, priming and evaluative conditioning). Serious gaming could therefore be an interesting technique to add to ICBT interventions to further optimize their effectiveness.

Most research has focused on basal health outcomes; however, health outcomes assessed in situations that challenge actual health status might better represent reactions to real-time stressors [17]. Few studies have incorporated immunological or psychophysiological challenges in their study design. Immunological challenges may comprise *in vitro* exposure to a chemical substance (eg, lipopolysaccharide or pokeweed mitogen [18,19]) to obtain insights into the cellular responses after a psychological intervention. Immunological challenges can also be applied *in vivo* to observe subsequent responses (eg, antibody responses after vaccination [20] or healing process of experimentally created wounds [21]). Psychophysiological challenges can provide insights into participants' responses to

stress after a psychological intervention (eg, exposure to a social evaluative stressor). The studies that incorporated challenges into their design often focused on incorporating one specific challenge and did not combine and compare effects on both *in vitro* and *in vivo* immunological as well as psychophysiological challenges [17]. For example, a recent systematic review of studies that specifically examined wound healing after a psychological intervention provided some support for the optimization of immunological markers after this challenge [22]. It is possible that incorporating multiple challenges will provide a more concise view on the effectiveness of a psychological intervention and therefore provide further insights into the link between psychological and immunological mechanisms.

The aim of this randomized controlled trial was therefore to investigate whether an ICBT intervention combined with serious gaming to optimize its effectiveness and engagement can effectively improve self-reported psychophysiological and immunological health endpoints in response to *in vitro* and *in vivo* immunological and psychophysiological challenges [17,23]. To gather more insights into the potential effectiveness of an ICBT intervention combined with serious gaming intervention in preventing adverse health endpoints and improving immune function, we included healthy participants in this study. Including healthy participants also provided us with the opportunity to incorporate multiple immunological and psychosocial challenges to gather more insights into the mechanisms underlying the effects of psychological interventions on health endpoints. It was hypothesized that participants in the intervention condition would show higher self-reported vitality and related health endpoints after the intervention compared with the control condition. In addition, improved self-reported psychophysiological and immune-related health endpoints after the *in vitro* and *in vivo* immunological and psychosocial challenges were expected in the intervention condition compared with the control condition.

Methods**Ethical Considerations**

The study protocol was approved by the Medical Ethical Committee of Leiden University Medical Centre (registration number P15.099/NL52434.058.15) and preregistered at the Netherlands National Trial Register (NTR5610). The study was conducted in accordance with the Declaration of Helsinki and the International Conference on Harmonisation Guidelines on Good Clinical Practice. Details on the study protocol and design have been published previously [23].

Study Population

To gather more insights into the potential effectiveness of ICBT combined with serious gaming in preventing adverse health endpoints and improving immune function, we included healthy participants in this study. The inclusion and exclusion criteria are described in detail in a previously published article on the

study protocol and design [20]. Briefly, healthy male participants between 18 and 35 years of age without any somatic or psychological conditions interfering with the study protocol were eligible to participate in the study. We only included male participants as the menstrual cycle is known to affect immune function [23,24]. Participants were recruited through digital and printed flyers at various faculties of Dutch universities from February 2016 until April 2018.

Procedure

Participants were informed that the study was about the effectiveness of a psychological training program directed at optimizing immune function. After signing an informed consent form, participants completed the self-reported and psychophysiological endpoints, and venous blood was collected. Participants who met the inclusion criteria were randomly assigned to a 6-week intervention or control condition. In the

week following the 6-week intervention or control period (ranging from 1 to 7 days after completion of the intervention period), all participants again completed the self-reported and psychophysiological endpoints, and blood was collected. Directly afterwards, participants were vaccinated with bacillus Calmette-Guérin (BCG). One day later, a test day followed, on which psychophysiological stress challenges (ie, Paced Auditory Serial Addition Task, Cold Pressor Test, and Trier Social Stress Test) were administered. At the start and end of the test day, self-reported and psychophysiological endpoints were assessed (see Table 1), and blood was again collected. After 4 weeks, a follow-up measurement was conducted, including self-reported endpoints as well as psychophysiological endpoints and collection of a blood sample. Total time investment for participating in the study was around 15-20 hours, depending on the group allocation. This also included 4 visits to the study center. Participants received €200 for their participation.

Table 1. Details of the endpoints at each measurement point.

Endpoint	Baseline	After intervention /pre-vaccination	Start test day	End test day	Follow-up
Self-reported endpoints	SVS ^a , CIS-20 ^b , RAND-36, PILL ^c , MOS ^d Sleep, PANAS ^e , and NRS ^f	SVS, CIS-20, RAND-36, PILL, MOS Sleep, PANAS, and NRS	SVS, CIS-20, PANAS, and NRS	PANAS and NRS	SVS, CIS-20, RAND-36, PILL, MOS Sleep, PANAS, and NRS
Psychophysiological endpoints	Heart rate variables, skin conductance, cortisol, and alpha amylase	N/A ^g	Heart rate variables, skin conductance, cortisol, and alpha amylase	Heart rate variables, skin conductance, cortisol, and alpha amylase	Heart rate variables, skin conductance, cortisol, and alpha amylase
Immune endpoints	Unstimulated as well as LPS ^h -stimulated serum samples	Unstimulated as well as LPS-stimulated serum samples	Unstimulated as well as LPS-stimulated serum samples	Unstimulated serum sample	Unstimulated serum sample

^gN/A: not applicable.

^hLPS: lipopolysaccharide.

Randomization and Blinding

Participants were randomized to the intervention or control condition based on a 1:1 allocation ratio. A block randomization was performed by the first author with random.org (block size of 4) to control for seasonal influences [23]. The test leader on the test day was blinded for group allocation.

Intervention

See Table 2 for an overview of the intervention. Participants in the intervention group received a guided ICBT intervention for 6 weeks [23], which was based on an ICBT intervention for chronic somatic diseases developed in our research group [25,26]. The intervention was delivered on the internet platform and software hosted by Karify [27]. The intervention could be accessed individually by the participant. It was provided for free, and the website was password protected. Access was granted by providing participants with an email link in which

participants were invited to set up a personal account. The intervention contained 6 modules (goal setting, healthy food and exercise, relaxation, sleep, cognition and worldview, and long-term goals). These modules were guided by a therapist (psychologist supervised by a CBT psychologist) from whom participants received homework assignments and asynchronously provided feedback messages. In addition, participants in the intervention condition played a serious game (ViaNova©) that incorporated comparable modules as the guided intervention (ie, healthy food and exercise, sleep, relaxation, and long-term goals) as part of the ICBT. A subset of these games that focused specifically on food-related health behavior was tested in a previous study that demonstrated preliminary support for the effectiveness of a single serious gaming session in optimizing virtual food choice and implicit food preference [28]. Two weeks after the intervention, participants received a booster session by telephone which lasted

15-30 minutes and focused on relapse prevention by asking participants how they worked on their goals after the last online

session and what strategies they used to keep up with their goals. The control condition did not receive any training.

Table 2. Overview of the intervention.

Week	Module	Actions
1	Module goal setting	Face-to-face intake with the therapist and setting goals for the online intervention
2	Module healthy food and exercise	Reading information, keeping a diary on goal progress, reading the information provided online by the therapist, completing assignments provided by the therapist
3	Module relaxation	Reading information, keeping a diary on goal progress, reading the information provided online by the therapist, completing assignments provided by the therapist
4	Module sleep	Reading information, keeping a diary on goal progress, reading the information provided online by the therapist, completing assignments provided by the therapist
5	Module cognition and world view	Reading information, keeping a diary on goal progress, reading the information provided online by the therapist, completing assignments provided by the therapist
6	Module long-term goals	Reading information, keeping a diary on goal progress, reading the information provided online by the therapist, completing assignments provided by the therapist

Challenges

In Vitro and In Vivo Immunological Challenges

As an in vitro immunological challenge, heparinized whole blood samples were stimulated in vitro with lipopolysaccharide (LPS) to stimulate cytokine production at baseline (before the intervention), at the start of the vaccination day, and one day later at the start of the test day [23]. The process consisted of stimulating 1 mL of sodium-heparinized blood in BD Vacutainer blood collection tubes (BD, Franklin Lakes, NJ) with LPS (*Escherichia coli*, ultra-pure, Invivogen, Toulouse, France) at a final concentration of 100 ng/mL or as a control without LPS, and samples were incubated at 37 °C for 6 hours. Tubes were spun at 3400 rpm for 10 minutes, and plasma was collected and stored until testing at –80 °C.

In addition, in the week following the intervention (or similar time frame for the control arm), all participants were vaccinated with *Mycobacterium bovis* BCG, a live-attenuated vaccine used against tuberculosis. This vaccine was incorporated as an in vivo challenge to the immune system. BCG (Intervax, via RIVM, Bilthoven, The Netherlands) was administered by intradermal injection (0.1 mL) in the upper arm.

Psychophysiological Challenges

On the day post-vaccination, participants were exposed to 3 psychophysiological challenges in the following order: a modified version of the Paced Auditory Serial Addition Task [29], a Cold Pressor Test [30], and the Trier Social Stress Test [31]. All challenges are known to reliably induce psychophysiological stress responses [30-33]. More information regarding these challenges has been published previously [23].

Primary Endpoints

Self-Reported Vitality

The Subjective Vitality Scale (SVS) [34] and Checklist Individual Strength (CIS-20) [35,36] were used to measure self-reported vitality. The composite score of the SVS and CIS-20 was used as a primary endpoint in this study, to gather a rather complete view on vitality. This composite score was

determined by subtracting the standardized sum score of the CIS-20 from the standardized sum score of the SVS. Scores on the composite scale can be interpreted as higher scores representing higher self-reported vitality. The SVS and CIS-20 have been shown to be reliable and valid in previous research [37,38] and had good internal reliability in the present study (Cronbach α =.84 and .87, respectively).

Secondary Endpoints

Self-Reported Quality of Life

In addition, the RAND-36 was used to assess physical and mental health-related quality of life by determining sum scores of the subscales physical functioning and emotional wellbeing [39], which has been shown to be reliable and valid in previous literature [40]. Standardized T-scores were computed for both scales, with higher scores representing higher self-reported quality of life.

Self-Reported Bodily Sensations

Bodily sensations were measured with the Pennebaker Inventory of Limbic Languidness [41]. The Pennebaker Inventory of Limbic Languidness showed good internal reliability in the present study (Cronbach α =.89).

Self-Reported Sleep Problems

Sleep problems were assessed with 9 items of the Medical Outcomes Study Sleep Scale [42], which showed good internal reliability previously [42]. Higher scores on this scale represent lower levels of self-reported sleep problems. Although this questionnaire yielded sufficient internal reliability at follow-up (Cronbach α =.73), the internal reliability in the present study was low at baseline and after the intervention (Cronbach α =.45 and .36, respectively); therefore, the results of this scale in the present study should be interpreted with caution.

Self-Reported Wellbeing

Wellbeing was assessed using the 20-item Positive and Negative Affect Schedule [43] and a 7-item numeric rating scale (NRS) on wellbeing. The Positive and Negative Affect Schedule was subdivided into the positive affect scale and the negative affect

scale, which both showed good reliability and validity in previous literature [44] as well as good reliability in the present study (Cronbach $\alpha = .88$ and $.70$, respectively). On the NRS that was used to measure wellbeing, scores ranged from 0 (not at all) to 10 (very much). Higher scores on this questionnaire represent higher levels of self-reported wellbeing. The NRS showed good internal reliability in the present study (Cronbach $\alpha = .80$).

Psychophysiological Endpoints

Heart rate (HR), heart rate variability (HRV), and skin conductance were assessed continuously with a BIOPAC MP150 system (BIOPAC Systems Inc, Goleta, CA) using AcqKnowledge software version 4.1.1. Furthermore, HR, HRV, and skin conductance were measured at a resting state for 5 minutes at specific time points (see Table 1). Recording of the electrocardiogram signal was performed with an ECG100C module set at 1000Hz. The high pass filter was set at 0.05 Hz and the low pass filter at 35Hz. For HR, electrodes were attached at the sternum and somewhat below the left lower rib. To measure skin conductance, Ag/AgCl electrodes were attached at the medial phalanges of two fingers of the non-dominant hand (ie, the middle and index fingers). A GSR100C module was used to measure skin conductance, set at 1000 Hz. Gain was set at 5 $\mu\Omega/V$ and the low pass filter at 10 Hz. The Physio Data Toolbox Version 0.4 was used for visual inspection of the data as well as for calculating the mean HR, HRV, and skin conductance levels at each time point [45].

Saliva samples were collected to measure cortisol and alpha amylase. Samples were stored at -80°C until analyzed. Cortisol was assessed in saliva with a competitive electrochemiluminescence immunoassay using a Modular Analytics E602 immunoanalyzer (Roche Diagnostics, Mannheim, Germany). Cortisol activities were measured and expressed in nmol/L. Determination of salivary alpha amylase was performed using a kinetic colorimetric assay for total amylase activity (Cat Nr. 03183742, Roche Diagnostics, Mannheim, Germany) on a routine clinical chemistry analyzer. Amylase activity was measured and expressed in U/L.

Immune Endpoints

Blood samples were collected in cloth-activating tubes (BD Vacutainer) at baseline, after the intervention/pre-vaccination, post-vaccination, and at the 4-week follow-up. Samples were clotted for an hour at room temperature before centrifugation at 2500 rcf for 10 minutes, and serum was collected and aliquoted for storage at -80°C .

The list of cytokines and chemokines that were analyzed is specified in Multimedia Appendix 1. Cytokine and chemokine levels were measured in serum as well as in stimulated or control plasma samples using the multiplex bead array (Bio-Plex Pro Human Chemokine Panel, 40-Plex #171AK99MR2, Bio-Rad laboratories, Veenendaal, The Netherlands [46]). C-reactive protein concentrations were determined in serum by ELISA according to the instructions of the manufacturer (Abnova, Heidelberg, Germany) at baseline, at the start of the vaccination day, at the start of the test day, and at follow-up.

In addition, immunoglobulin G (IgG) antibody levels were evaluated at baseline and 4 weeks after vaccination. Purified protein derivative (5 $\mu\text{g/mL}$; Statens Serum Institute, Copenhagen, Denmark) was coated to 96 well Microlon plates (Greiner, Alphen aan den Rijn, The Netherlands). Sera were diluted 1 to 25 and incubated overnight. IgG antibody binding was detected using HRP-labelled polyclonal rabbit anti-human IgG (Dako, Glostrup, Denmark), staining with TMB substrate buffer (Sigma Aldrich, Zwijndrecht, The Netherlands), stopped with H_2SO_4 and OD450 reading [47].

Statistical Analyses

All analyses were performed using SPSS Statistics (version 25; IBM Corp, Armonk, NY). As described in our design paper [23], a total sample size of 60 participants was deemed sufficient to detect scientifically and clinically relevant differences in the incorporated primary endpoint. An analysis of covariance (ANCOVA) with condition (intervention vs control) as the between-subjects factor, vitality after the intervention as the dependent variable, and baseline vitality as the covariate was conducted to assess the primary hypothesis that participants in the intervention condition would show higher self-reported vitality after the intervention (pre-vaccination) compared with the control condition. In addition, when a significant effect was found in the ANCOVA, it was investigated whether the effects were also present at the other time points. This was done with repeated measures analysis of variance (ANOVA) with condition (intervention vs control) as the between-subjects factor and time (ie, baseline, after intervention/pre-vaccination, after vaccination, follow-up) as the within-subjects factor. For the repeated measures ANOVAs, we were specifically interested in the interaction effects between time and condition, as well as in the main effects of time, which are therefore specified in the Results section. To examine at which time point(s) groups differed on vitality, represented by a significant interaction effect between time and condition in the repeated measures ANOVA, Holm's corrected ANOVAs were performed to compare the intervention condition with the control condition at specific time intervals by calculating difference scores between baseline and each of the other time points. Since we did not observe substantial missing data or deviations from the actual timeline within participants, we decided to test the secondary endpoints in a similar way (repeated measures ANOVA) as for the primary endpoint instead of the preplanned multilevel analyses for the secondary endpoints [23]. The results for bodily sensations, quality of life, and sleep problems were analyzed as described at 3 time points (ie, baseline, after intervention/pre-vaccination, follow-up). As the items on these questionnaires were based on the experiences of the last 4 weeks, these questionnaires were not completed post-vaccination.

To test any group differences for wellbeing and positive and negative affect in response to the test day, repeated measures ANOVAs were performed for wellbeing and positive and negative affect with condition (intervention vs control) as the between-subjects factor and the 4 time points (ie, baseline, start of the test day, end of the test day, follow-up) as the within-subjects factor. Data on cortisol, alpha amylase, HR, HRV, and skin conductance were analyzed in a similar way.

For both serum and LPS whole blood stimulation assay, principal component analysis was performed to identify and subsequently exclude extreme outliers. Interleukin (IL)-6 and IL-8 were excluded from the LPS whole blood stimulation analysis. For each time point comparison, two types of linear models were fitted. The first was a linear multiple regression model using Δ -cytokine concentrations at different time points (ie, pg/mL at start of the test day – pre-vaccination, pg/mL at the end of the test day – pre-vaccination, and pg/mL at follow-up – baseline) as dependent variables to estimate the effect of the intervention as an independent variable on changes in cytokine concentrations while correcting for age. The second was a linear mixed model with a random intercept per subject to estimate the effect of time on cytokine levels in either the control or intervention group while correcting for age. Resulting *P* values were false discovery rate (FDR)–corrected to obtain *q* values. Data were mean-centered and scaled to standard deviation units for the generation of volcano plots. Finally, principal component analysis, fitting of multiple linear regression models and linear mixed models, and plotting of analysis results were performed using R version 3.5.0 with the following packages: ‘mixOmics’ [48], ‘lme4’ [49], ‘lmerTest’ [50], and ‘ggplot2’ [51].

Results

Sample Characteristics

Of the 84 participants assessed for eligibility, 14 participants did not meet the inclusion criteria (7 due to somatic morbidity,

5 due to psychological morbidity, and 2 due to practical planning issues). One participant dropped out of the study directly after the screening. Therefore, 69 participants were randomized to one of the two conditions in the present study (see Figure 1). Then, 3 participants dropped out of the study, 1 in the control condition and 2 in the intervention condition. Additionally, 1 participant did not start in the intervention condition after group allocation, due to time constraints. Due to global production problems of the BCG vaccine, 2 participants in the intervention condition and 2 participants in the control condition dropped out of the study after completion of the primary endpoint. Furthermore, 1 participant in the intervention condition dropped out of the study after completion of the intervention due to time constraints. This resulted in 31 participants in the control condition and 29 participants in the intervention condition that completed all visits. Analyses were performed for available data. No significant differences were found in age or BMI between the participants in the control and intervention conditions ($P>.05$). See Table 3 for an overview of the age, BMI, and baseline level of vitality of the participants.

Primary Endpoint

Vitality

No significant differences were found between the groups for self-reported vitality within 1 week after the intervention (pre-vaccination; $P=.43$). The descriptive results for vitality at all time points are displayed in Figure 2.

Figure 1. Flow diagram.

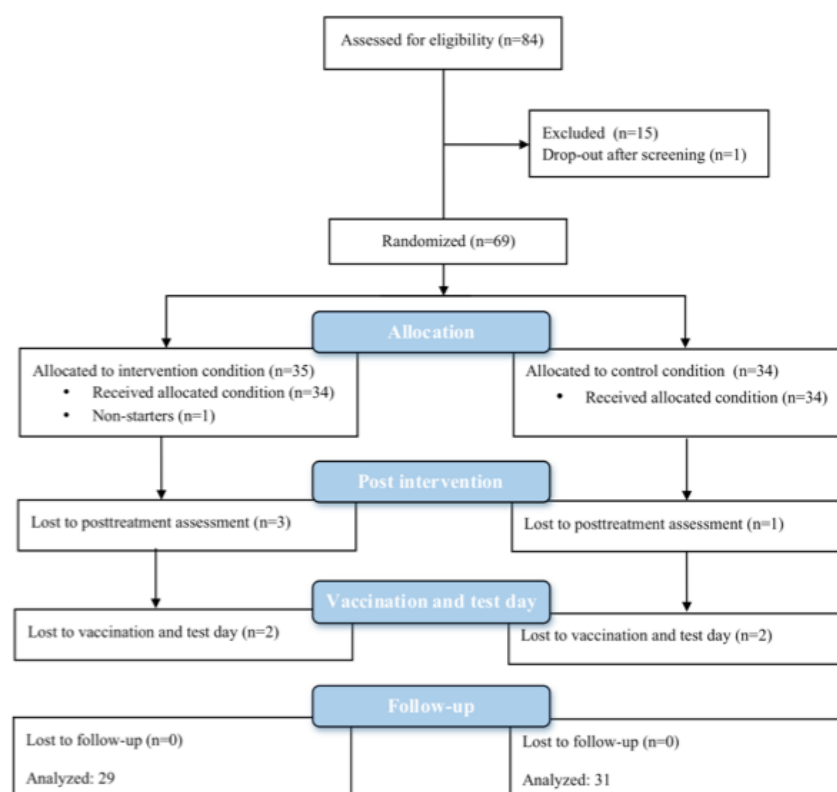

Table 3. Demographic characteristics for the control and intervention conditions.

Characteristics	Control condition	Intervention condition
Age (years), mean (SD)	22.9 (4.1)	22.5 (2.3)
BMI (kg/m ²), mean (SD)	23.0 (2.8)	22.5 (2.4)
Standardized vitality score, mean (SD)	0.05 (1.84)	-0.05 (1.66)

Figure 2. Mean and standard error of self-reported vitality at baseline, after intervention (pre-vaccination), after vaccination, and at follow-up, separately for the control condition and the intervention condition.

Secondary Endpoints

Self-Reported Quality of Life, Bodily Sensations, Sleep, Positive and Negative Affect, and Wellbeing

In [Multimedia Appendix 2](#), the results for quality of life for the physical (A) and mental (B) quality of life subscales are shown. Both ANCOVAs did not yield any significant group differences ($P=.92$, $P=.24$, respectively).

Figure 3 depicts the results for bodily sensations. The ANCOVA yielded a significant main effect for condition ($F_{1,62}=4.30$, $P=.042$, $n^2=.56$), indicating fewer bodily sensations for the intervention condition compared with the control condition directly after the intervention (pre-vaccination). The repeated measures ANOVA yielded a significant main effect of time ($F_{1,65,79,03}=7.30$, $P=.002$). Irrespective of condition, Holms corrected pairwise comparisons showed a significant decrease from baseline to after the intervention (pre-vaccination; $t_{64}=3.16$, adjusted $P=.004$), as well as a significant decrease from baseline to follow-up ($t_{49}=2.43$, adjusted $P=.019$). No significant interaction effect between time and condition was found ($P=.36$).

The results for sleep problems are presented in **Figure 4**. The ANCOVA showed a trend for an effect of the intervention ($F_{1,62}=3.30$, $P=.074$, $n^2=.44$). The repeated measures ANOVA did not yield a significant effect of time ($P=.18$) but showed a significant interaction between time and intervention ($F_{1,66,104,74}=4.02$, $P=.027$, $n^2=.06$). Holms corrected pairwise

comparisons showed a significant difference between the intervention condition and control condition from baseline to after the intervention (pre-vaccination; $F_{1,63}=4.60$, adjusted $P=.036$, $n^2=.07$), as well as from baseline to follow-up ($F_{1,63}=6.23$, adjusted $P=.030$, $n^2=.09$), indicating fewer sleep problems directly after the intervention (pre-vaccination) and also at follow-up for the intervention condition compared with the control condition.

The results for positive and negative affect are shown in [Multimedia Appendix 3A](#) and [Multimedia Appendix 3B](#), respectively. For positive affect, no significant interaction effect between time and condition was found, $P=.69$. Negative affect also yielded no significant interaction between time and condition, $P=.15$.

For wellbeing, the results are shown in **Figure 5**. The repeated measures ANOVA yielded a significant main effect of time ($F_{2,38,138,04}=18.97$, $P<.001$) and a significant interaction effect between time and intervention ($F_{2,38,138,04}=3.27$, $P=.033$, $n^2=.14$). Holms corrected pairwise comparisons showed a significant difference between the intervention condition and control condition from baseline to the end of the test day ($F_{1,58}=7.45$, adjusted $P=.024$, $n^2=.11$), indicating less of a decrease in self-reported wellbeing from baseline to the end of the test day for the intervention compared with the control condition.

Figure 3. Mean and standard error of the mean of self-reported bodily sensations at baseline, after intervention (pre-vaccination), and at follow-up, separately for the control condition and intervention condition.

Figure 4. Mean and standard error of the mean of sleep problems at baseline, after intervention (pre-vaccination), and at follow-up, separately for the control condition and the intervention condition.

Figure 5. Mean and standard error of the mean of self-reported wellbeing at baseline, the start of the test day, the end of the test day, and at follow-up, separately for the control condition and intervention condition.

Psychophysiological Endpoints

Multimedia Appendix 4 shows the descriptive statistics for HR, skin conductance, HRV, cortisol, and alpha amylase for the control and intervention groups. For cortisol, the repeated measures ANOVA yielded no significant interaction between time and condition ($P=.11$). Similar results were found for alpha amylase, as no significant interaction effect between time and condition was found ($P=.90$).

For HR, a significant main effect of time was found ($F_{2,40,132.24}=11.37$, $P<.001$). Irrespective of the conditions, Holms corrected pairwise comparisons showed a significant decrease from baseline to the end of the test day ($t_{56}=-3.78$, adjusted $P<.001$). A trend was found for an interaction effect between time and condition ($F_{2,40,132.24}=2.44$, $P=.081$), indicating a lower HR at follow-up in the intervention condition compared with the control condition. For HRV, a significant main effect of time was found ($F_{1,49,80.29}=4.74$, $P=.019$), which varied over time. Holms corrected pairwise comparisons indicated no significant differences over time. No significant interaction effect was found between time and condition ($P=.15$). For skin conductance, no significant main effect of time ($P=.46$)

nor an interaction effect between time and condition was found ($P=.26$).

Immune Endpoints

Figure 6 shows the volcano plots of significantly upregulated and downregulated serum analytes between pre-vaccination to the end of the test day. Negative values indicate analytes that are downregulated at the end of the test day compared with pre-vaccination, and positive values indicate upregulated analytes at the end of the test day compared to pre-vaccination. Analytes with an estimated effect <0.1 were not considered, since those estimates frequently represent very small changes in cytokine levels below the detection limits of variation in technical duplicates.

The multivariate linear regressions yielded no significant differences between the intervention and control groups at any time point. We therefore exploratively investigated the kinetic changes of the control and intervention conditions individually. Within the control or intervention group, significant changes over time were identified for unique sets of analytes. For the control condition, significant increases for various cytokines and chemokines (ie, IL-2, IL-10, chemokine [C-C motif] ligand [CCL]1, CCL17, CCL19, CCL23, CCL25, CCL26, chemokine [C-X-C motif] ligand [CXCL]2, CXCL6, CXCL13, CX3CL1,

granulocyte-macrophage colony-stimulating factor) as well as significant decreases in other chemokines (ie, CCL2, CCL15, CCL21, CCL27; all FDR-corrected $P < .05$) between pre-vaccination and end of the test day were found. For the intervention condition, significant increases were also found for various cytokines and chemokines from pre-vaccination to end of the test day (ie, IL-1 β , IL-2, IL-8, IL-10, IL-16, CCL1, CCL8, CCL11, CCL17, CCL19, CCL22, CCL23, CCL25, CCL26, CXCL1, CXCL2, CXCL5, CXCL6, CXCL9, CXCL11, CXCL13, macrophage migration inhibitory factor, tumor necrosis factor [TNF]- α) and a significant decrease in CCL15 (all FDR-corrected $P < .05$). The results for upregulated IL-8, CXCL5, and TNF- α as well as for downregulated CCL15 are shown in [Multimedia Appendix 5](#), as these analytes showed the most prominent group differences. Similar results were found from the start of the test day to the end of the test day. No significant differences were found from baseline to follow-up in the control condition, although the intervention condition showed significant increases in serum IL-10, CCL19, and CXCL9 concentrations as well as a significant decrease in CCL15 (all FDR-corrected $P < .05$).

The results for the IgG antibody levels are displayed in [Multimedia Appendix 6](#). The multivariate linear regressions yielded no significant differences between the intervention and control groups at any time point for IgG antibody levels. When looking at the within-group changes over time separately for the intervention and control conditions, no significant differences were found from baseline to follow-up in the control condition, whereas the intervention condition showed significant increases in purified protein derivative-specific IgG levels (FDR-corrected $P < .05$).

Serum C-reactive protein levels were not significantly different between groups (data not shown).

LPS stimulation of whole blood samples did not induce significant differences between the intervention and control groups (all FDR-corrected $P > .05$). In an explorative analysis, we investigated the intervention condition and control condition separately for the different time ranges. For the control condition from baseline to the test day, we found significant increases in IL-1 β and TNF- α (both FDR-corrected $P < .05$), whereas no significant differences were found for the intervention condition.

Figure 6. Volcano plots for the comparison between pre-vaccination to the end of the test day for the (A) control and (B) intervention conditions. Significance is displayed on the y axis, and estimate of variance is displayed on the x axis.

Discussion

Overview

The aim of the present study was to investigate the effects of an ICBT combined with a serious gaming intervention on optimizing self-reported psychophysiological and immunological endpoints in response to in vitro and in vivo immunological and psychophysiological challenges. No significant differences between the intervention and control conditions were found for self-reported vitality. The intervention group did show fewer bodily sensations and fewer sleep problems after the intervention. Furthermore, the intervention group had higher self-reported wellbeing after different psychophysiological stressors compared with the control group. No significant group differences were found for the psychophysiological and immunological endpoints, although some preliminary support was found for improved outcomes

on HR variables as well as increased IgG antibody responses at follow-up and differential chemokine endpoints at the end of the test day in the intervention compared with the control condition. The present study thus provides a first step towards unraveling the effectiveness of an electronic health psychological intervention combined with serious gaming elements on optimizing various self-reported psychophysiological and immunological health endpoints.

Primary Findings

Although the intervention condition showed improved self-reported vitality and the control condition did not, no significant group differences were found. Also, no significant group differences were found for quality of life; however, these scores were already rather high at baseline for both groups. We included a healthy population, which presumably already possessed a good quality of life that could not be maximized further by our psychological intervention. In contrast, bodily

sensations, including headache, itch, and other negative sensations, and sleep problems were significantly decreased after the intervention, compared with the control condition. This is in line with previous studies that showed that ICBT can decrease sleep problems and headache symptoms in patients with insomnia or chronic headache [52-55]. As bodily sensations and sleep problems affect general health outcomes [56,57], the intervention was effective in optimizing precursors of health. Due to the variations in the findings for bodily sensations, sleep problems, quality of life, and vitality, however, no conclusive view on the effectiveness of the intervention in improving self-reported health endpoints can be formulated. Furthermore, as the internal reliability of the Medical Outcomes Study Sleep Scale was insufficient in the present study, the outcomes on sleep should be interpreted with caution. However, possible health benefits may become especially clear when the system is challenged. The present study therefore also investigated the results of self-reported endpoints in response to in vitro and in vivo immunological as well as psychophysiological challenges. Although no significant differences were found between conditions in positive and negative affect, a higher self-reported wellbeing was found at the end of the test day for the intervention condition compared with the control condition. It is possible that the healthy population included here already possessed sufficient resilience and skills to handle the immunological and psychophysiological challenges. Future studies should therefore also include participants at risk for health problems, including participants with chronic somatic conditions or with (sub)clinical levels of anxiety or depression to see whether they may benefit from such a psychological intervention [58].

Secondary Findings

When specifically assessing the psychophysiological health endpoints (ie, HR, HRV, skin conductance, cortisol, and alpha amylase), preliminary evidence for improved endpoints after the intervention was found. Particularly, the intervention condition had a lower HR at follow-up as compared with the control condition. Although not significant, the results for HRV showed a similar pattern. As lower HR and higher HRV can be seen as biomarkers for better stress-related health outcomes [59-61], these data cautiously support the effectiveness of the psychological intervention on optimizing health. However, no significant effects were found for skin conductance, cortisol, and alpha amylase. The results therefore provide limited support for optimizing the response of the sympathetic-adrenal-medullary axis, but no support for influencing the hypothalamic-pituitary-adrenal axis, whereas the sympathetic-adrenal-medullary axis and hypothalamic-pituitary-adrenal axis are known to interact with each other in order to keep allostasis [62]. In addition, as no group differences were found on the test day for HR, HRV, cortisol, and alpha amylase, more research is needed on the external validity and clinical relevance of the present findings on psychophysiological health endpoints.

For the immune endpoints, the between-group analyses yielded no significant findings. The explorative analyses showed significant alterations in several cytokines and chemokines from baseline to follow-up in the intervention condition, whereas no

significant alterations were found in the control condition between these time points, providing some cautious support for higher responses for most analytes at the follow-up in the intervention condition. Previous literature on the effectiveness of psychological interventions on optimizing immune function have not yet focused specifically on cytokines and chemokines [6]. Cytokines and chemokines are known to have a significant influence on inflammatory processes, as they provide directional cues for the movement and tissue homing of leukocytes [63,64]. To make more conclusive statements on the effectiveness of psychological interventions in optimizing chemokine functioning, future research should incorporate a wide range of analytes with varying immunological characteristics into the study design, in order to replicate the present findings and to gather more insights in the mechanisms underlying differential immune responses after a psychological intervention.

Concerning the in vivo challenge (ie, the BCG vaccination), we found increased IgG antibody levels from baseline to follow-up for the intervention condition, whereas no such significant differences were observed in the control condition. This finding provides some preliminary support for an altered host response to the BCG vaccine after the intervention. This preliminary finding is in line with a previous study from Petrie et al [20] who found higher antibody levels in response to a hepatitis B vaccine in the intervention condition receiving an emotional disclosure intervention compared to a control condition receiving no intervention. In contrast to a hepatitis B vaccine, the BCG vaccine, being a live vaccine, actually is a human challenge model and as such approximates immune responses that are observed after natural infections [23]. Since antibody titers in the present study were not different in the between-group analyses, the findings need to be interpreted with caution. The present study was the first to incorporate BCG vaccination, and future studies incorporating BCG into the study design should provide further insights into the effects of training towards this infectious challenge.

When looking at the in vitro immunological challenge, the between-group analyses on LPS-stimulated cytokines and chemokines yielded no significant differences. In exploratory analyses, we found that IL-1 β , IL-8, CXCL5, and TNF- α were significantly increased from pre-vaccination to the start of the test day in the intervention but not in the control group. Furthermore, CCL2, CCL21, and CCL27 were significantly decreased from pre-vaccination to end of the test day only in the control group but not in the intervention group. Those findings suggest differential immune activation between the groups. However, the data do not support altered immune function following a psychological intervention in response to LPS as an in vitro immunological challenge. Moreover, LPS is a rather strong immune activator, possibly having masked subtle immunologic differences between the intervention and control groups.

Limitations

Despite the innovative features of the present study (ie, the combination of innovative intervention components directed at both automatic and conscious information processing and behavior change, multiple in vitro and in vivo immunological

and psychophysiological challenges, as well as the inclusion of a wide range of self-reported and psychophysiological endpoints), it has some limitations that should be mentioned. First, the present study population consisted of healthy men between 18 and 35 years of age. This represents a homogeneous healthy sample; however, future research should investigate whether the intervention might be (more) effective in other (at-risk) populations. Second, the present study design does not allow us to unravel the effectiveness of separate intervention components or separate challenges. Previously, preliminary support for the effectiveness of serious games on virtual food choice and implicit food preference was found [65]. Future research could further investigate the add-on effectiveness of serious games in optimizing engagement with the intervention and subsequent health endpoints by comparing ICBT with serious games versus ICBT alone. Moreover, future studies may investigate the effectiveness of serious games for adherence to the ICBT treatment. Third, although we tried to keep track of the time participants spent on the serious game by saving log files of the gaming activity, those log files were saved offline by participants themselves, and we did not receive log files from each participant, meaning that we could not verify whether they actually played the game 5 days a week. Although the therapist that guided the intervention tried to keep track of the gaming frequency by asking participants to report on their gaming activities in the online electronic health intervention, future studies should attempt to receive live tracking via online electronic records. Fourth, although we blinded the test leader to group allocation on the test day, the test leaders for the other measurement points were not blinded to group allocation. Although we do not have any indications that this has influenced our results, this cannot be excluded. Finally, although we asked participants not to use drugs and alcohol 48 hours before each

measurement and we checked this by verbally asking them whether they used alcohol or drugs, we cannot be entirely sure that participants did not violate these rules. As consumption of alcohol and drugs can alter cytokine responses [66], future research should include quantification of alcohol and drug consumption with objective tests.

Conclusion

In conclusion, although the present study did not find support for the optimization of vitality, it did find some support for the effectiveness of an ICBT combined with a serious gaming intervention in decreasing bodily sensations and sleep problems. Also, the present study showed that the intervention participants had higher levels of self-reported wellbeing in response to the psychophysiological challenges than control participants. Additionally, specific IgG antibody levels were increased at 4 weeks after BCG vaccination in the intervention condition. As this is one of the first studies incorporating multiple challenges to evaluate the effects of a psychological intervention on health endpoints, the present study provides a first step towards improving health endpoints with a psychological intervention, although clearly more research is needed on this topic. Future research should further investigate whether tailoring the intervention to specific populations, including patients with chronic somatic conditions or participants with (sub)clinical levels of stress or anxiety issues, enhances efficacy and impacts relevant disease-related parameters and biomarkers. Given the innovative study design, combining multiple new elements, future studies should consistently incorporate challenges and a wide range of immune parameters into the study design in order to get a more complete view on the effects of innovative psychological interventions.

Acknowledgments

The authors acknowledge Chantal Eckhardt, Dion de Hoog, Sander van den Oever, Shirley de Wit, and Rafael Bidarra of Delft University of Technology for their help in designing and developing the serious game ViaNova©. Abstract

Background: Diabetes and Alzheimer disease and related dementias (ADRD) are the seventh and sixth leading causes of death in the United States, respectively, and they coexist in many older adults. Caring for a loved one with both ADRD and diabetes is challenging and burdensome.

Objective: This study aims to explore diabetes-related topics in the Alzheimer's Association ALZConnected caregiver forum by family caregivers of persons living with ADRD.

Methods: User posts on the Alzheimer's Association ALZConnected caregiver forum were extracted. A total of 528 posts related to diabetes were included in the analysis. Of the users who generated the 528 posts, approximately 96.1% (275/286) were relatives of the care recipient with ADRD (eg, child, grandchild, spouse, sibling, or unspecified relative). Two researchers analyzed the data independently using thematic analysis. Any divergence was discussed among the research team, and an agreement was reached with a senior researcher's input as deemed necessary.

Results: Thematic analysis revealed 7 key themes. The results showed that comorbidities of ADRD were common topics of discussions among family caregivers. Diabetes management in ADRD challenged family caregivers. Family caregivers might neglect their own health care because of the caring burden, and they reported poor health outcomes and reduced quality of life. The online forum provided a platform for family caregivers to seek support in their attempts to learn more about how to manage the ADRD of their care recipients and seek support for managing their own lives as caregivers.

Conclusions: The ALZConnected forum provided a platform for caregivers to seek informational and emotional support for caring for persons living with ADRD and diabetes. The overwhelming burdens with these two health conditions were apparent for both caregivers and care recipients based on discussions from the online forum. Studies are urgently needed to provide practical guidelines and interventions for diabetes management in individuals with diabetes and ADRD. Future studies to explore delivering diabetes management interventions through online communities in caregivers and their care recipients with ADRD and diabetes are warranted.

KEYWORDS

diabetes; Alzheimer disease; dementia; caregivers

Introduction**Background**

Diabetes and Alzheimer disease and related dementias (ADRD) are the seventh and sixth leading causes of death in the United States, respectively, and they coexist in many older adults [1,2]. Both diseases are major public health concerns in today's aging world, and the combination of the two has further burdened individuals with the two diseases, their caregivers, and the society at large. As of 2019, 5.8 million Americans are estimated to live with Alzheimer dementia, and the population of people living with the disease is expected to triple by 2060 [3]. The total annual cost of managing and treating ADRD alone is estimated to be upward of US \$215 billion and is expected to increase to US \$500 billion by 2040 [3]. Likewise, diabetes affects roughly 30 million people in the United States as of 2015 and is expected to grow to affect approximately 55 million people between 2015 and 2030. Costs associated with the care and management of diabetes rose from US \$245 billion in 2012 to US \$327 billion in 2017 [2]. Together, the cost to care for persons with ADRD and diabetes comorbidity is higher than the cost to care for either disease alone. For example, the mean cost of diabetes care in persons with ADRD is approximately 3 times higher than the cost of diabetes care in those without ADRD [4].

A significant number of individuals living with ADRD have comorbid conditions, and diabetes is one of the most common comorbidities [5]. Increasing studies have documented that there is an association between ADRD and diabetes, and researchers have proposed that Alzheimer disease is *type 3 diabetes* because of the shared pathological mechanisms [6,7]. Moreover, the onset of diabetes may affect cognitive performance. For instance, higher levels of glycosylated hemoglobin and higher average blood glucose levels are correlated with poorer cognitive performance [8,9]. According to a longitudinal study, those who had type 2 diabetes at baseline demonstrated accelerated cognitive decline at 12-year follow-up [10]. Possible underlying mechanisms for this cognitive decline have been linked to insulin resistance, insulin-degrading enzyme, and so forth. Meanwhile, some studies suggest that there is a bidirectionality between the two diseases [11,12]. Previous studies have indicated that Alzheimer disease may affect the diabetic phenotype through behavioral changes, such as binge eating, or pathological changes, such as amyloid-beta deposition and tau protein phosphorylation [12].

Caring for Individuals With ADRD and Diabetes

Although the mechanisms connecting these two diseases are still largely unknown, the implications are important as ADRD can affect the self-management of diabetes and vice versa. Both ADRD and diabetes require a unique and sometimes extensive amount of care. The management of diabetes alone involves constant blood glucose monitoring, the discipline to adhere to dietary restrictions and physical activity guidelines, and proper antidiabetic medication use [13]. Poor glycemic control can

result in neuronal damage, increased ADRD incidence, and exaggerated cognitive function decline [12]. For those living with ADRD, the complexity of these regimens is often exacerbated by disease progression. Increased forgetfulness and confusion associated with the mid to late stages of dementia can result in improper meal choices or medication mismanagement [14]. This inability to participate in diabetes management as clinically instructed can result in harmful effects on the renal, cardiovascular, and peripheral nervous systems. As a result, people with ADRD may require assistance with the management of instrumental activities of daily living, such as diabetes management, from a caregiver.

Caring for persons with ADRD is often assumed by family members and close friends, with 83% of help to older adults in the United States being provided by these unpaid caregivers (referred to as family caregivers in this study) [1,15]. Recent estimates show that about 16 million family members and friends provided over 18 billion hours of unpaid care to people with ADRD at an average of 21.9 hours of care per week per caregiver [1]. This time spent caring for a loved one often comes at the expense of a caregiver's own needs, with some sacrificing vacations, hobbies, and quality time with other family members [16]. In addition, the burden of caregiving is shown to be higher in caregivers of people with ADRD as compared with caregivers of older adults without ADRD, and the impact of this can be both physical and emotional [1,17]. For example, 40% of these family ADRD caregivers suffer from depression, and 1 in 3 family caregivers reported worsening health since assuming caregiving responsibilities [1]. Moreover, it has been shown that ADRD caregiving is associated with elevated biomarkers correlating to cardiovascular disease risk and that hormones associated with stress can have negative effects on glucose metabolism [18,19]. However, a recent study that reviewed 89 papers concluded that despite personalized, continuity, and family-centered care being urgently needed when caring for people living with ADRD and diabetes, current health care systems cannot meet the caring needs [20]. Individuals with ADRD and their caregivers constantly struggle with managing diabetes and ADRD.

To mitigate the burden associated with caring for a loved one with ADRD, some caregivers turn to social media to discuss patient care and their personal struggles as they adjust to their everchanging responsibilities as caregivers. For those living with diabetes, social media allows for additional communication and discussion outside of the limited time allotted with their physicians while encouraging participation and engagement [21]. Whether being used for the discussion of personal health or to discuss the care of a loved one, social media connects caregivers not only to like-minded individuals but also to health information and tools that may have otherwise been unavailable to them [22]. ALZConnected [23], a free online forum run by the Alzheimer's Association in the United States, offers a range of forums for people with ADRD and their caregivers or friends and family members. For some, visiting this website means not

having to explain what living with Alzheimer means, and for others, it means no longer feeling alone [23].

Social Media Data

In this digital era, social media has provided platforms for users to seek health information, receive health interventions, and anonymously share thoughts and experiences that they may not feel confident or comfortable expressing in a real-world setting [24-27]. The increasing amount of user-generated information has become a valuable resource to guide health interventions and advance our knowledge of a variety of health conditions [28]. The data can be analyzed and built upon, allowing researchers to better understand user characteristics, social and information needs, and communication ecosystems as well as to serve the demographics being studied [29-32]. Such applications include, but are not limited to, the identification of individuals at risk for depression [33], the detection of drug-drug interactions or adverse side effects [34], the examination of health behaviors in various types of cancer survivors [35,36], and the investigation of the impact of social media on decision making and recovery in prostate cancer patients [37,38]. Whether the information gathered comes from well-known social media sites such as Facebook and Twitter or from more specific online support groups such as ALZConnected, the resulting analysis may provide much-needed insight to improve health outcomes in diverse groups [39-42]. However, despite the potential of media data to complement data from regulatory, clinical, administrative, and claims data sources, the utility and effectiveness of such data remain understudied in a variety of health conditions [43].

Study Objective

This study aimed to explore diabetes-related topics in the ALZConnected caregiver forums by family caregivers of persons living with ADRD.

Methods

Setting/Study Population

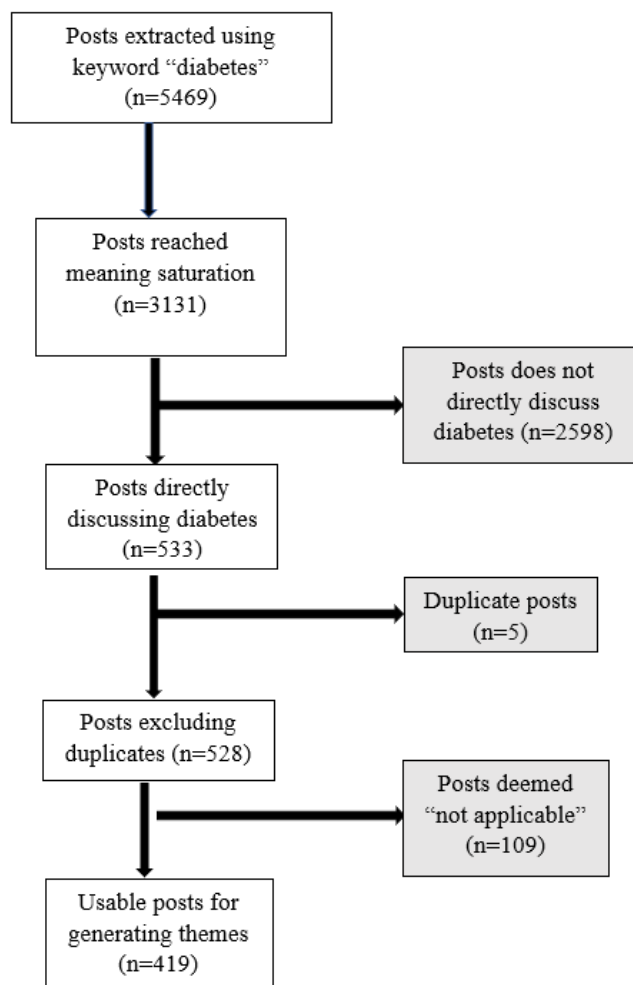

In this qualitative study, we collected and analyzed posts from users of the Alzheimer's Association ALZConnected caregiver's forum in the United States [41]. The forum is designed to

provide a community for ADRD caregivers and people with dementia alike. Caregivers, both professional and family, make up the majority of users in the forum and are often the spouse or child of the care recipient. Users must be registered in the ALZConnected community before they can post new threads or post in another user's thread. Users must also be registered to view a member user's profile. However, all posts can be viewed publicly without registering an account. The study was approved by the institutional review board of the University of Texas Health Science Center at San Antonio.

Data Collection

The earliest post in the forum was published on December 1, 2011. Posts were extracted from the forum backward in time via web scraping in January 2019. A total of 5469 user posts, posted from January 22, 2012, to January 3, 2019, were extracted using the keyword "diabetes." All extracted posts were imported into an Excel (Microsoft) file for analysis, with password protection. Due to the nature of the data and the study focus of diabetes in individuals living with ADRD in an ADRD forum, further selection of posts and preliminary data analysis were conducted simultaneously. Two trained research assistants independently reviewed posts from the beginning of the list. Codes, notes, and comments were made during this process. Saturation was reached, meaning no new ideas were presented [44], after reviewing 3131 posts. Of the 3131 posts reviewed, 2598 were excluded for not directly discussing diabetes, leaving 533 posts. An additional 5 duplicate posts were removed, leaving 528 posts for analysis. Upon further analysis and the application of codes, an additional 109 were deemed *not applicable* because of the use of diabetes for comparative purposes or without reference to a care recipient or caregiver. Posts coded as *not applicable* were excluded, leaving 419 posts included in generating themes. Figure 1 illustrates the selection scheme of the posts.

The study also obtained publicly available data on the relationship between the post generator and individuals living with ADRD, aggregately. When registering for an account in the forum, users are requested to identify their relationship with a person living with dementia (eg, the user is a person living with dementia, a type of relative, or a professional caregiver).

Figure 1. Flowchart of selection scheme of posts included in the study.

Data Analysis

"Thematic analysis is a method of identifying, analyzing, and reporting patterns (themes, topics, ideas) within a data" [45,46]. It has been widely used to identify themes or topics for web-based data (eg, blogs, web-based discussion boards, and tweets) [47-50] and data studying individuals living with ADRD [47,48,51]. Three trained research assistants analyzed the data using thematic analysis with the following steps [45,49,52]. First, data reduction and open coding were conducted during the preliminary analysis, and 2 coders developed a list of possible codes and definitions independently. The coding team and a senior qualitative scientist met to discuss and finalize the initial codes based on the feedback of all team members. Second, code validation was conducted by applying the initial codes to each of the 528 posts by 2 independent coders. Coders were instructed to code at the level of the post and were allowed to apply multiple codes to each post. Researchers coding overlapping sections of the dataset then came together in meetings to reconcile code differences in their respective analyses. They could discuss their reasoning for code applications. If in agreement, the 2 coders would combine code applications that served as the final analysis of the respective post being discussed. If the 2 coders were unable to reconcile code differences, the third coder provided insight allowing for a finalized analysis of the post. The initial codes from the first

step were refined during the second step, and 26 distinct codes were generated. During this process, 109 were deemed *not applicable*, leaving 419 posts for the next step. Third, following coding reconciliation, the coding team displayed all various codes in a table and categorized them according to similarities and differences. Consideration was given to the coding processes, categorization, and noting patterns, and they came to a consensus of the key themes identified from the forum.

The coding team used descriptive statistics to obtain basic counts regarding the use of each code as well as to compare the number of instances in which 2 codes appeared together within the same thread. In addition, publicly accessible data of a user's relationship with the individual living with ADRD were assessed aggregately using descriptive statistics.

Results

Caregiver-Patient Relationship

A total of 528 posts were generated by 286 unique users posting within 399 threads. Approximately 70% (200/286) of these users were the child of an individual with ADRD for whom they were caring for or concerned, whereas only 17.1% (49/286) of the users were spouses who were caring for a loved one with ADRD. Overall, the vast majority of these users (275/286, 96.1%) were related to the care recipient with ADRD in some

way, that is, a child, grandchild, spouse, sibling, or unspecified relative. In contrast, very few users were professional caregivers (6/286, 2.1%) or someone living with ADRD (3/286, 1.0%).

Themes

Thematic analysis revealed 7 key themes: (1) disease linkages and comorbidities, (2) ADRD or diabetes symptoms without

diagnosis, (3) diabetes management, (4) ADRD and diabetes complications and progress, (5) management strategies for ADRD and other comorbidities, (6) caregiver social support, and (7) caregiver health and self-care. Of these, the first 5 are predominantly focused on the individual living with ADRD and the last 2 focus on the caregiver. Table 1 shows the themes, codes, and code frequency.

Table 1. Themes, codes, and code frequency.

Themes and codes	Code frequency, n
Disease linkages and comorbidities	
ADRD ^a and diabetes comorbidity	267
ADRD and other comorbidities	123
ADRD and diabetes link	107
ADRD or diabetes symptoms without diagnosis	
Unconfirmed diagnosis of ADRD	46

^aADRD: Alzheimer disease and related dementias.

Disease Linkages and Comorbidities

This theme encompasses discussions on 2 or more diseases suffered by their care recipient. Within posts in this sample, it

was common for caregiver to provide context for their care recipient's situation by describing the health conditions of the care recipient. Posts falling under this theme either discussed

ADRD and diabetes, ADRD and another comorbidity, or the proposed link between ADRD and diabetes. Forum participants would often describe the kind of ADRD experienced by the care recipient. Given that this sample was focused on diabetes, many individuals with ADRD also had diabetes. If other comorbidities were discussed (eg, heart disease and stroke), it was extremely likely that individuals with ADRD also had diabetes in addition to other comorbidities:

My dad has congestive heart failure, has had 2 heart attacks, multiple TIAs, a stroke, stage 4 kidney disease, COPD, high blood pressure, diabetes, and after we moved them in with us four years ago was diagnosed with mild vascular dementia.

To a lesser degree but still important to the discussion of diseases related to ADRD and diabetes was the link between the 2 diseases. Frequently, this was discussed in terms of disease pathology and the common link of insulin resistance to both diseases. Users would speculate as to how strong the connection was between the 2 diseases and if one might lead to the other. Some users would also share links to articles to support their claims:

I myself find most compelling the connection between the top three listed and Alzheimer's type dementia: These include: insulin resistance, diabetes, and obesity; These three are very related anyway.

Here is a high level overview of the diabetes/Alzheimer's connection... Bottom line watch that sugar closely! This is a decades long thing. <https://tinyurl.com/y842evt8>.

ADRD or Diabetes Symptoms Without Diagnosis

Forum use was not limited to individuals with dementia and their caregivers. This theme encompasses discussions on a care recipient who had some symptoms of ADRD or diabetes but had not been formally diagnosed. Individuals questioning symptoms that a loved one was experiencing utilized the forum to ask users if the symptoms or behaviors could be a sign of ADRD. In some cases, a caregiver of an individual with a diagnosis of ADRD also questioned whether pre-existing conditions (eg, diabetes) might be the root cause of cognitive changes being displayed by a care recipient, rather than a diagnosis of ADRD. It was common for these forum participants to seek information about the process of diagnosis and how to work with their loved one to receive medical care:

Can anyone suggest a way to find a specialist who sincerely look at my mom's situation and make sure she is being correctly diagnosed with dementia. No one has really done the proper testing to rule out possible mimics and I have not gotten an exact diagnoses of the type. I have been to 2 neurologist and I feel they just do the verbal test and say she has dementia. What about b12 deficiencies or the fact that she is on blood pressure medicine.

Respondents to these forum participants, at times, provided a differential diagnosis based on the symptoms a user describes. Given the similar pathology of ADRD and diabetes (as well as

other diseases), it is possible that the symptoms a user described as possible dementia were diabetes:

With someone your dad's age, it is important to complete the testing because there are over 50 other illnesses that look like Alz but are not and most importantly of all, many of these illnesses can be reversed. Certainly mismanagement of diabetes can cause cognitive changes, even in young people.

Diabetes Management

Within this theme, caregivers discussed the challenges they face (eg, balancing diabetes management and quality of life) and shared some practical strategies they use when helping an individual living with ADRD to manage his or her diabetes. Overall, there were frequent discussions of diet and medications used to manage diabetes. Although some of these posts focused on individuals who had good management of diabetes, it was common for caregivers to question whether adherence to diabetes management practices was necessary for those with advanced ADRD. Caregivers expressed feelings that the overall quality of life was more important than strict adherence; however, they still maintained that diabetes management was important. Thus, caregivers commonly discussed how best to maintain a good quality of life for the care recipient, first and foremost, with a more relaxed approach to managing diabetes:

Mom, a type 2 diabetic, loves sweets...At some point in the last few months I decided that if having access to colas would give mom a 5 star day instead of a 3 star day and she should have the cola...I want to balance between having a good quality of life and a (somewhat) healthy life.

It was also frequent for forum respondents to discuss the lack of diabetes management and high or variable blood sugar readings, which an individual with ADRD might experience:

His blood sugar was over 1000! The hospital got it under control and recommended that he have his blood sugars checked four times a day and given oral medicine and injected insulin to control it. The problem is that he doesn't want to get up in the morning or the afternoon and he is refusing to eat frequently which he must do to take the insulin.

In contrast, very few caregivers discussed physical activity or exercise as a part of diabetes management for their care recipient. When they did, the discussion often centered around a concern for a lack of physical activity on the part of the care recipient:

I would like to ask for some advice on managing my father's repetitive behaviors. For example, he will sit idle for HOURS, sometimes ENTIRE days just staring off into space in the dark...My concern is the sitting idle for hours. He has diabetes, is in 3rd stage kidney failure, has poor circulation, and muscles that are getting VERY weak from being sedentary.

Given the complexity of managing diabetes in an ADRD care recipient, caregivers frequently discussed management strategies for their care recipients as well. For example, some caregivers

helped care recipients to manage their diabetes through a diet with inventive approaches such as halving juice with water, providing Meals on Wheels subscriptions, or slowly exchanging poor food choices with more healthy alternatives. Caregivers often noted that these changes had to be made slowly, as abrupt changes often resulted in resistance from their care recipients:

My mom would report cereal with OJ for breakfast...When I got over there, it turned out that was true, so I started a Meals on Wheels subscription for her and dad. One meal was diabetes health labelled with her name and one was heart healthy labeled with his name...With orange juice, what we did was save one of the empty containers of orange juice and then pour half into the empty container and dilute the OJ by half. Mom never noticed the difference.

However, some caregivers felt that a more direct approach better served their care recipients and, instead, opted to obtain the medical power of attorney or hire a home health professional to manage the care recipient's diabetes themselves. Whether their strategies were direct or indirect, caregivers frequently discussed practical ways to encourage or enforce adherence to diabetes management regimens through medication or diet:

Auditory memory is poor; she's repetitious and we are concerned about her continuing to live alone because she is an insulin dependent diabetic... I fill her pillbox and monitor it as much as possible, but I know that there are days when she doesn't take some of her pills...I have POA for healthcare and other POA is in the works.

ADRD and Diabetes Complications and Progress

This theme encompasses discussions on how an ADRD care recipient's resistance or forgetfulness complicates care management. Many caregivers came to the forum to discuss disease progress and disease complications in their care recipients. Often forum users discussed the changes in abilities or capacities that an individual living with ADRD experienced and how this complicated overall care. Many of these posts expressed a worsening of disease state, which ultimately led to a change in the caregiver's caregiving experience:

My mother has been having real issues with her memory for well over a year now. It has gotten progressively worse...We have been lengthening her visits over the past year to help her adjust to the idea of living with us.

When discussing complications and progress, some caregivers spoke about how resistance to diagnosis and forgetfulness affected the ability of the caregiver to provide appropriate care to care recipients for diabetes and ADRD, as it complicated how they provided care or how a care recipient responded to care:

I think my biggest concern about my mom continuing alone is the impact that her short term and auditory memory issues have on her medication management, more than anything else. My mom doesn't chart her blood sugars, never has. That's just who she is. If I

ask her if she ate or took insulin, she doesn't remember.

He has declined rapidly by his own choices not to follow the doctors orders from the very beginning. He won't monitor his blood sugars properly and rarely administers his insulin because he doesn't like the pricking of his finger or the pain of the shot. He eats whatever he wants and it consists entirely of carbs, high fats and sugar.

Although less frequent, some of the users described complications of diabetes as one of the many concerns that their care recipient was experiencing:

The consequences of untreated diabetes are not fun; things like blindness and amputations of toes, then feet, then below the knee...I am sure your LO [loved one] does not want those, and yet with dementia they cannot make rational choices based on future risk.

Management Strategies for ADRD and Other Comorbidities

Although this sample focused on diabetes, caregivers came to this forum, most importantly, to discuss ADRD. Within this theme, caregivers discussed how they helped an individual living with ADRD and with the management of comorbidities other than diabetes. As a result of the complexities caregivers experienced in caring for an individual with ADRD, caregivers frequently had questions or provided advice about how to navigate the housing, medical, legal, and day-to-day needs of their loved one:

After much discussion with my grandmother we have decided that my grandfather should be put in a nursing home. I unfortunately don't know a lick of anything related to senior care. I have been doing nonstop research and am so confused...I know some nursing homes take medicare but I am extremely weary.

It is time for you to step in and take control of the situation. You must protect her. I am hoping that you are already your mother's financial and medical POA. If not, you need to contact your family attorney. If your family doesn't have an attorney, then look for an eldercare attorney in your area.

A common management technique was using medication to help manage ADRD or other comorbidities that the individual with ADRD might be experiencing:

My mother was on Namenda 10mg once a day for two and a half years. I made the decision to stop the meds last June after many discussions (over time) with her PCP...My mom is currently taking Risperidone to manage anger and agitation and has been for two years. She also takes oral meds to manage Type II Diabetes and high blood pressure.

However, caregivers also had unconventional techniques to help them manage the complexities of multiple conditions for an individual living with ADRD. For example, some caregivers

would use a *fiblet* or a therapeutic lie to help a patient to adhere to a medical regimen, a diet change, or new living arrangements:

In the beginning we did tell mom and she was always shocked: "I have Alzheimers?!?!!" Now I just say her blood sugars levels are too high (she's diabetic) and once we can get control on them, she'll feel better. It's a lie, I know, but I don't see the point in continually telling her.

Occasionally, caregivers discussed the use of special diets, such as the Mediterranean diet, to prevent the worsening of ADRD. This was distinct from the use of diet to manage diabetes and blood glucose levels:

...The "grain brain" as a cause of dementia may be somewhat off because many grains also contain polyphenols that help protect against Alzheimer's disease such as ferulic acid in rice bran or flaxseed in some breads. That is why a Mediterranean diet relatively high in carbohydrates is partially protective against Alzheimer's disease.

Caregiver Social Support

A prominent theme within the forum was social support. Individuals frequently used the forum to seek support related to providing care or to provide support to other individuals in need of information or encouragement. Many users discussed the burden of taking care of a patient with ADRD and would use the forum to discuss frustrations or stress associated with caregiving as well as to seek support:

I struggle with the what if's even though everything says AD. Being her daughter, I want to throw her in the vehicle, drive her to the doctor and have them check her from head to toe everyday. But at what expense? Her dignity? Her comfort? I do everything I know to do and well...I just wish I guess...I feel like I'm rambling out of exhaustion.

Some users also provided emotional support to help encourage a user who was struggling:

I'm sorry to hear about what you are going through with your family. For myself, as someone on the outside looking in, the solutions seem easy, but it isn't.

In addition, users posed questions and gave advice that was strictly informational in nature. Some users provided guidance and suggestions derived from their personal experiences, and others provided links, articles, and phone numbers for resources that they believed would be valuable to the individual with the question:

To answer your main question - how do we convince our LO to do certain things that will help them? Well, that usually doesn't work because even if they are agreeable to the idea, their brains don't retain new information or learn new habits very well if at all. As far as my mom, for a long time we went back and forth with the idea of her living with me...mom had POA in order but had "capacity" (a psychiatrist evaluated her and found her able to make her own decisions) so I couldn't force anything.

I would like to invite you to contact the Helpline at the Alzheimer's Assn. which can be reached at: (800) 272-3900...Consultants are highly educated Social Workers who specialize in dementia and they can be wonderful support, provide education materials, have contact numbers for helpful community entities and who can assist with problem solving and more.

Caregiver Health and Self-Care

In contrast to social support, this theme was focused on discussions on caregivers' own physical and mental health and self-care. However, some caregivers did discuss having their own diagnosis of diabetes or another health concern:

Anxiety has now joined it, and Dad is now in the nh [nursing home]. But caring for Dad here at home for 12 years triggered it - along with hypertension and prediabetes. These are all stress related health issues.

In discussions of their own health outcomes, some caregivers discussed their inability to participate in self-care activities. This struggle to maintain a healthy lifestyle, whether physically or mentally, was often attributed to a lack of free time because of the sheer amount of time spent caregiving:

There are times, I am so exhausted that I just want to "drop dead". I am too tired of being tired...too tired to rest. But I keep moving forward.

I have no life at all, haven't seen friends in years, can't establish any new friends, can't set up any type of routine for my own enjoyment or benefit (school, hobbies, gym, martial arts) or work on my own life that I walked away from to take care of her and I am always exhausted these days.

In contrast, others were concerned about developing chronic diseases, such as dementia and diabetes, and participated in and promoted positive self-care behaviors to reduce their risk of developing diseases:

I say this as a caregiver who also has trouble taking care of myself sometimes, but life is forcing me to learn. In fact, right now, I need to get off the computer and get outside for some exercise, which is my daily medicine against encroaching diabetes, heart disease, and mental illness from all the stress.

My next health challenge is to NOT get dx with diabetes, so over the past few months I've stopped stress-eating chocolate foods, and have finally started exercising daily after the Mom-details, which took many months to sort out, are sorted.

Discussion

Principal Findings

This is, to the best of our knowledge, the first study to examine diabetes-related topics in individuals with ADRD from the perspectives of family caregivers participating in an online support community. Our findings advance knowledge regarding the role of social media in health management. The findings are consistent with previous findings that health forums provide support to forum users (eg, informational and emotional support)

[53,54] and offer platforms for users in communication of diseases in general, disease symptoms and treatments, and user opinions [55]. However, unlike other health forum users, most of whom are patients themselves [27,56], the ALZConnected forum was designed for caregivers. The study findings demonstrated how family caregivers used this online forum to obtain resources for informational and emotional support and to seek ways to relieve caregiving burden stress. As this study focused on diabetes-related topics, discussions of the analyzed posts were always related to (1) health conditions of care recipients, symptoms, and management of diabetes and ADRD; (2) the daily burden and struggles of diabetes management in individuals with both ADRD and diabetes, which might not be captured by traditional data collection; and (3) how constant caregiver burden and daily struggles affect their self-care and result in poorer physical and mental health in family caregivers.

Forum participants extensively discussed information related to the care recipients' health conditions with comorbidities, links between ADRD and comorbidities, and uncertainty of the root causes of some symptoms and behaviors. This may reflect the complex interactions of ADRD and its comorbidities [57] and the underlying causes of family caregivers' struggles. Older adults without dementia have 2 comorbidities on average, whereas those living with dementia have an average of 4 comorbidities, and almost 9 out of 10 individuals living with dementia have at least one comorbidity [58]. A scoping review found that little is known about the care of comorbidities for people living with dementia and comorbidities, especially from the perspectives of those with dementia and their family caregivers [59]. Our study further echoes and reinforces the importance of understanding the management of ADRD comorbidities, especially diabetes, from the experience of family caregivers. This line of discussion in the forum could serve as an outlet for forum users to relieve their frustrations and anxiety about the uncertainty of the disease progression in their care recipients living with multiple chronic comorbidities and how they can better care for their loved ones. Moreover, the information obtained from the forums by caregivers might also prove useful in supporting communication with their health providers, both for themselves and their care recipients.

Given the focus on diabetes in this study, we found that family caregivers commonly discussed challenges associated with diabetes management in their loved ones living with ADRD, regardless of type 1 or type 2 diabetes. For example, many challenges faced by caregivers centered on diet, exercise, and medication management in their care recipients. This is unsurprising, as diabetes is largely a self-managed disease that necessitates high-level cognitive capabilities for patients to properly adhere to medication and lifestyle regimens. However, memory loss, impaired problem-solving, and other ADRD symptoms make diabetes management extremely difficult for people living with ADRD and their family caregivers [14,60]. Previous recommendations and studies have suggested that for people with cognitive impairment, diabetes care should be individualized and patient-centered [60]. The glycemic target (eg, hemoglobin A_{1c}, fasting glucose, and postprandial glucose) should also be relaxed [14]. However, the incorporation of these recommendations into daily care regimens has rarely been

studied in individuals living with ADRD and diabetes. In fact, studies examining diabetes self-management often exclude individuals with cognitive impairment. In addition, despite the well-recognized importance of including family caregivers in the development of self-management plans for ADRD, few studies have evaluated structured interventions to provide education and support for family caregivers of ADRD [60], and even less studies have focused on diabetes management. Studies involving people living with ADRD and their family caregivers are urgently needed to address diabetes *self-management* in home settings for this population living with both ADRD and diabetes.

For challenges of diabetes management, the findings also highlight the difficulties caregivers face when trying to balance quality of life and diabetes control in their ADRD care recipients. Much of this is associated with the responsibility of providing proper health care to their loved ones that caregivers feel while still making sure their loved one's overall quality of life is high. Regardless of a caregiver's best efforts, uncontrolled blood glucose levels and subsequent hospital admission were often discussed by family caregivers. Balancing glycemic control and quality of life in ADRD care recipients warrants further exploration. Despite how challenges were frequently discussed, in the forum, some personal practical strategies for diabetes management were also shared. For example, some caregivers helped care recipients manage their diabetes through gradual diet changes or with the use of inventive approaches, such as halving juice with water. Whether the shared strategies were direct or indirect, caregivers frequently discussed practical ways by which they encouraged and enforced adherence to diabetes management regimens, whether through medication or diet. The various strategies shared may serve as examples for forum users looking to tailor the approaches to their own loved ones and situations. In addition, these suggestions might provide helpful information and examples for developing diabetes management guidelines for people living with ADRD and their family caregivers. This further reinforces the importance of involving caregivers and their loved ones in studies of developing diabetes management guides.

Our study revealed that forum users, who take care of individuals with ADRD and diabetes, frequently reported increased distress and neglect of self-care, both of which may contribute to a decrease in health status and quality of life for both the care recipient and family caregivers [61]. Previous studies reported that the time spent on daily activities and supervision by caregivers was higher when caring for individuals with ADRD and diabetes compared with caring for those with ADRD without diabetes [62]. Consequently, the level of the caregiver's perceived burden increases [63-66]. ALZConnected has provided a platform for family caregivers to seek information and emotional support in their attempts to learn more about how to manage ADRD of their care recipients and seek support for how to manage their own health and well-being as a caregiver. The study findings of challenges and struggles that caregivers constantly face have implications not just on their care recipients but also on their own health and well-being. We call for more practical diabetes management guidelines for individuals living with ADRD and their caregivers to ease the

burden of caregivers and improve the health and quality of life for both.

Limitations

This study has several limitations. First, the study used publicly available forum data, and as a result, the data collection process was out of the control of the study team. However, this could also be considered a strength as there was no interference with participants' opinions, meaning the posts reviewed truly reflect the caregivers' struggles and concerns. Second, the posts extracted for this study only represent a portion of posts made in the forum and may not be applicable to all discussions regarding diabetes. However, our analysis did reach saturation, which might minimize this limitation. Third, we attempted to explore discussion topics related to diabetes in this forum and used thematic analysis to analyze the data [67]. Thus, there is no theoretical framework to support this study. Fourth, this study only used data from one social media platform, and the discussions in the forum are largely user-driven. In the future, using multiple social media data sources may further extend our knowledge of the study topic. Finally, a majority of the posts included in this study were from adult children of ADRD care recipients, which might reflect their proportion of family

care or that younger persons are more likely to use social media/online forums. As a result, the generalizability of the results to all family caregivers might be limited.

Conclusions

In summary, the overwhelming burdens of diabetes management in individuals living with ADRD and diabetes were apparent for both caregivers and care recipients based on discussions from the ALZConnected forum. Research involving both care recipients and their caregivers in developing diabetes management guidelines and interventions for family caregivers of individuals with diabetes and ADRD would be important. In addition, the ALZConnected forum provided a platform for caregivers to seek informational and emotional support for caring for persons living with ADRD and diabetes. Studies are urgently needed to provide practical guidelines or tools available in online support communities as new ways to support daily diabetes management for individuals living with ADRD coexisting with diabetes and their caregivers. Future studies to explore delivering diabetes management interventions through online communities in caregivers and their care recipients with ADRD and diabetes are warranted.

Acknowledgments

The authors would like to thank the study participants who shared their data on ALZConnected. The study was supported by the Center on Smart and Connected Health Technologies at the University of Texas Health Science Center at San Antonio. YD is supported by the National Center for Advancing Translational Sciences, National Institutes of Health, through grant TL1 TR002647.

Authors' Contributions

YD, JW, KP, CW, SM, and SS designed the study. CL extracted and cleaned the data. YD, KP, AC, SK, and JW analyzed the data. YD, KP, AC, SK, JW, CW, SM, and SS reviewed the results. YD, KP, AC, and KL wrote the manuscript. All authors reviewed, edited, and approved the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: With the pervasiveness of social media, online health communities (OHCs) are an important tool for facilitating information sharing and support among people with chronic health conditions. Importantly, OHCs offer insight into conversations about the lived experiences of people with particular health conditions. Little is known about the aspects of OHCs that are important to maintain safe and productive conversations that support health.

Objective: This study aimed to assess the provision of social support and the role of active moderation in OHCs developed in accordance with and managed by an adaptive engagement model. This study also aimed to identify key elements of the model that are central to the development, maintenance, and adaptation of OHCs for people with chronic health conditions.

Methods: This study used combined content analysis, a mixed methods approach, to analyze sampled Facebook post comments from 6 OHCs to understand how key aspects of the adaptive engagement model facilitate different types of social support. OHCs included in this study are for people living with multiple sclerosis, migraine, irritable bowel syndrome, rheumatoid arthritis, lung cancer, and prostate cancer. An exploratory approach was used in the analysis, and initial codes were grouped into thematic categories and then confirmed through thematic network analysis using the Dedoose qualitative analysis software tool. Thematic categories were compared for similarities and differences for each of the 6 OHCs and by topic discussed.

Results: Data on the reach and engagement of the Facebook posts and the analysis of the sample of 5881 comments demonstrate that people with chronic health conditions want to engage on the web and find value in supporting and sharing their experiences with others. Most comments made in these Facebook posts were expressions of social support for others living with the same health condition (3405/5881, 57.89%). Among the comments with an element of support, those where community members validated the knowledge or experiences of others were most frequent (1587/3405, 46.61%), followed by the expression of empathy and understanding (1089/3405, 31.98%). Even among posts with more factual content, such as insurance coverage issues, user comments still had frequent expressions of support for others (80/213, 37.5%).

Conclusions: The analysis of this OHC adaptive engagement model in action shows that the foundational elements—social support, engagement, and moderation—can effectively be used to provide a rich and dynamic community experience for individuals with chronic health conditions. Social support is demonstrated in a variety of ways, including sharing information or validating information shared by others, expressions of empathy, and sharing encouraging statements with others.

Introduction

Overview of the Role of Social Support in Health

Social relationships and social support are purported to promote good physical and mental health for people living with a variety of chronic medical conditions [1-3]. Social support can be defined as “verbal and nonverbal communication between recipients and providers that reduces uncertainty about the situation, the self, the other, or the relationship, and functions to enhance a perception of personal control in one’s experience” [4].

Social relationships and social support can be beneficial to health in many ways. Numerous studies have examined the connection between an individual’s social relationships or networks and their physical health. Research demonstrates that, compared with individuals who are isolated, those who have a social network live longer, experience fewer physical symptoms of illness, and specifically have lower blood pressure [2,5,6]. Poor-quality or low-quality social ties have been associated with the development and progression of certain conditions, including high blood pressure, cancer, cardiovascular disease, autonomic dysregulation, and mortality [2,5,6].

Previous research has also shown an increased likelihood of survival in people who have stronger social ties or social relationships compared with those who have weaker ties or relationships [7]. A review of 81 studies revealed that social support was reliably related to beneficial effects on cardiovascular, endocrine, and immune health [8]. Additionally, social support is associated with increased health-promoting behaviors such as medication adherence [9,10], smoking cessation [11], and weight loss [12,13]. One study in particular showed that providing support was also related to lower measures of systolic and diastolic blood pressure among those who gave support [14].

Use of the Internet and Social Media for Social Support for Health

The use of the internet has changed how patients, caregivers, friends, family members, and interested citizen-scientists learn about and seek support for specific health conditions. In the United States, 61% of adults search on the web and 39% use social media to find health information [15]. Additionally, 1 in 4 internet users with a chronic illness has gone on the web to find others with similar health problems [16]. It is clear that patients rely on web-based resources, particularly when encountering specific situations, and being diagnosed with a chronic health condition is one such situation.

In a web-based *Health Information Experiences* survey of >2200 patients across 7 health conditions, the authors found that people used web-based resources at some points along their health care journey [17]. For example, 67% of the people used web-based resources when starting a new medication or treatment, 67% when experiencing a new side effect or symptom, 61% when making a medication treatment decision or change, and 57%

when needing emotional support [17]. In the same survey, patients were asked about the web-based resources they used; 71% used condition-specific websites and 65% used Facebook for health information and support [17].

Diverse population groups across different races, ethnicities, and education levels access health-related information using social media [18,19]. Social media platforms, such as Facebook, can facilitate dialogue between patients as well as between patients and providers [18].

Using a definition similar to that found in other recent research, online communities are defined in this study as the use of an internet-based platform with the purpose of bringing together a group of individuals with a shared interest or goal [20]. As online communities are hosted on the internet, the geographic location of the member is not a vital component of *membership* in the community or how the community functions. Online support groups and communities have been in existence since the 1990s in various forms. The more recent development of online communities focused on health has been especially beneficial for those living with or caring for someone with a chronic health condition [20,21].

Online health communities (OHCs) are internet-based platforms that allow people to connect over shared experiences and communicate about health [20-22]. OHCs are disrupting traditional hierarchies in the health care industry by offering what traditional health care cannot offer—conversations about the lived experiences of people with particular health conditions. Individuals living with specific health conditions and their caregivers or care partners can browse and search on the web. They can also control the content and flow of information available to them, and, in the case of social media, produce content, rather than just receiving information directly from a health professional in a face-to-face encounter [23]. Although there is criticism surrounding the role of technology in increasing rates of loneliness and social isolation in adults, many view social media as a means to connect with others [24,25].

There are different types of OHCs, both open and closed, with the early versions offering *bulletin board*-style forums where individuals could ask questions and receive responses from other participants. In a closed OHC, a prospective member must opt in to join and be accepted by the site administrators to access site resources and engage with other members, whereas open communities are accessible to all people without having to sign in or provide contact information [20]. Over time, OHCs have evolved to allow for more robust offerings in the ways in which community members can engage through the platform as well as with other community members. OHCs are now more complex ecosystems, capable of being programmed to be better able to adapt and respond to changes in health care and patient experience.

The Value of Online Communities for Health Promotion

A vital aspect of using OHCs and social media as avenues for health communication is that they can provide valuable peer, social, and emotional support [18,26]. In studies on online communities, 4 types of social support are demonstrated: informational support [27], emotional support [28], instrumental support [29], and appraisal support [28].

An additional type of support that can be garnered by participation in an online community is network support, which is the feeling of being part of a group that shares common interests, which in turn can widen an individual's social network [29].

Web-based communication and interaction have been shown to provide meaningful support to people seeking health information. This is the case, whether that support is more transactional and provides information support that may help an individual obtain a desired service or make a decision or emotional support where the individual receives validation of their feelings or experiences [30]. Previous research has demonstrated that social support is important for an array of health outcomes and can be provided in various ways. There is evidence that social support can flourish when provided specifically through a web-based environment and can even empower individuals [27,31,32].

Social media offers additional space for dialogue around health information and experiences. Although many individuals find comfort in openly sharing aspects of their health experiences on the web, other people are more passive in how they participate in online communities. Research has identified 2 main types of participation in online communities: active participation, which includes posting and sharing, and passive participation, defined as browsing and reading [33]. Whether participants in an online community are more active or passive, both groups can find the level of support they are seeking [34].

Social support through a web-based medium can offer similar depth, breadth, and level of intimacy that occurs in private offline conversations [21,35]. Face-to-face social support may not always be available or may be difficult for people who have a chronic health condition or are disabled; therefore, OHCs can provide the vehicle through which ongoing and regular interaction is available [29].

However, the effects of web-based social support on chronic disease management are less clear from the available literature [26]. Research examining online cancer support groups found that participants in these groups had decreased levels of depression as well as decreased reactions to pain [36]. Previous research has also examined perceived empathy as a key factor in patient health outcomes [37]. Recent research has shown that users of an online diabetes management community have higher levels of diabetes self-care and health-related quality of life [38]. Despite the value of online communities for engaging people in a variety of health issues, research on the use of social media platforms, such as Facebook, to help people manage chronic health conditions is in its relative infancy [39].

Purpose of This Study

This study aimed to assess the provision of social support and the role of moderation in OHCs developed in accordance with and managed by the adaptive engagement model described herein and created by Health Union. Health Union cultivates OHCs that are designed to have a positive impact on the lives of people living with chronic conditions by providing the information and support they are seeking. Health Union currently has 27 active condition-specific OHCs and corresponding Facebook pages that serve to extend the reach of the adaptive engagement model.

In this study, the authors, who also serve as OHC community managers, first demonstrate how the adaptive engagement model works to maintain safe web-based spaces for the provision of social support for people with chronic health conditions. In the study model, moderation includes responding to comments; thanking and welcoming comments; providing validation; linking to resources; and maintaining a respectful, inclusive tone. In this paper, the authors elucidate key elements of the model that are central to the development, maintenance, and adaptation of OHCs for people with chronic health conditions. For this study, the model was adapted using the principles of sharing content and supporting engagement on dedicated public Facebook pages to demonstrate the utility of the OHC model.

The Health Union OHC model encourages people to take an active role in their health by providing content that aligns with their needs and interests and by cultivating a safe environment where communication, understanding, and meaningful relationships can thrive. This original content can be accessed on condition-specific websites and their corresponding social media pages. In this study, we refer to this model as the "Health Union Online Health Community Adaptive Engagement Model," and in previous publications have referred to this as the "meeting people where they are at" model [40].

The OHC adaptive engagement model is developed with the belief that OHCs can be defined and have discernible features. First, similar to in-person communities, OHCs are situational, contextual, and involve a community of choice. There are 3 structural elements of the OHC adaptive engagement model: social support, adaptive engagement, and active moderation. Some features of OHCs can be categorized into more than one of the structural elements as there is often an overlap. These features include the following:

1. **Social identity:** OHCs, by definition, are for people with a health condition, caregivers, or others who have an interest in the health condition. People who live with a given chronic health condition may choose to identify as a person living with the condition or not, but regardless, being part of an OHC confers a social identity.
2. **Social relationships:** Relationships with others in OHCs are social relationships. This means they are imbued with a range of characteristics, including reciprocity, mutual support, and emotional connection, with the potential for shared meaning and conflict [41].
3. **Interdependence:** Being part of a social group means that there is a connection or relationship with others. A relationship entails interdependence in terms of

communication, expectations, behaviors, and other aspects of the relationship [41].

4. Experience of societal stigma: Chronic health conditions, because of their very definition as a state of ill health and the fear of contagion that underlies notions of illness in our society, bear a level of social stigma. Some health conditions bear more stigma than others, and individuals living with these health conditions may feel highly stigmatized if there are visible markers of their health condition or when their diagnosis is known to others [42,43]. The experience of stigma and people sharing how they confront or cope with it is an important aspect of community bonding.
5. Boundary marking: The community is defined by the diagnosis or experience of a health condition. Although there are usually clear definitions and an understanding of who is “living with the health condition,” these are based on self-disclosure. In addition, these boundaries are porous and let in new members [44].
6. Social norms: Norms that define interactions of the larger society are represented within OHCs. Often, these social norms are communicated in the form of “community rules,” and OHC participants may need reminders of the rules from time to time. There may be formal (warning and banning from the group) and informal (encouragement to use respectful language) sanctions for those who violate these community rules.

Methods

Overview of Methods

The Health Union OHC adaptive engagement model was developed to connect people with information that meets their health needs and as a means of providing social support [32,45]. This model includes a paid community management team encompassing dedicated community leads as well as peer moderators and content contributors who are living with a chronic health condition, caregivers, or health care professionals. Community managers also serve as moderators and may contribute to content [46].

OHCs included in this study are Health Union online communities created for people living with multiple sclerosis, migraine, irritable bowel syndrome, rheumatoid arthritis, lung cancer, and prostate cancer. Each OHC has a website with a

dedicated URL and corresponding linked social media channels, including a condition-specific public Facebook page. These OHCs were launched in the following order: Migraine, December 2010 [47]; Multiple Sclerosis, March 2013 [48]; Rheumatoid Arthritis, July 2013 [49]; Irritable Bowel Syndrome, June 2016 [50]; Lung Cancer, January 2017 [51]; and Prostate Cancer, December 2017 [52].

Original content is published on each of the community websites daily and is shared via the corresponding social media pages, including Facebook. All Facebook posts include a link to the original article that was first published on the corresponding community website. These Facebook posts include a customized clickable image with a short engaging message (approximately 80 characters, hereafter referred to as Facebook post copy) that links to an article published on the condition-specific community website. For this study, comments on Facebook posts were the primary unit of analysis. Any comments that were made directly on the condition-specific websites were excluded from this analysis.

Facebook analytics data were used to determine the reach and engagement of the 6 OHCs. The mixed methods combined content analysis (CCA) [53] was used to analyze the comments on 39 sampled Facebook posts from the 6 OHCs identified above to identify themes that aided the authors in illustrating how key aspects of the adaptive engagement model facilitate the different types of social support and other constructs of the model. Additionally, this analysis examined how the adaptive nature of this model can be used to support people regardless of their chronic health condition.

Facebook Reach and Engagement Data

Reach and engagement data were calculated using Facebook’s analytic tool, Facebook Insights. In this study, the authors used the Facebook definition of engagement as users reacting to (ie, clicking a reaction button such as “like”), sharing, commenting, or clicking on any posted content; in this case, a link to an original article on the corresponding community website. Reach refers to the number of people who saw the Facebook post, image, and short copy either in their newsfeed or by directly visiting the Facebook page. The reported gender and age cohort of those who reached and engaged were also collected. Weekly averages of reach and engagement were calculated for posts spanning the period from January 1 to June 30, 2018 (Table 1).

Table 1. Average weekly organic reach and engaged users per Facebook community (Facebook insights data from RheumatoidArthritis.net, ProstateCancer.net, MultipleSclerosis.net, Migraine.com, LungCancer.net, IrritableBowelSyndrome.net Pages, January 1 to June 30, 2018).

Facebook insights data	Rheumatoid arthritis	Prostate cancer	Multiple sclerosis	Migraine	Lung cancer	Irritable bowel syndrome
Weekly reach ^a (unique users), n	104,874	6617	160,906	161,958	9328	11,692

^aFacebook Insights data, average weekly organic reach (unique users).

^bFacebook Insights data, average weekly engaged users as the proportion of weekly organic reach.

^cGender and age for Facebook-defined engaged users; data reported from user profiles.

^dFacebook Insights data; total number of followers as of June 30, 2018.

Sampling and Data Collection

A diverse range of Facebook posts linking to original content from the 6 OHCs was purposefully sampled, resulting in a sample of 39 Facebook posts and their respective comment threads for a total sample of 5881 comments. Each selected post received comments from community members on Facebook. The content of the posts and comments included a broad range of topics, including impact on relationships, coping, quality of life, and treatment experience, all of which comprise the patient journey for people with a chronic health condition.

Using the principles of CCA, it is important to distinguish between the sampling unit, contextual unit, and coding unit as part of the methodology and the resultant analysis [53]. In this study, the Facebook posts with their corresponding extracted comments are the *sampling units*; the Facebook post copy along with the linked article, comments, and/or comment threads are the *contextual units*; and a sentence or phrase within an individual comment (as comments can range from a single word or phrase to a paragraph) are the *coding units*.

A purposeful sampling of the original articles and corresponding Facebook posts was drawn based on the following criteria: a range of content reflecting shared experience and sense of belonging of community members, stigma, and other challenges of living with a chronic health condition. An additional selection criterion for purposeful sampling was that the post needed to have a minimum of 20 comments to be included in the sample.

The Facebook posts that were analyzed for this study (Multimedia Appendix 1) [54-92] were originally posted on one of the OHCs' Facebook pages between February 11, 2017, and June 5, 2018. The comments from these Facebook posts

were extracted into a spreadsheet and imported into a qualitative and mixed method research data web application, Dedoose (Version 8.0.35; SocioCultural Research Consultants, LLC) [93]. Comment transcripts were labeled by community website and Facebook post ID (eg, PC 6 is used to label a specific Facebook post about PC on a specific date/time and all comments associated with that post). A total sample of 5881 comments were distributed as follows: PC, 1576; RA, 1417; migraine, 876; LC, 735; MS, 701; and IBS, 576.

Combined Content Analysis of Facebook Comments

CCA is a mixed methods approach used to analyze data from social media platforms [53]. This approach allows for the combination of qualitative and quantitative methods, inductive and deductive coding procedures, and manual and automated analytic modes [53]. As stated above, the authors used CCA as a methodological approach for deriving and analyzing a sample of Facebook post comments.

Virtual ethnography methods were used to develop a coding schema using an iterative deductive process [94]. As the authors serve as community managers and moderators, they are immersed in these communities on a day-to-day basis and have the ability to understand and tease apart some nuances in these conversations.

The analysis was carried out in 3 stages. In the first stage, the authors used a randomly selected subset of the sampled comments to identify initial thematic codes using content analysis. Using a concept-mapping process aided by Dedoose, the authors developed a conceptual framework to organize and further analyze the data to achieve theoretical saturation of themes rather than generalizability.

These initial coding samples were each tested by pairing the authors to confirm the interrater reliability (IRR) of the coding schema. The IRR of initial coding was calculated using Pearson correlation coefficient, and coding testing was repeated until the IRR achieved 90% agreement.

The second stage consisted of an in-depth review of these codes by the team, combining and collapsing codes when appropriate and developing the final coding schema with examples to generate the full codebook (Multimedia Appendix 2).

In the final round of coding, the full sample of Facebook post comments was coded by the authors, and an analytical set of thematic categories was identified throughout the full data set using Dedoose. As stated above, comments can be of variable length, from a phrase to several sentences. Code applications to a comment were not mutually exclusive (eg, a given comment could have multiple codes applied). The final set of codes was then juxtaposed against the thematic categories in the analysis to determine their relationship with the structural elements of the OHC model.

The qualitative analysis of the coded comments and patterns of code distributions were used to identify thematic categories that were further compared for similarity and differences across each of the 6 OHCs and by content descriptive category (eg, a comment about symptoms or treatment).

Results

Facebook Reach and Engagement

Facebook Insights data, which show the average organic reach (unique users) and engaged users per week for each of these OHCs, is presented in Table 1. Overall, the 6 OHCs reached an average of 455,375 people per week and engaged approximately 6% to 9% of them, which is considered a high level of engagement on a Facebook post [95]. Individual OHCs reached a range of users: from 6617 people in the PC OHC to 161,958 in the migraine OHC. The gender and age cohort of engaged users, as self-reported in individual user Facebook profiles, is presented to show the demographics of the participants. Except for the PC OHC, females made up a large majority of OHC users.

Facebook Post Comments and Model Elements

Qualitative thematic network analysis of comments from the OHCs corresponds to the structural elements of the Health Union OHC adaptive engagement model—social support, adaptive engagement, and active moderation. Examples of comments

that typify each of the structural elements of the model as well as the frequency with which each theme occurred in the comments are presented in Table 2. Overall, the majority (3405/5881, 57.89%) of the comments included one or more codes that represent an element of social support. In addition, almost one-third (1758/5881, 29.89%) of the comments included codes that represent adaptive engagement, and 12.21% (718/5881) reflected an element of active moderation.

Social support was demonstrated in a variety of ways, including giving advice, providing encouragement, and expressing empathy. Sharing knowledge and experience is one such manner of conveying support, with one commenter stating, “There’s many days when these posts remind me I’m not the only one having to deal with these same issues.” This is especially important as people suffering from chronic illness often feel that there are few people who truly understand what they are going through. For example, the previous commenter went on to post:

I constantly get looks and attitudes of ‘you look too young to be so sick, you don’t look sick.’ Even from naïve Dr’s [sic] on occasion and often have people attempt to tell me such. It’s infuriating.

Having a shared experience helps community members to feel understood and less alone, with another commenter stating:

Unfortunately, what I have learned is that unless you are someone who struggles with it, the rest of the world (including some family and health professionals) just doesn’t care. There will be no support nor empathy. Hence why I am thankful for this site.

Community participants share encouragement and express their willingness to be there for each other through hard times. The simple existence of the community, the daily content posted, and the experiences and support shared by users can help those who suffer from chronic illnesses feel less alone. This is shown by comments such as this one:

Your articles seem to come out at the perfect time and speak right to me. It’s as if I unknowingly wrote them myself. Thank you for being the biggest support system I have outside of my family.

Effective moderation by community managers helps to keep the discussion respectful and can help ameliorate some of the harmful effects that are often encountered on the internet, such as misleading medical advice, conspiracy theories, and the like.

Table 2. Exemplary quotes demonstrating qualitative themes and their frequency distribution.

Thematic primary code		
Subcode	Exemplary quote	Frequency distribution, n (%)
Social support (n=3405)		
Empathy and understanding	"I'm glad this post came up. Most people who have never had a Migraine cannot understand the degree of pain and the strange feeling."	1089 (31.98)
Knowledge and shared experience from community	"Sometimes I see some of your posts and I think YAY it's not just me...and your column makes me feel like it is not only just me, but it's me and 5 million of my closes [sic] friends."	1587 (46.61)
Express stigma	"A lot of people don't think I have a "real" illness, and that includes healthcare professionals. It is probably the most frustrating part of this illness...sometimes I am treated like a drug-seeker, and sometimes I am treated like a nutcase...The only battle worse than getting healthcare professionals to accept my illness and treat it, is getting my family members to accept and understand it as real, and not blame me for it."	381 (11.19)
Giving advice	"The monster is never very far away. Write a journal, buy a dog, start doing your bucket list. The busier you stay the better."	283 (8.31)
Advocacy and awareness	"It has helped me research, it has 'pushed out' things that I need to learn, it has provided a community that I can engage with and be a part of. It has saved me from feeling so alone."	133 (3.91)
Sense of belonging/group membership	"I do get much comfort coming here knowing I am not alone in this world."	378 (11.10)
Encouragement and motivation	"I applaud your courage and determination to have stayed the course... I plan to stay the course as well."	579 (17.00)
Caregiver perspective	"I am caregiver for my husband who is in advance stages. It is becoming more apparent that he will lose the battle due to respiratory issues...Reading your entries remind me that others have gone before me as caregivers for this disease that sucks."	180 (5.28)
Adaptive engagement (n=1758)		
General (tag person, agreement, and emoji)	"[tagged person] I'm glad this post came up...When you have the time, please read some of what people say in this post."	432 (24.57)
Information seeking	"My question is with 15-16 migraines a month, if not more, how [do] you work through them... Any tips would be greatly appreciated!"	332 (18.88)
Information giving	"I have learned there's new technology they do in FL and NY called Sperling Prostate Cancer Treatment Laser..."	272 (15.47)
Conflicts/difference of opinion	"I'm sorry, but I think your outlook is incorrect. You should not avoid asking an important question in order to spare someone's feelings. The goal should be to remove the negativity toward people that do/did smoke, instead of simply not asking the question."	51 (2.90)
Community norms and rules	"Thank you for voicing your concern...I did want to take a moment to clarify that migraine.com is not owned by a pharmaceutical company. You can visit the site for further information about who we are and what we do: https://health-union.com/ "	49 (2.79)
Boundary marking	"Hopefully you'll be able to enjoy some support and kinship here, with lots of folks who have similar experiences and can relate to what you've said."	51 (2.90)
Active moderation (n=718)		
Empathy and understanding	"I value you and am grateful to have you as part of our community...we can all relate to one another...and it is comforting to hear a kind response from you and others."	432 (60.2)
Share knowledge and resources	"When you have the time, please read some of what people say in this post. I hope the stories help to make those people without migraines understand that it is different for all people and ... try to understand odd behavior and debilitating pain."	298 (41.5)
Share patient/caregiver experiences	"I am so sorry to hear about the mental health struggles you have alongside your migraine. As we speak, I am 1-2 hours into a sudden and dramatic downturn in mood, and it has me worried about a potential bad migraine."	207 (28.8)
Resolve conflicts	"It's never our intention to make anyone feel that they are difficult to love- I believe the article was trying to address how difficult chronic pain can be in the relationship dynamic, but I hear you, and apologize that was the message that came across. Thanks for your feedback and for being part of our community."	25 (3.5)

Thematic primary code		
Subcode	Exemplary quote	Frequency distribution, n (%)
Maintain community rules	"Since the community is bound to disagree at some points when discussing politics, we wanted to post a friendly reminder that posts of all opinions are welcome as long as they are respectful of each other and not inflammatory."	24 (3.3)

As shown in [Table 2](#), social support is most frequently demonstrated by sharing knowledge of their health condition and experience among community members (1587/3405, 46.61%) and expressing empathy and understanding (1089/3405, 31.98%). Conversely, very rarely do members provide social support by giving advice (283/3405, 8.31%). Most likely, this is because the OHC community rules explicitly state that we do not provide medical advice [96]. Community managers mirror the behavior of discouraging giving advice and reminding participants that people may use a range of treatment options and have different treatment experiences.

From the perspective of the content featured in the Facebook posts and their respective linked articles, the topics discussed in the comments were a broad range. They included caregiver experiences, complications and comorbidities, complementary therapies, coping with the health condition, diagnosis, emotional impact, experiences with health care provider(s), insurance coverage or disability issues, laboratory and other tests, life impact of chronic illness, lifestyle measures, mental health, patient journey, relationship issues, sexual performance and sexual health, and treatment or specific medication discussions ([Table 3](#)).

Table 3. Frequency distribution of model elements by topic discussed.

Topic discussed	Number of comments per topic, N	Social support comments, n (%)	Adaptive engagement comments, n (%)	Active moderation comments, n (%)
Caregiver experience	128	102 (79.6)	18 (13.8)	8 (6.9)
Complications and comorbidities	265	173 (65.3)	81 (30.7)	11 (4.0)
Complimentary alternative medicine	142	78 (55.0)	50 (35.0)	14 (10.0)
Coping with condition	358	275 (76.8)	60 (16.8)	23 (6.4)
Diagnosis	181	125 (69.1)	32 (17.7)	6 (3.1)
Emotional impact	425	282 (66.4)	102 (24.0)	41 (9.6)
Health care provider experience	295	139 (47.1)	111 (37.5)	45 (15.3)
Insurance coverage and disability	213	80 (37.5)	86 (40.4)	47 (22.0)
Laboratory and other tests	326	202 (61.9)	49 (15.0)	75 (23.0)
Life impact of chronic illness	458	332 (72.4)	112 (24.2)	14 (3.0)
Lifestyle measures	116	64 (55.2)	28 (24.1)	24 (20.1)
Mental health	110	76 (69.1)	27 (24.5)	7 (6.4)
Patient journey	527	384 (72.9)	91 (17.3)	52 (9.9)
Relationship issues	303	199 (65.7)	87 (28.7)	17 (5.6)
Sexual performance and sexual health	122	77 (63.1)	21 (17.2)	24 (19.7)
Symptoms	725	460 (63.4)	234 (32.3)	31 (4.3)
Treatment discussion	1187	570 (48.02)	472 (39.76)	145 (12.21)

As seen in [Table 3](#), the original Facebook post content topic is often associated with different levels of engagement, with some content topics requiring more moderation than others. In addition, the social support provided or solicited within the context of content topics can differ greatly. For example, 72.4% (332/458) of comments where the life impact of the health condition is discussed also include asking or giving social support, whereas only 48.02% (570/1187) of comments where treatment is discussed include a social support message. However, it is notable that regardless of the content topic, there are still high levels of social support for others expressed. Even

for a *dry* topic like insurance coverage, 37.5% (80/213) of the comments were an expression of some type of support.

Content topics that have the highest proportion of comments that needed moderation of some sort, not surprisingly, are topics that are the most medical and/or technically scientific ([Table 3](#)). These are comment topics that also include insurance coverage and disability issues 22.0% (47/213), laboratory and other tests 23.0% (75/326), health care provider experiences 15.3% (45/295), and treatment discussions 12.21% (145/1187). These are also content topics with the corresponding lowest percentages of social support codes. These comment topics are more factual and may not elicit the same needs to provide

validation or seek empathy and understanding compared with other topics. This may reflect the perception that these topics are more centered on individual experiences, and other community members may perceive that they require less social support than other content topics.

In addition to differing across content topics, the distribution of codes falling into each of the model's thematic categories

also differs depending on the OHC from which the comments arose. As shown in Table 4, social support was highest in the RA and migraine communities and lowest in the PC and IBS communities, although it should be noted that in these groups as well, social support was reflected in 49.49% (780/1576) and 40.3% (232/576) of the comments, respectively.

Table 4. Comment counts and frequency distribution of model elements by community Facebook page.

Facebook page	Comment count, N	Social support comments, n (%)	Adaptive engagement comments, n (%)	Active moderation comments, n (%)
All community FB ^a pages	5881	3405 (57.89)	1758 (29.89)	718 (12.21)
RheumatoidArthritis.net (FB)	1417	860 (60.69)	517 (36.48)	40 (2.82)
ProstateCancer.net (FB)	1576	780 (49.49)	440 (27.92)	356 (22.60)
MultipleSclerosis.net (FB)	701	377 (53.8)	296 (42.2)	28 (3.9)
Migraine.com (FB)	876	479 (54.7)	309 (35.3)	88 (10.0)
LungCancer.net (FB)	735	397 (54.0)	255 (34.7)	83 (11.3)
IrritableBowelSyndrome.net (FB)	576	232 (40.3)	199 (34.5)	145 (25.2)

Discussion

Principal Findings

Results from the reach and engagement data on Facebook demonstrate that people with chronic health conditions want to engage on the web, particularly using social media. Overall, the 6 OHCs reached an average of 455,375 people per week and engaged approximately 6% to 9%, which is considered a high level of engagement on a Facebook post [95]. In addition to the benefits for those who actively engage with the content, previous research has shown that Facebook support groups provide group members who are less active with an important support network in the form of emotional support, informational support, and special companionship [34].

This highlights the importance of creating web-based spaces for the dissemination of information and facilitation of discussion regarding chronic disease. For some health conditions, people may suffer in silence because of social isolation, and the stigma of the condition may mean that online communities provide the only outlet for people to find others that are like them. In addition, people with more severe symptoms, such as those with severe MS, may look to share their experiences with others and provide support to those at earlier stages in their disease journey.

Social support is demonstrated in a variety of ways, including through information sharing, expressions of empathy, and sharing encouraging statements with others [21]. The most common manner of providing social support through Facebook comments was through the sharing of knowledge and experiences unique to people living with the chronic condition (47% of comments had this code). This shared lived experience helps members of the community, or people who visit the Facebook page, feel a bond with others living with the same health condition. This type of online community can then

provide an open space for sharing things that are not necessarily understood by users' in-person confidantes.

Previous research has shown that information seeking from people with similar experiences leads to greater perceived empathy among members of OHCs [37]. Allowing space for the expression of feelings and experiences that are not well understood by people without the condition likely helps to combat the stigma faced by people with chronic health conditions in their everyday lives. Importantly, as described above, it was much less common for these OHC members to give explicit advice to others (only 8% of comments had this code). This is important to mention as one of the common criticisms or concerns about social and peer support for health conditions is the possibility of posters sharing misinformation or pushing one's own treatment experience on others [18]. Community guidelines that discourage giving explicit medical advice, as well as active moderation that reminds people of this rule and provides for fair balance in information sharing, are important features of this model. These OHC moderation features allow for the sharing of knowledge and experience without the downside of inaccurate and potentially misleading or dangerous unqualified medical advice.

Knowing when to let community members engage in an exchange of comments without intervening as a moderator is as important as knowing when to apply specific moderation principles. Moderation sometimes involves enforcing community rules or removing comments that violate these rules. Maintaining a safe community environment that presents balanced and medically accurate information is essential to OHCs. When needed, moderators intervene to guide the conversation away from explicit giving of advice and emphasizing that all are welcome to share their experiences, but to be mindful that everyone has different experiences with certain treatments or procedures and there is most often no one right approach or answer.

Previous research has shown that moderators can serve several functions in OHCs: provide clinical expertise, suggest users talk to their physician about their specific question, point users to outside resources, provide community expertise, build rapport, and provide technical help [97]. These results add to the finding that moderation is needed more frequently when discussing scientific and technical subjects, such as labs, diagnostic tests, insurance, and disability, than when the focus is on sharing experiences such as those related to coping or relationship issues.

The skillful use of moderation helps these OHCs function smoothly and deal with any concerning issues as they arise, ensuring that the community is not endorsing misinformation or one specific treatment approach. Additionally, moderation needs may change over time as OHCs gain maturity. The frequency of codes that reflect the need for active moderation were lowest in the migraine, MS, and RA communities. These were launched by Health Union several years before the others and represent more *mature communities* from the perspective of community management. Several factors, including the length of time a community has been active, the number of active community members, and the frequency of member engagement are associated with more mature OHCs.

Analysis of the Health Union OHC adaptive engagement model in action demonstrates that the foundational elements (social support, adaptive engagement, and active moderation) are skillfully used to provide a rich and dynamic community experience for individuals with chronic health conditions. In addition, this analysis indicates that in an open community, social support can be provided and received through the use of active moderation and adaptive engagement. This standardized structure underlying the OHCs allows for adaptation to fit the specific needs of each particular community and provides a basis to facilitate the effective and beneficial exchange of social support.

Although the authors examine a proprietary OHC model, the features of this model, as outlined in this study, are part of other OHCs as well as social media apps and proprietary health apps. Thus, these findings may be extrapolated to these other platforms as well. How consumers or people living with chronic health conditions seek, find, and use information and support is important to a range of consumer health research and applications. Patterns of use and behavior identified herein can also be used as social media apps try to adapt their most notable features to better serve OHCs.

Another implication of this research could be applied to stand-alone health apps and the need for those apps to incorporate the ability to provide moderation to better mirror the experience of OHCs. Pharmaceutical and biotechnology companies interested in social media as a means of engaging communities would be well served to consider the implications of adverse events reporting and the role of active community moderators in maintaining safe spaces for engaging communities of people with chronic health conditions.

Limitations

The Facebook analytics data and the qualitative content of the Facebook comments presented in this study are descriptive and exploratory and are not designed for formal hypothesis testing. This study was initiated to analyze the features of support and engagement that are found organically within OHCs and enhanced through active moderation. We sought to elucidate these themes and understand whether they were consistent with the constructs of the theoretical model.

We note that a central feature of the model, that it is adaptive, is also a limitation of this research design. There is no control group to validate the extent to which social support is an inherent characteristic of OHCs or the additional effect added by features that are specific to the Health Union OHC adaptive engagement model, such as paid moderators and community rules. However, the fact that a high degree of *self-moderation* is observed among community members reacting to each other's comments in a mutually supportive manner in the more mature communities is noteworthy.

As noted in the methods section, given the desire to demonstrate the adaptability of the OHC adaptive engagement model to a social media platform, the authors intentionally only used comments from the OHC Facebook posts for this study and did not include any comments from the linked OHC native domains. As such, the findings from online Facebook communities may not be generalizable to online communities that do not have the same interaction features as this social media platform. However, like Facebook, the trend is for OHCs, in general, to incorporate both passive and active engagement features [35].

To develop a manageable and meaningful sampling frame for this study, the random selection of posts was not feasible, which poses an additional limitation. The sampling frame was driven by the need to ensure representative content types and a large enough sample of community participant comments to determine thematic relevance and redundancy.

A final limitation of this study is the lack of longitudinal data for individual community participants. This study and other research completed by the authors to date present analyses of aggregate data from OHCs, and we have replicated the model several times with success [98]. Future research will be needed to follow distinct cohorts of OHC participants over time to assess the long-term impact of community participation on health-related behaviors and outcomes.

Conclusions

OHCs, particularly those with clear community rules and active moderation, can offer a safe and supportive environment for people living with chronic health conditions. Despite the inherent limitations of the internet and social media, OHCs are dynamic communities of people engaging in social relationships. The dynamic nature of OHCs may make them challenging to research, but it is possible to examine the structural elements of a model in action as well as explore qualitatively and quantitatively the aspects of interactions [99].

Reaching people on the web is a promising approach to facilitate the exchange of social support among people with chronic health

conditions. Health care messages bombard patients on a daily or even hourly basis. Using social media to deliver a message and provide a space for people to engage with others of similar condition-specific interests is a valuable way to cut through that noise.

OHCs such as those analyzed herein allow people with chronic health conditions to learn and engage with others on their own time and at their own pace. However, it is important to design and maintain such OHCs and their associated social media sites as safe spaces, and a structured model with essential features such as those described in this study facilitates their success. The use of a well-designed model helped the OHCs studied to achieve their primary aim: to meet people where they are at with the health information and social support they seek.

Community-responsive content, or content tailored to the needs of the community, is the foundation of an OHC. However, content alone does not provide sufficient experience for an engaging OHC. It is important to provide both active and passive

opportunities for people to engage with other community members. In addition, active moderation is needed to ensure a balance of views, appropriate tone, and recognition of community rules and values.

Future research is needed to identify segments of OHCs that have different needs and different patterns of interactions. A comparative analysis of these community segments may be used to help design the features of online communities that provide for more real-time interaction, engagement features, and personalized content.

Focusing on the ongoing relationship with community members, which is enhanced through active moderation and adaptive engagement, provides a community experience that is mutually supportive and results in a healthy online community that can thrive and mature. This study has practical significance as it helps to demonstrate the value of OHCs for people living with chronic health conditions and provides support for the use of an underlying structured model to guide community interactions.

Acknowledgments

The authors would like to thank Michael Booth, PhD candidate, University of Michigan, and RheumatoidArthritis.net community advocate, for reviewing the previous versions of the Health Union OHC adaptive engagement model. The authors further recognize the Health Union community management team, user experience/creative team, and other Health Union business teams for the infrastructure that sustains the OHCs. The authors are indebted to Tim Armand and Olivier Chateau for founding Health Union, LLC, and contributing to the vision that inspired the OHC adaptive engagement model. Finally, the authors thank all our community members who contribute content, engage daily, and provide ongoing support to each other.

Conflicts of Interest

BMG, KTVH, KG, SH, and AB are employees of Health Union, LLC, whose OHCs and OHC adaptive engagement model are discussed and evaluated herein. The authors do not financially benefit from this publication.

Abstract

Background: Chronic kidney disease (CKD) is a major global health burden, and is associated with increased adverse outcomes, poor quality of life, and substantial health care costs. While there is an increasing need to build patient-centered pathways for improving CKD management in clinical care, data in this field are scarce.

Objective: The aim of this study was to understand patient-reported experiences, symptoms, outcomes, and treatment journeys among patients with CKD through a retrospective and qualitative approach based on data available through PatientsLikeMe (PLM), an online community where patients can connect and share experiences.

Methods: Adult members (aged ≥ 18 years) with self-reported CKD within 30 days of enrollment, who were not on dialysis, and registered between 2011 and 2018 in the PLM community were eligible for the retrospective study. Patient demographics and disease characteristics/symptoms were collected from this retrospective data set. Qualitative data were collected prospectively through semistructured phone interviews in a subset of patients, and questions were oriented to better understand patients' experiences with CKD and its management.

Results: The retrospective data set included 1848 eligible patients with CKD, and median age was 56 years. The majority of patients were female (1217/1841, 66.11%) and most were US residents (1450/1661, 87.30%). Of the patients who reported comorbidities ($n=1374$), the most common were type 2 diabetes (783/1374, 56.99%), hypertension (664/1374, 48.33%), hypercholesterolemia (439/1374, 31.95%), and diabetic neuropathy (376/1374, 27.37%). The most commonly reported severe or moderate symptoms in patients reporting these symptoms were fatigue (347/484, 71.7%) and pain (278/476, 58.4%). In the qualitative study, 18 eligible patients (13 females) with a median age of 60 years and who were mainly US residents were interviewed. Three key concepts were identified by patients to be important to optimal care and management: listening to patient needs, coordinating health care across providers, and managing clinical care.

Conclusions: This study provides a unique source of real-world information on the patient experience of CKD and its management by utilizing the PLM network. The results reveal the challenges these patients face living with an array of symptoms, and report key concepts identified by patients that can be used to further improve clinical care and management and inform future CKD studies.

Introduction

Chronic kidney disease (CKD) is a major global health concern with an estimated prevalence of 8%-16% worldwide [1,2]. It is associated with an increased risk of adverse outcomes, poor health-related quality of life (HRQoL), and substantial health care costs [1]. The patient voice has become an integral part of the management of chronic diseases and increasingly relevant to the development of new treatments. Therefore, an expanding need exists to build patient-centered pathways for improved CKD management in clinical care [3]. Patient-focused research can help identify priorities and outcomes that are important to patients and can enable the development of care components that can improve health care practice [4-6]. This information has also driven the development of tools that can promote self-management, which has been shown to slow disease progression, specifically in patients with CKD [5,7]. While qualitative studies have identified specific topics of importance to patients with respect to disease management [4,5], there is still an outstanding need for information directly from patients about their experience of symptoms and outcomes in CKD [8-10].

More recently, the collection of data on the patient perspective of new treatments during drug development has been encouraged by the US Food and Drug Administration, which has developed guidance related to the use of patient-reported outcome measures to support drug approvals and label claims [11]. Researchers in academia and industry are also increasingly seeking patients' voices and candid perspectives on a variety of clinical research-related areas through patient advisory boards. These activities have generated valuable insights, leading to improvements in study design (eg, adjustments in visit schedules), patient communication materials (eg, study pamphlets), and the development of new patient-centered endpoints [12].

Patients with serious and chronic diseases increasingly seek information and peer-to-peer support through online communities [13-16]. Online health communities and research networks, such as PatientsLikeMe (PLM), allow patients to connect with other patients, share experiences, and learn more about how to live better with their condition [17,18]. Through their engagement with such communities, patients experience improved emotional and social well-being, as well as increased confidence in their interactions with health care providers, and greater optimism and control in relation to their condition [14,15]. Ultimately, these networks provide an opportunity for clinicians, service providers, and researchers to listen to and better understand patients, and gather information outside of the clinical setting. An additional method for eliciting in-depth information is through patient interviews. Qualitative studies involving semistructured interviews have been scarcely used to understand patients' experiences of living with CKD and gain their perspective on various aspects of their care, so that any unmet needs can be identified and health care provision

improved [4,10]. To date, characteristics, treatments, and self-reported outcomes in patients with CKD who are members of the PLM network have not been evaluated.

To improve patient care and to construct patient-centered pathways, it is necessary first to understand how patients experience their disease. The objective of this study was to understand patient-reported experiences, symptoms, outcomes, and treatment management among patients with CKD through a retrospective approach based on data available through PLM, and then using a qualitative approach in a subset of patients from the retrospective study cohort.

Methods**Retrospective Study Population**

Adult PLM members (aged ≥ 18 years) were included in this study if they had registered with PLM between 2011 and 2018, if they had self-reported CKD within 30 days of registration, and if they were not receiving dialysis (N=1848).

Qualitative Study Population

This population was a subgroup of the retrospective study cohort (acknowledging patients' clinical profile, such as dialysis status, may have changed between enrollment on the retrospective study and the interview). All participants were adult PLM members (aged ≥ 18 years) who had self-reported CKD and were resident in the United States or other English-speaking countries (N=18).

PatientsLikeMe

PLM, described in [Multimedia Appendix 1](#), is an online network for patients with a range of diseases that allows them to connect with other patients and share personal stories and health data. Patients are directed to the website through multiple channels, including paid advertisements, public relations, press mentions, academic collaborations, word of mouth from other patients, provider referral, and web search [18]. Members provide information on their treatment and symptoms, including whether they are experiencing any core symptoms (pain, fatigue, anxious mood, depressed mood, and insomnia) that PLM asks members about regardless of their condition [19]. Participation is voluntary; patients did not receive an honorarium for providing data on the site, and their use of the site was not dependent on the provision of data. However, patients did receive an honorarium for interviews. Confidentiality of patient data was maintained and deidentified data were analyzed.

Study Using Retrospective Data

A cross-sectional observational descriptive study using deidentified retrospective data from the PLM network database was used to characterize patients with self-reported CKD. These data were used under license for this study; restrictions applied to the availability of the data. Demographics and clinical characteristics were described for all patients who provided information. We evaluated data on CKD diagnosis, symptom

severity (both general from the PLM symptom panel and other open-field symptoms), treatments, and comorbidities reported within 30 days of PLM registration. If multiple reports of the same symptom were entered within 30 days of registration, only the first report was included in these analyses. The 30-day period was chosen to reflect the status of patients when joining the PLM network. The data were standardized in PLM; comorbidities and symptoms were standardized to corresponding International Statistical Classification of Diseases and Related Health Problems, Tenth Revision codes, and treatments were standardized to prescription codes. Data were analyzed descriptively, presenting median with interquartile range (IQR), frequency, and proportion as appropriate. The study protocol was performed in accordance with International Conference on Harmonisation Good Clinical Practice and the Declaration of Helsinki, and the applicable legislation on noninterventional studies or observational studies or both. Patients who register on PLM are made aware that patient data will be used for research purposes, and results will be shared with the PLM community.

Study Using Qualitative Data

The aim of this study was to understand the patient's experience of CKD and its management. This involved questioning patients on their experience of CKD diagnosis, treatments, and comorbidities; the impact of symptoms on HRQoL and functioning; disease management, diet, and physical exercise in relation to CKD; and challenges around their interactions with their medical team, to better understand what is missing regarding specific CKD patient-reported management.

The qualitative study was performed in a subset of patients from the retrospective study using semistructured phone interviews (60-90 minutes). PLM members who met the inclusion criteria (ie, individuals who reported CKD as a condition, were over 18 years of age, and resided in the United States or in an English-speaking country) were identified and contacted by private message or email to participate. Those who indicated they wished to participate were contacted by the research team and any questions they had about the study were discussed. Consent forms were shared by email on scheduling, and verbal consent was obtained prior to starting the interview; all received US \$100 for participating. Interviews were open ended and followed a semistructured interview guide. Open-ended questions were followed by prompts to encourage more detailed conversations about issues relevant to CKD if a topic had not already been fully explored. All interviews were recorded and transcribed postinterview to ensure direct quotes were accurate; recordings were deleted after they were transcribed verbatim.

Data were descriptively evaluated, presenting median with IQR, frequency, and proportion as appropriate. The interview transcripts were reviewed consecutively in groups of 3 using a content analysis approach [20] to identify emerging themes within the interview guide categories using the ATLAS.ti software (Scientific Software Development GmbH). As additional interviews were coded and new themes arose, the coding schema was updated, refined, and further grouped to create a final list of themes. This process was continued until no further concepts were identified and content saturation had been achieved (ie, no new concepts were being mentioned). Study end was achieved when either 20 participants had been interviewed or concept saturation was reached. Qualitative analyses of individual verbatim interview transcripts included whether symptoms reflected the patient experience without any potential bias that might be introduced by the interview questions [21]. The study protocol, patient communications, and interview guide were approved by the New England Independent Review Board. Any privacy concerns were addressed by not including identifying information in the final report and by allowing only authorized research personnel to access the PLM database.

Data Availability

The data that support the findings of this study were collected from PatientsLikeMe. Restrictions apply to the availability of these data, which were used under license for this study.

Results

Retrospective Data

Demographics and Clinical History

Between 2011 and 2018, 1848 (from 2391) PLM members who self-reported CKD were not receiving dialysis and were included in this analysis ([Multimedia Appendix 2](#)). The majority of patients were female (1217/1841, 66.11%) and were US residents (1450/1661, 87.30%), with a median age of 56 years (IQR 45-64, n=1848) at the date they joined PLM ([Table 1](#)). Most of those who recorded race were white (1199/1496, 80.15%) and 79.1% (564/713) of patients who shared their education history had postsecondary education. The median age at onset of symptoms that patients associated with CKD was 43 years (IQR 28-54 years; n=378); median age of CKD diagnosis, reported by 578 members, was 47 years (IQR 33-56 years).

Table 1. Patient demographics and clinical history (retrospective study; total patients studied: 1848).

Characteristic	Total
Gender (N=1841), n (%)	
Female	1217 (66.11)
Age (years) at date joined PLM ^a (N=1848), median (IQR ^b); range	56 (45-64); 18-89

^dGED: General Educational Diploma.

^eCKD: chronic kidney disease.

^fPercent for medication class is percent of those reporting treatment (N=1369), whereas percent for top reported medication within treatment class is percent of treatment class.

^gTop reported medication within the specified drug class.

Comorbidities and Treatments

Conditions in addition to CKD were reported in 1374/1848 patients (74.35%), and the median number of different conditions per patient was 3 (IQR 0-4). There were 474 patients reporting no comorbidities, 685 patients reporting 1-3 comorbidities, and 689 patients reporting more than 3 comorbidities. The most common conditions among those

reporting comorbidities were type 2 diabetes (783/1374, 56.99%), hypertension (664/1374, 48.33%), hypercholesterolemia (439/1374, 31.95%), and diabetic neuropathy (376/1374, 27.37%; [Figure 1](#)). Treatments were reported by 1369 patients; the most common were for diabetes (702/1369, 51.28%) and hypertension (311/1369, 22.72%; [Table 1](#)). These comorbidities are highly prevalent in patients with CKD.

Figure 1. Patient-reported comorbidities (retrospective data). Comorbidities reported in addition to CKD (n=1374). CKD: chronic kidney disease; SLE: systemic lupus erythematosus.

Symptoms

Less than one-half of all patients (754/1848, 40.80%) entered any symptom within 30 days of registration. Core symptoms from the PLM panel were reported by 487 patients (26.35%), and 633 patients (34.25%) reported additional symptoms ([Figure 2A](#)). Core symptoms of fatigue, pain, and insomnia were rated

as moderate or severe by 71.7% (347/484), 58.4% (278/476), and 47.6% (198/416) of patients, respectively ([Figure 2B](#)). Of the additional symptoms, nerve pain, problems concentrating, and feet tingling were classified as moderate or severe by more than 30% of patients—37.1% (118/318), 34.6% (117/338), and 32.4% (102/315), respectively.

Figure 2. Patient-reported symptoms (retrospective data). (A) Core and additional patient-reported symptoms (total cohort, N=1848). (B) Severity of patient-reported symptoms. Core symptoms are symptoms that all patients registered with PatientsLikeMe are asked to track; additional symptoms are those patients themselves may choose to track, or symptoms patients may be asked about in relation to a condition other than CKD. *None* refers to those patients reporting *none* for a specific symptom; those who did not provide any response were not included. CKD: chronic kidney disease.

Qualitative Semistructured Interviews

Concept saturation ([Multimedia Appendix 3](#)) was reached with 18 patients, after which no additional patients were interviewed. In-depth patient perspectives on their disease and care were gathered during these semistructured interviews and 4 major concepts were explored: symptoms, financial burden, valued outcome, and care concepts. We explore the interview responses within these themes below.

Patient History With CKD, Including Diagnosis

This group of 18 patients had a median age of 60 (IQR 52-76) years, were mostly US residents (n=16), and female (n=13). At the time of the interview, 2 patients who had participated in the

retrospective study had stage 4 CKD and were receiving or about to initiate dialysis. Most patients described their current health status as *OK* (n=7) or *Good* (n=8). The median patient age at diagnosis of CKD was 55 (IQR 47-62) years and 15 patients were able to report disease stage at diagnosis ([Table 2](#)). Most patients explained that they were diagnosed by a nephrologist following referral by their primary care physician ([Textbox 1](#)), and their self-reported diagnosis was based on an abnormal metabolic panel or urinary protein on screening tests.

All patients had comorbidities, with the most common being hypertension (12/18, 67%; [Table 2](#)). These comorbidities also had symptoms that could be associated with CKD, especially fatigue, numbness/tingling, or nausea.

Table 2. Patient demographics (qualitative study).

Characteristic	Total (N=18)
Age (years), median (interquartile range)	60 (52-76)

^bThese comorbidities were probed for if not spontaneously described by patients.

Textbox 1. Direct patient quotes from the qualitative study. Patients provided consent to include their words in a deidentified format. CKD: chronic kidney disease.

Patient history with CKD, including how they were diagnosed

At one time I was on so many medications that it was ridiculous, and I've got off of everything except some Parkinson's medicine and blood pressure medicine and blood thinner that I have to take.

I discovered I had chronic kidney disease when I was participating in the dry eye study. During the study I was asked to provide a urine sample, which showed protein in my urine.

And she says, and another thing, she says, we're going to have to send you a specialist on is that you're showing signs of kidney disease, and she says we're looking at stage 3.

I had just had some routine lab work, and it showed that my eGFR was low consistently. He repeated it a few times. So they sent me to a nephrologist.

I never am really sure what's contributing to it, if the kidney disease is a part of that, especially my hemoglobin. I don't get anemic or anything how that fatigue really sets in. I usually attributed it to the fibromyalgia.

Patient symptom experience related to CKD

I could spit sand.

I'm doing a workup for a kidney transplant also, so that's why I had the day off today, and then just like this last month I've had like six different doctors' appointments.

I did have very severe anemia. I had many, many blood transfusions.

Financial impact of CKD

Well, I don't have the best insurance in the world, but so far I've been able to pay most of my bills.

When I was finally approved for disability, I was also approved for (inaudible) Medicare. So that helped a bunch. Because basically, I had to stop working in 2014 because of the health issues.

I'd say most of my problems are financial right now. So now it's taking the time off plus the drugs plus – it's just the whole situation and everything.

It can run up to \$700 a month with MRIs, CT scans, doctor bills. It's been bad lately.

CKD patient experience with diet and physical exercise

Yeah, there are times when I can't really go out or do anything even at home, because my muscles are so cramped up.

Losing weight, trying to exercise regularly.

Not really happy [about my diet] because I grew up on a farm and meat was the main – we had meat three times a day, and I'm a real meat eater. So that has been a huge change for me.

And they keep always saying you got – you have to exercise. The extra weight is hard on the kidneys. And I don't know what my problem is. It's a lack of motivation, I think.

He always talks to me about doing what I can. Don't overdo it, obviously ... Yeah, he tries to keep me motivated and at least doing some sort of exercise daily, even if just like for 10 or 15 minutes, whatever, to keep my body moving.

Patient perception of CKD care and management

... They didn't honestly seem very concerned about my kidney health as much.

But I was always having to remind everybody, hey, I've got a kidney problem. We have to keep that in mind that it's not always the pulmonary hypertension. It's not always the small fiber neuropathy. So, I have to make sure that they understand that.

I want to have the best life that I can, and if I can't take anything for pain because of my kidneys, my life isn't going to be the best life I have. So, I have to know what things will work for me but aren't going to continue damaging my kidneys.

He's just very understanding, very supportive, and he does a good job of explaining what's going on. He gives good praise for achieving results, which helps.

I think at this point it's me. That'll change, probably. But I'm pretty independent, and I want to be in control. I think most people do.

... so, I have learned that I don't ask him my questions. I ask my nephrologist my questions. And he will answer anything. And he wants to answer. But the primary doctor just doesn't seem to care.

For the record, I would never have another transplant – and God hope my kidneys don't go south, because I would never do it again. Never in a million years.

Shifting to a new one is a little bit scary.

You really need to have a doctor that's going to really listen to you because he's going to miss something if he's not listening to you.

Well, I just hope that I can live the rest of my life and not have serious problems with my kidney.

I just make sure that I speak up for myself and explain where I'm at or ask questions. I think that that's a key component that patients don't always do. If nothing else, nursing has taught me to be an advocate for myself.

Someone's taking care of it, and I know that I will know if my kidney function starts to fall or something, they'll know, and they'll start to get it taken care of right away.

It's just that nagging thought back there about well, will I be able to continue to live the quality of life that I do, and my kidney function remain high enough that I don't need more aggressive treatment?

But the doctors that I have here I feel are great doctors, and they really work with me ... So, they all have to be working in concert, which I've worked really hard to get them to do.

Patient Symptom Experience and HRQoL

In total, 28 different symptoms were reported by patients as potentially related to CKD (eg, edema, urinary tract infection, and urinary frequency). [Textbox 1](#) summarizes key quotes from patients. The most commonly reported symptoms (spontaneous and probed) included fatigue (n=15), thirst (n=11), itching

(n=10), sleep disturbance (n=10), and edema/swelling (n=8) ([Figure 3](#)). Edema/swelling and muscle cramps/spasms were 2 commonly reported symptoms not probed for during interviews. These symptoms also influenced both social interactions and the activities of daily living. For example, 1 patient noted that their body would suddenly *go rubbery* on them during yard work ([Textbox 1](#)).

Figure 3. Patient-reported symptoms (qualitative study, N=18). Spontaneous symptoms are symptoms that patients themselves choose to share during the interview that they considered to be related to CKD, probed symptoms are those that interviewers probed for if patients did not mention them (fatigue, sleep disturbance, itching, numbness/tingling, chest pains, dyspnea, nausea, thirst, mood, and sexual function). If a patient had not mentioned any issues related to sleep spontaneously, they were asked about “any impacts on their sleep”; similarly, if they had not mentioned any issues related to anxiety or depression, they were asked “how does CKD affect your mood?”. Uniformly, patients reported negative impacts on sleep, mood, and sexual functioning either spontaneously or prompted.

When asked which symptom had the biggest impact on their HRQoL, most patients (n=12) mentioned a symptom not related to CKD or said no symptoms had a significant impact. Of the CKD-related symptoms mentioned as having the biggest impact, fatigue was most commonly reported (n=4), followed by muscle cramping (n=2). Six patients reported experiencing fatigue *all of the time*, whereas 2 patients commented that CKD affected their sleep *all of the time* ([Multimedia Appendix 4](#)), and the impact of lack of sleep on fatigue was noted.

Only the 2 patients with end-stage renal disease (ie, stage 4 or 5, on or preparing for dialysis) stated that CKD was the single biggest health burden in their lives. One patient commented that bipolar disorder and CKD equally caused the most burden; another said diabetes and CKD. Most of the remaining patients ranked CKD third or lower in their list of comorbidities.

Financial Impact on Patients

Nine patients reported a financial impact, with 4 patients spending *some* and 3 patients spending *a lot* of their monthly

budget toward medical bills; 2 patients noted that only *a little* was related to medical bills. The level of financial impact varied across patients and was influenced by insurance status, severity of CKD, and comorbidities. The financial impact of CKD was highlighted by 12 patients in total ([Multimedia Appendix 4](#)). Concepts appearing when describing financial impact of CKD included concern about loss of insurance, high deductibles, insurance dictating care, losing time at work leading to lost wages, expensive drugs, cost of specialists, and time and knowledge required to scrutinize billing ([Textbox 1](#)).

Patient Experience With Diet and Physical Exercise

Physical activity was considered important; however, nothing more than regular exercise or walking for CKD was prescribed ([Textbox 1](#)). Some patients with comorbidities did report they received physical therapy, and it was clear that physicians were actively encouraging patients to engage in physical activity.

A total of 7 patients shared that they had received recommendations for physical activity from clinicians, but all

instances were very general and not specific for CKD. Patients received more information about diet monitoring than about physical activity, because they discussed diet details when reviewing their course of treatment for CKD. Almost all patients mentioned monitoring aspects of their diet, such as salt, potassium, protein, and water intake.

Many patients noted that they missed foods they like, such as pasta, but accepted diet changes. However, it was clear that for some patients, balancing diet changes with multiple conditions was challenging. Vitamin and mineral supplement use were reported, specifically when iron-deficiency anemia or hypokalemia were mentioned.

Disease Management

When asked what they valued in managing their CKD, most patients focused on the reduction of future harm (ie, minimizing kidney damage, preventing disease progression, and not losing kidney function; [Textbox 1](#)). For example, 1 patient recognized the importance of preserving kidney function: “I want to have the best life that I can, and if I can’t take anything for pain because of my kidneys, my life isn’t going to be the best life I have. So, I have to know what things will work for me but aren’t going to continue damaging my kidneys.” Another patient viewed their HRQoL as the most important aspect of care: “Quality of life is more important to me than length of life.”

Other concepts valued by patients included awareness of CKD by all their doctors, a firm diagnosis, regular monitoring, having future treatment choices (dialysis, transplant, or none) honored, preferring transplant to dialysis, and having a normal life ([Textbox 1](#)). Importantly, one patient summarized that “I want to be able to make my own choices, and if I decide that I go on dialysis, I want support for that. If I don’t want to, I want support for that, too”.

Patients with CKD require coordination of care with their primary care physician, renal specialists, and specialists managing their comorbidities. Most patients listed their primary care physician, psychiatrist, and nephrologist as the most helpful in managing their CKD; 4 patients said they themselves were most helpful ([Textbox 1](#)). Patients frequently commented on the aspects of their care that led to well-coordinated, effective CKD management. Concepts generated by patients fell into 3 overarching domains: listening, coordinating across providers, and clinical care management ([Figure 4](#)). Listening to patients’ needs was considered central to effectively coordinating care. There was an expectation among patients that coordinated care across providers should be seamless to ensure appropriate management of their CKD in the face of comorbidities. When any of these aspects of care were absent, patients felt these were unmet needs ([Textbox 1](#)).

Figure 4. Concepts related to optimal CKD care and management (qualitative study). CKD: chronic kidney disease.

Listening	Coordinating across providers	Clinical care management
Key to effective care coordination for patients	Is expected to be seamless and professional	Managing CKD in the face of comorbidities is critical, especially because of drug effects on the kidney
“Well, he’s encouraging, he’s somebody I can talk to. He explains very well the relationship of different things.”	“She coordinates with my nephrologist and with my rheumatologist which takes care of my lupus and all. And also my neurologist, now, that I have to see for my peripheral neuropathy and everything.”	“So it became kind of a dance with what’s going on, keeping my potassium at the right levels, making sure that I was taking my diuretics to keep the swelling away, but not overdoing it because it was hurting my kidneys.”

Discussion

Principal Results

The patient voice is often underrepresented in the clinical setting, yet it is critical to optimizing and improving clinical practice and research, and to better understand chronic conditions such as CKD. Our main objective in this study was to better understand the patient experience with CKD and its management through direct patient insight, unfiltered by interactions with health care professionals, from a large patient cohort within the PLM network. This study highlighted the array of symptoms that patients with CKD face, as well as key concepts that are important for optimal care and management.

To our knowledge, this is the first published analysis of real-world data gathered on CKD from an online community. Data from PLM have previously been used to explore patient perspectives on neuromyelitis optica and neuromyelitis optica

spectrum disorders [19], characterize the profiles of patients with atopic dermatitis [22] and systemic lupus erythematosus [23], and understand patient preferences for type 2 diabetes self-management [24]. This is the first study to utilize the PLM network to gain insights into self-reported experiences in patients with CKD. These approaches for data collection can also translate to the clinical trial design process. Engaging patients early in the process has the potential to ultimately yield more successful studies [25]. DISCOVER CKD is an example of a study that has been influenced by this patient-centric approach (ClinicalTrials.gov identifier: NCT04034992). This PLM study was the pilot study for developing the interviews used in the DISCOVER CKD study and guided decisions about which symptoms the DISCOVER CKD study should capture [26].

Retrospective Study

The retrospective study profiled a specific cohort of PLM members with CKD who were not receiving dialysis. Their characteristics are broadly consistent with US CKD populations from United States Renal Data System (USRDS), National Health and Nutrition Examination Survey (NHANES), and the Dialysis Outcomes and Practice Patterns Study (DOPPS), although the percentage of females is slightly higher [27-29]. Members of PLM with CKD included in this cohort were predominantly white, middle-aged (median 56 years), and women, whereas the prevalence of CKD is only slightly higher for women compared with men (17% vs 13%, respectively) in the general population, with the majority aged >60 [27]. PLM members also have a higher educational level than the general population with CKD; 79.1% (564/713) had postsecondary education compared with 56%-59% in the general population [27,28]. The overrepresentation of educated men and women in the cohort and the relatively young age of PLM members compared with the general population according to the references reflect the patient population who regularly use health-based internet sites [30,31].

Comorbidities were reported by 74.35% (1374/1848) of the PLM cohort studied, the most common being type 2 diabetes (783/1374, 56.99%), hypertension (664/1374, 48.33%), hypercholesterolemia (439/1374, 31.95%), and diabetic neuropathy (376/1374, 27.37%). This is reflective of the general CKD population, as reported by the USRDS, where diabetes (36%), hypertension (31%), and self-reported cardiovascular disease (40%) are the most common comorbidities [27]. While rates of major depressive disorder (148/1374, 10.77%) were close to the frequency of depressive symptoms among predialysis patients (13%) attending a single renal center [32], they were lower than the reported prevalence of depressive symptoms among patients with CKD who are not on dialysis (21%-42%) [33]. The proportion of patients with fibromyalgia (199/1374, 14.48%) was higher than that previously reported in patients with CKD receiving hemodialysis (3.9%-12.2%) [34-37] or peritoneal dialysis (9.7%-18%) [38,39]. This may be due to the nature of the PLM database, where large communities for chronic conditions including fibromyalgia exist [17]. Therefore, these comorbidities tend to be overrepresented. Overall, the similarities between the characteristics of the PLM network and the overall US CKD population indicate that the PLM platform is a useful format for gathering insights into CKD care and management.

Qualitative Study

Information gathered from semistructured interviews with a small subset of the retrospective study population provides a unique in-depth perspective on patient experiences and captures their opinions regarding the care they receive or gaps they perceive in their care, including insights that may not be collected in a routine clinical setting or captured by other patient-reported outcome tools. Four key concepts were explored in the interviews: symptoms, financial burden, valued outcome, and care concepts.

Patients shared how their symptoms affected their HRQoL, with fatigue noted by most patients as having the biggest impact.

Fatigue and insomnia were also among the top core symptoms reported in the retrospective population. Together, these findings highlight the significance of fatigue and sleep-related problems for patients, corroborating other CKD studies [40-43]. Patients with CKD are known to experience profound fatigue and it is one of the most common symptoms affecting their HRQoL [43,44]. One study reported how fatigue was associated with unemployment, comorbidities, and use of antidepressant medication; the authors suggested that the presence of fatigue may act as a clinical prognostic factor in CKD [45]. Patients experiencing sleep disorders and fatigue are also at increased risk of all-cause mortality [44]. Fatigue has also been related to poor physical functioning, although causality remains unclear [41].

The cause of fatigue experienced by this subset of PLM patients is likely to be multifactorial [41] and associated with prevalent complications such as anemia [41,45] and low albumin levels [42], psychosocial factors including depression and anxiety [41], and insomnia [46]. Improved understanding of the impact that fatigue and other symptoms such as depression and anxiety have on those living with CKD can help guide treatment and improve quality of care by prioritizing interventions that improve HRQoL, such as personalized care, precision medicine, or wearable technology and biometric devices.

Only the 2 patients with stage 4 CKD considered CKD to be their single biggest health burden. This finding is likely due to the predominance of earlier and less symptomatic stages of CKD (3a or 3b) in this study and to the nonspecific nature of CKD-related symptoms. Other patients identified other comorbidities (eg, diabetes) as more burdensome relative to CKD. These comorbidities are interrelated with CKD and one can affect another; therefore, awareness among patients regarding which symptoms are associated with specific diseases needs to be addressed in the clinical management of patients with CKD.

Financial concepts around loss of insurance and earnings, and the cost of treatment and specialist care arose from interviews. Importantly, patients' experiences of the financial impact of CKD were varied and influenced by insurance status (particularly in regions without universal health care), severity of CKD, and other comorbidities. According to the USRDS, total medical costs were US \$50.4 billion for CKD (excluding end-stage renal disease) among Medicare patients in 2013 [47]. In adult patients in the United States, direct annual health care costs for individuals with CKD were US \$17,472 higher compared with those without CKD from 2002 to 2011 [48]. Such financial pressures experienced by patients may impact other symptoms noted, such as depression [49], and should therefore be considered in the holistic management of patients in clinical care.

The personal experiences of some interviewees reflected but were not fully aligned with the current Kidney Disease: Improving Global Outcomes (KDIGO) guidelines [50,51]. Current guidelines recommend that those living with CKD should be encouraged to undertake physical exercise, achieve a healthy weight (BMI 20-25 kg/m²), and stop smoking. KDIGO guidelines state that expert dietary advice and information

should be provided to patients in the context of an education program and tailored to severity of CKD. Detailed recommendations on protein intake, glycemic control, and salt and potassium intake are also provided [50,52]. However, PLM patients in this study mentioned that any lifestyle advice they received was very general and they were more likely to receive information about diet than physical activity; almost all patients noted that they monitored aspects of their diet. Importantly, some patients found balancing diet changes with multiple conditions very challenging. These insights illustrate that KDIGO guidelines on exercise may not be implemented effectively in daily practice and patients with multiple conditions need additional support from health care providers to manage the changes in their diet.

Concepts identified by patients relating to optimal CKD care and management fell into 3 domains: listening, coordinating across providers, and clinical care management. Patients valued physicians who listened to their needs, coordinated their care effectively with other specialists, and managed their CKD in conjunction with comorbidities. When any of these aspects of care were absent, patients felt these were unmet needs. These differ slightly to The Renal Association and Kidney Care UK's Kidney Patient Reported Experience Measure, a UK initiative to gain insight into patient experiences and help shape renal services, which identified 3 aspects of renal care that affect patient experience: shared decision making, transport, and discomfort associated with needle insertions [53]. Such differences may reflect differences in health care systems between countries, such as the National Health Service in the UK versus an insurance-based system in the United States. These insights provide an opportunity for health care service providers to adapt local clinical practice to improve care and better reflect the experiences and needs of patients. Patient experience has been positively associated with patient safety and health outcomes, and clinical effectiveness across a number of diseases and settings [54].

Study Limitations

A limitation of this study was that members of PLM self-reported their diagnoses and treatment—there was no independent clinical corroboration; and treatment indication, although captured by PLM, was not analyzed as few patients provide this information. In addition, the extent and nature of missing data can reduce precision and lead to a systematic bias of results; however, missing variables and missingness in variables were assessed and reported. Because PLM members

were not expected to know details of their disease severity (ie, CKD stage), it is also not possible to derive information on how self-management and care needs to change with disease progression.

There is also a sampling bias as patients had an active choice to participate/enroll into the PLM network, so the cohort was self-selecting. As a result, generalizability of these results may be limited because the profiles of patients enrolling into the PLM network may differ from the profile of those not enrolling into PLM or of the general population. The observation that patients who enroll in PLM with CKD tend to be younger, more likely to have some college education, and more likely to have white ethnicity compared with the general population has also been noted in other disease groups [19,55].

The evaluation of the retrospective data in this study focused on information reported within 30 days of enrollment/registration (or as close as possible) into the PLM network. However, we cannot be sure all information reported during or outside this period relates specifically to CKD, as most patients reported multiple comorbidities. There may be a future opportunity to conduct a longitudinal study to describe patient experience over time.

Nonetheless, in the retrospective study, the use of data directly from an activated network of patients that were not filtered through an interviewer or clinician eliminated any potential interviewer bias and the use of an anonymous online survey may have improved willingness to disclose sensitive information.

Conclusions

This study provides a unique source of real-world information on the patient experience of CKD and its management by utilizing the PLM network. The data collected through PLM identified key symptoms affecting patients, including fatigue and depression/anxiety, and are broadly consistent with published data on CKD populations in the United States. In-depth semistructured interviews with members reveal the challenges patients face living with symptoms of CKD and the impacts they experience financially and on HRQoL. These interviews identified key concepts around optimal care and management of CKD such as listening to patients and coordinating health care across providers, indicating that this approach can provide insights outside of the clinical setting to inform clinical practice and drug development, and improve future studies.

Acknowledgments

The authors thank the patients, the patients' families, and the PLM interviewers involved in this study, without whom this research would not be possible. Medical writing support was provided by Georgina Collett, PhD, CMPP, and Laura Geuss, PhD, and editorial support was provided by Bethany King, BSc, all of Core Medica, London, UK, supported by AstraZeneca according to Good Publication Practice guidelines. The sponsor was involved in the study design, collection, analysis, and interpretation of data, as well as data checking of information provided in the manuscript. Ultimate responsibility for opinions, conclusions, and data interpretation lies with the authors. Development of this manuscript was supported by AstraZeneca.

Authors' Contributions

GJ, EN, KH, CE, and JH contributed to the design of the study. MF-R contributed to collection of data for the qualitative study. EN and MF-R conducted the data analysis and all authors contributed to data interpretation and manuscript preparation and review. All authors approved the final version of the manuscript and accept accountability for the overall work.

Conflicts of Interest

AMA, CMQ, EN, and JM are employees of AstraZeneca. AN, CE, ETW, GJ, JH, and KH are employees and stockholders of AstraZeneca. MF-R is an employee of PLM.

Abstract

Background: While selecting predictive tools for implementation in clinical practice or for recommendation in clinical guidelines, clinicians and health care professionals are challenged with an overwhelming number of tools. Many of these tools have never been implemented or evaluated for comparative effectiveness. To overcome this challenge, the authors developed and validated an evidence-based framework for grading and assessment of predictive tools (the GRASP framework). This framework was based on the critical appraisal of the published evidence on such tools.

Objective: The aim of the study was to examine the impact of using the GRASP framework on clinicians' and health care professionals' decisions in selecting clinical predictive tools.

Methods: A controlled experiment was conducted through a web-based survey. Participants were randomized to either review the derivation publications, such as studies describing the development of the predictive tools, on common traumatic brain injury predictive tools (control group) or to review an evidence-based summary, where each tool had been graded and assessed using the GRASP framework (intervention group). Participants in both groups were asked to select the best tool based on the greatest validation or implementation. A wide group of international clinicians and health care professionals were invited to participate in the survey. Task completion time, rate of correct decisions, rate of objective versus subjective decisions, and level of decisional conflict were measured.

Results: We received a total of 194 valid responses. In comparison with not using GRASP, using the framework significantly increased correct decisions by 64%, from 53.7% to 88.1% ($88.1/53.7=1.64$; $t_{193}=8.53$; $P<.001$); increased objective decision making by 32%, from 62% (3.11/5) to 82% (4.10/5; $t_{189}=9.24$; $P<.001$); decreased subjective decision making based on guessing by 20%, from 49% (2.48/5) to 39% (1.98/5; $t_{188}=-5.47$; $P<.001$); and decreased prior knowledge or experience by 8%, from 71% (3.55/5) to 65% (3.27/5; $t_{187}=-2.99$; $P=.003$). Using GRASP significantly decreased decisional conflict and increased the confidence and satisfaction of participants with their decisions by 11%, from 71% (3.55/5) to 79% (3.96/5; $t_{188}=4.27$; $P<.001$), and by 13%, from 70% (3.54/5) to 79% (3.99/5; $t_{188}=4.89$; $P<.001$), respectively. Using GRASP decreased the task completion time, on the 90th percentile, by 52%, from 12.4 to 6.4 min ($t_{193}=-0.87$; $P=.38$). The average System Usability Scale of the GRASP framework was very good: 72.5% and 88% (108/122) of the participants found the GRASP useful.

Conclusions: Using GRASP has positively supported and significantly improved evidence-based decision making. It has increased the accuracy and efficiency of selecting predictive tools. GRASP is not meant to be prescriptive; it represents a high-level

approach and an effective, evidence-based, and comprehensive yet simple and feasible method to evaluate, compare, and select clinical predictive tools.
