Abstract

Background: Hand hygiene is one of the most effective ways of preventing health care–associated infections and reducing their transmission. Owing to recent advances in sensing technologies, electronic hand hygiene monitoring systems have been integrated into the daily routines of health care workers to measure their hand hygiene compliance and quality.

Objective: This review aims to summarize the latest technologies adopted in electronic hand hygiene monitoring systems and discuss the capabilities and limitations of these systems.

Methods: A systematic search of PubMed, ACM Digital Library, and IEEE Xplore Digital Library was performed following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. Studies were initially screened and assessed independently by the 2 authors, and disagreements between them were further summarized and resolved by discussion with the senior author.

Results: In total, 1035 publications were retrieved by the search queries; of the 1035 papers, 89 (8.60%) fulfilled the eligibility criteria and were retained for review. In summary, 73 studies used electronic monitoring systems to monitor hand hygiene compliance, including application-assisted direct observation (5/73, 7%), camera-assisted observation (10/73, 14%), sensor-assisted observation (29/73, 40%), and real-time locating system (32/73, 44%). A total of 21 studies evaluated hand hygiene quality, consisting of compliance with the World Health Organization 6-step hand hygiene techniques (14/21, 67%) and surface coverage or illumination reduction of fluorescent substances (7/21, 33%).

Conclusions: Electronic hand hygiene monitoring systems face issues of accuracy, data integration, privacy and confidentiality, usability, associated costs, and infrastructure improvements. Moreover, this review found that standardized measurement tools to evaluate system performance are lacking; thus, future research is needed to establish standardized metrics to measure system performance differences among electronic hand hygiene monitoring systems. Furthermore, with sensing technologies and algorithms continually advancing, more research is needed on their implementation to improve system performance and address other hand hygiene–related issues.

Introduction

Background

Hand hygiene is one of the most effective ways of reducing the transmission of pathogens that cause health care–associated infections (HAIs) [1-3]. HAIs are infections that people acquire in health care settings [4] and are the most crucial challenge to patient safety in health care [5]. HAIs dramatically increase patients' length of stay, costs, mortality, and morbidity worldwide [6,7]. Moreover, HAIs also impose a heavy financial burden on health care systems. Solely in the United States, the estimated annual costs range from US $28 billion to US $45 billion [8]. The hands of health care workers (HCWs) represent the main pathway of pathogen transmission during health care [2], and Stone et al [9] estimated that at least one-third of HAIs can be prevented by achieving better hand hygiene in health care settings.

In 2009, the World Health Organization (WHO) issued the first *WHO guidelines on hand hygiene in health care* to provide a thorough review of evidence on hand hygiene in health care and specific recommendations to improve practices in health care settings [2]. In the guidelines, the WHO summarizes the five key moments when HCWs should ensure hand hygiene [2], as shown in Figure 1. The guidelines also recommend two standard hand hygiene techniques, *handwash with soap and water* for visibly soiled hands and *hand rub with alcohol-based formulation* for routine decontamination of hands [2], as shown in Figure 2.

Figure 1. The key moments when health care workers should perform hand hygiene. Source: World Health Organization: "My 5 Moments for Hand Hygiene" (with permission) [2].

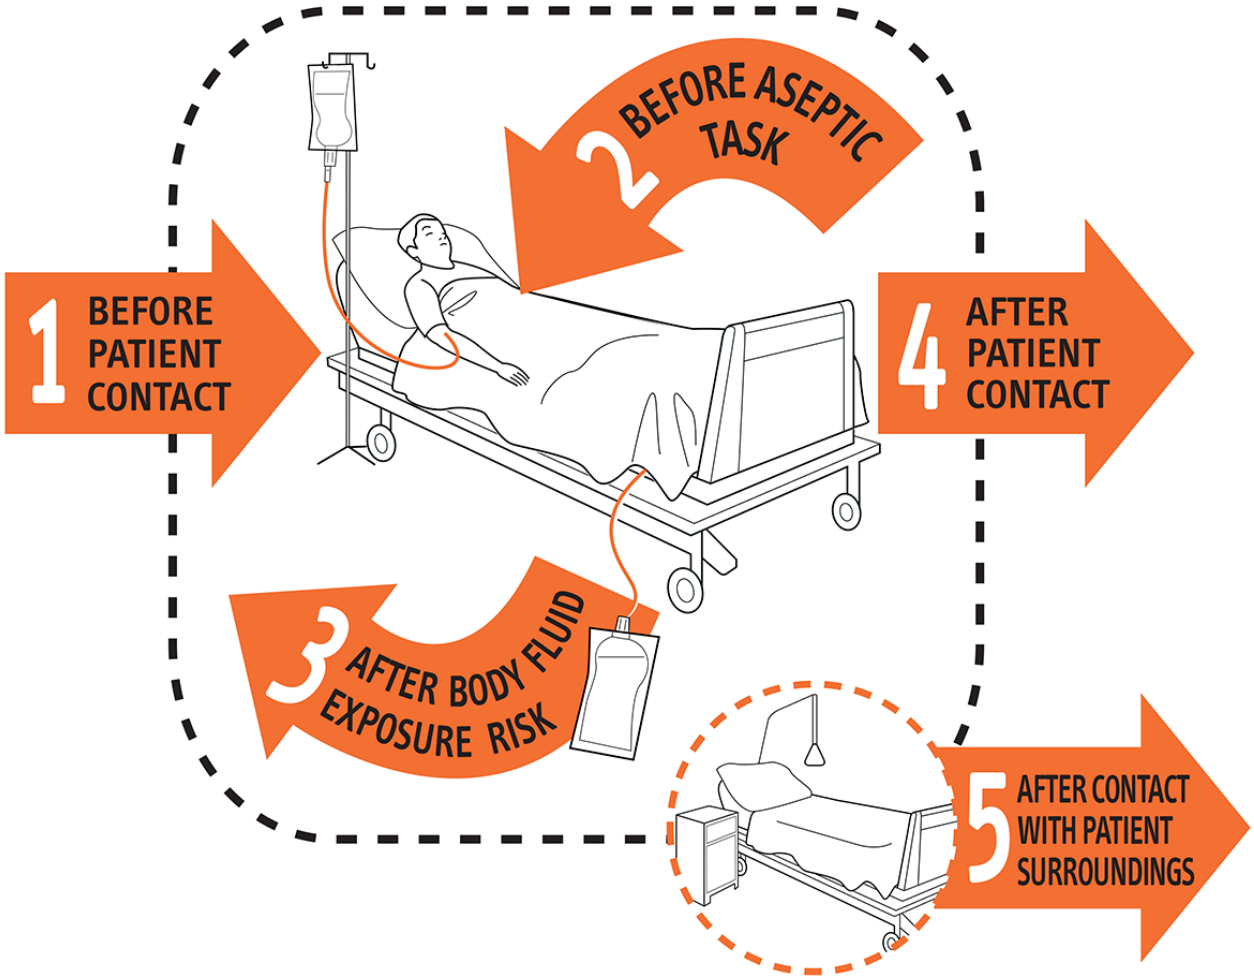

Figure 2. Standard World Health Organization procedures of alcohol-based hand rub and handwash with soap and water. Source: World Health Organization. How to Hand rub?/How to Handwash? (with permission) [10].

However, research has found that hand hygiene compliance is often poor [11,12]. By summarizing 96 empirical studies, Erasmus et al [12] reported that the median compliance rate was only 40% among HCWs. Meanwhile, research also found that hand hygiene quality was unsatisfactory [13-15]. Szilágyi et al [15] reported that only 72% of HCWs could adequately clean all hand surfaces immediately after hand hygiene training. Owing to the importance of hand hygiene, these findings suggest that monitoring hand hygiene practices and providing HCWs with feedback regarding their performance are essential to promote hand hygiene compliance and quality in health care settings [16].

Direct observation by trained auditors is considered the gold standard for monitoring hand hygiene compliance in health care settings [2,17]. Self-reporting by HCWs and the measurement of hand hygiene product consumption are also widely used to monitor hand hygiene compliance [18]. However, Boyce et al [18,19] argued that the disadvantages of direct observation include time and resource consumption, insufficient sample size, lack of standardized observational practices, and the Hawthorne effect. Furthermore, self-reporting is not recommended by experts, as HCWs tend to overestimate their level of compliance, and the measurement of hand hygiene consumption cannot assess the appropriateness of HCWs' hand hygiene timing and quality [18].

To assess hand hygiene quality, previous studies have used direct observation by trained auditors to observe HCWs' compliance with the WHO 6-step hand hygiene technique

[13,14,20]. Another common technique is using UV fluorescent substances to detect the surface coverage of hand hygiene products after hand hygiene [21,22]. Moreover, microbiological tests measure bacteria reduction count to evaluate hand hygiene quality [21,23,24]. However, using direct observation to monitor hand hygiene quality suffers from the same disadvantages as using direct observation to monitor hand hygiene compliance. Visual inspection of fluorescence is restricted to small sample sizes and a lack of standardized observational practices [25]. Furthermore, microbiological tests require time-consuming procedures and often overestimate the reduction of bacteria [21].

Given the above trade-offs, there has been increased interest in developing electronic monitoring systems to serve as an alternative or supplemental monitoring approach [19]. These electronic hand hygiene monitoring systems can be further categorized into electronic hand hygiene compliance monitoring systems and electronic hand hygiene quality monitoring systems.

Although previous reviews have described electronic hand hygiene compliance monitoring systems in detail, this is not the case for electronic hand hygiene quality monitoring systems [19,26,27]. Recent advances in sensor technologies and algorithms have also contributed to the development of new electronic hand hygiene monitoring systems. Furthermore, electronic hand hygiene monitoring systems have limitations that need to be identified and highlighted.

Objectives

This paper aims to (1) review the literature regarding the latest technological developments in electronic hand hygiene systems for monitoring compliance and quality and (2) summarize the limitations and challenges when developing and deploying such systems in health care settings.

Methods

Search Strategy and Selection Criteria

We conducted a bibliographic search of the following web-based databases: PubMed, ACM Digital Library, and IEEE Xplore Digital Library. This systematic review followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) [28] guidelines to reduce the risk of bias and increase its transparency and replicability. This systematic review is not registered on the network, and its review protocol is described below.

We derived the search query using a combination of key terms from previously published literature and expert advice. For the health-related database (PubMed), we specified search terms regarding hand hygiene, technological innovation, and observation to target electronic hand hygiene monitoring systems. For the technological databases (ACM Digital Library and IEEE Xplore Digital Library), we specified terms related to hand hygiene to include relevant technical innovations. The search queries for each database are given in Multimedia Appendix 1. Papers published between January 1, 2000, and June 30, 2020, were included in this study. As older literature is less relevant to today's electronic hand hygiene monitoring systems, we decided to exclude it.

Studies were included if they (1) developed an electronic method or system to monitor hand hygiene compliance or hand hygiene quality, (2) used an existing electronic device or application to support hand hygiene monitoring, or (3) adopted an existing electronic hand hygiene monitoring system and provided sufficient technical details. Meanwhile, studies were excluded if they (1) did not explicitly target electronic hand hygiene monitoring, (2) did not provide adequate technical details (eg, communication protocol and sensor specification), (3) were not published in English, or (4) were not original research papers (eg, abstracts, review papers, and editorials).

To identify the relevant studies, we first imported the search results into a spreadsheet for duplicate removal. Then, the titles were screened based on the selection criteria. If a publication passed the title screening, its abstract was assessed. Finally, the decision for inclusion was made according to the full text of the study. A total of 2 authors, CW and WJ, independently performed the study selection procedure for the retrieved publications. Disagreements between the 2 authors were further summarized and resolved by discussion with the senior author, VK, whenever necessary.

Data Extraction and Data Analysis

To collect information from the included studies in a consistent manner, we created a data extraction table (Multimedia Appendix 2). A total of 2 authors, CW and WJ, independently performed the data extraction procedure, whereas disagreements were resolved by discussion with the senior author, VK.

As we aimed to summarize the different technologies used in electronic hand hygiene monitoring systems, we adopted a narrative approach to synthesize the extracted data. All studies were first grouped by their study aims (monitoring either hand hygiene compliance or quality). After that, the categorized studies were further divided into several categories according to their technical details. Specifically, electronic hand hygiene compliance monitoring systems include (1) application-assisted direct observation, (2) camera-assisted observation, (3) sensor-assisted observation, and (4) real-time locating systems (RTLSs). Meanwhile, electronic hand hygiene quality monitoring systems include (1) measure compliance with the WHO 6-step hand hygiene techniques and (2) detect surface coverage or illumination reduction of fluorescent substances.

Owing to the high level of heterogeneity of the included studies, this study could not provide meta-analyses of the system performance and relevant HCWs' behavior changes. The significant heterogeneity also resulted in missing standardized automation tools to evaluate the risk of bias and assess the certainty for each included study.

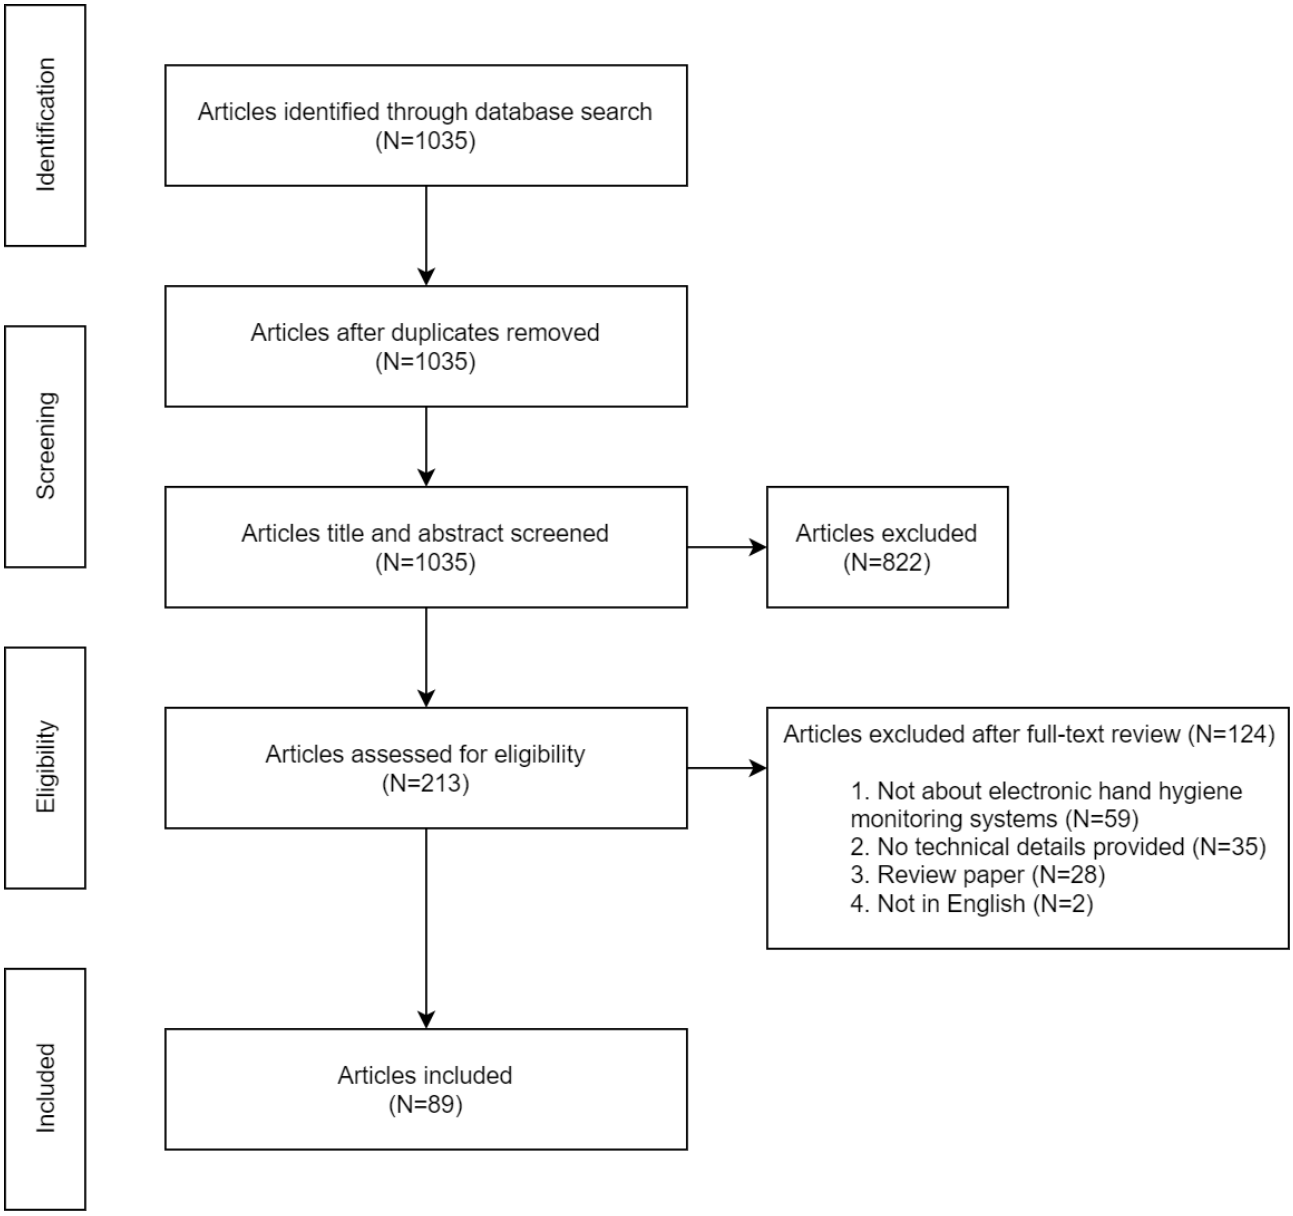
Results

Inclusion of Studies and Study Characteristics

In total, 1035 publications were retrieved by the initial search queries (777/1035, 75.07% from PubMed; 190/1035, 18.36% from the IEEE Xplore Digital Library, and; 68/1035, 6.57% from the ACM Digital Library). None of the retrieved studies were removed based on duplication. After screening the titles and abstracts, 79.42% (822/1035) of studies were excluded for

not meeting the eligibility criteria. Thus, 20.58% (213/1035) of studies were reviewed for the full text. Of these 213 studies, 124 (58.2%) studies were excluded. The main reasons for exclusion were the irrelevance of electronic hand hygiene monitoring systems (59/124, 47.6%) and insufficient technical details (35/124, 28.2%). No study was excluded if they met the inclusion criteria. Therefore, of the 213 studies, 89 (41.8%) fulfilled the eligibility criteria and were retained for review [25,29-116]. Figure 3 shows the process of searching for and selecting the studies included in the review.

Figure 3. Flowchart of the selection process for the systematic review.



All the 89 reviewed studies were published between 2009 and 2020, with 9 (10%) dated in or before 2010 [42,46,56,60,81,83,86,92,113], 38 (43%) dated between 2011 and 2015 [32,33,36,38,39,45,48,49,51,52,54,59,61,63-65,67,68,72,73,78-80,82,84,87-89,93-97,99-101,108,116], and 42 (47%) dated in or after 2016 [25,29-31,34,35,37,40,41,43,44,47,50,53,55,57,58,62,66,69-71,74-77,85,90,91,98,102-107,109-112,114,115]. Regarding the countries where the studies were conducted, 6 countries had ≥5 studies: United States (31/89, 35%) [25,30,31,36,38,39,41,46-48,51,52,59,61,63,68, 69,71,74,76,80-84,92,95,96,101,107,111], Canada (8/89, 9%) [42,72,86-89,98,100], Japan (7/89, 8%) [44,45,55,58,62,114,115], Brazil (6/89, 7%) [32,33,49,56,67,78], Germany (6/89, 7%) [37,40,50,66,108,109], and India (5/89, 6%) [64,65,94,99,102]. The demographic information of participants was provided in only 70% (62/89) of studies. Most studies (50/89, 56%) recruited HCWs from hospitals or clinics [29,30,32-40,44,46-57,59,61,66-68,73-75,77-80,82,84,86,87,89-91,95,96,98-100,103,106], and few (2/89, 2%) studies also involved patients from hospitals [66,94]. The remaining studies recruited the general public (7/89, 8%) [45,60,64,65,109-111] or students (4/89, 4%) [76,104,114,115] from communities or educational settings.

Compliance Monitoring Systems

We identified 73 studies that either implemented or adopted an electronic monitoring system for hand hygiene compliance and grouped them into 4 categories based on their enabling

technology [19,26]: application-assisted direct observation (5/73, 7%), camera-assisted observation (10/73, 14%), sensor-assisted observation (29/73, 40%), and RTLS (32/73, 44%).

Application-Assisted Direct Observation

Approximately 7% (5/73) of studies used applications to assist trained auditors in observing hand hygiene compliance (details are included in Table 1) [29-33]. With these applications, human observers could record their observations using smartphones or tablets. Unlike manual observation with paper forms, application-assisted observation avoids the need for transcription, which could cause delays in analysis, increase the associated cost, and introduce errors [117]. In addition, the prevalence of smartphones and tablets in health care settings makes data collection more unobtrusive and reduces the Hawthorne effect [26]. Both in-house and commercial applications have been used for application-assisted direct observations.

The monitored hand hygiene opportunities may vary in different studies. Most studies followed the instructions given by the WHO *5 moments for hand hygiene* [29,31-33]. Conversely, Sickbert-Bennett et al [30] simplified the observation process to *patient room entry or exit* events (as proxies for moments 1, 4, and 5).

Camera-Assisted Observation

In contrast with application-assisted direct observation, which solely relies on human auditors, studies with camera-assisted observation could rely on either human auditors [34-40] or algorithms [41-43] for analysis (details included in Table 2). Approximately 30% (3/10) of studies installed cameras inside and outside patient rooms to capture all five hand hygiene moments [34-36]. Researchers manually coded the streaming and recorded videos. Armellino et al [38,39] recruited a remote video auditing company (Arrowsight, Inc) to conduct compliance observations only when HCWs entered or exited the patient room (as proxies for moments 1, 4, and 5). Rather than installing cameras in the environment, Diefenbacher et al [37,40] proposed mounting a camera on the chest of HCWs that aimed at their hands, and researchers further analyzed these first-person view video recordings according to the WHO 5 moments for hand hygiene.

In terms of automated analyses, Zhong et al [41] attached a red green blue (RGB) camera to the chest of HCWs to collect egocentric videos. By feeding RGB images and optical flow images inside a two-stream convolutional neural network, they identified hand hygiene events in HCWs' daily routines [41]. Snoek et al [42] used an RGB camera with a microphone to observe handwash events in older adults with Alzheimer disease. Awwad et al [43] used an RGB-depth camera, Kinect (Microsoft Corporation), to achieve automatic detection of moment 1 (before touching a patient). Depth cameras generate pictures with stereo information, and these pictures have pixels with a value being the distance from the camera or *depth*. Hand hygiene compliance of moment 1 was then estimated by measuring the proximity between the subjects' hands and patient/bed with the presence of hand rub events [43].

Sensor-Assisted Observation

Of the 73 studies, 29 (40%) observed hand hygiene compliance using sensors (details are included in Table 3) [32,33,44-70]. These studies were grouped into 3 categories on the basis of sensor type: electronic dispenser, electronic dispenser assisted by other sensors, and inertial measurement unit (IMU) and microphone.

Of these 29 studies, 15 (52%) used electronic dispensers to record the frequency of hand hygiene events and estimate the volume of hand hygiene products dispensed [32,33,44-50,54-57,59,67]. A range of sensors was used to trigger the electronic dispenser counter, including pressure resistors [45,53], magnetic sensors [66], and photosensors [58]. These records were then manually collected by researchers or wirelessly transmitted to the associated servers for further analysis. Compared with direct observation, electronic dispensers can capture hand hygiene events with substantially fewer personnel resources and are unaffected by the Hawthorne effect [19]. However, electronic dispensers cannot detect the hand hygiene opportunities specified by the WHO 5 moments for hand hygiene [19]. Thus, several studies supplemented hand hygiene events with further information to estimate hand hygiene compliance, including outpatient visit records, the expected number of hand hygiene events, ward-specific conversion factors, the number of patients in the unit, nurse visit records, and documented activities [44,48-50,55,57,59].

As electronic dispensers cannot detect hand hygiene opportunities according to the WHO guidelines, other sensors were used to capture these opportunities [51-53,61,62,66,68]. A common practice was to use motion sensors to record patient room entry or exit events (as proxies for moments 1, 4, and 5) [51,61,66]. Here, the dispensers and motion sensors uploaded the time stamp of dispense and room entry/exit events to a server. Once a motion sensor was activated, the server measured the occurrence of a hand hygiene event within a predefined

period and thus estimated the hand hygiene compliance rate. Conversely, Geilleit et al [53] placed a motion sensor around HCWs' working area and pressure plates on patient couches and chairs. Hand hygiene opportunities were defined as the movement of HCWs into a patient zone when the pressure plates were activated. Furthermore, studies used electronic dispensers with other sensors, including IMUs and microphones, to recognize different types of hand hygiene events from HCWs' daily routines [52,62,68].

Of the 29 studies, 7 (24%) used an IMU and microphone to distinguish hand hygiene events from daily activities [58,60,63-65,69,70]. An IMU is an electronic sensor that measures a body's specific force, angular rate, and orientation. Of the 7 studies, 2 (29%) attached an IMU wristband to users' wrists to collect physical signals and utilize these signals to recognize hand hygiene events [63,69]. By using acceleration, gyration, and audio signals from participants' wrists, Wijayasingha et al [70] applied the naive Bayes algorithm to identify both hand hygiene and oral hygiene events from people with developmental disabilities. Instead of placing sensors on users' wrists, 43% (3/7) of studies embedded IMU sensors with or without microphones inside soap bars [60,64,65]. These augmented soap bars were then distributed to low-income households to monitor their soap use associated with hand and body wash. Furthermore, Miyazaki et al [58] attached a microphone to a sink to distinguish hand hygiene events from other daily activities.

Real-time Locating Systems

Of the 73 studies, 32 (44%) studies deployed RTLSs to track hand hygiene compliance (details included in Table 4) [67,71-101]. The RTLS was originally used to identify and track the location of objects or people in real time within a specified area. By sensing dispenser actuation and HCWs' movements, servers from an RTLS can measure HCWs' hand hygiene compliance rates as the ratio of dispenser actuation to the patient room or area entry or exit events (as proxies for moments 1, 4, and 5) [19]. On the basis of the underlying technology, we divided these systems into 6 categories: radio-frequency identification (RFID), infrared, ultrasound, Bluetooth low energy (BLE), IEEE 802.15.4/ZigBee, and Wi-Fi.

Of the 32 studies, 10 (31%) developed or deployed an RFID-based RTLS [71,73,75,76,83,84,90,93,97,99]. RFID uses radio waves to identify and track tags attached to objects. RFID tags can come in a variety of shapes and can be embedded into HCWs' name tags, wristbands, bracelets, and even shoes. When HCWs with RFID tags pass RFID readers, the readers detect the HCWs' tags and then communicate the collected information to a central server. To record HCWs' hand hygiene events, 30% (3/10) of studies placed RFID readers either next to dispensers or embedded RFID readers into dispensers [71,76,93], and these RFID readers were activated by dispensing events. By installing RFID readers next to dispensers and at the entrance of patient rooms or around patient beds, RFID-based RTLS could recognize both hand hygiene events and the entry and exit of

individuals into a patient room or a patient area [73,75,83,84,90,99]. Furthermore, several other sensors were used to assist in the observation of RFID-based RTLS, including motion sensors (recording movements around patient beds), IMUs (recording duration of hand hygiene events), and ethanol sensors (recognizing alcohol-based hand rub events) [90,97,99].

Of the 32 studies, 8 (25%) studies adopted infrared-based RTLSs to monitor hand hygiene compliance [72,74,77,86-89,98]. An infrared transmitter uses infrared light pulses to transmit a unique infrared code to its receiver, and the receiver can then estimate their relative position inside a building. For all 8 studies, infrared transmitters were installed across health care settings and continuously emitted their relative location information (eg, patient room, patient bed, and hallway). In addition, the transmitters were embedded in dispensers and activated for a short period after dispenser actuation. The infrared receivers were carried by HCWs and continuously received location information from the transmitter and counted HCWs' hand hygiene events. In addition, 63% (5/8) of studies used a wearable dispenser to facilitate HCWs' hand hygiene practices. Furthermore, an ethanol sensor was deployed in an infrared-based RTLS to recognize hand rub events rather than relying on a wall-mount dispenser [77].

Of the 32 studies, 2 (6%) studies deployed ultrasound-based RTLSs [79,100]. Similar to other RTLS, ultrasound-based RTLSs comprise transmitters, receivers, and dispensers. Transmitters emit sound in the ultrasonic range, and receivers detect these sounds and thus locate the transmitters. Unlike infrared-based RTLSs, ultrasonic transmitters were typically either placed in health care settings or carried by HCWs, and thus the sound contained either location information or HCWs' identity. Through the collected signals, the receivers could locate the HCWs' real-time location and recognize patient room entry/exit events. When dispensers were used in ultrasound-based RTLSs, transmitters or receivers were also embedded in these dispensers and transmitted dispensing events to the receivers.

[a]HCW: health care worker.

[b]N/A: not applicable.

Of the 32 studies, 3 (9%) studies developed RTLSs based on BLE technology [85,91,94]. BLE or Bluetooth is a wireless technology standard used for exchanging data between devices through ultra–high-frequency radio waves. These BLE-based RTLSs also contained transmitters (or beacons), BLE receivers, and dispensers. These transmitters were used as location reference points by placing BLE transmitters in health care settings. BLE receivers brought by HCWs could detect HCWs' real-time location to infer patient room entry/exit events. Unlike the aforementioned RTLSs, BLE receivers could be HCWs' own smartphones instead of carrying additional equipment. To measure hand hygiene events, dispensers triggered the embedded BLE transmitters once they were actuated.

Of the 32 studies, 8 (25%) studies used IEEE 802.15.4 or ZigBee-based RTLSs [67,78,80-82,92,95,96]. IEEE 802.15.4 is a wireless standard capable of low-power, low-cost wireless communication between devices with lower power consumption. ZigBee is a wireless mesh network specification based on the IEEE 802.15.4 standard [118]. Similar to other RTLSs, they comprise transmitters, receivers, and dispensers. Transmitters were either carried by HCWs or placed in a health care environment. Two individual systems were used in the studies, including one commercial system (Infectrack System, i-HealthSys) based on ZigBee and one in-house system based on IEEE 802.15.4. After collecting the relative distance and/or HCWs' identity from transmitters, receivers could identify HCWs' movement when HCWs entered or exited patient areas. The transmitters or receivers were also embedded inside dispensers to recognize hand hygiene events.

The last technology used in RTLSs was Wi-Fi [101]. Wi-Fi is a family of wireless network protocols for building wireless network connections between devices through radio waves. Wi-Fi transmitters were deployed across a room and above a sink, and when HCWs triggered the dispenser next to the sink, the dispenser transmitted the dispensing event to a server through the sink transmitter. The receivers were carried by HCWs, scanned for transmitters in the environment, and periodically uploaded their location to a server.

Quality Monitoring Systems

Of the 89 studies, 21 (24%) studies evaluated hand hygiene quality as performed by HCWs, grouped into 2 categories based on their measurement methods: (1) compliance with the WHO 6-step hand hygiene techniques (14/21, 67%) and (2) surface coverage or illumination reduction of fluorescent substances (7/21, 33%).

Compliance With WHO 6-Step Hand Hygiene Techniques

Of the 21 studies, 14 (67%) studies used a variety of sensors to monitor hand hygiene quality based on compliance with the WHO 6-step hand hygiene techniques (Figure 2). A common practice was to detect the duration of hand hygiene, which is considered a key indicator of quality [13,119]. Furthermore, these systems could recognize HCWs' hand motions as belonging to the individual steps from the WHO 6-step hand hygiene techniques. As such, these systems provided more details regarding HCWs' hand hygiene performance, including missed steps and out-of-order sequences, as noncompliance with all steps of hand hygiene procedures fails to cover all skin surfaces [14,20]. In these studies, sensors were either placed in the environment or attached to HCWs to monitor their hand hygiene performance (details are included in Table 5).

[b]RGB: red green blue.

[c]IMU: inertial measurement unit.

[d]HCW: health care worker.

[e]sEMG: surface electromyography.

Of the 14 studies, 5 (36%) studies measured compliance with the WHO 6-step hand hygiene techniques by placing sensors in the environment [102-106]. Khan et al [106] placed an RGB camera and a motion sensor above the sink in operation rooms to monitor HCWs' hand hygiene duration. Lacey et al [103] used a commercial automatic video auditing system (SureWash,

GLANTA Ltd) to monitor HCWs' compliance with the WHO 6-step techniques. Camilus et al [102] and Zhong et al [104] installed an RGB-depth camera (Kinect) above a sink to record hand hygiene events. Hand hygiene videos with stereo information were then analyzed by classifying each frame as an individual step from the 6-step hand hygiene techniques. Instead of using optical sensors, Khanmis et al [105] installed an mmWave sensor above a sink to measure hand hygiene performance. The mmWave is a sensing technology for detecting objects and provides the range, velocity, and angle of these objects. By using the generated frames from mmWave signals, they could classify each frame as one of the nine individual steps in line with the 6-step hand hygiene techniques.

Of the 14 studies, 9 (64%) studies monitored compliance with hand hygiene guidelines by attaching wearable sensors to HCWs [41,52,68-70,107-110]. Of these, the IMU was the most popular sensor and was used in 89% (8/9) of studies with several supplementary sensors. As mentioned above, the IMU can measure a body's specific force, angular rate, and orientation. Approximately 44% (4/9) of studies used the IMU of wristwatches to collect physical signals during hand hygiene events and classified hand motion within a certain time frame as one of the several individual steps of the 6-step hand hygiene techniques [52,68-70]. In addition, microphones have been combined with IMUs to evaluate hand hygiene performance, as the additional audio data could further improve the system accuracy [70]. Owing to hygiene reasons, 44% (4/9) of studies used sensor armbands (Myo armband, North Inc) with IMU to detect HCWs' compliance with hand hygiene techniques [107-110]. Of these 4 studies, 3 (75%) studies used both IMU and surface electromyography (sEMG) sensors from Myo armbands to recognize individual steps in line with 6-step hand hygiene techniques [108-110]. The sEMG sensor is an electrochemical sensor that detects biopotentials using electrodes placed on the skin. In contrast to the aforementioned studies, Zhong et al [41] attached an RGB camera to HCWs' chests. The camera recorded HCWs' hand hygiene practices, and then the collected RGB videos were processed by a deep learning algorithm (two-stream convolutional neural network) to classify hand motions into 7 self-defined hand hygiene steps.

Surface Coverage or Illumination Reduction of Fluorescent Substances

Of the 21 studies, 7 (33%) studies used fluorescent substances to automatically examine hand hygiene quality by computer vision algorithms. However, the means of detecting the quality of handwash and hand rub were distinct. For handwash, participants first applied fluorescent dye on their entire hands and then washed their hands with soap and tap water thoroughly. For hand rub, a hand disinfectant was mixed with a fluorescent dye, and participants used the disinfectant to perform an episode of hand rub. Then, their hands were checked under a UV light lamp and photographed using RGB cameras for further analysis. By comparing the disinfected areas that glowed under UV light and were free from pathogens, Lehotsky et al [120] stated that fluorescent substances could highlight the areas of the hand surface that were adequately disinfected with acceptable accuracy (95% sensitivity and 98% specificity). UV tests have been widely used to assess hand hygiene quality in medical education because of their easy application, low associated costs, and well-visible results [22].

There were two main ways to automatically analyze the collected RGB images: detecting illumination reduction before and after an episode of handwash or measuring the surface coverage of fluorescent substances (details included in Table 6). Approximately 29% (2/7) of studies calculated the illumination difference of fluorescent substances before and after an episode of handwash using Adobe Photoshop (Adobe Inc) and MATLAB (The Math Works, Inc) [25,111]. Hand hygiene quality was then measured by the value of illumination difference, where a bigger difference indicates better hand hygiene performance and vice versa.

Of the 7 studies, 5 (71%) studies analyzed the collected images from both handwash and hand rub by measuring the surface coverage of fluorescent substances [112-116]. For hand rub, the hand rub quality was acceptable if all areas were bright without dark spots, therefore suggesting that all parts of the hand were covered homogeneously with disinfectant [22]. Approximately 40% (2/5) of studies focused on measuring the surface coverage of fluorescent substances after hand rub by applying clustering algorithms [112,113]. For handwash, as fluorescent substances contaminated hands in advance, the handwash quality was measured by the range of cleaned hand areas (dark areas). Approximately 60% (3/5) of studies applied specific threshold values or deep learning algorithms to measure handwash quality [114-116].

Discussion

Recently, there has been increased interest in developing electronic monitoring systems to serve as an alternative or supplementary hand hygiene monitoring approach [19]. However, electronic hand hygiene monitoring systems do have limitations. The following sections discuss the limitations related to accuracy, data integration, privacy and confidentiality, potential risks, usability, associated costs, and infrastructure improvements [19,121].

System Accuracy

The system accuracy of electronic hand hygiene monitoring systems is the top concern for HCWs [121,122]. However, systems come with different metrics without standardized measurement tools. System accuracy is also affected by technical issues and geometric constraints.

The metrics often vary substantially in different types of electronic hand hygiene monitoring systems. For electronic hand hygiene compliance monitoring systems, the metrics are based on the number of detectable moments for hand hygiene described by the WHO (Figure 1). A total of 4 different metrics were mentioned in the included studies: (1) hand hygiene events, (2) patient room entry/exit events, (3) patient area entry/exit events, and (4) the WHO 5 moments for hand hygiene. Similarly, the metrics for electronic hand hygiene quality monitoring systems are also disparate. One way to measure HCWs' hand hygiene quality is through detecting their compliance with the WHO 6-step hand hygiene techniques (Figure 2). However, different systems often recognize different sets of individual steps of standardized techniques, which can vary between 6 and 14 individual steps. Detecting illumination reduction or surface coverage of fluorescent substances is another way to measure hand hygiene quality; however, different studies come with different metrics. Several systems can detect

pixel or segment levels of fluorescent areas from the collected RGB images; however, others measure the illumination reduction of the entire hand. Therefore, system results may not accurately reflect HCWs' hand hygiene compliance and quality, and results cannot be compared between different studies without further processing.

Technical issues dramatically affect system accuracy. One of the major concerns is hardware limitations, which result in systems not functioning well under certain situations. For instance, infrared-based RTLS could fail to work if an infrared transmitter or receiver taken by a person is obscured by objects or cloths as the infrared wave cannot penetrate opaque materials [123]. Systems using ethanol sensors to track alcohol-based hand rubs cannot sense HCWs' handwash events [77]. Systems solely relying on motion sensors (ie, without user identity) cannot provide information on who enters or exits patient rooms. Other systems also suffer from reflected signals, signal noise, and interference. Moreover, the algorithms used in these systems may introduce a variety of errors. An example is that machine learning algorithms used to recognize HCWs' compliance with WHO 6-step hand hygiene techniques can generate incorrect classifications [110]. In some extreme cases, these algorithms may not correctly recognize any individual steps and provide an entire sequence of erroneous predictions. Thus, both hardware and algorithm limitations need to be considered when implementing hand hygiene monitoring systems, and effective validation of an electronic hand hygiene monitoring system is required to identify associated technical issues.

System accuracy is also influenced by geometric constraints. To protect patient privacy, studies may attach a curtain in front of cameras [36] or point them toward nonsensitive regions only (handwashing sinks and sanitizer dispensers) [38], which may not allow observation of all hand hygiene opportunities and events and further affect system accuracy. Furthermore, systems based on wearable devices are restricted by device position. For example, recent studies have relied on sensor armbands to detect hand hygiene quality; however, their system accuracy is greatly affected by the actual armband position on the arm [110].

Data Integration

The use of multiple types of sensor data and system records raises new challenges for data integration. Systems use multiple sensors to collect more reliable, accurate, and useful information required for hand hygiene monitoring; however, sensor data fusion comes with problems and issues. One of the most common issues is sensor registration and calibration, as individual sensors have their own local reference frames [124]. Studies applied varying technologies to convert different data from multiple sensors (eg, IMU and sEMG) into one reference frame and starting time, including network time protocols, event-based synchronization methods, and their combination [125,126]. During data fusion and calibration, diverse formats of sensor data could also generate noise and ambiguity, resulting in competitive and conflicting errors, and adding redundancy of sensor data is one of the solutions to increase system reliability [124]. Other issues with multiple sensor data include granularity, timescale, and frequency [124].

Integrating hand hygiene data observed by different systems is another challenge. To increase result accuracy and credibility, studies might use multiple complementary systems to monitor hand hygiene compliance or quality among the same group of HCWs. However, the metric for each observation method was different, and a lack of correlation with their results raised concerns regarding data validity [32]. In addition, different data and result formats raise issues of data integration and require conversion. Moreover, systems could simultaneously observe hand hygiene compliance and quality; however, the means to store and retrieve the records of compliance rate and quality are unclear [41,52,68-70].

Privacy and Confidentiality

Privacy and confidentiality are two other major concerns associated with electronic hand hygiene monitoring systems. Privacy concerns are known to influence HCWs' attitudes toward electronic hand hygiene monitoring systems [19]. Some HCWs perceive these systems as an invasion of their privacy and a pretext for constant surveillance of their daily activities, which makes HCWs distrust these systems and refuse to change their hand hygiene behaviors [121]. Electronic hand hygiene monitoring systems also create special challenges regarding patient privacy [127]. Studies using video cameras to monitor all 5 moments of hand hygiene would require constant video surveillance of patients and patient rooms, resulting in violation of patient privacy [26]. However, limited studies have mentioned patient privacy protection before implementing electronic hand hygiene systems. Moreover, constant surveillance through electronic hand hygiene monitoring systems might raise legal issues, resulting in systems that are unpractical in health care settings, especially when involving cameras and microphones.

The continuous collection of personal data in unprecedented volumes also raises data security concerns [128]. During data collection and storage, users' personal information can be exposed to unauthorized third parties, and the collected data can also be modified or altered through communication protocols (eg, Wi-Fi and Bluetooth) [128]. Furthermore, use scenarios of the collected data are another noticeable concern in hand hygiene monitoring systems for HCWs. Ellingson et al [122] noted that HCWs were worried about the potential use of adherence data for punitive purposes. Thus, an efficient communication mechanism should be established to provide information to HCWs on what data will be collected and stored and how data will be used [121].

Potential Risks

HCWs may face some potential risks caused by electronic hand hygiene monitoring systems. One potential risk is UV-related skin and eye damage caused by UV lamps, which are used to detect HCWs' hand hygiene quality [129,130]. Efficient preventive measures should be placed to protect HCWs' safety and control their daily exposure under a threshold limit of 3.0 mJ/cm^2 [129]. Wearable sensors have gained popularity to assess HCWs' hand hygiene quality, especially wristwatches. However, wearing rings, wristwatches, and bracelets could cause hand contamination [131]; therefore, it is challenging to use wristwatches to monitor hand hygiene procedure compliance, as it can possibly defeat the purpose. Moreover, Ward et al [26]

noted that during the demolition and installation of monitoring systems in health care, the released particulates such as mold or fungus might increase the risk of infection.

Another risk of deploying electronic hand hygiene systems is radio-frequency interference (RFI) with medical devices. RFI, known as a subset of electromagnetic interference, has been reported to cause medical device failure because of interference from various emitters of radio-frequency energy [132]. Badizadegan et al [133] reported that RFI could also result in erroneous laboratory results. Specifically, van der Togt et al [134] noted that RFID might induce potentially hazardous incidents in medical devices. To prevent RFI-associated medical device failures, system designers and device manufacturers should ensure conformance with current RFI standards, and on-site electromagnetic interference tests are required during implementation [132].

Usability

Another challenge for implementing electronic hand hygiene monitoring systems in health care is usability, as the technology may interrupt HCWs' daily workflow to ensure the proper functioning of systems. These usability problems consist of hardware and information delivery. Conway et al [121] summarized hardware-associated usability problems of compliance monitoring systems, including wearable tags (1) as heavy, bulky, and difficult to use; (2) requiring battery power, but batteries are not durable with frequent battery failures; and (3) requiring HCWs to wear them in certain positions. Other usability problems, such as limited sensing range and angles, require HCWs to change their behavior to ensure that systems work properly [77].

Similarly, usability issues also exist when delivering HCWs' hand hygiene performance information. For hand hygiene compliance monitoring, systems use different types of instant prompts (eg, visual reminders, auditory reminders, vibrations, face-to-face feedback, and olfactory stimulus) to remind HCWs regarding missed hand hygiene opportunities; however, these prompts are associated with several usability problems. For example, Dyson et al [77] noted that systems using visual prompts with a red light could cause patient anxiety. Regarding instant prompts for inadequate hand hygiene quality, most systems are designed for medical training purposes, and thus, efficient delivery of instant feedback to HCWs about hand hygiene quality and integrating these systems into their daily routines are still open challenges.

Associated Costs and Infrastructure Improvements

Implementing an electronic hand hygiene monitoring system in health care facilities comes with high costs and infrastructure improvements [19,26,121]. Using electronic systems first requires expenditure on equipment and installation costs, which vary with the selected systems [19,26,121]. Morgan et al [59] estimated that the installation of electronic dispenser–assisted systems in a 15-bed intensive care unit requires a cost between US $30,000 and US $40,000. Another study installed 21 video cameras in the hallways and patient rooms of a 17-bed intensive care unit, costing US $50,000 [38]. For community settings, installing a complete set of electronic hand hygiene monitoring systems is not realistic. Instead of fixing sensors in the environment, studies attached wearable sensors to HCWs or embedded sensors into soap bars to track HCWs' hand hygiene events from their daily routines, which are more scalable and economical.

Except for expenditures on equipment and installation costs, maintenance and personnel costs represent a larger part of system-associated costs. Maintenance costs include system updates, hand rub and soap supplies, an increase in monitored HCWs, and replacement of batteries and defective devices [19]. For in-house systems, technology does not guarantee accurate measurements and requires continuous iteration developments, resulting in maintenance costs and increased personnel needs. Application-assisted direct observation and camera-assisted observation with human auditors are associated with high personnel costs, as these systems require in-house or remote auditors to continually observe hand hygiene opportunities and events.

The installation of electronic hand hygiene systems may disrupt physical infrastructure and require infrastructure improvements. Conway et al [121] noted that infrastructure improvements comprise existing dispenser replacement and fixed hard wiring. As wireless network infrastructure also dramatically affects the system performance, it should be arranged and updated when deploying such systems in health care facilities with outdated network infrastructure.

Performance Feedback

An important but sometimes overlooked aim of deploying electronic hand hygiene monitoring systems in health care settings is to provide educational interventions to HCWs and improve their practices. The intervention methods used in the included studies comprised instant prompts and periodic summaries.

To remind HCWs about missed hand hygiene opportunities, systems may provide instant prompts when noncompliance is detected. Instant prompts comprise visual reminders, auditory reminders, vibrations, face-to-face feedback, olfactory stimuli, and their combinations. To improve HCWs' hand hygiene quality, systems also provide instant prompts when detecting hand hygiene events with inadequate quality. Instant prompts include reminding HCWs about missed steps and disordered sequences of the WHO 6-step hand hygiene techniques and visualizing unclean areas from recorded UV test images. Periodic summaries are also widely adopted to improve HCWs' hand hygiene compliance and quality. Systems deliver periodic summaries to HCWs through reports, dashboards, games, notice boards/monitors, face-to-face feedback, and their combinations.

The included studies also delivered hand hygiene feedback by combining both instant prompts and periodic summaries. For example, Ellison et al [51] adopted auditory reminders as instant prompts and delivered periodic summaries through specific monitor screen savers to remind HCWs of hand hygiene compliance.

Nevertheless, each instant prompt type is associated with specific drawbacks. For visual reminders, Dyson et al [77] noted that red light light-emitting diodes (LEDs) on badges might

cause patient anxiety, so the color of badge LEDs should be adjustable and provide an option to disable the LEDs when necessary. Regarding auditory reminders, Baslyman et al [72] noted that sending audible alerts during the night is not acceptable as most patients are sleeping. Face-to-face feedback is associated with the Hawthorne effect, which causes different hand hygiene behaviors from their daily routines [30]. Using unpleasant odors is also not suitable for most health care facilities as they may cause physical discomfort.

Regarding periodic summaries, designing understandable periodic summaries for HCWs with different educational backgrounds is a challenge [121]. Conway et al [48] noted that HCWs or managers might have difficulty reading and interpreting periodic reports with charts. Efficiently disseminating collected information to HCWs and keeping them informed is challenging as well, as many HCWs have reported never or inconsistently receiving their performance information [48]. Moreover, ensuring that periodic summaries are used to drive hand hygiene improvement instead of punishment is another challenge. Hand hygiene improvement might be short-lived and moderate without HCWs' engagement, constant feedback delivery, detailed action plans, and leadership support [121].

By constantly delivering feedback to HCWs and educating HCWs and medical students on the importance of hand hygiene and the correct procedures, HCWs are likely to improve their hand hygiene techniques and habits. In Multimedia Appendices 3 [53,66,67,77,79,89,98,111], 4 [35,38,39,44,48,51,79,106], and 5 [30,51,88,89], we summarize the performance improvements of HCWs in studies that implemented instant prompts, periodic summaries, or their combinations. However, HCWs have diverse feedback needs. For example, Conway et al [121] and Levchenko et al [89] noted that most HCWs prefer instant prompts rather than periodic summaries, and their compliance rates increased immediately after receiving instant prompts. Nevertheless, Levchenko et al [89] also mentioned that a few HCWs improved their compliance only after they reviewed their individual results.

Implications

Owing to the high level of heterogeneity of the included studies, it is difficult to compare and analyze data across studies. A noticeable difference across the included studies was the variety of system metrics. To generate quantitative analyses, a high degree of standardization is required. Thus, standardized metrics across different hand hygiene monitoring systems need to be established based on system hardware limitations and WHO recommendations. For instance, the number of individual steps of the WHO 6-step hand hygiene techniques can be set to 9 in line with the WHO guideline as steps 3, 6, and 7 (shown in Figure 2) require repeats for both hands.

Given the recent advancements in sensing technologies, hand hygiene monitoring systems can adopt previously unused technology infrastructure or sensors to monitor HCWs' hand hygiene performance. For example, the aforementioned systems require a dedicated device being carried by HCWs to trace their indoor locations. Li et al [135] achieved device-free indoor location tracking by using commodity Wi-Fi, which has been installed in most health care facilities. Conversely, hand hygiene monitoring systems can apply new algorithms to improve their system accuracy. For example, previous studies adopted a hidden Markov model to classify the individual steps of 6-step techniques or smooth classification results, which assumes that HCWs will perform hand hygiene procedures according to predefined orders. However, once this assumption is relaxed, the performance of these systems dramatically drops [69]. Instead, classification results smoothed by change point detection algorithms (eg, E.Divisive [136]) might ease the performance decrease.

Hand hygiene monitoring systems and collected data can also be used to solve other hand hygiene–related issues. For example, systems detecting surface coverage of fluorescent substances could be considered as an alternative method to validate the efficacy of newly proposed hand hygiene techniques instead of microbiological tests, as fluorescent substances could highlight the hand surface areas that are adequately disinfected with acceptable accuracy [120]. Similarly, studies have used hand hygiene behavior data to monitor participants' levels of dementia, Alzheimer disease, and obsessive-compulsive disorder [137,138]. Furthermore, hand hygiene compliance history has been used to simulate the transmission of HAIs in health care settings [139].

Limitations

This study has several limitations. Some relevant studies may have been missed because of the keywords and databases chosen for the search query. Furthermore, some relevant studies may not have been included if they were not published in English, were outside the specified time frame, or did not provide adequate technical information.

Specifically, we included all types of studies regardless of their maturity, as it helps summarize the latest technological developments in electronic hand hygiene monitoring systems. However, early-stage or preliminary studies or methodology studies may present incomplete data or a lack of results. Owing to the heterogeneity of the studies and sparse metrics, we could not conduct a meta-analysis for the study population, system accuracy, and intervention effectiveness. In addition, because of the significant heterogeneity, we could not evaluate the risk of bias for each study using standardized automation tools and assess the certainty of the included studies.

This review describes different technologies for hand hygiene monitoring. Nevertheless, since we adopted the narrative approach to synthesize the outcomes rather than a meta-analysis, we did not assess the risk of bias because of missing results.

Conclusions

Our review provides an overview of the latest technological developments in electronic hand hygiene monitoring systems that measure compliance or quality. Systems utilize application-assisted direct observation, camera-assisted observation, sensor-assisted observation, and RTLS to monitor HCWs' compliance rates. For quality monitoring, systems either measure compliance with the WHO 6-step hand hygiene techniques or detect surface coverage or illumination reduction of fluorescent substances. Despite the technologies used in these

systems, we identify system-associated issues and challenges, including system accuracy, data integration, privacy and confidentiality, potential risks, usability, and associated costs and infrastructure improvements. Owing to the narrative approach adopted in these studies, more research is required to establish standardized metrics to measure system performance differences among electronic hand hygiene monitoring systems. With sensing technologies and algorithms continually advancing, more research is needed on their implementation to improve system performance and address other hand hygiene–related issues.

Abstract

Data integration, the processes by which data are aggregated, combined, and made available for use, has been key to the development and growth of many technological solutions. In health care, we are experiencing a revolution in the use of sensors to collect data on patient behaviors and experiences. Yet, the potential of this data to transform health outcomes is being held back. Deficits in standards, lexicons, data rights, permissioning, and security have been well documented, less so the cultural adoption of sensor data integration as a priority for large-scale deployment and impact on patient lives. The use and reuse of trustworthy data to make better and faster decisions across drug development and care delivery will require an understanding of all stakeholder needs and best practices to ensure these needs are met. The Digital Medicine Society is launching a new multistakeholder Sensor Data Integration Tour of Duty to address these challenges and more, providing a clear direction on how sensor data can fulfill its potential to enhance patient lives.

(J Med Internet Res 2021;23(11):e34493) doi:10.2196/34493

KEYWORDS

digital measures; data integration; patient centricity; utility

Introduction

Data integration has been defined as "...the technical and business processes used to (aggregate and) combine data from multiple sources to provide a unified, single view of the data" [1]. In practice, this means building bridges across different sources of data, to create an integrated data set that enables you to ask bigger questions or new questions (ie, integration followed by utilization) [2].

Data integration has been a force for innovation and scaling in many technological fields, helping new products become part of our everyday lives. Why do your new headphones work with your phone? Cross-industry collaboration on standards fueled the growth of Bluetooth from its initial invention at Ericsson in the late 1990s to one of the most prevalent current-day

technologies [3], incorporated into an estimated 5 billion new devices in 2021 [4]. Love that your credit card works practically everywhere, including internationally? This would not be possible without the Payment Card Industry Data Security Standard (and associated Security Council), which has been a globally accepted standard since 2004 [5]. Trying to get home the fastest way? The apps and services that help us plan and navigate our journeys rely on the General Transit Feed Specification [6], which began in 2005 as a collaboration between Google and the TriMet transport agency and is now a global standard driving the utilization of transit data [7]. All of these examples underline not only the practical impact of successful data integration, but also the critical role of multisector collaboration in achieving success.

Where is the new field of digital health, and sensor data in particular, in its data integration journey and what needs to be done to move it forward?

The Digital Medicine Society (DiMe), a nonprofit organization dedicated to advancing the safe, effective, ethical, and equitable use of digital medicine to optimize health [8], will examine these questions and more as part of a new Sensor Data Integration Tour of Duty. The tour will convene multistakeholder experts from Amazon Web Services, Evidation Health, the Food and Drug Administration (FDA) Center for Drug Evaluation and Research (CDER) and the Center for Devices and Radiological Health (CDRH), Human First, the Institute of Electrical and Electronics Engineers, Medable, the Moffitt Cancer Center, Oracle, Open mHealth, Savvy Cooperative, Takeda, and the United States Department of Veterans Affairs. The Sensor Data Integration Tour of Duty will build off other initiatives like The Playbook [9] in advancing the adoption and utility of digital medicine tools. In this paper, we will describe the current state of sensor data integration in health care, examine the importance of sensor data integration in achieving the promise of digital health to improve clinical research and patient care at scale, and offer a vision of what overcoming these challenges and continuing progress will enable.

Why Is Sensor Data Integration Important?

In the world of health care, examples of data integration can be found across the drug development and care delivery continuum:

- Modeling and understanding complex disease systems is typically only possible by considering and integrating a wide range of relevant data sources [10,11];
- Data integration supports translating observations from preclinical models to studies with human subjects and is common in early phase drug discovery [12,13];
- Similar data sources combined across different studies create meta-studies to increase statistical power to detect differences and improve the generalizability of results [14,15];
- Bridging clinical to real-world evidence studies aids the translation of observations from clinical development to the market. Examples include converting an outcome used in a clinical trial to deployment to support reimbursement [16] or treatment [17], or comparing error from research or clinical-grade and consumer-grade sensors to better validate large-scale observations [18].

Data integration is ubiquitous in digital health, but the definition above highlights three critical considerations pertaining to sensor data from digital health products:

- Solutions to sensor data integration challenges will be found in both “technical and business processes”;
- “Aggregating and combining data from multiple sources” will provide the critical context for sensor data to drive a learning health care system [19];
- Creating a “unified, single view of the data” will allow the use and reuse of trustworthy data to make better and faster decisions.

Sensor data (ie, data collected by wearable devices, smartphones, and other sensor-equipped connected digital medicine products [20]) is not a silver bullet. We cannot develop new sensor-based measures without combining data from different data sources [21,22], and we cannot deploy those measures without contextualization [23,24].

When we develop a sensor-based digital measure, establishing that it is fit for purpose in a given population involves cross-referencing with clinical and behavioral anchor data to demonstrate accuracy and validity [20,25]. As a therapy moves from clinical development into the hands of patients, it is also critical that clinical outcomes are integrated with real-world data, and that researcher stakeholders and other decision-makers such as payers and clinical policy makers can access and assess those data.

To support utilization and full patient value, health care providers and hospital administrators making treatment decisions all need access to the sensor data and digital measures captured during care and need to be able to digest and infer the same conclusions. Similarly, participants, investigators, statisticians, heads of medical affairs, or regulators need those data to be contextualized and appropriately presented to them, such that they are able to draw insights and value.

Currently, we are far from achieving this potential to improve lives, and it has been claimed that limitations in data integration and utilization are the primary rate limiter [26,27]. Improving lives is always at the front of our minds, making it worthwhile to think about how these tools and applications “look” from the patient’s perspective. Data integration should minimize additional burden caused by management and assessment tools to patients already burdened by their condition(s). Widespread adoption will require interfaces that provide immediate value and are simple, interactive, and intuitive. No longer should patients ask: why does my health care provider not have access to all relevant information? Why should I have to perform the same test in multiple trials, and why do they all have separate apps? I think this data is important; how do I share it with my doctor? Achieving truly integrated continuous care is not possible without effective data integration [28].

What Are the Key Issues?

There are several specific technical hurdles that get in the way of effective data integration, including the plethora of formats [29,30] and the corresponding lack of consensus around common metadata standards [14,26], although progress is being made [31]. Perhaps more worrisome is the fact that permissioning and consent often exclude integration and exploration [32], and massive gaps in digital health research remain regarding data rights and governance [33,34].

Yet, perhaps the biggest hurdles are cultural adoption, that is, effective incentivization to share data (within and across organizations) and make it easier to integrate [35-37]; recognition that data integration, while perhaps not a glorious pursuit, is central to scaling any digital health tool [38]; and lack of a unified signal from clinical (and other) stakeholders that would enable vendors to address needs around data integration [39,40].

Data integration for digital health, and for sensor data specifically, is in the early phases, and we have yet to see the kind of progress that has been made in other data-heavy health fields (eg, genomics) [41-44]. Currently, no widely adopted data standards or repositories exist, and while progress is being made on the integration of other data types (eg, electronic health records [EHRs], molecular data, patient reported outcomes), we see limited progress around sensor data specifically. This presents an opportunity to provide an early framework for sensor-based data integration and future success of this technology and avoid barriers in integrating other health care data (eg, EHRs). Moreover, understanding the legal and ethical consequences of sharing and integrating sensor data is at a nascent stage [45]. Recent work has shown that "the three most underrepresented areas of research into digital clinical measures were ethics, security, and data rights and governance" [33].

Where Has Progress Been Made?

Data integration has been recognized as a key driver of value creation in the private sector. In the past few years, we have seen companies invest to improve their data integration abilities through smaller venture capital deals [46], larger acquisitions [47], or internal initiatives like data42 from Novartis [48].

The public space has also been very active, perhaps helped by the inherently precompetitive nature of such work (ie, progress in data integration helps all parties, without any individual party needing to share proprietary data). Across research, clinical development, and in real-world practice, we are starting to see encouraging progress.

Research has been boosted by a number of initiatives, often focused on improving the awareness and availability of digital health data sets. Examples include meta-reviews of publicly available data sets in specific fields to accelerate integration and use of these data, as well as highlighting potential issues and shortcomings like demographic and ethnic underrepresentation [14]. Similarly, new repositories and portals are helping researchers connect and make their data available, such as Synapse and their Digital Health portal [49] or Zenodo [50]. Zenodo is a robust example as it grew out of OpenAIRE [51], a public project focused on enabling open science, demonstrating the concrete progress that specific projects can drive. The COVID-19 Evidence Accelerator [52] has also contributed to integration across the colossal volumes of data being developed as part of the pandemic response.

Clinical development and care delivery are also benefiting from public initiatives around data standards like Substitutable Medical Applications, Reusable Technologies on Fast Healthcare Interoperability Resources (SMART on FHIR) [53], which focuses on EHRs, or the Clinical Data Interchange Standards Consortium, which has had a substantial impact on the submission of evidence to regulatory bodies [54]. RADAR-base (Remote Assessment of Disease and Relapse) [55] grew out of the Innovative Medicine Initiative's RADAR-CNS (RADAR in Central Nervous System Disorders) [56] and aims to generalize data integration tools and best practices. These initiatives focus both on the integration of a range of devices and data sources, including mobile apps, and the utilization of the data through standardized visualization and analysis tools. Additional examples are the data integration centers in German medical universities, which have been set up to enable use of data across research and care [57]. Establishing these centers is a "meta-collaboration" of 4 consortia funded by the German Ministry of Education and Research. The recently formed Graphite Health is a nonprofit creating solutions for better health system interoperability [58].

Subsequent data utilization efforts bring data rights to the forefront. Who should be able to use the integrated data sets, and for what purpose? How can consenting and integration be structured such that innovation is not hindered and we remain within the ethical boundaries protecting patient rights? The FDA Sentinel Initiative combines claims data from multiple insurers, data from EHRs and patient reports provided by multiple health systems, and even some sensor technologies to evaluate the safety of medical products in the real world [59]. It combines a common data model with a distributed data architecture. Approved users are given secure, structured access to digital health data while respecting privacy and proprietary concerns. The Sentinel Initiative thus protects the data rights of organizations and individuals by keeping data with the holder while still allowing that data to be used for beneficial (eg, research) purposes. Similarly, the SELFIE Horizon 2020 consortium [60] also puts data rights at the forefront, recognizing that data integration is a key pillar of patient-centric, integrated, continuous care, while attempting to balance "preservation of individual privacy and the need for health data sharing" [28].

What does all this mean for sensor data? To achieve real impact on patient lives, sensor data needs to be integrated and contextualized with many other data types. Concerted progress must therefore be made across digital health, and sensor data must keep up with other sources of data like EHRs and break out of condition-specific efforts.

A Vision for the Future

Sensor data that is accessible, trustworthy, and relevant

Overcoming data integration challenges is immeasurably worthwhile. If we are to realize the potential of these new data flows to improve patient lives, then we will move toward integrated, holistic, and continuous care [28]. We will provide a smoother, less burdensome, and more valuable experience for patients. We will accelerate research and innovation, and enable the incorporation of data collected from everyday experiences to be included in decision-making. We will dovetail with more mature efforts across health care and do this using a collaborative, ethical, and multisector approach that will ensure that the potential of this data is realized for all stakeholders.

Imagine a situation where a diabetes patient is diagnosed with chronic obstructive pulmonary disease (COPD). The patient can log medication use via an app, and securely and privately funnel activity and sleep data from their user-friendly smartwatch into their doctor's health care systems. This data is of sufficient quality and accompanied by enough contextual information to facilitate the conversation between patient and doctor ("how have you been feeling?" becomes "I see you have been sleeping better; do you also feel better?"), and enable better shared decision-making. Exacerbations are tracked and alerts are shared with the patient's caregivers, which gives the patient peace of mind, and positive reinforcement to further improve this tool. The patient consents that researchers can access their data to improve the detection algorithm, and this data is later reused by a cross-industry consortium to drive qualification of a new COPD outcome.

In oncology settings, the potential is equally appealing. Passive biometric data provides additional data points on a patient's physical well-being, complementing patient reported outcomes and other data. Worrisome symptoms and activities can be triaged and brought to the clinical care team's attention. With just-in-time interventions, treatment toxicities can be mitigated or managed early, reducing the downstream costs of readmissions or emergency room visits. Simple interfaces that help patients track their data and symptoms would provide positive reinforcement to support behavior changes. Properly integrated, this data can also help industry partners such as pharmaceutical companies track outcomes and treatment toxicities in clinical trials.

A future where real-world data helps drive the health care system ultimately for preventive actions versus reactive care is a bright one. It is an environment where clinical research and care are not siloed and the data we generate can be referenced again and again, with appropriate consent, to reimagine a system informed by our physiology and how we feel, function, and survive.

Outlook

Integration and utilization of sensor data as part of the wider landscape of health-relevant data is still in its infancy, but progress is being made. Resolving current shortcomings will reduce burden to, and better serve, all stakeholders: patients, caregivers, clinicians, health care administrators, payers, industry partners, technology manufacturers, analytics companies, and researchers. The Sensor Data Integration Tour of Duty from DiMe includes experts from Amazon Web Services, Evidation Health, the FDA CDER and CDRH, Human First, the Institute of Electrical and Electronics Engineers, Medable, the Moffitt Cancer Center, Oracle, Open mHealth, Savvy Cooperative, Takeda, and the United States Department of Veterans Affairs. Our focus will be to examine stakeholder needs and define a framework for integrating sensor data and making it more useful for decision-making within the wider health care landscape.

Abstract

Background: There is huge variability in the way that individuals with tinnitus respond to interventions. These experiential variations, together with a range of associated etiologies, contribute to tinnitus being a highly heterogeneous condition. Despite this heterogeneity, a “one size fits all” approach is taken when making management recommendations. Although there are various management approaches, not all are equally effective. Psychological approaches such as cognitive behavioral therapy have the most evidence base. Managing tinnitus is challenging due to the significant variations in tinnitus experiences and treatment successes. Tailored interventions based on individual tinnitus profiles may improve outcomes. Predictive models of treatment success are, however, lacking.

Objective: This study aimed to use exploratory data mining techniques (ie, decision tree models) to identify the variables associated with the treatment success of internet-based cognitive behavioral therapy (ICBT) for tinnitus.

Methods: Individuals (N=228) who underwent ICBT in 3 separate clinical trials were included in this analysis. The primary outcome variable was a reduction of 13 points in tinnitus severity, which was measured by using the Tinnitus Functional Index following the intervention. The predictor variables included demographic characteristics, tinnitus and hearing-related variables, and clinical factors (ie, anxiety, depression, insomnia, hyperacusis, hearing disability, cognitive function, and life satisfaction). Analyses were undertaken by using various exploratory machine learning algorithms to identify the most influencing variables. In total, 6 decision tree models were implemented, namely the classification and regression tree (CART), C5.0, GB, XGBoost, AdaBoost algorithm and random forest models. The Shapley additive explanations framework was applied to the two optimal decision tree models to determine relative predictor importance.

Results: Among the six decision tree models, the CART (accuracy: mean 70.7%, SD 2.4%; sensitivity: mean 74%, SD 5.5%; specificity: mean 64%, SD 3.7%; area under the receiver operating characteristic curve [AUC]: mean 0.69, SD 0.001) and gradient boosting (accuracy: mean 71.8%, SD 1.5%; sensitivity: mean 78.3%, SD 2.8%; specificity: 58.7%, SD 4.2%; AUC: mean 0.68, SD 0.02) models were found to be the best predictive models. Although the other models had acceptable accuracy (range 56.3%-66.7%) and sensitivity (range 68.6%-77.9%), they all had relatively weak specificity (range 31.1%-50%) and AUCs (range

0.52-0.62). A higher education level was the most influencing factor for ICBT outcomes. The CART decision tree model identified 3 participant groups who had at least an 85% success probability following the undertaking of ICBT.

Conclusions: Decision tree models, especially the CART and gradient boosting models, appeared to be promising in predicting ICBT outcomes. Their predictive power may be improved by using larger sample sizes and including a wider range of predictive factors in future studies.

Introduction

Background

Tinnitus is the perception of a sound in the ears or head in the absence of a corresponding external sound source. It is very prevalent; it has been estimated that 10% to 15% of the adult population experiences tinnitus [1]. Various conditions are associated with developing tinnitus, such as ear disorders [2], exposure to loud noise, the presence of hearing loss, and increasing age [3]. Tinnitus experiences are highly heterogeneous in terms of how it manifests (eg, the types of sounds experienced, how individuals react to their sounds, the associated comorbidities, etc) and how individuals with tinnitus respond to treatment [4]. Although a majority of those with tinnitus are not bothered by their tinnitus, a significant number of people with tinnitus experience distressing tinnitus that affects their quality of life [5]. Nevertheless, tinnitus can affect people in different ways; the most common complaints include annoyance, irritability, fatigue, stress, sleep problems, and trouble concentrating [6]. Moreover, distressing tinnitus is often associated with an increased risk of anxiety and depression [7,8]. Various management strategies are used to help persons with tinnitus, including sound therapy (eg, hearing aids and masking); informational counseling for aiding people's understanding of tinnitus; and psychological approaches that address unhelpful thought patterns and reactions to tinnitus, such as cognitive behavioral therapy (CBT). Of these, CBT has the highest level of research evidence on reducing tinnitus distress [9,10].

Although the use of CBT is recommended in many tinnitus practice guidelines [11], it is seldomly provided. This is partly due to a lack of trained professionals who can offer CBT for tinnitus in an in-person format. To overcome this barrier, internet-based CBT (ICBT) was developed in the late 1990s [12]. In ICBT, the treatment strategies are offered to individuals with tinnitus as self-help materials that are provided over the internet together with professional guidance [13]. The feasibility and efficacy of such an approach have been demonstrated among several populations in Sweden, Germany, Australia, the United Kingdom [14], and, more recently, the United States [15,16]. In general, studies have shown that nearly 50% to 60% of those who undergo ICBT will experience a clinically significant reduction in tinnitus distress [17,18]. To date, no strong predictors of ICBT outcomes have been identified to indicate who is likely to benefit from ICBT interventions. The predictors of outcomes that were identified when examining the long-term (1 year) outcomes of ICBT in the United Kingdom were higher baseline tinnitus severity, more engagement with the ICBT program (ie, more modules opened), and higher self-reported satisfaction with the intervention [18]. To further explore predictors of outcomes, various univariate and multivariate (ie, logistic and linear) regression models were applied to a combined data set of multiple ICBT studies [19]. These linear and logistic regression models identified education level (linear regression: P=.01; logistic regression: P<.001) and baseline tinnitus severity (linear regression: P<.001; logistic regression: P<.001) to be significant predictor variables that contribute to reductions in tinnitus severity following an ICBT intervention. As per the linear regression model, participants who had received disability allowance showed a 25.30-point less (95% CI −46.35 to −4.24) Tinnitus Functional Index (TFI) score reduction when compared to those who did not have to work less due to tinnitus after adjusting for baseline tinnitus severity and participants' education levels.Although many other predictors, including age and tinnitus duration [19], were not identified to be significant under these linear models, these variables might have a nonlinear association with the response.

In the last 2 decades, various artificial intelligence and machine learning techniques have been developed and applied to hearing health data. Such approaches have mainly been used for disease profiling, although some studies have focused on the prediction of treatment outcomes [20-24]. It is noteworthy that the intervention trials in audiology and tinnitus research usually involve a few hundred participants and the collection of generally extensive data regarding demographic characteristics and clinical variables. Such a data set with many predictor variables may be best handled by exploratory data mining techniques, such as the use of tree-based models (eg, the random forest [RF] model). Such models tend to perform well even in the presence of multicollinearity among a large number of predictor variables, as these models decorrelate the variables [25]. For example, a recent study that examined various machine learning algorithms for predicting CBT treatment outcomes in the tinnitus population suggested that gradient boosted trees (area under the receiver operating characteristic curve [AUC]=0.89) have the best predictive power [21]. This study found that subjectively perceived tinnitus-related impairment, depression, sleep problems, physical health–related impairments in quality of life, the time spent on completing questionnaires, and educational level highly contributed to the model's predictions. However, no previous studies have examined the

application of artificial intelligence and machine learning techniques to ICBT outcomes in tinnitus research.

Objectives

To further explore outcome predictors for ICBT, this study aimed to examine the applications of various exploratory data mining techniques based on decision tree models. In particular, we wanted to (1) investigate which types of decision tree models were the most applicable to ICBT outcome prediction (ie, models with the best accuracy and predictive power) and (2) identify the most relevant predictive factors of ICBT outcomes by using the most appropriate decision tree models.

Methods

Study Design and Ethical Considerations

We included 228 participants who previously underwent ICBT for tinnitus and whose data were collected as a part of 3 separate ICBT trials [17,18,26] that were conducted from 2016 to 2018. This study was a secondary analysis of these ICBT intervention studies. Ethical clearance was obtained from the Faculty of Science and Technology Research Ethics Panel of Anglia Ruskin University (reference numbers: FST/FREP/14/478 and FST/FREP/14/478) and the East of England–Cambridge South Research Ethics Committee (reference number: 16/EE/0148) and Health Research Authority (Integrated Research Application System project ID: 195565).

Participant Characteristics

A heterogenous sample of individuals with tinnitus was obtained; thus, the sample represented typical tinnitus populations, as seen in Multimedia Appendix 1. The average age was 55.14 years (SD 12.92 years), and 98 out of the 228 (43%) participants were females. The majority of participants (154/228, 67.5%) had long-standing tinnitus with a mean duration of 17.68 years (SD 19.42 years). Of the 228 participants, 59 (25.9%) had completed high school education, 61 (26.8%) had an undergraduate degree, and only 30 (13.2%) had a postgraduate degree. Approximately 48% (109/228, 47.8%) of the participants experienced tinnitus in both ears, 26.8% (61/228) of them experienced tinnitus in 1 ear, and the others reported experiencing tinnitus in their head or in other locations. The majority (159/228, 69.7%) of participants did not wear hearing aids, and 25.4% (58/228) of them had sought tinnitus treatment previously.

Intervention

The study participants completed an 8-week ICBT intervention that was presented in a self-help format [13,27]. The intervention was administered by using a secure e-platform [28,29]. During this 8-week period, participants were presented with 2 to 3 learning modules that contained various elements of CBT that were specifically adapted for tinnitus, including applied relaxation, cognitive restructuring, and imagery. The digital materials were presented by using text, images, and videos. In addition, various exercises were presented in these learning modules to improve engagement.

Data Collection

The baseline data collection included an extensive questionnaire that focused on demographics and tinnitus-related and treatment-related information. Outcome data were gathered by using standardized primary and secondary self-reported questionnaires, which were administered before (baseline), during (weekly), and after the intervention. The primary outcome was a change in tinnitus severity, as measured by the TFI [30]. The secondary outcome measures included the Insomnia Severity Index [31] (a measure of insomnia), the Generalized Anxiety Disorder-7 [32] (a measure of anxiety); the Patient Health Questionnaire-9 [33] (a measure of depressive symptoms); the Hearing Handicap Inventory for Adults Screening version [34] (a measure of self-reported hearing disability); the Hyperacusis Questionnaire [35], which was used to assess the presence hyperacusis (ie, reduced tolerance to everyday sounds); the Cognitive Failures Questionnaire [36], which was used to assess cognitive functions; and the Satisfaction with Life Scales [37], which were used to assess global life satisfaction.

Data Analyses

Variables

The primary outcome variable (the dependent variable) in this study was a change in tinnitus severity. A 13-point reduction in TFI scores following the ICBT intervention was regarded as a clinically significant (successful) treatment outcome [30]. Significant differences in scores were assessed by using paired sample *t* tests. All tests were two-tailed, and significance was set to P=.05. There were 33 predictor variables selected, as outlined in Multimedia Appendix 2. These included the following:

- 7 demographic variables (ie, age, gender, education level, employment type, noise exposure, the presence of psychological conditions, and tinnitus that affects the ability to work)
- 15 tinnitus and hearing-related variables (ie, baseline tinnitus severity, tinnitus duration, how often tinnitus is heard, tinnitus location, 9 different types of tinnitus, tinnitus in which multiple tones are heard, and the presence of hearing loss)
- 4 treatment-related variables (ie, past treatment sought, tinnitus maskability, hearing aid use, and medication use)
- 7 clinical factors (ie, anxiety, depression, insomnia, hyperacusis, hearing disability, cognitive functions, and life satisfaction).

Decision Tree Models (Classifiers)

The data analysis focused on decision tree–based models, as they play an essential role in exploratory data mining and facilitate human decision-making by providing decision rules [38]. Despite their simplicity, decision trees usually exhibit high variance in their predictions and are not consistently robust. Given these issues, their powerful counterparts, such as the RF [39], gradient boosting (GB) [40], and extreme GB (XGBoost) [41], models were selected. For comparison, 6 decision tree models were used, namely the classification and regression tree (CART) [42], C5.0 [43], GB, XGBoost, AdaBoost algorithm

[44], and RF models. As the CART, C5.0, and RF decision tree models involve stratifying or segmenting the predictor space into a number of nonoverlapping regions [38], recursive binary splitting for classification via the Gini index was performed [45]. Many of these decision tree types have been applied to audiological data, and they were found to provide good results in previous studies [20-24].

Data Analysis Steps

Summary of Data Analysis Steps

The analyses were performed in 4 stages. First, the data were split into training and testing data, and the classifier models were trained on a data set before testing. Second, the six classifiers were applied to the test data to identify the most suitable models based on their performance evaluation. Third, the two best models were used to determine the predictors of ICBT outcomes. Fourth, the optimal CART decision tree model was used to identify the participants who were more (or less) likely to benefit from ICBT treatment. The steps are described in more detail below.

Step 1: Classifier Training

Prior to applying the decision tree classifiers, the entire data set was divided into the training (183/228, 80.3%) and testing (45/228, 19.7%) data sets. The training data set was used to develop the corresponding data mining model, while the testing data set was used to evaluate the model predictions. As the training data set was relatively small (n=183), a repeated 3-fold cross-validation was performed. This was not done for the CART model, for which the full training data set was used for model training. With this approach, each fold was given a chance to act as their own validation set to minimize the propensity of model overfitting. In total, 10 different models were created with several random initializations for each data mining method. Hyperparameter tuning for each of these decision models was performed, as required. For instance, when training the RF models, we explored a range of different numbers of predictors for the splitting at each tree node and their impact on the models' performance.

Step 2: Classifier Performance Evaluation

The trained models were evaluated (ie, by using the testing data set) in terms of their mean predictive accuracy, sensitivity (true positive rate), specificity (true negative rate), and AUCs. These were presented as means and SDs and based on the 10 replicated models for each data mining technique. The AUC is used as a measurement of model discrimination power. The optimal decision tree models were selected based on having the highest AUC value. In general, models with an AUC of 0.5 have no discriminatory power, models with an AUC of 0.7 to 0.8 are considered acceptable, models with an AUC of 0.8 to 0.9 are considered excellent, and models with an AUC of >0.9 are deemed to have outstanding discriminatory power (ie, the ability to identify patients with and without a disease or condition based on a new set of data).

Step 3: Predictors of ICBT Outcomes

Decision tree–based classifiers provide insights on different participant groups who show promising results following ICBT. After identifying the two most optimal models, the model-agnostic posthoc framework Shapley additive explanations (SHAP) was used for analyzing ICBT outcome predictors [46,47]. This framework facilitates model interpretations and identifies the most influential factors that result in successful ICBT outcomes (ie, a reduction in TFI scores following the ICBT intervention). SHAP measure the impact of variables and take into account variables' interactions with other variables. SHAP values indicate the importance of a feature and are calculated by comparing model predictions that account and do not account for a given feature. However, since the order in which a model sees features can affect its predictions, this comparison is done in every possible order, so that the features are compared in a fair manner.

Step 4: Identification of Participants Who Are Most Likely to Benefit From ICBT

The CART decision tree model was used to identify the participants who were the most (or least) likely to benefit from ICBT. In training, a minimum split of 20 and a max depth of 10 were used as the control parameters for the CART decision tree models. Tree pruning was conducted to reduce the overfitting in the CART decision tree models, although the best decision tree model remains the same even after pruning.

The data analysis was performed with R version 4.0.3 (R Foundation for Statistical Computing) software. The code is available in the GitHub repository for this study [48]. The data can be made available upon reasonable request.

Results

ICBT Effects

Undertaking ICBT significantly reduced tinnitus severity scores (t_{227}=16.37; P<.001) from a mean baseline severity score of 57.93 (SD 19.17) to a mean post-ICBT severity score of 34.22 (SD 22.78), as measured by the TFI. A clinically significant 13-point change in TFI scores was achieved by 150 of the 228 participants (65.8%) after the intervention.

Decision Tree Model Performance Evaluations

Table 1 contains the model evaluation information of all 6 decision tree classifiers that were based on the test data. Following training via the 3-fold cross-validation method, the mean accuracies of the six decision tree classifiers ranged between a minimum of 56.3% (the C5.0 model) to a maximum of 71.8% (the GB model). Model predictions showed variations in their sensitivity (range 68.6%-78.3%), specificity (range 31.1%-64%), and AUC values (range 0.52-0.69).

Table 1. Decision tree model evaluations.

Classification model	Accuracy (%), mean (SD)	Sensitivity (%; true positive rate), mean (SD)	Specificity (%; true negative rate), mean (SD)	AUC[a], mean (SD)
Classification and regression decision tree	70.7 (2.4)	74 (5.5)	64 (3.7)	0.69 (0.001)
C5.0	56.3 (1.1)	68.6 (1.9)	31.1 (6.3)	0.52 (0.001)
Gradient boosting	71.8 (1.5)	78.3 (2.8)	58.7 (4.2)	0.68 (0.02)
Extreme gradient boosting	65 (4.1)	77.9 (8.7)	39.2 (6.6)	0.62 (0.08)
AdaBoost algorithm	63.6 (3.2)	73.3 (5.2)	44 (7.8)	0.58 (0.05)
Random forest	66.7 (3)	75 (6.1)	50 (7.2)	0.60 (0.01)

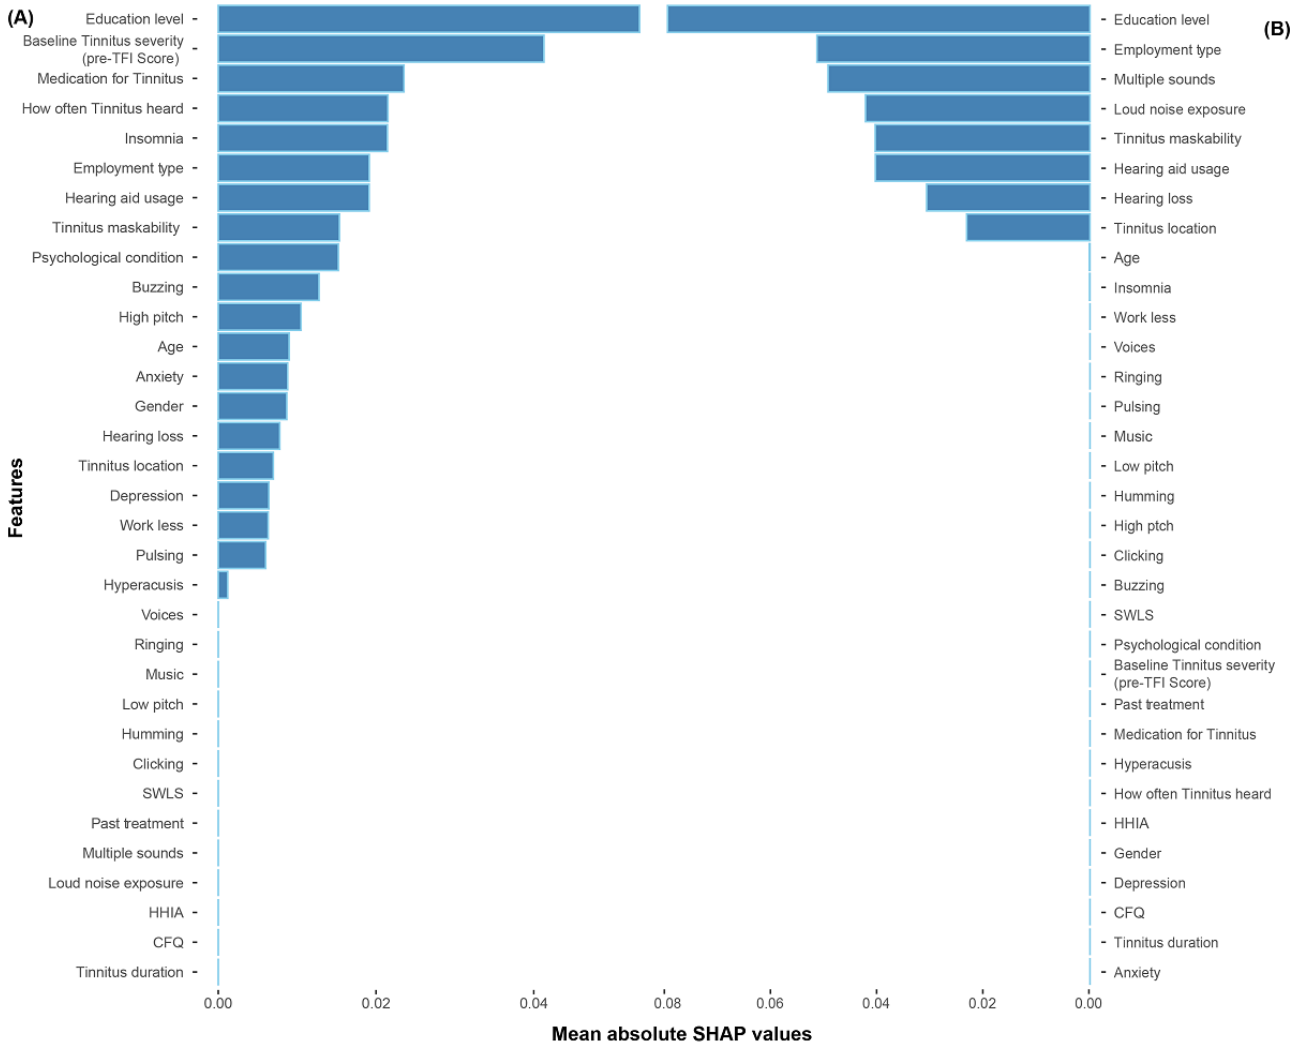
[a]AUC: area under the receiver operating characteristic curve.

None of the six models were considered robust, as their AUC values were below 0.80. As the CART and GB classifiers were found to be superior compared to the other four models when considering all evaluation measurements as a whole (accuracy, sensitivity, specificity, and the AUC), these two models were further examined.

Feature Importance

The SHAP framework was applied to the CART and GB classifiers to estimate each predictor variable's importance in predicting ICBT outcomes (Figure 1). Variables with larger SHAP values are relatively more important in terms of their contributions (ie, feature contribution) to a model prediction. Education level (average SHAP values: GB model=0.053; CART model=0.079) was identified as the most important influencing factor in both models. Although they were not ranked in the same order, the other features that ranked within the top 10 features for both models were employment type (average SHAP values: GB model=0.019; CART model=0.051), hearing aid usage (average SHAP values: GB model=0.019; CART model=0.040), and tinnitus maskability (average SHAP value: GB model=0.015; CART model=0.040). The differences between these models were that the GB model ranked baseline tinnitus severity (average SHAP value=0.041), how often tinnitus is heard (average SHAP value=0.022), insomnia (average SHAP value=0.021), the use of medication for tinnitus (average SHAP value=0.024), and the presence of a psychological condition (average SHAP value=0.015) among the top 10 features, whereas the CART model ranked the presence of multiple sounds (average SHAP value=0.049), loud noise exposure (average SHAP value=0.042), and tinnitus location (average SHAP value=0.023) as key features.

Figure 1. Feature importance based on the mean absolute SHAP values from (A) the best gradient model and (B) from the best classification and regression tree decision tree model. These SHAP values represent the absolute change in log odds. Relatively higher importance is indicated with larger SHAP values. CFQ: Cognitive Failures Questionnaire; HHIA: Hearing Handicap Inventory for Adults; SHAP: Shapley additive explanations; SWLS: Satisfaction with Life Scales; TFI: Tinnitus Functional Index.



Figures 2 and 3 present the effect that each feature category had on the outcome variable, as decided by the best GB and CART decision tree models. Features' impacts on the two classes are presented in 2 separate plots for each feature ("1" indicates the effect on the successful treatment class and "0" indicates the effect on the unsuccessful treatment class). Positive SHAP values in each successful treatment group indicate a higher log odd of achieving a 13-point or more tinnitus severity score reduction (ie, on the TFI for a given category) for a feature and vice versa. This log odd is relative to the training set average.

Figures 2 and 3 both depict positive SHAP values for the participants who had a vocational training degree or a master's degree (or above), those with higher levels of education (postgraduate degrees), and those who were using a hearing aid in only 1 ear. As per the GB model, this reduction was more likely to occur for participants with insomnia (scores of 14 or less on the Insomnia Severity Index), a psychological condition, and tinnitus that can be described as a buzzing sound and for participants who had median baseline tinnitus severity scores (ie, pre-TFI assessment) of >55.2.

Figure 2. The best gradient boosting model–based feature effects. Each graph represents a feature and their corresponding SHAP values. Plots labeled with "1" illustrate the impact that each feature has on achieving a successful treatment outcome (a 13-point or more reduction in TFI score). CFQ: Cognitive Failures Questionnaire; HHIA: Hearing Handicap Inventory for Adults; SHAP: Shapley additive explanations; SWLS: Satisfaction with Life Scales; TFI: Tinnitus Functional Index.

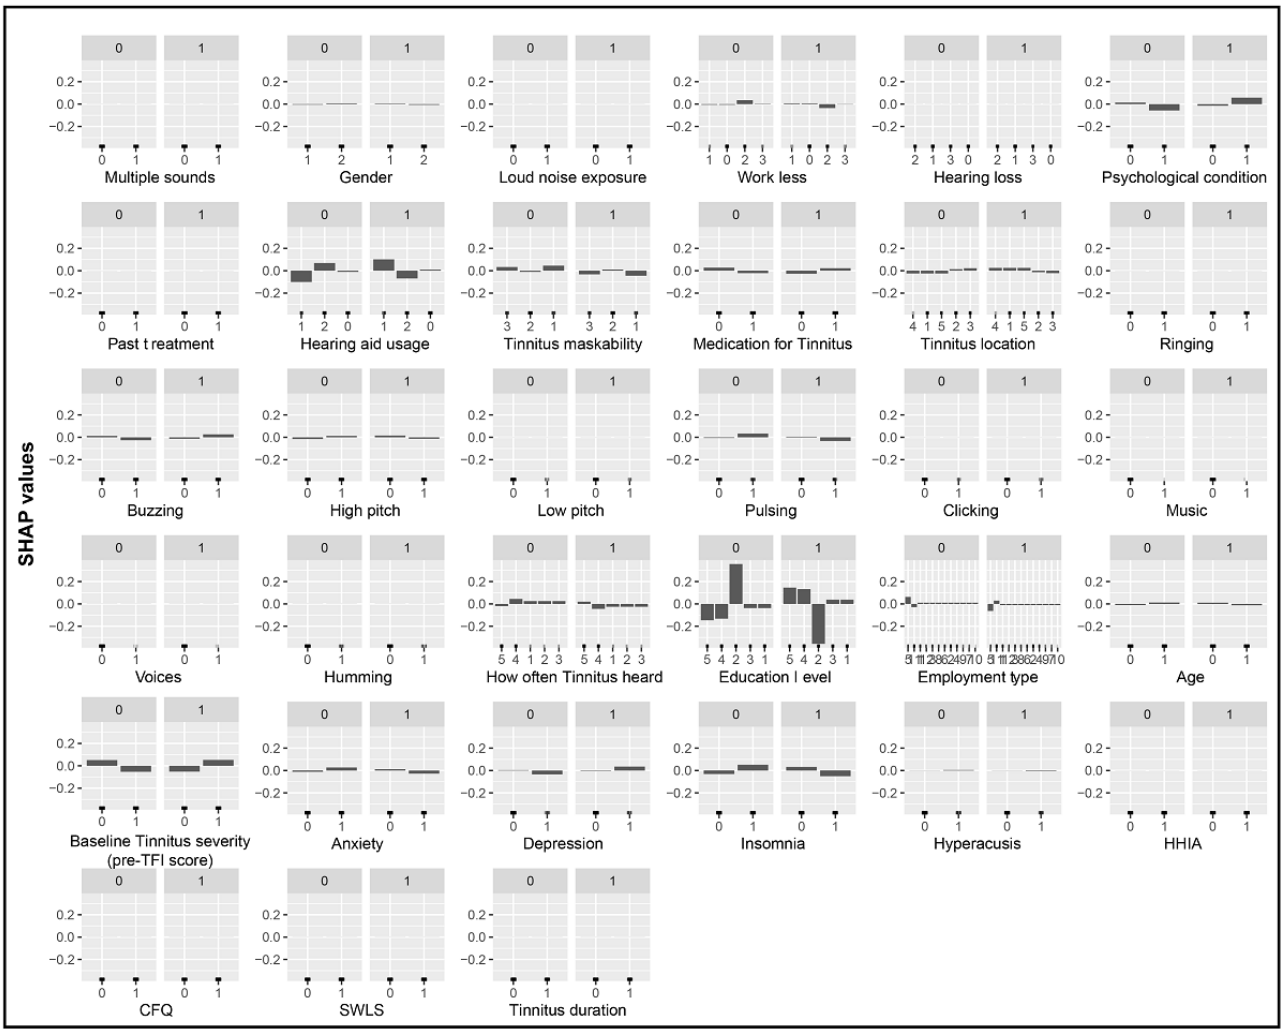


Figure 3. The best classification and regression tree decision tree model feature effects. Each graph represents a feature vs. corresponding SHAP value. Plots with "1" represent the effect that each feature has on achieving a successful treatment outcome. CFQ: Cognitive Failures Questionnaire; HHIA: Hearing Handicap Inventory for Adults; SHAP: Shapley additive explanations; SWLS: Satisfaction with Life Scales; TFI: Tinnitus Functional Index.

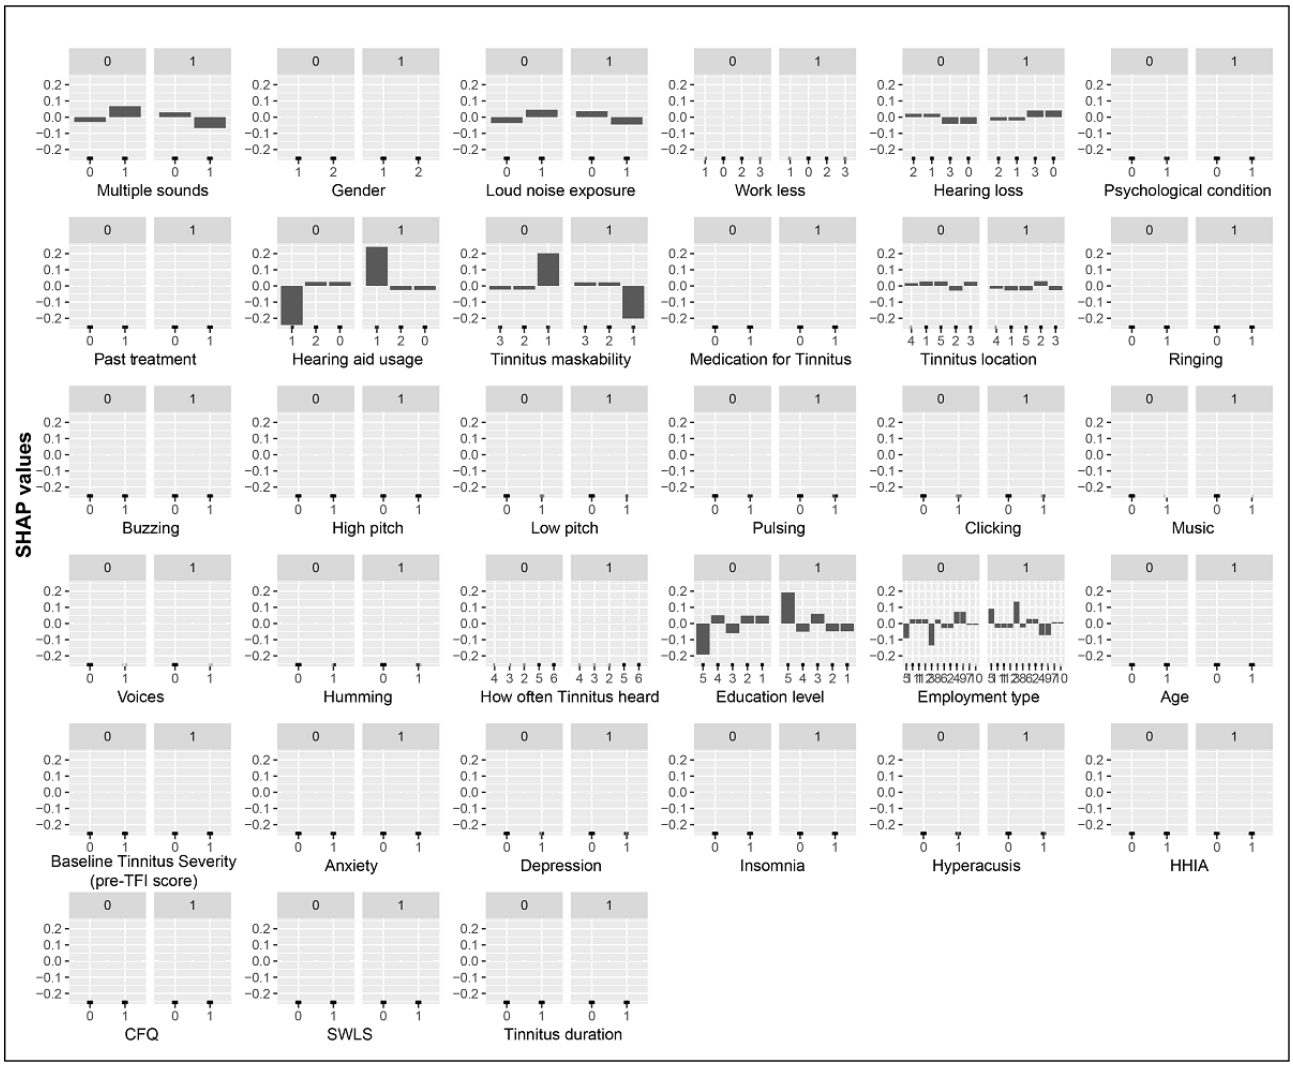
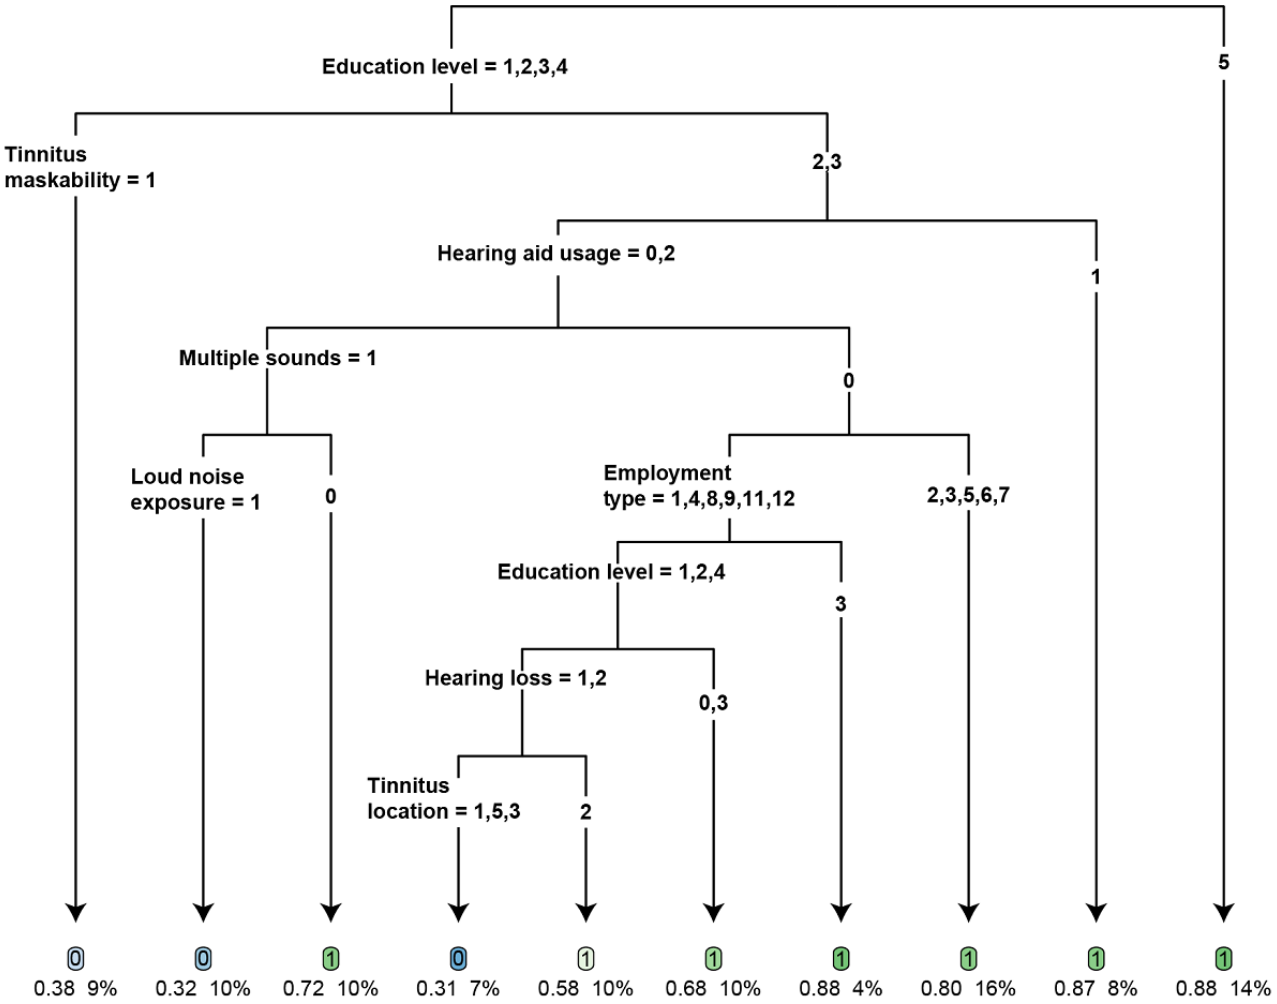


Identification of Participants Who Are Likely to Benefit From ICBT

Figure 4 presents the final decision tree model, which has 10 nodes. A detailed explanation is provided in Multimedia Appendix 3. In this model, homogenous groups were formed by creating binary splits at each node. The decision nodes represent the treatment groups (either 0 or 1) that were the most likely to achieve tinnitus severity reduction, and the decisions in the tree were based on the characteristics of each group. These characteristics were represented by each branch (based on their corresponding feature values) of the tree. This model showed that higher education level, tinnitus maskability, hearing aid usage, the presence of multiple tinnitus sounds, loud noise exposure, employment type, the presence of hearing loss, and tinnitus location were important factors for determining treatment outcomes. The following participant groups had at least an 85% chance of achieving a TFI score reduction of 13 points or more:

- Participants with postgraduate education (master's degree or higher)
- Participants with an education level other than a master's level of education and poor tinnitus maskability (or only partial tinnitus maskability) and those who wore a hearing aid in 1 ear
- Participants with no tinnitus maskability or only partial tinnitus maskability; those who did not wear a hearing aid or used hearing aids bilaterally; those who did not hear multiple tinnitus sounds; and those with an occupation that could described as *professional*, *technical*, *skills based* (ie, skilled tradesman), *service related*, or *medical*

Figure 4. The best classification and regression tree decision tree model. The fitted tree has 10 terminal nodes (denote the decision criteria). The variable categories (please refer to Multimedia Appendix 2 for variable category labels) corresponding to each split are given at the top of each branch. Each terminal node contains the predicted treatment class ("1" indicates the successful treatment class and "0" indicates the unsuccessful treatment class), the percentage of subjects with successful treatment outcomes, and the percentage of participants with the given characteristics in the training set.



Discussion

The aim of this study was to explore predictors of outcomes in ICBT for tinnitus by applying 6 types of decision tree models to a combined data set of participants from 3 clinical trials. The key findings are discussed below.

Best Decision Tree Models

In this study, we applied 6 different decision tree models to ICBT data. Although none of the six models attained an excellent or outstanding status, the CART and GB models' discriminative power can be considered to be satisfactory, given the moderate sample size with just 33 predictive factors (features). This is consistent with a recent study that used 10 decision tree models to predict the outcomes of CBT for patients with tinnitus (N=1416) and found that the GB model with 26 predictive factors had the best predictive power; it had an AUC value of 0.89 [21].

Further work however is needed in this area to determine which models and how many vital factors may result in an optimal predictive model. A larger sample size would likely improve the results. However, we are not sure if just adding factors would be helpful. This is because Niemann et al [21] included 205 factors in their analysis, and of these, only 26 were helpful in achieving optimal results. Moreover, of the 26 factors, only a handful had the most considerable effect. For instance, only 1 factor (ie, tinnitus impairment in terms of loudness, frequency, and distress) resulted in an AUC of 0.79, only 3 features resulted in an AUC of 0.85, and only 8 factors resulted in an AUC of 0.85. These results indicate that including key factors with high predictive power may be a better approach than just adding all of the possible factors.

Predictors of ICBT Outcomes

Among the best decision tree models (ie, the CART and GB models), various factors were found to be critical predictors of ICBT outcomes. These included demographics (ie, education level, employment type, and the presence of a psychological condition), tinnitus and hearing-related factors (ie, baseline tinnitus severity, tinnitus location, how often tinnitus is heard, a buzzing type of tinnitus, tinnitus maskability, and hearing loss type), treatment-related factors (ie, hearing aid usage), and clinical factors (ie, insomnia). However, education level was the most notable predictor among these.

Participants who had a master's degree or above had an 88% chance of achieving a successful outcome. This is

understandable, as the ability to read, understand, and follow instructions is key for undergoing self-help interventions. However, it is likely that the way in which the materials were written may also have played a role. For instance, UK ICBT materials are written at a ninth-grade reading level [49], which may require higher literacy skills. However, these materials have been rewritten at a sixth-grade reading level and below [49] to ensure accessibility for those with lower education levels. More and more people, including those with lower education, are using the internet and participating in internet-based treatments, particularly due to the constraints that have been placed on health care during the COVID-19 pandemic [50-52]. In our sample, over 85% (198/228, 86.8%) of the participants had a below–master-level education. This highlights the need for making ICBT more accessible to increase the chances of achieving improved outcomes for those with lower education levels.

Baseline tinnitus severity was found to be another critical factor for predicting ICBT outcomes in the GB model. Our previous studies on 1-year outcomes [53] and our previous application of univariate and multivariate analyses to this study's sample [19] identified baseline tinnitus severity as a critical predictive variable. In the Niemann et al [21] study, tinnitus loudness, frequency, and distress, which were measured by using a visual analog scale, were found to be key predictive factors. Further, tinnitus distress, which was measured by using the German version of the Tinnitus Questionnaire (a tool that is comparable to the TFI in this study), was not found to be the key predictive factor. However, based on both clinical experiences and findings from many previous studies, baseline tinnitus severity is an important factor for determining treatment outcomes. The clinical factors depression and anxiety were among the key predictive factors in the GB model. A recent clinical trial conducted by Beukes et al [54], as well as the Niemann et al [21] study, determined that those with high levels of depression had a better chance of achieving success.

Although various other tinnitus and hearing-related variables could have played a role in determining the outcomes of ICBT, the predictive power of our models was relatively low based on the AUC values. Nevertheless, it would be useful for hearing health care professionals to examine these factors when deciding on the candidacy of self-help psychological interventions such as ICBT. Moreover, it would be useful for future studies to examine any additional factors (eg, health literacy) that may have a bearing on ICBT outcomes.

Study Limitations and Future Directions

Although this study is among the first to apply data mining models to ICBT data, it has several limitations. The sample size was limited, and this may have contributed to the low predictive accuracies of the models. The exploratory decision tree models worked better when including a large number of predictive factors. In this study, we only included 33 predictive factors in our models, and this may have limited the performance of our models. Further, we may have missed some important factors (eg, health literacy) that have a bearing on ICBT outcomes.

The inclusion and exclusion criteria that were used in the three trials from which our data were generated may have resulted in a sample with high tinnitus severity levels that may not be representative of the general tinnitus population. This may have also contributed to our limited key findings. Future studies could include more extensive samples of heterogeneous patients with tinnitus as well as all of the possible predictive factors that could help with improving our models' predictive power. Moreover, developing nonlinear classifiers with artificial neural networks and support vector machines could help with achieving higher prediction accuracies and should be examined in future studies.

In conclusion, tree models, especially the CART and GB models, appear to be promising in predicting ICBT outcomes. Future studies should be undertaken with larger sample sizes and include a more comprehensive range of predictive factors to improve their models' predictive power.

Abstract

Background: HIV disproportionately affects young Thai men who have sex with men (YMSM). Recent studies report a high incidence and prevalence of HIV among Thai YMSM. The Thai national guidelines have recommended pre-exposure prophylaxis (PrEP) since 2014 for key populations; free PrEP has been piloted since 2019. Smartphone-based mobile health (mHealth) interventions provide an optimal platform for innovative PrEP adherence interventions for Thai YMSM.

Objective: This study aims to adapt the P3 (Prepared, Protected, emPowered) app, developed with YMSM and transwomen in the United States to improve PrEP adherence and persistence for YMSM in Thailand. The app aims to provide daily adherence support and addresses gaps in staff available for large-scale PrEP rollout needed to see population-level effects of HIV prevention.

Methods: We conducted focus group discussions (FGDs) with YMSM and key informant interviews (KIIs) with PrEP care providers in Bangkok, Thailand, to investigate PrEP adherence facilitators and barriers, preferences for functions and features in mHealth apps among YMSM, and how to best adapt the P3 app to the Thai context. We conducted four FGDs with 4-8 participants per group and 15 KIIs.

Results: For FGDs, 23 YMSM participated with a mean age of 20 years (range 18-21), 96% (22/23) enrolled in full-time education, and all owned smartphones. The mean age of KII participants was 40 (range 26-60) years; most were state health service providers, with the majority being counselors (6/15, 40%) and physicians (6/15, 40%). Overall, the facilitators and barriers for PrEP adherence identified were similar to those of MSM and YMSM globally including the United States. Key themes included

general recommendations for improving mHealth apps in Thailand, such as presenting reliable information in an appealing format, minimizing privacy risks, and addressing connectivity challenges. Additional themes focused on P3 Thailand adaptations and were related to cultural and stylistic preferences, engagement strategies, and recommendations for new functions. To develop the adapted app, P3 Thailand, these findings were balanced with resource limitations resulting in the prioritization of minor modifications: changes in app esthetics (color scheme, iconography, and imagery) and changes in the presentation of information in two of the app's features. FGDs identified similar PrEP adherence facilitators and barriers to those already addressed within the app.

Conclusions: The core elements of the P3 app address major PrEP facilitators and barriers for Thai YMSM; however, changes to the app features, including stylistic presentation, were needed to appropriately customize the app to the Thai context. Given the similarities of facilitators and barriers for PrEP adherence globally, adapting existing PrEP mHealth solutions based on input from end users and key informants provides a promising approach. However, partnerships with local app designers and developers can improve the adaptation process and final product.

KEYWORDS

mobile health; young men who have sex with men; pre-exposure prophylaxis; adherence; mobile phone

Introduction

In Thailand, gay, bisexual, and other men who have sex with men (MSM) are disproportionately affected by HIV [1]. Studies conducted in Bangkok have identified a high HIV incidence and prevalence among MSM, with young MSM (YMSM) at a significantly greater risk of HIV infection than older MSM [2-4]. Examinations of data from YMSM aged 18-24 years enrolled in the Bangkok MSM Cohort Study (40.8%; n=712) between 2006 and 2014 found a baseline HIV prevalence of 21.2% and an overall HIV incidence of 7.4 per 100 person-years, a rate much higher than that for MSM of all ages (5.3 per 100 person-years) [3,4]. To address disparities in HIV infection among YMSM in Thailand, the implementation of novel behavioral and biomedical interventions that are culturally and developmentally appropriate, useful, and scalable are urgently needed [4,5].

Pre-exposure prophylaxis (PrEP), a combination drug containing tenofovir and emtricitabine taken once daily, is a safe and effective method for preventing transmission of HIV among MSM [6-8]. Owing to the high levels of efficacy found in PrEP trials, the Thai National Guidelines on HIV/AIDS Treatment and Prevention in 2014 were revised to recommend PrEP for key populations, including YMSM [9,10]. Since October 2019, a coverage scheme providing free PrEP for key populations, including YMSM, has been piloted in Thailand's National Health Security Office, with a view for future scale up [11,12]. Although PrEP availability is expanding rapidly for Thai YMSM, PrEP effectiveness is highly correlated with adherence, and evidence suggests poorer adherence among YMSM, including those in Thailand [7,13-16]. For example, two studies evaluating the Princess PrEP program, the first key population-led PrEP initiative in Thailand, found lower levels of PrEP adherence among MSM participants aged <25 years compared with those aged >25 years [13,14].

Smartphones provide an optimal platform for the delivery of an innovative PrEP adherence intervention in addition to other chronic medical conditions in adolescents because they are an integral part of their lives, including Thai YMSM [14,17-21]. There is growing evidence to support the improvement in self-management related outcomes in adolescents using electronic health interventions, in addition to user feasibility, acceptability, and satisfaction of such interventions [20,22,23]. Data collected by the Thai Red Cross AIDS Research Center (TRCARC) from 2015 to 2017 on the use of social networking sites by MSM aged >18 years and at risk of HIV (n=465) showed that users were satisfied with web-based service delivery primarily delivered through smartphones [24]. In addition, app-based HIV prevention interventions have shown high rates of acceptance among MSM, including YMSM, in high-income countries and have potential use in low-middle income countries [25-29]. On the basis of high smartphone use and findings from other study teams in Thailand and globally, app interventions are likely to be acceptable, help to overcome barriers to engagement with in-person interventions such as inconvenience, transportation, and stigma; and address challenges associated with medication, including PrEP adherence and other HIV prevention behaviors among adolescents, including YMSM in Thailand [13,14,17,22-24,30].

Rather than building de novo smartphone HIV prevention apps, there is growing support for adapting and building on existing evidenced-based platforms that share common behavior change goals, theoretical underpinnings, and features to maximize the potential for intervention sustainability, affordability, and scalability [31-33]. As such, this study adapted the theory-based P3 (Prepared, Protected, emPowered) app designed by researchers at the University of North Carolina at Chapel Hill and Ayogo Health, Inc [33]. The P3 app aims to improve PrEP adherence, retention in PrEP clinical care, and PrEP persistence among YMSM and young transgender women who have sex with men in the United States. To achieve its aims, P3 uses social networking and game-based elements along with numerous evidenced-based features, including social cognitive theory, narrative communication, and principles of the Fogg behavioral model of persuasive technology to promote behavioral change through triggers, ability, and motivation [34]. The purpose of this study is to conduct formative research to

guide adaptations to P3 that will optimize app relevance, user engagement, and utility of the adapted app for Thai YMSM, henceforth known as P3 Thailand (P3T). We hypothesize that stylistic and cultural preferences will be different from US YMSM preferences, particularly with app esthetics and preference for more visual content and less text.

Methods

Overview

To adapt the P3 app to the Thai context, we collected qualitative data through focus group discussions (FGDs) with YMSM and key informant interviews (KIIs) in Bangkok, Thailand, between January and March 2019. Participants in both the FGDs and KIIs (1) described facilitators and barriers to PrEP adherence among Thai YMSM, (2) discussed mobile health (mHealth) app features and functions preferred by YMSM; and (3) provided specific feedback about P3 and offered suggestions for adapting it to create P3T.

Institutional review board approval was granted for this study by the Faculty of Medicine, Chulalongkorn University, with a waiver for parental consent granted. This study was registered with ClinicalTrials.gov (NCT04413708).

All study participants completed a brief computer-assisted self-interviewing survey on patient demographics, technology use, and previous experience using or providing PrEP before their session. All FGDs and KIIs were facilitated by a study staff member using a semistructured interview guide. After exploring PrEP adherence facilitators and barriers and mHealth app preferences among Thai YMSM, the facilitator gave a presentation of key features of P3 and elicited feedback and suggested changes from study participants.

The presentation of P3 features included screenshots and descriptions translated into Thai by the facilitator or interviewer starting with screenshots of onboarding activities (eg, review of community guidelines, app terms and conditions, setting up an account, option to lock screen with a PIN, brief introductory screens describing key P3 features, and profile setup). Next, participants were shown a screenshot of the user dashboard, or home screen, with an explanation of each icon. Five key features of P3 (Textbox 1) were demonstrated using screenshots and explained in detail by the facilitator, including the social wall, daily quests, medication tracking and adherence support, knowledge center, and collections. An additional key feature, adherence counseling, was not presented via screenshots but was explained during the presentation of the user dashboard screenshot. A brief description of these key features is provided in Textbox 1. Detailed information on all P3 features has been described elsewhere [34].

Textbox 1. P3 features discussed in focus group discussions and key informant interviews to adapt for Prepared, Protected, emPowered Thailand.

Key Prepared, Protected, emPowered (P3) features discussed in detail in focus group discussions and key informant interviews:

Social wall:

- Daily prompts (eg, "Share tips for being safe if you are having a lot of sex!") provide a safe space for discussions on topics related to pre-exposure prophylaxis (PrEP) adherence and sexual health such as mental health and positive sexual health habits
- Peer sharing, support, and reinforcement are intended to foster behavior change and build a sense of community among users
- Users are sent push notifications when someone has commented on or *liked* a post

Daily quests:

- Routine tasks that help users change behaviors by building knowledge and skills and setting goals (eg, "Why did you decide to start taking PrEP? Consider your reasons for starting PrEP and write them down. Knowing your reasons for taking PrEP can help motivate you!")

Medication tracking and adherence support:

- To promote medication-taking habits, users personalize adherence strategies based on the time or circumstances in which they plan to take their medication (eg, "I take PrEP when I brush my teeth")
- The medication (med) reminder system provides discreet and focused reminders based on user-selected time and adherence strategies. Reminders are linked to a med check prompt that allows users to track adherence or nonadherence for the past 3 days; data entered are used to update the in-app calendar, which shows adherence history. Users can also access the med check prompts and adherence history feature from the home screen
- Adherence support: The study team can monitor users' PrEP adherence and app use. Encouraging messages can be sent to the user to provide support and encouragement

Knowledge center:

- A multimedia library with information on PrEP use, frequently asked questions about PrEP, PrEP side effects, and sexual health–related topics. A progression bar shows completion of each section
- Users can read articles to build their knowledge, respond with one of three responses indicating the usefulness of the article, and answer questions that encourage personal reflections about the content (not visible to other app users)

Collections:

- A choose-your-own-adventure style story for the user that closely mirrors choices and circumstances they may face in their daily lives
- Playing through these storylines allows users to build problem-solving skills when faced with difficult choices
- The *collections* feature also acts as an incentive for users to engage with other features of the app to gain points to unlock stories

Adherence counseling:

- Personalized adherence counseling is provided via secure in-app messaging; addresses adherence challenges faced by young men who have sex with men
- Key features include reviewing sexual risk experiences of the participants, exploring PrEP adherence facilitators and barriers, identifying adherence needs and strategies to meet needs, discussing mental health and relationship issues, and developing an adherence action plan [35,36]

Recruitment for FGDs

FGD participants were recruited from (1) HIV prevention clinics at the Center for Excellence for Pediatric Infectious Diseases at the Chulalongkorn University, a major teaching hospital in Bangkok; (2) TRCARC, Thailand's largest HIV voluntary counseling and testing (VCT) center, which serves over 2000 adolescents per year; and (3) Two community-based organization branches of TRCARC, Service Workers IN Group and Rainbow Sky Association Thailand. Potential participants were approached at HIV VCT visits to assess their interest in study participation. In addition, study advertisements were posted in clinics, social media, and via the TRCARC website. The inclusion criteria were as follows: (1) age 16-24 years, (2) male sex at birth, (3) self-identification as MSM, (4) ability to speak and read Thai, (5) familiarity with smartphones, and (6) current or previous PrEP use. Those unable to provide consent due to substance use or psychological conditions were excluded.

FGDs lasting 60-120 minutes were conducted in private conference rooms either at offices in clinics or reserved private conference rooms in cafes in groups of 4-8. All participants were identified using a pseudonym to protect their confidentiality. At the conclusion of the FGDs, participants were provided THB 500 (US $16) to compensate them for their time.

Recruitment for KIIs

Key informants who had collaborated with the Center for Excellence for Pediatric Infectious Diseases or participated in academic conferences on adolescent health in Bangkok were recruited for KIIs via in-person contact, phone calls, text messages, and email invitations. To participate in a KII,

individuals were required to be a current PrEP provider for YMSM in Bangkok. KIIs, which lasted between 40 and 60 minutes were conducted face-to-face at PrEP clinics. The KII participants were not compensated.

Data Analysis

Pre-FGD and KII survey data were summarized using Adobe Acrobat. FGDs and KIIs were audio-recorded and transcribed in Thai. A directed content analysis approach, defined as categorization derived directly from text data and transcribed interviews, was used [37]. An initial codebook was developed collaboratively between the US and Thai study teams based on semistructured interview guides that reflected the study research themes and subthemes. An iterative approach was used when new codes arose, as interviews were conducted. New codes emerging were added, and any transcribed code that had already been coded was recoded. Two members of the Thai study team coded the FGD and KII transcripts using NVivo (version 12.5.0) [38]; statistical interrater reliability for coding was not calculated. Instead, divergence among coders was discussed among the analysis groups to reach consensus, resolved by the Thai site principal investigator. Data were then deductively analyzed using thematic analysis by the same Thai study team members to identify key themes and subthemes relevant to the adaptation of P3 for YMSM in Thailand. Quotes illustrative of key themes were identified and translated into English by bilingual Thai English speakers.

Results

Participant Characteristics

Characteristics of FGDs

A total of 23 YMSM participated in four FGDs. Participants were aged 18-21 years, with a mean age of 20 years. The majority were enrolled in full-time education 96% (22/23), with 70% (16/23) enrolled in university. All participants owned a smartphone and used it to access the internet; 74% (17/23) were on self-paid monthly internet plans. Over half of the participants (13/23, 57%) had phones that used an iOS (Apple iPhone operating system) and 35% (8/23) used an Android operating system. Most (22/23, 96%) were current PrEP users and 4% (1/23) were previous PrEP users.

Characteristics of KIIs

A total of 15 KIIs were conducted; participants were aged 26-60 years with a mean age of 40 years. Most were counselors (6/15, 40%) and physicians (6/15, 40%); the remaining 20% included 2 nurses and 1 social worker. All patients were employed at publicly accessible HIV VCT clinics. The majority of key informant interviewees had completed university level education (11/15, 73%), and 60% (9/15) had been providing PrEP to adolescents for 3-4 years.

Overview of FGD and KII Findings

General Overview

Key findings from the FGDs and KIIs were grouped into two main categories. The first focuses on the facilitators and barriers to PrEP adherence among YMSM in Bangkok. The second focuses on general and specific recommendations for ensuring P3T app relevance, user engagement, and utility for Thai YMSM. We present these themes and subthemes along with English translations of illustrative excerpted participant quotes.

PrEP Adherence Facilitators and Barriers

FGD Findings: Adherence Facilitators

Key subthemes that emerged regarding facilitators of PrEP adherence discussed by participants included risk perception, PrEP cost, and social support.

Risk Perception

FGD participants who felt they were at risk of HIV infection were more motivated to take PrEP:

> *I had a pretty risky history before. I use my history to determine my risk so now take it (regularly). I also take it because there were people that recommended it to me.* [FGD1, Participant 3]

PrEP Cost

PrEP being available free of charge was also important in supporting PrEP adherence:

> *It really helps with us being students [that PrEP is free] as it helps us save...if we had to pay for it, I would have to think a lot more whether or not to take it.* [FGD4, Participant 6]

Social Support

Social support from staff was another subtheme that FGD participants gave importance to in their willingness to adhere to PrEP:

> *For me what's important is staff that are constantly available for counseling. If we had providers that just gave us our meds and that was the end of it—no questions about how we were, I wouldn't want to come for PrEP services.* [FGD4, Participant 3]

KII Findings: Adherence Facilitators

The key facilitators of PrEP adherence discussed by key informants were similar and included social support as illustrated in the quote below.

> *For some couples who both take PrEP and are open to each other about this and have an open relationship, taking PrEP in front of each other does not need to be hidden for fear of being accused of being unfaithful.* [KII, Participant 14]

FGD Findings: Adherence Barriers

Subthemes that arose on the issue of major barriers for YMSM in PrEP adherence included stigma, logistical issues, and PrEP side effects.

Stigma

YMSM felt that taking PrEP was associated with stigma, risky sexual behavior, being gay, and also being seen to be infected with HIV:

> *People will feel that [PrEP] clinics are for gay men with risky behaviors. It's well known in Bangkok that a lot of gay men are infected with HIV...people look at gay men negatively as it is...that we're promiscuous.* [FGD4, Participant 5]

Logistical Issues

Logistical issues, including being busy with other activities, also featured prominently in reasons YMSM felt it was difficult to always adhere to PrEP:

> *We have a lot of classes and have to study for exams, there isn't always time to come for appointments.* [FGD2, Participant 3]

PrEP Side Effects

PrEP side effects were another issue adolescents felt made PrEP adherence challenging, particularly when it interfered with other activities in their daily lives:

> *I had a lot of side effects with PrEP, and I have to study everyday—it makes it impossible to study.* [FGD3, Participant 1]

KII Findings: Adherence Barriers

Findings of major barriers from the point of view of KIIs were very similar to those of YMSM as already discussed above, including logistical issues, risk perception, and peer influence.

KIIs experienced difficulties arranging logistics to come for appointments and low HIV risk perception, in addition to a number who initiate PrEP because of peer influence and discontinue it because of lack of intrinsic motivation or sense of self-risk perception for HIV:

> *Many kids who don't turn up to appointments will say its inconvenient for them to come in, they don't have time to come, or they are no longer at risk. Some say they want to come but borrow PrEP from friends...confess they don't have time for appointments but initially came because they saw their friends taking PrEP and wanted to join in, we see this a lot.* [KII, Participant 2]

Adaptations Made Based on PrEP Adherence Facilitators and Barriers

As the facilitators and barriers found in this study were essentially the same as those seen in the US P3 app, no changes were made to the app regarding this [34].

General and Specific Recommendations for Ensuring P3T App Relevance, User Engagement, and Utility for Thai YMSM

Six main themes emerged under this category: (1) information provided in mHealth apps, (2) stylistic preferences, (3) engagement strategies, (4) privacy risks, (5) connectivity challenges, and (6) recommendations for new functions. The first 3 themes focused on general recommendations for mHealth apps in Thailand based on discussions before the review of P3 features. The next 3 themes specifically focused on feedback and suggested adaptations to make the app more relevant to Thai users based on the review of P3 features.

Information Provided in the App

Three main subthemes related to app information emerged: (1) access to reliable information, (2) presentation of information, and (3) space for peer influence and information sharing.

Access to Reliable Information

In FGD findings, Several FGD participants discussed the ways in which Thai societal norms can be restricted to YMSM seeking information related to sexual health. However, they felt that access to such information was vital to self-care:

> *I think an app will help us feel less afraid to ask...sometimes society leads [us] to believe certain things are not okay [to ask] but it is actually beneficial. We want more freedom to be able to get hold of simple information to be able to look after ourselves. A lot of us worry looking after ourselves is too difficult and complicated.* [FGD1, Participant 5]

Despite the vast amount of information about PrEP available in Thai on the internet and social media sites, FGD participants were concerned that many sources lack reliability:

> *...it's better to have accurate information, for example, answers to questions from doctors, [but] it's so difficult to find official medical websites. Most of what I find is opinion sharing of the general public [on social media]...this is a problem.* [FGD3, Participant 2]

Presentation of Information

FGD Findings

Most FGD participants commented on the importance of the presentation of information in increasing app interest and engagement. They indicated a strong preference for information that was presented concisely and was visually oriented:

> *I think [information] should be [presented as] small nuggets of information, and when you click on it, it takes you to...an infographic, like a poster with concise information.* [FGD1, Participant 1]

> *Most teenagers will stop to read if there are graphics, but they will not read it if there is just text.* [FGD2, Participant 6]

In addition, participants highly recommended including video content and links to useful content outside the app.

> *When I open anything in Facebook, I see some interesting clips on pages for gay people—they will provide information about this stuff. If they have a collection of links of places to chill out, or links to You Tube videos, it just makes it more interesting.* [FGD1, Participant 2]

KII Findings

Another presentation style suggested was the use of social media influencers who use diverse methods to communicate information that is more appealing to YMSM:

> *I think having influencers on there with different messages. I've seen pictures on Instagram and Facebook and I think going there and being able to see their favorite movie star or whoever influences the community.* [KII, Participant 11]

Peer Influence and Information Sharing

FGD Findings

Participants noted the strong influence peers have on their decision-making; therefore, peers were viewed as key facilitators for app uptake and sustained engagement:

> *Thai teenagers listen much more to the opinion of their friends than making decisions on their own.* [FGD3, Participant 4]

> *I think if teens can see what other people think [is] worth reading, it would make me like, oh that looks like something I want to read, why are there so many people reading this?...like getting recommendations from others about it.* [FGD 1, Participant 4]

> *Sometimes teenagers may just want to talk to their friends or want information from them,-for example, who is taking PrEP and how they found it. People with previous experience will flood in to answer these queries, like on how they manage side effects. They tend to want experiential information from real-life users, which they find more convincing than information from doctors.* [KII, Participant 2]

KII Findings

Key informants also discussed the powerful nature of platforms for youth to connect with one another. They have the potential to provide a safe space for youth to discuss and share information about health-related topics that may be difficult to talk about in other settings while also creating opportunities to discuss similar life experiences with others:

> *I once had a closed online group for teenagers—this group were constantly talking. They would talk about health, then they would talk about something else, then back to health and medicines...an app could be potentially great for teens supporting each other towards a shared goal.* [KII, Participant 1]

Stylistic Preferences

FGD Findings

The presentation of key P3 features in the FGDs led to rich discussions about the *look and feel* of the app and its features. The app screenshots presented to study participants showed the P3 superhero theme, which included sleek, abstract superhero avatars, and a darker background color scheme. These features were found to be highly acceptable in formative research conducted in the United States [34,39]. FGD participants nearly unanimously agreed that the theme and design elements were not aligned with app preferences among Thai youth.

> *I think the color scheme is a little too dark, it should be more colorful and cute...there should be a wider choice of color schemes.* [FGD1, Participant 7]

> *The avatars look really mysterious...strange...I want the avatars to look more like us, like ones that can wave...cartoons...that we can choose...or use emojis that look more normal.* [FGD1, Participant 5]

YMSM also expressed the need for cartoon-style stickers, similar to other mainstream platforms used in Thailand, such as LINE, the most frequently used instant messaging service in Thailand [39]. They noted that they are a prominent part of contemporary communication in Thai culture; hence, they should be featured in a PrEP adherence app.

Furthermore, participants indicated a preference for the social wall feature of P3T to have a more attractive look and feel, similar to current popular social networking sites such as YelloTalk (Figure 1):

> *I want the Social Wall to look like YelloTalk.* [FGD 3, Participant 4]

Figure 1. Yellotalk screenshots as displayed in the Apple App Store.

KII Findings

KII participants commented in a similar way to FGD participants, expressing that youth would likely enjoy a lighter color scheme and a cuter style of graphics:

> *This looks too depressing and dark...a lighter color theme would be better...the avatars need to be cute cartoons for the kids to pick...* [KII, Participant 3]

KII participants noted that electronic stickers are a prominent part of contemporary communication in Thai culture; hence, they should be featured in a PrEP adherence app:

> *Here, everybody is about LINE and stickers. I even engage with senior ministry staff by line stickers. So, it's not only kids, it's everybody.* [Participant 11]

Engagement Strategies

FGD Findings

FGD participants provided several important recommendations for improving their engagement with the P3T app. First, the app content should be highly dynamic; suggestions include regularly adding new articles, posts about upcoming social events, tailoring to special dates, and current news tailored to individual users and adolescents. Notifications should be sent to alert users to the availability of new content, including contributions from other app users:

> *If there is an event somewhere it should notify us or notify us about interesting news that will make us want to click in to see. If there is nothing going on in the app and it's just a boring app, I have several apps on my phone, I would just scroll past.* [FGD1, Participant 2]

> *I look at what updates there are, whether they are interesting. There needs to be exchange of knowledge and notifications to make it more interesting, like notifying us a new post has been made on something that interests us, tailoring it to our interests to make us want to use it more.* [FGD3, Participant 4]

The importance of fun was emphasized by FGD participants, as they highlighted the need for more entertaining features than those found in the reviewed P3 features to optimize engagement:

> *Something that has a changeable theme, has fun gimmicks, like stress busting games...like the games you can get in Facebook will make the app more appealing.* [FGD1, Participant 8]

Study participants had varying opinions about rewards that may best incentivize user engagement with the app. Several felt that Thai YMSM would be most interested in earning points for completing app activities that could be redeemed for external rewards such as cash, tickets, or discounts for services.

> *Apps that I usually use have daily questionnaires...they give point rewards...we get gift vouchers...[we like to exchange points for]...bubble tea, cash, movie tickets, discounts for spas and botox, fastfood, cafes, shoes, buying games.* [FGD2, Participant 1]

Some FGD participants expressed interest in the choose-your-own-adventure style storytelling collections feature and suggested increasing the adventure and excitement of the storylines. However, to be effective as an incentive for app use, storylines would need to be more exciting and adventurous.

> *We enjoy reading stories about unique experiences of others...oral sex, group sex...* [FGD 1, Participant 2]

KII Findings

When asked about factors that should be taken into account to maximize engagement in a PrEP adherence app for Thai YMSM, a key informant provided critical insight into the importance of fun in Thai culture:

> *There is a strong need in the Thai context of interaction for fun. It has to all be about carrots not sticks. About fun. The Thai culture is about—what's the point if you're not going to have fun along the way.* [KII, Participant 11]

A key informant commented specifically about users being limited to redeeming their earned points in P3T to buy choose-your-own-adventure stories in the collections feature. The participant was not optimistic that this approach would incentivize app engagement among Thai YMSM:

> *Our teenagers don't have a lot of persistence to do things. If they have to go in to read something, it won't really motivate them to want to know more, unless it comes in the form of a game, and they get points for doing it...point exchange needs to be for something they want...using points to buy something to read [referring to Collections], I don't know, that's not really in the nature of Thai teenagers to do something like that.* [KII, Participant 9]

Privacy Risks

Many FGD participants expressed concerns about sharing their private information on the web and emphasized their preference for personal interactions with health care providers:

> *I would rather talk to doctors and counselors than tell my personal things to friends that I don't know.* [FGD4, Participant 6]

On the basis of the fear of private information being compromised, some FGD participants expressed the need for advanced methods of user authentication:

> *I want a highly secure system, maybe use a finger or face scan...to access the app...because our medication tracking information and blood results are sensitive information.* [FGD1, Participant 4]

Connectivity Challenges

A main challenge specific to the use of mHealth apps in Thailand is reliable internet access. Many apps, including P3T, require a continuous active internet connection to function. However, internet connectivity is not readily available or affordable for many Thai adolescents. The FGD participants noted the importance of offline app functionality:

> *For me, like if I don't have internet this week, or I haven't bought internet time or haven't gone home this week, I can fill in my questionnaire responses...and when I'm back online, my survey responses are sent.* [FGD 4, Participant 8]

Recommendations for New App Functions

FGD Findings

In FGDs, two additional app functions were discussed most frequently and recommended for inclusion in the P3T. The first recommendation was to add a search function that allowed users to search all of the app's content:

> *When I do an internet search [for information] there are so many websites, and sometimes they are focused on selling you things...it takes ages to find the information I actually want...information in an app will get this to information I want directly.* [FGD3, Participant 4]

The second recommendation was to include a function that allows users to monitor and plan a healthy lifestyle. For example, FGD participants wanted the ability to track HIV risk behaviors in the app and receive customized information about their HIV risk level based on their tracked data:

> *I want it [the app] to help determine [my risk] based on data I have inputted...if I had a risk event today...how should I deal with it...and use it to go through events with my doctor when I next visit them.* [FGD1, Participant 5]

KII Findings

Key informants pointed out that Thai YMSM appreciate health-related feedback from adolescent-friendly providers, and offering individually tailored information through P3T could be valuable:

> *One of the things we hear back from some of our participants in research is that they like having health information. We noticed that they're interested in coming back to their visits so they can get health information and feedback on how they're doing health wise. I think that can potentially be interesting to people. "Your kidney health is great" and "you don't have any evidence of STI that's awesome" or "keep up the good work" or whatever it is.* [KII, Participant 11]

Adaptations Made for P3T Based on Formative Research Findings

On the basis of formative research findings and the limited resources available for adaptations, we prioritized changes to app features while keeping the same content to address the presentation of information provided in P3T and some identified stylistic preferences. These included (1) changing the information presentation style in the knowledge center, (2) adapting stories and images in the collections feature, and (3) changing avatar options. Longer-term structural changes that were not immediately feasible because of resource constraints should be considered in future updates to the app.

Presentation Style Changes in the Knowledge Center

On the basis of feedback, we changed our information presentation style by creating chapter images more relevant to the Thai context (Figure 2), changing the text-based presentation of information to include less text and more infographics (Figure 3), and added links to outside video content, including those featuring social influencers (Figure 4). All of these videos were locally produced by the Thai HIV prevention NGO, Love Foundation, and reflected popular Thai presentation styles.

Figure 2. Comparison of knowledge center chapter images before (left) and after (right) adaptation for the Thai context.

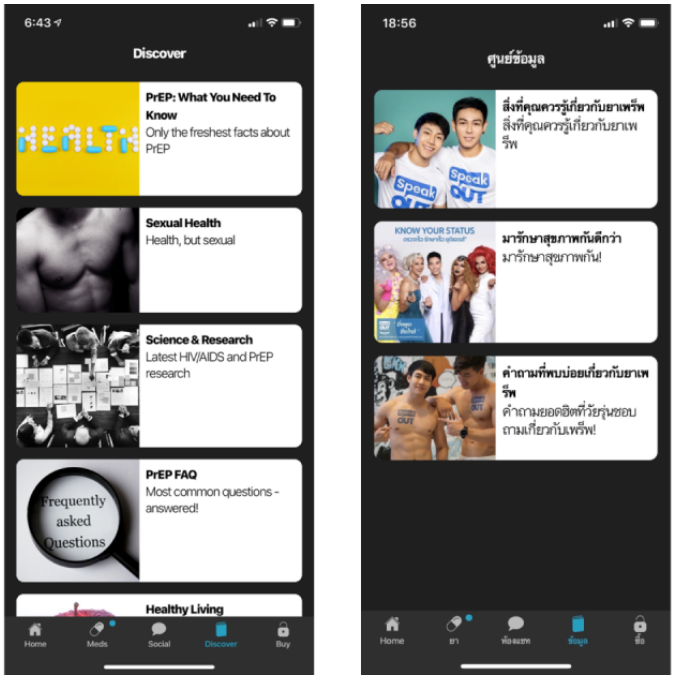

Figure 3. Comparison of knowledge center article on pre-exposure prophylaxis adherence before (left) and after (right) adaptation for the Thai context, including infographics.

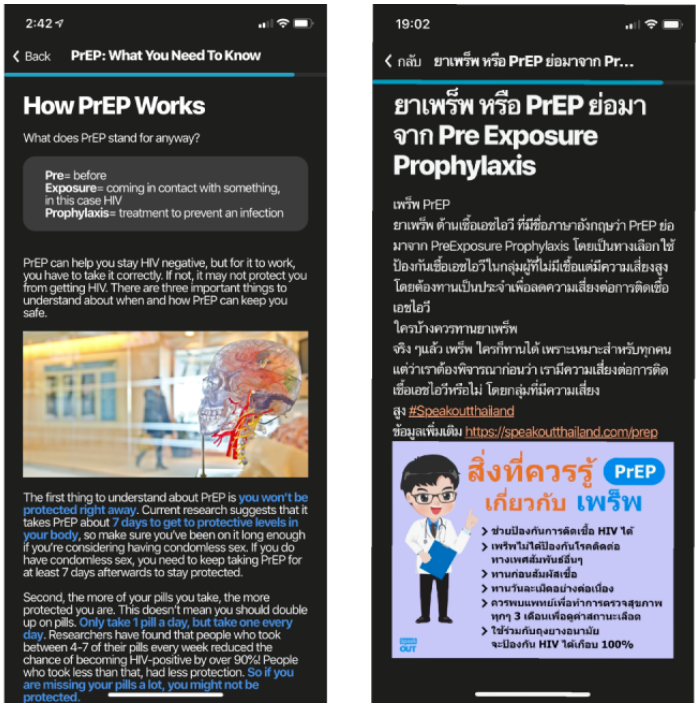

Figure 4. Postadaptation knowledge center page (left) with link to external video content (right).

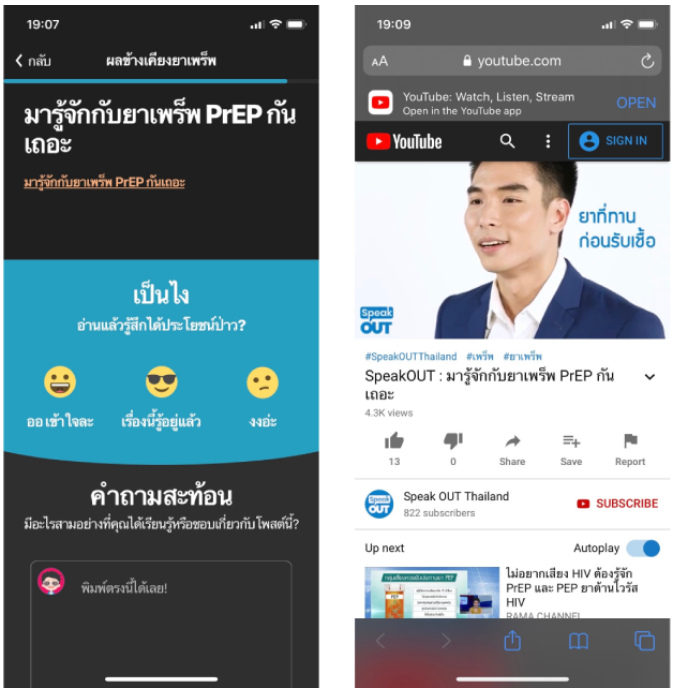
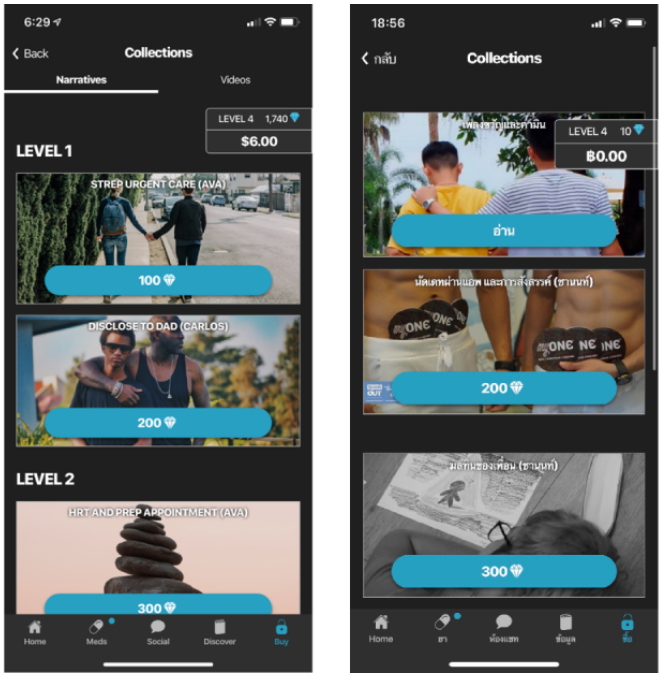


Adaptation of Stories and Images in the Collections Feature

The collections feature was adapted by giving story characters Thai names and locations and changing some story lines to increase relevance for Thai YMSM. In addition, image icons for the collection titles were changed to Thai characters (Figure 5).

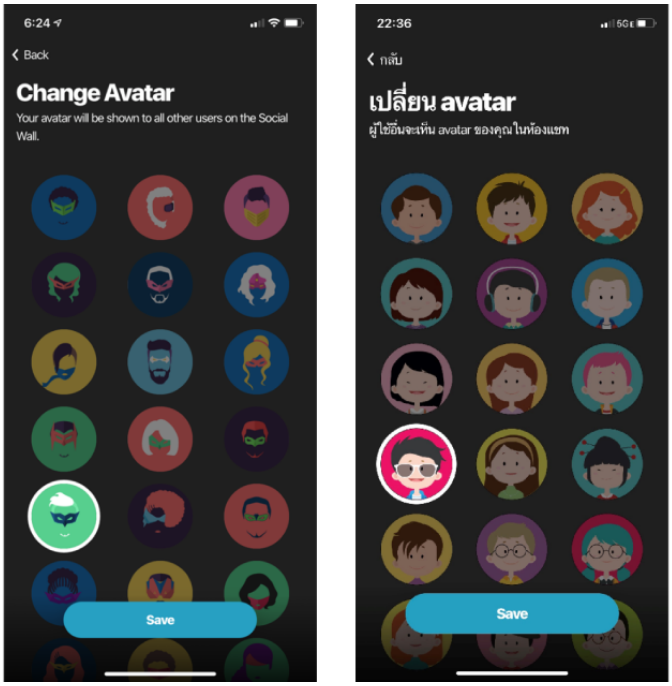
Figure 5. Comparison of Collection titles before (left) and after (right) adaptation for the Thai context.



Avatar Adaptations

As indicated by many FGD participants, the original avatars presented did not appeal to Thai YMSM and were considered a major detraction of the app. We partnered with Thai graphic designers to design a new set of avatars to replace the original avatars. Figure 6 compares the older version and the new version of avatars.

Figure 6. Comparison of avatars before (left) and after (right) adaptation to the Thai context.



Existing P3 Features That Foster PrEP Adherence Facilitators, Address Adherence Barriers, and Align With Key Recommendations

In addition to the specific changes made as indicated in the previous section, many P3 features already address PrEP adherence facilitators and barriers and general app recommendations identified in FGDs and KIIs. For example, P3 seeks to increase PrEP adherence facilitators by providing content that promotes accurate self-assessment of HIV risk via knowledge center content, promoting the exchange of support and information on topics related to PrEP adherence via the social wall, and offer personalized adherence support from a trained adolescent-friendly adherence counselor through the in-app counseling feature.

The knowledge center and social wall also already address some of the general app recommendations related to the reliability of

information, access to information, and peer information sharing. The knowledge center is designed to provide reliable information in an easy-to-understand manner. The social wall provides a space for users to discuss topics related to health anonymously. In addition, in terms of security and privacy concerns, the P3 app provides an in-app log-in option for the user to secure the app either by using a personalized PIN number for all platforms or using face recognition technology for iOS platform users when launched. The app helps to protect personal identity by asking users to set their own pseudonyms that do not contain any identifying information about them rather than using their real names in the app. A summary of key study findings and adaptations made is made in Table 1.

Table 1. Summary of key study findings and adaptations made.

Findings	Relevant quotes	Adaptations made
Presentation style preferences		
• Images more reflective of Thai YMSM[a] settings • Preference for more visually based information and less text • Preference for information from social influencers • Preference for a cuter style and lighter color theme • Content needs to reflect their local cultural context	• "I want the avatars to look more like us." [FGD[b]1, P[c]7] • "I think [information] should be [presented as] small nuggets of information...an infoographic, like a poster with concise infographic." [FGD1, P1] • "I think having influencers on there with different messages." [KII[d], P11] • "A lighter color would be better...the avatars need to be cute cartoons." [KII, P3] • "I want the Social Wall to look like YelloTalk." [FGD3, P4]	Knowledge center • Graphics incorporated more photos taken in the Thai YMSM context • More infographics and less text used • Links added to outside video content containing messages from social influencers Collections • Image icons changed to Thai characters • Story characters given Thai names and locations Avatars • Created by Thai graphics designer with cute theme and lighter color scheme
Facilitators		
• High HIV risk perception, PrEP cost support, social support	• "I used my [risky] history to determine my risk." [FGD1, P3] • "It really helps with us being students [that PrEP is free." [FGD4, P6] • "Some couples who both take PrEP are open to teach other." [KII, P14]	• No adaptations made as same facilitators and barriers as found in P3 US study results
Barriers		
• Stigma, logistical issues, PrEP side effects, low risk perception, and peer influence	• "People look at gay men negatively as it is." [FGD4, P5] • "We have a lot of classes...there isn't always time to come for appointments." [FGD2, P3] • "I had a lot of side effects...makes it impossible to study." [FGD3, P1] • "Some came because they saw their friends taking PrEP...but confess they don't have time for appointments." [KII, P2]	• No adaptations made to current version because of budgetary restrictions
New app function recommendations		
• Search function and risk behavior tracker	• "Information in an app to get information I want directly." [FGD3, P4] • "I want it to help determine [my risk]." [FGD1, P5]	• No adaptations made to current version because of budgetary restrictions

Discussion

Overview

This study explored facilitators and barriers related to PrEP adherence and elicited general and specific recommendations from Thai YMSM and key informants to ensure that adaptations of a PrEP adherence app originally developed for YMSM in the United States were relevant, engaging, and useful for the Thai context. To our knowledge, this is one of the few studies conducted outside high-income settings that address the adaptation of an mHealth approach to support PrEP adherence among YMSM [40].

The individual, societal, and systemic level facilitators and barriers to PrEP adherence among Thai YMSM identified in this study have also been reported in other studies of MSM and YMSM in the United States, Thailand, and other countries. Consistent with other studies [7,41-45], adherence facilitators included awareness of HIV risk and desire to protect themselves, concerns related to sexual partners, support from friends, sexual partners, family members, and adolescent-friendly providers, and PrEP affordability (PrEP is provided free of charge through universal health coverage for key populations in Thailand). Key barriers, also identified in other studies [41-44,46-49], included sexuality, HIV and PrEP stigma, attending regular PrEP medical appointments, forgetting to take PrEP daily or while intoxicated, not having PrEP with them at certain times, running out of PrEP, side effects, and low HIV risk perception. Because the PrEP facilitators and barriers identified in this study had been identified in prior research and were already addressed by the original P3 app, its content was already designed to foster these facilitators and address the barriers and consequently no content was changed; only app feature changes were made in adaptations in this trial.

In general, the main features, such as the social wall, daily quests, and collections of the P3 app were found to be acceptable among the study participants. It is likely that this is in part because of the ways in which the key app features address the factors identified by participants in this study as the most important PrEP adherence facilitators and barriers among YMSM in Thailand. For example, most participants expressed sexuality, PrEP, and HIV stigma as barriers to PrEP adherence and social wall of P3T provides an opportunity for positive social interaction and support related to these issues to take place, which has been shown in previous studies to be associated with reduced stigma [50,51].

However, the study participants provided critical recommendations for P3T app adaptations in the way the core features were presented that address cultural and contextual factors specifically relevant to Thai YMSM, which are expected to substantially enhance app acceptability, relevance, user engagement, and utility. For example, Thai YMSM voiced a strong preference for more visual content, such as infographics and video content, as opposed to text, similar to findings from formative work to develop P3 [34]. This may be because of the interest in consuming information via different mediums [35,36,52-54]. Therefore, these factors highlight the importance of understanding the reading ability and reading norms of the target population when developing app interventions [55]. The desire to keep the app fun and light through the use of stickers, a lighter color scheme, and ongoing seasonal promotions and games also featured prominently in both FGDs and KIIs. These suggestions reflect Thai culture and thus emphasize the importance of understanding cultural preferences and popular marketing practices when adapting mHealth interventions for use in different countries [56-58].

Both YMSM and key informants noted the strong influence peers have on the health beliefs, decision-making processes, and behaviors of Thai YMSM. This phenomenon has been identified in research in other cultures [59,60], and a study of Thai YMSM found that health beliefs and self-efficacy were associated with HIV prevention behaviors [52]—factors known to be influenced by peer groups [61]—were associated with HIV prevention behaviors [52]. App interventions focused on HIV prevention for Thai YMSM should assess whether functions that acknowledge the importance of peer relationships increase the likelihood of achieving the desired behavior. In P3T, peer interactions are possible via the social wall, and positive peer norms are presented in the videos added to the knowledge center that feature peer influencers. Future development of P3T will include the ability to visually represent the popularity of content among users via functions such as number of likes on comments and most popular topics, which could further capitalize on the influence of peers to promote behavior change.

There have been a small number of mobile apps that have tested YMSM at risk for HIV to support PrEP adherence and HIV prevention, mostly based in the United States. The availability of having reliable information on HIV and sexual health, reminder features for users to access relevant health care such as drug adherence and medical appointments, esthetically pleasing features for target users, and ease of use are common findings with what was found in this study from multiple studies previously conducted, including the LYNX and MyChoices apps [62-64]. Similar needs for medication reminders and education on their condition have been found in adolescents with other chronic health conditions, such as sickle cell disease [65]. No striking contrasts in YMSM needs using PrEP adherence apps in other studies compared with findings from those found in our study are apparent so far; however, many studies are underway that may produce differing outcomes to what has been seen so far [62,63,66]. Given the future potential scalability of the use of mobile phone apps in supporting PrEP adherence, understanding differences in feature preferences in different contexts, such as with age, gender identity, urban versus rural dwellers, and specific user profiles are valuable in adjusting mobile health technologies to maximize their benefits to specific populations [67]. Given the time limitations with data collection in adapting mobile technologies to user needs, future studies may benefit from sequential adaptive research trial designs to address this challenge.

Future Directions

We identified the benefits and challenges of adapting P3 for YMSM in Thailand. First, the remarkable similarities in PrEP adherence facilitators and barriers among YMSM in our study,

and in other studies, along with the general acceptability of the key features of P3 among our study participants support the growing trend of adapting evidenced-based apps, such as P3, for different cultures and contexts rather than developing new apps from scratch [31]. However, extensive formative research is critical to ensure that an app is appropriately adapted to meet the unique needs and population preferences in different settings [67,68]. Adapting an existing app with a common behavior change goal can increase the speed of app development, reduce costs, and ultimately expedite scalability [31-33].

However, even minor app changes or the addition of a few new features can require significant time and budgetary resources. Planning for a budget that is sufficient for formative research and app adaptations may ensure that the adapted app is culturally and contextually relevant and may shorten the time between adaptation, pilot study, and, if feasible and acceptable, a larger trial. Owing to the limited time and funding of a pilot grant and working with a commercial app developer based in North America, we were unable to implement all design changes that would better align the app with cultural preferences identified in the FGDs and KIIs. These changes focused on stylistic preferences and the inclusion of additional functions within the existing features. The main changes suggested included making the app color scheme lighter, offering customizable skins, adding stickers to enhance communication in the social wall, adding an app search function, adding engagement statistics to visualize content popularity among peers (eg, number of times a knowledge center article or social wall post has been read), adding health behavior tracking features that would allow for determination of HIV risk level based on data entered into the app, and regular content updates to make the app more dynamic. An additional need identified in using an app such as P3T in Thailand is the ability of the more features of the app to function offline. According to the study participants, most Thai YMSM are unable to afford data plans that would allow for consistent and reliable internet access. To maximize access of users to P3T, more extensive offline functionality is critically important in the Thai context. If justified by the findings from the pilot study, the remaining adaptations, along with additional findings anticipated from the pilot study, are planned for a subsequent development phase that could also inform the adaptation of other apps.

Including local designers and developers on the team may help stretch limited resources and ensure that local expertise leads to the cultural adaptation process [68]. For example, through the support of a Thai collaborator skilled in graphic design, we were able to make important design changes to the app that reflected a rich understanding of the esthetic preferences of Thai YMSM. The local designer rapidly developed avatars that were highly responsive to study participant preferences. We also faced unforeseen formatting challenges translating the content of the app from English to Thai, which substantially increased the amount of time required for this stage. Having a fluent Thai speaker on the development team could help address these and similar barriers in the adaptation process. Local app designers and developers also provide a capacity-building opportunity for local collaborators, which can then reduce cost and time during both adaptation and scale-up phases. Given that, particularly in the context of limited resources such as where this study was performed, it must be acknowledged that there are limited data to support the cost-effectiveness of digital health interventions [69]. Such considerations are important when considering future scalability and sustainability to inform policies on investments in this area of health care interventions [70].

In the COVID-19 era, it must also be noted that with its considerable challenges, there are opportunities to optimize digital approaches as well as psychosocial intervention health care delivery in adolescents. Multiple areas regarding this with relevance to future studies related to the P3T app could be explored, including the impact of the app on preventive behaviors, medication adherence, self-management, and cost-effectiveness [71,72].

Strengths

A major strength of this study was that it addressed a knowledge gap in the feasibility and acceptability of mHealth in low-middle income settings [29] and also in adolescent populations [28]. In addition, it provided practical guidance for adaptation of an existing mHealth platform in low-middle income settings rather than starting from scratch, a practical solution in the context of limited financial and staff resources as well as difficult-to-reach populations. It also highlighted the importance of using local expertise and capacity building in producing well-suited and sustainable interventions where mHealth interventions are adapted to very different settings for which they were originally intended. Finally, this study involved target user input from the start of its adaptation to the Thai context, an approach known to improve target user short- and long-term engagement [65,73-75].

Limitations

This study was conducted only in Bangkok; therefore, data collected from study participants may not reflect the perspectives of YMSM and PrEP providers nationwide. In addition, the majority of FGD participants were enrolled in full-time education, which in the context of Thailand signifies a higher socioeconomic status. Therefore, these findings may not be generalizable to the Thai YMSM of all socioeconomic groups. As parental consent was required for FGD participants under the age of 18 years, we were unable to enroll participants in this age group because of the unwillingness of potential participants to reveal their sexual orientation or risk behaviors to their parents. This may have led to findings biased toward the views, needs, and developmental requirements of older adolescents. In most countries, formidable challenges remain in conducting research with those under the age of 18 years, despite the need to gather information to inform interventions that address the current global HIV epidemic, which disproportionately affects young people [5,76]. In Thailand, parental consent is exempted for individuals under 18 years of age to receive sexually transmitted infection care, HIV testing, or PrEP initiation. However, the decision to allow those under 18 years to participate in HIV prevention research without parental consent is at the discretion of the ethical review boards. On the basis of our experience, some review boards in Thailand are willing to allow exemption of parental consent for adolescents in HIV

prevention trials where study involvement is a direct benefit to participants from this key population.

Despite these limitations, the adapted P3T app represents a significant step toward expansion and scale up of an app-based intervention to support PrEP adherence in Thailand, where PrEP has recently become available free of charge for YMSM through a national health coverage [5,77]. Additional studies in different geographical areas of Thailand with a high YMSM population density and studies focusing on young transgender women who have sex with men and other key populations would help further the adaptation processes of mHealth apps for those disproportionately affected by HIV in Thailand.

Conclusions

As observed in this study, most facilitators and barriers for PrEP adherence in the Thai context are similar to those observed in other global settings. The core features of the P3T app address the main facilitators and barriers related to PrEP adherence in Thailand for YMSM. The majority of the improvements suggested in this study focus on customizing the app to suit the stylistic presentation preferences of Thai YMSM and tailoring the app content to suit the cultural context of Thailand and the cultural nuances of the YMSM demography. Given that many of the facilitators and barriers are similar globally, adapting existing successful mHealth solutions will be the most effective and cost-efficient way forward as opposed to developing new apps. However, to obtain optimal results, it is vital that local app developers are included as partners in the adaptation process.

Abstract

Background: We present the results of a feasibility, randomized waitlist control group (CG) parallel design study with a 1:1 allocation ratio. Participants were randomized into an intervention group (IG) or a waitlist CG. The intervention was a 6-week digital self-management program, Help to Overcome Problems Effectively (HOPE), for people with cancer.

Objective: This study aims to test the feasibility of a digitally delivered self-management program for people with cancer. This will inform the design of a definitive randomized controlled trial. In addition, a preliminary assessment of the impact of the HOPE program via secondary outcomes will be used to assess signals of efficacy in a trial context.

Methods: Participants were drawn from an opportunity sample, referred by Macmillan Cancer Support, and were invited via email to participate in the study (N=61). Primary outcomes were rates of recruitment, retention, follow-up, completion and adherence, sample size and effect size estimation, and assessment of progression criteria for a definitive trial. Secondary outcomes were self-report measures of participants' positive mental well-being, depression, anxiety, and patient activation (ie, confidence in managing their cancer). The intervention and data collection took place on the web.

Results: The recruitment rate was 77% (47/61). A total of 41 participants completed the baseline questionnaires and were randomized to either the IG (n=21) or the waitlist CG (n=20). The retention rate (attending all program sessions) was greater than 50% (all: 21/41, 51%, IG: 10/21, 48%; and CG: 11/20, 55%). The follow-up rate (completing all questionnaires) was greater than 80% (all: 33/41, 80%; IG: 16/21, 76%; and CG: 17/20, 85%). The completion rate (attending ≥3 sessions and completing all questionnaires) was greater than 60% (all: 25/41, 61%; IG: 13/21, 62%; and CG: 12/20, 60%). Engagement data showed that participants viewed between half (5.1/10, 51%) and three-quarters (12.2/16, 76%) of the pages in each session.

Conclusions: All progression criteria for a definitive trial were met, as supported by the primary outcome data. The IG showed improved postprogram scores on measures of positive mental well-being, depression, anxiety, and patient activation. A full-scale trial of the digital HOPE program for people with cancer will allow us to fully evaluate the efficacy of the intervention relative to a CG.

Introduction

Background and Rationale

As of May 2021, the United Kingdom has seen 3 periods of national lockdown and widespread social and physical distancing measures implemented by the government in an attempt to curtail the spread of SARS-CoV-2. Such measures have resulted in significant reductions in the delivery of cancer services in the United Kingdom, as pressures on health services, lockdown demands, and the need to reduce face-to-face interactions have taken precedence [1]. Remote emotional support for these patients has recently been recommended by researchers [2] and cancer support specialists [3]. People with cancer are now experiencing increased health anxiety [4] owing to the risk of serious complications from the virus for people with cancer [5,6]. The need to implement alternative models of care during COVID-19, including more self-management support, has been noted by leading cancer care experts [7]. Moreover, before the COVID-19 pandemic, the UK National Health Service (NHS) had already called for greater emphasis on the delivery of digital, holistic, person-centered care for people with cancer [8]. Effective digital interventions have never been a more important aspect of care.

People with cancer are already known to face multiple challenges in terms of mental and physical health following primary treatment, including fatigue, pain, sexual problems, cognitive functioning, depression, anxiety, social isolation, and financial issues [9-13]. Furthermore, in the longer term, many patients with cancer experience negative impacts on their psychological well-being and mental health, including hypervigilance, anxiety, posttraumatic stress, and depression [14-20]. Research shows that 2 years after diagnosis, up to 20% of cancer survivors met the criteria for major depression and up to 40% met the criteria for an anxiety disorder [18-20]. As a result of the COVID-19 pandemic, people with cancer have reported a further decline in their mental and physical health [3].

Before the COVID-19 pandemic, there was a shortage of accessible self-management interventions, and there was an even greater need for digital interventions to comply with social distancing guidelines. Around a decade ago, we co-designed a face-to-face self-management program for survivors of all types of cancer [21,22]. People with cancer, oncologists, specialist cancer nurses, and representatives from a leading UK cancer charity (Macmillan Cancer Support; MCS) were involved in the co-design process. This led to the development of the *Help to Overcome Problems Effectively* (HOPE) program, which has been described in detail elsewhere [23,24]. The HOPE program aims to enhance well-being by fostering positive emotions and stimulating positive functioning. A parallel goal is to reduce depressive symptoms. The HOPE program is based on principles derived from positive psychology and focuses on positive experiences, strengths, and personal competencies rather than mental health problems such as anxiety and depression. It incorporates evidence-based exercises based on positive psychology, in addition to elements stemming from mindfulness, cognitive behavioral therapy, and problem-solving therapy. The HOPE program recognizes the common challenges and unmet needs across all types of cancer, including fatigue, fear of recurrence, and psychological distress [9-20]. The HOPE program was designed to provide support for these most common, typically overlapping needs in people living with most types of cancer. We regularly consult with MCS on their eHealth Needs Assessment data and review the most common needs indicated by people living with all types of cancer. The HOPE program provides general psychological and well-being support based on these needs and is open to all adult cancer survivors. The HOPE program differs from many other cancer self-management programs due to the focus on (1) positive psychology [25-27], (2) hope and gratitude [28] to improve well-being and coping, (3) co-created content, and (4) peer-facilitated delivery. The HOPE program is moderated by trained peer facilitators who are affected by cancer in some way. The facilitators received training from MCS and followed a delivery protocol. The facilitator's role is to offer encouragement to participants and stimulate discussion in social networking forums by inviting participants to respond with comments to specific questions or respond to questions or comments posted by participants. Facilitators also monitor daily social networking posts for safety and report technical problems to the research team. The facilitators spent approximately 2 hours per session, supporting the participants. The in-person program was adapted for digital delivery (see [24] for full details of adaptation), using a user-centered, iterative approach [29]. A set of design requirements and a design brief were drawn up in consultation with end users and stakeholders. The initial digital version of HOPE went through a number of iterative testing sessions, with improvements made to usability after each iteration. These iterations were intended to develop a system that was usable and accepted by the intended user group to increase the likelihood of uptake and continued use and to ensure that the technology did not prove a barrier to engagement and participation. Initial evaluation has suggested positive effects on anxiety, depression, and positive well-being in people with cancer, with positive user feedback [23]. This suggests that a trial of the digital HOPE program might be viable and meaningful. A feasibility randomized controlled trial (RCT) study of the digital intervention was required to assess whether participants consent to be randomized and to test the feasibility of running a wait-list control study design of the HOPE program.

Objectives

This study aims to test the feasibility of a digitally delivered self-management program for people with cancer. This will inform the design of a definitive RCT. In addition, a preliminary assessment of the impact of the HOPE program via secondary

outcomes will be used to assess signals of efficacy in a trial context.

The planned primary outcomes (trial feasibility objectives) of the study were as follows: (1) recruitment rates for participation and for randomization; (2) retention and follow-up rates as the participants move through the trial; (3) adherence rates to study procedures, intervention attendance, and engagement; (4) sample size and effect size estimation for a definitive trial; and (5) progression criteria for a definitive trial.

The secondary outcomes related to participant well-being are measures of positive mental well-being, depression, anxiety, and confidence in self-managing cancer (patient activation), as indicated by scores on validated measures.

Methods

The following sections were written in accordance with the 2016 CONSORT (Consolidated Standards of Reporting Trials) extension for pilot and feasibility trials [30].

Trial Design

This study used a feasibility, randomized waitlist control group (CG) parallel design, with a 1:1 allocation ratio. Participants were randomized into an intervention group (IG) or a waitlist CG. The IG received access to the digital 6-week HOPE program immediately. The CG was placed on a waiting list for approximately 6 weeks, after which time they also received access to the same digital 6-week HOPE program. Key outcome measures were collected via web-based questionnaires at time 0 (T0; baseline) and time 1 (T1; 6 weeks postrandomization and postprogram for IG). We also sent the questionnaires to the CG only again after they had received the intervention (time 2; T2; postprogram for CG).

Participants

The participants were referred by MCS, a leading UK cancer charity. They advertise the HOPE program through their social media networks, MCS websites, and word-of-mouth through specialist nurses.

Eligibility criteria for participants were as follows: (1) any cancer diagnosis, at any treatment stage; (2) adult (18 years or older), (3) located in the United Kingdom; (4) access to the internet and a device that allows them to engage with the intervention; and (5) fluent in English to be able to engage with all the material in the intervention.

All study data were collected on the web via questionnaires administered through the Qualtrics Survey Software (Qualtrics 2019; [31]).

Intervention

All participants had access to the same digital HOPE program. The IG received access immediately, and the CG was granted access approximately 6 weeks later.

The HOPE program was delivered on the web. Full details of the digital HOPE program development, content, and weekly topics have been described elsewhere (see [23,24]), but we provide a brief overview here. All the HOPE program modules have the same structure and format, with a variety of components each week, focusing on a particular issue or a set of techniques, and ending with goal setting activity. The HOPE program is asynchronous, and content is released on a weekly basis at set times (eg, at midday every Monday) over the 6 weeks of the intervention. Forums and messaging facilities acted as a conduit for communication between participants and facilitators, and the program was moderated by trained peer facilitators. Table 1 provides an overview of the content and activities within each weekly module of the HOPE program.

Table 1. Examples of content, exercises, and activities within each weekly module of the Help to Overcome Problems Effectively program.

Session	Examples of content	Examples of exercises and activities (self-management tools)
Week 1 (Introduction or instilling hope)	• Aims of the program • User guide to navigating the platform and setting up a profile • Introduction to self-management • The benefits of positive emotions • Video (Positive emotions for a flourishing life) • The power of gratitude • Personalized goal-setting • Video (How to set achievable goals) • Forum topic (Reasons for joining the program) • Further resources and links (eg, videos, podcasts, and websites) to gratitude, positivity, and goal-setting	• Interactive gratitude diary • SMARTER[a] goal-setting • Assessment: positivity ratio test and positive and negative emotions test
Week 2 (Stress management)	• Understanding stress • Managing stress • Videos (How to manage stress and how to make stress your friend) • Coping with unhelpful thinking patterns • Mindfulness for stress management and meditation • Self-compassion and acceptance • Video (How to be kind to yourself) • Forum topic (How do you deal with cancer-related stress?) • Further resources and links (eg, videos, podcasts, and websites) to self-compassion, mindfulness, and stress management	• Interactive gratitude diary • SMARTER goal-setting and goal feedback • Guided relaxation and meditation exercise (podcasts) • How to cope with unhelpful thoughts (worksheet)
Week 3 (Managing fatigue)	• Understanding the boom and bust cycle • Using the 3 Ps (prioritizing, planning, and pacing) for managing fatigue • Video (Tips for managing fatigue) • Sleeping better; podcast: Tips to improve sleep • Forum topic (Coping with fatigue) • Further resources and links (eg, videos, podcasts, and websites) to sleeping better	• Interactive gratitude diary • SMARTER goal-setting and goal feedback • Fatigue and pacing diaries (worksheets) • Quiz (What are the main challenges faced by cancer survivors?)
Week 4 (Body image and communication)	• Body image • Video (Body image and cancer) • Sexuality and intimacy • Video (Cancer as a passport to emotional intimacy) • Communication skills and tips for talking with the health care team and family • Forum topic: experiences of coping with body changes and experiences of communicating with the health care team • Further resources and links (eg, videos, podcasts, and websites) to sexuality, intimacy, and relationships	• Interactive gratitude diary • SMARTER goal-setting and goal feedback
Week 5 (Physical activity and fear of recurrence)	• Coping with fear of recurrence • Videos (Moving forward while being worried about cancer returning and the regrets of those who are dying) • Hopes and dreams for the future • Video: Before I die project • The benefits of physical activity • Video (Tips for becoming and staying active) • Forum topic (Concerns about cancer coming back) • Further resources and links (eg, videos, podcasts, and websites) to managing concerns about cancer coming back and getting more active	• Interactive gratitude diary • SMARTER goal-setting and goal feedback

Session	Examples of content	Examples of exercises and activities (self-management tools)
Week 6 (Character strengths and happiness)	• Understanding how using your strengths can lead to a more fulfilling life • Video (The science of character strengths) • Tips for authentic happiness; managing setbacks and keeping going • Forum topic (Learning from the program) • Further resources and links (eg, videos, podcasts, and websites) to MCS[b] web-based communities and happiness resources	• Interactive gratitude diary • SMARTER goal-setting and goal feedback • Assessment (positivity ratio test and positive and negative emotions test and character strengths) • Quiz (What contributes to happiness?)

[a]SMARTER: SMARTER is an acronym used by many organizations for goal-setting, and stands for specific, measurable, achievable, relevant, time-bound, enjoyable, and reward.

[b]MCS: Macmillan Cancer Support.

Primary Outcomes

The primary outcome measures for this feasibility RCT were as follows:

Recruitment Rates

Recruitment rates for participation and randomization were collected primarily through Qualtrics at the start of the trial. All eligible participants identified by MCS were sent a link to the Qualtrics study survey. Recruitment rates were then calculated from the following: (1) providing consent and (2) completing baseline questionnaires. Direct email from participants indicating refusal or declining to participate in the study indicated a refusal. These participants were still offered access to the HOPE program but did not participate in any further data collection.

Retention, Follow-up, and Completion Rates

The participant retention rate was calculated as the percentage of participants attending all 6 program sessions. Studies show that a median of 56% of participants complete the full program in digital interventions for mental well-being [32,33]. As high rates of nonuse attrition [34] are common and of concern in digitally delivered interventions, and because of uncertainties relating to the COVID-19 pandemic, we set a more conservative target of 50% of participants completing all 6 sessions of the intervention.

Follow-up was calculated as the percentage of participants who completed all web-based study questionnaires. Participants who were lost to follow-up were identified through Qualtrics as those who did not complete the postprogram questionnaires at the end of the intervention period. It is possible that these participants may still have attended some portions or the entire HOPE program, despite not completing questionnaires.

If participants attended at least half of the intervention (3 sessions) [32] and completed the study questionnaires, they were classified as intervention completers. Studies show a nonlinear relationship between the time spent on an intervention, the number of sessions completed, and outcomes [32]. The amount of use needed to obtain desired outcomes varies across groups, and individuals may stop using the intervention once personal goals are achieved [35]. Therefore, we set a more pragmatic target for our primary outcome measure of *completion rate* of at least 3 sessions attended, and completion of all study questionnaires.

Adherence and Engagement Measures

The intervention platform collects user engagement data, such as the number of pages viewed in each session and the number of goals set that assists the moderators with participant engagement and experience. We measured the mean percentage of pages viewed per session, and the number of posts or comments a participant made for key activities (gratitude, setting goals, goal feedback, liking posts, and comments posted).

Sample Size and Effect Size Estimation for Future Definitive Trial

To inform the sample size estimation for a future definitive trial, we calculated the SDs of key continuous secondary outcomes at baseline. To estimate potential effect sizes for a primary outcome in a future definitive trial from pre- to postprogram, we calculated the difference between the mean difference pre- and postprogram for the IG and CG and divided by the pooled SD at baseline [36].

Progression Criteria

There is little guidance available for determining progression criteria for exploratory studies, including feasibility trials [37]. Following good practice, our progression criteria were discussed with Patient and Public Involvement representatives [38] and within the trial project group. Our 3 progression criteria reflect specific uncertainties regarding the feasibility of a larger definitive trial. The web-based HOPE program has not previously been delivered in an RCT study context, so two of our progression criteria tested the willingness of people to participate in a trial (recruitment and questionnaire completion rate). Full intervention completion (now labeled as “retention” within the manuscript) is the most frequently reported metric for adherence to web-based interventions [39], which, through discussion, was set as our third progression criteria.

To inform the progression to a definitive trial, we compared our results to the progression criteria set *a priori* as follows: (1) recruitment rate >70% of eligible participants consented, (2) questionnaire completion rate >70% of participants completing T1 questionnaires, and (3) retention rate >50% of participants attending all 6 HOPE program sessions.

Secondary Outcomes

Sociodemographic and health data were collected at T0. Participants were asked to provide the following information via a web-based questionnaire: gender, age, ethnicity, marital status, highest level of education, employment and occupation, and details about their cancer diagnosis and other medical conditions.

Participants completed a set of validated questionnaires at T0 (baseline), T1 (6 weeks postrandomization), and T2 (postprogram for CG only). Postprogram (T1 and T2) questionnaires were made available to participants the week after the intervention ended and remained available for a further 4 weeks. The positive mental well-being, depression, anxiety, and patient activation measures are detailed below.

The Warwick Edinburgh Mental Well-being Scale (WEMWBS) [40] is a validated scale of 14 positively worded feelings and thoughts used to assess mental well-being within the adult population. The scale includes measures of positive affect, satisfying interpersonal relationships and positive functioning, for example, *Below are some statements about feelings and thoughts. Please tick the box that best describes your experience of each over the last 2 weeks*...(1) "I have been feeling optimistic about the future," (2) "I have been thinking clearly," and (3) "I have been feeling loved." Participants rated each of the 14 items on a scale of 1 to 5 (1=none of the time, 2=rarely, 3=some of the time, 4=often, 5=all of the time), providing a total positive mental well-being score ranging from 14 to 70, with higher scores representing greater positive mental well-being. The WEMWBS had good internal consistency (Cronbach α=.91). A change of 3 or more was seen as clinically meaningful change [41].

The 9-item Patient Health Questionnaire (PHQ-9) [42] is a validated 9-item measure, which assesses the frequency of experience of the symptoms of depression. For example, *Over the past 2 weeks, how often have you been bothered by any of the following problems*...(1) *little interest or pleasure in doing things*; (2) *feeling down, depressed, or hopeless*; and (3) *poor appetite or overeating*.

Responses to each of the 9 items ranged from 0 to 3 (0=not at all, 1=several days, 2=more than half the days, 3=nearly every day), leading to a summed score between 0 and 27, with higher scores indicating greater severity of depression. The PHQ-9 has good internal consistency (α=.89). Scores of 10 or more are presumed to be above the clinical range; thus, participants scoring 10 are categorized as depressed for the purpose of this study.

The 7-item Generalized Anxiety Disorder scale (GAD-7) [43] is a validated 7-item scale measuring symptoms of generalized anxiety disorder, for example, *Over the past 2 weeks, how often have you been bothered by the following problems*...(1) *feeling nervous, anxious or on edge*; (2) *trouble relaxing*; and (3) *becoming easily annoyed or irritable*. Responses to all 7 items ranged from 0 to 3 (0=not at all, 1=several days, 2=more than half the days, 3=nearly every day), providing a total score of 0 to 21, with higher scores indicating greater anxiety. GAD-7 has good internal consistency (Cronbach =.92). Scores of 8 or more are presumed to be above the clinical range; therefore, participants scoring 8 are categorized as having anxiety for the purpose of this study.

The Patient Activation Measure [44] is a validated, licensed tool with good internal consistency (Cronbach =.81), which has been extensively tested with reviewed findings from a large number of studies. It helps to measure the spectrum of knowledge, skills, and confidence in patients and captures the extent to which people feel engaged and confident in taking care of their condition. Individuals are asked to complete a short survey, and based on their responses, they receive a Patient Activation Measure score (between 0 and 100). The resulting score places the individual at 1 of 4 levels of activation, each of which reveals insight into a range of health-related characteristics, including behaviors and outcomes. The 4 levels of activation are as follows:

1. Level 1 (scores ≤47.0): Individuals tend to be passive and feel overwhelmed by managing their own health. They may not understand their roles in the care process.
2. Level 2 (scores 47.1-55.1): Individuals may lack the knowledge and confidence to manage their health.
3. Level 3 (scores 55.2-67.0): Individuals appear to be taking action but may still lack the confidence and skill to support their behaviors.
4. Level 4 (scores 67.1): Individuals have adopted many of the behaviors needed to support their health but may not be able to maintain them in the face of life stressors.

Sample Size for This Study

All study participants were drawn from an opportunity sample (N=61), provided by MCS, of eligible candidates who expressed an interest in taking part in the HOPE program. An arbitrary sample size of n=40 was deemed adequate for this feasibility study, informed by similar studies in this area, with sample sizes ranging from 10 to 20 in each arm [45]. All potential study participants were emailed a link to the study website hosted by Qualtrics, where they were asked to read the digital Participant Information Sheet, read and agree to the statements on the digital consent form, and complete the digital T0 questionnaire before randomization.

Randomization

Sequence Generation

All participants who provided informed consent and completed the T0 questionnaires were randomized into the IG or CG using a 1:1 ratio via the randomization function within the Qualtrics Survey Software.

Allocation Concealment Mechanism

Participants were informed on completion of the T0 questionnaires, via a notification in Qualtrics, whether they had been randomized to the IG (in this case, starting in May 2020), or the CG (in this case, starting in June 2020). The research team remained unaware of participant allocation until group contact lists were created at the next data collection point (ie, T1).

Implementation

Participants were allocated to the IG or CG via the randomization function in Qualtrics. Participants were then emailed with a link to the HOPE program starting in the following week (IG), or a message to say that they would be emailed a link to the HOPE program (CG) in approximately 6 weeks' time.

Blinding

Owing to the nature of the study design, it was not possible to blind the participants to their group allocation. However, statistical analyses of study data were conducted blind to participant allocation where possible (eg, IG and CG were labeled *A* and *B* arbitrarily).

Analytical Methods

Quantitative data were analyzed descriptively using IBM SPSS 26 (IBM Corporation, released 2019). Initial analyses involved tabulated and graphical summaries of primary and secondary outcomes for each randomized group using means and variance, including CIs and SDs, and number and percentages for categorical variables to describe the full range of data at baseline and postprogram. An intention-to-treat (ITT) analysis was carried out, where missing data were rectified using the last observation carried forward (LOCF) [46]. In line with CONSORT (Consolidated Standards of Reporting Trials) guidelines [47], a per-protocol (PP) analysis was also performed on secondary outcome data from intervention completers and is reported in the *AncillaryAnalyses* section.

The study was not powered to perform inferential statistical analyses, and so to signal efficacy, we report pre- and postprogram mean differences and CIs for scores on key secondary outcome measures for the IG and CG.

Protocol

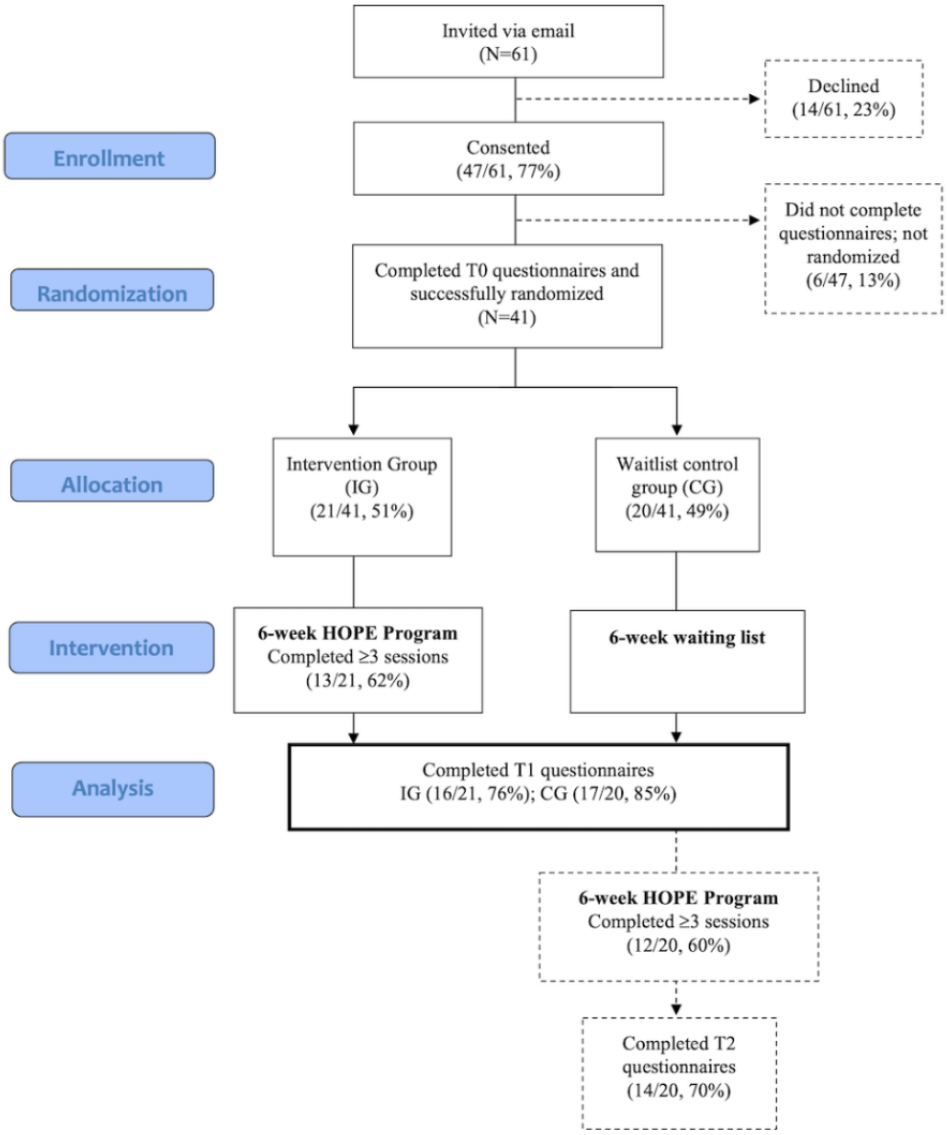
The feasibility trial protocol has been registered and published (International Registered Report Identifier IRRID: DERR1-10.2196/24264) [24].

Results

Participant Flow

Figure 1 provides the details of the participant flow through the study.

Figure 1. Participant flow through the study. HOPE: Help to Overcome Problems Effectively.



Recruitment

Recruitment started on April 30, 2020, and ended on May 5, 2020. Data collection started on April 30, 2020, for T0 baseline questionnaires and finished on September 2, 2020, for T2 follow-up questionnaires (CG only), which was 4 weeks after the end of the intervention for the CG as specified in the trial protocol.

Baseline Data

Sociodemographic and health information collected at baseline (T0) for the whole group and by treatment group are presented in Table 2. The sample consisted mostly of White participants (36/41, 87%), women (32/41, 78%) with an average age of 54.3 years. More than half of the sample (24/41, 58%) had postschool qualifications. Most participants were married or living with their partner (30/41, 73%), and more than half were employed (21/41, 51%), with just under half reporting that they had to reduce their working hours because of their cancer diagnosis (20/41, 49%). This variable was the most disproportionate across the trial arms, with more than twice as many reports of cutting work hours in the IG (14/21, 67%) than in the CG (6/20, 30%) The most commonly reported type of cancer was breast cancer (17/41, 41%), with less than half of participants still undergoing treatment (17/41, 41%). Participants may have reported more than one type of cancer; therefore, the sum of the group percentages may be >100%.

Table 2. Baseline characteristics for the whole sample and by trial arm.

Variable	All (N=41)	IG[a] (n=21)	CG[b] (n=20)
Age, mean (SD)	54.3 (11)	52.6 (11)	56.2 (12)
Female, n (%)	32 (78)	17 (81)	15 (75)
White ethnicity, n (%)	36 (88)	19 (90)	17 (85)
Married or living with partner, n (%)	30 (73)	17 (81)	13 (65)
Employed, n (%)	21 (51)	11 (52)	10 (50)
Cut work hours due to cancer, n (%)	20 (49)	14 (67)	6 (30)
Possessed postschool qualifications, n (%)	24 (58)	12 (57)	12 (60)
Still undergoing treatment for cancer, n (%)	17 (41)	9 (43)	8 (40)
Cancer type, n (%)

[a]IG: intervention group.

[b]CG: control group.

Numbers Analyzed

The total number of participants enrolled in the study was 41, with 21 in the IG and 20 in the CG. All participants completed baseline (T0) questionnaires, and missing data in T1 and T2 questionnaires were populated with the LOCF method for ITT analysis. Therefore, the entire sample was included in the ITT analysis (ITT, N=41; IG, n=21; CG, n=20). The numbers for the PP analysis are detailed in the *AncillaryAnalyses* section.

Outcomes and Estimation

We describe the results for each primary and secondary outcome. Primary outcome measures pertaining to recruitment, questionnaire, and intervention completion rates are presented in Figure 1, Table 3, and Table 4. Secondary outcome measures are presented in Table 5 for the whole group (n=41) and each trial arm (IG, n=21; CG, n=20).

Table 3. Number of participants who attended none, some, or all of the Help to Overcome Problems Effectively Program sessions, for the whole group and each trial arm.

Number of sessions attended	All (N=41), n (%)	IG[a] (n=21), n (%)	CG[b] (n=20), n (%)
0	5 (12)	2 (9)	3 (15)
1	5 (12)	3 (14)	2 (10)
2	5 (12)	3 (14)	2 (10)
3	2 (5)	1 (5)	1 (5)

Primary Outcomes

Recruitment rates

The recruitment rate for this feasibility study was 77% (47/61). MCS referred to 61 participants for the study, and 77% of participants (47/61) provided digital informed consent. Only participants who (1) consented, (2) completed baseline questionnaires, and (3) were randomized, were included in this feasibility study (n=41). Six participants provided informed consent but did not complete the T0 questionnaire; therefore, they were not randomized (6/47, 13%). The study participants who completed the baseline questionnaires (n=41) were randomized to either the IG (n=21) or the CG (n=20) groups.

Retention, Follow-up, and Completion Rates

The retention rate across the sample was 51%, with more than half of the participants attending all 6 program sessions (whole group: 21/41, 51%; IG: 10/21, 47%; CG: 11/20, 55%).

Across the whole group, there was a follow-up rate of 80% (33/41 participants completed T1 questionnaires). Across the trial arms, the follow-up rate was 76% (16/21) in the IG and 85% (17/20) in the CG.

The completion rates (3 sessions and T1 questionnaire) for the whole group were 61% (25/41), 62% (13/21) in the IG, and 60% (12/20) in the CG.

Adherence and engagement measures

Table 4 shows the selection of the engagement data collected by the intervention platform. The mean number of pages viewed per session generally decreased as the program progressed and ranged from 12.2/16 (76%) in session 1 to 5.1/10 (51%) in session 6, across the whole group. The mean pages viewed in each session were consistent across the entire group and both trial arms for sessions 1 and 6. The mean number of pages viewed was slightly higher for the CG than for sessions 2 to 5. Furthermore, the CG tended to set slightly more goals, give more likes, and post more comments than the IG, on average, across the course of intervention. There was a negligible difference in the mean gratitude entries and goal feedback between the 2 trial arms.

Sample Size and Effect Size Estimation for Future Definitive Trial

To guide the sample size estimation for a future definitive trial, we used the results of this study. Accordingly, we calculated the expected minimum effect sizes using the primary outcome variable, WEMWBS, and based on the present data, considering the mean change scores for IG and CG and a moderate between-group effect size. Given an *a priori* α of .05, 87 participants were required per group to minimally detect moderate effect sizes (ie, Cohen $f \geq 0.25$; Cohen $d \geq 0.5$), or 42 participants per group to minimally detect large effect sizes (Cohen $f \geq 0.4$; Cohen $d \geq 0.8$), both with a power of 0.95 [36]. Indeed, we must caveat this guide with acknowledgment that the inherent imprecision in between treatment group effect size estimates from studies with small samples can be high and thus must be considered pragmatically in future trials [48].

Progression Criteria

All predetermined progression criteria for a definitive trial were met, as described in the sections above.

Secondary Outcomes

An ITT analysis was carried out, with missing data rectified by LOCF. The mean scores and SDs for the secondary outcome measures for both trial arms are presented in Table 5. On average, participants in the IG made small improvements from T0 to T1. Participants in the CG showed little to no improvement during the same period. However, after attending the HOPE program (ie, T2), the CG made greater improvements in all secondary measures than the IG.

Table 6 shows the number and proportion of participants exceeding the cutoff scores for probable clinical depression and

anxiety at each time point across the trial. In the IG, the number of participants reporting probable clinical levels of depression decreased by 1 from preprogram (8/21, 38%) to postprogram (7/21, 33%), and cases of depression remained the same pre- and postprogram (10/21, 47%). In the CG, at the point of entry into the trial (T0), the proportion of participants reporting probable clinical levels of depression and anxiety was the same (10/20, 50%). From pre- to postprogram in the CG, there was a 15% decrease in cases of probable depression (T1, 7/20, 35%; T2, 4/20, 20%) and anxiety (T1, 8/20, 40%; T2, 5/20, 25%).

Table 6. Proportion of participants reporting probable clinical levels of depression and anxiety at each time point across the trial.

Secondary outcome measure	IG[a], n (%); n=21		CG[b], n (%); n=20		
	T0	T1[c]	T0	T1[d]	T2[e]
Cases of probable depression	8 (38)	7 (33)	10 (50)	7 (35)	4 (20)
Cases of probable clinical anxiety	10 (47)	10 (47)	10 (50)	8 (40)	5 (25)

[a]IG: intervention group.

[d]LOCF: last observation carried forward, n=3.

[e]LOCF: last observation carried forward, n=6.

Ancillary Analyses

We conducted a PP analysis, which included only those participants who completed all study questionnaires and attended at least 3 intervention sessions (PP whole sample n=25; IG n=13, CG n=12). Table 7 shows the secondary outcome measures for the participants. The data in Table 7 show patterns similar to those of the ITT in Table 5. On average, participants in the IG showed modest improvements from T0 to T1. Participants in the CG showed little to no improvement during the same period. The PP analysis shows a difference in the change scores (final column) of greater magnitude compared with the ITT analysis.

Table 7. Scores on secondary outcome measures for intervention group (IG; n=13) and control group (CG; n=12) intervention completers (PP), including mean difference in change scores (IG-CG).

Secondary outcome measure	IG (n=13)			CG (n=12)			Difference in change scores Δ IG-CG, mean difference (95% CI)
	T0, mean (SD)	T1, mean (SD)	Postprogram change Δ (T1-T0), mean difference (95% CI)	T0, mean (SD)	T1, mean (SD)	Control change Δ (T1-T0), mean difference (95% CI)	
WEMWBS[a]	44.9 (10.1)	49.5 (12.7)	4.6 (−0.5 to 9.7)	43.8 (12.0)	42.7 (11.7)	−1.1 (−4.7 to 2.5)	5.7 (−0.3 to 11.7)
PHQ-9[b]	9.1 (6.1)	6.8 (6.5)	−2.2 (−4.3 to −0.2)	9.1 (6.6)	10.8 (6.7)	1.7 (0.4 to 2.9)	−3.9 (−6.2 to −1.6)
GAD-7[c]	8.6 (6.4)	7.0 (6.6)	−1.6 (−4.4 to 1.2)	8.5 (5.7)	8.8 (4.8)	0.3 (−1.8 to 2.3)	−1.9 (−5.2 to 1.5)
PAM[d]	63.2 (15.2)	66.2 (14.6)	3.0 (0 to 6.0)	61.6 (12.8)	56.1 (11.2)	−5.5 (−11.7 to 0.7)	8.5 (2.2 to 14.8)

[a]WEMWBS: Warwick-Edinburgh Mental Well-being Scale.

[b]PHQ-9: 9-item Patient Health Questionnaire.

[c]GAD-7: 7-item Generalized Anxiety Disorder scale.

[d]PAM: Patient Activation Measure.

Harms

In line with the trial protocol [24], participants who indicated self-harm or suicidal thoughts on the PHQ-9 measure were contacted, along with the MCS administrator, by Hope for the Community (H4C) and were provided with the contact details of local mental health agencies and Samaritans and encouraged to visit their general practitioner. This was the case for 22% (9/41) of participants' preprogram, and 9% (4/41) of participants postprogram (data not shown in tables). At postprogram, there were no participants who indicated self-harm or suicidal thoughts where they had not already indicated this at the preprogram.

As detailed in the Methods section, participants scoring 10 on the PHQ-9 or 8 on the GAD-7 were categorized as having

reached a probable clinical level of depression or anxiety, respectively. Depression was indicated in 44% (18/41) of participants at preprogram and 34% (14/41) at T1. Anxiety was indicated in 49% (20/41) of participants at preprogram and 44% (18/41) at T1. In line with the trial protocol [24], all of these participants were contacted by H4C and encouraged to visit their general practitioner and were signposted to further sources of support as listed above.

At postprogram, there were no participants who reported a probable clinical level of depression where they had not already reported this at the preprogram. However, at postprogram, 5% (2/41) of participants reached a probable clinical level of anxiety but were not previously at this level in the preprogram. Both participants scored 7 on the GAD-7 measure at preprogram, increasing to scores of 8 (n=1) and 9 (n=1) at postprogram. Both participants were contacted by H4C, as outlined above, and in the trial protocol [24]. To provide further context, both participants were in the IG, and only attended 1 (n=1) or 2 (n=1) sessions of the intervention. Both participants were still undergoing treatment for cancer, and one described significant personal stress unrelated to their cancer. Although we cannot rule out the possibility that the intervention may have caused increased anxiety in these 2 participants, they did not engage in more than 2 sessions of the intervention, and the context of the COVID-19 pandemic is linked to increased anxiety among patients with cancer [1,3,5,6]. Furthermore, other participants showed positive changes in their pre- and postprogram mental well-being scores.

Discussion

Principal Findings

The feasibility RCT of the digital HOPE program aimed to assess primary outcomes measuring trial feasibility and secondary outcomes relating to measures of participant well-being. The trial yielded encouraging data on the primary outcome measures of recruitment, retention, follow-up, adherence, and engagement rates. More than three-quarters of the participants invited (47/61, 77%) were willing to provide consent and be randomized to either the HOPE program starting the following week, or to a 6-week waiting list. Just over half of the sample (ie, IG and CG combined; 21/41, 51%) completed all 6 sessions of the intervention, and almost two-thirds of the sample (26/41, 63%) completed at least 3 sessions (note that n=1 did not complete the T1 questionnaire, so it was not categorized as an intervention completer. The follow-up rate was encouraging, with a large proportion of participants completing the study questionnaires at T1 (33/41, 80%). Of the participants who completed the T1 questionnaires, 25 also attended 3 intervention sessions, meeting the criteria for intervention completion (25/41, 61%). In terms of engagement, within the sessions, participants viewed between half and three-quarters of the content, on average (range 76%-51%). All of the predetermined progression criteria were met, confirming that a full-scale, fully powered RCT of the digital HOPE program for people with cancer would be feasible.

On average, participants showed increased scores on positive mental well-being and patient activation and decreased scores on anxiety and depression at postprogram relative to baseline. We did not ask participants specific questions relating to their well-being during the COVID-19 pandemic. However, we can tentatively compare data from this study with a previous cohort of people with cancer in the digital HOPE program, collected before the COVID-19 pandemic [23]. The proportion of participants reporting probable clinical levels of depression at baseline was slightly higher in the prepandemic cohort [23] than in the current trial (24/51, 47%, and 18/41, 44%, respectively). However, at baseline, probable clinical levels of anxiety were lower in the prepandemic cohort (22/51, 43%) than in the current trial (20/41, 49%). Indeed, in the current trial, baseline GAD-7 scores for anxiety 8.9 (SD 6.0; pooled data not shown in *Results*) were higher than those in our prepandemic study 6.8 (SD 4.9) [23]. Given the widespread reports of the negative effect of the COVID-19 pandemic on the mental health of people with cancer [3], the baseline scores in the current trial may represent elevated COVID-19–related anxiety.

Exploration of the secondary outcome data highlights the safety of the HOPE program as a digital self-management intervention for people with cancer. There were no cases of participants reporting increased symptoms of depression, and only 2 participants reported increased postprogram anxiety. There were no cases where participants reported thoughts of suicide or harming themselves at postprogram, where they had not already reported this at baseline.

Limitations

This study found that overall engagement, measured by the percentage of pages viewed, seemed to decline as participants progressed through the sessions. This may be due to fatigue or redundant content. Qualitative investigation into what content participants engaged with, and elements they found more or less relevant or helpful would be a useful supplement to improve the intervention.

This feasibility RCT was not powered to detect statistically significant differences in pre- and postscores on secondary outcomes. However, the results indicate that the HOPE program has the potential to have a positive effect on mental well-being, depression, and anxiety in people with cancer. These have been identified as important outcomes for people with cancer [9-11] and echo the results of a previous pre- and poststudy of the HOPE program [23], giving further confidence in the potential efficacy of the intervention. Data from a fully powered trial will allow us, for the first time, to report statistically significant differences in pre- and postprogram scores for both IG and CG. However, unless we account for expectancy effects, we cannot be sure about the efficacy of the intervention [49]. Therefore, future trials will need to use an appropriate active control program, which equates expectations to those of the IG, to allow a causal conclusion about the effectiveness of the intervention effectiveness. There are a number of ways to address this issue in future work. First, empirical measures of expectancy could be collected before and after the program to assess for any correlation between expectancy and improvement in either group. Although this would not reduce any expectancy effects, it would allow us to account for these in statistical analyses, interpretation of the data, and evaluation of the intervention.

Second, in a future trial, we could use an active control program, such as an alternative digital self-management intervention, or a modified version of the HOPE program (eg, without the goal-setting feature; self-directed course). Active control needs to be carefully matched to the intervention in terms of expectancy, content, and interaction [49]. Researchers suggest that if participants' well-being is improved postintervention, then the mechanisms by which this benefit occurs are irrelevant. However, it becomes a problem if the improvement is only detectable in the laboratory, or in this case, at the time of the postprogram data collection. A third way to address expectancy in future trials would be to implement further follow-up time points (eg, 3, 6, and 12 months postrandomization) to assess whether improvements to participant well-being persist in the longer term. Ideally, in future trials, we would use all 3 methods to reduce placebo effects and increase confidence in the treatment effect of the HOPE program.

Generalizability

The recruitment for this feasibility RCT was from an opportunity sample of self-selecting participants referred by MCS. The self-selecting nature of the recruitment strategy may yield participants who are generally more motivated to seek help and/or help themselves. However, this recruitment strategy facilitated the rapid attainment of trial recruitment targets in this study [50]. Research has shown that recruitment via social media is more effective if advertised by a collaborative cancer charity [51]. In this respect, in the current climate of increased need for digital research and provision of self-management support, we optimized our recruitment strategy in this feasibility trial and will adopt this again in the definitive trial.

Most participants were White (36/41, 88%), female (32/41, 78.0%), married (30/41, 73%), and educated (24/41, 58%), and the most commonly reported type of cancer was breast cancer (17/41, 41%). This likely relates to the demographics of people who engage with the MCS charity. Although this may limit the generalizability of the results to other demographic groups, some aspects are in line with wider population statistics and research findings. The 2011 Census [52] reported that 86% of the population in England and Wales was White, and therefore, the sample in this study is representative of the wider population in this respect. Breast cancer is the most common type of cancer in the United Kingdom, accounting for 15.1% of malignant cancer registrations in England in 2017 [53]; however, 41.5% of participants in this study reported breast cancer. The data presented in this study may not be representative of other cancer populations. As such, the efficacy signal and feasibility findings of this study may not be generalizable to other types of cancer, or to non-White men, for example. We will seek advice from our partners and trial experts before proceeding to a definitive trial. It may be more appropriate to run a definitive RCT of the HOPE program for breast cancer survivors only, as (1) breast cancer is the most commonly diagnosed cancer in the United Kingdom, and (2) our own data, for example, 23 and unpublished studies, show that it is mainly women with breast cancer who participate in the HOPE program. However, the HOPE program was designed to help people living with all types of cancer; thus, the community HOPE program run by MCS will continue to be open to all cancer survivors.

A low attendance rate for men is common in self-management and is linked to their reluctance to seek help [54]. In terms of recruitment, men are more likely to respond to marketing and recruitment messages that emphasize stoicism, independence, and control [54] and where the materials contain images of men [55]. Once recruited, there are also qualitative differences in how men and women engage with their peers in the same- or mixed-sex web-based cancer support groups [56]. A recent systematic review confirmed that men are more oriented toward informational support and women toward emotional support [57]. In terms of the current intervention, further intervention development is required to ensure the relevance and acceptability of the intervention and potentially to co-design tailored versions for more diverse groups and communities. This may require (1) further consultation with MCS to co-design specific programs for gendered cancers (eg, a HOPE program for testicular, prostrate, or breast cancer); (2) co-development of course content and recruitment materials to increase the engagement of men in a general cancer intervention; and (3) partnering with different charities to enhance engagement with people with cancer from different ethnic groups, socioeconomic status, and educational attainment. A future trial could examine the feasibility of recruitment through the NHS, from clinics, consultation rooms, or waiting rooms, to broaden the recruitment strategy to wider communities. For future cohorts, we will encourage MCS to review their recruitment materials to ensure that they contain images and messages that appeal to multiple audiences and are advertised in (largely web-based) areas and locations frequented by people of all ages, ethnicities, genders, and income groups [54-57].

Interpretation

The digital HOPE program is a feasible self-management intervention for people with cancer, although almost half of our sample comprised people with breast cancer. All progression criteria were met, providing support for a full-scale definitive trial. However, caution must be taken when interpreting the generalizability of our feasibility estimates, and a further discussion with our research trial group will be undertaken to determine the appropriate action for progression. Generally, at postprogram, all participants showed increased scores on positive mental well-being and patient activation and decreased scores on anxiety and depression relative to baseline, signaling intervention efficacy. Minimal harm was indicated, and no participants reported postprogram symptoms of anxiety or depression that were not present at baseline, and similarly for thoughts of suicide and self-harm.

The asynchronous nature of the course and the autonomy afforded to participants means that they can broadly tailor the course to accommodate personal needs. Participants can attend sessions that are interesting or relevant to them, essentially creating their own person-centered support by self-selecting the content. Rather than interpreting attrition as a negative trial outcome, we concur with the view that participants can be *eAttainers* [35,58]. That is, participants take what they need from the course and then may appear to *drop out* but are nonetheless satisfied and fulfilled by the content they received. Participants do not need to engage with all available components of the intervention, or all use the same components, as goals

differ across individuals [35]. For example, some participants obtain reassurance from sharing their challenges and concerns with others, a common group curative factor described as "universality" by Yalom [59]. This approach aligns with the tailored nature of the HOPE program, enabling users to self-select the most relevant intervention tools, features, or content for themselves. This is supported by the overwhelmingly positive user evaluations collected postprogram in this feasibility trial (data not shown) and in a previous HOPE program study [23]. As the focus of this paper was to assess the feasibility of an RCT, and not to evaluate the efficacy and acceptability of the HOPE program [48], we did not present participant feedback data here.

Conclusions

The advent of the digital HOPE program has coincided with requests from academics, leading cancer charities, and the NHS, for more person-centered cancer self-management, especially during the recent global pandemic [2,3,8]. As such, there has been rapid and essential growth in the provision of health care digitally to allow remote care [60,61], and these advances in digital health care will still be viable in the postpandemic era. This feasibility RCT suggests that the digital HOPE program could supplement in-person emotional and psychological support for people with cancer, offering greater choice and flexibility in accessing support. Although digital cancer self-management interventions, such as the HOPE program, have boomed during COVID-19 [60-62], more data are needed to suggest whether digital could be considered an alternative, as well as complementary, format to in-person intervention programs. As the HOPE program content can be delivered on the web or in-person, it offers flexibility and a choice of formats for participants when social distancing measures are eased after the pandemic.

Acknowledgments

The research study was investigator funded and approved by the Coventry University Ethics Committee (P106024) on April 28, 2020.

Abstract

Background: People with serious mental illness (SMI) have significant unmet mental health needs. Development and testing of digital interventions that can alleviate the suffering of people with SMI is a public health priority.

Objective: The aim of this study is to conduct a fully remote randomized waitlist-controlled trial of CORE, a smartphone intervention that comprises daily exercises designed to promote reassessment of dysfunctional beliefs in multiple domains.

Methods: Individuals were recruited via the web using Google and Facebook advertisements. Enrolled participants were randomized into either active intervention or waitlist control groups. Participants completed the Beck Depression Inventory-Second Edition (BDI-II), Generalized Anxiety Disorder-7 (GAD-7), Hamilton Program for Schizophrenia Voices, Green Paranoid Thought Scale, Recovery Assessment Scale (RAS), Rosenberg Self-Esteem Scale (RSES), Friendship Scale, and Sheehan Disability Scale (SDS) at baseline (T1), 30-day (T2), and 60-day (T3) assessment points. Participants in the active group used CORE from T1 to T2, and participants in the waitlist group used CORE from T2 to T3. Both groups completed usability and accessibility measures after they concluded their intervention periods.

Results: Overall, 315 individuals from 45 states participated in this study. The sample comprised individuals with self-reported bipolar disorder (111/315, 35.2%), major depressive disorder (136/315, 43.2%), and schizophrenia or schizoaffective disorder (68/315, 21.6%) who displayed moderate to severe symptoms and disability levels at baseline. Participants rated CORE as highly usable and acceptable. Intent-to-treat analyses showed significant treatment×time interactions for the BDI-II ($F_{1,313}$=13.38; P<.001), GAD-7 ($F_{1,313}$=5.87; P=.01), RAS ($F_{1,313}$=23.42; P<.001), RSES ($F_{1,313}$=19.28; P<.001), and SDS ($F_{1,313}$=10.73; P=.001). Large effects were observed for the BDI-II (d=0.58), RAS (d=0.61), and RSES (d=0.64); a moderate effect size was observed for the SDS (d=0.44), and a small effect size was observed for the GAD-7 (d=0.20). Similar changes in outcome measures were later observed in the waitlist control group participants following crossover after they received CORE (T2 to T3). Approximately 41.5% (64/154) of participants in the active group and 60.2% (97/161) of participants in the waitlist group were retained at T2, and 33.1% (51/154) of participants in the active group and 40.3% (65/161) of participants in the waitlist group were retained at T3.

Conclusions: We successfully recruited, screened, randomized, treated, and assessed a geographically dispersed sample of participants with SMI entirely via the web, demonstrating that fully remote clinical trials are feasible in this population; however, study retention remains challenging. CORE showed promise as a usable, acceptable, and effective tool for reducing the severity of psychiatric symptoms and disability while improving recovery and self-esteem. Rapid adoption and real-world dissemination

of evidence-based mobile health interventions such as CORE are needed if we are to shorten the science-to-service gap and address the significant unmet mental health needs of people with SMI during the COVID-19 pandemic and beyond.

mobile health; schizophrenia; bipolar disorder; depression; mobile phone

Introduction

Background

People with serious mental illnesses (SMIs), including schizophrenia-spectrum disorders, bipolar disorder, and severe and persistent depression, experience significant psychiatric symptoms such as hallucinations, delusions, and severe mood episodes. SMI is often accompanied by functional and psychosocial impairments, housing and employment challenges, and poverty [1-3]. Treatment of people with SMI typically takes place in publicly funded clinics and community mental health centers that are chronically underresourced, understaffed, and overextended [4,5]. These public sector agencies are rarely able to meet the demand for services [6]. Barriers in the capacity to provide high-quality care on the provider's side may be compounded by hesitancy around treatment seeking on the patient's side [7]. People with SMI are often exposed to pervasive societal stigma about their conditions and therefore can be reluctant to openly seek services at a clinic if it risks them being labeled *mentally ill* [8,9]. The consequence of these intersecting challenges is a vicious cycle in which those who are most impaired receive the least amount of support, thus deteriorating even more over time.

People with SMI are not dramatically different from the general population in their use of mobile technologies [10,11]. Owing to subsidy programs that offer people with disabilities access to mobile phones and data plans (eg, Federal Communications Commission Lifeline Program) and the dropping prices of mobile phones worldwide, people with SMI now have unprecedented opportunities to access information, stay connected to others, and potentially receive services remotely via personal mobile devices [12]. Survey studies conducted in recent years have shown that approximately two-thirds of people with SMI in the United States already own smartphones and that most are interested in leveraging them to support their health care [13-16]. Academic research groups and commercial companies are responding to the opportunity and have begun to develop and test a range of smartphone-supported digital health technologies for people with SMI, including illness self-management apps, virtual peer support platforms, and sensor-enabled remote patient monitoring systems [17-19].

Conducting the research necessary to demonstrate the safety and clinical utility of novel smartphone interventions for people with SMI is challenging and costly. Recruitment of participants for clinical trials is the most salient cause of study delays and a major obstacle in expeditiously moving novel and potentially helpful interventions to real-world practice [20]. Traditional participant recruitment strategies are dependent on collaborative partnerships with study sites and clinician referrals [21]. This creates potential biases in clinical trial samples, as the enrolled individuals already need to be known by health care providers and be actively receiving care to be offered the opportunity to engage in research. Therefore, the participant samples used in standard clinical trials may be particularly unrepresentative of hard-to-reach populations, such as people with SMI, who are known to disengage from clinic-based services for extended periods [22,23].

To overcome these obstacles, a growing number of studies have used web-based participant recruitment strategies, including social media advertisements, virtual outreach through web-based interest groups, search engine advertisements, and various other website campaigns. Across clinical populations, these efforts have yielded impressive results in terms of cost-effectiveness, time efficiency, and reach [24]. In clinical trials where the experimental intervention is digital and behavioral in nature (ie, does not require direct contact between a patient and a provider) and the comparator condition does not require in-person contact with the research team (eg, no intervention control, waitlist control, or digital attention–control alternative), recruitment, treatment, and assessment of outcomes can all be conducted fully remotely and potentially on a single device [25-30]. To our knowledge, fully remote randomized controlled trials have not been conducted with people with SMI [24].

Objective

Here, we report the first fully remote randomized controlled clinical trial of a mobile health (mHealth) intervention for people with SMI. The first objective of this study is to evaluate whether individuals with SMI can be successfully recruited, assessed, and engaged in a digital intervention in a fully remote clinical trial. The second objective of the study is to evaluate the clinical effectiveness of the CORE intervention, a smartphone app designed to challenge dysfunctional thoughts that underlie common symptoms of SMI, self-stigmatizing attitudes, and maladaptive beliefs that impede treatment seeking and recovery.

Methods

Study Design

This study involved a fully remote randomized controlled crossover waitlist trial design. All participants were given the opportunity to receive the study intervention. Following enrollment, participants were randomized to either receiving the CORE intervention (indicated as *1*) or being in the waitlist control group (indicated as *0*) in blocks of 4. The group allocation for each block was selected randomly from a list of 6 possible sequences (ie, 1100, 1010, 1001, 0110, 0101, and

0011). In the active intervention group, participants completed the baseline assessment and were then immediately given access to the CORE app for 30 days of use. After a month, they concluded the intervention, uninstalled the app, and completed a second assessment. After an additional month (at 60 days), they completed a third assessment to measure the stability of symptom change post intervention. In the control arm, participants waited 30 days to receive the CORE app. After a month, they completed a second assessment and were provided access to the CORE app. After an additional month (at 60 days), they completed a third assessment to measure within-subject changes.

Procedures

All study procedures were reviewed and approved by the institutional review board of the University of Washington (ID number 00006898). We put a detailed and institutional review board–approved plan in place to respond to cases of increased risk. Web-based recruitment was conducted through advertisements on Google and Facebook. Google advertisements are presented depending on the user's search terms. For this study, we selected a range of terms associated with severe mental illness (eg, *schizophrenia*, *bipolar*, *seeing things*, and *am I crazy*) and related keywords generated by the Google *broad match* algorithm. Facebook advertisements use a similar methodology to target individual interests. For this study, we targeted interests such as mental health and schizophrenia. Individuals who clicked on the advertisements were directed to the study website. The study website provided written and video descriptions of the project, a downloadable version of the study consent form, and an option to complete a screening questionnaire via a *see if I am eligible* button. If eligible, participants were again presented with the consent form and were required to answer questions demonstrating their understanding of the study details. If they answered these questions correctly within 3 attempts, they could proceed to the baseline assessments. Participants were excluded if they were unable to complete this step successfully, as they were deemed unable to provide informed consent. Participants completed a battery of self-report questionnaires on the web at baseline. If participants' responses to questionnaires indicated the presence of suicidal ideation, they were immediately provided with resources for emergency support. Upon completion of baseline questionnaires, participants were randomized to either an active intervention or waitlist control group. Those randomized to the active intervention arm were given instructions on how to download and install the CORE mobile app.

At the start of the study period, staff contacted participants via email or SMS text messaging to welcome them to the study and remind them to complete the follow-up assessments at 30 and 60 days. After this welcome message, participants interacted with the study team only if they reached out to the study staff for technical support. When participants were due for an assessment, they were sent an automated SMS text message to alert them to complete the battery through a weblink. Participants were incentivized by being entered into lotteries to win US $500 and US $1000 after completing the 30- and 60-day assessments, respectively.

A member (JT) of our research team who was blinded to participant allocation completed all study analyses, and these analyses were determined beforehand. All outcome measures were preselected by the study team and examined in this study. The sample size was calculated to fit analytic requirements, and study recruitment was discontinued once the required sample size was met.

Participants

Participants were eligible if they could speak English; were aged >18 years; lived in the United States; self-reported a diagnosis of schizophrenia or schizoaffective disorder, bipolar disorder, or major depressive disorder; and owned a smartphone with a data plan. They were excluded if they had previously participated in the study or were unavailable for 60 days of participation.

Assessments

At all assessments, we administered measures of depression (Beck Depression Inventory–II [BDI-II] [31]), anxiety (Generalized Anxiety Disorder–7 [GAD-7] [32]), auditory hallucinations (Hamilton Program for Schizophrenia Voices Questionnaire [HPSVQ] [33]), paranoid thinking (Green Paranoid Thoughts Scale [GPTS] [34]), recovery (Recovery Assessment Scale [RAS] [35,36]), self-esteem (Rosenberg Self-Esteem Scale [RSES] [37]), social isolation (The Friendship Scale [38]), and functional disability (Sheehan Disability Scale [SDS] [39]). At baseline, we collected information from participants regarding demographics and technology use. After the intervention period, participants also completed a 26-item self-report usability and acceptability measure comprising adapted items from the System Usability Scale [40], Post Study System Usability Questionnaire [40], Technology Assessment Model Measurement Scales [41], and Usefulness, Satisfaction, and Ease questionnaire [42]. Participants were asked to rate their agreement with a series of statements about the intervention. A similar measure was used in previous studies conducted by our group [43].

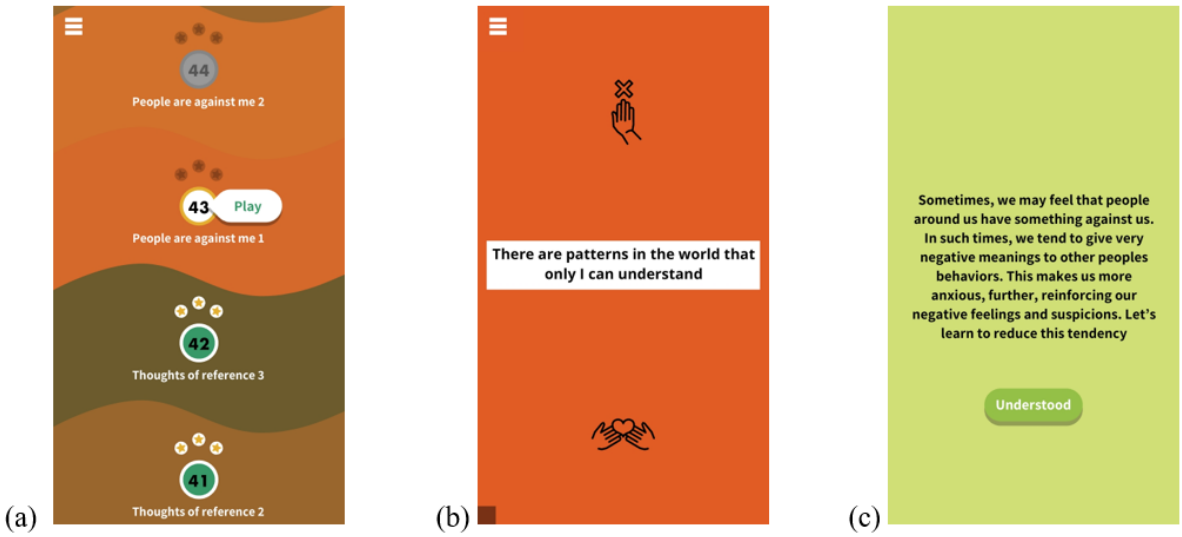
Intervention Description

The CORE intervention is a smartphone app that uses the GGtude platform, a system designed to increase the cognitive flexibility of individuals struggling with a range of mental health problems through brief daily training [44-47]. CORE was specifically designed to help counteract dysfunctional thoughts in multiple domains that are relevant to the subjective experience of having SMI. The intervention comprises daily brief game-like exercises designed to produce changes in the relative activation of adaptive and maladaptive beliefs about the self, others, and the world such that adaptive beliefs would be more easily retrieved than maladaptive ones.

CORE users were trained to respond to multiple statements in a sequence of modules that progress through the following domains: *self-talk*, *belief in change*, *self-stigma*, *self-care*, *self-worth*, *illness and identity*, *personal strength*, *social avoidance*, *feelings versus facts*, *catastrophization*, *thoughts of reference*, *paranoid ideation* (ie, *people are against me*), *treatment seeking*, and *recovery*. The modules begin with brief psychoeducation about the target domain and how maladaptive

beliefs can hamper recovery. Thoughts appear as statements on the smartphone screen, and users are required to either endorse (ie, *drag* the statement down toward them on the touchscreen) or discard them (ie, *push* the statement upwards away from them). Users learn to embrace self-statements reflecting more nuanced adaptive thoughts (eg, belief in change, importance of self-care, alternative explanations to threat perceptions, and value of treatment seeking). The module content was organized into 53 levels, and participants were recommended to not complete more than 3 levels a day for a period of 30 days. Push notifications reminded users to complete their daily training. After each level, participants had the option of adding to their personal toolbox 1 of 3 positive statements that they most related to. Participants could access their toolbox at any time. Figure 1 depicts screenshots of the targeted beliefs menu, an example of a maladaptive statement, and a psychoeducational element.

Figure 1. Screenshots of the (a) targeted beliefs menu, (b) an example of a maladaptive statement, and (c) a psychoeducational element.



Data Analysis

Means, SDs, and frequencies were reported using descriptive statistics for all participant demographics, symptom measures, and acceptability and usability scale items. A series of *t* tests and chi-square tests were used to test for group differences in demographic variables and symptom measures at baseline (T1) before examining intervention effects at 30 days (T2) and 60 days (T3). Pre- and postscores for both groups were explored using a series of repeated-measures analysis of variance (ANOVA). The intervention effect between groups at T2 was initially tested using a 2×2 mixed-design repeated-measures ANOVA, controlling for participant diagnosis and baseline assessment scores. A 1×3 repeated measures ANOVA tested the performance of the active group across T1, T2, and T3, with post hoc Bonferroni pairwise comparisons used to explore outcomes when significant differences occurred. Finally, a series of 1×3 repeated measures ANOVAs tested the intervention effect after crossover (T2 and T3) for the waitlist control group participants to see if intervention effects were replicated. A series of equivalence tests were conducted using independent sample 2-tailed *t* tests to determine whether the magnitude of intervention effects differed for the active group participants between T1 and T2 as compared with the intervention effect for waitlist control participants between T2 and T3. Spaghetti plots were provided to visualize changes over time across symptom measures in both groups. To minimize bias during analysis, we used an intent-to-treat approach and implemented a multiple imputation strategy to replace missing values [48]. Multiple imputation is considered the most appropriate method of handling missing data for a study of this size, has been used successfully in repeated measure designs, and has been shown to have utility with levels of missing data greater than that observed in this study [49,50]. Sensitivity analyses using pattern-mixture models were used to establish data that were missing at random before imputation [51]. Our imputation model was specified using data from participants in each condition and included participant demographic variables (ie, diagnosis, gender, age, and race) and all baseline assessment scores.

Results

Recruitment and Enrollment

Web-based recruitment advertisements were placed between January 2020 and September 2020, using a total budget of US $2984.26. We recruited a total of 1123 people from these advertisements; of these 1123 people, 315 (28.04%) were randomized for the trial, and 808 (71.95%) were excluded. Of the 315 participants, 154 (48.9%) dropped out of the study before T2 and 45 (14.3%) dropped out between T2 and T3. Approximately 41.5% (64/154) of participants in the active group and 60.2% (97/161) of participants in the waitlist group were retained at T2, and 33.1% (51/154) of participants in the active group and 40.3% (65/161) of individuals in the waitlist group were retained at T3. Those who dropped out of the study were not found to differ significantly from those who were retained in terms of demographic characteristics or baseline scores on outcome measures (Figure 2). Most participants were recruited from Google advertisements (226/315, 71.7%). Overall, Google advertisements were viewed 557,700 times

and were ultimately clicked on 5100 times. The states with the most clicks on the Google advertisement were California (540/5100, 10.59%), Texas (393/5100, 7.71%), Florida (295/5100, 5.78%), and New York (294/5100, 5.77%). The most successful Google advertisement keywords for increasing engagement from potential participants were *mental health*, *mental illness*, *depression*, *illuminati*, and *bipolar*. Most individuals (4734/5100, 92.82%) clicked on the advertisement through mobile phones, whereas few used desktop computers (256/5100, 5.02%) or tablets (110/5100, 2.16%). Participants that enrolled in the study were recruited from 45 states (Figure 3), with the most participants coming from California (24/315, 7.6%), Texas (21/315, 6.7%), Florida (17/315, 5.4%), New York (16/315, 5.1%), Pennsylvania (16/315, 5.1%), and Washington (16/315, 5.1%). We successfully enrolled participants from 80% (12/15) of the most rural states in the country.

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) diagram.

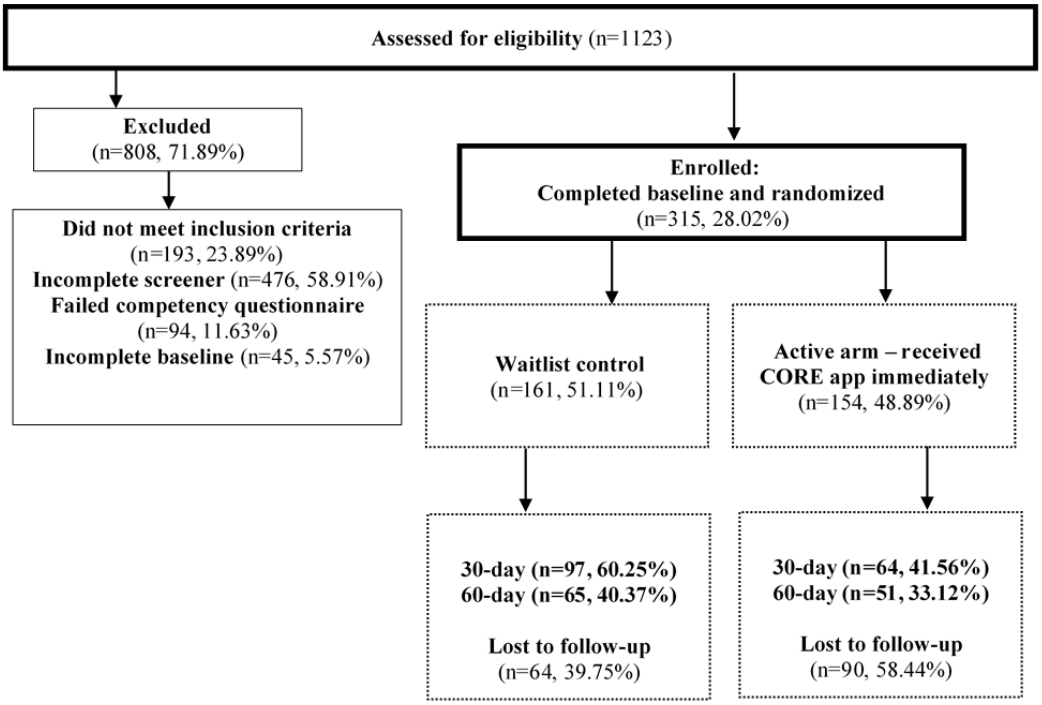


Figure 3. Map of participants enrolled based on location.

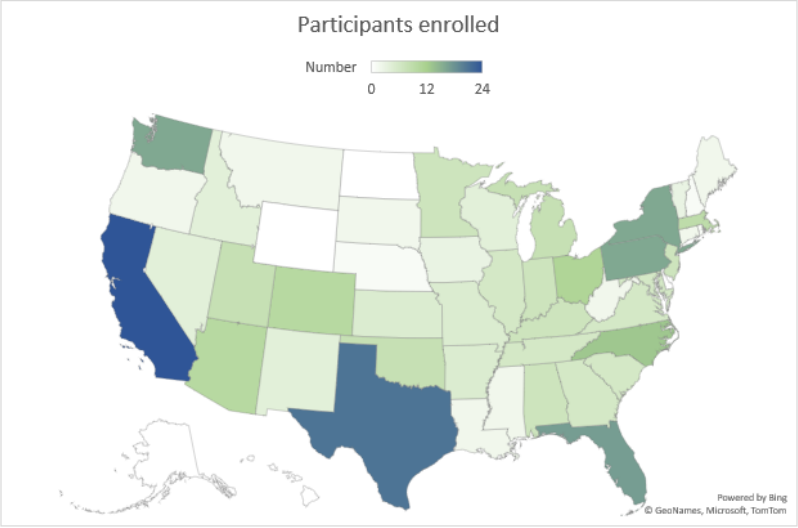

Demographics

Full demographics of the study participants are reported in Table 1. The final study participants were mostly female (264/315, 83.8%), White (241/315, 76.5%), heterosexual (218/315, 69.2%), living independently (150/315, 47.6%) or with family (136/315, 43.2%), unemployed (210/315, 66.7%), and aged between 18-78 years. No demographic differences were observed following randomization between the 2 study groups.

[b]FTM: female-to-male.

Clinical Characteristics

The sample comprised individuals with bipolar disorder (111/315, 35.2%), major depressive disorder (136/315, 43.2%), and schizophrenia or schizoaffective disorder (68/315, 21.6%). Approximately a quarter (75/315, 23.8%) of the participants reported experiencing auditory hallucinations on a weekly or more frequent basis at baseline. Approximately 23.2% (73/315) of participants reported experiencing a psychiatric hospitalization in the past year, and 25.4% (80/315) of participants reported having ≥6 psychiatric hospitalizations in their lifetime. Baseline scores on clinical outcome measures were in the severe range on both the BDI-II (mean 33.95, SD 13.61) and the GPTS (mean 87.51, SD 35.79) and in the moderate range on the GAD-7 (mean 14.12, SD 5.48) and HPSVQ (mean 19.08, SD 8.89). Participants had a moderate level of disability SDS (mean 24.07, SD 7.12). Significant correlations existed between scores on the BDI-II and GAD-7 (r=0.69; P<.001), BDI-II and GPTS (r=0.38; P<.001), and GAD-7 and GPTS (r=0.40; P<.001), indicating a high degree of comorbidity within the sample. No differences were found between groups on any clinical characteristics or baseline outcome measures after randomization. Diagnosis was not found to be a significant predictor of completion at T2 or T3, with the distribution of completion resembling the distribution of participants at baseline. At T2, 20.5% (33/161) of completers had a diagnosis of schizophrenia or schizoaffective disorder, 44.1% (71/161) had a diagnosis of major depressive disorder, and 35.4% (57/161) had a diagnosis of bipolar disorder. At T3, 23.3% (27/116) of completers had a diagnosis of schizophrenia or schizoaffective disorder, 46.6% (54/116) had a diagnosis of major depressive disorder, and 30.2% (35/116) had a diagnosis of bipolar disorder.

Engagement Metrics

We were able to collect the CORE app use data from 51.4% (162/315) of participants. Of the 162 participants, 82 (50.6%) completed all 53 intervention levels, whereas participants, on average, completed 35 levels. Most participants reported that they would like to use CORE more often; that if they had access to CORE, they would use it; that the app was easy to use and sufficiently interactive; and that they did not need technical support to use CORE. Participants rated that they were satisfied with the CORE intervention and that they would recommend

it to a friend. The distribution of participants' responses to all usability and acceptability questions is displayed in Table 2.

Table 2. Participant usability and acceptability ratings (N=119).

Item	Disagree, n (%)	Neutral, n (%)	Agree, n (%)
I think that I would like to use CORE often.	8 (6.7)	26 (21.8)	85 (71.4)
I thought CORE was easy to use.	1 (0.8)	5 (4.2)	113 (95.0)
I found that the different parts of CORE work well together.	1 (0.8)	23 (19.3)	95 (79.8)
I would imagine that most people would learn to use CORE very quickly.	0 (0.0)	6 (5.0)	113 (95.0)
I felt very confident using CORE.	1 (0.8)	24 (20.2)	94 (79.0)
Overall, I am satisfied with how easy it is to use CORE.	1 (0.8)	8 (6.7)	110 (92.4)
I was able to use the *modules* quickly in CORE.	3 (2.5)	8 (6.7)	108 (90.8)
I felt comfortable using CORE.	0 (0.0)	9 (7.6)	110 (92.4)
It was easy to learn to use CORE.	0 (0.0)	7 (5.9)	111 (94.1)
Whenever I made a mistake using CORE, I could recover easily and quickly.	2 (1.7)	17 (14.3)	100 (84.0)
It was easy to find the information I needed.	5 (4.2)	16 (13.6)	97 (82.2)
The information provided for CORE was easy to understand.	2 (1.7)	10 (8.5)	105 (89.7)
How things appeared on the screen was clear.	1 (0.8)	9 (7.6)	108 (91.5)
If I have access to CORE, I will use it.	6 (5.0)	17 (14.3)	96 (80.7)
I am satisfied with CORE.	7 (5.9)	11 (9.2)	101 (84.9)
I would recommend CORE to a friend.	6 (5.0)	23 (19.3)	90 (75.6)
CORE is fun to use.	7 (5.9)	44 (37.0)	68 (57.1)
CORE works the way I want it to work.	10 (8.4)	28 (23.5)	81 (68.1)
I feel I need to have CORE.	20 (16.8)	58 (48.7)	41 (34.5)
CORE helped me manage my symptoms.	12 (10.1)	41 (34.5)	66 (55.5)
CORE was interactive enough.	6 (5.0)	26 (21.8)	87 (73.1)
I found CORE to be very complicated	108 (90.8)	7 (5.9)	4 (3.4)
I think that I would need the support of a technical person to be able to use CORE.	103 (86.6)	7 (5.9)	9 (7.6)
I thought there was too much inconsistency in CORE.	99 (83.2)	13 (10.9)	7 (5.9)
I found CORE very awkward to use.	103 (86.6)	11 (9.2)	5 (4.2)
I needed to learn a lot of things before I could get going with CORE.	105 (88.2)	8 (6.7)	6 (5.0)

Between-Group Differences: Active Group Versus Waitlist Control Group

Analyses of differences between the active group and the waitlist control group from T1 to T2 revealed a significant treatment×time interaction effect for the BDI-II ($F_{1,313}$=13.38; P<.001), GAD-7 ($F_{1,313}$=5.87; P=.02), RAS ($F_{1,313}$=23.42; P<.001), RSES ($F_{1,313}$=19.28; P<.001), and SDS ($F_{1,313}$=10.73; P=.001). Large effects were observed at T2 for the BDI-II (d=0.58), RAS (d=0.61), and RSES (d=0.64). A moderate effect was observed for the SDS (d=0.44) and a small effect for the GAD-7 (d=0.20).

This indicates that participants engaging in the active condition showed improvements on these outcome measures after 30 days of using the app compared with participants in the waitlist control group who did not have access to the app over the same period (Figure 4). A significant main effect of time was found for the BDI-II ($F_{1,313}$=44.33; P<.001), GAD-7 ($F_{1,313}$=66.77; P<.001), GPTS ($F_{1,313}$=39.85; P<.001), RAS ($F_{1,313}$=46.15; P<.001), RSES ($F_{1,313}$=28.89; P<.001), Friendship Scale ($F_{1,313}$=21.05; P<.001), and SDS ($F_{1,313}$=51.644; P<.001). Table 3 displays the means and SDs for all measures at each time point for the active group participants and the waitlist control group participants.

Figure 4. Outcome measures (y-axis) at baseline (T1), 30 days (T2), and 60 days (T3) assessments points (x-axis) for active group and waitlist control group. BDI-II: Beck Depression Inventory-Second Edition; GAD-7: Generalized Anxiety Disorder-7; GPTS: Green Paranoid Thought Scale; HPSVQ: Hamilton Program for Schizophrenia Voices; RAS: Recovery Assessment Scale; RSES: Rosenberg Self-esteem Scale; SDS: Sheehan Disability Scale.

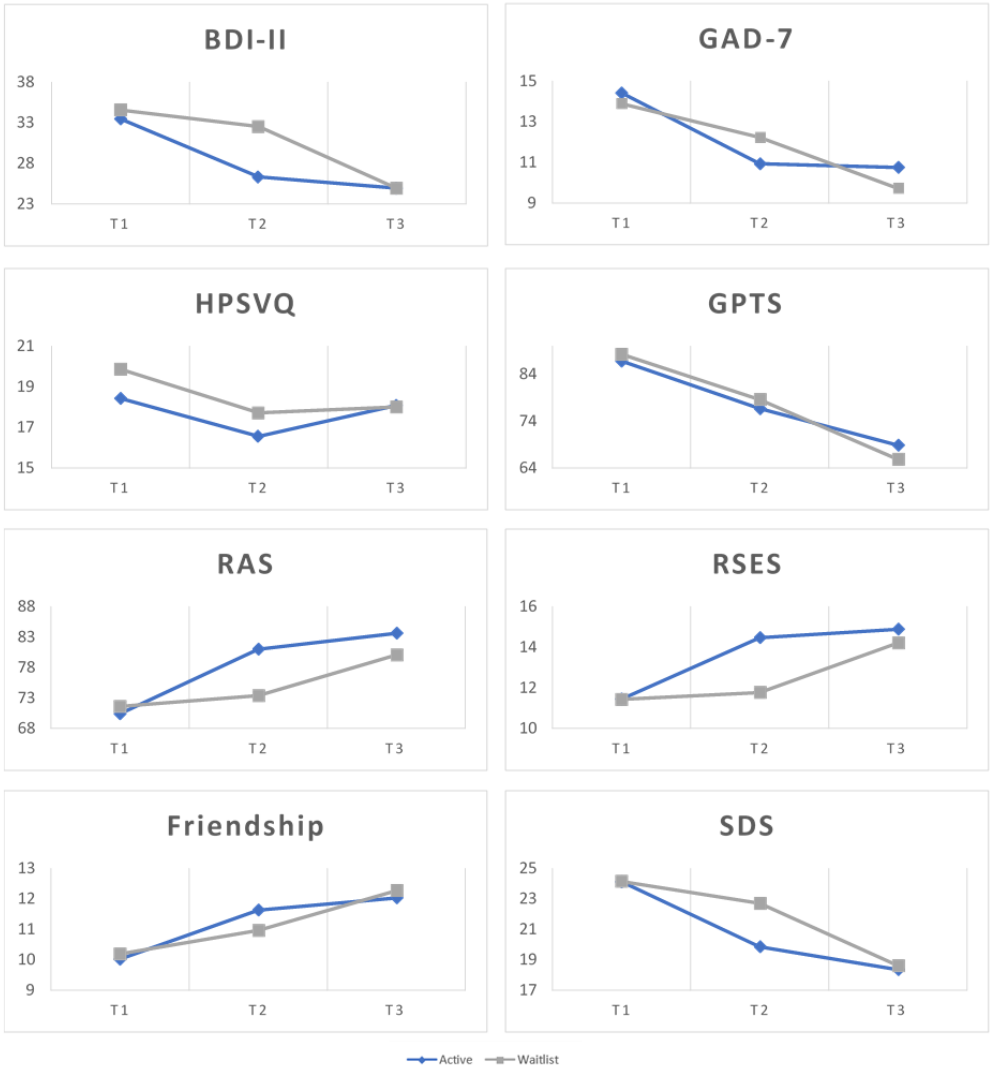

Table 3. Comparison of outcome measures across periods for each group.

Measure	Baseline, mean (SD)	30 days, mean (SD)	60 days, mean (SD)
Beck Depression Inventory–II			
Active	33.46 (13.75)	26.33 (10.43)[a,b]	24.94 (8.71)
Waitlist	34.57 (13.34)	32.52 (11.12)	24.93 (10.59)[b]
Generalized Anxiety Disorder-7			
Active	14.42 (5.16)	10.93 (4.17)[b,c]	10.75 (3.69)
Waitlist	13.89 (5.77)	12.23 (5.00)[d]	9.72 (4.53)[b]
Hamilton Program for Schizophrenia Voices Questionnaire			
Active	18.42 (8.81)	16.56 (8.54)	18.08 (6.07)
Waitlist	19.86 (9.03)	17.71 (10.20)	18.00 (11.99)
Green Paranoid Thoughts Scale			
Active	86.79 (36.01)	76.66 (23.97)[b]	68.84 (20.41)[b]
Waitlist	88.24 (35.63)	78.59 (27.54)[b]	65.84 (24.11)[b]
Recovery Assessment Scale			
Active	70.42 (16.62)	81.02 (11.01)[a,b]	83.64 (9.44)[b]
Waitlist	71.61 (17.18)	73.38 (12.44)	80.06 (13.08)[b]
Rosenberg Self-Esteem Scale			
Active	11.45 (6.39)	14.47 (4.28)[a,d]	14.89 (4.28)
Waitlist	11.43 (5.83)	11.77 (4.96)	14.21 (5.01)[b]
Friendship scale			
Active	10.02 (3.84)	11.63 (3.19)[b]	12.03 (3.00)
Waitlist	10.19 (3.56)	10.96 (3.39)	12.27 (3.28)[b]
Sheehan Disability Scale			
Active	24.12 (7.03)	19.85 (6.26)[b,e]	18.35 (6.38)[d]
Waitlist	24.14 (7.21)	22.70 (5.83)[d]	18.61 (6.54)[b]

Within-Group Change: Active Intervention Group at T2 and Maintenance at T3

A series of 1×3 repeated-measures ANOVA was used to examine intervention effects within the active group between T1 and T2 and whether these effects were maintained 30 days after discontinuation of app use (Table 3). Results of the ANOVAs showed significant within-group differences for the BDI-II ($F_{2,306}$=43.59; P<.001), GAD-7 ($F_{2,306}$=43.71; P<.001), GPTS ($F_{2,306}$=34.39; P<.001), RAS ($F_{2,306}$=65.22; P<.001), RSES ($F_{2,306}$=32.85; P<.001), Friendship Scale ($F_{2,306}$=17.94; P<.001), and SDS ($F_{2,306}$=56.21; P<.001). Large effect sizes were observed between T1 and T2 for the active intervention group on the BDI-II (d=0.60), GAD-7 (d=0.69), RAS (d=0.70), and SDS (d=0.63). Moderate to small effect sizes occurred during this period on the RSES (d=0.47), GPTS (d=0.35), and Friendship Scale (d=0.39). No significant change was found at any time point for the active group for the HPSVQ ($F_{2,306}$=0.704; P=.51). Bonferroni post hoc comparisons revealed significant improvements in each outcome measure at T2 except for the HPSVQ. All improvements were maintained between T2 and T3, with an additional small effect noted on the GPTS (d=0.33), RAS (d=0.27), and SDS (d=0.24), suggesting a prolonged intervention effect.

Within-Group Change: Waitlist Control Group at T2 and Following Crossover at T-3

Results from the active group were replicated following crossover in the waitlist control group between T2 and T3. Participants in the waitlist control group were found to have significant differences on the BDI-II ($F_{2, 322}$=60.79; P<.001), GAD-7 ($F_{2, 322}$=50.41; P<.001), GPTS ($F_{2, 322}$=55.15; P<.001), RAS ($F_{2, 322}$=32.03; P<.001), RSES ($F_{2, 322}$=34.35; P<.001), Friendship Scale ($F_{2, 322}$=26.28; P<.001), and SDS ($F_{2, 322}$=50.93; P<.001). The lack of change in the HPSVQ scores after 30 days of CORE use was also replicated ($F_{2, 322}$=1.14; P=.34). Post hoc analysis revealed that significant improvements took place for the waitlist control group between T2 and T3 for all outcome measures except HPSVQ. Effect size magnitudes were similar to those seen in the active group during the previous period, with large to moderate effects on the BDI-II (d=0.73), GAD-7 (d=0.46), GPTS (d=0.48), RAS (d=0.55), RSES (d=0.52), Friendship Scale (d=0.43), and SDS (d=0.67). Improvements in the waitlist control group were also found between T1 and T2 for GAD-7, GPTS, and SDS. These improvements as a result of time were sufficient to negate a between-subject effect for the GPTS but not for the BDI-II or the GAD-7. The magnitude of change observed after 30 days of CORE use between groups was equivalent across all outcome metrics except for the RAS (t_{105}=2.28; P=.03), with the active group showing a slightly larger improvement than the waitlist control group.

Discussion

Principal Findings

Recent studies have demonstrated the feasibility of conducting remote trials of digital health apps for common mental health problems, including stress, anxiety, and depression [27-29]. This paper reports on the first fully remote randomized controlled trial of a smartphone intervention involving people with more severe forms of psychopathology, including schizophrenia and bipolar disorder. Building on and expanding web-based enrollment strategies used in previous works [52,53], we were able to reach, recruit, randomize, treat, and assess a sociodemographically diverse sample of participants from 45 states, far exceeding the reach of traditional localized study recruitment approaches and at a fraction of the cost. A key advantage of remote research strategies leveraging web-based recruitment advertisements lies in the flexibility they afford the investigative team to determine the geographical regions and roll out of study recruitment materials. Similar to what has been shown with other clinical populations [24], this proved to be a remarkably efficient methodology of reaching people with SMI who are more impaired and often considered more complex to engage in research [54].

This study found that a novel smartphone app, CORE, proved to be usable, acceptable, and effective in improving recovery and reducing the severity of psychiatric symptoms among individuals with SMI. Our findings align with an ample body of digital mental health research suggesting that mHealth smartphone apps can be of clinical value to people with SMI [17,55,56]. Integration of technology with human support can bolster the engagement and clinical potency of technology-based treatments for SMI [57,58]. The CORE intervention was entirely self-navigated by users in the study who received minimal or no remote technical support from our study staff. We are not advocating for a shift toward fully automated approaches as the preferred model. However, what this study did demonstrate is that when technology is designed with the characteristics of the intended users in mind (ie, in terms of functionality, accessibility, navigability, and content), deployment of specialty digital mental health tools that do not involve humans in the loop of care can also produce significant clinical benefits.

The CORE intervention builds on a digital cognitive training strategy that has been previously demonstrated to reduce dysfunctional *self-talk* and increase resilience in community-based subclinical groups [44-46]. The app included modules focused on countering maladaptive beliefs in common mental health domains (eg, self-esteem, distinguishing thoughts from feelings, social anxiety, and catastrophizing) as well as modules specifically designed for people with SMI (eg, stigma related to mental illness, threat perception and persecutory ideation, hopelessness, strengths-based recovery, self-care, and treatment seeking). Thus, it is meant to be used transdiagnostically [59].

Although this study was a fully remote trial that relied entirely on participants' self-reports, we are confident that we were able to reach our intended target audience; most of our study sample reported having a psychiatric diagnosis of schizophrenia, schizoaffective disorder, or bipolar disorder; a history of multiple psychiatric hospitalizations; and being unemployed. Approximately one-tenth reported being currently homeless or residing in an assisted-living facility. Combined with the sample's average baseline ratings showing moderate to severe psychiatric symptom severity and moderate to high levels of disability, our data suggest that the sample comprised people with significant functional impairment.

The waitlist-controlled study design enabled the evaluation of both between-group effects during the intervention period and within-group changes in both groups over time. The results demonstrated a link between the timing of participants' exposure to the treatment app and when they experienced significant changes in key clinical and functional measures. A combination of factors such as simplicity, brevity, daily use, and game-like interactions may have encouraged the use of the CORE app. Daily practice comprising identification and categorization of self-statements, repeated exposure to adaptive self-statements, and psychoeducation may have facilitated retrieval of adaptive beliefs over maladaptive ones, thereby reducing the severity of symptoms [60]

This study has several limitations. The opportunity to participate was available only to individuals who used the internet (ie, to receive study recruitment advertisements) and who owned smartphones (ie, to download the CORE app) and therefore may not be representative of the full range of people with SMI. Similar to fully remote digital mental health trials involving participants with less severe psychopathology [61], our study sample was overrepresented by female participants (264/315,

83.8%), and study dropout rates were high, requiring significant data imputation. All screening and assessment questions relied on individuals' self-reports but were not corroborated by a trained clinician or additional documentation (eg, EHR data). Replication of our findings in samples that were screened, diagnosed, and assessed by trained clinical assessors could bolster confidence in the nature of our results. Using a waitlist control is often considered a more ethical study design than offering no treatment at all or sham interventions. However, it may also have artificially inflated estimates of the intervention effects; asking participants who are ready for treatment to wait to receive CORE may have frustrated them, stalled their attempts to make independent changes, or artificially delayed their seeking other treatment options. Finally, although our measure of recovery taps *willingness to ask for help* [35,36], we did not formally evaluate changes in treatment-seeking behavior, which is an area of focus in the CORE training program and the key variable of interest.

Conclusions

Mental health researchers, funders, industry leaders, patients, and their caregivers have been advocating for the development and deployment of effective digital health tools to improve the outcomes of people with psychiatric conditions [62,63]. The global COVID-19 pandemic has led to major disruptions in the delivery of standard mental health services and has shed light on the vulnerabilities intrinsic to complete reliance on clinic-based treatment models [64,65]. In the context of this ongoing public health crisis, new scientific evidence showing that remotely-accessed mHealth technologies such as CORE can be navigable and beneficial to people with SMI is very encouraging. Regulatory bodies have taken active steps to remove barriers to the use of digital health technologies for psychiatric disorders [66]. Currently, rapid adoption and real-world dissemination of evidence-based digital health interventions are needed if we are to shorten the science-to-service gap and help address the significant unmet mental health needs of people with SMI during the pandemic and beyond.

Acknowledgments

The authors DBZ, AC, JT, SN, and AC were supported by an award from National Institute of Mental Health (NIMH) (R01MH112641). BB was supported by a Mentored Patient-Oriented Research Career Development Award from NIMH (K23MH122504).

Conflicts of Interest

DBZ has an intervention content licensing agreement with Pear Therapeutics and has a financial interest in Merlin LLC and FOCUS technology. He has consulted with Trusst Health, K Health, eQuility, and Otsuka Pharmaceuticals Ltd. GD is the cofounder of GGtude Ltd and has a financial interest in the CORE app described in this paper. Data analyses were conducted by members of the team who were unaffiliated with GGtude Ltd. All the remaining authors have no conflicts of interest to declare.

Abstract

Background: Smartphone apps have shown potential in enhancing weight management in Western populations in the short to medium term. With a rapidly growing obesity burden in Asian populations, researchers are turning to apps as a service delivery platform to reach a larger target audience to efficiently address the problem.

Objective: This systematic review and meta-analysis aims to determine the efficacy of interventions that incorporate apps in facilitating weight loss and health behavior change in the Asian population.

Methods: A total of 6 databases were searched in June 2020. The eligible studies included controlled trials in which an app was used in the intervention. The participants were aged 18 years or older and were of Asian ethnicity. A meta-analysis to test intervention efficacy, subgroup analyses, and post hoc analyses was conducted to determine the effects of adding an app to usual care and study duration. The primary outcome was absolute or percentage weight change, whereas the secondary outcomes were changes to lifestyle behaviors.

Results: A total of 21 studies were included in this review, and 17 (81%) were selected for the meta-analysis. The pooled effect size across 82% (14/17) of the randomized controlled trials for weight change was small to moderate (Hedges *g*=–0.26; 95% CI –0.41 to –0.11), indicating slightly greater weight loss achieved in the intervention group; however, this may not be representative of long-term studies (lasting for more than a year). Supplementing multicomponent usual care with an app led to greater weight loss (Hedges *g*=–0.28; 95% CI –0.47 to –0.09). Asian apps were largely culturally adapted and multifunctional, with the most common app features being communication with health professionals and self-monitoring of behaviors and outcomes.

Conclusions: More evidence is required to determine the efficacy of apps in the long term and address the low uptake of apps to maximize the potential of the intervention. Future research should determine the efficacy of each component of the multicomponent intervention to facilitate the designing of studies that are most effective and cost-efficient for weight management.

KEYWORDS

systematic review; meta-analysis; mobile app; obesity; weight loss; Asian; diet; physical activity; adults; mobile phone

Introduction

Background

Asian countries typically have lower rates of obesity than Western countries [1,2]. However, globalization has contributed to rapid increases in Asian obesity rates over the last 10-15 years such that between 20% and 35% of Asian adults are overweight or obese [2,3]. Higher body fat percentage, prominent central adiposity, and possible genetic factors predispose Asians to insulin resistance, type 2 diabetes, and cardiovascular diseases that further aggravate the health care burden [4,5], with direct health care costs estimated to be US $100 billion in Asian countries alone [3]. As part of the global action plan for the prevention and control of noncommunicable diseases, the World Health Organization has recommended a focus on improving lifestyle behaviors, including adopting a healthy diet and increasing physical activity to modify the risk factors for obesity and noncommunicable diseases [6].

With the exponential growth of mobile technology in the past decade, researchers have explored the potential of digital health interventions using mobile apps as a service delivery platform to reach a larger target audience [7,8]. This is particularly promising in Asian countries where smartphone adoption is estimated to reach 84% by 2025 [9,10]. The ubiquity, accessibility, multifunctionality, and scalability of apps for health intervention provide health care professionals and researchers an unprecedented avenue for treating, monitoring, and interacting with patients en masse remotely [11,12]. With technological advancement, the number of health- and fitness-related apps targeted at behavioral change has burgeoned, with at least 325,000 apps available on the commercial market in 2017 [13].

To date, several systematic reviews on smartphone efficacy to improve weight and health have concluded that interventions that incorporate apps show potential in weight management as well as in improving diet, physical activity, and chronic disease outcomes and are acceptable in the short to medium term [7,8,14-17]. However, most of the studies included in these systematic reviews have been focused on Western populations. Given the differences in genetics, culture, lifestyle, health beliefs, and health-seeking behaviors between Asian and White populations [5,18,19], it is important to assess if interventions that incorporate apps are efficacious in achieving weight loss in Asians before considering them as part of a national strategy to combat obesity.

Objective

The aim of this review is to systematically synthesize evidence to address this gap in the literature and provide recommendations for future studies. The primary outcome of this review was absolute or percentage weight loss or other surrogate measures of body fat composition such as BMI or waist circumference. The secondary outcomes included dietary intake, physical activity, self-efficacy with regard to implementing healthy lifestyle behaviors, and user engagement with apps.

Methods

Literature Search

The review protocol was prospectively registered (PROSPERO ID: CRD42020165240), with modifications made over the course of the review (Multimedia Appendix 1), and conducted according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines (Multimedia Appendix 2) [20]. Systematic searches were conducted in June 2020 across 6 databases: MEDLINE, CINAHL, Embase, PsycINFO, Global Health, and the Cochrane Central Register of Controlled Trials. The search strategy incorporated Medical Subject Headings, keywords, and free-text search terms. The search terms included *app**, *application**, *mobile app**, *smartphone*, *mHealth*, *weight loss*, *weight change*, *body mass index change*, and *Asian**. A sample search for MEDLINE is detailed in Multimedia Appendix 3. *BMC Proceedings*, ProQuest Dissertations & Theses, and Google Scholar were searched for conference proceedings, dissertations, and any unpublished gray literature, whereas the ISRCTN registry, ClinicalTrials.gov, and the World Health Organization International Clinical Trials Registry Platform were queried for eligible clinical trials and research. Reference lists of the eligible studies and review articles were also manually searched for additional papers that warranted inclusion. In addition, a filtered search of the *Journal of Medical Internet Research* and *JMIR mHealth and uHealth* was conducted to locate papers that were published before the respective journals were indexed in MEDLINE.

Inclusion Criteria and Study Selection

Studies were included if they were randomized controlled trials (RCTs), quasi-randomized trials, or nonrandomized controlled trials (non-RCTs). Interventions with no control group, before-and-after interventions, and observational studies (cohort, case-control, cross-sectional, and ecological) were excluded. To be included in this review, studies needed to use a mobile app either in a single-component (ie, standalone use of apps) or multicomponent (ie, apps as part of an intervention with other components, eg, face-to-face consultation, phone calls, or email reviews) intervention. Given that app engagement typically declines rapidly by the second month [21], this was chosen as the minimum study duration to ensure that the intervention effects of app use and longer-term outcomes could be assessed. Participants had to be aged 18 years or older and of Asian ethnicity. Studies were excluded if participants were reported to have eating disorders or mental health conditions, bariatric surgery, or were within the pregnancy or postpartum period. This review was limited to research published in the English language and from 2008 to date because 2008 was the year in which smartphone apps emerged [22].

Data Extraction

All titles and abstracts of the retrieved records were independently screened by 2 reviewers (SMA and JC) to identify the records that potentially met the inclusion criteria. Relevant full-text articles were retrieved and independently assessed by both reviewers using the complete inclusion and exclusion criteria. Both reviewers independently extracted data from the articles based on a standardized data extraction form, including

study characteristics (author, year, country, study design, study aims, sample number, attrition rate, disease group, conflict of interest, and funding), intervention characteristics (intervention type, duration, app type, app features, and cultural adaptations), and predefined outcomes. The level of agreement between the reviewers for the main stages of screening were assessed using the Cohen κ coefficient. Discrepancies were discussed and resolved between the reviewers. Any missing data or further information required was requested by email from the corresponding authors, with a follow-up reminder sent after 2 months.

Study Quality Assessment

The Cochrane Collaboration Risk-of-Bias Tool [23] and the Risk of Bias in Non-Randomized Studies of Interventions Tool [24] were implemented independently by 2 reviewers (SMA and JC) to assess the risk of bias in the RCTs and non-RCTs, respectively. Discrepancies were discussed and resolved through a third reviewer (JJ). Each domain of the RCTs received an evaluation of low, moderate, or high risk, whereas the non-RCTs were judged as having low, moderate, serious, or critical risk.

Outcomes

The primary outcome of this review was absolute (kg) or percentage weight change. Other surrogate measures of body weight, such as BMI (kg/m^2) and waist circumference (cm), were also included. The secondary outcomes included app use and changes to lifestyle behaviors, including diet, physical activity, and self-efficacy for implementing healthy behaviors.

Data Analysis

The effect sizes used in the meta-analysis were Hedges *g* values calculated from the mean differences in outcomes (ie, changes in absolute or percentage weight, BMI, or waist circumference before and after treatment) between the treatment arms. Separate analyses were conducted for the RCTs and non-RCTs; studies without a standardized mean and SD were excluded from the meta-analysis. A unique study identifier was assigned to each intervention-control pair included in the meta-analysis (Multimedia Appendix 4 [25-41]).

Random effects models, which control for heterogeneity between studies, were used to fit the Hedges *g* scores. To account for within-study dependencies, comparisons were made separately for each outcome, namely, changes in absolute or percentage weight, BMI, and waist circumference. For studies with multiple time points reported, only the final outcome within the active intervention was included to avoid pseudoreplication. Furthermore, the overall data were also divided into 2 subsets comprising single-component (ie, standalone use of apps) and multicomponent (ie, apps as a part of an intervention with other components) studies, respectively, and analyzed separately. Subsequently, subgroup analyses were conducted to analyze the effects of adding an app to usual care (intervention group) compared with usual care alone (control group).

The possible moderating effect of study duration was also tested using moderation analysis, after which the possible differences in intervention outcomes in studies conducted over 3 months or less versus studies lasting for longer than 3 months were assessed post hoc. These were done as a preliminary assessment of the importance of app engagement levels on study outcomes because adherence to app use generally tails off after 2 to 3 months [8,11,42,43]. The post hoc analyses were conducted in lieu of a more robust meta-regression approach given the dearth of quantifiable app engagement data.

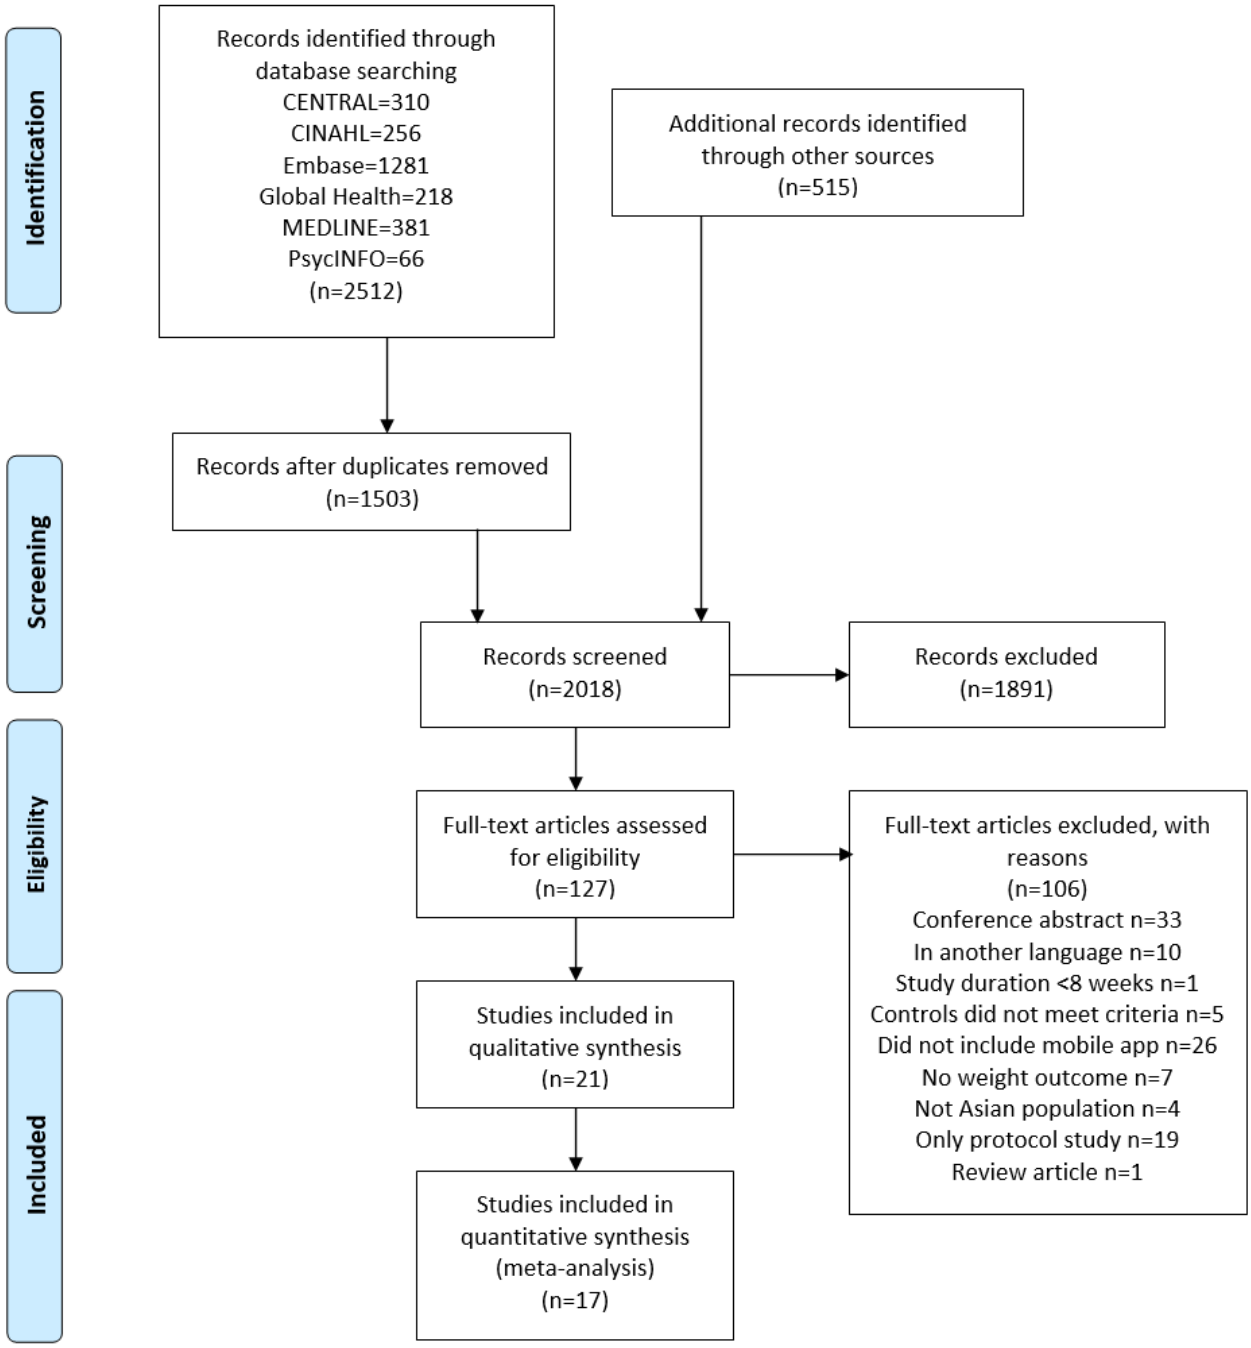
Heterogeneity among the studies for each comparison was assessed using the I^2 statistic, with values of 30% to 60%, 50% to 90%, and 75% to 100% considered to indicate moderate, substantial, and considerable levels of heterogeneity, respectively [44]. Publication bias was also assessed using a funnel plot. All analyses were conducted using the *metafor* package (2.4.0) in the R statistical environment (R Foundation for Statistical Computing) [45,46].

Results

Study and Sample Characteristics

A total of 3027 electronic records were identified through the search strategy and, after removal of duplicates, 2018 (66.67%) titles were screened. From these 2018 records, 127 (6.29%) full-text articles were retrieved (Figure 1). Of the 127 papers, 21 (16.5%) met all inclusion criteria for the systematic literature review [25-41,47-50]. Of these 21 papers, 17 (81%) were included in the meta-analysis [25-41]. The Cohen κ coefficients for the initial screening stage of titles and abstracts and the full-text screening stage were 0.72 (substantial agreement) and 0.92 (almost perfect agreement), respectively, with 97% level of agreement for each screening stage.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) flow diagram. CENTRAL: Cochrane Central Register of Controlled Trials. CINAHL: Cumulative Index to Nursing and Allied Health Literature.



Intervention characteristics and descriptions of the studies included in this review are summarized in Table 1 and Table 2, respectively. Of the 21 papers, 17 (81%) were RCTs and 4 (19%) were non-RCTs, with study locations in China [25,37-39,48], Hong Kong [34], India [26,31], Japan [35], Singapore [30], South Korea [27-29,32,33,36,40,50], Taiwan [41,49], and the United States [47]. The total number of participants across the 21 studies was 21,173 (RCTs: 4090 and non-RCTs: 17,083), with a mean age of 45.9 (SD 9.84, range 25.8-60.5) years; on average, 45.1% (SD 20.1) of the participants were women. The mean BMI of the population was 27.1 (SD 2.47, range 23.0-30.5) kg/m^2. Of the 21 studies, 9 (43%) were conducted among patients who were overweight or obese [28,30-35,47,49], 6 (29%) involved mainly patients with diabetes mellitus—4 (67%) [27,36,40,48] on type 2, whereas 2 (33%) [37,38] included a mix of type 1 and 2—and 3 (14%) included participants from the general population [26,39,41], whereas the remaining 3 (14%) individually targeted patients with metabolic abnormalities [50], coronary heart disease [25], or colorectal polyps [29].

Table 1. Characteristics of the interventions incorporating apps included in the review (N=21).

Author (year), country, ethnicity	Study characteristics, sample size (included in analysis)	Participant characteristics	App characteristic (name), cultural adaptation within app	Measured outcomes	Attrition rate (%)
Bender et al [47] (2018), United States, Filipino American	Pilot RCT[a], Filipino Americans who were overweight or obese and aged ≥18 years at risk of T2DM[b] or prediabetes, 3 months, n=67	Mean age, years (SD): 41.7 (12.0), mean BMI, kg/m^2 (SD): 30.5 (4.4), women (%): 52.2	Multicomponent, commercial (Fitbit), English, no	Weight, BMI, waist circumference, FPG[c], and HbA_{1c}[d] level	5; I[e]: 6; C[f]: 3
Dong et al [48] (2018), China, Chinese	RCT, patients with T2DM aged 18-60 years, 12 months, n=120 (119)	Mean age, years (SD): 42.7 (6.7), BMI ≥25 kg/m^2: I (%): 48.3, C (%): 42.4, women (%): 47.9	Multicomponent, commercial (WeChat), Chinese, yes	FPG, 2-hour PG[g], HbA_{1c} level, total self-efficacy score, diet score, exercise score, medication-taking score, blood glucose–monitoring score, foot-care score, and smoking score	0
Dorje et al [25] (2019), China, Chinese	RCT, patients with coronary heart disease aged ≥18 years, 2 months intervention+4 months step-down phase, n=312	Mean age, years (SD): 60.5 (9.2), mean BMI, kg/m^2 (SD): I: 25.5 (3.0), C: 25.4 (3.5), women (%): 19	Multicomponent, commercial (WeChat), Chinese, yes	Weight, BMI, waist-to-hip ratio, 6-minute walk test, knowledge and awareness of coronary heart disease, PG, lipids, psychosocial well-being, quality of life, smoking status, dietary habits, and physical activity	15; I: 14; C: 16
Kaur et al [26] (2020), India, Indian	Cluster RCT, adults aged 35-70 years, 6 months, n=732	Mean age, years (SD not reported): 52.7, mean BMI, kg/m^2 (SD): I: 27.03 (4.2), C: 27.45 (4.8), women (%): 76.1	Multicomponent, commercial (WhatsApp), English, Hindi, and Punjabi, emails in English, yes	Weight, BMI, dietary intake changes, ASE[h] score, BP[i], FPG, and lipids	9; I: 8; C: 10
Kim et al [27] (2019), South Korea, Korean	Multicenter RCT, stable patients with T2DM aged 19-80 years with HbA_{1c} level between 7% and 10%, 24 weeks, n=191 (172)	Mean age, years (SD): I: 60.0 (8.4), C: 56.7 (9.1), mean BMI, kg/m^2 (SD): I: 25.5 (3.2), C: 25.8 (4.1), women (%): I: 44, C: 52	Multicomponent, researcher design (mDiabetes), Korean, yes	Weight, body composition, score of the summary of diabetes self-care activities, World Health Organization quality-of-life scale, HbA_{1c} level, lipids, and BP	21
Lee et al [28] (2018), South Korea, Korean	Multicenter pilot RCT, university medical school students who were overweight or obese with metabolic syndrome, 24 weeks, n=422 (324)	Age: ≥20 years, mean BMI, kg/m^2 (SD): inactive I: 28.8 (2.72), C: 29.1 (3.10), moderately active I: 29.8 (4.39), C: 29.0 (2.46), health-enhancing physically active I: 29.3 (2.90), C: 29.8 (7.12), women (%): I: 52, C: 48	Multicomponent, researcher design (SmartCare), Korean, app is in English, yes	Weight, BMI, waist circumference, body composition, BP, FPG, HbA_{1c} level, and lipids	23; I: 17; C: 30
Lee et al [29] (2019), South Korea, Korean	Pilot RCT, patients aged 20-65 years with colorectal polyps diagnosis within the last 2 years of the study, 3 months, n=65	Mean age, years (SD): I: 49.1 (8.3), C: 50.7 (8.1), mean BMI, kg/m^2 (SD): I: 26.9 (3.4), C: 24.5 (3.9), women (%): I: 34.4, C: 45.5	Multicomponent, commercial (Noom), English or Korean (NFS[j]), no	Weight, changes in dietary intake through food frequency questionnaire, and Godin leisure-time exercise questionnaire	3; I: 0; C: 6
Lim et al [30] (2020), Singapore, multiracial	RCT, patients who were overweight or obese with nonalcoholic fatty liver disease and were aged 21-70 years, 6 months, n=108	Mean age, years (SD): I: 46.8 (11.1), C: 46.2 (10.1), mean BMI, kg/m^2 (SD): I: 30.1 (4.0), C: 30.8 (4.8), women (%): I: 42, C: 32	Multicomponent, researcher design (nBuddy), English, yes	Weight, BMI, waist circumference, BP, and liver enzymes	6; I: 9; C: 4
Muralidharan et al [31] (2019), India, Indian	Multicenter RCT, adults who were overweight or obese aged 20-65 years with prediabetes, 12 weeks, n=741 (561)	Mean age, years (SD): I: 37.8 (9.2), C: 37.8 (9.6), mean BMI not reported, only baseline weight was reported, women (%): I: 43.9, C: 42.1	Multicomponent, researcher design (mDiab), English, yes	Weight, target 5% weight loss	24; I: 28; C: 21

Author (year), country, ethnicity	Study characteristics, sample size (included in analysis)	Participant characteristics	App characteristic (name), cultural adaptation within app	Measured outcomes	Attrition rate (%)
Oh et al [32] (2015), South Korea, Korean	Multicenter RCT, adults who were obese aged 20-70 years with BMI≥25 kg/m^2 and metabolic syndrome diagnosis, 24 weeks, n=422 (334)	Mean age, years (SD): I: 46.78 (13.11), C: 50.35 (14.24), mean BMI, kg/m^2 (SD): I: 29.42 (3.53), C: 29.40 (3.39), women (%): I: 46.7, C: 51.4	Multicomponent, researcher design (SmartCare), Korean, app is in English, yes	Weight, BMI, waist circumference, body composition, change in diet habit, change in physical activity (IPAQ^k), and patient satisfaction	21; I: 15; C: 27
Shin et al [33] (2017), South Korea, Korean	Pilot RCT, men who were overweight or obese aged 19-45 years with BMI≥27 kg/m^2, 12 weeks, n=105 (98)	Mean age, years (SD): 27.8 (5.0), mean BMI, kg/m^2 (SD): 29.8 (2.7), women: 0	Multicomponent, researcher design (Fit.Life), Korean, app is in English, yes	Weight, BMI, body composition, physical activity changes (IPAQ), calorie intake changes, BP, FPG, lipids, and liver enzymes	7; C: 9; I1: 3; I2: 9
Suen et al [34] (2019), Hong Kong, Chinese	Feasibility RCT, healthy adults who were overweight or obese aged ≥18 years with BMI≥25 kg/m^2 without ear injuries, 8 weeks, n=59	Mean age, years (SD): 49.15 (10.54), mean BMI, kg/m^2 (SD): 30.35 (4.53), women (%): 85	Multicomponent, researcher Design (Auricular Acupressure for Weight Reduction version 1), Chinese, yes	Weight, BMI, body composition, waist and hip circumference, blood leptin and adiponectin, fullness rating, and patient satisfaction	10; C: 5; I: 11
Tanaka et al [35] (2018), Japan, Japanese	RCT, adults who were overweight, obese, or abdominally obese aged 20-64 years with cardiometabolic risk factors or metabolic syndrome, 8 weeks intervention+4 weeks postintervention follow-up, n=112	Mean age, years (SD): I: 45.6 (10.2), C: 47.8 (9.3), mean BMI, kg/m^2 (SD): I: 28.0 (3.3), C: 28.2 (3.0), women (%): 0.9	Single-component, commercial (FiNC), Japanese yes	Weight, waist circumference, BP, lipids, HbA_{1c} level, and obesogenic eating behaviors	28; I: 32; C:18
Yang et al [49] (2017), Taiwan, Chinese	Crossover RCT, patients who were overweight or obese with BMI≥24 kg/m^2 and metabolic abnormalities, 3 months intervention+crossover 3 months usual care, n=53 (46)	Mean age, years (SD): 33.2 (9.6), mean BMI, kg/m^2 (SD): I: 27.2 (3.4), C: 30.3 (4.9), women (%): I: 61.5, C: 59.2	Multicomponent, researcher design (self-monitoring app), NFS (Line, social communication app), NFS on app, Chinese and English noted on website, yes	Weight, BMI, waist circumference, change in physical activity, FPG, BP, and lipids	13; I: 19; C: 7
Yang et al [36] (2020), South Korea, Korean	Cluster RCT, adults aged ≥18 years with T2DM for ≥1 year and HbA_{1c} level 7%-10%, 12 weeks, n=247 (239)	Mean age, years (SD): I: 54.1 (10.1), C: 60.6 (10.2), mean BMI, kg/m^2 (SD): I: 26.3 (3.7), C: 25.7 (3.9), women (%): I: 46.6, C: 53.6	Multicomponent, researcher design (HiCare smart K), Korean, yes	Weight (not mandatory), BMI, waist circumference, BP, lipids, HbA_{1c} level, FPG, Diabetes Treatment Satisfaction Questionnaire, and medication adherence scale	3; I: 3; C: 3
Zhang et al [37] (2019), China, Chinese	RCT, adults aged 18-65 years, diagnosed with diabetes for more than 6 months and with HbA_{1c} level ≥8%, 6 months, n=234 (194)	Mean age, years (SD): 53 (11), mean BMI, kg/m^2 (SD): 25.03 (3.36), women (%): 38	Multicomponent, commercial (Welltang), Chinese, yes	Weight, BMI, BP, waist circumference, FPG, HbA_{1c} level, lipids, and liver enzymes	17; C: 19; I1: 14; I2: 18
Zhou et al [38] (2016), China, Chinese	Pilot RCT, adults aged 18-74 years with diagnosed diabetes without severe complications, 3 months, n=100	Mean age, years (SD): I: 55.0 (13.1), C: 53.5 (12.4), mean BMI, kg/m^2 (SD): I: 23.04 (4.09), C: 23.01 (4.04), women (%): I: 46, C: 40	Multicomponent, commercial (Welltang), Chinese, yes	Weight, BMI, waist and hip circumference, diabetes knowledge and self-care behavior score, HbA_{1c} level, FPG, 2-hour PG, BP, and low-density lipoprotein-c	Not reported
He et al [39] (2017), China, Chinese	Cohort-based non-RCT, general population aged ≥18 years who were keen on weight loss, 6 months, n=15,818 (15,310)	Mean age, years (SD): I: 35.1 (8.5), C: 39.0 (9.5), mean BMI not reported, women (%): I: 66.5, C: 40.5	Single-component, commercial (WeChat), Chinese, yes	Weight and waist circumference	3; I: 4; C: 2

Author (year), country, ethnicity	Study characteristics, sample size (included in analysis)	Participant characteristics	App characteristic (name), cultural adaptation within app	Measured outcomes	Attrition rate (%)
Kim et al [40] (2014), South Korea, Korean	Matched controlled non-RCT, adults aged 20-70 years with T2DM for more than 1 year with HbA_{1c} level 7%-10% at baseline, 3 months, n=73 (70)	Mean age, years (SD): I: 51.8 (10.3), C: 53.8 (9.0), mean BMI, kg/m^2 (SD): I: 25.0 (3.3), C: 24.9 (3.4), women (%): 49.2	Multicomponent, NFS, likely researcher design (Mobile SmartCare, version 1.0.7), Korean, yes	BMI, BP, HbA_{1c} level, lipids, and patient satisfaction	4; I: 8; C: 0
Kim et al [50] (2019), South Korea, Korean	Cohort-based non-RCT, control: individuals with metabolic abnormalities according to the Adult Treatment Panel III criteria, intervention: individuals recruited from among those who had previously completed a 24-week mobile service program as part of the First Year Public Health Center Mobile Healthcare pilot project, 24 weeks, n=1117	Mean age, years (SD): I: 44.68 (8.22), C: 44.69 (8.22), mean BMI, kg/m^2 (SD): I: 25.71 (3.34), C: 25.18 (3.48), women (%): I: 50.8, C: 65.5	Multicomponent, researcher design (Public Health Center mHealth app), Korean, yes	Health behavior scores, mini–dietary assessment scores, BP, FPG, triglycerides, high density lipoprotein-c, and waist circumference	Not reported
Wijaya and Widiantoro [41] (2018), Taiwan, Indonesian	Pretest-posttest design, Indonesian international students aged ≥20 years who owned a smartphone with internet access, not participating in other training program, and literate in English, 10 weeks, n=75 (70)	Mean age, years (SD): 25.86 (4.33), mean BMI, kg/m^2 (SD): 23.25 (3.05), women (%): 45.7	Multicomponent, researcher Design (iNCKU smartphone app) English, yes	Body weight, BMI, BP, physical fitness, physical activity measures (step count, distance covered, caloric expenditure, and time spent on activity), self-efficacy, social support, and outcome expectation	7; I: 8; C: 5

[a]RCT: randomized controlled trial.

[b]T2DM: type 2 diabetes mellitus.

[c]FPG: fasting plasma glucose.

[d]HbA_{1c}: glycated hemoglobin.

[e]I: intervention.

[f]C: control.

[g]PG: plasma glucose.

[h]ASE: attitude, social influence, and self-efficacy.

[i]BP: blood pressure.

[j]NFS: not further specified.

[k]IPAQ: International Physical Activity Questionnaire.

Table 2. Description and primary outcome of the interventions included in the review (N=21).

Author (year), country, ethnicity, study design	Intervention	Health staff involvement	Control treatment	Change in weight or weight-related outcomes
Bender et al [47] (2018), United States, Filipino American, pilot RCT[a]	Fit&Trim, a DPP[b]-based, culturally adapted, mobile phone–based weight loss lifestyle intervention delivered by Filipino research staff, augmented with tracker Fitbit Zip and private Facebook virtual support group. Provided individual tailored goals for weight, diet, physical activity or steps, and encouraged to monitor lifestyle habits and progress on app	Baseline+5 in-person Fit&Trim education intervention office visits	Active waitlist. Received Fitbit Zip physical activity tracker with 2 education sessions on hepatitis A and B	Weight change (kg) calculated: I[c]: –3.39, C[d]: –0.82, SD or further values not reported, achieved 5% weight loss: I: 36%, C: 6%, large effect of 0.93 (Cohen *d*) reported
Dong et al [48] (2018), China, Chinese, RCT	Received conventional health education with nursing care for diabetes. Patients received multimedia-type diabetes-related knowledge from nurses on app. Able to communicate with educators and friends on app. Phone reviews on app use and hospital physical examination offered	Baseline visit and 6-month and 12-month visits, nurses communicating with patients through WeChat	Conventional health education with nursing care for diabetes	There was no significant difference in BMI between groups at baseline, 6 months, and 12 months. No further values reported
Dorje et al [25] (2019), China, Chinese, RCT	Received usual care+SMART-CR/SP[e] program. During the intensive phase, participants received 4 educational cartoon modules per week through WeChat. In the step-down phase, participants received only 2 cartoon pictures with key motivational message per week; Cartoon education touched on cardiovascular health and disease, physical activity, healthy nutritional advice, support for medication adherence, psychological well-being, and modification risk factors; Individualized feedback, recommendations, and remote supervision were provided based on regular reviews of monitoring data. Coach support available on app for health and lifestyle advice. Additional alerts and WeChat messages were sent when measurements were outside target blood pressure or steps	Baseline, 2-month, and 6-month visits for measurements and assessments by blinded researchers. Remote supervision through messages, telemonitoring, feedback, and video calls from coaches as necessary based on regular reviews of data	Standard care provided by doctors with a brief education carried out by a nurse. Medication management and ad hoc review visits to a cardiologist or other health care providers according to the patient's self-assessment of their own cardiovascular health; WeChat used for sending review visit reminders, did not receive any form of health information or intervention	BMI change (kg/m^2), mean (SD), baseline: I: 25.5 (3.0), C: 25.4 (3.5), 2 months: I: 25.0 (2.9), C: 25.2 (3.2), between-groups *P*=.64, 6 months: I: 24.9 (3.5), C: 24.5 (3.2), between-groups *P*=.14; Waist circumference change (cm), mean (SD), baseline: I: 0.9 (0.1), C: 0.9 (0.1), 2 months: I: 0.9 (0.1), C: 0.9 (0.0), between-groups *P*=.36, 6 months: I: 0.9 (0.0), C: 0.9 (0.1), between-groups *P*=0.95
Kaur et al [26] (2020), India, Indian, cluster RCT	Provision of *SMART Eating* kit, which included a kitchen calendar, dining table mat, and measuring spoons. Received weekly review information through SMS, email, social networking app (WhatsApp), and *SMART Eating* website; Fortnightly addition of diet and health-related content to website, quizzes, and a web-based help assistant to ask questions	Single home visit to provide education and guide family champions on how to use the different components of the intervention; No further face-to-face interaction. Further advice and supervision was conducted through the website	Pictorial pamphlet on the dietary recommendations with information written in Hindi language. Asked to read the pamphlet in their own time, make changes to their diet accordingly, and convey the same information to their family members; Same educational content and materials were offered to intervention group	Weight change (kg), mean (95% CI; SD not reported), 6 months: I: –0.42 (–0.8 to –0.1) *P*=.01, C: 0.24 (–0.1 to 0.6) *P*=.14, net change between groups: –0.66 (–1.1 to –0.2), *P*=.01

Author (year), country, ethnicity, study design	Intervention	Health staff involvement	Control treatment	Change in weight or weight-related outcomes
Kim et al [27] (2019), South Korea, Korean, multicenter RCT	Participants were divided into 4 groups based on antidiabetic treatment. Nil baseline education. Provided individualized targets for diet and physical activity at baseline. Encouraged to monitor blood glucose levels and lifestyle habits on app and informed that physicians can view and monitor their progress through telemonitoring. App provided immediate feedback according to an algorithm when a reading on blood glucose level, food intake, or activity was entered. Detailed information on diet and physical activity was made available through a range of educational and interactive component on app. Social networking service and bulletin board enabled users to share experiences and tips with each other, whereas research staff could answer questions from patients	Baseline, 2 in-person visits (week 12 and week 24), and 2 phone call reviews. Remote supervision and advice provided on app as well	Nil baseline education. Provided logbook to record blood glucose readings, Bluetooth glucometer, test strips, and a printed education booklet. Received 2 in-person visits at 12 weeks and 24 weeks	Weight change (kg), mean (SD), baseline to 6 months: I: 67.7 (11.8) to 67.1 (11.6), *P*=.005, C: 68.4 (13.0) to 68.0 (12.7), *P*=.04
Lee et al [28] (2018), South Korea, Korean, multicenter pilot RCT	Provided with a smartphone equipped with SmartCare app and Bluetooth-enabled bioimpedance analyzer. Instructed to monitor body composition, data were transmitted to the SmartCare system through the app; Health reports were automatically created based on the personal health information of participants according to the clinical decision support system algorithm function of the SmartCare system. Health managers provided prevention, consultation, and educational services remotely to participants based on health reports through messages and weekly emails. Monthly progress evaluation was offered along with in-person consultation with a physician at least once every 2 months (follow-up study by Oh et al [32], 2015)	Baseline, 2-monthly in-person visits with physician. Measurements at baseline, week 12, and week 24. Weekly remote supervision over app	Provided with weighing scale and pedometer and asked to record weight and physical activity steps progress in a diary. Offered 3 in-person visits at baseline, week 12, and week 24. No further visit details	Weight change (kg), mean (SD) 6 months, insufficiently active: C: –0.1 (1.94), *P*=.64, I: –1.6 (3.03), *P*<.001, between-groups *P*=.001, minimally active: C: –0.3 (2.24), *P*=.49, I: –2.5 (3.81), *P*=.001, between-groups *P*=.01, health-enhancing physical activity: C: –1.5 (3.12), *P*<.001, I: –2.6 (3.91), *P*<.001, between-groups *P*=.05
Lee et al [29] (2019), South Korea, Korean, pilot RCT	Received app and taught to use under supervision during first visit without further education. Health-related information, lifestyle recommendations, and feedback sent through app; Encouraged to track lifestyle habits on app, and users may mutually compete and share progress on the bulletin board. Monthly phone interview to assess the proper use of the app and provide motivation	In-person session to download and teach the app use during baseline visit. Measurement taken at baseline and 3 months; Nil further face-to-face interaction. Monthly phone calls (2 calls)	Received a diary to record food intake and exercise. Staff members provided health behavior change education at baseline visit; Health-related newsletters sent monthly, containing the same information about behavior as those received by the experimental group. Received monthly phone interview motivation and review	Weight change (kg), mean (SD) 3 months: I: –1.25 (1.14), *P*<.01, C: –0.42 (1.23), *P*<.07, between-groups *P*<.01; The effect was most pronounced in app users with good adherence (1.45 kg more weight reduction than the control group participants)

Author (year), country, ethnicity, study design	Intervention	Health staff involvement	Control treatment	Change in weight or weight-related outcomes
Lim et al [30] (2020), Singapore, multiracial RCT	Guided on the use of the app and educated on dietary and physical activity modification through a 1-hour face-to-face session with the research dietitian at the first study visit. Set individualized weight and lifestyle goals on the app. Advised to monitor lifestyle and progress on app. Educational videos and daily tips on healthy lifestyle available on app. Reminders and push notifications in place for meal and weight logging. Remote coaching with dietitians on progress, received encouragement and advice on app. Provided weighing scale	1-hour individual face-to-face education session with the research dietitian at baseline visit; Remote dietitian coaching on app; 2 optional workshops; Measurements at baseline, 3-month, and 6-month visits	Counseled individually for 30-40 minutes on diet and exercise by a nurse practitioner during baseline visit. Healthy food plate, physical activity, and the importance of weight loss are key areas of focus during the counseling. Provided weighing scale	Weight change (kg), mean (SD), 3 months: C: –0.8 (2.1), I: –3.2 (3.1), between-groups *P*<.001, 6 months: C: –0.5 (2.9), I: –3.2 (4.1), between-groups *P*<.001. achieved 5% weight loss, 3 months: C: 8%, I: 25%, 6 months: C: 8%, I: 44%
Muralidharan et al [31] (2019), India, Indian, multicenter RCT	Received app at baseline visit. App offered reality television show video lessons to educate and encourage lifestyle behavior tracking and change. Video lessons highlighted challenges and suitable solutions. Automatic motivational messages offered according to user's progress, alerts to prompt tracking, quizzes to reinforce learning, and message function to chat with coaches. Coaches provided weekly calls to revisit topics and emailed reports	Baseline visit to download app, weekly coach calls, emails, and text messages. Remote coach support through app chat. Measurements at baseline and 12-week visit	Received standard care that included a brochure on healthy eating, weight loss, and exercise at baseline visit. Offered face-to-face counseling with nutritionist	Weight change (kg), mean, 3 months: I: –1.1, within-group *P*<.01, C: –0.3, within-group *P*=.05, between-groups: –0.8, *P*<.05, achieved 5% weight loss: I: 15%, C: 9%
Oh et al [32] (2015), South Korea, Korean, multicenter RCT	Received information on increasing physical activity and controlling diet habits. Provided mobile phones for remote monitoring, body composition monitors, and pedometers. Advised to weigh daily or minimally 3 times weekly. Data were transmitted to the central server for immediate feedback through the designed algorithm. Received weekly, monthly health reports on progress through app; Provided phone consultations by educated consultants on disease management, health education, exercise, medication, and proper nutrition	Baseline visit, 12-week, and 24-week measurement visits. Remote app support and phone consultations by educated consultants	Received basic information on increasing physical activity and controlling diet habits at baseline visit. Body weight scales and pedometers were provided along with body weight journal for self-recording of weight and waist circumference; Returned for 2 in-person visits for measurements, consultations with physicians, and received advice about their nutrition and exercise	Weight change (kg), mean (SD) 6 months: I: –2.21 (3.60), *P*<.001, C: –0.77 (2.77), *P*<.001, between-groups *P*<.001

Author (year), country, ethnicity, study design	Intervention	Health staff involvement	Control treatment	Change in weight or weight-related outcomes
Shin et al [33] (2017), South Korea, Korean, pilot RCT	Received a 5-minute face-to-face education on diet and exercise from a nurse with standardized education material (1200 kcal sample menu), exercise recommendations, and behavior modification. Offered Fit.Life wireless physical activity tracker with Bluetooth transmission and detailed instructions on activity tracker use with demonstration and handouts. Provided clear activity goals and advised to track activity on app; Additional features for tracking progress to hit financial goals; Intervention I1: app, intervention I2: app+financial incentives	Baseline visit for 5-minute education, detailed demonstration, and instruction on app use; 4 measurement visits (baseline, week 4, week 8, and week 12)	Received a 5-minute face-to-face education on diet and exercise from a trained nurse. Content included the clinical consequence of obesity, a dietary recommendation for weight loss with an example of a 1200 kcal sample diet menu, and a physical activity recommendation with specification of frequency, intensity, time, and type	Weight change (kg), mean (SD) 3 months: I2 (app + financial incentives): –3.1 (3.7), I1 (app): –1.1 (2.9), C: –0.4 (2.5), *P* value between C and I2<.001, between C and I1=.38, and between I1 and I2=.006
Suen et al [34] (2019), Hong Kong, Chinese, feasibility RCT	Received coaching on applying auricular acupressure with instructions on frequency of application. Return demonstration was required to ensure proper treatment. Information booklet and mobile app provided. App provided daily reminders for self-pressing, encouraged compliance, and tracking of self-pressing and bowel movement; App provided relevant multimedia information and precaution on auricular acupressure. Users could communicate with researchers through app and were reminded of return visit dates on app	Researchers met patients twice weekly to change tapes. Remote communication and advice provided on app if patients had questions or problems	Received coaching on applying auricular acupressure with instructions on frequency of application. Return demonstration was required to ensure proper treatment; Information booklet provided. Patients were requested to manually record the frequency of daily pressing and bowel movement. Researchers met patients twice weekly to change tapes	Weight change (kg), mean, 8 weeks: C: –1.33, *P*=.005, I: –1.56, *P*<.001, no significant difference between groups
Tanaka et al [35] (2018), Japan, Japanese, RCT	Assigned to a group with up to 6 members where users could share meal photos in the group chat of the culturally tailored app, FiNC, and receive direct feedback, instructions, advice, and encouragement from a nutrition professional. Users could also communicate with other users for social support. Specific FiNC-method dietary recommendations were provided without any calorie restriction. Self-monitoring and group learning were encouraged on the app	Baseline, 8-week, and 12-week in-person measurements. No further human intervention. Remote communication with certified nutrition professional through app	Nil intervention provided during the 12-week waitlist period (Controls received intervention afterward for 8 weeks)	Weight change, mean (95% CI), 8 weeks: I: –1.4 (–2.0 to –0.8), C: –0.1 (–0.6 to 0.4), between-groups *P*=.001, week follow-up after active intervention, 12 weeks: I: –1.4 (–2.1 to –0.8), C: –0.1 (–0.7 to 0.6), between-groups *P*=.004

Author (year), country, ethnicity, study design	Intervention	Health staff involvement	Control treatment	Change in weight or weight-related outcomes
Yang et al [49] (2017), Taiwan, Chinese, crossover RCT	Received mobile physical activity promotion tool inclusive of lifestyle counseling, professional personal counseling, constructive feedback, health information, individualized reminder message at least once a week through Line app and email. A self-monitoring app with mobile activity sensor was provided along with an interactive internet webpage where users could track their health, compare results with peers, and receive recommendations	Lifestyle counseling at baseline, minimal human contact; Remote coaching on app and sending of reminder messages at least once weekly through Line and email; Baseline, 12-week, and 24-week in-person measurement visits	Received lifestyle counseling and booklet containing health education in support of behavioral and educational advice for diet control, increased physical activity, less smoking and drinking, stress, and regular health examination. Information on the related risk factors, development and prevention of metabolic syndrome, and various websites were also provided to the patients	Weight change (kg), mean (SD), 6 months, with activity promotion system: pre–activity promotion system: 77.7 (15.1), post–activity promotion system: 76.4 (15.5), pre–usual care: 78.1 (16.6), post–usual care: 76.8 (15.8), between-groups *P*=.93; (Crossover study without washout period, nil results on specific phases of intervention)
Yang et al [36] (2020), South Korea, Korean, cluster RCT	Physicians provided education on the use of the medical instruments and smartphone app. Explained management targets and guidelines to patients. Provided glucometer, test strips, and electronic manometer monitoring. Users were asked to upload their daily SMBG[f] results, other biometric information, and weight through the app; Data automatically transmitted to the main server where physicians could check the results through a website and send feedback messages (praise, encouragement, feedback, and advice) at least once per week. Additional direct phone calls were conducted as required. Monthly face-to-face consultations offered	Baseline education on instruments, smartphone app, management targets and guidelines. Weekly feedback message through website or additional calls as necessary. Monthly in-person consultations to review progress, measurements, and management	Visited the private clinics and received face-to-face consultations every month for review and measurements	Weight change (kg), mean (95% CI), 3 months: I: −0.63 (−1.02 to −0.24), C: −0.88 (−2.65 to 0.90), adjusted mean difference to control: 0.22 (−1.26 to 1.71), between-groups *P*=.77
Zhang et al [37] (2019), China, Chinese, RCT	Group I1: app (basic), received basic diabetes education, including diet control, adequate exercise, SMBG, and regular review. Provided with glucose meter, test strips, and targets and encouraged to track BG[g], habits, and obtain diabetes-related knowledge through the app. Users could contact clinicians by phone or app; Group I2: app, interactive group I1 intervention+third-party professional diabetes health care team comprising a dietitian and a health manager. Health team provided feedback and recommendations on progress, BG, and lifestyle habits. Provided daily prompts (first month) and then monthly on the app by health care team and reviewed weekly glucose reports. Users were given BG targets and were able to contact clinicians by phone or app	Baseline, 3-month, and 6-month measurement visits, ability to contact clinicians on the web through app or phone. Group I1 received support from a clinician, group I2 had additional interactive support on app with web-based management health care team comprising a dietitian and a health manager	Provided basic education. Patients obtained diabetes-related knowledge and skills by self-learning and summarizing, and they adopted lifestyles and behaviors voluntarily. Equipped with a designated BG meter and test strips, patients were advised to record results in a logbook. They could contact clinicians through phone	Weight change (kg), mean (SD), baseline: C: 69.6 (10.0), I1 (app, basic): 72.3 (11.6), I2 (app with health team): 70.8 (11.9), 3 months: C: 69.6 (9.6), I1: 72.2 (11.9), I2: 70.9 (11.6), 6 months: C: 69.4 (9.9), I1: 72.0 (11.7), I2: 71.0 (11.6); There were no significant differences among the 3 groups for body weight at both 3 and 6 months

Author (year), country, ethnicity, study design	Intervention	Health staff involvement	Control treatment	Change in weight or weight-related outcomes
Zhou et al [38] (2016), China, Chinese, pilot RCT	Downloaded the Welltang app at baseline visit and received diabetic knowledge on diet, exercise, medicine, blood glucose monitoring, and the latest guidelines for diabetes care. Users were asked to monitor 7-point finger blood glucose level for 1 day every 1-2 weeks (prompts in place) and track lifestyle habits. Advice on progress, values, target goals, and medication were offered by clinicians or study team through app once a week or fortnight. Users could communicate with clinicians through app, and an electronic action plan facilitated clinic review	Baseline, 1-month, 2-month, and 3-month in-person consultations. Remote interaction with clinicians on app as necessary. Weekly or fortnightly feedback from clinicians	Monthly visits to see physician to review blood glucose readings through logbooks. Patients were asked to monitor their 7-point finger capillary blood glucose level with a blood glucose meter 1-3 days before each clinic attendance to facilitate medication regimen adjustments	Weight change (kg), mean (SD), baseline: I: 62.4 (12.8), C: 62.5 (12.8), 3 months: I: 62.2 (11.0), C: 62.7 (12.1), *P* value not significant within or between groups
He et al [39] (2017), China, Chinese, cohort-based non-RCT	Received an official WeChat account for self-monitoring and immediate feedback on lifestyle habits. Users communicated and competed on weight loss progress. Users received scores for interactions, feedback information, or activity on the app, and top scorers were rewarded. Multimedia information on weight loss and an expert consulting group in place to answer questions	Nil baseline education or in-person session; 2 weight managers per work organization were trained to obtain participants' data on height, weight, and waist circumference before and after the interventions were initiated for both groups. Remote communication with experts through app	Routine publicity, such as the slogan "Take the stairs and lose weight," was provided to the control group. No further details specified	Weight change (kg), mean (SD): I: –2.09 (3.43), C: –1.78 (2.96), mean weight loss between the 2 groups for men was significant based on the stratification of age and educational level, weight loss changes were not significant for women
Kim et al [40] (2014), South Korea, Korean, matched controlled non-RCT	Baseline data recorded were transmitted to the app at first visit. Thereafter, users self-measured blood pressure and blood glucose levels, and data were automatically transmitted to hospital or medical staff through the app. Medical staff analyzed the data and sent tailored feedback to the patient once per week on average; App provided warning messages and advice when blood glucose levels were too high or too low. Study staff called users if they had hypoglycemia or no data were recorded	Nil baseline education. Measurement visits at baseline and 12 weeks. Remote supervision and weekly coaching on app. Staff called users if they had hypoglycemia or no data were recorded	Standard care, not clearly reported in paper	BMI change (kg/m^2), mean (SD), baseline: I: 25.0 (3.3), C: 24.9 (3.4), 3 months: I: 25.0 (3.4), within-group *P*=.80, C: 24.3 (3.1), within-group *P*=.06, no significant difference between groups

Author (year), country, ethnicity, study design	Intervention	Health staff involvement	Control treatment	Change in weight or weight-related outcomes
Kim et al [50] (2019), South Korea, Korean, cohort-based non-RCT	Received face-to-face counseling service at public health center from physician, nutritionist, exercise specialist, and nurse at baseline, 12 weeks, and 24 weeks. Offered activity monitors, sphygmomanometers, glucometers, body composition measuring devices, and app for self-monitoring. Instructed to sync activity at least 5 times weekly and upload meal pictures once a month. Remote weekly individualized service related to healthy lifestyles was provided by health professionals along with monthly reports. Access to web-based communities for each health center facilitated consultations; Received intensive nutritional consultations at health centers based on meal photos (Rewards such as mobile gift cards were offered to users with excellent performances, but this was not duly reported in the *Methods* section)	Baseline, 12-week, and 24-week consultations and measurements. Weekly individualized advice and services related to lifestyle habits provided by physicians, nurses, nutritionists, and physical activity experts who monitored health information on the web in real time; Intensive nutrition consultations at each visit to health center	After classification according to test results, tailored care plans were established. Face-to-face counseling services offered at public health center by team comprising a health manager (a health expert such as a physician or nurse), nutritionist, and certified exercise expert, who provided individual or group health consultation (consultations adhered to the 2011 One-Stop Health Service Consultation Manual)	BMI measured at baseline but not reported in results. Change in proportion of patients with metabolic risk factor (elevated waist circumference) according to Adult Treatment Panel III criteria: I: –62 male patients, I: –78 female patients, significant difference within group for both genders, C: –2 male patients, C: –20 female patients, significant difference within female group only. No significant difference between groups
Wijaya and Widiantoro [41] (2018), Taiwan, Indonesian, pretest-posttest design	The intervention group received Social Cognitive Theory skill-building by WGTC[h] for a 10-week program. The participants formed teams of 3 or 4 members based on friendship, received a booklet that provided physical activity–related knowledge, and were offered a 50-minute guidance on watch and app use at baseline. Individual and group performances were shown in the WGTC of the webpage where information was automatically transmitted by the iNCKU watches and the smartphone apps through daily use	Nil baseline education. Provision of items, booklet, guidance on use and purpose of study at baseline. Measurements at baseline and 10 weeks. No further human contact	Received explanation for the purposes of the study and a booklet that provided physical activity–related knowledge	Weight change (kg), mean (SD), baseline: I: 59.04 (65.44), C: 58.11 (66.83), 10 weeks: I: 57.78 (64.30), C: 57.92 (66.70), between-groups *P*=.64, intervention recorded lower body weight, *P*<.002

[a]RCT: randomized controlled trial.

[b]DPP: diabetes prevention program.

[c]I: intervention.

[d]C: control.

[e]SMART-CR/SP: Smartphone and Social Media–Based Cardiac Rehabilitation and Secondary Prevention.

[f]SMBG: self-monitoring blood glucose.

[g]BG: blood glucose.

[h]WGTC: web-based game with team competition.

The active intervention period ranged from 8 to 52 weeks, with a mean period of 18 weeks; the most common intervention periods were 6 months [25-28,30,32,37,39,49,50], followed by 3 months [29,31,33,35,36,38,40,47]. Of the 21 studies, only 1 study (5%) included a 4-week follow-up outcome measurement after the active intervention [35]. The average attrition rate was 11.5% (SD 8.53, range 0%-28%). Of the 21 studies, 2 (10%) consisted of single-component interventions using a mobile app exclusively [35,39], whereas 19 (90%) were multicomponent interventions incorporating additional components such as face-to-face consultations [25-30,32-34,36-38,47-50], reviews through phone calls or emails [26,27,29,31,32,36,40,48], supporting webpage [41], or financial incentives [33]. Of the

16 studies with face-to-face consultations, 4 (25%) also included tutorials to familiarize users on app use [29,30,36,41].

Across interventions, of the 21 studies, 12 (57%) used a researcher-designed app [27,28,30-34,36,40,41,49,50], whereas 9 (43%) used a commercially available app [25,26,29,35,37-39,47,48]. All studies had either used a culturally adapted app or had an app that was locally developed, except for 2 (10%) studies [29,47] that used a generic app developed in the United States. All studies reported using a multifunctional app, with the most common features being interactivity with health professionals; calorie, activity, or weight tracking; health and lifestyle information; and progress feedback (Multimedia Appendix 5 [25-41,47-50]). Other features such as gamification, which included scoring of app use to gain points for reward redemption and leader board positions, were less commonly reported. The average number of app features was 8.7 (SD 3.36, range 3-15). Comparing between commercially available and researcher-designed apps, the average numbers of app features were comparable at 7.7 (SD 3.15, range 3-12) and 9.5 (SD 3.45, range 5-15), respectively.

Risk-of-Bias Assessments

RCTs and Bias

The risk-of-bias assessments of the included studies are summarized in Tables 3 and 4 for RCTs and Table 5 for non-RCTs, respectively. More than half of the RCTs included in both the systematic review and meta-analysis were rated low risk for selection bias, attrition bias, reporting bias, and other biases. Of the 17 RCTs, 1 (6%) was rated high risk for random sequence generation because of errors in patient randomization [27] and 5 (29%) were rated unclear risk for allocation concealment because of insufficient details reported by the authors [27-29,37,38]. Performance bias was rated high risk for 53% (9/17) of the studies [26-30,32,33,35,38], whereas 29% (5/17) of the studies scored unclear risk [25,31,34,36,37]. Of the 17 studies, detection bias was rated unclear for most, except for 3 (18%) that were rated low risk [25,34,35]. Of the 17 studies, 3 (18%) were rated high risk for attrition bias, with attrition rates between 21% and 24% [27,28,31]; 2 (12%) were rated unclear risk [32,38]; and 1 (6%) was rated high risk for reporting bias because the authors did not report the primary outcome registered in the trial registration [31]. Apart from these bias domains, of the 17 studies, 4 (24%) and 3 (18%) were rated high risk and unclear risk with regard to other biases, respectively.

Table 3. Risk of bias within the randomized controlled trials for selection, performance, and detection bias domains (N=17).

Study design	Cohort-based non-RCT	Matched controlled non-RCT	Cohort based non-RCT	Pretest-posttest design
Bias due to confounding	Moderate risk	Serious risk	Critical risk	Moderate risk
Bias in selection of patients into the study	Low risk	Low risk	Low risk	Low risk
Bias in classification of interventions	Low risk	Low risk	Low risk	Low risk
Bias due to deviations from intended interventions	Moderate risk	Moderate risk	Serious risk	Low risk
Bias due to missing data	Low risk	Low risk	Low risk	Low risk
Bias in measurement of outcomes	Moderate risk	Serious risk	Moderate risk	Moderate risk
Bias in selection of the reported result	Moderate risk	Moderate risk	Moderate risk	Moderate risk
Overall bias	Moderate risk	Serious risk	Critical risk	Moderate risk

[a]RCT: randomized controlled trial.

Non-RCTs and Bias

The overall risk of bias for non-RCTs ranged from moderate to critical risk. All studies were rated low risk for selection bias, classification bias, and attrition bias. The studies were mostly rated moderate risk of bias for the other domains, except for 1 study that was rated serious risk for confounding bias and detection bias, leading to the overall rating of serious bias for the study [40]. A non-RCT that was excluded from the meta-analysis had an overall critical risk score because of critical risk of bias for confounding and serious risk of bias for deviation from the intended intervention [50].

Intervention Efficacy

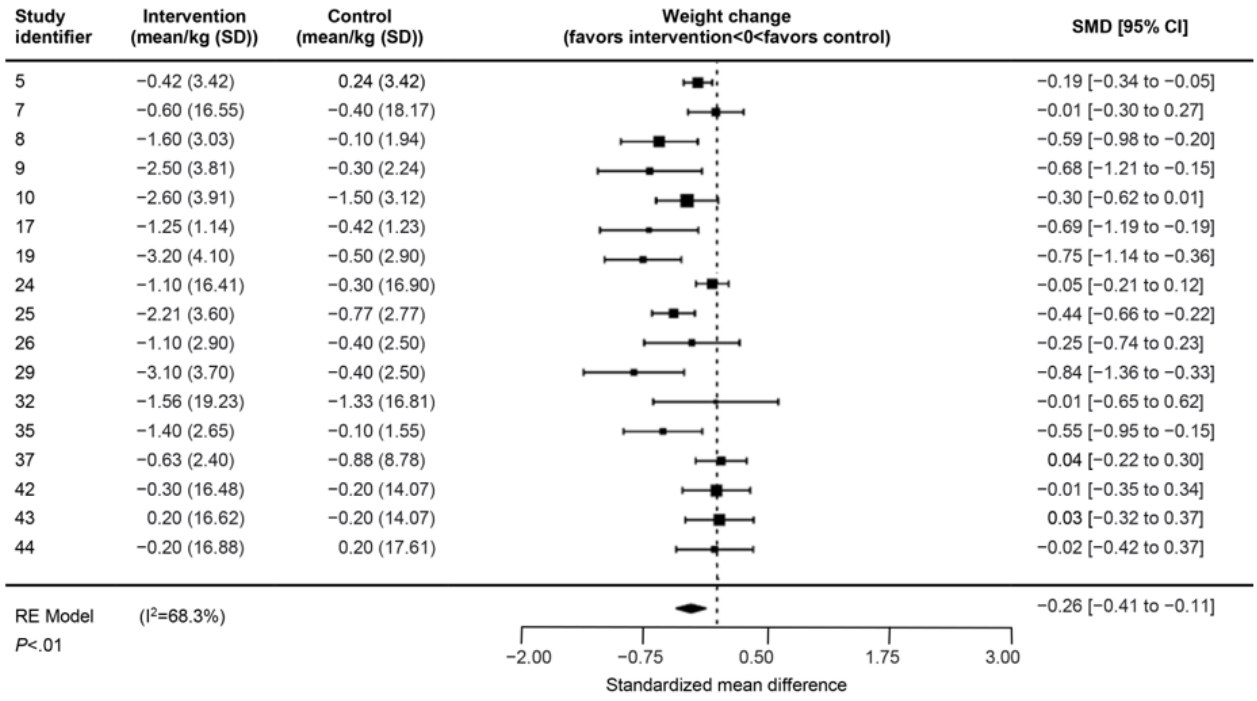
Of the 21 studies, 4 (19%; 3 RCTs and 1 non-RCT) were excluded from the meta-analysis because they did not provide specific values for weight-related outcomes that could be pooled [47-50]. In Bender et al [47], the authors reported significant

weight loss and higher percentage of intervention patients achieving 5% weight loss, whereas the remaining 3 studies did not report any significant results.

Among the 14 selected RCTs for the quantitative analysis, 9 (64%) reported a positive effect for the intervention on weight loss between the treatment arms [26,28-33,35,47]. In the 8 RCTs that did not report significant differences between the treatment groups, 7 (88%) nonetheless found that the intervention arms contributed to greater weight loss compared with the controls [27,34,38,39,41,49,50]. In all, 3 RCTs assessed the proportion of participants achieving clinically significant weight loss (ie, 5% weight loss) and found that between 15% and 44% of the participants in the intervention groups achieved 5% weight loss, whereas 6%-9% of the control participants achieved clinically significant weight loss [30,31,47].

The pooled weighted effect size across 14 RCTs for weight change (Figure 2) was small to moderate (Hedges g=–0.26; 95% CI –0.41 to –0.11; P<.01) with substantial heterogeneity (I^2=68.3%), whereas similar effect sizes were also observed for BMI (Hedges g=–0.21; 95% CI –0.42 to –0.01; P=.04; I^2=69.9%) and waist circumference (Hedges g=–0.24; 95% CI –0.45 to –0.02; P=.03; I^2=65.5%; Figures S1 and S2 of Multimedia Appendix 6). In terms of absolute weight, BMI, and waist circumference reduction, the raw mean difference revealed that the intervention group lost 1.16 kg (95% CI 0.81-1.52), 0.42 kg/m^2 (95% CI 0.16-0.68), and 1.21 cm (95% CI 0.22-2.21) more than the control group, respectively (Figures S3-S5 of Multimedia Appendix 6). Visual assessment of the funnel plots revealed no obvious asymmetry, suggesting a low risk of publication bias (Multimedia Appendix 7).

Figure 2. Forest plot showing the pooled effects of the interventions that incorporate apps on weight change. RE: random effects; SMD: standardized mean difference.

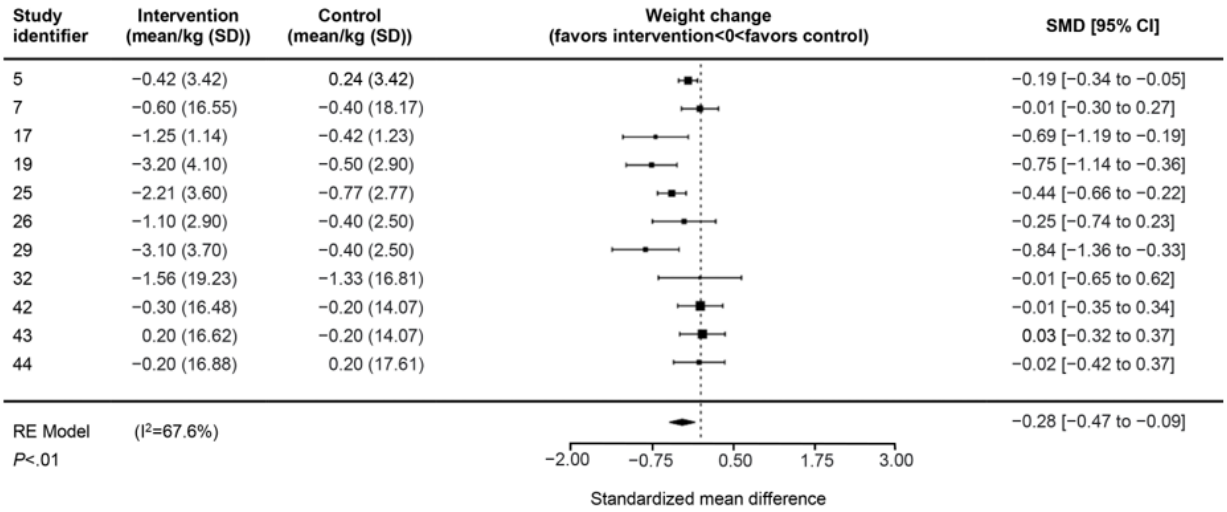


In a separate analysis of non-RCTs, 2 studies were included for each outcome: weight and BMI (Figures S6 and S7 of Multimedia Appendix 6). The effect size for weight change was statistically significant but small, with Hedges g=–0.09 (95% CI –0.13 to –0.05; P<.01; I^2=0%). In contrast, the effect size for BMI was not statistically significant (Hedges g=0.06; 95% CI –0.27 to 0.39; P=.74; I^2=0%). No analysis was conducted for waist circumference because only 1 study reported this outcome [39]. Overall, the results for the non-RCT meta-analysis should be interpreted with caution because there were very few data points included in the analyses and the data from the studies included were highly variable.

In the subgroup analyses for single-component (standalone app interventions) studies, no meta-analysis was conducted because of a lack of data points to assess the outcomes for RCTs and non-RCTs separately. Tanaka et al [35] reported a statistically significant weight loss between the groups but not He et al [39], although the intervention patients achieved a greater weight loss.

For interventions with the addition of apps to usual care, the effect size for weight (Figure 3) was statistically significant with a small to moderate Hedges g=–0.28 (95% CI –0.47 to –0.09; P<.01; I^2=67.6%); however, this was not the case for BMI and waist circumference outcomes (Figures S8 and S9 of Multimedia Appendix 6).

Figure 3. Forest plot showing the pooled effects of interventions combining usual care with app (intervention) versus usual care alone (control) on weight change. RE: random effects; SMD: standardized mean difference.



Moderation analysis suggested that study duration was not a significant moderator of intervention effects on weight, BMI, and waist circumference, with *P* values of .72, .67, and .69, respectively. All studies included in this meta-analysis had an intervention period of 6 months or less. Post hoc analyses (Figures S10 and S11 of Multimedia Appendix 6) revealed that changes in body weight were significantly different between the intervention and control groups, both in studies with a duration of 3 months or less (Hedges *g*=–0.28; 95% CI –0.52 to –0.05; *P*=.02; I^2=75%), as well as those between 3 and 6 months (Hedges *g*=–0.29; 95% CI –0.51 to –0.08; *P*=.01; I^2=72.2%). Conversely, changes in BMI and waist circumference did not differ significantly between the treatment arms in both data subsets (Figures S12-S15 of Multimedia Appendix 6).

Secondary Outcomes

Across all 21 studies, 17 (81%) reported at least one secondary outcome measured through a range of tools and approaches, as described in Multimedia Appendix 8 [25-41,47-50]. In all, 8 out of 11 studies (73%) showed that an app intervention improved dietary outcomes, with 5 studies [26,32,38,48,50] reporting concomitant within-group and between-groups differences, whereas Suen et al [34] and Lee et al [29] reported within-group differences. Physical activity outcomes were mostly reported as changes in exercise frequency, intensity, or duration. A total of 7 out of 11 studies (64%) showed an increase in physical activity level or exercise scores, with significant within-group and between-groups differences reported in 3 [29,38,50] and 6 studies [25,33,38,41,49,50], respectively. Significant improvements in self-efficacy scores were reported in 4 out of 6 studies (67%) [26,38,48,50], whereas 2 studies reported no significant change [27,41].

Among the 9 studies reporting significant weight change, 2 (22%) [26,32] reported significant improvements in diet, whereas 1 (11%) [33] reported significant increment in physical activity. Of the 9 studies reporting significant weight change, 3 (33%) studies did not find a significant improvement in diet [29,33,35], whereas the others did not report dietary outcomes [28,30,31,47]. Similarly, for physical activity, 3 (33%) studies [28,29,32] did not find any significant improvement, whereas the remaining studies did not report this outcome [26,30,31,35,47].

Of the 21 studies, 9 (43%) reported on app use and engagement [25,29,30,33,35,37-39,50]; however, only 6 offered use statistics, albeit by using various measures [25,30,35,37-39]. These statistics included number of daily log-ins [30]; meal, activity, or weight logging [30]; uploading of meal photos [35]; reading of messages [25]; frequency of app use [37]; interactivity with coaches [37,38]; and number of questions asked and cumulative app use scores [39]. Of the 9 studies, 4 (44%) reported that increased app use or adherence was associated with greater weight loss and health outcomes [29,33,35,39], whereas the remaining 5 (56%) did not explore any associations. In addition, of the 9 studies, 2 (22%) found that app use declined over time [30,35], whereas the remaining 7 (78%) did not report app engagement trends.

Discussion

Principal Findings

The interventions that incorporated apps produced a small to moderate effect in reducing weight, BMI, and waist circumference in Asian populations, although substantial heterogeneity was present. It was unclear if single-component standalone app studies were efficacious for weight loss; however, supplementing usual care with an app seemed to be beneficial for enhancing weight loss compared with usual care alone. However, the results may not be representative of long-term studies because of a lack of data. This review also found that app interventions may be beneficial for improving diet and increasing physical activity and self-efficacy for healthy behaviors. In these interventions, apps made for Asian populations were largely culturally adapted and multifunctional, with the most common app features being communication with health professionals and self-monitoring of behaviors and outcomes. Overall, the quality of the studies ranged from low to unclear risk of bias for most domains, apart from performance bias where most of the studies were graded high risk because

of the lack of blinding, which is challenging in interventions that incorporate apps. Therefore, the results should be interpreted with caution.

Among the studies in our review that reported a significant difference in either between groups or within group for weight loss favoring the intervention or a greater likelihood among the intervention groups for clinically significant weight loss, most were multicomponent. They typically included face-to-face consultations and reviews through phone calls or emails in addition to the app component.

Our review found that supplementing multicomponent usual care practices with an app was successful in achieving greater results. Reviews of studies in Western populations have observed similar findings [8,15]. This could be attributed to the provision of social support, accountability, and increased opportunities for patients to be reviewed beyond the confines of the app [51], thus underscoring the importance of additional components to raise contact frequency, enhance self-monitoring, and maximize outcomes.

Monitoring of weight, diet, and physical activity behaviors was a common feature of apps in the interventions reviewed. The addition of an app to usual care aligns with the understanding that self-monitoring can improve self-regulation of behaviors and weight loss [52,53]. By enhancing convenience for users, apps thus encourage more consistent self-monitoring [54] to promote treatment adherence and weight loss [15,42]. This review also observed that the outcomes of healthy eating and increased physical activity, which are key determinants of weight loss, tend to occur alongside improved self-efficacy for implementing healthy behaviors. As self-efficacy was previously found to be positively associated with self-monitoring, it is likely that increased self-monitoring may account for the behavioral improvements seen [55].

It was also apparent from our review that multifunctional, *all-in-one* apps were common among Asian interventions. The features included direct communication with health professionals through the app, in addition to functionalities for calorie, activity, and weight tracking as well as provision of health information and progress feedback, thereby matching the features found in effective digital weight loss interventions reported in a recent review [54].

In contrast with apps designed in Western countries, which tend to focus more on independent learning [8], apps designed for Asians frequently include accessibility to health professionals. It is plausible that having health coaches within apps reduces the barriers for Asians to seek health information, validation, and support from their clinicians [18,19,56], while conferring increased credibility to the coaching and support given to users [54,57]. App users recognize the benefit of health professionals such as dietitians providing support, particularly as they offer effective, evidence-based, culturally appropriate, and tailored dietary counseling to participants [58,59]. Correspondingly, most studies that employed a dietitian or nutrition-trained professional reported a greater weight loss with the intervention [28,30-32,35,37,50].

Furthermore, all but 2 studies [29,47] either used a culturally adapted app or an app that was locally developed; employed the respective country's native language; and incorporated localized educational content, food databases, and recommendations. Research supports that using culturally appropriate content, engaging local facilitators, and offering the app in the native language are important factors that may promote app use and outcomes [57,60].

Only 6 of the 21 studies reported app use statistics, whereas 2 others provided associations between app adherence and outcomes without reporting actual app engagement data. Meyerowitz-Katz et al [61] reported in a recent meta-analysis that the pooled estimate of app nonuse (defined as attrition rate) was 43%, indicating a serious limitation of app-based interventions if strategies for maintaining long-term engagement with the intervention (longer than a year) are not considered. In this review, the interventions that incorporated an app achieved statistical significance for weight change in studies with durations that were 6 months or less. However, the efficacy of these interventions in long-term studies remains unclear because none of the studies reviewed included durations longer than a year. App engagement levels in this review varied across studies, making comparison difficult. Nevertheless, evidence from this review echoed the results reported by previous reviews that increased app use is associated with greater adherence and weight loss [8,15], notwithstanding the fact that app engagement typically declines over time [8,61].

Strengths and Limitations

This is the first meta-analysis to report on the efficacy of apps incorporated into interventions targeting weight loss with or without healthy behavioral change in populations of Asian ethnicity. The review and meta-analysis were conducted according to best practice and followed PRISMA guidelines with a comprehensive search strategy and assessment of risk of bias using Cochrane Collaboration tools. The study selection, data extraction, and quality assessment were conducted independently by 2 reviewers.

This review is not without some limitations. The heterogeneity observed across studies was substantial, making it challenging to effectively interpret the results. Substantial heterogeneity could be due to the differences in study aims, targeted outcomes, methods, populations, and interventions. The lack of consistent and detailed reporting among the studies limited our ability to assess the true dose of intervention received, user engagement levels, and behavior change techniques that may have been employed in the apps. Therefore, the results of the meta-analysis should be interpreted with caution. Future studies that incorporate apps should consider using a standardized tool such as the Behavior Change Technique Taxonomy to code app features in a systematic and replicable manner and report user engagement statistics to evaluate app use and outcomes. This review was also limited to studies that were published in the English language. This may be problematic, given that we were studying apps in Asian populations, and English may not have been the first language in many countries; hence, some articles in other languages would not have been captured in this review. Finally, as most of the studies were multicomponent in nature,

components apart from the app, such as in-person education or review calls, may have more strongly influenced the outcomes; however, it was not possible to identify the contribution of these components to the weight loss outcomes.

Conclusions

This review contributes to the literature by presenting quantitative evidence that multicomponent interventions that incorporate apps produce a small to moderate effect toward weight loss in studies of Asian populations with intervention periods of 6 months or less. It is unclear if single-component standalone-app studies are efficacious for weight loss; however, adding apps to multicomponent usual care confers better outcomes. More evidence is required to determine the efficacy of apps in the long term. Cultural adaptation and offering the app in the native language of the users seem to be a priority in Asian apps. Multifunctional apps with features that include self-monitoring, individualized feedback, and a link to health professionals within the apps may be key to raising awareness and engagement, as well as promoting weight loss. Finally, it is recommended that investigators monitor and address the low uptake of apps and attempt to enhance engagement level before using apps as part of national health strategies for reducing obesity.

Acknowledgments

The authors wish to thank librarian Monica Cooper from the University of Sydney for her assistance with the development and refinement of the search strategy. The authors are also grateful for the support from the Singapore Ministry of Health's National Medical Research Council under its Health Services Research Grant program (NMRC/HSRG/0063/2016).

Authors' Contributions

SMA and JC jointly designed the research question and research protocol, and JHL, JJ, YYD, MAF, and SLL approved the protocol. SMA and JC performed the searches, screened the studies, extracted the data, and assessed quality. SMA and JJ conducted the gray literature searches, hand searching of reference lists, and extraction of data on app features from the studies. LJH conducted the meta-analysis and guided the quantitative data analysis. SMA and JC drafted the manuscript. All authors contributed to writing the final manuscript.

Abstract

Background: Digital interventions have tremendous potential to improve well-being and health care conveyance by improving adequacy, proficiency, availability, and personalization. They have gained acknowledgment in interventions for the management of a healthy lifestyle. Therefore, we are reviewing existing conceptual frameworks, digital intervention approaches, and associated methods to identify the impact of digital intervention on adopting a healthier lifestyle.

Objective: This study aims to evaluate the impact of digital interventions on weight management in maintaining a healthy lifestyle (eg, regular physical activity, healthy habits, and proper dietary patterns).

Methods: We conducted a systematic literature review to search the scientific databases (Nature, SpringerLink, Elsevier, IEEE Xplore, and PubMed) that included digital interventions on healthy lifestyle, focusing on preventing obesity and being overweight as a prime objective. Peer-reviewed articles published between 2015 and 2020 were included. We used the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines and a framework for an evidence-based systematic review. Furthermore, we improved the review process by adopting the Rayyan tool and the Scale for the Assessment of Narrative Review Articles.

Results: Our initial searches identified 780 potential studies through electronic and manual searches; however, 107 articles in the final stage were cited following the specified inclusion and exclusion criteria. The identified methods for a successful digital intervention to promote a healthy lifestyle are self-monitoring, self-motivation, goal setting, personalized feedback, participant engagement, psychological empowerment, persuasion, digital literacy, efficacy, and credibility. In this study, we identified existing conceptual frameworks for digital interventions, different approaches to provide digital interventions, associated methods, and execution challenges and their impact on the promotion of healthy lifestyle management.

Conclusions: This systematic literature review selected intervention principles (rules), theories, design features, ways to determine efficient interventions, and weaknesses in healthy lifestyle management from established digital intervention approaches. The results help us understand how digital interventions influence lifestyle management and overcome the existing shortcomings. It serves as a basis for further research with a focus on designing, developing, testing, and evaluating the generation of personalized lifestyle recommendations as a part of digital health interventions.

eHealth; digital intervention; lifestyle; obesity; challenges; mobile phone

Introduction

Overview

Deaths caused by lifestyle diseases are increasing rapidly compared with deaths caused by infectious disease [1-4]. Most lifestyle diseases arise from unhealthy and sedentary lifestyles, low nutritional propensities, and poor living conditions, affecting individuals from different financial backgrounds, beyond age and gender biases [1-3]. Lifestyle diseases are a monetary burden to individuals, families, businesses, and governments. They cause 41 million deaths each year, equivalent to 71% of all deaths worldwide [1-6]. Every year, 15 million people die from lifestyle diseases between the ages of 30 and 69 years, and more than 85% of these *premature* deaths occur in low- and middle-income countries [1-6]. The fundamental risk factors [7-13] behind lifestyle diseases are excessive alcohol and tobacco consumption, improper food plan, and physical inactivity, resulting in excess weight gain (obesity), increased blood glucose, hypertension, high blood cholesterol, and social detachment [7-13]. Obesity is a primary lifestyle disease that leads to other lifestyle diseases, such as cardiovascular diseases (CVDs), clinical obstructive pulmonary disease, cancer, type 2 diabetes, hypertension, and depression [7-13]. In 2016, more than 1.9 billion adults age ≥18 years were overweight. Of these, over 650 million were obese [2-4]. In 2016, 39% of adults aged ≥18 years were overweight, and 13% were obese [2-4]. In 2019, an estimated 38.2 million children aged ≤5 years were overweight or obese [2-4]. Once considered a problem in high-income countries, overweight and obesity are now rising in low- and middle-income countries (especially in urban environments) [2-4]. Since 2000, the number of overweight children aged ≤5 years has increased by nearly 24% in Africa [2-4,8]. In 2019, almost half of the children aged ≤5 years who were overweight or obese lived in Asia [2-4,8]. Thus, control plans need to include detection, screening, treatment, and prevention methods. Digital interventions may provide viable and hypothetically cost-effective models to improve well-being. They provide widely distributed, trusted, and personalized well-being information and services to fulfill individualized needs to maintain a healthy lifestyle [14-19].

Digital interventions for changing negative health behaviors to advance a healthy lifestyle are instigated by persuasion studies. The World Health Organization (WHO) has classified digital health interventions into the following 4 categories: clients, health care providers, health system managers, and data services, where digital and mobile technologies are being used to help well-being system needs and achieve health objectives [20-26]. Digital intervention methods include conceptualization, intervention strategies, policy design, understanding of the environment, motivation, behavioral determinants and psychology, persuasion, self-determination theory, self-regulation, participation (engagement), decision-making and feedback generation, goal setting and evaluation, incorporation of digital technologies (eg, smartphones, computers, and wearable sensors), and digital recommendation generation. Its success depends on credibility, satisfaction, privacy, digital literacy, proper connectivity, cocreation, and efficacy evaluation [20-26]. According to the WHO, harnessing the power of digital technology is critical to achieving universal health coverage, and digital technologies are not an end in themselves; they are essential tools for promoting health, maintaining world security, and serving the disadvantaged [18-24]. Digital interventions have been carried out effectively for well-being advancement and psychological well-being and for enabling self-administration of enduring conditions [18-24]. Nonetheless, their capability is restricted by low use rates, with noncommitment being a significant challenge. The use of digital technology provides new opportunities to improve health [18-24]. However, the evidence also highlights the challenges posed by certain interventions. If digital technologies are to be maintained and integrated into health systems, they must be able to demonstrate long-term improvements compared with traditional methods of providing health services [23,24].

Limitations

Digital intervention depends heavily on the context and ensures the proper design, including the structural issues in the environment in which they are used, the available infrastructure, the health needs they are addressing, and the ease of use of technology [1,15-17]. Consequently, it is important to discover successful procedures for expanding individual engagement with digital interventions. Digital interventions can also support health workers to give them more opportunities to clinical protocols around, for example, decision support mechanisms or telemedicine consultation [15-17]. Digital interventions should supplement and enhance the functions of the health system by accelerating information exchange and other mechanisms but cannot substitute the essential components required by the health system, such as the health workforce, funding, leadership and governance, and access to critical medicines. However, digital interventions in health care have tremendous potential as scalable tools to enhance well-being and health care service conveyance by improving viability, proficiency, openness, and personalization [1,15-17]. The WHO is working hard to ensure that it can be used as efficiently as possible, which means adding value to medical staff and individuals who use these technologies, considering the limitations of the infrastructure, and making appropriate coordination [22-24]. Although digital intervention's application area is broad, we have focused only on *digital behavioral intervention for healthy lifestyle* studies in this paper.

Study Aim

Efficiency, acceptability, and compliance are 3 necessary indicators of digital behavioral interventions, as they are prerequisites for positively affecting health or healthy behavior. Efficacy refers to the effect of using technology in behavioral interventions. Acceptability means that users are satisfied with the technology. Compliance refers to the degree to which technology is used, as expected. This systematic literature review addresses the following research questions (RQs):

RQ1: what are the existing conceptual frameworks for digital interventions for healthy lifestyle management?

RQ2: what are the different *approaches* to provide digital interventions for healthy lifestyle and what are the essential *methods*?

RQ3: what is the importance of digital intervention in promoting healthy lifestyles targeting obesity and overweight?

Methods

Overview

We used a systematic literature review method to obtain a broad overview of the current literature on the subject in a reproducible and understandable manner. A systematic review is a study of the evidence of a clearly expressed problem. It uses systematic and transparent strategies to understand, select, and strictly evaluate related basic research and extract and explore facts from the research covered in the evaluation. Systematic reviews represent scientific synthesis of evidence. We used the PRISMA [27] and Rayyan [28] evidence-based frameworks for systematic literature reviews. Subsequently, for article selection, we used the Scale for the Assessment of Narrative Review Articles (SANRA) scaling [29]. We conducted our systematic literature review following the Wendler [30] proposals to search scientific databases, as explained in *Strategy* subsection.

Strategy

The system's search strategy was designed using a combination of thesaurus, Oxford dictionary, and free terms covering the following terms: *eCoach, e-Coach, eHealth, e-Health, electroniccoaching, online, automatic, persuasion, persuasive technology, mHealth, mobilehealth, digital health, mobile, digitalintervention, smartphone, smart-phone, application, app, prevention, healthybehaviour, healthybehavior, behaviourchange, behaviorchange, exercise, activity, walk, step, fitness, sitting, inactive, screen time, sport, leisure activity, nutrition, nutritional, diet, dietary, healthy eating, salad, vegetables, fruit, discretionary food, snack, sweet beverage, carbonated beverage, soft drink, habit, tobacco, alcohol, computer, sedentary, lifestyle, intervention, lifestyle recommendation, digital recommendation, behavioral recommendation, program, programme, conceptual model, health promotion, prevention, obesity, overweight, weight-gain, weight gain, weight change, engagement, effectiveness, efficiency, credibility, trust, motivation, regulation, challenges, preferences, sample*, and *study duration*. We filtered our search with the following search string: ((*eCoach* OR **Coach* OR **coaching* OR *automatic* OR *online* OR *eHealth* OR *e-Health* OR *persuasion* OR *persuasive** OR *mHealth* OR *mobile** OR *digitalhealth*) AND (*digitalintervention* OR *smartphone* OR *smart-phone* OR *computer* OR *app** OR *prevention* OR **recommendation*) AND (**behavior** OR **behaviour** OR *sedentary** OR *lifestyle* OR *exercise* OR **activity* OR *walk* OR *step* OR *fitness* OR *inactive* OR *screentime* OR *sport* OR *nutrition** OR *diet** OR *healthyeating* OR *salad* OR *veg** OR *fruit* OR *discretionary** OR *snack* OR **beverage* OR *softdrink* OR *habit* OR *tobacco* OR *alcohol*) AND (*engagement* OR *persuasion* OR *effectiveness* OR *efficacy* OR *efficiency* OR **motivation* OR **regulation* OR *challenge** OR *limitation** OR *credibility* OR *trust* OR *preferences* OR *program* OR *programme* OR *conceptual** OR *sample* OR **duration*) AND (*obesity* OR **weight**)). We conducted the search in collaboration with the library of the University of Agder in Norway on the following 5 electronic databases including Nature, SpringerLink, Elsevier, IEEE Xplore, and PubMed, as they produced the maximum number of scientific sources related to digital intervention studies for healthy behavior targeting on the prevention of obesity and overweight as a primary objective. Related search keywords were identified using Medical Subject Headings terms, keywords from relevant articles, synonyms, and self-established search terms. *EndNote (V.9.x)*, *DOAJ*, *SHERPA/RoMEO*, and *Microsoft Excel (Office 365, 2019)* were used to search, collect, and select related articles effectively.

Studies on digital intervention are promising and have an enormous scope in the health care domain with information and communication technologies. A systematic literature review produced related older studies, but they are primarily in the theoretical phase, and the practical implementation is very young. Therefore, to keep our systematic literature review focused, articles related to digital interventions for healthy lifestyle management were included when published between January 1, 2015, and December 15, 2020. The search was limited to English literature, humans, digital health intervention methods, and research focused on improving healthy lifestyles. We aim to include peer-reviewed articles that describe digital intervention methodologies, conceptual models, theories, key challenges, lifestyle recommendations, and research related to healthy lifestyle management focusing on preventing obesity and being overweight with digital means. Articles are classified into the following groups: quantitative, qualitative, both quantitative and qualitative, and short papers, such as posters, editorials, and commentaries. Quantitative analysis is the factual examination of information gathered by the framework to test explicit speculations. Qualitative analysis centers around words and implications to investigate thoughts and encounters inside and out. The selection criteria (or specific parameters) for the quantitative and qualitative articles were (1) articles associated with a healthy lifestyle, with the main goal of preventing obesity and being overweight using digital interventions (or recommendations); (2) methods, theories, and strategies associated with digital interventions; and (3) challenges of digital interventions for lifestyle change.

We aim to adopt the explicit inclusion and exclusion criteria, as described in Textbox 1 and divide and distribute the articles among authors to complete the screening using the *Rayyan* collaboration and research tool. After individual screening, the results will be verified by other authors to resolve discrepancies between the reviewers. Subsequently, eligible peer-reviewed articles will be identified by manual search, quality score, and manual assessment of reference lists of related papers. Initially, titles, keywords, abstracts, and conclusions will be screened for inclusion. Then, we review the screened articles independently and check for individual eligibility for final inclusion.

Textbox 1. Inclusion and exclusion criteria for systematic literature review.

Inclusion criteria

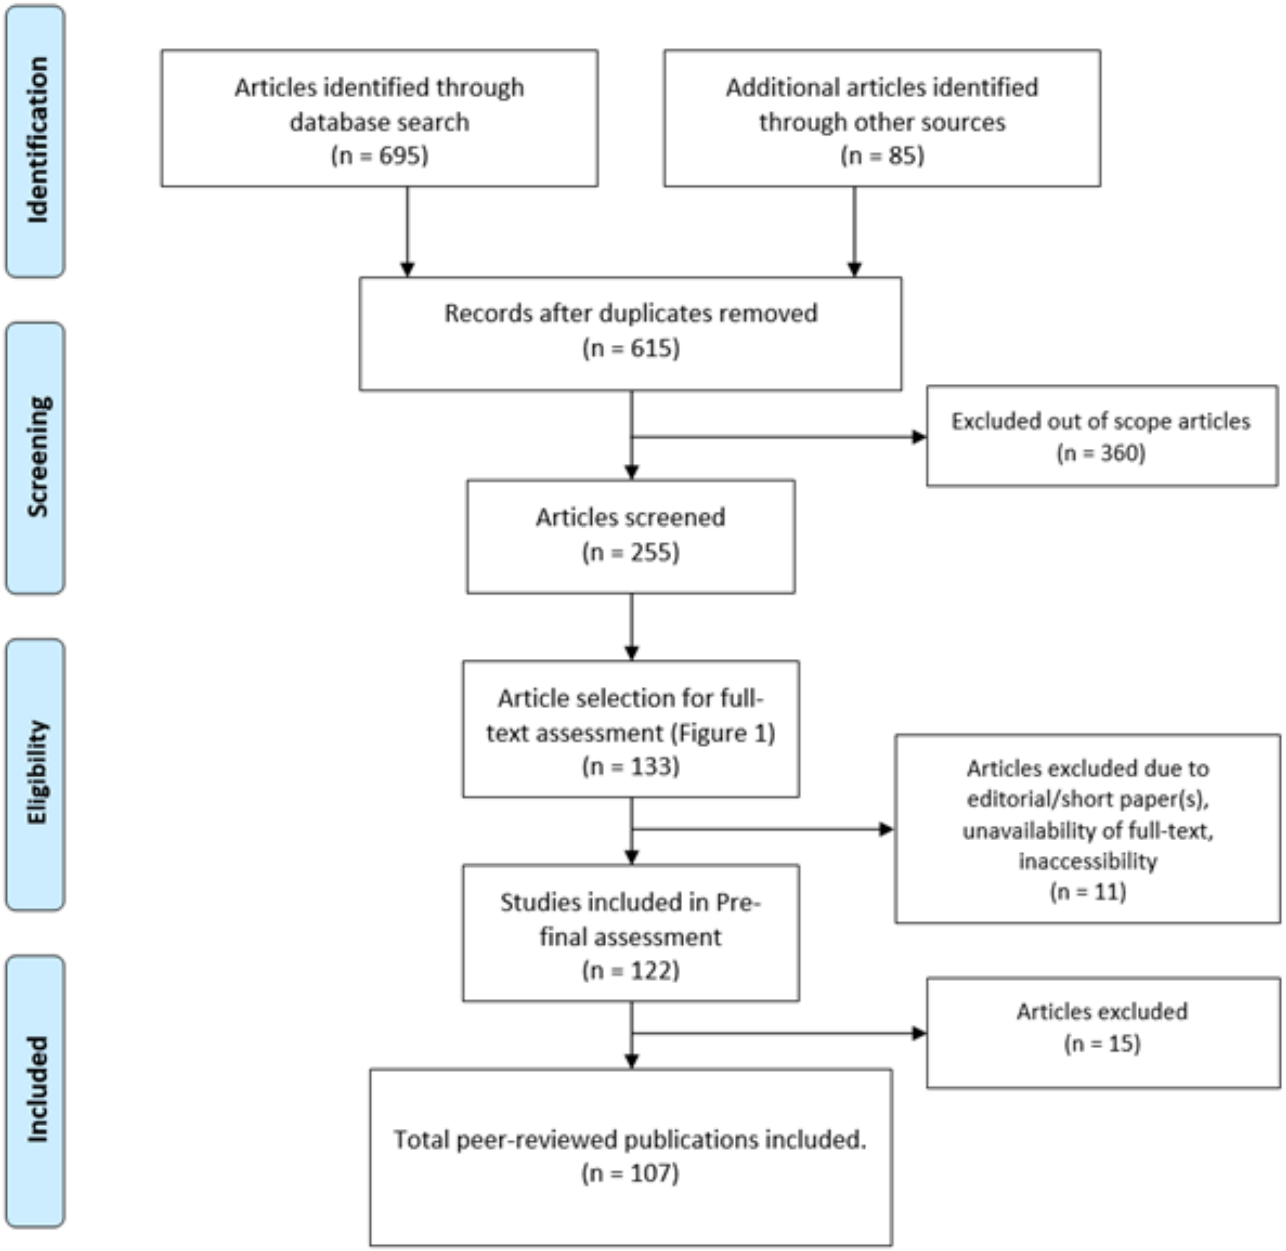
- Peer-reviewed, full-length articles written in English
- Digital intervention on healthy lifestyle articles published in the selected databases between 2015 and 2020
- Articles indexed in *Google Scholar* and (*SCOPUS* or *SCI* or *SCIE*)
- Journal papers, conference papers, or books
- Both qualitative (primary and secondary research) and quantitative studies
- *Open access* and accessible through the university library
- Studies associated with behavior change prevention rather than treatment and management of health conditions

Exclusion criteria

- Articles not written in English
- Incomplete, non–peer-reviewed articles
- Nonexperimental studies
- Poster, editorial, and commentary papers
- Articles published outside the selected time frame (<2015 and >2020)
- Articles not indexed in *Google Scholar* and (*SCOPUS* or *SCI* or *SCIE*)
- Studies related to offline human behavior interventions
- Papers having a considerable amount of analogous content or exact duplicate articles
- Economic, investment, and policy-making articles related to digital interventions
- Articles related to impacts from social interactions on behavior changes
- Articles related to traditional nutritional and physical activity assessment without any adoption of digital intervention methodologies
- Articles related to behavioral impacts on other lifestyle diseases apart from obesity such as cancer, mental health, chronic obstructive pulmonary disease, cardiovascular disease, dysglycemia, type 2 diabetes, loneliness, and hypertension
- Articles related to the treatment and management of health conditions rather than prevention of lifestyle disease (obesity and overweight in context)
- Articles related to cultural adaptation, nutrition policy, pregnancy, and genetics
- Articles related to worksite wellness, remote patient monitoring, hospital care, osteoporosis prevention for older adults, and web-based intervention for victims of cyberbullying

The search results from the databases for full-text assessment are as follows: IEEE Xplore (n=2), Nature (n=4), Elsevier (n=28), PubMed (n=40), and SpringerLink (n=59); “n” signifies total number articles screened for full-text assessment. We then excluded short research articles (1-2 pages) from the previous search list (Figure 1). In the prefinal assessment, for data extraction, we maintained an Excel spreadsheet with the following fields: title, reference in the American Medical Association format, author, population size, study duration, target group (children, adolescents, adults, and older adults), nature of the paper (review, conceptual or methodology, survey, and implementation), year, country of research, key terms, keywords, intervention type, publication channel, technology use, peer-reviewed, key findings (outcome, measures, intervention methods, theory, intervention components, effectiveness, and results), nature of assessment (qualitative, quantitative, or both), key challenges, and quality score based on SANRA. The primary outcome indicators extracted from the preliminary research results were digital intervention methods, nutritional intake, physical exercise, and healthy habits (consumption of tobacco and alcohol). The quality of the included articles was assessed using the SANRA 0-2-point scale. We graded individual papers based on the 6 quality parameters, as defined in Textbox 2. Individual quality parameters were subcategorized into a 0-2–point scale. Finally, we calculated the mean score of the 6 quality parameters. The number of studies included in the prefinal assessment was 122 with a SANRA score >1.90. Out of 122 studies, 15 had a SANRA score between 1.9 and 2.0. Therefore, we selected 107 articles that scored scale 2 based on the SANRA scale (Textbox 2).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart for article selection process.



Textbox 2. Searched article scaling based on quality parameters.

Quality parameters

- Justification of the article's importance for readership
- Statement of concrete or specific aims or formulation of questions
- Conference and journal papers to describe the overview of this study
- Referencing
- Scientific reasoning
- Appropriate presentation of data

In the final stage, we had articles with grade 2 and cited them as references (Textbox 3). In addition, we added 30 articles to the reference list (Textbox 3), including websites (accessed URLs), conference and journal papers to describe the overview of this study, risks of lifestyle diseases, and healthy behavior plans. The complete process of choosing the source for this study is shown in the flowchart in Figure 1. The article selection process consists of four stages—identification, screening, eligibility, and inclusion. Instead of depicting all the included studies as separate tables, we have presented significant findings from the respective studies.

Textbox 3. Nature of studies in the reference list.

Nature of studies

- Articles and web resources (URLs) to describe the overview of this study, risks of lifestyle diseases, and healthy behavior plan [2-31]
- Included studies with the Scale for the Assessment of Narrative Review Articles scale 2 (107 articles) [1,32-137]

Results

Study Selection and Study Characteristics

The searches (electronic database and manual databases) resulted in 780 papers (695 in electronic databases and 85 manually), of which 165 were duplicates. A total of 360 articles were excluded from the study following the exclusion criteria, and 255 articles were screened by reading abstracts, keywords, and conclusion sections. We selected 133 articles for full-text reading. We decided on 122 articles after a full-text review and checked the paper's length and the full-text availability in the prefinal stage. The final search produced 107 core peer-reviewed articles eligible for citation (4 from Nature, 49 from Springer, 23 from Elsevier, 1 from IEEE, and 30 from PubMed) related to digital intervention for healthy lifestyle management. Of the 107 papers, 72 (67.3%) were qualitative, 29 (27.1%) were quantitative, and the remaining 6 were both qualitative and quantitative. The final 107 papers were selected from 4 continents, including Asia, Europe, North America, and Oceania with the subsequent detailed search results as indicated by "n": Europe (n=56), North America (n=32), Oceania (n=16), Asia (n=2), Asia and North America (n=1), North America and Europe (n=1), and Oceania and North America (n=1).

The selected studies were clustered among the following 4 study groups that helped to answer our RQs: review (n=38), implementation (n=37), conceptual or methodology (n=23), and survey (n=9) studies related to digital interventions for healthy lifestyle management. Here, *n* signifies the total distribution of studies in the 4 study groups.

The findings related to the identified RQs are elaborated as follows.

RQ1: What Are the Existing Conceptual Frameworks for Digital Interventions for Healthy Lifestyle Management?

Mummah et al [32] proposed the concept of a conceptual framework with the following 10 phases: empathize with target users, define the target behavior, the basics of behavioral theory, come up with implementation strategies, potential prototype products, gather user feedback, build a real minimum product, a pilot test to evaluate potential efficacy and utility, evaluation of effectiveness in randomized controlled trials, and sharing of interventions and results. These phases are grouped into 4 overarching categories: integration, design, evaluation, and sharing.

Muench et al [33] proposed an overarching framework to perform digital triggering (text messages, emails, and push alerts) focusing on individual goals with the following 5 components: who (sender), how (stimulus type, delivery medium, and heterogeneity), when (delivered), how much (frequency and intensity), and what (trigger target, trigger structure, and trigger narrative). They showed how user characteristics, conceptual models, and clinical aims help to plan digital interventions and initiate tailoring with product features and user states.

Lewis et al [34] provided an idea to understand human behavior technology engagement to measure digital behavior change interventions (DBCIs) using a proposed framework. The proposed framework conceptualizes the 2 basic categories of commitment measured in digital behavior interventions (DBIs). The types are committed to health behaviors known as *Big E* and involvement of DBI known as *Small E*. DBI engagement has been further broken down into 2 subclasses: user interactions with intervention features designed to encourage frequent use, such as simple log-in, games, and social interactions and make the user experience attractive, and interactions of the user with the components of a behavior change intervention (ie, behavior change techniques) that influence determinants of health behaviors and then affect health behaviors.

Wang et al [35] proposed a holistic TUDER (Targeting, Understanding, Designing, Evaluating, and Refining) framework to integrate taxonomies into the theory-based digital health behavior intervention model. They showed how digital health behavior intervention is guided and influenced by theoretical concepts, such as behavior theories, behavior change technologies, and persuasive technology.

Lubans et al [36] proposed a framework for designing and delivering organized physical activity (PA) sessions for children and adolescents for effective dissemination. Recommended strategies include creating partnerships, presentations, intervention dissemination, scaling up research, and embedding evidence-based interventions.

According to Morgan et al [37], the limitations of digital health intervention programs include the lack of attention to critical sociocultural factors that affect participation and interventions on research results. Their research provides a conceptual model that illustrates the design and implementation of social and cultural interventions.

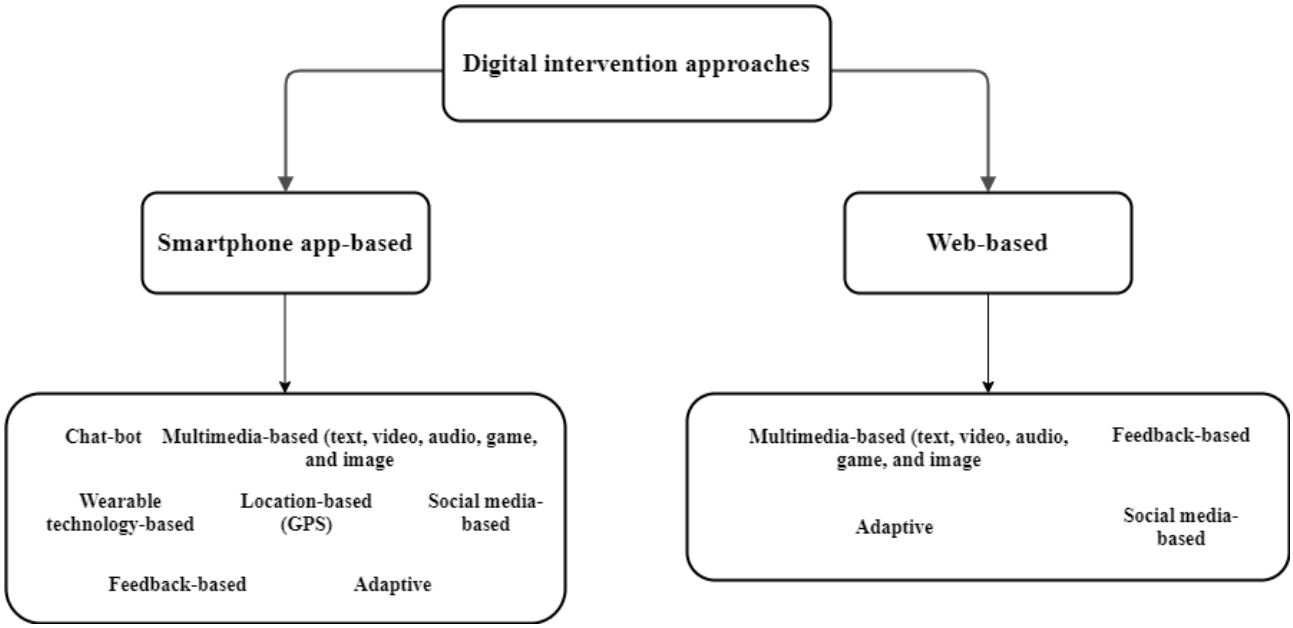
Hekler et al [38] proposed models and theories for DBCI based on international experts' discussions (including behavioral, computer, and health scientists and engineers) and provided suggestions for developing models and theories that can be learned from DBCI and can provide references. The proposed framework provides state-space representations to define when, where, for whom, and for the person in which the intervention will have a targeted effect. *State* refers to an individual's state based on various variables, which define the *space* in which an action mechanism may affect. The state-space representation can be used to help guide theorization and determine interdisciplinary methodological strategies to improve

measurement, experimental design, and analysis so that DBCI can match the complexity of real-world behavior changes.

RQ2: What Are the Different Approaches to Provide Digital Interventions for Healthy Lifestyle and What Are the Essential Methods?

In this systematic literature review, we identified the following 2 digital intervention approaches for a healthy lifestyle, and they are further structured in Figure 2: *smartphone app–based intervention (health monitoring and personalized recommendation generation)* [33,39-60,80-106] and *web-based intervention (web-based monitoring and self-management or self-reporting program)* [1,61-79,97-102].

Figure 2. Structuring of digital intervention approaches for a healthy lifestyle.



In this systematic literature review, 35 studies targeted app-based interventions, 18 targeted web-based interventions, and 19 targeted both app-based and web-based interventions. The essential methods associated with both types of intervention approaches are listed in Textbox 4.

Textbox 4. Essential methods associated with digital interventions for healthy lifestyle.

Study and key methods associated with digital interventions

- Lindwall et al [107]: motivation, satisfaction, self-determination, human-centered design, psychological needs (competence, autonomy, and relationship), and exercise-related behavior in selected motivational profiles
- Nicklas et al [108]: motivation and self-determination
- Yu et al [109]: self-monitoring for dietary intake—pen and paper documentation, self-check, and PDAs
- Karppinen et al [110]: motivation, persuasion with persuasive technologies, self-monitoring, goal setting, and evaluation
- Nouri et al [111]: user-centered design, observation, persuasive prompts, and feedback generation
- Sharpe et al [112]: efficacy evaluation, encouragement, and engagement
- O'Connor et al [113]: complexity analysis and identification of challenges
- Yardley et al [114]: feasibility study, usability study, beliefs, attitudes, needs, and conditions of people
- Fischer et al [105]: behavior change techniques, personal coaching, regular prompting, and efficacy evaluation
- Mitchell et al [53]: engagement, goal setting, incentives, and goal evaluation

RQ3: What Is the Importance of a Digital Intervention to Promote a Healthy Lifestyle Targeting Obesity and Overweight?

In recent years, an increasing number of digital intervention approaches have been implemented to promote a healthy lifestyle in different age groups. This RQ found modest evidence for effective digital interventions to improve PA, diet, and habits to prevent obesity and overweight. In individuals who are overweight and obese, therapeutic weight control approaches contribute to clinically significant weight losses; however, due to limited access, expense, and time constraints, many people cannot engage in these face-to-face treatments. The advancement of several digital weight loss services has resulted in

technological advances, such as universal access to the internet, expanded use of smartphones, and newer behavioral self-monitoring tools.

Verjans-Janssen et al [99] recognized the importance of implementing a long-term, locally relevant, holistic approach to promoting healthy weight status, stimulating the PA levels of children, and preventing them from wasting unnecessary time throughout school days on sedentary behaviors.

Brigden et al [115] designed interactive DBI for younger children based on the following characteristics: participation of parents, gaming functionality, additional therapist assistance, behavioral (rather than cognitive) approaches, and unique feedback and monitoring, shaping knowledge, repetition and substitution, and reward.

Nicklas et al [108] conceptualized a multi-exposure theory-based motivational theater, which can be an efficient behavior technique to improve preschool children's intake of vegetable dishes that can be conveniently disseminated to a large sample.

Lubans et al [36] used the Supportive, Active, Autonomous, Fair, and Enjoyable concepts to develop realistic strategies to engage young people with PA sessions to maximize involvement in PA and facilitate physical literacy by optimizing the results of affective, emotional, motivational, and movement skills.

Burrows et al [79] supported the need for web-based delivery of a balanced lifestyle program that addresses higher nutritional parental issues rather than infant weight. Parents were interested in a web-based family healthy lifestyle program and shared a desire for the program’s website to be easy to navigate and user-friendly, casual, but with personalized guidance and goal-setting opportunities.

Carrà et al [41] investigated *the Interactive Alcohol Risk Alertness Notifying Network for Adolescents and Young Adults (D-ARIANNA)*, a publicly accessible evidence-based eHealth app to estimate the current health risks by queries and fit-defined risk factors and include an overall risk score in percentage terms, accompanied by relevant images showing the main contributing factors in overview graphs and achievement.

Helle et al [57] conducted a study and identified 6 main behavioral risk factors as strong determinants of chronic diseases in adolescents (risky alcohol consumption, smoking, low diet, physical inactivity, sedentary behavior, and unhealthy sleep patterns). The study revealed that web and mobile technology interventions benefit adolescent participation, scope, and scalability to prevent the identification of health risk behaviors.

Stockwell et al [67] reported that PA and sedentary behavior are modifiable risk factors for lifestyle diseases and healthy aging; however, most of the older adults remain inadequately active. DBCIs can reach many older adults to promote PA and reduce sitting time. DBCIs may increase PA and physical function and reduce sedentary lifestyle and systolic blood pressure in older adults, but more high-quality testing is required.

According to Stephenson et al [40], machines, smartphones, and wearable technology resources can reduce the average sedentary time (minutes/day).

Weegen et al [62] showed that behavioral approaches were not successful without digital resources, and the integration of behavioral interventions with digital media proved to be an efficient way to stimulate PA.

Geidl et al [98] performed a recommendation generation study in adults with lifestyle diseases for PA and PA promotion over a week with a guideline of performing at least 150 minutes of aerobic PA with moderate intensity, 75 minutes of aerobic PA with vigorous intensity, or a combination of both. The PA and PA promotion guidelines advise adults impacted by lifestyle diseases and health providers on how much PA for adults with lifestyle diseases would be ideal. The guidelines provided the best strategies and approaches for growing low PA levels in adults with lifestyle diseases to professionals entrusted with PA promotion.

Gans et al [81] performed a study on 2525 worksite employees, and after 4 months, dietary fat intake decreased significantly with a multimedia-based (video) intervention strategy. Individually tailored videos helped office workers minimize dietary fat and increase fruit and vegetable consumption. Recently, to minimize sedentary behavior, technology-enhanced solutions such as mobile apps, activity monitors, prompting apps, SMS text messages, emails, and websites have been exploited.

Step-count sensors can improve walking, helping to tackle physical inactivity (pedometers, body-worn trackers, and smartphone apps). Chaudhry et al [87] assessed the influence of step-count monitors on PA in community-dwelling adults in randomized controlled trials, including longer-term results and discrepancies between step-count monitors and components of the intervention.

Muench et al [33] performed a multimedia-based (text) qualitative intervention to show the positive impact of digital triggers (such as SMS text messages, emails, and push alerts) in adults to change in curative conduct in health interventions. New technology apps for mobile health (mHealth) are emerging and provide the basis for fundamentally changing medical research, treatment practices, and scope.

Lin et al [43] conducted a web-based study on 4144 adults, collaborating with Quit Genius, an mHealth app focused on cognitive behavioral therapy that helps users quit smoking, to explore the successful nature of an mHealth digital app, which provides its users with substantial benefits and helps them modify their habits for a healthy lifestyle. The app's ability to improve users' hedonic well-being and inspire them mentally in their everyday lives was described as essential to help users quit smoking. The findings found that users whose well-being was improved via the app were 1.72 times more likely to quit smoking successfully.

Korinek et al [101] revealed that an adaptive phase target plus reward intervention using a mobile app appeared to be a feasible solution to increasing walking activity in overweight adults. Satisfaction with the app was strong, and the participants enjoyed having variable targets every day.

Mummah et al [32] tested the effect of a mobile app to increase vegetable consumption among overweight adults seeking to

sustain weight loss. The findings showed the effectiveness of a mobile app in increasing the consumption of vegetables among overweight adults.

Hanze University [104] launched a health promotion initiative to enable workers to lead a less sedentary life. The use of an activity tracker for tracking the regular step count of participants was one of the program's measures. For a fortnightly coaching session, the regular move count acted as feedback. They argued that the use of machine learning in the process of automated personalized coaching might become an invaluable advantage. Individualized algorithms allow PA to be predicted during the day and provide the ability to intervene in time. Machine learning techniques empower automatic coaching and personalization.

Since attending a weight control program, many individuals who are overweight find it difficult to sustain weight loss. Self-weighing and telephone support are useful tools for weight loss monitoring. Partridge et al [82,84] and Sidhu et al [83] tested the efficacy of a weight maintenance program based on SMS text messaging to facilitate daily self-weighing in adults and found it to be effective for young men and women.

Ball et al [69] organized an incentive-based, promising web-based intervention study to increase PA and reduce sitting among adults (ACHIEVE: Active Choices IncEntiVE). They explored the effectiveness, appeal, and impact of offering nonfinancial incentives for inactive middle-aged adults to encourage increased PA, decreased sedentary time, decreased BMI, and blood pressure.

Franssen et al [90] performed a study on consumer wearable activity trackers to promote PA levels.

Oosterveen et al [72] conducted a qualitative analysis of eHealth behavioral interventions aimed at analyzing smoking rates, nutritional habits, alcohol consumption, PA levels, and obesity in young adults and revealed that because of their high level of use of technology, eHealth interventions have potential among young adults.

Therefore, this RQ reveals that digital interventions have the potential to promote a healthy lifestyle (regular PA, healthy habits, and proper dietary intake) in all age groups, for personal weight management. In therapeutic approaches, self-monitoring is a crucial part of digital intervention [73]. According to a study [73], participants participating in behavioral interventions have lost 8%-10% of their initial body weight. These results are considered positive based on studies suggesting that losses of 5% can yield positive health improvements such as reductions in triglycerides, blood glucose, blood pressure, improved blood lipid levels, and a reduction in the risk of developing type 2 diabetes for a person. It is difficult to sustain long-term weight reductions achieved through behavioral therapy, and a different set of skills may be needed for success following interventions [1,32,42]. Many teenagers have low diet and PA patterns, which in later life can contribute to the development of lifestyle diseases. Web-based networks provide an affordable means of providing health interventions, but their efficacy is poorly understood. Investigation of the locations of PA and dietary patterns can promote *setting-specific* lifestyle interventions and increase knowledge of contextual vulnerabilities to poor health. As future directions for digital weight management, distribution, and policy implications should be emphasized [131-133].

Discussion

Research Questions

RQ1 helps to identify that behavioral theory, design thinking, evaluation, and the identification of limitations in the existing digital intervention frameworks are essential for successful, healthy lifestyle management. In contrast, *RQ2* reveals different approaches and methods associated with digital health interventions. Digital interventions for healthy lifestyle management have been categorized as discrete usefulness of advanced innovation applied to accomplish well-being goals and is executed inside digital well-being programs and information and communication technology frameworks, including communication channels, such as instant messages (SMS text message), alerts, and app-based notifications [116-118]. Digital intervention can motivate and stimulate individuals with self-tracking, goal setting, evaluation, and feedback or recommendation generation to promote a healthy lifestyle [118,119]. Different methods appear to impact health outcomes and usability. It would be interesting to test variants of component design and their impact on health outcomes and usability. Use of personalization to account for differences in preferences between groups of participants and even within groups of participants is essential in addition to cocreation between intervention developers and the target group [118-121]. Participants who attempted to self-manage their healthy lifestyle found that the most challenging part was to remain motivated [39]. They require apps that give them power and inspiration [39]. The study has confirmed that motivation is a multidimensional construct and people have different, sometimes competing, reasons for engaging in activities [39]. Moreover, human-centered analysis in digital intervention to study the intrinsic interactions of motivation and different regulations must be addressed. Despite the widespread use of mobile phones, digital literacy barriers are common among vulnerable people [39]. Participants have different participation levels in various activities, from higher to lower levels of participation. Researchers using traditional user-centered design methods should routinely measure these communication domains in their end-user samples. Future research should replicate these findings to a larger sample through direct observation, and persuasive prompts may be more effective in providing feedback to those with communication difficulties. *RQ3* summarizes the evidence on the importance of digital intervention that were exclusively directed at promoting healthy lifestyles, especially in children, adolescents, adults, and older adults. In the next section, we discuss the importance of digital intervention on healthy lifestyle promotion elaborately.

Digital Intervention and Healthy Lifestyle

A healthy lifestyle is a lifestyle that reduces the risk of severe illness or early death. Not all diseases are preventable, but a large proportion of deaths can be avoided, especially lifestyle or noncommunicable diseases. According to the *Harvard Medical School*, the key lifestyle factors to be monitored are

healthy diet, healthy PA level, healthy body weight, no tobacco consumption, and moderate alcohol intake [31]. According to *RQ3*, digital intervention can have a significant impact on healthy lifestyle management.

A study conducted by Steene et al [86] found significant country- and region-specific variations in PA and sedentary time in the European population, with lower PA levels. Boys in all age groups were more aggressive and less sedentary. At about 6 to 7 years of age, the initiation of age-related decline or leveling-off of PA and rise in sedentary time begins to become evident [86]. In children and adolescents, sedentary behavior strategies successfully decrease screen time; however, the scale of the effect tends to be limited [129]. The potential of digital intervention in older age groups outside of occupational settings and during sedentary leisure time must be examined in future studies. The sustainability of lifestyle changes in a positive direction remains a challenge [129]. Mobile apps to improve PA in young adults should include customized and personalized feedback and provide a coaching feature [58-60]. It is essential to create a well-oriented and easy-to-use interface with the ability to customize the app. The new area of mHealth is mHealth apps that target willing participants to enhance self-management of chronic conditions [58-60]. However, we found that only a small fraction of the mHealth apps available had been reviewed, and the amount of evidence was of inferior quality [58-60]. Improving the quality of evidence includes supporting prerelease app performance monitoring, designing few experiments, and performing better reviews with a rigorous risk of bias assessments [43,115]. Without enough evidence to back it up, for some time to come, digital intervention and app practicability will stall in their infancy [43,115,121]. Evidence suggests that an unhealthy lifestyle is associated with poor health outcomes [40,63]. It can have severe implications for health and well-being at any age, [63,64,126]. Therefore, there is a need to review the effects of multicomponent, complex interventions that include effective unhealthy lifestyle reduction strategies. We must focus on optimizing the effects of an intervention. Future intervention studies should use more rigorous methods to improve the quality of studies, considering larger sample sizes, randomized controlled designs, and valid and reliable lifestyle measurements. An overview of intervention development methods can help researchers understand various existing methods and comprehend the range of actions taken in intervention development before evaluating feasibility or pilot interventions [32,126,135].

One way to encourage PA and enhance health is to change the physical environment, but research on intervention efficacy is mixed [92-94]. Theoretical perspectives and conceptual problems are used in evaluative studies, and related literature can contribute to these inconsistencies [92-94]. Environmental and policy initiatives are socially incorporated into the framework and function through it. Therefore, a philosophical viewpoint must be considered and should be understood by evaluators. Future research should aim to explain how interventions function across disciplinary fields by considering these structures, the context in which interventions occur, and the measurable and unmeasurable mechanisms that might work [92-94,98]. It can be beneficial to promote health-based actions, such as PA, by using innovative and interactive media-based health education [92-94,98,134]. Therefore, to successfully influence behavior, it is essential to establish user-based techniques and reinforce the theories and hypotheses of behavioral change based on digital media. Step-count tracking [87] leads to improvements in short- and long-term step counts. There is no proof that either wearable sensors or smartphone apps, or extra counseling or incentives have additional benefits over more straightforward approaches focused on the pedometer [63,64]. To overcome the public health issue associated with physical inactivity, basic step-count tracking strategies should be prioritized. In general, it is not clear how self-reported sedentary behavior (eg, questionnaires, logs, and momentary ecological evaluations) compares with system measurement measures (eg, accelerometers and inclinometers) [63,64]. Evidence from this study indicates that when compared with system tests, single-item self-report measures typically underestimate sedentary time [63,64]. Therefore, to evaluate the reliability and validity of different self-report measures for evaluating sedentary activity, studies should exercise caution when comparing associations between various self-report and system measures with health performance.

In addition, video and adapting technologies have been effective in diet change measures; however, these methods have never been combined with researching personalized video efficacy [81]. Theory-based mobile interventions could provide a low-cost, scalable, and efficient approach to improving dietary habits and preventing associated chronic diseases. To encourage a healthy dietary pattern, nutrition messages or nutrient labeling, offering healthier choices, and portion size management of unhealthy foods have been potentially effective strategies in tertiary education environments [75]. The reduction in rates and the increased availability of nutritious choices in conjunction with nutrition knowledge have contributed to changes in dietary habits [75]. Further studies comparing the long-term efficacy of the climate and the combination of environmental policies to improve health outcomes are warranted. Dietary consumption has increased by increasing the availability of nutritious foods and reducing the portion size of unhealthy foods. In terms of modifying overall dietary patterns, the existing evidence base is misleading, as rising intake of desirable food groups was more effective than reducing unfavorable food habits, and fruit or vegetable intake and sugar-sweetened beverage consumption are the most notable observed changes [75,79]. Social support, followed by a demonstration of conduct, self-monitoring, goal setting, and feedback, is the most popular digital health behavior intervention [55,67,85,96]. In addition, a customized Facebook-based obesity prevention program for teenagers in Korea (Healthy Teens) [76] revealed usability problems in terms of material, appearance, and navigation. Facebook [76,96] has tremendous potential in promoting communication and engagement with immigrant teens, considering its prominence among adolescents. Interventions focused on social media (eg, Facebook) [66,96] are productive in facilitating meaningful improvements in adolescent eating habits. However, more research is required to explore effectiveness variations based on component tailoring, best use stimuli to promote behavior change over time, and keep people involved in changing

physical health behavior. The first step is to dismantle digital triggers into their parts and reassemble them according to their goals for improvement.

PA, sedentary time, and dietary habits vary across homes, schools, and other locations [95]. Health habits vary depending on the place or environment in which the participants are [95]. Although eating habits are typically more beneficial in home or school locations, PA is usually low and sedentary time in these locations is higher [95]. To optimize health habits in each area, digital interventions that address the various locations in which participants spend time and use location-specific behavior change techniques should be explored [95]. Among young people, binge drinking is prevalent [41]. eHealth technologies [41] are appealing to them and can be useful in raising awareness. However, to make eHealth apps suitable for longer-term effects, additional components, including daily feedback and repeated administration by different multimedia interventions, may be needed. Mass media campaigns [65] for smoking or tobacco programs are also effective over long periods. Digital interventions have been associated with decreased drinking and smoking frequency, with a slight yet persistent impact on teenagers and adults. Protective effects against alcohol and tobacco [65] use can be demonstrated through digital initiatives focused on a combination of social maturity and approaches to social influence. Evidence tends to be mixed with internet-based interventions, policy proposals, and incentives, and requires further study. Various distribution systems can enhance the effects of alcohol or tobacco misuse among teenagers and adults, including interactive platforms and policy initiatives. Adolescents are easily accessible by digital media and can represent a scalable and inexpensive opportunity to engage this audience in changing behavior [65]. Smartphone-based interventions [39-59] (such as apps, SMS text messages, sports, multicomponent interventions, emails, and social media) are readily available, inexpensive, and use tools already used by most teenagers. Therefore, it is essential to perform and publish high-quality academic literature studies and formally evaluate apps that have already been developed to inform the creation of potential interventions to change behavior. Essential improvements in behavior were also seen when interventions involved schooling, setting goals, self-monitoring, and parents' participation. Digital approaches [66] that include education, goal setting, self-monitoring, and parental participation can affect adolescents' meaningful health behavior changes. Most of the evidence relates to goal setting, further research into alternative media is needed, and it is essential to assess longer-term effects. There is a lack of evidence on the cost-effectiveness of digital health initiatives, and these data should be recorded in future trials. The young population has broadly embraced social media, so health researchers are searching for ways to exploit this social media involvement to deliver programs and health promotion campaigns [66,96]. In young adults, weight gain and suboptimal dietary choices are popular, and social media can be a possible instrument for encouraging and supporting healthy choices. The dissemination of information is now an appropriate use of social media by young adults. Careful evaluation is needed to use social media effectively for social support, either by private or by public sites, as its efficacy has yet to be demonstrated in experimental designs. In digital intervention studies aimed at manipulating weight, concerns about public social media use can lead to low engagement with social media [66,96,115]. Future research should explore how to use social media to better connect with young adults, how to use social media more efficiently to help young adults, and how to encourage social and peer-to-peer support to make healthy choices.

The systematic literature review has revealed that the identified digital intervention methods affect lifestyle behavior outcomes, focusing on PA, diet, habit, and associated primary and secondary health outcomes, such as fitness, motivation, reduced sedentary bouts, weight augmentation or weight status, blood pressure, glycemic responses, lipid profile, and quality of life in different study groups, as explained in the next section. Effectiveness (n=55), conceptualization (n=24), selection of appropriate methodology (n=25), effective and technological engagement (n=24), selection of strategies or techniques (n=20), motivation (n=15), feedback generation (n=15), environment (n=10), satisfaction (n=6), credibility (n=6), digital literacy (n=6), self-determination (n=5), and user-centric design (n=4) were responsible for the successful implementation of digital interventions for healthy lifestyle management. Here, *n* signifies the total number of overlapped studies in which the respective parameters are identified. Digital interventions [84,106,124] focused on mobile phone apps may be an acceptable and efficient way of encouraging weight loss in people who are overweight or obese. Digital health coaching can be a revolutionary approach to reduce barriers to access to much-needed weight loss therapies for obesity, given the ubiquity of mobile phones.

Strength and Limitation

A systematic literature review revealed that a healthy diet, healthy habits, and regular PA are powerful tools for reducing obesity and associated health risks. These findings bolster the use of digital interventions as a preventive option for obesity and overweight. Therefore, behavior change should be given the highest preference to avoid severe health damage. Planned digital interventions may potentially change growing negative behavior in humans with the adoption of persuasion, observation, goal evaluation, evidence-based personalized recommendation generation, health risk predictions (decision-making), automation, motivation, pragmatism, and trust. Developing and maintaining an empathetic relationship is perhaps the most critical determinant of successful digital intervention [106,124]. It is essential to know the participant first, and the interaction aspects are challenging owing to the delay in reaction time (both ways). Health care professionals need to ensure both relationship communication and goal-oriented coaching when using such digital intervention solutions. In the future, the quality of the interaction between the system and the participant will require attention if participants are to fully benefit from collaboration in digital intervention programs.

Digital intervention for healthy lifestyle management has great potential as a scalable tool that can improve health and health care delivery by improving effectiveness, efficiency, accessibility, security, and personalization. Therefore, a

knowledge base must be accumulated to provide information for developing and deploying digital health interventions [116,118]. However, the evaluation of digital health interventions poses unique challenges. Methodological limitations, selection of appropriate intervention methods, evaluation of efficacy, limitations of research on different populations, loss to follow-up, attrition rate, lack of participation in tracking, financial incentives and intervention burdens (long term or short term), digital literacy, technical participation, personalization, useful evidence-based automatic tailored lifestyle recommendation generation (intervention design), research heterogeneity, meta-analysis, cost-effectiveness (technical and financial feasibility analysis), trial selection, trial recruitment, scalability, accessibility, ethics, policy development, cyberbullying, safety, trust, user-centeredness, adoption of health care and collaboration methods that promote cooperation, unsustainable growth in complexity, and efficacy evaluation are some of the existing limitations of digital health interventions that should be overcome in existing research [126,128]. Although new technologies and rapidly changing technologies pose many unsolved problems, the broad consensus is that successful intervention design requires user-centered iterative development methods, hybrid methods, and in-depth qualitative research to gradually improve interventions to satisfy users. Therefore, conceptual participation (effective engagement) is essential to understand the relationship between the involvement in digital interventions and required behavioral changes and to achieve population-level benefits. Interventions must be delivered effectively at scale. Small effect sizes and high dropout rates [78,126] often affect web-based computer-tailored interventions, particularly among people with a low education level. The results and attractiveness of these remedies can theoretically be enhanced by using videos as a delivery format. The most successful and most appreciated intervention was the web-based video version of the computer-tailored obesity prevention intervention. Future research needs to analyze whether the results are sustained in the long run and how to maximize the intervention.

Conclusions

Digital intervention in health care is the intersection of health care, behavior science, computing, and engineering research and requires methods borrowed from all these disciplines. Digital interventions have effectively improved many health conditions and health behaviors; besides, they are increasingly being used in different health care fields, including self-management of long-term conditions, prevention of lifestyle diseases, and health promotion. In low-resource primary care environments, digital health strategies can be useful for preventing obesity. To minimize obesity and chronic disease risk among medically vulnerable adults in the primary care environment, digital health intervention uses an advanced digital health approach. The lack of user involvement hinders the full potential of digital interventions. There is an urgent need to develop effective strategies to promote user participation in digital interventions. One potential method is to use technology-based reminders or personalized recommendation generation. Compared with no strategy, technology-based strategies can promote participation. However, the findings of this systematic literature review should be understood with prudence, as only a few qualified studies have been identified for review, and the results are heterogeneous. The number and dates of studies indicate that a digital health intervention strategy is an emerging field. More research is needed to understand what strategic features are useful, their cost-effectiveness, and their applicability to different age groups. The results of this literature review will help to understand the concepts and parameters behind different DBI methods, thereby developing, testing, and evaluating the performance of a useful digital intervention in the future.

Acknowledgments

The authors (AC and AP) thank the coauthors (MG and SM) for reviewing the paper and providing useful comments to improve its quality. This research is unique, original, and has not been published or submitted elsewhere.

Authors' Contributions

The authors (AC and AP) divided and distributed the articles to complete the screening using the Rayyan tool. After individual screening, the results were verified by other authors (MG and SM) to resolve discrepancies between the reviewers.

Conflicts of Interest

None declared.

Abstract

Background: Internet or mobile device use as a form of information and communication technology (ICT) can be more effective in weight loss and weight maintenance than traditional obesity interventions.

Objective: The study aims to assess the effectiveness of child-centered ICT interventions on obesity-related outcomes.

Methods: Articles were retrieved from the Cochrane Central Register of Controlled Trials, Embase, and PubMed web-based databases. We selected randomized controlled trials in which the participants were aged <18 years. The primary outcomes were BMI, body weight, BMI *z*-score, waist circumference, and percentage body fat.

Results: In total, 10 of the initial 14,867 studies identified in the databases were selected according to the inclusion criteria. A total of 640 participants were included in the intervention group and 619 in the comparator group. Meta-analyses were conducted considering various subgroups (intervention type, comparator type, target participants, mean age, sex, BMI status, and follow-up period). Overall, ICT interventions demonstrated no significant effect on BMI, body weight, BMI *z*-score, waist circumference, and percentage body fat. Subgroup analyses revealed that the effect of the intervention was statistically significant for the following: *web* intervention (weighted mean difference [WMD]=−1.26 kg/m^2, 95% CI −2.24 to −0.28), *lifestyle modification* comparator (WMD=−1.75, 95% CI −2.76 to −0.74), intervention involving both *boys and girls* (WMD=−1.30, 95% CI −2.14 to −0.46), and intervention involving *obesity only* (WMD=−1.92, 95% CI −3.75 to −0.09).

Conclusions: The meta-analysis results for children with obesity who used the *web* intervention program confirmed significant effects on BMI reduction compared with *lifestyle modification*. Evidence from the meta-analysis identified internet technology as a useful tool for weight loss in children with obesity.

Introduction

Background

The prevalence of obesity among children and adolescents worldwide has increased at an alarming rate [1,2]. Children with obesity are now prone to developing diseases that were only observed in adults, including high blood pressure, impaired glucose tolerance, type 2 diabetes mellitus, dyslipidemia, sleep apnea, joint problems, and fatty liver disease [3-5]. In addition, children with obesity may be at risk for a variety of social and

psychological problems such as low self-esteem, bullying, and discrimination [6].

Given the adverse health outcomes and high prevalence rate, effective interventions are imperative for the management of childhood obesity. Traditionally, many forms of intervention have been attempted to address childhood obesity, and they have mainly comprised lifestyle modifications and mental health care as well as medication and surgical treatment [7-10]. However, some methods have limited indications in children, and their effectiveness is debatable [11,12]. Therefore, it is necessary to develop more efficient and effective approaches for children.

Information and Communication Technology

Internet and mobile use in childhood and adolescence are already becoming essential elements of young people's lives [13-15], providing several advantages such as learning, information, and entertainment but also causing many problems. Excessive internet and mobile use has resulted in more sedentary behavior, decreased physical activity, and unhealthy dietary patterns, and it is emerging as a social problem that suffices diagnosis as a form of addiction disorder [16]. In addition, studies have reported that increased screen time and obesity are strongly correlated [17].

In contrast, there have been some attempts to use active internet and mobile use during childhood as a means of obesity intervention. Mobile health (mHealth), defined as *medical and public health practice supported by mobile devices, such as mobile phones, patient monitoring devices, personal digital assistants, and other wireless devices* [18], has the potential to influence a variety of health outcomes and has become a key trend in health service provision during recent years [19]. In addition, previous research has demonstrated that internet-based behavioral interventions have the potential for weight management [20-22].

Information and communication technology (ICT) is a technology that can be used to connect information technologies such as computers and software with communication technologies such as telephones and telecommunication networks. ICT includes cell phone calls, SMS, and apps using a mobile phone, email, and web services using a computer, and telehealth, including health education services, remote monitoring, and remote counseling [23].

Objectives

Internet or mobile device use as a form of ICT can be more effective in weight loss and weight maintenance than traditional obesity intervention, as it offers benefits in terms of cost, ease of use, accessibility, and time to visit, while improving compliance with prescribed treatments through extensive patient monitoring and continuous support.

Therefore, we conducted a systematic review and meta-analysis to assess the effectiveness of child- and adolescent-centered ICT interventions on obesity-related outcomes.

Methods

Overview

We performed a meta-analysis based on the Cochrane Handbook for Systematic Reviews of Interventions [24] and the Centre for Reviews and Dissemination's guidance for undertaking reviews in health care [25]. We reported based on the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement [26].

Literature Search

A systematic search of the effects of ICT on obesity-related outcomes was conducted. We searched the Cochrane Central Register of Controlled Trials, Embase, and PubMed web-based databases and retrieved articles published before January 1, 2021. The search terms used were as follows: *ICT OR information and communication technology OR Internet OR web OR social media OR mobile OR smartphone OR application OR app* AND *obesity OR obese OR weight OR metabolic syndrome*. The search was limited to randomized controlled trials (RCTs) and English articles; however, there were no restrictions on the calendar date. Reference lists of the retrieved articles were also reviewed. Information that was unavailable in the selected articles was requested by contacting the relevant authors; however, no response was received.

Two of the authors (JP and MJP) independently reviewed the titles and abstracts after the removal of duplicates. Discrepancies were resolved either by a discussion between the authors or by requesting comments from the third author (YGS). The 3 authors independently analyzed the full text of the remaining articles to determine the final inclusion.

Eligibility Criteria

We selected the trials to be included in the meta-analysis using the following criteria: (1) the trial was a human RCT written in English, and the full text was available; (2) participants were aged <18 years; (3) the intervention group underwent ICT intervention alone or along with other lifestyle interventions; (4) the comparator group did not undergo ICT intervention; (5) the trial included an assessment of the following primary outcomes: BMI, body weight (BW), BMI *z*-score, waist circumference (WC), and percentage body fat (%BF); and (6) mean values of changes from baseline (or postintervention values if not available) with SD (or data suitable for calculating SD: 95% CI or SE). Uncontrolled, cross-sectional, and animal studies were excluded. The selection criteria did not limit the type of ICT used.

Risk of Bias Assessment

We used guidelines from the Cochrane Handbook for Systematic Reviews of Interventions to assess the risk of bias in the RCTs [24]. Sources of bias, such as selection bias (random sequence generation and allocation concealment), detection bias (blinding of outcome assessment), attrition bias (incomplete outcome data), and reporting bias (selective reporting) were evaluated. Each domain was assessed in terms of methodological quality, with low or high risk of bias. If data were insufficient to make

a reasonable judgment, the domain was described as *unclear risk of bias*.

The risk of bias was reported graphically using Review Manager (RevMan, Version 5.3; Copenhagen: The Nordic Cochrane Center, The Cochrane Collaboration, 2014).

Data Extraction

Data were independently extracted by 2 authors (JP and YGS) from the selected RCTs. From each RCT, the following data were extracted: name of the first author, year of publication, country where the RCT was performed, sample size, participant-related variables (age, sex, and BMI status), intervention-related variables (ICT type, study duration, target participants, intervention details, comparator details, intervention frequency, and feedback frequency), and treatment effects (mean difference and SD of 2 time point values or mean and SD of postintervention values). The primary outcomes were BMI, BW, BMI *z*-score, WC, and %BF.

Data Synthesis

The data set was constructed using the mean differences and SDs between the pre- and postintervention values. When the mean difference and SD were not published, the mean and SD of the postintervention values were used. In a meta-analysis, it was possible to combine both the mean differences and the means of postintervention values, assuming that the relative effects assessed by both the mean differences and the means of postintervention values are the same [24]. The final results were calculated and aggregated by one author (YGS).

Meta-analysis

For the meta-analysis, we used Stata/MP (version 14.0; StataCorp). The weighted mean differences (WMDs) of BMI, BW, BMI *z*-score, WC, and %BF in the intervention and comparator groups were calculated. We used the Cochran Q test and I^2 test to test the heterogeneity between the study results. For interpretation, I^2 values of 25, 50, and 75 were considered to represent low, moderate, and high heterogeneity, respectively [27]. To consider heterogeneity, the DerSimonian and Laird [28] random-effects model for estimating WMD with 95% CI was used. The effect size and 95% CI of each study were expressed as forest plots. We checked the symmetry of the funnel plots to evaluate the presence of publication bias. In addition, we used the Egger regression test to evaluate the small study effects [29]. Heterogeneity between studies was analyzed using a meta-regression. We used covariates that may influence the association between ICT and BMI, namely, intervention type (web vs web plus vs app vs app plus), comparator type (control vs print-based vs lifestyle modification), target participants (parents and children vs children vs parents), mean age (<10 vs ≥10 years), sex (boys and girls vs boys vs girls), BMI status (normal to obese vs overweight or obesity vs obesity), and follow-up period (≥6 vs <6 months). The cutoff for the intervention period (6 months) was based on the transtheoretical model [30]. The statistical significance level was set at 5%. For heterogeneity, a threshold *P* value of .10 estimated using the Cochran Q test was considered statistically significant [27].

Results

Study Selection and Characteristics

In total, 10 [31-40] of the initial 14,867 studies identified in the databases were selected according to the inclusion criteria, and they contained sufficient data for meta-analysis (Figure 1). The meta-analysis included 13 data sets (2 studies each had 2 ICT types [32,34]: web and web plus; one study had two comparator types [38]: lifestyle modification and lifestyle modification plus). A total of 640 participants were included in the intervention group (range of the number of participants, 15-181) and 619 (range of the number of participants, 13-180) in the comparator group. All participants were aged <18 years. Of the included studies, one evaluated boys only [40], another evaluated girls only [39], and the other 8 did not differentiate between the sexes of the participants. Six out of 10 studies had intervention periods of 12 weeks, and the remaining 4 had intervention periods >12 weeks. Five studies had follow-up periods of 12 weeks, and the remaining 5 had follow-up periods of >12 weeks. The frequency of interventions and feedback varied from study to study. The average attendance rate of the participants in the study was 86.49% (1089/1259). The characteristics of the selected RCTs are summarized in Table 1.

[b]IG: intervention group.

[c]CG: comparator group.

[d]LSM: lifestyle modification.

[e]sLMP: simplified lifestyle modification program.

ICT Interventions

Of the included 10 studies, 5 (50%) were web-based interventions, and the other 5 (50%) were app-based interventions.

Two of the 5 web-based intervention studies were *web* interventions, one for providing web-based nutrition and physical activity information for children [35] and one for providing web-based nutrition information for children [37]. One of the 5 web-based intervention studies was *web* or *web plus* intervention, which provided web-based physical exercise programs and motivational emails for children [34]. Two of the 5 web-based intervention studies were *web plus* interventions, one for providing web-based nutrition and physical activity information as well as SMS feedback for children [38] and one for providing web-based telehealth dietitian consultation, nutrition information, and SMS feedback for parents and children [32].

Four of the 5 app-based intervention studies were *app* interventions, one for providing app-based weight loss target curve, physical activity information for parents and children [31], one for providing app-based nutrition information for parents [33], one for providing app-based nutrition and screen-time information for children [39], and one for providing app-based physical activity and screen-time information for children [40]. One of the 5 app-based intervention studies was *app plus* intervention, which provided app-based nutrition and physical activity information and SMS feedback for children [36].

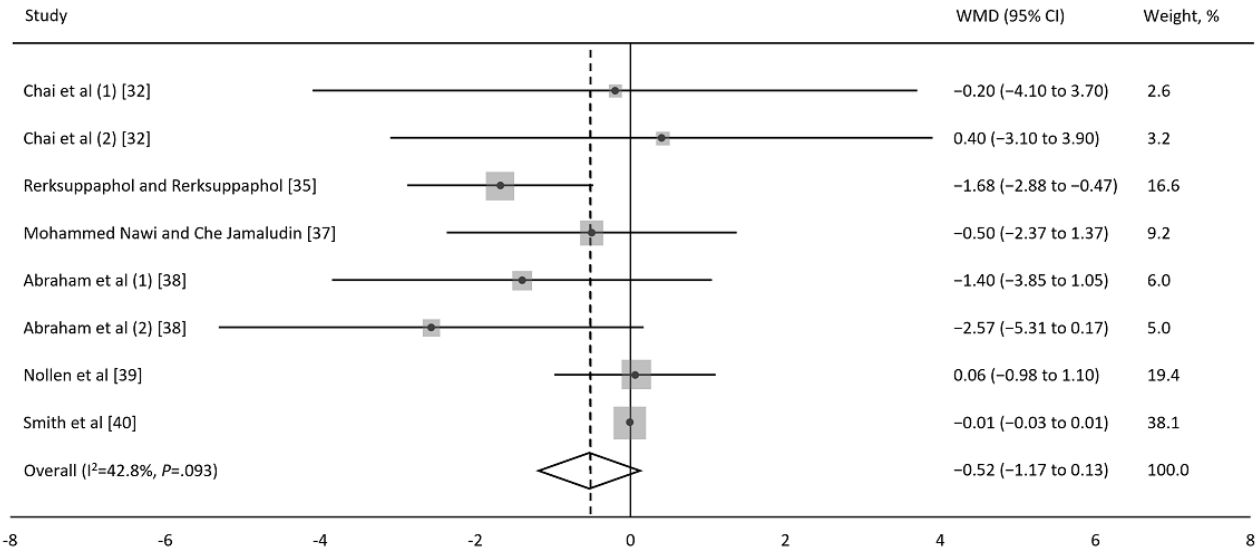
Risk of Bias

Participant blinding was not possible because of the characteristics of the intervention. Therefore, performance bias was not considered in the risk of bias assessment. There was some risk of bias in the individual studies. Two studies lacked sufficient data to evaluate the randomization sequence generation. Four studies lacked sufficient data to evaluate allocation concealment. Three studies indicated blinding of outcome assessment; however, one study stated that assessors were not blinded at follow-up. Two studies lacked sufficient data to evaluate the attrition bias. Three studies lacked sufficient information to evaluate the study protocol, and one study did not report all of the information. The risk of bias assessment is reported graphically in Figure S1 in Multimedia Appendix 1 [31-40].

Synthesis of Results

To evaluate the overall intervention effect, we calculated the mean difference in BMI for each study. Figure 2 shows the effect size for each study and the overall effect size. The intervention demonstrated no significant effect on BMI (WMD=−0.52 kg/m^2, 95% CI −1.17 to 0.13). Categorization of target participants, mean age, and BMI appeared to have moderate to high heterogeneity. Categorization of the follow-up period appeared to have low to moderate heterogeneity. For all other categories, the heterogeneity was low. We also calculated mean differences in BW, BMI *z*-score, WC, and %BF to determine the overall intervention effect, and no significant intervention effects were identified for BW (WMD=−0.22 kg, 95% CI −1.05 to 0.62), BMI *z*-score (WMD=−0.22, 95% CI −0.49 to 0.04), WC (WMD=−1.70 cm, 95% CI −3.91 to 0.51), and %BF (WMD=−0.00%, 95% CI −0.07 to 0.07; Figure S2 in Multimedia Appendix 1).

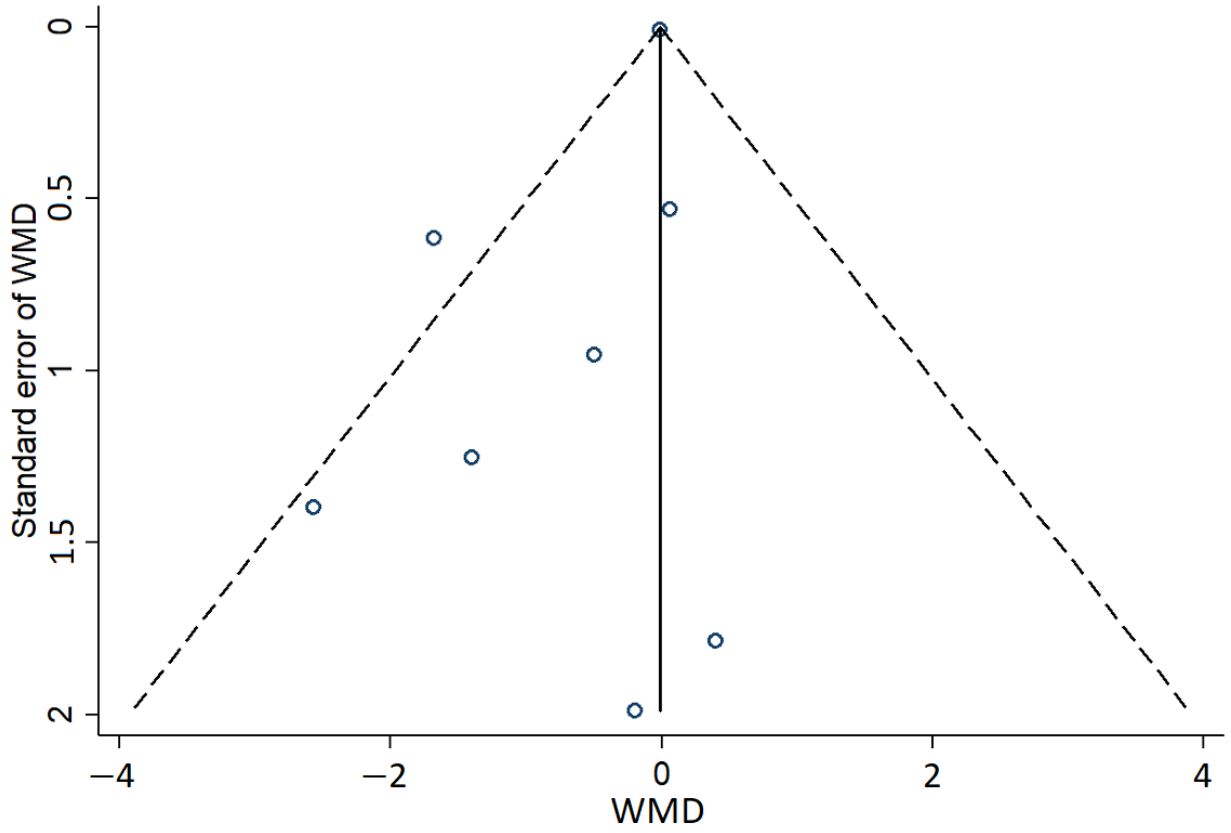
Figure 2. Forest plot for changes in BMI. Meta-analysis of the effect of the information and communication technology (ICT) on BMI (kg/m^2). The mean difference for each study reporting changes in BMI is depicted along with the 95% CI. The random-effects model was used to estimate the weighted mean differences with 95% CIs. Negative values favor ICT because the ICT intervention group experienced more BMI reduction than the comparator group did. WMD: weighted mean difference.



Publication Bias

To verify possible publication bias, we plotted the effect size against the SE to generate a funnel plot (Figure 3). There was no statistically significant publication bias according to the Egger test (*P*=.09).

Figure 3. Funnel plot for changes in BMI. The funnel plots of SE of weighted mean difference (WMD) against WMD for BMI to assess for publication bias. WMD: weighted mean difference.



Meta-regression

The results of the simple meta-regression analysis were significant for categorical covariates of intervention type (β=.69, 95% CI 0.10 to 1.28) and comparator type (β=−.73, 95% CI −1.39 to −0.07). A subgroup analysis by intervention type revealed that the intervention effect was statistically significant only in the *web* intervention (WMD=−1.26 kg/m^2, 95% CI −2.24 to −0.28). A subgroup analysis by comparator type demonstrated that the intervention effect was statistically significant only in the *lifestyle modification* comparator (WMD=−1.75 kg/m^2, 95% CI −2.76 to −0.74). A subgroup analysis by sex revealed that the intervention effect was statistically significant only in the intervention involving both *boys and girls* (WMD=−1.30 kg/m^2, 95% CI −2.14 to −0.46). In addition, a subgroup analysis by BMI status demonstrated that the intervention effect was statistically significant only in the intervention involving *obesity only* (WMD=−1.92 kg/m^2, 95% CI −3.75 to −0.09; Figure S3 in Multimedia Appendix 1).

Subgroup analyses were also performed for other outcome variables, and the results of subgroups containing only one study data were excluded. For BW, subgroup analysis revealed that the intervention effect was statistically significant only in the *web* intervention (WMD=−1.21 kg, 95% CI −2.36 to −0.06) and the intervention involving a follow-up period *<6 months* (WMD=−0.87 kg, 95% CI −1.73 to −0.01; Figure S4 in Multimedia Appendix 1). For BMI *z*-score, subgroup analysis demonstrated that the intervention effect was statistically significant only in the intervention targeting *parents and children* (WMD=−0.23, 95% CI −0.37 to −0.08) and that where the average age of participants was *<10 years* (WMD=−0.23, 95% CI −0.37 to −0.08; Figure S5 in Multimedia Appendix 1). For WC, subgroup analysis revealed that the intervention effect was statistically significant only in the *web plus* intervention (WMD=−4.88 cm, 95% CI −8.93 to −0.83), *lifestyle modification* and *control* comparator (WMD=−3.58 cm, 95% CI −6.30 to −0.85 and WMD=0.50 cm, 95% CI 0.43 to 0.57, respectively), intervention involving both *boys and girls* (WMD=−2.95 cm, 95% CI −5.18 to −0.71), and intervention involving *obesity only* (WMD=−5.50 cm, 95% CI −9.89 to −1.12; Figure S6 in Multimedia Appendix 1). Subgroup analyses demonstrated no statistically significant effect on %BF (Figure S7 in Multimedia Appendix 1).

Behavioral Change

Nine of the included 10 studies reported the initial results, and only one study reported the results of an additional 6 months follow-up after reporting the initial results of a 6-month intervention [33].

Five of the included 10 studies also reported results on behavioral changes. Some studies have shown that there were no significant intervention effects on sedentary time [33], physical activity [33,38], consumption of fruits and vegetables,

and sugar-sweetened beverages [33,39]. However, one study reported that screen-time and sugar-sweetened beverage consumption [40] were improved, and another study reported that dietary intake was improved in the intervention group [32]. One study reported no significant intervention effects on stress or dietary knowledge scores [38]. However, another study reported that emotional functioning significantly increased after the intervention [37].

Discussion

Principal Findings

This study identified the effects of ICT intervention on obesity-related outcomes in children and adolescents in RCTs through a systematic literature review and meta-analysis. We found that although ICT intervention is not significantly effective in reducing BMI, BW, BMI z-score, WC, and %BF, it does work in certain groups.

A subgroup analysis by intervention type revealed that the intervention effect was statistically significant only in the *web* or *web plus* intervention for BMI, BW, and WC. This result is consistent with those of previous studies that showed that web-based health programs are effective in managing obesity. Meta-analyses have demonstrated that web-based interventions are effective in achieving weight loss in adults [41,42]. Several systematic reviews have explored the use of web-based interventions for the prevention or treatment of obesity and related conditions in pediatric populations [20,22]. In addition, a meta-analysis demonstrated that mobile-based interventions are effective in achieving weight loss [43,44] and reducing BMI [45-47] in adults. However, there has been no meta-analysis of mobile-based obesity intervention studies in children. Several systematic reviews have indicated that mobile-based interventions in obesity treatment programs have a modest effect on weight control [47-51]. However, these effects are inconsistent. Owing to the nature of mobile use, access is possible from anywhere; hence, the possibility of giving formal responses in situations where participants are unprepared to take certain actions cannot be ruled out. Therefore, additional RCTs and meta-analyses targeting the weight-loss effect of mobile-based interventions in children and adolescents are warranted.

Another subgroup analysis by comparator type revealed that the intervention effect was significant only in the *lifestyle modification* comparator rather than in the *control* comparator for BMI and WC. A previous meta-analysis [52] that analyzed the weight loss effect of circuit training demonstrated that focusing on circuit training alone rather than adding other lifestyle interventions to circuit training is effective. Among the RCTs included in our meta-analysis, 2 [35,38] had the *lifestyle modification* comparator. In these 2 studies, the comparator group did not focus on one lifestyle, intervened in various lifestyle habits, and the number of contacts was not frequent. Recognizing that they are undergoing an intervention, participants tend to act passively, hoping to elicit changes to their lifestyle habits; therefore, where there is no intensive intervention, the intervention can be counterproductive. However, as there may be other factors influencing the research results, additional studies comparing ICT with a comparator group focusing on one lifestyle are needed.

For WC, a significant intervention effect was also obtained when the comparator type was *control*. Among the RCTs included in our meta-analysis, 2 [32,40] had the *control* comparator. However, the difference in sample size was large between the 2 studies; thus, the results of the subgroup were not different from those of one study [40], which had a large sample size. Therefore, it is unreasonable to interpret this as a subgroup result.

The intervention effect was significant only in the intervention involving both *boys and girls* for BMI and WC. Among the RCTs included in our meta-analysis, one evaluated boys only [40], another evaluated girls only [39], and the other 8 did not differentiate between the sexes of the participants. Sex differences in response to ICT interventions are likely to be because of differences in participation. In cases where boys and girls participate together, the resultant mutual competition can increase participation, which subsequently increases the effect of the intervention. Several studies have compared the sex-dependent effects of school-based physical activity interventions [53-56]. However, to date, no meta-analysis has shown sex differences in the effects of ICT intervention on children with obesity. Therefore, additional RCTs are needed to investigate the sex-dependent weight loss effects of ICT interventions.

In addition, the intervention effect was significant only in the intervention involving obesity only for BMI and WC. Participants with normal weight or overweight status may be less motivated than with participants with obesity, which may dilute the overall effect. It is encouraging to identify meaningful results from studies solely involving children and adolescents with obesity. In other words, significant results can be obtained if ICT intervention is implemented in children and adolescents with obesity. Further well-designed ICT intervention studies targeting children and adolescents with obesity should be conducted.

When both parents and children were involved in children less than 10 years of age, a reduction in BMI *z*-score was observed. In the same situation, other outcome variables did not show a statistically significant effect; however, considering the BMI *z*-score only, ICT could be used as a means of preventing obesity-related outcomes by intervening in early childhood with the involvement of parents. Therefore, there is a need for additional long-term RCTs involving high-quality ICT interventions targeting parents and children under 10 years of age.

Previous studies have demonstrated that mHealth programs or internet technology have a higher attrition rate than conventional face-to-face methods [57,58]. However, the average attendance rate of the participants in this meta-analysis was 86.5%. Children with obesity are often ashamed because of social stigma and may face prejudice against weight [59]. Moreover, because children and teenagers have a high level of interest in and concentration with electronic devices, access through mobile means or the internet can be more efficient [60]. Therefore, the effect of obesity intervention through mHealth programs or

internet technology is considered superior because of enhanced accessibility and an increased participation rate compared with conventional interventions such as the face-to-face method.

The advantage of childhood-obesity management using mHealth programs or internet technology is that it is possible to operate programs led by peer participants and provide real-time feedback. In particular, by presenting a mission aimed at improving dietary habits or increasing exercise among peers as well as providing rankings or rewards, it is possible to induce mutual participation through goodwill competition. However, among the studies included in this study, no study was conducted in a manner that induced competition among participants. Therefore, further research on the participation rates is imperative.

Strengths

Our meta-analysis had the following strengths: First, to the best of our knowledge, this is the first meta-analysis to assess the association between ICT intervention and weight loss in children and adolescents. Second, we examined the differences in weight-loss effects among subgroups according to the type of intervention, type of comparator, target participants, mean age, sex, BMI status, and follow-up period. We found that ICT intervention is effective for weight loss in the *web* intervention, *lifestyle modification* comparator, intervention involving both *boys and girls*, and intervention involving *obesity only*. Finally, the heterogeneity among the included RCTs was low.

Limitations

Our meta-analysis has several limitations. Although the meta-analysis found a moderate effect size that was statistically significant, as not many studies were included in the meta-analysis, generalization of the study results is limited because of potential publication bias. However, there were no small study effects according to the Egger regression test results. In addition, many of the studies were of short duration, making it unclear whether weight loss was sustained in the long term. Although the clinically significant threshold for weight loss was not always achieved across the studies, studies of longer duration might have found clinically significant weight loss. Therefore, further evidence is necessary to confirm this hypothesis. Outcome measurements based on participants' self-reports for many studies were recorded using mobile apps and websites and the lack of comments on the reliability of the measurement method using mobile apps can limit the results analysis. In addition, no RCT has focused on sex differences in the use of mHealth programs and internet technology. Therefore, future research should investigate the sex-dependent weight loss effects of ICT interventions.

Conclusions

The meta-analysis results for children and adolescents with obesity who participated in the *web* intervention program confirmed significant effects on BMI reduction compared with the *lifestyle modification* intervention. Evidence from the meta-analysis identified internet technology as a useful tool for weight loss in children and adolescents with obesity.

Authors' Contributions

YGS and JP wrote the manuscript; YGS, JP, and MJP analyzed the data and interpreted the results; YGS participated in the design of the study; all authors reviewed the manuscript, contributed to the discussion, and read and approved the final manuscript.

Abstract

Background: Cognitive behavioral therapy is known to improve the management of chronic pain. However, the components of this therapy are still being investigated and debated.

Objective: This study aimed to examine the effectiveness of an integrated cognitive behavioral therapy program with new components (attention-shift, memory work, video feedback, and image training) delivered via videoconferencing.

Methods: This study was unblinded and participants were recruited and assessed face-to-face in the outpatient department. We conducted a randomized controlled trial for chronic pain to compare 16 weekly videoconference-based cognitive behavioral therapy (vCBT) sessions provided by a therapist with treatment as usual (TAU). Thirty patients (age range, 22-75 years) with chronic pain were randomly assigned to either vCBT (n=15) or TAU (n=15). Patients were evaluated at week 1 (baseline), week 8 (midintervention), and week 16 (postintervention). The primary outcome was the change in pain intensity, which was recorded using the numerical rating scale at 16 weeks from the baseline. Secondary outcomes were pain severity and pain interference, which were assessed using the Brief Pain Inventory. Additionally, we evaluated disability, pain catastrophizing cognition, depression, anxiety, quality of life, and cost utility.

Results: In the eligibility assessment, 30 patients were eventually randomized and enrolled; finally, 15 patients in the vCBT and 14 patients in the TAU group were analyzed. Although no significant difference was found between the 2 groups in terms of changes in pain intensity by the numerical rating scale scores at week 16 from baseline (P=.36), there was a significant improvement in the comprehensive evaluation of pain by total score of Brief Pain Inventory (–1.43, 95% CI –2.49 to –0.37, df=24; P=.01). Further, significant improvement was seen in pain interference by using the Brief Pain Inventory (–9.42, 95% CI –14.47 to –4.36, df=25; P=.001) and in disability by using the Pain Disability Assessment Scale (–1.95, 95% CI –3.33 to –0.56, df=24; P=.008) compared with TAU. As for the Medical Economic Evaluation, the incremental cost-effectiveness ratio for 1 year was estimated at 2.9 million yen (about US $25,000) per quality-adjusted life year gained.

Conclusions: The findings of our study suggest that integrated cognitive behavioral therapy delivered by videoconferencing in regular medical care may reduce pain interference but not pain intensity. Further, this treatment method may be cost-effective, although this needs to be further verified using a larger sample size.

Introduction

Global reports indicate that chronic pain affects an estimated 20%-50% of people [1-4]. The COVID-19 pandemic has made it more difficult for people with chronic pain to safely visit hospitals. Chronic pain results in significant economic losses, with studies suggesting that pain management imposes a substantial burden on health care resources worldwide [5,6]. In Japan, it has been reported that economic loss from the inability to work due to pain is approximately 1.8 trillion yen per year [7]. It is, therefore, necessary to establish an urgent treatment system to benefit such patients and, in turn, the nation. Although multidisciplinary pain management is recommended as effective treatment for chronic pain, in clinical practice, psychosocial approaches to chronic pain are generally considered a last resort, thus delaying psychosocial intervention. Therefore, one can say that psychosocial approaches to chronic pain are underdeveloped or insufficient [8].

Cognitive behavioral therapy (CBT) is a structural intervention that encourages the transformation of a patient's cognition and behavior and directly addresses major psychological problems associated with chronic pain, such as repetitive ideation, concerns, emotions, and behaviors. CBT is recognized and recommended as an effective treatment for managing chronic pain [9]. The latest review on the effect of CBT verified by randomized controlled trials (RCTs) has added 41 new studies to the existing 34 studies, thus creating a large pool of 75 verified RCTs. Comparisons of CBT with active controls showed a slight benefit in terms of pain intensity, disability, and distress immediately after treatment [10]. It was also observed that there were small merits in each of the 3 outcomes as compared to no treatment. At follow-up, pain, disability, distress, and other variables were maintained in comparison with no treatment, but there is a lack of rigorous studies that involve active controls [10]. In summary, there is evidence of efficacy, although the effect size of CBT for chronic pain is small and insufficient.

The use of remote treatment across the internet has been increasing and its effectiveness has been demonstrated for various intractable diseases [11-14]. Internet-based CBT conducted for chronic pain has been on the rise [15-18]. While such remote treatment is known by several names such as internet-delivered CBT, web-based CBT, and telemedicine, these are all strictly different interventions. Web-based CBT and internet-delivered CBT were used synonymously in a study in which patients performed CBT on their own as self-help training or received regular therapist feedback that was not face-to-face [19,20]. Moreover, many studies involved treatment programs delivered via the internet or through smartphone apps, with the aim of self-management by patients (no intervention by the therapist) [21-23].

Only a few studies have examined the effectiveness of videoconference-based CBT (vCBT), which is face-to-face CBT using a videoconference system and not a general internet-delivered CBT for chronic pain management [24-26]. The aim of this study was to verify the cost and clinical effectiveness of a new integrated CBT program for chronic pain, delivered through videoconferencing (vCBT), and to compare with treatment as usual (TAU) for pain intensity, pain interference, disability, pain-related catastrophizing cognition, depression, anxiety, quality of life, and cost utility.

Methods

Study Design, Setting, and Participants

This study was designed as a prospective randomized unblinded pilot trial comparing vCBT as the intervention group to TAU as the control group at the academic outpatient clinic of the Cognitive Behavioral Therapy Center at Chiba University Hospital. Patients with intractable chronic pain, aged 18-75 years, were randomized and enrolled in one of the two groups. The intervention period was 16 weeks for both groups. The vCBT group received 1 weekly session of an integrated CBT program in addition to regular medical care. The TAU group continued outpatient consultation more than once for 8 weeks. For primary and secondary outcomes, patients were evaluated at week 1 (baseline), week 8 (midintervention), and week 16 (postintervention).

Although it is difficult to define intractable chronic pain, it is considered "drug-resistant" because almost all patients with acute pain receive pharmacotherapy. A review of evidence-based clinical trial designs for chronic pain pharmacotherapy states that "regulatory agencies such as the United States Food and Drug Administration and European Medicines Agency require studies of 12-weeks duration for chronic pain such as neuropathic pain to demonstrate the durability of response" [27]. Another review states that "some longer duration trials have shown efficacy of the investigational medication early in the course of treatment, only to lose statistical significance as the placebo group catches up" [28]. Consequently, the appropriate period of drug resistance cannot be determined, although taking these previous studies into account, the condition of drug resistance can be thought of as one in which individuals with chronic pain do not show moderate to remarkable improvement owing to poor tolerability, despite receiving sufficient pharmacotherapy for at least 12 weeks.

Ethics and Dissemination

This study was conducted with the approval of the Institutional Review Board of the Chiba University Hospital (approval ID G29049). In addition, the Clinical Research Ethics Review Committee oversaw the proper implementation of the test at least once a year. The trial registration number was University Hospital Medical Information Network UMIN000031124. The patients willing to participate in this study were informed of the study objectives and were asked for their consent to participate. Each patient was informed that participation was voluntary and full anonymity would be provided. Each patient was required to provide written consent for participation.

Recruitment

We recruited participants through web-based and newspaper advertisements from April 2018 to November 2019. Patient recruitment was announced by the doctors at outpatient clinics in the Department of Orthopedics and Pain Anesthesiology at Chiba University Hospital and in all medical institutions in the Chiba prefecture as well. All recruitment materials referred patients to our study website, which explained the study in detail. All participants who gave their permission to be enrolled in the study were required to continue treatment with their general practitioners as TAU. Patients who were interested in the study could inquire about the details via email. This mail was also used as an application form to ask patients to record their age, sex, condition of chronic pain, contact information, and so forth.

Eligibility Procedure for Participation and Diagnosis

Written informed consent was obtained face-to-face from all patients after they were fully briefed on the procedure. Following this, a screening eligibility assessment for inclusion and exclusion criteria was performed. Participants were asked to record their pain intensity rated by the Numerical Rating Scale (NRS) daily for a week. Inclusion criteria were as follows: (1) fulfillment of the criteria of somatic symptom disorder, with predominant pain according to the fifth edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5), (2) age ranging from 18 to 75 years to avoid the risks from cognitive decline, (3) not showing moderate to remarkable improvement despite receiving sufficient pharmacotherapy for more than 8 weeks or due to poor tolerability, and (4) appropriate mental and physical conditions to maintain therapy. In the case of patients with depression or other anxiety conditions, they met the criteria to take part in the study if their pain was the primary impairment. The exclusion criteria were (1) comorbidity of serious mental disorders such as neurocognitive disorder, psychotic disorder, bipolar disorder, or substance-related disorder based on the criteria in DSM-5; (2) major pain caused by cancer; (3) if their pain did not interfere with their daily life (PDAS: Pain Disability Assessment Scale score of 9 or less); (4) mental retardation, neurocognitive disorders (dementia), and autism spectrum disorder; and (5) litigation or compensation concerning pain symptoms. In this study, patients were required to be able to use a videoconferencing system at home. In case of patients who did not have an internet connection in their houses, we rented tablet computers and mobile Wi-Fi devices for them.

Randomization and Case Registration

The eligible patients were randomly assigned to either the vCBT group or the TAU group using the minimization method used in clinical trials to ensure a balance in pain intensity score and gender. Per the allocation adjustment factor, the pain intensity score on NRS was allocated at 6.3 for each group [29]. The randomization and assignment were done by the Clinical Research Data Center, and the results were informed to the researchers by fax.

Intervention

The intervention period was from May 2018 to April 2020. In both groups, patients underwent 16 weeks of intervention and answered questions regarding primary and secondary outcomes at 1 week (baseline), 8 weeks (middle), and 16 weeks (post). All patients continued the regular medical care that they would normally receive as treatment. While participating in this study, no patient was permitted to seek any new treatment other than those that their primary care doctor ordered. In addition to regular medical care, those allocated to the vCBT group received weekly 50-minute sessions over 16 weeks of integrated CBT program using real-time internet videoconferencing. If the therapists or patients found it impossible to continue owing to adverse events, a gap of maximum 30 days during the intervention was permitted.

Videoconference-Based Integrated CBT Program

The CBT program that we adopted is an integrated CBT program that is longer than conventional interventions and consists of several new sessions not used in traditional CBT protocols. Our developed protocol with face-to-face CBT sessions provided by the videoconference system (web-based CBT) has been shown to improve catastrophic cognition, disability, and mood [30]. Conventional CBT programs for chronic pain often comprise 8-12 intervention sessions. In almost all programs, psychoeducation for pain, case formulation for understanding cognitive behavioral models of chronic pain, relaxation exercises such as breathing, and cognitive reconstruction, among others, were included [31]. Each of the 16 sessions lasted 50 minutes. We added 4 new sessions: tactile attention-shift training (session 4), memory work based on peak-end rule (session 10), sharpening behavioral image training (session 11), and video feedback (session 12) to the conventional CBT program (shown in Table 1).

Table 1. Integrated cognitive behavioral therapy program for chronic pain.

Session	Program	Description
Session 1	Introduction	Therapists explained the purpose of cognitive behavioral therapy and set short-, medium-, and long-term treatment goals.
Session 2	Psychoeducation	Patients studied ideas such as the mechanism of pain, gate-control theory, and acceptance of pain.
Session 3	Relaxation	Patients practiced progressive muscle relaxation and abdominal breathing techniques.
Session 4	Tactile attention-shift training	Patients practiced flexibly shifting their excessive attention to pain.
Session 5	Case formulation	Patients learned their own cognitive behavioral models and vicious pain-causing cycles.
Session 6	Safety behaviors	For behavioral activation, patients understood avoiding action due to pain and learned the demerits of continuing safety action such as avoidance, makeshift action.
Session 7	Cognitive restructuring 1	Patients' thinking habits were examined and they learned how to change their irrational thinking.
Session 8	Cognitive restructuring 2	Patients' thinking habits were examined and they learned how to change their irrational thinking.
Session 9	Activity pacing	Patients spaced out activities to manage pain.
Session 10	Memory work using the peak end rule	By reexamining their pain memory, patients learned that it influences chronic pain.
Session 11	Mental practice	Patients practiced imagining the movement of their body in pain and maintaining hope.
Session 12	Visual feedback	Patients performed mirror therapy as an alternative, recording own actions and observing ideal movement.
Session 13	Behavioral experiments 1	Patients practiced step by step those actions that could not be performed because of pain.
Session 14	Behavioral experiments 2	Patients practiced step by step those actions that could not be performed because of pain.
Session 15	Summary	We reviewed all the sessions and confirmed any remaining issues.
Session 16	Relapse prevention	Patients learned to think about how to respond when the pain recurred.

Tactile attention-shift training (session 4): Patients with chronic pain tend to demonstrate "attention bias." Excessive attention causes patients' pain to increase. Patients were trained to flexibly shift their attention. Furthermore, it has been found that pain may be relieved by gentle strokes that promote the secretion of oxytocin. This is referred to as the Science Touch method and suggests relief from chronic pain [32]. Attention-shift training takes place while being conscious of the sense of touch.

Memory work based on the peak-end rule (session 10): With significant chronic pain, patients tend to consider their memory of pain to be worse than the actual intensity of the pain. This is because the memory of an intense pain experience is saved as a traumatic memory [33]. The peak-end rule theory explains that "unpleasant experiences like pain are memorized as the average of the strength of the pain peak and the strength of the end" [33]. Patients with chronic pain tend to retain the memory of the peak of their pain experience, when the pain was too intense, and they may not be able to remember the end or release of their pain. Their peak (painful) memories are thus surpassed by the end (good) memories. Therefore, in their pain memory, the average degree of the pain and unpleasantness is high, and it remains as an extreme memory where objectivity about the pain condition is lost. This causes negative emotions such as anxiety and depressive feelings, which can be a factor for negative thoughts. This is considered catastrophic cognitionit is caused by pain but at the same time, it becomes the factor of chronicity. This session seeks to reduce pain by recalling memories of intense pain in detail and reconstructing them in objective memory.

Sharpening behavioral image training (session 11): We were inspired by sports training and poststroke rehabilitation [34,35] to compose this session. Many patients with chronic pain cannot imagine that they can move the injured body part since they have not moved it in a long time. Therefore, this session helped patients increase their daily movement using "image training" until they could clearly imagine moving their painful body parts themselves.

Video feedback (session 12): We developed this session in line with the principles of mirror therapy, a treatment used for phantom limb pain [36]. In this therapy, when the patient moves their healthy side, it is reflected in the mirror and the patient visually recognizes the movement. As a result, the brain interprets it as the amputated side that is moving and thus, the pain is alleviated [37,38]. When there is no movement in the painful area for a long time, it is considered to be a state in which the sensory and motor contact with the brain is severely disconnected. This is regarded as being similar to experiencing phantom limb pain. Thus, we considered that if pain can be alleviated by observing repeated normal movements in the

mirror, observing normal movements in videos should also have similar effects.

System Safety

In this study, we adopted the ISO 27001-certified Cisco WebEx as the internet conference system. Countermeasures against unauthorized access, information leakage, and others were taken, and safety problems were cleared.

Measures and Evaluation

Pretreatment Measures

After enrollment, we assessed the baseline characteristics of the patient's sex, age, education, marital status, comorbidity, employment status, age at onset of pain, duration of pain, and treatment history before they entered the intervention period (shown in Table 2). The following outcome measures were set based on the Initiative on Methods, Measurement, and Pain Assessment in Clinical Trials. Furthermore, "Assessment of Chronic Pain" was recommended by the International Pain Society [39].

Table 2. Baseline characteristics of the patients.

Characteristics	Videoconference-based cognitive behavioral therapy (n=15)	Treatment as usual (n=14)
Age (years), mean (SD)	50.0 (14.3)	43.9 (12.5)
Females, n (%)	10 (67)	9 (64)
Education history (years), mean (SD)	13.6 (2.6)	13.4 (3.8)
Currently employed, n (%)	4 (26)	5 (35)
Family members living together, mean (SD)	2.0 (2.1)	1.8 (1.0)
Chronic pain site, n (%)[a]		
Lower back	8 (53)	3 (21)
Back	6 (38)	3 (21)
Neck	4 (27)	1 (7)
Arm	3 (21)	4 (27)
Leg	7 (47)	7 (50)
Other	8 (53)	2 (14)
Duration of disease (years), mean (SD)	11.0 (12.6)	7.6 (5.8)
Mental status comorbidity, n (%)	6 (40)	8 (57)

[a]For chronic pain site, duplicate answers were possible.

Adverse Events

All adverse events were reported irrespective of their relevance to the intervention of this study, and serious adverse events were immediately reported to the institutional review board of the Chiba University Hospital and registered with the hospital risk management system as well. Moreover, an independent data monitoring committee accurately verified the detailed records of the clinical study's progress, critical efficacy variables, and safety data.

Primary Outcome Measures

The primary outcome was the change in the pain intensity from baseline to week 16, as indicated by the NRS score. The NRS is a self-rated questionnaire that measures pain intensity on a scale of 0-10, where 0=nothing and 10=severe. Patients were made to keep a daily pain diary. They recorded (1) maximum pain throughout the day, (2) minimum pain, (3) usual pain, and calculated the weekly average for pain on the day of the session (each NRS score=sum total of 1-week NRS score/7). Numerical values obtained by averaging the values in (1), (2), and (3) were taken as the main evaluation items comprising the composite value of NRS. The measurement has been shown to be reliable and valid [40].

Secondary Outcome Measures

All secondary outcomes were measured at 8 weeks and 16 weeks from the baseline.

Pain intensity: The secondary outcome was change in pain intensity (maximum, minimum, usual score) from baseline to week 8 on the NRS.

Comprehensive pain score: Comprehensive pain was assessed with the Japanese translation of the Brief Pain Inventory (BPI) [41]. BPI is composed of 2 factors: pain severity and pain interference. Pain severity means the pain intensity, but we use the original term as used in the BPI. The scale has a high reliability (coefficient alpha greater than .80) and established validity. Pain severity on the BPI comprises 4 items (worst, least, average, and current). They are assessed as 0 (nothing) to 10 (severe), with higher scores representing worse pain. Pain severity was calculated as the average of the 4 scores. Pain interference of BPI is a 7-item measure designed to assess pain interference by sleep, mood, social relations, and enjoyment of life. On an 11-point scale (0=does not interfere, 10=completely

interferes), patients indicated how much pain had interfered "in the past 24 hours" with different functional aspects. This score was the average of the 7 scores, and the total score was calculated as a composite score.

Cognition related to pain: Catastrophizing one's perception of pain was measured using the Pain Catastrophizing Scale (PCS). This scale has been shown to have high internal consistency (Cronbach α range .67-.87) [42]. The PCS comprises 13 items that evaluate the degree of catastrophizing cognition about pain. The responses are recorded on a 5-point Likert scale, where 0=not at all to 4=all the time. The total PCS scores ranged from 0 to 52, and the clinical cutoff value for the score was over 30 [42,43].

Disability: The degree of life disability due to pain was measured using PDAS. It is composed of 3 factors and supported by a high level of internal consistency (Cronbach α range .87-.95). It consists of 20 items on a 4-point Likert scale and is evaluated from 0 to 60 points, with a higher score indicating a higher degree of daily disability [44]. The clinical cutoff for PDAS is 10 points.

Depression and anxiety: Depressive symptoms were assessed with Beck's Depression Inventory II and Patient Health Questionnaire-9 items (PHQ-9). BDI-II has an internal consistency of approximately .90, and the test-retest reliability ranges from .73 to .96. It consists of 21 items with 4 response statements designed to assess the severity of current symptoms of depressive disorders. The total scores on the measure range from 0 to 63. Scores below 10 are regarded as reflecting "minimal or no" depression, whereas score ranges of 10-18, 19-29, and 30-63 reflect "mild to moderate," "moderate to severe," and "severe" depression, respectively [45,46]. PHQ-9 has diagnostic validity (for the diagnosis of any one or more PHQ disorders, κ=0.65; overall accuracy, 85%; sensitivity, 75%; specificity, 90%). It consists of 9 items scored on a 4-point Likert scale (0=not at all, 1=on several days, 2=half or more of days, and 3=almost daily). The minimum score is 0 and the maximum score is 27 (0-4, 5-9, 10-14, 15-19, and 20-27, indicating no, mild, moderate, moderate to severe, and severe symptoms, respectively) [47]. The PHQ cutoff score for clinically significant depressive symptoms is 10. Anxiety was measured on the Generalized Anxiety Disorder (GAD-7) scale, which has been shown to have reliability, criterion, construct, factorial, and procedural validity. Cutoff points that optimized sensitivity (89%) and specificity (82%) were identified. The scale has 7 items that assess the severity of GAD in the previous 2 weeks on a 4-point Likert scale (0=not at all, 1=one episode, 2=on half or more days, and 3=almost daily). The minimum score is 0 and the maximum score is 21 (0-4, 5-9, 10-14, and 15-21 indicating no, mild, moderate, and severe symptoms, respectively). The cutoff score for clinically significant symptoms of anxiety is 10 [48].

Health-related quality of life: European quality of life 5-dimensions 5-level (EQ-5D-5L) is a widely applied, valid, and reliable measure of quality of life. Its reliability was shown by Cronbach alpha (.70) [49]. EQ-5D-5L consists of 5 items related to mobility, self-care, common activities, pain/discomfort, and anxiety/depression. Patients answer each item on a scale of 1 to 5 (good to severe), and based on the score, the utility value, 0 to 1 (death to in good health), is calculated from the conversion device, which is used for medical economic evaluation [50,51].

Medical Economic Evaluation

All enrolled patients were asked to collect and submit receipts of their medical and drug expenses for chronic pain during this study (for 4 months). The incremental cost-effectiveness ratio (ICER) for the comparators vCBT versus TAU was estimated based on prepost evaluation (from baseline to 16 weeks), differences in medical costs, and effects of the condition. To estimate the cost utility of the intervention, quality-adjusted life years (QALYs) were calculated using the utility score of EQ-5D. To calculate the ICER, QALY values were calculated by multiplying one life year by the quality of life score. Quality of life scores were measured using the EQ-5D. We could not use quality of life scores 1 year (52 weeks) after the start of the intervention since the follow-up study had not been done. Therefore, we assumed that quality of life scores at week 16 could return to baseline at 1 year (week 52) as the minimum effect case. Conversely, we assumed that quality of life scores at week 16 could be the same as baseline at 1 year (week 52) as the maximum effect case.

Sample Size

In this study, we assumed that the difference in the amount of change in the NRS was 1.67 and the standard deviation was 1.8 and set the detection power to 80% and bilateral significance level to 5% in the two-sided *t* test. As a result, the required number of subjects per group was estimated to be almost 20. In the main analysis, analysis of covariance (ANCOVA) with the allocation factor as the covariate was used, and the detection power was calculated to be 82%. As this study is a pilot study, the number of cases was determined based on its feasibility.

Data Management

All data were properly managed by the submitting the case report form to the Clinical Research Data Center. In this center, researchers entered all the data using an access-log-restricted data system, which could be verified, and they created data sets. Independent data monitoring committees were regularly held and they performed risk-based monitoring. After the intervention was finished, the responsible doctors confirmed their data sets and locked the data. Then the locked data were transferred to the Pharmaceutical Statistics Office of the Department of Clinical Trials, Chiba University Hospital.

Statistical Analysis

Statistical analysis and reporting of this trial were conducted in accordance with the Consolidated Standards of Reporting Trials guidelines. Baseline variables were compared using Fisher exact test for categorical outcomes and an unpaired two-tailed *t* test for continuous variables. The significance level was set at .05. For the primary analysis of comparing treatment effects, the means of the least squares and their 95% CIs were estimated by ANCOVA with the change in the NRS composite score at week 16. This ANCOVA model took into account the variation caused by treatment effects, and gender and baseline NRS scores (≥6.3 and <6.3) were entered as covariates. As a sensitivity

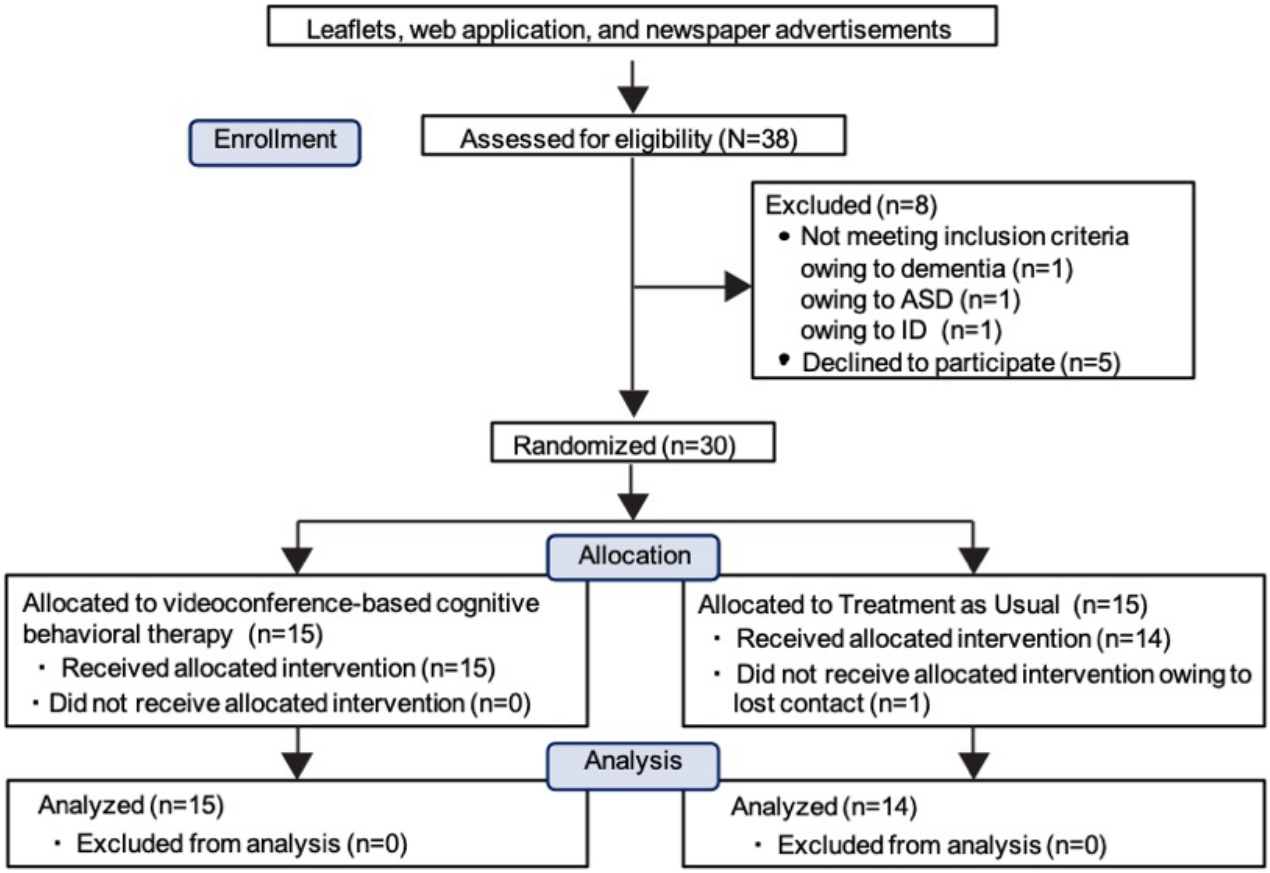
analysis, we showed the transition over time of the NRS scores of each group, confirmed the time course measurement data using the linear mixed effect model, and confirmed that it was not significantly different from the covariance analysis result. All comparisons were planned, and all *P* values were two-sided. *P* values <.05 were considered statistically significant. No special complementary processing by statistical methods was performed for the missing values. However, if necessary, complementary analysis using Mixed Model Repeated Measure was carried out for exploratory analysis. This analysis plan was created before the trial was started, and the protocol was approved. All statistical analyses were performed using SAS V.9.4. (SAS Institute, Cary).

Results

Participants

Figure 1 depicts the participant enrollment for this study. The recruitment process resulted in a total of 38 participants. Three participants were excluded owing to dementia (n=1), autism spectrum disorder (n=1), suspected intellectual disability (n=1), and 5 declined to participate. In the eligibility assessment, 30 patients were eventually enrolled and randomized.

Figure 1. Flowchart of participant selection in the trial. ASD: autism spectrum disorder; ID: intellectual disability.



Patients' Demographic and Clinical Characteristics

A total of 93% of the patients (14/15) completed all 16 sessions of the vCBT program and participated in the intervention throughout its duration; 2 patients missed 1 session each due to adverse events (see below). No patients in the vCBT group were excluded from the analysis. One patient in the TAU group did not report receiving regular medical treatment at week 8 and was excluded from the analysis. Finally, 15 patients in the vCBT and 14 patients in the TAU group were analyzed.

Adverse Events

In this study, 4 adverse events were reported by 4 different patients in the vCBT group. The first patient was hospitalized owing to worsening Behcet disease and declined to participate in the study for the fourth session. The second patient had sudden difficulty in opening his eyes due to medically unexplained eyelid pain and declined to participate in the study for the fifth session. The third patient had common cold. The fourth patient had temporomandibular joint disorders.

Table 2 shows the demographic data of the patients. There were no significant differences between vCBT and TAU in age, gender, length of education, employment status, and number of families living together (*P*=.24, *P*>.99, *P*=.73, *P*=.70, *P*=.73; respectively). Duration of illness in vCBT (mean 11.03 [SD 12.64] years) was significantly longer than that in TAU (mean 7.56 [SD 5.84] years). In both groups, more than 65% (19/29) of the patients were women. All patients in the vCBT group had an education period of 12 years or more (high school graduation or above), and TAU group had also 12 years or more except for one patient (9 years). There was no significant difference between the two groups. At baseline, nearly 70% (20/29) of patients were not working (vCBT 11/15, 55% vs TAU 9/14, 45%). Patients were living with at least one family, and only 1 patient receiving vCBT lived alone. The most

reported site of chronic pain was lower back pain. Many patients had orthopedic pain, while others had oral pain such as tongue pain, toothache, and general pain such as rheumatism and fibromyalgia.

Primary Outcomes

Table 3 shows the adjusted mean reductions of NRS in vCBT and TAU at 16 weeks (primary outcome) and at 8 weeks (secondary outcome) from the baseline. No significant difference was found between the 2 groups in terms of changes in composite NRS scores at week 16 from baseline (P=.36). Table 4 shows the raw data on the means and standard deviations of NRS scores in vCBT and TAU at 16 weeks and 8 weeks.

[a]vCBT: videoconference-based cognitive behavioral therapy.

[b]TAU: treatment as usual.

[c]NRS: numerical rating scale.

Secondary Outcomes

Tables 5 and 6 show the results of efficacy on the secondary outcomes. *P* values lesser than .05 were considered statistically significant. No significant difference was found between the 2 groups regarding changes in maximum, minimum, and usual NRS scores at week 16 from the baseline. In addition, there was no significant difference in the changes in all NRS scores at week 8 from baseline.

Comprehensive pain score: The adjusted mean reduction of the total BPI score in vCBT was significantly larger than that of TAU at 16 weeks (–1.43, 95% CI –2.49 to –0.37, *df*=24; *P*=.01). There was no significant difference between the 2 groups in the adjusted mean reduction of BPI pain severity at 16 weeks. The adjusted mean reduction of BPI pain interference in vCBT was significantly larger than that of TAU at 16 weeks (–1.95, 95% CI –3.33 to –0.56, *df*=24; *P*=.008). There was no significant difference between the 2 groups in the adjusted mean reduction of BPI total score, pain severity, and pain interference at 8 weeks.

Disability: The adjusted mean reduction of the PDAS score in vCBT was significantly larger than that of TAU at 16 weeks (–9.42, 95% CI –14.47 to –4.36, *df*=25; *P*=.001). There was no significant difference between the 2 groups in the adjusted mean reduction of PDAS at 8 weeks.

Catastrophizing cognition: The adjusted mean reduction of the PCS score in vCBT was larger than that of TAU at 16 weeks, although the difference was not statistically significant (–6.25, 95% CI –12.89 to 0.38, *df*=25; *P*=.07). There was no significant difference between the 2 groups in the adjusted mean reduction of PCS at 8 weeks.

Depression and anxiety: There was no significant difference between the 2 groups in the adjusted mean reduction of BDI-II, PHQ-9, and GAD-7 at 16 weeks and 8 weeks, respectively.

Health-related quality of life: The adjusted mean change of the EQ-5D-5L index score in vCBT was larger than that of TAU at 16 weeks, although the difference was not statistically significant (0.09, 95% CI –12.89 to 0.38; *P*=.06). There was also no significant difference between the 2 groups in the adjusted mean change of the EQ-5D-5L index score at 8 weeks.

Medical Economic Evaluation

Complete data for the direct medical economic evaluation were available for 12 (80%) patients in the vCBT group and 12 (80%) patients in the TAU group with their informed consent. The data consisted of medical expenses covered by public health care insurance, prescription drug prices, and uncovered health care expenses for chronic pain during the intervention period (16 weeks or 4 months). The mean total cost per person for 4 months was 145,846 yen (1 USD=114.05 yen) in vCBT and 169,312 yen in the TAU group, thereby showing no significant difference between the 2 groups (P=.73) (Table 7). To calculate the ICER, we extracted incremental effects from EQ-5D and incremental costs from collected receipts of medical and drug expenses. The incremental effect of vCBT on TAU was determined to be 0.033 to 0.064 QALY for 1 year. We adopted 0.033 QALY as the incremental effect as the best case. Regarding the incremental cost, the total cost of 16 sessions of the vCBT program was 96,000 yen per person with 6000 yen per session. Therefore, we adopted 96,000 yen as the incremental cost for vCBT compared with TAU. A cost-benefit analysis based on the data showed that the ICER was almost 2.9 million (yen/QALY=96,000 yen divided by 0.033 QALY). Previous research that used willingness to pay (WTP) to obtain the criterion of the ICER showed that 5.0 million yen (US $48,158) per QALY gained is considered an acceptable threshold in Japan [52]. Therefore, it was suggested that vCBT is more cost-effective than TAU, even though it was a minimum effect case, as the improvement in quality of life returned to the baseline in 1 year (shown in Figure 2).

Table 7. Comparison of costs (in yen) for treatment of chronic pain.[a]

Costs	1st month	2nd month	3rd month	4th month	Total amount	*P* value
Insurance medical treatment for chronic pain (100% burden), mean (SD)						.69
TAU[b] (n=12)	16,057 (16,232)	15,898 (16,711)	10,681 (14,060)	18,014 (23,755)	60,650 (64,292)	
vCBT[c] (n=12)	9309 (8754)	19,182 (24,923)	28,728 (42,755)	17,153 (33,133)	74,372 (98,889)	
Outpatient prescription amount for chronic pain, mean (SD)						.99
TAU (n=12)	13,503 (14,082)	16,373 (17,924)	12,163 (11,756)	19,517 (23,939)	61,556 (58,758)	
vCBT (n=12)	23,129 (28,480)	8149 (10,933)	15,578 (15,318)	15,078 (14,047)	61,933 (59,961)	
Private insurance amount for chronic pain, mean (SD)						.35
TAU (n=12)	9637 (23,676)	12,049 (29,535)	11,710 (32,480)	13,710 (41,539)	47,106 (132,486)	
vCBT (n=12)	1817 (4051)	2233 (6249)	3811 (8236)	1680 (3723)	9541 (21,859)	
Total cost for chronic pain, mean (SD)						.73
TAU (n=12)	39,197 (39,425)	44,319 (46,594)	34,554 (50,316)	51,241 (63,891)	169,312 (195,072)	
vCBT (n=12)	34,255 (29,983)	29,564 (23,755)	48,116 (45,076)	33,910 (35,109)	145,846 (123,008)

Discussion

To our knowledge, this study is the first RCT to evaluate the effectiveness of vCBT for chronic pain. In addition, we performed a cost-effectiveness analysis of the CBT program by using ICER. Although composite pain intensity by the NRS did not change, vCBT significantly improved the total BPI score, especially pain interference and disability in daily life. Furthermore, in the medical economic evaluation, although our

results showed no statistically significant difference, it has been suggested that vCBT may be more cost-effective than TAU for various reasons that we discuss in the following sections.

The latest systematic review of 75 RCTs about the effectiveness of face-to-face CBT has shown that CBT versus TAU at the treatment end for pain, disability, and distress showed a small effect size, and versus active treatment showed few effects (n=9401) [9]. In general, internet-based CBT is delivered through a computer application for administering self-management programs without a therapist. According to a systematic review of internet-based CBT for depression, anxiety disorder, and other functional disorders, including chronic pain, the CBT for chronic pain showed small to medium effect size from 10 RCT studies with low levels of evidence. Conversely, internet-based CBT for depression, social anxiety disorder, and panic disorder was classified as established, that is, they met the highest level of evidence criteria [11]. A systematic review of internet-based CBT for lower back pain reported high effectiveness for pain intensity and disability in 9 RCT studies (n=1796) [53]. Although there are several studies on internet-based CBT, there are only a few RCTs on vCBT, and almost all of them focus on self-care by patients. Only a pilot study of hematopoietic stem cell transplantation has reported on the feasibility and improved self-efficacy of vCBT [26].

As reported by multiple internet-based CBT studies, use of self-care programs or apps, treatments in which specialists check progress every other week, or telephone sessions have been demonstrated to be effective. Such internet-based CBT does not require multiple therapists, and interventions can be conducted for many patients concurrently. However, there is insufficient evidence for the effectiveness of the treatment. Chronic pain is unique to each individual and therefore, there is a need to consider stepped care for chronic pain, which is a system of delivering an evidence-based staged approach and provides treatment that matches individual needs and status. Ideally, it is desirable for patients to receive internet-based CBT in the early stage as first aid, such as through a self-care smartphone app. Moreover, patients who do not respond well to first aid should receive vCBT as the second aid.

vCBT is intended for the treatment of higher levels of chronic pain. We need to examine treatments for several levels of pain for treating complex and intractable chronic pain. This was the first RCT on vCBT showing significant improvement in interference (distress) and disability. Our primary outcome, pain intensity as measured using NRS, was not significantly different; however, we adopted the BPI total score as a comprehensive pain score, which showed significant results. The reason for the NRS result could be that TAU also improved pain intensity. According to the BPI total score, pain interference appeared to greatly improve, while pain severity only showed a slight change, which comprehensively improved the total score. We hypothesized that patients who received CBT increased their previously avoided daily movement by doing the CBT-related homework and confronting their pain, thus maintaining their pain intensity. Conversely, it was possible for patients with TAU to avoid several behaviors owing to pain; as a result, their pain interference score worsened gradually. Considering this development, a composite score such as a BPI total score should be adopted for assessing the effectiveness of treatment for chronic pain. A recent consensus recommended the use of comprehensive indicators such as a BPI [54]. In particular, the composite score of BPI is the right choice because it comprises 2 domains, pain severity and interference due to pain, which are measured as outcomes in all chronic pain clinical trials. Few studies have set the BPI total score as primary [23] and there might be a need to set a comprehensive scale, instead of a single rating scale, as the primary outcome in future research.

We expected improvement of cognition-related pain-related catastrophic thoughts, anxiety, and depressive symptoms, because a previous review had shown small-to-moderate effect size of catastrophic thinking and mood [9]. Moreover, one of the new additional sessions of our protocol focused on emotions related to pain (session 10). Contrary to expectations, there was no significant difference between PCS and mood. However, if the sample size is a little large, it may show a positive result as the PCS score of vCBT improves compared to TAU (shown in Table 6). Considering the previous review, it is not easy to improve mood by CBT for chronic pain [55]. Our new protocol also did not treat their anxiety and depression.

We thus added a new session to address emotions such as anxiety and depression. However, in this session, many patients could not recognize the emotions related to pain. They thought of their pain and emotions as separate and did not acknowledge emotions that accompanied the pain memory or emotions that accompanied the moment pain was felt. An RCT found that emotion-focused exposure intervention (10-15 sessions) compared to normal CBT for chronic pain is effective for catastrophic cognition and depression, in addition to other outcomes [56]. The research concluded that the emotion-focused approach is an effective option. We had a single emotion-focused session, which was too little time for patients to learn how to treat their emotions.

In medical economic evaluation, a cost-benefit analysis showed that ICER was almost 2.9 million (yen/QALY), which was lesser than Japan's WTP of 5 million yen. Furthermore, it was also shown to be lesser than the British WTP of £23,000 (approximately 3 million yen) and the United States WTP of $62,000 (approximately 6.7 million yen) [51]. At postintervention (16 weeks), the total cost of each group was not significantly different; however, the cost of vCBT did not change even though TAU increased gradually. In particular, the decrease in outpatient prescriptions of vCBT increased TAU costs, which may have affected the overall costs. We understand that the results of economic assessments are somewhat uncertain for a variety of reasons. Since this was a pilot study, the number of verifications was small. In addition, since no follow-up data were taken, the cost-effectiveness results were derived from assumptions of the sustainability of therapeutic efficacy. This uncertainty should be kept in mind if clinicians and policymakers set treatment guidelines or offer this program in a clinical setting.

This study has several limitations. First, the sample size was relatively small. In addition, this study was performed as a single-center study at our hospital. In the near future, large-scale multicenter trials are necessary. Second, further studies targeting

patients with specific types of chronic pain will be required to examine the effectiveness of this vCBT program. Third, because we did not use a psychological placebo group as a control condition, we were unable to control nonspecific factors and unravel the concrete effects of the vCBT program. Finally, the lack of follow-up data limited the generalizability of the conclusions. Long-term follow-up studies should be conducted in the future.

Despite the problems in this study, vCBT has the possibility of usability and effectiveness for patients with chronic pain. During COVID-19, in particular, vCBT may provide safety and alleviate the patient's stress through face-to-face counseling. In the future, we may study other pandemics and help patients to decrease their anxiety and symptoms by using internet-based CBT.

In summary, videoconference-based integrated CBT for chronic pain could improve pain interference and disability in daily life, and as a result, could even relieve comprehensive pain. Therefore, this program can be a valuable addition to regular medical care. Further research is needed to examine augmentation strategies, including an examination of the components of CBT that are best suited for different types of pain. Furthermore, while this study indicated the cost-effectiveness of this treatment within a small sample, this needs to be verified with a larger sample size.

Acknowledgments

We thank the Department of Clinical Trials and the Medical Research Data Center of Chiba University Hospital. We thank our research nurses, Hiroe Ota and Yoko Suwabe, for their huge support and our therapists, Yoko Okamoto and Yoichi Seki, who provided cognitive behavioral therapy in this study. We would also like to thank Editage (www.editage.com) for English language editing. Funding for this study was provided by the Health and Labor Sciences Research Grant (H29, Refractory, General, 062). The funding body had no role in the design of the study, collection, analysis, and interpretation of data and manuscript writing.

Abstract

Background: Alcohol use is a major contributor to health loss. Many persons with harmful use or alcohol dependence do not obtain treatment because of limited availability or stigma. They may use internet-based interventions as an alternative way of obtaining support. Internet-based interventions have previously been shown to be effective in reducing alcohol consumption in studies that included hazardous use; however, few studies have been conducted with a specific focus on harmful use or alcohol dependence. The importance of therapist guidance in internet-based cognitive behavioral therapy (ICBT) programs is still unclear.

Objective: This trial aims to investigate the effects of a web-based alcohol program with or without therapist guidance among anonymous adult help-seekers.

Methods: A three-armed randomized controlled trial was conducted to compare therapist-guided ICBT and self-help ICBT with an information-only control condition. Swedish-speaking adult internet users with alcohol dependence (3 or more *International Classification of Diseases, Tenth Revision* criteria) or harmful alcohol use (alcohol use disorder identification test>15) were included in the study. Participants in the therapist-guided ICBT and self-help ICBT groups had 12-week access to a program consisting of 5 main modules, as well as a drinking calendar with automatic feedback. Guidance was given by experienced therapists trained in motivational interviewing. The primary outcome measure was weekly alcohol consumption in standard drinks (12 g of ethanol). Secondary outcomes were alcohol-related problems measured using the total alcohol use disorder identification test-score, diagnostic criteria for alcohol dependence and alcohol use disorder, depression, anxiety, health, readiness to change, and access to other treatments or support. Follow-up was conducted 3 (posttreatment) and 6 months after recruitment.

Results: During the recruitment period, from March 2015 to March 2017, 1169 participants were included. Participants had a mean age of 45 (SD 13) years, and 56.72% (663/1169) were women. At the 3-month follow-up, the therapist-guided ICBT and control groups differed significantly in weekly alcohol consumption (−3.84, 95% Cl −6.53 to −1.16; t_{417}=2.81; *P*=.005; Cohen *d*=0.27). No significant differences were found in weekly alcohol consumption between the self-help ICBT group and the therapist-guided ICBT at 3 months, between the self-help ICBT and the control group at 3 months, or between any of the groups at the 6-month follow-up. A limitation of the study was the large number of participants who were completely lost to follow-up (477/1169, 40.8%).

Conclusions: In this study, a therapist-guided ICBT program was not found to be more effective than the same program in a self-help ICBT version for reducing alcohol consumption or other alcohol-related outcomes. In the short run, therapist-guided ICBT was more effective than information. Only some internet help-seekers may need a multisession program and therapist guidance to change their drinking when they use internet-based interventions.

Introduction

Background

Alcohol consumption causes substantial health loss. It is the leading risk factor for both mortality and disability-adjusted life years worldwide among those aged 15-49 years, with 3.8% of female deaths and 12.2% of male deaths attributable to alcohol use [1]. There are dose-response relationships between alcohol consumption and many major diseases [2]. Heavy use over time, as discussed by Rehm et al [3], is responsible for most of the attributable burden of disease, mortality, and social consequences of alcohol. When alcohol use is diagnosed as alcohol dependence (*International Classification of Diseases, Tenth Revision* [*ICD-10*]), it is characterized by impaired control and continued heavy use despite negative consequences [4]. The prevalence of alcohol dependence is estimated to be 2.6% worldwide and 3.7% in Europe [5]. In Sweden, 4% of adults are estimated to fulfill the diagnostic criteria for alcohol dependence [6].

Different interventions are available to reduce an individual's alcohol consumption. Brief interventions, often used in primary care settings, are effective in reducing alcohol consumption [7]. Psychological and pharmacological treatments have also shown effects in terms of reduced alcohol consumption (eg, cognitive behavioral therapy [CBT] vs minimal intervention, g=0.67 [8]) and in terms of abstinence from alcohol (eg, acamprosate vs placebo, g=0.36 [9]). However, there have been problems with the implementation of brief interventions; that is, health professionals have limited time or might be reluctant to address alcohol use [10]. Only approximately 7% of people with substance use disorders are estimated to receive at least minimal treatment [11]. Possible reasons for not seeking treatment are lack of access, shame, stigma, not wanting to change one's alcohol use, or a wish to deal with it by oneself [12,13].

Internet-based interventions can help overcome some of the problems associated with implementation, limited accessibility, and stigma [14]. The internet has developed over the past decades from being an alternative way of finding health-related information to being the common way. Approximately >85% of Swedes use the internet to find information about health or medicine, and approximately 40% do so at least every month [15]. Internet-based interventions for reducing alcohol use have been developed during the past 20 years [16] and include content similar to that of face-to-face interventions, such as personal normative feedback, motivational interviewing (MI), and CBT, intended to motivate the user to reduce their drinking and give them strategies to do so [17]. In a Cochrane review of digital alcohol interventions, including internet-based interventions (37/57, 65% studies), the effect compared with no or minimal interventions was 23 g (95% CI 15 to 30) of less alcohol consumed weekly. According to a recent individual patient data meta-analysis of internet-based alcohol interventions, the effect on alcohol consumption compared with various controls was −22 g less per week (95% CI −8.7 to −34.6) [18]. The same meta-analysis also found that guided internet-based alcohol interventions (with human guidance from health professionals or trained volunteers) are more effective than unguided (fully automated) interventions (−67.8 g alcohol per week, 95% CI −121.1 to −14.5).

However, most of the previous studies on digital and internet-based alcohol interventions have been on brief interventions, such as personal normative feedback, and have been limited to at-risk populations, such as students [17,19]. More extended internet-based alcohol interventions are intended to be used over a number of weeks or sessions and are usually internet CBT (ICBT), for example, based on treatments for alcohol dependence, such as relapse prevention or behavioral self-control training, often combined with principles from MI [19,20]. There are indications that longer, multisession interventions are more effective than shorter or single-session internet-based alcohol interventions [21]. A literature search of multisession internet-based alcohol interventions revealed 14 randomized controlled trials of ICBT aimed at drinkers among the general public with at least hazardous use [22-35] (see Multimedia Appendix 1 for further details). In 5 of these studies [23,25,27,28,35], ICBT as self-help was significantly more effective in reducing alcohol consumption than minimal control interventions or waiting lists. However, several previous large studies did not find a significant difference between self-help ICBT and minimal control [26,32,34]. Therapist-guided ICBT for alcohol was tested in 5 of the 14 previous studies and was found to be more effective than waiting list in 4 studies [22,27,28,35] and unguided self-help in 2 studies [24,28]. However, therapist-guided interventions were not more effective than self-help interventions in the 2 most recent studies on ICBT for alcohol [27,35]. Although many of the participants in previous studies of ICBT programs for alcohol have had alcohol use disorder identification test (AUDIT)–scores indicating a high level of alcohol-related problems, there is a need for studies on internet-based interventions that are aimed specifically at people with harmful use or alcohol dependence [19].

As described above, the effects of ICBT programs, as well as therapist-guided ICBT for alcohol, are still unclear. This could be explained by the fact that many trials have used small sample sizes and included users with different levels of problems (eg, included risky alcohol users), who may change their drinking more easily or to a lesser extent. Most previous studies have also used waiting list control conditions or open (unblinded)

design, possibly making the control groups disappointed or less likely to change [36]. In this study, the sample size was larger than in previous studies that investigated the effect of guided ICBT. The participants were also blinded to the interventions that the other participants received. The purpose of this randomized controlled trial was to investigate the effects of a web-based alcohol program with or without therapist guidance among anonymous adult help-seekers with harmful use or alcohol dependence.

Hypotheses

The hypotheses of the trial were:

1. A therapist-guided ICBT program would lead to a greater reduction in alcohol consumption and alcohol-related problems than information alone.
2. A self-help ICBT program would lead to a greater reduction in alcohol consumption and alcohol-related problems than information alone.
3. A therapist-guided ICBT program would lead to a greater reduction in alcohol consumption and alcohol-related problems than a self-help ICBT program.

Methods

Study Design

In a three-arm randomized controlled trial with a parallel design, participants were randomly assigned to an internet-delivered CBT (ICBT) program as self-help, with therapist guidance or information control in a ratio of 1:1:1 and a block size of 30. The trial was approved by the Stockholm Regional Ethical Review Board (No. 2014/1758-31/2).

Recruitment

Overview

Participants were recruited at the Swedish internet site Alkoholhjälpen [37], an open access website that provides information and a discussion forum for individuals seeking web-based help for alcohol consumption. The site has been publicly accessible since 2007. During the recruitment period of this study, Alkoholhjälpen had approximately 20,000 unique visitors every month and approximately 100 new forum posts every day. All service use was free of charge, and no advertising was allowed on the website. All visitors on Alkoholhjälpen from March 2015 to March 2017 were invited to participate in a study to develop and test different forms of internet-delivered support for changing alcohol habits. Interested users were informed that they would answer a survey and be randomized to one of three different forms of support but were not informed about the specifics. Adult individuals who gave their informed consent were instructed to create a personal account with a unique username and password. They were then directed to a screening page where they were required to give informed consent for participation in the study, answer demographic questions, questions in AUDIT [38], and questions about alcohol dependence (*ICD-10*) criteria.

Inclusion Criteria

Individuals were included if they had harmful use (defined as >15 total score in AUDIT) or alcohol dependence (defined as 3 or more *ICD-10* criteria). Registrants who did not meet either of these criteria were informed that they did not qualify for the study and were invited to use the open parts of the website. To be able to complete the registration, the participants needed to understand written Swedish and be computer literate enough to access and navigate the website via a computer, tablet, or smartphone. Before registering, potential participants were also informed that the interventions were not intended for users who were experiencing withdrawal symptoms, psychosis, schizophrenia, bipolar disorder, or suicidal thoughts.

Baseline Assessment

Eligible participants were asked to complete web-based baseline questionnaires, including primary and secondary measures (*Measures* section). All participants were treated as anonymous users. They were asked to provide an email address and a mobile phone number for notifications and follow-up reminders. Email and phone numbers were neither verified nor used for identification or for any other purposes. Participants whose assessments showed indications of an increased risk of suicide (Montgomery Asberg Depression Rating Scale–Self-rated [MADRS-S] item 9>3) at baseline or follow-up received a message offering additional support with phone numbers to call in case of emergency. No eligible participants were excluded based on baseline assessment. The baseline questionnaires were followed by a survey on why participants chose to use web-based services and their preferences regarding such services. Data from this survey will be presented elsewhere.

Randomization

Participants who completed the baseline measures were randomized according to a fully automated and concealed procedure on the web-based platform. Participants were assigned to one of 3 groups: (1) self-help ICBT: a self-help program; (2) therapist-guided ICBT: a program with web-based guidance from a therapist; or (3) control: information on changing alcohol habits. Participants were blinded to the kind of support received by participants in the other groups.

Intervention Groups

Self-help ICBT

Directly following randomization, the self-help ICBT group was given access to the program. The program was based on self-help materials used in previous studies on the internet and in specialist care [24,34,39,40]. Content and exercises in the program were based on MI [41,42], relapse prevention [43,44], and behavioral self-control [45,46]. The program was divided into 5 main modules, 3 extra problem-solving modules, and 10 fact sheets (refer list of modules in Table 1). The length of the program was approximately 17,000 words in total, with 5500 words in the extra modules and 3000 words in the fact sheets. The module texts were alternated with checklists and open questions that prompted the user to give their view of the content in relation to their own situation. The modules also included videos with examples or expert-interviews. Refer to Figure 1 for example pictures of the program. Automatic reminders with

suggestions on what module to work on were sent at 1-4, 6, and 8 weeks. Users were also encouraged to register alcohol consumption or craving, as well as details of the situation when they drank or experienced a craving. This was done in a private drinking calendar included in the web program, which could be used daily or for a whole week retrospectively. Continual feedback on the users' alcohol consumption was offered through a private statistics page. Here, users could see their average personal consumption in standard drinks weekly, monthly, and in total, as well as the number of days drinking, the number of days sober, and binge drinking occasions. In addition, they could also view a summary of their own risk situations. To allow participants to complete the modules at the recommended pace, with room for some delay, the participants had access to the program for 12 weeks after allocation.

Table 1. Program modules and number and percentage of participants in the therapist-guided and self-help internet-based cognitive behavioral therapy (ICBT) who used each module.

Module[a]	Therapist-guided ICBT (n=386), n (%)	Self-help ICBT (n=391), n (%)
Motivation (including brief feedback on assessment)	272 (70.5)	265 (67.6)
Drinking-goal and self-control	202 (52.3)	172 (43.8)
Behavioral analysis of drinking and risk situations	148 (38.3)	113 (28.8)
General problem solving	102 (26.4)	73 (18.6)
Handling cravings	103 (26.7)	72 (18.4)
Handling feelings	77 (19.9)	46 (11.7)
Drink-refusal skills	65 (16.8)	35 (8.9)
Preventing relapse	63 (16.3)	34 (8.6)

[a]All modules were available to the user from the start. Each module contained general information, audio or video, examples, and exercises. Additional fact sheets included in the program concerned blood alcohol level, anxiety, depression, anger, stress, managing thoughts, relaxation, sleep, leisure activities, and communication.

Figure 1. Program module on a computer and the drinking calendar on a smartphone.

Therapist-Guided ICBT

Participants in the therapist-guided ICBT group had the same access to the same program as the self-help ICBT described above but the drinking calendar and module answers were shared with a therapist. The therapist-guided ICBT group could communicate with the therapist through asynchronous SMS text messages on the intervention website during the 12 weeks of the program. The guidance from the therapist focused on motivating the user to continue using the program and change their drinking. Each time the participant had completed any of the modules, the therapist wrote personal feedback and answered any questions about the program via private comments on the web platform. The feedback highlighted parts of what the participant had stated in the exercises included in each module, which were important from an MI or CBT perspective. Users

who did not use or stopped using the program for several weeks were reminded by the therapist 2 times through personal messages on the website (with notification on mail). The 3 therapists involved had several years of experience on the Swedish alcohol helpline [47] and had all reached an approved level in phone-based MI before entering the study. They had been trained in ICBT and received regular supervision from the first author, who is a trained therapist with several years of experience with CBT and ICBT programs.

Control

The control group was given access to text-only information on changing their alcohol habits based on the text Alcohol and you [41]. The information material was equivalent to 5 pages of printed text.

All 3 groups also had access to the discussion forum on the website as well as facts on alcohol and health and information about how to find additional support within the health care or social welfare system. Communication between the server hosting the intervention and the participant was encrypted and protected with an individual login name and password.

Measures

Overview

Follow-up was conducted 3 (after treatment), 6, 12, and 24 months after recruitment. In this paper, the results from the 3- and 6-month follow-ups are presented. Primary and secondary outcomes were assessed at all time points.

Primary Outcome

The primary outcome was the difference between the groups in alcohol consumption and mean weekly standard drinks. The number of standard drinks each of the 7 days in the preceding week was self-reported using the timeline follow-back (TLFB) method [48]. One standard drink contains 12 g of pure alcohol, according to the Swedish definition. The TLFB has been shown to be a valid and reliable procedure to document recent drinking when administered via the internet [49] and in a 7-day version [50].

Secondary Outcomes

Alcohol-related outcomes were assessed with a number of different instruments. AUDIT [38] is a 10-item instrument that covers both alcohol consumption and problems and has been validated in Swedish and via the computer [51,52]. The total AUDIT score was used as a continuous measure of alcohol-related problems. For description at baseline as well as for assessment of nonimproved and deteriorated participants at the 6-month follow-up, the AUDIT score was categorized into 4 zones as follows: I nonproblematic, 0-6p; II hazardous use, 7-15p; III harmful use, 16-19p; and IV probable dependence, 20-40p. The sum of the 3 first items (AUDIT-C) was also used to assess alcohol consumption [53]. Alcohol dependence was assessed by the number of self-reported alcohol dependence criteria during the past year according to *ICD-10* [4]. Alcohol use disorder was assessed by the number of self-rated alcohol use disorder criteria during the past year according to the *Diagnostic and Statistical Manual of Mental Disorders* (Fifth Edition) (*DSM-5*) [54]. Measures of both alcohol dependence and alcohol use disorder diagnostic criteria were included to facilitate comparisons between the study population and diverse community and clinical populations reported in the research literature, where problem severity level can be assessed according to both *ICD-10* and *DSM-5*.

At the 3- and 6-month follow-ups, the time frame for AUDIT, *ICD-10*, and *DSM-5* was changed from 12 months to 3 months. The number of nondrinking days, number of binge drinking days (defined as ≥3 drinks for women and ≥4 drinks for men), the average number of drinks on drinking days, and low-risk consumption at follow-up (≤14 drinks per week for men and ≤9 drinks per week for women and no binge drinking) were also assessed using the TLFB. Health-related quality of life was assessed using the EuroQol-5 dimensions (EQ-5D-5L). An index score was calculated with Crosswalk value sets, using the United Kingdom as a reference [55,56]. Symptoms of depression were measured using the total score of MADRS-S [57,58]. Symptoms of anxiety were measured using the total score of the Generalized Anxiety Disorder Assessment-7 items (GAD-7) [59,60]. *ICD-10*, *DSM-5*, MADRS-S, and GAD-7-scores were categorized for description at baseline (see Multimedia Appendix 2 for details). Use of other support was assessed by 4 questions covering who and where participants talked to someone about their alcohol problems and which medication or which other internet resources they had used regarding alcohol.

Additional Measures

Readiness to change was measured at all time points with 2 visual analog scales [61], where users responded on a scale of 0-10 from “I am not ready to reduce/quit my drinking” (0) to “I am very much ready to reduce/quit my drinking” (10). Working alliance was measured 3 and 6 weeks after randomization when all participants were invited via one email and message to log in to the website and answer the Session Rating Scale [62] regarding the use of the website and the intervention that they had received. After each module in the program, users in the therapist-guided ICBT and self-help ICBT groups could rate, on a scale of 0 to 5 stars, how helpful they found the module to be. All uses of the intervention were logged for each user. Participants who completed 4 or more modules in the program were regarded as treatment completers.

Follow-up

Follow-up was conducted at 3 and 6 months after recruitment. Based on previous web-based studies, high attrition from follow-up could be expected [63]. Reminders and incentives [64] were used to prevent attrition without affecting the intended target group by forcing participants to have personal contact or identify themselves. At follow-up, participants were emailed a link or redirected when logging in on the intervention website to the follow-up questionnaires. The email included information that all participants who completed follow-ups would have a 0.8% (1/120) chance of receiving a free iPad. The same questionnaires, with all primary and secondary outcomes used at baseline, were also used at follow-up and adjusted for the time since the last assessment (3 months). Participants who did not respond to this initial request received up to 5 automated email reminders, a manual email reminder, and a mobile SMS

text message. Additional follow-ups at 12 and 24 months after recruitment have recently been completed but have not yet been analyzed.

Sample Size

Sample size was determined a priori using an effect-size estimate. We aimed to detect a Cohen *d*=0.2 in 2-group comparisons using 2-tailed *t* tests at follow-ups, which based on SDs from a study of alcohol treatment in primary care [40], equated to a between-group difference of Δmean=3.7 drinks. With α=.05 and 80% power, n=394 per group was required for the desired effect size, totaling n=1182. However, to allow analyses of observed data only, assuming 50% missing data at follow-up, the enrollment goal was increased to n=2400.

Analytic Plan and Statistical Procedure

All statistical analyses were two-sided tests and, unless otherwise specified, used a significance level of *P*<.05. Factorial analysis of variances was used to test differences in baseline measures between users who were retained and those who were lost to follow-up, including interactions between groups and lost to follow-up (at either 3 months or 6 months). Differences in categorical measures were analyzed using the chi-square test. All tests were performed using SPSS version 25 (IBM Corporation).

In accordance with the original protocol, differences in observed means at each follow-up were analyzed with *t* tests under the "missing at random" assumption; however, significant contrasts were supplemented with tipping point sensitivity analyses that systematically imputed missing data at a group level across a range of plausible mean values in the 2 nonrespondent groups (with the same SD) [65,66]. A custom R function was developed that, per contrast, created a matrix of all possible combinations of group-level imputed means (in steps of 0.1 and within the plausible range) of the 2 nonrespondent groups, calculated the new whole-group means and SDs, performed a *t* test using this summary data, and saved the *P* value. This allowed us to estimate the conditions under which (means among nonrespondents) the contrast would no longer be significant (tipping point), thereby testing the appropriateness of the "missing at random" assumption. Two-group *t* tests were corrected for multiple comparisons by considering *P*<.02 as significant, corresponding to the Bonferroni adjustment.

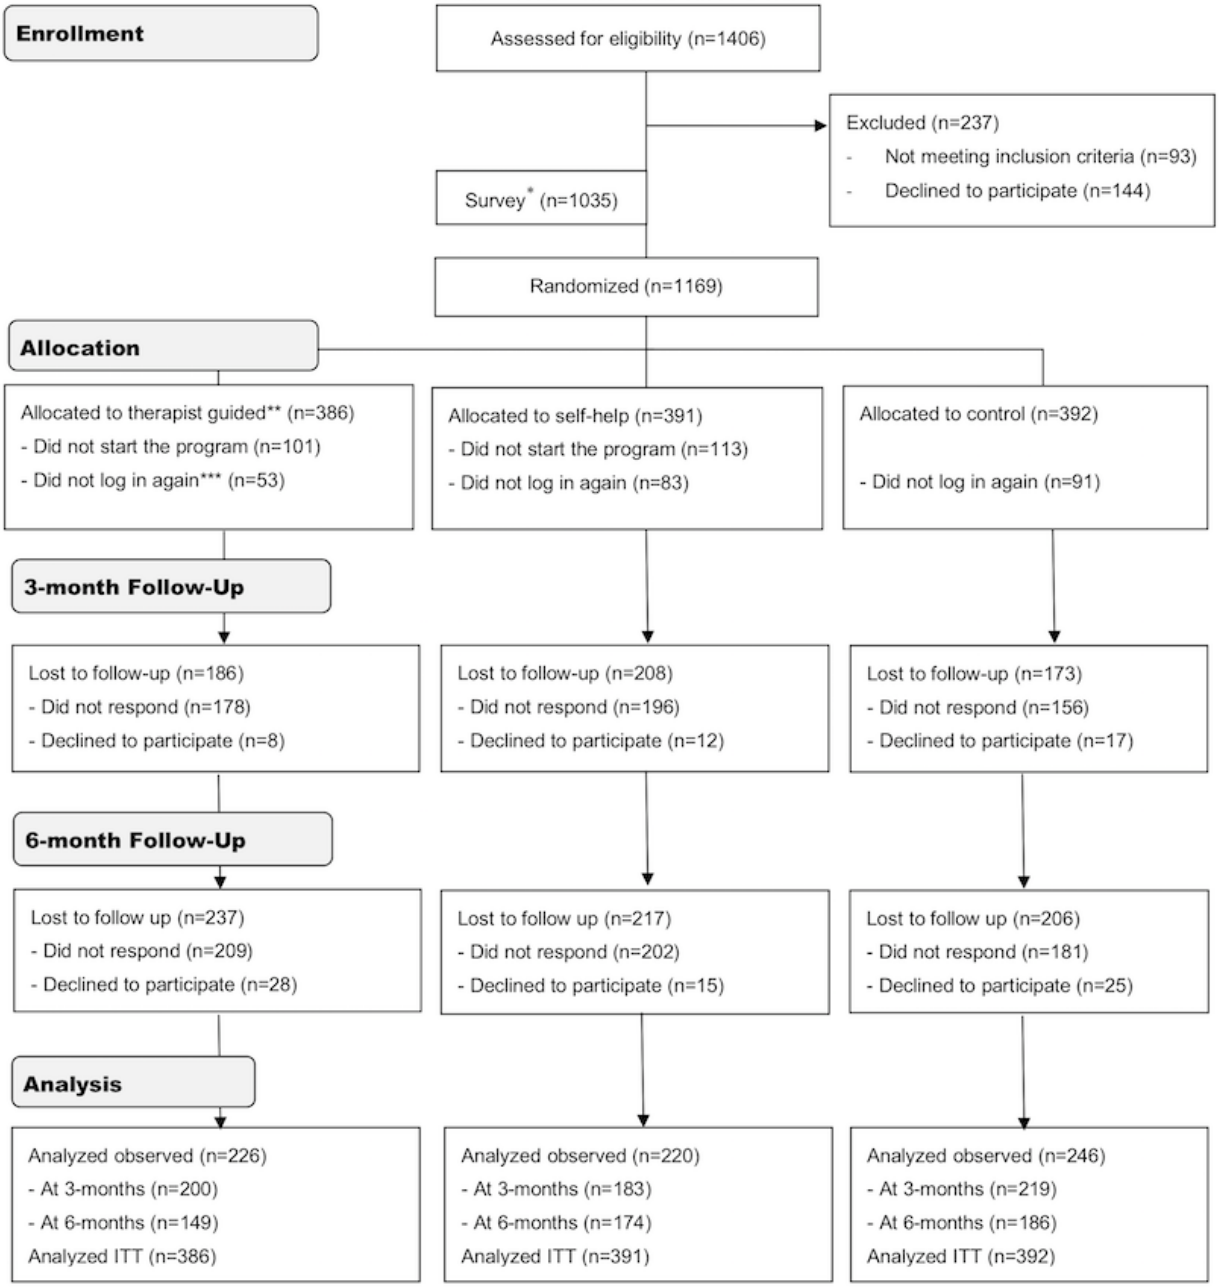
Before analyzing the data, the decision was made to supplement the original analytic protocol with mixed-effects modeling that would be fully compliant with the intention-to-treat principle and better equipped to handle the presumed high degree of missing data [63]. By modeling data at both group (fixed) and individual (random) levels, mixed models are well-suited for data from repeated observations (modeling clustering of data at an individual level) [67], and maximum likelihood estimation is used to handle missing data [68]. Analyzing outcomes with (generalized) mixed-effects models also allowed the use of family functions that were more appropriate for the distribution of the outcome. Weekly alcohol consumption (as well as other outcomes based on TLFB) was analyzed using generalized linear mixed models [69] with a negative binomial distribution and log link to avoid overestimation of effects [70]. AUDIT, *ICD-10*, *DSM-5*, GAD-7, MADRS-S, readiness, and EQ-5D-5L were analyzed with linear mixed models. Mixed-effects modeling was performed using SPSS 25. First, a random intercept model was specified to calculate an interclass correlation score [71]. After visually inspecting the average and individual growth curves, an unconditional model was specified by adding both linear and quadratic time (time^2) as predictors. A conditional growth model was then specified by adding the self-help ICBT and therapist-guided ICBT groups as dummy-coded variables to be compared against the control (reference), together with the time×group and time^2×group interactions. Different covariance structures for random effects and errors were tested, and a likelihood ratio test was used to assess which model best fitted the data [67]. There was a significant dependency among the observations (intraclass correlation=0.62) as well as significant individual variability in the initial level (intercept *P*<.001) and rate of change (slope *P*<.001) in the primary outcome.

Results

Participants

A total of 1169 participants were randomly allocated to the 3 study arms (refer to Figure 2 for the flow chart). This was lower than the target sample size required to adjust analyses on observed data only for estimated attrition at follow-up but only negligibly smaller than in the raw power calculation with estimated missing data (n=1182). Nonetheless, recruitment ceased after the prespecified 24 months recruitment window for funding reasons. Individuals who declined participation after the screening did not differ from those included in the AUDIT (mean 22.1, SD 5.6 vs mean 22.6, SD 6.5; t_{1308}=1.00; *P*=.32) or *ICD-10* (mean 4.2, SD 1.3 vs mean 4.2, SD 1.2; t_{1308}=0.10; *P*=.92) scores. The randomized participants had a mean age of 45 years (SD 13), and 56.72% (663/1169) were women. During the past year 5.05% (59/1169) had talked to someone in specialized care and 18.99% (222/1169) to a professional about their alcohol use. Participants indicated significantly higher mean readiness to reduce their drinking compared with mean readiness to quit drinking (mean 8.8, SD 1.9 vs mean 5.7, SD 3.6; t_{1168}=32.4; *P*<.001). The full demographic and clinical variables at baseline are shown in Multimedia Appendix 2.

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) flow diagram. *All included participants were asked to complete a survey on why they had chosen to use web-based services and their preferences regarding such services. **Overall, 390 users were randomized to the therapist group, but 4 of them (due to a temporary technical error) never completed the baseline assessment and were never allocated to the intervention. ***Users who did not log in a second time after allocation to intervention. ICBT: internet-based cognitive behavioral therapy; ITT: intention-to-treat.



Loss to Follow-up

Attrition was 49% at the 3-month and 66% at the 6-month follow-up. The number of participants who completed at least one of the follow-ups at 3 or 6 months was 692 (59.2%). There were no significant differences in the number of participants in each group who completed at least one of the follow-ups (X^2_2=3.5; *P*=.17). Comparisons between those lost to follow-up and those who completed at least one follow-up showed greater baseline drinking, as well as greater severity on most baseline measures, among those who were lost to follow-up (Table 2). However, no significant interactions between group assignment and being lost to follow-up were found for baseline outcome variables.

Table 2. Differences in baseline variables between participants who were lost to follow-up (both assessment) and those who completed at least one assessment (N=1169).

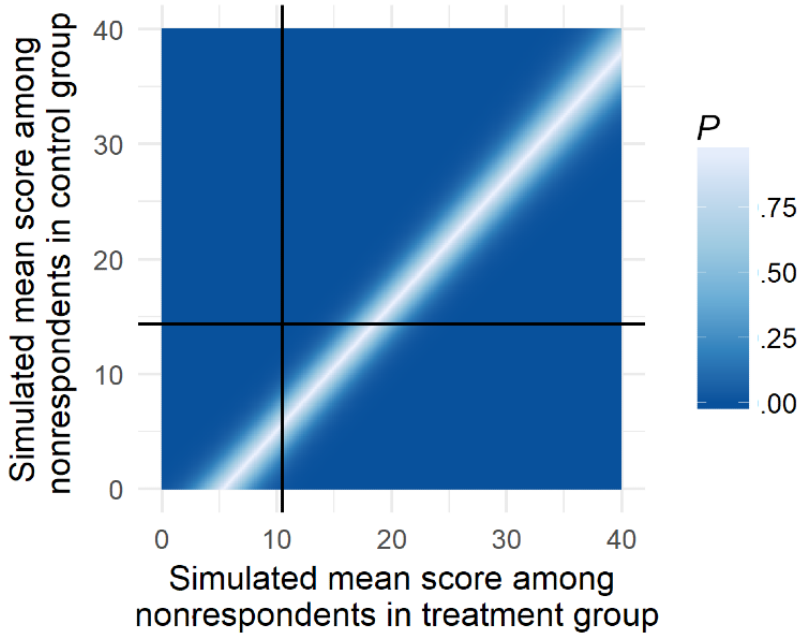
Differences in Observed Means

Outcomes at 3 Months (Posttreatment)

The therapist-guided ICBT group had significantly lower weekly alcohol consumption than the control group at 3 months (mean difference −3.84, 95% Cl −6.53 to −1.16; Cohen *d*=0.27). A tipping point sensitivity analysis revealed that missing data in the control group would need to have a mean of 11.0 to render this contrast insignificant (assuming missing at random in the therapist-guided ICBT group), or that the missing data in the therapist-guided ICBT group would need to have a mean of 13.6 (assuming missing at random in the control group). Refer to Figure 3 for the *P* value heat map for each of the possible combinations of imputed means among nonrespondents in the 2 groups. No significant differences in weekly alcohol consumption were found between the self-help ICBT group and the control group (mean difference −2.41, 95% Cl −5.53 to 0.71) or between the therapist-guided ICBT group and the self-help ICBT group (mean difference −1.43, 95 CI −4.26 to 1.40).

Figure 3. Tipping point analysis of significant contrast in primary outcome at 3 months.



At 3 months (posttreatment) there were significant differences between the therapist-guided ICBT group and the control group in the secondary outcomes AUDIT (mean difference −2.91, 95% Cl −4.33 to −1.50; Cohen *d*=0.39), AUDIT-C (mean difference −0.77, 95% CI −1.34 to −.20; Cohen *d*=0.26), *DSM-5* (mean difference −0.76, 95% CI −1.34 to −0.17; Cohen *d*=0.25), and *ICD-10* (mean difference −0.47, 95% Cl −0.82 to −0.14; Cohen *d*=0.26). A difference was also found between the self-help ICBT and control groups on the AUDIT (mean difference −1.95, 95% Cl −3.44 to −46; Cohen *d*=0.26) at 3 months. No significant differences in secondary outcomes between the therapist-guided ICBT and self-help ICBT were found at 3 months. See Multimedia Appendix 3 for details and Multimedia Appendix 4 for the tipping point analyses of secondary outcomes. Of the participants who completed the 3-month follow-up, 42.9% (258/602) reported low-risk alcohol consumption (14 or fewer drinks per week for men and 9 or fewer drinks per week for women and no binge drinking) at 3 months, with no significant differences between groups (X^2_2=1.9; *P*=.38).

Outcomes at 6 Months

There were no significant differences in weekly alcohol consumption among any of the groups at 6 months. The difference in means between the therapist-guided ICBT and control group was −0.60 (95 CI −3.70 to 2.50), between self-help ICBT and control group −0.45 (95% Cl −3.87 to 2.96), and between the therapist-guided ICBT and the self-help ICBT −0.15 (95% Cl −3.70 to 3.41). No significant differences in secondary outcomes were found among any of the groups at 6 months. Low-risk alcohol consumption was reported by 42.6% (217/509) of participants at 6 months, with no significant differences between the groups (X^2_2=0.2; *P*=.92). Participants reported no adverse events because of the intervention. Among participants followed up at 6 months, 3.3% (17/508) had changed their alcohol use to a more severe category according to AUDIT, and 19.5% (99/508) remained in the highest AUDIT category.

Post Hoc Intention-To-Treat Mixed Models Analysis

The mixed-model intention-to-treat analysis showed a significantly larger decrease in weekly alcohol consumption over time in the therapist-guided ICBT (time×therapist; *P*=.02) compared with the control but not in the self-help ICBT (time×self-help; *P*=.09) compared with the control (refer models in Table 3). A model comparing only the participants in the therapist-guided ICBT and self-help ICBT did not reveal any significant effect of group×time (*P*=.57). There was a significant decrease in weekly alcohol consumption over time for participants in all 3 groups according to the estimate of time in the unconditional model (*P*<.001).

Table 3. Post hoc mixed models of weekly alcohol consumption, alcohol-related problems, alcohol use disorder, and alcohol dependence[a].

Characteristics	Weekly drinks[b]		AUDIT[c,d]		AUDIT-C[c,e]		*ICD-10* [c,f]		*DSM-5* [c,g]

[a]Time was coded in 3-month-periods (0, 1 and 2). A model with quadratic time (time^2) was chosen since it fitted the data better than a model with linear time only. Reference group was control.

[b]Generalized linear mixed-model. Neg-binominal distribution, dispersion coefficient: 0.944. Covariance structure for random effects Variance component and for repeated effects Diagonal.

[c]Linear mixed-model. Covariance structure for random effects Variance component and for repeated effects First-Order Autoregressive.

[d]AUDIT: alcohol use disorder identification test.

[e]AUDIT-C: alcohol use disorder identification test consumption questions.

[f]*ICD-10*: *International Classification of Diseases, Tenth Revision*.

[g]*DSM-5*: *Diagnostic and Statistical Manual of Mental Disorders* (Fifth Edition).

[h]ICBT: internet-based cognitive behavioral therapy.

According to the mixed-model analysis of secondary outcomes, a significantly larger decrease in AUDIT over time was found for both therapist-guided ICBT and self-help ICBT compared with the control group, as shown by therapist-guided ICBT×time (*P*<.001) and self-help ICBT×time (*P*=.03). There were also significant therapist-guided ICBT×time group effects for the AUDIT-C (*P*=.01), *ICD-10* (*P*=.02), and *DSM-5* (*P*=.04) diagnostic criteria. No other significant time×group effects were found in the mixed-model analysis of secondary outcomes. Over time, there was a significant decrease among all participants on the AUDIT, AUDIT-C, *ICD-10*, *DSM-5*, MADRS-S, GAD-7, binge drinking days, and drinks on drinking days as well as a significant increase in EQ-5D-5L and nondrinking days. See Multimedia Appendix 5 for additional models.

Changes at follow-ups showed strong correlations between similar outcome variables, such as alcohol dependence and AUD, GAD7, and MADRS-S or weekly drinking and binge drinking days but only moderate or weak correlations between alcohol-related variables and other outcomes. Refer to Multimedia Appendix 6 for further details.

Intervention Use and Rating

The number of modules completed by the therapist-guided ICBT (mean 3.3, SD 3.5) was significantly higher (t_{775}=2.9; *P*=.004) compared with the self-help ICBT (mean 2.6, SD 3.2); however, there was no significant difference in the number of calendar entries (therapist-guided ICBT: mean 39, SD 61 and self-help ICBT: mean 37; SD 102; t_{776}=0.60; *P*=.58). In the therapist-guided ICBT, 39.9% (154/386) were treatment completers, and in the self-help ICBT, 30.4% (119/386) (X^2_1=6.5; *P*=.01). In the therapist-guided ICBT, 58% (224/386) sent at least one message to their therapists. They sent a mean 4.7 (SD 4.7) messages and received a mean 6.0 (SD 4.1) from their therapist. Refer to Table 1 for the details of program use. The number of participants who used the discussion forum was higher in the control group compared with the therapist-guided ICBT group (107/386, 27.7% vs 71/391, 18.2%; X^2_1=8.7; *P*=.003). However, there were no significant differences between self-help ICBT (88/392, 22.4%) and the therapist-guided ICBT or the control group in forum use. Of those who participated in at least one follow-up, 47% (325/692) answered that they had talked to a professional about their alcohol use since entering the study, there were no significant differences between the

groups. Participants gave a significantly higher rating of the working alliance with the intervention (Session Rating Scale) in the therapist-guided ICBT (mean 27, SD 11; t_{269}; $P<.001$) and self-help ICBT (mean 29, SD 10; 185/392, 47.1%; t_{305}; $P<.001$) compared with the information control group (mean 19, SD 12). The mean rating of program modules were 3.8 (SD 1.0) on a scale 0-5, with no difference in rating between the therapist-guided ICBT and the self-help ICBT ($t_{731}=0.69$; $P=.49$).

Discussion

Principal Findings

The aim of this web-based randomized controlled trial was to investigate the effect of a program for harmful alcohol use and alcohol dependence, delivered as self-help ICBT or therapist-guided ICBT. The results only partly confirmed the first hypothesis. Participants randomized to therapist-guided ICBT reduced their weekly alcohol consumption as well as alcohol-related problems (measured with AUDIT) and signs of alcohol use disorder significantly more than participants in the control group at the 3-month follow-up. These findings are in line with the results of previous studies on therapist-guided ICBT [22,24,27] but with smaller differences between the groups. The results did not confirm the second hypothesis. Self-help ICBT was not more effective than the control condition in changing alcohol consumption. This is in line with the results of the first study of Alkoholhjälpen [34] and 2 other large studies of publicly available services [26,31]. However, the self-help ICBT group did change their alcohol-related problems significantly more than the controls at 3 months. No support was found for the third hypothesis. There were no significant differences in changed drinking or other outcomes between therapist-guided ICBT and self-help ICBT. This finding differs from our pilot study [24] and the previous study by Blankers et al [28], in which therapist guidance was significantly more effective than self-help, but in line with recent studies by Boß et al [27] and Sundström et al [35].

A possible factor explaining the difference in results between trials could be the intensity of guidance [72]. Participants receiving therapist-guided interventions completed approximately 60% of the programs in the 3 trials for which data are available [22,24,27]. The study by Postel et al [22], showing the largest effects of a therapist-guided intervention, had a high level of guidance, whereas the study by Boß et al [27] had low intensity, with only 33% of the therapist-guided group using the guidance. In this study, 58% (224/386) of patients in the therapist-guided group used the guidance, which was neither low nor high in intensity compared with the previous studies. The differences between the groups were smaller than those in previous studies. This might be explained by the fact that the participants in this trial were blinded to group allocation, which reduced the risk of being negatively affected by being put in a control group [36,73]. The control group in this study reduced their alcohol consumption by 11 weekly drinks between baseline and the 3-month follow-up compared with, for example, 3 drinks for the waiting list in the study by Postel et al [22]. The difference between groups at 3 months faded at 6 months in this trial. The therapist guidance and program ended after 12 weeks; offering more extended support might have increased the effects at 6-months.

The results of this study also suggest that the decrease in alcohol consumption and related outcomes might result from factors other than the interventions that affected all participants or occurred before the randomization. A significant decrease in alcohol consumption and alcohol-related problems occurred in all 3 study groups in the first 3 months, and this decrease remained stable up to 6 months after inclusion. All study participants were recruited based on their initial harmful use or alcohol dependence. Regression toward the mean [74] could explain some of the decreases in alcohol use and other outcomes in all 3 groups. Participants were recruited from a website about changing alcohol use and could be characterized as help-seekers. Even though they did not know what kind of interventions they would receive, they had already taken steps in the direction of changing their alcohol consumption by signing up to the website. This was also indicated by the high mean readiness to change alcohol consumption (8.8/10). All participants also had to answer a large number of assessment questions about their alcohol, an activity that has been shown to lead to reductions in alcohol consumption [75,76].

All 3 groups in this trial had access to a well-established and moderated discussion forum, which might have affected their alcohol use [77,78]. Significantly more participants in the control group used the forum than in the therapist-guided ICBT group, which might indicate that some participants compensated for the lack of human contact in the intervention by using the forum. Symptoms of depression and anxiety were reduced, and health improved over time in all 3 groups but not more in those who received self-help ICBT or therapist-guided ICBT. This finding differs from findings by Boß et al [27], where a multisession program for risky drinking had a small-size effect on depression, stress, and anxiety at follow-up relative to control.

Generalizability

The generalizability is likely limited to Swedish-speaking people with harmful alcohol use or alcohol dependence seeking help for their drinking on the internet. This study tried to recruit participants that were as similar as possible to the intended target group of the intervention as used in regular service at Alkoholhjälpen. The trial was conducted in the same setting. Information on needed language skills and the limitations of the interventions in helping those with severe psychiatric problems were provided; however, no other criteria were used to exclude participants who fulfilled the criteria set for harmful use or alcohol dependence. There were no differences in alcohol-related problems (AUDIT) or dependence criteria (*ICD-10*) between those who accepted and those who declined participation. The high attrition rate also limits the generalizability of our results.

Strengths

This randomized controlled study of therapist-guided ICBT and self-help ICBT is one of the largest among anonymous internet help-seekers to date. The study reached a large number of people

with harmful use or alcohol dependence, most of whom had not previously received support from specialized care. The number of dependence criteria met by participants was similar to that in a recent Swedish clinical trial in specialized and primary care [40]. The participants in this study were relatively well-educated, full-time employed individuals with stable living arrangements and with equal representation of men and women. This represents most individuals with alcohol dependence [6], a population that is different from those who usually receive treatment for alcohol use disorders [79,80], but that might be reached with internet-based interventions.

Limitations

Despite great efforts to remind and reinforce participants to answer follow-up questions, attrition was high. Participants lost to follow-up showed some differences to those retained, a factor that limits the generalizability of the results. However, tipping point analyses and the fact that there were no significant arm×attrition interactions on outcomes suggest that no sampling bias was introduced as a result of the attrition. Attrition could be a consequence of allowing users to be relatively anonymous and having a fast and accessible way of signing up for the study, lowering the threshold for engagement. The high attrition also means that the power to detect effect sizes was smaller than planned. In the between-group comparison of the self-help and therapist-guided arms at the 3-month follow-up, observed sample sizes would have given 80% power to detect an effect size of $d>0.29$, which is to be considered a small difference. However, we cannot rule out that the true difference is smaller than this. Adherence to the program was relatively low, with only 30.4% (119/391) completers in the self-help ICBT and 39.9% (154/386) in the therapist-guided ICBT, which is consistent with previous studies on ICBT (Multimedia Appendix 1). Higher adherence might improve the effects of the internet-based program. Owing to the web-based setting, the participants did not go through a clinical diagnostic interview, and some participants may not have been diagnosed as having alcohol dependence had an interview been included in the study design.

Future Directions

There is still a need for more studies on multisession internet-based interventions for harmful alcohol use and alcohol dependence, including studies with long-term follow-ups. No differences between the groups were found in number of participants that reported low-risk drinking at follow-ups. Only some internet help-seekers might need ICBT and therapist guidance to change their drinking when they use internet-based interventions. Others who did not improve might have benefited from more intensive support. A model of support-on-demand or accelerated care could be tested in future studies on the internet. One important challenge for future studies is to improve follow-up rates and adherence to interventions without reducing the willingness to use the interventions. Increased demands on users to identify themselves or have contact with a professional might make people who wish to remain anonymous or feel ashamed or stigmatized more reluctant to seek support [81]. Treatment-seeking increases the rates of recovery from alcohol dependence [82], and internet-based interventions seem to be a possible way to reach individuals currently not seeking treatment [83]; however, it is still unclear whether internet-based interventions actually increase treatment-seeking. Research on other psychiatric disorders [84] and on internet-based alcohol interventions so far [17] suggest that therapist-guided internet treatment has effects comparable with those of face-to-face treatment; however, more studies are needed that directly compare these interventions, as a recent study by our group has done [85]. In sparsely populated countries such as Sweden, where some people have to travel far to visit a clinic in person, psychological treatment [86], medical management [87], and after care [88] could, in part, be handled with internet-based interventions. More studies are needed to understand how internet-based interventions can be used effectively to improve treatment for people with alcohol dependence.

Conclusions

In this study, a therapist-guided ICBT program was not found to be more effective than the same program as a self-help ICBT for reducing alcohol consumption or other alcohol-related outcomes. In the short run, therapist-guided ICBT seems to be more effective than information. Only some internet help-seekers might need a multisession program and therapist guidance to change their drinking when they use internet-based interventions.

Acknowledgments

The authors would like to thank the therapists at Alkoholhjälpen—Rosette Lind, Liselott Sahlberg, and Karin Romberg—who delivered guided treatment.

Abstract

Background: Cognitive stimulation therapy appears to show promising results in the rehabilitation of impaired cognitive processes in attention deficit hyperactivity disorder.

Objective: Encouraged by this evidence and the ever-increasing use of technology and artificial intelligence for therapeutic purposes, we examined whether cognitive stimulation therapy implemented on a mobile device and controlled by an artificial intelligence engine can be effective in the neurocognitive rehabilitation of these patients.

Methods: In this randomized study, 29 child participants (25 males) underwent training with a smart, digital, cognitive stimulation program (KAD_SCL_01) or with 3 commercial video games for 12 weeks, 3 days a week, 15 minutes a day. Participants completed a neuropsychological assessment and a preintervention and postintervention magnetoencephalography study in a resting state with their eyes closed. In addition, information on clinical symptoms was collected from the child´s legal guardians.

Results: In line with our main hypothesis, we found evidence that smart, digital, cognitive treatment results in improvements in inhibitory control performance. Improvements were also found in visuospatial working memory performance and in the cognitive flexibility, working memory, and behavior and general executive functioning behavioral clinical indexes in this group of participants. Finally, the improvements found in inhibitory control were related to increases in alpha-band power in all participants in the posterior regions, including 2 default mode network regions of the interest: the bilateral precuneus and the bilateral posterior cingulate cortex. However, only the participants who underwent cognitive stimulation intervention (KAD_SCL_01) showed a significant increase in this relationship.

Conclusions: The results seem to indicate that smart, digital treatment can be effective in the inhibitory control and visuospatial working memory rehabilitation in patients with attention deficit hyperactivity disorder. Furthermore, the relation of the inhibitory

control with alpha-band power changes could mean that these changes are a product of plasticity mechanisms or changes in the neuromodulatory dynamics.

Introduction

Inhibitory control deficit is one of the core impairments in attention deficit hyperactivity disorder (ADHD) [1,2]. This deficit is directly related to the levels of impulsiveness present in the symptoms of ADHD [1,3-5] and produces difficulties in the everyday activities of those afflicted [6] while adversely affecting academic performance [7]. According to the literature reviewed, other impairments can be found in ADHD including the performance of cognitive processes, such as working memory [8], sustained attention [9,10], alternating attention [11], and planning [12,13].

In ADHD, the indices of inhibition, task switching, and emotional control appear to be related to relative power values of the alpha frequency band (7-13 Hz) in midline brain regions measured at resting state [14,15] and with performance in attentional tasks [16]. These patients consistently present a decrease in the alpha band in the central and posterior regions [17-24], as well as an increase in the theta frequency band (3-7 Hz) and the theta: beta ratio [17-21,25-28]. The decrease of the alpha band in regions that engage the default mode network (DMN; active network at resting state which includes the caudate nucleus, medial prefrontal cortex, posterior cingulate cortex, hippocampus, inferior parietal lobe, cerebellum, and precuneus) could modulate impairments in the functional connectivity of this network [29-33]. These impairments in the DMN also seem to be related to inhibitory control deficits [34,35].

Cognitive stimulation therapy appears to be effective in patients with ADHD [36]. The progressive increase of the workload in cognitive stimulation tasks is one of the main treatment dynamics of this type of therapy [37], and there are many examples of its effectiveness in ADHD and other disorders [38-42]. Its effectiveness seems to stem from the fact that these increases in the workload in cognitive tasks trigger an increase in long-distance connections supported by alpha and beta bands, and a decrease in short-distance connections supported by delta and theta bands [43-46].

Although the increase of the workload in cognitive stimulation tasks has shown promise in neurocognitive rehabilitation in children with ADHD, a case-based reasoning (CBR) system [47] that allows the adaptive workload to increase for each patient has never been used. The CRB system has been successful in various clinical areas [48-50], but its efficacy in a digital treatment for rehabilitation of neurocognitive alterations and its relation to electrophysiological dynamics and its efficacy in the rehabilitation of clinical alterations in ADHD remain unknown. With the aim of providing evidence, we examined whether a CRB digital training regimen would be effective in an ADHD child population after 12 weeks using the continuous performance test (CPT) inhibitory control measure as the main outcome. We hypothesized that after the intervention, the inhibitory control, as a core symptom of ADHD, would show a better performance and that this would be related to changes in the alpha band in the posterior regions and the DMN according to magnetoencephalography (MEG). We also tested whether treatment-produced changes in secondary outcomes would be related to ADHD and, finally, whether it could decrease the clinical symptoms associated with ADHD and change those behaviors related to executive functioning.

Methods

The study was approved by the local ethics committee of the San Carlos Hospital (Madrid, Spain). All legal representatives of the participants gave their written informed consent to participate in the study. This clinical trial is registered in the ISRCTN registry (ISRCTN71041318).

Participants

A total of 41 children diagnosed with combined-type ADHD (ADHD-C) were recruited (34 males). Contact with participants' legal guardians was made through health facilities, schools, and associations in the community of Madrid. Research staff first contacted those private and public clinical centers asking for permission and agreement to recruit. The order in which centers were contacted was at random. The following recruitment actions were performed: emailing study information, phone calls, and teleconferences and webinars with legal guardians summarizing study information. Participants' legal guardians who agreed to participate authorized communications with research staff. Eligibility criteria were checked by phone and email with legal guardians prior to visit 1. Before any other study activity, legal guardians read and signed an informed consent. There were no artificial intelligence (AI) requirements for the eligibility.

To be eligible, participants had to meet the following 5 criteria: (1) aged 8 to 11 years; (2) diagnosis of ADHD-C by an authorized professional (chartered psychiatrists at the medical college); (3) cessation of ADHD medication 3 days before each visit day, as, according to the technical specification of the drug methylphenidate (Concerta), it has a half-life of 3.5 hours (90% is excreted in urine and 1 to 35 in feces as a metabolite at 48-96 hours); (4) maintenance of the same level of medication during the at-home intervention period; and (5) compliance with the intervention protocol.

ADHD diagnosis was performed by accredited expert professionals following the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) criteria. These diagnostic criteria were the same across all participants. The average time from ADHD diagnosis confirmation to study enrollment was 2.58 (SD 1.21) years.

Participants meeting any of the following 5 exclusion criteria were dropped from the trial: (1) the initiation or abandonment of behavioral therapies or psychoactive drugs during the at-home intervention period; (2) motor difficulties which made the use of the mobile device (tablet or smartphone) impossible; (3) use of psychoactive drugs (such as benzodiazepines) which could have acted as a confounding factor, presence or suspicion of substance abuse for the past 6 months; (4) presence of blindness or uncorrected visual acuity difficulties; and (5) any additional psychological diagnosis.

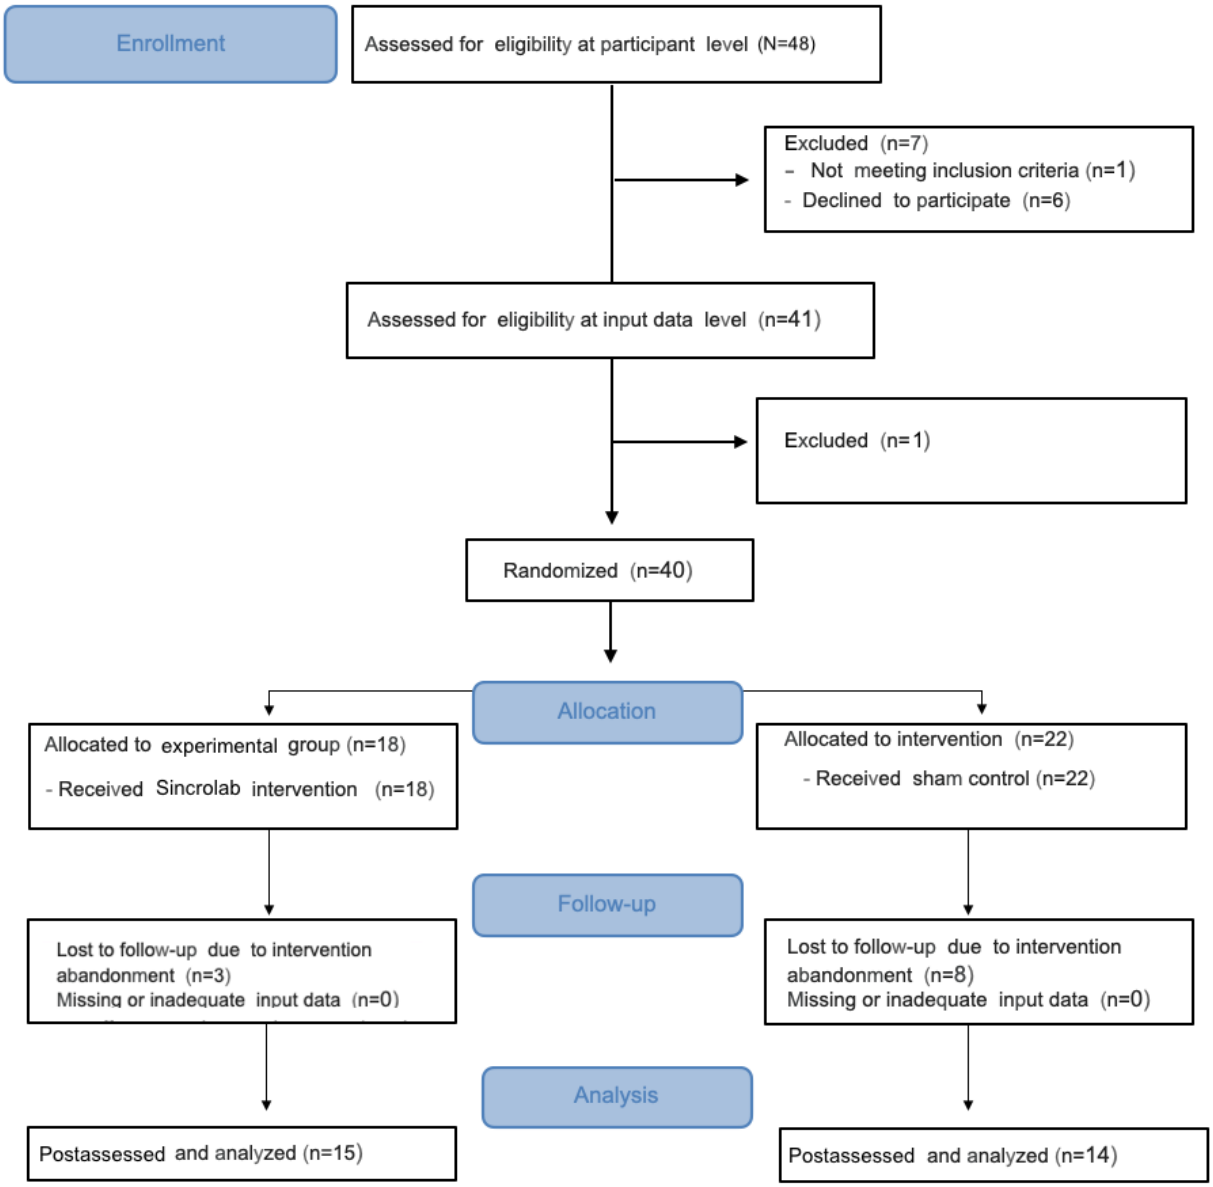
The inclusion criterion at the level of input data for the AI was a diagnosis of ADHD-C by an authorized professional in order to register the patient on the platform.

The use of other psychoactive drugs different from those approved by the Spanish Agency of Medicines and Medical Devices or European Medicines Agency for pediatric ADHD intervention (dextroamphetamine, levoamphetamine, lisdexamphetamine, methylphenidate, atomoxetine) also made participants ineligible for the study. The compliance was checked at the beginning and the end of the participant's participation through the child's legal guardians.

From the initial pool of 41 volunteers, 40 were randomly allocated into 1 of the 2 trial conditions (experimental or control). Of these, 28% (n=11) dropped out during the intervention period (control=8, experimental=3). One participant did not the meet inclusion criterion of stopping ADHD medication prior to treatment. The Consolidated Standards of Reporting Trials (CONSORT) 2010 flow diagram is presented in Figure 1.

From the final sample of 29 participants, 20 were taking pharmacological interventions (experimental=9, control=11), 7 participants were taking nonpharmacological interventions such as psychological interventions (experimental= 4, control=3), and 4 were taking both (experimental=2, control=2). The pharmacological interventions were based on methylphenidate (Concerta; n=7), methylphenidate (Equasym; n=7), methylphenidate hydrochloride (Medikinet; n=2), lisdexamphetamine (Elvanse; n=2), and methylphenidate hydrochloride (Rubifen; n=2).

Figure 1. Consolidated Standards of Reporting Trials flow diagram.



Experimental Design

This was single-center, parallel, single-blind, randomized controlled trial that examined a pediatric population (8-11 years) diagnosed with ADHD of combined presentation. It was conceptualized as a proof-of-concept study intended to assess the preliminary efficacy of a digital, videogame-like, cognitive stimulation therapy, as well as its safety and engagement. Proof-of-concept trials are useful in the framework of novel drugs and devices, so knowledge regarding their administration (eg, dosing, user instructions) may be acquired in small samples in order to develop larger clinical trials [51,52].

Digital Intervention

Experimental Condition

KAD_SCL_01 games are designed to work on different cognitive processes with an increase of the cognitive load following evidence that the brain's reconfiguration networks seem to be fixed by this type of training routine [43-46,53]. The 14 games which compose the KAD_SCL_01 cognitive intervention are described in Multimedia Appendix 1. The game level is adapted based on a case-based reasoning algorithm. This algorithm and the human-AI interaction are described in Multimedia Appendix 2.

Control Condition

Participants received a sham intervention composed of 3 videogames which were not specifically designed to improve

cognitive performance [54]. The specifications are described in Multimedia Appendix 3. The sham intervention tasks are accessible through Kongregate open-access platform (Kongragate Inc).

Main Outcome Measure and Magnetoencephalography

Main Outcome Measure

The main outcome measure of this study was the change in score found in the commission score from Conners CPT (CPT-III) between both groups' differences (pre- and postintervention) [55]. Commissions in CPT-III as a measure of inhibitory control was chosen as main outcome measure due to its use as an efficacy intervention measure in several previous studies about the methylphenidate effect in ADHD [56].

Magnetoencephalography

Neurophysiological data were acquired using a whole-head Elekta-Neuromag MEG system with 306 channels (Elekta AB) at the Center for Biomedical Technology (Madrid, Spain). MEG data were collected at a sampling frequency of 1000 Hz and online band-pass filtered between 0.1 Hz and 330 Hz.

Head shape was defined relative to 3 anatomical locations (nasion and bilateral preauricular points) using a 3D digitizer (Fastrak), and head motion was tracked through 4 head-position indicator coils attached to the scalp. Eye movements were monitored by a vertical electrooculogram assembly composed of a pair of bipolar electrodes.

Other Cognitive Outcome and Clinical Outcome Measures

The secondary cognitive outcome, aimed at measuring other several aspects of cognitive processing, and clinical questionnaires on ADHD behavioral symptoms and executive functioning in daily activities are included in Multimedia Appendix 4.

Safety and Compliance

Intervention safety was assessed through adverse events. Potential adverse events were monitored and recorded during the intervention period. Intervention dropouts were also recorded in order to assess compliance with intervention protocol.

Study Procedure

The study procedure occurred in 4 stages: recruitment and screening, preintervention assessment (visit 1), at-home intervention, and postintervention assessment (visit 2). Recruitment and screening were carried out as described in the Participants section. The details of the Al are described in Multimedia Appendix 5.

Preintervention and postintervention assessments were performed at the Center for Biomedical Technology, at the Technical University of Madrid. Assessments were carried out by a blinded Sincrolab researcher (JB) who only knew the number associated with the participant. Assessments including neuropsychological batteries and MEG recordings were administered in the same order as reported here. Questionnaires for the clinical outcome measures were filled out by the legal guardians. The cognitive assessment lasted for approximately 60 minutes. The resting-state MEG was also recorded during visits 1 and 2. The order in which participants received both was counterbalanced.

The intervention allocation was created by a nonblinded Sincrolab researcher (RM) and performed with a simple randomization function, with a ratio of 1:1 and an allocation probability of 0.50. Intervention allocation was performed once the eligibility criteria were met, according to the 2010 CONSORT statement [57].

The intervention was scheduled for 12 weeks, with 3 sessions (15-20 minutes each) per week in both groups. The whole intervention period was telematically monitored. Both the KAD_SCL_01 and sham control platforms allowed for a daily checking of performed sessions for a nonblinded Sincrolab researcher (RM). The number of weekly intervention sessions performed by the participants was monitored to ensure compliance with the 12-week intervention protocol. Safety and adequacy (the number of games played and the consecutive extreme punctuations of 0 or 100 in the performance, which could reflect an issue in the calibration of the AI outputs) were also assessed. Legal guardians were contacted by study staff in order to report any adverse event.

Right after the at-home intervention period was over, participants who achieved at least 80% completion of intervention sessions (28 alongside the 12 prescribed weeks) were appointed for postintervention assessment with same characteristics as the preintervention one. After the postintervention assessment, the participants who were allocated in the control arm were offered training with the KAD_SCL_01 for 12 weeks.

Statistical Analyses

Data analysis in this proof-of-concept randomized trial followed a per-protocol approach [58]. A per-protocol population was defined as any participant who had been randomly allocated to 1 of the 2 conditions (experimental or control), complied with at least an 80% completion of scheduled sessions (28 of 36), and had received the postintervention assessment.

Statistical Analyses of Cognitive Outcome Measures

Descriptive statistics of average, distribution shape, and scatter were calculated. Standardized statistics of asymmetry and kurtosis were used to assess the normality assumptions of each distribution. These standardized statistics are calculated by dividing the statistic between its SE.

Next, cognitive outcome measures which did not deviate from normality were adjusted to mixed-effects models. Each model was adjusted with a random intercept and fixed slope (due to the number of repeated measures). An unstructured covariance matrix (Sigma) was estimated for the random effect factor. Robust restricted maximum likelihood was chosen as the estimation method of preference due to its robustness with small samples and its capability to estimate an unbiased parameter matrix in the presence of missing values. A stepwise method was used for age as a demographic covariable in the main outcome's mixed model as a method applied to explicative models.

As the commission score from CPT-III was set as main outcome measure, only 1 comparison was performed (1 dependent variable). Therefore, no correction for multiplicity was applied. Regarding the rest of the cognitive outcome measures, every *P* value under significance α value of .05 was taken as statistically significant due to the exploratory nature of this pilot study. Still, *P* values were corrected for multiple comparisons under a Bonferroni correction within a statistical family. The outcome measures from the different cognitive processes (ie, visuospatial working memory) were treated as independent statistical families for Bonferroni adjustments.

Effect sizes greater than 0.4 (considered as the minimum practical effect size [59] in the experimental condition but not in the control condition) were highlighted. Likewise, for the main outcome, the predictive positive value (PPV) was estimated, as the small sample size could have led to overestimation of the effect size. Due to the novelty of this type of training methodology, a priori effect size and unspecified prestudy odds (*R*=0.5) were used in order to estimate the PPV.

Respondent analysis was also performed over the main cognitive outcome measure (commission score on CPT-III) in order to study the proportion of participants per intervention arm who achieved a pre-post difference of at least 0.64 SD, according to other literature [56]. Moreover, with consideration to this a priori effect and because the estimated sample size could not be achieved, post hoc power analysis for the mixed model's interaction component was carried out with 200 simulations, and PPV was computed following the procedure in Button et al [60].

Statistical Analyses of Clinical Outcome Measures

Clinical outcome measures were standardized according to Behavior Rating Inventory of Executive Function (BRIEF) and Evaluación del Trastorno por Deficit de Atención e Hiperactividad (EDAH) standardized scores (*T* scores). Paired-samples *t* tests were performed over each outcome measure and in each intervention group. Respondent analysis was also performed on the EDAH outcome measures by counting the proportion of participants who reached the cutoff point of pathology set by the interpretation of the EDAH manual for each condition. BRIEF and EDAH were treated as independent statistical families for Bonferroni adjustments.

Magnetoencephalography Signal Preprocessing and Statistical Analyses

With the intention of facilitating this paper's interpretation, signal preprocessing analyses are detailed in Multimedia Appendix 6.

Regarding the statistical analyses of the MEG preprocessed signal, the aim of this study was the detection of any robust correlation between power ratio values derived from the clusters of nodes localized in certain brain regions and CPT's commission ratio (CPT commission postintervention or CPT commission preintervention). The goal of this methodology included the extraction of any neurophysiological markers whose dynamic could be associated with the evolution of the inhibition-control performance. Such analysis relied on network-based statistics [61,62]. Clusters were built according to a criterion of spatial and frequency adjacency. Each cluster consisted of several adjacent nodes, which systematically showed a significant partial correlation (with age as the covariate) in at least 4 consecutive frequency steps (a 1-Hz interval) between their corresponding power ratio values and CPT ratio (Spearman correlation coefficient *P* value <.05). Importantly, all nodes within a cluster needed to show the same sign of the correlation coefficient for the cluster to be considered a functional unit. Only clusters involving at least 1% of the nodes (ie, a minimum of 12 nodes) in each frequency step were considered. Cluster-mass statistics were assessed through the sum of the Spearman ρ values across all nodes and significant frequency steps.

To control for multiple comparisons, the entire analysis pipeline was then repeated 5000 times, with the correspondence between power ratio estimates and CPT ratio being shuffled across participants. At each repetition, the maximum statistic of the surrogate clusters (in absolute value) was kept, creating a maximal null distribution that would ensure control of the familywise error rate at the cluster level. Cluster-mass statistics on each cluster in the original data set were compared with the same measure in the randomized data. The network-based statistics *P* value represented the proportion of the permutation distribution with cluster-mass statistic values greater or equal to the cluster-mass statistic value of the original data.

Power ratio values were averaged across all nodes and frequencies that belonged to the cluster. This average was considered to be the representative MEG marker value for that cluster and further participated in subsequent correlation analyses. Therefore, the statistics presented in the results section was derived from the correlation between the averaged power ratio value of each significant cluster and the corresponding CPT ratio for each participant. As already mentioned, correlations were first performed within the whole sample. In a second step, correlations between the average power ratio and the CPT commission ratio scores were performed independently for both intervention conditions within the sample (experimental and control). Statistical analyses were carried out using MATLAB R2020b (Mathworks Inc).

Sample Size Justification

A priori sample size was estimated to detect a standardized mean difference of 0.64 SD in the commission score from the CPT-III [56], with a significance level of α=.05 and a power of 0.8 (1-β=.8). The calculation procedure followed the sample size estimation for a 2-tailed, 2-samples mean difference with a correction factor for repeated measures [63]. The total sample size required was 56, but the actual sample was 29. Nevertheless, sample sizes of between 10 and 15 participants per condition are well-supported in similar literature [64-66].

The last enrolled participant ended study procedures in February 2020. With the COVID-19 crisis and the consequences in Spain (since March 2020), the study sponsor and principal investigator (FM) decided to stop the recruitment procedures due to difficulties and in order to assure protocol compliance in 2020. Therefore, assuming the exploratory nature of this pilot randomized trial, it was decided that the statistical analysis plan be applied to the presented sample.

Results

Demographic and Baseline Characteristics

Baseline demographics and other characteristics in each group, as well as the between-group comparison, are shown in Table 1. No significant differences were found between groups.

Table 1. Demographic characteristics in the experimental and control conditions.

Characteristic	Experimental group, (%)[a] (N=15)	Control group, (%)[a] (N=14)	*t* or X^2	*P* value
Age (years)	9.2 (1.21)	9.71 (1.33)	1.09	.27[b]
Males	13 (44.8)	12 (41.4)	0.005	.94[c]
Using medication	9 (31)	11 (37.9)	1.17	.28[c]
Receiving psychological treatment	4 (13.8)	3 (10,3)	0.11	.74[c]

[a]The characteristic of age is expressed as mean (SD).

[b]*P* values are from a *t* test (between-participant, 2-tailed).

[c]*P* values are from a chi-squared test (2-tailed).

Safety and Compliance

Three adverse events were reported by legal guardians during the at-home intervention period (Multimedia Appendix 7). Dropout (n=11) details are shown in Multimedia Appendix 8.

Main Outcome

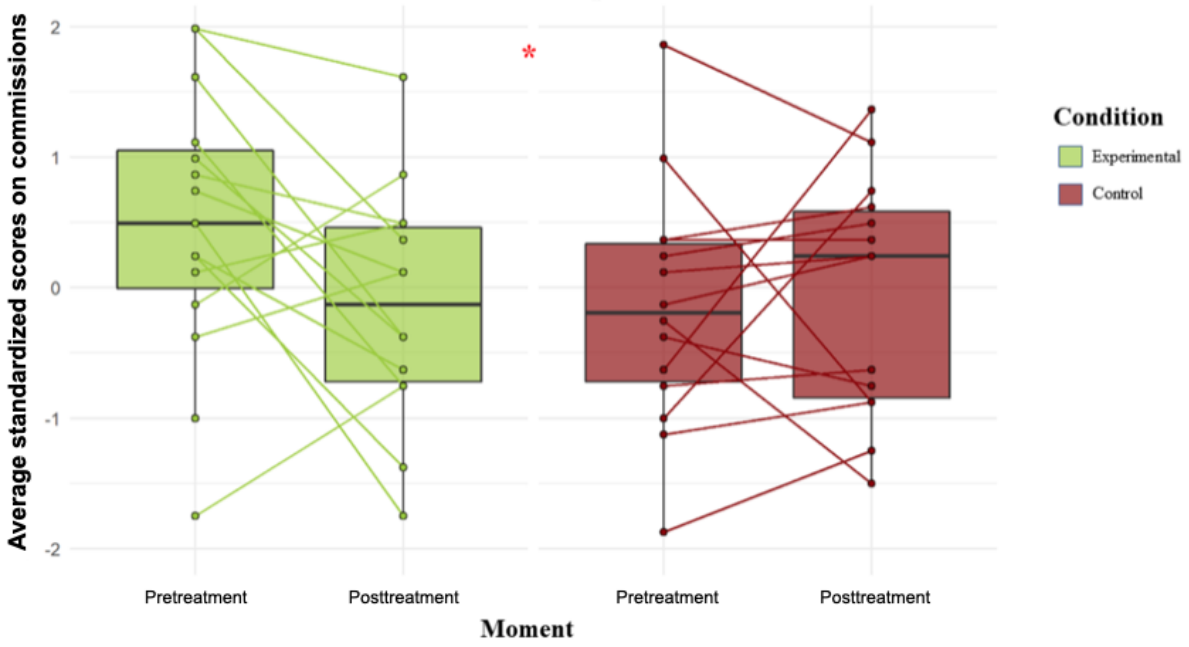
Descriptive statistics for the main outcome measure in each condition at each study period are shown in Table 2. The evolution trend (pre-post training) of each participant and the distribution of each group is shown in Figure 2. No statistically significant difference was found between the conditions (experimental and control) in the preintervention (baseline) measures (t_{27}=1.72; *P*=.10). Critical ratios for skewness indicated no deviations in skewness or kurtosis in the normal distribution.

Table 2. Descriptive statistics for main outcome measure commission score on Conners continuous performance test (CPT-III).

Descriptive statistic	Treatment group		Control group	
	Pretreatment	Posttreatment	Pretreatment	Posttreatment
Mean (SD)	53.87 (8.37)	47.80 (8.21)	48.79 (7.53)	49.64 (7.32)
Asymmetry	–0.37	–0.17	0.28	–0.09
Kurtosis	–0.61	–0.76	–0.33	–1.52
CR[a] asymmetry	–0.32	–0.15	0.23	–0.08
CR kurtosis	–0.27	–0.34	–0.14	–0.66

[a]CR: critical ratio.

Figure 2. Main efficacy outcome: individual and average change in commission errors from Conners continuous performance test per condition.



Mixed-effects models for main outcome measured with and without interaction effects were estimated with the robust restricted maximum likelihood procedure. The stepwise introduction of the condition-period interaction effect significantly improved the model adjustment (X^2_1=4.596; *P*=.03). Standardized mean difference (β estimator) for the condition-period interaction effect in the final model (Figure 2) was statistically different from 0 (β=.86; SE 0.39; t_{27}=2.21; *P*=.04). The standardized mean differences (β estimators) for model comparison (baseline model to final model) are shown in Multimedia Appendix 9. Comparison criteria (Akaike information criterion and Bayesian information criterion) between the models, in addition to model performance statistics (R^2 and adjusted R^2), are also reported in Multimedia Appendix 9. The graphical diagnosis for the final model with interaction effect is shown in Multimedia Appendix 10.

Pre-post standardized mean differences per condition were calculated as Hedges g statistic for effect size. A large pre-post standardized mean difference (g>|0.4|) was found in the experimental group (g=–0.62), but not in the control group (g=0.1). A high PPV (PPV=0.81) was found to be related with the pre-post standardized mean difference.

Respondent analysis for the main outcome measure shows that 53.33% (8/15) of the experimental participants (KAD_SCL_01 intervention) achieved the a priori clinically meaningful effect: an improvement of at least 0.64 standardized points. In the control arm, this percentage was just 21.42% (3/14). More details about respondent analysis are shown in Multimedia Appendix 11.

A post hoc power analysis yielded a statistical power of 43% (1 – β=0.43) for the detection of the condition-period interaction effect and a PPV of 0.81. A priori effect size was used to simulate post hoc power rather than observed effect size.

Magnetoencephalography Outcomes

A significant cluster (*P*=.04) was found in the frequency interval (11.67-13.33 Hz) mainly comprising the posterior regions of the brain (see Figure 3A and Table 3).

The power ratio in all frequencies of this interval negatively correlated with the CPT ratio across the whole sample (ρ=–0.562; *P*=.003). The maximum cluster size was found at 12-12.33 Hz (51 nodes). The cluster size oscillated between a minimum of 50 nodes at the beginning of the frequency range and 16 at the end of that frequency range (see Figure 3B). Furthermore, 12 Hz showed the highest average correlation coefficient value across all nodes of the cluster ρ= –0.547).

The correlation between the CPT commission ratio and the power ratio (11.67-13.33 Hz) in the interval within the cluster generated in the previous step remained significant for the experimental group (ρ=–0.783; *P*=.004; Figure 3C) but not for the control group (ρ=–0.358; *P*=.21; Figure 3C).

Figure 3. Brain region whose magnetoencephalography alpha power (11.67-13.33 Hz) was found significantly correlated with CPT commission ratio. (A) Brain regions within the significant cluster (depicted in blue). (B) Evolution of the cluster size through the different frequency steps (maximum size at 11.75 Hz). (C) Scatter plot showing the Spearman correlation coefficient between the cluster's average power ratio and CPT commission ratio and each subgroup of the sample. CPT: continuous performance test; Freqs: frequency steps.

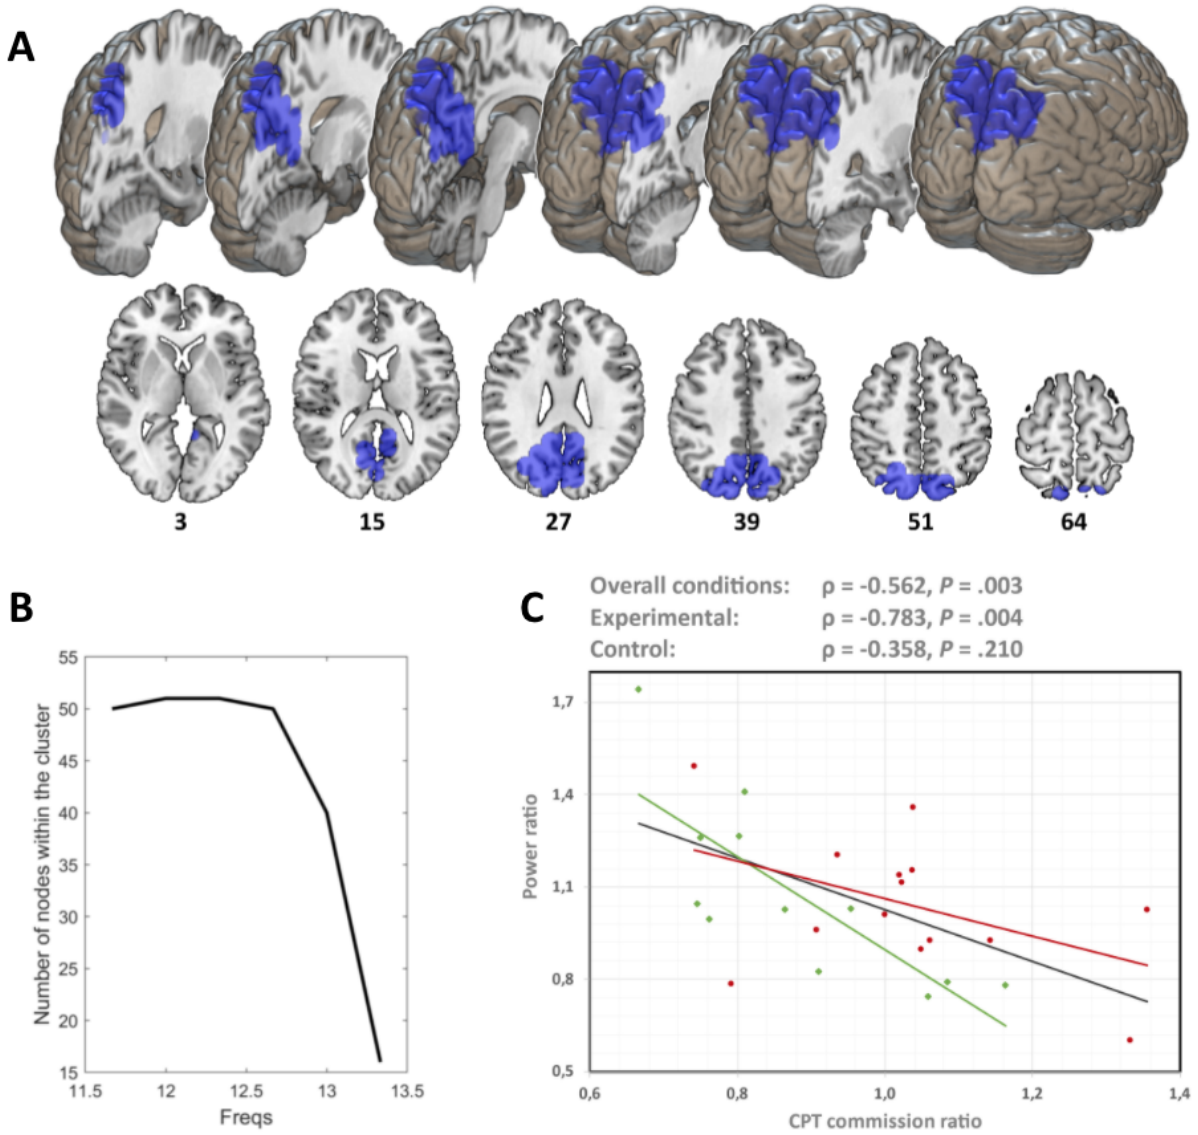


Table 3. The automated anatomical labeling atlas ROIs[a] that were partially captured by the significant cluster.[b]

ROI	Portion of ROI occupied, n/N (%)[c]
Left precuneus	11/28 (39.29)
Right precuneus	8/21 (38.10)
Left cuneus	7/11 63.64)
Right cuneus	7/13 (53.85)
Right superior parietal gyrus	6/18 (33.33)
Left cingulate gyrus, posterior part	3/5 (60.00)
Right superior occipital lobe	3/10 (30.00)
Left superior parietal gyrus	2/16 (12.50)
Right cingulate gyrus, posterior part	1/4 (25.00)
Left calcarine fissure and surrounding cortex	1/20 (5.00)
Left superior occipital lobe	1/11 (9.09)
Right middle occipital lobe	1/17 (5.88)

[a]ROI: region of interest.

[b]Regions of interest are from the Anatomical Labeling Atlas that are part of the significant cluster where the continuous performance test commission ratio correlates with power in the alpha band.

[c]N is the number of magnetoencephalography sources in our head model that are contained within the ROI volume; n indicates how many sources, among the corresponding N, are enclosed within the significant cluster; and % is the percentage of each ROI that was captured by that cluster.

Other Cognitive and Clinical Outcomes

Descriptive analysis for each secondary outcome measure is shown in Supplementary Material (Multimedia Appendix 12). No statistically significant differences were found between conditions (experimental and control) in preintervention measurement.

The mixed-effects model analysis was performed the for main outcome measure. Only, the backward span score (from the Corsi block-tapping test) as a dependent variable (X^2_1=4.64; *P*=.03) was significant. The standardized mean difference for the condition–moment interaction effect (β estimator) in the final model was statistically different from 0 (β =–.84; SE 0.38, t_{27}=–2.24; *P*=.03). Multimedia Appendix 13 shows the graphical representation of the average pre- and postintervention standardized scores for each intervention group (experimental and control) in this outcome measure. Standardized mean differences and CIs for cognitive secondary outcomes are shown in Multimedia Appendix 14, as classified by the cognitive process each measures (inhibitory control, cognitive flexibility, working memory, short-term memory, attention, speed processing, and verbal fluency).

Effect sizes of g>0.4 in the experimental group but not the control group were found in 19 cognitive secondary outcome measures, plus the main outcome. In contrast, only 1 cognitive secondary outcome measure showed a greater effect size (g>0.4) in the control group compared to the experimental one. See Multimedia Appendix 15 for the complete analysis.

The results in the parent version of the BRIEF questionnaire showed statistically significant pre-post mean differences, favoring the KAD_SCL_01 intervention participants in shifting score (t_{14}=2.32; *P*=.03), working memory score (t_{14}= 2.43, *P*=.02), behavioral composite index (t_{14}=2.62, *P*=.02), and general executive composite index (t_{14}= 2.7, *P*=.01). No significant differences in the sham intervention group were found. The experimental arm (KAD_SCL_01 intervention) showed statistically significant pre-post mean differences in all EDAH measures (hyperactivity score *P*=.05), inattention score (*P*=.001), behavior disorder score (*P*=.001), and global score (*P*=.001). The control arm also showed statistically significant pre-post mean differences in inattention score (*P*=.001), hyperactivity + inattention, and global score (*P*=.002), but not in hyperactivity or behavior disorder score. Respondent analysis, descriptive analysis, *t* statistics, *P* values, CIs, and respondent percentage per score in the EDAH scale are detailed in Multimedia Appendix 16.

No statistically significant differences were found between conditions (experimental and control) in the preintervention measurement either in the BRIEF or the EDAH outcome measures.

Discussion

Empirical evidence points suggests that cognitive stimulation based on progressive workload increments leads to improvements in cognitive performance [38-42,67], along with beneficial regulation of cortical activity patterns [43-46,53].

The results in our study indicate that cognitive intervention triggers significant improvements in inhibitory control in child and adolescent patients with ADHD as measured by Conners CPT-III. Moreover, this improvement in inhibitory control seems to be similar to that found in pharmacological studies on the effectiveness of methylphenidate [68]. Meanwhile, the effect size of our study (g=0.62) is consistent with that found in the meta-analysis by Losier et al [56] on the effectiveness of the

drugs used in ADHD. Therefore the digital treatment proposed in the present study could be a therapeutic option complementary to the pharmacological route.

Despite there being no significant differences between the groups in the measure of previous treatment (P=.09), the possible differences between both groups could be producing a type I error or false-positive result. However, as observed in Figure 2, within the range of 1 to –1 SD, 7 of the 10 patients who received the KAD_SCL_01 treatment show an improvement in their performance (70%). On the contrary, 6 of 9 participants belonging to the control group, in the same range, show worse scores in the postintervention measure.

Although several studies have reported that digital cognitive exercises do not show effects superior to those found in other commercial video games not intended for therapeutic uses [37,69,70], these findings, like those reported by Davis et al [41] and Kollins et al [42], seem to indicate that adaptive digital training, built on a proven empirical basis, could be effective for the treatment of ADHD.

The relationship between alpha-band power and performance in tasks involving attentional and inhibitory control processes has been published in recent publications [14-16,71,72]. In order to clarify the relationship between the changes in inhibitory control and the possible changes in alpha band power—given its association with performance in inhibitory control tasks [14,15]—we completed a MEG registry of the participants of both groups. The results seem to indicate that there is a direct relationship (ρ=–0.56; P=.003) between the improvement in inhibitory control and the alpha-band power in the posterior brain areas. These changes in the power of brain oscillations appear to be associated with brain plasticity processes [73]**,** as well as changes in the dynamics of neuromodulators such as dopamine [74] that are affected in these patients. This relationship remained significant when the experimental group (ρ= –0.78; P=.004) was analyzed separately, but this was not the case with the control group (ρ= –0.35; P=.21). This suggests that the improvements produced in the experimental group are strongly associated with the previously mentioned plasticity and neuromodulation phenomena.

Although this was intended as a power study, we believe our results are relevant to the functional connectivity literature due to the participation of the precuneus and posterior cingulate cortex in the main cluster examined of this paper. These 2 regions of interest conform to the posterior part of the DMN. Consequently, the alpha-power increment linked with the CPT decrement may be associated, under our interpretation, with an improvement in the functional integrity of the DMN. The decrease in alpha-band power in regions of the DMN could be mediating the impairments present in ADHD in the functional connectivity of this network [75-77] and its neurocognitive correlate [34,35,78]. This effect seems to be due to frequency band having special importance in the communication between the regions of this network [33]. In this regard, the data from Sonuga-Barke and Castellanos [79] seems to indicate that the decrease in connectivity between the regions of the DMN generates interference in the task-oriented network, producing impairments in the performance of patients with ADHD [79]. From this perspective, this digital cognitive stimulation intervention, based on progressive workload increases governed by CBR algorithms, might be effective for the treatment of ADHD.

One of the secondary objectives of the study was to measure the effectiveness of the intervention on a set of cognitive processes that are usually part of the ADHD deficits. The results indicate that cognitive intervention triggers improvements in visuospatial working memory total score. Moreover, practical minimum effect size (g> 0.4) was observed in visuospatial working memory span and in visuospatial working memory total score, while numeric working memory total score or numeric working memory span seemed to be not be affected by the treatment. These results are similar to those found by another digital study, which based its training on empirical principles [41]. In our study, no significant differences were found in other measures. However, these results might be due to a type II or false-negative error, since small sample sizes frequently generate this type of error [80]. Indeed, we found a practical minimum effect size in 12 of the 42 secondary outcome indices, which is a possible indicator of treatment efficacy. In contrast, the control group showed equivalent effects in just 1of the 42 secondary measures (see Multimedia Appendix 15 for detailed information).

Finally, in this study, the parent version of the BRIEF questionnaire was used to obtain a measure of executive functions in everyday life. The results indicate that cognitive training triggers significant changes in flexibility, working memory, and the composite indices of both behavior and executive functions. These changes appear to be similar to the effects of methylphenidate-based pharmacological treatments [81] and treatments administered by clinical professionals for executive functions [82].

In the ADHD rating scale, in the overall rating, 60% (9/15) of the participants who underwent cognitive training exceeded the cutoff point (<30), compared to 21% (3/14) who worked with commercial video games, which seems to indicate that this type of cognitive training may have positive effects on the behavioral impact of the disorder.

In conclusion, this study reports the preliminary results of a digital cognitive stimulation intervention in a population with ADHD. The results suggest that such treatment is effective at improving inhibitory control and visuospatial working memory in patients with ADHD. Moreover, this improvement was observed in the executive measures of daily life and was associated with a reduction of symptoms.

The main limitation of the study relates to the small size of the sample (N=29) compared to the a priori calculated sample size (N=56). Consequently, the statistical power was lower than the one desired a priori. Therefore, these results must be interpreted as the first evidence of a digital treatment using CBR algorithms, and more extensive studies are needed to confirm the findings of this proof-of-concept study.

Acknowledgments

This study was funded by Sincrolab and partly funded by the Centre for the Development of Industrial Technology of the Spanish Ministry of Economy, Industry, and Competitiveness.

Authors' Contributions

Author contribution: RM, JB, IR, JQ, and FM designed research; JB, LAT, and PC conducted the research; RM, JB, LAT, and PC analyzed data; and RM, JB, IR, LAT, JQ, JARQ, and FM wrote the paper.

Conflicts of Interest

Sincrolab provided financial support in the form of salaries used for partial salary support for the authors. PC received punctual financial support for carrying out the magnetoencephalography analysis. Sincrolab participated in the study design, data analysis, decision to publish, and preparation of the manuscript. IR is the cofounder of Sincrolab. JQ and JARQ are members of the Scientific Board of Sincrolab. JQ is also a shareholder of Instituto Neuroconductual de Madrid Ltd and a speaker on the advisory board for Takeda & Jansen. He also receives investigation funding from the Carlos III Health Institute. JARQ was on the speakers' bureau and/or acted as a consultant for Janssen-Cilag, Novartis, Shire, Takeda, Bial, Shionogi, Sincrolab, Novartis, Bristol Myers Squibb, Medice, Rubió, Uriach, and Raffo in the last 3 years. He also received travel awards (air tickets and hotel) for taking part in psychiatric meetings from Janssen-Cilag, Rubió, Shire, Takeda, Shionogi, Bial, and Medice. The Department of Psychiatry chaired by JARQ received unrestricted educational and research support from the following companies in the last 3 years: Janssen-Cilag, Shire, Oryzon, Roche, Psious, and Rubió. RM and JB are employees of Sincrolab. The other authors have no conflicts of interest to declare.

Abstract

Background: Digital health interventions (DHIs) are efficacious for several mental disorders in youth; however, integrated, evidence-based knowledge about the mechanisms of change in these interventions is lacking.

Objective: This systematic review aims to comprehensively evaluate studies on mediators and mechanisms of change in different DHIs for common mental disorders in children and adolescents.

Methods: A systematic literature search of the electronic databases Cochrane Central Register of Controlled Trials, Embase, MEDLINE, and PsycINFO was conducted, complemented by backward and forward searches. Two independent reviewers selected studies for inclusion, extracted the data, and rated the methodological quality of eligible studies (ie, risk of bias and 8 quality criteria for process research).

Results: A total of 25 studies that have evaluated 39 potential mediators were included in this review. Cognitive mediators were the largest group of examined intervening variables, followed by a broad range of emotional and affective, interpersonal, parenting behavior, and other mediators. The mediator categories with the highest percentages of significant intervening variables were the groups of affective mediators (4/4, 100%) and combined cognitive mediators (13/19, 68%). Although more than three-quarters of the eligible studies met 5 or more quality criteria, causal conclusions have been widely precluded.

Conclusions: The findings of this review might guide the empirically informed advancement of DHIs, contributing to improved intervention outcomes, and the discussion of methodological recommendations for process research might facilitate mediation studies with more pertinent designs, allowing for conclusions with higher causal certainty in the future.

KEYWORDS

children and adolescents; mental disorders; mediator; mechanisms of change; digital health intervention; psychotherapy; mobile phone

Introduction

Background

Mental disorders in children and adolescents are common, with prevalence rates ranging from 10% to 20% worldwide [1]. These disorders contribute substantially to the global burden of disease in youth [2], and about half of all mental disorders across the life span have their onset in adolescence [3]. Hence, early psychotherapeutic interventions are essential to counteract the risk of chronification and prevent possible negative long-term effects [1]. However, a substantial proportion of children and adolescents with mental disorders do not receive adequate psychotherapeutic or psychosocial care [4-6] owing to different

individual and structural barriers to treatment uptake [7]. Furthermore, the availability of mental health care is often insufficient to adequately meet treatment demands, particularly in rural regions [8] and low-income countries [9].

Digital health interventions (DHIs), such as internet- and mobile-based interventions with a psychotherapeutic focus (DHI_{PSY}), offer the possibility of addressing some barriers to treatment uptake and might contribute to extending mental health care, given their various presumed advantages, such as possible cost- and time-efficient use, independence from spatial and temporal circumstances, potential anonymity, high degrees of flexibility, and autonomy for users. These assets may be especially important during the COVID-19 pandemic and allow for continued mental health care despite contact restrictions and physical distancing [10]. Furthermore, in view of the fact that youth are particular familiar with digital devices (so-called *digital natives*; Children in a digital world [11]), the use of DHIs might be especially appealing to this younger age group [12]. DHIs can be distinguished and characterized based on their theoretical basis, the type of technical implementation, the area of application, and the extent of accompanying human support [13,14]. The type and the intensity of *guidance* in DHIs can vary on the continuum from (1) pure self-help interventions without any human support (so-called *unguided interventions*) to (2) interventions with some support (*guided interventions*), to (3) videoconference-based psychotherapy with the internet as the sole communication medium between therapists and patients [15].

The efficacy of DHI_{PSY} for some common mental disorders in children and adolescents has been established using meta-analyses [12,16-19]. For example, Vigerland et al [19] evaluated the efficacy of internet-based cognitive behavioral therapy for a range of mental disorders, including anxiety, depression, behavioral problems, obsessive-compulsive disorder, and some somatic disorders such as chronic pain and insomnia. This meta-analysis revealed a moderate, aggregated effect size favoring internet-based cognitive behavioral therapy over waitlist (g=0.62, 95% CI 0.41-0.84; P<.001). In contrast, Hollis et al [20] appraised the evidence on the efficacy of DHI_{PSY} for other mental disorders, including attention-deficit/hyperactivity disorder, autism, psychotic disorders, and eating disorders in their review as uncertain and necessitating future research regarding moderators of intervention effects. Current empirical knowledge suggests that older children and adolescents benefit more from DHI_{PSY} than younger children [12,20]. In addition, the well-established finding that guided interventions are more efficacious than unguided interventions in adults [21,22] also seems to apply for DHI_{PSY} in youth [12,20]. Complementing the evidence base and representing another major area of application, DHIs with a focus on health promotion (DHI_{HP}), for example, on alcohol consumption or other lifestyle and health behaviors, revealed a considerably smaller effect size (Cohen d=0.14, 95% CI 0.00-0.27) [23] when compared with DHI_{PSY} with a genuine psychotherapeutic foundation such as cognitive behavioral therapy (g=0.72, 95% CI 0.55-0.90; P<.001) [16].

Given this rather heterogeneous body of research regarding the efficacy and effectiveness of DHIs, comprising various interventions with different theoretical orientations, foci, and delivery modes, for mental health issues in children and adolescents, it seems both timely and worthwhile to investigate the presumed working mechanisms in these technology-delivered interventions. This is because evidence-based knowledge on the mediators and mechanisms of change (specific for different approaches of DHI_{PSY} and DHI_{HP}) can inform intervention development and mental health care practices, illustrating pathways to more powerful intervention packages and improved outcomes [24-26]. The first step in understanding the underlying processes in DHIs is to analyze the mediators. A mediator is an intervening variable that can explain the statistical relationship between an independent variable (eg, a DHI) and a dependent variable (eg, a symptom change) [25], and can thereby potentially point to a mechanism through which an intervention achieves its effects. Although various methods for statistical mediation analysis are available (eg, MacKinnon et al [27]), comprising different approaches such as latent growth curve modeling [28] or structural equation modeling [29], the seminal approach of Baron and Kenny [30] is still one of the most applied procedures to evaluate the intervening variable effect of a potential mediator, despite having received criticism with regard to some limitations, such as low statistical power, difficulties in the assessment of multiple mediators, or quantification of the mediation effect magnitude [24]. Although statistical mediation may be established either with the so-called causal-steps approach by Baron and Kenny [30] or by more recent methods correcting some of its limitations (eg, Kraemer et al [31]), it is important to consider that mediators might be identical to a mechanism of change (ie, the actual process responsible for change), but might also be a proxy for 1 or more other variables that do not explain the hypothesized mechanism [25]. Thus, to determine the degree of validity that a mediator is actually representative of for being considered a true change mechanism, Kazdin proposed several quality criteria for psychotherapy process research [25] that can be consulted when assessing the scope and justification of causal inferences: (1) Strong association (among treatment, mediator, and outcome), (2) specificity (a mediator accounts for the indirect effect of treatment on outcome), (3) consistency (the association must be replicable), (4) experimental manipulation (use of either a randomized controlled trial [RCT] design where the intervention variable is manipulated or an experimental design where the mediator itself is directly manipulated), (5) timeline or temporality (the intervention must lead to changes in the mediator, which must temporally precede changes in the outcome), (6) gradient (ie, a dose-response relationship: greater activation of the mediator is associated with greater change in the outcome), and (7) plausibility or coherence (the proposed mediator must be embedded in a plausible theoretical framework).

The evidence base for the mediators and mechanisms of change in conventional face-to-face psychotherapies for children and adolescents is scarce, and only a few studies have been designed to investigate the therapeutic processes in these interventions

[32]. For example, 2 systematic reviews dedicated to evaluating the mechanisms of change found that only a small number of eligible primary studies actually conducted mediation analyses, with only 9% (6/67) [33] and 17% (8/46) of included clinical trials [34] attempting to evaluate mediation effects. In addition, Schmidt and Schimmelmann [35] reviewed the empirical literature on mediators in psychotherapeutic interventions for common mental disorders in youth and concluded that most eligible studies evaluated mediators referring to the parent-child interaction (eg, family cohesion and parental support), next to mediators within the patient (eg, self-efficacy, motivation, coping, interpersonal skills, as well as changes in dysfunctional cognitions and negative emotions) and characteristics of the intervention (eg, duration of treatment, number of patient-therapist contacts, and application of specific intervention techniques). The included studies revealed inconsistent patterns of mediation effects related to therapist factors, such as flexibility, adherence to treatment, or therapeutic alliance [35]. Moreover, as central conceptual and methodological requirements for mediation analyses were often not met by studies in this review, causal inferences were widely precluded, necessitating future process research with higher methodological rigor [35].

Objectives

Although research on DHIs is a fast growing field [36] and might also offer intriguing opportunities for psychotherapeutic process research [24,37], we are not aware of any systematic review of the mediators and mechanisms of change in DHI_{PSY} and DHI_{HP} for common mental disorders in youth published to this point. Therefore, this study aimed to: (1) systematically review the current state of research on mediators and mechanisms of change in various DHIs for mental disorders in children and adolescents, (2) identify mediators and potential mechanisms of change in these interventions, and (3) evaluate the methodological quality of eligible mediation studies according to the quality criteria for process research mentioned above.

Methods

This systematic review was reported in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [38] and was a priori registered with the Open Science Framework [39].

Eligibility Criteria

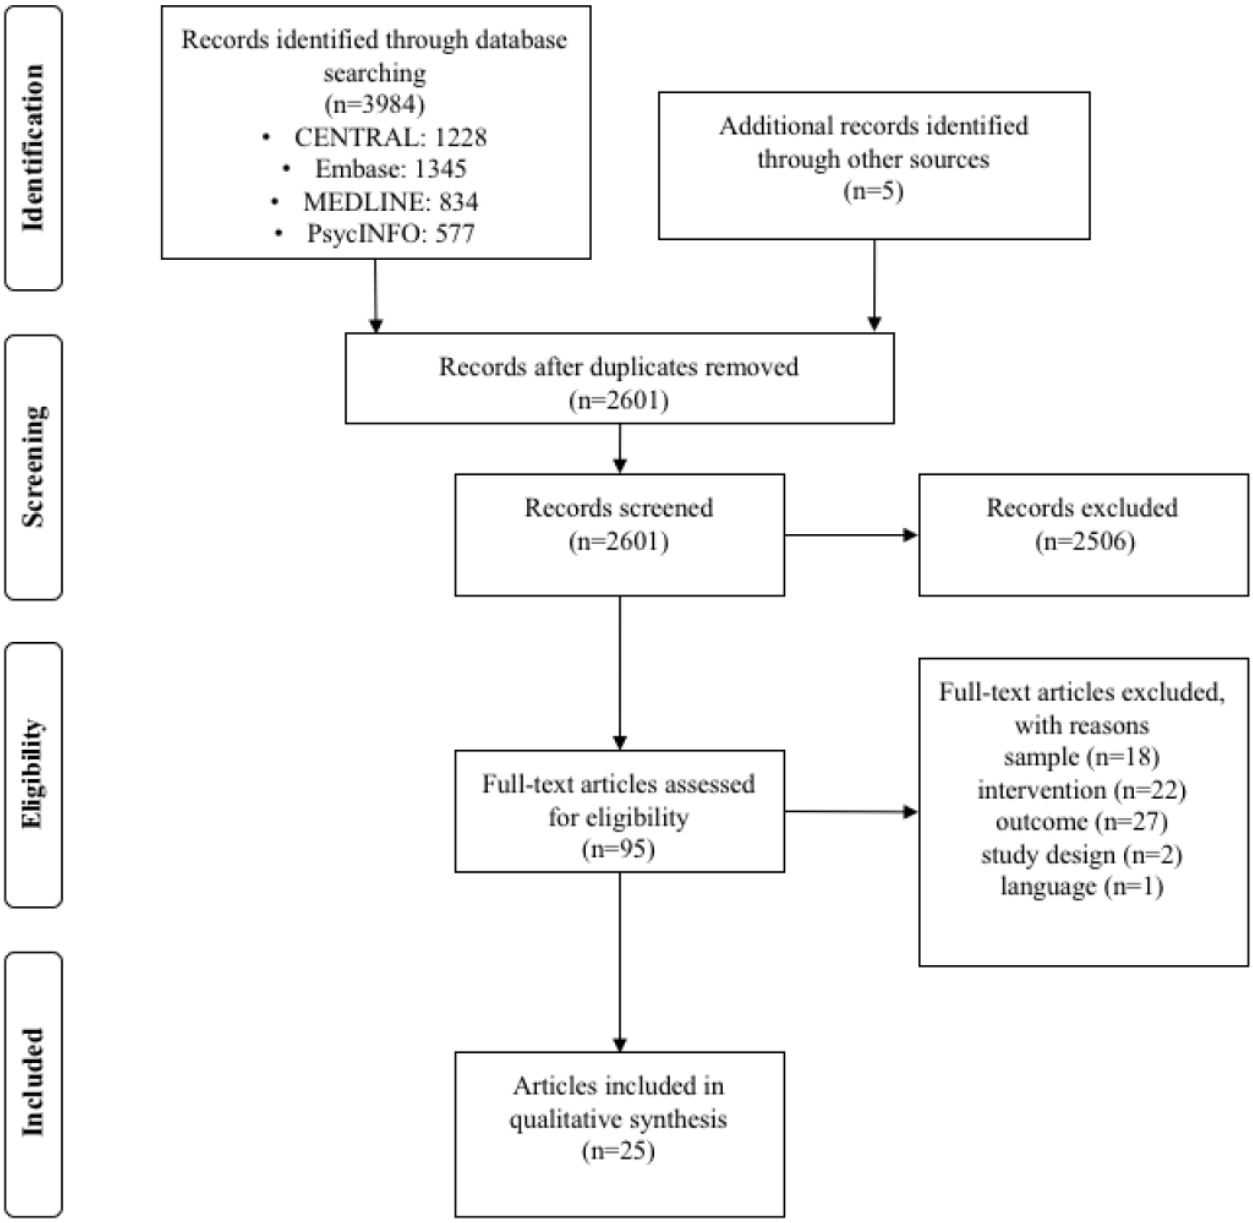
Studies were eligible for inclusion if they fulfilled the following criteria: (1) participants were children (0-13 years) or adolescents (14-21 years) diagnosed with a mental disorder or exhibited clinically relevant symptoms of a mental disorder; (2) in the case of mixed samples with adolescents and young adults, the mean age of the sample was not above 21 years; (3) the interventions were designed for children or adolescents, or for parents of children or adolescents fulfilling the first criterion; (4) the diagnosis of mental disorders was based on the diagnostic and statistical manual of mental disorders, or the International Classification of Diseases criteria and was assessed with a validated and standardized clinical interview, or a standardized self-report instrument, or standardized ratings by significant others (eg, parents, teachers, clinicians); (5) samples of mixed or comorbid mental disorders were included; (6) studies with different recruitment strategies were eligible; (7) interventions with different theoretical orientations were eligible; (8) the intervention was predominantly delivered through the internet (eg, via web browsers or mobile or smartphone apps); (9) interventions with different degrees of human guidance and completely self-guided interventions were eligible for inclusion; (10) different active and passive control groups (CGs) were included; (11) changes in the symptoms and (12) mediators were reported; (13) at least one mediation analysis was performed; (14) studies were RCTs or secondary analyses of RCTs published in a peer reviewed journal in English language.

Systematic Literature Search and Study Selection

The search strategy was 3-fold. First, systematic literature searches were conducted in the Cochrane Central Register of Controlled Trials, Embase, MEDLINE (ie, Ovid MEDLINE, Ovid MEDLINE Epub Ahead of Print, Ovid MEDLINE In-Process and Other Non-Indexed Citations, Ovid MEDLINE Daily Update), and PsycINFO databases from database inception until May 30, 2020. The search strings were built on established prior search strings [24,40] further adapted to specifically meet the research questions at hand and modified for each database in Ovid (for details on all search strings, see Multimedia Appendix 1). Second, the reference lists of all eligible studies and other relevant reviews were manually searched to identify further studies that met our inclusion criteria (ie, backward searches). Third, a citation-search (ie, forward search) was conducted in the Web of Science database.

Study selection was conducted with the support of a software tool for systematic reviews [41]. Duplicates were detected automatically by the software or were manually removed. First, 1 reviewer (SE) screened titles and abstracts of all the remaining studies and discarded irrelevant articles. Second, the full texts of all potentially relevant articles were screened in terms of the aforementioned eligibility criteria independently by 2 reviewers (SE and HN). Disagreements were resolved by consultation with a third reviewer (MD). The full process of the systematic literature search and study selection is displayed in the PRISMA flowchart of Figure 1.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart.



Data Extraction

Two independent reviewers (SE and HN) extracted the following data: study information items (name of first author, country, and year), sample information (sample size and age), intervention characteristics (theoretical orientation, number of modules, and duration of intervention), information about control conditions, and information about outcomes (mediator type, instrument, and statistical analysis of mediation). Authors were contacted via email in case of missing information essential for decisions on study selection and the application of the systematic review.

Categorization of Studies

The included studies were divided into 2 categories: studies evaluating interventions with a psychotherapeutic focus (ie, DHI_{PSY}) and studies evaluating interventions with a focus on health promotion (comprising interventions targeting health behavior, lifestyle, and behavior change interventions for the purpose of primary and secondary prevention; ie, DHI_{HP}). Of note, interventions with rehabilitation or tertiary prevention focus were not included.

Quality Assessment

Risk-of-Bias Assessment

The methodological quality of the included studies was assessed independently by 2 reviewers (SE and HN) using the Cochrane risk-of-bias (RoB) tool for randomized trials (version 2, RoB2; [42]) on 5 domains: (1) bias arising from the randomization process, (2) bias due to deviations from intended interventions, (3) bias due to missing outcome data, (4) bias in measurement of the outcomes, and (5) bias in selection of the reported result. The included studies were rated as having *low*, *unclear*, or *high RoB* in each domain [42]. Interrater reliability was calculated using the Cohen κ in RStudio (version 1.2.1335; [43]).

Quality Criteria for Process Research and Approximating Causality

The included studies were rated by 2 independent reviewers (SE and HN). The rating system was based on Kazdin's [25] initial criteria to approach causality, modified by Domhardt et al [24] and Lemmens et al [44]. To meet the respective criteria, studies had to: (1) use an appropriate RCT design, (2) include a CG, (3) report a theoretical foundation for mediators, (4) have a minimum sample size of 40 participants per group, (5) examine multiple mediators within 1 study, (6) assess temporality (3 or more assessments of the mediator variables and outcomes), (7) experimentally manipulate the mediator, and (8) reveal a strong statistical association among intervention, mediator, and outcome (operationalized as statistical significance of $P<.05$, as suggested by Moreno-Peral et al [45]). All criteria were rated as fulfilled or not fulfilled. In accordance with prior research [24,44], criteria specificity, consistency, and gradient were not assessed, as they are not meaningfully applicable in single studies (consistency) or are too exclusive for some therapeutic processes (gradient and specificity).

Results

Study Characteristics

Altogether, data from 25 (k=25) publications were analyzed [46-70]. Specifically, 52% (13/25) of the studies [46,47,49,54,56,58-60,64-67,69] evaluated DHI_{PSY} and 48% (12/25) of the studies evaluated DHI_{HP} [48,50-53,55,57,61-63,68,70]. In the studies, a total of 4884 participants were randomized. Studies on DHI_{PSY} accounted for 43.2% (2110/4884) of participants, and studies on DHI_{HP} accounted for 56.8% (2774/4884) of participants. The overall sample sizes varied from 51 [59] to 818 [63]. The median publication year was 2014 (2002 [48] to 2020 [49]). Most studies were conducted in the United States (17/25, 68%), and most of the study participants were female (2985/4884, 61.18%). In 1 study, no information was provided regarding the distribution of sex [54]. The mean age of participants was 18.49 (SD 2.01) years. The lowest mean age was 5.4 (SD 2.2) years [67], and the highest was 21.02 (SD 2.16) years [70]. Participants were younger in studies evaluating DHI_{PSY} compared with participants in studies evaluating DHI_{HP} (17.11 vs 19.67 years). The exact information on the average age of the final sample was not provided in 4 studies [54,56,63,68]. Most interventions took place without parental involvement and were directed at the youth themselves (20/25, 80%). In 20% (5/25) of the studies, interventions for children [54,67] as well as interventions for both children and adolescents [46,65] and for adolescents only [64] were evaluated with the involvement of parents (including intervention components for parents or parent training). Demographic information about the parents who participated was provided in 16% (4/25) of the studies [46,54,65,67]. Study participants were recruited predominantly from educational or health-related settings (15/25, 60%). In 32% (8/25) of the studies, participants were made aware of the study through both web-based advertising (including social media and websites) and conventional advertising (including letters and flyers). To identify potential participants, one study (1/25, 4%) used data from a mass web-based survey [59]. Information on recruitment strategy could not be identified in 4% (1/25) of the studies [68]. Across studies, the average study dropout rate accounted for 18% (range 0% [62] to 39.3% [54]). In 4% (1/25) of the studies, the dropout rate was not reported [46].

The interventions were directed toward a broad range of mental health problems, including risky drinking behavior (including risky or heavy drinking and binge drinking; 11/25, 44%), depressive disorders (5/25, 20%), anxiety disorders (including separation anxiety, generalized anxiety disorder, social phobia, and specific phobia; 3/25, 12%), behavioral problems (2/25, 8%), and insomnia (1/25, 4%). Furthermore, 12% (3/25) of the studies evaluated interventions that addressed multiple disorders simultaneously (ie, transdiagnostic interventions). De Bruin et al [47] addressed transdiagnostic *psychopathological abnormalities* (including affective, anxiety, and somatic problems; problems concerning attention-deficit/hyperactivity disorder; oppositional defiant behavior; and conduct problems). Levin et al [60] addressed *psychological problems* such as depressive disorders, generalized anxiety disorder, social phobia, alcohol consumption, academic worries, worries concerning eating, hostility, and negative stress. Another intervention addressed depression, anxiety, and stress [56]. Of note, there were 2 interventions evaluated and applied in more than 1 study (the *e-CHUG* interventions in 4 studies; and the *BRAVE* interventions in 2 studies), but the investigated mediators differed in all studies; thus, these publications were regarded as distinct entities and single studies (see Multimedia Appendix 2 [46-70] for details).

Internet-based interventions were evaluated in 92% (12/13) of the studies on DHI_{PSY}. Most interventions were based on the components of cognitive behavioral therapy [46,47,49,59,66]. In addition, relaxation strategies, such as progressive muscle relaxation and autogenic training [49], and elements of social learning theory [54] were deployed. Further interventions were based on the acceptance and commitment therapy [60], components of systemic family therapy, problem solving and communication training, cognitive restructuring, and alternative family roles [64]. One intervention [56] was based on the *temporal model of control*. In 23% (3/13) of the studies, precise information on the theoretical orientation and background of the intervention was not available [58,67,69]. Moreover, 7% (1/13) of the studies evaluated a mobile-based intervention based on a self-monitoring program [58].

All DHI_{HP} studies were internet-based and included a feedback component (12/12, 100%). The so-called *e-CHUG* tool was evaluated in 33% (4/12) of the studies [51,57,62,68]. Feedback was provided via email [48,53] or in person using a motivational interviewing approach [51,52]. In addition to the feedback components, cognitive components such as expressive writing [70] and retrieval of remembered information from feedback were evaluated [57]. A detailed overview of the study characteristics is provided in Multimedia Appendix 2.

Mediators

An overview of the classification of mediators and their empirical support is provided in Table 1. A total of 39 potential

mediators were investigated in the included RCTs. Among these, more than half of the mediators were evaluated as significant (21/39, 54%). With 48% (19/39) intervening variables, the largest group of all examined intervening variables was of a cognitive nature. A total of 13 cognitive mediators were evaluated as significant in the primary studies (13/19, 68%). We further divided the group of cognitive mediators into the *assessment* (examined: 8/39, 20%; significant: 5/8), *motivation* (examined: 1/39, 2%; significant: 0/1, 0%) and *cognitive processes* subcategories (examined: 10/39, 25%; significant: 8/10, 80%). Further evenly investigated mediator categories were emotional/affective (examined: 4/39, 10%; significant: 4/4, 100%), interpersonal (examined: 4/39, 10%; significant: 1/4, 25%), and parenting behavior mediators (examined: 4/39, 10%; significant: 0/4, 0%). The second largest group of mediators was not clearly classifiable into one of the aforementioned categories and was thus subsumed into a separate *other* mediator category (examined: 8/39, 20%; significant: 3/8, 38%). Of note, a Wilcoxon rank-sum test revealed no difference in the sample sizes between studies that found at least one significant mediator and studies that found no significant mediator (W {19,6}=59; *P*=.93).

Table 1. Classification of mediators.

Mediators	Studies, n (%) (n=25)	Age (years), range[a]	Guidance	Disorder	Effect size[b]	Significance	Criteria met ≥5
Emotional and affective mediators							
Emotional self-perception	1 (4)	14-22	Unguided	Depression	Partially standardized ES[c]=−1.049 (95% CI −1.35 to −0.755)	Yes	(+)[d]
Fear	1 (4)	16-24	Internet-based psychotherapy	Depression	Between groups ES=0.49 (95% CI 0.24 to 0.75)	Yes	(+)

[a]If age range was not reported, participant group labels were used.

[b]Effect size measures differed across studies.

[c]ES: effect size

[d]Met 5 or more criteria.

[e]Not available.

[f]Met fewer than 5 criteria.

[g]If mediator was assessed in more than 1 study, data and results were separated with ";".

[h]The only mediator nonsex-specific perceived norm was not significant.

[i]Transdiagnostic intervention targets more than one disorder.

A broad range of different approaches to mediation analyses was deployed, with some studies relying on several strategies at once. Bootstrapping (eg, Preacher and Hayes [71]) was used in almost half of the studies (11/25, 44%). In 32% (8/25) of the studies, the mediation analysis was based on the approach of Baron and Kenny [30], and in addition, 8% (2/25) performed a Sobel test. Furthermore, 32% (8/25) of the mediation analyses were performed using structural equation modeling (7/25, 28% using the MPlus software). Moreover, 4% (1/25) of the studies performed multiple regression analysis according to the Judd and colleagues paradigm [72], and another study did not provide any information on the statistical analysis.

Quality Assessment of Included Studies

Risk-of-Bias Assessment

As illustrated in the *RoB2 Graph* (Figure 2), approximately three-quarters (19/25, 76%) of the included studies were rated as having a *high* RoB. In more than half of the studies (14/25, 56%), the *bias due to deviation from the intended intervention* was rated as *high*. The RoB on this domain was more often evaluated to be *high* in studies on DHI_{HP} (10/25, 40%) when compared with studies on DHI_{PSY} (4/25, 16%). Both the randomization procedure and the process of reporting results were predominantly rated with *some concern* across studies (19/25, 76% and 22/25, 88%). Interrater reliability varied across domains from Cohen κ=0.76 to Cohen κ=0.93. According to Landis and Koch [73], these agreements can be rated as *substantial* to *almost perfect*. A summary of the RoB2 assessments is shown in Figure 3.

Figure 2. Risk-of-bias graph.

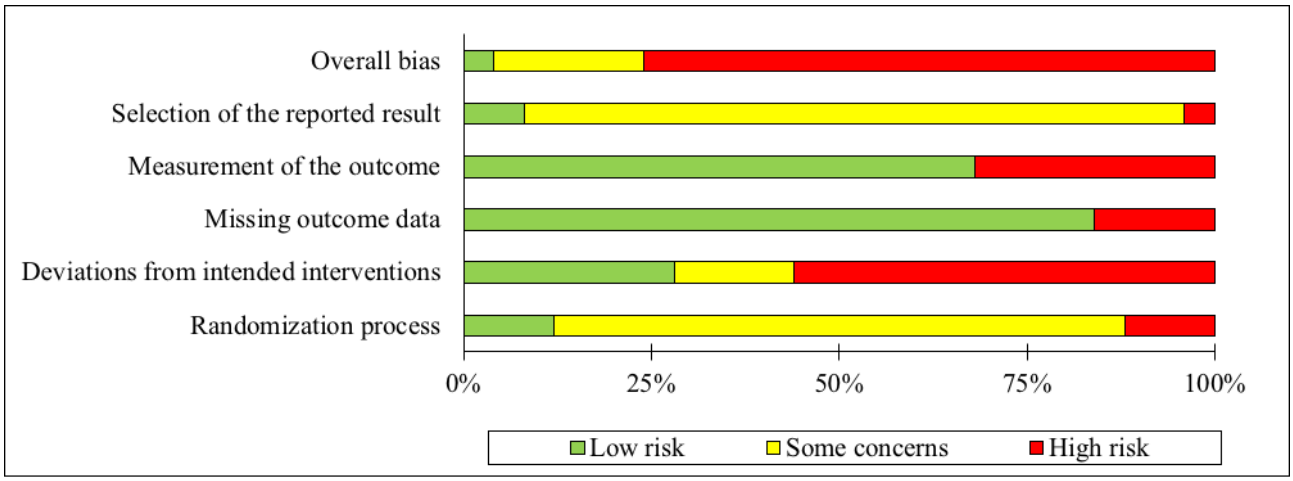

Figure 3. Risk-of-bias summary.

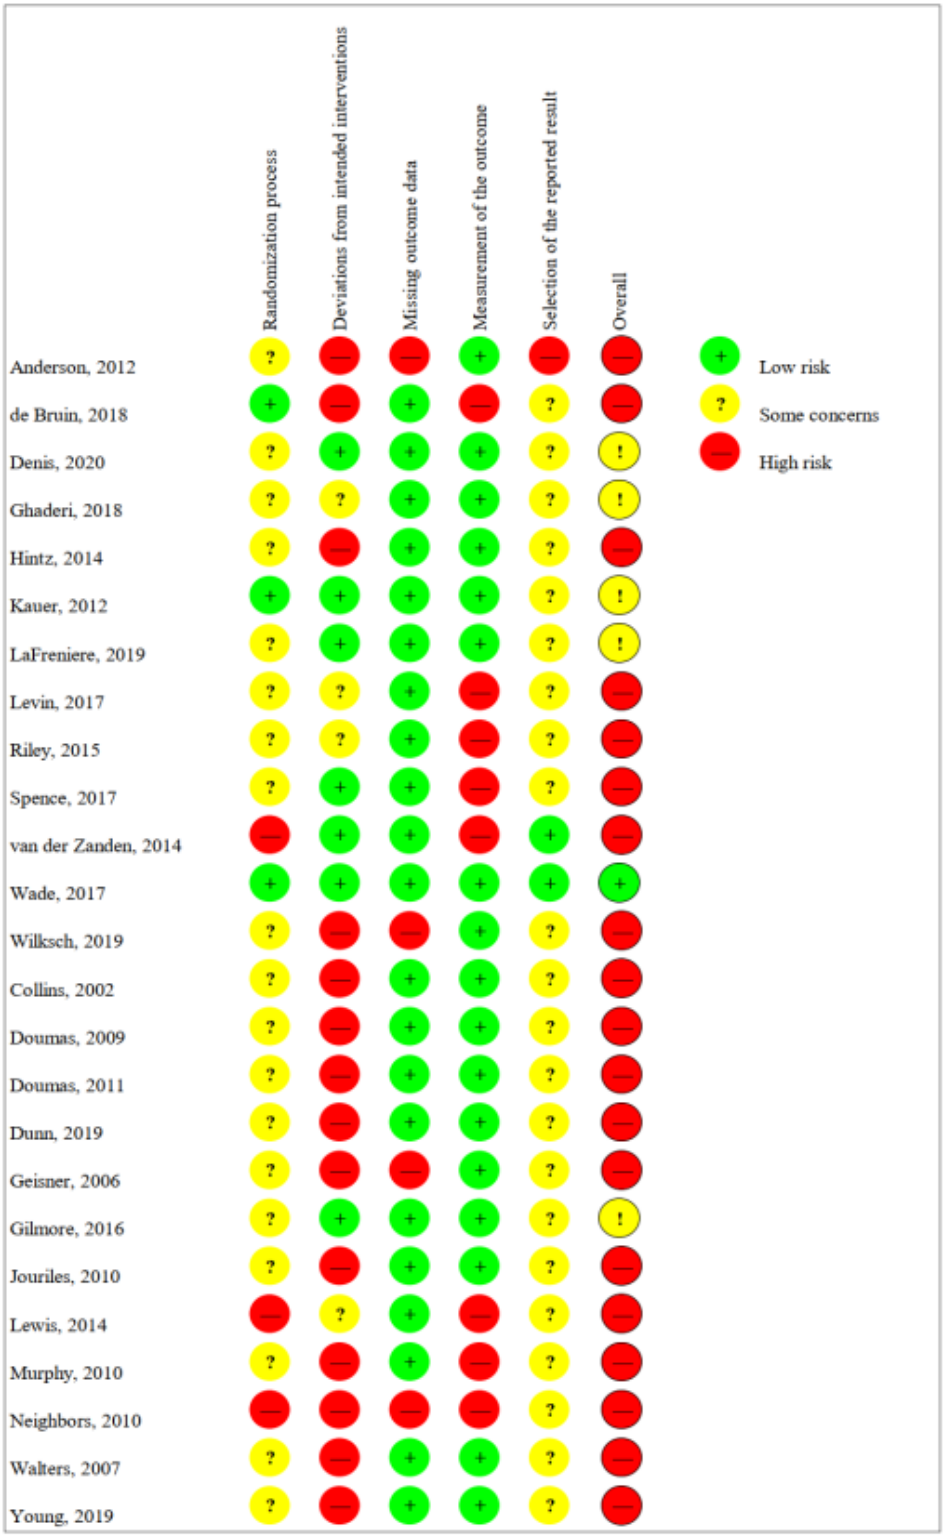

Evaluation of the Quality Criteria for Process Research and Approximating Causality

The evaluation of the included studies with regard to the methodological quality of process research revealed that in both the DHI_{PSY} and the DHI_{HP} groups, most studies (DHI_{PSY}: 9/13, 69% vs DHI_{HP}: 11/12, 92%) fulfilled 5 or more out of the 8 criteria. Owing to the eligibility criteria used in this review, almost all studies met the requirement of an RCT design (24/25, 96%) and a CG (24/25, 96%). In the publication by Anderson et al [46], the results from 8% (2/25) of the studies were jointly reported, with only the second study evaluating a DHI_{PSY} without a direct comparison with the CG, although this criterion was fulfilled in the first study. Even if mediators were collected at more than 2 measurement time points in more than half of the studies (15/25, 60%; including follow-up), an evaluation of the chronology of changes in the mediator variable or variables and outcomes was conducted in only 4% (1/25; de Bruin et al

[47]) of the studies. Furthermore, 8% (2/25) of the studies, Hintz et al [56] and Jouriles et al [57] implemented direct experimental manipulation of mediators. A detailed overview of the evaluation of the methodological quality criteria for process research and the approximation of causality are outlined in Tables 2 and 3, as well as in Multimedia Appendix 3.

Discussion

Principal Findings

This systematic review, to the knowledge of the authors the first of its kind, comprehensively evaluated research on mediators and mechanisms of change in DHIs for common mental disorders in youth. Altogether, 25 studies were included in the review, that have examined 39 distinct mediators. Cognitive variables were found to be the most often investigated mediators, followed by a broad range of other mediators. Even though our eligibility criteria were not limited to a specific mental health condition in youth, only a rather low number of studies were identified by our systematic literature searches, a finding that corresponds to the limited evidence base of research on mechanisms of change in psychotherapy in general [37,74], and for children and adolescents in specific [24,35,37], necessitating further high-quality research efforts to improve interventions and mental health care practices for this younger age group.

Remarkably, our findings indicate that the mediator category with the highest percentage of significant intervening variables was the affective or emotional mediator group (4/4, 100%). The proportions of significance in other mediator categories were by far less high and included combined cognitive (13/19, 68%), other (3/8, 37%), interpersonal (1/4, 25%), and parenting behavior–related mediators (0/4, 0%). The consistent nonsignificant findings on parenting behavior–related intervening variables are astonishing, as parenting behavior is otherwise thought to be of paramount importance in the treatment of behavioral problems in youth, both in conventional interventions delivered face-to-face [75] and in digital parent training alike [76,77]. Therefore, the findings of our study are in contrast to those of a systematic review [75], which revealed that in 45% (39/86) of the included studies on face-to-face parent training programs, parenting behavior served as a mediator for the association between the intervention and symptom change in children. Furthermore, the importance of emotion regulation might be underestimated in (digital) psychotherapeutic interventions for children and adolescents, considering the consistent pattern of significant findings across studies in our review, as well as by allowing for comprehensive earlier research highlighting the overall importance of emotion regulation competencies for mental health in childhood and adolescence [78]. However, given the rather small number of mediation studies per category in our review, these findings need to be interpreted with caution and must be considered as preliminary. This is also owing to the rather heterogeneous evidence base, where included studies varied broadly in terms of the theoretical foundations of the intervention as well as the simultaneous consideration of various mental disorders, which may further restrict the comparability between studies. Nevertheless, a Wilcoxon rank-sum test revealed no differences in the sample sizes between studies that found at least one significant mediator and studies that found no significant mediator, suggesting that there is no effect of sample size on the evaluation of intervening variables, strengthening the robustness and validity of the findings on the mediators in this regard.

Importantly, participants were most often adolescents, with only 16% (4/25) of eligible studies evaluating interventions for children, suggesting an additional research gap for this younger age group. Here, all interventions for children were conducted with the involvement of parents, suggesting a crucial role of the accompanying human support in DHIs for younger children, which must be corroborated and further specified by forthcoming research [12,79]. In studies evaluating DHI_{HP}, only cognitive mediators (perceived norm and alcohol-related expectation) were investigated. This finding is consistent with prior research, where the cognitive mediator, perceived norm, was established as one of the most evaluated mediators in interventions for problematic drinking behaviors in adolescents and young adults delivered on site [80]. However, this result rather highlights the researcher's presumptions than the evidence base of the superior relevance of cognitive mediators over other, not yet well examined, affective and behavioral mediators.

The results of the RoB assessment indicated a rather limited overall study quality, with 76% (19/25) of the included studies rated with a *high RoB*, a finding that aligns with the review by Christ et al [81], in which 92% (22/24) included studies on DHIs for adolescents and young adults were assessed with a *high RoB*. These findings on RoB2 might be largely due to the specifics of psychotherapy research [82], where masking of therapists or personnel and participants is difficult to achieve, as well as the more conservative novel RoB2 algorithm [83]. Of note, in our review, the mean study dropout rate was 18%. Therefore, only a fraction of the included studies fulfilled the RoB2 criterion that 95% of randomized participants' data should be available for data analysis. Although the current mean dropout rate in this review is rather small compared with other high dropout rates found in DHIs, the well-known issue of limited engagement still warrants future research to further investigate approaches to remedy (study and intervention) attrition [84,85]. In this particular field, primary studies in the review at hand may offer guidance and direction to more effective engagement in youth (Multimedia Appendix 2), such as interactive intervention components and age-appropriate content presentation in the form of puzzles, videos, or cartoons [12].

The results of the methodological quality assessment for process research revealed that most studies adhered to certain quality criteria satisfactorily (ie, using an RCT design and CG, evaluation of a strong statistical association, describing a theoretical foundation for mediators and sample size per trial group). However, in contrast, most primary studies did not experimentally manipulate the potential mediators, did not assess several mediators simultaneously, and did not evaluate the time sequence or temporal ordering of changes in mediators and outcomes. However, this latter criterion is considered to be of utmost importance for causal inferences and is sometimes referred to as the *fifth step* of mediation analysis [86]. Even though mediators and outcomes were assessed more than twice in 60% (15/25) of the included studies, only 4% (1/25) of the studies [47] actually conducted a statistical evaluation of the time sequence of cause and effect. Taken together, the findings of our review seem to be in line with those of other research [24,44,45,83], pointing to important methodological

shortcomings of mediation studies, which should be amended by future research. At this point, 1 high-quality RCT [58] sets an example, fulfilling 6 out of 8 quality criteria.

Strengths and Limitations

This systematic review offers several strengths, including a comprehensive literature search, as well as the broad consideration of common mental disorders and theoretical orientations, resulting in an extensive overview of the research on mediators and mechanisms of change for DHIs in children and adolescents conducted so far. Furthermore, with the differential consideration of the 2 categories of DHI_{PSY} and DHI_{HP}, we intended to provide specific evidence-based information that might be valuable for digital psychotherapeutic and health promotion interventions alike. However, some limitations must be considered when interpreting the findings of this review. First, the number of eligible studies is rather small; the generalizability of the findings might be reduced as most studies were conducted in Western countries; these studies evaluated internet-based interventions; participants were predominantly female; and these studies relied on older participants. Second, only English language papers were included, and we did not incorporate gray literature in our study as recent findings indicated a negligible relevance of gray literature in systematic reviews [87]; further, publication bias cannot be ruled out. Third, although we only included RCT studies in our review (which might have led to an overestimation of the study quality in general, omitting other design studies with potentially lower methodological rigor), the RoB assessment indicated substantial shortcomings in the included studies. However, this finding should be weighed against the typical constraints of research on psychological interventions.

Future Directions

The following recommendations might be helpful for future mediation studies, aiming to advance our understanding of the working mechanisms of DHIs for youth. First, it is essential to avoid the methodological shortcomings outlined in the assessment of quality criteria for process research, especially with regard to the temporality of changes and experimental manipulation of mediators, both of which are key for the justification of causal inferences. Furthermore, future studies should resort to more sophisticated and current methods of mediation analysis (eg, Grimm et al [88] and Hofmann et al [89]), ideally capable of clarifying temporal precedence and illustrating the actual pattern of change [24]. Second, the therapeutic or working alliance (ie, the professional relationship between therapists and patients; eg, Grawe et al [90]) was not evaluated as a mediator in any of the included studies. However, the recent development of the working alliance inventory for digital interventions [91] may contribute to future process research, informing the evidence base of the effects of a *digital* therapeutic alliance in DHIs for youth [37,92]. Furthermore, mediators that have not been investigated so far, such as behavioral and biological variables, should be evaluated in future studies. At this point, the possibilities of novel technological methods in process research seem not to be fully exploited in this research field [37]. Passive sensing methodologies and digital phenotyping approaches with smartphones [93] might generate insights on behavioral and biological mechanisms in real life, in addition to the predominant information on cognitive variables derived from self-reports identified in the current review. Third, although worldwide about 90% of youth live in countries with low or medium income, 90% of RCTs investigating mental disorders in children and adolescents are conducted in high-income countries [1], mirroring the findings of the review at hand. In contrast, the presumed advantages of DHIs may be especially relevant in structurally weak and low-income countries. To overcome this contradiction, replication studies should aim to include and reach populations from low-income countries as well. Finally, our review revealed that mediators focusing on emotional and cognitive processes might be of paramount importance as potential mechanisms of change in DHIs for youth. However, the processes covered by these mediators varied to some extent. Thus, future studies focusing on both emotional and cognitive processes in a systematic way within one framework could be of great importance for the field.

Conclusions

This systematic review is the first to comprehensively investigate the mechanisms of change in different DHIs for youth. The key findings indicate that the largest group of examined mediators are cognitive variables, followed by an array of other mediator variables, including interpersonal, parenting behavior, and affective mediator categories. Of note, emotional and affective mediators consistently reached statistical significance across studies, whereas parenting-related mediators were evaluated constantly as nonsignificant. However, these findings must be considered cautiously, as we detected only a limited number of primary studies, despite including a broad range of mental disorders and interventions. Future studies should aim to lessen this research gap, ideally adhering to the quality criteria for process research and recent methods of mediation analyses, enabling more causally robust findings. These forthcoming studies might contribute to disentangling the therapeutic processes in DHIs, providing evidence-based knowledge to inform intervention development and augmented mental health care practices worldwide.

Acknowledgments

This work was supported by the German Federal Ministry of Education and Research (grant identification FKZ01KG1802). The funding source, the Federal Ministry of Education and Research, had no role in the study design, collection, analysis, or interpretation of the data, writing of the manuscript, or the decision to submit this paper for publication.

Authors' Contributions

MD, SE, and HB developed the study design. SE and HN conducted the systematic literature searches, extracted the data, and rated the risk of bias and methodological quality criteria of included studies under the supervision of MD. MD wrote the first draft of the manuscript. All authors (MD, SE, HN, AL, AB, and HB) have contributed to the writing of the manuscript and have approved the final manuscript.

Conflicts of Interest

AB has received payment for consulting from Pro-Change Behavior Systems. All other authors (MD, SE, HN, AL, and HB) stated no conflicts of interest.

Abstract

Background: New parents face increased risks of emotional distress and relationship dissatisfaction. Digital interventions increase support access, but few preventive programs are optimized for both parents.

Objective: This study aims to conduct the first randomized controlled trial on universal self-guided digital programs to support positive perinatal adjustment of both mothers and fathers. Effects of childcare information (*Baby Care*) and information plus an interactive program (*Baby Steps Wellbeing*) were compared from the third trimester baseline to 3 and 6 months subsequently.

Methods: The study recruited 388 co-parenting male-female adult couples expecting their first single child (26-38 weeks' gestation), using web-based registration. Most (337/388, 86.8%) were obtained from prenatal hospital classes. Couples' randomization was automated and stratified by Edinburgh Postnatal Depression Scale (EPDS) scores (50% couples scored *high* if either mother >7, father >5). All assessments were web-based self-reports: the EPDS and psychosocial quality of life were primary outcomes; relationship satisfaction, social support, and self-efficacy for parenting and support provision were secondary. Linear mixed models provided intention-to-treat analyses, with linear and quadratic effects for time and random intercepts for participants and couples.

Results: Selection criteria were met by 63.9% (248/388) of couples, who were all randomized. Most participants were married (400/496, 80.6%), tertiary educated (324/496, 65.3%), employed full time (407/496, 82%), and born in Australia (337/496, 67.9%). Their mean age was 32.2 years, and average gestation was 30.8 weeks. Using an EPDS cutoff score of 13, 6.9% (18/248) of men, and 16.1% (40/248) of women screened positive for depression at some time during the 6 months. Retention of both partners was 80.6% (201/248) at the 6-month assessments, and satisfaction with both programs was strong (92% ≥50). Only 37.3% (185/496) of participants accessed their program more than once, with higher rates for mothers (133/248, 53.6%) than fathers (52/248, 20.9%; $P<.001$). The EPDS, quality of life, and social support did not show differential improvements between programs, but *Baby Steps Wellbeing* gave a greater linear increase in self-efficacy for support provision ($P=.01$; Cohen $d=0.26$) and lower reduction in relationship satisfaction ($P=.03$; Cohen $d=0.20$) than *Baby Care* alone. Mothers had greater linear benefits in parenting self-efficacy over time than fathers after receiving *Baby Steps Wellbeing* rather than *Baby Care* ($P=.01$; Cohen

d=0.51). However, the inclusion of program type in analyses on parenting self-efficacy and relationship satisfaction did not improve model fit above analyses with only parent gender and time.

Conclusions: Three secondary outcomes showed differential benefits from *Baby Steps Wellbeing*, but for one (parenting self-efficacy), the effect only occurred for mothers, perhaps reflecting their greater program use. Increased engagement will be needed for more definitive testing of the potential benefits of *Baby StepsWellbeing* for perinatal adjustment.

Introduction

Background

Psychological distress before and after childbirth is common in both parents. Although recent meta-analyses estimate that 12%-17% of recent mothers become depressed [1,2], the rate for fathers is approximately 8% [3]. Depression in one parent poses significant coping challenges for their partner and increases their own risk of depression [4-6]. However, few fathers receive treatment for depression or subclinical distress [7], and research on its treatment is sparse [8,9]. Preventive interventions targeting both parents' distress and promoting quality of life are also likely to benefit the couple's relationship [10,11] as well as their child's emotional and social adjustment [12,13].

Digital delivery may be expected to reduce some of the stigma associated with help seeking, which is especially evident in fathers [7], and allow large-scale access to interventions aimed at preventing or treating distress. Web-based cognitive behavior therapy programs for postpartum depression have demonstrated a moderate average effect size in mothers (Cohen *d*=0.54) [14]. However, a search of published papers identified no research on interactive programs specifically for fathers, although interactive exercises for couples are sometimes included [15]. Even web-based information focusing on new fathers is limited [16,17].

Baby StepsWellbeing is a free, self-guided web program that is optimized for multiple devices and aims to prevent distress and promote the well-being of new parents [18]. It was developed by clinical psychologists and a midwife, with a particular focus on new fathers, and was based on unpublished qualitative research on the issues faced by 10 couples with babies aged 3-6 months and on semistructured interviews with 21 recent parents who reviewed the draft program. To maximize the engagement of new parents, the program contained 4 modules with practical tips on preparing for the baby and addressing issues related to feeding, sleep, and soothing (*Baby Care*). The full *Baby Steps Wellbeing* program had an additional four modules providing information and interactive problem solving on self-care, relationships, interacting with the baby and adjusting to the new roles, as well as a module specifically focused on fathers that covered the ways in which they could support their partner and share childcare tasks. Selecting a tip in *Baby Steps Wellbeing* allowed users to choose specific baby care and well-being tips and set calendar reminders to try them. They could also upload photos about good times with their baby for use at times of stress.

Digital provision of a support program does not guarantee that men will access it, and users of digital mental health services remain predominantly women [19]. Encouraging partners to enroll in a program together may be one way to maximize fathers' engagement. This strategy may also provide opportunities to build mutual support and relationship satisfaction, which are key predictors of perinatal well-being [20]. Accordingly, this study required that both partners participate, protecting their confidentiality through separate usernames and passwords.

Objective

The aim of this randomized controlled trial is to compare the efficacy of the full, interactive *Baby Steps Wellbeing* program (containing all modules and planning tools) with that of *Baby Care* informational tips alone over a period of 6 months from the third trimester of pregnancy onward. The primary outcomes were self-rated depression and psychosocial quality of life, whereas the secondary outcomes included relationship satisfaction, parental self-efficacy, and social support. We predicted that the *Baby Steps Wellbeing* program would result in better outcomes at 3 and 6 months from baseline, compared with *Baby Care* information only. Although we did not have a directional hypothesis about the relative effects of the programs on fathers and mothers, we tested whether the inclusion of an interaction of treatment and parent gender added to the prediction of outcomes. Effects for time were partialed into linear and quadratic effects because of the potential for deterioration in mental health and well-being during the early postpartum period, with some recovery at 6 months. We were interested both in whether the two treatments had differential effects linearly over the study period and whether they modified any tendency for short-term changes at around 2 weeks after childbirth (ie, 3 months from baseline).

Methods

Brief Description

A detailed description of the methodology is provided in the research protocol [21]. A summary is provided below, highlighting the changes from the published protocol.

Ethical Approval, Inclusion Criteria, and Recruitment

The trial received ethical approval from the human research ethics committees of Queensland University of Technology (#1400000687) and Mater Health Services (HREC/14/MHS/166). The participants were co-parenting male-female couples aged 18 years or older who were expecting a single first child at 26-38 weeks' gestation. Recruitment was timed during late pregnancy to engage parents before they faced the heavy demands of childcare [22], while ensuring that their entry was sufficiently proximal to the birth to maximize engagement and later recall. The participants were proficient in English, had access to the internet and a mobile phone, and had completed the baseline assessments. Recruitment occurred between March 2015 and October 2015, and the registration was conducted on the web. The study had a recruitment target of 240 couples, which was expected to enable the detection of a small effect size of f=0.082 (α=.05; power=0.80; repeated measures *r*=0.50, using repeated measures analysis of variance, G*Power 3.1 [Heinrich Heine University] [23]). However, we recruited 248 couples (124 couples in each arm). Most recruited couples (216/248, 87.1%) entered the study through prenatal parent education classes at the Mater Mothers' Hospital, Brisbane, Australia, where a member of the research team presented information about the research trial immediately before the class. The remaining participants were recruited through a trade exhibit at the *Pregnancy, Babies, and Children's Expo* in Brisbane, Australia (25/248, 10.1%); were referred by a friend, family member, or medical practitioner (6/248, 2.4%); or responded to advertising on a parenting website (1/248, 0.4%).

Measures

Demographic and Pregnancy Data

At baseline, each parent reported their age, marital and employment status, education level, country of birth, years living in Australia, and indigenous background (where applicable). The assessment at 3 months after childbirth included weeks of gestation at birth, birth type, baby's sex, and information about any inpatient care of the baby.

Program Use and Satisfaction

The number of log-ins, modules viewed, the number of saved action plans from baseline to 6 months, and the period between the first and last log-in to the program were downloaded from the program's database. Overall program satisfaction and the program's perceived relevance, usefulness, and ease of finding what the participants wanted were self-reported at 3 months on a scale from 0 (not at all) to 100 (extremely), and average scores across these four items are reported below (in this sample, Cronbach α=.93; corrected interitem correlations=0.73-0.91).

Outcomes

Except for the Assessment of Quality of Life-8 Dimensions (AQoL-8D), all self-reported outcomes used unweighted sums or averages of items. The primary outcome measures were the scores derived from the 10-item Edinburgh Postnatal Depression Scale (EPDS) [24,25], which provides a total score of 0-30, with higher scores indicative of depressive symptomatology, and the Psychosocial Super Dimension Scale from the AQoL-8D [26,27], which gives an average weighted score of increasing utility from 0 to 1.

Relationship satisfaction was measured using the 16-item Couples Satisfaction Index (CSI-16) [28], which gives a score of increasing satisfaction from 0 to 81. Social support was assessed using the 4-item version of the Medical Outcomes Study Social Support Survey (Short MOS-SSS) [29], which provides a total score from 4 to 20. A new measure of parenting self-efficacy used an average across the items on feeding, sleep, and settling (eg, "Thinking about the next 13 weeks, how confident are you with putting your baby to sleep?"), each of which was rated on an 11-point scale from 0 (not at all confident) to 100 (extremely confident). At baseline, the scale had high internal consistency (Cronbach α=.94; corrected item-total correlations=0.78-0.95). Self-efficacy for support provision to their partner used a single item ("Thinking about the next 13 weeks, how confident are you with providing support to your partner," which was also rated on an 11-point scale from 0 to 100) that was moderately related to the CSI-16 (Spearman ρ=0.32; $P<.001$) and inversely related to the EPDS (Spearman ρ=–0.30; $P<.001$). Data on income, work time, productivity, and health care were also collected but will be reported in a separate paper.

Web Programs

The participants randomized to the *Baby Care* trial arm received the four informational modules giving information and tips on getting prepared, feeding and soothing their baby, and improving their baby's sleeping habits. A *Get Help* tab provided a list of relevant digital or telephone support services.

The participants receiving *Baby Steps Wellbeing* could also access modules on physical and emotional self-care, their relationship with their partner, changing roles, and interacting with their baby, as well as the module meant especially for fathers (ie, a total of 9 modules, including those focused on baby care). For either *Baby Care* tips or the ones in other modules, the participants in *Baby Steps Wellbeing* could identify goals, solve problems, develop a plan, set times to take action, and record their successful completion. A list of successfully completed plans was available. A web-based scrapbook was used to store photos of good times with their baby, and their dashboard presented due dates for their action plans, together with a rotating quiz question about baby care, a tip, and a scrapbook photo. The database for *Baby Steps Wellbeing* was hosted at the Queensland University of Technology. The participants were not given advice on the number of modules to access, and there was no limitation on the pace of module access. No changes to either program were made during the study, and no major technical issues were encountered.

All participants received automated text messages at 2, 4, 7, and 10 weeks after allocation, reminding them to log in to the program and select tips to apply. Texts sent to the *Baby Steps Wellbeing* participants also included a recommendation to review their goals and plans. A final SMS text message was sent to all participants, thanking them and expressing the hope that they found the website useful.

Procedure

After the volunteers for the study registered on the web, they were emailed a link to the web-based consent form and eligibility screen. Prospective participants could also email or call the research team to ask questions about the trial. After informed consent and initial automated confirmation of eligibility, they were given a link to self-complete the baseline assessments. Both these and later measures were delivered through Qualtrics (Qualtrics, LLC; [30]) and stored separately from identifying data, using a numerical code for the couple plus a letter to signify father or mother. Completion of all items in each measure was required. If a respondent screened positive for a medium or high risk of major depression or self-harm (EPDS item 10 ≥1, or totals of ≥10 for mothers, ≥6 for fathers) at either the baseline or a later assessment, they were contacted by a member of the research team, who implemented a risk management plan [21].

The web-based completion of baseline measures by both the father and mother triggered a fully automated random allocation of the couple to a treatment by Goji, a web-based trial management system developed at Queensland University of Technology [31]. Randomization was performed in permuted blocks, stratified by EPDS (screening negative for anxiety or major or minor depression: mother ≤7 *and* father ≤5; screening positive: mother >7 *or* father >5) [25]. These cutoffs resulted in 123 couples (49.6%) screening positive—ie, approximating a median split of the couples on the EPDS.

At 13 and 26 weeks, the participants were sent automated emails with links to self-complete assessments on the web. All outcome and economic measures were readministered, together with details about the birth, a check on marital status, and ratings of program satisfaction. Nonresponse resulted in emails or calls by a research officer, who was blind to the treatment, to provide further reminders. The participants were given a retail store voucher for Aus $20 (approximately US $16) for each completed follow-up assessment.

Statistical Analyses

The primary analyses adopted an intention-to-treat approach using RStudio version 1.3.1093 lme4 (RStudio, PBC), which provided mixed models analyses of data over the three measurement occasions (baseline, 3 months, and 6 months). Given the potential for correlations within couples, each analysis incorporated random intercepts for both the couple and individual participant. Preliminary analyses demonstrated that the inclusion of a first-order autocorrelation between test occasions did not improve predictions; therefore, it was not included in the reported analyses. As mothers are somewhat more vulnerable than fathers to issues with perinatal mental health and well-being [1-3], all analyses included effects for parent gender and the interaction of parent gender and time. In compliance with CONSORT (Consolidated Standards of Reporting Trials) guidelines, analyses of outcomes did not control for any differences between the treatments at baseline (contrary to the protocol paper) [21], but tests for any baseline differences are reported in the interests of full disclosure.

In the primary analyses, we compared two models: (1) a hypothesized model, examining the relative impact of the two programs, controlling for parent gender (ie, including effects of treatment×time, parent gender×time, and the relative main effects) and (2) the full factorial model, testing all potential effects. Post hoc analyses were also undertaken to examine a model that only included parent gender and time. The reported *t* tests used the Satterthwaite method, and the degrees of freedom were calculated using the Kenward-Roger method. The effect sizes in these analyses use Cohen *d*, with difference scores being divided by shared baseline SD units (taken from analysis of variance values of baseline scores, with treatment and parent gender as independent variables).

Results

Participant Characteristics

The CONSORT diagram is presented in Figure 1. Of the 726 people who expressed initial interest in the study, 388 couples registered; 248 (53.4) fulfilled the eligibility criteria and were randomly allocated to the two treatments. As shown in Figure 1, retention at 3- and 6-month assessments was high in both treatments. One couple had to be withdrawn from the study because of a stillbirth, but their baseline data were still included in the intention-to-treat analyses. An attempt was made to contact participants who screened positive for risk of depression or self-harm and implement the risk management procedure (112 at baseline, 175 at 3 months, 132 at 6 months), but no one had to be withdrawn from the study for this reason. Very few participants received concurrent mental health treatment during the study in either treatment (medication: 5%-7% and counseling: 4%-6%).

On average, the participants receiving *Baby Steps Wellbeing* entered the study a little less than a week earlier in the pregnancy compared with those receiving *Baby Care* (mean 30.4, SD 2.8 vs *Baby Care* mean 31.2, SD 3.1; $F_{1,246}$=4.35; *P*=.04; η^2=0.017), but there were no other significant differences between the treatments in terms of demographic characteristics. Tests of any differences between the fathers and mothers in the study are presented in Tables 1 and 2. Mothers were slightly younger than fathers on average and were more likely to have a university degree but less likely to be employed full time. At baseline, they had higher EPDS scores, lower AQoL-8D Psychosocial Super Dimension scores, and lower self-efficacy in the provision of social support. However, they had higher relationship satisfaction scores on the CSI-16 and higher perceived social support on the Short MOS-SSS.

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) diagram.

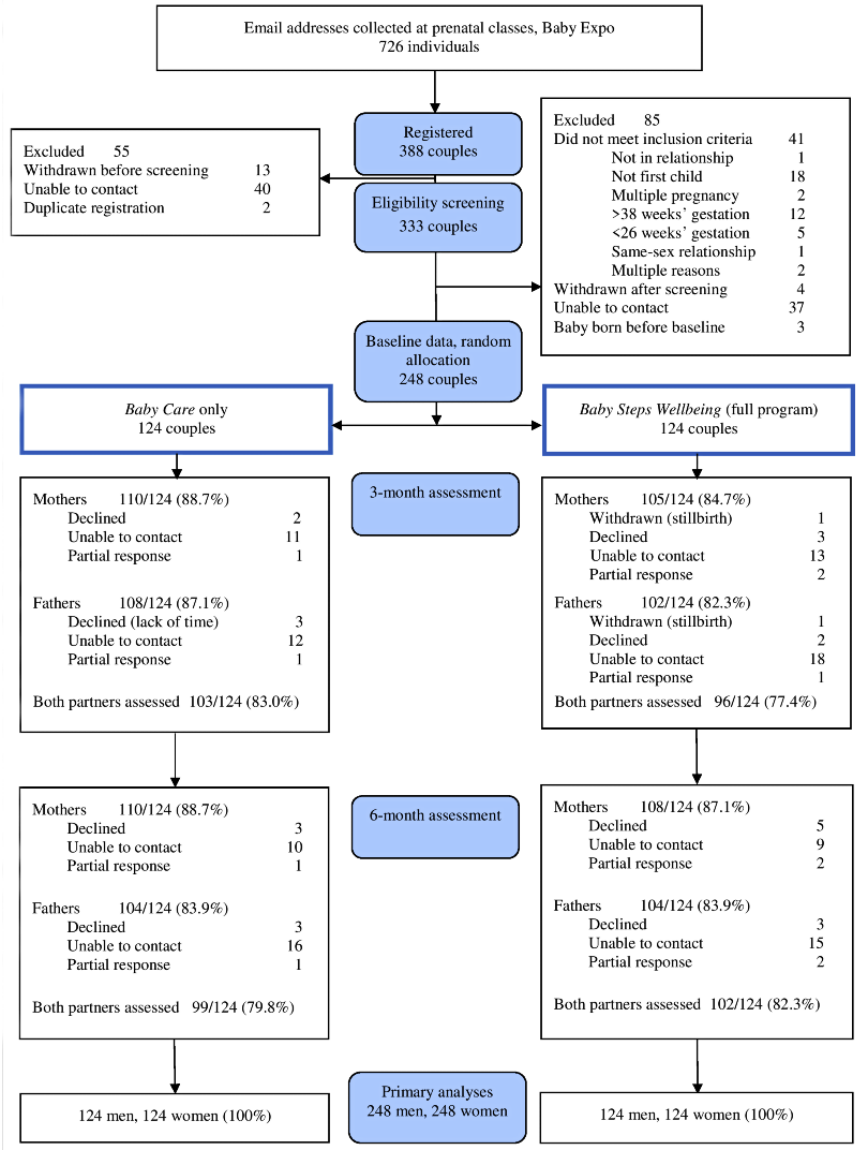

Table 1. Baseline characteristics and scores by parent gender (fathers: n=248; mothers: n=248): categorical variables.

Variable	Fathers, n (%)	Mothers, n (%)	Chi-square test (*df*)	*P* value
University degree	142 (57.2)	182 (73.3)	14.24 (1)	<.001
Employment			13.98 (2)	.001
Full time	219 (88.3)	188 (75.8)		
Part time or casual	20 (8.0)	35 (14.1)		
Unpaid leave, benefits or retired	9 (3.6)	25 (10.0)		
Indigenous	4 (1.6)	0 (0)	4.03 (1)	.045
Region of birth			4.12 (2)	.13
Australia	163 (65.7)	174 (70.2)		
New Zealand or Pacific or United Kingdom or Ireland or North America or other European countries	53 (21.4)	36 (14.5)		
Asia or Southeast Asia or Middle East or South America or Africa	32 (12.9)	38 (15.3)		

Table 2. Baseline characteristics and scores by parent gender (fathers: n=248; mothers: n=248): continuous variables.

Variable[a]	Fathers, predicted mean (SE)	Mothers, predicted mean (SE)	*t* test (*df*)	*P* value
Age (years)	33.0 (0.27)[b]	31.5 (0.27)[b]	15.77 (247.0)	<.001
Years living in Australia[c]	12.2 (1.02)[d]	10.5 (1.08)[e]	–1.37 (68.6)	.18
Depression (EPDS[f] total)	4.47 (0.25)	5.42 (0.25)	2.81 (247.0)	.005
Quality of life (AQoL-8D[g] Psychosocial)	0.474 (0.01)	0.434 (0.10)	–3.13 (247.0)	.002
Relationship satisfaction (CSI-16[h])	69.8 (0.60)	71.9 (0.60)	3.26 (247.0)	.001
Social support (Short MOS-SSS[i])	15.8 (0.21)	16.6 (0.21)	2.81 (247.0)	.005
Parenting self-efficacy	65.2 (1.20)	65.3 (1.20)	0.08 (247.0)	.94
Self-efficacy: support provision	81.2 (1.26)	71.8 (1.26)	–5.43 (247.0)	<.001

[a]Analyses of continuous variables include a random intercept for a couple.

[e]n=74.

[f]EPDS: Edinburgh Postnatal Depression Scale.

[g]AQoL-8D: Assessment of Quality of Life-8 Dimensions.

[h]CSI-16: Couples Satisfaction Index-16.

[i]MOS-SSS: Medical Outcomes Study Social Support Survey.

The participants had a median age of 32 (mean 32.2, SD 4.4; range 20-47) years, and 80.6% (400/496) were married. Most had a university degree (324/496, 65.3%), were employed full time (407/496, 82%), had been born in Australia (337/496, 67.9%), or had lived in Australia for a substantial period (mean 11.2 years, SD 9.5 years). Using a cutoff score of 12/13 on the EPDS [5] and no data substitution, 16.1% (40/248) of the mothers and 6.9% (18/248) of the fathers screened positive for depression at some time during the study. The rates at 3 months (approximately 2 weeks after childbirth) were 9.1% (20/217) for the mothers and 2.9% (6/209) for the fathers. If the Australian cutoffs for major or minor depression reported in the study by Matthey et al [25] were used (8/9 for mothers and 9/10 for fathers), 41.5% (103/248) of the mothers and 18.5% (46/248) of the fathers screened positive at some time, with the rates at 3 months being 27.2% (59/217) and 9.1% (19/209), respectively. The details are presented in Multimedia Appendix 1, Table S1.

Program Satisfaction and Use

Satisfaction with the program was high among the participants who accessed it at least once (median 75, 92% ≥50; Table 3), with no substantial differences due to treatment or parent gender, but access and use were suboptimal, especially for the fathers. The median number of log-ins across the sample was 1 (range 0-23; 90th percentile=5). Only 36.7% (91/248) of *Baby Care* and 37.9% (94/248) of *Baby Steps Wellbeing* participants (χ^2_1=0.08; *P*=.781) accessed programs on two or more occasions. While 53.6% (133/248) of the mothers used a program at least twice, only 21.0% (52/248) of the fathers did so (χ^2_1=56.56; *P*<.001). Among the *Baby Steps Wellbeing* participants, 44.4% (55/124) of the mothers set a goal, whereas only 12.9% (16/124) of the fathers did so (χ^2_1=30.02; *P*<.001). These parent gender differences were observed for all continuous variables related to program use (Table 3; Multimedia Appendix 1, Table S2). Despite the fact that the fathers receiving *Baby Steps Wellbeing* could access more than twice the number of modules (nine) than those receiving *Baby Care* (four), fathers only accessed an average of just one module in either treatment. The significant interaction between treatment and parent gender (t_{246}=2.35; *P*=.020) was a reflection of the fact that the mothers took greater advantage of the additional modules, although on average they still accessed fewer than half of those in *Baby Steps Wellbeing* (Table 2). More *Baby Care* modules were viewed by the participants in the *Baby Care* treatment (t_{492}=–3.40; *P*<.001), but there were no statistically significant differences between the treatments in terms of log-ins or duration of use (Multimedia Appendix 1, Table S2). The baseline EPDS scores had a negligible association with the use of the programs (Multimedia Appendix 1, Table S2), but a weak negative correlation with program satisfaction (*r*=–0.18; *P*=.03).

Table 3. Program use and satisfaction[a].

Variable	Values, predicted mean (SE)			
	Baby Care only		Baby Steps Wellbeing	
	Fathers	Mothers	Fathers	Mothers
Log-ins	1.09 (0.24)	2.67 (0.24)	0.89 (0.24)	2.77 (0.24)
Duration of use (days)	10.87 (4.08)	34.62 (4.08)	12.27 (4.08)	41.47 (4.08)
Modules viewed				
Total	0.98 (0.17)	2.23 (0.17)	1.07 (0.17)	3.10 (0.17)
Baby Care	0.98 (0.12)	2.23 (0.12)	0.40 (0.12)	1.56 (0.12)
Program satisfaction[b]	69.2 (2.03)	71.8 (2.01)	70.8 (2.10)	72.5 (2.06)

[a]Predicted means are derived from analyses that include a random intercept for a couple.

[b]Mean of responses across participants who had accessed a program to items on overall satisfaction, relevance, usefulness, and ease of finding what they wanted.

Model Comparisons

Initially, a comparison was made of model fit from the hypothesized model and from a full factorial model. With the exception of parenting self-efficacy, the hypothesized model gave a better fit than the full factorial model in terms of both Akaike Information Criterion (AIC) and Bayesian Information Criterion (BIC), and the simpler model did not result in a significantly poorer likelihood ratio (Table 4). In the case of parenting self-efficacy, AIC favored the full factorial model. Although penalization for the greater number of predictors resulted in a slightly poorer BIC value, a better fit from the full model approached significance on the likelihood ratio test (P=.05). Accordingly, the subsequent main analyses on this variable used the full factorial model, whereas the hypothesized model was used for the remaining outcome variables. Results for each variable using the nonpreferred model are displayed in Multimedia Appendix 1, Table S3.

In additional post hoc analyses, we also tested the fit from a model with only parent gender and time to assess whether any significant effects for treatment resulted in an improved model fit overall (Multimedia Appendix 1, Table S4). For self-efficacy for support provision, this model gave a significantly poorer fit and a larger AIC value than the hypothesized model, although the reduction in model complexity resulted in a slightly lower BIC value. For the remaining outcomes, the AIC and BIC values were slightly smaller for the simpler model, but the likelihood ratio test was not significantly different. We note that these results for the model fit moderate the conclusions from the analyses on the effects of treatment on relationship satisfaction (CSI-16) and parenting self-efficacy, which are described below.

Table 4. Comparison of hypothesized and full factorial models for analyses of outcomes[a].

Dependent variable	Parameters, N	AIC[b]	BIC[c]	Log likelihood	Deviance	Chi-square test (*df*=3)	*P* value
Depression (EPDS[d])							
Hypothesized model[e]	12	7247.7	7310.2	–3611.9	7223.7	3.34	.34

[h]MOS-SSS: Medical Outcomes Study Social Support Survey.

Primary Outcomes

The effects for each outcome variable from the preferred model are displayed in Table 5, and the means are shown in Figure 2 and Multimedia Appendix 1, Table S5. Over the course of the study, the mothers had higher EPDS scores for depression (Cohen *d*=0.37) and a lower average quality of life on the AQoL-8D Psychosocial Super Dimension than the fathers (Cohen *d*=0.27). The EPDS scores did not significantly change across the sample from baseline to 6 months, but the mothers' depression had a greater tendency to peak soon after childbirth, as shown by a significant parent gender×quadratic time effect (Table 5). For example, from baseline to 3 months, their EPDS scores rose 0.27 SD units more than those of the fathers. There was a linear improvement in quality of life over the study period (Cohen *d*=0.27), which once again was modified by an interaction between parent gender and quadratic time (eg, from baseline to 3 months): the psychosocial quality of life of the fathers increased by 0.16 SD units more than that of the mothers. However, there were no significant interactions between treatment and time on either primary outcome when the hypothesized model was used.

Table 5. Outcomes, using the preferred model.

Dependent variable	Estimate	SE	*t (df)*	*P* value
Depression (EPDS[a])				
Intercept	0.6744	0.2431	–2.77 (427.0)	.006
Treatment	–0.1820	0.2875	–0.63 (247.2)	.53

[a]EPDS: Edinburgh Postnatal Depression Scale.

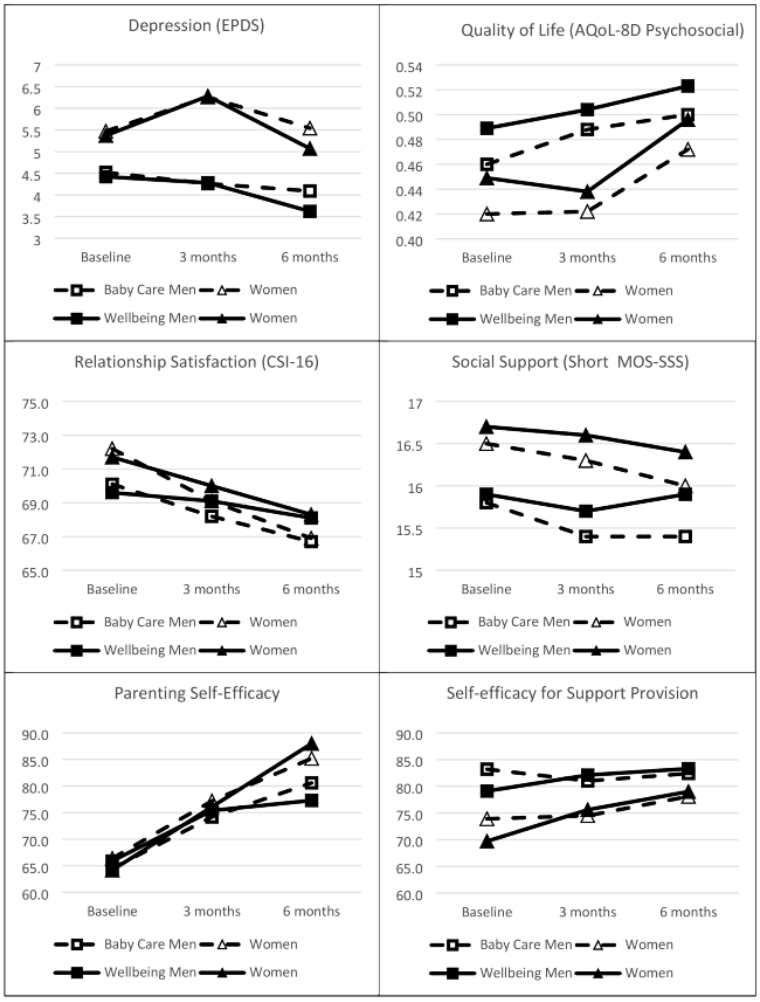
[b]AQoL-8D: Assessment of Quality of Life-8 Dimensions.

[c]CSI-16: Couples Satisfaction Index-16.

[d]MOS-SSS: Medical Outcomes Study Social Support Survey.

[e]The reported effects are from the hypothesized model, except for parenting self-efficacy, which is from the full factorial model.

Figure 2. Predicted mean outcomes, using the preferred model. Estimations of means used the hypothesized model, except for parenting self-efficacy, which used the full factorial model. AQoL-8D: Assessment of Quality of Life-8 Dimensions; CSI-16: Couples Satisfaction Index-16; EPDS: Edinburgh Postnatal Depression Scale; MOS-SSS: Medical Outcomes Study Social Support Survey.



Secondary Outcomes

Relationship satisfaction on the CSI-16 fell over the course of the study (Cohen *d*=–0.36), especially for the mothers (Cohen *d*=–0.46 vs –0.26 for the fathers). However, the reduction in relationship satisfaction was less in *Baby Steps Wellbeing* than in *Baby Care* (Cohen *d*=0.20). Significant interactions with treatment were also observed in the two self-efficacy measures. In the case of self-efficacy for support provision, the *Baby Steps Wellbeing* participants showed a greater linear increase over time than those in *Baby Care* (Cohen *d*=0.26). Across the whole study, the mothers had lower scores than the fathers (Cohen *d*=–0.33), but their scores improved to a greater extent over the study period (Cohen *d*=0.34 vs 0.08 for the fathers). The interaction of time and parent gender was not further modified by treatment. In contrast, the mothers had higher scores on parenting self-efficacy than the fathers on average (Cohen *d*=0.17), as well as showing a greater linear improvement over time (Cohen *d*=1.12 vs 0.72 for the fathers). In this case, there was also a three-way interaction: as presented in Figure 2, the mothers tended to have greater increases in *Baby Steps Wellbeing* than in *Baby Care* (Cohen *d*=0.26), but the reverse was the case for the fathers (Cohen *d*=–0.25). The only secondary outcome not showing any interactions between treatment and time was social support on the Short MOS-SSS. The mothers scored somewhat more highly than the fathers across the study period (Cohen *d*=0.22), but there were no other significant effects.

Discussion

Principal Findings

Although satisfaction with the *Baby Care* and *Baby Steps Wellbeing* programs was moderately high, the average number of log-ins and viewed modules was suboptimal, especially for the fathers. Joint access to the program by some partners may have led to underestimates of individual access, but little use was made of the key planning and goal-setting segments of *Baby Steps Wellbeing*.

Consistent with this limited access, perinatal distress on the EPDS, psychosocial quality of life, and social support on the Short MOS-SSS did not show significant differential improvements for the two treatments. However, there was some evidence of differential benefits from the full, interactive *Baby Steps Wellbeing* program compared with the *Baby Care* information modules in 3 of the 4 secondary outcomes. The participants who received the full program had a greater linear rise in self-efficacy for support provision and an attenuated

reduction in relationship satisfaction over the study than those who only received *Baby Care* information. Furthermore, consistent with greater program access by the mothers, they had greater linear increases than the fathers in their parenting self-efficacy if they received *Baby Steps Wellbeing* than if they were only given *Baby Care* information. These results are partially consistent with those from a recent universal prevention trial on parental stress, which used a booklet, video, home visit, and telephone call focused on baby care and being sensitive to the needs of both the parents and the baby and did not detect benefits over usual care on the EPDS [32]. However, that earlier study did not find differential effects on any other outcomes, including a single-item measure of parenting self-efficacy.

The interpretation of greater benefits from the full *Baby Steps Wellbeing* program is moderated by small effect sizes and by the fact that self-efficacy for support provision comprised a new single-item measure. In addition, the results from analyses in Multimedia Appendix 1, Table S3 that used a nonpreferred model differ from those in the preferred-model analyses, casting doubt on the robustness of the reported effects, and post hoc analyses showed that the significant interactions between time and treatment for 2 outcomes (relationship satisfaction and parenting self-efficacy) were insufficient to give a better model fit compared with a model that only included parent gender and time. Furthermore, all significant interactions between treatment and time involved linear changes to 6 months, rather than specifically modifying outcomes immediately after childbirth, when the greatest vulnerability is seen.

However, the fact that some significant effects were seen at all remained noteworthy, given the limited degree of program involvement and the fact that this was an unselected sample, with average scores on all outcome variables showing little dysfunction throughout the study. In this context, the lack of significant differential effects of the treatments on EPDS scores should not have been surprising, given the study's low point-prevalence of screening positive for self-reported depression (3% of the fathers and 9% of the mothers at 3 months, using an EPDS cutoff at 12/13) compared with the rates in meta-analyses (8% of fathers [3] and 12%-17% of mothers [1,2]), which restricted the opportunity to detect differential changes.

There were insufficient couples who both accessed and set goals for multiple *Baby StepsWellbeing* modules or continued to use the program postnatally (ie, for more than approximately 10 weeks) to allow a post hoc examination of whether more sustained or intensive program use would have provided stronger results, but this study's results clearly suggest that these should be goals for future research. Our program had already attempted to maximize ongoing program engagement in multiple ways: (1) by recruiting couples who might reinforce each other's engagement in program use and resultant actions; (2) by providing information related to baby care, which we expected to have salience late in the pregnancy; (3) by repeatedly reminding participants to log in and giving brief tips that changed at each visit; and (4) by offering opportunities to upload photos that would cue memories of good times with their baby and make it pleasurable to visit the site. We timed entry into the study and initial program exposure while the women were pregnant because of the time pressures experienced after childbirth, but solutions to childcare or general well-being issues might not have immediately seemed relevant to an unselected sample at that time. Furthermore, recruitment primarily through prenatal classes could have resulted in redundancy in some baby care information. In fact, a median of 1-2 website visits suggested that many participants may have regarded the program as just one of many web-based information repositories on baby care, which they only used once.

The absence of a predetermined, sequential progression through the program's modules might have been a significant factor in the limited use of the program [33,34]. Gamification of progression may increase program use (eg, rewarding module completion or progressive gains in knowledge or skills and inclusion of animations or videos or audios that modeled functional problem solutions [35,36]). The positive effects of coaching on maintained program engagement [17] could be simulated by digital *coaches* who might offer some features that approximated human interaction (eg, greeting and praising completion of tasks) [37], even if the individualization of these responses was limited. Although motivational interviewing before beginning the program may be more feasible in a depression treatment program than in a program that seeks to prevent depression [35], a brief digital adaptation of motivational interviewing (together with a rationale for regular program use) may also assist, especially in relation to addressing the couple's well-being. Impact and perceived relevance of the program might also be increased if the SMS text messages incorporated tips [38] or empowering messages rather than just reminding users to return to the program.

Problems with engaging fathers in prevention or treatment of mental health conditions are endemic, both perinatally and more generally [8,9], and occur for digital interventions as well as face-to-face services [19]. We had hoped that the provision of a module especially for fathers would increase its perceived relevance and that parallel use of the program by mothers would encourage its use by fathers. However, it seems that further refinement of the approach with a more extensive co-design is required.

There were several indications that the mothers reported more pronounced mental health and well-being issues than the fathers in this study, particularly in the perinatal period. They had higher average EPDS scores as well as lower psychosocial quality of life and self-efficacy for support provision over the course of the study, together with a greater tendency for their EPDS scores to peak. Their quality of life rose less strongly soon after childbirth, and their relationship satisfaction fell over time. Although they had slightly higher average social support over the course of the study and (not unexpectedly) were more confident about their parenting skills than the fathers, these gender differences further substantiate the particular vulnerability of new mothers to issues with mental health and well-being [1-3].

Strengths and Limitations

To our knowledge, this is the first controlled trial that specifically attempted to engage fathers in a digital perinatal intervention and provided an interactive module especially for

them. The trial had a substantial sample size and a very high retention in postbaseline assessments. Randomization was performed through an automated trial management program that ensured equivalence between treatment groups of the EPDS scores at baseline. All assessments were conducted on the web, and the follow-up research staff were blinded to the participants' allocation. We conducted intention-to-treat analyses, with secondary analyses examining effects in the participants who accessed the program. However, the study's predominant recruitment through prenatal classes and the sample's high rate of university education mean that the results may not be generalizable to populations that are less highly educated or less engaged in learning about birthing and childcare. Although recruitment during the third trimester was intended to maximize the perceived relevance of the content, this may also have reduced its perceived novelty as well as excluding parents with early births or pregnancy complications from the sample. The exclusion of parents who were not cohabiting, were not in a male-female relationship, were aged below 18 years, or were expecting multiple infants also restricted the potential application of this study.

Conclusions

There was some evidence of differential benefits from the full *Baby Steps Wellbeing* program, although these benefits were more consistently seen in the mothers than in the fathers, and the effect sizes were relatively small. A major contributor to these results may have been the low level of use of the self-guided program, especially by the fathers. Increasing this program's use will be a prerequisite for more accurate future estimation of the degree of potential impact of the *Baby Steps Wellbeing* program on the well-being of new parents.

Acknowledgments

This trial was funded by the men's health charity Movember through *Beyond Blue* (project grant: KAVA11NPD). The sponsor had no role in the development of the program; in the design, conduct, or analysis of the trial; or in preparing this manuscript for publication. The authors acknowledge the contributions of Anne Chang, Lynne Daniels, and Jennifer Connolly to the study proposal; the contributions of Leigh Davis, Amy Kelly, Elizabeth Hurrion, and Jane Swan to program content; the programming of Steven Edge and Jeremy Gibson; and the graphic design of Brendan Pearce. The program development was informed by the prior qualitative research of Lindsay Bennett. Trial recruitment was assisted by Anne Tremellen, Patricia Wilson, Katy Woodcock, and midwives from the Mater Mothers' Hospital. The authors also acknowledge the contribution of 41 parents who informed the program's content and design.

Authors' Contributions

All authors contributed to the conceptualization and design of the web program and trial, to the conduct of the trial, and the paper. The research officers for this trial were DS, SA, Georgia Stein, Elloise Brake and David Rodwell. Analyses were undertaken by JM and DJK, with advice from Dimitrios Vagenas and Shu-Kay Angus Ng. Joshua Byrnes and Peter Lee undertook cost-effectiveness analyses that will be reported in a separate paper.

Conflicts of Interest

The authors declare no competing financial interests. DJK, JF, JM, and HR collaborate in the development of digital programs and apps to treat or prevent perinatal depression or distress. AW is a member of the Triple P Research Network and has advised the Triple P International Scientific Advisory Committee in a research capacity. LH is supported by a senior research fellowship from the National Health and Medical Research Council (APP1119098).

Abstract

Background: Caring for children with cancer can be a stressful experience for parents and may have negative effects on their physical and psychological well-being. Although evidence has shown that resilience is associated with positive psychological well-being, few interventions have been specifically designed to enhance the resilience of parents of children with cancer.

Objective: The aim of this study is to examine the effectiveness of a mobile device–based resilience training program in reducing depressive symptoms and enhancing resilience and quality of life (QoL) in parents of children with cancer.

Methods: Parents of children diagnosed with cancer were recruited from the pediatric oncology wards of 3 tertiary hospitals in China. The participants were randomly assigned to either the experimental group (52/103, 50.5%) to undergo an 8-week mobile device–based resilience training program or to the control group (51/103, 49.5%) to receive an 8-week program of placebo information. The study outcomes included resilience, depressive symptoms, and QoL, as measured by the Connor–Davidson Resilience Scale, the Self-Rating Depression Scale, and the Short Form of the 6-Dimension Health Survey, respectively. All data were collected at baseline and at 2 and 6 months of follow-up. The data analysis followed the intention-to-treat principle. A generalized estimating equation was used to examine the effects of the intervention.

Results: The participants were mostly female (72/103, 69.9%), and their mean age was 33.6 (SD 5.2) years. The participants in the experimental group showed significantly higher levels of resilience (mean 67.96, SD 15.8 vs mean 58.27, SD 19.0; $P<.001$) and lower levels of depressive symptoms (mean 40.17, SD 9.9 vs mean 46.04, SD 10.9; $P<.001$) than those in the control group at 6 months of follow-up. The intervention showed statistically significant effects in improving resilience ($\beta=6.082$; $P=.01$) and decreasing depressive symptoms ($\beta=-2.772$; $P=.04$) relative to the control group. The QoL score in the experimental group was higher than that in the control group at 6 months of follow-up (mean 0.79, SD 0.2 vs mean 0.76, SD 0.3; $P=.07$); however, no statistically significant intervention effect was detected ($\beta=.020$; $P=.38$).

Conclusions: The mobile device–based resilience training program effectively enhanced resilience and alleviated depressive symptoms in parents of children with cancer. It is highly recommended that health care professionals incorporate this resilience training program when providing psychological care to parents of children with cancer.

Introduction

Background

Approximately 300,000 new cases of childhood cancer are diagnosed annually worldwide [1]. The incidence of childhood cancer in China is similar to that of the world and has increased at a rate of 2.8% per year [2]. The diagnosis of cancer in children and long-term treatment are not only stressful events for the child but also disrupt the parents' daily lives, especially within the first year after the diagnosis, which has been described as the most chaotic moment of the parents' lives [3]. Parents must reorganize their family roles and routines, learn cancer-related information and care skills, prepare for overwhelming medical expenses, and manage intensive treatment regimes, each of which can cause tremendous stress and affect the parents' physical and psychological well-being [4].

Of all the negative psychological consequences, depressive feelings are one of the most common concerns reported by parents of children with cancer [5,6]. A recent meta-analysis found that the prevalence of depressive symptoms among parents of children with cancer varied from 7% to 91%, with a pooled prevalence of 28% [5]. A cross-sectional study of Chinese parents of children with leukemia found that as many as 77% of mothers and 42% of fathers had depressive symptoms [7]. Although the negative effects of parents' depressive symptoms on the quality of life (QoL) and well-being of both the parents and their children with cancer are widely acknowledged [8,9], little attention has been devoted to the prevention and alleviation of depressive symptoms in Chinese parents of children with cancer.

Resilience is the process of adapting well in the face of stress or adversity; it involves personal virtues and strengths that can be accessed and cultivated to achieve growth under detrimental conditions [10]. Evidence has shown that resilience is associated with psychological well-being in both clinical and nonclinical populations [11,12]. A strong negative relationship between resilience and depressive symptoms has also been found in parents of children with cancer [13]. It has been suggested that resilience can play an important role in protecting individuals from stress-related disorders [14]. Therefore, interventions that enhance resilience in the parents of children with cancer may influence their depressive symptoms and well-being.

A recent meta-analysis revealed that resilience training programs that aim to equip individuals with the resources and skills to navigate adversity and thrive in challenging environments had a moderately positive effect on the subjects' resilience [15]. These resilience training programs tend to include a combination of evidence-based training in areas such as cognitive strategies and mindfulness [15]. A review of the literature shows that most resilience training programs target students and patients with chronic illnesses [16]. No study has yet examined the effectiveness of resilience training programs in promoting the psychological well-being of parents of children with cancer. A study in the United States demonstrated the moderate effectiveness of a resilience training program delivered face-to-face to the parents of children with serious illnesses [17]. However, face-to-face training is time-consuming and requires frequent visits, which often leads to low compliance [15]. It has also been reported that some parents of children with cancer have less motivation to attend face-to-face training because of their busy schedules [18]. Mobile health (mHealth), which refers to health practices conducted via mobile devices, is increasingly common and has gained support from the World Health Organization for health promotion and treatment compliance [19,20]. It has also been suggested that internet- and mobile-based psychological interventions are cost-effective for both psychiatric and medical conditions [21]. The use of mobile apps to deliver resilience training has certain advantages; for example, health care professionals can give the participants remote support and feedback to promote their psychological well-being. Most importantly, training via mobile apps is more flexible and efficient than face-to-face interventions [22], particularly during a pandemic, when the delivery of face-to-face health care interventions may not be feasible. It is worth noting that with the rapid development and high use rate of WeChat (Tencent Holdings Limited) [23], such mobile apps may have the potential to deliver health interventions, increase adherence to training, and serve a large number of participants. This study aims to explore the effectiveness of a mobile device–based resilience training program in reducing depressive symptoms and enhancing the resilience and QoL of parents of children with cancer.

Theoretical Framework

The training program used in this study was guided by the resilience framework developed by Kumpfer [24]. The resilience framework generated 5 internal resilience factors: cognitive, emotional, spiritual, behavioral, and physical. Specifically, cognitive competency can help individuals think rationally and protect them from negative thoughts; emotional stability can help individuals recognize and deal reasonably with negative emotions; an individual's spiritual belief in his or her ability to improve the situation and achieve goals can help them survive difficult times; behavioral skills such as problem-solving can increase an individual's self-efficacy to tackle life's problems; and individuals with few physical problems may internalize

their physical strength and interpret themselves as being psychologically healthy [24]. These internal resilience factors represent fundamental elements that have been shown to be essential to cope effectively with life stressors and to adapt well in the face of adversity [10]. Therefore, by cultivating the skills and resources to foster these internal resilience factors, we expect that the intervention would promote parental resilience and improve parents' well-being.

Methods

Trial Design

This study was a 2-arm, parallel-group, randomized controlled trial (RCT) that adheres to the CONSORT (Consolidated Standards of Reporting Trials) guidelines [25]. This study was approved by the institutional review board of the University of Hong Kong/Hospital Authority Hong Kong West Cluster (UW 19-436) and registered at ClinicalTrials.gov (NCT04038242).

Participants

From August 2019 to July 2020, the parents of children who received a diagnosis of cancer in the pediatric oncology wards of 3 tertiary hospitals in China and who met the following inclusion criteria were invited to participate in this study: (1) a child (aged 0-19 years) in whom cancer was diagnosed within the past year, (2) the ability to read Chinese and speak Mandarin, and (3) a smartphone with the WeChat app. Parents with cognitive impairments or physical disabilities identified from medical records and those who were participating in other psychological interventions or consultations were excluded.

Power analysis using G*Power 3.1 was performed to estimate the sample size [26]. According to a previous study that explored the effectiveness of a resilience training program in parents of children with serious illnesses [17], the effect size for resilience was 0.59. Thus, to predict the difference between the 2 groups at a 5% level of significance and a power of 0.8, 37 subjects were required for each group. Given a potential attrition rate of 20%, an additional 10 subjects were needed for each group. Therefore, the total sample size for this study was 94, with 47 subjects in each group.

Randomization and Blinding

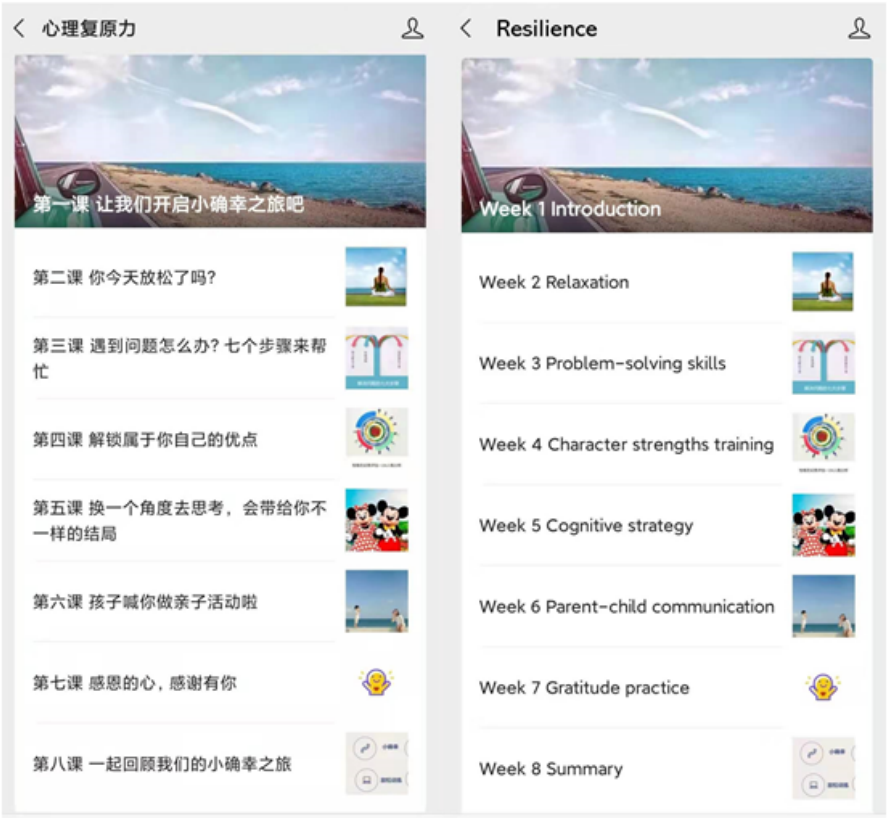
Simple randomization was used in this study. The participants were randomly allocated to the experimental group or control group in a 1:1 ratio. Random numbers were generated using IBM SPSS Statistics (version 25.0, IBM Corp) before recruitment. To guarantee allocation concealment, an independent researcher who was not involved in the recruitment matched the random numbers with the participants in chronological order of recruitment based on a WeChat official account follow list. Single blinding was used, and the research assistants who collected the data were blinded to the participants' group allocation.

Intervention

All participants were required to scan a quick response code to follow the WeChat official account at enrollment to participate in the intervention. The WeChat official account is the equivalent of a Facebook page and synthesizes functions, including tweet design and instant interaction communication [27]. The public can receive tweets after following the official WeChat account.

The participants in the experimental group participated in the resilience training program with 8 tweets that focused on the cultivation of internal resilience factors that enhance parental resilience (Figure 1). Each tweet session was constructed in 3 parts, including detailed skill training methods with pictures or short videos, examples of applying the skills when caring for children with cancer, and an assignment to reinforce the training (Multimedia Appendix 1). The participants were required to read the tweet sessions and finish the web-based assignments, which took approximately 15 minutes for each training session. Feedback on the assignment from a psychological consultant was sent back to the participants via WeChat within 1 working day. We sent the tweets weekly on each Saturday at 8 PM, and a reminder of the assignment was sent at the same time the next Wednesday to promote the participants' enrollment in training. To ensure that the intervention had an adequate effect on the outcome measures of this study, the dosage was assessed in terms of amount, frequency, and duration by a research committee that comprised a professor of psychology and an associate professor of psycho-oncology with extensive experience in psychological interventions, a professor of pediatric oncology and 2 senior pediatric oncology nurses with considerable clinical experience, and a research fellow with rich experience conducting resilience training programs. The feasibility and acceptability of the interventional dosage and content were evaluated in a 1-group pilot trial with 10 participants. Most of the participants commented that the length and frequency of the tweets were acceptable, and they were able to comprehend the content of the tweets. Hence, no changes were made to the content of the intervention. To control for potential contamination in the study, we set up the tweets to be sent only to specified participants, and the tweets could not be shared. Table 1 presents the detailed content of the mobile device–based resilience training program.

Figure 1. The total 8 tweets in the mobile device–based resilience training program.



The participants in the control group received 8 tweets that contained information from a caring manual distributed by the hospital to every child with cancer. The content of the tweets included oral care, symptom management, peripherally inserted central catheter maintenance, dietary guidance, medication care, knowledge about bone marrow biopsy, and infection prevention. The number and frequency of tweets were the same as those in the experimental group. No assignments or feedback were delivered to the participants in the control group.

Several strategies were adopted to ensure the integrity of the intervention. First, a research protocol was developed, and the interventions strictly followed the protocol. Second, the number of tweets and feedback sent to each participant was recorded in Microsoft Excel (Microsoft Corporation) to monitor the delivery of the interventions. In addition, team meetings were held monthly to evaluate the quality of the intervention's implementation.

Table 1. Content of the mobile device–based resilience training program.

Sessions or tweets and internal resilience factors	Details		
	Objectives	Core content	Assignment
Week 1: introduction			
Emotional	• To help the participants understand the purpose of the intervention • To help the participants initially understand the intervention content	Definition of resilience, purpose of the study, science of the intervention, general content of all tweets, and encouragement to cultivate positive emotions in daily life	The 3 good things practice: write down 3 things that go well for you that day and reflect on why they went well
Week 2: relaxation			
Emotional and physical	• To practice relaxation techniques • To reduce the participants' stress	Definition of meditation, science and specific practice methods of meditation exercise, and guided meditation audio	Guided breath awareness: sit quietly and be aware of your breath and exercise following the guided meditation audio
Week 3: problem-solving skills			
Behavioral	• To learn problem-solving skills • To cultivate a positive coping style	Introduction and science of the problem-solving therapy, specific 7 steps to solve problems, and examples of solving problems encountered in caring for children with cancer	Problem-solving practice: complete the problem-solving worksheet according to the instructions
Week 4: character strength training			
Cognitive	• To help the participants understand their own character strengths • To increase confidence in dealing with difficulties in life	Definition of character strength, establishment of character strength assessment system, and science and specific methods of character strength training	Character strength training: finish web-based character strength assessment to find your top 5 strengths. Use your strengths in caring for your child
Week 5: cognitive strategies			
Cognitive and emotional	• To help the participants reframe negative or unhelpful cognition • To learn emotion management skills	Recognize and accept emotions, definition of cognition, science of cognition restructuring, examples of cognition restructuring scenarios from parents of children with cancer, and emotion management strategies	Cognition restructuring practice: complete the cognitive reconstructing worksheet according to the instructions
Week 6: parent–child communication			
Behavioral	• To promote effective communication between parent and child • To help the participants build a good relationship with their child	Ways to achieve effective parent–child communication, examples of good communication from parents of children with cancer, and tips for managing children's emotions	Parent–child activity: accompany the child for an appropriate activity and apply the communication skills in the activity
Week 7: gratitude practice			
Spiritual	• To help the participants cultivate positive beliefs • To help the participants attain personal growth	Manifestations, benefits, science and specific exercise of gratitude; steps to make a realizable goal; and examples of goal setting from parents of children with cancer	Gratitude activity: write a gratitude letter or keep a gratitude diary or prepare a gratitude card
Week 8: summary			
Cognitive	• To review the learned skills and related assignments • To help the participants make a plan to reinforce the learned skills in their future life	Simple summary for each tweet, emphasis of the learned resilience skills and related assignments, and encourage the participants to make a plan to practice the learned skills	Plan-making: make a plan to practice all skills and choose a favorite exercise to keep up

Outcomes and Measures

At baseline, the participants' demographic information and their children's clinical characteristics were collected using a demographic information sheet. The questionnaire requested information about the participants' gender, age, marital status, educational attainment, and monthly income. The participants also reported their child's age, type of cancer, time since diagnosis, and risk stratification of cancer. In resilience intervention studies, it has been suggested that a posttest at the end of the training program and a follow-up assessment at 6 months are necessary to evaluate the efficacy of the interventions [28]. Hence, the outcomes in this study were assessed at baseline and at 2 and 6 months after the intervention began.

The primary outcome was resilience, which was measured at 6 months using the Connor–Davidson Resilience Scale, a self-rated scale designed by Connor and Davidson [29]. The Chinese version was translated and tested by Yu and Zhang [30] and has shown good reliability and satisfactory validity. It consists of 25 items and is scored on a 5-point Likert scale (0-4). The total score ranges from 0 to 100, with a higher score reflecting a higher level of resilience. It has been widely used in clinical practice and treatment-outcome research [31].

The secondary outcomes were depressive symptoms and QoL at 6 months of follow-up and resilience, depressive symptoms, and QoL at the 2-month follow-up visit. The Self-Rating Depression Scale was used to measure participants' depressive symptoms during the previous week [32]. It includes 20 items, and half of the items are scored in reverse. The frequency of the symptom in each item was evaluated on a 4-point Likert scale (1=never or seldom, 2=sometimes, 3=often, and 4=always). The total score ranges from 20 to 80, and a higher total score indicates worse depressive symptoms. The Chinese version of this scale has shown good reliability and satisfactory internal consistency [33].

The Short Form of the 6-Dimension Health Survey was used to measure the participants' QoL. It was developed by Brazier et al [34] and is derived from the 36-item Short Form Health Survey. Hong Kong scholars translated it into Chinese and produced a scoring algorithm [35]. This scale is a 6-dimension health survey that assesses physical functioning, role limitations, social functioning, pain, mental health, and vitality. The total score based on the scoring algorithm ranges from 0.32 for worst health to 1 for full health. The scale has been shown to be reliable and valid in a Chinese population [36].

Data Collection

To identify potential participants, posters with information about the study were posted on the notice board in the hospitals' pediatric oncology wards and outpatient clinics. Parents who were willing to participate scanned a quick response code on the poster to complete a simple application form. The research assistant then contacted the person who filled out the application form after assessing their eligibility. The research assistant also visited each ward and invited parents of children with cancer to participate. The study details, including purpose, procedures, and potential benefits and harm, were explained, and the parents were given the option of participation or refusal. The parents were also told that their participation was voluntary and that they had the right to withdraw at any time without reprisal. Written informed consent was then obtained from parents who agreed to participate. The baseline and 2-month follow-up data were collected using written questionnaires in the wards of the hospitals. Outcome measures at the 6-month follow-up were collected using web-based questionnaires.

Statistical Analysis

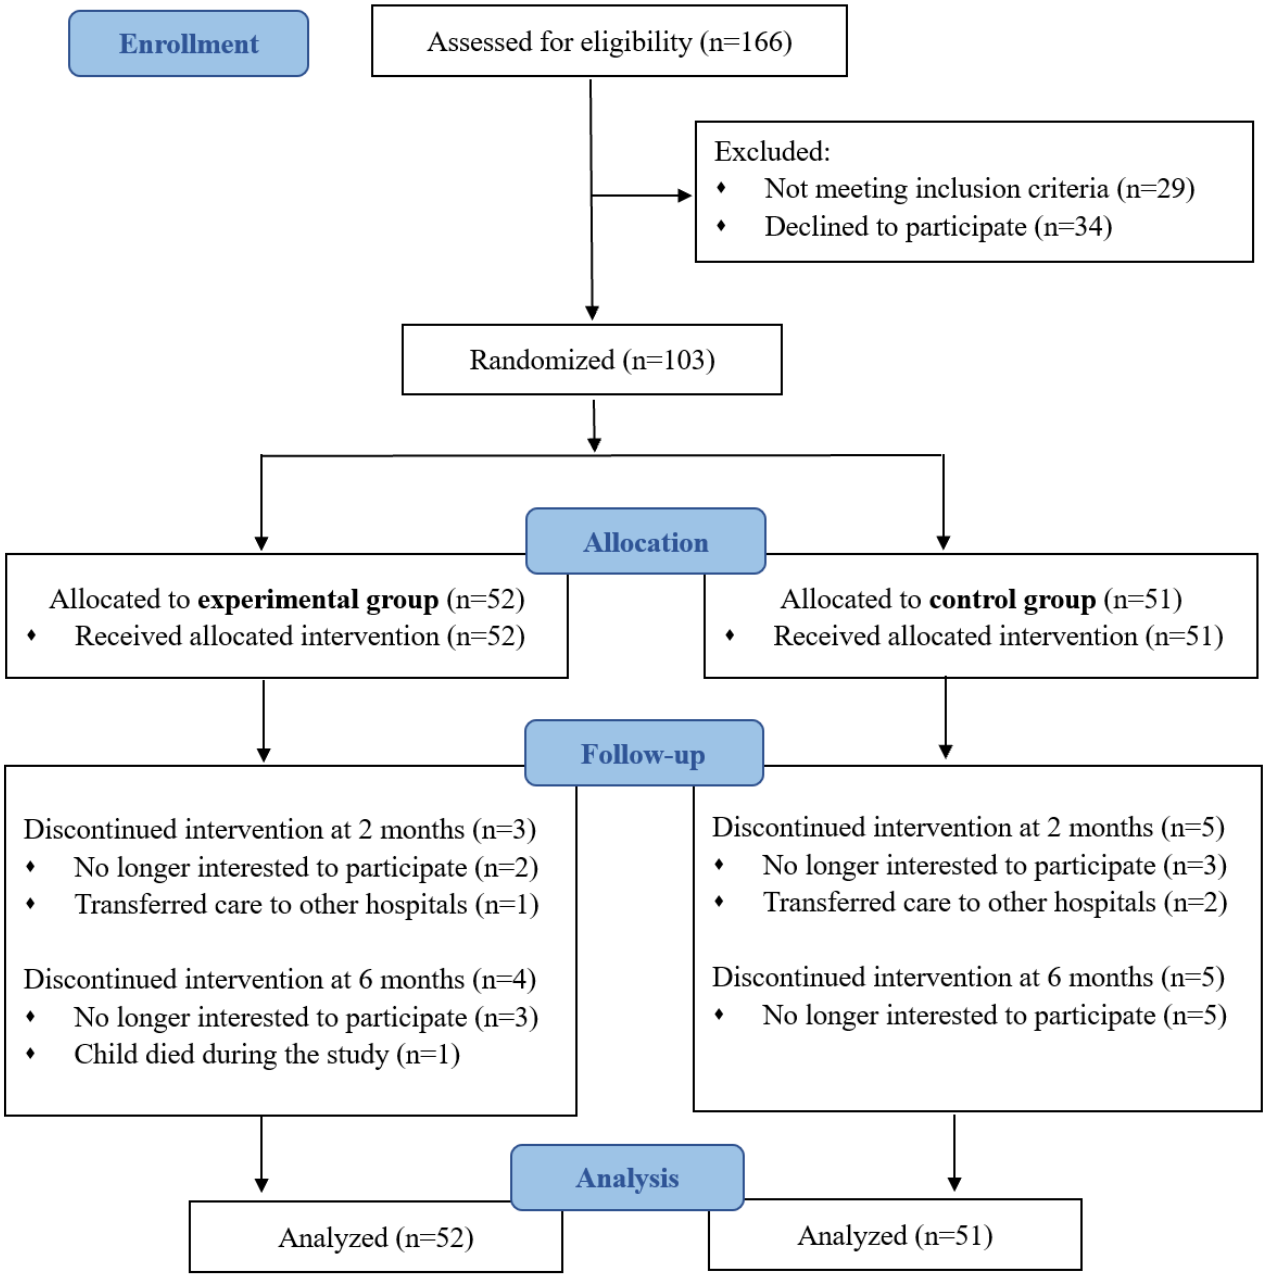
IBM SPSS Statistics 25.0 (IBM Corp) was used for data analysis. The intention-to-treat principle was applied, and the participants were analyzed according to their initial group assignments. Missing data were handled with multiple imputation using the Markov chain Monte Carlo method. Complete case analysis was conducted to test the robustness of multiple imputation. Descriptive statistics were applied to calculate the mean and SD for continuous data and the frequency and percentage for categorical data. The range and median values for the study outcomes were displayed as a complement. The differences in the baseline characteristics and outcomes between the experimental and control groups were examined using a chi-square test or Fisher exact test for categorical variables and 2-tailed independent-sample *t* test and Wilcoxon signed-rank test for continuous variables. A generalized estimating equation was used to estimate the effects of the intervention on all outcomes with repeated measures [37]. Statistical significance was set at $P<.05$.

Results

Participants Characteristics

A total of 103 participants were recruited; of the 103 participants, the experimental and control groups had 52 (50.5%) and 51 (49.5%) participants, respectively. Figure 2 presents the flowchart of the study. The overall attrition rate was 16.5%, and no significant differences were found in the baseline characteristics between the participants who withdrew and those who remained.

Figure 2. A CONSORT (Consolidated Standards of Reporting Trial) flow diagram.



The participants were mostly female (72/103, 69.9%) and married (100/103, 97.1%), and their mean age was 33.6 (SD 5.2) years. Approximately one-third (29/103, 28.2%) had attained tertiary education, and half (52/103, 50.5%) had a monthly income of <Chinese ¥3000 (US $427.35). Approximately two-thirds (69/103, 67%) of the participants' children received a diagnosis of a hematologic tumor, and the remaining one-third (34/103, 33%) had a solid tumor. The children's mean age was 5.9 (SD 3.9) years, and most had received their diagnosis <6 months earlier (85/103, 82.5%). No significant differences were detected in the baseline characteristics between the experimental and control groups (P>.05); details are given in Table 2.

Table 2. Baseline characteristics of the participants in the experimental and control groups (N=103).

Characteristics	Experimental (n=52)		Control (n=51)		Chi-square (*df*)	*t* test (*df*)[a]	*P* value

Comparisons Between Experimental and Control Groups

Table 3 presents comparisons of resilience, depressive symptoms, and QoL between the 2 groups at each measuring point. Compared with the participants in the control group, those in the experimental group showed statistically higher levels of resilience at 2 months (mean 61.90, SD 14.6 vs mean 69.35, SD 13.4; *P*=.005) and 6 months (mean 58.27, SD 19.0 vs mean 67.96, SD 15.8; *P*<.001) and lower levels of depressive symptoms at 2 months (mean 44.66, SD 8.0 vs mean 40.40, SD 9.1; *P*=.009) and 6 months (mean 46.04, SD 10.9 vs mean 40.17, SD 9.9; *P*<.001). Although the QoL scores in the control group were lower than those in the experimental group, no significant differences were found between the 2 groups at 2 months (mean 0.75, SD 0.1 vs mean 0.77, SD 0.2; *P*=.11) and 6 months (mean 0.76, SD 0.3 vs mean 0.79, SD 0.2; *P*=.07).

Table 3. Comparison of resilience, depressive symptoms, and quality of life in the experimental and control groups (N=103).

Outcomes measures	Experimental (n=52), mean (SD)	Control (n=51), mean (SD)	*t* test (*df*)[a]	*P* value	Experimental (n=52), median (range)	Control (n=51), median (range)	*Z*	*P* value

[a]The significance of *t* test is 2-tailed.

Generalized Estimating Equation Model

There were 16.5% (17/103) of cases with missing data on the variables during follow-up, including resilience, depressive symptoms, and QoL. Table 4 shows the results of the generalized estimating equation model for study outcomes under the intention-to-treat and complete case analyses. Similar results between the 2 analyses reflected the robustness of multiple imputation. Statistically significant main effects were found for the intervention in promoting resilience (β=6.082; *P*=.01) and decreasing depressive symptoms (β=−2.772; *P*=.04), whereas no significant intervention effect was observed for QoL (β=.020; *P*=.38). In addition, significant group-by-time interaction effects were detected for resilience at 2 months (β=5.812; *P*=.01) and 6 months (β=7.167; *P*=.01) and for depressive symptoms at 2 months (β=−5.553; *P*<.001) and 6 months (β=−6.504; *P*<.001). No significant interaction effects were observed for QoL at 2 months (β=.021; *P*=.42) or 6 months (β=.023; *P*=.43).

Table 4. A generalized estimating equation model for resilience, depressive symptoms, and quality of life.

Outcome measures	Intention-to-treat (N=103)		Complete case (N=86)	
	β (SE; 95% CI)	*P* value	β (SE; 95% CI)	*P* value
Resilience				
Main effect[a]	6.082 (2.360; 1.455 to 10.709)	.01	6.055 (2.652; 0.858 to 11.253)	.02
Group×time 1[b,c]	5.812 (2.363; 1.177 to 10.448)	.01	6.373 (2.226; 2.011 to 10.736)	.005
Group×time 2[b,c]	7.167 (2.921; 1.436 to 12.899)	.01	7.605 (2.739; 2.236 to 12.974)	.004
Depressive symptoms				
Main effect	−2.772 (1.354; −5.427 to −0.117)	.04	−2.454 (1.581; −5.553 to 0.644)	.12

[c]Time 1 and time 2 refer to 2 and 6 months of follow-up, respectively.

Discussion

Principal Findings

This RCT addressed an important health issue related to the consequences of children's cancer on their parents' psychological well-being and QoL, an area that has not been well explored. Most importantly, this study is original and helps to clarify the effectiveness of a mobile device–based resilience training program in reducing depressive symptoms and enhancing resilience and QoL in Chinese parents of children with cancer. To our knowledge, this study is the first RCT that combines mHealth and resilience training to improve mental health in the parents of children with cancer.

This study demonstrated that over a 2-month period, this mobile device–based resilience training program was sufficient to enhance resilience in the parents of children with cancer. The findings were in accordance with those of a previous study conducted in students using a computer device compared with educational attention control [38]. Guided by the resilience framework of Kumpfer [24], our program provided training in skills to foster internal resilience factors and enhance the resilience levels of parents of children with cancer. For example, the practice of recording 3 good things every day could encourage the participants to focus on positive things so as to cultivate positive emotions and optimism related to internal emotional characteristics [39]. Cognitive reframing training, which usually involves internal cognitive characteristics, could help the participants view the situation from various perspectives and change their negative thoughts into positive ones, thus allowing them to deal with trouble in cognition [40]. Moreover, to foster internal spiritual characteristics, the participants were encouraged to express their gratitude in various ways to those who supported them. Such gratitude practices have been shown to cultivate participants' positive beliefs and help them attain personal growth [41]. In addition, the difference in resilience between the experimental and control groups was still significant after 6 months of follow-up, which indicates that the effectiveness of a mobile device–based resilience training program can be sustained over an extended period. Increased proficiency in skills use may play a role in maintaining resilience levels and help parents better navigate adversity [42].

The mobile device–based resilience training program significantly alleviated depressive symptoms in parents of children with cancer. The depressive symptoms score increased continuously across the study for the parents in the control group, whereas the score for the parents in the experimental group showed an opposite trend. These findings were consistent with those of previous resilience training programs for patients with chronic illnesses [16] and contrary to the changes in resilience in this study. The negative relationship between resilience and depressive symptoms has been widely acknowledged [33,43], and our findings further support this relationship in parents of children with cancer. It has been noted that resilience can protect individuals from stress-related disorders such as depressive symptoms via positive cognition and enhanced self-efficacy [44]. Individuals with high levels of resilience are more likely to believe that they have the skills to deal with an adverse situation and to appraise the situation as a challenge to overcome [45]. In this study, problem-solving skills were taught to help parents deal with the issues they encountered in caring for their children with cancer. Combined with character strength training, parents were expected to use their cultivated strengths to solve related problems in daily life. Hence, the learned skills that could increase parents' confidence in coping with their children's cancer may have a positive effect on alleviating their depressive symptoms. Furthermore, evidence has shown that relaxation techniques and strong relationships

are beneficial for ameliorating depressive symptoms [46,47]. The guided breath awareness practice and parent–child communication training included in the resilience training program may also play a role in reducing depressive symptoms in parents of children with cancer.

Although the QoL scores in the experimental group were higher than those in the control group, no significant effects were detected. The improvements in resilience and alleviation of depressive symptoms did not significantly promote QoL in the parents of children with cancer, possibly because of the relatively short study period. It has been well demonstrated that a change in QoL usually takes a longer time than behavior changes or mental health improvement [48]. Previous studies generally included 3 months of follow-up to explore the effect of a resilience training program on QoL, and the pooled results of the systematic review showed no significant improvement [16]. It is recommended that future studies add further evidence on the long-term effects of a mobile device–based resilience training program on QoL in parents of children with cancer. In addition, QoL is regarded as a multidimensional concept that is influenced by various factors other than resilience and depressive symptoms [49,50]. The skills trained in this study focused mainly on promoting the parents' psychological well-being, and strategies that target the cultivation of social resources and improvement of physical health are worth considering in future interventions. Evidence has shown that COVID-19 is a stressful event for the general public and can have an impact on their QoL [51]. Given that the study period covered the first wave of COVID-19 in China, the pandemic might have had an impact on the parental QoL and weakened the intervention effects. However, the efficacy in enhancing resilience and reducing depressive symptoms indicated that the learned skills in resilience training could help parents adapt to adversities, including the pandemic.

Limitations

There were 2 limitations to this study. First, we only examined the effects of the mobile device–based resilience training program on parents of children with cancer for 6 months. Whether the improvement in resilience and the reduction in depressive symptoms could be sustained or whether the changes in QoL could show a significant difference over the long term should be further explored. Second, because of the small sample size, we did not perform a statistical assessment to identify the potential impacts of social demographics and children's clinical characteristics (ie, time since diagnosis) on parents' outcomes. Nevertheless, we conducted a cross-sectional study to explore the relationships between resilience and QoL in Chinese parents of children with cancer [52] before this RCT. The results showed that the time since diagnosis did not correlate with parents' resilience and QoL.

Implications for Future Practice and Research

Given the increasing incidence of childhood cancer and considerable stress in caring for these children [1], it is critical in clinical practice to provide effective psychological interventions for parents of children with cancer. Our findings indicate that our mobile device–based resilience training program was efficient in enhancing resilience and reducing depressive symptoms. As a potential preventive strategy for stress-related disorders [14], the application of a resilience training program is recommended at an early stage when parents first face the diagnosis of their child's cancer. The learned skills would then promote parental resilience and help them adapt more quickly to their child's cancer and deal with the adversity without the harassment of stress-related disorders. Considering the effectiveness and convenience of the mobile device–based resilience training program, health care professionals could use popular social media apps such as WeChat, Facebook, and WhatsApp to implement such programs to benefit more parents of children with cancer via mHealth care. As objective biometric data can complement the subjective evidence of the effects of the mobile device–based resilience training program, relative biometric outcomes should be assessed in future studies. In addition, given that changes in children's health conditions might affect the parents' outcomes, it is recommended that future studies also assess the health condition of children with cancer over time. Finally, the parental physical symptoms, such as insomnia, could be good indicators of the effectiveness of resilience training programs, which should be assessed in future studies.

Conclusions

Our mobile device–based resilience training program was developed under the resilience framework of Kumpfer [24] and included 8 tweets and assignments to train skills that foster internal resilience factors. The parents of children with cancer who participated in this program revealed higher levels of resilience and fewer depressive symptoms than the control subjects. It is highly recommended that health care professionals incorporate this resilience training program when providing psychological care to parents of children with cancer.

Conflicts of Interest

None declared.

Abstract

Background: Behavioral habits are often initiated by contextual cues that occur at approximately the same time each day; so, it may be possible to identify a reflexive habit based on the temporal similarity of repeated daily behavior. Mobile health tools provide the detailed, longitudinal data necessary for constructing such an indicator of reflexive habits, which can improve our understanding of habit formation and help design more effective mobile health interventions for promoting healthier habits.

Objective: This study aims to use behavioral data from a commercial mindfulness meditation mobile phone app to construct an indicator of reflexive meditation habits based on temporal similarity and estimate the association between temporal similarity and meditation app users' perceived health benefits.

Methods: App-use data from June 2019 to June 2020 were analyzed for 2771 paying subscribers of a meditation mobile phone app, of whom 86.06% (2359/2771) were female, 72.61% (2012/2771) were college educated, 86.29% (2391/2771) were White, and 60.71% (1664/2771) were employed full-time. Participants volunteered to complete a survey assessing their perceived changes in physical and mental health from using the app. Receiver operating characteristic curve analysis was used to evaluate the ability of the temporal similarity measure to predict future behavior, and variable importance statistics from random forest models were used to corroborate these findings. Logistic regression was used to estimate the association between temporal similarity and self-reported physical and mental health benefits.

Results: The temporal similarity of users' daily app use before completing the survey, as measured by the dynamic time warping (DTW) distance between app use on consecutive days, significantly predicted app use at 28 days and at 6 months after the survey, even after controlling for users' demographic and socioeconomic characteristics, total app sessions, duration of app use, and number of days with any app use. In addition, the temporal similarity measure significantly increased in the area under the receiver operating characteristic curve (AUC) for models predicting any future app use in 28 days (AUC=0.868 with DTW and 0.850 without DTW; $P<.001$) and for models predicting any app use in 6 months (AUC=0.821 with DTW and 0.802 without DTW; $P<.001$). Finally, a 1% increase in the temporal similarity of users' daily meditation practice with the app over 6 weeks before the survey was associated with increased odds of reporting mental health improvements, with an odds ratio of 2.94 (95% CI 1.832-6.369).

Conclusions: The temporal similarity of the meditation app use was a significant predictor of future behavior, which suggests that this measure can identify reflexive meditation habits. In addition, temporal similarity was associated with greater perceived mental health benefits, which demonstrates that additional mental health benefits may be derived from forming reflexive meditation habits.

Introduction

Background

Practicing healthier daily behaviors would improve many important physical and mental health outcomes for adults in the United States [1-5]. However, even when healthy behaviors are successfully initiated, many people find it difficult to maintain them as long-term habits [6-8] and thus do not attain the corresponding health benefits. One theory of habitual behaviors from psychology and neuroscience contends that habits are unconsciously or reflexively cued by environmental stimuli [9-11]. By repeatedly pairing an environmental or contextual cue with the performance of a desired behavior, our brains routinize the cue-behavior association, reducing the use of deliberative cognitive processes to instigate the daily performance of the behavior [12-14]. Recent research suggests that these contextually cued reflexive responses underlie many of our daily behaviors [9,15], and reflexively instigated habits are a commonly reported behavioral strategy among those who successfully maintain healthy habits, such as daily medication adherence and physical activity [16-20]. However, research has yet to examine mindfulness meditation practices, where the reduction in cognitive effort associated with reflexively instigating meditation [20-22] may enhance the mindfulness experience and increase the corresponding mental health benefits.

An additional limitation to the existing psychology research on habitual behaviors has been the reliance on self-reported measures of habit strength [23]. Habits are theorized to be unconsciously initiated, and as such, individuals should not be able to accurately recall their experience of performing a habitual behavior. Thus, self-reported measures are more likely to capture an individual's perceived self-efficacy or fluency in their behavior [24]. The historical reliance on survey-based habit measures stemmed from a lack of detailed, longitudinal behavioral data necessary for observing daily behavioral patterns. With the recent advent and popularity of mobile health (mHealth) tools that collect precise, high-frequency data on users' daily behaviors, there is a new opportunity for developing more objective indicators of daily habits. These data-driven measures offer the potential to more accurately describe the habit formation process and inform the design of new mHealth interventions that can more successfully promote the formation of healthier habits. As this type of high-frequency daily data are available for many health behaviors, such as physical activity (via wearable fitness trackers), medication adherence (via pill bottles with electronic caps), and mobile phone app–based mindfulness meditation, objective identifiers of reflexive habits will also allow the research on habitual behaviors to be translated across behavioral settings with a higher degree of fidelity.

Goals of This Study

The 2 aims of this study are to construct and test an objective indicator of contextually cued mindfulness meditation habits and to estimate the association between this indicator and improvements in physical and mental health. For this research, we examined detailed observations of mindfulness meditation practices among users of *Calm*, a popular commercial meditation smartphone app. Our novel indicator of contextually cued habits was constructed to capture the temporal similarity of daily app use (ie, using the app at approximately the same time of the day) based on the dynamic time warping (DTW) distance between app use on consecutive days (detailed below). Existing research has shown that most contextually cued habits are performed at approximately the same time and in the same location each day [25,26], which motivates the use of temporal similarity to identify reflexively instigated meditation habits. However, as contextually cued habits are rarely based strictly on time, DTW is used to flexibly measure temporal changes in app-use patterns. For example, a person's daily meditation habit could be cued by finishing lunch or arriving home after work, both of which may occur at slightly different times each day. Accordingly, we apply the DTW measure to capture the broad changes in daily app use start time, duration, or both, while allowing for small daily variations in these dimensions. As a large difference in temporal similarity between 2 days signals that the individual was meditating with the app in a different pattern on those days, we hypothesize that our measure of temporal similarity will indicate when the individual's meditation behavior occurred outside of their usual behavioral context and routines. Admittedly, not all reflexive habits are performed at approximately the same time each day; however, our approach aims to identify most meditation habits that are initiated by temporally similar contextual cues.

In this study, we evaluate our measure of temporal similarity as an indicator of meditation habits by estimating the relative importance of temporal similarity for predicting users' future app use. As contextually cued habits are known to underlie many of our long-term daily behaviors, we hypothesize that our temporal similarity measure will successfully identify many users' reflexive meditation habits and thus significantly predict users' future behavior. We test this hypothesis by comparing the predictive strength of temporal similarity with measures of the frequency and duration of app use [27-31]. Toward the second aim of this study, we then estimate the association between our temporal similarity measure and perceived physical and mental health benefits from using the meditation app. This second set of analyses was exploratory in nature and was designed to investigate the potential relationship between reflexive medication habits and changes in physical and mental health.

This is the first study to offer an objective indicator of reflexive meditation habits based on detailed mHealth data. This measure will allow researchers to better describe the habit formation process and to better target and measure future behavioral

interventions for promoting healthier habits. This study is also the first to examine the potential mental health benefits of forming a mindfulness meditation habit, which provides new directions for future mHealth interventions that aim to improve mental health outcomes.

Methods

Recruitment and Data Description

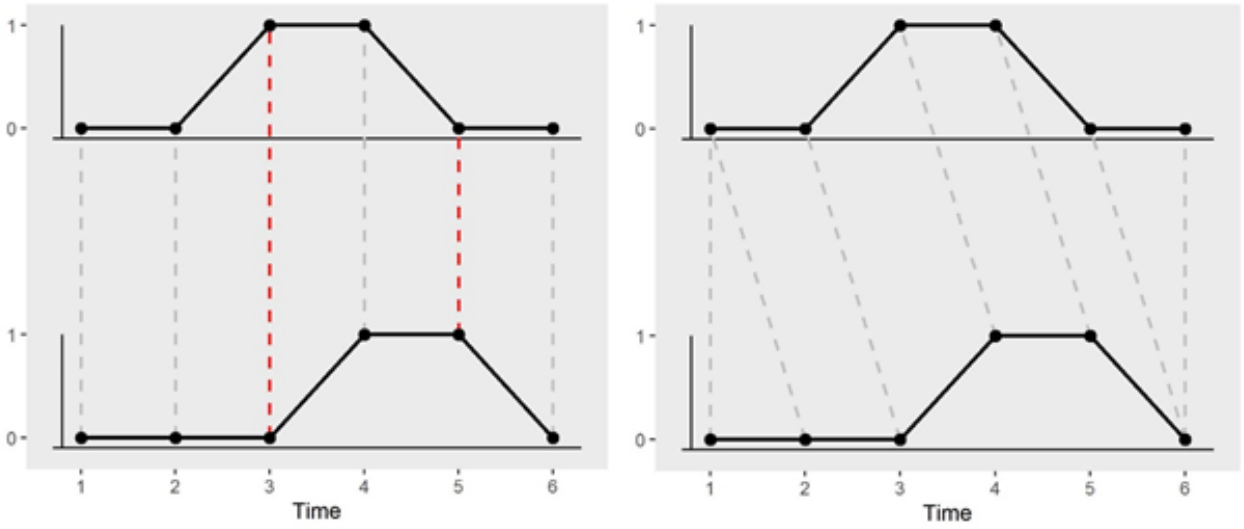
We used longitudinal mindfulness meditation app user data from the commercial app Calm, which had >2 million paying subscribers at the time of data collection. Subscribers in December 2019 who were (1) aged at least 18 years, (2) had a subscription expiration that was at least 2 months away, and (3) had opened at least one email from Calm in the past 90 days were recruited via email to complete a survey on their perceived sleep quality improvements from using the app. These eligibility criteria were used to recruit persistent users of Calm who likely had high intrinsic motivation for meditation, which helps our analyses by reducing the potentially confounding influence of motivation on our ability to identify reflexive meditation habits; the average length of time since first subscribing to Calm was 11.5 months (SD 10.4 months) in this sample. The survey assessment also contained measures of users' socioeconomic status, self-reported app use, physical and mental health status, and perceptions of the physical and mental benefits they experienced after using the app. The survey was approved by the institutional review board of the Arizona State University (STUDY00009725), and the results and additional details on the survey methods and findings have been published elsewhere [32].

Minute-level app use data for the same set of survey respondents were used to develop an objective identifier of habitual app use to predict future use of the app after completion of the survey and to estimate the association with perceived mental health benefits from using the app. The minute-level data set was compiled from all app sessions that were observed 6 months before (June 2019) to 6 months after (June 2020) respondents completed the survey in December 2019. The Calm app offers a wide range of mindfulness content, and a session was recorded when using any one of the following 7 session types: guided or timed meditations, sleep stores, breath training exercise (*breathe*), music, nature sounds (*soundscape*), in-depth audio classes (*masterclass*), and video lessons on mindful movement routines (*body*). For each observed session, the data contained information on the session's start time, duration, type, title of the specific content, and whether the session was completed.

Statistical Analysis

To characterize app use before and after completing the survey, we calculated the number of total sessions used, number of unique sessions used, duration of use, start time, and whether any app use occurred on a given day [27-31]. In addition to these measures, temporal similarity was estimated by converting each day in our sample period into a 1440-minute time series of 0s (when the app was not in use) and 1s (when the app was being used) and then calculating the DTW distance between the time series of app use on consecutive days. As shown in Figure 1, the DTW distance measure is a more flexible calculation than the Euclidean distance between any two 1440-minute time series as it compares the use on one day to use over a wider range of minutes on the other day. Although the Euclidean distance compares use between the exact same minute on each day, Figure 1 shows that the DTW distance is calculated by comparing use on one day with a similar pattern of use that occurred slightly later on the next day. In this way, DTW distance does not penalize users for engaging in the same overall pattern of daily app use that is simply shifted a few minutes earlier or later on a given day. This measure of temporal similarity was calculated using the *dtw* package in R version 4.0.1 (R Foundation for Statistical Computing) and additionally modified to penalize nonuse on consecutive days (see Multimedia Appendix 1 for details). In this way, the final measure of temporal similarity can be interpreted as the average percentage of daily minutes that are inconsistently performed between consecutive days. See Multimedia Appendix 2 for a visualization of the DTW calculation and other attributes found in the Calm app use data.

Figure 1. Visualization of the dynamic time warping (DTW) distance between 2 consecutive days of use, where 0 indicates not using the app and 1 indicates app use during the indicated period. The left panel shows the Euclidean distance between 2 days of equal total use (ie, two time periods with a 1) but the use pattern is shifted in time. As shown on the right panel, DTW compresses or stretches a time series so that the points on one day are mapped to nearby points in the other day that have similar values. The Euclidean distance between these 2 days is 2, whereas the DTW distance is 0. DTW: dynamic time warping.



Each of the objective measures of app use, including frequency, duration, and the temporal similarity measure, were calculated daily for each user and averaged within nonoverlapping 14-day intervals. We then analyzed changes in these measures over multiple intervals to describe how app use patterns changed over time. As some of the users had infrequent app use at the start of our sample period, each user was assigned a unique start date based on the first Monday after at least 5 days of use within a 14-day period. We started each user on a Monday to control for the observed differences in behavior between weekdays and weekends. The objective measures of app use were then defined for all users over 10 nonoverlapping 14-day intervals preceding the date of survey completion. The use of 14-day intervals was chosen so that each interval would contain an equal number of weekdays and weekends, and the results were largely unchanged when these intervals were shortened or widened. For users without 10 nonoverlapping 14-day intervals between their start date and the date of survey completion, additional 14-day intervals were constructed after the survey date so that all users had 10 intervals (140 days) over which the aforementioned objective measures were calculated. These additional postsurvey intervals were not used to analyze the survey-based mental health outcomes (second aim) but were used to test the ability of temporal similarity to predict future app use (first aim).

Finally, these objective measures of app use were calculated based on all observed sessions, as well as separately by session type and session timing, stratified by *Morning* (4 AM to 12 PM), *Evening* (12 PM to 8 PM), or *Night* (8 PM to 4 AM the next day). These measures, along with users' socioeconomic status, were summarized using means and SDs for continuous variables and counts and percentages for dichotomous variables; group differences in dichotomous variables were compared using the *prtest* command in Stata/MP 16.1 (StataCorp) [33].

Toward our first aim of testing temporal similarity as an indicator of reflexive meditation habits, we estimated the predictive ability of temporal similarity on 3 dichotomous measures of future app use: any app use 28 days later, any app use 6 months later, and an identifier for whether the total duration of app use during the 28-day period following the survey was above the median duration during this period. For each of these 3 outcomes, 3 predictive modeling techniques were used. First, logistic regression was used to estimate the associations between each dichotomous outcome and all available objective app-use measures. Second, the same logistic models with and without the DTW-based temporal similarity measures were used to calculate the receiver operating characteristic (ROC) curves and the corresponding areas under the ROC curve (AUCs), a measure of model fit. AUCs from the 2 models (ie, with and without the DTW-based temporal similarity measure) were compared using a chi-square test [34] performed by the *roccomp* command in Stata/MP 16.1. Finally, using the same set of objective app-use measures, we estimated the relative importance of each app-use measure using a random forest algorithm from the *sklearn.ensemble.RandomForestClassier* command in Python 3.8.3 (Python Software Foundation) [35].

To investigate the relationship between reflexive meditation habits and changes in health, we used logistic regression to estimate the association between perceived physical and mental benefits from using the app and the objective app-use measures, including temporal similarity. Physical and mental benefits were measured from survey questions that separately asked whether 7 different physical health conditions (hypertension, high cholesterol, asthma, emphysema, other lung diseases, heart disease, cancer, pain, and arthritis) and 3 different mental health conditions (anxiety, posttraumatic stress disorder, and depression) were *improved* and whether these measures were *very improved*. The dichotomous measure of whether physical

health was *improved* was set equal to 1 if participants responded with an affirmative response (ie, yes, the condition was improved) to any of the physical health conditions and equal to 0 otherwise. Similar procedures were used to construct the dichotomous measure of *improved* mental health and to construct separate dichotomous measures for physical and mental health reported as *very improved*. Logistic regressions estimated the association between these dichotomous measures of physical and mental health improvements and objective app-use measures, controlling for users' socioeconomic status. To better compare model estimates for the different objective app-use measures, a logarithm transformation was applied to each app-use measure so that each association measured the correlation between a 1% increase in the indicated behavioral measure and the odds of experiencing improved health from using the app. Similar log transformations were also applied to the predictive logistic models described above to further improve comparability across the estimated statistical relationships. The logistic regressions were performed by the *logit* command in Stata/MP 16.1

Data Exclusion

Survey respondents that did not have sufficient app use to meet the start date definition detailed above were not included in these analyses (n=2239). However, their irregular app use provides strong evidence that these users did not habitually use the app. Therefore, the results of this study and subsequent discussion serve to describe how *regular* users of the app may benefit from temporally consistent meditation habits, both in their odds of persistent app use and experiencing health benefits.

Results

Sample Characteristics

The sample of Calm users was aged between 21 and 87 years (mean 48.0 years, SD 14.2 years), was primarily female (2359/2771, 86.06%) and White (2391/2771, 86.29%), with a median household income of US $80,000 (mean US $105,927, SD US $86,940.20). Table 1 illustrates the demographic and socioeconomic characteristics, which are largely the same between those with above and equal to or below the median number of meditation sessions used during the 14 days before completing the survey (median=2 sessions). Between both groups, less than two-thirds of users worked full-time. Approximately 43.27% (1199/2771) reported having at least one mental health condition (stress, depression, or anxiety), and approximately 39.01% (1081/2771) reported at least one chronic physical health condition (eg, emphysema or cancer). Household income is presented as a categorical variable in Table 1 to better describe the distribution of income in the sample, which was >US $61,000 for 61.1% (1693/2771) of the participants.

[a]Number of meditation sessions measured over the 14 days before survey completion; median number of meditation sessions over the 14 days before the survey was 2 sessions.

[b]*P* values from proportion tests comparing those with above and those with equal to or below the median number of meditation sessions during the 2 weeks before survey completion.

Most users, approximately 69.87% (1936/2771), reported using the app ≥5 times per week, as shown in Table 2. Importantly, 38% (1053/2771) of users noticed improved mental health status from using the app, whereas 19.38% (537/2771) experienced improved physical health. Table 2 also illustrates the mental health benefits from mindfulness meditation, as the users with above the median number of meditation sessions during the 14 days before completing the survey were 3.5 percentage points (*P*=.05) more likely to experience improved mental health and 8.5 percentage points (*P*<.001) more likely to experience very improved mental health than those with equal to or below the median number of meditation sessions.

Table 2. Self-reported use and health benefits by observed meditation sessions (N=2771).

Characteristics	Total sample, n (%)	Above median meditation sessions[a] (n=1546), n (%)	Equal or below median meditation sessions[a] (n=1225), n (%)	*P* value[b]
Self-reported app use				
1-2 days/week	190 (6.86)	110 (7.12)	80 (6.53)	.55
3-4 days/week	549 (19.81)	280 (18.11)	269 (21.96)	.01

Very much improved mental health (only)	430 (15.52)	295 (19.08)	135 (11.02)	<.001

[a]Number of meditation sessions measured over the 14 days before survey completion; median number of meditation sessions over the 14 days before the survey was 2 sessions.

[b]*P* values from proportion tests comparing those with above and those with equal to or below the median number of meditation sessions during the 2 weeks before completing the survey.

Table 3 presents the mean, SD, and maximum values of the objective measures of app use calculated over the 14 days before survey completion. On average, the likelihood of using any session type on a given day was 55.7%, the likelihood of using meditation features was 28.4%, and the likelihood of using sleep stores was 32% over this period. Approximately 1.14 (SD 2.26) sessions of any type were used per day, with 0.35 (SD 1.11) sessions occurring in the mornings and 0.66 (SD 1.21) sessions occurring in the evenings. Meditation sessions were performed with equal frequency in the mornings—approximately 0.17 (SD 0.36) sessions per day—and the evenings—approximately 0.16 (SD 0.34) sessions per day—whereas sleep stories were largely performed at night (mean 0.37 sessions per day, SD 0.51 sessions per day). A similar pattern was observed for users' average duration in minutes of app use per day by session type, where meditation sessions were used for approximately 2.30 (SD 5.91) minutes in the mornings and 2.84 (SD 6.56) minutes in the evenings, and sleep stories were used for an average of 11.54 (SD 16.19) minutes in the evenings. Finally, the average DTW distance measure across all session types, which incorporated the penalty for nonuse and was standardized by users' average duration of daily use over these 14 days, was equal to 0.539 (SD 0.35). In contrast, the DTW distance measured just among meditation and sleep story features was smaller, at approximately 0.489 (SD 0.44) and 0.474 (SD 0.45), respectively.

Table 3. Objective app use measures over 14 days before survey completion (N=2771).

Characteristics	Value, mean (SD)	Maximum
Any session/day	0.557 (0.37)	1.000
Meditation sessions/day	0.284 (0.36)	1.000
Sleep stories sessions/day	0.320 (0.35)	1.000
Sessions/day in mornings	0.351 (1.11)	48.286
Sessions/day in evenings	0.121 (0.32)	6.786
Sessions/day at night	0.666 (1.21)	45.643
Sessions/day weekdays	0.836 (1.87)	81.643
Sessions/day weekends	0.302 (0.46)	12.286
Sessions/day total	1.139 (2.26)	93.929
Meditation sessions/day in mornings	0.173 (0.36)	4.357
Meditation sessions/day in evenings	0.067 (0.19)	2.571
Meditation sessions/day at night	0.168 (0.34)	3.214
Sleep stories sessions/day in mornings	0.081 (0.25)	2.786
Sleep stories sessions/day in evenings	0.025 (0.12)	2.357
Sleep stories sessions/day at night	0.369 (0.51)	4.929
Duration/day in mornings (minutes)	7.149 (16.82)	352.309
Duration/day in evenings (minutes)	2.137 (5.86)	81.578
Duration/day at night (minutes)	18.043 (25.83)	596.222
Duration/day weekdays (minutes)	19.737 (29.93)	768.200
Duration/day weekends (minutes)	7.592 (11.97)	239.941
Meditation duration/day in mornings (minutes)	2.295 (5.91)	142.167
Meditation duration/day in evenings (minutes)	0.814 (2.36)	35.801
Meditation duration/day at night (minutes)	2.836 (6.56)	83.739
Sleep stories duration/day in mornings (minutes)	2.480 (7.62)	91.848
Sleep stories duration/day in evenings (minutes)	0.750 (3.51)	78.647
Sleep stories duration/day at night (minutes)	11.535 (16.19)	169.736
DTW[a] distance	0.539 (0.35)	3.207
DTW distance (only meditation sessions)	0.489 (0.44)	1.386
DTW distance (only sleep stories)	0.474 (0.45)	1.902

[a]DTW: dynamic time warping.

Predictive Models

The first set of analyses used the objective measure of app use over 140 days to predict users' future app use to test the ability of temporal similarity to identify reflexive habits. Table 4 displays the exponentiated logistic regression coefficients and 95% CIs using the objective app-use measures to predict the 3 dichotomous measures of future app use. The table displays the results for all objective app-use measures calculated over the 6th through the 10th 14-day interval after each user's start date. The app-use measures calculated over intervals 1-5, and the demographic controls displayed in Table 1 were also included in each logistic regression model but were suppressed from Table 4 for ease of presentation.

Table 4. Objective measures in the 10th (2-week) interval predicting future app use (N=2771).[a]

Predictor	Odds ratio (95% CI)					
	Any use 28 days later	Any use 28 days later	Any use 6 months later	Any use 6 months later	High duration in next 28 days	High duration in next 28 days
Days of any use

[a]This table displays the odds ratios (exponentiated coefficients) from separate logistic regression models of each outcome indicated by the column headers on the objective app-use measures indicated by the row labels; 95% CIs are displayed in parentheses. Each objective app-use measure was log transformed to improve the comparability of the estimated relationships, and all models, in addition, included measures of users' demographic and socioeconomic characteristics and the objective app-use measures estimated over intervals 1-5.

[b]$P<.05$.

[c]$P<.01$.

[d]$P<.001$.

[e]DTW: dynamic time warping.

[f]The dynamic time warping distance variables were excluded from one model of each outcome and included in the second model for the same outcome to compare the variable importance results from these 2 approaches.

[g]The indicated variables were also assessed in the model.

Table 4 shows that the number of days of any app use in the 10th 14-day interval (closest interval to the outcomes) was the strongest predictor of the odds of any future use 28 days later (odds ratio [OR] 3.378, 95% CI 2.32-4.92) and the odds of any future use 6 months later (OR 1.527, 95% CI 1.11-2.10). However, this measure was not significantly associated with

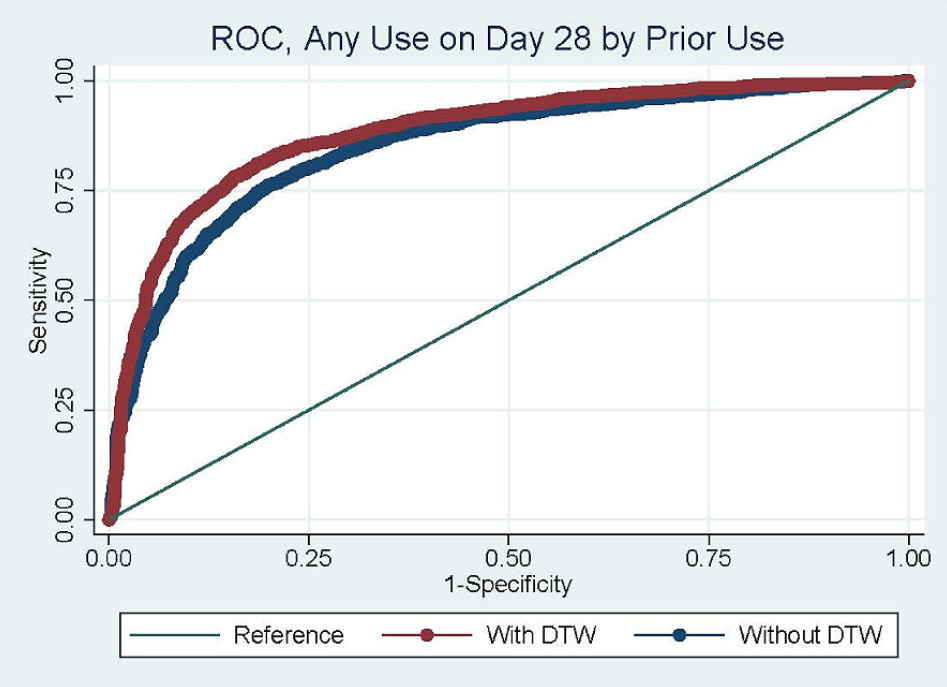
the odds of having a high duration of total app use over the following 28 days. The results also demonstrated that the total number of sessions was a weak predictor of future app use across all 3 outcomes. In addition, total duration was a significant predictor of the odds of having a high duration over the following 28 days (OR 1.108, 95% CI 1.02-1.20). Importantly, the DTW measure of temporal similarity was significantly associated with all 3 outcomes describing future behavior. Specifically, a 1% increase in DTW distance in the 10th 14-day interval (ie, less similar timing of daily app use), which corresponds to a 0.015 SD increase from the mean DTW distance, is associated with an OR of 0.719 (95% CI 0.69-0.88) of any app use 6 months later.

The first panel of Table 5 presents a second statistical test of the predictive value of the temporal similarity measure by comparing the AUC from the same set of logistic regression models shown in Table 5. The AUC without DTW-based temporal similarity measures was 0.818 when predicting any future use 28 days later, and this area was increased by 0.003 (P=.02) when the DTW distance measures were included in the model. To visualize this improvement in prediction accuracy, these 2 ROC curves are displayed in Figure 2. The second panel of Table 5 performs the same comparison between logistic regression models with and without the DTW distance measures, where all objective app-use measures were separately calculated over only the weekdays and weekends in each 14-day interval. These more granularly defined measures of app use improved the overall model fit, as the AUC increased to 0.820 when predicting the odds of any use 28 days later without DTW measures. The AUC increased to 0.828 (P<.001) when including the DTW measures defined over weekdays and weekends. Finally, the third panel in Table 5 displays the results when all objective app-use measures were separately calculated for each of the 7 session types and between weekdays and weekends. When the DTW distance measures were included in these logistic regression models, the AUC was significantly increased for the prediction of any future use 28 days later (P<.001), any use 6 months later (P<.001), and having a high duration of total app use over the next 28 days (P<.001).

Table 5. Area under the receiver operating characteristics curve (AUC) with and without dynamic time warping (DTW) to predict future app use.

Predictor	AUC		
	Any use 28 days later	Any use 6 months later	Above median duration of use over next 28 days
By aggregating all sessions			
Not including DTW	0.818	0.729	0.953
Including DTW	0.821	0.732	0.953
Difference	0.003	0.003	0.000
P value	0.02	0.10	.77
By session timing (weekday, weekend)			
Not including DTW	0.820	0.741	0.950
Including DTW	0.828	0.747	0.956
Difference	0.008	0.008	0.006
P value	<.001	.006	<.001
By session type and timing			
Not including DTW	0.850	0.802	0.958
Including DTW	0.868	0.821	0.963
Difference	0.018	0.019	0.005
P value	<.001	<.001	<.001

Figure 2. The receiver operating characteristic (ROC) curves for logistic regression models that include objective app-use measures calculated over the first 10 14-day intervals from users' start date and demographic controls for predicting the likelihood of any future app use 28 days later. The 2 curves show the models without and with the dynamic time warping (DTW) distance measures, and the area under the ROC curves are equal to 0.850 and 0.868 for the models without and with DTW distance measures, respectively. DTW: dynamic time warping; ROC: receiver operating characteristic.



A second demonstration of the importance of temporal similarity for predicting future app use is presented in Multimedia Appendix 3, which displays the variable importance statistics from random forest models that used the objective app-use measures defined over all session types and timing to predict the same 3 dichotomous measures of future app use presented in Tables 4 and 5. The results show that at least one of the DTW distance measures is among the top 5 predictors of all 3 outcomes, further reinforcing the important association between temporal similarity and behavioral persistence in this setting.

Associated Physical and Mental Benefits

The second set of analyses estimated the association between the objective app-use measures and self-reported mental and physical benefits from using the app. Table 6 displays the exponentiated coefficients from logistic regression models of the dichotomous outcomes indicating users' self-reported *improved* or *very improved* mental or physical health from using the app on the demographic and socioeconomic dimensions presented in Table 1. From Table 6, we can see that older adults were significantly less likely to have reported experiencing mental health improvements but were more likely to have experienced physical health improvements. Specifically, adults aged between 71 and 80 years had an OR 0.239 (95% CI 0.15-0.39) of reporting improved mental health and an OR 2.35 (95% CI 1.15-4.80) of reporting improved physical health relative to users aged under 31 years. These estimated associations highlight the need to include user demographics in subsequent models for predicting perceived health benefits.

Table 6. Self-reported health benefits on user demographics (N=2771).

Demographics	Odds ratio (95% CI)[a]			
	Improved mental health	Improved physical health	Very much improved mental health	Very much improved physical health
Age (years)

[b]*P*<.001.

[c]*P*<.05.

[d]*P*<.01.

Table 7 shows the estimated association between improved mental and physical health and the objective measures of app use, conditional on the user demographic and socioeconomic dimensions presented in Table 6. The first panel (model 1) of Table 7 presents the exponentiated coefficients for a model containing the objective app-use measures averaged over the 6 weeks (3×14-day intervals) before survey completion. Conditional on the total number of sessions, total duration of use, and the total number of days with any use, a 1% increase in DTW distance over the 6 weeks before survey completion was associated with an OR 0.34 (95% CI 0.16-0.55) of experiencing improved mental health. The model also estimated a negative relationship between DTW distance and improved physical health; however, this relationship was not statistically significant.

Table 7. Self-reported health benefit on objective app use averaged over the past 6 weeks (N=2771).[a]

Characteristics	Value, odds ratio (95% CI)			
	Improved mental health	Improved physical health	Very much improved mental health	Very much improved physical health
Model 1				
Total number of sessions	1.094 (0.822-1.456)	1.340 (0.965-1.862)	1.718[b] (1.249-2.362)	1.879[c] (1.131-3.121)
Total duration	0.955 (0.874-1.044)	0.929 (0.824-1.048)	0.822[b] (0.733-0.921)	1.006 (0.826-1.225)
Total days with any use	1.244 (0.957-1.618)	1.233 (0.879-1.729)	1.836[b] (1.316-2.562)	0.925 (0.535-1.601)

Demographic controls	✓[f]	✓	✓	✓

[a]This table displays the odds ratios (exponentiated coefficients) from separate logistic regression models of each outcome indicated by the column headers on the objective app-use measures indicated by the row labels for each of the 2 predictive models. Each objective app-use measure was log transformed to improve the comparability of the estimated relationships, and all models, in addition, included measures of users' demographic and socioeconomic characteristics.

[b]$P<.001$.

[c]$P<.05$.

[d]DTW: dynamic time warping.

[e]$P<.01$.

[f]Demographic controls were also assessed in the model.

The second panel (model 2) in Table 7 presents the same set of objective app-use measures calculated for the 2 most commonly used session types: meditation and sleep stories. The results show that DTW distance for meditation sessions is a significant predictor of both improved and very improved mental health. Specifically, a 1% increase in DTW for meditation sessions was associated with an OR 0.72 (95% CI 0.50-0.97) of experiencing improved mental health and an OR 0.44 (95% CI 0.27-0.69) of experiencing very improved mental health from using the app. Changes in DTW distance for sleep story sessions were also negatively associated with the odds of experiencing improved (OR 0.72, 95% CI 0.44-1.43) and very improved mental health (OR 0.57, 95% CI 0.31-1.06); however, these relationships were not statistically significant nor were they significant for either measure of physical health improvement. In addition, the DTW distance measure was also a significant predictor of using the app for a greater number of meditation sessions and sleep stories over the next 28 days (Multimedia Appendix 4 and Table S1 of Multimedia Appendix 5).

Discussion

Principal Findings

The 2 aims of this study were to construct and test an objective indicator of reflexive meditation habits and to explore the association between meditation habits and mental health. Toward this first aim, we constructed and provided evidence that our novel measure of temporally similar app use strongly predicted future app use and, thus, is likely to indicate the presence of reflexive meditation habits. Specifically, after controlling for user demographics and common app use metrics, such as frequency and duration of app sessions, the temporal similarity of app use on consecutive days was shown to significantly predict the odds of any future app use and the duration of future use. That is, using the meditation app at roughly the same time each day was associated with greater persistence in meditation app use, which suggests that this measure of temporal similarity was able to indicate the formation of reflexive meditation habits.

We then found that there was a significant association between increased temporal similarity in daily meditation app use and improved mental health from using the app. This finding suggests that the reduced cognitive effort required to instigate meditation that results in a reflexive meditation habit may enable individuals to use more cognitive resources in their mindfulness meditation practice and, thus, experience greater mental health benefits. This interpretation is supported by research describing the impact of attentional resources [36] and mental effort [37-39] on the success of different meditation practices. As the goal of

mindfulness meditation is to direct one's attention to the present moment, these findings indicate that this practice may be easier to perform if meditation is instigated reflexively and without effortful deliberation. However, our study did not investigate the specific mechanism or mechanisms underlying the association between temporal similarity and improved mental health, which is an important area for future research.

Additional Findings

Our descriptive results found that many observable demographic and socioeconomic characteristics were significantly associated with self-reported mental and physical health improvements. Conversely, only the individual's age was significantly associated with measures of the likelihood and duration of future app use (Multimedia Appendix 3). These findings suggest that behavioral habits are equally experienced across demographic characteristics; however, future research assessing the health benefits of mindfulness meditation practices should carefully control for these significant demographic and socioeconomic factors. In addition, the results showed that larger improvements in mental health were reported among individuals who used more than the median number of meditation sessions in the 14 days before the survey, which adds additional evidence for the mental health benefits of mindfulness meditation.

Limitations

Overall, this was a very active sample of app users, with a 55.7% average likelihood of using any app session on a given day over the study period. This is not surprising as the sample consisted of paying subscribers who responded to emails from the app and volunteered to take part in a study to help improve the app; so, the results of this research should be extrapolated to other user types with caution. Although the demographic and socioeconomic minorities of this sample did not display significantly different app-use patterns, the small sample size of these groups limits the statistical power of these comparisons. Future research on mindfulness meditation behaviors should aim to collect data from a wider demographic range of users to better characterize meditation habits and the mental health benefits experienced by all users.

Another limitation was the nature of the data set compiled for these analyses. Specifically, the objective measures of daily app use were compiled for the period around the date when users completed the survey on their perceived mental and physical health benefits. This means that many of the users had been using the app before being included in the sample; so, neither were the analyses able to characterize the initial behavior of app users nor could the results identify the initial period necessary to form a temporally similar meditation habit. In addition, the measure of meditation habits focused on the temporal dimensions of app use as no direct measure was collected on users' behavioral context or environment. Future research that combines the temporal dynamics of daily behavior with additional contextual information could provide a more complete picture of this habit formation process. As temporal data are readily available from a wide range of health apps and other mHealth devices, this study provides a method for analyzing the habit formation process that can be readily applied across these different health behavior settings. Finally, not all reflexive behavioral habits will be performed at approximately the same time each day, and our measure of temporal similarity will only identify the habits that are initiated by temporally similar contextual cues. As past research has found that most habits are instigated by temporally similar contextual cues [25,26], a high degree of temporal similarity is an important indicator of reflexive habits but is not a necessary condition.

Comparison With Prior Work

This study constructed a measure of temporally similar daily meditation app use based on the DTW distance between consecutive days, which adds to the bourgeoning literature using DTW distance to detect temporal patterns in a wide range of behavioral and health data settings [40-45]. One of the most common existing uses of DTW distance has been to categorize patterns of daily health behavior. For example, unhealthy dietary routines were identified by analyzing the variation in DTW distance between participants' eating behaviors over 24-hour periods [43]. DTW distance measures have also been used to identify unhealthy sedentary behaviors [41] and to diagnose hyperactivity disorder from the patterns in children's bodily movements while completing stationary computer tasks [42]. In a clinical setting, DTW-based measures have been used to identify early signs of kidney transplant rejection [40] and to categorize the experience level of surgeons [44]. Recent research has also used DTW-based measures for making predictions from longitudinal health data, such as predicting future glucose levels of patients with type 2 diabetes [45]. In this study, we extended this forecasting approach to the prediction of future health behaviors and showed that a DTW distance measure of temporal similarity in meditation app use on consecutive days significantly predicts an individual's future meditation behavior. This study adds to the nascent literature that uses measures of temporal similarity to characterize health habits [46].

This paper also contributes to the mHealth literature characterizing mobile phone app engagement over time. Declining app use is an important concern and limitation of many app-based health promotion tools, and researchers have found that app engagement durations are becoming increasingly shorter [47]. This is consistent with declining engagement with other mHealth tools over the course of behavioral interventions, which has been observed for self-monitoring technologies, such as physical activity trackers [48] and glucose monitoring [49], as well as adherence to a telemonitoring program for heart failure [50]. This study shows that the temporal similarity of daily meditation app use is an important predictor of continued app use, which suggests that future app-based health promotional tools and interventions should also promote temporal similarity when providing health benefits that require consistent performance over time.

Conclusions

Promoting healthier habits is an important public health objective for improving many health outcomes. However, to date, the study of habit formation has relied on self-reported measures and has yet to use the abundance of new behavioral health data being collected through mHealth devices. The field's limited methods for measuring health habits and understanding of the habit formation process have likely contributed to the

lack of behavioral health interventions that have successfully established persistent behavioral changes.

This study presents a novel objective indicator of reflexive habits derived from detailed, objective behavioral data collected by a mindfulness meditation mobile phone app. Our measure of temporal similarity in meditation app use on consecutive days significantly predicted future app use, even after controlling for users' demographic and socioeconomic characteristics and common measures of app use, such as the frequency and duration of use. Importantly, this temporal similarity measure was also associated with greater odds of experiencing improved mental health from using the app, which suggests that forming a reflexive meditation habit may provide additional mental health benefits. This measure of temporal similarity can be readily applied to other sources of behavioral health data, and future research should build on these findings by investigating the ability of temporal similarity to identify habits in these other behavioral settings. In addition, future research should investigate whether reflexively initiated meditation habits can increase the mental health benefits from mindfulness meditation.

Conflicts of Interest

At the time this paper was written, JH conducted investigator-initiated research and utilized the Calm app to deliver mindfulness meditation interventions. Calm financially supports her research with a postdoctoral scholar and 2 research coordinators (contractors). The roles of these persons are to help JH with her investigator-initiated research using the Calm app. JH consults for Calm as the director of science and director of the scientific advisory board at Calm. Her role is to ensure the quality of Calm's science and she has no specific obligations to the company. She receives no stocks or equity related to the growth or success of the company.

Abstract

Background: Mobile health (mHealth) interventions have been shown to effectively improve the quality of life (QOL) among people living with HIV. However, little is known about the long-term effects of mHealth interventions.

Objective: This study aims to explore the intervention mechanisms of a social media–based intervention, Run4Love, on the QOL of people with HIV over across a 9-month follow-up period.

Methods: We recruited people living with HIV who were concurrently experiencing elevated depressive symptoms from an HIV outpatient clinic in South China. A total of 300 eligible participants were randomized either to the intervention group or the control group in a 1:1 ratio after they provided informed consent and completed a baseline survey. The intervention group received a 3-month WeChat-based intervention, comprising cognitive-behavioral stress management (CBSM) courses and physical activity promotion. The control group received a printed brochure on nutrition guidelines in addition to the usual care for HIV treatment. Neither participants nor the research staff were blinded to group assignment. All patients were followed at 3, 6, and 9 months. The primary outcome was depressive symptoms. Structural equation model (SEM) with longitudinal data was conducted to examine the sequential mediating effects of HIV-related stigma and depressive symptoms on the long-term intervention effects on participants' QOL.

Results: About 91.3% (274/300), 88.3% (265/300), and 86.7% (260/300) of all participants completed follow-up surveys at 3, 6, and 9 months, respectively. Results showed that the intervention had significantly improved participants' QOL at 9 months, via complete mediating effects of reduced HIV-related stigma at 3 months and decreased depressive symptoms at 6 months. No adverse events were reported.

Conclusions: These findings underscore the critical roles of HIV-related stigma and depressive symptoms in an mHealth intervention with long-term effects on QOL improvements. We call for targeted mHealth interventions to improve QOL among people living with HIV, especially social media–based interventions that can address HIV-related stigma and alleviate depressive symptoms.

mHealth; HIV; depressive symptoms; quality of life; structural equation model

Introduction

Owing to widely available antiretroviral therapy (ART), living with HIV has become a manageable chronic condition [1]. The 90-90-90 targets that by 2020, 90% of people living with HIV are diagnosed, 90% of those diagnosed receive sustained ART, and 90% of those on treatment are virally suppressed have been unevenly achieved in different contexts [2,3]. In addition, other challenges, such as suboptimal quality of life (QOL), high levels of stigma, and poor mental health among people living with HIV, are still prevalent [4-6]. A great body of evidence has shown that high levels of stigma and depressive symptoms could worsen existing disease conditions and lead to poor QOL [7-9]. A new goal called the fourth "90"—that 90% of people living with HIV have optimal health-related QOL—has been proposed and widely concurred [4]. Emerging research has developed multilevel effective psychosocial, behavioral, and contextualized interventions to improve the QOL among people living with HIV [10].

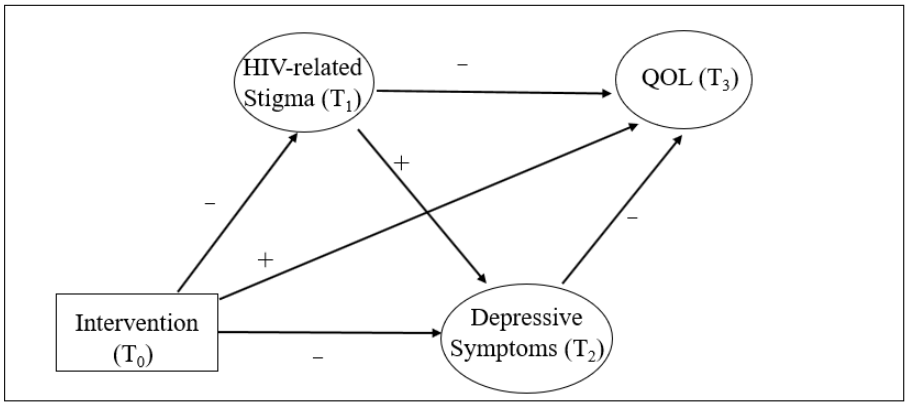
Although psychosocial interventions such as cognitive-behavioral stress management (CBSM) have been proved effective in improving the QOL among people living with HIV, few studies have explored the mechanisms of the effects of such interventions on QOL, especially in the long term [11-14]. Existing studies were often conducted with a pre- and post-design and a short-term follow-up, such as an 8- or 10-week follow-up [15,16]. Few studies examined the long-term intervention mechanisms of QOL improvement [17,18]. Furthermore, most of these interventions were delivered face-to-face in group settings. Given the prevalent HIV-related stigma and discrimination in many countries, including China, a large number of people living with HIV would prefer web-based or mobile-based interventions rather than face-to-face interventions due to privacy concerns.

Mobile health (mHealth) interventions have proved effective in improving QOL among people living with HIV [19-22]; however, to the best of our knowledge, no study has ever explored the intervention mechanisms on improving QOL in mHealth interventions. As mHealth interventions may reach a large number of populations with increased accessibility, convenience, identity protection, and potentially lower cost, such interventions are well suited for marginalized and stigmatized populations, such as people living with HIV [23]. With the increasing number of people living with HIV and wide coverage of smart phones, studies that explore the mechanisms of mHealth interventions on improving the QOL of people living with HIV are much needed, especially those that would examine long-term intervention mechanisms.

Previous studies have suggested that HIV-related stigma and depressive symptoms are important predictors of QOL; however, the mechanisms among these three variables have only been examined in cross-sectional studies, but not in interventional studies [7,24-27]. One cross-sectional study in Ontario, Canada, found that HIV-related stigma was associated with lower QOL, and depressive symptoms partially mediated the association between HIV-related stigma and QOL among African and Caribbean women living with HIV [24]. Another cross-sectional study in Vietnam found that people living with HIV who reported having experienced stigma were more likely to have elevated depressive symptoms and lower QOL [27]. Existing interventional studies have only explored the interventional effects on QOL and potential associated factors using regression analyses. For example, a study found that the improvement of QOL among people living with HIV was positively associated with a reduction in depressive symptoms at the 6-month follow-up in an intervention targeted on depression by regressing the change of QOL on that of depressive symptoms during the 6-month interval [28]. A similar study was also conducted on the association between improvement in QOL and reduction of HIV-related stigma [18]. Due to the limitation of the methodology, existing studies have not yet investigated the mechanisms of intervention effect on QOL.

To investigate the intervention mechanisms, it is important to examine the sequential relationships among influencing factors and the outcome. Structural equation model (SEM) using longitudinal data can provide a better understanding of intervention mechanisms with sequential orders. To fill the gaps of the literature, the current study aimed to explore the intervention mechanisms in the effects of a social media-based intervention, Run4Love, on QOL over 9 months. Using SEM and longitudinal data of 4-time repeated assessments, we examined the sequential relationships among HIV-related stigma, depressive symptoms, and QOL in the mHealth intervention. We hypothesized that the HIV-related stigma and depressive symptoms would play mediating roles in the intervention effects on QOL at the 9-month follow-up. Specifically, the intervention would reduce HIV-related stigma first and subsequently reduce depressive symptoms, which in turn would lead to long-term improvement in QOL among people living with HIV. The hypothesized model is illustrated in Figure 1.

Figure 1. Hypothesized model of intervention, HIV-related stigma, depressive symptoms, and QOL in people living with HIV and depressive symptoms. QOL: Quality of life; T_0: baseline; T_1: 3-month follow-up; T_2: 6-month follow-up; T_3: 9-month follow-up.



Methods

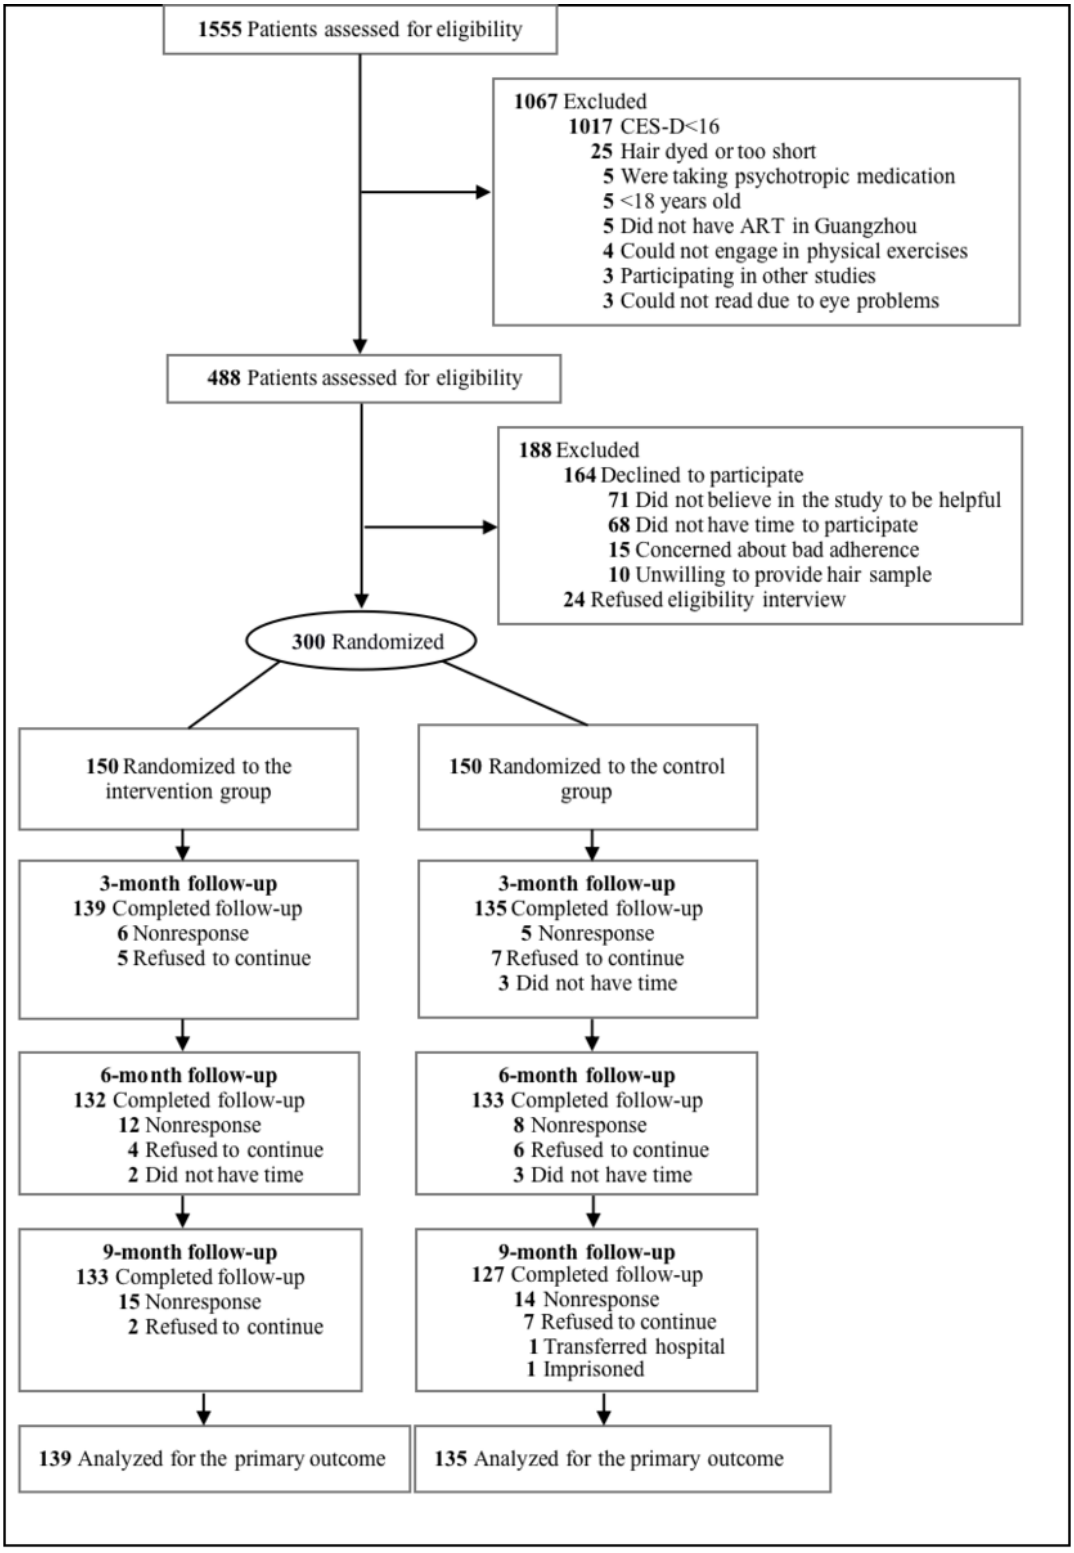
Research Setting

This study used the data from a parallel-design randomized controlled trial (RCT). The CONSORT (Consolidated Standards of Reporting Trials) checklist was used. The study was conducted in Guangzhou, China, between September 2017 and October 2018. A total of 300 people living with HIV and depressive symptoms were recruited by the research staff from a designated hospital for HIV/AIDS treatment in Guangzhou in 2017. Guangzhou is the capital city of Guangdong province, and it is the third largest city in China. The Run4Love RCT protocol was approved by the Institutional Review Board at Sun Yat-Sen University (2018 No. 31) [29].

Participant Eligibility

Participants were recruited if they (1) were aged 18 years or above, (2) tested HIV-seropositive, (3) had elevated depressive symptoms (measured by the Center for Epidemiologic Studies-Depression; CES-D score ≥16), (4) were WeChat users, and (5) were willing to provide hair samples (for the purpose of measuring cortisol as a biomarker of chronic stress). Participants were excluded if they were (1) currently on psychological treatment, (2) unable to complete baseline and follow-up surveys, or (3) unable to engage in the intervention (eg, unable to read or listen to the intervention materials on WeChat or perform physical exercise due to medical or other reasons). Participants who met the eligibility criteria and were willing to participate completed a baseline survey and were randomized to the intervention or the waitlist control group with a 1:1 ratio by the research staff (Figure 2).

Figure 2. Flowchart of participant screening and recruitment. ART: antiretroviral therapy; CES-D: Center for Epidemiologic Studies-Depression.



Run4Love WeChat-Based Intervention

The intervention protocol has been detailed elsewhere [29]. Briefly, the Run4Love WeChat-based intervention comprised two components: adapted CBSM courses and physical activity promotion [29]. The intervention adapted the evidence-based CBSM courses into China's context and included 9 sessions and 3 review sessions with information on meditation, muscle relaxation, and coping skills. The courses were adapted into multimedia formats, including articles, audio clips, and posters. These materials were sent through an enhanced social media platform of WeChat 3 to 5 times a week for 3 months. Physical activity promotion consisted of information on instructions and benefits of regular physical exercise. The enhanced WeChat platform had extended functions, including automatic sending of materials, patient engagement tracking on course completion, and personalized feedback on a weekly basis. In the booster session, a total of 7 most read items were redelivered to the

participants in the intervention group in the 3 months following postintervention. Participants in the control group received a printed brochure on nutrition guidelines in addition to the usual care for HIV treatment.

Sample Size

We calculated the sample size of the RCT based on the primary outcome of depressive symptoms measured by CES-D. Effect size was used to calculate between-group differences. We hypothesized an effect size of 0.4, with α=.05, β=.15, and a dropout rate of 20%, thus arriving at a sample size of 282 for the RCT. Finally, a total of 300 participants were recruited. For SEM, the recommended sample size of 5 observations per estimated parameters was considered [30]. Given a total of 46 estimated parameters in the SEM of our study, the sample size of 300 was sufficient for the analysis.

Randomization and Masking

The research staff randomly assigned the participants to the intervention group or the control group by a computer-generated randomization list with a block size of 4 using SAS software version 9.4 (SAS Institute, Inc). By the nature of the trial design, neither the participants nor the research staff were blinded to the intervention.

Study Outcomes

Overview

Individuals' sociodemographic characteristics, HIV-related stigma, and psychosocial outcomes, including their depressive symptoms and QOL, were included in this study. Sociodemographic characteristics such as age, gender, marital status, sexual orientation, educational level, and household registration (urban and rural) were collected at baseline. Self-reported psychosocial outcomes measured at baseline and at 3-, 6-, and 9-month follow-ups were collected by researchers face-to-face via electronic questionnaires administered using a tablet device.

HIV-Related Stigma

HIV-related stigma was measured by the 14-item HIV Stigma Scale [31,32]. The scale measures 2 dimensions of stigma: perceived stigma and internalized stigma [31]. Perceived stigma comprises 6 items, such as "Most people think that a person who has HIV is dirty"; internalized stigma comprises 8 items, such as "I feel guilty because I have HIV." Each item is rated on a 4-point Likert-type scale (ie, strongly disagree, disagree, agree, and strongly agree). The total score of the scale ranges from 14 to 56, with higher scores indicating higher levels of HIV-related stigma. Total scores ranging from 14 to 28, 29 to 42, and 43 to 56 are considered as low, medium, and high levels of stigma, respectively [33]. In SEM, stigma was measured by the 2 subscales (perceived and internalized stigma). Validity and reliability of the scales have been examined and established for Chinese people living with HIV [32,34]. A good reliability of HIV Stigma Scale was also shown in this study, and the Cronbach α values at baseline, 3-, 6-, and 9-month follow-ups at .92, .95, .95, and .96, respectively.

Depressive Symptoms

Depressive symptoms were assessed using the CES-D scale. The CES-D scale measures 4 dimensions of depressive symptoms, including depressed affect, positive affect, somatic and retarded activity, and interpersonal problems [35,36]. The scale consists of 20 items, such as "I felt depressed" and "I did not feel like eating; my appetite was poor." Items are evaluated using a 4-point Likert scale ranging from 0 (rarely or none of the time) to 3 (most or all the time). A total score of CES-D ranges from 0 to 60, with higher scores indicating a higher level of depressive symptoms. Individuals with CES-D scores no less than 16 are considered as likely having clinical depressive symptoms [37]. The CES-D scale is one of the most widely used self-rated questionnaires on depressive symptoms and has been validated in Chinese populations, including people living with HIV [35,38,39]. In this study, CES-D showed a good reliability, with Cronbach α values reported at .77, .76, .84, and .83 at baseline, 3-, 6-, and 9-month follow-ups, respectively. In SEM, depressive symptoms were measured by the 4 dimensions of the scale.

QOL Assessment

QOL was assessed by World Health Organization Quality of Life HIV–short version (WHO-QOL-HIV BREF), with 31 items measuring the following 6 dimensions: physical, psychological, level of independence, social relationships, environment, and beliefs [40]. Items are rated on a 5-point Likert scale. The total score of WHO-QOL-HIV BREF ranges from 24 to 120, with higher scores indicating better QOL. Validity and reliability of the scale have been examined and established for the Chinese people living with HIV [41-43]. Cronbach α values of WHO-QOL-HIV at baseline, 3-, 6-, and 9-month follow-ups were reported at .84, .91, .94, and .94, respectively.

Data Analysis

First, descriptive statistics were reported on demographic characteristics, baseline HIV-related stigma, depressive symptoms, and QOL. Mean and SD values were used to describe continuous variables with normal distribution, and median and IQR values, for continuous variables with skewed distribution. Frequencies and percentages were used to describe categorical variables. Kolmogorov-Smirnov and Levene tests were used for normality and homogeneity tests.

Second, group differences were examined for the outcome and mediators at 4 assessment points by independent sample *t* test for continuous variables with normal distribution and Wilcoxon rank-sum test for continuous variables with skewed distribution.

Third, bivariate analyses were performed to examine relationships between baseline demographic characteristics and QOL. Independent samples *t* tests were used to examine differences in QOL by different demographic characteristics. Pearson correlation analyses were performed to examine relationships between QOL and continuous demographic variables, such as age. Significance level of potential associations was $P<.10$. Variables significant in bivariate analyses were considered as potential confounders and controlled in the SEM.

Fourth, in SEM analyses, HIV-related stigma, depressive symptoms, and QOL were treated as latent variables and measured by their subscales [44]. SEM allows to control for measurement error of variables; thus, it yields unbiased estimates of latent variables [45,46]. To assess the goodness of fit of the measurement models, confirmatory factor analyses (CFAs) of HIV-related stigma, depressive symptoms, and QOL were performed, respectively. With satisfactory measurement models, the SEM was then conducted to examine the hypothesized mechanisms of long-term intervention effects on participants' QOL.

Finally, a mediation model of SEM was performed to test the hypotheses of sequential mediating effects of HIV-related stigma and depressive symptoms by using longitudinal data. Such models were designed to explore the mechanisms, direct and indirect effects of the intervention, and sequential relationships [47]. Based on the associations between HIV-related stigma, depressive symptoms, and QOL in previous studies, we assigned sequential orders to the SEM variables [24,25,48-50]. Specifically, HIV-related stigma at 3-month follow-up, depressive symptoms at 6-month follow-up, and QOL at 9-month follow-up were estimated using the model. The pathways of intervention→QOL, intervention→depressive symptoms→QOL, intervention→HIV-related stigma→QOL, and intervention→HIV-related stigma→depressive symptoms→QOL were examined separately (dummy coded as 0=control group, 1=intervention group). Baseline QOL and sociodemographic characteristics that were significantly associated with QOL in bivariate analyses were controlled as covariates in the model. The statistical significance in SEM was defined at $P<.05$.

To evaluate the goodness of fit of the model, multiple indicators were used, including the chi-square statistic, Comparative Fit Index (CFI), Tucker-Lewis Index (TLI), root mean square error of approximation (RMSEA), and standardized root mean square residual (SRMR). A smaller chi-square value indicates better model fit. Moreover, CFI ≥0.95, TLI >0.90, RMSEA ≤0.06, and SRMR ≤0.08 indicate good model fit [51,52]. Descriptive statistics, bivariate statistics, and correlation analyses were performed using SAS version 9.4 (SAS Institute, Inc). CFA and SEM were tested by robust maximum likelihood method (estimator=MLR in Mplus) and performed using Mplus version 7.0 [53,54].

Results

Baseline Characteristics

The Run4Love program recruited 300 participants; their baseline characteristics are described in Table 1. Participants' mean age was 28.3 (SD 5.8) years. Most of the participants were male (277/300, 92.3%), nonheterosexual (245/300, 81.7%), not married (262/300, 87.3%), and well educated (high school and above: 182/300, 60.7%). The mean scores of HIV-related stigma, CES-D, and QOL were 37.5 (SD 7.6), 24.1 (SD 6.6), and 77.0 (SD 9.2), respectively, at baseline. A majority (213/300, 71.0%) of the participants had a moderate level of stigma, whereas 20.3% (61/300) had high level and 8.7% (26/300) had low level of stigma.

Table 1. Baseline characteristics and outcomes of study participants by intervention and control group in the Run4Love program (n=300).

Baseline characteristics	Total (n=300)	Intervention group (n=150)	Control group (n=150)	*P* value
Age (years), mean (SD)	28.3 (5.8)	28.0 (5.8)	28.6 (5.9)	.39[a]
Male, n (%)	277 (92.3)	142 (94.7)	135 (90)	.13[b]
Educational level above high school, n (%)	182 (60.7)	98 (65.3)	84 (56)	.10[b]
Homosexual, bisexual, or uncertain, n (%)	245 (81.7)	130 (86.7)	115 (76.7)	.03[b]
Married, n (%)	38 (12.7)	18 (12)	20 (13.3)	.73[b]
Employed, n (%)	251 (83.7)	123 (82)	128 (85.3)	.17[b]
Depressive symptoms, mean (SD)	24.1 (6.6)	23.9 (6.4)	24.3 (6.9)	.68[a]
QOL[c], mean (SD)	77.0 (9.2)	77.4 (9.0)	76.6 (9.4)	.44[a]
HIV-related stigma, mean (SD)	37.5 (7.6)	37.1 (7.7)	38.0 (7.5)	.31[a]
Low, n (%)	26 (8.7)	15 (10)	11 (7.3)	.36[b]

High, n (%)	61 (20.3)	26 (17.3)	35 (23.3)	

[a]Based on independent-samples *t* test.

[b]Based on chi-square test.

[c]QOL: quality of life.

The proportion of homosexual, bisexual, or sexual orientation-uncertain participants in the control group was slightly lower than that in the intervention group (115/150, 76.7% vs 130/150, 86.7%; $P=.03$). Other demographic

characteristics and psychosocial outcomes (HIV-related stigma, depressive symptoms, and QOL) were balanced between the two groups at baseline.

Changes in QOL and Mediating Variables Over Time

The proportion of participants who lost to follow-ups was less than 15% over 9 months. Of all participants, 91.3% (274/300; n=139 in the intervention group; n=135 in the control group), 88.3% (265/300; n=132 in the intervention group; n=133 in the control group), and 86.7% (260/300; n=133 in the intervention group; n=127 in the control group) completed the follow-up surveys at 3, 6, and 9 months. The characteristics of the participants who lost to follow-ups were not significantly different from the remaining participants.

As shown in Table 2, the Run4Love social media-based intervention had significant effects on QOL and potential mediating variables over 9 months. Repeated measurements of the outcome variable (QOL) and potential mediators, including HIV-related stigma and depressive symptoms at 4 assessment points for the intervention and control groups, are shown in Table 2. The intervention significantly reduced HIV-related stigma and depressive symptoms, and improved QOL in intervention group participants compared to control group participants at 3-, 6-, and 9-month follow-ups. No adverse events were reported.

Table 2. Repeated measurements of QOL[b] and potential mediators in the Run4Love program.

Variables	Intervention group, mean (SD)	Control group, mean (SD)	Effect size (95% CI)	*t* test (*df*)	*P* value

Correlations Between Demographics and QOL

Table 3 shows the correlations between demographic characteristics and QOL at baseline. Bivariate analyses indicated that gender, sexual orientation, education, marital status, and household registration were significantly associated with QOL among people living with HIV and depressive symptoms at baseline. Specifically, those who were male, nonheterosexual, and unmarried; had a higher education level; or had an urban household registration had better QOL at baseline. These factors were included as controlling covariates in the SEM.

Table 3. Bivariate analyses of quality of life (QOL) and demographic characteristics at baseline among people living with HIV and depressive symptoms in the Run4Love program.

Demographics	QOL	*t* value (*df*)	*P* value
Age (years)	N/A[a]	N/A	.76[b]
Gender		1.76 (25)	.09[c]
Male, n (%)	77.33 (9.02)		
Female, n (%)	73.22 (10.9)		
Sexual orientation		−1.95 (72)	.055[c]
Heterosexual, n (%)	74.58 (10.49)		
Homosexual, bisexual, or uncertain, n (%)	77.56 (8.85)		
Education		−3.64 (234)	<.001[c]
Less than or up to high school, n (%)	74.61 (9.51)

Measurement Model

CFA indicated that the measurement models of HIV-related stigma, depressive symptoms, and QOL yielded good model fit. Indices of the measurement models were reported in Table 4. All factor loadings of each scale were significant at P<.05 level. Results of the standardized factor loadings are shown in Figure 3.

Figure 3. Estimation of the structural equation model. Covariates including gender, sexual orientation, education, marital status, and household registration were controlled in the structural equation model. ** *P*<.01, *** *P*<.001. QOL: Quality of life; T_0: baseline; T_1: 3-month follow-up; T_2: 6-month follow-up; T_3: 9-month follow-up.

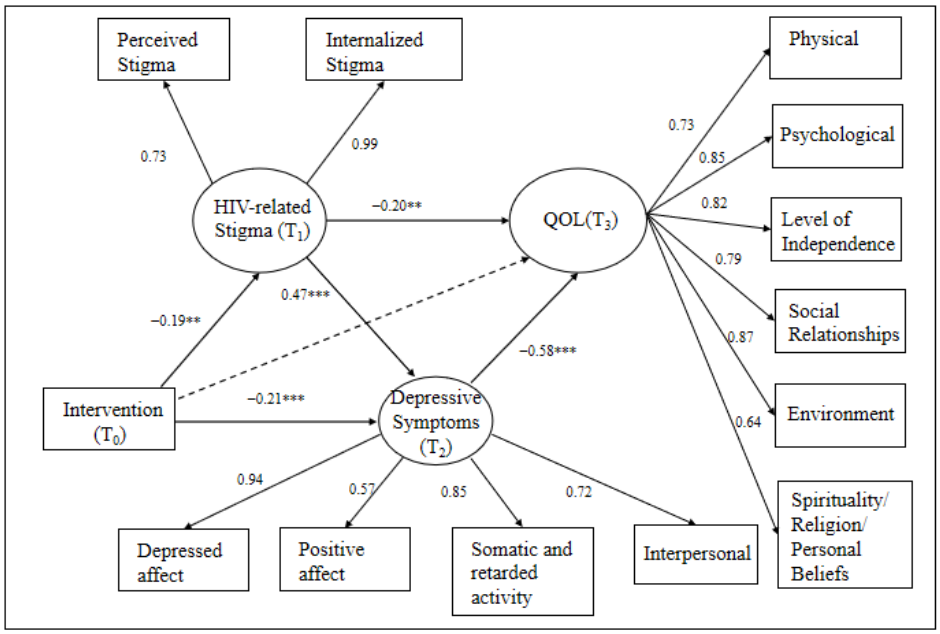

Table 4. Confirmatory factor analyses indices of HIV-related stigma, depressive symptoms, and quality of life.

	Chi-square (*df*)	CFI[a]	TLI[b]	RMSEA[c]	SRMR[d]
HIV-related stigma	0 (0)	1.00	1.00	<0.01	<0.01
Depressive symptoms	3.04 (2)	1.00	1.00	0.04	0.01
QOL[e]	6.47 (8)	1.00	1.00	<0.01	<0.01
Good model fit	N/A	≥0.95	≥0.90	≤0.06	≤0.08

[a]CFI: Comparative Fit Index.

[b]TLI: Tucker-Lewis Index.

[c]RMSEA: root mean square error of approximation.

[d]SRMR: standardized root mean square residual.

[e]QOL: quality of life.

Structural Model

The structural model showed a satisfactory model fit (X^2_{138}=240.4; *P*<.001; CFI=0.93; TLI=0.92; RMSEA=0.06; SRMR=0.06). Demographic characteristics, including gender, sexual orientation, education, marital status, and household registration, were controlled as covariates in the model.

Except for the pathway from intervention to QOL, other pathways were significant, which means that the Run4Love intervention had complete mediation effects on QOL via stigma and depressive symptoms. Standardized regression coefficients for the model are reported in Figure 3 and Table 5. Results indicated that the intervention reduced participants' stigma at the 3-month follow-up (standardized β=−.19, *P*=.001), which was positively associated with depressive symptoms at the 6-month follow-up (standardized β=.47, *P*<.001) and negatively associated with QOL at 9-month follow-up (standardized β=−.20, *P*=.005). The intervention also reduced depressive symptoms (standardized β=−.21, *P*<.001), which consequently resulted in improved QOL at 9 months (standardized β=−.58, *P*<.001). The pathway from depressive symptoms to QOL had the strongest effect size in the mediation model (standardized β=−.58, *P*<.001). There were complete mediation effects of the intervention on QOL via stigma and depressive symptoms. Specifically, the pathway through depressive symptoms alone accounted for the largest mediation effect size of 57.1% (0.12/0.21). The path through stigma→depressive symptoms and stigma alone accounted for 23.8% (0.05/0.21) and 19% (0.04/0.21) of the total effect size on long-term QOL, respectively.

Table 5. Pathway coefficients of the structural equation model.

Pathways	Estimate β	Standardized estimate β	95% CI	SE	*P* value
Intervention→stigma	−2.11	−.19	−3.37 to −0.85	0.64	.001
Intervention→depressive symptoms	−2.05	−.21	−3.11 to −0.99	0.54	<.001
Intervention→QOL[a]	.21	.05	−0.18 to 0.60	0.05	.28

[a]QOL: quality of life.

Discussion

Principal Findings

To our knowledge, this study is among the first efforts to explore the potential causal mechanisms of long-term improvement in QOL in an mHealth intervention using longitudinal data. The findings revealed significant mediating roles of stigma and depressive symptoms in improving long-term QOL for the mHealth intervention participants. Specifically, the long-term (9-month follow-up) intervention effect on the improvement of QOL was entirely mediated by the reduction of stigma in the short term (3 months) and reduction of depressive symptoms in the mid term (6 months).

Although several studies have explored the mechanisms of psychosocial interventions, the mechanisms of QOL improvement in the long term remain understudied. For example, studies on mind-body therapies have found that mindfulness might serve as a potentially important mechanism for patients' QOL improvement in such interventions [16,55]. However, literature examining the mechanisms of QOL improvement in psychosocial interventions are scarce, especially in the long term. In addition, methods employed in previous studies such as repeated measures analyses of covariance and latent growth curve model could not identify the sequential and causal relationships when exploring intervention mechanisms [16,17,56]. Our study contributed to the literature by affirming the sequential and potential causal relationships between HIV-related stigma, depressive symptoms, and QOL, which have not been reported in previous studies. Furthermore, only a small number of studies used longitudinal data, of which, to the best of our knowledge, none examined the sequential relationships [16,17,56]. In this study, the use of SEM with longitudinal data allowed us to assign mediators and the outcomes in chronological order, thus shedding light on the potential causal relationships of the intervention mechanisms.

Practical Implications

Given the critical roles of stigma and depressive symptoms in improving long-term QOL, it is important to address stigma and alleviate depressive symptoms in interventions aiming for QOL improvement among people living with HIV. There are several effective ways to reduce HIV-related stigma and to alleviate participants' depressive symptoms as suggested in the literature and shown in this study. First, the intervention content should be evidence-based in reducing HIV-related stigma and alleviating depressive symptoms [5,12]. The intervention materials of the Run4Love program were adapted from the evidence-based and theory-guided CBSM courses, which have been proved effective in reducing stigma and depressive symptoms among people living with HIV [12,57,58]. The core elements of the CBSM courses, such as stress management and coping skills, were preserved and adapted into multimedia formats. The participants in the intervention groups had a moderate level of patient engagement. The cumulative completion rates were 50.6%, 51.5%, and 50.8% at 1, 2, and 3 months, respectively, in the intervention group, which were comparable to other mHealth interventions [59]. The positive relationship between patient engagement and health outcomes has been confirmed in our previous study [59]. Therefore, evidence-based intervention content, rigorous design, and implementation might have contributed to the significant reduction of HIV-related stigma and depressive symptoms in the intervention group.

Second, another effective way to reduce stigma is through social contact; this is one of the most effective strategies to reduce stigma, provide social support, and alleviate depressive symptoms [5,60,61]. Comparatively, mHealth interventions provide varied forms of social contact with better convenience and privacy than face-to-face interventions [62,63]. For example, anonymous virtual communities, such as community message board and web-based forums, serve as easy and secure access for people living with HIV to interact with peers and receive social support [62,63]. Earlier studies suggested that mass media

communication or supportive virtual groups could be incorporated in interventions to mitigate stigma among people living with HIV [62,64]. Such web-based communities and connections are much needed by people living with HIV because of persistent stigma—both perceived and internalized—against HIV and people affected by HIV, as well as the consequent fear of discrimination and social isolation [65,66]. In addition, mHealth interventions allow alternative web connections (eg, human-machine interactions) to incentivize and engage participants. For example, the Run4Love program incorporated automatic weekly feedback on each participant's completion status of the intervention materials, with personalized verbal incentives. Such personalized and patient-centered human-machine interaction is a unique advantage of mHealth interventions. Future mHealth interventions for people living with HIV need to incorporate social contact in various forms as an essential component to address HIV-related stigma and decrease social isolation, so as to reduce depressive symptoms and achieve long-term improvement in people living with HIV's QOL.

Third, since HIV-related stigma is a multidimensional aspect, public policies and coordinated efforts are needed to reduce HIV-related stigma at multiple levels [67,68]. At the societal level, public policies and effective interventions targeting on stigma reduction, HIV testing, ART provision, and social empowerment are needed to address HIV-related stigma among people living with HIV [69]. Community-based support services and educational campaigns should be prioritized to reduce stigma and discrimination [70]. For example, in China, many celebrities, including the First Lady Peng Liyuan, joined the public campaign to reduce discrimination against people living with HIV and promote HIV testing and treatment [71,72]. At the health care level, Voluntary Counseling and Testing program has been instituted at the Centers for Disease Control and Prevention (CDC) and local hospitals [73]. At the individual level, a number of intervention programs focused on stigma reduction, problem-solving skills, and psychological support have been implemented [68].

Limitations

There are some limitations to this study. First, we only focused on HIV-related stigma and depressive symptoms as two important mediators; however, other variables, such as stress, social support, and self-efficacy, might also be potential mediating factors and were not included in this study. Future studies are needed to explore the mediating effects of these factors to better understand the mechanisms of social media-based mHealth interventions. Second, the measurements of stigma, depressive symptoms, and QOL were self-reported and thus might introduce potential recall bias. However, SEM analysis has already considered the measurement errors of these psychosocial variables and therefore provided more reliable model estimations. Third, since the participants were recruited from one hospital in an urban setting and the sample comprised mostly male participants, the generalizability of the study findings to other patients or geographical locations needs to be taken with caution, especially for women and those living in rural areas.

Conclusions

In conclusion, this study is one of the first efforts to examine the potential causal mechanisms of an mHealth intervention in long-term QOL improvement by using longitudinal data and SEM. We found that the long-term intervention effect on QOL improvement was entirely mediated by the reduction of stigma in the short term and reduction of depressive symptoms in the mid term. The findings underscore the critical roles of reducing HIV-related stigma and depressive symptoms in mHealth interventions targeting QOL improvements among people living with HIV. We call for targeted mHealth interventions to improve long-term QOL among people living with HIV, especially social media-based interventions that can reduce HIV-related stigma and alleviate depressive symptoms.

Acknowledgments

This study was supported by a grant from the National Natural Science Foundation of China (grant 71573290) and China Medical Board (grant 17-271). The funders had no role in study design, data collection and analysis, or writing of the manuscript.

Authors' Contributions

YL analyzed the data and drafted the paper. YG and YAH contributed to funding obtaining, study design, and manuscript revision. CZ helped in statistical analysis. YZ, HZ, MZ, JQ contributed to clinical trial and data acquisition. WC, LL, and CL provided administrative, technical, and material support for the clinical trial.

Abstract

Background: Universal access to assessment and treatment of mental health and learning disorders remains a significant and unmet need. There are many people without access to care because of economic, geographic, and cultural barriers, as well as the limited availability of clinical experts who could help advance our understanding and treatment of mental health.

Objective: This study aims to create an open, configurable software platform to build clinical measures, mobile assessments, tasks, and interventions without programming expertise. Specifically, our primary requirements include an administrator interface for creating and scheduling recurring and customized questionnaires where end users receive and respond to scheduled notifications via an iOS or Android app on a mobile device. Such a platform would help relieve overwhelmed health systems and empower remote and disadvantaged subgroups in need of accurate and effective information, assessment, and care. This platform has the potential to advance scientific research by supporting the collection of data with instruments tailored to specific scientific questions from large, distributed, and diverse populations.

Methods: We searched for products that satisfy these requirements. We designed and developed a new software platform called *MindLogger*, which exceeds the requirements. To demonstrate the platform's configurability, we built multiple *applets* (collections of activities) within the MindLogger mobile app and deployed several of them, including a comprehensive set of assessments underway in a large-scale, longitudinal mental health study.

Results: Of the hundreds of products we researched, we found 10 that met our primary requirements with 4 that support end-to-end encryption, 2 that enable restricted access to individual users' data, 1 that provides open-source software, and none that satisfy all three. We compared features related to information presentation and data capture capabilities; privacy and security; and access to the product, code, and data. We successfully built MindLogger mobile and web applications, as well as web browser–based tools for building and editing new applets and for administering them to end users. MindLogger has end-to-end encryption, enables restricted access, is open source, and supports a variety of data collection features. One applet is currently collecting data from children and adolescents in our mental health study, and other applets are in different stages of testing and deployment for use in clinical and research settings.

Conclusions: We demonstrated the flexibility and applicability of the MindLogger platform through its deployment in a large-scale, longitudinal, mobile mental health study and by building a variety of other mental health–related applets. With this release, we encourage a broad range of users to apply the MindLogger platform to create and test applets to advance health care and scientific research. We hope that increasing the availability of applets designed to assess and administer interventions will facilitate access to health care in the general population.

Introduction

Background

This section begins with acknowledging the global burden of mental illness and barriers to care, as well as the increasing need of patients, clinicians, and scientists for digital, mobile, remote mental health care and research. We have then highlighted the advantages of mobile apps, passive monitoring, and experience sampling. To provide context for the rest of the paper, we have described 2 studies: the Healthy Brain Network study and the National Institute of Mental Health (NIMH) Family Study of Affective Spectrum Disorders.

Global Burden of Mental Illness and Barriers to Care

The global burden of mental illnesses is staggering. Epidemiologic studies indicate that 75% of all diagnosable psychiatric disorders begin before the age of 24 years [1] and the lifetime prevalence of a severe disorder among children and adolescents is 21.4%. The most common diagnoses during childhood are anxiety disorders, attention-deficit/hyperactivity disorder, and mood disorders [2]. Despite their high prevalence, only about 50% of children with a mental health disorder receive treatment (Centers for Disease Control and Prevention, NIMH). Adults and children remain untreated, even though effective treatments exist. The World Health Organization has reported large median treatment gaps for alcohol abuse and dependence (78%), generalized anxiety disorder (58%), obsessive-compulsive disorder (57%), depression (56%), dysthymia (56%), panic disorder (56%), bipolar disorder (50%), and schizophrenia (32%) [3,4]. There is a general dearth of mental health resources, especially in low- to middle-income settings [5] and for disadvantaged youth [6], and there are many barriers to care that do not involve finances, insurance, and availability of treatments [6-16]. Simply scheduling an appointment in the United States can be difficult [8], and wait times may take months [8,11]. Additional barriers include concerns about stigma and privacy, as well as exceptional circumstances when telehealth is the only option, such as with the current COVID-19 crisis.

An Increasing Need for Digital, Mobile, Remote Mental Health Care, and Research

People seeking mental health care can use web-based resources to overcome barriers to treatment, such as distance, cost, long waits, inconvenience, stigma, privacy, and problems associated with in-person visits. In recent years, people have been increasingly turning to the internet as a preferred source of knowledge about mental health [7,17,18]. However, the abundance of inaccurate and misleading information on the internet makes it difficult to evaluate the credibility of information sources, the veracity of claims, and the effectiveness of recommendations and therapies. In addition, there are many scenarios in which obtaining data or care without access to the internet or a computer is important. Furthermore, receiving scheduled notifications at any time and place can be critical for a realistic assessment and effective intervention. In the context of these requirements, mobile devices with dedicated apps offer a better way of receiving vetted, curated content and of communicating relevant information without having to sit in front of a computer or find the right person to talk to at the right time.

Clinicians and health organizations, particularly those in the mental health sector, are overwhelmed. General health practitioners, in particular, struggle to meet the needs of their local communities. Better assistance is required to identify mental health issues during checkups to ensure that these concerns are caught early on and that patients benefit from referral to a specialist. Health organizations struggle to provide broader assistance to the vast majority of people around the world who have limited or no access to mental health resources. They need better tools to scale up mental health efforts that reduce or remove face-to-face interactions to inform, assess, and provide therapy. Digital and mobile tools are especially important to reach people who need care and who are in remote

areas, in socioeconomically disadvantaged conditions, or in situations where there is profound stigma surrounding mental illness. Telehealth options that involve video teleconferencing with a health care provider are becoming more prominent and have some evidence of scalability [19]. However, these services require the time and attention of expensive and limited human resources, and therefore do not scale as well as digital, mobile, and remote resources that do not require human interaction. The current COVID-19 crisis has made it starkly apparent that telehealth, with or without human interaction, may at times be the only option for seeking and receiving care. This pandemic is causing a widespread impact on mental health, from anxiety and stress related to helplessness, fear, and uncertainties of the crisis itself to the isolation and loneliness of home confinement and social distancing [20,21]. The need for remotely administered information, assessment, and therapy will only grow as nations have been forced to discover the extensive possibilities of these novel technologies.

Scientists often struggle to acquire relevant mental health and behavioral data when using traditional research paradigms. Study participant recruitment efforts are usually restricted to individuals who can be evaluated in person and provide written consent, which drastically reduces the size and scope of study samples. Smaller sample sizes are less likely to detect effects that exist at the population level, so for data to be relevant, robust, and replicable, it is important to frequently sample from large and diverse populations. Off-the-shelf, web-based tools, such as mobile apps for collecting data, do not meet the needs of most scientists who must configure their data collection tools to reach the right population and address specific questions of scientific and clinical relevance. Even tools that are configurable often require considerable mobile app software engineering expertise that is outside of most laboratories' capabilities. For laboratories attempting to create their own mobile app from scratch, they may turn to outsourcing for its development only to find that it is far more costly than anticipated and requires consistent maintenance and upgrading to keep up with changing software dependencies, operating system versions, and hardware, let alone the changing requirements of the research itself. In addition to the engineering, content, design, and financial challenges of creating mobile apps, there can be considerable logistical and governance challenges involved in dissemination and the incorporation of an electronic consent process.

Appropriately constructed, configured, and vetted mobile apps are currently the most promising avenue for satisfying all of the abovementioned requirements, as mobile devices with internet access are rapidly becoming widely available to diverse populations around the world. It is currently estimated that 60% of the world's population uses the internet and that 93% of users gain internet access through mobile devices [22]. They provide a convenient way to passively or actively collect and present information that can be relevant to the natural variations and social and environmental contexts of people's lives. Passive methods usually involve sensors carried or worn on some part of the body and can collect objective, real-world data about participants to monitor motor activity, sleep, heart rate, cognition, behaviors, mood, and physiological states, as well as detect important outcomes such as medication response [23]. Some recent examples of sensor-based technologies that track mental health include phone apps, such as Northwestern University's Center for Behavioral Intervention Technologies' Purple [24,25] and Intellicare [26,27] platforms, Harvard University's Beiwe platform [28,29], and apps such as mPower [30,31] built on top of Apple's ResearchKit for iOS [32] and ResearchStack for Android [33]. The Beth Israel Deaconess Medical Center maintains an extensive database of apps that claim to respond to mental health needs [34] and provides a protocol for their evaluation [35,36]. There is an unmet need for a free, open, configurable platform to translate pencil-and-paper assessment instruments, cognitive tasks, and therapies into attractive, engaging, and effective digital, mobile, and remote tools that exceed current standards of privacy, security, and accessibility.

One important limitation in the interpretation of data acquired through passive monitoring is the lack of contextual information on variables that may influence sleep, activity, or mood changes inferred from speech, texting, GPS location, or other interactions with mobile devices. Although studies have combined subjective symptom ratings with passive monitoring, retrospective reporting over the past week or month is common among many traditional clinical questionnaires and may miss important real-time associations between subjective and objective data. Gaining insight into the directional associations between events and psychological states and their association with sleep and physical activity can be enhanced through the administration of tools that simultaneously capture descriptions of symptoms of mood, cognition, and other subjective experiences, which remain the core components of psychiatric disorder criteria. These active methods of recording individuals' internal states and experiences include explicit self-reports that may range from occasional and detailed survey instruments to more frequent, brief, and in-the-moment questionnaires. Repeated assessment of people in real time is best known as *experience sampling* [37] and in the context of medicine and physiological or event-related data capture has been referred to as ecological momentary assessment (EMA) [38]. As pointed out by Marije aan het Rot et al [39] in their excellent review of experience sampling methods and EMA [39], the 2 terms are increasingly used together, so we will simply refer to them as *experience sampling*.

As described by Trull and Ebner-Priemer [40], experience sampling offers major benefits over traditional clinical assessments, including the reduction of retrospective bias, real-time tracking of dynamic processes, simultaneous integration of multi-level data (eg, biological and psychological), characterization of context-specific relationships of behaviors and symptoms, inclusion of feedback, and enhanced generalizability of results. Experience sampling has been shown to be highly feasible and valid in the assessment of diverse categories of mental illness, including patients with mood disorders, anxiety disorders, substance use disorders, and psychosis [41-45] as well as in the assessment of transdiagnostic mental health issues such as suicidal ideation [46]. More recently, experience sampling has been used to assess cognitive functions [47]. Batteries of cognitive tasks, such as the NIH Toolbox [48,49], ACE [50], and Cambridge Cognition [51], are

primarily used for research and are not currently intended for clinical practice; they are for the most part commercial, proprietary, and permit limited (if any) configuration options for presenting and collecting data. Although mental health professionals may not adopt new technologies for clinical assessment more readily than traditional tools [52], their use in clinical practice may be encouraged by increasing their personalization and integration into standard care [53].

The Healthy Brain Network Study and NIMH Family Study of Affective Spectrum Disorders

The Child Mind Institute's Healthy Brain Network study [54] is an ongoing initiative focused on creating and sharing a biobank of data from 10,000 New York area participants (age group 5-21 years). The biobank houses data on psychiatric, behavioral, cognitive, and lifestyle phenotypes, as well as multimodal brain imaging (resting and naturalistic viewing functional magnetic resonance imaging (MRI), diffusion MRI, and morphometric MRI), electroencephalography, eye tracking, voice and video recording, genetics, and actigraphy.

The NIMH Family Study of Affective Spectrum Disorders was a large, community-based, controlled family study [55] that collected assessment data 4 times per day for 2 weeks from phones provided to participants of the study. The assessments included questions about daily life experiences and behaviors at the moment of acquisition (current location, social company, performance of specific behaviors, and mood states) and since the previous assessment or since waking up (experience of daily events and event negativity, food intake, substance use, experience of headache, and specific symptoms). Assessments at the beginning of the day also included questions about duration, quality, and problems with sleep, and at the end of the day included ratings of the stressfulness of the day, food craving for the day, and specific physical symptoms (gastrointestinal symptoms and muscle pain). Response options included Likert scales for dimensional constructs (such as mood or event negativity) and checklists for multiple responses (such as for food consumed) or single responses (such as current physical location).

The data from the NIMH Family Study that evaluated the association between daily events and emotional experience yielded important differences in patterns of reactivity among the major subtypes of mood disorders, including bipolar I disorder, bipolar II disorder, major depression, anxiety disorders without a mood disorder, and controls [56]. These findings demonstrate how experience sampling is a particularly well-adapted tool for assessing affective dynamics as well as emotional reactivity following daily life events. The value of combined passive and active monitoring in this study further showed bidirectional associations between energy, motor activity, and sleep, and unidirectional associations between activity and mood, suggesting that increased activity could be used as an intervention for depression [57]. Using the novel analytic approach of fragmentation to test the stability and instability of emotional states in this study showed greater instability of energy and attention in people with a history of bipolar I disorder, whereas those with bipolar II disorder or major depression exhibited greater fragmentation of mood and anxiety [58].

Outline of the Paper

In this paper, we (1) review customizable, mobile, experience sampling products for configurable data collection and content delivery, (2) summarize the motivation for and development of a new mobile platform called MindLogger, and (3) describe MindLogger applets, including an initial use case that applies a MindLogger version of the NIMH Family Study's app as part of the Healthy Brain Network study.

Methods

Overview

In this section, we have discussed our criteria for selecting and evaluating customizable, mobile, experience sampling products; provided an overview of the development of the MindLogger platform for experience sampling and interventions; and presented an example app of MindLogger in a large-scale mental health study. The *Results* section follows up on each of these, presenting the results of the product review, the current state of the MindLogger platform, and example apps of MindLogger.

Criteria for Reviewing Customizable, Mobile, and Experience Sampling Products

In this review, we did not consider mobile apps limited to specific assessments, cognitive tasks, or therapies, but rather examined platforms that enable the creation and distribution of such apps. We wanted to find products that have an administrator interface for creating and scheduling recurring, customized questionnaires, where users receive and respond to scheduled notifications on a mobile device.

The detailed outline of the protocol we followed has been provided in Multimedia Appendix 1, which is briefly summarized in the paper. Over the last 3 years, clinical and research collaborators and colleagues have helped us gather information about products with desired characteristics. To extend this search, we conducted 3 queries in Google's search engine (without quotation marks or Boolean operators): (1) *digital electronic data capture systems*, to broadly identify any electronic tools for capturing data; (2) *mobile phone software sensor data collection*, to identify mobile data collection software that may involve sensors; and (3) *alternative to Qualtrics*, to identify alternatives to one of the most prominent products that enables web-based customization of surveys (although Qualtrics itself does not currently have a mobile app). We visited the websites of the first 20 search results from each query (not including advertisements) and identified the candidate products. For example, if a website listed the *Top Ten Apps for...*, we would include these 10 apps in our initial set of candidates. We then filtered this set using the following inclusion criteria: the candidate product had to (1) be in current use, (2) have (Android and iOS) mobile apps, and (3) have an administrative user interface for creating and scheduling times and days for recurring, customized questionnaires, where end users receive and respond to scheduled notifications via an iOS or Android app on a mobile device. Where there was any ambiguity, we contacted the company or organization to clarify,

scheduled a web-based demonstration, and requested a free trial to explore the product. We excluded products that do not currently fulfill the above requirements or for which we could not receive a demonstration or trial without a legal agreement. We also excluded products that require SMS text messaging, email, or other modes of communication outside of their mobile app to send and receive notifications.

Because the type of notification is important in experience sampling applications, we identified which products can deliver local operating system notifications or push notifications, where an end user receives notifications in their mobile device's notification bar at scheduled times, and a tap on a notification takes them to their scheduled activity within the mobile app. Local operating system notifications do not require an internet connection at the time that the notification is to be received, whereas push notifications do, and both of these are distinct from simple in-app notifications, which require the end user to use the app to see their notifications.

We collected additional information from product websites, and via teleconferences and web-based demonstrations with the product creators, and from free trials to determine the degree to which each is (1) customizable in its information presentation and data capture capabilities, (2) private and secure, and (3) accessible (easy to use, economical, and open source). Customization is important to ensure that content, language, and presentation can be adapted and updated to meet the specific needs of a given population of intended end users, and to expand the scope of possible dimensions to assess, analyses to perform, and inferences to make. Privacy and security is a central concern, especially as we conduct research involving a triply vulnerable population of end users: (1) child and adolescent (2) patients with (3) mental health and learning disorders. Data access, encryption, and deletion capabilities are the primary considerations in this domain. *Accessible* can mean many things; here we refer to whether and how the administrator can access the product, its source code, or its data. The degree to which a product is affordable will often determine the degree to which it is adopted. Possibly, the most stringent accessibility criterion one could have is for the software to be open source. Open-source software is important because the product does not live or die with a given company, provides an opportunity for anyone to build on and improve the software, and it is open to greater scrutiny to ensure the quality of the software, accuracy of any claims made about the software, and transparency of clinical and scientific practices that use the software. Each of these characteristics offers a competitive advantage; however, they should be considered together. For example, a company offering a free product can store or transmit user data insecurely.

Development of the MindLogger Platform

MindLogger [59] is intended as an *open ecosystem to create, edit, share, and administer mobile or web applets for data collection and content delivery*. We use the term *applet* to refer to a customized collection of activities within the MindLogger app administered to target end users. Our focus with MindLogger is to easily create and edit digital mental health assessments and interventions and administer them to users via mobile or web applets. The 3 key innovations we sought to accomplish with MindLogger were *customizability* of content, response options, and appearance; an extensive library of applets built using *open standards* (open, reusable parts defined by an open protocol), and distribution as a *single app* that appears differently to different user groups.

MindLogger's development began in 2017, with a focus on mental health assessments. After the significant development of an early prototype for mental health research and clinical colleagues at the Child Mind Institute and the Child Mind Medical Practice in New York City, we revisited development with a greater emphasis on human-centered design [60,61]. We included a variety of key stakeholders to ensure that their needs would be met by the platform: clinicians (psychiatrists, psychologists, social workers, etc), scientists (neuroscientists, cognitive psychologists, etc), and directors of schools specializing in learning and developmental disorders, as well as technology consultants. We integrated their feedback at different stages throughout the development of the platform. Regarding user experience, both structured and informal user feedback collection has been iterative and ongoing throughout the development process. The MindLogger apps described in this paper use an assessment frequency, duration, and question content that has been substantially validated over recent years by members of our team for a wide range of age groups (children, adults, and older adults) [62-66], for healthy individuals [62,63,67], and for persons with diverse forms of mental [62,63,67-71] or physical [72-74] disorder. The NIMH's predecessor to the MindLogger applet described below (using a highly similar protocol for daily assessments and with identical question content) documented an average completion rate of 77.9% (SE 0.81%) for repeated daily assessments, with no significant fatigue effect, defined as an increase in missing data as a function of time in the study (ordinary least squares linear model β coefficient=–.041; P<.001). In addition to user experience considerations and other stakeholder feedback, the information we gathered over the last 3 years that preceded the above review of customizable, mobile, experience sampling products also helped to guide MindLogger development.

Application of MindLogger in the Healthy Brain Network Study

To obtain more in-depth information on real-time tracking of emotions, behavior, daily activities, and their contextual influences in the Healthy Brain Network study [54], we adapted the combined actigraphy and experience sampling mobile assessment tools and content from the NIMH Family Study of Affective Spectrum Disorders [55]. Although the findings of that study (summarized in the Introduction section) were primarily based on adult samples, the inclusion of a substantial subset of offspring aged 10-18 years of parents with mood disorders and controls provided compelling evidence for the feasibility, acceptability, and clinical significance of experience sampling in youth. Therefore, the goal of the present initiative was to create a version in MindLogger, with updated content (particularly with regard to sleep, positive and negative thoughts, food and drink, internet, and social media), enhanced with clarification of the content, inclusion of colorful images, and formats adapted for children and young adults to encourage engagement [75].

Results

Overview

In this section, we present the results of our review of customizable, mobile, experience sampling products, the current state of the MindLogger platform (including roles and permissions, software architecture, and current set of features), and the applet we have deployed in the Healthy Brain Network study.

Results of the Review of Customizable, Mobile, and Experience Sampling Products

Our search resulted in 392 products, of which 315 appear to be in current use. Multimedia Appendix 1 contains a list of 101 products that have Android and/or iOS mobile apps. Upon closer inspection of their websites, 59 appeared relevant to scheduling questionnaires and notifications for a group of respondents, so we contacted the 59 products' companies/organizations through their web-based contact forms or via email to clarify their products' capabilities and exchanged emails with the 47 companies that responded. On the basis of these exchanges, we were able to identify 21 products that appeared to satisfy our primary criteria (administrator interface for creating and scheduling recurring, customized questionnaires, where users receive and respond to scheduled notifications on a mobile device). Five potential candidates were omitted as they are intended for use by internal business employees of a company, not by patients or by participants of a study, and require individual licenses, log-ins, or fees per device. Two more candidates were omitted as they required a legal agreement to demonstrate their products. Of the 14 remaining products for which we engaged in demonstrations and free trials, 10 met the primary criteria and are included in Figures 1-3. In these figures, *yes* or *no* (filled vs empty) correspond to the questions in the bulleted lists below. The questions represent specific instances of broader criteria that can be complex and nuanced.

- *Multiuser*: Can more than one end user access the app on the same mobile device, even if it means logging out and logging back in again?
- *Offline notification*: Can end users receive and respond to notifications without an internet connection?
- *Tap notification*: When an end user taps on a notification in their mobile device's notification bar, does it take them directly to their scheduled activity within the app?
- *Visualize data*: Is there a data visualization dashboard to review any individual end user's response data?
- *Reviewers*: If there is a data visualization dashboard, can an administrator give someone access to review only one end user's response data in the dashboard?
- *Setup languages*: When administrators create a customized questionnaire, can they choose from at least 5 different languages to use the interface, in addition to English? (This is distinct from how many different languages the end users can see.)
- *API*: Is there a consumer-facing application programming interface (API)?
- *Open*: Is the product's mobile app software fully open source and free to set up?

Figure 1 contains information about access to the product, software, and data (for both Android and iOS).

Figure 1. Access to experience sampling products, software, and data (filled means yes). API: application programmer interface.

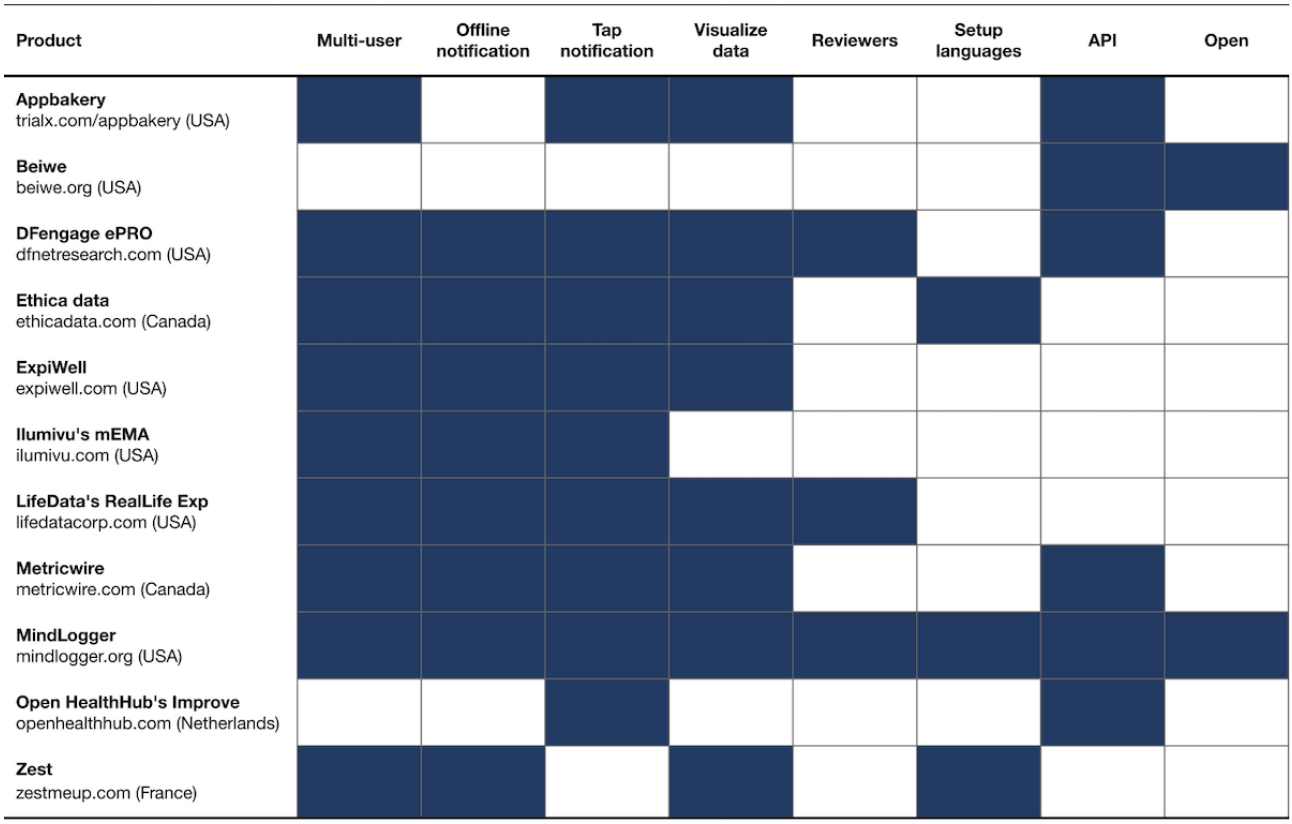

Figure 2 contains information about presentation and data capture features:

- *Play video/audio*: When administrators create an activity, can they include video or audio clips?
- *Type text, take photo, record video/audio, draw*: When administrators create an activity, can they include any of the following to capture data from end users? (Text entry, camera photo, audio/video recording, and drawing.)
- *GPS*: Can GPS location data be acquired through the app?
- *Sensor*: Can any additional sensor (eg, accelerometer) data be acquired?
- *Time*: Can any question include a countdown or timer?
- *Logic*: Can the response to a question determine which is the follow-up question (skip/branch logic)?
- *Score*: Can a questionnaire's scoring logic be entered when creating the questionnaire?

Figure 2. Presentation and data capture features of experience sampling products (filled means yes).

Figure 3 contains information about privacy and security:

- *Encrypt on (device, server)*: Does the product encrypt data on the mobile device or on the server?
- *End-to-end encryption*: Is the product end-to-end encrypted or could someone within the company or organization hosting apps on their server see (even anonymized respondents') response data?
- *Admin delete*: Can an administrator delete an individual end user's data without having to make a request from the product creator?
- *Own server*: Can the product be hosted on an administrator's own server?

Current State of the MindLogger Platform

Roles and Permissions

Figure 4 shows a schematic of MindLogger, where an administrator selects, edits, or creates an applet; administers the applet to end users; and views or makes use of their data. Figure 5 outlines the different roles (owner, manager, coordinator, editor, user, or reviewer) and their permissions with regard to administration, content, use, and data management. For instance, a principal investigator of a research study could be the owner of a new applet as well as its editor and might assign a laboratory manager who recruits participants (applet users) to be the manager of the applet, and 2 data analysts to be the reviewers of all deidentified participants' data. As a second example, a clinical director of a pediatric mental health clinic could be the owner of a copy of an applet containing assessments, assigns a clinical coordinator who manages patients (applet users) to be a manager of the applet, and assigns parents to be reviewers of their child's responses. As a trivial example, anyone could sign up for a MindLogger account and own their own applet and be its only user. This last scenario enables any user to customize their own applet to send scheduled notifications to themselves to remind themselves to take their medication, perform breathing exercises, practice mindfulness meditation, or log their thoughts within the app.

Figure 4. MindLogger schematic. Left: select, edit, or create activities with scheduled notifications, such as questionnaires, tasks, or interventions, for use on mobile (iOS, Android) devices or the web. Middle: assign yourself or others to do these activities for data collection, annotation, research, or remote clinical assessment or therapy. Right: view end user data for which you have access.

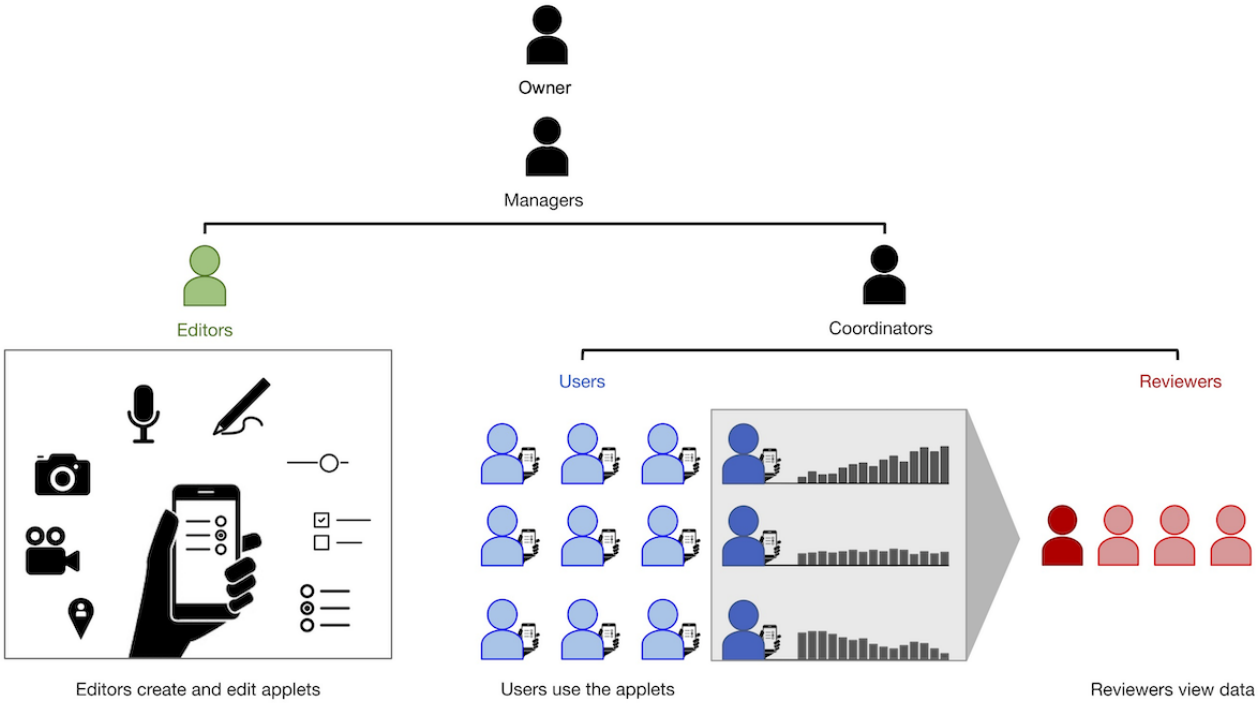

Figure 5. MindLogger roles and permissions for administration, content, use, and data management.

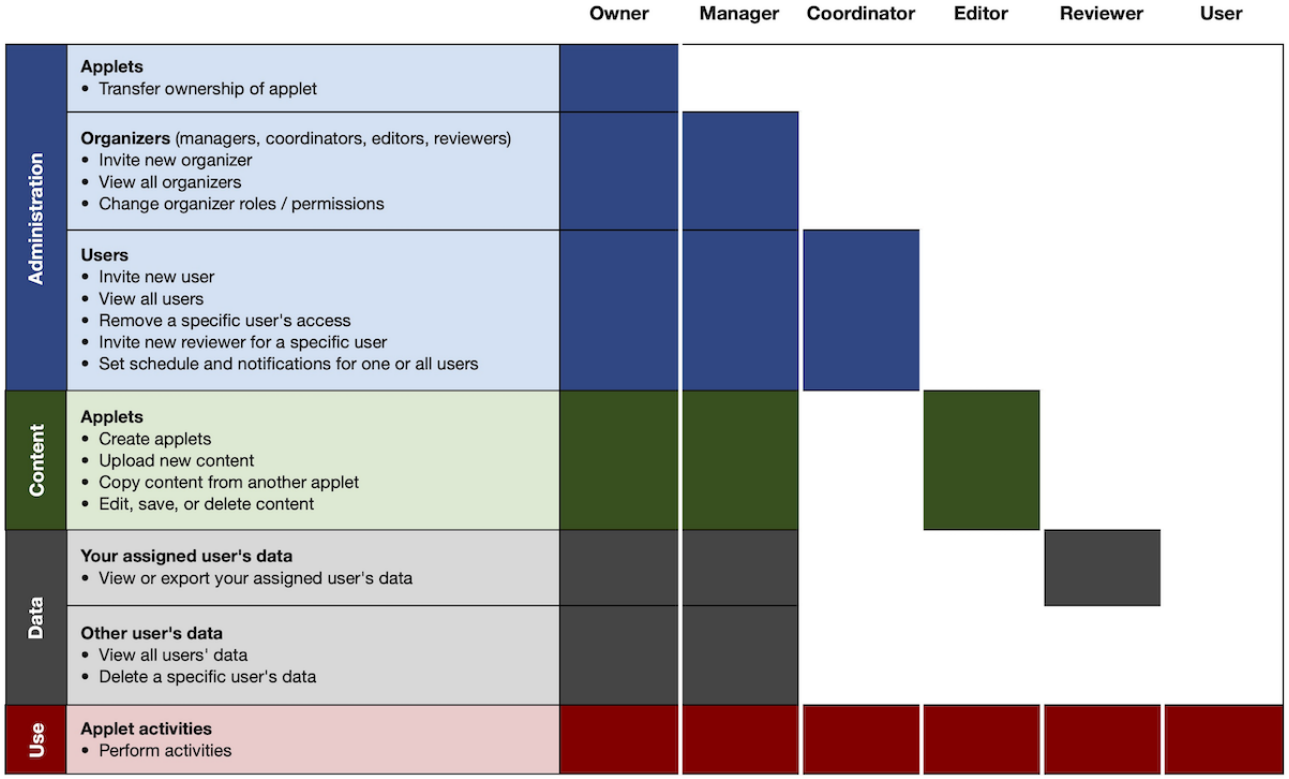


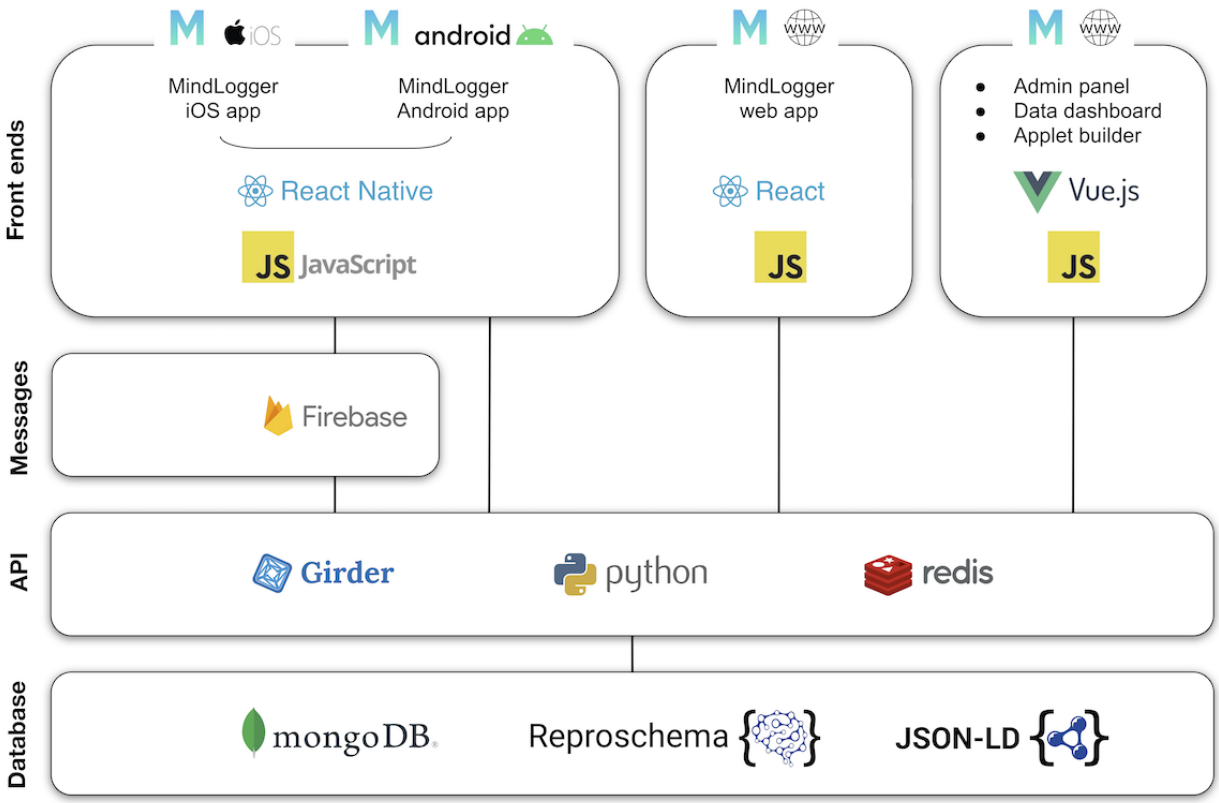
Administering permissions

1. All roles and associated permissions are restricted to a specific applet.
2. A person can have multiple roles for an applet, and different roles for different applets.
3. A person can become a User of an applet only via an invitation.
4. A person can become a Manager, Coordinator, Reviewer, or Editor of an applet via an administrator website.
5. Coordinators cannot invite themselves to be a Manager, Reviewer, or Editor unless they are the applet's Owner.

MindLogger Software Architecture

MindLogger's software architecture (Figure 6) consists of a set of end user–facing front ends (2 mobile apps and a web application) and organizer-facing front ends (an admin panel, data dashboard, and applet builder) with a shared RESTful HTTP API using MongoDB [76] for data storage. The mobile front ends, Android, and iOS apps are built using React Native [77]. This allows us to share a single code base across mobile platforms, resulting in increased speed of development and ease, and cost-effectiveness of maintenance. The web application is a ReactJS browser-based counterpart to mobile apps and currently provides a subset of their functionality. Administrators (managers, coordinators, editors, and reviewers) have access to different single-page applications built using VueJS [78]. The admin panel and applet builder manage user roles and applets, and the data dashboard is used to review user data, with custom charts implemented using d3.js [79]. The computer security firm Alpine Security [80] conducted extensive cybersecurity black, gray, and white penetration tests to ensure that MindLogger follows best practices for privacy and security. These practices can be adapted to the specific regulations and guidelines of different countries, including the General Data Protection Regulations of the European Union [81], which are among the strictest concerning data use, access, and storage. As shown in Figure 3, MindLogger has end-to-end encryption, permits administrators to delete an individual's data, and can be set up on one's own server (accommodating European regulations concerning the physical location of data processing and storage [81]), so the platform should already meet the security requirements of most use cases.

Figure 6. MindLogger software architecture diagram. API: application programmer interface.



Our application front-end and backend code base is accessible as web-based GitHub repositories [59] and is licensed under an extremely permissive Open Source Initiative–approved open-source license, the Common Public Attribution License (CPAL-1.0) [82]. The license requires that attribution be given by including (1) the copyright notice: "Copyright (c) 2017 MATTER Lab at the Child Mind Institute," (2) the MATTER Lab website address, (3) the Child Mind Institute's logo, and (4) the attribution phrase: "Child Mind Institute product intended for building applications for good." We include the attribution phrase to give credit to the developers while also making it clear that although we intend for people to build MindLogger applets that will be benevolent, we have no control over their intent, content, or the data they collect [83].

Our administrative software is licensed under a new license, the Delayed Open Source Attribution License (DOSA-1.0) [84]. Although it is not itself an open-source license, the purpose of this Delayed Open Source Attribution License is to provide open access to software for noncommercial use while giving attribution to its original developer, and after a delay of 3 years, forcing the software to fall under the terms of the open source CPAL-1.0 license that preserves the attribution information of this license. This delay is intended to protect the commercial interests of the licensor without compromising on the many benefits of creating open-source products [85].

The backend API is built in Python using Girder's RESTful API [86] with the CherryPy framework [87]. This software layer provides a set of RESTful endpoints that allow users, applets, activities, items (such as individual questions), and user responses. All user data are stored in a MongoDB database hosted in an Amazon Web Services [88] cloud instance with password-based encryption. Specifically, user response data are encrypted using their own password on the client side so that only managers or reviewers can view their data using an applet password; other sensitive information (name and email) is encrypted on the server side. We have Health Insurance Portability and Accountability Act compliance agreements with Amazon Web Services, Google Cloud Platform [89], and MongoDB Atlas [90], and the software permits installation on an arbitrary backend server (eg, on a university or hospital server and not on any cloud service provider's servers). For improved performance, MindLogger uses a Redis [91] instance as a temporary storage for data caching. MindLogger uses Firebase Cloud Messaging to send notifications from the backend server to the end user's mobile device. All additional data are consumed from the backend API through the HTTPS requests.

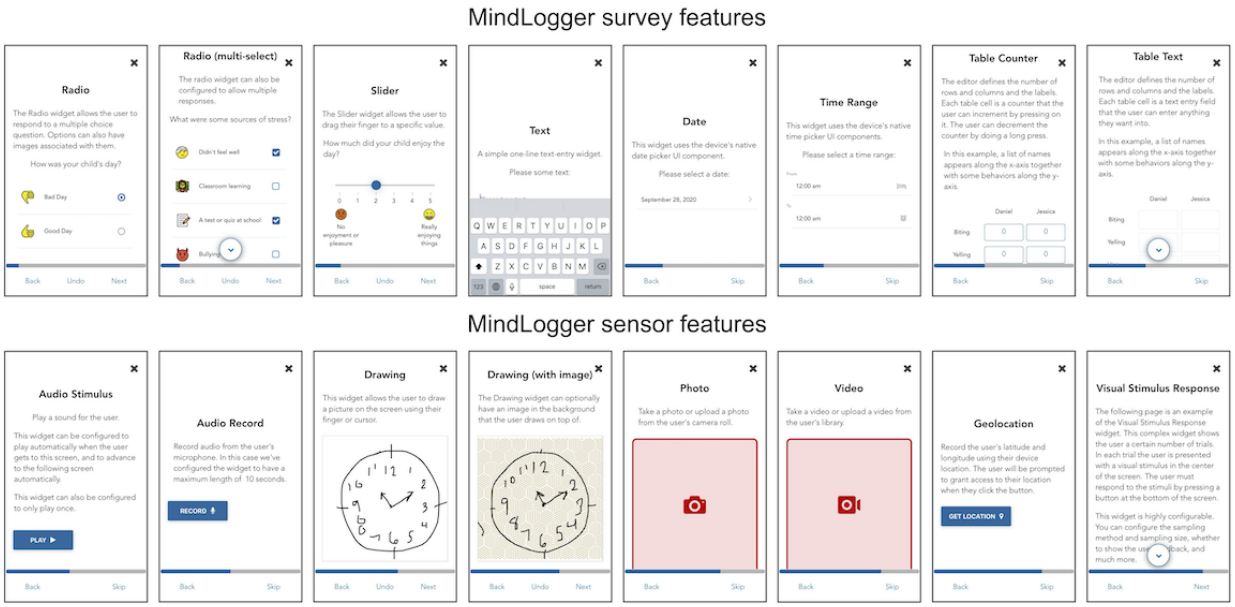
The applets, activities, and items are described using ReproSchema [92], an emerging standard for capturing and harmonizing cognitive, clinical, and behavioral assessments and responses in a provenance-preserving manner. The schema uses JSON for linking data (JSON-LD) [93] as its representation format and captures, as a connected graph of information, the details of the questions, presentation logic on the basis of responses or scheduling, computation of scores, and interface hints for applications such as MindLogger. The schema uses GitHub to maintain versions and provide persistent Uniform Resource Identifiers for applets and activities, supports multilingual applets, and uses World Wide Web Consortium

provenance specifications [94] to establish provenance between the response, the responder, and the applet.

MindLogger Current Features

We have succeeded in implementing many user- and administrator-facing features (see the MindLogger website [59] for updated information about features, installation, administration, and use). There are an arbitrary number of activities in an applet and an arbitrary number of screens in an activity (with response-based conditional logic directing the sequence of screens). Each screen of a MindLogger applet can display text and a picture or video, play a sound file, and present an interactive component with different possible response options, such as single- or multiple-selection check boxes, image selection, slider bar, text entry, table text or number entry, audio recording, photo or video capture, drawing or tapping on images, or GPS location button. Response delay and timer options are also available for each screen. MindLogger is cross-platform (iOS, Android, and web browser compatibility) and has open-source code for apps and applets, and data are end-to-end encrypted. The browser-based administration panel enables user management, easy creation, and customization of one's own mobile or web applications without programming or design experience, scheduling of applets and notifications per activity per user or group of users, and visualization and export of data. Figure 7 shows screenshots of the MindLogger mobile phone app features. We have created applets to remotely administer assessments as well as therapies and are currently constructing a public library with over 100 mental health and cognitive assessments that have open licenses for general use.

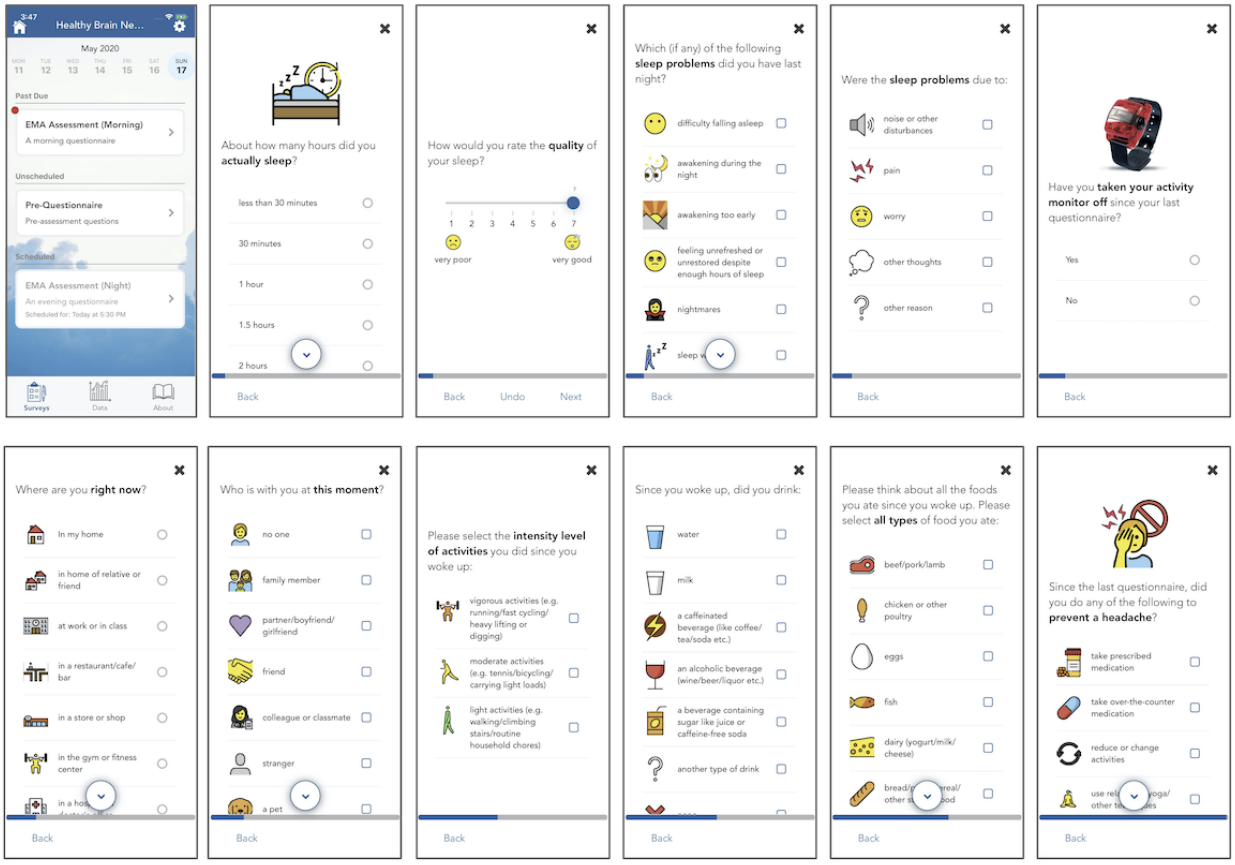
Figure 7. MindLogger screenshots showing survey and sensor features.



Deployment of MindLogger in the Healthy Brain Network Study

MindLogger's *NIMH-EMA* applet has been launched as part of the Healthy Brain Network study [54] to a vulnerable transdiagnostic New York City community sample (current n=4315; enrollment rate: 90 per month; >90% have mental health or learning disorders). Participants of the study receive multiple notifications per day on their Android or iOS devices to respond to morning, afternoon, and evening assessments. Figure 8 shows screenshots of the NIMH-EMA applet. We are currently enrolling children and adolescents who are at least 11 years old to use the NIMH-EMA applet as part of the Healthy Brain Network study. This applet is about to be deployed in the NIMH research program as well.

Figure 8. MindLogger National Institute of Mental Health-ecological momentary assessment applet screenshots.



EDUCATE Study's Daily and Weekly Diary Applet

Having developed and deployed the NIMH-EMA applet as part of one research study, we were able to rapidly develop and deploy a second assessment applet as part of a different research study on reading disability. Reading disability is the most common learning disability, affecting 10%-15% of school-age children [95]. It causes major functional impairments at all stages of life. A wealth of data documents lifelong disadvantages in educational and occupational attainment. Current evidence-based reading interventions largely rely on services by trained specialists, either in well-resourced classrooms or clinical settings. As such, under-resourced schools (or regions) are often unable to provide reading interventions for their students. The significance of this dilemma is compounded when considering that children of lower socioeconomic status and children with other serious comorbid behavioral health conditions may have more severe or complex reading disability profiles [96-98]. Thus, the children most in need are the least likely to have access to evidence-based treatment.

The EDUCATE study, funded by the National Institute of Child Health and Human Development, is a collaborative effort between researchers at the University of Connecticut and the Child Mind Institute. This clinical trial will examine the effectiveness of an at-home, game-based intervention for reading disorders. Parents of participants in this study are completing daily and weekly assessments in MindLogger, which will allow researchers to assess the home environment and compliance with the intervention protocol throughout the study period. These data are critical for evaluating the impact of this clinical trial.

Discussion

Principal Findings

In this paper, we reviewed customizable, mobile experience sampling products for configurable data collection and content delivery, summarized the motivation for and development of a new mobile platform called MindLogger, and described an initial use case that applies a MindLogger version of the NIMH Family Study app as part of the Healthy Brain Network study.

Our review returned an initial set of 392 products, of which 59 appeared to be in current use, had Android and iOS mobile apps, and were capable of scheduling questionnaires and notifications for a group of respondents. Of the 47 companies that responded to our inquiries and did not require a legal agreement, we identified 10 products that satisfied our primary criteria (administrator interface for creating and scheduling recurring, customized questionnaires, where an arbitrary number of users can receive and respond to scheduled notifications on their mobile devices). Four of these products supported end-to-end encryption, 2 enabled restricted access to individual users' data, 1 provided open-source software, and none provided all 3 of these capabilities. Our review is not exhaustive regarding either the products that could possibly be used for experience sampling or the range of features that these products support. Existing

products include an impressive assortment of nonoverlapping features and complement each other in ways that reflect the different niches or markets for which they were intended. The limitations of our search for existing products are as follows: (1) our search queries and Google's search algorithm may not reflect the optimal search criteria for some relevant products; (2) product websites are sometimes unclear and incomplete and may even misrepresent the capabilities of their products; and (3) some companies did not respond to questions even through their website's question or support page. Products are also adding features over time, and some companies or organizations offer paid services to build the desired features. Our comparison should be seen as a snapshot of the current state of a subset of features provided by software products intended for experience sampling.

We successfully developed MindLogger, a new platform that meets most of the stated needs of our collaborators around the world, who desire an open source, mobile mental health platform to inform, assess health, acquire data, and administer therapies. We prioritized clinicians' and researchers' needs and users' experience during development, aligned technologies to meet these priorities, and are on track to achieve the full feature set we set out to include. MindLogger has end-to-end encryption, enables restricted access, is open source, and supports a variety of data collection features. One limitation of MindLogger is that it currently does not support passive data collection or interaction with peripheral devices. This was intended to reduce concerns about surveillance in an app whose first use case was for assessing children and adolescents. However, in the future, we intend to support passive monitoring of location and behaviors, and communication with other devices, so long as these are opt-in by the end user and there are clear reminders to the end user concerning what data are collected and how they will be used. Another potential limitation lies in its core strength: by making MindLogger flexible, modular, cross-platform, and configurable to help meet the unforeseen needs of future applet builders and users, the creation of variants of even well-vetted instruments is likely and will necessitate their careful validation. We have recently built a web-based *applet library* for viewing, copying, editing, and sharing applets. Applets in the library are labeled to indicate which have been created or vetted by the Child Mind Institute and which have been contributed by others.

We have demonstrated the flexibility and applicability of the MindLogger platform through the deployment of the NIMH-EMA applet in the Healthy Brain Network, a large-scale, longitudinal, mobile mental health study. The NIMH is about to launch the same applet in its own research program. For future directions in the near term, there are a variety of other mental health–related applets in preparation for deployment and in the planning stages as described below.

MindLogger Applets in Preparation for Deployment

We are currently refining and testing MindLogger applets to assess and administer interventions targeting specific subgroups of youth with particular mental health and learning disorders. Although some of these applets support specific collaborators' research, others are for broader use (listed below, with video screencast demonstrations on the MindLogger website [59]).

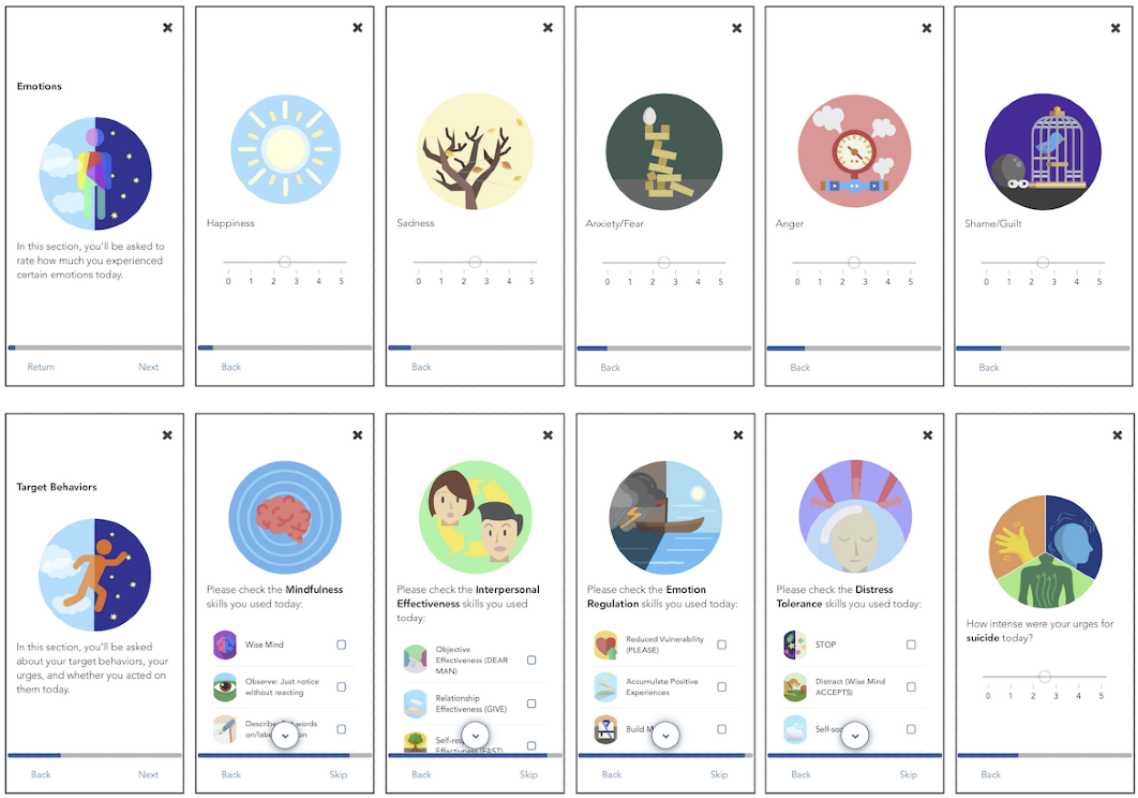
Pediatric Screener Mental Health Screening Applet

Integrating primary care and mental health has been associated with improved patient outcomes [99]; therefore, mental health screening in pediatric clinics could lead to earlier diagnosis and improved outcomes for patients. The Hearst Foundations supported the development of a pediatric screener tool using MindLogger. This tool will administer assessments to children or their parents, for children receiving a wellness checkup at their pediatric clinic, and alert their physician if a child shows signs of a mental health disorder. We have built the applet and will pilot it at the Richmond University Medical Center in Staten Island, New York. The initial screening questionnaire assesses internalizing and externalizing symptoms, issues of attention and hyperactivity, depression and suicidal ideation, disordered eating behavior, and experiences of bullying. It also collects demographic information about the child and parent. Children with a clinically significant level of symptoms were prompted to complete additional questionnaires to collect more detailed information. A similar questionnaire was piloted in several New York City–based pediatric settings and found it to be an effective tool for identifying children at risk of a serious mental health disorder. The MindLogger platform will create a much more streamlined process and user-friendly experience, increasing the probability of adoption by more pediatric practices and clinics.

Dialectical Behavior Therapy Applet

The Dialectical Behavior Therapy (DBT) Diary Card is a digitized version of the diary card used in evidence-based DBT programs. This tool is a daily tracker of mood, targeting behavioral urges and specific behaviors, and the use of coping skills to manage these emotions, urges, and behaviors. Our DBT applet (Figure 9) will enable therapists to create a digital DBT diary card with a patient to include specific treatment targets for that individual. This will allow patients to set notification reminders to complete the diary card on a daily basis. The patient's device will automatically update with the new targets and schedule, allowing the user to progress in the therapy without having to change the way the data are retrieved. Both patients and therapists will have access to the diary card data to guide treatment planning and sessions.

Figure 9. MindLogger Dialectical Behavior Therapy applet screenshots.



TokenLogger Behavior Intervention Applet

We are refining a behavior intervention applet called *TokenLogger* that can be customized to retrospectively and prospectively track specific behaviors and help promote and reinforce desirable behaviors while reducing or extinguishing undesirable behaviors. It will also help track the frequency, duration, and severity of target behaviors to inform modifications in behavioral treatment plans and assess progress toward outcomes and goals. The TokenLogger applet will be evaluated by clinical experts at the Child Mind Institute and piloted with patients at the Child Mind Medical Practice, to better understand the timing, duration, and frequency of undesirable behaviors, and to test the efficacy of this digital rendition of behavior modification therapy.

Planned MindLogger Applets

We intend to replace all of the Child Mind Institute's and the Child Mind Medical Practice's pencil-and-paper assessments with MindLogger applets and, where appropriate, create and test digital renditions of therapies as MindLogger applets, and make these universally accessible as part of a web-based public library of MindLogger applets for anyone to use, modify, and translate. In addition, there are a few applets in the planning stages.

Diagnostic Screening Applet for Kiddie Schedule for Affective Disorders and Schizophrenia

We are currently developing a MindLogger applet with part of the Composite International Diagnostic Interview Screener that has been incorporated into the NIMH version of the epidemiologic version of the Kiddie Schedule for Affective Disorders and Schizophrenia. This screener is being tested for parents and self-administration in order to streamline the process as we transition to more automated approaches for large-scale studies of youth.

Taction Exposure Therapy Applet

We created a prototype iOS and Android mobile app called *Taction* that is a simple exposure therapy game for children who have obsessive-compulsive disorder or anxiety-related issues. The app rewards users for tapping on images that heighten their anxiety, potentially helping them progress in their treatment between exposure therapy sessions. Once incorporated into MindLogger, the Taction applet will be evaluated at the Child Mind Institute and piloted with patients at the Child Mind Medical Practice to assess the relative efficacy of a digital rendition of exposure therapy.

NIMH Cognitive Task Battery

In the same manner as we want to enable anyone to create, configure, and administer their own mobile questionnaires, we also want to enable anyone to do the same for different types of cognitive assessments. In this spirit, we created a Flanker task applet that is thoroughly configurable (presentation and timing of a fixation target, stimulus, and feedback), and we are collaborating with the NIMH to create a small battery of cognitive tasks for research in modeling behaviors.

Acknowledgments

This project was supported by the Hearst Foundations, the Intramural Research Program of the National Institute of Mental Health (grants with principal investigator KRM: ZIA MH002954 Motor Activity Research Consortium for Health and ZIA MH002804-15 Family Study of Affective and Anxiety Spectrum Disorders); the Centre for Research and Interdisciplinarity, Université de Paris; the Blanca and Sunil Hirani Foundation, Massachusetts Institute of Technology through the laboratory of SSG (SSG and SAA were supported by grants: NIH P41 EB019936) and Joseph Healey. The authors thank the companies and organizations that responded to the questions and provided demonstrations of their products. The authors thank Rangle.io for their help in refactoring MindLogger's mobile app code base and Alpine Security for conducting penetration tests of the entire code base. They also thank Paul Mitrani and Stephanie Samar for clinical feedback during the development of MindLogger applets and volunteers Chynna Levin, Mairav Linzer, and Benjamin Vogel. Finally, the authors would like to thank all of their colleagues and collaborators around the world who have encouraged and helped guide the development of MindLogger in anticipation of using it for their many different data collection, research, clinical, and other endeavors.

A Krishnakumar was affiliated with the MATTER (Mind-Assisting Technologies for Therapy, Education, and Research) Lab at the Child Mind Institute and with the Centre for Research and Interdisciplinarity, Université de Paris at the time of this study and is currently affiliated with the ETH Library Lab, ETH Zurich, and Citizen Science Centre in Zurich. JC and A Keshavan were affiliated with the MATTER Lab at the Child Mind Institute for part of this study; JC is currently affiliated with the Computational Neuroimaging Laboratory at the Child Mind Institute, and A Keshavan is currently affiliated with Octave Bioscience.

Authors' Contributions

A Klein founded and led the MindLogger project, led this study, wrote the manuscript, and contacted all of the companies or organizations as part of the product comparison that led to Figures 1-3. A Klein, A Krishnakumar, AB, and KK collected information for Figures 1-3 (detailed in Multimedia Appendix 1). SSG and SAA lead the Repronim effort underlying MindLogger's data schema. A Krishnakumar helped to identify candidate features for MindLogger based on discussions with different stakeholders. JC, BT, IS, NA, A Keshavan, and HR contributed to the software engineering of MindLogger. WVA helped to direct all aspects of MindLogger software development and design as MindLogger's project manager. KRM and JS contributed to the MindLogger project through content developed by the NIMH Family Study of Affective Spectrum Disorders. YX helped to coordinate content in the National Institute of Mental Health-ecological momentary assessment (NIMH-EMA), Dialectical Behavior Therapy (DBT), and Kiddie Schedule for Affective Disorders and Schizophrenia applets, and found, modified, and designed images and icons for the NIHM_EMA, DBT, and EDUCATE applets. SS conducted repeated, extensive quality assurance of MindLogger functionality. AB and A Krishnakumar managed MATTER Lab volunteers in the United States and in France. LMA managed research collaborations as Research Operations Manager for the Child Mind Institute. ABL and A Krishnakumar oversaw formulation of MindLogger requirements relevant to Centre for Research and Interdisciplinarity (CRI) projects. MM and SSG provided consultation. KRM, JS, JC, LMA, WVA, BT, IS, NA, and MM reviewed and modified the manuscript for scientific content. AB helped in formatting the manuscript.

Conflicts of Interest

While currently employed by Octave Bioscience, A Keshavan was not an employee while contributing to this manuscript.

Abstract

Background: Smartphones and their built-in sensors allow for measuring functions in disease-related domains through mobile tests. This could improve disease characterization and monitoring, and could potentially support treatment decisions for multiple sclerosis (MS), a multifaceted chronic neurological disease with highly variable clinical manifestations. Practice effects can complicate the interpretation of both improvement over time by potentially exaggerating treatment effects and stability by masking deterioration.

Objective: The aim of this study is to identify short-term learning and long-term practice effects in 6 active tests for cognition, dexterity, and mobility in user-scheduled, high-frequency smartphone-based testing.

Methods: We analyzed data from 264 people with self-declared MS with a minimum of 5 weeks of follow-up and at least 5 repetitions per test in the Floodlight Open study, a self-enrollment study accessible by smartphone owners from 16 countries. The collected data are openly available to scientists. Using regression and bounded growth mixed models, we characterized practice effects for the following tests: *electronic Symbol Digit Modalities Test (e-SDMT)* for cognition; *Finger Pinching* and *Draw a Shape* for dexterity; and *Two Minute Walk*, *U-Turn*, and *Static Balance* for mobility.

Results: Strong practice effects were found for *e-SDMT* (n=4824 trials), *Finger Pinching* (n=19,650), and *Draw a Shape* (n=19,019) with modeled boundary improvements of 40.8% (39.9%-41.6%), 86.2% (83.6%-88.7%), and 23.1% (20.9%-25.2%) over baseline, respectively. Half of the practice effect was reached after 11 repetitions for *e-SDMT*, 28 repetitions for *Finger Pinching*, and 17 repetitions for *Draw a Shape*; 90% was reached after 35, 94, and 56 repetitions, respectively. Although baseline performance levels were highly variable across participants, no significant differences between the short-term learning effects in low performers (5th and 25th percentile), median performers, and high performers (75th and 95th percentile) were found for *e-SDMT* up to the fifth trial (β=1.50-2.00). Only small differences were observed for *Finger Pinching* (β=1.25-2.5). For *U-Turn* (n=15,051) and *Static Balance* (n=16,797), only short-term learning effects could be observed, which ceased after a maximum of 5 trials. For *Two Minute Walk* (n=14,393), neither short-term learning nor long-term practice effects were observed.

Conclusions: Smartphone-based tests are promising for monitoring the disease trajectories of MS and other chronic neurological diseases. Our findings suggest that strong long-term practice effects in cognitive and dexterity functions have to be accounted for to identify disease-related changes in these domains, especially in the context of personalized health and in studies without a comparator arm. In contrast, changes in mobility may be more easily interpreted because of the absence of long-term practice effects, even though short-term learning effects might have to be considered.

Introduction

Background

Multiple sclerosis (MS) is a multifaceted and variable chronic autoimmune neurological disease affecting approximately 2.3 million people worldwide [1]. It is among the most common causes of nontraumatic disabilities in young adults [2].

MS progresses in different phases with highly variable speed and severity. To optimize treatment strategies, timely and precise monitoring of patients' disease status is essential. As MS affects multiple functional domains, a range of validated clinical tests are used: for cognition, the Symbol Digit Modalities Test (SDMT) measures mental processing speed and is highly established as a screening tool for cognitive impairment in MS [3,4]. The 9-hole peg test (9HPT) is routinely used to measure dexterity [5,6], and the timed 25-foot walk (T25FW) is used to measure mobility [7]. Usually, stable patients with MS have half-yearly to yearly clinical routine visits with neurologic examinations and regular magnetic resonance imaging (MRI), limiting insight into symptom fluctuations and reversible deficits [8].

Wearable technologies, such as smartphones and smartwatches, are expected to capture more representative data at a higher resolution not only in the patients' natural environments in MS but also in other neurological diseases such as Parkinson disease and Huntington disease [9-11]. Data can be collected passively during the patient's everyday activities (eg, capturing step counts, turn speed, or keyboard dexterity [9,12,13]) or actively during specific functional tests [14-16]. They can possibly improve both clinical trials by providing more sensitive outcome measures and clinical practice by allowing more personalized disease course monitoring [14,17].

Acknowledged difficulties in interpreting the results of repeated tests are learning and practice effects, especially in neuropsychology [18,19]. Without a comparator, it is difficult to disentangle whether longitudinal improvement constitutes remission, practice, or treatment effects. In the same light, disease progression and worsening of disability may be masked by practice effects when specific tests feign stability. These issues have been adequately addressed by control groups in randomized controlled trials [20]. For trials without control groups and for intraindividual comparisons—a cornerstone of personalized medicine—interpretation remains challenging. Furthermore, practice effects hamper test-retest reliability, which is illustrated by recommendations to discard the results from 3 prebaseline repetitions of the MS functional composite [21]. However, more recently, it has been suggested that person-specific learning curves can be used as new outcome measures, leveraging the information inherent in practice effects [14].

Objective

The aim of this analysis is to examine short-term learning and long-term practice effects in high-frequency smartphone-based tests representative of the assessment of 3 domains often affected by MS: cognition, dexterity, and mobility.

Methods

Study Data and Participant Selection

We used publicly available data from the *Floodlight Open* study, which collects smartphone-based test data from self-declared persons with MS with a number of different tests implemented in the Floodlight Open app [22]. The study is the successor of a small, closed feasibility study [9,17], and the data are openly available to researchers [23]. Currently, several phase 3 studies are using variations of the Floodlight app as part of their test batteries, for example, the CONSONANCE trial, a single-arm interventional trial evaluating ocrelizumab treatment in participants with progressive MS (NCT03523858) [17]. Recruitment for *Floodlight Open* started in April 2018, and some participants have been using the app continuously since then, amounting to more than 3 years of follow-up. However, most patients have only used the app for a very short time, leading to a strong right-skewness of the distribution of follow-up times. Among the 1147 patients who have performed at least one smartphone-based *e-SDMT* test in the period we examined, the median number of repetitions was 2, the IQR was 1-4 and the range was 1-119.

We included data up to and including July 31, 2021, and focused our analyses on the following 6 tests [9]: *e-SDMT* for cognition; *Finger Pinching* and *Draw a Shape* for dexterity; *Two Minute Walk*, *U-Turn*, and *Static Balance* for mobility. The dexterity tests have been shown to correlate with the 9HPT, the first 2 mobility tests with the T25FW and *Static Balance* with the Berg Balance Scale [9]. The Floodlight Open app allows performing *e-SDMT* up to a weekly frequency and all other tests up to a daily frequency, but the actual frequency was completely determined by the participant's choice. For dexterity tests, the left and right hands were alternated.

The *e-SDMT* consisted of consecutively tapping symbol-corresponding digits on a number pad on the smartphone screen as quickly as possible for 60 seconds. Thus, there was a dexterity component that may potentially introduce bias. Floodlight's *e-SDMT* included a second step termed *baseline*, simply showing digits instead of symbols, asking users to consecutively tap these digits on the same number pad for 15 seconds, without the symbol-association task. Using this second step by taking the quotient of the correct responses of the main test and the *baseline* potentially corrects for dexterity and reaction speed, representing only the true information processing speed.

Participants were selected for each test separately if at least 5 repetitions per test and at least 5 weeks between their first and

last repetitions were available. This yielded slightly different but largely overlapping subsets of participants for each test.

Statistical Analysis

Short-term Learning and Long-term Practice Effects

First, summary analyses were performed to investigate the mean scores of the first, fifth, and last trials of each test. We assumed that improvements up to the fifth score were more likely due to short-term learning effects, where participants learned to execute a test, and improvements from the fifth trial onward were more likely because of long-term practice effects. Naturally, these effects are intertwined, but using the fifth trial as the baseline was supported by Solari et al [24].

To examine group differences in baseline performances and potential short-term learning effects in low and high performers, linear quantile regression was performed on each test for the first 5 trials for the 5th, 25th, 50th, 75th, and 95th percentiles. Quantile regression *P* values were corrected with the Bonferroni method, and the 5 slopes were compared with an analysis of variance (ANOVA)–type test.

Long-term practice effects were assumed for tests with a significant mean difference from the fifth to the last score. The positive association of this difference with the number of repetitions (log-transformed to account for the strong right-skewness) adjusted for the potential confounders, age, first score, and fifth score, was considered as an additional indicator of long-term practice effects.

Long-term Learning Curve Analysis

For tests suggestive of long-term practice effects that meet the 2 abovementioned criteria, learning curve analysis was performed with 1 nonparametric and 3 parametric mixed effect models of increasing complexity, each modeling performance as a function of repetition, grouping by patient for cognition and mobility and by hand for dexterity. The performance of the 4 models was compared using both root mean squared error (RMSE) and the number of (effective) *df* used.

For the nonparametric model, smoothing splines calculated by generalized additive models were fitted to examine the unbiased shape of the potential learning curves, exhibiting different effective *df* per test [25,26].

For the parametric models, simple linear (*df*=4) and linear quadratic (*df*=5) mixed models were fitted, both using time and in addition the latter using time squared as fixed effects. As the third parametric model, we considered bounded growth mixed models (*df*=6) using the following formula:

$$y_{(t)} = \text{boundary} + (y_0 - \text{boundary})\, e^{-ct} \quad \textbf{(1)}$$

We treated boundary and baseline (y_0) as random effects, while we considered the growth constant *c* as a fixed effect.

Sensitivity Analyses

In addition to our main analysis on practice effects as a function of repetition with the selection criteria of a minimum of 5 weeks and 5 repetitions, we performed 3 additional sensitivity analyses: sensitivity analyses 1 and 3 were modeling practice effects as a function of weeks since the first test instead of the number of repetitions, and sensitivity analyses 2 and 3 were performed using stricter selection criteria of a minimum of 10 weeks and 10 repetitions (Table 1).

Table 1. Comparison of the main analysis with the 3 sensitivity analyses performed.

Criteria	Minimum of 5 weeks and 5 repetitions	Minimum of 10 weeks and 10 repetitions
Practice effects as a function of number of repetitions	Main analysis	Sensitivity analysis 2
Practice effects as a function of weeks since first test	Sensitivity analysis 1	Sensitivity analysis 3

All statistical analyses were performed using R 4.0.3 (R Foundation for Statistical Computing). Point estimates are accompanied by 95% CI in brackets, unless otherwise stated. *P* values were based on two-tailed *t* tests, unadjusted unless otherwise stated and considered significant if <.05. All analysis codes can be found on the web [27]. The data set used can be found on the web [28].

Results

Overview

Of the 1147 patients who performed at least one cognitive *e-SDMT*, 262 (22.8%) fulfilled our selection criteria of a minimum of 5 repetitions and 5 weeks between the first and last repetitions, accounting for 77.31% (4824/6240) of all performed *e-SDMT* tests. For *Finger Pinching* and *Draw a Shape*, 23.8% (264/1109) and 24% (259/1079) patients were selected, accounting for 87.14% (19,650/22,550) and 87.18% (19,019/21,816) of the performed tests, respectively. For *Two Minute Walk*, *U-Turn*, and *Static Balance*, 29.7% (171/575), 24.1% (217/901), and 24.34% (257/1056) patients were selected, representing 92.79% (14,393/15,512), 89.37% (15,051/16,841), and 88.41% (16,797/19,000) of the respective tests (Table 2). The minimum intertest interval was constrained by the app to 7 days for *e-SDMT*, 2 days for *Finger Pinching* and *Draw a Shape* for each hand, and 1 day for *Two Minute Walk*, *U-Turn*, *and Static Balance*, explaining the lower number of *e-SDMT* repetitions. However, participants had highly variable intertest intervals, making this an irregular time series, as indicated by each participant's median intertest interval and IQR. Table 2 shows the median of these statistics for all the selected participants.

Table 2. Characteristics of included patients with multiple sclerosis.

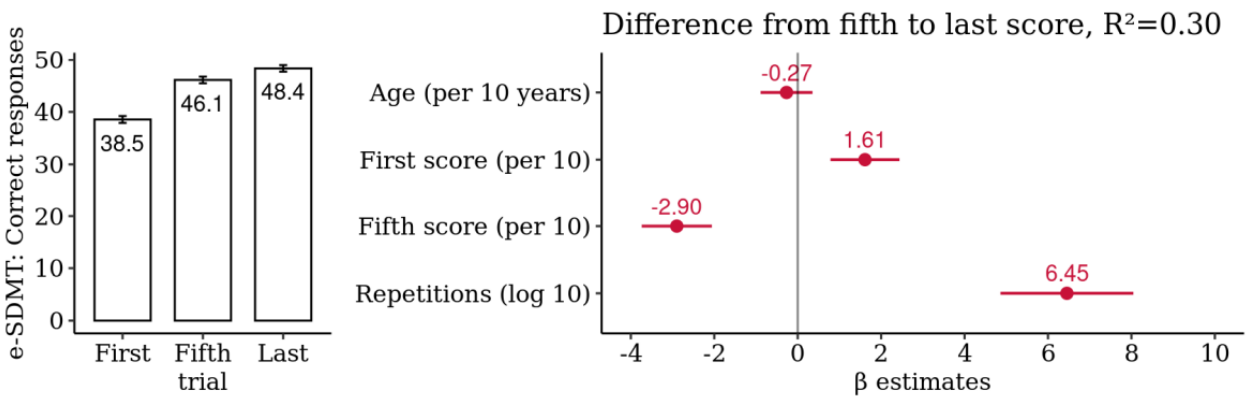
[a]With 26.19% (499/1905) of hands selected.

[b]With 26.23% (484/1845) of hands selected.

Cognition: e-SDMT

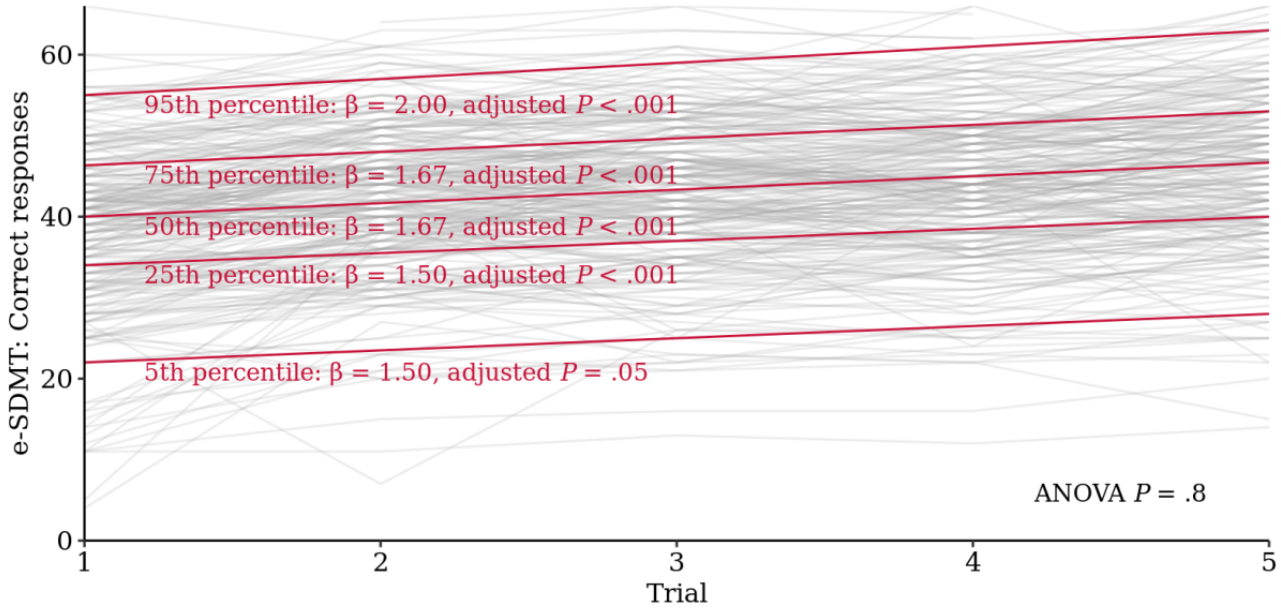
A summary analysis of the 262 selected patients yielded a mean difference from the first to last score of 9.8 correct responses, representing an average observed improvement of 25.4% (95% CI 23.1% to 27.8%) from the first score. Although the majority of this improvement (19.7%, 95% CI 17.5% to 21.9%) occurred up to the fifth score and can thus be considered a short-term learning effect, there was still a significant improvement from the fifth score onward of, on average, 5.7% (95% CI 4.1% to 7.4%), suggesting a long-term practice effect. A multivariate regression model of this difference yielded a significant association with the total number of repetitions, further supporting the long-term practice effects (Figure 1). Age was positively correlated with the number of repetitions performed (Pearson correlation coefficient, R=0.19; P=.003), but the first score was not (R=−0.03; P=.70; Multimedia Appendix 1).

Figure 1. Patient-level summary analysis for the *electronic Symbol Digit Modalities Test*: comparison of the first, fifth, and last score. Multivariate association of the difference from the fifth to last score with age, first and fifth score, and the log-transformed number of repetitions (n=262 patients). *e-SDMT*: *electronic Symbol Digit Modalities Test.*



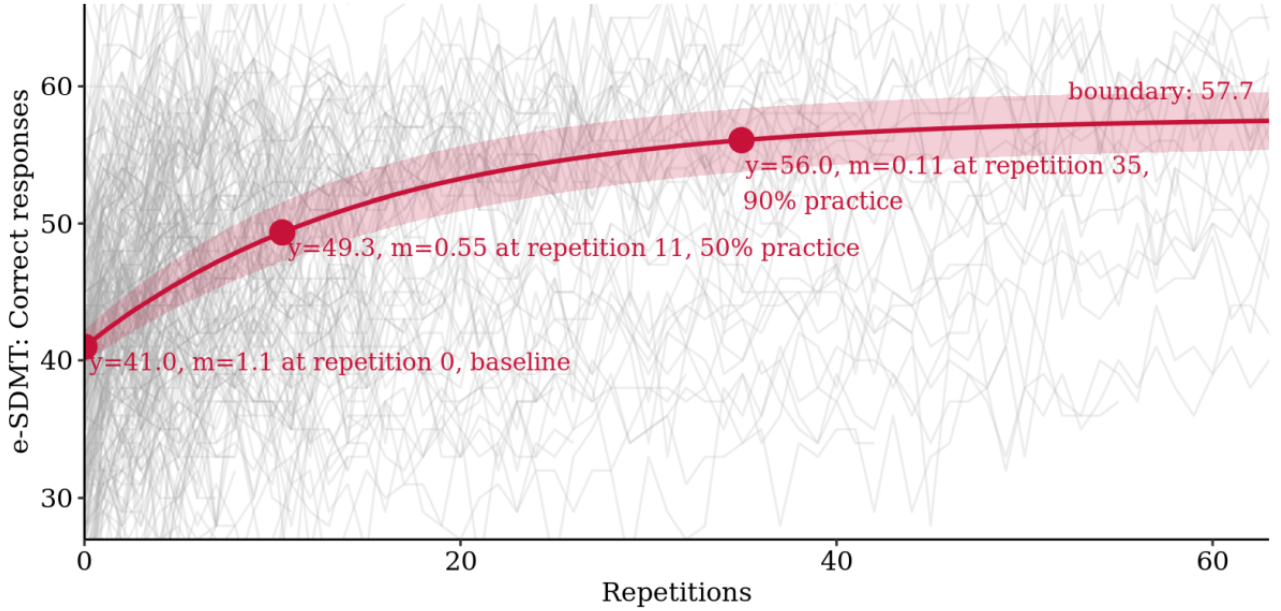
When comparing performances by 5th, 25th, 50th, 75th, and 95th percentile groups up to the fifth trial with quantile regression, baseline performances were normally distributed with intercept estimates of 22.0 (19.1-24.9), 34.0 (32.7-35.3), 40.0 (38.8-41.2), 46.3 (45.1-47.6), and 55.0 (53.4-56.6), respectively. The ANOVA-type test for all 5 slopes (β=1.5-2.0) did not suggest that short-term learning rates for these groups differed significantly (*P*=.80; Figure 2).

Figure 2. Linear quantile regression for the *electronic Symbol Digit Modalities Test* of short-term learning effects up to the fifth repetition. Comparison of baseline performance and linear slope of low (5th and 25th percentiles), median, and high performers (75th and 95th percentiles). Quantile regression *P* values are Bonferroni-adjusted (n=1310 tests). ANOVA: analysis of variance; *e-SDMT*: *electronic Symbol Digit Modalities Test*.



The long-term learning curve analysis showed that the bounded growth model fit the data best with an RMSE of 3.3 correct responses, followed by 3.6 for the smoothing spline, 3.8 for the quadratic, and 4.0 for the linear model (Multimedia Appendix 2). Strong boundary practice effects were found with baseline estimates of on average 41.0 (95% CI 39.8 to 42.2) correct responses and boundary estimates of 57.7 (95% CI 55.7 to 59.8) correct responses, leading to an average improvement over baseline of 40.8% (95% CI 39.9% to 41.6%). Half of the practice effect was reached after 11 repetitions and 90% after 35 repetitions (Figure 3).

Figure 3. Learning curve analysis for the *electronic Symbol Digit Modalities Test*: bounded growth mixed model of practice effects with 95% CI band and baseline, 50% and 90% practice points marked (m=slope of tangent; n=4824 tests). *e-SDMT*: *electronic Symbol Digit Modalities Test*.



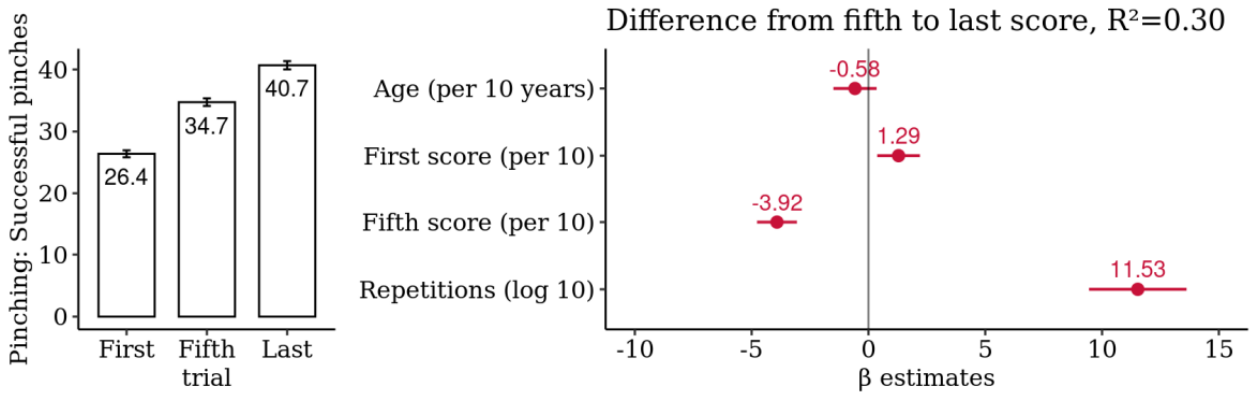
For *e-SDMT* corrected for dexterity and reaction speed, Spearman correlation of all 6190 corrected scores with their uncorrected counterpart yielded ρ=0.55. The resulting practice effects were very similar to the uncorrected *e-SDMT*, with an observed improvement from the first to last score of 19% (95% CI 16.1% to 22%), consisting of 12.4% (95% CI 9.8% to 15%)

from the first to fifth score, and 6.6% (95% CI 4.6% to 8.7%) from the fifth to last score. As with the uncorrected *e-SDMT*, no significant differences in short-term learning rates were found between low, median, and high performers (ANOVA-type *P*=.30). Boundary long-term improvements were 23.5% (95% CI 23% to 24%), with half of the practice effect reached after 7 repetitions and 90% practice effect reached after 23 repetitions (Multimedia Appendices 3-6).

Dexterity: Finger Pinching

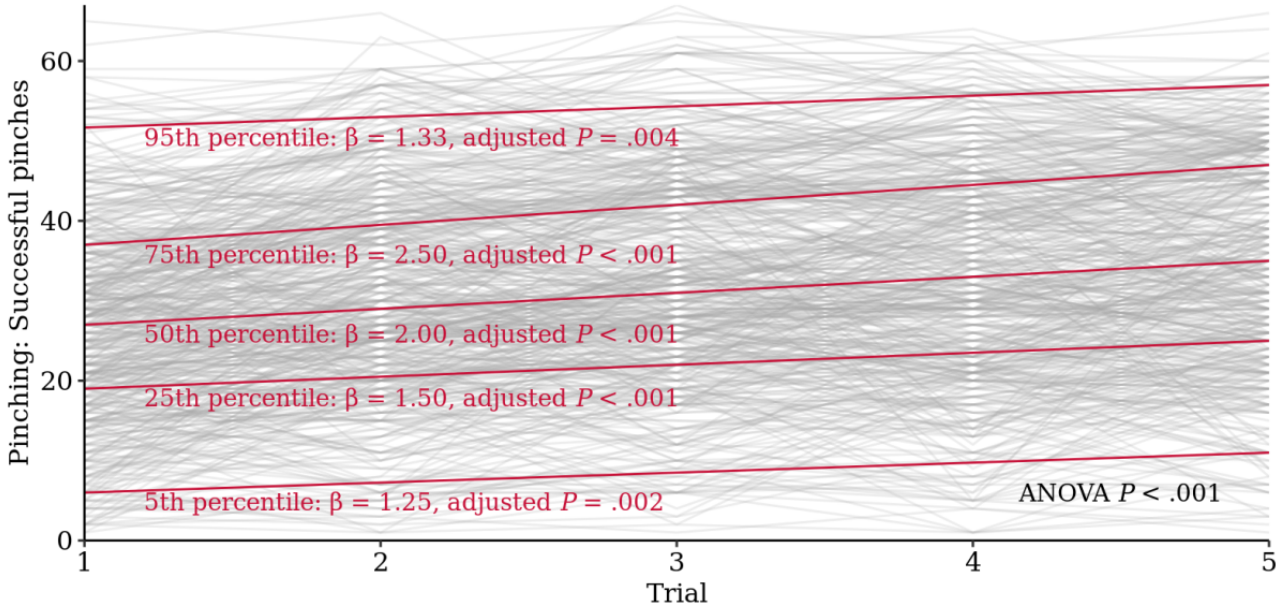
A summary analysis of the 499 selected hands yielded a mean difference from the first to last score of 14.3 successful pinches, representing an average observed improvement of 54.2% (95% CI 49.3% to 59.1%) over the first score. Similar to the findings on the *e-SDMT*, the majority of this improvement (31.5%, 95% CI 27.5% to 35.4%) occurred up to the fifth score, compatible with a short-term learning effect. However, the remaining improvement of 22.7% (95% CI 18.6% to 26.8%) occurred after the fifth trial. This improvement was significantly associated with the total number of repetitions, indicating a strong long-term practice effect (Figure 4). Age was positively correlated with the number of repetitions performed (*R*=0.21; *P*<.001) but the first score was not (*R*=−0.06; *P*=.20; Multimedia Appendix 7).

Figure 4. Hand-level summary analysis for *Finger Pinching*: comparison of the first, fifth, and last score. Multivariate association of the difference from the fifth to last score with age, first and fifth score, and the log-transformed number of repetitions (n=499 hands).



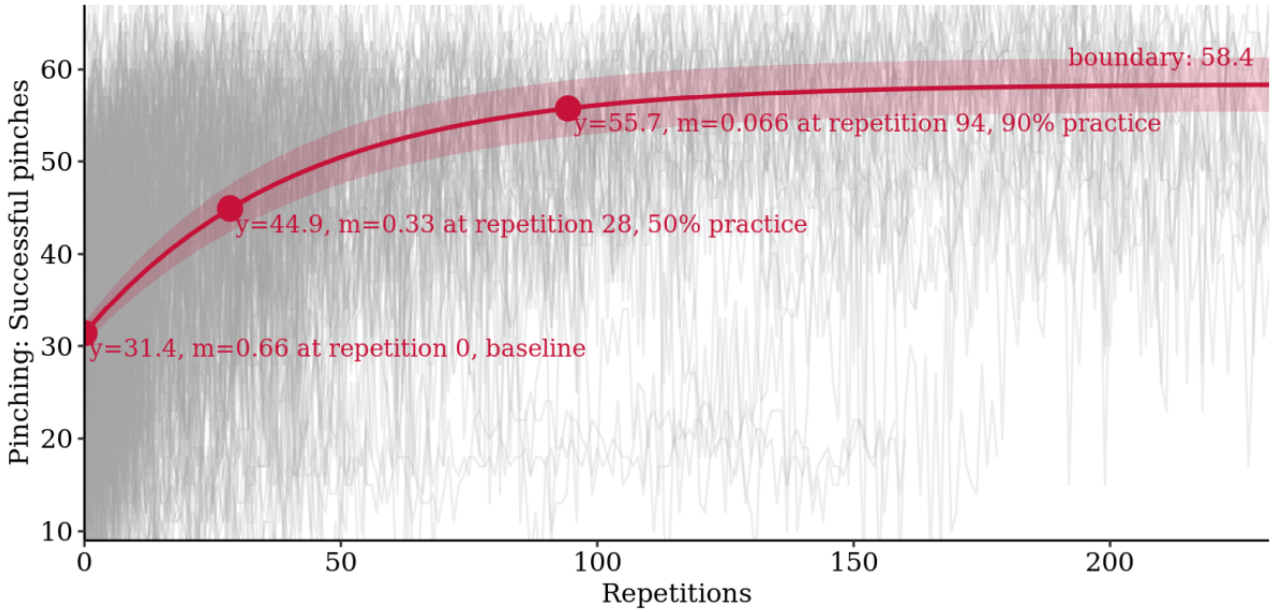
Baseline performances were normally distributed with intercept estimates of 6.0 (95% CI 4.5 to 7.5) for the fifth percentile, 19.0 (95% CI 17.8 to 20.2) for the 25th, 27.0 (95% CI 25.8 to 28.2) for median performers, 37.0 (95% CI 35.6 to 38.4) for the 75th, and 51.7 (95% CI 49.6 to 53.8) for the 95th percentile with quantile regression. The β coefficients for short-term learning up to the fifth trial were the highest for the 75th percentile and median performers with 2.50 (95% CI 1.96 to 3.04) and 2.00 (95% CI 1.45 to 2.55) additional successful pinches per repetition, lower for the 25th percentile (1.50, 95% CI 1.00 to 2.00) and the lowest for the 5th and 95th percentiles (1.25, 95% CI 0.57 to 1.93, and 1.33, 95% CI 0.56 to 2.11, respectively). These differences in slopes between performance levels were significant (ANOVA-type *P*<.001; Figure 5).

Figure 5. Linear quantile regression for *Finger Pinching* of short-term learning effects up to the fifth repetition. Comparison of baseline performance and linear slope of low (5th and 25th percentiles), median, and high performers (75th and 95th percentiles). Quantile regression *P* values are Bonferroni-adjusted (n=2495 tests). ANOVA: analysis of variance.



Long-term learning curve analysis again showed that the bounded growth model fit the data best with an RMSE of 6.8 successful pinches, followed by 7.5 for the smoothing spline, 7.9 for the quadratic, and 8.1 for the linear model (Multimedia Appendix 8). Strong boundary practice effects were found with baseline estimates of, on average, 31.4 (95% CI 30.2 to 32.5) and boundary estimates of 58.4 (95% CI 55.5 to 61.4) successful pinches, leading to an average improvement over baseline of 86.2% (95% CI 83.6% to 88.7%). Half of the practice effect was reached after 28 repetitions and 90% after 94 repetitions (Figure 6).

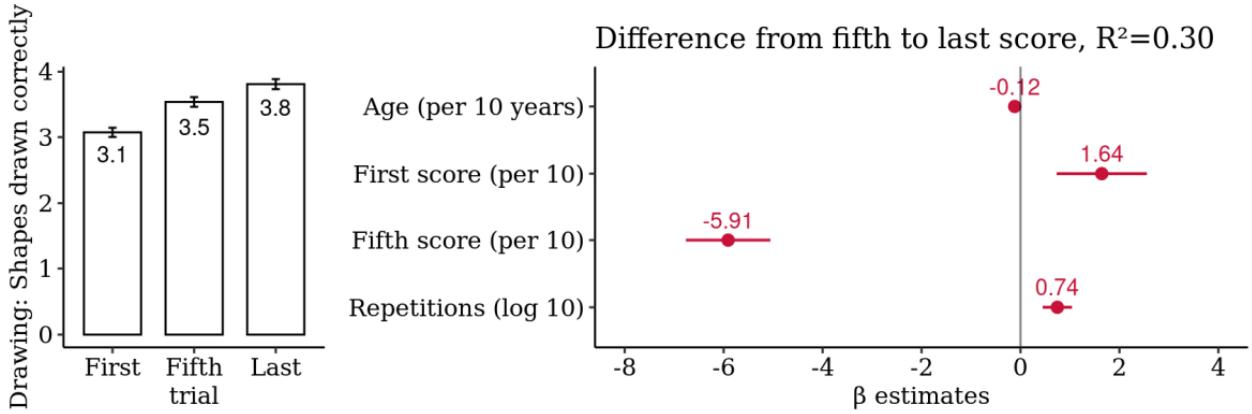
Figure 6. Learning curve analysis for *Finger Pinching*: bounded growth mixed model of practice effects with 95% CI band and baseline, 50%, and 90% practice points marked (m=slope of tangent; n=19,650 tests).



Dexterity: Draw a Shape

A summary analysis of the 484 selected hands yielded a mean improvement in the number of shapes drawn correctly from the first to last score of 23.9% (95% CI 18.3% to 29.5%), from the first to fifth score of 15.1% (95% CI 9.8% to 20.3%), and from the fifth to last score of 8.8% (95% CI 3.8% to 13.8%). This difference was significantly associated with the total number of repetitions, suggesting a long-term practice effect (Figure 7). Age was positively correlated with the number of repetitions performed (R=0.22; P<.001) but the first score was not (R=−0.08; P=.09; Multimedia Appendix 9).

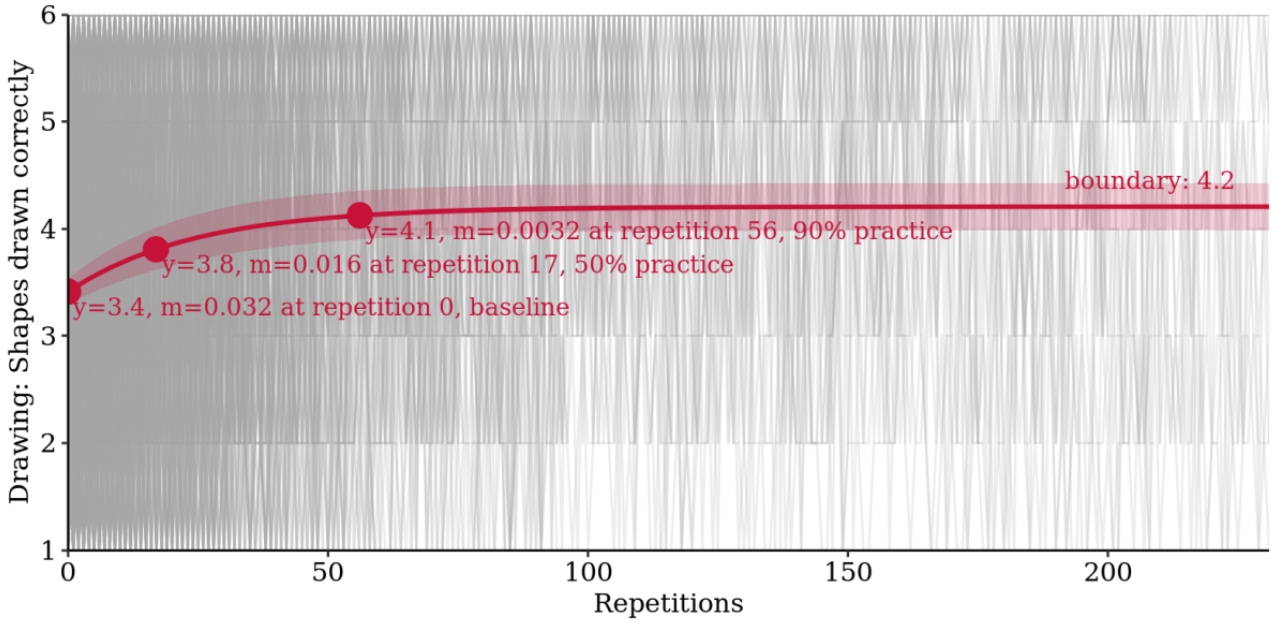
Figure 7. Hand-level summary analysis for *Draw a Shape*: comparison of the first, fifth, and last score. Multivariate association of the difference from the fifth to the last score with age, first and fifth score, and the log-transformed number of repetitions (n=484 hands).



Intercept estimates for baseline performances were 1 shape drawn correctly for the 5th percentile, 2 for the 25th percentile, 3 for the median performers, 5 for the 75th percentile, and 6 for the 95th percentile with quantile regression. In this analysis, only median performers showed a significant short-term learning rate up to the fifth trial (Multimedia Appendix 10).

The long-term learning curve analysis again showed that bounded growth models fit the data best with an RMSE of 1.02 shape drawn correctly, followed by 1.06 for the smoothing spline, 1.07 for the quadratic, and 1.08 for the linear model (Multimedia Appendix 11). Boundary practice effects were found with an average improvement over baseline of 23.1% (95% CI 20.9% to 25.2%), reaching half of the practice effect after 17 repetitions and 90% after 56 repetitions (Figure 8).

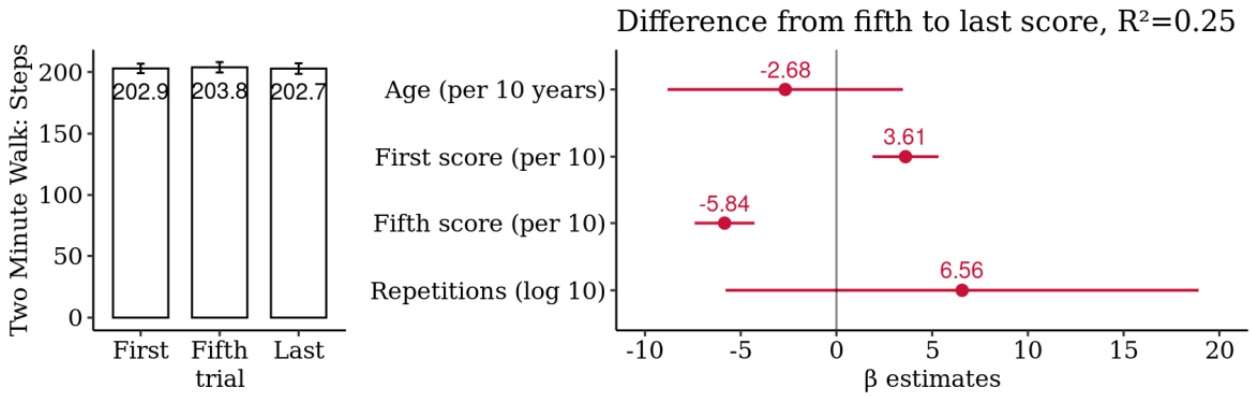
Figure 8. Learning curve analysis for *Draw a Shape*: bounded growth mixed model of practice effects with 95% CI band and baseline, 50%, and 90% practice points marked (m=slope of tangent; n=19,019 tests).



Mobility: Two Minute Walk

A summary analysis of the 171 selected patients yielded no significant difference between the first, fifth, and last scores with a mean difference from the fifth to last score of 1.4 (95% CI −5.2 to 7.9) steps. This difference was also not associated with the total number of repetitions performed (Figure 9 and Multimedia Appendix 12).

Figure 9. Patient-level summary analysis for *Two Minute Walk*: comparison of the first, fifth, and last score. Multivariate association of the difference from the fifth to the last score with age, first and fifth score, and the log-transformed number of repetitions (n=171 patients).

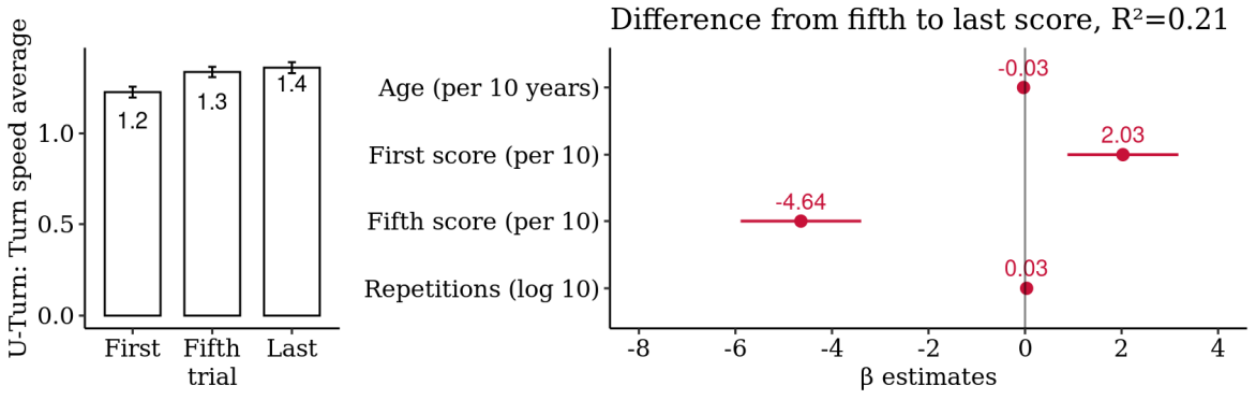


The distribution of baseline performance was left-skewed with performers in the 5th percentile achieving, on average, 87.0 (95% CI 52.2 to 121.8) steps; in the 25th percentile, 181.0 (95% CI 170.7 to 191.3) steps; on median, 219.0 (95% CI 212.6 to 225.4) steps; in the 75th percentile, 236.0 (95% CI 230.6 to 241.4) steps; and in the 95th percentile, 260.0 (95% CI 255.2 to 264.8) steps. No significant slopes up to the fifth trial could be observed (Multimedia Appendix 13).

Mobility: U-Turn

A summary analysis of the 217 selected patients yielded a significant improvement from the first to last score with a mean difference in turn speed average of 0.13 rad/s, representing an average observed difference of 11.0% (95% CI 5.7% to 16.2%) over the first score. However, the majority of this difference occurred up to the fifth score (9%, 95% CI 3.7% to 14.3%), and the remaining difference from the fifth to last score (1.9%, 95% CI −2.3% to 6.1%) was neither significant nor associated with the total number of repetitions performed (Figure 10 and Multimedia Appendix 14).

Figure 10. Patient-level summary analysis for *U-Turn*: comparison of the first, fifth, and last score. Multivariate association of the difference from the fifth to the last score with age, first and fifth score, and the log-transformed number of repetitions (n=217 patients).

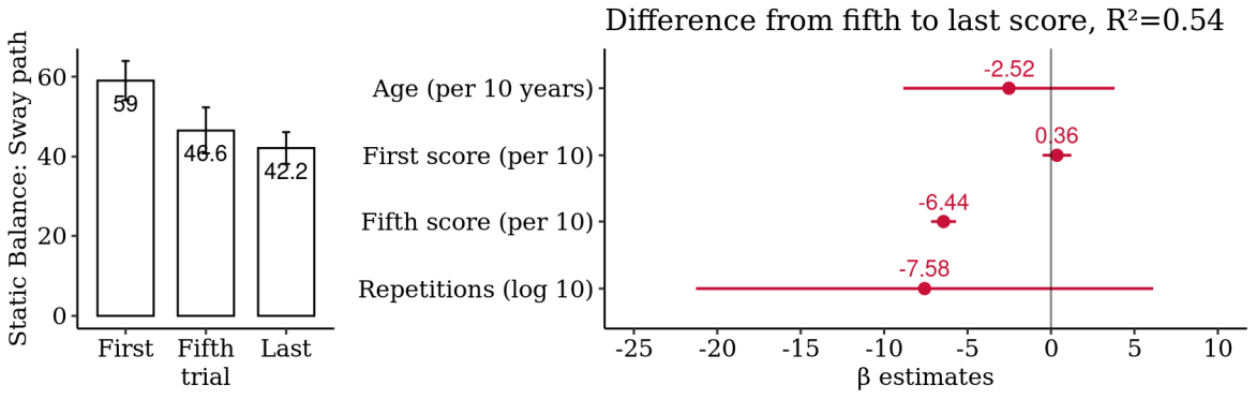


Baseline performances estimated with quantile regression were normally distributed with 0.5 rad/s (95% CI 0.5 to 0.6) for the 5th percentile, 0.9 rad/s (95% CI 0.9 to 1.0) for the 25th percentile, 1.3 rad/s (95% CI 1.2 to 1.3) for median performers, 1.5 rad/s (95% CI 1.5 to 1.6) for the 75th percentile, and 2.0 rad/s (95% CI 1.9 to 2.1) for the 95th percentile groups. Only the slope of the 25th percentile group was significant in this analysis up to the fifth trial (β=.04; 95% CI 0.02 to 0.06), and the difference in slopes was not significant in the ANOVA-type test (*P*=.40; Multimedia Appendix 15).

Mobility: Static Balance

A summary analysis of the 257 selected patients yielded a significant difference from the first to last score, with a mean difference in sway path of −16.9 m/s². This is the only test in which fewer numbers are better. Thus, the average observed improvement was −28.6% (95% CI −48.6% to −8.5%) over the first score. However, the majority of this improvement occurred up to the fifth score (−21.1%, 95% CI −45% to −2.8%), and the remaining difference from the fifth to last score (−7.5%, 95% CI −24.1% to 9.2%) was neither significant nor associated with the total number of repetitions performed (Figure 11 and Multimedia Appendix 16).

Figure 11. Patient-level summary analysis for *Static Balance*: comparison of the first, fifth, and last score. Multivariate association of the difference from the fifth to the last score with age, first and fifth score, and the log-transformed number of repetitions (n=257 patients).



Baseline performance estimates were strongly right-skewed with 5.7 m/s² (95% CI 4.3 to 7.0) for the 5th percentile, 11.7 m/s² (95% CI 9.4 to 14.0) for the 25th percentile, 23.8 m/s² (95% CI 20.7 to 26.8) for the median performers, 68.0 m/s² (95% CI 55.7 to 80.3) for the 75th percentile, and 260.2 m/s² (95% CI 200.4 to 320.0) for the 95th percentile. In this test, the 5th and 25th percentiles are the top performing groups, and their quantile regression slopes up to the fifth trial are not significant. However, the significant negative slopes of median (β=−2.32; 95% CI −3.47 to −1.17), 75th percentile (β=−8.46; 95% CI −12.21 to −4.72), and 95th percentile (β=−27.25; 95% CI −46.30 to −8.20) performers were increasingly steep, and the overall ANOVA-type difference test yielded *P*<.001(Multimedia Appendix 17).

Sensitivity Analyses

The results of the sensitivity analyses were in line with the results of the main analysis. Sensitivity analysis 2, which used stricter inclusion criteria with a minimum of 10 weeks and 10 repetitions, was overall very similar with expected further increases in mean improvement from the fifth to last score (mean improvement 5.7% for main analysis vs 9.1% for sensitivity analysis 2 for *e-SDMT*; 22.7% for main analysis vs 35.0% for sensitivity analysis 2 for *Finger Pinching*; and 8.8% for main analysis vs 13.3% for sensitivity analysis 2 for *Draw a Shape*) and a slight decrease in average boundary increase in performance (average boundary increase 40.8% for main analysis vs 34.3% for sensitivity analysis 2 for *e-SDMT*; 86.2% for main analysis vs 73.8% for sensitivity analysis 2 for *Finger*

Pinching; and 23.1% for main analysis vs 19.8% for sensitivity analysis 2 for *Draw a Shape*). Sensitivity analyses 1 and 3, which modeled practice effects as a function of weeks since the first test instead of the number of repetitions, also supported the main findings. However, the association of the maximum number of weeks from the first to the last tests with the difference from the fifth to last score was generally lower and so was the average increase in performance (Multimedia Appendix 18).

Discussion

Principal Findings

Strong long-term practice effects were found for *e-SDMT*, *Finger Pinching*, and *Draw a Shape*, with mean observed improvements of 25.4%, 54.2%, and 23.9% from the first to last score, respectively. Of these, 5.7%, 22.7%, and 8.8% occurred from the fifth score onward. However, the number of repetitions differed widely among participants with a range of 5-119 repetitions for *e-SDMT* (median 11), 5-416 for *Finger Pinching* (median 17), and 5-414 for *Draw a Shape* (median 17), introducing bias. To estimate boundary practice effects independent of the number of repetitions in our sample, we modeled learning curves with bounded growth models, a subtype of nonlinear mixed models. This approach yielded boundary improvements over the baseline of 40.8% for *e-SDMT*, 86.2% for *Finger Pinching*, and 23.1% for *Draw a Shape*. Interestingly, the practice effect seemed to last longer for the dexterity tests *Finger Pinching* and *Draw a Shape*, reaching half of the practice effect after repetition 28 and 17, respectively, compared to repetition 11 for *e-SDMT*.

These practice effects likely include both short-term learning effects, where patients become acquainted with the tests, and long-term practice effects. We believe these effects have not only different origins, time scales, and magnitudes but also different implications for the use of digital assessments in clinical studies and clinical practice. Short-term learning effects can be addressed by ensuring that participants have sufficient training before the observational period; long-term practice effects constitute a significant challenge for all applications beyond trials with a comparator arm. Although these effects are impossible to untangle in an unsupervised setting like this, we considered improvements up to the fifth trial to be more likely due to short-term learning and improvements afterward more likely because of long-term practice effects, based on the recommendation to use the fifth trial of the 9HPT as baseline [24].

For *U-Turn* and *Static Balance*, only short-term learning effects could be observed, ceasing after a maximum of 5 repetitions. Interestingly, for *Static Balance*, these short-term learning effects were not present in those with high baseline performance and were most pronounced in those with low baseline performance, potentially highlighting that the test instructions were not clear from the beginning. For *Two Minute Walk*, neither short-term learning nor long-term practice effects were observed.

For *e-SDMT*, quantile regression analysis suggested that the short-term learning rate was independent of the baseline performance. However, for *Finger Pinching*, median and high performers improved significantly faster than low and highest performers, with the learning rate decreasing toward the extremes. One can hypothesize that low performers might be more physically disabled, preventing them from improving as quickly as the median performers. On the other hand, the highest performers might reach their boundary sooner, leaving less room for improvement.

The 3 sensitivity analyses confirmed our main findings. However, for sensitivity analyses 1 and 3, which modeled practice effects as a function of weeks since the first test instead of the number of repetitions, the effect sizes were smaller. We believe this is caused by the irregular nature of these time-series data, as the intertest intervals differed widely, highlighting a complication in user-scheduled testing (Table 2).

Comparison With Previous Work

Overview

Only a few studies have examined practice effects in smartphone-based tests for patients with MS. Bove et al [14] analyzed the data from 38 patients, 22 of whom completed the planned study period of 12 months. They found strong practice effects for both their custom-made cognitive tests (digital adaptations of the trail-making test, the n-back test, a verbal fluency test, and an attention test), and a digital adaptation of the 9HPT. Interestingly, they suggest using person-specific learning curves quantified by binary spline inflection point analysis as a potential outcome measure [14].

In addition, Liao et al [29] recently reported significant practice effects for information processing speed and manual dexterity but not for walking speed in a tablet-based test battery called *MS Performance Test*, broadly confirming our results. However, they only analyzed 2-5 repetitions per patient and per test and could thus not examine long-term practice effects. Interestingly, they found that younger age was associated with larger practice effects, whereas we observed the opposite for *e-SDMT* and *Finger Pinching* (Multimedia Appendices 1 and 7), potentially highlighting differences between their low-frequency and our high-frequency testing.

Cognition: SDMT

Practice effects are well known for SDMT in both healthy controls and patients with MS, although the effect sizes reported were highly variable. Morrow et al [30] studied 660 natalizumab-treated patients with MS with a total of 13 repetitions of the oral SDMT over 48 weeks with average baseline scores of 46.8 (SD 15.3) correct responses and average final scores of 62.2 (SD 18.1) at week 48, resulting in an average improvement of 32.9% over baseline. Although the improvement was most pronounced over the first 3 repetitions, there was no obvious boundary [30].

In contrast, Benedict et al [31] found only minimal practice effects in 76 patients with MS with a total of 6 repetitions of oral SDMT over 5 months. Average baseline scores of 49.8 (SD 12.4) correct responses and average final scores of 52.5 (SD 14.3) at month 5, representing an improvement of only 5.4% over baseline, were found. However, their 25 healthy controls

improved from 62.0 (SD 11.3) to 71.4 (SD 13.2), representing a practice effect of 15.1% [31].

Roar et al [32] examined practice effects in 80 natalizumab-treated patients with MS with up to 31 repetitions over 30 months and reported improvements of roughly 25% over baseline, on average, with the rate of improvement slowing down after 6 months. Baseline performance and relative improvement were worse for the more severely affected patients with MS [32]. Interestingly, rearrangement of the SDMT symbol key resulted in a return to baseline performance, suggesting that the practice effect could be attributed to key memorization and that no generalizable learning or improvement of processing speed occurred [32].

Indeed, all of the traditional paper and pencil SDMT versions have the limitation of a fixed key, which is why Benedict et al [33] recommend the use of equivalent forms with alternate keys to mitigate practice effects. The smartphone-based *e-SDMT* version examined in this study has changing keys, thus emulating the process of alternate forms. Key changes are not truly random, and the subtlety of the original SDMT, in which the first 26 items only use the first 6 symbols in the key, is preserved [34].

With our result of an average boundary improvement over baseline of 40.8%, we can show that with weekly testing, practice effects for SDMT are likely to be stronger than with monthly testing, as performed by the abovementioned studies, and at least partly independent of the key.

As a limitation, the smartphone-based test in this study was not oral but based on touching a number pad, potentially biasing the results by dexterity problems (and dexterous practice effects). However, our analysis of *e-SDMT* corrected for dexterity and reaction speed by using Floodlight's *baseline* showed very similar results, suggesting that this is not a major issue, potentially because patients are free to use their preferred hand for this test.

Dexterity: 9HPT

Practice effects often become apparent in the examination of test-retest, intrarater, and interrater reliability. In this way, Cohen et al [35] found evident practice effects for the 9HPT first in 10 and later in 436 secondary progressive patients with MS over 4-6 repetitions in up to 4 weeks, which stabilized after 3 repetitions [21].

Solari et al [24] found even stronger practice effects in 32 patients with MS with 6 repetitions in 24 hours, which stabilized after 4 repetitions. As a consequence, they recommend performing 9HPT 4 times before baseline in any study to mitigate practice effects [24].

The smartphone-based *Finger Pinching* and, to a slightly lesser extent, also the *Draw a Shape* tests we examined seem to have much stronger and longer-lasting practice effects than the 9HPT. It can be speculated that high-frequency testing (ie, sustained daily practice over multiple months) maximizes the long-term practice effect.

Mobility: T25FW

No practice effects were found for T25FW, which was examined alongside 9HPT in the abovementioned studies [21,24,35]. This result is in line with our finding of no long-term practice effect in the smartphone-based mobility tests, *Two Minute Walk* and *U-Turn*, which have been validated with the T25FW [9]. However, the outcome reported for *Two Minute Walk* in this study (ie, number of steps) is a quantitative gait parameter and thus representative of endurance, unlike the more qualitative gait parameter *step power* used by Montalban et al [9] for validation against T25FW.

Limitations

MS diagnoses of study participants were self-declared, and there was no confirmation or assessment by health professionals. In addition, no clinical information was available for the participants to compare with their performance in digital tests. Differences caused by disease duration, severity, or treatment could not be analyzed.

In addition, we observed a high variability of results, which is most likely partly due to biomedical day-to-day fluctuations and partly due to circumstantial and technical noise, for example, caused by interrupted test performance or sensor error. However, it is impossible to determine these effects using the present data set.

Finally, these time-series data are highly irregular and have strong right-skewness. Our models expect data missing at random. We found no evidence that baseline performance influenced adherence and the number of repetitions, but age was found to be a confounder for all domains. Interestingly, older people tended to perform more repetitions than younger people (R=0.19 for *e-SDMT*; R=0.21 for *Finger Pinching*; and R=0.22 for *Draw a Shape*; Multimedia Appendices 1, 7, and 9). One can hypothesize that this is because older patients with MS tend to be more severely affected and thus might have higher intrinsic motivation. Another possible explanation is that younger people might have more competing time commitments, for example, because of their occupation or family. As age was associated with larger observed improvements from the fifth to last score for *e-SDMT* and *Finger Pinching* (both R=0.16; Multimedia Appendices 1 and 7), this confounder might lead to slight overestimation of the practice effects. However, in the multivariate models, age was not a significant confounder (Figures 1 and 4). Nevertheless, there might be unobserved confounders that differ between those participants who quit early and those who stayed engaged for a long time, which we aimed to mitigate by sensitivity analyses 2 and 3.

Conclusions

In summary, we analyzed the practice effects in 6 active smartphone-based tests for cognition, dexterity, and mobility performed at high frequencies. Smartphone-based tests promise to help monitor MS disease trajectories, and there are currently multiple initiatives in development [22,36-39]. Our results suggest that strong long-term practice effects in cognitive and dexterity tests must be accounted for to identify possible disease-related changes in these domains, lasting for more than 35 repetitions for *e-SDMT*, 94 for *Finger Pinching*, and 56 for

Draw a Shape. This is important for the interpretation of these tests in the context of personalized health and in studies with no comparator arm. On the other hand, the lack of long-term practice effects in mobility tests simplifies their interpretation, even though short-term learning effects might have to be considered.

Acknowledgments

The authors thank all the participants of the Floodlight Open study for their participation and Roche for making the data set publicly available.

Authors' Contributions

TW designed the study, performed the analysis, interpreted the data, and drafted and revised the manuscript. JL designed the study, interpreted the data, and revised the manuscript. TW and JL had full access to the available source data and guaranteed the integrity of the analysis. SP, AW, LK, and YN helped interpret the data and revised the manuscript for important intellectual content.

Conflicts of Interest

The research activities of the Research Center for Neuroimmunology and Neuroscience Basel, the affiliation of TW, SP, LK, YN, and JL, are supported by the University Hospital Basel, the University of Basel, and by grants from Novartis and Roche. One of the main projects of Research Center for Neuroimmunology and Neuroscience Basel is the development of a new comprehensive MS digital solution. TW and SP report no further conflicts of interest. AW reports no conflicts of interest. The University Hospital Basel, as the employer of LK, has received and dedicated to research support fees for board membership, consultancy or speaking, or grants in the past 3 years from Actelion, Bayer, Biogen Idec, CSL Behring, Eli Lilly EU, Genmab, GeNeuro SA, Janssen, Merck Serono, Novartis, Roche, Santhera, Sanofi-Aventis, Teva, European Union, Innosuisse, Roche Research Foundation, Swiss MS Society, and Swiss National Research Foundation. The University Hospital Basel, as the employer of YN, has received financial support for lectures from Teva and Celgene and grant support from Innosuisse (Swiss Innovation Agency). JL received research support from Innosuisse, Biogen, and Novartis; he received speaker honoraria and/or served on advisory boards for Biogen, Novartis, Roche, and Teva.

Abstract

Background: *Cyberchondria* describes the detrimental effects of health-related internet use. Current conceptualizations agree that cyberchondria is associated with anxiety-related pathologies and may best be conceptualized as a safety behavior; however, little is known about its exact underlying mechanisms.

Objective: This systematic review and meta-analysis aims to give an overview of the conceptualizations of cyberchondria and its relation to anxiety-related pathologies, quantify the strength of association to health anxiety by using meta-analyses, highlight gaps in the literature, and outline a hypothetical integrative cognitive-behavioral model of cyberchondria based on the available empirical evidence.

Methods: A systematic literature search was conducted using PubMed, Web of Science, and PsycINFO electronic databases. A total of 25 studies were included for qualitative synthesis and 7 studies, comprising 3069 individuals, were included for quantitative synthesis. The meta-analysis revealed a strong association of cyberchondria (r=0.63) and its subfacets (r=0.24-0.66) with health anxiety.

Results: The results indicate that cyberchondria is a distinct construct related to health anxiety, obsessive-compulsive symptoms, intolerance of uncertainty, and anxiety sensitivity. Further studies should distinguish between state and trait markers of anxiety-related pathologies and use experimental and naturalistic longitudinal designs to differentiate among risk factors, triggers, and consequences related to cyberchondria.

Conclusions: Health-related internet use in the context of health anxiety is best conceptualized as health-related safety behavior maintained through intermittent reinforcement. Here, we present a corresponding integrative cognitive-behavioral model.

cyberchondria; health anxiety; online health information seeking; anxiety; systematic review; meta-analysis

Introduction

Background

The internet allows anonymous access to a huge amount of specific information and opinions from nearly everywhere, at any time, and at relatively low costs [1,2]. It is increasingly being used to research health-related questions. Approximately 60% to 80% of internet users search the web for health-related information [3-5]. Of all internet search queries, 2% have medical content [6]. In 2013, 35% of surveyed American adults reported that they had started at least one web-based search session with the specific purpose of figuring out which medical condition they themselves or another person suffered from [7]. Arguably, a web-based search for perceived symptoms or feared illnesses can be helpful. Lemire et al [8] found that individuals feel empowered (ie, competent and in control) by conducting health-related internet use. In addition, health-related internet use seems to enable patients to take a more active role in patient-doctor–relationships [9]. It opens new opportunities for

illness prevention and health care, such as developing statistical models based on individual queries that might be used as a warning system, for example, for cancer [10]. However, there is also evidence of detrimental effects, such as an increase in worries or (health) anxiety, and as a consequence, an increase in the use of health care resources [11,12] (eg, 46% of a general population sample stated that health information found on the web led them to think they needed an appointment with a medical professional [7]).

In this context, journalists have coined the term *cyberchondria* [4,13] from the words *cyber*, referring to internet use, and *hypochondriasis*, referring to pathological health anxiety (HA). It is the belief in or the fear of having a serious disease, often without a matching medical condition. However, the term *cyberchondria* itself does not say anything about causality, the nature of the relationship between these two constructs, or the relevance of cyberchondria for patients with pathological HA. The most common definition of cyberchondria provided by Starcevic and Berle [14] postulates a bidirectional relationship. Elevated HA triggers health-related internet use, which in turn leads to amplification and, in the long term, to the maintenance of HA. Others classify cyberchondria-related behavior as a form of reassurance seeking that initially leads to an immediate decrease of HA but maintains HA in the long term through negative reinforcement [15].

Associations between cyberchondria-specific behavior and anxiety-related pathologies other than HA have also been proposed. First, a connection to obsessive-compulsive symptoms has been hypothesized [16-19], such that individuals experiencing greater cyberchondria also experience greater obsessive-compulsive symptoms. The interruption of other activities because of health-related internet use appears to be common in both constructs. Second, uncertainty about the seriousness of bodily symptoms and their appraisal as dangerous were proposed to be triggers for health-related internet use [1,14]. Several studies found medium-sized positive correlations between cyberchondria and intolerance of uncertainty (Multimedia Appendix 1 [20-23]). Furthermore, intolerance of uncertainty has been shown to moderate the impact of health-related internet use on HA [20,24]. The results suggest that the desire to avoid uncertainty and negative reactions to uncertainty are strongly associated with the experience of negative affective states because of health-related internet use [21,25]. Positive correlations were also found between anxiety sensitivity (ie, the tendency to interpret anxiety-related symptoms as signs of impending danger) and cyberchondria (Multimedia Appendix 2 [21,22,25]). Furthermore, anxiety sensitivity predicts cyberchondria in addition to the contributions of intolerance of uncertainty [25].

Different conceptualizations and theories have been developed that focus on certain aspects, such as emotional or behavioral consequences, cognitions, or characteristics of the search process itself; however, no consensus has yet been reached. The fact that cyberchondria is a current topic is also made clear by the fact that in 2019, for example, a systematic narrative review [26] and a meta-analysis of cyberchondria and HA [27] were published. Brown et al [26] presented an integrative cognitive-behavioral therapy (CBT) model of health-related internet use that distinguishes between reassuring health-related internet use on the one hand and problematic as well as compulsive health-related internet use on the other hand, according to the emotional consequences of this behavior. McMullan et al [27] found a meta correlation between HA and cyberchondria of r=0.62 (P<.001; n=10 studies).

Objective

This review aims to (1) give an overview of the current state of research regarding existing theoretical conceptualizations of cyberchondria and its relation to anxiety-related pathologies (ie, broader compared with the previous focus on HA), (2) quantify the strength of associations between cyberchondria and HA by using a meta-analysis according to the current data situation (ie, year 2020), (3) highlight gaps in the current literature, and (4) outline a hypothetical integrative cognitive-behavioral model of cyberchondria based on the available empirical evidence. This model follows a new approach by integrating existing results in the context of elevated HA and by waiving the artificial conceptual separation of health-related internet use according to the valence of its emotional effects.

Methods

Protocol and Search Strategy

A systematic literature search was conducted according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [28,29], using the computerized databases PubMed, Web of Science, and PsycINFO. They were searched three times, first in February 2016, second in July 2017, and third in February 2020, to include the latest research findings. A keyword search was performed using the following search terms and logics: *cyberchondria, cyberchondriasis, health-related internet use AND health anxiety, health-related internet use AND hypochondriasis, illness-related internet use AND health anxiety,* and *illness-related internet use AND hypochondriasis*, as well as the German translations of these terms. Searches were restricted to study titles and abstracts.

Inclusion and Exclusion Criteria

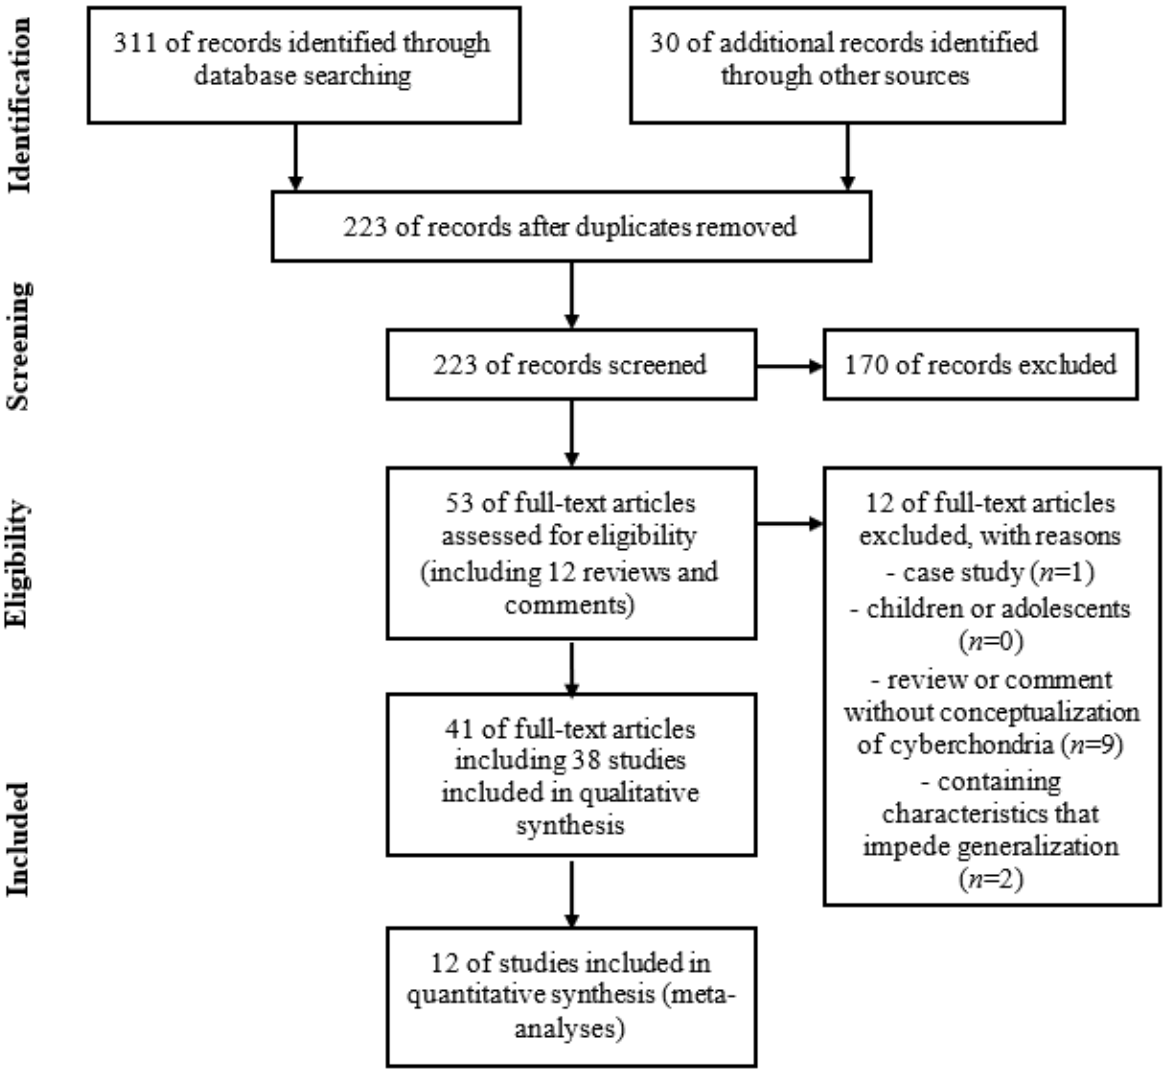
Only a few eligibility and exclusion criteria were specified to make this search as inclusive as possible. Studies were included if they (1) examined health-related internet use in the context of HA, (2) were published research papers or accepted manuscripts, (3) were written in English or German, and (4) investigated a general population or a health-anxious sample. Articles were excluded if they (1) reported a case study or data exclusively from children or adolescents or both, (2) were literature reviews or comments that did not postulate their own conceptualization or definition of cyberchondria, or (3) contained special characteristics that impeded the generalization of results (eg, investigation of a sample with symptoms outside the anxiety-related spectrum). All included research articles were already published in peer-reviewed journals.

Data Extraction and Synthesis Process

First, study titles were screened. Then, the abstract, method, and discussion sections were read consecutively (especially to

detect assumptions concerning the concept or function of cyberchondria), followed by reading full texts. Studies that did not fulfill all eligibility criteria or that fulfilled one or more exclusion criteria were eliminated. The electronic search was supplemented by reading the reference lists of the retrieved studies to identify more potential literature. Then, information from each eligible study was extracted and tabulated. Extracted data included names of the authors, publication year, journal, country of origin, type of study (primary vs secondary), proposed conceptualization of cyberchondria (yes or no), research question, study design, number of reported studies per paper, sample characteristics (age, range, type, and total sample size), methodology (operationalization of the construct, type of hypothesis, and analysis), and main findings. No paper was excluded because of insufficient information being reported. Applying these criteria to the searches resulted in the inclusion of 38 studies (Figure 1). All studies proposing a conceptualization of cyberchondria were then picked (irrespective of whether the study was primary or secondary). Different elements of conceptualization (eg, suggestion of detrimental effects of health-related internet use) were then extracted, which, in turn, were used as categories to group the corresponding primary studies (eg, studies investigating the effects of health-related internet use). Accordingly, one primary study could be assigned to more than one group. All primary studies were assigned. In the following sections, we present the studies according to the assigned groups (ie, *Conceptualizations of Cyberchondria*, *Cyberchondria and Anxiety-Related Pathologies*, *Triggers for Health-Related Internet Use*, and *Consequences of Health-Related Internet Use*).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) flow diagram of studies.



Results

Conceptualizations of Cyberchondria

Conceptualizations of cyberchondria differ in the proposed immediate impact of health-related internet use on HA, and thus, also regarding the function of cyberchondria-related behavior in the context of HA (ie, *cyberchondria as an Amplifier of HA* vs *Cyberchondria as a Safety Behavior*). Multimedia Appendix 3 [6,14,15,26,30,31] summarizes the current conceptualizations.

Cyberchondria as an Amplifier of HA

Cyberchondria as a Failed Safety Behavior

Starcevic and Berle [14] presented a definition of cyberchondria as "an excessive or repeated search for health-related information on the internet, driven by distress or anxiety about health, which only amplifies such distress or anxiety"; moreover, "it does not denote a diagnosis and occurs as part of health anxiety and hypochondriasis." While giving a theoretical and empirically based framework, this definition also reformed the operationalization of cyberchondria by defining a process that includes a causal bidirectional relationship between cyberchondria and HA. It is important to underline that defining the precursors (HA as a trigger) and consequences (exacerbation of HA) of health-related internet use differentiates cyberchondria from merely searching the web for health-related information. Moreover, the multidimensionality of the construct was implied (eg, distress, excessiveness, and compulsion) [17]. Starcevic and Berle [14] hypothesized that cyberchondria-related behavior may be a form of reassurance seeking but that it should not be classified as a *classic* safety behavior, as in the short term, it increases anxiety instead of decreasing it [32]. If this definition is correct, it is important to explain how health-related internet use increases HA and why this behavior does not stop despite its adverse effects. In this regard, factors that amplify anxiety during health-related internet use are presented [33], which are assumed to set vicious circles in motion. They include the misinterpretation of the rank order of search results as pointing to the likely cause of a searched symptom [6,34] and the questionable trustworthiness of web-based health information [35]. However, current and partly inhomogeneous results raise doubts in this context [13,34,36].

Query Escalation

White and Horvitz [6] hypothesized that a process referred to as *query escalation* is highly relevant for increased HA during medical web-based searches. They defined cyberchondria as "the unfounded escalation of concerns about common symptomatology, based on the review of search results and literature on the Web." Escalations, in turn, were defined as special cases of cyberchondria during health-related internet use. They were operationalized as a shift of attention concerning the content of the information sought: away from a probable cause (eg, dehydration) for a common symptom (eg, a headache) to a serious illness (eg, cancer), which is a very unlikely cause for the bodily sensation.

To investigate this process, 11,158 naturalistic logs of a large (N=515) nonclinical sample's internet searches were analyzed [6]. Approximately 2% of all queries had medical content, and 5.3% of them escalated, thus verifying the existence of query escalations. However, as the direct effects on HA were not assessed, it could not be shown that this was a mediating process for experiencing increased anxiety. Evidence was found that searches were performed repeatedly, as 78.3% of all medical queries contained a symptom that was sought again within 2 weeks after the initial search. Moreover, the results indicated that health-related internet use occurred impulsively with a switch between longer abstinent episodes and episodes of intensive searching behavior, which might be indicative of an intermittent reinforcement pattern.

Singh and Brown [37] investigated the occurrence and consequences of query escalations in dependence on the HA level of their participants in a laboratory experiment. They found that escalations resulted in higher anxiety compared with nonescalations, regardless of previously existing HA, and highly health-anxious individuals were significantly more likely to escalate. Approximately 60% of all participants performed at least one escalated health-related internet use.

There are initial indications for the relevance of *query escalation* as a moderating mechanism for the negative effects of health-related internet use and these lead to the conclusion that attentional aspects might be of relevance in cyberchondria. In a consecutive study, White and Horvitz [34] showed that potentially alarming content (eg, *heart attack* and *medical emergency*) in captions, snippets, and URLs of search results influences the search-result click-through behavior so that this attribute makes them more likely to be selected.

Dimensional Conceptualizations of Cyberchondria

Cyberchondria was usually assessed using single items referring to the frequency or duration as well as the emotional consequences of health-related internet use [4,13,20]. These operationalizations neither took into account the postulated process character nor the multidimensionality of this construct [6,14]. In 2014, McElroy and Shevlin [17] developed the Cyberchondria Severity Scale (CSS), designed as a continuous measure of distress because of health-related internet use (according to previous conceptualizations [4,6,13,14]). This self-assessment questionnaire comprises 33 items that ask questions on a 5-point Likert scale about the frequency of web-based health-related behaviors. In contrast to previous assessment strategies, the CSS consists of five interpretable factors that reflect different dimensions of cyberchondria [16,17,38,39]. The factor *compulsion* reflects the different ways in which a web-based health-related search can unintentionally interrupt other web-based and offline activities. The dimension *distress* mirrors subjective negative emotional states because of health searches on the internet (stress, worry, anxiety, panic, and irritation). The factor *excessiveness* captures repeated searches for the same topic and the use of numerous sources. These 3 dimensions were also proposed by Starcevic and Berle [14]. Two additional subfacets are presented: all items loading on the factor *reassurance seeking* (hereafter called *reassurance*) indicate the felt need for reassurance from medical professionals triggered by information found on the web, representing a behavioral consequence of cyberchondria. The factor *mistrust of medical professionals* (hereafter called *mistrust*) reflects the conflict that web searchers have concerning whether to trust their medical professional over their own research results and self-diagnosis.

As detailed in Multimedia Appendix 4 [16-19,26,40,41] all CSS subscales showed moderate to strong intercorrelations, except for the *mistrust* factor, where only small or nonexistent associations were observed.

Although factor analyses revealed a five-factor structure of the CSS items, further analyses and observed correlation patterns raised doubts concerning the affiliation of *mistrust* to the concept of cyberchondria [16,38,39]. Higher-order factor analyses showed that a model consisting of a separate *mistrust* factor and a bifactor model comprising a general cyberchondria factor and 4 independent dimensions (*compulsion*, *distress*, *excessiveness*, and *reassurance*) best fit the data [16,38]. This showed that models generating a general cyberchondria factor had a superior fit to the data when *mistrust* was excluded. The four-factor structure was also found in a network analysis [42] that additionally revealed that no symptom seemed to be more central to the cyberchondria construct than others. On the other hand, Norr et al [38] pointed out that the findings regarding the *mistrust* factor may be attributable to method variance as all items of the scale are designed inversely. However, this approach has not been further investigated. Furthermore, qualitative data suggest that a certain mistrust of medical professionals and, specifically, of doctors, may play an important role [1]. In this context, a distinction has to be made between the affiliation of *mistrust* to the CSS and the affiliation of mistrust of doctors to cyberchondria; however, this question cannot be answered at this time. Further investigation is needed that takes into account the possibility that the CSS may not assess the construct in its entirety and that the general cyberchondria factor may represent a dimension of cyberchondria that is only weakly associated with *mistrust*. The original and revised CSS total scores (removing the *mistrust* items) were highly correlated (r=0.99 [16]).

Regarding convergent validity, the most important indicator for the CSS is its potential association with HA (see section *Health Anxiety*). Correlation analyses demonstrated that the CSS data were more strongly associated with *anxiety* (r=0.43; P≤.01) than with *stress* (r=0.37; P≤.01) and *depression* (r=0.24; P≤.01 [17]) using the short version of the Depression, Anxiety and Stress Scale [43]. The degree of association varies according to the theoretical similarities of the different constructs. Moreover, Fergus [16] showed that the CSS total score and the total score revised were more strongly associated with HA (r=0.59 and r=0.58, respectively; both P<.01) than with obsessive-compulsive symptoms (for both total scores, r=0.49; P<.01), as assessed using the Dimensional Obsessive-Compulsive Scale (DOCS) [44]. Barke et al [39] found medium positive correlations between the CSS global score and somatic symptoms (r=0.40; P<.01; assessed with the somatic symptom scale of the Patient Health Questionnaire [45,46]), depressive symptoms (r=0.31; P<.01; assessed with the short form of the Center for Epidemiologic Studies Depression Scale [47,48]), and health care use (r=0.29; P<.01; assessed with the Health Care Utilization questionnaire [49]).

As can be seen in Multimedia Appendix 4, the CSS subscales show different internal consistencies ranging from a high level for *compulsion* and *distress* to a good level for *excessiveness*, *reassurance*, and *mistrust*. The CSS total scale showed excellent internal consistency and split-half reliability without exception (α=.93-.96 [16,17,19,38,39]).

The first results show that the CSS seems to be unrelated to age [39], whereas results regarding sex differences are heterogeneous [2,39]. Too little information is currently available to finally evaluate these factors.

Other versions of the CSS regarding language (German [39] and Polish [40]) and length (short versions in English [50] and German [39]) show psychometric qualities comparable with the original version.

Jokić-Begić et al [51] developed a short questionnaire (4 items) to assess cyberchondria as a safety behavior. Besides predictors and negative outcomes, positive consequences were also intended to be measured; however, analyses revealed an unclear factor structure.

Cyberchondria as a Form of Problematic Internet Use

Problematic internet use describes the excessive use of the internet [52] for purposes other than searching for medical information and an inability to control that use [53], therefore reflecting behaviors from the fields of compulsion and addiction. Fergus and Dolan [30] define cyberchondria as a form of problematic internet use that is intended to reduce negative emotions but actually leads to greater subjective distress. To investigate this assumption, they used the Compulsive Internet Use Scale [54] and operationalized cyberchondria as the impact of health-related internet use on HA assessed with a single item. Individuals experiencing increased HA because of health-related internet use reported significantly greater levels of problematic internet use (mean 25.35, SD 11.58) compared with individuals experiencing no impact on (mean 18.63, SD 10.56; Cohen d=0.61; P<.01) or a decrease in HA (mean 21.76, SD 10.43; Cohen d=0.33; P<.01). These group differences stayed robust even after controlling for the frequency of health-related internet use and negative affect. These findings were supported by Fergus and Spada [31], who found a strong association between cyberchondria (operationalized by the CSS) and problematic internet use (r=0.59; P<.001). In this study, problematic internet use was assessed using the Problematic Internet Use Questionnaire [55], which consists of 3 dimensions (obsession, neglect of other activities, and control disorder). In addition, multiple linear regression with N=337 participants showed the robustness of this relationship (step 2; β=.41; P<.001) by controlling for age, gender, physical health, negative affect, and HA, where HA was the only covariate that accounted for variance in cyberchondria scores. Besides, Starcevic et al [42] found a stronger relationship between cyberchondria and problematic internet use than with HA. However, their network analysis showed that cyberchondria and problematic internet use were related but distinct constructs.

Fergus and Spada [31] concluded that cyberchondria could be viewed as a specific form of problematic internet use, indicating that concepts of problematic internet use may be of relevance to understanding cyberchondria. In addition, cognitive-behavioral treatments for problematic internet use may also be used to treat cyberchondria [30].

Moreover, Singh and Brown [11] found significant positive correlations between HA and 6 indicators of addiction to health-related internet use (inter alia, unsuccessfully trying to cut back, negative feelings regarding a real or anticipated loss, negative consequences, and increasing use over time).

Together, these findings underline the relevance of the compulsive and addictive aspects of cyberchondria-specific behavior.

Metacognitive Conceptualization of Cyberchondria

Fergus and Spada [22,31] hypothesized the conceptualization of cyberchondria according to the metacognitive model of emotional disorders [56]. Following this model, individuals engage in self-regulation strategies that maintain and worsen negative affective states because of their metacognitive beliefs. In terms of cyberchondria, this would mean that health-related images, memories, or thoughts trigger HA. At the same time, metacognitive beliefs are activated, which can be distinguished into two types: *positive* metacognitions associated with advantages of health-related worries (eg, "Considering all possibilities will help keep my mind at rest" [31]) and *negative* metacognitive beliefs associated with disadvantages or the uncontrollability of health-related worries (eg, "My thoughts are uncontrollable" [31]). To reduce the triggered HA, a self-regulation process, namely health-related internet use, is initiated. Plans for supposed successful self-regulation are represented as mentioned in metacognitive beliefs and additionally in beliefs about rituals and stop signals. Rituals refer to plans for coping with aversive inner emotional experiences, and stop signals refer to self-relevant goals that signal when to stop the self-regulation process. Negative metacognitive beliefs, especially regarding the performance of health-related internet use (eg, "Once I start searching I cannot stop" [31]), which can arise in the course, may lead to an increase in negative affect and, thus, lead to further self-regulation processes in the form of health-related internet uses, resulting in a repetitive and distress-evoking vicious circle.

The relevance of metacognitive aspects for cyberchondria was supported by several results from 3 web-based questionnaire surveys by the same authors [22,31], in which the Metacognitions Questionnaire–Health Anxiety (MCQ-HA; [57]) was used. It incorporates three metacognitive beliefs: thoughts can cause illness (MCQ-HA-C), biased thinking (MCQ-HA-B; eg, "Worrying about my health will help me cope"), and thoughts are uncontrollable (MCQ-HA-U). In all studies, zero-order correlation analyses revealed that all metacognition subscales were significantly correlated with cyberchondria (MCQ-HA-C: *r*s=0.32-0.49, all *P*<.001; MCQ-HA-B: *r*s=0.47-0.58, all *P*<.001; and MCQ-HA-U: *r*s=0.51-0.66, all *P*<.001).

Hierarchical multiple linear regression analyses statistically controlling for relevant covariates (ie, age, gender, physical health status, HA negative affect, and anxiety sensitivity) showed that *negative* metacognitions (ie, uncontrollability of thoughts [22,31], beliefs about rituals [22], and beliefs about stop signals [22]) and obsessive-compulsive symptoms [22] contributed significantly to the variance in cyberchondria. However, the analyses yielded inhomogeneous findings regarding the relevance of *positive* metacognitive beliefs [22,31]. Interestingly, neither anxiety sensitivity nor intolerance of uncertainty shared significant, unique associations with cyberchondria [22]. A supplemental analysis using HA as the criterion variable (instead of cyberchondria) and cyberchondria as a covariate revealed that beliefs about rituals and stop signals distinguish cyberchondria from HA.

In summary, the presented results support the importance of metacognitive aspects in the conceptualization of cyberchondria. Nevertheless, the proposed function as a predisposing and maintaining factor in the cyberchondria process needs to be further investigated. In particular, the heterogeneous findings regarding the relevance of *negative* (vs *positive*) metacognitive beliefs need further attention to clarify if they have a unique function in maintaining health-related internet use despite its adverse effects.

Cyberchondria as a Safety Behavior

The cognitive-behavioral model of HA and hypochondriasis by Warwick and Salkovskis [58] postulates that the perception of normal bodily symptoms and their misinterpretation as harmful and as a sign of a serious illness as well as the mechanism of somatosensory amplification [59] lead to negative affect (eg, anxiety and worry). Safety behavior is exhibited to reduce the negative affective states. Bleichhardt and Weck [15] classified health-related internet use as a new form of reassurance-seeking behavior that is carried out on the internet rather than by reading books or magazines or visiting a physician.

Support for this categorization of cyberchondria was given by Newby and McElroy [60]. They adapted regular strategies for reducing safety behavior to cyberchondria and integrated them into an internet-delivered CBT for HA. Strategies comprised, for instance, increased awareness of the frequency and personal cost of health-related internet use, activity scheduling, and reduction of excessive health-related internet uses through a behavioral experiment. Analysis of variance analyses revealed a significant reduction in cyberchondria pre- and post-CBT (within-group Hedges g=1.57, 95% CI 1.05-2.09). This reduction was greater than that in an active control group (Hedges g=1.1, 95% CI 0.60-1.61; time by group, $F_{1,67}$=25.41; *P*<.001). Mediation analyses showed that decreases in HA were partly mediated by a reduction in cyberchondria. Nevertheless, these promising results have to be interpreted in the light of several limitations, such as the influence of other therapeutic strategies and the moderate correlative association between cyberchondria and HA. Changes in cyberchondria might be reflective of changes in HA rather than of a unique process.

In 2019, the first CBT model was presented by Brown et al [26] based on a comprehensive review of existing data accounting for reassurance-related and compulsive elements.

According to the model, health-related internet use is commonly performed to eliminate health threats and is moderated by metacognitive beliefs (eg, "I need HIU to control my anxiety"), among other factors. Depending on the results of the health-related internet use, two possible forms of problematic health-related internet use can occur: first, if the search results can eliminate the perceived threat, relief is experienced, and health-related internet use is negatively reinforced. Consequently, health-related internet use is terminated, and metacognitive beliefs regarding the beneficial effects of this strategy are developed. This form is termed *pathological health-related internet use* and describes health-related internet

use functioning as a reassurance-seeking behavior in the context of HA (ie, cyberchondria, although the authors recommend not to use this term because of ambiguities in the definition). A second possible outcome occurs if search results strengthen the perceived threat. Resulting anxiety and worry lead to the continuation of health-related internet use, even to the point of query escalation. In consequence, metacognitive beliefs about the internet search itself and its possible negative consequences (eg, "I can't control my HIU") are developed and lead to distress. This form is termed *compulsive health-related internet use*. The perceived threat does not focus on health (in contrast to pathological health-related internet use) but on the internet search itself. Individuals affected then might feel stuck and out of control regarding health-related internet use.

Cyberchondria and Anxiety-Related Pathologies

In this section, show the associations between several anxiety-related pathologies (ie, HA, obsessive-compulsive symptoms, intolerance of uncertainty, anxiety sensitivity, and pain catastrophizing) and health-related internet use. Moreover, we discuss the distinctiveness of cyberchondria to anxiety-related pathologies.

Health Anxiety

All the aforementioned concepts and theories contain interrelations between HA and cyberchondria. For instance, Starcevic and Berle [14], as well as Brown et al [26], postulated that individuals who previously suffered from elevated HA are especially likely to experience negative affective states because of health-related internet use. Therefore, the following section illuminates the results regarding the relationship between HA and cyberchondria and is subdivided by the existing operationalizations of cyberchondria (by the CSS, including our meta-analyses, and by frequency and duration). As HA is seen as a dimensional rather than a categorical construct [61,62], findings from its whole spectrum are relevant.

A Meta-analytic Integration of Cyberchondria Operationalized by the CSS

As cyberchondria is supposed to be a multidimensional construct, it is conceivable that its different dimensions have dissimilarly strong relations to HA [38]. Multimedia Appendix 5 [18,19,38-40,63,64] displays the corresponding correlation coefficients. Individual dimensions have differing but significant associations with HA, ranging from high correlations with *distress* and *excessiveness*, moderate to high correlations with *reassurance* and *compulsion*, to moderate correlations with *mistrust*. To quantify the associations between (1) HA as a trait and cyberchondria, as well as between (2) HA and the different dimensions of cyberchondria as operationalized by the CSS, we conducted several meta-analyses. This examination is of particular importance to test the validity of the cyberchondria concept, as postulated by Starcevic and Berle [14].

Description of Included Studies

For the described purpose, we examined studies included in this review that reported results regarding a correlational hypothesis between a standardized measure of HA and the CSS total scale and subscales. On the basis of the aforementioned results regarding the questionable affiliation of the *mistrust* factor with the cyberchondria construct (or at least with the CSS total scale), only results that did not include the 3 *mistrust* items were incorporated. We contacted the authors of the primary studies to obtain missing data (eg, coefficients regarding the CSS total scale or subscales and internal consistencies). They were included if available. Quality ratings were conducted for the included articles, whereby the quality criteria according to Brown and Reuber [65] were adjusted based on the characteristics of the available studies (eg, some criteria were also met by all studies included in this study, such as correlative design and standardized measuring instruments, which were then not used as criteria). To assess the quality of the studies and especially the generalizability of the results, the following criteria were used and evaluated (by the 2 authors SKS and SMJ): consecutive sampling; validity items or data check, for example, missing values; control of possibly confounding variables; sufficiently reported inclusion and exclusion criteria; sufficiently reported sample characteristics; and approximate representativeness of the sample. According to Brown and Reuber [65], these ratings were used to calculate the overall quality of the study methods, which was defined as the proportion of items given a *yes* rating in combination with a sufficiently large sample size. We rated the sample size according to Cohen [66], who suggested that 85 participants were needed to detect a medium effect size (r=0.3), given an α level of .05 and power of 0.8. The overall quality was rated as high (≥80% *yes*, equating to no more than one of the methodological standards given a *no* rating and N≥85), medium (50-79% *yes* and N≥85), low (20-49% *yes* and N≥85), and unacceptable (<20% *yes* or N<85). Any unacceptable studies were excluded from the meta-analyses. Interrater reliability (between the 2 authors SKS and SMJ) across all categories was κ=0.75, indicating a substantial interrater agreement [67]. Quality ratings are provided in Multimedia Appendix 6 [16,21,22,25,31,39,40,63,64]. Of the 12 studies rated, 8 (67%) were judged to be of high quality, 3 (25%) of medium quality, 1 (8%) of low quality, and no study was rated to be of unacceptable quality, resulting in 12 studies that were included in the first meta-analysis regarding the first question (Table 1). Owing to unavailable missing data, 17% (2/12) of these studies were not considered in the meta-analysis regarding the second question, resulting in 10 studies for the second question.

[a]HA: health anxiety.

[b]CSS: Cyberchondria Severity Scale.

[c]Ex: exclusion criterion.

[d]In: inclusion criterion.

[e]SHAI: Short Health Anxiety Inventory.

[f]WI: Whiteley Index.

[g]mSHAI: modified version of the Short Health Anxiety Inventory.

[h]Missing data.

[i]MIHT: multidimensional inventory of hypochondriacal traits.

[j]Excluded from the second meta-analysis (association between dimensions of cyberchondria and HA) because of unavailable data.

[k]TI: subscale thought intrusion of the SHAI.

[l]FOI: subscale fear of illness in SHAI.

Study Characteristics

Most studies were conducted in the United States (9/10, 90%). HA was mostly operationalized by the Short Health Anxiety Inventory (SHAI [68]) or a short version (7/10, 70%). Approximately 40% (4/10) used the Whiteley Index [41], and 10% (1/10) used the multidimensional inventory of hypochondriacal traits [69].

Participant Characteristics

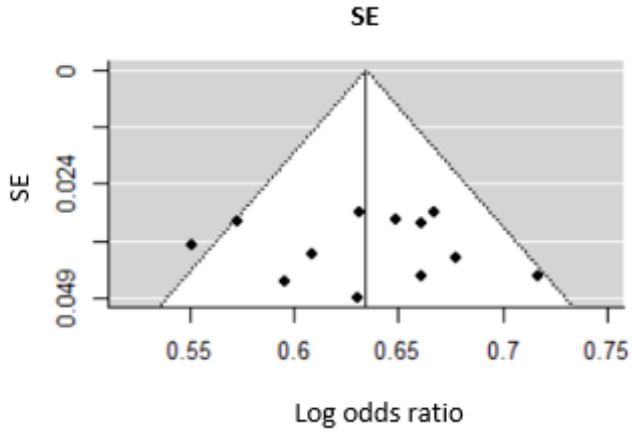
In total, 4653 participants were included in the meta-analyses, with a mean age of 30.5 years; 58.3% were women.

Approximately 30% (3/10) of studies excluded participants who reported that they suffered from a diagnosed medical condition, and 40% (4/10) of studies only included participants who stated that they regularly performed health-related internet use.

Data Analysis

The random-effects model, considered to be the most appropriate in applied sciences was chosen [70,71]. This model is based on the assumption that the population effect differs randomly from study to study and accounts for within- and between-study variability [72,73]; therefore, more general inferences can be made compared with fixed-effect models. For statistical evaluation, the method provided by Hunter and Schmidt [74,75] was applied using the *metafor* software package in R (R Foundation) [76], following Viechtbauer's [77] recommendations. This method aims to investigate relations on the level of constructs rather than measured values; therefore, it allows correction for the effects of several statistical artifacts, inter alia, concerning measuring accuracy (or more specifically for internal consistencies [78]). Potential publication bias was explored using a funnel plot (Figure 2). The Egger regression asymmetry test was used to detect publication bias. These analyses were also performed using the *metafor* software package in R [76]. For all the results, a two-sided *P* value of ≤0.05 was considered significant.

Figure 2. Funnel plot of integrated studies.



Meta-analytic Results

First, correlation coefficients were corrected for measurement error (Cronbach α [74]) of the instruments used to assess HA and cyberchondria. To quantify the association between these two constructs (question 1), a model with no moderators was estimated, revealing a small heterogeneity of integrated effects (I^2=27.8%; Q_{11}=16.7; *P*=.12 [79]); so no moderator analysis was conducted. A strong positive association between HA and cyberchondria was found (*r*=0.63; *P*<.001, 80% CI 0.61-0.66). Figure 3 shows the integrated effects. The Egger regression analysis showed that publication bias was not present (z=0.25; *P*=.80). Another meta-analysis concerning the strong positive association between HA and cyberchondria closely corresponded to our findings (*r*=0.62; *P*<.001 [27]).

To quantify the association between the different dimensions of cyberchondria and HA (question 2), a second model was estimated that integrated the corrected correlation coefficients between HA and all subscales of the CSS (Figure 4).

In line with our expectations, high heterogeneity of effects was found (I^2=95.59%; Q_{44}=1020.81; *P*<.001). Therefore, subscales were included in the model as moderators and accounted for R^2=67.26% of the variance. Table 2 shows the results of this meta-regression analysis. All subscales showed significant, small to strong associations with HA, and most strongly with *distress* and *excessiveness*.

Figure 3. Forest plot of integrated study effects and meta-effect regarding the association between cyberchondria and health anxiety.

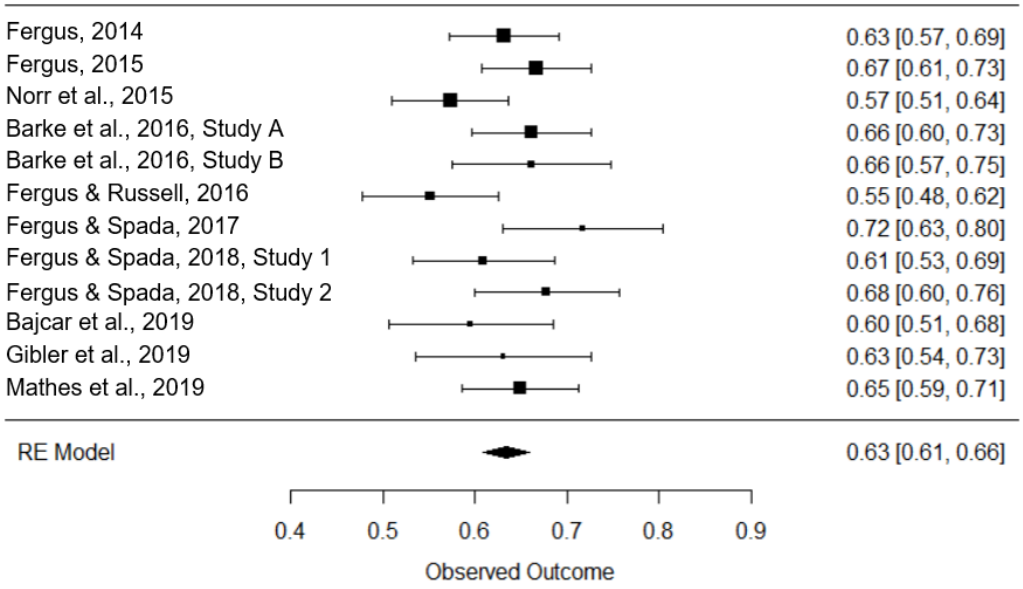


Figure 4. Forest plot of integrated study effects regarding the association between cyberchondria dimensions and health anxiety.

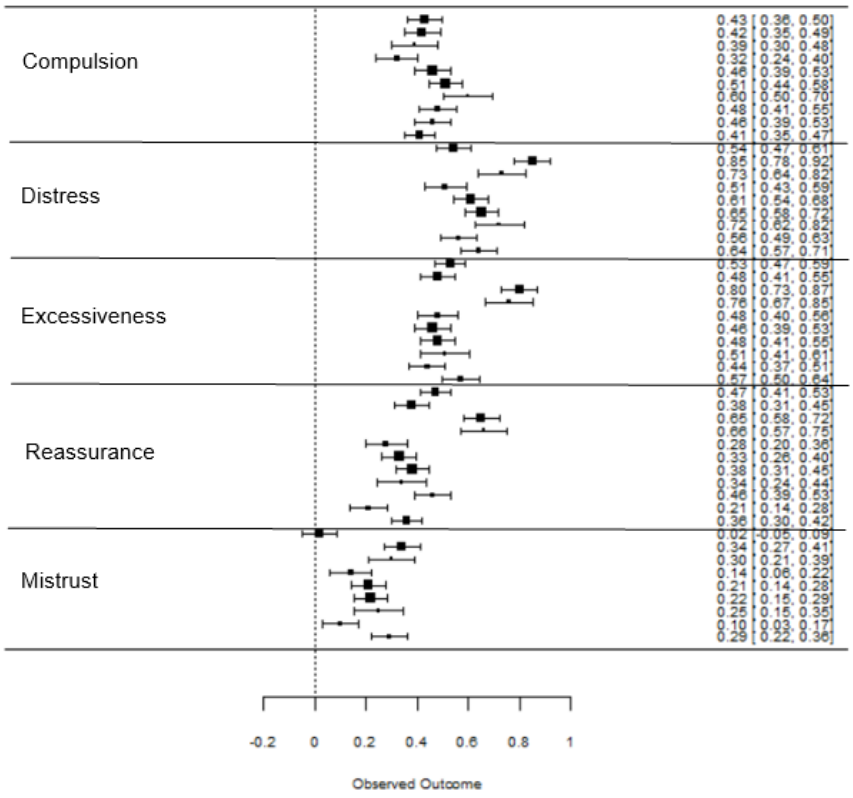

Table 2. Results of meta-regression to quantify the association between cyberchondria dimensions and health anxiety.

Dimension of cyberchondria	β	*P* value	95% CI
Compulsion	.46	<.001	0.23-0.69
Distress	.66	<.001	0.43-0.89
Excessiveness	.59	<.001	0.36-0.83
Reassurance	.44	<.001	0.21-0.67
Mistrust	.24	<.05	0.01-0.47

Correlational Results Regarding Subfacets of HA

Correlation analyses further revealed that cyberchondria clusters most strongly correlated with the affective component of HA, more precisely with health worries (r=0.57; P<.01 [19]; Multimedia Appendix 5). This finding is consistent with the results of Norr et al [38], who found relations between cyberchondria and the SHAI, which is argued to primarily assess an affective component of HA [24]. As worry was found to be linked to safety behavior [80], the authors suggest that health-related internet use may be an activity performed to reduce health worries.

Cyberchondria Operationalized by Frequency and Duration of Health-Related Internet Use

Until the publication of the CSS [17], cyberchondria was assessed in two parts using two items: (1) frequency or duration of health-related internet use, and (2) its effects. Corresponding studies are detailed in Multimedia Appendix 7 [4,11,13,20,36,81,82]. Mostly moderate positive correlations were reported, indicating that the more health-anxious a person was, the more frequently and longer he or she searched the web for health- and illness-related information. This association was also found when HA was not operationalized continuously but dichotomously by ranking the SHAI scores of participants and using the bottom and top quartiles [4]. TePoel et al [81] observed a moderate positive association between HA and health-related internet use, indicating that individuals with higher HA reported more health-related internet use. This was true for both HA groups, clinical (β=.26; P<.001) and nonclinical (β=.29; P<.001).

Obsessive-Compulsive Symptoms

It is hypothesized that cyberchondria is connected with obsessive-compulsive symptoms. Correlational studies have used DOCS [44] to assess these. It consists of 4 dimensions: *contamination*, *responsibility for harm* (hereafter called *responsibility*), *unacceptable thoughts* (hereafter called *thoughts*), and *symmetry*. Each is judged for time spent, avoidance, distress, interference, and attempts to control. It was shown that the DOCS total scale is significantly correlated to the CSS total scales with (r=0.49, P<.01 [16]; r=0.38, P<.01 [40]) and without *mistrust* (r=0.49, P<.01 [16]; r=0.56, P<.001 [22]; r=0.38, P<.0 [40]) and to all CSS subscales (*distress:* r=0.50, P<.01 [16]; r=0.43, P<.01 [40]; *compulsion:* r=0.46, P<.01 [16]; r=0.34, P<.01 [40]; *excessiveness:* r=0.35, P<.01 [16]; r=0.31, P<.01 [40]; *reassurance*: r=0.27, P<.01 [16]; r=0.23, P<.01 [40]; *mistrust:* r=0.11, P<.01 [16]; r=0.07, not significant [40]), such that individuals with greater obsessive-compulsive symptoms experience greater cyberchondria. Moreover, as detailed in Multimedia Appendix 8 [18,19,40], all CSS and DOCS subscales showed significant and mostly moderate intercorrelations. No statement can be made about the *mistrust* factor as it was excluded from the primary analyses. Interestingly, correlation coefficients were consistently smaller in the study conducted by Fergus and Russell [16] compared with those by Norr et al [18]. This might originate from a range restriction because of stricter eligibility criteria used by Fergus and Russell [19] regarding the performance of health-related internet use and the nonexistence of a diagnosed medical condition.

Although an association between cyberchondria and obsessive-compulsive symptoms was confirmed, different hypotheses exist about the nature of this relationship. First, it is supposed that obsessive-compulsive symptoms are an essential part of the cyberchondria construct. As was seen in section *Dimensional Conceptualizations of Cyberchondria*, McElroy and Shevlin [17] argue that health-related internet use can interrupt other web-based and offline activities. The results regarding the CSS dimension *compulsion* are reported in the aforementioned section. Here, we recap the results briefly. The subscale correlates highly with the CSS total scale (r=0.82; P<.01) and shows moderate to strong correlations with the other CSS subscales (r=0.26-0.80, excluding *mistrust*). Factor analyses [16,38] showed that *compulsion* seems to be part of a higher-order cyberchondria factor.

Another group of authors hypothesized that obsessional and compulsive behavioral elements contribute to the maintenance of cyberchondria [26]. Starcevic and Berle [14] suggested that maintenance is because of the combination of (1) an *obsessional doubt* regarding the validity and sufficiency of information found on the web, and (2) a hope to find the one *perfect* explanation for the symptoms experienced, which may represent a compulsive element of the cyberchondria construct. Following this argument, the subject would assume that continuing to perform health-related internet use would increase the probability of finding the *ultimate* answer, and for this purpose, any anxiety triggered by health-related internet use is acceptable. However, no empirical findings exist to address this hypothesis. Norr et al [18] postulated maintenance of health-related internet use because of a positive bidirectional association between cyberchondria and symptoms related to the DOCS subscale *contamination*. If health-related internet use is carried out to obtain reassurance, this behavior may lead to an increased obsession with physical health, owing to the strong link between cyberchondria and HA. This, in turn, may lead to an increased urge to prevent contamination and illnesses, for example, by increased hand washing. This amplified obsession with health may lead to further health-related internet use. Moreover, it is conceivable that if individuals with cyberchondria believe that health-related internet use gives them the power to prevent future illnesses, there may be a connection to the DOCS subscale *responsibility*. The *symmetry* and *thoughts* subscales are postulated to be unrelated. The structural equation model confirmed the predicted unique relationships. This model, controlling for negative affect (Positive and Negative Affect Schedule [83]) and HA (SHAI [68]), provided a good fit to the data (χ^2=2954.63; P<.05; CFI=0.94; Tucker–Lewis index=0.93; root mean square error of approximation=0.05; 90% CI 0.05-0.06). Norr et al [18] concluded that a co-occurrence of both constructs and repeated health-related internet use might function as a safety behavior to reduce contamination concerns or responsibility for harm.

Another approach by Fergus and Russell [19] hypothesized that the existing findings regarding associations are because of a redundancy of the constructs. Health-related internet use may represent the behavioral component of both HA (eg, reassurance

seeking) and obsessive-compulsive symptoms (eg, neutralizing behavior). They conducted confirmatory factor analyses to examine whether intercorrelations among these 3 constructs were best represented by indicator loadings on the same or separate latent constructs. Analyses showed that cyberchondria seems to be a distinct construct from HA and obsessive-compulsive symptoms, although they are related as a correlated three-factor model provided the best fit to the data ($\chi^2_{(41)}$=149.3; comparative fit index=0.96; nonnormed fit index=0.95; standardized root mean square residual=0.06; root mean square error of approximation=0.08; 90% CI 0.69-0.99). In this model, a latent correlation of r=0.58 (P<.001) between cyberchondria and obsessive-compulsive symptoms was observed. This finding of distinctness of both constructs was confirmed by a network analysis by Starcevic et al [42].

In summary, the available empirical evidence is insufficient to finally characterize the nature of the relationship between cyberchondria and obsessive-compulsive symptoms. Moreover, it remains unclear whether obsessive-compulsive symptoms contribute to the maintenance of cyberchondria or vice versa. One clear shortcoming of research to date is that exclusively cross-sectional questionnaire-based surveys exist, which do not allow the investigation of processes and causality. Experimental studies and longitudinal data are needed to answer these questions.

Intolerance of Uncertainty

Intolerance of uncertainty is defined as a dispositional fear of the unknown [84]. It captures the inability to tolerate the uncertainty of ambiguous situations. It was found to comprise 2 dimensions, which are operationalized in the multidimensional Intolerance of Uncertainty Scale [85]: *prospective* intolerance of uncertainty reflects perceptions of threat as well as implications of future uncertainty. *Inhibitory* intolerance of uncertainty mirrors the desire to avoid uncertainty and behavioral symptoms of apprehension when faced with it. Considering intolerance of uncertainty as a risk factor for cyberchondria seems to be justified because of its substantial associations with HA [25,86].

The results from a qualitative interview study by Singh et al [1] support the relevance of uncertainty about whether one has an undiagnosed health issue for developing a felt need to go on the web and search for medical content. An association was confirmed by mainly medium-sized correlations (Multimedia Appendix 1), and a network analysis also revealed that both constructs were distinct [42]. In particular, *inhibitory* intolerance of uncertainty may be a risk factor for experiencing distress because of health-related internet use [21,25].

In addition, during health-related internet use, multiple medical possibilities are presented to the user [6], and for people with high intolerance of uncertainty, ambiguous situations were found to be distressing. Moreover, creating catastrophic interpretations of unclear health information is only related to HA at a high intolerance of uncertainty [24]. The moderating role of intolerance to uncertainty on the relationship between cyberchondria and HA seems conceivable to explain why some individuals experience worse HA as a consequence of health-related internet use, whereas others do not (see section *Consequences of Health-Related Internet Use*). A regression analysis by Fergus [20] confirmed this finding. The relationship between the frequency of health-related internet use and HA because of these searches was significant at high levels of intolerance of uncertainty (b=0.27; partial r=0.21; P<.01) but not at low (b=–0.06; partial r=–0.03, not significant).

This indicates that the desire to avoid uncertainty and negative reactions to it are strongly associated with experiencing negative affective states because of health-related internet use, potentially because of increased catastrophic thinking about the meaning of bodily symptoms, as concluded by Fergus [21]. Another conceivable explanation for this finding may be that the tendency to react negatively to uncertainty and the resulting desire to avoid it may lead to further health-related internet use to reduce uncertainty. However, the more health-related internet uses are conducted, the greater the possibility of finding ambiguous and inconsistent information, which has the potential to trigger the negative affect.

In addition, intolerance of uncertainty was also found to moderate another detrimental effect of health-related internet use concerning anxiety sensitivity (see section *Anxiety Sensitivity*). Only individuals with high intolerance of uncertainty experience elevated anxiety sensitivity as a consequence of viewing web-based medical content [23].

Anxiety Sensitivity

Although people with intolerance of uncertainty experience uncertainty in general as dangerous, people with high levels of anxiety sensitivity interpret anxiety-related symptoms as dangerous [23]. This was found to be a potential risk factor for HA [87], and therefore, a link between anxiety sensitivity and cyberchondria-specific behavior was hypothesized [21,25]. It is commonly operationalized by the Anxiety Sensitivity Index-3 [88], which consists of three lower dimensions reflecting different types of concerns: *cognitive* (ie, concerns about mental incapacitations), *physical* (ie, concerns about immediate complications), and *social* (ie, concerns about social rejection because of publicly observable symptoms of anxiety). Correlational analyses supported the relevance of anxiety sensitivity for the cyberchondria construct (Multimedia Appendix 2). The coefficients range from a moderate to a high level. Different conclusions can be drawn from this study. The results may indicate that health-related internet uses are performed on various concerns (*cognitive*, *physical*, and *social*). Moreover, anxiety sensitivity may be relevant, especially for those experiencing distress because of health-related internet use. The structural equation models that included anxiety sensitivity, intolerance of uncertainty, and HA (operationalized by the SHAI) as independent variables to predict cyberchondria (operationalized by the CSS total score, excluding *mistrust*) highlighted the important role of anxiety sensitivity as a predictor for cyberchondria in addition to the contributions of intolerance of uncertainty and HA [25]. However, besides the role of anxiety sensitivity as a risk factor, it was also hypothesized to be a detrimental consequence of health-related internet use. Corresponding results are reported in detail in the section *Consequences of Health-Related Internet Use*.

Pain Catastrophizing

In the context of chronic pain, the contribution of pain catastrophizing to cyberchondria has been investigated [63]. It has been shown that pain catastrophizing (ie, the tendency to ruminate and worry about pain [89]) significantly predicts cyberchondria and its facets (operationalized by the CSS), even when controlling for negative affect and HA. Individuals with chronic pain often experience anxiety and distress about the origin and consequences of their pain perceptions and search for answers on the web. Pain catastrophizing may amplify the negative affect and may contribute to the initiation of the cyberchondria-specific vicious circle, as postulated by Starcevic and Berle [14]. Further support is provided by logistic regression analysis that aims to predict engaging in health-related internet use by psychopathologies and somatic symptoms [5] and comprises data from 992 adults from the general population of whom, 751 (75.7%) reported engaging in health-related internet uses in the past 3 months. It was shown that conducting health-related internet uses was associated with HA, obsessive-compulsive symptoms, and intolerance of uncertainty (among other psychopathologies); however, only the severity of somatic symptoms independently predicted health-related internet use when each of these pathological domains was controlled for.

Triggers for Health-Related Internet Use

Another relevant aspect in these models are the triggers for health-related internet use. For instance, Starcevic and Berle [14] postulated that health-related internet use is triggered by elevated levels of HA or distress. However, till now, research has paid little attention to the precursors, motivations, and triggers for health-related internet use. To our knowledge, only 2 qualitative studies have addressed this question, both using semistructured interviews with participants with high levels of HA (ie, participants' SHAI scores exceeded a critical cutoff, indicating clinically significant HA (N=8, SHAI>16 points [90]; N=20, SHAI>18 points [1]). The studies yielded similar results, which are reported in the following section and integrated as far as possible with the superordinate themes identified by McManus et al [90] (*information is power* and *novelty of internet searching*). If no literature reference is given in parentheses, the 2 studies report the same results.

"*Information is power*" describes a participant's hope to be able to prevent future illness, the deterioration of an already existing one [1], or death because of an illness [90] by gathering information, such as appropriate health promotion strategies or remedies [1]. In this context, Singh and Brown [1] found a positive association between HA and the frequency of using the internet to obtain *wellness* information. This can be interpreted as an attempt to prevent the onset of a serious disease, resulting in a feeling of being more in control of one's health. The internet is also used for self-diagnoses to find a label for a health issue so that more specific information can be collected [90]. The possibility of failing to prevent an illness leads to the anticipation of dreadful consequences, which increases the perceived urgency to conduct health-related internet use [1]. Moreover, uncertainty about the probability of having a serious disease primed illness-related thoughts and worries leading to heightened anxiety, whereas being uncertain about nonserious issues led to curiosity [1]. In addition, health-related internet use is initiated by negative experiences and expectations concerning health care professionals that may lead to mistrust: inconvenience, too short appointment times, lack of reassurance, and past negative experiences. Participants also use the internet as a first filter for information to prepare for or justify a consultation with a physician.

The second superordinate theme was *novelty of internet searching* and included the perceived advantages of the internet as a medium of information compared with other methods. Advantages were a low threshold for use, the possibility to share others' experiences and, in consequence, feel comforted by the knowledge that one is not the only person who suffers from this health issue [90], as well as speed, convenience, the possibility of obtaining opinions and advice from other persons affected, the huge size of the source, and its ability to provide reassurance. Reported disadvantages included the following: the information obtained was too broad, confusing, and often conflicting, as well as the presence of false, noncredible, or irrelevant information [1].

It can be concluded that a combination of different factors seems to lead to the initiation of health-related internet use. Besides situational factors (states) such as uncertainty and anxiety, more permanent or predisposing factors such as prior beliefs (eg, mistrust of medical professionals and *information is power*), seem to be important [1] as the metacognitive conceptualization of cyberchondria proposes [31]. There is still a lack of research investigating predisposing factors and triggers. Studies with naturalistic designs appear to be especially promising when investigating situational factors.

Consequences of Health-Related Internet Use

Emotional Consequences of Health-Related Internet Use

Negative Emotional Consequences of Health-Related Internet Use

The impact of health-related internet use on HA has mainly been assessed using questionnaires. Multimedia Appendix 9 [4,11,13,20,36,82] gives an overview of the results. The studies differ in terms of (1) the operationalizations of HA, health-related internet use, and its emotional effects; (2) the predictor for emotional effects (HA vs frequency of health-related internet use); and (3) the type of hypothesis and analysis (correlational vs difference). The results indicate that individuals with higher HA are more likely to experience negative emotional consequences after health-related internet use, which is in accordance with the study by Starcevic and Berle [14]. This finding is also supported by the results of the meta-regression that we conducted, as described in the section *A Meta-analytic Integration of Cyberchondria Operationalized by the CSS*, regarding the CSS subscale *distress* and its association with HA (β=0.66; P<.001). In addition, about one-third of individuals in general population samples stated that they felt increased anxiety after health-related internet use (31.4% [30]; 38.5% [91]). However, it should be noted that no measure of HA was included in this study.

To our knowledge, 2 experimental studies were conducted in this regard and supported the results of the questionnaire studies. Participants in a study by Baumgartner and Hartmann [13] read a text about a fictitious bacterial disease that is accompanied by ordinary symptoms such as stomach and intestinal pain. In addition, the trustworthiness of the source of information was manipulated. The information about the fictitious illness indeed increased negative responses in health-anxious individuals but only if the information was judged as trustworthy (perceived relevance of information: b=0.70, *P*<.01; chance of being already infected: b=0.94, *P*<.01; chance of getting infected: b=1.02, *P*<.01; and worry about disease: b=0.99, *P*<.01). Singh and Brown [37] showed that query escalations reduced postsearch anxiety immediately in 17.0% of the cases in the high HA group, remained the same in 27.65% of cases, and increased in 55.3% of cases. Proportions were comparable for the low HA group (χ^2_2=0.491; *P*=.78). Interview studies revealed that uncertainty, fright, anxiety, worry, and nervousness [1,90] could be experienced as a consequence of health-related internet use. Moreover, significant positive associations (*r*=0.31, *P*<.01 [19]; *r*=0.34, *P*<.001 [22]; *r*=0.44, *P*<.01 [63]) between cyberchondria (operationalized by the CSS total score) and negative affect (operationalized by the Positive and Negative Affect Schedule) were found, indicating that the higher the level of cyberchondria, more negative the affect experienced is. It should be noted that no statements can be made about a causal relationship.

Norr et al [23] hypothesized that being exposed to medical web-based information that is congruent with catastrophic interpretations of anxiety symptoms (namely, as a threat to health) may contribute to the development and maintenance of elevated anxiety sensitivity. They compared undergraduate students (N=52) in two conditions. The experimental group was exposed to medical websites converted to PDF files that provided catastrophic interpretations of bodily symptoms. The control group viewed the PDF files generated from general health and wellness websites. Hierarchical regression analyses showed that individuals in the experimental group experienced significantly higher anxiety sensitivity after the manipulation than did the control group (R^2=0.81, *P*≤.001 and ΔR^2=0.4, *P*≤.01). This relationship was moderated by the individuals' levels of intolerance of uncertainty, such that viewing medical websites only affected anxiety sensitivity in participants with high levels of intolerance of uncertainty. Therefore, it was concluded that health-related internet use and the concomitant exposure to medical content might call users' attention to potentially alarming causes of bodily sensations and may thereby fuel both HA and anxiety sensitivity [21,25].

Positive Emotional Consequences of Health-Related Internet Use

Besides the reported results confirming the postulated negative emotional consequences of health-related internet use, it should be noted that positive emotional consequences were also found, such as relief and calm [1,11,90]. The process of searching itself can provide reassurance by giving a person the feeling of having done something instead of ruminating [90]. As mentioned above, Singh and Brown [37] found that in escalated health-related internet use, anxiety after search was reduced in 17.0% of cases, even in individuals with high levels of HA. Doherty-Torstrick et al [82] found that a considerable proportion of their sample (32.8% in the high HA group and 71.2% in the low HA group) experienced no impact or decreased anxiety during and after health-related internet use. Fergus and Dolan [30] stated that 40.7% of their sample experienced reduced HA after health-related internet use. White and Horvitz [91] reported that 76% of their participants felt reassured, and 50.3% experienced reduced anxiety.

Predictors of Emotional Consequences of Health-Related Internet Use

Some of the factors influencing whether positive or negative emotional consequences are more likely experienced have already been discussed above (ie, HA, intolerance of uncertainty, anxiety sensitivity, and obsessive-compulsive symptoms). However, certain characteristics of the searching process itself also seem to have an influence. Substantial associations between the frequency and the duration of searches and elevated HA postsearch were found (Multimedia Appendix 9). Individuals engaging more often or longer in this behavior are more likely to experience negative consequences. McManus et al [90] found that the longer individuals searched the web, the more likely they were to find alarming information that, in turn, would lead to heightened anxiety. Another important factor seems to be the type of information found: participants stated that negative emotions occurred during health-related internet use if unfamiliar health issues were researched or potentially alarming information was found [1,90]. Conversely, positive emotions were experienced if familiar issues were researched or nonserious causes for experienced symptoms were found. Postsearch negative emotions occurred when people perceived the information as inconclusive, conflicting, confusing, or serious. In this case, new searches were initiated. Postsearch positive emotions were the result of finding a nonserious answer, diagnosing oneself, finding a remedy, or clarifying uncertainties. In these cases, the search was terminated. The results regarding query escalations support these findings [6,37]. Furthermore, the type of web-based service used seems to have an impact: using forums that provide web-based contact with experts or the possibility of sharing with other affected persons seems to alleviate anxiety, whereas using diagnosis systems and video platforms seems to have the opposite effect [36].

Reciprocity Between Health-Related Internet Use and HA

TePoel et al [81] investigated whether HA influences health-related internet use and vice versa. They chose a -wave longitudinal study design with 2-month time lags between the waves. Health-related internet use was operationalized by frequency. Analyses were conducted separately for individuals with lower levels of HA (N=4,564, Dutch version SHAI score<18) and pathological levels of HA (N=751, Dutch version SHAI score≥18); this is of particular importance regarding the distinctiveness of cyberchondria from HA and the question of whether the mechanisms underlying cyberchondria are different in individuals with different levels of HA. A random intercept cross-lagged panel model was chosen for the data analysis. This multilevel approach is able to control for stable (trait-like) individual differences by distinguishing between within-level

and between-level variances. In this model, two random intercepts were included for HA and health-related internet use. In the pathological HA group, changes in an individual's HA score were not predicted by a change in health-related internet use 2 months earlier. Conversely, changes in an individual's health-related internet use score were not predicted by changes in HA 2 months earlier. Thus, no evidence for a reciprocal relationship between HA and health-related internet use was found in individuals with pathological HA. In contrast, evidence for a reciprocal association was found in the nonclinical group with lower HA, such that increases in an individual's HA were predicted by increases in health-related internet use and vice versa.

This indicates that the underlying mechanisms for the impact of health-related internet use on HA differ depending on the previously existing level of HA. In the pathological HA group, health-related internet use seemed to be a maintaining rather than an increasing factor. This suggests that findings from samples with normal levels of HA should only be transferred to clinical samples with care. This highlights the importance of investigating the whole range of HA (especially clinical samples) and its immediate effects. The question of causality remains unanswered in this context.

Effects of Health-Related Internet Use on Behavior: Reassurance Seeking and Health Care Use

It has been hypothesized that health-related internet use is able to trigger further health care use to receive reassurance, especially in individuals with elevated HA. This hypothesis is supported by several findings. Singh and Brown [11] found a medium correlation between HA and the likelihood of visiting a physician after the search (r=0.22; P<.01). Our meta-regression (see section *A Meta-analytic Integration of Cyberchondria Operationalized by the CSS*) regarding the association between the CSS subscale *reassurance* and HA yielded a strong correlation (β=.44; P<.001). Eastin and Guinsler [92] investigated the moderating role of HA in this process. HA was operationalized by the Health Anxiety Questionnaire [93], health-related internet use by its frequency, and health care use because of health-related internet use by the frequency of physician consultations and the number of different physician visits. Regression analysis confirmed a significant interaction, indicating that as HA increases, the relationship between the frequency of health-related internet use and health care use increases. Furthermore, individuals with high HA (Illness Attitude Scale≥47 [41]) considered dysfunctional behavior (eg, physician hopping and ordering nonprescribed medication on the web) to be more likely because of health-related internet use [36]. In terms of the Cyberchondria model proposed by Brown et al [26], these results might indicate that individuals with normal levels of HA are better able to correctly judge the seriousness of the threat originating from health-related internet use and decide whether a physician consultation is necessary. Interestingly, it seems as if the use of physical health care plays a more important role compared with mental health care use. Using structural equation modeling, the CSS subscale *reassurance* showed a stronger association with the use of physical health care (β=.70) than with mental health care (β=.50) over the past 60 days [64]. In addition, the subscale *excessiveness* was negatively associated with mental health care use (β=–.49*;* P<.001), indicating that individuals who repeatedly engage in health-related internet use report less use of mental health care.

Effects of Health-Related Internet Use: Quality of Life and Functional Impairment

In an extension of the *compulsion* subfacet of cyberchondria [17], which reflects different ways in which health-related internet use can interrupt other web-based and offline activities, it was hypothesized that cyberchondria might lead to significant impairment in psychosocial functioning.

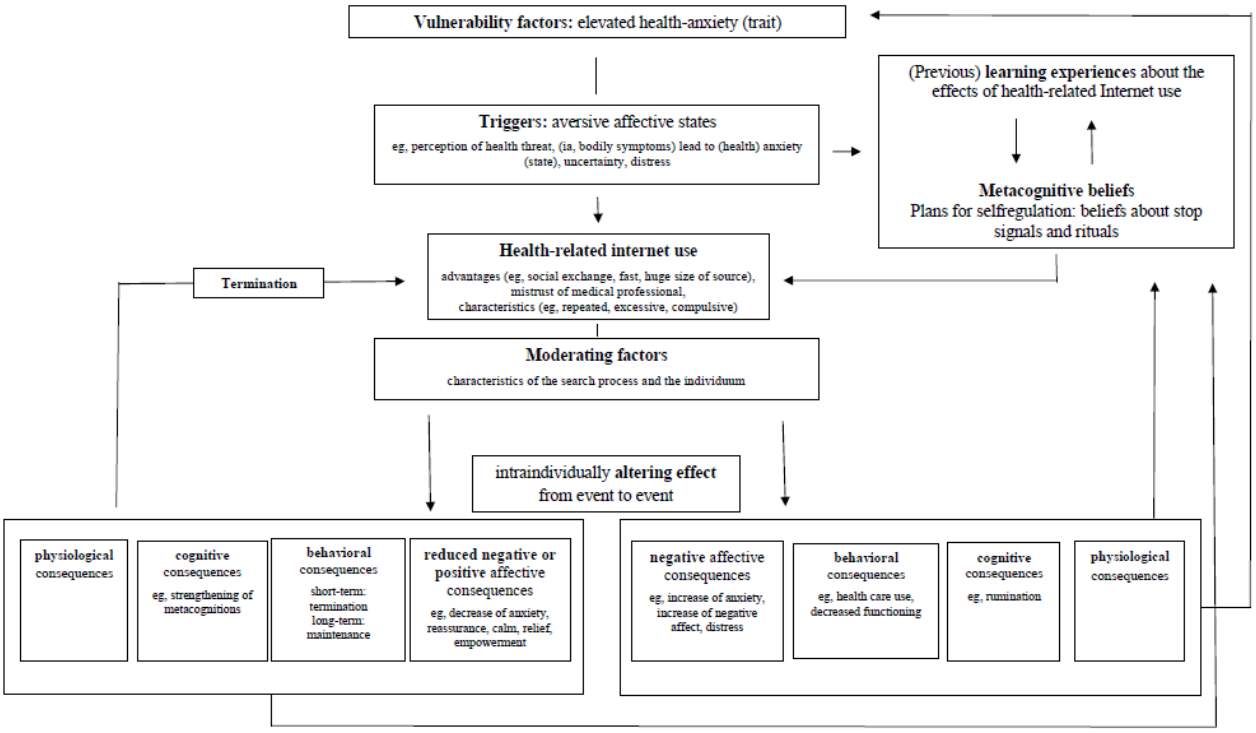
In line with this, it was found that cyberchondria was strongly associated with greater functional impairment even when controlling for the effects of HA (operationalized by the SHAI [68]) [64]. Functional impairment was defined as one's ability to engage in daily activities, operationalized using the Sheehan Disability Scale [94]. Interestingly, when accounting for HA, CSS was not associated with decreased quality of life, which was operationalized as one's overall level of contentment and satisfaction regarding 4 domains: physical and psychological health, social relationships, and environment (World Health Organization Quality of Life Assessment [95]). These results might indicate that individuals with cyberchondria may be satisfied with their lives, although they feel functionally impaired by their cyberchondria-specific behavior.

Discussion

Principal Findings

The aims of this work were to (1) give an overview of existing conceptualizations of cyberchondria and its relation to anxiety-related pathologies, (2) quantify its association with HA, and (3) highlight gaps in the current literature. In an attempt to summarize and reconcile the partly contradictory models and findings, an integrative hypothetical cognitive-behavioral model of cyberchondria as a health-related safety behavior that is maintained through intermittent reinforcement was developed (aim 4; Figure 5).

Figure 5. Hypothetical cognitive-behavioral model of cyberchondria as a health-related safety behavior maintained through intermittent reinforcement.



Previous conceptualizations of cyberchondria proposed that health-related internet use should be divided into *cyberchondria* and *classic safety behavior* based on its (emotional) impact. However, in the context of pathological HA, there is no evidence that health-related internet use followed by negative emotional consequences is conceptually different from health-related internet use followed by positive ones. This distinction marks the crucial point regarding the incompatibility of definitions and the integration of existing findings on emotional consequences. Regarding elevated levels of HA, we, therefore, propose the conceptualization of cyberchondria as a classic health-related safety behavior that is maintained by intermittent reinforcement. In addition, following Brown et al [26], we recommend not to use the term *cyberchondri*a any longer, inter alia, as this would imply a conceptual distinction between health-related internet use and other health-related safety behaviors. In the following, *cyberchondria* is used only to mark results that were assessed using previous conceptualizations (eg, the CSS). In the following, the components of our model are explicated in detail.

All existing theories suggest that cyberchondria-specific behavior is triggered by emotions that can be summarized as aversive emotional states. A more recent model [26] suggests that the perception of a health threat may be central to initiation. We also share this view in the field of elevated and pathological HA. Confronted with *situations* that are evaluated as threatening to health, highly health-anxious individuals are hypothesized to experience, for example, (health) anxiety, uncertainty, and distress. Such a situation may be, for instance, viewing illness-related materials or even the perception of bodily symptoms. As is known for pathological HA, there is also support for the view that this factor may be relevant. To mention, there are the substantial associations between cyberchondria and health concerns triggered by bodily sensations (as assessed with the Whiteley Index), anxiety sensitivity, and the severity of somatic problems (as seen in the context of chronic pain). However, to our knowledge, no study exists that examines the perception of bodily symptoms as a trigger.

Besides the emotional aspects, the perception of a health threat may have consequences on the cognitive (eg, health concerns) and physiological levels (ie, changes corresponding to the affective state). Regarding the latter point, the process of somatosensory amplification [59] may contribute to the initiation and maintenance of health-related internet use. At the behavioral level, health-related internet use may be conducted to reduce (concordant) negative affect. Interview studies give the first indications that health-related internet use is triggered by a combination of stable and situational factors, supporting the conceptualization of cyberchondria in a cognitive-behavioral model. To our knowledge, no studies have addressed the important question of immediate precursors (especially state HA) in an experimental or naturalistic study design.

The first existing questionnaire-based studies highlighted the relevance of metacognitions regarding cyberchondria-specific behavior. Moreover, the reported results of interview studies contained results that can be integrated into this context (eg, *Information is power*). In terms of content, metacognitions are usually distinguished as positive and negative with distinct functions (initiation vs maintenance of health-related internet use); however, the results are heterogeneous. Therefore, this separation was not included in our model. Following Fergus and Spada [22,31] as well as Brown et al [26], we also propose for the field of elevated and pathological HA that aversive negative affective states activate metacognitive beliefs that may represent plans for self-regulation strategies (namely health-related internet use), rituals, and stop signals that are

conducted to cope with aversive (affective) states. At this point, we expand existing theories by supplementing the interaction between metacognitions and previous learning experiences regarding the (short-term emotional) consequences of health-related internet use. The latter may include the experience that health-related internet use may have altering effects from event to event; that is, that besides negative emotions, positive consequences (eg, relief) can also occur. Therefore, on the one hand, metacognitions may develop from learning experiences (eg, "HIU is useful. At some point, I will feel better"). On the other hand, these metacognitions may influence how negative outcomes of health-related internet uses are processed and contribute to its maintenance.

Health-related internet use seems to have certain advantages compared with other health-related safety behaviors that may make it more likely for health-anxious individuals to select this strategy over others. Besides obvious aspects (ie, anonymity, huge amount of specific information, low costs, and promptness), social contact and exchange seem to be relevant. Regarding mistrust of professionals, partly contradictory results were reported, and the general recommendation of not to include this aspect in the construct of cyberchondria was critically discussed. Brown et al [26] included this factor as previous experiences in their model as a kind of vulnerability factor. We also see sufficient support for this but interpret mistrust in the context of why health-related internet use is selected over other safety behaviors. In addition, it is conceivable that this aspect may be more relevant in samples with pathological levels of HA, given that the relationships between physicians and highly health-anxious patients are often difficult and characterized by dissatisfaction [96].

In addition, numerous results exist regarding the characteristics of health-related internet uses once the vicious circle process is set into motion. The reported findings support the notion that health-related internet use occurs repeatedly and has excessive and compulsive subcomponents. Individuals with higher HA engage in health-related internet use for longer periods and more frequently (Multimedia Appendix 7). Moreover, they are more likely to repeat searches and use numerous sources, as well as to experience that health-related internet use interrupts other activities. Correlational and factor analysis examinations yielded further evidence (especially regarding the positive association between HA and the CSS subfacets, *excessiveness* and *compulsion*). Concerning compulsive elements, further supportive results were found: first, an association between HA and the 6 indicators of addiction to health-related internet use, and second, a strong association between problematic internet use (reflecting behaviors from the fields of compulsion and addiction) and cyberchondria.

Concerning the consequences of health-related internet use, all authors agree that immediately after health-related internet use, both positive emotional consequences (especially reduction of HA), as well as negative ones (increase of HA) can occur. Indeed, the existence of both valences was confirmed even in highly health-anxious individuals. Most previous studies have focused on interindividual differences concerning emotional consequences in cross-sectional study designs. With this approach, the effects of health-related internet use are indirectly assumed to be stable over time within an individual (almost trait-like); however, this has not yet been investigated. Future studies should follow an event-based approach to investigate possible changes in intraindividual effects over time. If individuals experience different effects of health-related internet use, altering from event to event, this may be an indicator of the presented conceptualization.

Previous findings suggest that individuals with higher degrees of anxiety-related pathologies (obsessive-compulsive symptoms, intolerance of uncertainty, and anxiety sensitivity) are more likely to experience cyberchondria, especially negative emotional consequences (Multimedia Appendix 9). Following TePoel et al [81], we hypothesize that an illness-related bias may be of certain relevance regarding the moderating role of emotional outcomes. It was found to occur in highly health-anxious individuals [97,98], as well as in patients with pathological HA [99-101] and describes the tendency to focus on information that confirms their health worries and to ignore information that is contradictory [58]. However, to our knowledge, no study has addressed this bias in the context of cyberchondria. In addition, the characteristics of the medical search session itself seem to influence emotional outcomes. The type of information found may also be relevant (alarming and unfamiliar and *query escalation*), as well as the greater frequency and longer duration that is more likely to produce elevated negative emotional states (Multimedia Appendix 9). The results regarding the moderating role of the perceived trustworthiness of a source are inhomogeneous and therefore not included in the model. We also propose the consequences of health-related internet use on other behavioral components corresponding to the affective outcome, as shown in Figure 5. As the results indicate that bodily symptoms may be a trigger, it seems conceivable that they increase and decrease corresponding to the emotional effects of health-related internet use. Cognitive and physiological consequences need to be further investigated.

We hypothesize that health-related internet use is maintained through intermittent reinforcement (ie, altering valences of effects). For the positive valence effects, we propose two possible ways of maintenance. First, through negative reinforcement, that is, in consequence of health-related internet use, aversive states may be reduced, such as the perceived health threat, concordant negative feelings (eg, HA), or aversive physiological (anxiety) symptoms. Second, through positive reinforcement, positive valence emotions may occur (eg, reassurance, relief, calm, empowerment, and increased sense of control). Regarding negative valence consequences, the above-described metacognitive beliefs ("Some time or other, I will feel better") may maintain health-related internet use besides its negative effects. In addition, it seems conceivable that amplification of aversive states may retrigger self-regulative behavior (ie, health-related internet use).

Strengths and Limitations

The strengths of this review include the updated systematic research strategy based on the PRISMA guidelines and the focus on the models underlying the studies. All potentially eligible studies were assessed for inclusion. The meta-analyses make

an important contribution to this field by aggregating the results of numerous studies and quantifying the association between cyberchondria and HA. The development of a hypothetical CBT model for elevated and pathological HA provides further starting points for future research and treatment. There were also limitations of the review. Although trying to make the literature search as inclusive as possible, the exclusion criteria may have resulted in the omission of relevant studies. Potential papers not written in English or German or those investigating children and adolescents were excluded, which may have resulted in linguistic, cultural, or age bias. Moreover, the generalizability of the meta-analytic results to the level of constructs is restricted: first, because of the inclusion of relatively few studies and the operationalization of cyberchondria and HA, and second, because samples were mainly recruited via the internet. This may lead to an artificially heightened homogeneity of samples, which restricts the search for moderators.

Conclusions

Cyberchondria-specific behaviors appear distinct from but strongly related to HA, intolerance of uncertainty, obsessive-compulsive symptoms, and anxiety sensitivity. Numerous findings support the dominant conceptualization of cyberchondria by Starcevic and Berle [14], which postulates a bidirectional relationship between health-related internet use and HA. However, no clear evidence exists for the key elements of previous definitions regarding the conceptual differentiation of cyberchondria as a classic safety behavior based on its emotional consequences. Future research needs to further investigate the immediate emotional consequences of health-related internet use, especially in individuals with pathological HA on an interindividual level, using experimental and naturalistic longitudinal study designs. Additional variables besides HA (eg, feelings of uncertainty) have to be taken into account when examining the mechanisms of initiation and maintenance that are mediated by the immediate effects of health-related internet use.

Abstract

Background: The representation of migraine in the media is stereotypical. Standard images of migraine attacks display stylish young women holding their head in a pain pose. This representation may contribute to the social stigmatization of patients with migraine.

Objective: We aimed to analyze how patients with migraine and health care workers perceive online images of migraine.

Methods: The study consisted of an anonymous web-based survey of patients with migraine at the Headache Center of Charité – Universitätsmedizin Berlin (migraine group) and employees and students at our university (health care group). A total of 10 frequently used Adobe Stock photos of migraine attacks were presented to the participants. Each photo was rated on a scale of 0% to 100% based on how closely it resembled a realistic migraine attack (realism score). Patients with migraine also indicated how much each photo corresponded to their own experience of migraine as a percentage (representation score). We calculated the mean realism and representation scores for all photos and conducted further analyses using the categories male or female models, younger or older models, and unilateral or bilateral pain pose.

Results: A total of 367 patients with migraine and 331 health care employees and students completed the survey. In both groups, the mean realism score was <50% (migraine group: 47.8%, SD 18.3%; health care group: 46.0%, SD 16.2%). Patients with migraine identified their own migraine experience in these photos to a lesser degree (mean representation score 44.4%, SD 19.8%; P<.001 when compared to the realism score). Patients and health care workers considered photos with male models to be more realistic than photos with females (P<.001) and photos with older models to be more realistic than those with younger people (P<.001). In the health care group only, a bilateral pain posture was deemed more realistic than a unilateral pose (P<.001).

Conclusions: Standard images of migraine attacks are considered only slightly or moderately realistic by patients and health care workers. Some characteristics perceived as more realistic such as male sex or older age are in contrast with migraine epidemiology. A more accurate representation of migraine in the media could help to raise awareness for migraine and reduce the associated stigma.

(J Med Internet Res 2021;23(11):e32707) doi:10.2196/32707

Introduction

Migraine is one of the most common neurological diseases, with a prevalence of 15% in the general population and rising to over 25% in women of childbearing age [1-3]. Migraine causes significant limitations in quality of life and functioning [4]. It is the second most common cause of health impairment among nonfatal diseases worldwide, as shown by the years lived with disability measure [4]. Among individuals aged 15 and 49 years, migraine ranks first among the most disabling of diseases [5].

Despite the substantial impact on patients' lives, migraine burden is often underestimated [6]. Many patients feel that their symptoms are dismissed as insignificant [7,8]. Platitudes such as "everybody has headaches" or "it's just stress" are omnipresent in the lives of patients with migraine [7,8]. In a survey by Buse et al [9] , almost half of patients with chronic migraine had the impression that their partner did not believe in their disease. The invisibility of migraine can lead to frustration and stigmatization [7]. Out of fear of being doubted, some patients even hide their symptoms and do not seek treatment, which in turn can have a negative impact on the course of the disease [10,11].

The lack of acceptance of migraine as a real disease has historical roots. Until recently, patients with migraine were portrayed as frail women with weak nerves [12]. Although this representation originates from a cultural background different from the present times, these stereotypes continue to shape the common view of patients with this disease [12].

Currently, digital media, and especially the internet, have become an important source of information on health topics [13]. Portrayals of people with migraine in the media can provide an overview on how society currently sees these patients [14]. Most images resulting from the search term "migraine" show slim and stylish young women holding their temples with an expression of pain on their faces [14]. This trivializing and one-sided portrayal could contribute to the insufficient recognition of migraine-related burden and the growth of social stigma [14].

While this stereotypical representation has already raised concerns among experts [14], no study has assessed how the public perceives such images of migraine. In this study, we aimed to investigate the following questions: (1) do patients with migraine and nonaffected health care workers perceive such photos as realistic? and (2) can patients with migraine relate to these portrayals?

Methods

Study Design

This anonymous web-based survey was performed on the REDCap (Research Electronic Data Capture) platform. The link to participate in the survey was distributed among the following two groups:

1. The migraine group: patients at the Headache Center, Charité – Universitätsmedizin Berlin, with a diagnosis of migraine in 2020 per International Classification of Headache Disorders–3 (ICHD-3) criteria [15];
2. The health care group: employees and students at the medical school of Charité – Universitätsmedizin Berlin without migraine.

Patients with migraine received the link to participate via a letter in order to comply with data protection law, while the health care group was invited via email distribution lists and social media groups.

The survey structure is illustrated in Table 1. After the assessment of demographic, occupational, and migraine characteristics, 10 different photos of migraine attacks were presented to the participants on the screen. The participants were instructed to rate on a scale between 0% and 100% how much each picture corresponded to a realistic migraine attack. We defined this percentage value as the realism score. Patients with migraine then indicated how closely each image resembled their own migraine experience on the same 0%-to-100% scale. This score was named the representation score.

Table 1. Structure of the survey.

Section	Description
Study information	Written information about the study design and aim, as well as the data protection statement agreement. Subjects could download the study information to keep for their records.
Written consent form	In order to access the other questionnaires, participants must confirm that they are ≥18 years of age, that they are voluntarily participating in the survey, and that they agree to the publication of the study results in an anonymous form. Participants could download a consent form to keep for their records.
Demographic characteristics	Participants are asked about their gender, age, ethnic background, height, weight, and highest level of education.
Migraine information	Participants are asked whether they experienced migraine, if they have close family members or friends with migraine, and how they assess the impairment caused by migraine in the general population and in their own migraine experience (on a numerical analog scale from 0% to 100%).
Occupational characteristics	Participants are asked whether they work or study at the Charité – Universitätsmedizin Berlin, in which field, and if they have regular contact with patients with migraine at work.
Photos 1-10	Participants are asked to look at 10 photos of migraine attacks and rate how realistic each photo is. Patients with migraine are also asked how representative of their own migraine experience these photos are.

The photos with models were obtained from the stock photo website Adobe Stock (Adobe Inc) [16]. We purchased a commercial license for the use of the 10 photos in the survey. Image selection was based on the following criteria:

- Result of the search term "migraine";
- Sorting by the number of times the photos were downloaded;
- 7 females and 3 males (to match the epidemiological sex distribution of migraine);
- Only 1 person in the photo;
- No black-and-white images;
- No heavy editing or heavy filters and effects;
- Face is visible;
- Only 1 photo of each model;
- Person in the foreground (ie, the background does not take more than half of the image).

Outcomes and Objective

The primary outcomes of the study were the mean realism score for all photos in both groups and the mean representation score for all photos in patients with migraine.

The secondary outcomes were the mean realism and representation scores for the following categories of photos:

- Photos with female models (n=7);
- Photos with male models (n=3);
- Photos with a unilateral pain posture (ie, models holding one side of the head, n=6);
- Photos with a bilateral pain posture (ie, models holding both sides of the head, n=3);
- Photos with younger models (n=5);
- Photos with older models (n=4).

The allocation of the photos into each category was agreed upon unanimously by all authors of this paper. To differentiate between younger and older models, we focused on physical characteristics such as face wrinkles or hair color (ie, white or gray).

Statistical Analysis

The analysis comprises all participants who rated all 10 photos. Employees or students with self-reported migraine were excluded from the health care group.

Demographic and occupational characteristics, as well as realism and representation scores, were summarized with descriptive statistics (absolute frequencies and percentages for categorical variables and mean (SD) values for numerical variables).

We compared the primary and secondary outcome measures between the migraine and health care groups using independent *t* tests. The realism and representation scores were compared within the migraine group using paired-sample *t* tests.

We further assessed the correlation of the primary and secondary outcomes with sex, age, ethnicity, highest level of education, and occurrence of migraine among family and friends using Pearson correlation analyses. A 2-tailed *P* value ≤.05 was considered statistically significant. *P* values were corrected for multiple comparisons with the Bonferroni method.

Ethics Approval and Consent to Participate

The study was approved by the ethics committee of the Charité – Universitätsmedizin Berlin (EA1/213/20). Participants were required to provide electronic consent prior to completing the survey.

Results

Population

Between October 27, 2020, and January 15, 2021, 367 patients with migraine and 331 Charité employees and medical students completed the survey. The participant selection process is illustrated in Figure 1.

The majority of patients were female (n=318, 86.6%), with an average age of 45.3 (SD 12.7) years. Participants in the health care group were younger (mean 32.1, SD 11.1 years), but their gender and ethnic distribution was similar to that of the migraine group (Table 2).

Figure 1. Flowchart of participant selection in both groups.

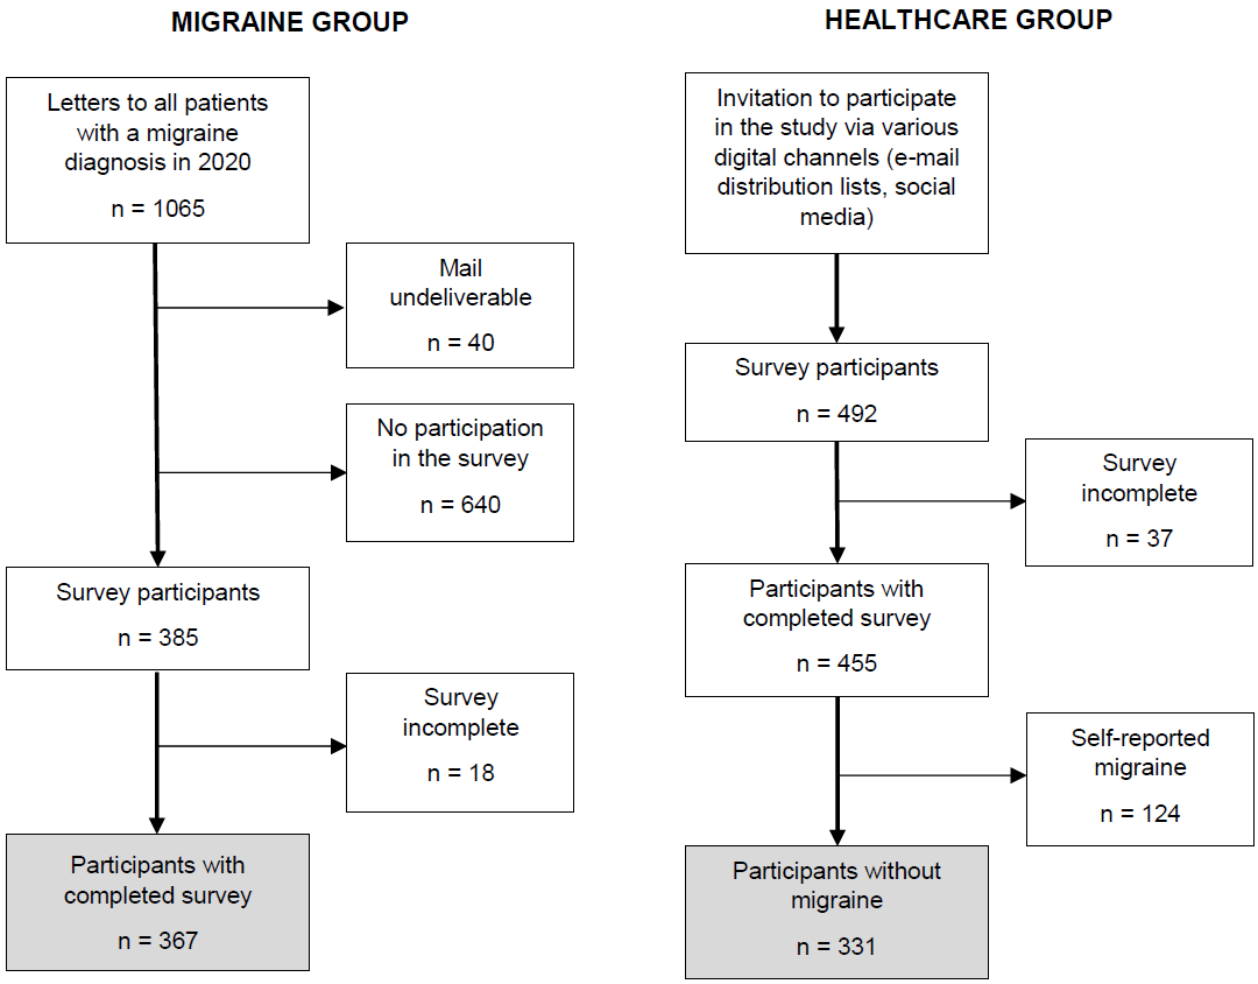

Table 2. Demographic and occupational characteristics of the survey participants.

Characteristic	Migraine group	Health care group
Age (years), mean (SD)	45.3 (12.7)	32.1 (11.1)
Female sex, n (%)	318 (86.6)	245 (73.9)
Northern or Central European descent, n (%)	314 (85.6)	283 (85.6)
Height (cm), mean (SD)	168.9 (8.1)	171.5 (9.7)
Weight (kg), mean (SD)	69.4 (14.6)	68.3 (13.3)
Highest level of education, n (%)		
University degree	154 (42.1)	118 (35.6)
High school diploma	63 (17.2)	155 (46.8)
Technical baccalaureate	29 (7.9)	8 (2.4)
Apprenticeship	60 (16.4)	20 (6.0)
Intermediate secondary school diploma (Realschulabschluss)	38 (10.4)	13 (3.9)
General secondary school diploma (Hauptschlussabschluss)	4 (1.1)	2 (0.6)
Other	19 (4.9)	15 (4.5)
Close friends or family members with migraine, n (%)	196 (53.4)	104 (31.4)
Health care workers' occupation, n (%)	—[a]	167 (50.5)
Physician	—	42 (25.1)
Nurse	—	33 (19.8)
Other medical professionals	—	27 (16.2)
Other nonmedical professionals	—	65 (38.9)
Health care students' study subject, n (%)	—	164 (49.5)
Human medicine	—	122 (74.4)
Dentistry	—	11 (6.7)
Other	—	31 (18.9)
Regular professional contact with patients with migraine, n (%)	—	68 (20.5)

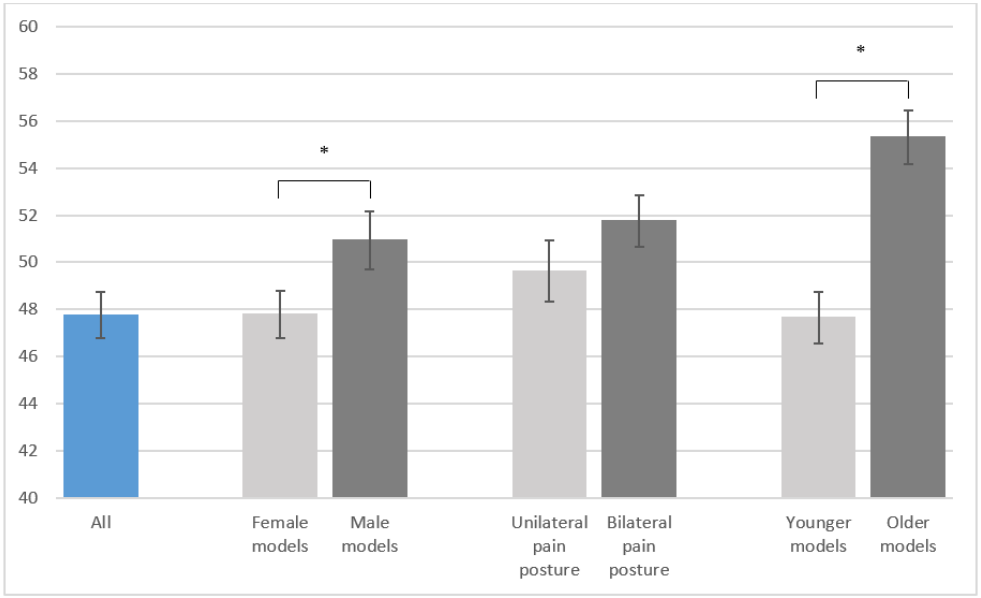
[a]Not applicable.

Patients With Migraine

Realism Scores

Among patients with migraine, the mean realism score for the 10 photos was 47.8% (SD 18.3%). Only 3 out of 10 photos had a mean realism score >50%. Photos with male models were considered more realistic than photos with female models (mean 51.0%, SD 22.4% vs mean 47.8%, SD 18.3%; *P*=.002). Patients rated images with older models as more realistic than those with younger models (mean 55.3%, SD 21.0% vs mean 47.7%, SD 20.1%; *P*<.001). Photos with unilateral and bilateral pain postures had similar realism scores (*P*>.99, Figure 2).

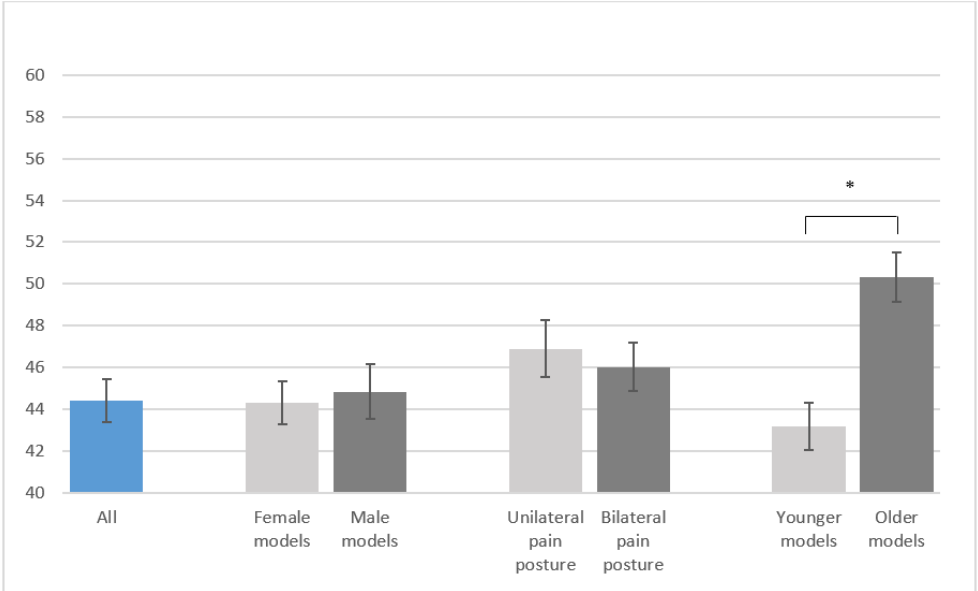
Figure 2. Realism scores of patients with migraine for all photos and different categories. Values are mean (SD), and the asterisk indicates *P*<.001.



Representation Scores

When asked how much the images corresponded to their own experience of migraine, the patients answered with a mean representation score of 44.4% (SD 19.8%). Photos with older models were considered more representative than photos with younger models (mean 50.3%, SD 22.7% vs mean 43.2%, SD 21.9%; *P*<.001). The gender of the models did not lead to significant rating differences in the representation score (*P*>.99). Photos with a unilateral pain posture had similar scores as did photos with a bilateral pain posture (*P*>.99, Figure 3).

Figure 3. Representation scores of patients with migraine for all photos and different categories. Values are mean (SD), and the asterisk indicates *P*<.001.



The mean representation score for all photos and in each category was significantly lower than the corresponding realism score (*P*<.001 for all categories).

There was a negative correlation between the highest level of education and both realism and representation scores: the higher the degree, the less realistic (*P*<.001, *r*=0.26) and representative (*P*<.001, *r*=0.29) the images were rated in all categories. Further analyses revealed a positive correlation between the patients' age and the realism (*P*=.047, *r*=0.11) and representation scores (*P*=.04, *r*=0.12) of images with older models. There was no correlation with the gender or ethnicity or with the occurrence of migraine among close friends or family members.

Health Care Workers and Students

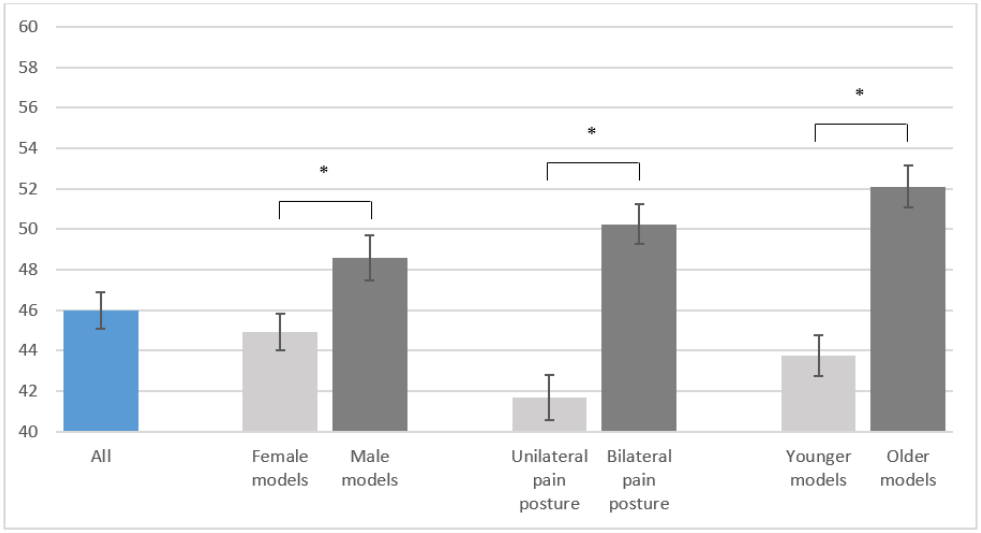
Realism Scores

In the health care group, the 10 photos had a mean realism score of 46.0% (SD 16.2%). Similar to the migraine group, only 3 photos were rated as >50% for realism. Photos with male models received higher scores than photos with female models (mean 48.6%, SD 20.2% vs mean 44.9%, SD 16.4%; *P*<.001). A bilateral pain posture was considered more realistic than a

unilateral pain posture (mean 50.2%, SD 18.1% vs mean 41.7%, SD 20.0%; *P*<.001). Photos with older models were rated higher than photos with younger models (mean 52.1%, SD 18.8% vs mean 43.8%, SD 18.3%; *P*<.001). Figure 4 shows the mean realism scores in the different categories.

There was no correlation to the gender, ethnicity, or age of the participant nor to regular contact with people with migraine (*P*>.99). Further, we detected a negative correlation with the highest level of education in this group (*P*=.004, *r*=0.16).

Figure 4. Realism scores of health care workers and students for all photos and different categories. Values are mean (SD), and the asterisk indicates *P*<.001.



Comparison Between Patients With Migraine and Health Care Workers and Students

Patients with migraine rated photos with a unilateral pain posture as significantly more realistic than the health care group (*P*<.001). Overall, the mean realism score for all photos did not differ between the two groups (*P*=.23). Both groups rated photos with male and older models as more realistic than photos with female and younger models. The mean realism scores for photos with females (*P*=.20), males (*P*>.99), younger models (*P*=.14), and older models (*P*=.53) were similar between groups.

Discussion

Patients with migraine and health care workers perceived commonly used stock photos of migraine attacks as slightly or moderately realistic. Patients identified their own migraine experience in these photos to an even lesser degree. Both groups rated photos with male and older models as more realistic than photos with female or younger ones. Among health care workers, a bilateral pain representation was considered more realistic than a unilateral pose.

The differences between media-based representations and the clinical reality have been described by Gvantseladze et al [14]. An analysis of the top 200 images under the search term “migraine” in 2 popular image-searching websites revealed that the majority of these images represented slim White females in a classic pain pose holding one or both temples [14]. The authors argued that this overrepresentation of ectomorph body types and stereotypical pain behaviors may contribute to the social stigmatization of patients with migraine [14]. Our results confirmed that not only experts but also patients doubt the realism of these images. In line with these findings, the Coalition for Headache and Migraine Patients (CHAMP) stated that media representation is often unrealistic and unlikely to display the severity of migraine [17]. The difference between the standard migraine representation and actual migraine behavior may result in the minimization of symptoms and misunderstanding of people living with this disease.

Such an example was illustrated by a social media trend from 2018, in which models and influencers published photos of themselves in the so-called “migraine pose,” touching one side of their face [18]. The fashion magazine *Elle USA* stated that this “flattering” pose “tightens the face, makes your cheekbones look more prominent, and lifts the brows” [18]. The use of the term migraine to name a glamorous pose indicates a lack of public acceptance for migraine as an extremely burdening condition. In line with the CHAMP Image Guide [17], our results support the need for a more accurate portrayal of migraine attacks. A better representation could include migraine symptoms other than headache, such as photophobia, nausea, or cognitive impairment [17]. A more diverse depiction could also help to move away from the classic temporal headache as the only accepted form of migraine pain. For example, a large proportion of migraine patients also have neck pain during attacks [19], which is almost never displayed as a feature of migraine [20].

Hospital employees and medical students shared the patients’ critical view of these images. This selected population was able to recognize that this stereotypical representation does not substantially correspond to reality. A more realistic representation of migraine attacks could also have a positive impact on patients’ treatment. The process toward effective migraine therapy is often lengthy and difficult [10]. The inaccurate, yet commonly accepted, representation of attacks could lead to a delay in the recognition and diagnosis of migraine, if patients experiencing an attack do not resemble

these common depictions [10]. Giving visibility to migraine in all its facets could therefore alleviate not only social stigmatization but also the therapeutic burden.

Migraine patients and the health care group rated the laterality of the headache pose differently. A unilateral representation was perceived as more realistic by the patients. Unilaterality is one of the key migraine characteristics according to the ICHD-3 but is not a mandatory criterion for migraine diagnosis [15]. Bilateral pain occurs frequently and, in older patients, it is even more common than strict unilateral attacks [21]. Patients with migraine at a tertiary headache center like ours might be better educated about the typical characteristics of migraine and therefore rate unilaterality as a more realistic migraine feature than the nonaffected group.

Migraine prevalence is 3 times higher in women than in men [3]. However, photos with male models were considered significantly more realistic than those with female models in this analysis, regardless of the rater's gender. This observation fits in well with the literature on gender bias, according to which pain disorders in women are taken less seriously than in men [22,23]. Pain expressions of females with chronic pain are underestimated compared to males, and women's pain is considered less severe [24]. In the health care system, women are less likely to receive pain medication than men [25]. On the contrary, psychosocial treatments are more often recommended to female patients experiencing pain [26]. Women with pain diseases are frequently met with skepticism and have to struggle to be believed, which might lead to shame and frustration [27]. If the woman is physically attractive, the credibility of her pain is even lower, which might be applicable to our photo models [28].

Similar considerations may apply to younger patients, especially if female. Young people with pain are often perceived as less ill, based on their healthy physical appearance [29]. This might explain why photos with older models were perceived as more realistic in our survey. This is in contrast with the epidemiology of migraine, which shows a prevalence peak during young adulthood [30].

Finally, our analysis showed that less educated people rated migraine stock images as more realistic than participants with a high level of education. People with a lower education are more likely to be influenced by the media [31,32]. Therefore, it is possible that they are accustomed to this type of migraine representation and do not question its realism. This high receptivity to the media could be useful for educational programs and campaigns to raise awareness for migraine and convey a more accurate and realistic representation.

This is the first study to analyze the perception of commonly used migraine images in a large cohort of patients with migraine and health care workers. Patients with migraine were selected directly from our Headache Center, which ensured a correct diagnosis. Due to data protection regulations, patients could not be contacted by email or telephone. Given that the only possible way to contact the patient was via mail, the response rate of over 30% is within the normal range of response.

A limitation of the study is that participants completed the survey anonymously online without supervision, which might have a negative impact on data reliability. Some biases may have affected our findings: people with a pre-existing awareness of this topic might have participated to a higher extent in the survey; this applies to younger people who are frequent users of the internet as well. We also divided the photos in six categories, but not all image characteristics were taken into account. For example, the outfit of the models, the surrounding environment, or the severity of the expression of pain were not considered and may represent confounding factors. In addition, only health care workers and students were enrolled in the comparison group, which might not be entirely representative of the general population. The extension of the survey to other members of the public might provide further insights on the perception of migraine.

To conclude, the media representation of migraine was considered at best moderately realistic in our large cohort of patients with migraine and health care workers. The rating of male and older models as more realistic contradicts migraine epidemiology. A more truthful representation of migraine is needed in order to raise awareness of the burden of this disease and to reduce migraine-related social stigma.

Abstract

Background: Communicating official public health information about infectious diseases is complicated by the fact that individuals receive much of their information from their social contacts, either via interpersonal interaction or social media, which can be prone to bias and misconception.

Objective: This study aims to evaluate the effect of public health campaigns and the effect of socially communicated health information on learning about diseases simultaneously. Although extant literature addresses the effect of one source of information (official or social) or the other, it has not addressed the simultaneous interaction of official information (OI) and social information (SI) in an experimental setting.

Methods: We used a series of experiments that exposed participants to both OI and structured SI about the symptoms and spread of hepatitis C over a series of 10 rounds of computer-based interactions. Participants were randomly assigned to receive a high, low, or control intensity of OI and to receive accurate or inaccurate SI about the disease.

Results: A total of 195 participants consented to participate in the study. Of these respondents, 186 had complete responses across all ten experimental rounds, which corresponds to a 4.6% (9/195) nonresponse rate. The OI high intensity treatment increases learning over the control condition for all symptom and contagion questions when individuals have lower levels of baseline knowledge (all P values ≤.04). The accurate SI condition increased learning across experimental rounds over the inaccurate condition (all P values ≤.01). We find limited evidence of an interaction between official and SI about infectious diseases.

Conclusions: This project demonstrates that exposure to official public health information increases individuals' knowledge of the spread and symptoms of a disease. Socially shared information also facilitates the learning of accurate and inaccurate information, though to a lesser extent than exposure to OI. Although the effect of OI persists, preliminary results suggest that it can be degraded by persistent contradictory SI over time.

disease; social information; official information; network experiments

Introduction

During a contagious disease outbreak, public health campaigns provide people with relevant information, including symptoms and methods of transmission. The public's understanding is critical for people to know which behaviors they should avoid and whether they should seek medical attention. To this end, public health campaigns are led by federal, state, local, and other organizations, which we refer to as *official* sources of information. However, many people may not directly encounter these campaigns and instead rely on information provided by social contacts, perhaps via social media. Rumors [1], lack of understanding [2], mis and disinformation campaigns [3], and motivated reasoning [4], among other factors, may inhibit understanding of the disease and contribute to a disconnect between accurate official information (OI) and inaccurate socially shared information. Furthermore, the spread of inaccurate information may have important downstream effects beyond the impact of the disease itself, such as on mental health [5].

Public health campaigns have been shown to be broadly effective. A recent examination of the COVID-19 pandemic in Italy found that most survey respondents knew of and believed in OI related to the disease [6]. This is particularly important, because in many ways socially shared misinformation about the disease was spreading more quickly than the disease itself [7]. In addition, experimental work demonstrates that individuals become more trusting of scientific experts and political actors with relevant expertise when encountering anxiety inducing external threats, such as H1N1 [8]. However, in addition to OI from the government and relevant policy actors, public health researchers have long recognized that people receive information from other sources, including media and friends, and that effective campaigns integrate these strategies [9]. A key challenge is understanding the impact that campaigns may have not only through direct exposure but also via social interactions and the sharing of disease-related information via social media.

People often rely on information from others to inform their own beliefs, attitudes, and behaviors related to health [10,11]. Studies have shown the importance of social networks in predicting health-related behaviors [12,13]. However, previous studies have not addressed the relative impact of socially transmitted information with respect to officially communicated public health information [see 14,15]. Specifically, van der Meer and Jin [14] studied the effectiveness of corrections to misinformation about infectious diseases coming from government health agencies, the news media, and social peers and found that government health agencies and the news media are more successful in combating misinformation about the disease than social peers. Similarly, Vraga and Bode [15] also looked at the effectiveness of corrections coming from the Centers for Disease Control and Prevention (CDC) or a social peer and found that the CDC is more effective in reducing misperceptions. Thus, engineers of public health interventions have little knowledge of how messages interact with socially spreading information. To address this, we used an experiment to causally test the hypothesis that health-related beliefs are socially influenced by the beliefs that others share with them in their social networks.

There is reason to believe that official, accurate health information is in competition with socially circulating inaccurate information. Rumors and misinformation are likely to spread across many domains [16]; research has shown this during recent infectious disease outbreaks, including HIV [17], H1N1 influenza [18], severe acute respiratory syndrome [19], the 2014-2015 Ebola outbreaks [20], the Zika epidemic [21], and the COVID-19 pandemic [7]. This information may be inaccurate and misinform the public or inhibit reliance on OI. Examining how these two information sources interact provides a deeper understanding of how the information environment leads to beliefs about an infectious disease.

This paper examines the interaction between official and social information (SI) about the disease. We use the term *social information* throughout, although we acknowledge that socially shared information differs from OI in many ways and that SI may be best understood as socially shared beliefs. To what extent does accurate, official public health information contribute to the learning of disease symptoms and transmission? To what extent does socially shared information magnify or inhibit learning? We used evidence from a randomized trial in a simulated network environment to shed light on these questions. In particular, we tested the hypotheses that participants who view relevant OI and those who view accurate SI will answer knowledge questions correctly more frequently than those with other informational experiences. We also examined whether these 2 effects reinforce each other. Finally, we tested the hypothesis that a positive teaching effect from a single viewing of OI can fade over time among those exposed to persistently inaccurate SI.

Theory and Expectations

Individuals' psychological dispositions interact with information from the external environment when making decisions [22]. However, individuals receive information from numerous sources. Individuals can receive information directly from the media, but most individuals are more likely to receive mediated information from opinion leaders in their social networks [23]. In today's digital age, this *social communication* frequently comes via the internet, including social networking sites. On the internet, owing to the ease of digital publishing, everyone has the ability to become an opinion leader [24]. Individuals are then tasked with determining which information is correct or incorrect and whether and how to update their beliefs based on the information they consume.

Public health information from official sources, where official sources include public health agencies such as the CDC and the World Health Organization (WHO), is likely to be accepted as factual by the public [15]. This is primarily because the public views these sources as credible, conveying both trustworthiness and expertise [14]. Specifically, work in public health demonstrates that government health agencies and news media organizations are viewed as more credible and are more successful than social peers in increasing perceptions of the severity of a public health crisis [14].

Although research has consistently found that individuals accept and view information from official sources as credible, the reality that individuals receive much of their information from social sources makes the overall information environment more challenging to navigate. Information from the social environment can contain correct, factual information about a disease, such as repetition of information shared by the CDC or WHO, or it can be misleading or even completely false. During the 2018 Ebola outbreak, for example, inaccurate socially supplied information about the disease was widespread, and individuals who believed in the misinformation were less likely to adopt preventative behaviors such as agreeing to be vaccinated and seeking formal care [25]. Still, SI can also be helpful in correcting misinformation, though to a lesser extent than information shared from official sources [14,15,26]. Given the complex nature of the information environments that people encounter, it is critical to understand how people reconcile official and SI, especially when it conflicts.

Several other features of the information environments that people encounter may affect how they process the messages they encounter. First, communication environments, particularly social media, are often dynamic in that there may be repeated interactions between users over time, and the use and effects of social media can be reciprocal [27]. In such situations, the effects of exposure to initial messages may degrade or be reinforced through repeated or subsequent interactions [28]. Therefore, understanding how conflicting social and OI signals affect people's attitudes over multiple interactions may provide a more nuanced understanding of how conflicting sources of information are processed.

In addition to being dynamic in time, communication on social media is often multidimensional even when it is limited to one overarching topic. For example, in the context of an infectious disease, two highly important dimensions of understanding the disease are the symptoms of the disease, so that a person may observe if they or others around them are likely to have contracted the disease, and how it spreads, so they know which actions are relatively risky or relatively safe in the context of the disease. Although it is important to know how people understand particular messages associated with either dimension in isolation, in many instances people process messages with multiple dimensions simultaneously, which may impact the effectiveness of a given message.

One of the primary features of social media is its ability to control self-presentation. Using the affordances of social media sites, users may selectively disclose information they wish their social contacts to know regarding their attitudes or beliefs [29] or may moderate their expressed attitudes because of their perception of the expectations of others [30]. In many instances, these processes are thought of in a research context as examples of social desirability bias, which are limitations of research designs or which research designs attempt to minimize to enable the observation of true attitudes or beliefs. Like many studies, our study cannot distinguish between sincerely and insincerely expressed beliefs. However, it is important to remember that even insincerely expressed attitudes or beliefs that are shared on social media platforms may still be taken at face value by others. Therefore, it is important to understand how attitudes and beliefs are expressed to others when people have the expectation that others will view those attitudes and beliefs. Because of the design of our study, we were able to examine the potential effects of the expression of beliefs, whether they were sincere or not.

Taken together, we expect that OI about a disease, that is, information received directly from official sources, will lead individuals to hold more factual beliefs about the disease. At the same time, socially shared information should lead to learning about disease, though to a lesser extent than OI. Specifically, we expect OI to be more effective in increasing learning about a disease when individuals are also exposed to accurate SI. On the other hand, we expect the effect of OI about a disease to persist but degrade as individuals are exposed to inaccurate SI over time.

Methods

Overview

To examine how official and SI interact in a dynamic information environment, we designed an experiment in which participants were exposed to both OI and structured SI over a series of ten rounds of computer-based interactions. The social connections between people are simulated with *bots* that are programmed to agree or disagree with key pieces of information in each round. These simulated alters allow us to control the social messaging received by each participant.

The research design for this study was reviewed and approved by the institutional review board of The Ohio State University (protocol #2014B0543).

Participants

Participants fluent in German were recruited from a participant research pool of a European university in 2016 and were compensated with a modest monetary incentive. Students signed up to participate in short sessions scheduled during the course of a single week. All students participating in the same session were randomly assigned to the same treatment combination, as described below.

The experiment was conducted using the oTree [31] software. After providing consent, the participants began by answering demographic and opinion questions. Participants were then asked to read a description of the study, which explained that they would be asked questions and claimed that their answers would be shared with other participants (as described below, actual participant responses were not shared with other participants). Specifically, participants were told that they were embedded in a social network with other student participants contemporaneously completing the experiment, that their responses would be shared with other participants, and that they would view the responses of 3 other participants. However, no network was actually created, and participants viewed responses preprogrammed to mimic those observed in a previous set of experiments that involved actual networked interactions.

Outcome Measures

Participants were then asked a battery of 14 true or false knowledge questions about hepatitis C, including six questions

about the modes of transmission and eight about the symptoms. The topic of each question is listed in Table 1, and Multimedia Appendix 1 [32,33] contains the complete knowledge question text.

Our novel 14 question instrument gauges participants' professed knowledge about hepatitis C. We reduce the impact of guessing by providing an uncertain answer, as well as true and false. The correct answers to all of the questions are presented in Table 1. Because participants learned about different topics related to hepatitis C at different times during the experiment (as described below), we did not combine participant responses across questions or across time points. Thus, we considered 14 separate outcome measures of professed knowledge, which correspond to indicators of a correct answer to each knowledge question. We did not distinguish between incorrect and uncertain responses in the analysis. Participant answers to the knowledge questions before exposure to treatments (as described in the *Design and Treatments* section below) provide a baseline to which we compare their future responses to the instrument as solicited throughout and at the end of the experiment.

Table 1. Summary of knowledge questions included in the experimental instrument, including the raw percent of participants who answered each question correctly at baseline, whether the question was subject to different social information, and the experimental round (if any) during which relevant official information was presented to participants in each intensity condition (high, low, and control). Note that infographics viewed by the low official information group were also viewed in the same round by participants in the high official information group.

Question topic	Correct answer	Correct at baseline (n=186), n (%)	Social manipulation	Round presented		
				High	Low	Control
Kissing	False	96 (51.6)	Different across conditions	1[a]	—[b]	—
Loss of appetite	True	81 (43.5)	Different across conditions	3[a]	3[c]	—
Headache	False	44 (23.7)	Different across conditions	—	—	—
Vomiting	True	78 (41.9)	Identical across conditions	3[a]	3[c]	—
Unprotected sex	True	154 (82.8)	Identical across conditions	5[a]	5[c]	—
Fever	True	127 (68.3)	Identical across conditions	7[a]	—	—
Fatigue	True	140 (75.3)	Identical across conditions	7[a]	—	—
Needle sharing	True	179 (96.2)	Identical across conditions	9[a]	9[c]	—
Breastfeeding	False	32 (17.2)	Identical across conditions	—	—	—
Diarrhea	False	35 (18.8)	Identical across conditions	—	—	—
Skin rash	False	43 (23.1)	Identical across conditions	—	—	—
Hair loss	False	83 (44.6)	Identical across conditions	—	—	—
Gym equipment	False	156 (83.9)	Identical across conditions	—	—	—
Tattoo equipment	True	165 (88.7)	Identical across conditions	—	—	—

[a]Official information treatment group.

[b]Not available.

[c]Social information treatment group.

We chose to measure knowledge about hepatitis C because it is a common disease with low public salience. Hepatitis C affects more than 3 million people in the United States (Department of Health and Human Services [34]), 14 million in Europe (WHO [35]), and approximately 71 million people worldwide (WHO [35]). We expected participants to have few entrenched beliefs and to find information about the disease novel. Summaries of the instrument responses reported in Table 1 show a range of baseline knowledge about hepatitis C topics, spanning from only 17.2% (32/186) reporting that hepatitis C is not spread via breastfeeding though an unsurprising 96.2% (179/186) reporting that hepatitis C is spread through sharing needles. The primary outcome measures capture changes in the proportion of correct answers within treatment groups, and the construction of these change score statistics is described in the *Statistical Analysis* section below.

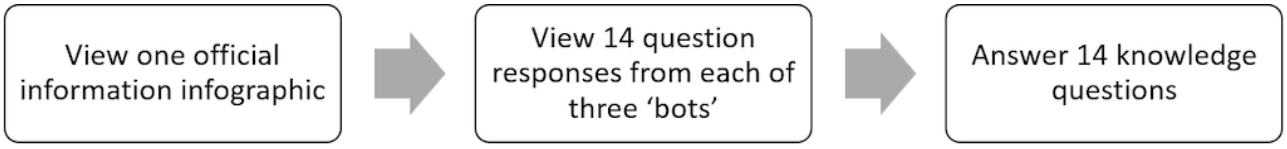
Design and Treatments

Ten experimental rounds were conducted at this point. We outline the overall structure of the rounds before describing how the treatments determine the nature of various components. Each round consisted of 3 parts, as shown in Figure 1. First, participants were exposed to an infographic intended to mimic information from a public health authority (*official* information). Some of this OI was related to knowledge questions about the modes of transmission and the symptoms of hepatitis C, and some were not. The infographics that were viewed in each round were determined by the treatment conditions, as described below (Table 1 for the infographic viewing schedule and question relevance and Multimedia Appendix 1 for the infographics themselves). Second, participants were exposed to ostensible SI from 3 other (purported) participants in the form of the participants' most recent answers to the 14 knowledge questions. A depiction of this SI is provided in Multimedia Appendix 1.

Third, participants were asked to answer the 14 knowledge questions.

We took care to create an environment in which participants believed that the observed SI was actually a response from other participants. First, participants completed the experiment in the same room as many other participants (sometimes participating in a different experiment). Second, our preprogrammed patterns of socially shared information were inspired by a pilot test of the experiment, such that relatively easy questions had more frequent accurate preprogrammed responses. Finally, we included time delays intended to mimic other participants that progressed more slowly. Although this SI does not mirror information shared from *friends*, it does correspond to information shared from casual connections across a social media platform.

Figure 1. Each round of the experiment consists of three parts. First, participants are exposed to official information, then they are exposed to ostensibly social information, and finally they are asked to respond to 14 knowledge questions.

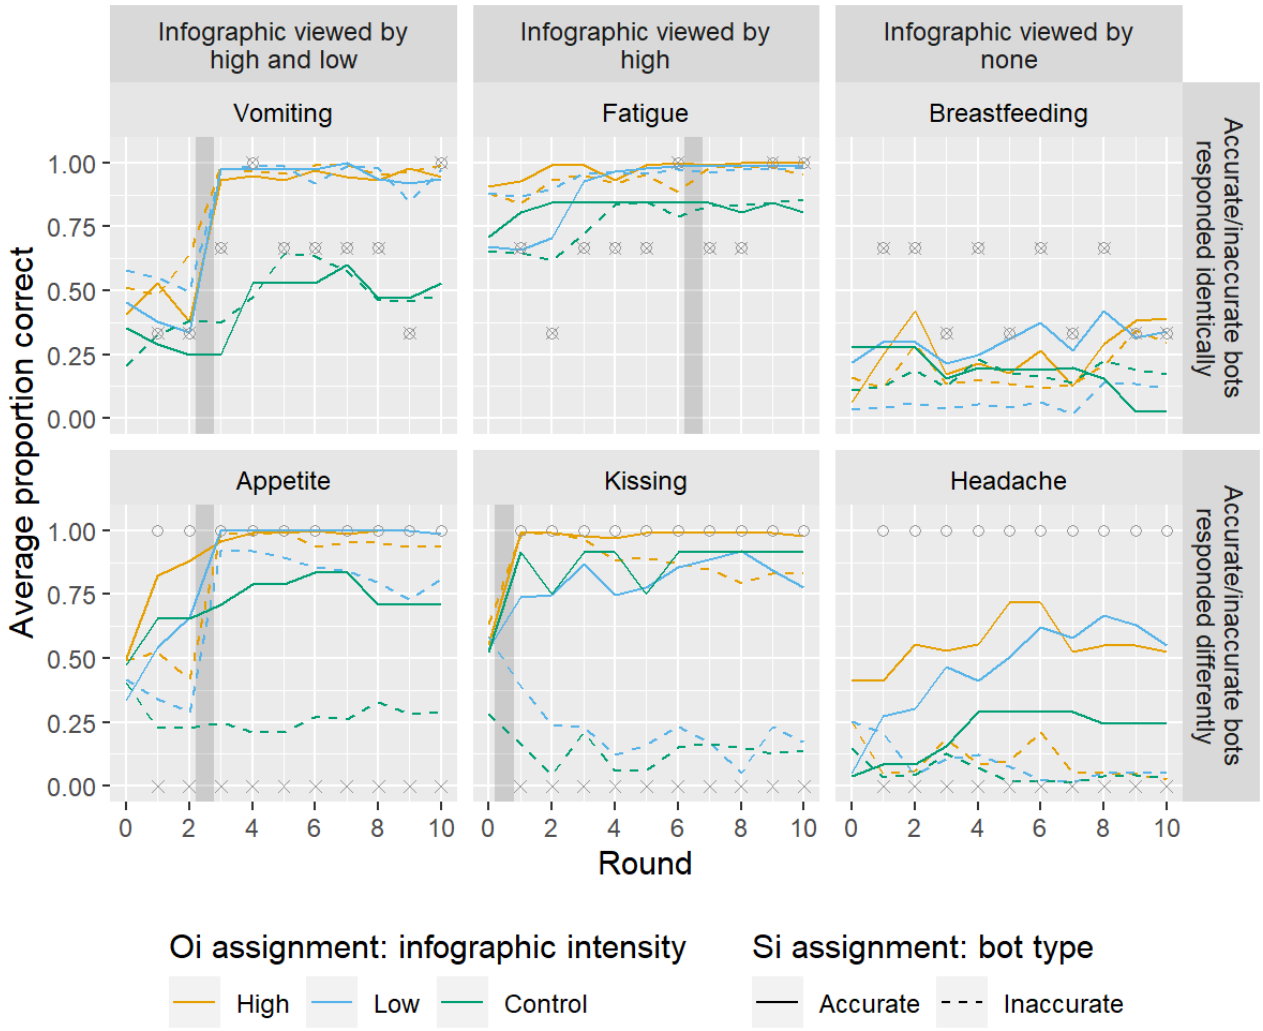


Participants were assigned by session via cluster randomization to one of three degrees (*high*, *low*, or *control*) of relevant OI and to either reinforcing (*accurate*) or contradicting (*inaccurate*) SI conditions. After combining extremely small sessions (Multimedia Appendix 1), the 22 resulting sessions were assigned to the cross-classified conditions. Four sessions were assigned to accurate SI and high degree of relevant OI (total n=38), 4 sessions were assigned to accurate SI and low degree of relevant OI (total n=26), and 3 sessions were assigned to accurate SI and control for OI (total n=17). Four sessions were assigned to inaccurate SI and high degree of relevant OI (total n=33), 4 sessions were assigned to inaccurate SI and low degree of relevant OI (total n=33), and 3 sessions were assigned to inaccurate SI and control for OI (total n=39).

Depending on their assigned OI condition, each participant could view 5, 3, or 0 OI infographics, each of which contained information directly relevant to 1 or 2 of the knowledge questions during the course of the experiment. Table 1 identifies the questions for which the participants were assigned to the *high*, *low*, or *control* categories. OI treatment conditions were presented directly relevant OI and the round during which this OI was presented. Infographics that conveyed information about hepatitis C unrelated to contagion or symptoms were presented in the remaining 5-10 rounds. The infographics are shown in Multimedia Appendix 1. All presented OI infographics contain accurate information.

The SI treatment conditions were intended to provide some participants with systematically accurate social influence and others with systematically inaccurate social influence, while maintaining the plausibility of real response sharing among participants. Thus, all participants viewed identical sequences of preprogrammed SI responses for 11 of the 14 knowledge questions. These preprogrammed responses were designed to mimic real participant responses to the same battery of questions deployed in a similar experiment. For the three remaining questions related to kissing, loss of appetite, and headache, participants assigned to the *accurate* SI condition were led to believe the three friends responded with false, true, and false (respectively, to the three questions) across all ten rounds, which are the correct responses. Those assigned to the *inaccurate* SI condition were led to believe the 3 friends responded with true, false, and true (respectively, to the 3 questions) across all ten rounds, which are the incorrect responses. Summaries of the displayed SI (bot) responses for 6 of the questions are depicted as circles and crosses in Figure 2. Multimedia Appendix 1 provides more information about the treatments and random assignment. At the end of each session, participants were provided with all correct factual information and were debriefed.

Figure 2. Proportion of correct responses for a representative subset of knowledge questions, averaged across sessions within the same cross-classified treatment assignments, as indicated by line color (official information [OI]) and type (social information [SI]). Direct interplay with treatment assignments differs across questions, as indicated by the columns (OI) and rows (SI) of panels. For OI, relevant infographics are viewed by the groups of participants indicated in the column heading in the round indicated by the vertical gray bar. For SI, the proportion of correct answers provided by bots are displayed as o and the proportion of incorrect answers provided by bots are displayed as x symbols. These symbols are always overlaid in the first row.



Statistical Analysis

For exploratory data analyses, we present question-specific longitudinal trends in the average proportion of correct responses across sessions stratified by treatment assignment. We colloquially refer to increases in the percentage of responses that are correct as learning, but recognize that these changes could also reflect changes in expressed attitudes rather than sincerely held beliefs. For formal statistical tests, we capture learning across rounds separately for each knowledge question via differences in average log odds ratios across sessions stratified by treatment assignment. This approach is similar to a random effects logistic regression where round is treated as a categorical factor but allows us to implement adjustments (Multimedia Appendix 1), which makes our calculations computationally feasible where classical random effects logistic regression is not.

Differences in learning over rounds and across treatment groups were summarized by subtracting the appropriate average log odds or log odds ratios. Most within-group summary statistics compared the log odds of a correct answer in a particular round to those at baseline, and some compared responses at round ten with those in the round where correct OI was viewed.

Finally, we compare learning across groups by taking the differences in within-group average log odds ratios across relevant treatment conditions. Large differences across treatment conditions imply that treatment causes differences in learning. We used permutation to approximate the exact reference distributions. To test the equality of learning across groups, we estimated 2-sided *P* values with the proportion of summary measures from 5000 permuted assignments that were further from zero than the summary measure based on the true assignment. Permutation-based tests rely on minimal assumptions but also typically have relatively low statistical power. Additional details regarding the statistical analyses are presented in Multimedia Appendix 1. A significance level of *P*=.05 was used for all tests. All analyses were conducted using R statistical software [32].

Results

Overview

A total of 195 participants across 23 sessions consented to participate; only data for the 186 who completed all ten rounds were included in the primary analyses and are described in Table 2. As noted in the table, 65.1% (121/186) of respondents were female, and their average age was 23 years. Overall, 56.5% (105/186) of respondents reported attending university for 4 or fewer semesters. Further demographic summaries as well as examination of missing data patterns and randomization balance are included in the Multimedia Appendix 1.

We tested four expectations linked to the relationship between accurate official public health information and accurate SI. These expectations imply that increases in correct responses across rounds (which we term *learning*) will differ across the 6 treatment groups in various ways for various questions.

Table 2. Baseline demographic and other characteristics for study completers (n=186).

Characteristic	Values
Age (years), mean (SD; range)	22.85 (2.44; 19 to 31)
Sex (female), n (%)	121 (65.1)
Parental socioeconomic status, self-assessed (n=180), n (%)	
Limited	35 (19.4)
Middle	95 (52.8)
Upper	50 (27.8)
Childhood environment, self-assessed (n=185), n (%)	
City	47 (25.4)
Small town	61 (32.9)
Suburbs	11 (5.9)
Country	66 (35.7)
Freshmen or sophomore class rank, n (%)	105 (56.5)
Political science major, n (%)	34 (18.3)
Political orientation score[a] (n=159), mean (SD; range)	−0.38 (0.75; −2 to 2)

[a]Political orientation was self-assessed on a 5-point scale from *very left* to *very right* and then recoded as integers from −2 to +2. Note that our European university recruitment pool provided little racial and ethnic diversity.

Learning From OI

We expect viewing OI to increase the learning of information about a disease, as previous literature demonstrates [6,8,15]. Those assigned to the high, low, and control intensity OI groups saw infographics relevant to seven, four, and zero questions. Thus, for 7 questions, we expect those who saw a relevant infographic (ie, those in higher intensity groups) to have greater learning for that question as compared with those who did not.

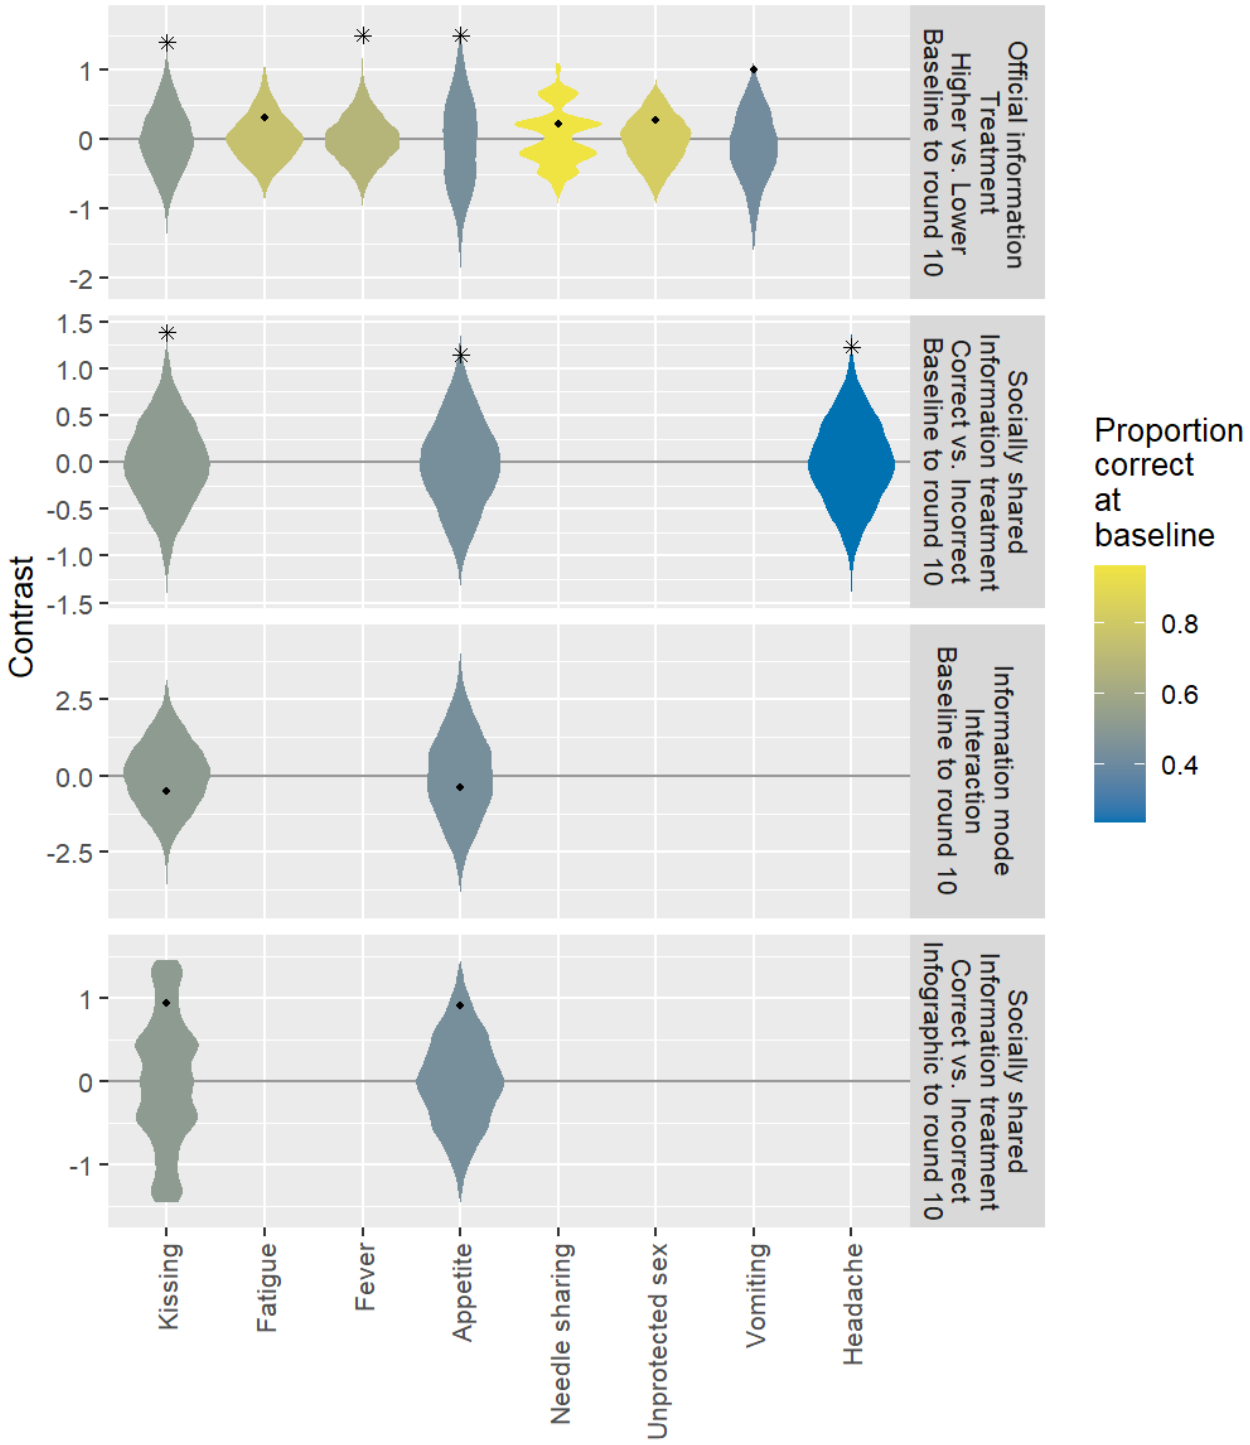
Visualization of data summaries highlights trends that may support our expectations. The lines in Figure 2 depict trends in the proportion of correct responses for each of the 6 groups (where color indicates OI treatment assignment and line type indicates SI treatment assignment) for 6 representative questions. Because all bots gave the same responses for the questions in the first row (as indicated by superimposed *x* and *o* symbols), these questions straightforwardly address the effect of OI. The leftmost plot in this row summarizes the responses to questions related to vomiting. The gray-shaded vertical bar indicates that a relevant infographic was shown to groups assigned to high-and low-intensity treatments before they answered the knowledge questions in round 3. For these 2 groups (yellow and blue lines), we see a dramatic increase in the proportion correct between rounds 2 and 3, suggesting that these groups learned from the relevant infographics. In contrast, we do not see similar learning among those assigned to the control intensity condition (green lines), suggesting that these groups did not learn from the irrelevant infographics they were shown.

For the question related to fatigue, we expected to see a similarly large learning in round 7 among the high intensity groups (and not among the low and control intensity groups who did not view a relevant infographic). However, differences in participant answers did not clearly follow this pattern, perhaps because of high baseline knowledge about this symptom or consistent longitudinal trends in bot responses. Further experiments are required to confirm this hypothesis. Finally, as expected, we see no substantial sustained learning about the potential contagion of breastfeeding in any group, as no group was shown a relevant infographic. Among the questions in the second row where the SI treatments differed, we also see substantial learning in rounds where relevant infographics are viewed, although these trends are complicated by differential socially shared information, as explained below.

Formal tests that compare groups assigned to view relevant infographics with those that did not are summarized for germane questions in the first row of Figure 3, where stars indicate statistically significant differences in the average log odds of a

correct question response across groups defined only by the OI treatment assignment. We found statistically significant differences in learning from baseline to round ten for all questions where the baseline knowledge was at most moderate (less than 75% correct), except for the question related to vomiting (P=.051). The results of pairwise comparisons across the assigned information treatment groups for all questions are included in Multimedia Appendix 1.

Figure 3. Observed (points) and permutation reference distributions (violins) for observed contrasts in average log odds of correct responses across treatment assignment groups (first two rows) and in difference-in-difference of average log odds (third row). Stars indicate permutation P≤.05.



Learning From Socially Shared Information

We expect (in) accurate socially shared information to affect learning of (in) correct information. For three of the questions (related to kissing, appetite, and headache), the (in) accurate bot responses were always (in) accurate; for the remaining 11 questions, all responses were identical across both types. Thus, for the 3 questions, we expect those assigned to the accurate bot treatment groups to learn more than those assigned to the inaccurate bot groups. The second row of Figure 2 shows the

response trends for these three questions, where the differential bot responses are indicated by 100% (3/3) and 0% (0/0) accurate responses for the accurate (*o*) and inaccurate (x) bots, respectively. Because no group was shown an infographic directly relevant to headache, this question (rightmost column) directly addresses the effect of SI. We see that across the ten rounds, those groups with whom accurate information is socially shared (solid lines) have positive learning, whereas those socially receiving inaccurate information (dashed lines) have flat or negative learning. In other questions, we see similar trends among groups that do not view relevant infographics (ie, the low and control intensity groups for the kissing question and the control group for the appetite question). The second row of Figure 3 shows that permutation tests confirm strong statistically

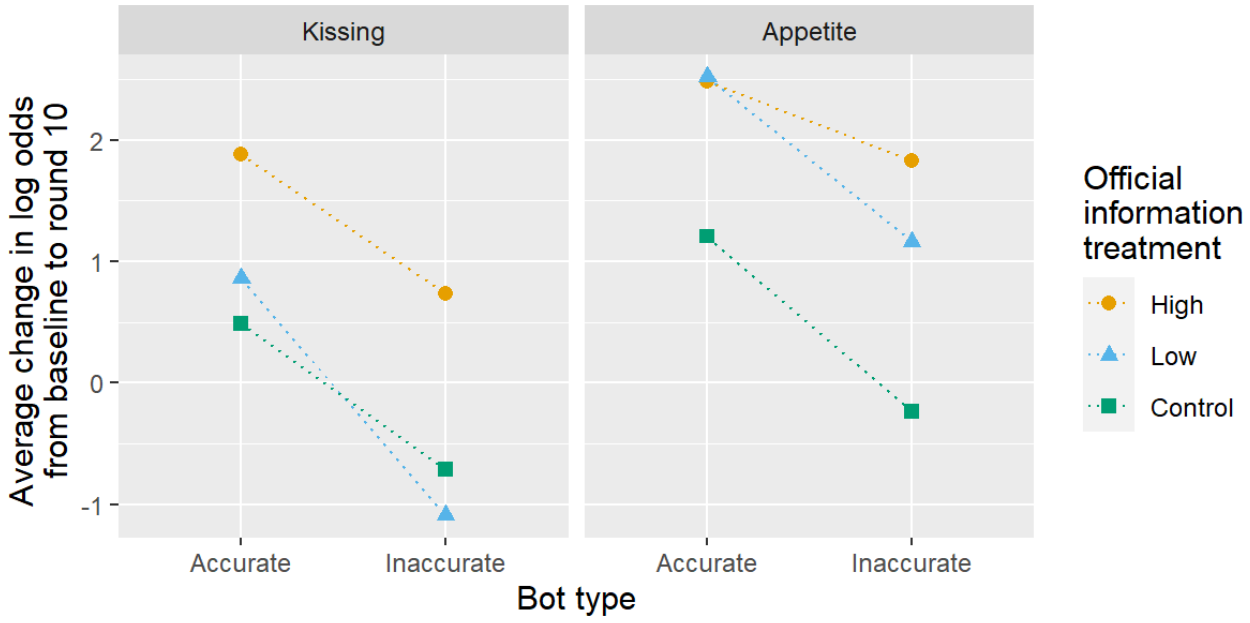
significant differences in learning from baseline to round 10 across the assigned bot types for all three questions, where the information shared by bots differed (all $P \leq .01$). Note that the participants had poor-to-moderate baseline knowledge for all three questions.

Interaction Between Information Sharing Modes

To the extent that official and SI interact, we expect OI to overwhelm SI. That is, we expect the effect of socially shared information to be smaller within groups who viewed germane infographics as compared with those who did not view germane infographics. Infographics relevant to appetite and kissing were shown to some groups, and the accurate and inaccurate bots differed in their responses to these questions. Thus, we focus on these two questions to explore information-mode interactions.

First, we consider the question related to appetite (lower left panel of Figure 2). Because all groups had similar knowledge at baseline, the effect of socially shared information can be approximated by the group differences in the average proportion correct at round 10. The effect of socially shared information is approximated by the difference between the corresponding solid and dashed lines. These differences are relatively small for the groups that viewed germane infographics (yellow and blue) and much larger for the groups that did not view germane infographics (green lines). This pattern is also present for the kissing question and seems to suggest that the effect of socially shared information is greater for groups that did not view germane infographics. However, this perception may be influenced by the boundary effects of the proportion scale. Figure 4 suggests that such differences disappeared after changing to the log odds scale. The log odds-based permutation tests (third row of Figure 3) confirm no strong evidence of an interaction between the modes of information sharing.

Figure 4. Treatment group-specific change in average log odds from baseline to round ten. Dotted lines connect pairs of groups with the same official information treatment group; parallel lines suggest no interaction between information modes.



Persistence of OI

Although we saw no global interactions among the effects of mode on learning from baseline to round 10, we explored a fourth, more targeted hypothesis that the effect of receiving official public health information persists but degrades in the face of contradictory SI. For the question related to appetite, we see that high- and low-information intensity groups achieved nearly unanimously correct responses after viewing the infographics in round 3 (all 4 yellow and blue lines in Figure 2). Of these, groups that are also assigned to socially receive accurate information (yellow and blue solid lines) retain a nearly unanimously correct response proportion at the end of the experiment. However, those groups with which inaccurate information is socially shared (yellow and blue dashed lines) tend to have small declines in the proportion of correct answers by round ten. We see similar trends for the high information intensity group (yellow lines) in answering the question related to kissing. The bottom row of Figure 3 confirms that these trends may be unusual relative to permuted treatment assignments, but the strength of evidence does not reach statistical significance (P=.29 and P=.09 for kissing and appetite, respectively).

It may also appear that there is more degradation in learning because of inaccurate SI for participants in the low OI group versus the high OI group (Figure 4, right panel, blue vs orange), and it is possible that participants receiving less OI overall might be more susceptible to social influence. However, we have only 2 groups with which to measure the variability of the persistence of learning because of OI; so, we did not attempt a formal comparison between these groups.

Discussion

Principal Findings

This work demonstrates that both official and SI influence people's reported understanding of infectious diseases. As expected from the previous literature, exposure to official public health information about hepatitis C increased the learning related to its spread and symptoms. Learning followed socially supplied information, whether accurate or inaccurate, though to a lesser extent. Trends in our data suggest that learning from OI is remarkably resilient even in the presence of persistent contradictory SI, although some modest degradation may be hidden by low statistical power. In an era in which official public health campaigns are frequently in competition with information shared on social media, this study provides some reason to be optimistic that public health campaigns may be able to overcome socially shared misperceptions.

Our work is consistent with previous work on misperceptions in the context of health, which finds that corrective information may inhibit false beliefs [14,15,36]. A web-based experiment investigating corrections to misinformation about a disease outbreak found that official sources of information were more effective at correcting misinformation than peers [14]. Our work examines the competing relationship between official and SI, rather than corrections to misinformation. However, we find that OI sources are much more effective at inducing changes in expressed beliefs, which is consistent with this previous work.

This study addresses the longitudinal effect of SI about diseases in tandem with official public health information in an experimental setting. Many studies of this type would include a one-shot intervention or follow up with participants after a short period. Here, we investigated how expressed beliefs update over multiple rounds and through multiple interactions with members of their experimentally constructed social networks. Because of this, we are able to provide a more nuanced understanding of competing messages in dynamic information environments.

It is important to note that our study used expressed beliefs about hepatitis C as the primary dependent variable. Of course, nearly any study of beliefs about disease relies on expressed beliefs in one way or another. However, because our study is premised on participants' understanding that they are viewing the responses of other participants who are completing the study contemporaneously, these expressed beliefs may be impacted by not only their own beliefs and any changes in them because of the experimental stimuli but also by social desirability bias that may impact their expressed beliefs [37]. Studies on the expression of belief in political falsehoods [38] have shown that the strategic expression of insincerely expressed beliefs is modest. However, the knowledge that you are sharing beliefs, whether sincerely held or not, means that these are beliefs that the participant expected others to see and experience. In this way, this work explores whether sincerely held beliefs are affected by official sources of information or not and whether the information environment becomes more clearly aligned with public health officials, reducing the degree of conflict between official and SI sources.

Although our work focuses on the context of a contagious disease, the results may contribute to our understanding of how social media may affect other aspects of health or may relate to other domains. Of course, OI may be in competition with (or be reinforced by) socially shared information across a number of domains, including other diseases, such as Zika [15], or aspects of health such as mental health [39]. Future work may wish to investigate whether and how socially circulating information affects beliefs in OI across other domains.

Strengths and Limitations

Our ability to control available information lends strong credibility to the causal interpretation of our results. Experiments on networks help bridge the gap between observational studies of people in their natural social environments and lab experiments that abstract away social influences.

Reliable extension of our conclusions to real-world situations relies on participants' interpretation of the information presented as legitimate. This hurdle may be easier to clear for OI than for SI. One major strength of our controlled experiment is that participants were embedded in an environment that promoted realism in a fictional social network.

This experiment has several important limitations, which we elaborate on here. First, the social networks we examined appeared to be among participants who were anonymous to one another within the setting of the experiment. Although this situation may be encountered on an anonymous message board or comment thread, it is possible that in real social networks, in which participants have strong social bonds and reputations, the effects of SI may be different. Future work may wish to investigate whether and how SI is transmitted in social networks among participants who are already connected to one another.

Second, our experiment limited SI responses to true, false, or unsure. In reality, people make intentional and nuanced attempts to convince others in the social sphere of their beliefs. It is difficult to envision a controlled experiment in which participants are allowed to communicate so freely and also maintains a degree of control that enables clear causal interpretation, but this should be addressed in future studies. We view this as a trade-off between tight control that enables us to make clear causal claims and less tight control that not only enables a greater variety of communication but also reduces the ability to interpret the social component in a clear causal fashion.

Third, the participants in our study were all similar in age. Previous work in a different context (politics) found that an official message with a reinforcing social component was more effective at changing behavior among older participants than

an official message without the social component [40]. It is possible that the limited interaction we find between social and OI owes to the age distribution of the participants of the study, the fact that the official and SI are contradictory, to the fact that our study examines health information, or to some other factor. Future work may examine contradicting official and SI in a more diverse sample to understand whether heterogeneous treatment effects exist.

Fourth, the study did not test for potential mediating and moderating variables that may explain how or to what degree official and SI affect beliefs. This limitation is related to, but distinct from, concerns about how anonymous networks may impact network effects. Mediating and moderating relationships may be a result of aspects of existing relationships, in which case anonymous studies would help to control for these effects but would also limit researchers' ability to examine them. However, it is also possible that mediating or moderating relationships are a result of aspects of relationships between people that develop rapidly, perhaps during the course of a few interactions. In this case, even in a short network experiment among anonymous individuals, mediating or moderating relationships may be examined. For example, the degree of trust in information sources may affect the degree to which participants respond to the beliefs shared by either official or SI sources. In this study, participants were informed that they would be connected to other anonymous participants; so, any interpersonal trust would have to be established during the course of the study. We believe it is unlikely that, in the context of this study, varying levels of trust would be created during the course of the study. However, in real-world situations in which people have ongoing relationships with those from whom they receive SI, trust and reputation are likely to impact how people process and respond to the messages shared by their social contacts. Future studies may wish to investigate trust, perhaps through experiments that enable researcher control over not only message content but also cues related to trust. We note that trustworthiness is one of multiple possible mediating or moderating variables that may enable a more nuanced understanding of the competing or reinforcing effects of social and OI.

Finally, the small number of experimental sessions limit the power of permutation-based statistical inference. The permutation-based approach used here makes very few assumptions and, therefore, enables us to make clear claims based on the statistical evidence that does not depend on common assumptions used in model-based analyses that may not hold for the data we collected. Future reanalyses based on longitudinal models may provide more nuanced, though more model-dependent results. In addition, reliance on college student volunteers and participant buy in to treatment legitimacy raises external validity concerns.

Nonetheless, our results provide some good news for sponsors of public health campaigns even in a time of overwhelming prevalence of SI with a wide range of accuracy. Consistent fact-based official messages can break through the SI noise.

Conclusions and Future Work

This experiment is one of multiple related projects examining social processes of information spread in networks and includes 2 additional experiments that address some of these limitations. First, human participants are randomly assigned to prespecified networks, which provides insight into how aspects of the network structure affect the diffusion of information about the disease. Second, participants share disease information with individuals in a real-world social network, providing a test of the external validity of our findings. Although this analysis focuses solely on the *bots* experiment, future work will incorporate the other 2 experiments. Although the studies of actual networks will enable the analysis of more complex network relationships, they will have a substantial trade-off in the degree of researcher control over what participants experience.

In the real world, our results present a puzzle for web-based health communities, particularly those that are moderated by professionals. In such communities, moderators may play a role similar to that of the official sources of information in our experiment [41,42]. In such communities, it may be possible for moderators to leverage network effects to broaden the impact of their official message. Web-based health communities often provide opportunities for users to connect in anonymous ways and must develop relationships with other users over time, similar to the design of our experiment. However, it is important to note that in such communities, professionals and moderators may have an outsized influence and the positive impact that they may have can lead to the propagation of misinformation just as it may lead to the spread of correct information [43,44]. Future work may wish to further investigate the interaction of official and SI or instances in which the line between them is not as clear, such as when a moderator or user of a web-based health community presents themselves as having expertise and other users must evaluate the user's credibility.

Our results underscore the importance of public health practitioners taking into account the effects of both OI sources, which may have a degree of control over, and SI sources, over which they may have limited control. We also show that OI is substantially more effective at promoting learning than socially supplied information, underscoring the importance of public health campaigns for inducing correct beliefs. Although we do not find evidence that official and SI interact, it is possible that the effects of such an interaction are small and nuanced, and we would nonetheless encourage practitioners to consider how OI may be transmitted through social ties.

Abstract

Background: There is a limited amount of data on the safety profile of the COVID-19 vector vaccine Gam-COVID-Vac (Sputnik V). Previous infodemiology studies showed that social media discourse could be analyzed to assess the most concerning adverse events (AE) caused by drugs.

Objective: We aimed to investigate mild AEs of Sputnik V based on a participatory trial conducted on Telegram in the Russian language. We compared AEs extracted from Telegram with other limited databases on Sputnik V and other COVID-19 vaccines. We explored symptom co-occurrence patterns and determined how counts of administered doses, age, gender, and sequence of shots could confound the reporting of AEs.

Methods: We collected a unique dataset consisting of 11,515 self-reported Sputnik V vaccine AEs posted on the Telegram group, and we utilized natural language processing methods to extract AEs. Specifically, we performed multilabel classifications using the deep neural language model Bidirectional Encoder Representations from Transformers (BERT) "DeepPavlov," which was pretrained on a Russian language corpus and applied to the Telegram messages. The resulting area under the curve score was 0.991. We chose symptom classes that represented the following AEs: fever, pain, chills, fatigue, nausea/vomiting, headache, insomnia, lymph node enlargement, erythema, pruritus, swelling, and diarrhea.

Results: Telegram users complained mostly about pain (5461/11,515, 47.43%), fever (5363/11,515, 46.57%), fatigue (3862/11,515, 33.54%), and headache (2855/11,515, 24.79%). Women reported more AEs than men (1.2-fold, $P<.001$). In addition, there were more AEs from the first dose than from the second dose (1.1-fold, $P<.001$), and the number of AEs decreased with age ($\beta=.05$ per year, $P<.001$). The results also showed that Sputnik V AEs were more similar to other vector vaccines (132 units) than with messenger RNA vaccines (241 units) according to the average Euclidean distance between the vectors of AE frequencies. Elderly Telegram users reported significantly more (5.6-fold on average) systemic AEs than their peers, according to the results of the phase 3 clinical trials published in *The Lancet*. However, the AEs reported in Telegram posts were consistent (Pearson correlation $r=0.94$, $P=.02$) with those reported in the Argentinian postmarketing AE registry.

Conclusions: After the Sputnik V vaccination, Russian Telegram users reported mostly pain, fever, and fatigue. The Sputnik V AE profile was comparable with other vector COVID-19 vaccines. Discussion on social media could provide meaningful information about the AE profile of novel vaccines.

adverse events; Sputnik V; Gam-COVID-Vac; social media; Telegram; COVID-19; Sars-CoV-2; deep learning; vaccine safety

Introduction

The current COVID-19 pandemic is one of the most critical global health problems. The main strategies for its mitigation involve both nonpharmaceutical interventions (eg, testing and contract tracing) and up-to-date anti-COVID-19 treatments. However, the most promising intervention has been vaccines that have effectively prevented severe COVID-19 outcomes. In addition to novel messenger RNA (mRNA) vaccines, vector vaccines have been developed. One of the first was Gam-COVID-Vac (Sputnik V), which is a viral, 2-dose, vector vaccine based on 2 human adenoviruses. Each dose contains a different vector: rAd26 and rAd5. This vaccine was developed by the Gamaleya Research Institute of Epidemiology and Microbiology. Sputnik V contains a gene that encodes SARS-CoV-2's spike (S) protein [1]. As of the time of this manuscript submission, 2 reports of clinical trials had been published. In the first study, phases 1/2 involved a total of 76 participant, who were included in the safety analysis [2]. The report on the phase 3 trial included detailed descriptions of serious and rare adverse events (AE) as well as mild AEs described in individuals [3] older than 60 years. The overall frequency of AEs was mentioned without complete characteristics of the safety profile, such as the co-occurrence of AEs. Mild AEs are common among all vaccines. Extensive fact sheets on AEs, as well as possible adverse reactions, were provided for vaccines trialed under the US Food and Drug Administration (FDA), UK Medicines and Healthcare products Regulatory Agency (MHRA), or EU European Medicines Agency (EMA), which was not the case with Sputnik V. As of April 17, 2021 (the end of the period for collecting data in our sample), 15,700,803 single doses of COVID-19 immunization had been administered in Russia [4]. The vast majority were of the Sputnik family (>95%), and the share of other vaccines was minimal (4.7% for EpiVacCorona and 0.1% for CoviVac) [5]. Moreover, the Russian Federation had signed contracts with dozens of countries to deliver 1.4 billion doses at less than €7 (US $8.13) per dose for international buyers [6]. Therefore, there is an emerging need to update the information on Sputnik V's safety profile using postmarketing surveillance. Because a registry of AEs after vaccination with Sputnik V is difficult to access, social media discourse may be an alternate source of information on AEs. The Sputnik vaccine gave rise to dubious situations in not only its safety profile but also other aspects [7].

An increasing number of studies has analyzed English-language social media in the context of vaccinations [8] or vaccine-prevented infectious disease [9]. However, only a few similar studies on Russian social media have been published [10,11]. Accounts of adverse reactions to drugs have been widely extracted from social media [12] in the context of mining consumer reviews on the internet [13]. To date, most of these studies processed data collected from Twitter [14-23]. Although social media platforms such as Twitter and Facebook are used in Russia, Telegram Messenger is ranked second in the Russian App Store, having 27 million active users in Russia [24]. Developed in Russia, this platform is much more popular than alternatives such as Twitter [25].

Most previous studies on social media vaccine discourse have focused on the personal beliefs of users. For example, Wang et al [26] developed a framework to detect vaccine AEs mentioned by Twitter users. However, to date, no study has analyzed social media discourse on nonsevere AEs in response to COVID-19 vaccines. In this study, we collected social media (a Telegram group in the Russian language) data to bridge the gap in information on the most prevalent AEs involving Sputnik V. We focused on the most common AEs and established which were the most prevalent, their co-occurrence, and their associations with users' characteristics [27]. Finally, we compared the AE profile of Sputnik V with those of other approved COVID-19 vaccines.

Methods

The dataset analyzed in our study was collected retrospectively from the Telegram group, "Sputnik_results" [28]. The data contained no personal information, and the analysis was performed according to the Terms of Service of the platform [29]. Our analysis was completely anonymous and performed in aggregated form. No possible harm to Telegram users was identified. Therefore, the study did not require ethical committee approval.

Data Description

Originally, Telegram aimed to provide secure communication (which is very important for post-Soviet societies [30]), but later, functionality was expanded; it added support for public channels, groups, video calls, and many other features [29]. Telegram groups may be public or private. If a group is public, it may be accessed via the Telegram search engine, and every user may read all its content. A main priority claimed by Telegram is security; users' data are not disclosed, and only the user's screen name and picture are shown to the public. The largest Telegram channels have millions of subscribers.

The description of the "Sputnik_results" [28] public group states that its main aim is to collect information on AEs regarding the Sputnik V vaccine. Telegram users may post a description of their symptoms. Moderators of the group oversee the messages and verify that they contain only descriptions of AEs; otherwise, the message is deleted. An example message is as follows: "М, 33 года. V1 24.01.21 через 12 часов темп 39, боль в руке (все плечо целиком, мышцы), заложенность носа, диарея. На следдень темп 38, боль в руке, заложенность носа. На третий день слабость, температура в норме" (translation: M, 33 years old. V1 24.01.21 after 12 hours, temp. 39, pain in the arm (the entire shoulder, muscles), nasal congestion, diarrhea. The next day, temp. 38, pain in the arm, nasal congestion. On the third day, weakness, temperature is normal).

In this study, we collected all messages from the "Sputnik_Results" group using Python Telegram Client telethon [31]. We saved only text messages that were posted in the group; users' personal details were not extracted. In total, we collected 18,833 messages. After filtering messages that contained only

pictures, 11,515 messages remained. The first message was sent on December 9, 2020, and the most recent message was sent on April 17, 2021. The dataset contained 25,660 unique lowercase words.

Adverse Event Classification

The gold standard used to identify adverse reactions is the MedDRA System Organ Class, which is applied in the European Union (EudraVigilance [32]), the United States (Vaccine Adverse Event Reporting System [VAERS] [33]), and the United Kingdom (MHRA Yellow Card scheme [34]). However, the system uses a specialized medical vocabulary. In our study, because users of social media communicated in colloquial language [12], we chose a simplified FDA classification system [35-37] that was subdivided into 2 groups: local reactions (ie, redness, swelling, and pain at the injection site) and systemic reactions (ie, fever, fatigue, headache, chills, nausea/vomiting, diarrhea, new or worsening muscle pain, and new or worsening joint pain). Moreover, muscle pain, joint pain, and pain at the injection site were categorized as a single class. However, we added the classes of pruritus, enlarged lymph nodes, and insomnia, which are common adverse reactions to anti-COVID-19 vaccines [38,39]. Insomnia was chosen due to its high frequency by simple keyword analysis on a sample of material from Telegram. The final list of 12 classes of symptoms of mild AEs, which were based on subjective experiences of a potential health issue, is provided in the Results section.

Labeling

We utilized the LabelStudio data labeling tool [40] to label the dataset. We randomly sampled 1000 messages in the dataset, which were labeled by 3 raters who were native Russian speakers. The raters labeled each occurrence of an AE in the messages, thus making the dataset suitable for named entity recognition tasks. Because of such labeling and the existence of different descriptions of the same AEs in multiple sentences, we augmented the dataset by splitting each message into sentences. The resulting dataset contained 4579 entities.

Model Architecture

Each message in our dataset could have included multiple AEs. We therefore adopted a multilabel text classification scheme. A formal definition of multilabel classification is as follows: Consider a dataset

where $x_i \in X$ is the i-th observed variable for the dataset of cardinality n, $y_i \in Y$ is the corresponding set of labels for the i-th element. Our goal was to learn a mapping $\hat{y}_j = f(x_j,\theta)$, where $\hat{y}_j$ is the set of predicted classes and θ is a vector of parameters. To find the vector of optimal parameters θ, we needed to minimize the loss function $L(y,\hat{y})$ between the actual and predicted classes. Multiple machine learning methods may be applied to support multilabel classification. In the case of artificial neural networks (ANNs), the activation function of the last layer of the ANN is set to be a sigmoid:

and binary cross-entropy loss is used. In this case, ANN will map the probability of each class to a value between 0 and 1, and each data item could be mapped to multiple classes.

Because of the recent success of ANNs, specifically transformers, in text analysis tasks, we adopted a deep Bidirectional Encoder Representations from Transformers (BERT) architecture to perform our multilabel classification task [41]. We utilized a pretrained BERT model for the Russian language DeepPavlov [42]. We tuned the last layer of the model, which consisted of 12 sigmoid neurons. As a baseline, we used a standard long short-term memory (LSTM) ANN, which consisted of embedding as the first layer and 1 LSTM layer (100 cells), dropout (P=.20), and a subsequent multilabel dense layer with sigmoid as the activation function.

Model Evaluation

We trained the BERT and LSTM models using a stratified k-fold validation scheme where k=5. Because the classes were imbalanced, we utilized an up-sampling strategy; that is, underrepresented classes were up-sampled in the training dataset. The testing set distribution was not modified. Table 1 displays the evaluation results. Precision and recall were calculated for both micro- and macro-averaged aggregations [43]. As shown in Table 1, precision and F1 scores were reported for thresholds equal to 0.5. We utilized a computer with a Tesla T4 GPU to train the models. Table 1 shows that BERT outperformed the LSTM model by a large margin. We therefore chose the BERT model and trained it on 95% of the data; in this case, it returned a micro-averaged accuracy of 0.94 and an area under the receiver operating characteristic (ROC) curve (AUC) score of 0.991.

Regarding gender, age, and dose number (if available), we used counts of corresponding abbreviations and regular expression matching because the administrators of the group had provided detailed instructions for the reporting of this information.

Table 1. Bidirectional Encoder Representations from Transformers (BERT) and long short-term memory (LSTM) model evaluation results.

Model	Micro-averaged aggregations			Macro-averaged aggregations	
	AUC[a], mean (SD)	Precision, mean (SD)	F1, mean (SD)	Precision, mean (SD)	F1, mean (SD)
LSTM	0.969 (0.002)	0.866 (0.024)	0.769 (0.033)	0.514 (0.048)	0.431 (0.042)
BERT	0.991 (0.002)	0.915 (0.016)	0.920 (0.002)	0.863 (0.025)	0.858 (0.006)

[a]AUC: area under the curve.

Analysis of AE

To evaluate the time relationship between the number of reports and vaccination volume, a univariate linear regression coefficient was calculated. Because the number of reports (P<.001) and vaccination volume (P<.001) failed to be normally distributed based on the Shapiro-Wilk test, a Spearman correlation was calculated. Because the number of AEs failed to be normally distributed based on the Shapiro-Wilk test (P<.001), the difference between the 2 groups was analyzed with a Mann-Whitney U test. To compare frequencies of AEs between 2 samples of AEs, a Fisher test was applied. To compare the frequencies of 2 vectors of AEs, the normality was checked with the Shapiro-Wilk test, and Pearson correlations could be calculated (P=.10 and P=.07, respectively, comparing Telegram with the Argentinian Registry; P=.13 and P=.34, respectively, comparing Telegram with the Moscow trial). Community detection was conducted to evaluate the internal structure (co-occurrence) of AEs in the network representation.

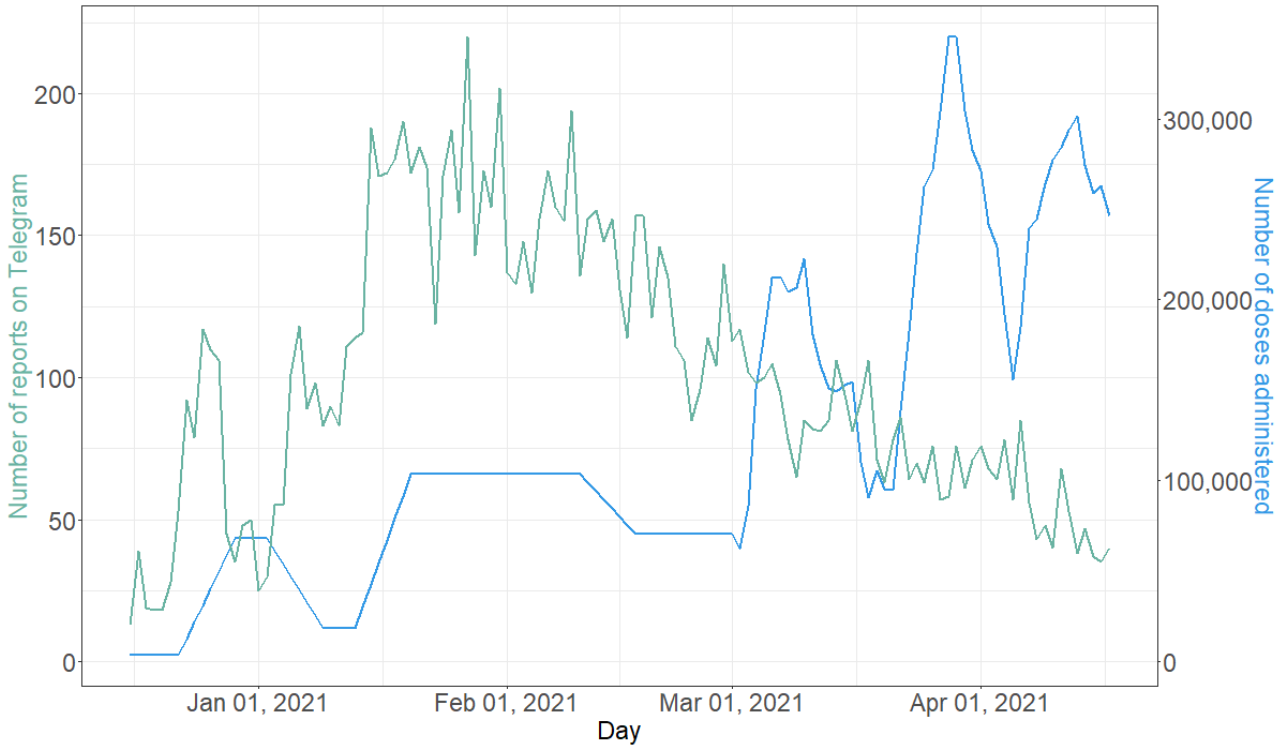
Results

Reactogenicity assessment based on opt-in civic surveillance was performed to obtain results of clinical importance (similar to endpoints in trials).

Temporal Dynamics

The peak in the volume of self-reports corresponded with the time at which vaccinations were sped up (Figure 1). Moreover, after 3 months of vaccinations (the end of February 2021), the popularity of self-reporting started to decrease despite the increasing vaccination roll-out. However, the Spearman correlation coefficient between the volume of self-reports and doses administered from December 9, 2020 until February 28, 2021 was very high (r=0.75, P<.001), and the subsequent count of administered doses increased, while reports on AEs decreased (Figure 1).

Figure 1. Daily counts of reports of adverse events (AE) and doses administered in Russia (data according to Our World in Data [4,44]).



Revealed AE Frequencies (BERT Classes)

Our analysis revealed that fever and generalized pain were the most commonly reported AEs (Table 2). Injection site irritations (local reactions) were an order of magnitude less likely to be reported than fever and pain (systemic reaction). Gastric symptoms (especially diarrhea, with a frequency of 0.6% per report) were less likely to be reported than the average prevalence among the general population (1%-5% for diarrhea [45,46]).

Table 2. Frequencies of mild adverse events extracted from the Telegram group (n=11,515).

Adverse events	n (%)
Systemic	
Fever	5461 (47.43)
Pain	5363 (46.57)
Fatigue	3862 (33.54)
Headache	2855 (24.79)
Chills	2651 (23.02)
Insomnia	600 (5.21)
Lymph node enlargement	186 (1.62)
Local	
Erythema/redness	319 (2.77)
Swelling	206 (1.79)
Pruritis	199 (1.73)
Gastric	
Nausea/vomiting	351 (3.05)
Diarrhea	66 (0.57)

Variations Across Age, Gender, and Dose

Gender was reported by 3992 women and 2762 men. On average, women reported 2.5 AEs (σ=1.79; Q1=1; Q2=2; Q3=4), and men reported 2.1 AEs (σ=1.64; Q1=1; Q2=2; Q3=3). Women reported statistically significantly more AEs (P<.001) according to the results of a Mann-Whitney U test (Table 3).

Age was provided by 6754 users. A linear regression analysis was performed for those who reported being at least 18 years old (minimal age of Russian registration [1]). We found a clear and significant linear relationship (β=.0457, SE=.0014), showing that with every year of life, users reported .0457 fewer AEs (Figure 2). In univariate regression analysis, β is an estimated coefficient with a given SE. Mild AEs among the elderly are known to be less frequently observed for most anti-COVID-19 vaccines [35-37,47].

AEs in response to other anti-COVID-19 vaccines have been found to depend on whether the vaccination was the first or the second dose (if applicable). For instance, AEs in response to mRNA vaccines have tended to be stronger with the second dose [36,37,47]. In contrast, AEs in response to vector vaccines have tended to be milder with the second dose [48,49]. Regarding the Sputnik V vaccine, this difference might be because a different vector is used in each dose, which might lead to different reactions. Among the self-reports, 4174 described AEs after the first dose, 1251 described AEs after the second dose, and 3049 described AEs after both doses. It is also possible that the users did not receive the second dose because of contraindications or just lost interest in reporting.

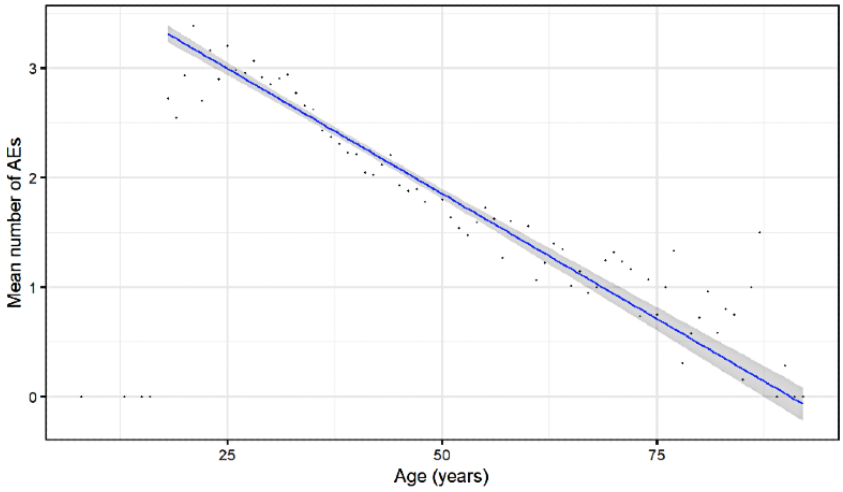
Here, we considered only reports that discussed the first and second doses separately. On average, there were 2.2 (σ=1.80; Q1=0; Q2=2; Q3=4) AEs for the first dose and 1.9 (σ=1.69; Q1=0; Q2=2; Q3=3) AEs for the second dose. According to the results of the Mann-Whitney U test, there were statistically significantly more AEs after the first dose (P<.001; Table 3).

Table 3. Comparisons of the mean numbers of adverse events (AEs) by gender and by dose using Mann-Whitney U tests.

Variable	Number of AEs, mean	OR[a]	*P* value
Gender			
Male	2.1	1.20	<.001
Female	2.5		
Dose			
First	2.2	1.13	<.001
Second	1.9		

[a]OR: odds ratio.

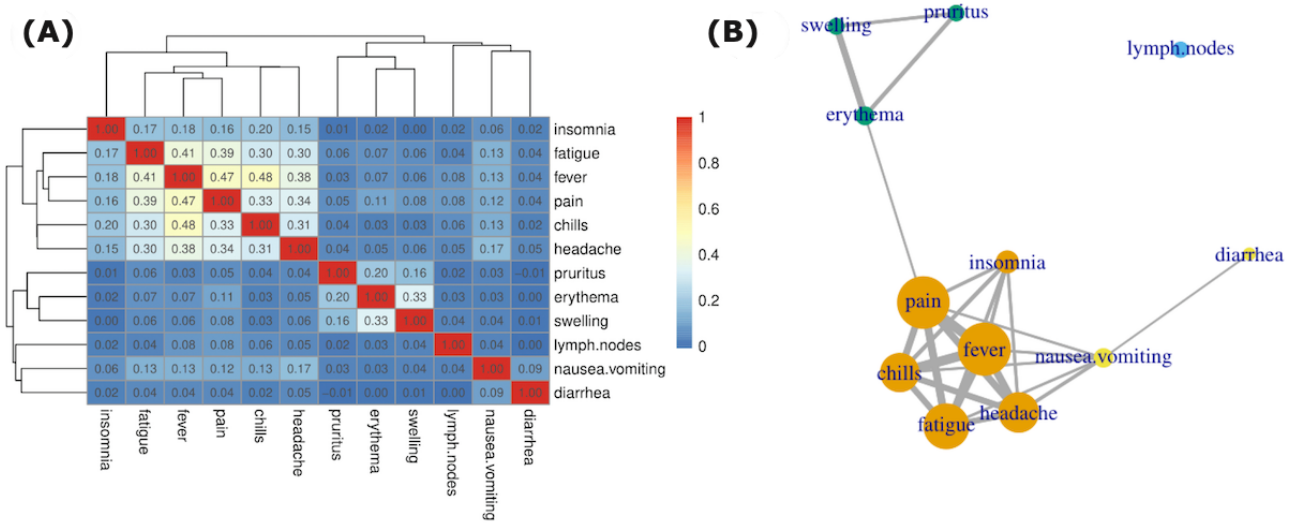
Figure 2. Scatterplot of the number of adverse events (AEs) reported by user vs. age. Dots indicate the mean number of AEs for a given age, while the blue line indicates the linear regression trend and shadowed area indicate its CIs.



Co-occurrence of AEs

To quantify the co-occurrence of symptoms, we calculated Spearman rank correlation coefficients between each pair of classified symptoms. We observed systemic, local, and gastric clusters (Figure 3). We also provided a network representation in which vertex size represents symptom prevalence and edge width represents co-occurrence as measured by the correlation coefficient. Only edges with a correlation coefficient above 0.09 are shown (Figure 3). An unsupervised weighted Louvain algorithm [50] for community detection was used for this purpose, and the vertices were colored the same if they belonged to the same community, which revealed a meaningful structure in which orange denoted systemic, green denoted local, and yellow denoted gastric communities of symptoms.

Figure 3. Co-occurrence of adverse events (AEs), shown as (A) hierarchical clustering based on the correlation matrix of AE symptoms and (B) the corresponding network of AE symptoms with different communities denoted by color code.



Telegram Versus Other Trials or Registries of Sputnik V

We compared our results with 2 available datasets of AEs in response to the Sputnik V vaccine. The first one was collected in Moscow. The second one was collected in Argentina.

Moscow Clinical Trial

Mild AEs in 1029 patients older than 60 years in the phase 3 clinical trial [3,51] in Moscow were compared with 690 self-reports by Telegram users older than 60 years (Table 4). Because there were inconsistencies in various definitions of AEs, a simplified classification was provided, and only headache and diarrhea comprised similar symptoms (at least *sensu lato*). We performed the following calculations to compare both datasets. To obtain *fever* according to our definition, we summed the results for pyrexia, fever sensation, and elevated body temperature from the clinical trial. Similarly, to obtain *pain*, we summed the results for myalgia, arthralgia, and local reaction. To obtain *fatigue*, we summed the results for asthenia and malaise. To obtain *nausea*, we summed the results for nausea and dyspepsia. For *erythema*, we chose the results for contact dermatitis.

In all systemic reactions, Telegram users reported AEs significantly more often than measured in the clinical trial (Table 4). In contrast, diarrhea was less likely to be reported than measured in the clinical trial.

Table 4. Comparisons of adverse events with the Sputnik vaccine between the Telegram and Moscow clinical trial [3] datasets (r=0.69, P=.09).

Adverse event	Moscow clinical trial, n (%)	Telegram, n (%)	OR[a]	P value[b]
Pain	67 (6.70)	177 (25.65)	3.82	<.001
Headache	30 (2.92)	89 (12.90)	4.42	<.001
Fatigue	31 (3.01)	141 (20.43)	6.78	<.001
Fever	32 (3.11)	163 (23.62)	7.59	<.001
Nausea	12 (1.17)	9 (1.30)	1.12	.83
Erythema	39 (3.79)	15 (2.17)	0.57	.09
Diarrhea	8 (0.78)	3 (0.43)	0.56	.54

[a]OR: odds ratio for the Moscow clinical trial.

[b]Fisher test results for the comparison between samples.

Argentinian Postregistration AE Registry

Another available dataset on AEs in response to Sputnik V was compiled from the Argentinian registry of passive AE monitoring (Table 5). This registry contains 23,804 events of all kinds of AEs (mild AEs: 22,971/23,804, 96.5%) from 2,541,362 doses administered. To compare, we chose 7797 Telegram posts that reported at least one AE, and we adjusted new disjoint subsets of symptoms according to the Argentinian methodology [44].

We categorized gastric as the frequency of the logical function nausea OR diarrhea. We categorized site irritation as the frequency of the logical function pruritus OR erythema OR swelling. We categorized fever_pain as the frequency of the logical function fever AND (pain OR headache). We categorized fatigue_pain as the frequency of the logical function fatigue AND (pain OR headache). We categorized only_fever as the frequency of the logical function fever AND ˜(pain OR headache OR fatigue); ˜ denotes logical negation.

The comparison showed that the statistics, despite the significant differences shown in Table 5, were similar in magnitude and highly correlated (r=0.94). The comparison of the Telegram reports (a selected sample with at least one AE constructed by multilabel classification) with the Argentinian registry (multiclass classification [44]) was conducted by the aforementioned mapping. The results of the comparison must be interpreted with caution.

Table 5. Comparisons of adverse events with the Sputnik vaccine between the Telegram and Argentinian safety monitoring [44] datasets (r=0.94, P=.02).

Adverse event	Argentinian registry, n (%)	Telegram, n (%)	OR[a]	P value[b]
fever_pain	8210 (33.25)	4142 (54.70)	1.66	<.001
fatigue_pain	9407 (38.10)	2998 (39.67)	1.05	.05
gastric	1447 (5.98)	395 (5.14)	0.90	.07
site irritation	2306 (9.34)	558 (7.31)	0.80	<.001
only_fever	2065 (8.34)	697 (9.53)	1.11	.02

[a]OR: odds ratio for the Argentinian registry.

[b]Fisher test results for the comparison between samples.

Comparison With Other Vaccines

Regarding vaccines registered by the EMA and FDA, lists of the frequencies of the most common adverse events are accessible; however, they vary across regulatory bodies. Thus, we chose a subset of symptoms for frequencies that were reasonably comparable (pain, headache, fatigue, fever, chills, and nausea). We built a distance (Euclidean) matrix of AEs based on clinical trial registries (EMA [48,52-54], FDA [35-37]) and from the Telegram group (Table 6). From the FDA dataset, for 2-dose vaccines, the dose with higher reactogenicity was selected. In clinical trials, pain is usually considered as pain at the injection site. Fever was the sum of pyrexia and fever in the EMA database. EMA used the injection site tenderness/irritation category. However, regarding redness/erythema, the FDA classified swelling and pruritus separately. Thus, erythema was not included. Sputnik V is a vector vaccine, as are those from AstraZeneca and Johnson & Johnson. The results showed that Telegram Sputnik V AEs were clustered with other vector vaccines, which was possibly due to similar safety profiles (Figure 4).

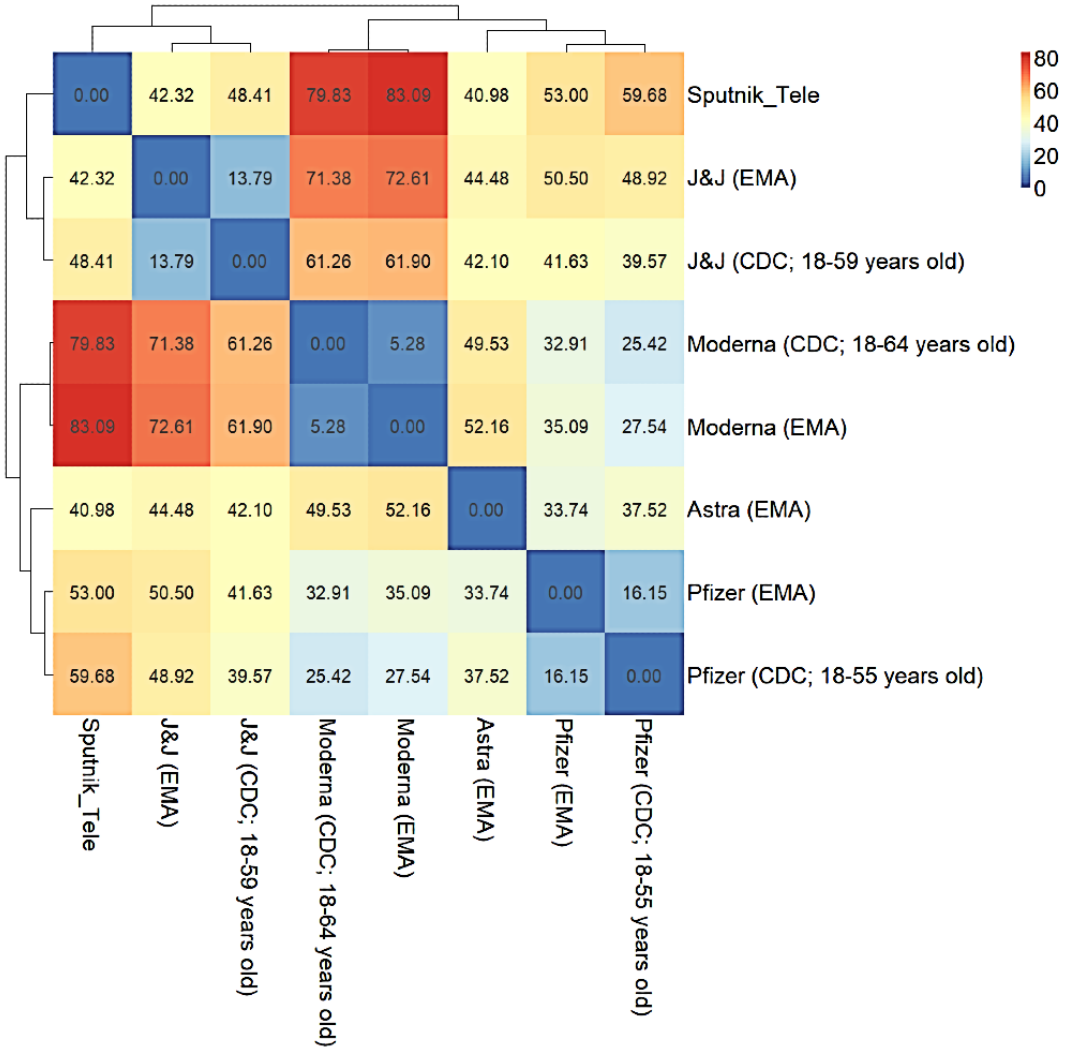
It is important to note that the Telegram users also submitted reports without any AEs at all. Thus, our surveillance system included a sentinel property of samples in contrast to VAERS (North America), EudraVigilance (European Union), and the Argentinian registry [44], which gather reports only if there is any AE to be reported.

Table 6. Adverse events in response to Sputnik V (Telegram) and other vaccines (European Medicines Agency [EMA] and Centers for Disease Control and Prevention [CDC]/Food and Drug Administration [FDA]).

Vaccine	Pain, n (%)	Headache, n (%)	Fatigue, n (%)	Fever, n (%)	Chills, n (%)	Nausea, n (%)
AstraZeneca (EMA)	–[a] (54.20)	– (52.60)	– (53.10)	– (41.50)	– (31.90)	– (21.80)
Johnson & Johnson (EMA)	– (48.60)	– (38.90)	– (38.20)	– (14.00)	– (5.00)	– (14.20)
Johnson & Johnson (CDC; 18-59 years old)	1193 (59.80)	905 (44.40)	891 (43.80)	261 (12.80)	– (5.00)	315 (15.50)
Pfizer (EMA)	– (80.00)	– (50.00)	– (60.00)	– (30.00)	– (30.00)	– (5.00)
Pfizer (CDC; 18-54 years old)	1632 (77.80)	1085 (51.70)	1247 (59.40)	331 (15.80)	737 (35.10)	– (10.00)
Sputnik (Telegram)	5363 (46.57)	2855 (24.80)	3862 (33.54)	5461 (47.43)	2651 (23.02)	351 (3.00)
Moderna (CDC; 18-64 years old)	9335 (90.10)	6500 (62.80)	7002 (67.60)	1806 (17.40)	5001 (48.30)	2209 (21.30)
Moderna (EMA)	– (92.00)	– (64.70)	– (70.00)	– (15.50)	– (45.40)	– (23.00)

[a]Not reported.

Figure 4. Hierarchical matrix of adverse event (AE) similarity of various vaccines and reporting systems (Euclidean distance) of vaccinations investigated in the present study. Astra: AstraZeneca; CDC: Centers for Disease Control and Prevention; EMA: European Medicines Agency; FDA: Food and Drug Administration; J&J: Johnson & Johnson.



Discussion

Principal Findings

According to clinical trials [3] and official registries [44], only partial information could be retrieved on the Sputnik V safety profile. Previously, multiple researchers have raised concerns about the safety of the Sputnik V vaccine [6,55,56]. Our study aimed to increase transparency regarding the safety of Sputnik V [57], because drug regulatory agencies such as in Brazil were delaying Sputnik V emergency registration: “Anvisa was unable to validate the methodology Russian studies used (...) to track

and describe adverse events following vaccination" [58]. In this study, we showed that community-based surveillance via social media can provide meaningful information that could be useful, and this phenomenon should be carefully investigated. The frequencies of AEs extracted from Telegram samples in which at least one AE was reported were in line with other safety surveillance.

Mild, nonsevere AEs have usually been ignored by medical communities because they are common to all vaccines. Antivax movements have emphasized severe AEs, which have been widely discussed in social media [59] in the wider context of vaccine safety [60,61]. In the discourse on COVID-19 vaccines, the main issues were that they were developed quickly and they could compromise safety. Those issues included the fear that vaccines would alter human DNA, cause allergic reactions to vaccine ingredients, result in sudden deaths due to frailty syndrome, or cause infertility [62,63]. Wide anti-COVID-19 immunization programs promulgated a discourse in which risk (eg, the discomfort of common, but mild, AEs as well as rare, but serious AEs) and benefits (eg, efficacy in protecting from the disease) were described as "tradeoffs" of being vaccinated. Mild AEs have become an important issue for many people; moreover, they have the economic component of the potential need for sick leave. This discourse led to the formation of a public Telegram group, where users were asked to report AEs.

In this study, we demonstrated that, in the first phase of the vaccination roll-out, the AE reports were correlated (r=0.7) with vaccination volume (Figure 1). However, Telegram users tended to lose interest after a few months. It is possible that because of the prioritization of vaccine delivery, which began with public and military servants, scientists, teachers, and medical staff, these "early adopters" were more likely to post on social media and be actively involved in reporting AEs. Subsequently, users in the general population were vaccinated, and they were less involved in reporting on the Telegram platform (Figure 1). Thus, interest in COVID-19, Sputnik V, and its AEs was influenced by social context and media to much extent [64].

The results of this study showed that the number of reported AEs decreased linearly according to age (β=.05 AE per year; Figure 2). This result was dependent on biology, which was confirmed in previous clinical trials [36,37,52] and postmarketing observations [47] of other anti-COVID-19 vaccines. Telegram users older than 60 years reported significantly more systemic AEs compared with their peers in clinical trials, who tested negative for or had recovered from COVID-19 [51] (Table 4). On one hand, it is possible that people previously infected with COVID-19 were more likely to report AEs after receiving other vaccines [47]. On the other hand, self-reporting bias could be an important factor in explaining the difference between the "Moscow" clinical trial and the Telegram reports.

The safety profile of the Sputnik V vaccine includes mild AEs that are more similar to vector vaccines than to mRNA anti-COVID-19 vaccines, which was quantified by the Euclidean distance between AE frequencies (Figure 4). The Sputnik V safety profile also showed a high fever-to-fatigue ratio (Table 6) and a stronger reaction to the first dose than to the second one (Table 3), which was also analyzed in a retrospective observational study in San Marino [65].

Women reported more AEs than men (1.2-fold, P<.001; Mann-Whitney U test). This phenomenon is well recorded in other anti-COVID-19 vaccine registries [47,66] and has even been noticed among Argentinian medical staff [67], which could indicate sex-dependent vaccine reactivity. However, this result needs to be understood with caution. The Centers for Disease Control and Prevention has warned that gender bias in reporting could be more important than possible biological mechanisms [35]. The likelihood of disclosing personal information (even anonymously) is known to vary, such as according to gender [68] and social class [69]. A potential reason is that women are more likely to be interested in health, write about health on the internet, and disclose their information [68].

On Telegram, self-reports are most likely to underestimate gastric symptoms (eg, diarrhea at 0.6%). These symptoms could be a taboo effect [70], such as a response to public speaking anxiety. Alternatively, it could be easily ignored because of its high prevalence, or it could be eliminated using an over-the-counter medicine such as loperamide [45,46]. Insomnia was detected so often that it suggests an epidemiological link with the vaccine, which needs further investigation. Local AEs, such as injection site irritation, have rarely been reported. Underlying conditions of erythema/redness, which is usually one of the most common AEs in response to all injected substances including vaccines, are probably overlooked due to low subjective discomfort and lack of physical investigation by a doctor. The findings showed that their actual prevalence was probably underreported.

Our study has several limitations. First, we analyzed participatory and community-based surveillance among Russian Telegram users. Therefore, the results may be specific to the Russian population in a given stage of the pandemic and therefore should not be extrapolated to other contexts. Second, Telegram users may overlook less troublesome side effects, and the social context could influence decisions on taking part in discussions and being selective in reporting AEs [68,69]. For example, local or gastric AEs could be underreported. Third, the classifications developed in this study should not be strictly applied to other contexts. For example, pain at the injection site and pain in other parts of the body were not differentiated. Observed correlations and odds ratios do not imply causation. Fourth, we did not assess the authenticity and credibility of posts [15]; thus, incorrect information could be included in the data. Finally, because our infodemiology study focused on community research initiatives (independent and nonprofit projects, with already known strengths and weaknesses from the history of medicine [71]), our observations cannot replace real-world studies [55-57]. The symptoms reported by social media users only partially reflect their prevalence in the real world [72]. Therefore, the frequencies of symptoms should not be interpreted without considering the contexts and proportions of other symptoms (ie, fever-to-fatigue ratio), phase of the epidemic, and vaccination roll-out (ie, the number of doses administered daily and the population that is vaccinated), as willingness to report AEs satisfies typical product life-cycle temporal characteristics [73,74]).

Conclusion

After the Sputnik V vaccination, Russian Telegram users reported mostly pain, fever, and fatigue. The Sputnik V mild AE profile was comparable with other vector COVID-19 vaccines. Discussions on social media could provide meaningful information about the AE profile of novel vaccines. Further research on severe AEs reported on social media and their credibility is needed.

Acknowledgments

The authors acknowledge the initiators and users of the Telegram group “Sputnik_results” for creation of the data analyzed and express gratitude to the editor and 3 anonymous referees. AJ and VB were partially funded by the German Research Foundation (DFG: 458528774) and Polish-German Foundation for Science (PNFN: 2019-21). Support from The Endowment Fund of St. Petersburg State University is gratefully acknowledged by AS. MK is medicine practitioner at Individual Medical Practice, Oborniki, Poland.

Conflicts of Interest

MK received remuneration for performing vaccinations against COVID-19 in primary care. The vaccinations did not involve Sputnik V.

Abstract

Background: The role of telemedicine in intensive care has been increasing steadily. Tele–intensive care unit (ICU) interventions are varied and can be used in different levels of treatment, often with direct implications for the intensive care processes. Although a substantial body of primary and secondary literature has been published on the topic, there is a need for broadening the understanding of the organizational factors influencing the effectiveness of telemedical interventions in the ICU.

Objective: This scoping review aims to provide a map of existing evidence on tele-ICU interventions, focusing on the analysis of the implementation context and identifying areas for further technological research.

Methods: A research protocol outlining the method has been published in JMIR Research Protocols. This review follows the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews). A core research team was assembled to provide feedback and discuss findings.

Results: A total of 3019 results were retrieved. After screening, 25 studies were included in the final analysis. We were able to characterize the context of tele-ICU studies and identify three use cases for tele-ICU interventions. The first use case is *extending coverage*, which describes interventions aimed at extending the availability of intensive care capabilities. The second use case is *improving compliance*, which includes interventions targeted at improving patient safety, intensive care best practices, and quality of care. The third use case, *facilitating transfer*, describes telemedicine interventions targeted toward the management of patient transfers to or from the ICU.

Conclusions: The benefits of tele-ICU interventions have been well documented for centralized systems aimed at extending critical care capabilities in a community setting and improving care compliance in tertiary hospitals. No strong evidence has been found on the reduction of patient transfers following tele-ICU intervention.

Introduction

Telemedicine has been increasingly used in intensive care, and approximately 15% of intensive care beds in the United States currently partake in telemedical programs [1-3]. A range of rationales for the implementation of telemedical systems in intensive care has been suggested. Tele–intensive care unit (ICU) technologies have been used to address staffing shortage in intensive care and as a cost-effective response not only to a lack of intensive care availability in some areas but also as a means of increasing adherence to evidence-based best practices using benchmark performance data [3-5].

The American Telemedicine Association defines tele-ICU as "a network of audiovisual communication and computer systems that provide the foundation for a collaborative, interprofessional care model focusing on critically ill patients" [3]. Tele-ICU interventions are varied, can be offered in different levels of intensive care service, and can be customized to meet the specific intensive care needs of hospitals [3,5-7]. For example, some tele-ICU systems provide 24/7 remote monitoring staffed by intensivists, while other systems provide scheduled remote intensivist consultations during nighttime only.

The main characteristics of tele-ICU systems have been well described in the literature. First, technical architectures can be described as centralized or decentralized. Centralized architecture features a command center, or a *cockpit*, connecting one or multiple centers. Decentralized systems (also named *virtual consultant*) allow one-on-one connections without the need for central coordination [3]. Second, staff allocation and availability can vary (eg, day presence or 24/7) [8]. Third, the mode of interaction between telemedicine teams and bedside staff may allow various levels of staff reactivity (reactive vs proactive to patient alerts) and intervention scope (minimal intervention allowed vs full discretion on patient care) [4]. Several guidelines, such as the US [3] or the German Guidelines for Telemedicine in Intensive Medicine [9], provide general recommendations on aspects of equipment, staffing, and organization for implementing tele-ICU systems.

A significant body of primary and secondary literature has been published on ICU telemedical interventions [10]. To date, 9 systematic reviews and 9 other review types have been published on this topic [11], as well as 3 meta-analyses with a focus on medical outcomes (eg, hospital mortality and length of stay) [12]. In previous reviews, the results of tele-ICU interventions have been characterized as heterogeneous [13,14]. Although positive medical outcomes could be detected in some interventions, other contexts could only demonstrate mixed or no positive results at all [4,14,15]. Authors have suggested that the context of implementation may be a factor in explaining the variability of these results. We define context of implementation as the clinical structures and processes where telemedical interventions are deployed [16]. It has been suggested that the efficacy of tele-ICU interventions is dependent on where and how they are deployed in the organization [6,10], and there is a need for broadening the understanding of the organizational factors influencing the efficacy of tele-ICU interventions [8]. We found that no previous study has attempted to provide a review of current evidence by systematically analyzing the implementation setup and context.

This scoping review seeks to address a research gap on the characterization of the context of implementation for tele-ICU interventions [14,17]. The first objective is to characterize the implementation context of tele-ICU interventions with a consistent set of domains on hospital organization. The second objective is to characterize the configurations and structures of tele-ICU systems in relation to their context of implementation. The third objective is to describe the outcomes of tele-ICU interventions and to characterize current evidence according to their intervention contexts.

Methods

A research protocol for this review was published in JMIR Research Protocols in December 2020 [11], which was developed in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) and best practices advanced by Arksey and O'Malley [18] and the Joanna Briggs Institute [19]. The method included the steps *identification of relevant studies*, *selection of study*, *data charting*, and *data collating*.

For the step *identification of relevant studies*, a search for peer-reviewed studies in the databases Web of Science Core Collection, MEDLINE, ERIC, PsycINFO, PSYNDEX, CINAHL, and IEEE was performed without date restrictions. Manual searches were performed additionally to identify gray literature. The search query was developed according to the guidelines of the Peer Review of Electronic Search Strategies and included keywords on the topics of intensive care and telemedicine. The full queries are provided in Multimedia Appendix 1. The search records were downloaded in the reference software Citavi version 6 (Swiss Academic Software).

In the step *selection of study*, both titles and abstracts were screened, and studies not dealing with a relevant topic or method were removed. Results were then screened to find articles where the PICO (Patient, Intervention, Comparison, Outcome) framework could be identified. We included articles with at least three of the PICO criteria summarized in Textbox 1. Studies concerning interventions in neonatal and pediatric ICUs were excluded from this scoping review.

In the step *data charting*, article information was collected and classified into extraction sheets according to the five domains defined in the review protocol (see Textbox 2).

In the step *data collating, summarizing, and reporting*, the information was organized and clustered into an evidence map. The evidence map provided a summary of the scoping review results. During the review process, a core research team was created to provide feedback and discuss findings. The research team was composed of a doctoral researcher with a background in health economics (author CG), a medical data science professor (author FB), a medical informatics professor (author MB), an anesthesiologist with intensive care specialty and main coordinator of a tele-ICU project (author BW), an anesthesiology researcher with a specialty in digital health (author ASP), a professor of digitalization (author DF), and an anesthesiologist

with intensive care specialty (author RM). The research team was asked to consider the information from data charting, provide insights, and discuss results. Differing views were resolved through discussion until consensus was reached.

Textbox 1. PICO (Patients, Intervention, Comparison, Outcomes) criteria.

Patient

Participants provided telemedical intensive care.

Intervention

Telemedical system implemented with one more an intensive care units (ICUs).

Comparison

Comparison with the standard of care without tele-ICU intervention.

Outcomes

All outcomes eligible for inclusion.

Textbox 2. Data charting domains.

Implementation context

A. Clinical focus

Level of intensive care specialization. Generalist (medical intensive care unit [ICU], surgical ICU) or specialized clinical focus (ie, sepsis, cardiology, neurocritical).

B. ICU type

Level of intensivist involvement in patient care. Defined by staffing model of ICU (ie, open vs closed ICU models).

C. Hospital type

Category of hospital involved in tele-ICU intervention (ie, tertiary or community hospital). Community hospitals are defined as nonfederal, short-term general hospitals under 500 beds [20].

D. System configuration

Technical architecture (ie, centralized vs decentralized), staff allocation (ie, continuous vs scheduled), and mode of communication of the tele-ICU system (ie, high or low data intensity).

E. Implementation rationale

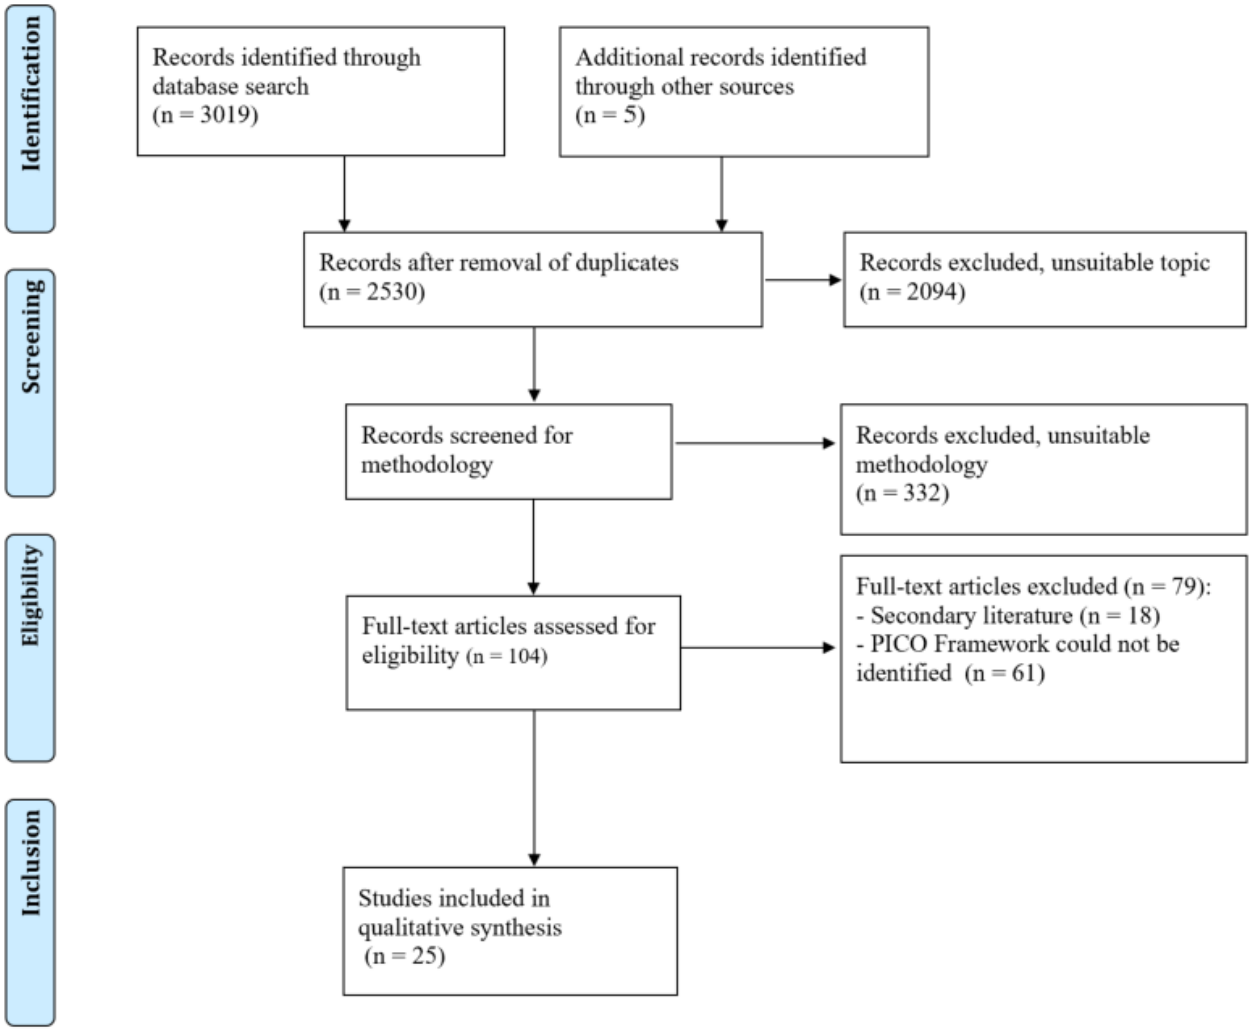
Main rationale provided in the study for tele-ICU intervention, use case for telemedical system in the ICU.

Results

Selection of Relevant Studies

The flowchart in Figure 1 outlines the records yielded by the search. A total of 3019 results were retrieved, including 489 duplicates. After screening, 104 records were eligible for full-text analysis and 25 were included in the final analysis.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart. PICO: Patient, Intervention, Comparison, Outcomes.



Characteristics of Tele-ICU Studies Included in the Scoping Review

The 25 studies included in this review were published between 2004 and 2019. Out of 25 articles, 21 (84%) referred to tele-ICU implementation within the Unites States, while the remaining papers described implementation in Germany, India, Australia, and Saudi Arabia. Regarding the research methods used in the studies, we found that 21 articles used pre-post comparison designs, of which only 7 included a control group. The pre-post design has been described as a quasi-experimental research design [12,21], for which a random assignment of patients between treatment and control group was not performed. The remaining 4 publications used other methods, such as interrupted time series, and half of these included a control group. We found no examples of randomized controlled trials.

Results From Data Charting

Table 1 summarizes the data charting results for the 5 research domains and provides definitions for each category.

First, we outline results for the domains pertaining to context of implementation (domains A to C). For domain A, most telemedical implementations did not have a specific clinical focus (n=21, 84% of the studies), with only a few cases of specialized interventions. For domain B, tele-ICU interventions were predominantly implemented in ICUs featuring aspects of the open model. In these interventions, the primary physicians or surgeons retained full responsibility for the patient (n=10, 40% of the studies) or with limited intensivist involvement only (n=9, 36% of cases open/closed). Regarding domain C, although 44% (n=11 studies) of interventions were implemented in tertiary hospitals, a large subset was in community settings and in organizations spanning both tertiary and community hospital settings.

Second, concerning the system configuration results in domain D, centralized architectures (eg, tele-ICU Command Center) were the predominant implementation setup. Relating to the staffing model, the continuous care setup was used in 13 (52%) of the studies, where the remote care team assumes constant patient monitoring. Scheduled interventions (eg, daily intensive care rounds) were found in 9 (36%) cases. Finally, most telemedical systems (n=19, 76%) enabled remote real-time access to patient data. To summarize this information, we classified the system configurations into three clusters, as outlined in Figure 2.

Finally, concerning the implementation rationale defined in domain E, three main use cases were defined for tele-ICU interventions. We classified 13 (52%) publications under the use case 1 summarized by the term *extending coverage*. In this group, studies cited intensivist shortage, need for additional intensivist coverage, and extension of intensivist resources as a rationale for the intervention. A total of 10 (40%) studies were classified under use case 2, summarized by the term *improving compliance*. In this group, studies cited the increase in adherence to compliance with care bundles, clinical practice guidelines, or care quality initiatives as the main rationale. We classified two studies in use case 3, summarized by the term *facilitating transfer*. Studies in this category cited the screening or monitoring of patients prior to transfer to or from an ICU as the main rationale.

Table 1. Data charting results: interventions and context.

Domain and category	Definition	Studies (N=25), n (%)
Implementation context		
Clinical focus		
General	No specific clinical focus identified (MICU[a], SICU[b])	21 (84)
Specialized	Specific clinical focus (ie, sepsis, cardiology, neurocritical)	4 (16)
ICU[c] type		
Open	Primary physician has full-time responsibility for patient care	10 (40)
Open/closed	Features of both open and closed models	9 (36)
Closed	Intensivists available with full responsibility for patient care	6 (24)
Hospital type		
Tertiary	Tertiary care institutions or teaching hospitals	11 (44)
Mixed	Care organization spanning tertiary and community settings	4 (16)
Community	Community hospitals or small medical facility	9 (36)
Not available	N/A[d]	1 (4)
System configuration		
Continuous	Continuous patient critical care monitoring	5 (20)
Mixed	Continuous monitoring including scheduled rounds	9 (36)
Scheduled	Scheduled consultation at regular interval. Virtual rounds.	9 (36)
Not available	Insufficient information provided	2 (8)
Centralized	Tele-ICU Command Center or Hub centralizing patient care	19 (76)
Decentralized	Distributed architecture without centralized hub	5 (20)
Not available	N/A	1 (4)
Direct access	Direct staff remote access to patient data	18 (72)
Limited access	Limited staff remote access (screen sharing) to patient data	4 (16)
Not available	N/A	3 (12)
Implementation rationale		
Coverage	Intensivist shortage, provision of extended coverage	13 (52)
Compliance	Adherence and compliance to critical care guidelines	10 (40)
Transfer	Patients screening or triage for transfers to or from ICU	2 (8)

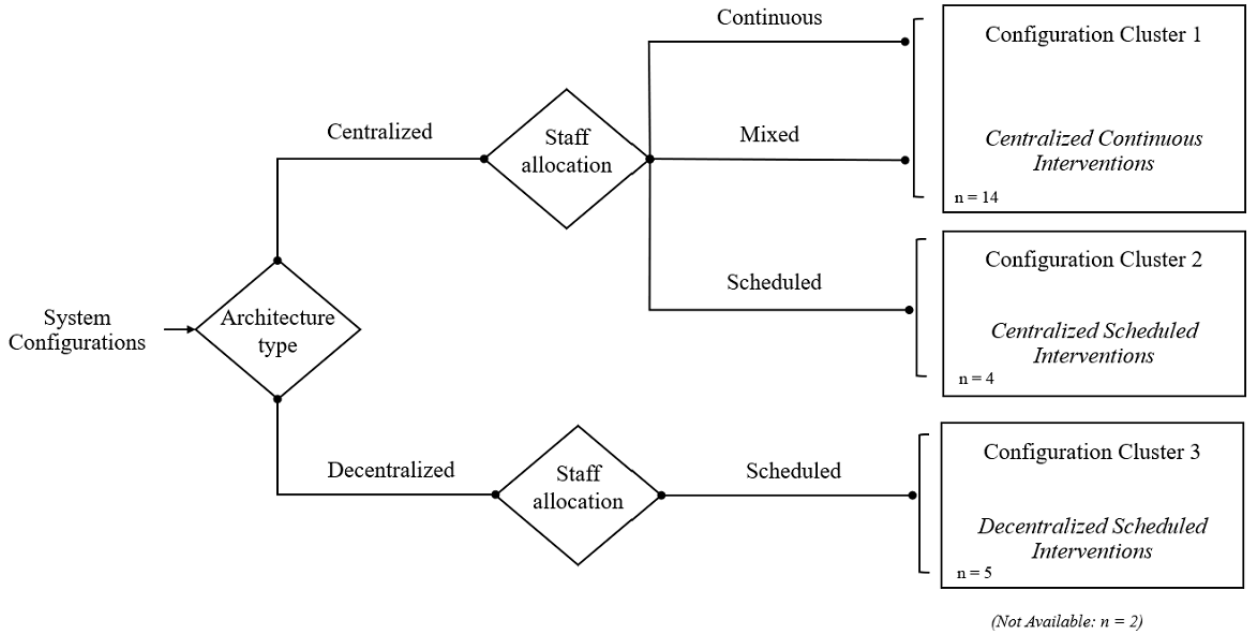
[a]MICU: medical intensive care unit.

[b]SICU: surgical intensive care unit.

[c]ICU: intensive care unit.

[d]N/A: not applicable.

Figure 2. Clustering system configurations.



Intervention Outcomes

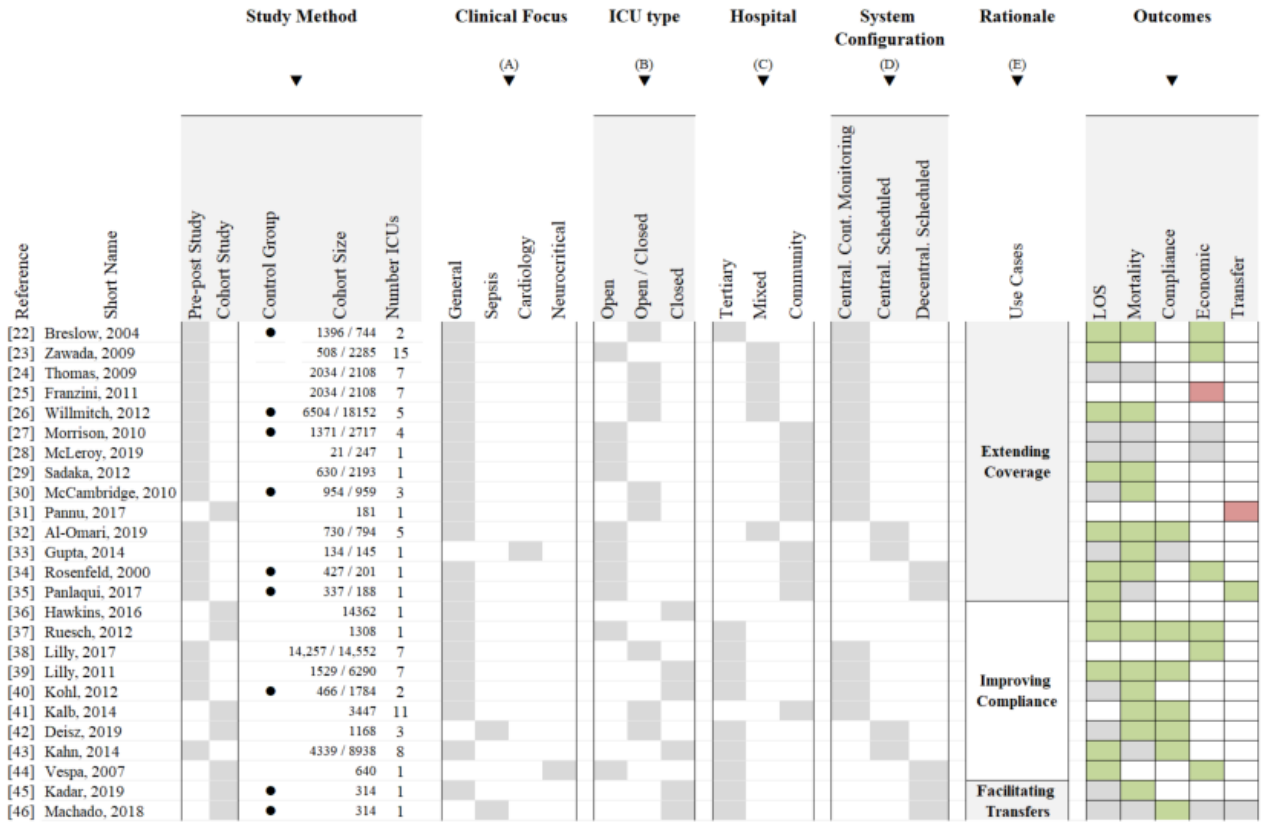
This section presents results on the range of outcomes that were found in the studies on ICU implementation, which are summarized in Table 2.

First, a significant subset of studies provided results on at least one medical outcome. Effect of tele-ICU intervention on length of stay (LOS) was reported in 21 (84%) studies. This outcome was defined as the number of inpatient days for the episode of care in the ICU or in aggregate in the hospital. Results on mortality rates were provided in 19 (76%) studies, including ICU and hospital mortality. In 12 studies, reduction in LOS was found to be significant. Reduction in mortality was significant in 13 studies. Second, 8 (32%) studies measured the rate of adherence to best practices and guidelines implementation, summarized by the term *compliance*. A large subset indicated a statistically significant increase in the level of adherence to ICU standards. Third, under the header *economics*, 9 (36%) studies provided results regarding cost-effectiveness of tele-ICU interventions. In this subset, 6 (67%) studies reported interventions as being cost-effective. Lastly, 2 studies in the category *transfer* measured changes in rate of patient transfer following intervention. One study measured the number of transfers within the same facility (eg, for preadmission diagnostic) and another the number of transfers to another facility (eg, for advanced care). Finally, we note that none of the studies included patient satisfaction scores. These results are summarized as an evidence map in Figure 3.

Table 2. Data charting results: outcomes.

Outcome category	Reporting on outcome, n	Of which reporting positive results, n
Length of stay	21	12
Mortality	19	13
Compliance	8	7
Economics	9	6
Transfer	2	1

Figure 3. Evidence map [22-46]. ICU: intensive care unit; LOS: length of stay.



Discussion

Principal Findings

This scoping review provided an overview of the literature on telemedical interventions in the ICU. Based on a set of defined domains, we were able to characterize the context of tele-ICU studies and identify three use cases for tele-ICU interventions. This analysis aimed to identify common features within the heterogenous use of telemedical systems. Recent research findings relevant for implementation under each use case were outlined.

The first use case, *extending coverage*, included interventions aimed at increasing intensive care coverage in contexts where it is not (or only partially) available at the bedside. This use case was found predominantly in community hospitals having limited onsite critical care capacity. The second use case, *improving compliance*, included interventions targeted at improving patient safety, intensive care best practices and quality of care. These interventions were found primarily in tertiary care context. The third use case, *facilitating transfer*, included telemedicine interventions targeting toward the management of patient transfers to or from the ICU.

Use Case: Extending Coverage

Interventions were predominantly found in community hospitals and in mixed community/tertiary contexts (eg, hospital groups spanning one or several community branches). Tele-ICU systems in this use case have been used to address specific issues related to the delivery of critical care in community and rural areas. Particularly in the United States, recent surveys indicate that hospitalists (ie, physicians whose main focus is on general medical care of patients who are hospitalized [47]) are still the main physician in rural and community settings, reflecting a general shortage in intensive care staffing [48]. Although community hospitals face difficulties in hiring qualified critical care personnel, some of them are subject to minimum requirements to have full intensivist staffing during the day [49,50]. In underserved areas, tele-ICU implementation can therefore represent a valuable solution for the onsite provision of intensive care expertise [51].

The predominant tele-ICU system configuration in this use case was a centralized system featuring continuous remote staff intervention from a workstation, with direct involvement in patient care (configuration cluster: *centralized continuous monitoring*). Team cooperation and sharing of responsibility over patient care between the bedside and remote team are central issues in this type of configuration. Our analysis showed that different modalities of a remote care team have been implemented. In some interventions, the main role of the remote team was to consult and advise the bedside team (Zawada et al [23], McLeroy et al [28], and Al-Omari et al [32]; n=3, 12% of studies), whereas in other cases, remote staff were granted a different level of authority on patient care at the discretion of the bedside team (Sadaka et al [29], Morrison et al [27], Thomas [24], Willmitch et al [26], Franzini et al [25], and Breslow et al [22]; n=6, 24% of studies). Achieving an appropriate degree of cooperation between bedside and remote care has been described as a success factor of telemedical interventions [10,52]. Recent literature on the impact of tele-ICU interventions suggest that effectiveness is enhanced when comanagement and clear autonomy of the remote care team are allowed [10,36].

Particularly for intensive care nurses, there is a need to establish clear rules of engagement to avoid conflicting orders between bedside and remote teams [53]. A recent ethnographic review also indicates that the perceived value of the intervention by bedside staff is a contributing factor to the success of the intervention [14]. The core research group discussed in particular the aspect of bedside physician's trust in the remote specialist. As an example, situations where an experienced physician of a nonacademic hospital in a rural area collaborates with a less experienced physician at a university hospital telemedical center can raise the issues of perceived value and trust between remote and bedside personnel. Therefore, the involvement of bedside staff during planning, system implementation, and training is recommended to enhance organizational acceptance [54,55]. As part of the implementation process, actions targeted at team cohesion (eg, team building) and use of standardized communication practices between teams can enhance the implementation of new workflows [56,57]. Implementation of health technology can lead to changes in work practice inside the care team, in particular for nursing and support staff [58]. Clear definition of the roles, responsibility, and composition of the team should therefore be addressed early on during the planning of the intervention.

Implementation of tele-ICU systems has been advanced as a solution for community hospitals facing the challenge of sustaining the cost of maintaining a local ICU with high standard of care. Economic evaluations of tele-ICU interventions are therefore an important aspect for consideration in the community settings. With tele-ICU systems, community hospitals have the potential to treat patients with a higher case mix index locally and at lower cost [51]. At the same time, high cost of tele-ICU systems has been described as a barrier to implementation [59]. Our finding indicates that studies on cost-effectiveness in this use case have not yielded uniform results. The included studies in this review have used heterogeneous approaches to estimate savings and revenue increase following tele-ICU implementation. We corroborate previous observations concerning the lack of transparency and comprehensive data on costs, which hinder comparisons and clear statements regarding cost-efficacy [59,60].

Use Case: Improving Compliance

In this use case, ICU systems were primarily configured as scheduled daily rounds from a tele-ICU center (configuration cluster *centralized scheduled interventions*; n=4, 16% of studies) and decentralized systems allowing expert remote consultations (configuration cluster *decentralized scheduled interventions*; n=5, 20% of studies). Interventions in the use case are mainly focused on advancing adherence to best practices in the ICU and increasing patient safety. They consisted in establishing critical care processes in which the remote care teams monitor relevant quality indicators (eg, prophylaxis for stress ulcer, ventilator-associated pneumonia, or deep vein thrombosis). In our analysis, there is some evidence that ICU interventions are conducive to higher adherence to best practices in the ICU and enhance patient safety, thereby corroborating earlier observations on efficacy [51]. We found that most evidence for this type of intervention has been reported in tertiary care hospitals with a closed or mixed ICU model. Additional research would be needed to understand how this type of intervention could be beneficial in other hospital contexts. The review highlighted an intervention specialized on prevention of sepsis (Deisz et al [42]), for which compliance to the care bundle was found to remain low [61,62].

We hypothesize that the efficacy of these interventions is derived from a combination of change in the care process (eg, increased use of reminders and checklists) and the use of decision support systems (eg, smart alerts). Tele-ICU systems are conducive to real-time benchmarking of performance and allow targeted actions to enhance compliance and care quality. Surveillance systems can improve resource allocation by allowing for more rapid response time and faster escalation of the most acute cases [54]. Additionally, tele-ICU systems have been shown to reduce alarm fatigue through triage and curation of automatic alerts by remote care teams [51,59]. In recent literature, the potential of population management systems allowing targeted interventions on patients with high risk factors has been highlighted [63]. Significant amount of data generated by tele-ICU systems can be leveraged for the development of advanced applications [64]. A recent systematic review on telemedicine with clinical decision support for critical care indicated the need for further research on the use and efficacy of advanced applications in units equipped with telemedical systems [65].

Use Case: Facilitating Transfer

Interventions in this use case are aimed at supporting patient transfers between hospitals (ie, referral to higher level hospital) and monitoring patients during admission in the ICU from another department (eg, emergency department). This form of intervention has been described in the literature as consultative critical care services [66]. One study in the review documented the benefit of these interventions for patients in the emergency department with suspected sepsis diagnosis [54]. Based on the studies in the review, we can corroborate previous reports that no strong evidence has been found regarding the benefit on the number of transfers for this type of interventions [67].

Limitations

Our approach has multiple limitations. First, the studies included in the review used heterogeneous research methods. Authors provided varying degree of details to describe the intervention setup and implementation context. Aspects such as staff interaction and level of autonomy have been provided only in a limited number of studies, so that our ability to draw generalizable conclusions on these aspects of tele-ICU interventions has been limited. Second, relying on the expertise of the core research group to complete the data charting was qualitative in nature and potentially subject to bias. A discussion process section was established to mitigate the interpretation bias in our approach. Third, the scope of this review was limited to the implementation of tele-ICU systems for adult patients, and critical care telemedical interventions have also been documented in pediatrics and neonatology. Some of our conclusions might therefore not be applicable to these settings.

Conclusion

Tele-ICU systems have been deployed in numerous implementation contexts, which we characterized in three main

use cases. The benefits of tele-ICU interventions have been well documented for centralized systems aimed at extending critical care capabilities in community settings and improving care compliance in tertiary hospitals. This scoping review provides teams involved in the implementation of tele-ICU systems with an overview of existing evidence on the technology. It highlights factors that are conducive to successful implementation for different critical care context. This review also mentions areas for future research on tele-ICU interventions. Furthermore, the framework for describing the implementation context used in this scoping review could be used for analyzing other types of telemedical interventions or other domains of intervention (eg, traumatology, pediatrics, neonatology).

Abstract

Background: Emergency telehealth has been used to improve access of patients residing in rural and remote areas to specialist care in the hope of mitigating the significant health disparities that they experience. Patient disposition decisions in rural and remote emergency departments (EDs) can be complex and largely dependent on the expertise and experience available at local (receiving-end) hospitals. Although there has been some synthesis of evidence of the effectiveness of emergency telehealth in clinical practice in rural and remote EDs for nonacute presentations, there has been limited evaluation of the influence of contextual factors such as clinical area and acuity of presentation on these findings.

Objective: The aims of this systematic review are to examine the outcome measures used in studying the effectiveness of telehealth in rural and remote EDs and to analyze the clinical context in which these outcome measures were used and interpreted.

Methods: The search strategy used Medical Subject Headings and equivalent lists of subject descriptors to find articles covering 4 key domains: telehealth or telemedicine, EDs, effectiveness, and rural and remote. Studies were selected using the Population, Intervention, Comparator, Outcomes of Interest, and Study Design framework. This search strategy was applied to MEDLINE (Ovid), Cochrane Library, Scopus, CINAHL, ProQuest, and EconLit, as well as the Centre for Reviews and Dissemination databases (eg, National Health Service Economic Evaluation Database) for the search period from January 1, 1990, to May 23, 2020. Qualitative synthesis was performed on the outcome measures used in the included studies, in particular the clinical contexts within which they were interpreted.

Results: A total of 21 full-text articles were included for qualitative analysis. Telehealth use in rural and remote EDs demonstrated effectiveness in achieving improved or equivalent clinical effectiveness, appropriate care processes, and—depending on the context—improvement in speed of care, as well as favorable service use patterns. The definition of effectiveness varied across the clinical areas and contexts of the studies, and different measures have been used to affirm the safety and clinical effectiveness of telehealth in rural and remote EDs. The acuity of patient presentation emerged as a dominant consideration in the interpretation of interlinking time-sensitive clinical effectiveness and patient disposition measures such as transfer and discharge rates, local hospital admission, length of stay, and ED length of stay. These, together with clinical area and acuity of presentation, are the outcome determination criteria that emerged from this review.

Conclusions: Emergency telehealth studies typically use multiple outcome measures to determine the effectiveness of the services. The outcome determination criteria that emerged from this analysis are useful when defining the favorable direction for each outcome measure of interest. The findings of this review have implications for emergency telehealth service design and policies.

Introduction

Background

The significant health disparities for residents of rural and remote communities compared with metropolitan or urban populations raise questions of equity and access to health services. Multiple reasons have been put forward internationally to explain these health disparities [1-4]. Limited access to health care is seen as a major contributor to rural or remote and metropolitan or urban health disparities, with workforce supply central to this discourse [5-10].

Emergency department (ED) services are an essential component of the health system, often serving as the first or only point of contact for patients requiring medical care. Patients presenting to tertiary center EDs, often in an urban location, can be assured of a well-supported ED with sufficient post-ED care within the same hospital or at another hospital within a short distance [11]. Transfer decisions in rural and remote EDs do not generally have the assurance of timely and appropriate follow-up care. The challenges in rural and remote ED care are 2-fold. First, variations are evident in the capability of local hospitals, arising mainly from the lack of economy of scale to justify investments in a full range of capabilities and inpatient wards for continued treatment and monitoring after completion of ED care. Second, the time needed and distance involved to reach definitive health care compared with suburban or urban settings [12] can delay time-critical treatments such as thrombolytic treatments to resolve a dangerous clot in the blood vessels. This means that, in making decisions around patient dispositions, local hospital capabilities and distance from destination hospitals should be considered together with the patient's clinical conditions.

Emergency telehealth services provide rural and remote hospitals with timely specialist expertise to increase staff support during critical ED encounters [12], to some extent mitigating the inequities in workforce supply. The key question in the evaluation of the effectiveness of an emergency telehealth service is whether this increased specialist workforce participation in rural and remote ED presentations improves patient outcomes by delivering more timely and effective care.

Only 1 systematic review has examined the use of telehealth in rural and remote EDs, and its focus was on noncritical emergency presentations [11]. The scope of ED services included in the review ranged from telepsychiatry to assist with mental health emergency presentations and teleophthalmology for acute eye concerns requiring ophthalmologist assessment to tele-emergency, half of which involved the use of teleradiology and consultation with other subspecialists [11]. The outcomes of interest were uptake of the telehealth program, change in diagnosis or management plan, patient transfer rate, and patient dispositions (discharge, local admission, and discharge against medical advice) [11]. Of the 15 studies reviewed, 5 reported the influence of telehealth on patient diagnosis or management, with teleconsultations changing the diagnosis or management in 18%-66% of the consultations [13-17]. The review also discussed the dependence of patient dispositions on telehealth program design and observed close linkages between the rate of patient transfer, discharge, local admission, and discharge against medical advice and emergency telehealth use [11]. Most of the studies included in the review reported increases in patient transfer rates [11]. A total of 4 studies aligned telehealth with a reduction in unnecessary patient transfers [15,18-20]. Apparent in the review was the reduction of unnecessary transfers and secondary overtriage (misidentification of noncritical patients as critically ill at initial presentation), which translated into increased local hospital admissions and reduced discharge after teleconsultation [19,20].

Whether reduced unnecessary transfer and increased local admission are favorable outcomes for patients depends on the acuity and health conditions being treated as well as the infrastructure and workforce capabilities of the local hospitals to accommodate the increased demand. For the same reasons, transfer avoidance may not always result in favorable outcomes for patients presenting to rural and remote EDs. Similarly, an increase in local hospital admission may not always lead to favorable patient outcomes if specialist consultations through telehealth alone do not change the capability of local (receiving-end) hospitals to continue caring for patients presenting to the ED in critical conditions. While identifying outcome measures, the systematic review of the use of telehealth in managing emergencies in rural and remote EDs did not consider the relevance of outcome measures across the various clinical contexts such as clinical area and the acuity of presentation. In addition, its focus was on noncritical presentations only [11].

Objective

The aim of this systematic review is to examine the outcome measures used in studying the effectiveness of rural and remote emergency telehealth services and analyze the clinical context in which these outcome measures were used and interpreted. The findings from this review provide insight into evaluating the clinical impact of telehealth services in rural and remote EDs and will assist in the design of future studies on the

effectiveness and cost-effectiveness of emergency telehealth services in the rural and remote context.

Methods

Study Selection

This systematic review followed the effectiveness part of a published protocol on reviewing the literature on the effectiveness and cost-effectiveness of telehealth services in rural and remote EDs [21]. Studies were selected using the Population, Intervention, Comparator, Outcomes of Interest, and Study Design framework (see Table 1 for inclusion and exclusion criteria). Although there was a substantial body of literature on using telehealth to support prehospital emergency medical services, to restrict the scope, this review only included studies taking place in hospital EDs and excluded records reporting on the use of prehospital emergency telehealth.

Table 1. Selection criteria.

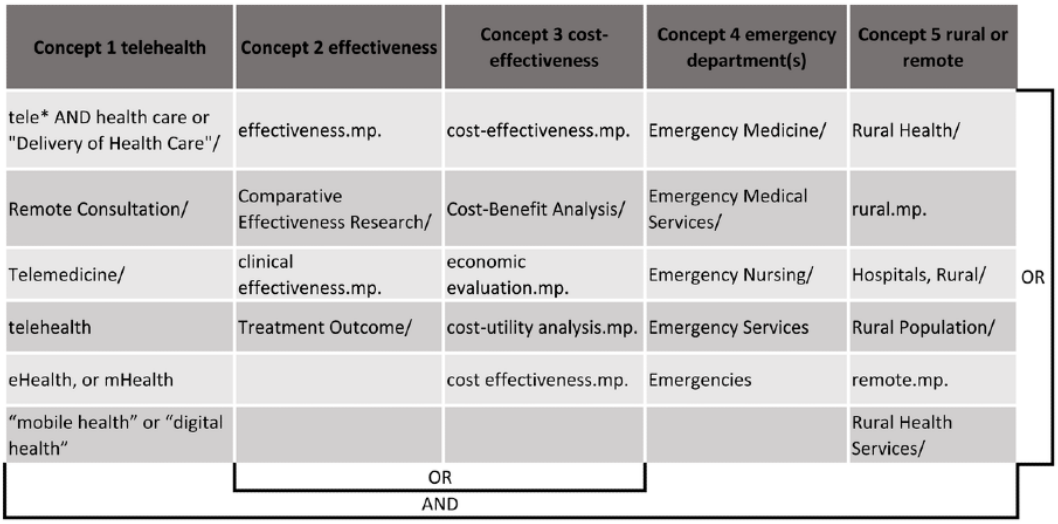
Parameter	Inclusion criteria	Exclusion criteria
Population	• Rural and remote populations treated in emergency departments	• Rural and remote populations treated outside of the emergency department
Intervention and comparator	• Emergency telehealth versus treatment as usual including the following: • Telephone versus face-to-face consults • Videoconference versus telephone consults	• Descriptive studies without comparators • Study focused on a mobile device or electronic health records
Outcomes	• Timeliness of care • Health service use • Clinical effectiveness	• Descriptive statistics without a well-defined effectiveness measure
Study design	• Randomized controlled trials • Nonrandomized controlled trials • Qualitative research	• Commentaries • Expert opinions • Government reports • Strategic documents • Single-case reports

Information Sources and Search Strategy

The search strategy used Medical Subject Headings and equivalent lists of subject descriptors to find articles covering 4 key domains: telehealth or telemedicine, EDs, effectiveness, and rural and remote (Figure 1).

This search strategy was applied to MEDLINE (Ovid), Cochrane Library, Scopus, CINAHL, ProQuest, and EconLit, as well as the Centre for Reviews and Dissemination databases (eg, the National Health Service Economic Evaluation database) for the search period from January 1, 1990, to May 23, 2020. The reference lists of the included studies were hand searched to include other peer-reviewed publications relevant to this review. Finally, a search was conducted on Google using the phrase “effectiveness of rural and remote emergency department telehealth.”

Figure 1. Search strategy.



Study Records

Data Management and Selection Process

The identified records were downloaded into EndNote (Clarivate), where duplicate records were identified and removed. A reviewer (CT) screened all the downloaded titles and excluded those that were irrelevant to the review. The abstracts of the preliminary list were classified into included, excluded, and *gray area* according to the study selection criteria [21]. The *gray area* abstract entries were independently reviewed by 1 of the 3 other reviewers (SR, DH, or JB). The articles excluded at full-text review were reviewed by another reviewer. Data extraction was organized into data collection tables, which were checked by a second reviewer (SR, DH, or JB). Any disagreements were reviewed by a third reviewer and agreed upon through discussion. The Joanna Briggs Appraisal Checklists [22] that corresponded to the study designs were used to assess the quality of the studies included for detailed review. Alignment to more than 75% of all checklist items was considered high-quality reporting, alignment to between 50% and 74% was considered moderate-quality reporting, and alignment to less than 50% was considered poor-quality reporting [23,24].

Data Extraction and Synthesis

The articles included for full-text review were categorized by clinical area, country, and operational use of telehealth interventions (whether the telehealth was used to provide direct consultation to patients at a remote end, to support local clinicians in face-to-face patient care, or for remote monitoring of changing health conditions). The outcome measures from each study were also mapped against the clinical areas to understand the use context of each type of measure. Each of the study outcomes was separately reviewed by categorizing them into clinical effectiveness or service use measures, the context in which the outcomes were used, and any validity or data quality issues noted. Data from the effectiveness studies summarized above were used to build an evidence table for each of the outcome measures identified. Salient trends were extracted from this evidence table to compile separate summaries on outcome measure use with favorable directions of change for the time-sensitive clinical effectiveness (Figure 2), service use (Figure 3), and clinical effectiveness measures (Figure 4).

Figure 2. Summary of time-sensitive clinical effectiveness.

	Duration	Length of Stay
Burns		(+*/+) Mean hospital LOS (Saffle et al)
Cardiovascular	(-*/-) FMC to wire passage through the culprit lesion (Kleinrok et al)	
	(-/-) Onset to FMC (Kleinrok et al)	
Mental health	(-*/-) Mean door to consult time (Southard et al)	(-*/-) Mean ED LOS (Southard et al)
	(-*/-) Mean order to consult time (Southard et al)	(-/-) Mean ED LOS (Vakkalanka et al)
Minor injury	(+*/0) Mean consult duration (Benger et al)	
	(+*/0) Wait time for consultation (Benger et al)	
Rural and Remote ED	(-*/-) Mean door to provider time (Mohr et al RR)	(+*/+) Mean ED LOS (Mohr et al RR)
		(0/dns) Local hospital LOS (Westbrook et al)
		(0/dns) Tertiary hospital LOS (Westbrook et al)
Stroke	(-*/-)Mean decision to rtPA time (Barlinn et al)	(0/dns) Mean hospital length of stay (Wang et al)
	(-*/-)Median door to EVT (Barlinn et al)	
	(-*/-)Median image to EVT (Barlinn et al)	
	(-*/-)Mean onset to call (Sairanen et al)	
	(-*/-)Median door to FMC (Bladin et al)	
	(-*/-)Median door to CT (Bladin et al)	
	(0/-) Mean door to call (Meyer et al)	
	(0/-) Mean door to CT (Wang et al)	
	(0/-) Mean door to decision (Meyer et al)	
	(0/-) Mean door to EKG (Meyer et al)	
	(0/-) Median door to imaging (Barlinn et al)	
	(0/-) Mean door to lab (Meyer et al; Wang et al)	
	(0/-) Mean door to FMC (Meyer et al)	
	(0/-) Mean door to tPA (Wang et al)	
	(0/-) Mean onset to door (Meyer et al)	
	(0/-) Median onset to door (Barlinn et al)	
	(0/-) Median onset to IVT (Barlinn et al)	
	(0/-) Mean onset to treatment (Sairanen et al)	
	(0/-) Median onset to arrival (Bladin et al)	
	(+*/0) Door to neurological examination time; call to neurological examination time; call to decision time; consultation duration	
Trauma	(-*/-) Transfer time (Duchesne et al)	(-*/-) Difference in ED LOS (Mohr et al T)
		(-*/-) Local hospital LOS (Duchesne et al)
Improve	No change	Worse

Figure 3. Summary of health service use measures.

	Patient disposition	Service coverage
Mental health	(+*/+) Admission rate (hospital) (Vakkalanka et al) Changes in disposition plan (disposition type) (Southard et al)	Changes in shift when consult completed (redistribution to evening and night shift); Changes in triage shift distribution (redistribution to evening and night shift) (Southard et al)
Minor injury		(+*/+) Patient asked to attend follow-up; (+*/+) Patient radiographed (Benger et al)
Paediatrics	(+*/+)Odds of transfers to a lower level care (Harvey et al) (-/-) Rate of transfer of highest acuity children to higher level care (Yang et al)	
Rural and Remote ED	(-* for critical care/-) Likelihood of local admission; (+* for moderate trauma/+) Likelihood of discharge from ED; (+*/+ for critical care; -*/- for moderate trauma) Likelihood of transfer (Westbrook et al) (-*/-)Discharge rate from ED; (+*/+) Local admission rate (Sterling et al)	(0/dns) Total ED patient volume (hospital median) (Sterling et al)
	(0/dns) Transfer rate (Sterling et al)	
	(+*/0) Discharge against medical advice (Sterling et al)	
Trauma	(0/dns) Interhospital transfer (Mohr et al T)	(0/dns) Use of diagnostic imaging (Mohr et al T)
Improve	No change	Worse

Figure 4. Summary of clinical effectiveness.

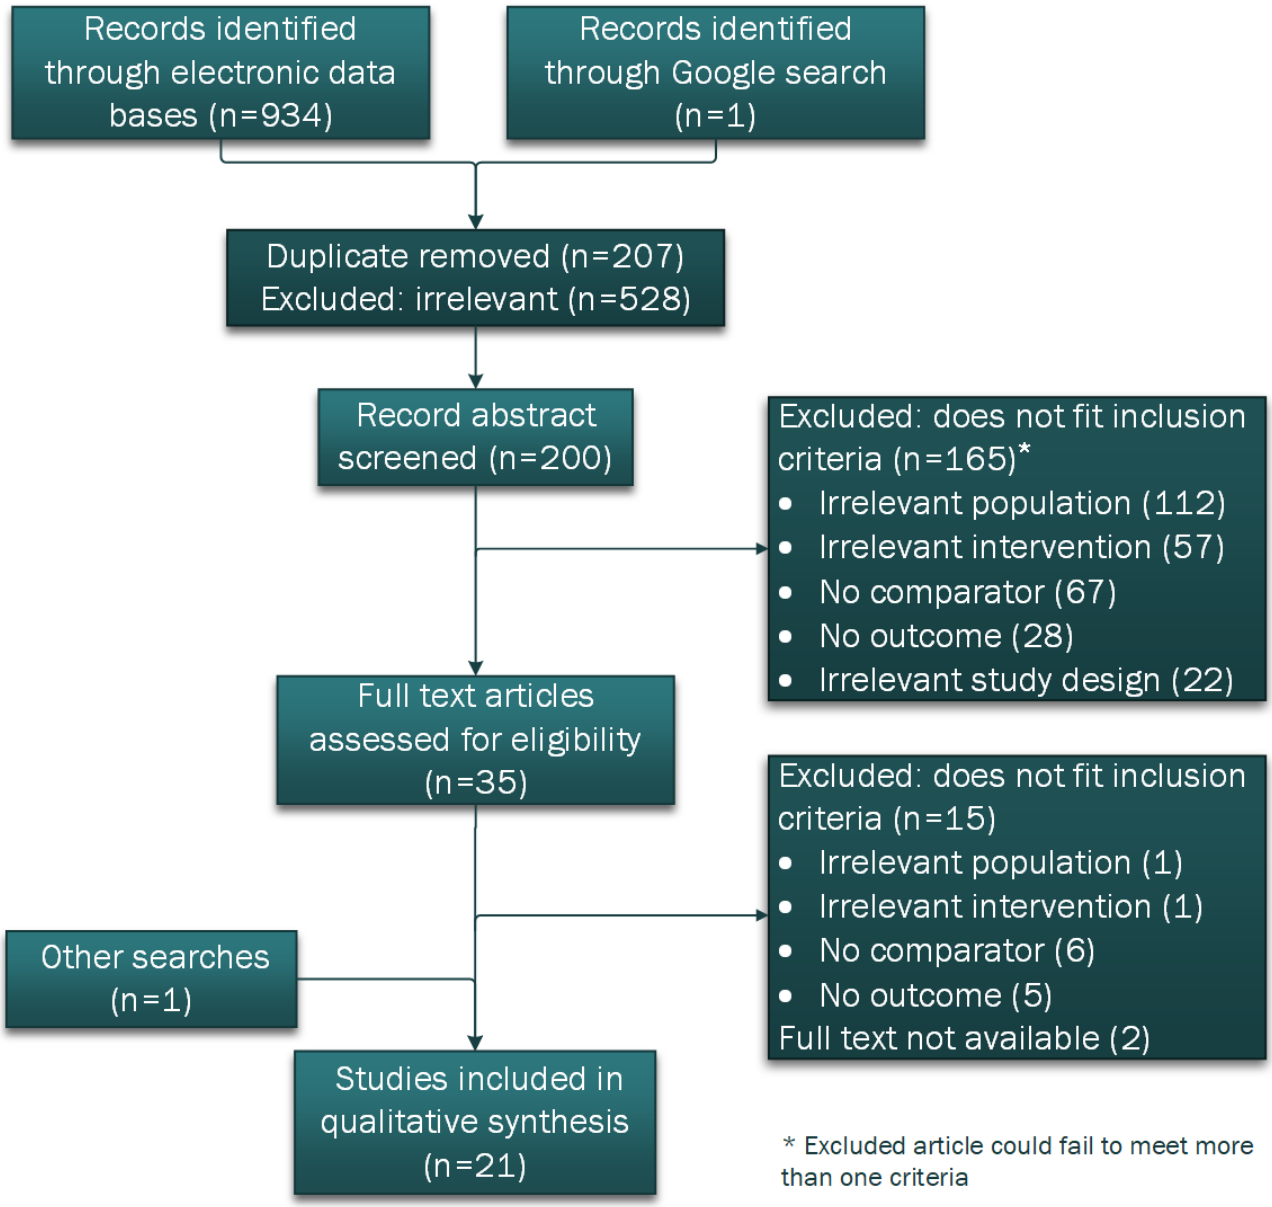
Outcome Themes	Diagnosis accuracy	Quality of consults	Treatment appropriateness	Mortality/survival	Patient outcome
Burns	(+*/+) Burn-size estimate (Saffle et al)				
Mental Health			(-*/-) Involuntary hold placement (Vakkalanka et al) (+/-) Restraint use (Vakkalanka et al)	(0/+) 6-month survival (Vakkalanka et al)	
Minor Injury			(+/0) Under treatment rate (Benger et al)		
Ophthalmology	(+*/+) Agreement on diagnosis (Bowman et al)				
Paediatrics	(+*/+) Accuracy of clinical picture (Harvey et al)	(0/0) TM improve or greatly improve quality of consult (Harvey et al)	(-*/-) Physician-related medication error (Dharmar et al)		
Rural and Remote ED				(0/0) Mortality (in-hospital) (Sterling et al)	(0/-) Change in rapid acute physiology score from time of presentation to arrival of air retrieval service (Westbrook et al)
Stroke	(+*/+) Correctness of thrombolytic treatment decision (Meyer et al)		(+/+) rtPA use rate (Meyer et al)	(0/-) Mortality (3-months) 26 28	(0/-) Intracranial bleeding (Myer et al, Barlinn et al, Sairanen et al, Yaghi et al) (0/+) Major reperfusion (Barlinn et al) (0/-) mRS score (3 months; 90-days; discharge) (Sairanen et al) (+/+) mRS >2 (3 months); (0/-) Recurrent stroke or TIA within 90 days (Yaghi et al) (+/+) mRS show good outcome (admission v discharge) (Wang et al)
			(+*/+) Odds of receiving thrombolysis among telestroke patients (Bladin et al)	(-*/-) Mortality (in-hospital) (Barlinn et al)	(+*/0) mRS >2 (3 month) patient with NIHSS > 8 (Yaghi et al)
Trauma				(0/0) Mortality (in-hospital) Duchesne et al; Mohr et al)	
Improve	No change	Worse			

Results

Study Selection

The search of the electronic databases identified 934 records for title screening. An additional record was identified from the Google search. Of the total 935 records, 207 (22.1%) duplicate titles and 528 (56.5%) irrelevant titles were removed. Of the remaining 200 abstracts screened, 165 (82.5%) were excluded because they did not fit 1 or more of the inclusion criteria. A full-text review of the remaining 35 records identified a further 15 (43%) that did not meet 1 of the inclusion criteria. An additional record was identified from hand searching of the reference lists of the included records. Detailed review and data extraction were performed on 21 articles. A PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram is presented in Figure 5.

Figure 5. Flow chart diagram of the study selection.



Multimedia Appendix 1 [25-36] summarizes the bibliographic information from individual records, including information related to the telehealth intervention, study details, and the authors' assessment of the reporting quality. Of the 21 studies, 14 (67%) were of high-quality reporting according to the criteria used in this review.

Study Characteristics

The studies were categorized according to clinical area and country of implementation (Table S1 of Multimedia Appendix 2 [25-36]). Of the 21 records reviewed, the most frequently assessed service (6/21, 29%) was telestroke [16,25-28,36]. Other clinical area categories included ED services in rural and remote regions [12,19,20,29], trauma [30-32], pediatrics [15,33], mental health [18,34], ophthalmology [14], minor injury [13], cardiovascular [35], and burns [17]. Of the 21 studies, 13 (62%) reported telehealth interventions implemented in the United States [12,15-18,20,27-29,31-34]; the other countries reporting on telehealth interventions were the United Kingdom [13,14], Australia [19,36], Finland [26], Germany [25], Norway [30], and Poland [35].

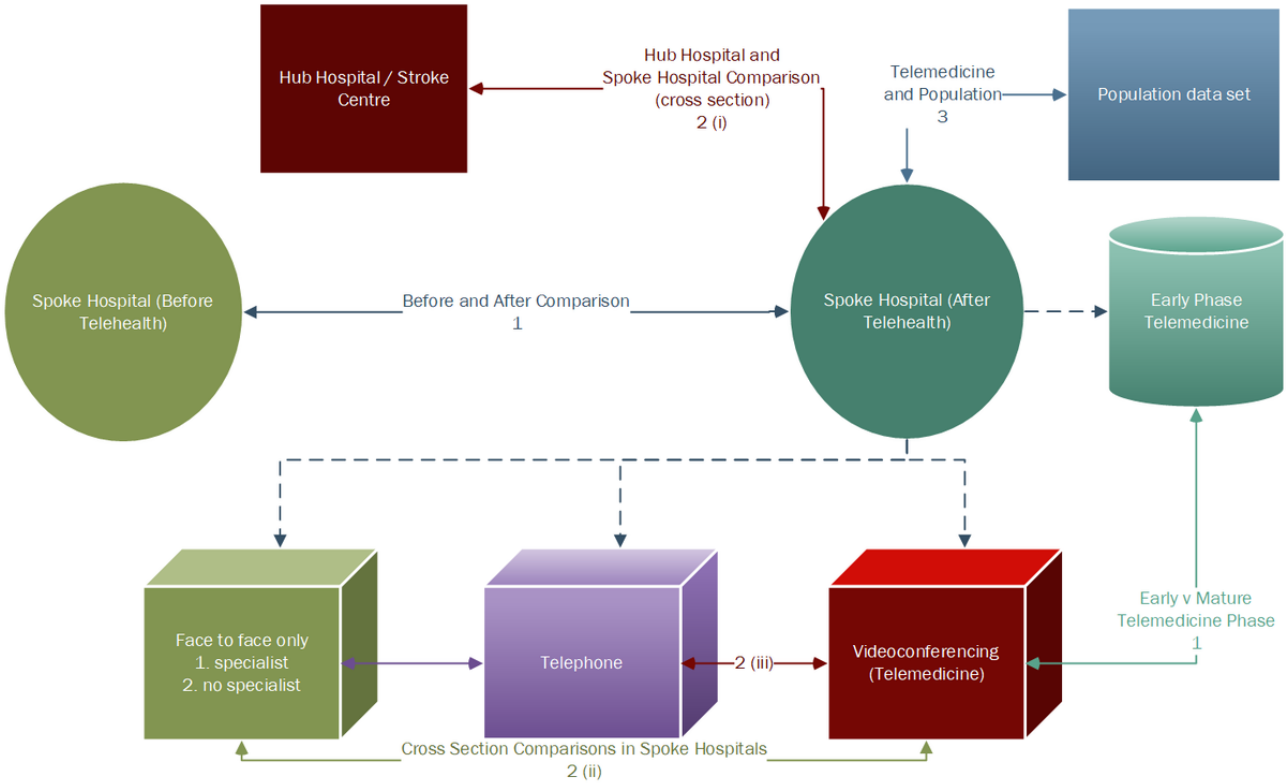
A further categorization was conducted of the clinical area by operational use of telehealth (Table S2 of Multimedia Appendix 2 [25-36]). Of the 21 studies, 12 (57%) involved a specialist supporting local clinicians [12,14,15,17,19,25-28,33,34,36], 8 (38%) involved a direct consultation by a specialist physician [13,16,18,20,29-32], and 1 (5%) concerned the provision of diagnostic services [35]. Of the 8 direct consultations, 7 (88%) were to a location staffed by a nurse practitioner, whereas 1 (12%) [18] involved a mental health specialist directly consulting the patient in the absence of a local clinician. No study documented an intervention involving remote monitoring in the rural and remote emergency setting.

Study Designs of Included Studies

The studies included in this review identified study cohorts according to whether the patients had telephone, videoconferencing, or face-to-face consultations. In terms of

the study design, 14% (3/21) of the studies were intervention studies—of these 3 studies, 2 (67%) were randomized [13,16] and 1 (33%) was nonrandomized [14])—10% (2/21) were qualitative studies [12,30], and 76% (16/21) were cohort studies [15,17-20,25-29,31-36]. There were 3 types of comparisons: (1) comparing before-and-after telehealth interventions at spoke hospitals [12,17-20,29,31] (the comparison of early-phase telemedicine implementation with the mature phase of telemedicine implementation in Kleinrok et al [35] and Bladin et al [36] is also a form of before-and-after comparison); (2) cross-sectional comparisons such as the following: (i) comparison between the videoconferencing consultation (typically referred to as telemedicine) at the spoke hospital and face-to-face consultation at the hub hospital [25,27,28], (ii) comparison within spoke hospitals between cohorts of patients who received telemedicine consultation and patients receiving only face-to-face consultations with a local clinician [13,14,32-34], and (iii) comparison between telemedicine and telephone consultations [15,16,30,33]; and (3) comparison of a telemedicine study cohort with population cohort–based data. A study on patients who had received thrombolysis compared the study group with population thrombolysis data sets [26]. Table S3 of Multimedia Appendix 2 [25-36] lists author names and year of publication against the study design categories and comparison categories. Figure 6 illustrates the different types of comparisons.

Figure 6. Comparisons used in rural and remote emergency department telehealth studies.



There was variability among the hub-and-spoke comparison studies, all of which were related to telestroke. The focus of 10% (2/21) of the studies was on patient disposition after thrombolysis: Wang et al [27] compared patients who received thrombolysis locally with patients who were transferred and then received thrombolysis at the hub, whereas Yaghi et al [28] compared the data of patients who had received thrombolysis locally, were transferred to the hub, and stayed locally. Barlinn et al [25] compared patients who had had a stroke and who had been transferred to the hub after telestroke consultation with patients who had been admitted directly to the hub.

Synthesis of Effectiveness Findings

Overview

The included quantitative studies typically used multiple measures within a study to assess effectiveness. Of the 19 quantitative studies, 13 (68%) showed improvement in 1 of the primary outcomes [14-20,27-29,31-35] and 6 (32%) in 1 of the secondary outcomes [13,15,17,18,29,34]. The effectiveness measures were categorized into time-sensitive effectiveness, service use measures, and clinical effectiveness, including patient outcome.

Time-Sensitive Effectiveness Measures

Overview

Of the 19 quantitative studies, 11 (57%) showed improvement in time-sensitive clinical effectiveness, including significant changes in ED length of stay [18,29,32], hospital length of stay [17,31], and reduction in duration of ED care processes (increased speed of care) [18,25,26,29,31,35,36]. Figure 2 summarizes the direction and findings on length of stay and care process measures by clinical area.

Length of Stay

Length of stay was a measure of clinical effectiveness used in the studies, and this has direct implication on resource use. However, a decreased length of stay was not always interpreted

as a favorable outcome across all studies. Increased hospital length of stay at the burn center was used to indicate a higher degree of diagnostic accuracy at the local hospital [17], whereas videoconferencing consultation was shown to improve the accuracy of triage [17]. Decreased local hospital length of stay was considered favorable in trauma care because of the promptness of radiologic evaluation through telehealth intervention [31], leading to faster disposition decisions. Similarly, a reduction in the ED length of stay reflected timely ED care for trauma [32] and mental health [18,34], whereas a longer ED length of stay reflected the expanded capacity of local EDs to manage patients locally [29]. Of the 19 studies, 2 (10%) showed equivalent local and tertiary hospital lengths of stay [19,27]; no study showed a worse outcome in terms of length of stay.

Care Processes

The process-of-care measures have been used to indicate service efficiency, but they are not always related to effectiveness. Improvements in care processes were shown in cardiovascular, stroke, and trauma care and were related to reaching clinical decisions and providing treatment interventions faster than usual care [16,25,26,31,35]. A significant reduction in door-to-consultation time was noted in delivering specialist mental health services [18] and when a combined rural and remote ED cohort [29] was studied. Treatment-related duration can affect clinical effectiveness in some clinical areas, for example, in the case of telestroke, time to thrombolysis (recombinant tissue plasminogen activator) or door-to–endovascular thrombectomy time. None of the studies provided direct evidence on the relationship between treatment-related durations and patient outcome.

Telehealth in rural and remote EDs made little difference to speed of care when the time gap was calculated from the point of symptom onset [16,25-27,35,36]. In the context of stroke care, earlier studies demonstrated that involving telehealth did not delay or speed up time to imaging and laboratory tests [16,25,27]. This was likely to be related to the reliance of stroke diagnosis on imaging and pre-established clinical standards in practice. However, an Australian study has shown results to the contrary where telestroke resulted in shorter door-to–computed tomography scan time and door-to-needle time for stroke thrombolysis [36]. A telestroke study showed longer time to receiving a neurology examination and reaching a clinical decision when videoconferencing was compared with telephone consultations [16]. Consult durations were longer in the clinical areas of minor injury than in face-to-face specialist consultations and among patients who had had a stroke and who received thrombolysis [13,26]; however, the duration of the consult decreased as health services became acquainted with the telehealth technology. These studies did not discuss the significance of this finding; however, a 2- to 10-minute difference in consult duration was minimal, considering the improved accuracy and appropriateness of the transfer decisions.

Health Services Use Measures

Of the 19 quantitative studies, 6 (32%) showed significant improvement in service use patterns in the clinical areas of rural and remote EDs [19,20], mental health [18,34], minor injury [13], and pediatrics [15]. In all, 5 of the service use measures were related to patient disposition, including significant change in hospital admissions [19,20,34], rate of discharge from ED [19,20], appropriateness of transfer [15,19], and changes in disposition plan [18], whereas 2 were related to significant changes in service coverage, including an increasing proportion of out-of-hour triage and consultation [18] and the proportion of patients asked to attend follow-up clinics [13]. The direction of outcome deemed favorable depended on the context of the study. Figure 3 summarizes patient disposition and service coverage measures and findings from the included studies by clinical area.

Transfer Rates

Whether to transfer a patient and to which location are important clinical decisions in rural and remote EDs. Depending on the capability and capacity of local hospitals, the acuity of presentation and the level of definitive care sought by the transfer are directly related to the decisions to transfer or stay locally. Transfer rates were interpreted together with admission and discharge rates and had the function of examining the appropriateness of service use. An acuity subgroup analysis in Westbrook et al [19] demonstrated significant variation in transfer rates between critical care and moderate trauma. That is, telehealth increases the transfer rate of patients classified as high acuity, which is mirrored in the reduced likelihood of local admission in this cohort. Similarly, the significant reduction in transfer likelihood of patients with moderate trauma is reflected in the increased likelihood of discharge from local EDs [37]. Pediatric emergency telehealth studies reported increased odds of transfer to lower-level care in pediatric triage [15] and reduced transfer in pediatric patients with the highest-acuity ED presentations compared with telephone consultations [38]. A study interpreted the observations on rates of transfer together with the clinicians' subjective perception of increased accuracy of the clinical picture before arrival at the tertiary hospital [15], whereas another study regarded changes in transfer rates as an indication of health services use appropriateness [19].

Local Admissions and Discharge From ED

Patients who are not transferred are either admitted locally or discharged home. This is another decision made by ED clinicians in consultation with emergency medicine specialists through telehealth. The reduction in the rates of discharge from local EDs and increased local admission was observed in Sterling et al [20] after the implementation of emergency medicine specialist consultation with a local nurse practitioner. This study did not stratify by acuity of presentation, and the higher rate of local admission explained the decreased ED discharge rate [20]. The change in discharge rate accompanying increased local admission is contrary to that reported in Westbrook et al [19], which involved decision-making by local ED physicians in consultation with emergency medicine specialists.

A reduced likelihood of local admission for patients classified as critical care and increased likelihood of discharge from the ED for patients with moderate trauma in Westbrook et al [19] indicated the effectiveness of the intervention in identifying patients who did not require further care, whereas in Sterling

et al [20], increased local admission rate and decreased rate of discharge from the ED were used to reflect the benefit of telemedicine in augmenting local capacity to care for patients locally, and this translated into increased financial viability of local hospitals. The patients in Westbrook et al [19] were classified as triage category 1 or were those with major or moderate trauma, skewing toward higher acuity compared with the Sterling et al [20] patient cohort. The variation in patient acuity reflected the base local hospital capability that the emergency medicine specialists were supporting. This demonstrated the differing use of these measures across patient acuity levels.

In addition, the different patterns of changes in the rates of transfer and discharge from the ED between the Westbrook et al [19] and Sterling et al [20] studies are not likely to be attributable to telehealth consultations. It is more likely a result of the difference in disposition practices for patients who stayed locally. Spoke hospitals in Westbrook et al [19] may have cared for and discharged patients from EDs, whereas in Sterling et al [20], the patients may have been transferred to the inpatient department for the same care, which is why they were not considered discharged from the ED.

For mental health ED presentations, an increased combined rate of hospital admissions [34] and an increased range of dispositions [18] were considered a favorable outcome from telehealth interventions. Sterling et al [20] showed an increased rate of discharge against medical advice after implementation of a telehealth service. In other words, when the treating physician was not physically present, patients were more likely to act against medical advice.

Service Coverage

Telemedicine was effective in redistributing or increasing service coverage in the ED. Southard et al [18] demonstrated a redistribution of mental health triage and consultation completed in the evening and night shifts, and Benger et al [13] showed an increase in the proportion of patients with minor injuries asked to attend follow-up appointments after telemedicine consultation. Other service coverage measures included the proportion of patients radiographed for minor injury [13], median total ED patient volume [20], and the odds of using diagnostic imaging in patients with trauma [32], but the studies did not show significant change in these service coverage measures.

Clinical Effectiveness Measures

Clinical effectiveness is an indication of safety and quality and can be used as a surrogate measure for patient outcome. Of the 19 quantitative studies, 9 (47%) showed improvement in clinical effectiveness, including diagnosis accuracy [14,15,17], treatment appropriateness [16,33,34], and improved patient outcome [25,27,28], whereas 15 (71%) showed that telemedicine can achieve effectiveness similar to that achieved by the comparator interventions. The effectiveness measures included in-hospital mortality [20,31,32,36], 3-month [26,28] and 6-month [34] mortality, treatment complications [16,25,26,28,36], patient outcomes [16,19,25-28], treatment rates [13,16,34], and consult quality [15].

The measures for diagnosis accuracy and patient outcome were clinical area dependent. A generalized study on telehealth in rural and remote EDs used change in the rapid acute physiology score from time of presentation to arrival of air retrieval service as a measure of stability among transferred patients [19]. Apart from the rapid acute physiology score, all other patient outcome measures were stroke related (ie, functional scores, major reperfusion after thrombolysis, intracranial hemorrhage, and recurrent stroke rates) [16,25-28]. Figure 4 summarizes the categories of the clinical effectiveness measure by clinical area, with suggested outcomes hierarchy among these measures. As reported above, treatment-related, time-sensitive clinical effectiveness measures can also be surrogate measures for patient outcomes.

Risk of Bias in Individual Studies

The most significant risk of bias within the studies was related to study design. The risk of bias is high in before-and-after comparison studies because systems change over time, which cannot be controlled [20]. The studies did not report on the details of system change; therefore, this risk of bias could not be addressed in this review. Study designs involving cross-sectional comparisons could not be randomized and experienced selection bias pertaining to severity, with higher severity among the telemedicine groups, that is, tendency to consult emergency medicine specialists when managing patients classified as more severe.

The tendency to recruit greater number of telemedicine cases from larger spoke hospitals diluted the effect of remoteness on the effectiveness of telehealth when the results were interpreted as a whole. This is a significant selection bias in telehealth studies and highlights the gap in the published literature on the impact of telehealth in remote and very remote regions.

Other risks of bias in individual studies related to the sample sizes. Of the 21 studies, 7 (33%) had sample sizes of fewer than 100 patients [14,16-19,26,27]. The studies also reported selection bias in relation to local (receiving-end) clinicians' preselected cases for telehealth consultations when hospital transfers were considered. This process selected patients whose transfers were more imminent after telemedicine specialist consultations.

A further weakness in many of the included studies was that of attribution. The studies assumed the clinical or service use effectiveness to be associated with the telehealth interventions without considering potential confounders.

Discussion

Principal Findings

Context of Intervention

Telehealth interventions were considered effective when their implementation resulted in improvement or equivalent clinical or service use outcomes. The indicators used to measure favorable patient outcome were unidirectional; that is, better outcome pertains to change of the indicator in 1 direction. However, time-sensitive effectiveness and service use measures

were interpreted differently, depending on the context of the intervention.

Patient Dispositions

Patient disposition measures were dependent on the severity of the presenting illness and the level of definitive care compared with the hospital of origin and clinical area. Higher rate of transfer and shorter local ED or hospital length of stay were considered favorable in higher acuity ED presentations such as triage 1 or major trauma, and the reverse was true in less life-threatening conditions such as mental health and moderate trauma. This concurs with the findings from the observational study conducted on the North Dakota critical-access hospital ED cohorts where the interhospital transfer rate was not associated with telehealth use after adjusting for severity of illness [39]. The pediatric emergency telehealth studies considered an additional factor of the relative level of definitive care. Transfers to lower-level care increased with telehealth consultations [15], whereas transfers to higher-level care decreased in pediatric cases with the highest acuity [38].

Timeliness of Care Measures

Telestroke was effective in maintaining the same level of timeliness once a patient arrived at the ED, whereas in other clinical areas, telehealth resulted in faster transitions from consultation to diagnosis and treatment. Timeliness of the care measures reflected factors modifiable by telehealth. For example, the significant reduction of door-to-consultation time may be explained by the shortage of workforce and specialist skills in the rural and remote EDs, which were modifiable using telehealth consultations. The observation in telestroke—no significant change in timeliness of care—was explained by the dependence on access to imaging and other diagnostic tests, which were local processes that were not modifiable by telehealth consultations. The competent use of technology was also a factor influencing time-sensitive clinical effectiveness.

Changing Service Use Patterns

Favorable service use patterns involved a redistribution of resources, such as changes in disposition plan, changes in the pattern of interhospital transfers [19,20,32,37,38], or redistribution of ED triage and medical consultation to evening and night shifts instead of a concentration of medical consultations during day shifts [18]. These changes indicated the effectiveness of telehealth in facilitating more appropriate use of health resources, which did not always translate into an absolute reduction of service use or cost savings for the health systems. Furthermore, transfer rates stratified by acuity of presentation and their impact on local hospital admission and ED discharge rates are also a meaningful service use measure for emergency telehealth service evaluation. This also indicates the effectiveness of specialist consultation in changing resource use patterns at a local level.

The synthesis from this review indicated that favorable health service use patterns can be expected across different clinical areas where the impact of a specialist workforce shortage is modifiable by telehealth implementation in these settings. Dorsey et al [40] observed 3 interlinking trends shaping telehealth, including the transformation from increasing access to eventually reducing cost rationalizing the potential for telehealth to reduce time spent accessing specialist services and increase the intensity of services to the 20% of the people accounting for 80% of the health expenditure. Changes in cost were not considered in this review, and the synthesis in this systematic review did not find conclusive evidence to support this trend in the context of acute presentation to rural and remote EDs. However, the increasing local hospital admission rate due to the addition of clinical expertise through emergency telehealth has been discussed in a study as a means of increasing local hospital revenue [20]. The changes in patient disposition, such as reduction in admissions and transfers [19], also align with the changes in the cost profile of the overall service delivery.

Patient Outcomes

Studies reporting clinical effectiveness demonstrated improved clinical effectiveness in stroke, pediatrics, burns, mental health, and ophthalmology, albeit by using different clinical or patient outcome measures. We have identified a hierarchy of outcomes in the studies: treatment-related timeliness, diagnosis accuracy, quality of consults, and treatment appropriateness are all categories of outcomes with potential impact on patients' functional outcome or survival.

This review was conducted as part of a larger study on the cost-effectiveness of telehealth in rural and remote EDs [21]. Patient outcomes are the foundation of cost-effectiveness analyses in rural and remote EDs. The ideal outcome measure to accommodate the wide range of ED presentations is quality-adjusted life years (QALYs). When direct data collection on QALYs is not a pragmatic option, it is often calculated from a patient outcome measure. In telestroke studies, for example, QALYs are derived from the modified Rankin Scale scores. A further extension to this review on effectiveness measures in rural and remote emergency telehealth services is the question of using mortality and patient outcome measures to derive QALYs for economic evaluation. This calls for future research into the relationship between diagnosis accuracy and mortality and functional outcomes and the derivation of QALYs from the appropriate patient outcome measures for rural and remote EDs and the receiving-end (local) hospital context of the emergency telehealth service.

Limitations

Timeliness of the clinical decision and, where appropriate, clinical intervention is critical to the effectiveness of acute ED care. In this review, 2 components that contribute to timeliness were not considered: the impact of prehospital emergency medical services and the distance factor. The decision to exclude studies on prehospital emergency medical services was made to restrict the scope of this review to the effectiveness of emergency telehealth services delivered in hospital settings.

The second limitation is related to the distance between the EDs and the destination of transfer. This, combined with the appropriateness of interhospital transfer decisions, contributes to treatment delays in transit and may affect further patient care (clinical) decisions. We were unable to determine the extent to which telehealth was effective in bridging this gap across clinical areas from the evidence reviewed. Although most studies

reported on the distance between spoke and hub hospitals, it was not possible to synthesize the impact of distance on the effectiveness findings using the available information. The small number of spokes included in the studies also made it difficult to make meaningful comparisons in relation to the distance in the studies.

The heterogeneity of the studies in this field rendered the observation of relationships among different levels in the outcomes hierarchy an impossible task. However, based on the findings in this systematic review, future studies or evaluation efforts are well placed to consider an outcomes hierarchy, with surrogate outcomes leading to changes in patients' functional outcome and mortality in the same study.

Comparison With Prior Work

This review is the first in rural and remote emergency telehealth to demonstrate the importance of understanding the context in which effectiveness measures are applied in evaluating telehealth. In designing telehealth services in rural and remote EDs, the purpose of telehealth by clinical area and acuity of presentation should be ascertained before setting targets for the telehealth services or program. The context around the benefit of telehealth in supporting more informed clinical decisions and accurate diagnosis, more favorable health service use patterns, and longer-term patient outcomes also has policy implications.

Policy makers should be cognizant of the complexities around, and the limitations of, emergency telehealth in rural and remote settings so as to set reasonable expectations regarding the expected outcomes from this modality of service delivery. The ascertainment of service goals should commence by examining the purpose of telehealth by clinical area, acuity of presentation, receiving-end hospital capability, and the level of definitive care to set appropriate performance targets.

Conclusions

Ascertaining outcome measures to accurately reflect the contribution of telehealth in rural and remote EDs is a complex task. Emergency telehealth studies typically use multiple outcome measures to determine the effectiveness of the services. The analysis in this systematic review has revealed 3 criteria in outcome determination in this context: clinical area, acuity of presentation, and the level of definitive care relative to the hospital of origin. These criteria are useful when defining the favorable direction for each outcome measure of interest.

The findings from this review inform the motivation and expectation of emergency rural and remote telehealth services in the design phase. The evidence from this review indicates that emergency telehealth service adoption has resulted in better service use patterns by improving the diagnosis and making first-line management modifiable by bringing in specialist expertise in emergency medicine. However, the factors that influence clinical decisions but are not modifiable by emergency telehealth, such as receiving-end hospital capability, have not been directly studied in the rural and remote ED context.

Acknowledgments

This research was initiated by the WA Country Health Service, Curtin University, and received financial support from both institutions as well as the Digital Health Collaborative Research Centre in the form of PhD scholarships. WA Country Health Service also contributed in-kind support in the form of clinician time, academic supervisors, and administrative and research infrastructure support.

Authors' Contributions

AJ, JY, and JM ensured relevance of the review to patient care in rural and remote emergency department settings. KB and SW ensured the relevance of this review to emergency telehealth service design, implementation, and evaluation. RB provided input from a health consumer's perspective. CT and DH conceptualized and drafted the manuscript with support from SR and JB in terms of the processing of articles downloaded for the systematic review.

Abstract

Background: High-frequency patient-reported outcome (PRO) assessments are used to measure patients' symptoms after surgery for surgical research; however, the quality of those longitudinal PRO data has seldom been discussed.

Objective: The aim of this study was to determine data quality-influencing factors and to profile error trajectories of data longitudinally collected via paper-and-pencil (P&P) or web-based assessment (electronic PRO [ePRO]) after thoracic surgery.

Methods: We extracted longitudinal PRO data with 678 patients scheduled for lung surgery from an observational study (n=512) and a randomized clinical trial (n=166) on the evaluation of different perioperative care strategies. PROs were assessed by the MD Anderson Symptom Inventory Lung Cancer Module and single-item Quality of Life Scale before surgery and then daily after surgery until discharge or up to 14 days of hospitalization. Patient compliance and data error were identified and compared between P&P and ePRO. Generalized estimating equations model and 2-piecewise model were used to describe trajectories of error incidence over time and to identify the risk factors.

Results: Among 678 patients, 629 with at least 2 PRO assessments, 440 completed 3347 P&P assessments and 189 completed 1291 ePRO assessments. In total, 49.4% of patients had at least one error, including (1) missing items (64.69%, 1070/1654), (2) modifications without signatures (27.99%, 463/1654), (3) selection of multiple options (3.02%, 50/1654), (4) missing patient signatures (2.54%, 42/1654), (5) missing researcher signatures (1.45%, 24/1654), and (6) missing completion dates (0.30%, 5/1654). Patients who completed ePRO had fewer errors than those who completed P&P assessments (ePRO: 30.2% [57/189] vs. P&P: 57.7% [254/440]; P<.001). Compared with ePRO patients, those using P&P were older, less educated, and sicker. Common risk factors of having errors were a lower education level (P&P: odds ratio [OR] 1.39, 95% CI 1.20-1.62; P<.001; ePRO: OR 1.82, 95% CI 1.22-2.72; P=.003), treated in a provincial hospital (P&P: OR 3.34, 95% CI 2.10-5.33; P<.001; ePRO: OR 4.73, 95% CI 2.18-10.25; P<.001), and with severe disease (P&P: OR 1.63, 95% CI 1.33-1.99; P<.001; ePRO: OR 2.70, 95% CI 1.53-4.75; P<.001). Errors peaked on postoperative day (POD) 1 for P&P, and on POD 2 for ePRO.

Conclusions: It is possible to improve data quality of longitudinally collected PRO through ePRO, compared with P&P. However, ePRO-related sampling bias needs to be considered when designing clinical research using longitudinal PROs as major outcomes.

patient-reported outcome (PRO); data quality; MDASI-LC; postoperative care; symptoms

Introduction

Scientific Background

Patient-reported outcomes (PROs) are commonly assessed as primary or secondary outcomes in clinical trials or observational studies to evaluate the effect of medical interventions from the viewpoint of patients without interpretation by professionals [1-3]. PROs can help clinicians monitor adverse events [4], relieve symptom burdens [5], guide clinical care [4,6], and improve patient outcomes [6], such as quality of life (QOL) and survival. However, PROs involve multiple self-evaluations over time, and symptoms change frequently over the course of treatment in clinical studies [7]. Especially in surgical research and practice, daily assessments have been used to precisely describe the trajectory of symptom relief and functional recovery because the daily changes in symptoms in surgical patients have been found to be statistically significant [8-10]. However, whether the high frequency of assessment affects data quality has seldom been discussed in studies using longitudinal PROs as major outcomes.

What does “data quality” actually mean? Wang and Strong [11] and Kahn et al [12] proposed that data should be of sufficient quality to be of use to data consumers pursuing specific goals. For longitudinal data repositories, Weiskopf et al [13] characterized “data quality” as completeness. Charnock [14] conducted a systematic review in 2019 and reported that all papers referred to the importance of accuracy and completeness when evaluating data quality. Currently, data quality evaluations in longitudinal studies have focused on missing assessments [15-17]. However, other issues, such as item nonresponse and sample bias, have emerged over time [18,19], and these issues may impact data availability and consistent interpretations. Recent studies reported that repeated source data verification could improve accuracy and completeness by 40% [19], and better data quality could improve epidemiological inferences [20]. Additionally, partly due to the lack of an international definition of “error” [21], very few descriptions of the determinants of poor data quality have been provided in clinical studies [22]. Thus, there is an urgent need to characterize types of errors and the factors that affect longitudinal data quality to enable more interpretable results to be obtained from more complete data.

Paper-and-pencil (P&P) or electronic-based assessment of PRO (electronic PRO [ePRO]) are the 2 common modes used in clinical practice [23,24]. Compared with the P&P method, ePRO is more likely to generate complete data [17]; results in fewer data entry errors [25]; is more user friendly [26]; results in a shorter turnaround time [27]; and allows data to be processed, reviewed, and disseminated quickly [28,29]. Currently, interactive ePRO assessments can provide immediate feedback from patients [30] and are a convenient means of monitoring patients and delivering early warnings to clinicians [31,32]. In surgical research, due to the daily changes in symptoms after surgery [8-10], daily ePRO assessments have been used to precisely describe symptom relief and functional recovery. However, the often-mentioned disadvantages of ePRO assessments are sample bias [15,22,33] and a lower response rate [15-17,33]. Thus, generating a profile of the quality of data obtained with P&P and ePRO assessments will guide the appropriate selection of the mode of assessment.

Objectives

Daily PRO data collected via either P&P or ePRO assessments over the course of recovery from thoracic surgery for malignant or benign lung tumors were used in this analysis, with the following aims: (1) to describe error patterns in PRO data collected via the 2 major PRO measurement modes (ie, P&P and ePRO); (2) to identify factors influencing the incidence of errors; and (3) to generate profiles of the trajectories of errors over the course of a high-frequency data collection schedule.

Methods

Data Sources

Data were extracted from 2 prospective studies: 1 observational study [34] and 1 randomized controlled trial (RCT) [35]. The 2 original studies were approved by the Ethics Committee of Sichuan Cancer Hospital (No. SCCHEC-02-2017-042 and No. SCCHEC-02-2018-045).

All patients were assessed with the MD Anderson Symptom Inventory Lung Cancer Module (MDASI-LC) [36] and the single-item QOL scale [37] within 3 days before surgery and then daily after surgery until discharge or for up to 14 days if the patient stayed in the hospital for longer than 14 days after surgery. The MDASI-LC consists of 2 parts. Part I includes not only items regarding 13 core symptoms but also 3 items specific to lung cancer. Part II includes 6 interference items.

All data collection communications with medical staff were conducted face-to-face, and reminders were provided in the hospitals. Patients were asked to consider their symptoms over the previous 24 hours. When a participant completed and submitted a survey, he or she was not able to later modify the answers. On P&P assessments, signatures and data were collected from the patients and researchers for each record. Any time a patient modified a P&P form, the patient was asked to sign below the modified item. Assessment through ePRO only required the patient’s e-signature for each record.

The observational study used P&P, ePRO, phone-to-paper, and mixed assessments, while the RCT used only ePRO assessments. All PRO data were stored in the REDCap [38,39] online management system. EPRO data were automatically imported into REDCap within 24 hours, whereas the P&P forms were manually entered into this platform. Both studies were approved by the ethics committees of all participating hospitals. All participants signed informed consent forms [34,35].

For the P&P assessments, the original paper questionnaires were first checked by the data collectors for amendable errors (eg, missing researcher signatures at the end of completed

questionnaires). After both the P&P and ePRO data were entered into REDCap, the database was closed and sent for a data audit by a third team. The classification of errors was performed by 2 independent data management experts (QS and WD) with experience in clinical research data management. Inconsistencies were discussed within the audit team to reach a consensus. Data with errors identified during the audit were then entered into an electronic database in REDCap by 2 independent investigators (HY and QY) and cross-checked. The audit included (1) the withdrawal rate of each study; (2) patient compliance with the scheduled times of the assessments; (3) the completeness and accuracy of PRO forms with regard to individual items; and (4) rate of missing signatures and dates of completion.

Outcome Defined

Six types of errors were summarized into 2 groups, namely, incompleteness and inaccuracy, and used as indicators of PRO data quality:

- Incompleteness: any missing (1) individual items; (2) patient signatures; (3) researcher signatures; or (4) dates of completion.
- Inaccuracy: any (1) multiple selections for 1 item or (2) missing patient signature on any modified answer.

When any type of error mentioned above was found for any item on the MDASI-LC or QOL scale, it was counted as 1 error, and the corresponding patient was defined as a *patient with error*. A record of an error was defined as any error found for each PRO instrument (MDASI-LC or single-item QOL). A time point with any error in the record was labeled a *time point with an error*. Overall errors refer to all errors of all types in all records.

Data Analysis and Management

Reporting was performed according to STROBE guidelines [40]. To be included in the analysis, a patient must have provided PRO data at baseline and at least one additional time point during follow-up. We used the mean (SD) or median (range) for continuous variables and frequency (%) for categorical variables to describe the variables. Differences were analyzed using the 2-sample independent *t*-test, 2-sample Wilcoxon test, chi-square test, and Fisher exact test as appropriate. The withdrawal rate refers to the proportion of patients who did not provide a response to the assessment prior to the day of discharge. Patient compliance was calculated as the number of PRO assessments returned divided by the number of PRO assessments that should have been returned. We analyzed at most 8 time points (1 time before surgery and 7 days after surgery) when creating the profiles of the trajectories of the errors over time.

A multivariate generalized estimating equation (GEE) model was constructed to select and estimate the associations between potential risk factors and the incidence of errors for each mode of assessment. The factors included age (≤55 year vs. >55 year), sex (male vs. female), education (median school graduate or below vs. above), employment status (employed vs. other), surgical approach (video-assisted thoracoscopic surgery [VATS] vs. thoracotomy), hospital type (provincial vs. municipal or county level), BMI (≤23.9 kg/m^2 vs. >23.9 kg/m^2), smoking status (yes vs. no), Charlson Comorbidity Index (CCI) score (≤1 vs. >1), number of chest tubes (1 vs. 2), disease type (not-lung cancer vs. lung cancer with pathological tumor–node–metastasis [pTNM] stage>I, lung cancer with pTNM stage ≤I vs. lung cancer with pTNM stage>I), and postoperative hospital stay days (>6 vs. ≤6). The effect of risk factors is presented as odds ratios (ORs) with 95% CIs. Using Bonferroni correction [41] for multiple comparisons of risk factor identification, statistical significance level was set at the adjusted cutoff of $P<.004$, adjusted by the number of risk factors (0.05/number of risk factors).

The GEE model was also used to describe the trajectories of the incidences of errors over the 7 time points after surgery between those who used the P&P and ePRO assessments. The incidence of all errors or missing items was the dependent variable and the baseline covariates (the significant variables in the previous GEE model analysis), days after surgery (as a continuous variable), assessment modes, and the interaction between time and assessment mode were the independent variables. The binomial distribution and logit link function were adopted in all models. Co-variance structure types, such as unstructured, autoregressive, independent, exchangeable, and compound symmetric, were compared via quasi-likelihood under the independence model criterion (QIC). The models with QICs closest to 0 were closed as the final models. Two-piecewise random coefficient models were used to analyze trends before and after surgery. Time points with the highest proportion of errors were defined as the change points in the 2-piecewise models. All *P* values were 2 tailed, and statistical significance was set at the conventional cutoff of $P<.05$. All data analyses were performed using the statistical software SAS (version 9.4; SAS Institute).

Results

Participants

We extracted data pertaining to patients scheduled for lung surgery from the observational study (n=512) and the RCT (n=166). Thirty-six patients were excluded because they used phone-to-paper or mixed assessments, and 13 patients had only 1 PRO record. Finally, 629 patients responded to either P&P (n=440) or ePRO (n=189) assessments.

Patient characteristics are presented in Table 1. Compared with those using P&P assessments, patients using ePRO assessments were younger (51.5 vs. 55.5; $P<.001$), had higher levels of education (67.2% [127/189] vs. 50.0% [220/440]; $P<.001$), lower CCI scores (75.7% [143/189] vs. 60.7% [267/440]; $P<.001$), earlier stages of disease (compare with lung cancer with pTNM stage >I, 85.2% [161/189] vs. 68.0% [299/440]; $P<.001$), were more likely to have undergone VATS (93.1% [176/189] vs. 81.4% [358/440]; $P<.001$), and had shorter postoperative hospital stay (5 days vs. 6 days; $P<.001$). However, the differences in employment status, hospital type, and BMI were not significant (Table 1).

Table 1. Baseline characteristics of participants who filled out the P&P[a] or ePRO[b] assessment.[c]

Variables	ePRO (n=189)	P&P (n=440)	*P* value[d]

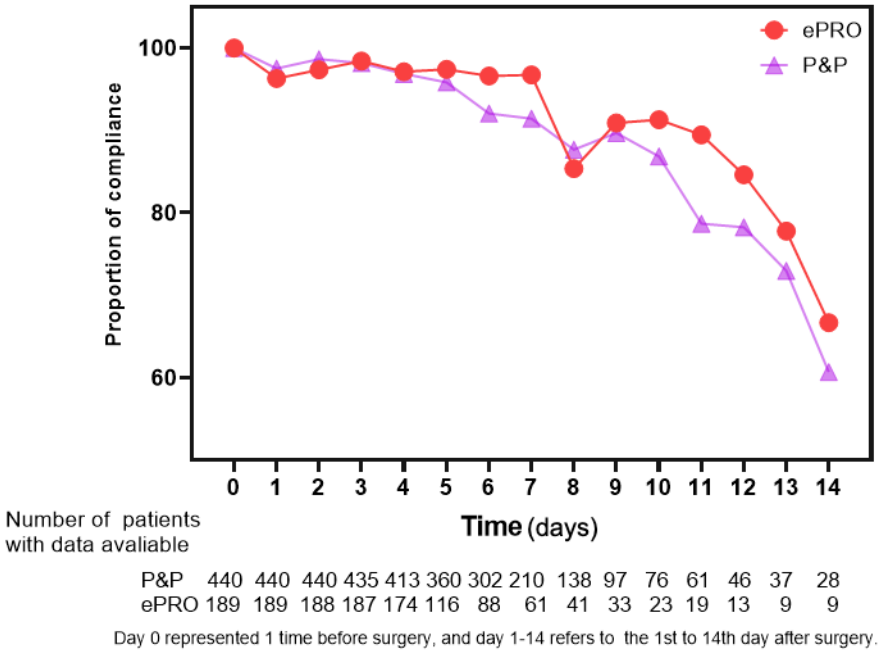
Compliance With Scheduled Assessments Over Time

Of the 629 patients included in the analysis, 6.4% (28/440) of the patients in the P&P group and 3.7% (7/189) of the patients in the ePRO group withdrew from the studies during hospitalization. A total of 440 P&P patients generated 3347 PRO records, whereas 189 ePRO patients generated 1291 records. The compliance rates ranged from 67% (6/9 in POD 14) to 100% (189/189 before surgery) for the ePRO group and from 61% (17/28 in POD 14) to 100% (440/440 before surgery) for the P&P group over time (Figure 1).

Figure 1. Proportion of patient compliance during 15 timepoints between different modes. ePRO: electronic PRO, P&P: paper and pencil, PRO: patient-reported outcome.



Error Patterns

We found that 49.4% (311/629) of the patients had at least one error, and a total of 1654 errors were identified. In Multimedia Appendix 1, missing items (64.69%, 1070/1654) and modifications without signatures (27.99%, 463/1654) were the top 2 most frequently observed errors, followed by multiple selections for 1 item (3.02%, 50/1654), missing patient signatures (2.54%, 42/1654), missing researcher signatures (1.45%, 24/1654), and missing completion dates (0.30%, 5/1654).

Multiple selections for a single item, modifications without patient or researcher signatures, and missing completion dates were only identified on P&P assessments, accounting for 32.77% (542/1654). Shown in Table 2, significant differences in the number of involved patients were found for the overall errors (ePRO: 30.2% [57/189] vs. P&P: 57.7% [254/440]; $P<.001$) and missing items (ePRO: 28.6% [54/189] vs. P&P: 55.0% [242/440]; $P<.001$). Very few "missing patient signature" errors were identified, and the proportion did not differ between the ePRO and P&P groups (2.1% [4/189] vs. 1.8% [8/440]; $P=.76$).

The error rates of each item (including missing items, modifications without signatures, and multiple selections for 1 item) within PRO instruments are presented in Multimedia Appendix 2. Overall errors and missing items were found in 4% of the items pertaining to distress and interferes (mood and relations) on both types of assessments (ePRO and P&P).

Table 2. Counts and proportion of involved patients and errors between assessment modes (ePRO[a] vs. P&P[b]).

Error types	Errors (count), n		Involved patients, n (%)		*P* value[c]
	ePRO (n=189)	Paper (n=440)	ePRO (n=189)	Paper (n=440)

Factors Contributing to the Incidence of Errors

As shown in Table 3, patients with lower education levels (OR 1.82, 95% CI 1.22-2.72; *P*=.003), those treated at provincial hospitals (OR 4.73, 95% CI 2.18-10.25; *P*<.001), and those with severe disease (lung cancer with pTNM stage >I vs. nonlung cancer: OR 2.70, 95% CI 1.53-4.75; *P*<.001) were more likely to generate errors in the ePRO group. In the P&P group, a lower level of education (OR 1.39, 95% CI 1.20-1.62; *P*<.001), treatment in a provincial hospital (OR 3.34, 95% CI 2.10-5.33; *P*<.001), severe disease (lung cancer with pTNM stage >I vs. nonlung cancer: OR 1.63, 95% CI 1.33-1.99; *P*<.001), being younger (OR 1.47, 95% CI 1.15-1.88; *P*=.002), male sex (OR 1.41, 95% CI 1.12-1.78; *P*=.003), thoracotomy (OR 1.28, 95% CI 1.13-1.46; *P*<.001), a higher CCI score (OR 1.58, 95% CI 1.36-1.84; *P*<.001), and more chest tubes (OR 1.66, 95% CI 1.26-2.17; *P*<.001) were associated with a higher risk of errors. The details of risk factors for missing items in P&P and ePRO are shown in Multimedia Appendix 3.

Table 3. Factors associated with the error incidence rate of participants who filled out the (ePRO[a] vs. P&P[b]) assessments[c].

Factors	ePRO (n=189)		Paper-and-pencil mode (n=440)	
	OR[d] (95% CI)	*P* value[e]	OR (95% CI)	*P* value[e]
Age (under 55 years vs. 55 years or older)	0.96 (0.48-1.93)	.91	1.47 (1.15-1.88)	*.002*
Gender (male vs. female)	0.93 (0.60-1.42)	.73	1.41 (1.12-1.78)	*.003*
Education (middle school or below vs. higher than middle school)	1.82 (1.22-2.72)	*.003*	1.39 (1.20-1.62)	*<.001*
Employment status (others vs. employed)	0.93 (0.65-1.34)	.71	1.15 (1.02-1.31)	.03
Surgical approach (thoracotomy vs. video-assisted thoracoscopic surgery)	1.95 (1.17-3.25)	.01	1.28 (1.13-1.46)	*<.001*
Hospital type (provincial level vs. municipal or county level)	4.73 (2.18-10.25)	*<.001*	3.34 (2.10-5.33)	*<.001*

Trajectories of Errors

The trajectories of overall errors and missing items over time are illustrated for the ePRO and P&P assessments separately (Figure 2). In the P&P group, 14.8% (65/440) of patients made errors before surgery and then peaked on postoperative day 1 (POD 1; 117/440, 26.6%). The trajectory gradually decreased after surgery, but remained higher than that before surgery (17.2% [33/192] on POD 7). In the ePRO group, overall error was 3.2% (6/189) before surgery, followed by a continuous increase after surgery, peaking on POD 2 (13.1% [24/183]), and then gradually decreased but remained higher than that before surgery (POD 7 in 5.1% [3/59]). Similarly, missing items peaked on POD 1 in the P&P group (25.9% [111/429]) and on POD 2 in the ePRO group (12.0% [22/183]; Figure 2B). The details are presented in Table 4.

Figure 2. Error incidence rate of responded records with overall errors or item missing during 8 timepoints in hospital. ePRO: electronic PRO, P&P: paper and pencil, PRO: patient-reported outcome.

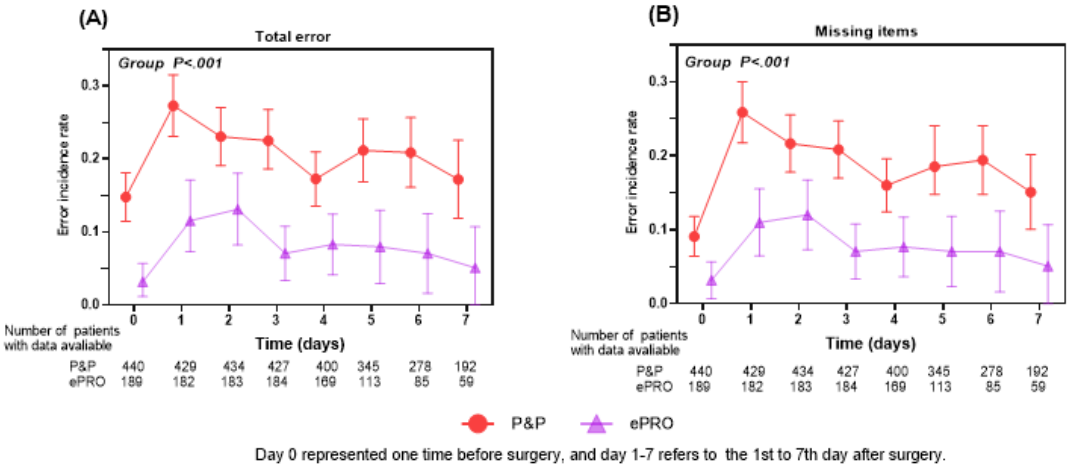

Table 4. Error incidence records of responded records with overall errors or item missing during 8 time points in hospital.[a]

Time (days)	Overall errors			Item missing			Completed patients

[a]Administration: generalized estimated equation (GEE) model.

[b]ePRO: electronic PRO (patient-reported outcome) (web-based).

[c]P&P: paper-and-pencil.

[d]Adjusted GEE model *P* values reported for time effect (as continual variable), mode effect (reference as P&P mode), interaction between mode and time effect (MT). All others are baseline covariant.

[e]Statistically significant values are italicized (*P*<.05).

[f]Day 0 represented the 1 time before surgery, and 1-7 refers to the 1st to day 7th after surgery.

[g]MT: interaction between mode effect and time effect.

The inflection time points were POD 2 for the ePRO assessment and POD 1 for the P&P assessment (Table 5). The incidence of errors on the ePRO assessments significantly increased from before surgery to POD 2 (estimate=0.51; *P*=.01, in model 2) and significantly decreased after POD 2 (estimate=–0.21; *P*<.001). However, errors on the P&P assessment significantly increased over the first 2 assessment time points (estimate=0.73; *P*<.001, in model 2) and slightly decreased after POD 1 (estimate=–0.10; *P*<.001). The details of item missing using 2-piecewise model are described in Multimedia Appendix 4.

Table 5. Two-piecewise regression analysis for each mode with overall errors during 8 time points in hospital.[a]

Mode	Overall errors

[h]Model 5: adjustment for age group, gender, education, surgical approach, hospital type, Charlson Comorbidity Index score, chest tube, and disease type.

Discussion

Principal Findings

For the first time, using data from studies that included PROs as major outcomes in the setting of thoracic surgery, we profiled 6 types and 2 trajectories of errors for PRO data collected daily using 2 major assessments (ePRO or P&P). Nearly one-fifth of the records and half of the patients had errors when longitudinal PROs were used as outcomes, even when a quality check was implemented immediately after the completion of data collection. We demonstrated that, compared with the P&P assessment, the ePRO assessment had higher compliance, which is necessary to maintain data quality, but needed more time for patient adaptation. In addition, significant selection bias was identified for the ePRO assessment, with younger, better educated, and more physically active patients being more likely to use. This quantification of the quality of frequently collected PRO data might support study design, data quality control, and data audits for surgical studies using PROs as outcomes and will help guide resource allocation when implementing PRO-based surgical patient care.

Magnitude of Data Errors

The ePRO assessment had fewer errors. Over one-third of the errors occurred on P&P assessments, and these were errors that could be avoided by using the ePRO assessment. One study described missing items on anxiety questionnaires at 3 assessment points, and the results were as follows: 31.8% for P&P versus 2.08% for ePRO in the hospital [15]. Another study that investigated food-frequency questionnaires at 2 time points over 10 years revealed that the average rate of missing items on the form was 9% for P&P assessments and 3% for the electronic version [17]. The lower rates of errors observed in those 2 studies may be attributed to the lower frequency of measurement and the younger participants. Zeleke et al [42] analyzed 2492 records in an RCT involving healthy people and reported that 41.89% of the paper records and 30.89% of the electronic records had 1 or more types of data quality issues. Compared with those studies, our analysis, which had clear definitions of data inaccuracy and incompleteness, suggested the need for careful data quality monitoring plans in studies that require frequent assessments of PROs.

Missing items on assessments of PROs is a core issue and is nearly ubiquitous in clinical research. In this study, missing items accounted for a significant proportion (over three-fifths) of all errors. There is strong evidence that much of these missed items occur at random and are therefore almost impossible to eliminate in the real world [19,43,44]. Our results showed that missing items decreased by one-fifth when ePRO assessment was used, indicating that using this format could improve PRO data quality in further studies.

Adaptation

The trajectories in errors significantly changed each day during the perioperative period, and different trends were observed for each assessment mode. Interestingly, constant trends, with an initial increase followed by a decrease over time, were observed with both the P&P and ePRO assessments in this study, whereas

the results in a similar study showed random peaks and irregular trends when the data were presented according to the date of collection [42]. There are 2 possible reasons for the difference. First, the sequence of time points that this study followed merely ordered the data according to the natural progression of days, from day 1 of the survey to day 25 of the survey, whereas our analysis considered the sequence of response time points for each patient. Second, that study was performed at public health and demographic surveillance sites, whereas we targeted surgical patients in hospitals. By contrast, a learning curve usually occurs for the use of a new technological progress (reflected by a decreasing error rate) as a function of the accumulation of experience over time [45]. Errors peaked on POD 1 for P&P assessments and on POD 2 for ePRO assessments, suggesting that patients took less time to adapt to the former. Studies have reported that more experience and time are needed to adapt to electronic methods [46]. Basch et al [4] found that patients with prior computer use experience benefited relatively more from the web-based PRO monitoring and alerting system.

In general, paper-based assessments are expected to be the first choice [17]. P&P is still a major method of assessment in clinical research, especially for older, poorer, or sicker patients. To accommodate a more representative patient set, ePRO needs to be made more user-friendly. For example, reducing the complexity of operating the interface, adding or optimizing automated interactive voice functions, and designing automated telephone systems outside of the hospital should be considered [47]. Given the convincing equality in measuring patient perception, a mixed-mode system involving both P&P and ePRO assessments could be a better choice. The preferred option might be ePRO assessments, with P&P assessments as the secondary choice for almost all patients in clinical studies.

What Are the Factors That Influenced Data Quality?

In this analysis, patients treated in provincial hospitals were more likely to produce poor-quality PRO data regardless of whether they used the P&P or ePRO assessments. The explanation was that the majority of patients and heaviest clinical workload are concentrated in provincial hospitals in China [48]. Medical staff in provincial hospitals are busier than those in municipal or county-level hospitals in routine clinical practice, which may result in less effort given to data monitoring. For any patient-centered practice or research, more efforts are required to obtain better data availability and accuracy in health care system. Other shared factors affecting errors in both modes are education level and physical status. Therefore, we suggest that there should be prespecified means of assistance provided to participants who are more likely to struggle to complete the assessments [49]. For example, measures might be taken to help patients complete scheduled PRO assessments when they have greater difficulties filling in the form [50]. Compared with P&P assessments, ePRO assessments had fewer risk factors for poor data quality. One possible explanation might be the homogeneous population using ePRO assessments due to biased sampling, as their use requires a certain level of education [51].

Limitations

We acknowledge that the results are limited by the potential sample bias and the differences in study designs and data collection tools. We may have overestimated the differences between the P&P and ePRO assessments because RCTs are managed better than observational studies [52], although the same team of clinical coordinators and same data quality control standard operating procedure were used for both projects. A second limitation is that the data were only collected during hospitalization because almost all ePRO assessments were administered after discharge in our study. This is similar to a study that showed that the ePRO assessment was more cost-effective and user friendly for clinical staff and patients [16,31] and suggested that there is a trend in the implementation of ePRO assessments in clinical research. Finally, this study lacks evidence of the equivalence of the data collected with the 2 forms of assessment, and therefore cannot state whether the data collected with the 2 assessments are equally valid. Further research is needed to confirm these results.

Conclusions

In conclusion, this study with substantial sample and longitudinal design demonstrates the pros and cons of the 2 most commonly used methods (ePRO and P&P), which will help promote web-based patient care [53]. It is possible to improve the quality of longitudinal PRO data by using web-based assessments. Although ePRO was found to be superior to P&P in terms of data quality, ePRO-related sampling bias should be taken into consideration when designing clinical research using longitudinal PROs as a major outcome.

Alternatively, providing the option of using either the ePRO or the P&P assessment would improve the representativeness of samples if the comparativeness of the data obtained with the ePRO and P&P assessments is confirmed by well-designed equivalence studies.

Acknowledgments

This work was supported by the Chongqing Graduate Student Research Innovation Project (CYS20209), National Natural Science Foundation of China (No. 81872506), and Sichuan Science and Technology Program (No. 2019YFH0070). The authors thank Yaqing Wang, Jia Liao, Xiaozun Yang, and Shaohua Xie (Department of Thoracic Surgery, Sichuan Cancer Hospital), Wenhong Feng (Department of Thoracic and Cardiovascular Surgery, Jiangyou People's Hospital), Yuanqiang Zhang (Department of Cardiothoracic Surgery, Zigong First People's Hospital), Yunfei Mu (Department of Thoracic Surgery, Chengdu Third People's Hospital), Rui Zhang (Department of Thoracic Surgery, Chengdu Seventh People's Hospital), and Xiaoqing Liao (Department of Cardiothoracic Surgical Oncology, Dazhu County People's Hospital, Dazhu County) for their contributions to the data collection of this paper. We also thank our senior fellow apprentice, Li Tang, for statistical method support.

Authors' Contributions

All authors took part in the study concept and design; acquisition, analysis, and interpretation of data and in the final approval of the version to be published. HY, QS, and XW were responsible for drafting of the abstract. QS, WD, and XW contributed to revising the article critically for important intellectual content. HY, QY, YN, WX, and YP performed statistical analysis. QS and WD obtained funding and offered administrative, technical, or material support. The study was supervised by QS. Both HY and QS had full access to all the data in the study and take responsibility for the integrity of the data and the accuracy of the data analysis.

Abstract

Background: The 2020 COVID-19 pandemic prompted the rapid implementation of new and existing digital technologies to facilitate access to health and care services during physical distancing. Older people may be disadvantaged in that regard if they are unable to use or have access to smartphones, tablets, computers, or other technologies.

Objective: In this study, we synthesized evidence on the impact of digital technologies on older adults' access to health and social services.

Methods: We conducted an umbrella review of systematic reviews published from January 2000 to October 2019 using comprehensive searches of 6 databases. We looked for reviews in a population of adults aged ≥65 years in any setting, reporting outcomes related to the impact of technologies on access to health and social care services.

Results: A total of 7 systematic reviews met the inclusion criteria, providing data from 77 randomized controlled trials and 50 observational studies. All of them synthesized findings from low-quality primary studies, 2 of which used robust review methods. Most of the reviews focused on digital technologies to facilitate remote delivery of care, including consultations and therapy. No studies examined technologies used for first contact access to care, such as online appointment scheduling. Overall, we found no reviews of technology to facilitate first contact access to health and social care such as online appointment booking systems for older populations.

Conclusions: The impact of digital technologies on equitable access to services for older people is unclear. Research is urgently needed in order to understand the positive and negative consequences of digital technologies on health care access and to identify the groups most vulnerable to exclusion.

digital health; social care; access; older adults; review of reviews; umbrella review

Introduction

For at least a decade, the World Health Organization has encouraged member states to become leaders in serving citizens online, using digital technology to improve health and social care services [1]. Digital technologies are electronic tools, systems, and resources that generate, store, or process data [2]. The emergence of a novel coronavirus (SARS-CoV-2, which causes COVID-19) has led to the rapid rollout of digital technologies to support patient access to health and social care, while ensuring physical distancing [3]. Digital technologies were playing a growing role in connecting health and social care services with their users before the COVID-19 pandemic. A survey of patients aged 65 years and over in 9 countries in 2013 reported that over three-quarters preferred to book and manage their medical appointments online, and over three-quarters felt that online access to medical records was important [4]. The annual survey of 770,000 patients in UK family practice has described small increases in the proportion of people booking appointments (14.9% in 2019, up from 12.9% in 2018) and ordering repeat prescriptions online (16.2% in 2019, up from 14.3% in 2018) [5].

Supporting people to use digital health resources may help improve access to services, improve physical and mental well-being, and encourage shared decision-making [5]. However, estimates suggest that 37% of the world's estimated 7.8 billion population are digitally excluded [6], with older people, people on low incomes, and other marginalized groups most likely to be affected [5,7]. In the United States, around 80% of the population accesses the internet, but its use falls sharply with increasing age. Approximately 70% of the people aged 65 to 74 years are online, compared with 52% of those aged 75 to 84 years, and 38% aged ≥85 years [8]. In the United Kingdom, out of a total population of 66.4 million, approximately 11 million (20%) lack digital skills, and 8.4 million (8.5%) never go online [9], and just over half of the latter are aged over 65 [5]. There is a clear relationship between internet use and health, with increasing age, female gender, and greater deprivation being associated with lower internet use [10]. Potential barriers to digital access include lack of awareness, confidence, capacity, or skills [11,12], a reluctance to change established behaviors, and poor internet access [5]. Affordability and acceptability of digital technology is important in later life, and it is noteworthy that many devices have been developed without the involvement of older people [13]. The involvement of older adults in technological design and development can facilitate acceptability, although it is a complex matter and requires careful consideration [14].The recent widespread introduction of digital alternatives to face-to-face interactions makes it vital that we understand their impact on older adults' ability to access health and social care services that they need. In the United Kingdom, the National Health Service (NHS) roadmap sets out the milestones for digital health and social care to support people to live healthier lives and use fewer care services using technologies such as mobile phones and smartphones, tablets, and smart televisions [15]. It includes NHS digital health and wellbeing apps, such as the NHS app, which provides access to a range of NHS services via smartphones or tablets, and NHS login, which allows patients to view and access their personal health information online [16]. These technologies could potentially improve access to services by (1) facilitating first contact with services, (2) replacing face-to-face care with remote service delivery, and (3) providing access to professional support through remote patient monitoring [2]. Therefore, this review of reviews aims to answer the question of whether digital technologies improve access to health and social care for older adults and identify the characteristics of any digital interventions that are effective in increasing access to services for older adults.

Methods

Reporting Standards

We employed an umbrella review methodology to summarize the findings of previously published reviews [17]. The review adheres to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) checklist for the reporting of systematic reviews [18]. The PRISMA checklist for this study is provided in Multimedia Appendix 1. Moreover, a review protocol was registered in the PROSPERO database [19].

Inclusion Criteria

The inclusion criteria were based on the PICOS (Population, Interventions, Comparator, Outcomes, and Study Designs) [20] criteria, which will be described in the following section.

Participants

Reviews of studies on older adults aged ≥65 or a combination of older and younger populations were selected in order to compare the effects of digital technologies on health care access between younger and older people.

Intervention

We used studies on any form of digital technology intended to facilitate access to appropriate health and social care services. These technologies enable first contact access (eg, online appointment scheduling) and are used as platforms for consultations and therapy interventions. They are also used in the remote care of patients. Furthermore, we recognized the fact that access to health and social care services would encompass availability and supply (ie, the degree of availability and quantity of supply at hand, regardless of whether they are used), utilization, equity, effectiveness, and quality of care [21].

Outcomes

We aimed to study the impact of digital technology on access to health and social care, which included the changes made in access and use of services as well as the cost-effectiveness of interventions that facilitate access and delivery of health and social care.

Study Designs

The study design of this paper encompassed any type of systematic review.

Search Strategy

We searched the following databases: Epistemonikos, MEDLINE (Ovid), Cochrane Database of Systematic Reviews (Wiley), ASSIA (ProQuest), PROSPERO, and for gray literature in Health Management Information Consortium (Ovid) and King's Fund. We used thesaurus headings along with title and abstract terms to search for digital technologies combined with specified outcomes for older people. The Canadian Agency for Drugs and Technologies in Health systematic review filter was adapted for databases that contained multiple study designs [22]. Searches were limited to the English language and the material published from January 1, 2000, to October 2019. The MEDLINE strategy is reported in Multimedia Appendix 2. The search results were downloaded to Endnote X9 (Clarivate Analytics) and deduplicated.

Data Collection

Two-stage screening was conducted by 2 reviewers independently using the Rayyan (Rayyan Systems) systematic review application [23]. We first tested and refined the inclusion and exclusion criteria on a sample of titles and abstracts to ensure that they were robust enough to capture relevant articles. The titles and abstracts of the reviews were screened against the refined inclusion criteria, followed by full text assessment of the selected articles. We resolved disagreements between the reviewers by discussion or by arbitration from another member of the review team.

Data Extraction

We extracted data into an Excel (Microsoft Corporation) spreadsheet, using a form based on the Cochrane Data Extraction and Assessment Template [20] to record the relevant review characteristics. The extracted data included: (1) author and year of publication; (2) title; (3) objective of the review; (4) description of the included population; (5) total number of older people; (6) intervention; (7) technology type; (8) what the intervention is enhancing; (9) primary outcomes; (10) secondary outcomes; (11) overall statement on quality appraisal; and (12) review authors' summary. To ensure comprehensiveness, we piloted the abstraction form on 2 reviews, which identified a need for minor modifications. Risk of bias was assessed using the ROBIS (Risk of Bias in Systematic Reviews) tool [24]. We chose to use ROBIS as opposed to AMSTAR 2 (A Measurement Tool to Assess Systematic Reviews) because we are experienced with the former, and a comparative analysis of the two tools showed little difference between them [25].

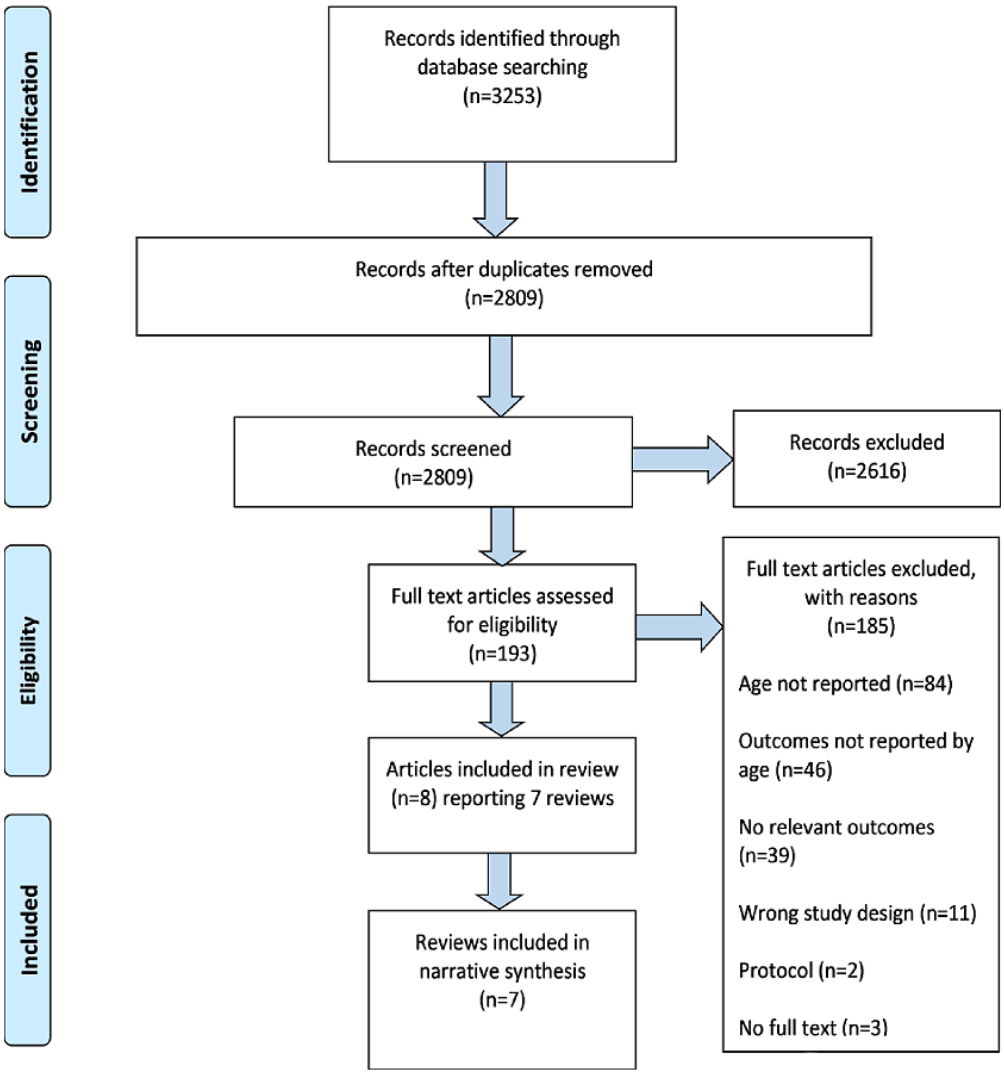
Data Analysis

We presented our main results in tabular format with a narrative synthesis. We grouped the results according to the three purposes of digital health technology, which consist of enabling first contact access, consultations and therapy, and remote monitoring. Due to a lack of data, we were unable to analyze the effects of interventions at ages over 65 years.

Results

Database searches identified 2809 unique records. The initial screening of title and abstracts excluded 2616 records, leaving 193 for full text assessment (Figure 1). We identified 7 reviews eligible for inclusion.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) flow diagram.



Characteristics of the Included Reviews

A total of 7 reviews published between 2006 and 2019 met the inclusion criteria [26-32]. A descriptive summary of review characteristics is presented in Table 1. The 7 included reviews include a total of 77 randomized controlled trials (RCTs) and 50 observational studies. We assessed the overlap across the reviews and identified 7 RCTs [33-39] reported in more than 1 review, but no observational studies that were included in more than 1 review. The studies in the reviews included 49 from the United States, 40 from Europe (including 7 from the United Kingdom), 9 from Australia, 6 from Canada, and 6 from the rest of the world. Country of origin was not stated for the remaining 17 studies. All of the studies reported outcomes for adults aged 65 and older, and 2 reviews included adults from age 18 [26,32].

Table 1. Summary of included systematic reviews.

Author	Study designs included in the review	Population	Intervention	Type of technology	Outcome
Bauce [26]	RCT,[a] observational	Adults aged >65 (in 10 out of 11 studies)	Telemonitoring	Videophones, smartphone, and mobile phone	Hospital admissions and emergency department visits
Harerimana [27]	RCT, observational	Adults aged ≥65 with a diagnosis of depression or self-reported depressive symptoms	Telehealth (mental health)	Telephone and computers	Hospital admissions and emergency department visits
Husebo [28]	Observational	Adults aged >65, either living alone or receiving informal care	Telehealth	Videophones, personal computers or laptops, and TV	Hospital admissions and readmissions
Inglis [29,40]	RCT	Adults with heart failure (8 studies included people with a mean age of ≥70)	Structured telephone support or telemonitoring (heart failure)	Telephone	Heart failure and all-cause hospitalizations
Martinez [30]	RCT, observational	Adults with heart failure (11 studies included people with a mean age of ≥65)	Home telecare	Not reported	Hospital readmissions
Marx [31]	RCT, observational	Adults with a mean age of ≥65 years living independently, in receipt of intervention for management risk of malnutrition	Telehealth for managing risk of malnutrition	Telephone and computer	Hospital readmission and healthcare costs
Sanyal [32]	RCT, observational	Older adults (11 studies included people with a mean age of ≥65 years)	Telehealth, cognitive behavior therapy	Computer	Cost-effectiveness or utility of eHealth technologies

[a]RCT: randomized controlled trial.

Risk of Bias Assessment

Details of the risk of bias assessment can be found in Table 2. Overall, the risk of bias was high for 5 reviews [26-28,30,32], and low for 2 reviews [29,31]. The main issues were the absence of clear inclusion criteria and the lack of publicly available protocols with predefined criteria. A detailed description of risk of bias assessment is reported in Multimedia Appendix 3.

Table 2. Risk of bias using ROBIS (Risk of Bias in Systematic Reviews) assessment.

Review	Phase 2				Phase 3
	Study Eligibility Criteria	Identification and selection of studies	Data collection and study appraisal	Synthesis and findings	Overall risk of bias
Bauce [26]	High	Unclear	High	High	High
Harerimana [27]	High	Unclear	High	High	High
Husebo [28]	High	High	High	High	High
Inglis [29,40]	Low	Low	Low	Low	Low
Martinez [30]	High	High	High	High	High
Marx [31]	Low	Low	Low	Low	Low
Sanyal [32]	High	Low	Unclear	High	High

Outcomes

Table 3 summarizes the identified evidence, presenting it according to the purpose of the digital technology and the reported outcomes. None of the reviews reported outcomes that were related to the changes in access to services. In total, 6 reviews reported on hospital admissions [26-31], 1 reported on healthcare costs [31], and 1 on the cost-effectiveness of digital technology [32]. A variety of digital technologies were used by healthcare professionals and older adults to support interventions for telemonitoring or telecare: videophones or video conferencing equipment, internet-based applications, and smartphones.

Table 3. Overview of the identified evidence by type of digital technology and outcome.

Objective	Outcome	
Purpose of digital technology	Health service utilization	Costs and cost-effectiveness
Digital technology to enable first point of contact access (eg, online appointment scheduling)	No reviews identified	No reviews identified
Digital technologies or platforms for consultations and therapy interventions	Harerimana [27]; Marx [31]; Husebo [28]; Inglis [29]; Martinez [30]	Sanyal [32]
Digital technology for remote monitoring interventions	Bauce [26]	Sanyal [32]

First Point of Contact Access

No systematic reviews reported evidence about the impact of digital technology to facilitate first point of contact access with health services, such as online appointment scheduling.

Consultations and Therapies

In total, 5 reviews reported on health care service utilization, in malnutrition [31], heart failure [29,30], and mental health [27,28], as outcomes of digital technologies, but only 2 reviews were judged to be at low risk of bias and thus of higher quality [29,31].

Malnutrition

Marx and colleagues [31] reported weak evidence for the effectiveness of telehealth interventions to address malnutrition among community-dwelling older adults. They identified 9 studies (7 RCTs and 2 observational); 2 of the 9 studies reported significant reductions in hospital readmissions in the intervention groups. However, when the data were pooled, the reduction in hospital admissions was not significant; (odds ratio 0.52, 95% CI 0.24-1.16); *P*=.11; n=160; I^2=0%).

Heart Failure

Inglis and colleagues [29] focused on whether structured telephone support and telemonitoring were effective for older people with heart failure. They found 41 RCTs that assessed heart failure–related hospitalizations. A meta-analysis of some of the included studies reported a 15% reduction in risk for heart failure–related hospitalizations with structured telephone support (relative risk 0.85, 95% CI 0.77-0.93; n=7030; 16 studies; I^2=27%) and a 29% reduction in telemonitoring (relative risk 0.71, 95% CI 0.60 to 0.83; n=2148; 8 studies; I^2=20%). There were no impacts reported on all-cause hospitalizations. The quality of the evidence reported for these heart failures and all-cause hospitalization studies was rated very low [29]. Evidence from the lower-quality reviews reported positive impacts of digital technology interventions on service utilization. Martinez and colleagues [30] reviewed 42 articles on the value of home monitoring for heart failure patients, 5 of which reported findings for older people. Remote consultations and follow-up care were associated with lower admission and readmission rates.

Mental Health

Husebo and colleagues [28] sought to understand the care content and utilization of virtual visits, particularly the uses and experiences of adults aged 65 and over. In their review, 1 study reported that all-cause readmissions were lower in the telehealth group (n=102) compared with standard care (n=116). At 30 days, 16 (16%) versus 22 (19%) and at over 6 months, 46 (46%) versus 60 (52%) of intervention versus control patients were readmitted [41]. Telehealth has also been used to deliver mental health care for older adults with depressive symptoms (telemental health). In a 6-month single (quasi-experimental) study of 76 patients, identified by Harerimana and colleagues [27], telemental health reduced hospital admissions by 80% (46 versus 9 admissions) and emergency room visits 60% (80 versus 32 visits) [42]. Evidence for the impact of digital technologies on economic outcomes was sparse. Moreover, 1 single review of eHealth technologies in the management of chronic diseases reported limited evidence, which did not support the assessment of cost-effectiveness [32].

Remote Monitoring

Two reviews reported evidence about technologies for remote monitoring, both of which were judged to be of poor quality. Bauce and colleagues [26] assessed the effectiveness of telemonitoring (videoconferencing) interventions on heart failure outcomes in 11 studies (10 RCTs and 1 single-group study). Five studies reported significant reductions in hospital admissions, and 2 others reported significant reductions in emergency department visits. The authors speculated that the reduction in healthcare use was likely to be due to the early detection and treatment of symptoms attributable to the intervention. Reduction in hospital admissions due to telemonitoring was supported by Queirós and colleagues [43]. Their systematic review assessed the use of technologies in the remote care of patients with long-term conditions such as diabetes, congestive heart failure, chronic obstructive pulmonary disease, and mental disorders [43].

Discussion

Principal Results

We identified evidence on a variety of digital technologies to facilitate interaction between older people and services at different parts of the care pathway. However, we found no reviews of technology to facilitate first point of contact access such as online appointment booking systems. There was no significant difference in hospital admissions for telehealth interventions (but this may have been due to the studies' lack of power as there were only 160 participants in the pooled analysis) [31]. However, for heart failure, structured telephone support resulted in 15% reduction in admissions [29]. Other reviews were of too low a quality to permit confidence in

findings, however, and there were no signs that a focus on reviews with too low a risk of bias would change anything. From the 7 overlapping RCTs [33-39], benefits to the older population in access were poorly measured and not clearly reported. In these RCTs, focus was on reducing hospital admissions, and there was little account of whether these technologies are enabling older people to interact with or access health and social care services more effectively. There was also no review evidence for newer technologies such as smartphone apps (eg, the NHS app in the United Kingdom), some of which were already in widespread use before COVID-19 [15].

The 2020 COVID-19 pandemic prompted the rapid implementation of alternatives to face-to-face interactions in health and social care [3]. This was a pragmatic response to a novel emergency that allowed care delivery to continue. As the pandemic evolves, digital innovations that have been implemented at speed should be evaluated to ensure that they are effective and affordable so that they can promote equitable access and do not selectively overlook certain sections of the population [14]. However, none of the included reviews addressed the issue of affordability and acceptability of digital technology in later life. For sections of the population who lack digital literacy or a means of digital engagement, the benefits are less clear, and there is every possibility that they will be harmed by losing the ability to access services in traditional, nondigital ways.

Most of the evidence [26-31] was concerned with digital technologies to facilitate remote delivery of care, including consultations and therapy, reflecting a research focus congruent with policy priorities [15]. However, these evaluations were more focused on reducing hospital utilization rather than enhancing access to services. Whether digital technologies do reduce hospital admissions and visits by facilitating timely access to appropriate alternative care is impossible to determine from the evidence presented. Evidence on the cost-effectiveness of digital health technologies was confined to 1 low-quality review, from which no clear conclusions can be drawn [32].

Limitations

To the best of our knowledge, this is the first rapid synthesis of systematic reviews on digital technology aimed at enhancing access to health and social care services for older adults. We followed a rapid evidence synthesis approach, and our database searching, handling of data, and reporting adhered to published guidelines for undertaking a robust standard systematic review [18,44]. We restricted our searches to English language publications due to time constraints and acknowledge that this may have excluded relevant material. Two limitations of the material should be highlighted. First, most of the studies contained within our included reviews were randomized trials of effectiveness and cost-effectiveness. However, we found that the benefits to the older population in access are poorly measured and not clearly reported in studies of digital technology. Second, most of the reviews failed to adequately report their findings, and formal assessments of the methodological quality indicated a low-quality evidence base. This leads us to be cautious in our interpretation of the evidence and any conclusions drawn.

Comparison With Prior Work

Our assessment of the dearth of evidence on first point of contact digital technology is supported by other works. A recent review of approaches to the evaluation of digital health interventions identified little evidence from randomized controlled trials and carried out measurement of service utilization in only a minority of the studies [45]. Our review suggests that digital health technologies may be associated with reductions in health service use. This is supported by multiple systematic reviews in younger populations of patients with long-term conditions [43]. There is a particular gap in the evaluation of any digital technologies used in social care.

Implications for Policy, Research, and Practice

The COVID-19 pandemic has resulted in the rapid implementation of digital interventions to allow continued access to services when infection risk was high. This rapid rollout went beyond any evidence for effectiveness, driven by the extraordinary need to reduce face-to-face contact. However, prepandemic concerns about the adverse effects of digital technologies on access to services for older people remain valid. For older people who are digitally excluded, these digital interventions risk exacerbating any problems they already faced when trying to access health and social care services. This, in turn, has implications for workload in primary care, and health care providers must take on greater responsibility to ensure that this important section of the population receives the care it needs. There is a notable gap in the evidence for studies assessing the impact of technologies to enable first point of contact for health and social care services (eg, online platforms to book appointments). A mapping review of primary studies is required to understand this impact on different population subgroups, but this is unlikely to be sufficient. Further work is needed to understand the effectiveness and cost-effectiveness of digital technologies and their effect on equity of access to health and social care services. This should encompass access to appropriate care, which may lead to reductions in the use of other services as well as changes in health outcomes. The paucity of evidence in this area points to the need for a broad research program in partnership with older people and service providers in order to understand the characteristics of digital technologies, which can enhance access to services.

Conclusions

The current systematic review evidence on the potential for digital technologies to improve access to health and social care for older adults is limited in both scope and quality. However, these limited attempts raise the possibility that providing digital interventions in addition to or as a replacement for face-to-face services may reduce demands on hospitals. Further research is required, and the widespread use of digital technologies to facilitate access to health and social care during the COVID-19 pandemic offers an ideal opportunity to better understand the barriers, facilitators, and limitations of their use.

Acknowledgments

Abstract

Background: Viewing their habitual smoking environments increases smokers' craving and smoking behaviors in laboratory settings. A deep learning approach can differentiate between habitual smoking versus nonsmoking environments, suggesting that it may be possible to predict environment-associated smoking risk from continuously acquired images of smokers' daily environments.

Objective: In this study, we aim to predict environment-associated risk from continuously acquired images of smokers' daily environments. We also aim to understand how model performance varies by location type, as reported by participants.

Methods: Smokers from Durham, North Carolina and surrounding areas completed ecological momentary assessments both immediately after smoking and at randomly selected times throughout the day for 2 weeks. At each assessment, participants took a picture of their current environment and completed a questionnaire on smoking, craving, and the environmental setting. A convolutional neural network–based model was trained to predict smoking, craving, whether smoking was permitted in the current environment and whether the participant was outside based on images of participants' daily environments, the time since their last cigarette, and baseline data on daily smoking habits. Prediction performance, quantified using the area under the receiver operating characteristic curve (AUC) and average precision (AP), was assessed for out-of-sample prediction as well as personalized models trained on images from days 1 to 10. The models were optimized for mobile devices and implemented as a smartphone app.

Results: A total of 48 participants completed the study, and 8008 images were acquired. The personalized models were highly effective in predicting smoking risk (AUC=0.827; AP=0.882), craving (AUC=0.837; AP=0.798), whether smoking was permitted in the current environment (AUC=0.932; AP=0.981), and whether the participant was outside (AUC=0.977; AP=0.956). The out-of-sample models were also effective in predicting smoking risk (AUC=0.723; AP=0.785), whether smoking was permitted in the current environment (AUC=0.815; AP=0.937), and whether the participant was outside (AUC=0.949; AP=0.922); however, they were not effective in predicting craving (AUC=0.522; AP=0.427). Omitting image features reduced AUC by over 0.1 when predicting all outcomes except craving. Prediction of smoking was more effective for participants whose self-reported location type was more variable (Spearman ρ=0.48; *P*=.001).

Conclusions: Images of daily environments can be used to effectively predict smoking risk. Model personalization, achieved by incorporating information about daily smoking habits and training on participant-specific images, further improves prediction performance. Environment-associated smoking risk can be assessed in real time on a mobile device and can be incorporated into device-based smoking cessation interventions.

Introduction

Background

Cigarette smoking is the leading cause of preventable deaths in the United States [1], and tobacco use is responsible for more than 7 million annual deaths worldwide [2]. Although most smokers are motivated to quit [3], fewer than 10% of quit attempts are successful [4], which has motivated ongoing efforts to develop more effective cessation strategies.

New, mobile device-based cessation interventions have improved 6-month [5] and 12-month [6] cessation outcomes, and success rates can be further improved [7] by tailoring interventions to individual users and momentary contexts, such as the user's geographic location [8]. This paradigm has been formalized as the just-in-time adaptive intervention (JITAI) [9,10], wherein a cessation support system continuously monitors contextual factors through ecological momentary assessment (EMA; ie, repeated self-reporting), passive sensing, or a combination of the two, then provides context-sensitive support to smokers at times when it is most needed. By monitoring user physiology [11-14], geographic location [8,15], and recent smoking events [15], a cessation support system can estimate smoking risk from moment to moment and then intervene when the estimated risk is high.

However, most smoking cessation interventions neglect an important contributor to smoking behaviors—the smoker's external environment. A growing body of evidence, collected in both laboratory and real-world settings, suggests that smoking risk is affected not only by internal factors but also by the smoker's current environmental context. For example, images of personal smoking environments increase smoking behaviors and self-reported craving [16-19] and activate neural circuits associated with craving, contributing to subsequent smoking behaviors [20]. Consistent with these findings, a recent study showed that self-reported environmental conditions, such as being around other smokers or in a place where smoking is permitted, were stronger predictors of smoking lapse than internal states (eg, smoking urge) [21].

Current technologies can now quantify the effects of environmental factors on real-world smoking behaviors [22]. Wearable cameras and mobile devices allow images of daily environments to be acquired near continuously at low cost [23-26], and computer vision models, now highly accurate and optimized for mobile devices [27], can identify environmental features in these images. These features can then be linked to smoking and craving, along with other behaviors or outcomes of interest. This process is objective, does not require manual annotation of images, and scales to large data sets and study populations.

In a previous study, we demonstrated that computer vision could distinguish between daily environments where smokers commonly smoke and those where they rarely smoke. Using the approach outlined above, we also uncovered specific objects and settings associated with smoking versus nonsmoking environments [28]. These findings suggest that environmental features monitored via computer vision may provide important contextual information that can improve the prediction of momentary smoking risk. However, these two extremes, known smoking and nonsmoking environments, do not reflect the full range of environments that smokers encounter in their daily lives.

Objective

In this study, we collected a representative sample of images of smokers' daily environments through photograph-augmented EMA (photoEMA). In each assessment, participants self-reported recent smoking and their current craving level and then took a picture of their environment. A mobile-optimized convolutional neural network was trained to predict smoking risk and other outcomes relevant to smoking (craving, whether smoking was permitted in the current environment, and whether the participant was outside) based on environmental images and other participant-specific features. We hypothesized that out-of-sample prediction would be effective, providing a basis for an environment-aware JITAI, and that prediction performance could be improved through model personalization, in which images from a given participant are used to refine model predictions for that participant. We also aim to understand how model performance varies by location type, as reported by participants. Our final prediction model, QuitEye, was deployed on a mobile device and can assess environment-associated smoking risk and craving in real time to support environment-aware smoking cessation interventions.

Methods

Study and Participants

Recruitment and all study procedures were approved by the Duke University Health System Institutional Review Board, and written consent was obtained from all participants. Smokers (≥10 cigarettes per day for ≥2 years) aged ≥18 years were recruited from the Durham, North Carolina area. Participants were recruited from the community for a study of smoking behavior via printed and web advertisements and word-of-mouth. Participants were excluded if they regularly used noncigarette tobacco products (eg, e-cigarettes); currently used smoking cessation medications; planned to quit smoking, otherwise altered their smoking pattern, left the study area or anticipated a major life event during the study; had current or recent alcohol or drug abuse problems; or were pregnant, breastfeeding, or planning to become pregnant during the study. Eligible participants completed an initial visit to (1) biochemically verify their smoking status (ie, carbon monoxide breath test) and test for illicit drug use, (2) test for pregnancy, and (3) complete questionnaires on nicotine dependence and tobacco use history. Participants who met all eligibility requirements (n=52) then downloaded the photoEMA app

(Metricwire) to their smartphone and were trained on its use. Following the 14-day photoEMA period, participants completed a follow-up visit during which an interview was conducted to assess drug and alcohol use, tobacco purchasing, and any other events that might have affected smoking (eg, illness) or daily living (eg, death in the family) patterns. Participants were compensated for up to US $350 in total, including daily (US $5) and weekly (US $50) incentives for high photoEMA completion. All procedures were observational, and no randomization or intervention was performed.

PhotoEMA Collection

Participants completed the photoEMA assessments for 14 days.

Random Prompts

Participants specified their typical wakeful hours during the screening. They were prompted six times daily at randomly spaced intervals. The average interval between prompts was 120 minutes in duration. At each assessment, participants rated their current levels of urge to smoke (1 item) and affect and stress (11 items; not reported here). In addition, they captured a time-stamped image of their current location. Finally, they were prompted to label the location with a prepopulated list of common locations (eg, bedroom, office, car, or park), other location information (eg, indoors or outdoors and whether smoking was permitted), current activity (eg, working or running errands), social environment (eg, presence of others), and recent alcohol and caffeine use.

Smoking-Initiated Assessments

Participants were also instructed to complete assessments each time they smoked. They were asked how many cigarettes they smoked in this location on this occasion and all items from the random prompt assessments.

Across Prompt Types

Participants were instructed to delay responding if they were in situations or locations where responding to, or initiating prompts, would be distracting (eg, in a meeting) or dangerous (eg, while driving). Across assessments, participants were asked to compose pictures to avoid including other people but to otherwise leave environments as they are.

Craving data were dichotomized based on the median self-reported craving for all participants. Self-reported craving of a *moderate* or lower level was coded as negative, and self-reported craving of *quite a bit* or higher level was coded as positive. Other outcomes (smoking, whether smoking was permitted, and whether the participant was outside) were binary; therefore, no binarization was required.

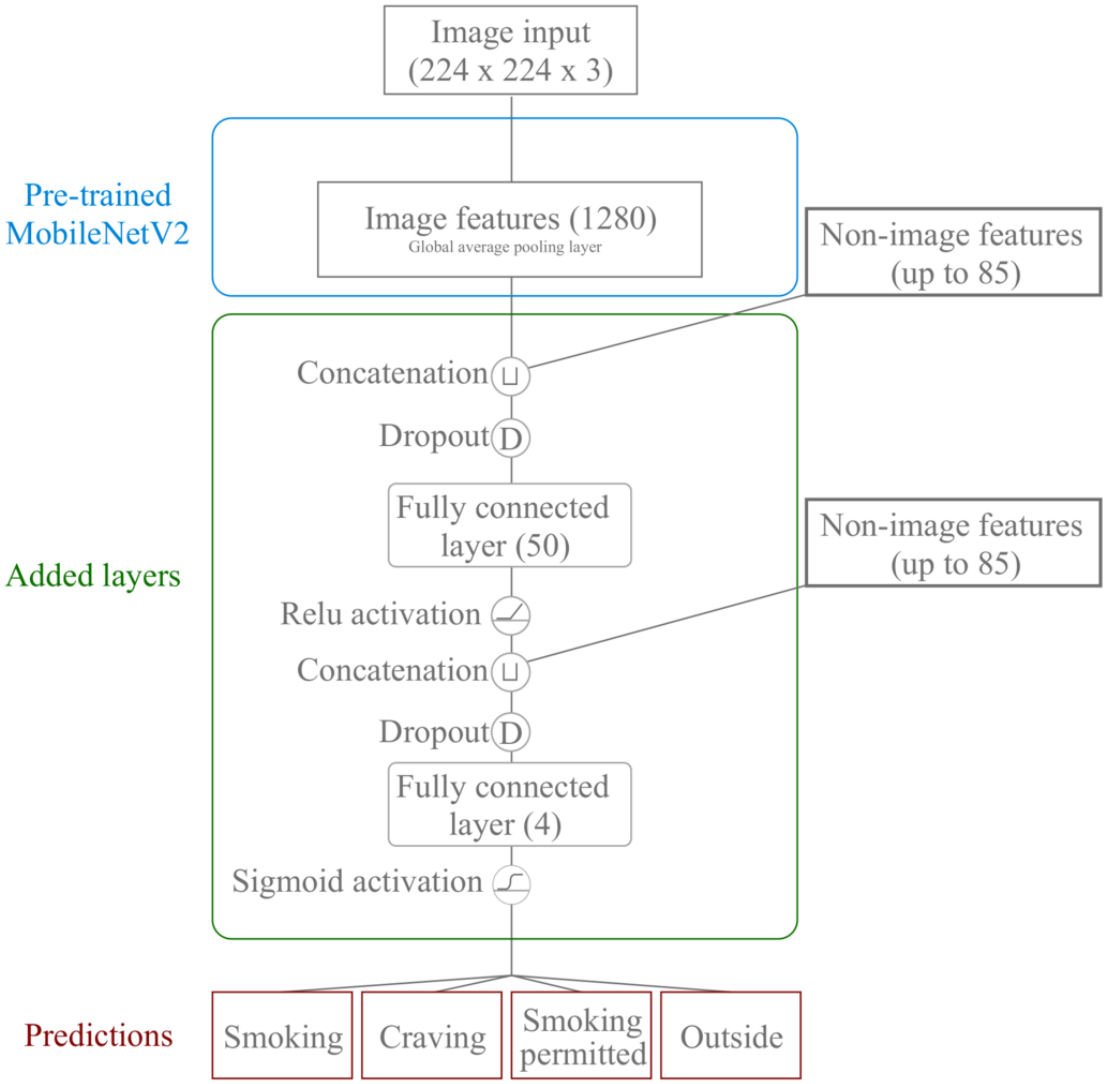
Convolutional Neural Network Model

QuitEye is based on MobileNetV2, a convolutional neural network architecture optimized for mobile devices [27] pretrained on ImageNet [29]. QuitEye also incorporates the following additional information: (1) participant age and sex, (2) known smoking locations inside and outside the home as indicated by self-report at baseline, (3) time since the last cigarette, (4) time of day and day of the week, and (5) a participant-specific indicator variable (in the longitudinal models only).

To determine the impact of each of these elements on prediction performance, we conducted ablation studies in which models *that did not incorporate* a given element were also trained and evaluated. For example, we trained a model *without* age and sex to assess the impact of these factors on prediction performance, and to estimate performance for a possible deployment in which these were not available. Models that did not incorporate image features were also trained and evaluated to determine the impact of the images on prediction performance.

QuitEye is a multi-task architecture that jointly predicts four binary outcomes: smoking, craving, whether smoking is permitted, and whether the participant is outside. Prediction of whether the participant is outside was included both to contextualize other performance figures and because inside or outside status is associated with smoking behaviors. Nonimage features were concatenated with image features from the global pool layer of MobileNetV2, and a single hidden neural network layer (rectified linear unit activation) was applied. Nonimage features were again concatenated to the output of this layer, and a second fully connected layer (sigmoid activation) was then used to predict each of the four binary outcomes. The QuitEye architecture is shown in Figure 1.

Figure 1. Diagram of QuitEye, which extracts image features using the MobileNetV2 convolutional neural network, then predicts smoking status, craving, whether smoking is permitted, and whether the participant is outside based on a combination of image features and additional data collected from participants with a mobile device.



Training and Evaluation

QuitEye was trained using Tensorflow v1.15 in Python v3.7 on a single Titan XP GPU. MobileNetV2 parameters were initialized to values learned on ImageNet [29], and all parameters were fine-tuned. Two training and evaluation procedures were used to evaluate out-of-sample performance (ie, *out-of-the-box* performance, without first learning from images from a given participant) and personalized model performance (ie, after learning from a subset of that participant's images).

Out-of-sample performance was assessed by training and evaluating the model using nested cross-validation [30] with five outer folds and five inner folds. In the nested cross-validation procedure, out-of-sample performance was evaluated on each outer fold after developing the model using data from the remaining folds. In each development set, an inner cross-validation procedure was used to determine the optimal hyperparameter settings.

Personalized model performance was assessed by developing the model with data from all participants from days 1 to 10, then evaluating it on data from days 11 to 14. Images used in model development were divided at random into training (80%) and validation (20%) sets.

Hyperparameters included the width of the hidden layer (Figure 1), hidden layer dropout rate, and learning rate. Performance was evaluated using the area under the receiver operating characteristic curve (AUC) for each of the four prediction tasks.

Additional models were trained using the procedures outlined above to quantify the impact of additional (nonimage) features on performance. Features were categorized as (1) baseline information, including participant demographics and smoking habits; (2) information that could be collected via mobile devices, including the time elapsed since the participant last smoked and the time of day; and (3) a unique participant identifier, which was incorporated as a categorical feature in the personalized models only. Including this identifier adds participant-specific parameters to the model, allowing predictions to be explicitly personalized. However, even when this identifier is omitted, the personalized model development scheme (ie, training on days 1-10 from all participants) allows

the model to learn from each participant's previously visited locations when predicting their current risk.

Mobile Device Implementation (QuitEye)

A nonpersonalized (out-of-sample) model incorporating image features only was implemented in TensorFlow Lite to allow prediction via mobile devices. Other features were omitted so that predictions could be made based on images only without additional data collection. A prototype mobile app was built using Flutter or Dart and tested on Google Pixel 3 (Android). QuitEye is applied to individual frames from a live video feed at a rate of approximately eight samples per second and is configured to display smoking and craving predictions corresponding to each frame.

Data Availability

The data sets analyzed in this study are not publicly available because they contain images of participants' personal daily environments that cannot be deidentified. However, the code supporting this work is available from the corresponding author upon reasonable request.

Results

Demographics and Descriptive Statistics

Of the 77 individuals screened for the study, 52 (68%) were eligible and consented to participate. Four participants were withdrawn or lost to follow-up, and the remaining 48 participants completed the study. One participant completed their study visits remotely because of in-person visit restrictions related to COVID-19. Among the participants who completed the study, a total of 8008 images were collected, 3648 (45.55%) of which were from completed random prompts and 4360 (54.45%) of which were from completed smoking prompts. Demographic characteristics, image details, and other descriptive statistics are presented in Table 1.

Model Performance

Without personalization (out-of-sample performance), QuitEye predicted smoking with AUC=0.723 and average precision (AP)=0.785, craving with AUC=0.522 and AP=0.427, whether smoking was permitted with AUC=0.815 and AP=0.937, and whether the participant was outside with AUC=0.929 and AP=0.922. With personalization, performance was substantially improved: QuitEye predicted smoking with AUC=0.827 and AP=0.882, craving with AUC=0.837 and AP=0.789, whether smoking was permitted with AUC=0.932 and AP=0.981, and whether the participant was outside with AUC=0.977 and AP=0.956 (Figures 2 and 3).

Figure 2. Receiver operating characteristic curves for each of the four outcomes for both the nonpersonalized (out-of-sample) and personalized (longitudinal) models. AUC: area under the receiver operating characteristic curve.

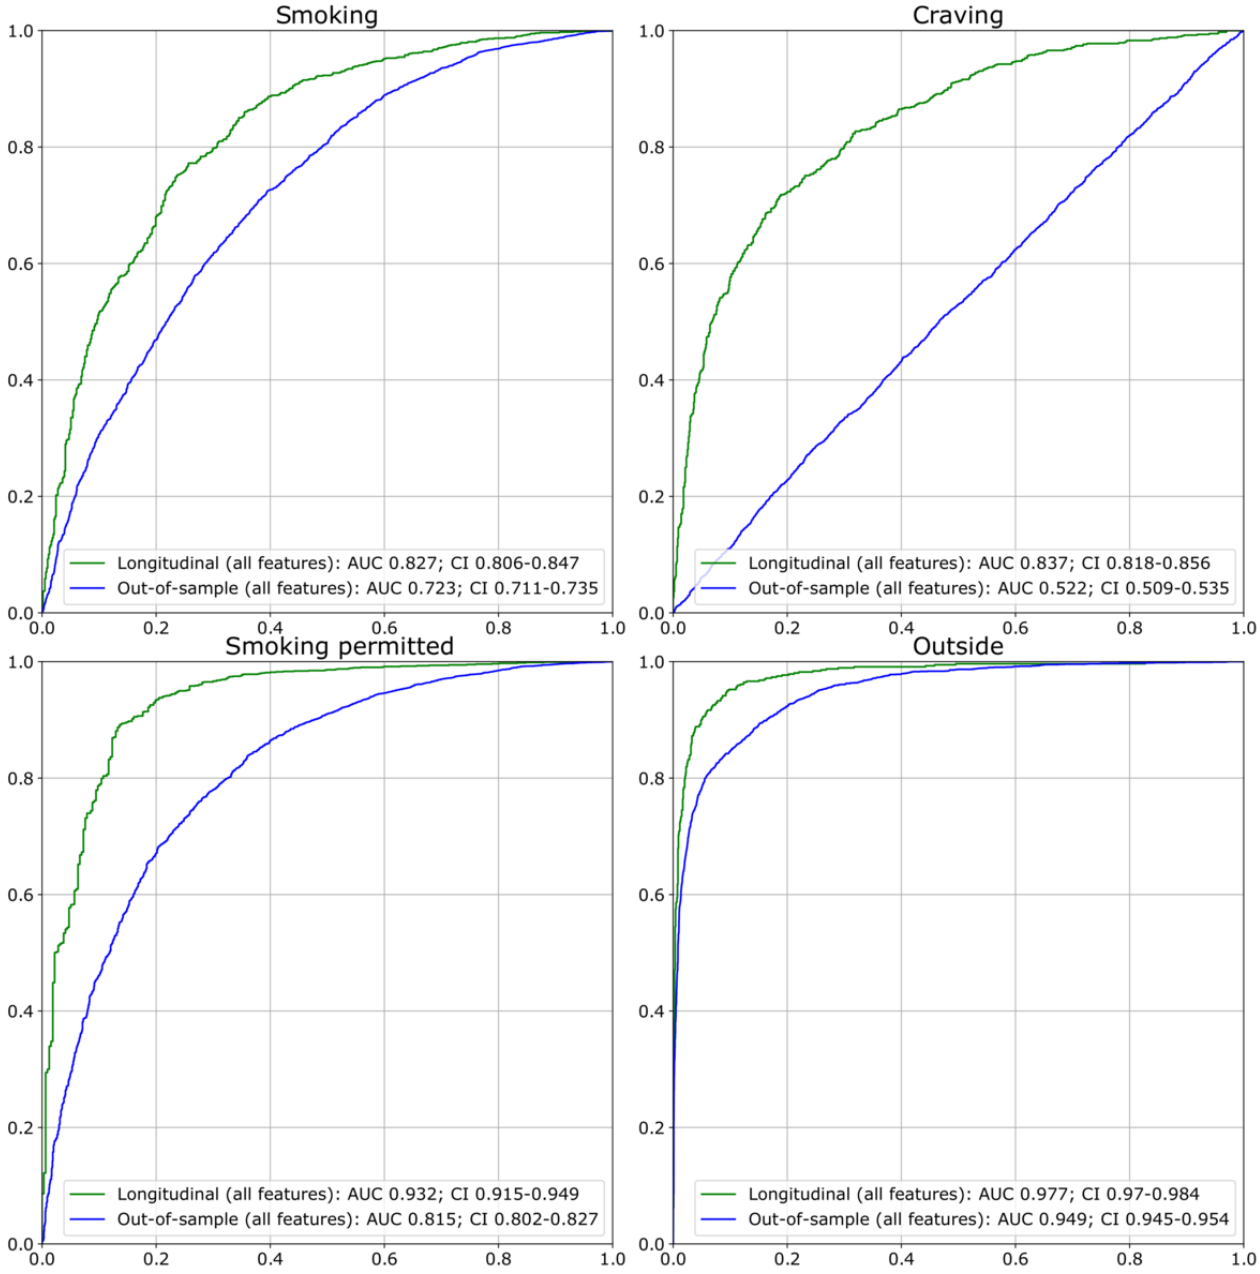

Figure 3. Precision recall curves for each of the four outcomes for both the nonpersonalized (out-of-sample) and personalized (longitudinal) models.

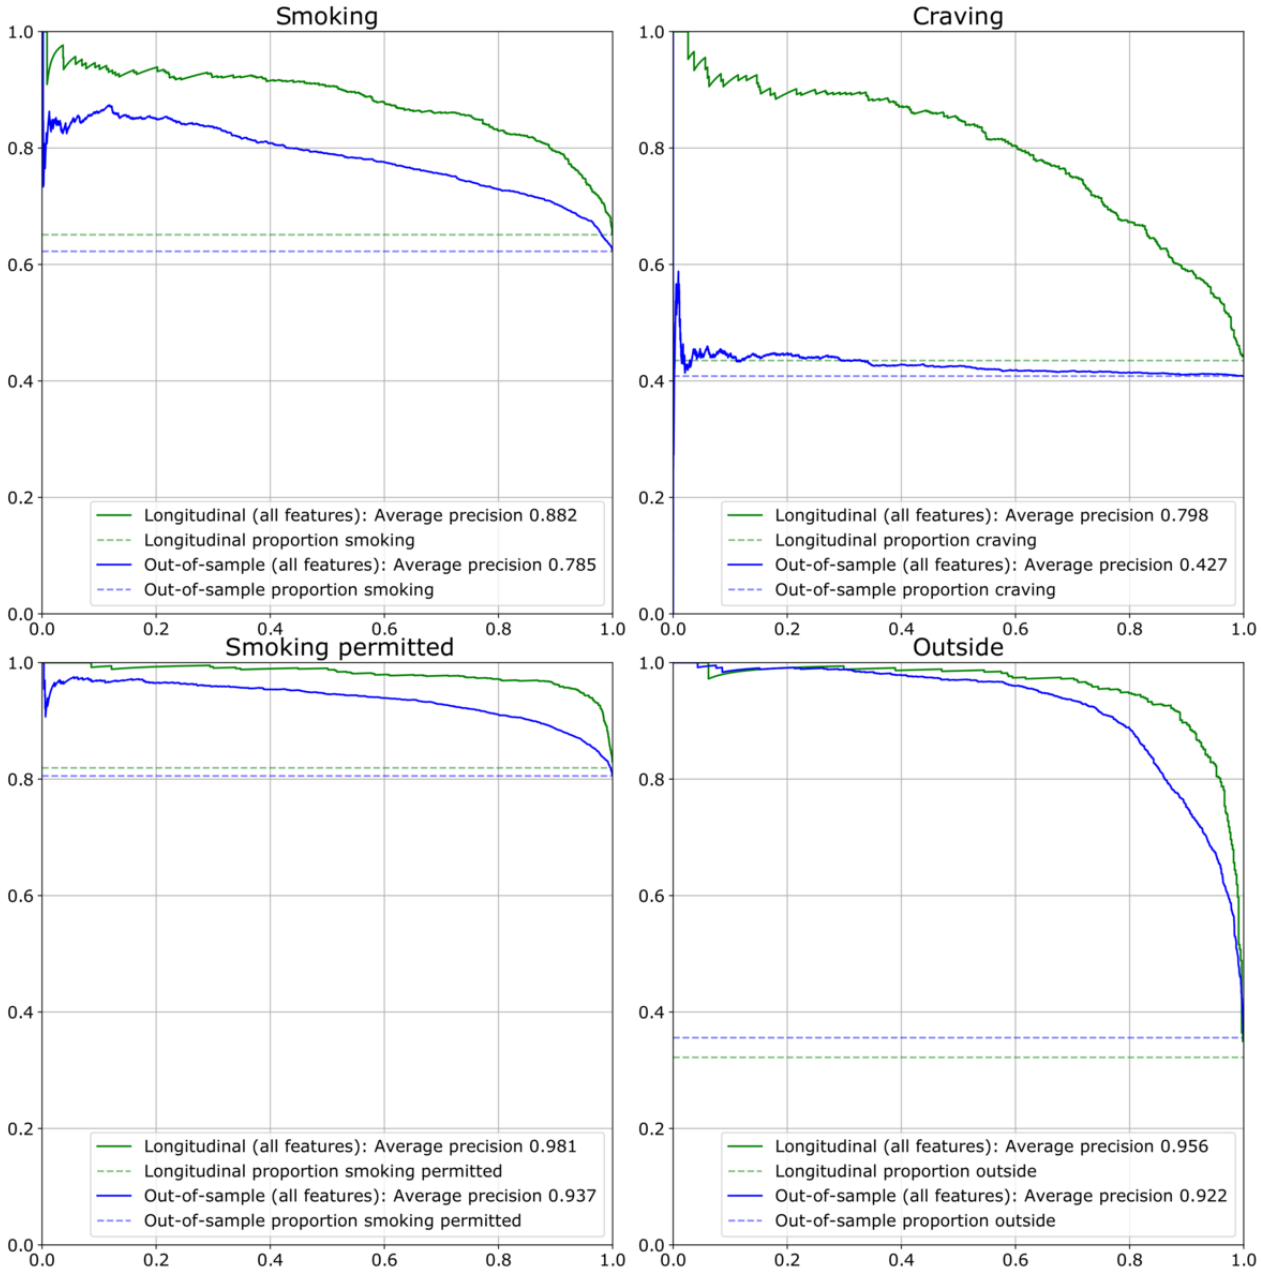

Image features were critical to these performance figures for all outcomes except craving. In the nonpersonalized (out-of-sample) models, removing the image features lowered AUC by 0.221 when predicting smoking, by 0.229 when predicting whether smoking was permitted, and by 0.253 when predicting whether the participant was outside but by only 0.027 when predicting craving. In the personalized (longitudinal) models, removing the image features lowered AUC by 0.192 when predicting smoking, by 0.168 when predicting whether smoking was permitted, and by 0.178 when predicting whether the participant was outside but increased AUC by 0.034 when predicting craving (Table 2).

In the out-of-sample models, baseline information about household smoking locations improved the prediction of craving (ΔAUC=0.050) and whether smoking was permitted (ΔAUC=0.020), but other nonimage features had less impact. Surprisingly, knowing the time since the last cigarette did not improve the prediction of smoking (ΔAUC=−0.014) or craving (ΔAUC=−0.026; Table 2). Performance among individual participants when predicting smoking was highly correlated with performance predicting whether smoking was permitted (Spearman ρ=0.55; P<.001), whereas correlations between other pairs of outcomes were not statistically significant.

In the personalized models, the participant identifier substantially improved the prediction of craving (ΔAUC=0.070), and baseline information about smoking locations outside of the household slightly improved the prediction of craving (ΔAUC=0.013); however, nonimage features had little effect on performance (ΔAUC<0.007). Similar to the out-of-sample models, performance among individual participants when predicting smoking was highly correlated with performance predicting whether smoking was permitted (r=0.71; Spearman ρ<0.001). However, this was not the case for any other pairs of outcomes.

Analyses of model calibration showed that outcome probabilities predicted by QuitEye were consistent with true outcome rates, except when predicting craving via the out-of-sample model (Figure 4). This suggests that the predicted smoking probability reflects the true environment-associated smoking probability.

Table 2. Model performance (area under the receiver operating characteristic curve) before and after removal of specific data elements.

Model performance	Area under the receiver operating characteristic curve (Δ[a])			
	Smoking	Craving	Smoking permitted	Outside
Out-of-sample models				
Base model (all features)	0.723 (N/A[b])	0.522 (N/A)	0.815 (N/A)	0.949 (N/A)
Images	0.502 (−0.221)	0.495 (−0.027)	0.586 (−0.229)	0.696 (−0.253)
Demographics	0.729 (0.006)	0.542 (0.021)	0.810 (−0.005)	*0.952*[c] (0.002)
Time since last cigarette	*0.737* (0.014)	0.548 (0.026)	*0.819* (0.004)	0.944 (−0.005)
Time of day, weekday or weekend	0.726 (0.003)	*0.553* (0.032)	0.806 (−0.008)	0.945 (−0.004)
Household smoking locations	0.735 (0.012)	0.472 (−0.050)	0.795 (−0.020)	0.950 (0.001)
Other smoking locations	0.717 (−0.006)	0.513 (−0.009)	0.812 (−0.003)	0.948 (−0.001)

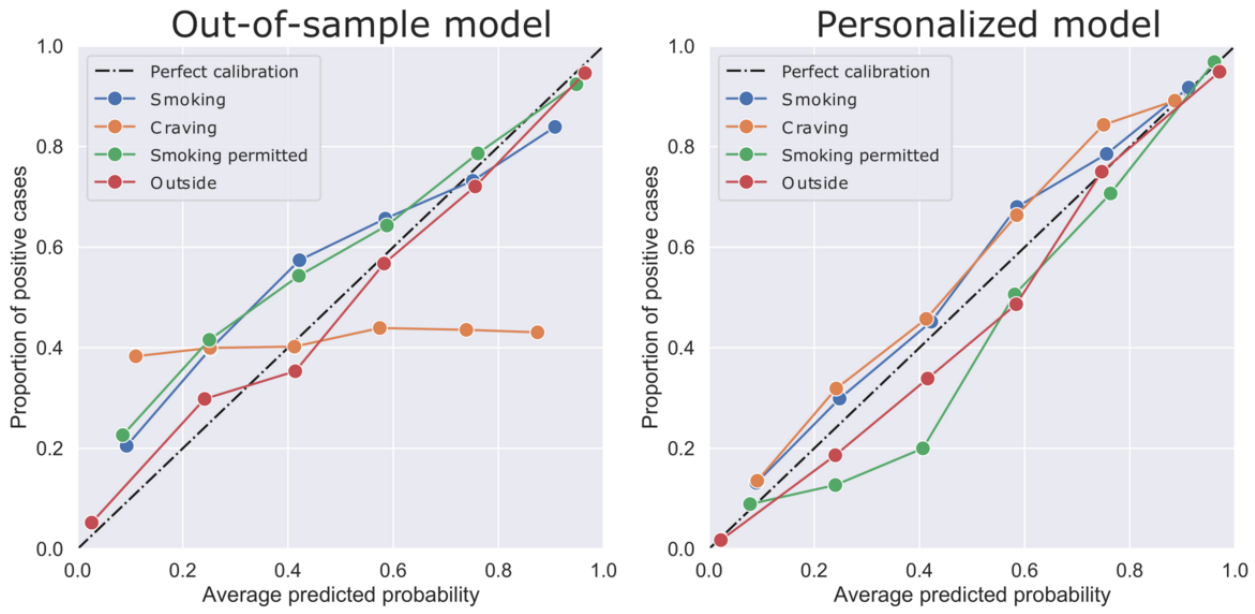
[a]Change in the area under the receiver operating characteristic curve compared to the base model.

[b]N/A: not applicable.

[c]Italics indicate the best performing model for that outcome.

Figure 4. Calibration curves for the nonpersonalized (out-of-sample; left panel) and personalized (longitudinal; right panel) models. Model-predicted probabilities are aggregated by percentile (N=6 bins), then compared with the proportion of positive outcomes in each bin. Good calibration implies that model predictions are an accurate estimate of the true probability of a positive outcome.



Effect of Location on Performance

Analyses of model performance by self-reported location type showed that QuitEye is more effective in some locations than others. For the nonpersonalized (out-of-sample) model (Figure 5), smoking prediction was most effective at work (AUC=0.848), followed by stores or restaurants (AUC=0.806). Across all prediction tasks, prediction tended to be less effective for images taken within vehicles. Many of these images showed outside scenery as viewed from the vehicle, leading the model to incorrectly predict that the participant was outside (AUC=0.603) rather than inside the vehicle.

Improvements in performance from personalized training also varied by location (Figures 5 and 6). AUC was improved most for outdoor home locations—prediction of smoking was improved by ΔAUC=0.230 in these locations, and prediction of whether smoking was permitted was improved by ΔAUC=0.435.

Smoking prediction was more effective for participants whose self-reported location type was more variable (r=0.48; *P*=.001), quantified as the entropy of self-reported location type. This effect was not observed in other prediction tasks. Smoking prediction was also more effective for those with higher mutual information between smoking and self-reported location type (r=0.53; *P*<.001); the mutual information quantifies the degree to which location type provides information about smoking behavior (Figure 7). This effect was not observed in other prediction tasks.

Figure 5. Outcomes and model performance by location type (out-of-sample). The bar plots indicate the proportion of positive outcomes (with SE) by self-reported location type, and the line plots indicate model performance (average precision) for images taken in each location. NA: prediction performance is not applicable, because there is no variability in the outcome in this location type.

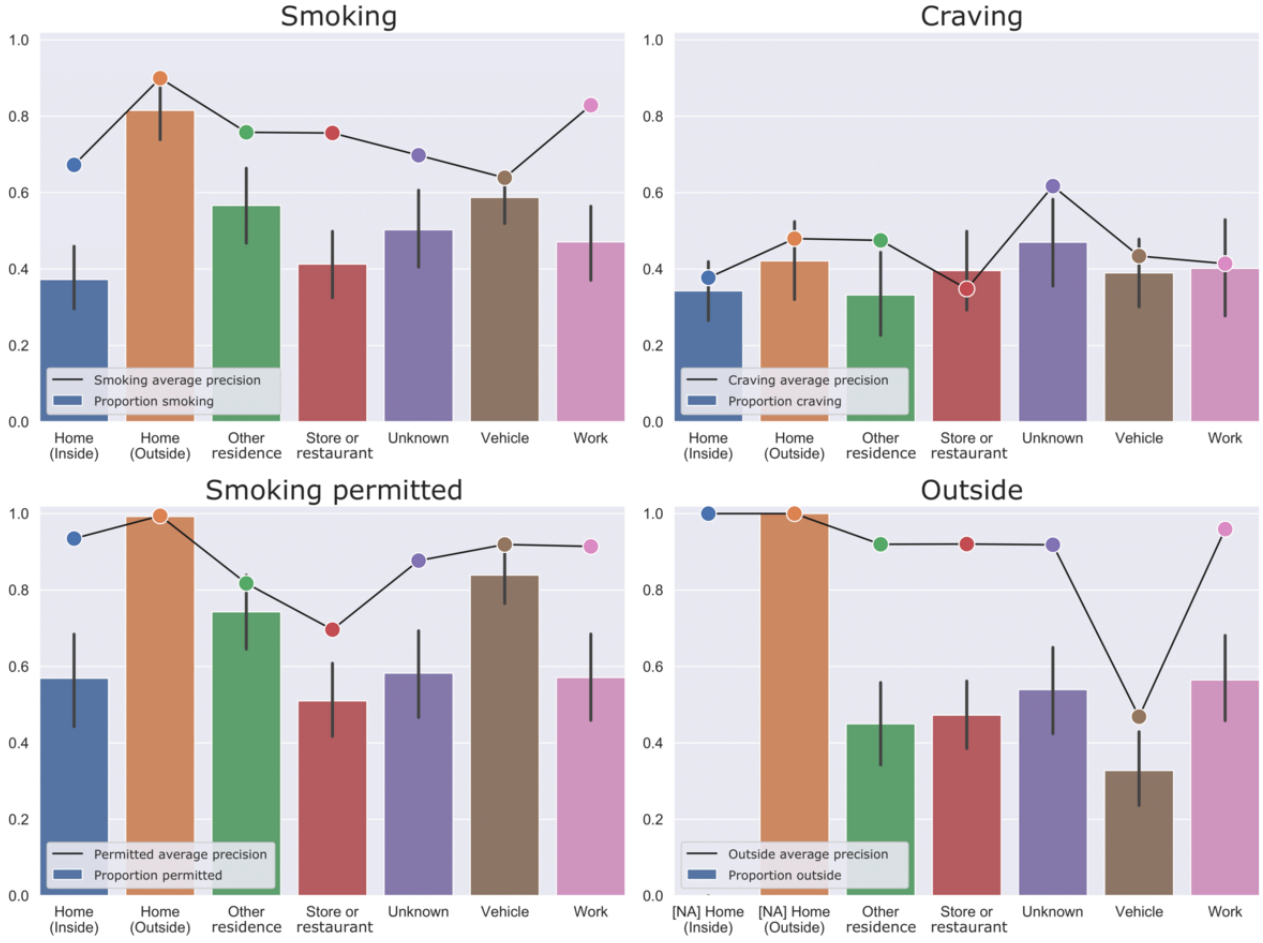


Figure 6. Outcomes and model performance by location type (personalized). The bar plots indicate the proportion of positive outcomes (with SE) by self-reported location type, and the line plots indicate model performance (average precision) for images taken in each location. NA: prediction performance is not applicable, because there is no variability in the outcome in this location type.

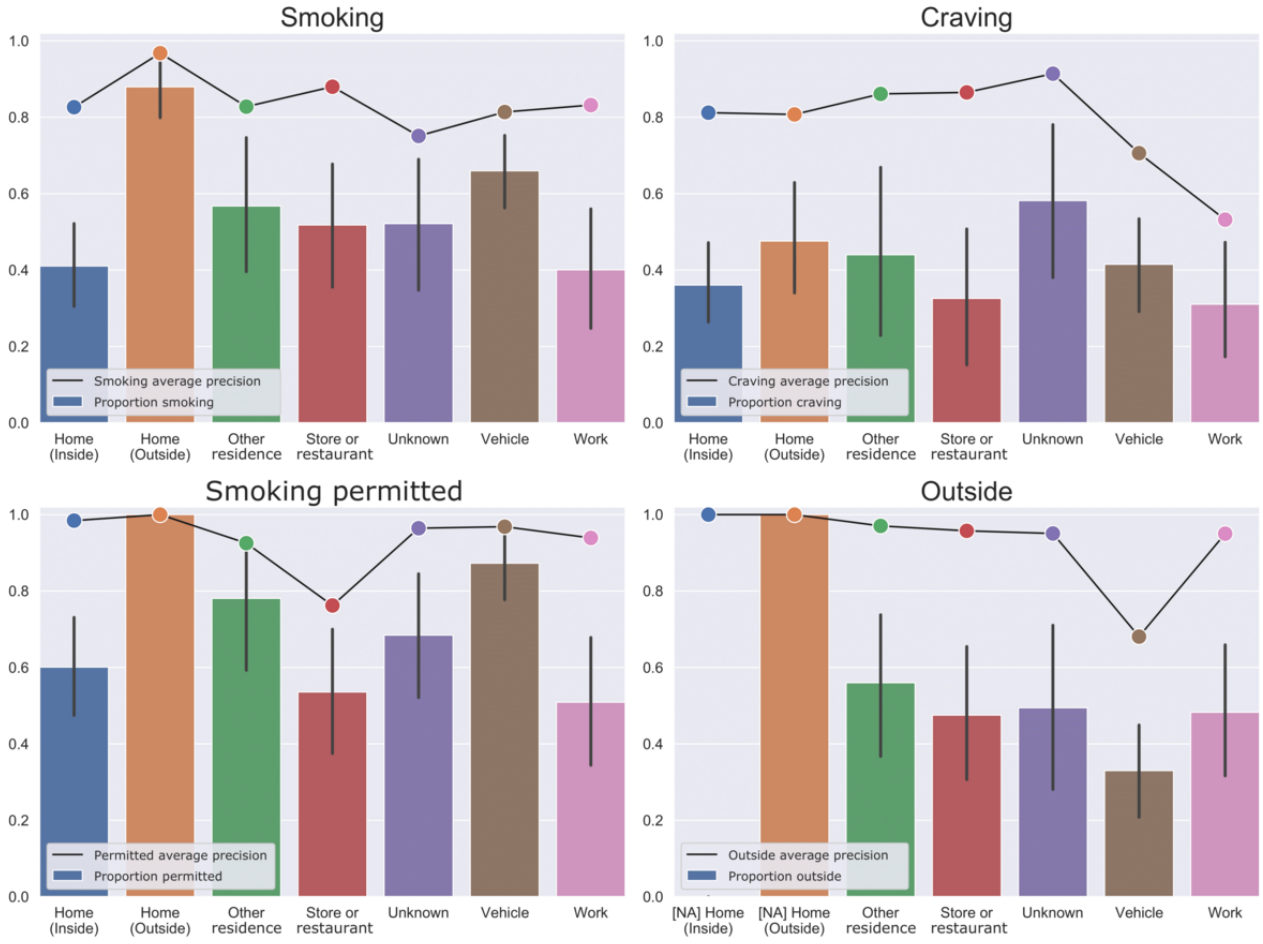

Figure 7. Effect of location variability on performance. Higher performance of smoking risk prediction among individual participants is associated with higher variability in self-reported locations (left panel) and higher mutual information between self-reported location type and smoking status (right panel). AUC: area under the receiver operating characteristic curve.

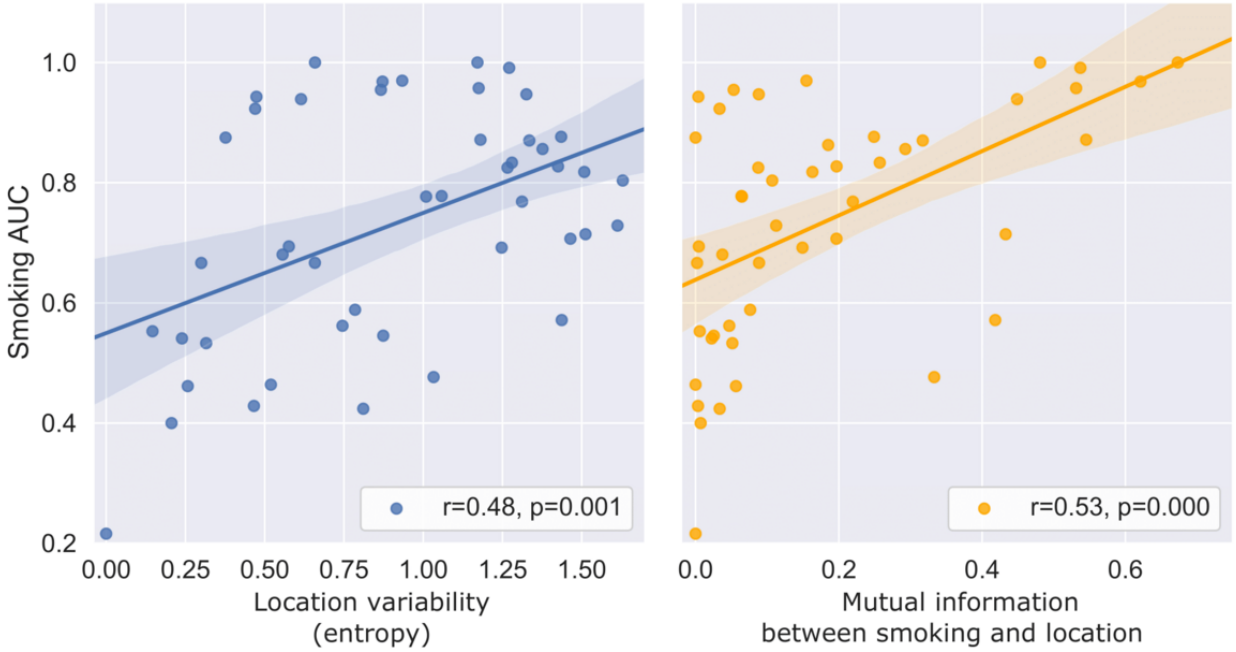
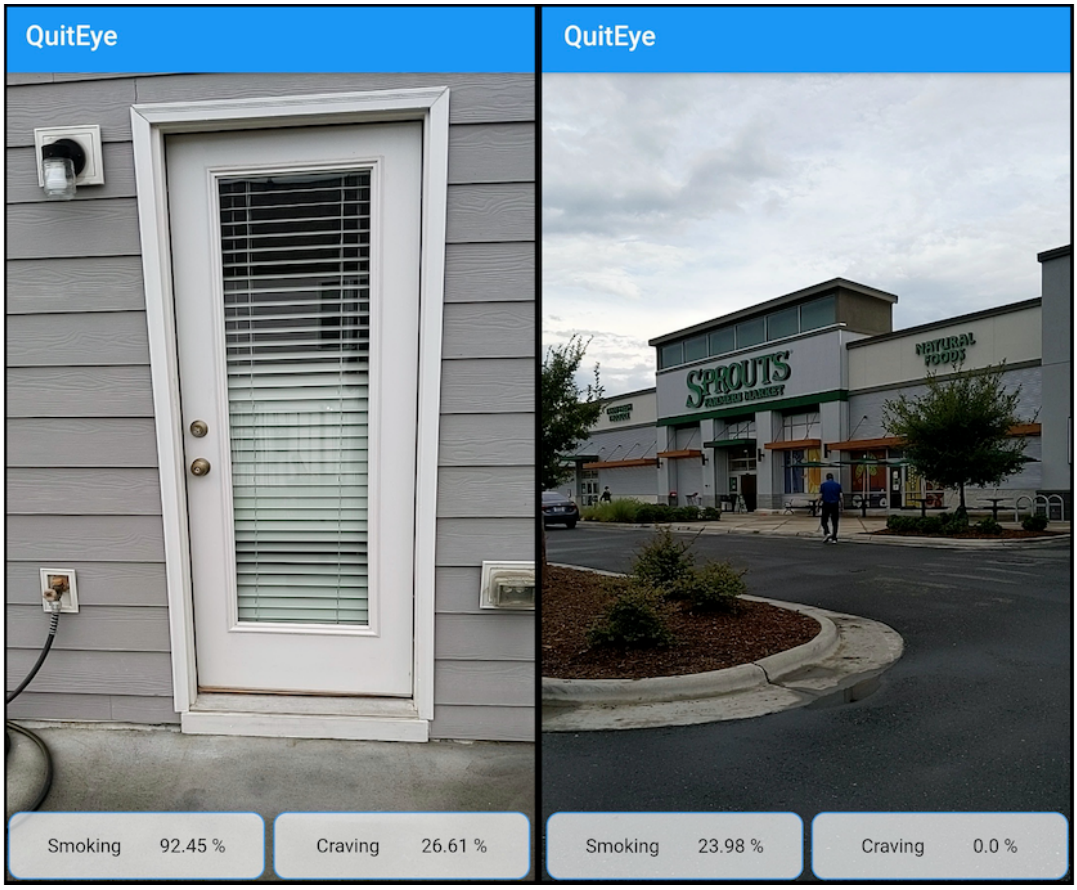


Mobile Implementation

Screenshots of real-time smoking and craving risk prediction using the QuitEye mobile app are presented in Figure 8.

Figure 8. Mobile implementation of QuitEye. Screenshots of real-time smoking and craving risk prediction via the QuitEye mobile app in a high smoking risk environment (left panel) and a low smoking risk environment (right panel).



Discussion

Principal Findings

A growing body of knowledge suggests that habitual smoking environments promote craving and smoking behaviors. Our previous study demonstrated that computer vision could distinguish between habitual smoking and nonsmoking environments, leading us to hypothesize that real-world smoking risk has important, quantifiable environmental correlates that can be leveraged to predict smoking behaviors more effectively in real time. This study confirms this hypothesis: QuitEye effectively predicted smoking status and associated outcomes across the full range of environments encountered by our sample of smokers in their daily lives. By learning from other smokers' behaviors, our models can scan a smoker's environment to predict their current smoking risk. QuitEye also predicted whether smoking was permitted in the current location and whether the smoker was inside or outside, providing important context relevant to smoking cessation interventions. The results show that knowledge of recent smoking and daily smoking habits (eg, time of day) improved these predictions, but it is the images themselves that contributed most to good prediction performance for all outcomes except craving.

Importantly, these results provide additional evidence that the environmental correlates of smoking vary among smokers. Our nonpersonalized models achieved good out-of-sample prediction performance, suggesting that environmental factors are shared among smokers more than they are distinct. However, model personalization led to statistically significant improvements in smoking risk prediction, implying that there are meaningful environmental correlates of smoking behaviors that are specific to individual smokers.

To achieve personalization in this study, smokers had to self-report their smoking behaviors for 10 days while collecting images of their daily environments. These data were then used to refine the prediction model. This process is burdensome but may be particularly important for smokers whose daily environments are atypical or whose smoking behaviors do not follow common patterns. If this is not possible, a lesser degree of personalization can be achieved by asking smokers to provide information about the locations where they commonly smoke. Alternatively, models can be iteratively improved during use, for example in a mobile app, by prompting the user to confirm or deny smoking predictions made by the model.

The ability to predict environment-associated smoking risk in real time unlocks a range of environment-focused smoking cessation interventions. Real-time risk prediction can be used to trigger a JITAI [9] in which support is provided to smokers via a mobile device at the time and place when it is most needed [31]. Information about environment-associated risk can be

combined with information about the smoker's internal state, provided by wearable devices, to obtain a more comprehensive estimate of smoking risk and craving. We anticipate that information about the external environment would enhance the prediction of smoking risk from other data streams (eg, heart rate from wearable devices), but the degree to which these data sources complement one another has yet to be explored. Ultimately, we envision a system in which wearable eyewear (eg, smart glasses) continuously acquires images of the user's external environment, alerts them with visual feedback when high-risk environments are detected, and suggests appropriate coping strategies for a given context. As augmented reality technologies mature [22], this paradigm can be used not only to support smoking cessation but also to understand and respond to environmental correlates of a broader range of health-related symptoms and behaviors.

However, several other intervention types are possible. For example, QuitEye could be used to identify environmental correlates of smoking risk in a smoker's daily environment before a quit attempt, allowing them to restructure their environments or daily activity patterns to increase the likelihood of quitting successfully. As QuitEye can predict the smoking risk associated with any image, including images of locations not yet visited, it can help smokers preemptively avoid visiting prosmoking environments. During a quit attempt, for instance, a smoker might choose to visit a restaurant that has a lower smoking risk, as determined based on images available on the internet.

Although images improved the prediction of smoking substantially, they did not improve the prediction of craving. To the contrary, our best-performing craving prediction models do not incorporate image features, and out-of-sample prediction performance for craving was poor. Our laboratory research suggests that habitual smoking environments do provoke craving, but this study's results do not provide additional support for this finding. Consequently, the role of environmental factors in the emergence of craving, or in the progression from craving to smoking itself, remains unclear. These conflicting findings may be partly owing to our EMA procedure. At the time of smoking, participants were asked to report their craving *before* smoking. Thus, the corresponding image taken at the time of smoking may not match the external environment corresponding to self-reported craving. However, in a follow-up analysis, we attempted to predict craving only from random prompts, and similar AUC values were observed. Further studies are needed to examine the environmental correlates of craving more thoroughly. In particular, continuous image acquisition (via wearable cameras or smart glasses) may provide additional environmental or social cues that are relevant to craving but not captured by a single image. Alternatively, general craving may be driven more by internal (eg, low plasma nicotine levels and negative affect) rather than external factors.

As shown in Figure 7, smoking risk prediction was more effective for participants whose locations were more variable and for whom location type provided more information about smoking behavior. Some participants' smoking environments were mostly distinct from their other daily environments, allowing our models to identify a strong relationship between environmental factors and smoking status. Other participants tended to smoke in the same environments where they spent most of their time, making it difficult to identify robust environment-smoking associations. Notably, this difference was not associated with demographic factors in this study. More studies are needed to understand these groups and determine whether there are identifiable subpopulations of smokers among whom QuitEye is particularly effective or ineffective.

Limitations

Although EMA provides more accurate smoking tracking than other self-report methods [32], smoking events may have been omitted or incorrectly reported. Our models predicted self-reported smoking, which may differ from true smoking events. Although our EMA procedure was designed to be brief and minimally burdensome, picture-taking and other EMA requirements may have increased the number of smoking events omitted by our participants. Furthermore, some EMA responses may not have been completed promptly upon smoking, thus reducing self-report validity. Other outcomes were also self-reported and subject to participant error or omission. As previously discussed, our EMA asked participants to self-report their craving *before* smoking in the smoking-initiated prompts, which may have introduced additional errors or variability.

In addition to smoking-initiated prompts, participants completed a total of six system-initiated prompts at randomly selected times throughout the day. More frequent prompts would have provided a more comprehensive sample of participants' daily environments, but this might have also resulted in reduced EMA adherence. Camera design and image quality varied among participants, who used their own smartphones to take pictures. Variability in image quality can be reduced by acquiring images using wearable cameras or smart glasses. This approach would also allow images to be captured throughout the day, providing complete information about the participants' daily environments.

Future Directions

This study did not include a quit attempt. The results showed that QuitEye predicts smoking risk effectively outside of a quit attempt, but its ability to predict lapses and relapse after quitting is unknown. Other (nonimage) data streams from mobile devices have been used to predict lapse risk [21], and we anticipate that QuitEye would provide complementary information about environment-associated risk factors. In future work, we will explore the relationship between the environmental correlates of smoking before quitting and the environmental correlates of lapse and relapse.

Owing to privacy concerns, participants were asked to avoid taking pictures of other people. However, this restriction may have prevented us from identifying interpersonal triggers and other important social determinants of smoking. The ability to recognize these and other dynamic environmental features is an important advantage of our approach compared with other sources of environmental information, such as GPS. In future work, we hope to explore the use of computer vision to identify the social determinants of smoking.

Now that QuitEye has been implemented as a mobile app, we can prospectively evaluate the real-time prediction of

environment-associated risk and develop *environment-aware* mobile health cessation interventions. These interventions will incorporate information about the environment in addition to user physiology and other information with recognized predictive values [11-15]. An important goal of this study is to quantify the contribution of each data source (eg, physiology vs environment) to overall prediction performance. Initial interventions incorporating QuitEye will use smartphone cameras to identify environment-associated smoking risks in smokers' daily environments. Later interventions will use smart eyewear to continuously acquire images of the smoker's environment and provide support when high-risk environments are encountered. An important component of this study will be to evaluate the benefit of just-in-time support versus the cost of false alarms, which will allow us to select an appropriate risk threshold for triggering the intervention.

Conclusions

Images of daily environments can be used to predict smoking risk effectively. Our risk prediction system, QuitEye, also predicts craving, whether smoking is permitted, and whether the participant is outside, providing important contextual information that could inform JITAIs for smoking cessation. Performance can be further improved through personalization, achieved by (1) fine-tuning QuitEye with images of a given smoker's daily environment or (2) asking participants to provide information about their habitual smoking environments. QuitEye has been optimized for mobile devices and implemented as a mobile app, allowing environment-associated smoking risk to be continuously assessed in a mobile device-based smoking cessation intervention.

Acknowledgments

Funding support for this study was provided by National Institute on Drug Abuse R21DA047131 (FJM) and K23DA042898 (JAO). The authors would like to thank Christianne Carson, Anthony DeVito, and Patricia Sabo for their assistance with data collection and processing, Abhishek Jadhav for assistance with preliminary analyses, and Cynthia Conklin for conceptual support and feedback.

Authors' Contributions

MME, JAO, and FJM developed the concept. MME, JAO, RK, and FJM designed the study. RK and FJM oversaw this study. MME, JAO, JD'A, and FJM designed the analyses. MME and JD'A conducted the analyses. JD'A developed the mobile app. MME drafted the manuscript. All authors have revised the manuscript accordingly.

Conflicts of Interest

MME, JAO, and FJM declare that they are authors of a US patent app related to this work and have no competing interests. JD'A and RK declare that they have no competing interests.

Abstract

Background: Patient engagement is a worldwide trend in health care. Patient portals have the potential to increase patients' knowledge about their health and care and therefore enhance patient engagement. Portal users' experiences are needed to determine if these portals work appropriately and if there are barriers to achieving the aims that were set before their implementation.

Objective: The aim of this study is to analyze pharmacy customers' experiences of the Finnish nationwide patient portal My Kanta in terms of benefits, problems, and potential improvements.

Methods: A questionnaire survey was conducted among pharmacy customers in the spring of 2019. The questionnaires (N=2866) were distributed from 18 community pharmacies across mainland Finland to customers aged ≥18 years who were purchasing prescription medicines for themselves or their children aged <18 years. Using open-ended questions, customers were asked about their experiences of the benefits and problems of My Kanta and what improvements could be made. Their responses were encoded and categorized using inductive content analysis, stored in SPSS Statistics for Windows, and analyzed using frequencies.

Results: Of the 2866 questionnaires, a total of 994 (34.68%) questionnaires were included in the analysis. Most respondents were My Kanta users (820/994, 82.5%); of these 820 users, 667 (81.3%) reported at least one benefit, 311 (37.9%) reported at least one problem, and 327 (39.9%) reported at least one potential improvement when using My Kanta. The most commonly mentioned benefits were opportunities to view health data (290/667, 43.5%) and prescriptions (247/667, 37%) and to renew prescriptions (220/667, 33%). The most extensively reported problems with My Kanta were that the portal lacks health data (71/311, 22.8%), navigating the service and searching for information is difficult (68/311, 21.9%), and the delay before health data are incorporated into the service (41/311, 13.2%). The most frequently suggested potential improvements were that My Kanta needs more comprehensive health data (89/327, 27.2%); the service should be easier to navigate and information easier to access (71/327, 21.7%); the service should have more functions (51/327, 15.6%); and health data should be entered into the portal more promptly (47/327, 14.4%).

Conclusions: Pharmacy customers reported more benefits than problems or potential improvements regarding the use of My Kanta. The service is useful for viewing health data and prescriptions and for renewing prescriptions. However, portal users would like to see more data and functions available in the portal and data searches to be made easier. These improvements could make the data and functions provided by the portal easier to view and use and hence promote patient engagement.

benefit; problem; improvement need; patient portal; patient engagement; experience; survey

Introduction

Background

Promoting patient engagement is a worldwide trend, with the goal of improving patient-centered care and providing greater safety in health care [1]. The opportunity to access one's own medical data is regarded as a key element in patient engagement, as it provides patients with more information about their own health and care. In recent decades, many countries have developed national eHealth strategies, including the implementation of electronic health record systems [2]. Some of these systems include an opportunity for patients to view their electronic health records via patient portals. However, enhancing patient engagement requires not only implementing patient portals for data viewing but also ensuring that these services are user-friendly and can be used appropriately [1]. Collecting data regarding patients' perceptions, needs, and experiences when updating patient-centered health services is also part of patient engagement. In the case of patient portals, it is important to understand how patients use the medical data provided and whether the portal has achieved the goals set before its implementation. The aims of portals are to increase patients' empowerment and thus encourage them to take more responsibility for their own health and care.

As patient portals have only been introduced in recent years, only a limited number of studies have investigated users' experiences of their usability. However, some studies have been conducted, mainly in the United States and the Netherlands, where patient portals are targeted at certain regions, diseases, or organizations [3-7]. On the other hand, few studies have investigated nationwide patient portals [8-10], partly because they have been implemented in only a few countries, mainly Nordic countries. Studies focused on users' experiences of patient portals have shown that users are mostly satisfied with these portals [6-10]. Commonly reported benefits that portals have provided for their users are that medical records are viewable and can be read before or after visits and that users find themselves better informed and more empowered and engaged in their own care [3-7,9-11]. Being able to communicate with health care professionals has also been viewed as beneficial [3-6,11]. The problems encountered when using portals are mostly related to difficulty in understanding the information recorded within the portal and to the log-in process [3-5,10,11]. Users have reported that the portals could be improved by including more information, facilitating faster entry of data into the portals, and making the information more understandable [4,8-11]. Previous studies seem to indicate that experiences of patient portal use are fairly similar regardless of whether the portal is nationwide or specific to a certain area, disease, or organization.

Study Context

Kanta Services is a Finnish nationwide entity providing services such as Patient Data Repository and Prescription Center into which health records and prescriptions recorded in all public and private health care units and pharmacies across Finland are saved [12]. Users of the services are health care professionals, pharmacists, and the public.

My Kanta, a nationwide patient portal, is part of Kanta Services and allows patients to access their health and prescription information [13]. Access to My Kanta requires a Finnish social security number and electronic authentication, such as a web banking code, an electronic ID, or a mobile certificate. My Kanta was initially introduced in 2010, and its content has been extended over the years [12,13]. In its early years, it only provided an opportunity to view e-prescriptions. Today, however, patients can browse their own or their dependents' e-prescriptions and health data recorded as part of both public and private health care (Textboxes 1 and 2) [13,14,15]. Patients can also request prescription renewal and save their living will and organ donation testament. My Kanta also provides an opportunity to view in which health care units or pharmacies the user's own data have been browsed or processed. We have reported a more detailed description of My Kanta and the Finnish e-prescription system in a previous study [16].

Textbox 1. Contents of My Kanta.

Contents

- e-Prescriptions (all prescriptions have been issued electronically in Finland since 2017)
  - Name, dosage, and indication of medicine
  - Prescribing date and organization, prescriber
  - Valid date of prescription
  - Quantities of medicines outstanding
  - Medicine purchases and dispensing events
  - Prescription renewals
  - Health care units and pharmacies where prescription information has been processed
- Health data
  - Records of health care visits, diagnoses, critical risk factors
  - Laboratory test results, x-ray examinations
  - Referrals, medical certificates and reports
  - Health care units where health records have been browsed

Textbox 2. Functions of My Kanta.

Functions

- Viewing e-prescriptions and health data
- Printing out a summary of e-prescriptions
- Requesting a prescription renewal
- Giving informed consent to share health data
- Preventing the sharing of certain health data or e-prescriptions
- Saving a living will and organ donation testament
- Giving consent to other European pharmacies to dispense e-prescriptions (currently possible in Estonia, Croatia, and Portugal)
- Acting on behalf of dependents (at the time of the study, this refers to dependents aged <10 years. Access has only been extended gradually to underage dependents, aged 10-17 years, since October 2020).
  - Viewing e-prescriptions and health data
  - Submitting a prescription renewal request
  - Giving informed consent to share a dependent's health data

According to Kanta Services statistics, the My Kanta portal is widely used in Finland [17]. In 2019, more than 2 million people (total Finnish population 5.5 million) were using My Kanta, and the total number of log-ins was about 21 million. The familiarity of pharmacy customers with My Kanta, portal use, and experiences of its usability for viewing e-prescriptions were investigated in its early years in 2015 [18]. Since then, health data have been added to the portal, and portal use has increased significantly; hence, up-to-date studies are now needed. This study is part of a larger research project studying My Kanta use for viewing and monitoring health and prescription information from the patients' perspective. We have previously reported on the use of different functions and the usability of the service surveyed by means of structured questions and have investigated the factors related to the use and nonuse of the service [16,19].

Objectives

The aim of this study is to investigate pharmacy customers' experiences of the benefits and problems of the Finnish nationwide patient portal My Kanta and how it could be improved.

Methods

Study Setting

A questionnaire survey was conducted in early spring 2019 of pharmacy customers aged ≥18 years who were purchasing prescription medicines for themselves or their children <18 years. This target group was chosen as we wanted to reach people who potentially have a need to use My Kanta. Questionnaires (Multimedia Appendix 1) were distributed in

18 community pharmacies from 6 regions across mainland Finland. Using convenience sampling, 1 university pharmacy branch (owned by a university but operating as a privately owned pharmacy), 1 large privately owned city pharmacy, and 1 small privately owned rural pharmacy were recruited from each region. The number of questionnaires delivered to each pharmacy was in proportion to the number of prescriptions dispensed annually by the pharmacy and ranged between 40 and 320. A total of 3560 questionnaires were mailed to the pharmacies. Pharmacists were instructed to inform all eligible customers about the survey after dispensing prescription medicines and to offer them the questionnaire. Pharmacies were not required to keep a record of customers who declined to participate. Customers filled in the questionnaires at home and mailed them in return envelopes to the research group. Questionnaires were handed out as long as there were forms left for a maximum of 2 weeks. After the study period, pharmacists reported the number of remaining questionnaires to allow the calculation of the response rate. Reminders could not be sent because the respondents' personal data were not collected. Altogether, 2866 questionnaires were distributed.

Questionnaire

The 4-page questionnaire included 22 structured, Likert-scale, and open-ended questions (Multimedia Appendix 1). The questionnaire consisted of 3 parts. The first part was for all respondents and concerned background information, the second part was for those respondents who used My Kanta, and the third part was for respondents who did not use My Kanta. The questionnaire was designed using My Kanta pages and previous surveys of patient portals [7,13,18,20-25]. It was initially tested for face validity by 3 researchers who were experienced in designing questionnaire surveys. Thereafter, the questionnaire and data collection procedure were piloted in a pharmacy, with minor revisions made as a result.

This study reports the results from 3 open-ended questions from the second part of the questionnaire. The questions were as follows: *What advantages or benefits has the use of My Kanta provided to you?What problems have you experienced when using My Kanta*? *How could My Kanta be improved to make it easier for you to monitor and manage your medication and health information?* We used open-ended questions to ask about the benefits, problems, and potential improvements to get an overview of issues that spontaneously come to respondents' minds when they think about their experiences of My Kanta use. Background information was obtained by means of structured questions, except for the respondent's year of birth and number of regularly used prescription medicines, which were obtained using open-ended questions.

Data Analysis

A 2-phase analysis (qualitative and quantitative) was used. In the qualitative analysis, responses to open-ended questions were encoded and categorized using inductive content analysis. The analysis started by recording the answers in a table in Word 2016 (Microsoft Corp). This was continued to the point of saturation, which means that no new aspects related to the research questions emerged in the answers. After the saturation point, the remaining answers were examined, and only supplements to the previous aspects and new ideas were recorded. The saturation points for benefits, problems, and potential improvements were questionnaires 176, 248, and 250, respectively. In addition, if the answer to the question about benefits included a problem, it was moved to the analysis of problems, and if the answer to problems included an improvement idea, it was moved to the analysis of potential improvements. An analysis unit could be a single word, a sentence, or a group of sentences describing an idea related to benefits, problems, or potential improvements. Accordingly, an answer pertaining to more than 1 subject was separated into several analysis units. Simplifications were then made using these units. The simplifications were compared and then sorted into emerging subcategories, which were named according to all the simplifications in that subcategory. Similar subcategories were combined into main categories, and the main categories were named according to their content. Each questionnaire was then studied, and the responses were encoded into the main categories formed. The categorized data were stored in SPSS Statistics for Windows 10 (version 27.0; IBM Corp) for quantitative analysis. Data were analyzed using frequencies. Inductive content analysis was conducted by 2 researchers (AO and MS) after the simplifications were made. Contradictory categorizations were discussed by the research group. Content analysis was discussed by the research group throughout the process.

Ethical Statement

Ethical approval required by the funding organization was granted by the Committee on Research Ethics of the University of Eastern Finland (statement 23/2018). Participation in the survey was voluntary. Filling in the questionnaire and mailing it to the research group were regarded as informed consent to participate. No incentives were provided to the participants. Pharmacy owners consented to handing out questionnaires in their pharmacies.

Results

Study Population

Altogether, 996 questionnaires were returned. Two questionnaires, however, were blank and were therefore excluded. Consequently, 34.68% (994/2866) of questionnaires were included in the study. Most respondents were female (687/994, 69.4%; Table 1). The mean age of the respondents was 62 (SD 14.484; range 18-99) years. Most respondents (820/994, 82.5%) were My Kanta users. The characteristics of My Kanta users were very similar to those of all respondents, with the exception of more frequent internet use and internet use to search for health-related information.

Table 1. Characteristics of the questionnaire respondents.

Characteristics	Total respondents (n=994), n (%)	My Kanta users (n=820), n (%)
Gender[a]	990 (99.6)	819 (99.9)

Has never used it	153 (15.4)	0 (0)

[a]Some of the respondents did not answer the question.

Benefits

Of the My Kanta users, 81.3% (667/820) described at least one benefit that My Kanta use had provided (Table 2). The most frequently stated benefits were opportunities to view one's own health data (290/667, 43.5%) and e-prescriptions (247/667, 37%) and to renew prescriptions (220/667, 33%). Many users (107/667, 16%) also thought it was useful in general that their own information was viewable via the service.

Table 2. Benefits that My Kanta has provided for its users.

Benefits[a]	Respondents (n=667), n (%)
Health data viewable in the service	290 (43.5)
Viewing health data	—[b]
Viewing laboratory results	—
Viewing records of health care visits	—
e-Prescriptions viewable in the service[c]	247 (37)
Monitoring e-prescriptions	—
Monitoring validity of prescriptions	—
Monitoring amounts of outstanding medicines	—
Monitoring the need for prescription renewals	—
Prescriptions are in the service	—
Prescription renewals	220 (33)
Opportunity to renew prescriptions	—
Ease of prescription renewing	—
One's own information viewable in the service	107 (16)
One's own information can be viewed or checked	—
Ease of viewing one's own information	—
One's own information viewable anytime or anywhere	—
One's own information viewable at home	—
All information in one place	—
Fever contacts and calls to health services	42 (6.3)
Fewer calls	—
No need to visit a physician	—
No need to visit a health care center or pharmacy	—
Easy to take care of health-related matters	35 (5.2)
Easy	—
Can be used anytime or anywhere	—
Can be used at home	—

Printing out information	—
Saving organ testament	—
Saving living will	—
Acting on behalf of others	—

[a]From each main category, the most common subcategories are reported in the table.

[b]Not available.

[c]In Finland, all prescriptions are issued electronically.

The main category *Health data viewable in the service* included responses concerning laboratory results, records of health care visits, and health data in general (Table 2). It was thought useful that laboratory results, records of health care visits, and health

data in general were viewable and could be easily monitored via the service. The respondents stated that by using My Kanta, they could keep up to date with their health information. They also found it useful, after their health care visit, to be able to check what had been discussed during the visit or what the physician had recorded.

The most frequent response in the main category *E-prescriptions viewable in the service* was that e-prescriptions could be (easily) viewed and monitored via the service (Table 2). Some users said that they kept a check on how long e-prescriptions were valid, whether there were any medicines outstanding, or whether e-prescriptions needed to be renewed. Some users found it useful that e-prescriptions were included in the service as there was no longer any need to keep paper versions and all prescriptions were safe in one place.

The main category *Prescription renewals* included responses that regarded the opportunity to renew prescriptions via the service as beneficial (Table 2). The renewal process was described as straightforward and fast.

In the main category *One's own information viewable in the service*, the responses focused on the benefits of having access to one's own information in general and that it was useful that information could easily be checked in one place, at anytime and anywhere (Table 2). Many respondents said that it was useful to be able to view this information in the privacy of their homes.

Problems

More than 1 in every 3 users (311/820, 37.9%) described at least one problem in the use of My Kanta (Table 3). The most frequently mentioned problems were that the service lacked health data (71/311, 22.8%) and that users had difficulty navigating within the service and searching for information (68/311, 21.9%). Some users regarded the delay in health data being downloaded into the service to be a problem (41/311, 13.2%).

Table 3. Problems that users have experienced with My Kanta.

Problems[a]	Respondents (n=311), n (%)
The service is lacking health data	71 (22.8)
Laboratory results not available	__[b]
Records of certain health care visits or units not available	—
Old data not available	—
Difficulty navigating the service and searching for information	68 (21.9)
Difficulty finding information	—
The service is badly organized	—
Problems switching between pages	—
Health data viewable with a delay	41 (13.2)
Health data downloaded into the service with a delay	—
Records of health care visits downloaded into the service with a delay	—
Laboratory test results downloaded into the service with a delay	—
Telecommunication problems	33 (10.6)
The service does not open properly	—
The service cuts off the user or is disrupted	—
Problems with the internet connection	—
User-driven challenges in using the service	31 (10)
Illnesses inhibit use of the service	—
Uncertainties about using computer or internet	—
Unaware of the content of the service	—
Difficulty understanding the health data recorded	—
My Kanta and other patient portals get mixed up	—
Inconveniences in logging in	27 (8.7)
Logging in is not possible without web banking codes	—
Web banking codes are not always carried	—
Web banking does not work properly	—
Logging in with web banking codes is laborious	—
Difficulty in prescription monitoring	23 (7.4)
Invalid and valid prescriptions become mixed	—
Difficulty understanding valid dates of prescriptions or amounts of outstanding medicines	—
Prescriptions cannot be arranged	—
Inconveniences in renewing prescriptions	21 (6.8)
Certain[c] prescriptions cannot be renewed	—
Physician has not renewed the prescription	—
Problems choosing a health care unit for renewal	—
Incorrect information in the service	13 (4.2)
Information recorded incorrectly	—
Other persons' data in the service	—
Difficulty correcting erroneous information	—
Other	37 (11.9)
Difficulty printing out e-prescriptions and health data	—

Problems[a]	Respondents (n=311), n (%)
Guardian cannot see the data of dependents who are younger than 10 years	—
Uncertainties in data sharing procedures	—

[a]From each main category, the most common subcategories reported in the table.

[b]Not available.

[c]For example, prescriptions issued in private health care or prescriptions issued over 28 months ago.

The main category *The service is lacking health data* included responses that My Kanta is lacking certain data (Table 3). Users reported that laboratory results were either partly or completely unavailable. In addition, some users reported that the records of certain health care visits or units did not seem to have been entered into the system. Some responses said that records of private health care providers, such as occupational health care, were missing. Users also reported that some information had disappeared, or they would like to see their health information from the years before the introduction of My Kanta.

Difficulty finding information in the service was frequently reported to be a problem in the main category *Difficulty navigating the service and searching for information* (Table 3). Some respondents did not specify what information they could not find, whereas others mentioned laboratory results or records of a particular health care visit. Some users thought that the service was badly arranged. For example, layout, menus, and headings were considered unclear, which complicated their ability to navigate within the service. Some users reported that switching between different pages did not work properly, as they could not move back to the previous page but instead were transported to the starting page.

Responses in the main category *Health data viewable with a delay* refer to the feeling that there are delays in health data being downloaded into the service (Table 3). Some respondents did not specify what health data they meant, whereas others mentioned records of health care visits or laboratory results.

Potential Improvements

Of My Kanta users, 39.9% (327/820) reported at least one potential improvement in the service (Table 4). The most common suggestions for improvements were that the health data provided in the portal should be more comprehensive (89/327, 27.2%) and navigating the service and searching for information should be made easier (71/327, 21.7%). Some users suggested new functions that could be incorporated into the service (51/327, 15.6%) or would like health data to be entered more promptly into the service (47/327, 14.4%).

Table 4. Potential improvements proposed by users.

Proposed improvements[a]	Respondents (n=327), n (%)
More comprehensive health data	89 (27.2)
Data from all health care units should be available	—[b]
All data viewable in the service	—
Records of health care visits in more detail	—
Old data should be incorporated into the service	—
Facilitating navigation in the service and searching for information	71 (21.7)
Data grouping more clearly	—
Clearer layout	—
Simplification of the service	—
Use guidance	—
More functions incorporated into the service	51 (15.6)
Secure messaging	—
Notifications	—
Vaccinations	—
More information about medicines	—
Opportunity to correct erroneous information	—
Faster downloading of health data	47 (14.4)
Laboratory results entered into the service with a shorter delay	—
Record of health care visits into the service with a shorter delay	—
Data entered into the service with a shorter delay	—
Easier monitoring of prescriptions	33 (10.1)
Certain[c] prescriptions should be removed	—
Clearer order for prescriptions	—
Clearer prescription information	—
Health data in plain language	23 (7)
Diagnosis, terms, and medical reports in easy-to-comprehend language	—
Laboratory results in easy-to-comprehend language	—
Easier logging in and mobile use	22 (6.7)
Other ways[d] to log-in than web banking codes	—
Simplifying the log-in procedure	—
Mobile app should be introduced	—
Making it easier to act on behalf of others	19 (5.8)
Opportunity to act on behalf of dependents aged 10-18 years[e]	—
Opportunity to act on behalf of adults (>18 years)[e]	—
Other	26 (8)
Improvements in prescription renewals	—
Improvements in printing out information	—
Data protection	—

[a]From each main category, the most common subcategories are reported in the table.

[b]Not available.

[c]For example, invalid or noncurrent prescriptions.

[d]For example, username and password or PIN code.

[e]In Finland, the age of majority is 18 years.

Responses in the main category *More comprehensive health data* related to health data that is or should be in the portal (Table 4). These responses included the view that health data from all visits or units should be added to the service. Some respondents did not specify from which units' data were missing, whereas others mentioned as an example of private health care providers or oral health care. Many users wanted the laboratory results to be viewable in the service. Some of these respondents had no laboratory results in the service, whereas for others, they were only partially available. Some users wanted records of health care visits to be more detailed. A few respondents wanted data from the years before My Kanta or data that had disappeared to be added to the service.

In the main category *Facilitating navigation in the service and searching for information*, some respondents wanted the data to be grouped more clearly (Table 4). It was also suggested that there could be clear sections for different data, such as laboratory results, data from certain units, or the latest data. Some respondents wanted data to be arranged in a clearer chronological order. Some thought that searching for particular information should be made easier and the layout of the service clearer. Specifically, the headings and menus were considered to be unclear. Some users wanted the service to be simpler. Others reported that they would like to have more guidance in using the service. A few would like to receive face-to-face guidance, whereas others thought that some kind of manual or more general information should be provided.

The main category *More functions incorporated into the service* included responses proposing the addition of new functions to the portal (Table 4). Some users wanted secure messaging between patients and health care providers. It was considered an advantage if patients could ask physicians or nurses about their care or medicines via the service, or, in the case of prescription renewals, if they could send messages to their physician. Respondents also proposed the introduction of novel notifications, for example, an SMS text message to a mobile phone informing them when prescriptions had to be renewed or when new records were downloaded to the portal. Some users wanted more information about medicines to be included in the portal, such as drug interactions or costs. It was also suggested that vaccinations should be included. Some users wanted to have an opportunity to correct erroneous information via the service or to report incorrect information.

In the main category *Faster downloading of health data*, some respondents wanted to see laboratory results, records of health care visits, or data in general to be viewable in the service more promptly (Table 4). A few respondents wanted data to be entered into the service without delay or with a shorter delay, so they could use the information at their next appointment.

Discussion

Principal Findings and Comparison With Prior Work

In this study, more pharmacy customers reported benefits than problems or potential improvements when using the nationwide patient portal My Kanta. Users consider My Kanta beneficial because health and prescription information can be easily viewed and monitored, and prescription renewals can be submitted via the service. In general, the fact that all these services are available regardless of time and place, for example, in the privacy of the patient's home, is regarded as a benefit. However, the system is not perfect, and some drawbacks were reported. Ideas for improvement mainly concerned certain frequently mentioned problems. The results of this study are mostly in line with those of previous studies investigating users' experiences regarding the benefits, problems, and potential improvements of patient portals [3-11]. This suggests that there are no major differences in users' experiences between nationwide and organization-specific portals, although these portals differ slightly from each other in terms of content and functions.

The My Kanta functions rated most beneficial, that is, viewing health data and prescriptions and renewing prescriptions, are also the most widely used [16]. According to a study conducted in 2014 among the Finnish population on the use of electronic services in health care, respondents said that in the future, they would like to have access to their laboratory test results, health records, and prescriptions, and an opportunity to submit renewal requests [24]. Thus, as these options are now available, individuals naturally regard them as the most beneficial, and these functions are most extensively used. The present results also indicate that My Kanta met users' expectations well. In addition, the portal has achieved its intended goal of making it easier for patients to obtain their health information and hence participate in their own care.

In line with previous studies [3-7,9-11], the ability to view one's own health data was regarded as the most beneficial function of the patient portal. However, users reported some problems that may discourage the use of health data and thus patient engagement. Some users found the language used in their health records too difficult to understand. This is also a finding from previous studies conducted in Finland [16] and other countries [3,5,10,11]. My Kanta is a nationwide portal that can be used by anyone living in Finland with an ID for electronic services. It is important that the language used in the portal is plain enough to allow everyone to easily understand the recorded data. Physicians should be informed about this finding so that they can avoid writing reports with professional terminology that laypeople will not understand. It would also be useful if My Kanta contained explanations of laboratory test abbreviations and reference values.

To increase and facilitate patient engagement, there are other issues that require attention. Many users reported that not all their health data, especially laboratory results and data from certain health care units, were available. This prevents patients from gaining a comprehensive picture of their health and care. Health data from public health care started to be included in My Kanta in 2013 and from private health care in 2016 [12]. It may be that at the time of this study, not all units had started to record their data in My Kanta, as this took place step by step. It should also be noted that the portal is continuously developing

and that the amount of health data that can be accessed is constantly increasing [26]. For example, since the questionnaires were returned, oral health care data and vaccinations have begun to be downloaded to the portal. Furthermore, there is a possibility that data on some health care visits or units are delayed as health care professionals want to discuss the significance of findings with the patient before the data are made available in My Kanta [27]. In Finland, there is no exact time period determining when certain data should be entered in My Kanta; instead, this is left to the discretion of health care units or professionals. In some cases, records can be delayed indefinitely if their availability is seen as a risk to the patient's life or care. It would be important to inform patients about these delay procedures as many users wanted their health data to be downloaded to My Kanta more promptly. The wish of patients to have their health data downloaded to the portal without delay has also emerged in studies conducted in other countries [3,9,11]. In contrast, in a study conducted in the Netherlands, users did not want their health data to be downloaded to the portal before they had visited a physician [5]. Some users may not have the ability to understand information, such as the meaning of laboratory results, and thus, delaying the data may be necessary to prevent unnecessary concerns. Nevertheless, it may be that patients are unaware of the reasons for a delay, and they should be informed accordingly, for instance, when visiting the health care provider.

Users also stated that some data were difficult to find in My Kanta. This was also highlighted in a previous study that investigated My Kanta usability [16]. In this study, many suggestions were made to make searching for information easier, for example, organizing data in the portal in different ways. Users also wanted the service to be simpler, especially headings. However, many of the suggestions differed from each other, so the first step in making information easier to find could be better instructions on the use of the portal, which was also the wish of users. It is evident that further investigations should be conducted to determine the optimal information search strategy. At the moment, Kanta pages on the internet include a considerable amount of self-guidance. There is a My Kanta web-based course including guidance videos and instructions to acquaint users with My Kanta functions and how to start using the portal [28]. Clients can also request help from the customer service [29]. However, as the wishes for easier use of the portal and more guidance were mentioned in many responses and as some users reported they were unaware of the content of My Kanta, it can be assumed that this information and guidance have not reached all citizens. A wish for further guidance on My Kanta use was also reported in a previous study [16]. As suggested in this study, it may be necessary to provide face-to-face guidance or a manual.

Opportunities to view and renew prescriptions emerged as the most commonly experienced benefits, which is a finding at odds with previous studies [3,5,7,10]. This difference may be due to the fact that there are only few countries where the use of e-prescriptions is as widespread as in Finland, where all prescriptions have been issued electronically since 2017 [30]. In Finland, My Kanta is the only way for patients to view and monitor their prescriptions, other than by visiting or calling health care units or pharmacies. In addition, the survey respondents were pharmacy customers who used prescription medicines, which may have biased the result. Although users experienced the ability to view prescriptions as beneficial, some suggested ways to make prescription monitoring easier. Respondents wanted to see prescriptions not in use removed from the service or the opportunity to arrange prescriptions or hide unnecessary prescriptions. This would simplify the overall view of their prescriptions in the service. Kanta Services is developing a national medication list [31]. This will be an up-to-date list of currently used medicines to be included in My Kanta, which may help patients to obtain an overview of their medication. Users also had difficulty understanding prescription information, especially valid dates and amounts of outstanding medicines. Health care professionals should explain this information to patients in health care units and pharmacies.

In this study, prescription renewal via My Kanta was experienced as easy, and some users stated that they now visited or called health care providers less often because they were able to send renewal requests via the portal. This saves time for health care professionals, which is one of the aims of eHealth services [2]. However, the renewal of prescriptions without any communication between the patient and health care professionals may pose risks for pharmacotherapy monitoring. More studies are therefore needed on prescription renewal via My Kanta so that the overall impact of this function on health care professionals' workload and pharmacotherapy monitoring can be evaluated.

Users also wanted to see new information or functions included in the portal. This is in line with previous studies [3,4,8,10,11], indicating that portal users want all their health-related data to be available via these services. It could be argued that users would prefer patient portals to be web-based places where they could deal with many aspects of their health and medication. Communicating with health care professionals and notifications were the most often desired new functions. In Finland, some private health care providers have their own organization-based patient portals, which include communication features. It is common worldwide for these functions to be part of organization- or area-specific portals, and when available, these are also some of the most beneficial functions reported by portal users [3-7,11]. However, they have not been implemented in nationwide portals [9,10]. A communication function could be a useful way to enhance patient engagement and decrease the need for contact with health care. However, this might increase the workload of health care professionals, and therefore, before such a function is implemented in a nationwide patient portal, its impacts would need to be scrutinized in detail. The possibility of including notifications in My Kanta, as suggested in this survey, should also be evaluated. Users also wanted an opportunity to correct erroneous information on the portal. Some users reported that they had noted that their own data were incorrect or that there was some other person's data in their portal. This problem was also mentioned in a previous study on My Kanta use [16]. In Finland, the procedure for correcting erroneous information is for the patient to contact the health care unit where the incorrect information has been entered and

ask them to correct the error [13]. Evidently, this procedure is regarded as inconvenient.

Strengths and Limitations

This study has both strengths and limitations. The findings are based on a nationwide patient portal that has been widely adopted by the Finnish population. By handing out the questionnaires from the pharmacies after dispensing the prescription medicine, we reached our target group (ie, medicine users who potentially have a need to use My Kanta). People who have prescription medicines also have contacts in health care and hence health data recorded in the service. Thus, medicine users represent a population with both health data and prescriptions recorded in My Kanta. This makes it a good population to study the use of My Kanta service. However, this target group may bias the results concerning prescriptions, as all respondents used prescription medicines.

The study sample was large and included pharmacy customers from all parts of the country. Evaluating the representativeness of the results is challenging because there are no comparable statistics on the characteristics of Finnish pharmacy customers. As the customers were recruited anonymously, we have no knowledge of the characteristics of those who declined to participate or those who did not return the questionnaires. The response rate in this study (994/2866, 34.68%) was low. However, the respondents' characteristics (age, gender, education, and region) were fairly similar to those in earlier Finnish studies of pharmacy customers conducted using the same method with better response rates (40%-44%) [18,32].

The questions reported in this study were not validated measures. However, the questions were based on previous studies, with minor revisions [25,33]. In addition, both face validity and pilot tests were conducted. Many users (311/820, 37.9%-667/820, 81.3%) responded to the open-ended questions presented in this study. The reliability of categorization was ensured by the fact that 2 researchers conducted an inductive content analysis. Contradictory categorizations were discussed in the research group to obtain a consensus.

Conclusions

Finnish pharmacy customers experience more benefits than problems or potential improvements when using the nationwide patient portal My Kanta. They perceive the portal as an easy and beneficial way to view their health data and prescriptions and to renew their prescriptions. However, portal users wanted the service to include more information and functions, and for data searches to be made easier. Fulfilling these wishes could encourage even greater use of the portal and help patients use the data recorded there. These improvements could allow patients to become more involved in their own health and care.

Acknowledgments

The authors would like to thank the pharmacies for their cooperation in distributing the questionnaires. This study was funded by the Social Insurance Institution of Finland (Kela). The statements presented in this document are those of the authors and do not reflect the official position of Kela.

Authors' Contributions

MS, RA, and JT designed the study and collected the data. MS and AO conducted the analyses and drafted the first version of the manuscript. MS drafted the final version of the manuscript. All authors participated in discussing the analyses and findings, critically revised the manuscript, and read and approved the final version to be submitted. AO was affiliated with the University of Eastern Finland at the time of the study and is currently affiliated with Humalisto Pharmacy.

Conflicts of Interest

None declared.

Abstract

Background: Secure patient portals are widely available, and patients use them to view their electronic health records, including their clinical notes. We conducted experiments asking them to cogenerate notes with their clinicians, an intervention called *OurNotes*.

Objective: This study aims to assess patient and provider experiences and attitudes after 12 months of a pilot intervention.

Methods: Before scheduled primary care visits, patients were asked to submit a word-constrained, unstructured interval history and an agenda for what they would like to discuss at the visit. Using site-specific methods, their providers were invited to incorporate the submissions into notes documenting the visits. Sites served urban, suburban, and rural patients in primary care practices in 4 academic health centers in Boston (Massachusetts), Lebanon (New Hampshire), Denver (Colorado), and Seattle (Washington). Each practice offered electronic access to visit notes (open notes) to its patients for several years. A mixed methods evaluation used tracking data and electronic survey responses from patients and clinicians. Participants were 174 providers and 1962 patients who submitted at least 1 previsit form. We asked providers about the usefulness of the submissions, effects on workflow, and ideas for the future. We asked patients about difficulties and benefits of providing the requested information and ideas for future improvements.

Results: Forms were submitted before 9.15% (5365/58,652) eligible visits, and 43.7% (76/174) providers and 26.76% (525/1962) patients responded to the postintervention evaluation surveys; 74 providers and 321 patients remembered receiving and completing the forms and answered the survey questions. Most clinicians thought interim patient histories (69/74, 93%) and patient agendas (72/74, 97%) as good ideas, 70% (52/74) usually or always incorporated them into visit notes, 54% (40/74) reported no change in visit length, and 35% (26/74) thought they saved time. Their most common suggestions related to improving notifications when patient forms were received, making it easier to find the form and insert it into the note, and educating patients about how best to prepare their submissions. Patient respondents were generally well educated, most found the history (259/321, 80.7%)

and agenda (286/321, 89.1%) questions not difficult to answer; more than 92.2% (296/321) thought sending answers before the visit a good idea; 68.8% (221/321) thought the questions helped them prepare for the visit. Common suggestions by patients included learning to write better answers and wanting to know that their submissions were read by their clinicians. At the end of the pilot, all participating providers chose to continue the *OurNotes* previsit form, and sites considered expanding the intervention to more clinicians and adapting it for telemedicine visits.

Conclusions: *OurNotes* interests patients, and providers experience it as a positive intervention. Participation by patients, care partners, clinicians, and electronic health record experts will facilitate further development.

Introduction

Background

Patient engagement is essential for improving patient experience, reducing the cost of care, and improving population health [1]. With the proliferation of secure patient portals over the past decade, patients have gained a powerful engagement tool [2,3]. Millions of patients and their care partners now go on the web to communicate with members of the care team and review their medical records. Beginning in April 2021, as part of the 21st Century Cures Act, patients nationwide have access to virtually all information in their electronic health records, including the notes of their clinicians [4].

Hundreds of provider organizations implemented *open notes* on their patient portals following publication of the first open notes study in 2012 [5,6]. Patients rate note reading as very important for remembering what happened in their office visits, remembering their care plan, taking care of their health, and feeling in control of their care [7-10]. Patients have also expressed interest in doing more than passively reading their notes. In the first study of open notes, 60% wanted to be able to comment on notes, and 35% wanted to be able to approve their notes [5]. Though few primary care physicians thought patients should approve the content of notes, approximately one-third agreed they should be able to comment. Researchers have since shown that reading notes and inviting patients to comment on their notes can benefit patient safety [11-16]. Though many clinicians face time pressures, a majority report spending the same or less time writing open notes [17]. The National Academy of Medicine's Vital Directions for Health and Health Care initiative recommends that patients and authorized family caregivers be able to modify their health records [18]. Though many ambulatory care practices collect information from patients in brief questionnaires, we know of no efforts inviting them to actively write in their records. As a step in this direction, we decided to mount a pilot inviting patients to contribute to their visit notes, thus transforming the official record of their care into cogenerated *OurNotes*.

We designed, implemented, and evaluated portal mechanisms for patients and their care partners to contribute to notes of providers documenting their ambulatory visits. Following advice from expert interviews, we determined to focus on previsit communications by asking patients to (1) write a brief history since the last visit and (2) to identify up to three priorities for the upcoming visit [19].

Objectives

Our objectives were to have providers incorporate this previsit input into their visit notes, thereby taking a first step toward *OurNotes*, and to assess patient and provider experiences with this pilot intervention. We hypothesized that clinicians and patients would find it beneficial to submit the information before visits, especially patients with a heavy burden of illness, and that the intervention would be time-neutral or possibly save time for clinicians. This paper reports the principal findings from 12-month pilots of this intervention in 4 sites.

Methods

Overview

Primary care practices associated with 4 sites across the United States participated: Beth Israel Deaconess Medical Center (BIDMC) in Boston, UCHealth (UCH) in Aurora, Colorado (including a women's health clinic), Dartmouth-Hitchcock Medical Center (DHMC) in Lebanon, New Hampshire, and University of Washington Medicine (UW) in Seattle (including a safety net clinic and a clinic that serves primarily privately insured patients). Each site has well-established mechanisms for offering open notes to patients. The *OurNotes* and site project teams developed an overall intervention design and evaluation plan. The study protocols were approved by the institutional review boards of the participating institutions.

Intervention

The intervention included primary care providers and patients who were registered on the patient portal. During the 12-month pilot period, these patients were invited via a secure portal message or email to complete a form addressing two questions before a scheduled visit: *How have you been since your last visit?What are the most important things you would like to discuss at your visit? (list up to 3)*. Answers were limited to 2000 and 300 characters, respectively. Clinicians could view the completed forms before and during the visit, and when they wrote the visit note, they could decide whether and to what degree to incorporate the patient's words.

Between mid-2017 and early 2019, each site built its own implementation process and supported the information technology infrastructure. Although all asked the same two questions up to 1 week before the visit, the sites differed in their

approaches (Multimedia Appendix 1). Notably, 2 sites implemented practice-wide approaches with many clinicians (UC and UW), and 2 recruited volunteer clinicians (BIDMC and DHMC). Two sites (UC and UW) used Epic (Epic Systems Corporation, Verona, Wisconsin) to facilitate the insertion of patients' submissions into notes. They were able to launch 9 months earlier than the other 2 sites.

In all sites, invitations to patients (Multimedia Appendix 2) included links to the form (Multimedia Appendix 3). The invitation described the intervention, explained that completing the form was voluntary, and noted that the form might not be read if they did not keep the appointment. At BIDMC, UC, and UW, automated processes sent the previsit invitations; physicians at DHMC selected patients from the weekly schedule, and clinic staff or the physician sent the invitation message.

Evaluation

Pilot interventions were conducted between June 2018 and April 2020. Three sites (BIDMC, UC, and UW) used portal tracking data to monitor the use of the form throughout the pilot, and clinicians at DHMC made periodic estimates. The evaluation plan also included surveys of both clinicians and patients at each site and moderated discussions with the selected groups. However, the COVID-19 pandemic led to restrictions on research activities and diversion of information systems resources to support clinical care. Therefore, we were unable to complete all parts of the planned evaluation. We completed both patient and clinician surveys at the 2 sites that finished their 12-month pilots in 2019 (UC and UW), and surveyed clinicians at the other 2 sites (BIDMC and DHMC) in Spring 2020. However, without information systems resources to identify and track participants in early 2020, we were unable to conduct patient surveys at BIDMC or DHMC. We were also unable to convene focus groups.

The research team developed survey items based on pilot objectives, informal comments, and feedback from each site. We asked clinicians about the usefulness of patient responses, effects on workflow, and ideas for the future. We asked patients about the difficulties and benefits of answering the questions and about ideas for future improvements. To assess the burden of illness, we asked the patients if they had a chronic illness. The surveys included brief sets of sociodemographic items and both closed-ended and free-text questions. The questionnaires are available on request.

We invited clinicians who had received at least three completed previsit forms in the previous 6 months to complete the survey. We invited patients at UC and UW who had submitted at least one form during the pilot study. Clinicians in the 4 sites were contacted between June 2019 and July 2020, and UC and UW patients were contacted between September and October 2019. All participants received an invitation and up to two reminders. Each site offered an incentive of US $10 to US $50, following local guidelines. The surveys were conducted using Research Electronic Data Capture (REDCap, Vanderbilt).

Analysis

Descriptive statistics were used to summarize response rates for the survey, survey responses, and the proportion of visits for which patients returned forms (using portal tracking data at BIDMC, UC, and UW, and clinician estimates at DHMC). In addition, patient results were stratified according to whether they reported having a chronic illness.

We completed thematic analyses of the free-text comments from the surveys. Patients were asked two questions: one for ways to improve the *OurNotes* previsit process, and one for other comments. To analyze responses, 2 authors first scanned the responses and noted that both questions drew comments related to both *OurNotes* and to other topics; therefore, we combined the comments for analysis. We reviewed 30 comments independently and drafted six topics, then independently reviewed 30 new comments and defined the final set of themes for coding: comments about the two questions, the form, workflow, patient engagement, whether the submitted form was read by clinicians, and others. Using REDCap, both authors coded all responses with up to three codes each, and 1 selected representative examples.

Clinicians were asked a single question about how to improve the previsit *OurNotes* process and any other comments. Two authors reviewed 30 comments to establish a list of nine themes, then 1 author reviewed all comments, assigned 1 or more themes to each, and selected representative thematic examples.

Results

Overview

In the 3 sites with portal tracking, patients were invited to complete forms before 58,652 scheduled visits, 5365 (9.1%) forms were submitted, and in the site without portal tracking, forms were returned before approximately 50% (260/520) visits (Multimedia Appendix 1). We invited 174 clinicians to complete the evaluation survey, and 76 (43.7%) responded. Two respondents did not remember receiving any completed forms, leaving an analytic data set of 74 clinicians. We contacted 1962 patients who had submitted at least one form and 525 (26.8%) responded; 204 did not remember completing a form, leaving an analytic data set of 321 patients.

Clinician Results

Among the 74 clinician respondents, 49 (66%) were women, 61% (45/74) obtained their licenses since 2000, and 54% (40/74) reported 21 or more patient visits per week. On average, clinicians reported receiving between 1 and 3 patient forms per week in the previous 3 months (Table 1). Nearly all respondents agreed that having the information from the forms was a good idea, and 70% (52/74) reported that they usually or always incorporated responses of patients in the visit notes. Almost 90% (66/74) of clinicians reported that having the previsit information of patients either saved time or did not change the visit length.

Table 1. Responses from 74 clinicians about their experiences with OurNotes.[a]

Survey question	Response options	Value, n (%)
In the last 3 months, about how many questionnaires did you receive from patients?		
	<1/week	17 (23)
	1-3/week	38 (51)
	4-10/week	19 (26)
	>10/week	0 (0)
In general, receiving the interim history before a visit is a good idea.		
	Agree or somewhat agree	69 (93)
	Disagree or somewhat disagree	5 (7)
In general, receiving the patient agenda before a visit is a good idea.		
	Agree or somewhat agree	72 (97)
	Disagree or somewhat disagree	2 (3)
How often did you incorporate some or all of what the patient wrote into your visit note?		
	Never or rarely	12 (16)
	Sometimes	10 (14)
	Usually or always	52 (70)
How having patients' answers to the questions affected time spent writing notes?		
	Took longer	4 (5)
	No change	61 (82)
	Took less time	9 (12)
How useful were interim histories sent by patients?		
	Not useful	7 (9)
	Somewhat useful	50 (68)
	Very useful	17 (23)
How useful to have patients' visit priorities at start of visit?		
	Not useful	1 (1)
	Somewhat useful	31 (42)
	Very useful	38 (51)
	Not available at start	4 (5)
Recall one or more instances where a patient's submission was very important?		
	Yes	25 (34)
	No	49 (66)
Did it change the time to complete a patient encounter?		
	Increased time	8 (11)
	No change	40 (54)
	Saved time	26 (35)

[a]Table excludes 2 respondents who did not remember receiving previsit forms.

The process of entering the responses of a patient to the record varied among the participating sites. In 2 sites where the previsit information could be automatically inserted into the visit note, 92% (45/48) preferred this approach. At the other 2 sites, most clinicians copied and pasted the information, 48% (11/23), read or typed all or part of the words of patients into the note, 13% (3/23), or simply referred to having read what the patient wrote, 30% (7/23).

Clinicians were asked to describe their experiences with the intervention and to suggest changes or improvements. Their 57 text responses centered on better notifications about completed forms, the need for easy insertion of patient text into the note, and ways to support patient participation (Textbox 1). Clinicians

suggested that patients could be encouraged to be more engaged and taught about how to complete the form so that it would be more helpful for the visit.

Textbox 1. Examples from 57 clinicians' responses to: "What changes/improvements would you suggest for the process tested in this pilot? Did it help or hinder you in providing care? Do you have other comments?"

Timely notifications to clinicians

- Send the questionnaire results to my in-basket so I am more likely to see them before the visit.
- There were times I only learned of the patient's written comments from the patient during the visit. I think the patient was disappointed that I had not seen the comments in advance.

Incorporating patient's writing into note

- It would be great if there was an easier way to incorporate patient notes into my own note.
- Improve the way the content of the message is incorporated into the body of the note: it would ideally blast in inside of quotation marks at whatever point the cursor is in the note body.

Supporting patient participation

- This could be very useful but for it to pay off would require "training " my patients so that the responses are helpful to both patient and provider.
- Having this done on a regular basis would require a culture change where patients are less passive and more engaged and proactive about their care and ultimately get more out of each clinic visit.
- I do hope patients receive some type of disclaimer that their doctor might not be able to address all their concerns in a visit, even if the patient lists them all.
- Integration with our existing previsit questionnaires.

Other

- Good system. Please keep it very simple for patients and providers.
- [Customize for] differences between annual visits, [follow-up] visits, and urgent visits.

Patient Results

Among the 321 patients who completed the survey from 2 sites (UC and UW), 57.9% (186/321) were women, 79.7% (255/320) were White, and 73.1% (234/320) had completed a 4-year college degree (Table 2). Half (158/320, 49.3%) of the respondents reported having three or more visits to their primary care provider in the previous 12 months, 68.2% (219/321) reported having one or more major chronic conditions, and 77.2% (247/320) reported their health as excellent, very good, or good. There were very few differences between respondents at the 2 sites (data not shown), other than more women responding in Colorado than in Washington (74% and 47% of respondents, respectively), and a higher proportion of respondents reporting White race in Colorado versus Washington (88% vs 74%, respectively).

Table 2. Self-reported characteristics of 321 patient respondents.[a]

Patient characteristic	Values, n (%)
Age (years)	
18-44	78 (24.4)
45-64	102 (31.9)
≥65	140 (43.7)
Sex	
Female	186 (58.1)
Male	123 (38.4)
Transgender	5 (1.6)
Prefer not say	6 (1.9)
Race	
White	255 (79.7)
Black	11 (3.4)
Asian, Hawaiian, or Pacific Islander	25 (7.8)
Other	13 (4.1)
Multiple races	16 (5.0)
Ethnicity	
Non-Hispanic	300 (94.0)
Hispanic	19 (6.0)
Education	
Masters or doctoral degree	126 (39.4)
4-year degree or some grad school	108 (33.7)
Some college or technical school	72 (22.5)
High school or less	14 (4.4)
Overall health	
Excellent, very good, or good	247 (77.2)
Fair or poor	73 (22.8)
Chronic illness[b]	
Yes	219 (68.2)
No	102 (31.8)
Visits to primary care provider in last 12 months	
1-2	162 (50.6)
3 or more	158 (49.4)

[a]Respondents from UCHealth University of Colorado Hospital and University of Washington Medicine only; we were unable to survey patients at Beth Israel Deaconess Medical Center and Dartmouth-Hitchcock Medical Center in Spring 2020 due to constraints imposed by the COVID-19 pandemic. Table excludes 204 respondents who did not remember completing any previsit forms.

[b]Do you have a chronic illness such as asthma, chronic obstructive pulmonary disease, diabetes, high blood pressure, arthritis, heart disease, or cancer?

More than half of the patients (170/321, 52.9%) completed more than one previsit form (Table 3). In general, few patients reported any difficulty, and more than 80.6% (259/321) had no difficulty answering the questions. About 68.8% (221/321) reported that answering the questions helped them prepare for the visit. Among the 85% (273/321) who reported reading their notes after the visit, 41% (112/273) found that the note included some or all that they had written on the previsit form, whereas more than one-third did not know whether what they had written was included in their visit notes. Patients overwhelmingly agreed that sending their commentary was a good idea (296/321, 92.2%). Most patients preferred to receive the previsit form 2-7 days before their visit. We found no substantive differences in responses between patients who did and did not report having a chronic illness (data not shown).

Table 3. Responses from 321 patients about their experiences with OurNotes.

Question	Responses	Value, n (%)
In the last 12 months, how many times did you complete the OurNotes questionnaire before a visit?		
	Once	151 (57)
	More than once	170 (53)
How difficult was it to answer, "How have you been since your last visit?"		
	Not at all difficult	259 (80.7)
	Somewhat difficult	60 (18.7)
	Very difficult	2 (0.6)
How difficult was it to answer, "What issues would you like to focus on at your visit?"		
	Not at all difficult	286 (89.1)
	Somewhat difficult	32 (10)
	Very difficult	3 (0.9)
Did answering the questions help you prepare for the visit?		
	Yes	221 (68.8)
	No	66 (20.6)
	Don't know	34 (10.6)
Did answering the questions change the conversation between you and your provider?		
	Yes, positive effect	135 (42.1)
	No effect	100 (31.2)
	Yes, negative effect	7 (2.2)
	Don't know	79 (24.6)
Did answering the questions help you and your provider make decisions about your care?		
	Yes, it helped	150 (46.7)
	No effect	90 (28.1)
	No, more difficult	3 (0.9)
	Don't know	78 (24.3)
After the visit, did you read your provider's note?		
	Yes	273 (85)
	No	33 (10.3)
	Don't know	15 (4.7)
Did the provider's note include what you had written? (If yes)		
	Yes, some or all	112 (41)
	No, but clearly provider had read my answers	35 (12.8)
	No, not included	23 (8.4)
	Don't know	103 (37.7)
In general, sending an update about myself before a visit is a good idea.		
	Agree or somewhat agree	296 (92.2)
	Disagree or somewhat disagree	21 (6.5)
	Don't know	4 (1.3)
In general, sending the issues that I want to focus on before visit is a good idea.		
	Agree or somewhat agree	301 (93.8)
	Disagree or somewhat disagree	17 (5.3)
	Don't know	3 (0.9)

Question	Responses	Value, n (%)
When would you like to receive the request for your answers?		
	2 days before the visit	131 (43)
	3-7 days before the visit	161 (53)
	>7 days before the visit	12 (4.0)

The patients wrote 282 comments in free text (Textbox 2). The coders agreed on codes for 161 responses and reached a consensus through discussion on the remaining 121. The comments most often (N=55) addressed the two questions in the form; about half wrote that they liked the questions as they were, and half found the questions too general. More specific comments related to the question asking for an interim history, with many making suggestions for more detailed queries, or requesting guidance on how to respond. The respondents wrote 33 comments about other aspects of the form and suggested some improvements. About half of the respondents commented on the space available for answers thought it adequate, and half wanted more room. Respondents saw the form as a tool supporting their engagement with care (27 comments), most often as a mechanism and incentive for collecting their thoughts before a visit. The 20 comments related to workflow often focused on improved visit efficiency, although several mentioned finding it inefficient when they were asked the same questions again at the visit; 27 comments referenced perceptions that the submitted forms were not read by their clinicians. Several suggested alerts to let the provider know the form was available, and to let the patient know it had been opened. Among other topics mentioned were concerns about privacy, patients for whom the form might present difficulties, and appreciation for specific staff, clinicians, portals, or institutions.

Textbox 2. Examples from 282 patient responses to: “What improvements would you suggest for the future?” and “Please write any other comments you would like to make.”

The 2 questions

- The questions seem alright. It leaves room for the response to be personalized.
- The first question is a bit broad. It wasn't entirely clear to me how much detail my doctor would like or need.
- As someone not familiar with health care, I want more guidance around what is helpful for me to share with my provider about my health. I need examples or clearer descriptions.
- When it says “since last visit”—tell me when the last time I saw this provider was, I see several different doctors...

The form

- I think the form is easy to use, very clear and has just the right amount of space.
- I would not suggest making it any more complicated.
- The shorter the form, the more likely I'll do it.
- It would be helpful to have a brief recap of what our last visit entailed.
- Need more space and the ability to attach documents.

Patient engagement

- I like how it focuses me on what needs to be accomplished.
- Sometimes, I have to sit there and think about more than the first question, but that's ok.
- It leads me to the point that I have superior care in part because of my proactive participation in my own care.
- This program improves doctor-patient communication and facilitates my sense of being connected to the physician.
- I think leaving it so we can fill it in is super helpful. It makes some of the tougher subjects easier to approach.

Workflow

- I found that this makes the flow of the appointment better.
- I prefer to provide the updates online rather than filling out the form when I check in. It seems more efficient for all of us.
- Although, I spend time answering these, it seems I am asked again at the start of my appointment. This is repetitive and unnecessary.
- Some kind of follow up-did the provider open the note? After the visit, did my issues/concerns get addressed?
- Have the doctor have a printout before they enter patient’s room so they can discuss every issue together.

Was the submitted form read?

- I really don't know if it is read before the visit.
- The breakdown was from the doctor, who either had not read them or else for some reason wanted to quiz me to see if I knew what I had written...The time I had spent completing the notes was not treated with respect.
- I did not feel that the questionnaire was helpful, as it was not mentioned or referenced by the doctor or the team.
- I’m not sure the providers saw my answers before the visit. Perhaps they need an alert or flag when the patient has completed these questionnaires?
- It would be nice if I received some confirmation that my notes were received and read.

Other

- I would caution using this method with older people: my 79-year-old mother has difficulty with online medical forms and gets angry or frustrated with them.
- Too many complex medical issues for me to place this in a previsit note.
- I have some privacy issues with typing details of my doctor's concerns into the system in advance. I’m ok typing in the general purpose. I don’t have control over the information once I type it into the system and data tends to stick around forever.
- Let me know if it will be anonymous or who will know.

Discussion

Principal Findings

To our knowledge, this is the first study published on patients and clinicians cogenerating visit notes, or *OurNotes*. Patients were asked to prepare both interim histories about their conditions and their goals for an upcoming scheduled primary care visit, and participating patients and clinicians were strongly supportive. Consistent with our prime hypothesis, patients found completing the forms largely beneficial, and our hypothesis that *OurNotes* would have a neutral or positive impact on the time of clinicians appears to have been substantiated. We did not find additional benefits for patients with chronic illnesses.

In this pilot inquiry, participants offered many suggestions on how to improve the process. Patient respondents described how thinking through and providing the information supported their own engagement with care and helped visits flow more efficiently, but many wrote that they needed guidance about what to write. Clinicians often included the submissions of patients in their visit notes, suggested technical changes that would facilitate the process, and encouraged future efforts to teach patients to write interim histories that are more informative. Overall, both patients and clinicians suggest that this provides an important opportunity for better care. Based on this early proof of concept, all 4 sites decided after the 12-month pilot to continue the intervention, while considering also how to enhance this new approach to transparent patient-clinician communication and patient engagement.

Challenges in the Pilot Implementation

Patients, in aggregate, submitted forms for fewer than 10% of eligible visits. We have no direct evidence from nonparticipants about why they chose not to send forms, and demographic data to analyze differences between them and participants were not available. A number of factors could explain this low level of participation, including insufficient communication with patients about the project before the intervention began, and the stated desire of patients in survey comments for guidance in answering the questions. The factors discussed below may have also contributed to this. Although evaluating reasons for nonparticipation was not among the objectives of this pilot study, it will be important to ascertain this in future research.

Although patients generally liked the idea of submitting information before visits, if such submissions are not readily available to providers before or during the visit, it could prove hurtful, as some patients may feel their input is being overlooked. Another challenge is how to support patients who may feel intimidated by being asked to write free text. Perhaps emphasizing the acceptability of writing phrases rather than complete sentences, allowing dictation functions such as those on smartphones, or offering other ways to record a verbal history may help. For patients to prepare and for clinicians to respond, designing a variety of effective approaches will require input from clinicians, patients, researchers, and information systems specialists.

Incorporating patient-written text into visit notes was an entirely new functionality in all 4 sites, and each designed and implemented an approach within the timeframe of the pilot to enable the most important steps in the process while attempting to minimize the impact on clinicians' workflow. All sites experienced occasional glitches; clinicians commented particularly about sometimes not knowing that a patient had submitted a form until after the visit, and about issues with getting text of patients into their notes. After 12 months, each practice clearly required technical changes to facilitate various steps in the process. Although most clinicians reported no negative impact on their time, this important factor needs further study.

Three Recommendations for Future Implementations

First, both patients and clinicians wanted a *closed communication loop* for previsit information. Clinicians expressed frustration about sometimes not knowing patients had submitted forms, or not being able to find them, and patients were disappointed or frustrated after taking time to complete the forms and then having their clinicians seemingly ignore what they had done. In a closed loop, clinicians would always know before an appointment that the patient had sent information, and patients would know whether the clinician had viewed their submissions. Using automated notifications for both patients and providers, technology can create such a system. Completed forms could be delivered directly to clinicians, although they worry about keeping up with an ever-growing in-box and potential medicolegal liability in unread items. Including links to submitted forms on daily schedules of clinicians could be one way to avoid additional messaging. Providers may also consider deadlines or messaging to encourage early patient submissions, in consideration for clinicians who review patients' data the day or evening before a session, rather than at the time of the visit.

Second, both patients and clinicians explicitly asked for *education* that would help patients write *informative interim histories.* Some patients wrote of simply not knowing how to approach a request for a history. Lacking educational interventions, clinicians found the histories to be less useful than the visit priorities patients formulated. A foundational question concerns whether to ask patients to use a semistructured format, in addition to or in place of free text. In an informal meeting with members of one patient family advisory council, participants suggested that patients should be offered both options. Alternatively, might we prompt for interim histories by problem, or make forms that solicit unstructured histories before primary care visits, whereas those to subspecialists might be better suited to structured queries and responses?

Third, it is clear from the patient participation rate that we must learn more about how to *encourage patients* to take advantage of new opportunities to provide information to their clinicians outside of time-pressured encounters. For many, this involves registering more patients on patient portals, particularly those from vulnerable populations, and ensuring that they have adequate access, education, and support to use the portal [20,21]. Today, many patients fill out forms on paper or tablet computers in the waiting room [22]. Completing a web-based form at home facilitates timely review of prior open notes and may invite more consideration and thought, but it may also raise privacy

concerns. Some survey respondents were intimidated by the form. Many of these concerns can be addressed with education, testimonials by patients and clinicians, and other outreach strategies. An appealing interface, dictation function, and seamless submission process may be helpful. Using some principles of behavioral economics, such as incentives for both patients and clinicians, may also improve rates of participation [23-25]. Encouraging patient engagement is always a multi-pronged, long-term undertaking.

Limitations

This pilot study had important limitations. Most importantly, the proportion of patients who returned previsit forms was modest, and we were unable to conduct postimplementation evaluations with patients in 2 of the 4 sites because of the COVID-19 pandemic. Although we found no difference between the experiences of patients with and without chronic illness, we did not examine records to more fully ascertain their burden of illness. Response rates were within the usual range for web-based surveys [26], but nearly 40% of the patients did not remember submitting a previsit form, a function perhaps of having completed a single form many months before the survey, or of the ever-increasing amount of electronic communication with which patients contend. Finally, we did not collect quantitative information about the proportion of submitted forms that were actually used in the visits.

Conclusions

Overall, in 4 different sites, each with a common goal but many degrees of freedom to design their own intervention, providers and patients liked the idea of patients providing information in advance of their visits and incorporating their observations into visit notes. Further development and research will be needed to assess barriers to patient participation, establish reliable notifications about information submitted by patients, and enable seamless incorporation of patient-generated text into notes.

This exploration is just beginning, and many questions arise. For both patients and clinicians, how should one balance time and effort before an encounter with time spent during a visit? Can cogenerating notes improve a crucial element of care: supporting mutual trust among patients, families, and clinicians? Could cogeneration of notes have particular benefits for those with multiple chronic conditions and those nearing the end of life? Can we effectively bring care partners into the process? Should we ask patients to think more broadly about their goals for health care, addressing issues germane to far more than an individual, time-constrained visit? As care delivery evolves in response to the COVID-19 pandemic, might *OurNotes* prove an effective component of telemedicine [27]? Future exploration may provide useful insights.

Acknowledgments

The authors thank the Commonwealth Fund for primary support and the Gordon and Betty Moore Foundation, Cambia Health Foundation, and Drane Family Fund for further support of this work. The authors gratefully acknowledge colleagues at UCHealth: Kate Sanfillippo, RN, Program Manager, and Matthew Mimnall, Manager of Information Technology, for their work with Epic to enable the technical infrastructure and for building tools and reports that allowed this work to succeed. The authors also thank Jon Darer, MD, MPH, who coined the term '*OurNotes*.' Finally, the authors offer their sincere gratitude to the patients and clinicians who took a chance and participated in the pilot study.
