RT–PCR is the definitive method for diagnosing COVID-19. However, the nucleic acid test is very time-consuming, and sputum analysis may take several days. This test's high cost and low sensitivity have caused major problems to health care systems during the pandemic. Consequently, people with false-negative findings on RT–PCR have been a source of virus transmission and have spread the virus to others. When the WHO emphasized the need to increase diagnostic tests and comprehensively evaluate suspected individuals, physicians and health care systems were encouraged to utilize cheaper and faster tests [36-38]. When attempting to detect COVID-19 in its initial stages, a lung CT scan does not always demonstrate the lung consolidation areas, and no GGO findings are observed in many cases. Machine learning models can enhance the efficiency of radiological diagnostic methods and serve as a suitable alternative to the RT–PCR test. The core of the CAD system designed in this study is based on a deep CNN architecture and uses an input with 4 slices. NASNet was utilized here because it could determine the best architecture for feature engineering [24]. No previous study has employed this technological model for analyzing the CT scans of individuals suspected with COVID-19. Further examination of medical image processing revealed the remarkable performance of this model in image feature extraction. This study achieved maximum sensitivity and precision in detecting COVID-19 compared to previous studies. Considering the algorithm and the use of multiple chest CT scan slices for a single patient, the proposed system can be employed at diagnostic centers as a reliable method to detect individuals with COVID-19 with high precision in the early stages of the disease. In the future, this CAD can be included in the picture archiving and communications systems of radiology wards to achieve an automated and more efficient diagnosis.

Conclusions

Using the CAD system for detecting COVID-19 during the pandemic minimizes the time of image interpretation and consequently the number of patients waiting at radiology centers.

Furthermore, by increasing the number of images produced by the CT scanner and increasing the population size, better classification results for differentiating positive and negative cases can be expected.

Acknowledgments

This study was part of a research project conducted at Shahid Beheshti University of Medical Sciences (Tehran, Iran) and was approved by Iran National Committee for Ethics in Biomedical Research (approval ID IR.SBMU.RETECH.REC.1399.132).

Abstract

Background: Although Pinterest has become a popular platform for distributing influential information that shapes users' behaviors, the role of recipes pinned on Pinterest in these behaviors is not well understood.

Objective: This study aims to explore the patterns of food ingredients and the nutritional content of recipes posted on Pinterest and to examine the factors associated with recipes that engage more users.

Methods: Data were collected from Pinterest between June 28 and July 12, 2020 (207 recipes and 2818 comments). All samples were collected via 2 new user accounts with no search history. A codebook was developed with a raw agreement rate of 0.97 across all variables. Content analysis and natural language processing sentiment analysis techniques were employed.

Results: Recipes using seafood or vegetables as the main ingredient had, on average, fewer calories and less sodium, sugar, and cholesterol than meat- or poultry-based recipes. For recipes using meat as the main ingredient, more than half of the energy was obtained from fat (277/490, 56.6%). Although the most followed pinners tended to post recipes containing more poultry or seafood and less meat, recipes with higher fat content or providing more calories per serving were more popular, having more shared photos or videos and comments. The natural language processing–based sentiment analysis suggested that Pinterest users weighted *taste* more heavily than *complexity* (225/2818, 8.0%) and *health* (84/2828, 2.9%).

Conclusions: Although popular pinners tended to post recipes with more seafood or poultry or vegetables and less meat, recipes with higher fat and sugar content were more user-engaging, with more photo or video shares and comments. Data on Pinterest behaviors can inform the development and implementation of nutrition health interventions to promote healthy recipe sharing on social media platforms.

Introduction

Background

Healthy eating patterns and their effect on disease prevention have been demonstrated robustly across the scientific literature [1-9]. The US government has dedicated enormous resources to improve Americans' eating patterns through programs such as the National School Lunch program and the Special Supplemental Nutrition Program for Women, Infants, and Children. In 2015, the Dietary Guidelines Advisory Committee published the 2015-2020 Dietary Guidelines for Americans, providing guidance for choosing a healthy diet. Despite such efforts, between 2003 and 2016, although the intake of sugar by Americans decreased by 4.8 teaspoons per day, no appreciable changes occurred in the intake of vegetables, total meat, poultry, and seafood [10]. Although from 2003-2004 to 2015-2016, Americans increased whole grain consumption, the mean intake of grains, vegetables, and dairy continued to be lower than the Dietary Guidelines recommendations [10]. Only 42% of the US population met dietary recommendations between 2013 and 2014, and less than half of the older adults met the recommendations between 2013 and 2016 [11,12].

Social media has become a new and efficient way to distribute and consume influential information that shapes people's dietary behaviors [13,14]. Several internet-based intervention programs have been implemented to enhance individuals' knowledge of healthy eating [15,16]. With the growing popularity of social media, there is an urgent need to assess the contents of healthy food and nutrition information on social media and their associations with user engagement among both posters and information seekers.

Pinterest, launched in 2010, is a unique social media platform where users can save images (*pins*) and upload it to the board (a collection of pins from different users) [17]. It has also become a popular social media site for users to share recipes. According to a survey conducted by the Pew Research Center in 2018, 28% of US adults reported that they had used Pinterest [18], and over 60% of active users made a new recipe inspired by Pinterest in 2015 [19]. Pinterest provides us with a platform and unprecedented opportunities to study the effect of social media on dietary behaviors and, consequently, public health [20]. This study aims to examine the patterns in which nutrition information on recipes is received and shared among Pinterest users and identify the key elements of recipes that influence the perceptions and preferences of Pinterest users. Our findings will shed light on future social media–based dietary intervention program design and implementation.

Objectives

To the best of our knowledge, no prior study has evaluated the recipe content on Pinterest. This study provides a first glimpse of this domain to advance the understanding of the relationship between social media use and dietary behavior. We aim to achieve the following 2 goals. First, we aim to examine the patterns of food ingredients and nutrients prescribed by recipes posted on Pinterest. Second, by employing both traditional content analysis and a natural language processing (NLP) technique, we sought to understand the factors that distinguish the most popular recipes among users.

Methods

Data Collection

Data were collected between June 28 and July 12, 2020. Although there is no "rule of thumb" on how long the data collection should persist, we adapted a proper time frame based on previous literature that specifically focused on Pinterest [21,22]. All samples were collected using the Pinterest search engine by 2 new user accounts with no search history, no posts and boards or pins, 0 followers, and 0 following. The keywords *recipe*, *breakfast*, *lunch*, and *dinner* were used to identify samples on Pinterest. Pins with recipes containing all the required information were selected by scrolling down the search results page for each keyword. This approach was developed based on previous studies on Pinterest content [21,22]. Pins that were duplicates or missing any of the following information were excluded: eating occasion, cooking method, cooking time, ingredients, and nutrition information. A total of 207 collected pins or boards that met our criteria and all comments (2818 comments) under the 207 recipes were included in the analysis. A codebook was developed in an Excel spreadsheet (Microsoft Corp) to document the URL, time of data collection, comments, number of replied photos and videos, poster's number of followers, eating occasion, cooking method, cooking time, ingredients, and nutrition information.

Data Analysis

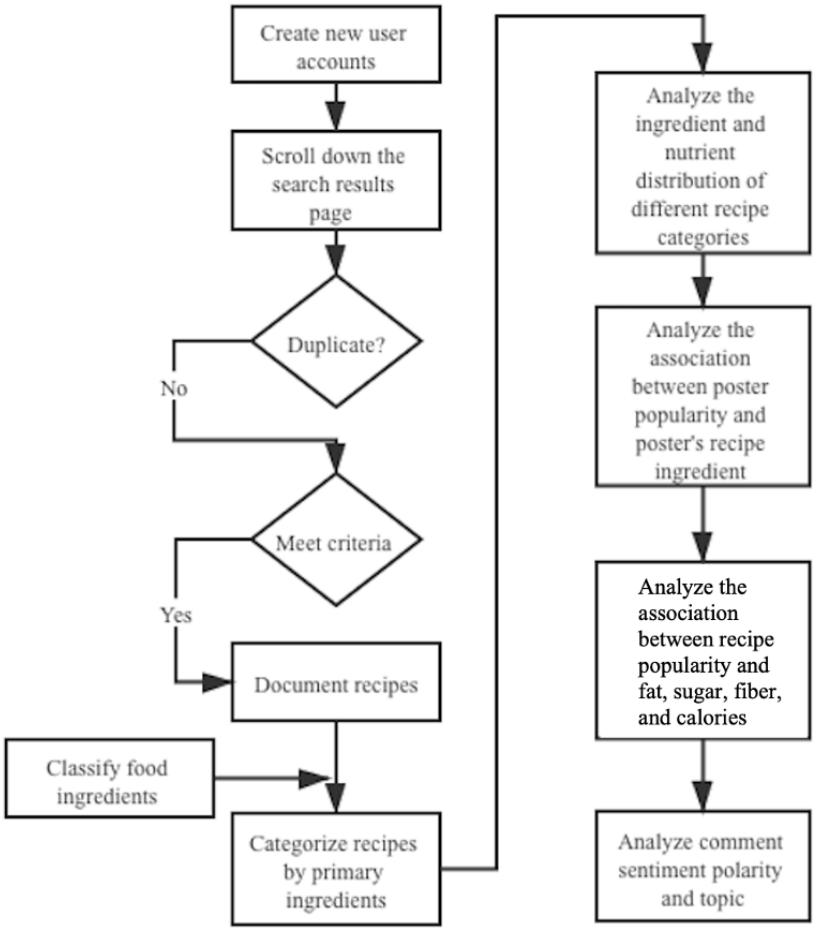
For the content analysis, following the 2015-2020 United States Department of Agriculture Dietary Guidelines, food ingredients were classified as dark green vegetables, red and orange vegetables, legumes (beans and peas), starchy vegetables, other vegetables, fruits, seafood, meats, poultry, eggs, nuts or seeds or soy products, dairy, oil, and butter [23]. The recipes were then categorized into 4 types based on their primary ingredients: meat, poultry, seafood, and vegetable recipes. Recipes that only contained meat, poultry, or seafood were further categorized according to whether they contained any vegetables. All measurement units were converted into grams per serving. The variables measured at the nutrient level included total energy (calories per serving); sodium (mg per serving); and, in grams per serving, fat, protein, carbohydrate, fiber, sugar, and cholesterol. Each pinner's number of followers was classified based on a tertile distribution. Overall, 2 coders independently analyzed all study samples and performed cross-checks to ensure intercoder reliability. The raw agreement rate was 0.97 for all variables.

For the comment analysis, 3 keyword dictionaries were created with keywords related to health (eg, *health*, *healthy*, *calorie*, and *cholesterol*), taste (eg, *yummy*, *delicious*, *tasty*, and *creamy*), and the complexity of the recipe (eg, *quick*, *easy*, *sample*, and *difficult*). Keyword searching was applied to assess sentiment of comments posted by Pinterest users.

Descriptive analyses were performed for each type of food ingredient and their corresponding nutrient content. In addition, the popularity of recipe ingredients was assessed by the number

of recoded followers (presented in tertiles). The level of engagement for each recipe was also evaluated by categorizing comments and shared photos or videos into tertiles, with regard to the fat, sugar, and fiber content of the recipes. Comments and shared photos or videos were chosen as indicators of engagement based on prior literature that suggested that, in the context of Pinterest, the number of *likes* on each pin indicates relatively low engagement (users simply acknowledge or agree with content), whereas the number of comments indicates medium engagement (users created and shared such content) [24]. High engagement is indicated by actual offline participation and can be captured by users' shared photo or videos (images of what they made based on the same recipes) [24]. To process and analyze natural language data from the comments, both keyword search and sentiment analysis technology were applied. The sentiment analysis method we used was VADER (valence aware dictionary and sentiment reasoner). VADER performs sentiment analysis on textual data to determine whether the sentiment of a text is positive, negative, or neutral. VADER is a lexicon- and rule-based sentiment analysis method. It was developed specifically to analyze the sentiment of English text in microblog-like social media [25]. VADER requires no training data and provides high-speed analysis [26]. VADER helped us categorize all comments as being positive, neutral, or negative by polarity, that is, the representation of sentiment. All statistical analyses were conducted using STATA 15.1 (StataCorp LP) and Python 3.6 (Python Software Foundation). Figure 1 shows the entire data collection and analysis process.

Figure 1. Process of data collection and analysis.



Results

Summary Statistics

Table 1 describes the quantity of food ingredients and nutrients served by meat, poultry, seafood, and vegetable recipes. Although not statistically significant, 7 patterns were identified in the data. First, we found that meat, poultry, and seafood weighed more in recipes that only served these main dishes than those that also contained vegetables. For example, 124.79 g meat was served in meat-only recipes compared with 100.65 g in meat recipes that also contained vegetables. Second, recipes containing vegetables provided more total energy than recipes served without vegetables. For instance, poultry recipes that contained vegetables provided an average of 442.79 calories per serving compared with 433.31 calories provided by poultry-only recipes. Third, seafood recipes (329.38 calories per serving) or vegetable recipes (293.67 calories per serving) provided lower total energy content compared with meat- or poultry-based recipes (430-490 calories per serving). Fourth, 48.6% (230/473) and 56.5% (277/490) of the total energy in meat-only and meat-with-vegetable recipes came from fat, higher than the other types of recipes. Fifth, meat recipes, in general, contained higher fat (25.62-30.13 g per serving) than poultry- and seafood-based recipes (16.79-22.35 g per serving).

Sixth, seafood recipes tended to contain less sodium and sugar than meat and poultry recipes. Seventh, 38.2% (112/293) of total energy in vegetable-based recipes came from carbohydrate, with less sodium (483.63 mg per serving) and cholesterol (47.65 g per serving), compared with other types of recipes.

Table 1. The ingredient and nutrient distributions of meat, poultry, seafood, and vegetable recipes.

Recipes	Meat[a]		Poultry[a]		Seafood[a]		Vegetable[a,b] with eggs[c] (n=59), mean (SD)
	Meat only (n=25), mean (SD)	Meat with vegetable[c] (n=45), mean (SD)	Poultry only (n=35), mean (SD)	Poultry with vegetable[c] (n=76), mean (SD)	Seafood only (n=6), mean (SD)	Seafood with vegetable[c] (n=13), mean (SD)	
Food ingredients (g per serving)[d]							
Dark vegetable	N/A[e]	75.6 (0)	N/A	49.6 (14.1)	N/A	29.5 (15.4)	113.3 (0)

[a]Recipes that included a main dish only and those that included a main dish served with vegetables were mutually exclusive. For example, a meat-only recipe was defined as a recipe that only included meat, whereas recipes that included both meat and vegetables were listed in the meat with vegetable category.

[b]No recipes were purely vegan; therefore, we reported ovo-lacto recipes.

[c]The calculation of sample average used only complete data, that is, some of the denominators were smaller than 45 and did not have standard errors.

[d]The food ingredients were categorized based on the guidelines of the United States Department of Agriculture.

[e]N/A: not applicable.

[f]The sum of column percentages of each recipe class may exceed 100% because each value was calculated separately as the percentage of energy from specific nutrients divided by the total energy provided in a recipe class.

Relationship Between Popularity and Ingredients of Shared Recipes

The bar charts in Multimedia Appendix 1 describe the relationship between the pinner's popularity and the ingredients of their shared recipes. Popularity was measured as the number of followers per pinner, stratified by tertile. Pinners in third tertile had more followers. Although not statistically significant, 3 patterns emerged. First, as the number of followers increased, the amount of meat served in the recipe decreased. Second, recipes with greater followings contained more poultry and seafood but fewer red and other vegetables. Third, starchy vegetables were distributed similarly, regardless of the number of followers.

Relationship Between Photo or Video and Comments Sharing and Recipe Features

Multimedia Appendix 2 presents the mean number of shared photos or videos and comments under the recipes according to the absolute amount of fat per serving in the recipes, classified in tertiles. Recipes in the third tertile had the highest fat content. Data showed that more photos or videos and comments were shared as the absolute amount of fat per serving increased. Although not statistically significant, among the 172 recipes with complete information, the average number of shared photos or videos and comments increased from 25 to 35 between the first and third tertiles, suggesting that recipes with higher fat content, such as creamy garlic butter chicken, were more popular among Pinterest users.

Multimedia Appendix 2 also presents the mean number of shared photos or videos and comments under recipes based on the recipes' sugar content. Among 166 recipes that had complete sugar information, the mean number of photos or videos and comments were distributed as an inverse *U* shape. Although not statistically significant, this pattern indicated an upward trend in the number of shared photos or videos and comments received (between the first and second tertiles) when a recipe contained high sugar content, but the trend turned down when the recipe's sugar level reached the third tertile. In terms of sugar, our data suggested that the number of comments was similar regardless of the fiber content. However, although not statistically significant, recipes containing the highest amount of fiber (third tertile) were less popular, having fewer shared photos and videos compared with those in the first or second tertile.

Multimedia Appendix 2 further presents the mean number of shared photos or videos and comments based on the recipes' number of calories per serving. Data suggested that the number of shared photos and videos and the number of comments were positively correlated with the number of calories per serving. Recipes that provided more calories per serving (in the second and third tertiles) were more popular than recipes that provided fewer calories per serving (in the first tertile), with fewest shared photos or videos and comments.

Comment Analysis

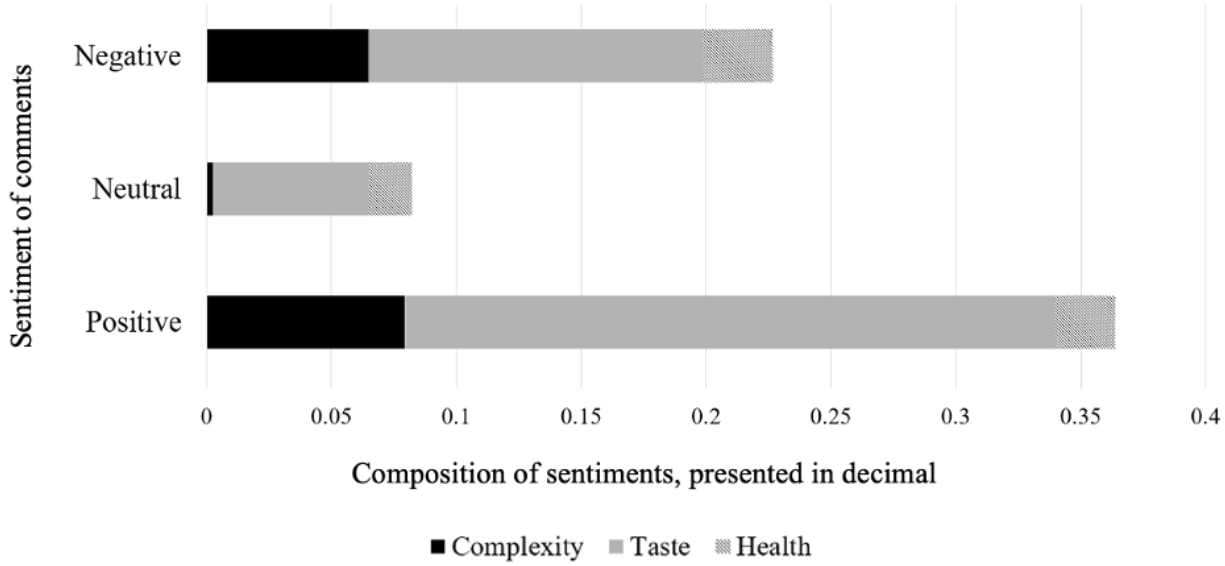
Table 2 shows sample comments, corresponding sentiment polarity, and related topic. Figure 2 shows the results of text mining from all 2818 comments analyzed. Out of 544 comments deemed as *taste* related, 25.9% (141/544) were positive, significantly higher than negative (72/544, 13.2%) and neutral (33/544, 6.1%; $P<.05$). The complexity of a recipe and its health attributes were commented on less frequently: less than 8% (225/2818) of the comments contained text related to complexity, and less than 3% (84/2828) of the comments contained text related to health. We found that *taste* and *complexity* were the most important factors in shaping Pinterest users' sentiments.

Table 2. Comment samples and polarity.

Comment	Sentiment polarity	Keyword	Topic
"How long do I leave them in the oven?"	Neutral	N/A[a]	N/A
"How many calories is this?"	Neutral	Calories	Health
"I do not like brown sugar in my meatloaf...ugh"	Negative	N/A	N/A
"Definitely way too salty and too greasy for me."	Negative	Salty and greasy	Taste
"It's easy! I did this again and LOVED it!"	Positive	Easy	Complexity
"It turned out amazing!! Very delicious."	Positive	Delicious	Taste

[a]N/A: not applicable.

Figure 2. Pinterest users' attitudes toward different aspects of recipes.



Discussion

Principal Findings

In this study, recipes posted on Pinterest were collected, analyzed, and compared for ingredients and nutrients. We found that, in most cases, recipes using seafood or vegetables as the main ingredient, for example, tuna salad (main ingredient: tuna; other ingredients: celery, onion, flat-leaf parsley, mayonnaise, mustard, and black pepper), had, on average, fewer calories and less sodium, sugar, and cholesterol than meat- or poultry-based recipes, for example, crispy chicken wraps (main ingredient: popcorn chicken; other ingredients: tomatoes, cheddar cheese, buffalo wing sauce, and flour tortillas) and Mongolian beef (main ingredient: flank steak; other ingredients: cornstarch, canola oil, ginger, garlic, soy sauce, dark brown sugar, and scallions). Recipes using meat as the main ingredient, for example, creamy herbed pork chops (main ingredient: pork chops; other ingredients: milk, Montreal steak sauce, butter, flour, basil, black pepper, and instant beef bouillon granules), provided more energy by fat. Although the most followed pinners tended to post recipes containing more poultry or seafood and less meat, recipes serving higher fat or providing more calories per serving were more popular, having more shared photos or videos and comments. Sentiment analysis based on text mining showed that Pinterest users, in general, valued taste more than health qualities when making comments or sharing photos or videos.

With the sharp increase in the number of social media users, platforms such as Pinterest have become influential mechanisms to transform knowledge sharing and acquisition, including dietary choice [27]. According to a survey conducted by the Pew Research Center in 2018, about 28% of US adults used Pinterest [18]. Although evidence has shown that intervention tactics through tailored web-based platforms can help promote evidence-based nutrition education to the public [28,29], members of the academic community have urged for more research evaluating the mutual influence between social media users and information or content providers [30]. Our study provides the first glimpse into how recipe information is disseminated and viewed from 2 distinct perspectives: Pinterest posters (pinners) and users.

From the perspective of content providers, we found that the most popular pinners, by sharing recipes containing more seafood and poultry (Multimedia Appendix 1) with less sodium, sugar, and cholesterol, are overall more health conscious. This finding can be understood in terms of the social cognitive theory. The social cognitive theory states that a human is an agent that has not only been a forethinker but also a motivator and self-regulator. In a sense, humans learn by observing others' actions and their consequences [31]. In our case, pinners are more likely to imitate posts that are socially rewarded. Early research on popular food blogs (webpages that can be pinned to Pinterest) aligned with our findings, suggesting that vegetarian and seafood recipes had significantly lower nutrition risks and more health benefits compared with red meat and poultry recipes [32]. Many health-conscious *social elites* do not eat meat at all; they only eat vegetables or seafood. It is not surprising that celebrities or social influencers, such as those with many followers on Pinterest, embrace this *elite social norm*, considering that most Pinterest users are from high-income households [18], which reinforced the role of self-reactiveness portrayed in the social cognitive theory [31]. In theory, an agent acts intentionally [31]. Popular pinners, such as celebrities, might be more health orientated and have implicitly or explicitly engaged in education, inspiration, and activism—the 3 stages of celebrity narratives—when they post recipes on Pinterest [33]. Red meat, for example, is classified as probably carcinogenic to humans (group 2A) by the Working Group of the International Agency for Research on Cancer [34] and is associated with type 2 diabetes, cardiovascular diseases, malignancies, and other diseases [35,36]. Such joint activity requires commitment to a shared intention [31,37]. Pinners may or may not be aware of this fact, but by posting recipes containing less red meat, they may have contributed to shifting public dietary choices to a healthier direction.

From the users' perspective, they are often learners in pursuit of inspirational recipes [38]. We found that recipes with higher

fat and sugar content tended to generate higher user engagement and greater numbers of shared photos or videos and comments. High engagement refers to actual offline use of the recipe rather than simply clicking *like* on a particular pin [24]. The social cognitive theory postulates that people are more motivated when they consider a subject worthwhile [37]. Our sentiment analysis corroborated the theory and literature by showing that users attached more importance to the taste of a recipe than its healthfulness and complexity. The social cognitive theory of mass communication also shows that behavior changes of an agent can be directly affected by media and indirectly influenced by connections to social systems that are diffused by media. The diffusion process relies heavily on the social-prompting power of the modeling [31]. Previous qualitative research showed that learners often quickly assumed the role of an expert or teacher when sharing nutrition information from social media [38]; therefore, it is concerning that ordinary people paid more attention to taste and were motivated by fat- and sugar-heavy pins. A likely downstream effect of these preferences of ordinary people is that *tasty* recipes will be disseminated quickly on social media through users' social networks (a part of the social system) and make their way into regular recipe rotations for more people [39]. Our findings suggest a high priority area for future social media–based nutrition interventions.

There appears to be a discrepancy between what pinners posted and how users consumed information, leading to an opportunity for future health interventions via Pinterest. Previous studies have shown that social media interventions can have a positive effect on nutritional outcomes [14]. Strategies to increase users' health consciousness can include, but are not limited to, (1) encouraging pinners to provide healthier (low sugar and cholesterol) alternative ingredients, (2) promoting recipes provided by health professionals and supported by evidence-based research [40,41], and (3) designing and promoting healthy recipes that are tasty and easy to prepare.

Limitations

This study had some limitations. First, because of the restrictions imposed by Pinterest, the content scrolling process is not automated. The manual data collection resulted in a relatively small sample size and a large margin of error. To address the issues related to the small sample size, we applied a machine learning technique to mine text from the comments. A total of 100 comments were randomly selected to assess sentiment error rates. We found that the error rate was 18%, which is better than the acceptable level used in previous studies by convention [42]. Second, only recipes posted in English were included. Thus, the sample was not representative of non–English-speaking cultures or users. Third, the measurement of healthfulness was assessed based on the types of food ingredients and amount of fat, sugar, and fiber; other aspects of health, such as cooking methods, were not included. Future research should incorporate these aspects. Finally, demographic information such as gender or race and ethnicity of the Pinterest users was unavailable from Pinterest. Our sample was restricted to those who could adopt the food culture embedded in Pinterest. As seafood- or vegetable-only recipes are often more expensive or beyond the reach of low-income populations, more research is needed to address the potential socioeconomic disparities inherent in popular social media platforms.

Conclusions

In this study, we used both content analysis and NLP techniques to analyze recipes posted on Pinterest. Seafood-based recipes and vegetarian recipes had fewer calories and less sodium, sugar, and cholesterol than meat-based recipes. Although the most popular pinners tended to exhibit more health consciousness by posting recipes with more seafood, poultry, and vegetables and less meat, recipes with higher fat and sugar content had higher user engagement, as demonstrated by the higher numbers of photo or video shares and comments. Population health could be improved with targeted interventions to address this disparity through efforts to enhance interest in and adoption of healthy recipes by Pinterest users.

Authors' Contributions

HX, XC, and SL made significant contributions to the conception and study design. HX, XC, and SL conducted data analyses. HX, KW, AH, DG, XZ, JW, and LC provided significant support for the interpretation of results. HX, XC, SL, KW, AH, DG, XZ, JW, and LC drafted the paper. All authors approved the final manuscript submitted.

Abstract

Background: An accurate understanding of dietary supplements (DS) is a prerequisite for informed decisions regarding their intake. However, there is a need for studies on this understanding among the public based on validated research tools.

Objective: This study aims to assess the knowledge about DS among Polish internet users with no medical education and to identify its determinants and design an appropriate predictive model.

Methods: The study protocol was prospectively registered with a statistical analysis plan. Polish users of a web-based health service and a social networking service were administered a survey consisting of the recently developed questionnaire on knowledge about DS, the questionnaire on trust in advertising DS, the beliefs about medicines questionnaire, and several other health-related single-item measures and sociodemographic questions. The results were subjected to general linear modeling.

Results: A total of 6273 participants were included. Of the 17 yes or no questions in the questionnaire of knowledge about DS, the mean number of correct responses was 9.0 (95% CI 8.9-9.1). Health service users performed worse than social networking users by 2.3 points (95% CI 2.1-2.5) in an analysis adjusted for potential confounders. Internet users had fewer true beliefs about DS if they presented higher trust in their advertising (adjusted β=−.37; 95% CI −.39 to −.34), used DS (adjusted β=−.14; 95% CI −.17 to −.12), experienced their positive effect (adjusted β=−.16; 95% CI −.18 to −.13), were older or younger than 35 years (adjusted β=−.14; 95% CI −.17 to −.12), expressed interest in the topic of DS (adjusted β=−.10; 95% CI −.13 to −.08), reported getting information about the products from friends (adjusted β=−.13; 95% CI −.15 to −.11), and believed that medicines are harmful (adjusted β=−.12; 95% CI −.15 to −.10). The proposed 5-predictor model could explain 31.2% of the variance in knowledge about DS. The model appeared resistant to overfitting and was able to forecast most of the observed associations.

Conclusions: Polish internet users with no medical education exhibit some false beliefs regarding DS. Trusting the advertising of DS appears to conflict with knowledge about them. There is an urgent need for effective web-based educational campaigns on DS and the promotion of advertising literacy. After the proposed predictive model is externally validated, it may help identify the least informed target audience.

KEYWORDS

dietary supplements; knowledge; beliefs; advertising; education; statistical model; health services; Poland; online social networking

Introduction

Background

Dietary supplements (DS) are consumed by approximately half of the adult population in developed countries [1-3]. They are used not only to fill potential nutrient gaps, as they are intended to, but also ostensibly to improve and maintain overall health and well-being, prevent or treat diseases, enhance cognitive and sports performance, and extend life expectancy [3-8]. The recommendations of health care providers seem to play only a minor role in the decision to use DS [4]. Instead, media, including the internet, appear to shape DS consumption patterns [5,9]. The internet is able to build a highly positive picture of DS [10-15]. In contrast, recent findings of large-scale, high-quality research studies highlight overall negligible benefits [2,16] and potential threats [2,17,18] related to DS use. It is important to evaluate the actual knowledge about DS held by the public and its determinants, not only for cognitive reasons but also for tailoring educational campaigns capable of fostering informed decisions regarding DS consumption [3,19-22].

Knowledge about DS has already been examined in numerous research studies worldwide, in multiple populations [3,23-29], including the general public [30-33]. Most participants were likely internet users [34]. Although the findings consistently reported an inadequate knowledge level, a systematic review could not draw any conclusions regarding knowledge about DS because of the heterogeneity of the data [35]. Moreover, most of the reports had multiple methodological limitations: the sample sizes were fairly low and selected with highly nonprobabilistic techniques, and the methods applied to examine knowledge about DS presented modest or vaguely described validity proofs. Apart from a general nutrition knowledge questionnaire [36] and similar measures for health care workers [28,37], no satisfactorily validated tool was available to test knowledge about DS in the general population until such a test was developed in 2019 [38]. The questionnaire exhibited acceptable and well-documented validity and was designed to screen commonly identifiable beliefs that are important from the public health perspective. This questionnaire was developed in the same country and the same language as this research was performed, thus allowing a valid assessment of knowledge about DS and its determinants on a large scale.

Objectives

This study aims to evaluate the level of knowledge about DS and identify its determinants among adult Polish internet users without medical education. The following research questions were addressed: (1) what is the level of knowledge about DS among Polish internet users? (2) what are the characteristics of the population members who are unknowledgeable about DS? and (3) how can the level of knowledge about DS be modeled in this population? These research questions were additionally addressed to some subpopulations with a high impact on public health: older people, residents of rural areas, and people with low earnings.

Methods

Ethical Considerations

The study was approved by the Bioethics Committee of the Medical University of Lodz, Poland (KE/1382/19, received on October 15, 2019). Expressing informed consent in an electronic manner was mandatory to participate in the study. The study protocol with the data analysis plan was prospectively registered on November 26, 2019, in the public repository Open Science Framework (Center for Open Science; Open Science Framework) [39]. A few changes to the preregistered study protocol were made after the study commencement, which are presented and discussed in Multimedia Appendix 1. DOZ.pl (Pelion), a web-based health service entity, was the research partner in this study. The only role of DOZ.pl was to prepare promotional materials (each one approved by the researchers) to help recruit participants and to enter the survey content (authored by the researchers with no influence of DOZ.pl) into an external web-based survey system (see section *Research Instruments*). This paper was outlined according to the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines for cross-sectional studies [40] and, to some extent, the TRIPOD (Transparent Reporting of a multivariable prediction model for Individual Prognosis Or Diagnosis) guidelines [41].

Study Design

This was a nationwide cross-sectional study conducted among Polish internet users. A self-administered survey was accessed on the web. Each participant was asked to complete the survey once.

Research Instruments

The survey was created using the Survio web-based survey system (Survio). It was pretested in a qualitative manner by 5 nonmedically educated people (3 women; mean age 52.0 years, SD 19.1 years) for readability, understanding, appearance, face validity, and time to survey completion according to the procedure described in a study by Hilton [42]. The survey was modified according to the feedback received to construct the final version.

The survey comprised 5 consecutive parts:

1. *Introduction*: the first page provided the volunteers with basic information about the purpose of the study, the structure of the survey, the rights of participants, and contact person data. This page also included a statement of informed consent, which was to be expressed electronically by ticking a Start the survey now button.
2. *Knowledge about DS*: this part included a recently developed and validated questionnaire on knowledge about DS in its original Polish language version [38]. The questionnaire consisted of 17 true-or-false statements; the respondent received a point for each correct answer with a maximum of 17 points. The questionnaire was formed of 2 subscales to examine general and specific knowledge. Knowledge about DS–general assessed “familiarity with the useful facts concerning the legal status of DS in general” [38]. It included 7 items related to DS definition, DS quality

standards, and DS package labeling. Knowledge about DS–specific assessed "familiarity with common, scientifically proven and useful facts about popular dietary supplements" [38]. It included 10 items related to the efficacy of vitamin C, vitamin D, multivitamin, calcium, magnesium, and antioxidants and their adverse effects and oral absorption. The content of each questionnaire item is presented in Multimedia Appendix 2. The sum of correct answers in knowledge about DS–general and knowledge about DS–specific formed knowledge about DS–total, which operationalized the construct of knowledge about DS.

3. *Dietary supplement advertising*: this part included a single-item measure of having contact with DS advertisements within the past week and a recently developed and validated questionnaire on trust in advertising DS in its original Polish version [38]. The tool consisted of 8 pairs of opposing expressions characterizing DS advertisements and information conveyed by them to be assessed on a 5-point semantic differential scale. The questionnaire was formed from the reliability, intelligibility, and affect subscales. The sum of scores on the subscales operationalized the construct of the trust in advertising DS.
4. *Beliefs about medicines*: this part included the Polish version [43] of the beliefs about medicines questionnaire (BMQ) [44]. The tool included in this study involved only the BMQ-General, as it may be used separately from BMQ-Specific to assess ideas about medicines in general among people who may take no medicines [44]. The BMQ-General consisted of 8 statements for a respondent to express their opinions using a 5-point Likert scale. The BMQ-General was composed of 2 separate 4-item subscales to operationalize the construct of beliefs that medicines are overused by doctors (BMQ Overuse) and the construct of beliefs that medicines are harmful, addictive, poisonous, and should not be taken continuously (BMQ Harm).
5. *Other medical and sociodemographic data*: this part included a set of single-item measures of health (4-point Likert scale), diet and physical activity (5-point semantic differential scale), use of any DS within the past 30 days (further called use of DS; 2-point Likert scale), personal experience of positive (or negative) effect of DS (further called positive [or negative] effect of DS, for DS users only; both 2-point Likert scale), interest in DS (5-point semantic differential scale), sources of getting knowledge about DS (assessed in 5 categories: medical doctors, pharmacists, dieticians, friends with no medical education, and media such as magazines, television, radio, and internet; each of the categories assessed in 4-point Likert scale), and conventional cigarette smoking and electronic cigarette use (both as 3-point Likert scales: never; no, but I smoked/used in the past; and yes). A measure of self-rated diet used in this study was found in a pretest study (a convenience sample of 117 healthy adults from the general population and medical students) to significantly correlate (Pearson r=0.48; P<.001) with the Polish version (own translation with no full validation) of the Starting the Conversation scale, a brief dietary assessment tool [45]. In the same pretest study, a measure of self-rated physical activity was found to significantly correlate with the Polish version of the International Physical Activity Questionnaire Short Form [46] (Pearson r=0.49; P<.001). Demographic data in the survey used in this study included age, sex, educational level (with 5 options to choose from), having medical education (*no* or *yes*), number of inhabitants in a place of residence, and monthly net household earnings per family member (both with 4 options to choose from).

None of the survey questions employed forced answering. In all semantic differential scales, the central value was set as the default answer. It was predicted that the survey would take 5 to 10 minutes to complete. After completing the survey, participants were provided with correct answers to the knowledge about DS questionnaire with expert comments for educational purposes. A survey could be completed only once from a single internet protocol address to avoid duplicate records.

The detailed characteristics of the survey questions and their method of operationalization are described in the study protocol [39]. The questions asked in the survey and its layout are presented in Polish (original version) and English in Multimedia Appendix 3.

Participants

The desired sample size was set to 10,000 participants. It was determined not according to the analysis of statistical power but based on the estimated ability of DOZ.pl to reach the audience. A nonprobability convenience sampling technique was used to recruit internet users. They were accessed through a web-based health service and a general social networking website between November 26, 2019, and March 11, 2020. DOZ.pl was used as the health service, whereas Wykop.pl (Wykop; modeled after the American Digg service) was the social networking service. In the 3 months from December 2019 to February 2020, when the study was conducted, DOZ.pl was the sixth most popular web-based health service and the first most popular web-based pharmacy in Poland, with a mean of 37.91 million page views and 4.39 million unique users (15.72% of internet users in Poland) per month. In the same period, Wykop.pl was the fifth-to-sixth most popular web-based social networking service in Poland, with 74.31 million page views and 4.28 million unique users (15.36% of internet users in Poland) each month [47].

Apart from the refusal of electronic informed consent, there were no specific exclusion criteria in the study. The survey could be completed by anybody who reached it on the web; however, a knowledge of Polish was needed to complete it.

Procedure

Throughout the period during which the study was conducted, promotional material encouraging participation with a link to the survey was temporarily placed in a slider on the main DOZ.pl website and some subpages, DOZ.pl social media (Facebook), and some other DOZ.pl channels. Moreover, the invitation to participate was emailed twice to the subscribers of DOZ.pl newsletter. Similarly, the promotional material with a link to the survey was posted on the Wykop.pl website to be entered and promoted by service users.

Data Analysis

Each survey record was assumed to be completed by a single respondent. Before performing the analysis, survey data were cleaned by removing records considered potentially meaningless [48] (as detailed in Multimedia Appendix 4). The number, frequency, and pattern of missing values were examined (Multimedia Appendix 5). Before any further analysis, the missing values were completed using a multiple imputation by chained equation procedure under a *missing at random* assumption about the unobserved data.

Details of the data analysis are depicted in a preregistered data analysis plan [39]. Briefly, descriptive statistics were presented, and participants' characteristics from the 2 web-based services were compared using the asymptotic Mann-Whitney *U* test, Pearson chi-square test, and general linear models (GLMs). Then, the associations between all the examined characteristics of participants and knowledge about DS–general, knowledge about DS–specific, and knowledge about DS–total were tested. The associations were examined in raw analyses and with adjustment for potential confounders (age, following its transformation; sex; education; the number of inhabitants; earnings; type of web service through which the survey was accessed; and calendar year in which a participant completed the survey). Adjustment for calendar year was performed to correct for the potential effect of "Broadcasting agreement about the rules and regulations for advertising dietary supplements," which was signed in Poland and became effective on January 01, 2020. Although the Likert and semantic differential scale data should be perceived as ordinal variables, parametric tests were used to allow for multivariate modeling with GLM. Sensitivity analysis of the associations was performed in 2 steps. First, univariate associations were tested using a corresponding nonparametric procedure (Spearman rho). Second, all parametric associations were repeated in a complete case database before data imputation. The Benjamini and Hochberg procedure was used to reduce the false discovery rate to 0.05, which was inflated by testing multiple hypotheses.

The predictive model of knowledge about DS was built using multivariate linear regression analysis. The selection of knowledge about DS predictors was based on the following criteria: first, the characteristics substantially associated with the knowledge about DS–total were preferred. Second, objective measures, which reflect the underlying constructs with strong proof of validity, were favored. Third, a set of predictors with negligible collinearity was retained. Collinearity was assessed using explanatory factor analysis and Pearson *r* correlation matrix. Data transformation was also considered. The final model was selected according to the best subset selection algorithm to promote model simplicity based on the Akaike and Bayesian information criteria. Its performance was illustrated with a calibration plot as well as mean absolute error (MAE) of prediction (the mean difference between predicted and observed knowledge about DS–total score) and root mean squared error (RMSE). The final model was internally validated using a 10-fold cross-validation procedure to correct for overfitting bias.

P lower than Benjamini-Hochberg corrected significance level or $P<.05$ were considered statistically significant. The analyses were performed using STATISTICA software version 13.3 (Statsoft) and R software version 4.0.0 (package *mice* version 3.8.0; R Foundation for Statistical Computing).

Results

Database

The survey was displayed 24,400 times and completed 7632 times (7632/24,400, 31.28% of the displayed surveys). A total of 6273 records (6273/7632, 82.19% of the completed records) were retained in the final database following the cleaning procedure, which is detailed in Multimedia Appendix 4. Missing data comprised 0.38% of the values in the database, and convincing evidence was found against the pattern of *missing completely at random*. Details of the data missingness analysis are presented in Multimedia Appendices 5 and 6. Participants completed the survey in a median time of 6 minutes and 25 seconds (first to third quartile: 5 minutes and 9 seconds to 8 minutes and 34 seconds).

Study Participants Characteristics

Following the missing data imputation, out of 6273 study participants, 3640 (58.03%) were female. The study participants' mean age was 38.4 years (SD 13.4 years; range 18-90 years). A total of 64.05% (4018/6273) of participants accessed the survey through the health service and 35.95% (2255/6273) through the social networking service.

Substantial differences were found between the participants from different web-based services. Those from the health service—according to their reports—were older, mostly women, living in a smaller place of residence, and a little better educated but earning less money. Although they reported having worse overall health, they tended to eat a healthier diet, engage in more physical activity, and were less likely to smoke cigarettes or use e-cigarettes. Health service visitors were more negative about medicines, more likely to use DS, and were more interested in DS issues. They also declared having more contact with DS advertisements and trusting them more. Media were reported to be the major source of knowledge about DS, irrespective of the type of web-based service used, followed by pharmacists, medical doctors, friends, and dieticians. Detailed characteristics of the study participants, with differences between the participants from 2 web-based services, are presented in Table 1.

Table 1. Sociodemographic characteristics, health-related characteristics, and dietary supplement–related characteristics of the study participants. Data for the total sample and the comparison of participant characteristics from different web-based services are provided.

Characteristics	Total sample (N=6273)	Differences between the type of web-based service

[f]Within the past 30 days.

[g]Frequency calculated in relation to the number of dietary supplements users.

[h]Within the past week.

Knowledge About DS

The knowledge about DS of web-based service users could be assessed as low, being not much better than a random guess, the success rate of which is 50% for binary questions. Knowledge about DS–general presented overall better results than knowledge about DS–specific. Knowledge about DS of health service users was lower than that of social networking users in both its subscales, approaching an effect size of 6%, as expressed by partial eta-squared, in an analysis adjusted for potential confounders. Details of the knowledge about DS analysis of web-based service users are presented in Table 2. The numbers and frequencies of correct answers to each item of the knowledge about DS questionnaire are presented in Multimedia Appendix 2.

Table 2. Knowledge about dietary supplements among web-based health service users and social networking service users.

Variable	Total sample (N=6273)		Differences between the type of web-based service							
			Type of analysis[a]	Health service users (n=4018), mean (95% CI)	Social networking service users (n=2255), mean (95% CI)	Effect size of the difference[b]		Test statistics and *P* values for the comparison		
	Mean	95% CI				$p\eta^2$ value (%)[c]	Mean (95% CI)	*F* test (*df*)	*F* test (*df*)	*P* value
Knowledge about dietary supplements–General[d]	4.4	4.4-4.5								
			Raw	4.0 (3.9-4.1)	5.3 (5.2-5.3)	8.7	−1.3 (−1.4 to −1.2)	595.4 (1,6271)	N/A[e]	<.001
			Adjusted	4.1 (4.1-4.2)	5.0 (4.9-5.1)	2.0	−0.9 (−1.0 to −0.7)	N/A	129.7 (1,6265)	<.001
Knowledge about dietary supplements–Specific[f]	4.5	4.5-4.6								
			Raw	4.0 (3.9-4.0)	5.5 (5.4-5.6)	13.8	−1.5 (−1.6 to −1.4)	1008.1 (1,6271)	N/A	<.001
			Adjusted	4.0 (4.0-4.1)	5.5 (5.4-5.5)	6.2	−1.4 (−1.5 to −1.3)	N/A	411.9 (1,6265)	<.001
Knowledge about dietary supplements–Total[g]	9.0	8.9-9.1								
			Raw	8.0 (7.9-8.1)	10.8 (10.7-10.9)	16.5	−2.8 (−3.0 to −2.7)	1237.9 (1,6271)	N/A	<.001
			Adjusted	8.2 (8.1-8.3)	10.5 (10.3-10.6)	5.9	−2.3 (−2.5 to −2.1)	N/A	393.4 (1,6265)	<.001

[a]Raw analyses: performed only with the variables reported; adjusted analyses: adjusted for |Age−35|, sex, education, number of inhabitants, earnings, and calendar year—all included as linear factors; estimates in adjusted analyses reported as estimated marginal means.

[b]Reported as a partial eta-squared ($p\eta^2$) and a difference between knowledge about dietary supplements of health service users and knowledge about dietary supplements of social networking service users (95% CI).

[c]$p\eta^2$: partial eta-squared.

[d]An expected result of random guess is 3.5.

[e]N/A: not applicable.

[f]An expected result of random guess is 5.

[g]An expected result of random guess is 8.5.

Determinants of Knowledge About DS

As depicted in Table 3, people less knowledgeable about DS were female, older, had a lower education status, lived in an area with fewer inhabitants, and earned less money per family member. Age appeared to be not linearly linked with knowledge about DS; people around 35 years were the most knowledgeable, and any increase or decrease in age from this point was linked to lower knowledge about DS in a nearly linear manner (such a curvilinear relationship was stable across the type of web-based service and after adjusting for potential confounders). Health-related habits were negligibly linked to knowledge about DS after adjusting for potential confounders. People who believed medicines were harmful or overprescribed by doctors had lower levels of knowledge about DS. Using a DS within the past 30 days was also an indicator of lower knowledge about DS. Among DS users, DS's perceived beneficial effect was a negative modulator of knowledge about DS, whereas the harmful

effect was a positive modulator. Trust in advertising DS appeared to be the strongest negative predictor of knowledge about DS, which was equal in both knowledge about DS domains. The effect of trust in advertising DS on knowledge about DS was particularly high among those who had contact with the respective advertisements. Interestingly, having contact with DS advertisements, without taking trust in advertising DS into account, had a somewhat positive effect on knowledge about DS. Being interested in DS was linked to a lower level of knowledge about DS. Although reported as the major source of knowledge about DS for web-based service users, internet and traditional media were negatively but weakly associated with knowledge about DS. Instead, the major source of false information regarding DS was found to be friends with no medical education. Among health care specialists, pharmacists appeared to be a misleading source of knowledge about DS.

High compatibility was found between nonparametric and parametric tests for the sensitivity analysis of the associations reported in Table 3 (the correlation of Spearman rho with Pearson *r* coefficients in univariate analyses was *r*=0.9985; 95% CI 0.9976-0.9990, and the median absolute difference between the corresponding coefficients was 0.004 of a maximum value of 0.034). Sensitivity analysis performed using GLM methods in a database of complete cases only (n=5633) was also highly consistent with the analysis performed in the original database following missing data imputation (the correlation of corresponding β regression coefficients was *r*=0.9991; 95% CI 0.9988-0.9993, and the median absolute difference between the corresponding coefficients was 0.003 of a maximum value of 0.018).

Table 3. Association between characteristics of the study participants and their knowledge about dietary supplements. Analyses were performed in the total sample of 6273 internet users. The results presented in italics are statistically significant at the Benjamini-Hochberg-corrected significance level of 0.036.

[a]Performed only with the variables reported.

[b]Adjusted for |Age−35|, sex, education, number of inhabitants, earnings, type of web-based service, and calendar year—all included as linear factors.

[c]DS: dietary supplement.

[d]Adjusted analyses do not include |Age−35|; the association between Age and Knowledge about dietary supplements seemed to be an inverted-U shape with a maximum in knowledge for age of about 35 years; consequently, Age was transformed in further analyses to |Age−35| to approximate the association to linear; the assoction between Age and Trust in advertising dietary supplements similarly looked as a nonlinear U shape with a minimum of trust for age of about 30 years.

[e]Adjusted for contact with dietary supplements advertisements and trust in advertising dietary supplements; having contact with dietary supplements advertisements in this model associated with knowledge about dietary supplements total in adjusted analysis with β of .11 (95% CI .04 to .18), *P*=.001; Moreover, trust in advertising DS associated with knowledge about dietary supplements—total in adjusted analysis among those who reported having contact with dietary supplements advertisements with β of −.38 (95% CI −.41 to −.36), *P*<.001, and those who did not report having contact with β of −.24 (95% CI −.31 to −.18), *P*<.001.

[f]The associations of knowledge about dietary supplements with getting knowledge about dietary supplements from a particular source were adjusted for all other sources of knowledge about dietary supplements.

Prediction Model of Knowledge About DS

The variables selected for knowledge about DS modeling were trust in advertising DS, BMQ Harm, Age (following transformation to |Age−35|), Sex, and Getting knowledge about DS from friends. The model explained 31.2% of the variance in knowledge about DS. The predictors in the model were intercorrelated to a low extent, with a median absolute correlation coefficient of 0.114 and a maximum of 0.214 for trust in advertising DS and sex. The assumption of a linear contribution of predictors to the model was satisfactory. The model characteristics are listed in Table 4. According to this model, knowledge about DS can be predicted using the following formula:

$$\text{Knowledge about DS} = 19.397539 - 0.412775 \times \text{Trust in advertising DS} - 0.23657 \times \text{BMQ Harm} - 0.113879 \times |\text{Age} - 35| + 1.850937 \times \text{Sex} - 0.691575 \times \text{Getting knowledge about DS from friends}$$

In the formula, *Trust in advertising DS* represents trust in advertising DS operationalized with the questionnaire on trust in advertising DS, ranging from 8 to 40; *BMQ Harm* represents BMQ operationalized with the BMQ questionnaire, subscale Harm, ranging from 4 to 20; *|Age−35|* is the absolute value of the difference between age (years) and 35; *Sex* was operationalized as 0 for females and 1 for males; and *Getting knowledge about DSfrom friends* represents a self-reported declaration on the extent of getting knowledge about DS from friends with no medical education (operationalized as 0 for *not at all*, 1 for *to little extent*, 2 for *to medium extent*, and 3 for *to large extent*).

Table 4. Characteristics of a model to describe knowledge about dietary supplements. The total sample of 6273 internet users was included. Test statistics, *P* value and coefficient of determination of a full model are *F*(5,6267)=568.2; *P*<.001; R^2=0.312, respectively.

Predictor	Effect size			*F* test (*df*)	*P* value
	β coefficient	95% CI	$p\eta^2$ (%)[a]		
Trust in advertising DS[b]	−.39	−.41 to −.37	16.4	123.4 (1,6267)	<.001
Beliefs that medicines are harmful	−.13	−.15 to −.11	2.2	143.1 (1,6267)	<.001
|Age−35|	−.17	−.19 to −.15	3.9	251.2 (1,6267)	<.001
Sex (0=female and 1=male)	.15	.13 to .17	2.9	187.7 (1,6267)	<.001
Getting knowledge about DS from friends	−.08	−.11 to −.06	1.0	62.0 (1,6267)	<.001

[a]$p\eta^2$: partial eta-squared.

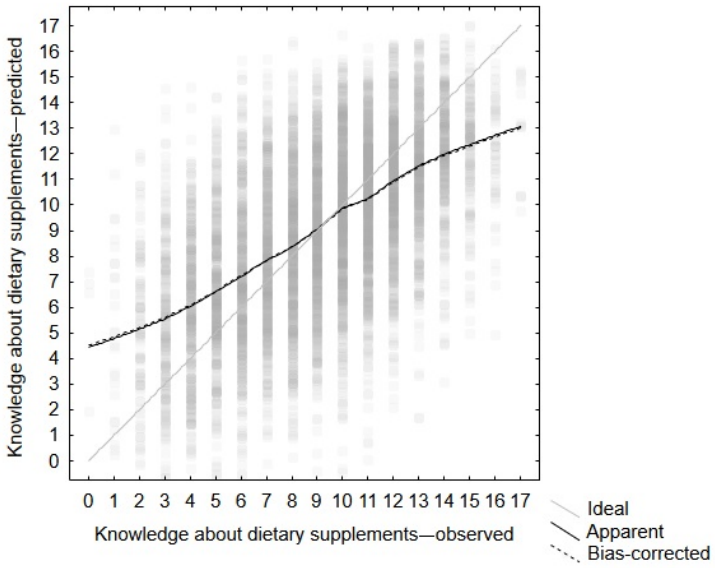
[b]DS: dietary supplement.

The model could predict knowledge about DS with an MAE of 2.52 and an RMSE of 3.19 points (median 2.09, 1st to 3rd quartile 1.00-3.60). Although this performance was far from ideal, it was significantly better than a random guess based

solely on knowledge about DS distribution that yielded MAE of 3.82 and RMSE of 4.76 points (median 3.23, 1st to 3rd quartile 1.59-5.49). Results of the model internal validation indicated that predictions of a bias-corrected model almost overlapped the original model with MAE of 2.51 and RMSE of 3.17 points (median 2.09, 1st to 3rd quartile 1.00-3.58), and the correlation between knowledge about DS values predicted by the original model and the bias-corrected one was very close (r=0.99986; 95% CI 0.99985-0.99986). Extreme values predicted by the bias-corrected model did not exceed an upper limit of 17 points; however, a lower limit was below zero due to the *Age* component not being restricted (36, ie, 0.57% of observations were below zero, with a minimum of −5.76). The model could predict relatively well the knowledge about DS values around its central value of 8.99 but exhibited worse performance with extreme knowledge about DS values, which was reflected by the deviation of a calibration plot from linearity. A calibration plot of the model is shown in Figure 1.

The 5 predictors could model not only knowledge about DS–total but also knowledge about DS–general and knowledge about DS–specific separately, with each of the predictors making a significant contribution to modeling both constructs, reaching determination coefficients of 20.4% and 22.0%, respectively. Importantly, although the model did not include as a predictor the type of web-based service through which a study participant accessed the survey, the model could predict (though overestimate) that the health service users had lower knowledge about DS than the users of the social networking service (7.6, 95% CI 7.5-7.7 vs 11.5, 95% CI 11.4-11.6, respectively; P<.001; a bias-corrected model). Moreover, the knowledge about DS score predicted by the bias-corrected model was found to be associated with the other participant characteristics examined in this study in a similar pattern as the associations of the observed knowledge about DS scores. The link between both associations, as expressed by Pearson r, was 0.95 (95% CI 0.91-0.97); the median absolute difference between the corresponding β coefficients was 0.03 (1st to 3rd quartile 0.01-0.09), and the maximum absolute difference was 0.38. Associations between knowledge about DS, predicted with the biased-corrected model and characteristics of the study participants, are reported in Multimedia Appendix 7.

Figure 1. Calibration plot of the model to describe knowledge about dietary supplements. Black lines represent lowess (locally weighted scatterplot smoothing) fitted curves with a smoothing parameter of 0.25. The solid black line denotes the original (apparent) model, whereas the dotted black resulted from cross-validation (bias-corrected). The gray diagonal line represents hypothetical ideal prediction. Gray-filled circles depict individual data points predicted by the bias-corrected model. The circles are partially transparent; thus, the intensity of gray shadings reflects the density of points in an area.



Knowledge About DS in Selected Subpopulations

Knowledge about DS was determined in some subpopulations thought to be critical to public health: older people aged 60 years or more, residents of rural areas (below 5000 inhabitants), and people with low earnings (below 1000 PLN [US $256] of monthly net household earnings per family member). All these subpopulations were found to have lower knowledge about DS than the remaining internet users. However, after adjusting for potential confounders, the effect persisted only for the older people and, to some extent, rural residents. For people with low earnings, the effect shrank to insignificant, as explained by confounders. The analysis of knowledge about DS in subpopulations is presented in Table 5. The proposed 5-predictor model to describe knowledge about DS worked well for rural residents and people with low earnings: all the predictors significantly contributed to prediction and presented a similar prediction error to other people. On the other hand, knowledge about DS among older people was not efficiently predicted by the 5-predictor model, with only trust in advertising DS and Age contributing significantly. The model performance according to subpopulations is presented in Table 5.

Table 5. Knowledge about dietary supplements and the model performance in subpopulations.

Discussion

Principal Findings

There is an ongoing debate over DS [49,50]. Recently, in Poland, several influential high-quality reports suggested unsatisfactory control over the DS market, resulting in inadequate safety [21,22,51]. These reports highlight the need for adequate public education to make informed decisions regarding DS intake [21,22]. This study fits into this discourse by examining knowledge about DS among Polish internet users. The results indicate the level of knowledge to be low and not much different from the previous preliminary report, which used the same research tool [38]. Several characteristics were found to be associated with knowledge about DS, with trust in advertising DS being the most influential; this study outlines a predictive model that could explain almost a third of the variance in knowledge about DS.

Although the results indicate the level of knowledge to be low, such a pessimistic diagnosis appears incomplete. A low level of knowledge about DS is not only derived from the unavailability of knowledge or ignorance; it should be interpreted rather as holding a *false belief* [52] that DS are thoroughly controlled, well tested, effective, and harmless or an expression of the overall confidence in DS properties, as outlined by the other authors [3,25,53]. A qualitative study aimed at exploring beliefs about DS and their use confirmed such interpretation as it identified that beliefs about DS people hold are largely related to their definition, effectiveness in health enhancement and illness prevention, and risks [54], which are the areas covered by the knowledge about DS questionnaire used in this study.

Our results indicate that the users of a web-based health service presented false beliefs about DS to a greater extent than the users of a web-based social networking service. This can be explained in at least three ways. First, health services may attract people who believe DS are effective and safe, as confidence in a product coexists with seeking information about it [55]. Second, web-based health services may not be efficient in promoting evidence-based facts regarding DS, which is obscured by advertising [56]. Third, social networking services users may be influenced to a strong degree by the nature of this environment [57] and may hence not fully engage with the survey and provide biased responses.

In general, people with low knowledge about DS presented such characteristics as interest in the topic of DS, tendency to seek information about them and eagerness to know more, use of DS, and subjective experience of their positive effects without negative effects. The literature on the relationship between DS intake and knowledge about DS appears confusing, with some of the studies reporting positive links [30] and others negative links [38]. However, this is only an apparent discrepancy, as the result depends on the method used. DS users seem to present high *subjective* awareness and confidence in DS [25], which are, in fact, *objectively* false beliefs [33]. The major reason why subjective and objective knowledge are not in line was outlined by the Dunning-Kruger effect [58], stating that unknowledgeable people tend to overestimate their ability [53]. However, the reason why some people do not achieve high scores in objective knowledge about DS, despite the efforts made, should be sought in the quality of information sources they use to learn about DS. Popular beliefs about DS are in conflict with evidence-based facts. Media coverage, particularly DS advertisements, often reinforces popular beliefs rather than providing facts [10-15]. For example, Wierzejska [59], while analyzing the Polish DS market, found that most DS advertisements promise beneficial effects to the human body, going beyond the standards established for food. Trusting such messages may contribute to the accumulation of false beliefs regarding DS.

trust in advertising DS was found to be the strongest among the examined predictors of knowledge about DS and was expressed in a negative way. trust in advertising DS was particularly negatively linked with knowledge about DS among those who reported having contact with DS advertisements recently; however, it could associate with knowledge about DS even among those who did not. Interestingly, having contact with DS advertisements itself, irrespective of trust in advertising DS, was weakly associated with knowledge about DS, but in a

positive way. Developing trust, particularly in its cognitive form, is a long-lasting process that requires deeper commitment than just *having a contact* [60,61]. The DS consumer who trusts advertisements is *dependent* on a message and therefore exposed to a significant risk [62] of being misinformed by DS advertisements, which spread unverified and misleading claims regarding health benefits of DS [59]. On the other hand, having contact with DS advertisements appears incapable of deceiving consumers. Moreover, being chronically exposed to DS advertisements may result in the opposite effect of advertising fatigue [63], leading to advertising distrust, which may, in turn, promote prudence and true beliefs regarding DS.

Causal relationship between knowledge about DS and trust in advertising DS is not evident, although possible [38]. The idea of gaining false beliefs about DS in response to high trust in advertising DS is particularly attractive to opponents of advertising. This is to some extent supported by our findings, as people reporting to get information about DS from media presented lower knowledge about DS. On the other hand, the idea of trust in advertising DS being shaped as a result of holding false beliefs about DS appears similarly likely and may reflect the natural phenomenon of gaining confidence in messages that appear to be true [55].

This study found the media (magazines, television, radio, and the internet) to be the primary source of information about DS to internet users. This is not surprising regarding the nature of the population studied and is in line with some [4,31], but not all [28], previous studies. The top rank of media may be regarded as undermining the unwavering position of health care specialists in providing health-related information [3,64,65]. Considering that web-based resources about DS leave much to be desired [10-15] and are full of deceitful DS advertisements, one could suspect that using the internet as a source of information about DS blurs the knowledge about DS to a large degree. Strikingly, the link presents merely a small effect size, and for knowledge about DS–general, the association was even positive. Although some popular internet resources about DS suggest their therapeutic benefits (possibly contributing to lower knowledge about DS–specific), they present the true characteristics of the products, quoting the definition or introducing the regulatory framework (possibly contributing to an increase in knowledge about DS–general) [66-68]. Similarly, the association of *interest in DS* and *use of DS* was found to be negative only with knowledge about DS–specific but not (or almost not) with knowledge about DS–general. Finally, accessing web-based DS information should not be perceived as a source of criticism. Quite the opposite, it offers new opportunities to improve the patient-physician relationship and, in turn, verify and reinforce true beliefs about DS [69].

Concerns should be raised about the negative link between knowledge about DS and getting information about DS from friends with no medical education. Word-of-mouth advertising was suggested to be efficient in spreading ideas long ago [70]. It is considered more credible than a commercial and may be successfully applied to informal promotions of health-related products [71]. As internet users report experiencing positive, much more frequently than negative, DS effects (according to our results) and word-of-mouth is likely to transmit subjective—yet unproven—information, it may strengthen false beliefs about DS.

Among health care practitioners, only obtaining information about DS from pharmacists was associated with lower knowledge about DS. Although the effect size was very small, it may mean that pharmacist advice contributed to strengthening false beliefs about DS. This is particularly worrying, as pharmacists were reported as the second most important source of information about DS and the first personal one. Concerns related to the ethics of DS being sold in pharmacies have already been raised, and a conflict between dispensing and counseling on DS has been identified [72]. Yet this is the role of pharmacists to educate patients about these products [73].

Our results indicate a negative association between knowledge about DS and both subscales of the BMQ-General, implying a link between confidence in DS and overall negative views about medicines. This association reflects an existing conflict between alternative and conventional medicine [74,75]. This confirms previous findings that individuals who advocate alternative medicine distrust or are dissatisfied with conventional care [76-78]. Our results support the need for reconciliation and integration of both attitudes for the sake of patients [74,75].

Some sociodemographic determinants of knowledge about DS were identified in this study. Women exhibited lower knowledge about DS than men. However, the result was not replicated by other knowledge about DS studies, which found insignificant [23,25,38] or inconsistent [28] differences between sexes. The effect size of the difference in this study, although very small following adjustment for confounders, was significant. It could partially reflect the overall tendency for women to use DS more than men [1,6,28,79] or hold more positive attitudes toward advertising [80], associated with more confidence in DS and lower objective knowledge about DS, as discussed above. A detailed consideration of the reasons why women are apparently more willing to use DS is presented elsewhere [5]. This study also found that people who are generally better educated, living in larger places of residence, or having more money for living presented higher knowledge about DS, particularly in its general domain. A previous preliminary study using the same knowledge about DS measuring tool also reported such findings for the overall education status [38]. Better educated people tend to rely less on advertising [81,82], which is a factor linked to better knowledge about DS. This finding may support our results.

Age presented the most complicated pattern of a relationship with knowledge about DS, with its peak observed in people around 35 years. There is a scarcity of literature linking age to knowledge about DS. In the only study that could be mentioned, knowledge about DS was tested in the general population of young adults with a mean age of 25 years and an SD of 5 years. A subgroup of participants aged >31 years was able to provide the definition of supplementation (objective knowledge about DS) in a greater percentage in comparison with younger participants. Moreover, there was a trend for younger participants to express higher levels of subjective, possibly false knowledge [33]. Although the cited study is in line with this study concerning young adults, it did not include older people. Studies examining DS intake across various age groups

suggested that older people used more DS [31,83], possibly having more false-positive beliefs about DS, or no significant difference was found [26,30]. It is not surprising that there is no clear replication of these results in the literature, as the knowledge about DS–age pattern revealed is not linear and would require an explorative research approach and a large sample size. Obtaining such results was not possible until this study was performed. Research on advertising attitudes may help to explain this phenomenon. Consumers aged 40 years or more were found to have a more positive attitude toward advertisements [81]. Older adults were also more likely to be persuaded by advertising messages [84]. In another study, a more favorable attitude was expressed by younger people aged less than 30 years [85]. None of these studies found a curvilinear relationship between age and susceptibility to advertising; however, their synthesis may approximate such an association. Interestingly, in this study, trust in advertising DS, which is a similar construct to the one considered above, also achieved its minimum in young adults around 30 years old and increased in both younger and older people. As trust in advertising DS is closely associated with knowledge about DS, it may contribute to the explanation of this phenomenon. On the other hand, not all the reports replicate the above findings [80], and such interpretation should not be regarded as straightforward.

In the culminating part of this study, a predictive model of knowledge about DS was built using a multivariate linear regression strategy. The model was able to explain almost one-third of the knowledge about DS variability and included 5 predictors. Although the choice of the predictors was based to some extent on statistical significance, the most objective characteristics outlined a priori in the study protocol [39] were reflected in the final model, which makes it partially based on subject matter knowledge as generally advised [86]. The proposed model was simple enough not to be prone to overfitting, as tested by the internal validation procedure, and versatile enough to predict differences between the 2 web-based services tested and forecast most of the associations tested. The model worked well in subpopulations of rural citizens and people of low income, but worse in older people, whose beliefs related to DS require special attention [26]. This is likely the model will predict the outcome not much worse in an external validation study and in practice. It also has the potential for electronic application. Although the model still made significant mistakes, leaving more than two-thirds of knowledge about DS variance unallocated, it may help scientists recognize further paths of research: health care workers identify people endangered with illusory beliefs about DS, and educators tailor campaigns to the public to induce behavioral change [20,87,88].

The issue of generalizability requires some debate before any conclusions are drawn. First, a convenience sample of internet users from a restricted number of services may present a barrier to these findings' generalizability to the entire web-based community. Health and social networking services presented extreme demographics, likely covering the scope of internet users in general. Considering the relatively large number of possibly not overlapping users of both services [47], this study could capture a broad range of internet users in Poland. Labeling the sample as representative, however, should be avoided. Similarly, the sample should not be regarded as reflecting the overall Polish population. Although most young people access the internet, more than three-fourths of Poles aged 65 years or more remain offline [89], and the group may represent different attitudes toward DS [26].

Apart from generalizability issues, this study has some limitations that warrant mention while interpreting the results. First, the results come from self-reported declarative data, which may be shifted according to the social desirability bias theory [90]. Such results may only approximate the true beliefs and behaviors of study participants and require cautious interpretation [91]. Second, the study did not include external validation of the findings, particularly the predictive model of knowledge about DS. External validation is essential before implementing the model in practice [92]. Third, although single-item measures have the potential to accurately reflect the construct assessed [93], some of the measures in this study were not rigorously validated, although they were used in the same form elsewhere [25]. Fourth, the study did not examine other potential knowledge about DS predictors such as general medical knowledge [94], experience with particular DS products, or personality traits. The survey did not include these variables to keep it short and to minimize the burden of responding [95]. This study, however, substantially reduced possible bias through prospective registration of the study protocol, using some valid research instruments, reporting data transparently, and performing sensitivity analyses.

This report requires further testing to establish the results' external validity among different groups of internet users to account for their diversity. Further investigation into the mechanisms explaining the relationships between the analyzed constructs is needed; this should be supplemented with more qualitative research to confirm the obtained results and reveal a deeper understanding of the problem. Finally, this and any follow-up studies should aim to develop and implement an effective strategy for public education regarding DS, ideally in a web-based form, to ensure rational use of the products for the public's greatest benefit.

Conclusions

Internet users in Poland with no medical education, particularly those attending a health service, exhibit some false beliefs regarding the quality requirements, efficacy, and safety of DS. Holding such false beliefs is positively associated with trusting DS advertising; their intake, particularly when positive effects are subjectively experienced; being interested in the issues of DS; getting information about them through word-of-mouth; beliefs that medicines are harmful or overused; and some demographic characteristics. The proposed 5-predictor model to forecast knowledge about DS can explain almost a third of its variability and appears resistant to overfitting. The results call for implementing efficient education about DS, including the promotion of advertising literacy, to correct consumers' attitudes toward DS. The results also underline the need to introduce more conservative regulatory frameworks for DS marketing. Further research is needed for external validation of the results and to obtain a more comprehensive understanding of the revealed phenomena.

Acknowledgments

This work was supported by DOZ.pl Sp. z o.o, with the grant received by MSK (contract date October 31, 2019), and by the Medical University of Lodz, Poland, with the grant received by JS (grant 500/6-086-01/500-41). The authors thank DOZ.pl Sp. z o.o. for the partnership in this study.

Authors' Contributions

MSK was a manager of the project, conceptualized the study, obtained part of the funding, developed the methods, designed and approved the survey, preregistered the study protocol, performed the analysis, interpreted the results, and drafted the paper as the first author. RH helped interpret the study results, contributed to the study validity, and reviewed and edited the drafted paper. EP helped develop the methods, helped interpret the study results, and reviewed and edited the drafted paper. EK supervised the project, and reviewed the drafted paper. JS obtained part of the funding, supervised the project, and reviewed the drafted paper.

Conflicts of Interest

EP, a coauthor of this study, has been employed in Osom Studio, an e-marketing agency. The role of DOZ.pl Sp. z o.o. in this study was to prepare promotional materials to help recruit participants and to enter the survey content into an external web-based survey system. DOZ.pl Sp. z o.o, Medical University of Lodz, and Osom Studio had no role in the study design; data collection; analysis and interpretation; decision to publish; or preparation, review, and approval of the manuscript.

Abstract

Background: The availability and use of mobile apps in health and nutrition management are increasing. Ease of access and user friendliness make diet-tracking apps an important ally in their users' efforts to lose and manage weight. To foster motivation for long-term use and to achieve goals, it is necessary to better understand users' opinions and needs for dietary self-monitoring.

Objective: The aim of this study was to identify the key topics and issues that users highlight in their reviews of diet-tracking apps on Google Play Store. Identifying the topics that users frequently mention in their reviews of these apps, along with the user ratings for each of these apps, allowed us to identify areas where further improvement of the apps could facilitate app use, and support users' weight loss and intake management efforts.

Methods: We collected 72,084 user reviews from Google Play Store for 15 diet-tracking apps that allow users to track and count calories. After a series of text processing operations, two text-mining techniques (topic modeling and topical n-grams) were applied to the corpus of user reviews of diet-tracking apps.

Results: Using the topic modeling technique, 11 separate topics were extracted from the pool of user reviews. Most of the users providing feedback were generally satisfied with the apps they use (average rating of 4.4 out of 5 for the 15 apps). Most topics referred to the positive evaluation of the apps and their functions. Negatively rated topics mostly referred to app charges and technical difficulties encountered. We identified the positive and negative topic trigrams (3-word combinations) among the most frequently mentioned topics. Usability and functionality (tracking options) of apps were rated positively on average. Negative ratings were associated with trigrams related to adding new foods, technical issues, and app charges.

Conclusions: Motivating users to use an app over time could help them better achieve their nutrition goals. Although user reviews generally showed positive opinions and ratings of the apps, developers should pay more attention to users' technical problems and inform users about expected payments, along with their refund and cancellation policies, to increase user loyalty.

Introduction

Obesity and overweight are the result of a plethora of environmental factors that are known to influence individuals' food intake and physical activity [1,2]. As obesity is a global public health challenge that leads to numerous health, social, and economic difficulties [3], it is important to help individuals make better and healthier dietary choices. Changing lifestyles (eg, the modern sedentary lifestyle) along with other features of an obesogenic environment (eg, physical design challenges; political, social, and cultural factors; the (in)ability to promote an active lifestyle; better food choices) have created a complex environment for consumers to manage their weight and diet [4,5]. Despite this dysfunctional environment, people are aware

of the negative impact that inappropriate diets can have on their health and well-being, and are generally interested in making healthier choices and educating themselves about the foods they consume and their nutritional value [6].

Technological advancements, including those related to mobile devices, are enabling developments of an increasing number of tools to help individuals take control of their health and nutrition. Mobile apps have become an important source of information for their users. A study conducted in the United States showed that more than half of the population using a mobile phone has downloaded at least one health-related app. Most of these were fitness and nutrition apps, which also have the highest reported usage rates [7,8].

Particularly in the area of nutrition, people use apps for a variety of purposes, including to learn about products, read or contribute recipes, interact in app community forums, evaluate their food choices, check product labels, and obtain an overview of the healthiness of products [9], as well as to track their food intake and diets [8]. Given the importance of self-monitoring and diet tracking in motivating behavior change and persistence in healthier eating [8,10], we have been focusing on the nutrition apps that provide a calorie-tracking option (ie, diet-tracking apps). These apps promote diet tracking and maintenance of healthier habits and do not necessarily include weight loss as a goal, which has often been the focus of previous studies (eg, [7]).

The low inclusion of behavior change strategies in diet tracking apps may hinder their ability to help users achieve their long-term diet and nutrition goals [11,12]. However, diet-tracking apps that successfully employ behavior change strategies can have a positive effect on their users' motivation, habits, and diet and nutrition outcomes [13-16]. These apps have also proven to be helpful in behavioral control and weight management [15]. Self-monitoring is considered the cornerstone of successful weight management [17], and can be particularly helpful when combined with tailored goals [16]. Goal setting, which diet-tracking apps enable, is one of the relevant factors influencing behavior change, along with motivation and self-efficacy [15]. Together with apps that offer personalized meal planning programs [18], there is evidence that diet-tracking apps can efficiently support behavior change and weight management [18,19].

Nevertheless, the usability of diet-tracking apps in the weight management process has not always been positively assessed. Intervention studies focusing on diet-tracking apps show that users sometimes dislike the apps due to their complexity, lack of personalization and long-term support for users, and the focus on calorie counting, which can easily become an obsession [20]. Maintaining high levels of motivation throughout the weight management journey is challenging for most people, and diet-tracking apps sometimes fail to provide proper motivational support for sustainable weight loss and weight management [20,21]. In addition, the long-term effects of diet-tracking apps on food intake and user behavior remain unexplored [16]. These issues indicate that additional research on diet-tracking apps and their features is needed [7].

As consumers increasingly rely on apps to support their daily activities, they also generate invaluable feedback for both developers and potential users through app reviews and ratings. These reviews typically contain information that is valuable for app evaluation, including user opinions about the app, information about their experiences with the app, and bug complaints or feature suggestions [22]. A previous study showed that almost a quarter (23.3%) of app reviews contain an app feature request or app assessment [23].

App developers and companies have recognized the value of user reviews and frequently examine these reviews to improve the user experience. Most mobile health apps are free to use, with the option to upgrade profiles to paid premium options (for more features or personalized advice). The initial free download and use make these apps easily disposable and users' decision to switch between them is widespread [24]. This drives app developers' interest in listening to users' comments, complaints, ideas, and suggestions [25]. In reviews, users are text producers for other potential consumers, businesses, and society at large. This text can then be used to predict and understand user preferences and behaviors [26].

To increase usage and enable better health and nutrition outcomes, it is necessary to better understand user needs. It is evident that users are not simply looking for pure information when using mobile health apps. The way the information is presented; the usability of the app; the degree to which it engages and connects users; and its effectiveness, timeliness, design, and functionality are also important considerations [27]. A deeper analysis of user reviews of apps can lead to better knowledge of desired features and user preferences, and ideally increase the usability, appeal, and effectiveness of the app in achieving users' health and nutrition goals [7]. These aspects require more academic research into user reviews [22], especially as functionality and appearance often have greater contributions to the popularity of dieting apps than the quality of the information provided by the app [28].

Owing to their presence and relevance in the dieting field, diet-tracking apps have attracted the interest of many researchers who have used app evaluation strategies in an attempt to better understand and evaluate app features [29-32]. The influence of diet-tracking apps on users' food choices and their opinions about these apps have been tested using experimental and survey data collection methods [10,15,18,33]. Previous studies also assessed the consistency of information provided by different apps, and recommended further collaboration and harmonization of information [34,35].

To improve the understanding of user opinions on diet-tracking apps, this study was performed based on the collection and analysis of the textual reviews and numerical ratings that users leave for these apps. We focused on identifying the main positive and negative aspects that users express about diet-tracking apps and openly share in app reviews. By identifying the features or functions that attract consumers' attention, this study suggests areas for app development and improvement that have potential to increase users' positive evaluation and motivation, leading to nutrition/health improvement.

Methods

Data Collection

To evaluate users' views on diet-tracking apps, we used a different methodology from the experimental and survey data collection methods previously reported [10,15,18,33]. We performed a thorough content analysis of the app user reviews available on Google Play Store. The text mining method was used to detect the word and topic combinations that are frequently mentioned in user reviews. These word combinations (n-grams) were evaluated and the most frequent combinations were selected for further analysis. The identified topics were named and are briefly discussed.

The search for diet-tracking apps in Google Play Store included the following keywords: "nutrition apps," "diet apps," "calorie counter apps," "food scanner," "calorie app," "calorie tracker," and "calorie scanner." We identified 131 unique apps that offer calorie information (eg, calorie tables, calorie tracking, diet diaries). These apps were further reviewed to determine if they offered a calorie counting option for food items and an intake diary for users, and if their operating language was English. Final app selection was based on the number of downloads and reviews (impact evaluation; apps with over 1 million downloads and at least 10,000 user ratings were selected), which is a standard procedure in the app assessment process (eg, [7,30]). A total of 15 apps were identified that met all of the above conditions (Table 1), and their reviews were scraped from Google Play Store using a custom-written Python script. In total, 81,660 of the latest user reviews for these apps were collected at this stage.

Table 1. Overview of apps included in the study.

App	Mean app rating	Number of downloads	Number of ratings
Health Pal-Fitness, Weight Loss Coach, Pedometer	4.1	>1 million	>20,000
iEatBetter: Food Diary	4.2	>1 million	>20,000
Health & Fitness Tracker with Calorie Counter	4.1	>1 million	>20,000
Calorie Counter by Fat Secret	4.7	>10 million	>300,000
Calorie Counter by Lose It!	4.6	>10 million	>100,000
Fooducate-Eat better. Lose weight. Get healthy.	4.4	>1 million	>15,000
Calorie Counter-MyNetDiary, Food Diary Tracker	4.6	>1 million	>40,000
Healthify me-Calorie Counter, Weight Loss Coach	4.5	>10 million	>100,000
MyPlate Calorie Tracker	4.6	>1 million	>30,000
Calorie Counter-My Fitness Pal	4.4	>50 million	>2 million
Lifesum-Diet Plan, Macro Calculator & Food Diary	4.4	>10 million	>200,000
Noom: Health & Weight	4.4	>10 million	>200,000
YAZIO Calorie Counter, Nutrition Diary & Diet Plan	4.6	>10 million	>300,000
Calorie, Carb & Fat Counter	4.5	>1 million	>50,000
Calorie Counter Calories!	4.5	>1 million	>10,000

Data Analysis

Text Mining Approaches

With the increase in publicly available user-generated content due to the proliferation of internet-assisted communication, researchers have developed several automated approaches to identify, summarize, and classify the available information [26,36]. The development of new tools allows researchers to obtain more information about users' opinions and sentiments in their writing. There is a trend to shift the focus of opinion mining from studying long texts to shorter user posts on various social media platforms and websites [22]. The rapid development and increase in the efficiency and capabilities of text mining and natural language processing (NLP) algorithms is evident, and they are becoming an important part of social science research in the study of user-generated content [37,38]. Speed, reproducibility, and reliability are considered some of the most important advantages of text mining when it comes to classifying and categorizing text [39].

In this study, we applied two text mining methods to our dataset: topical n-grams identification and topic modeling. Both methods work by identifying and grouping words that occur simultaneously in the text (user reviews in our case). Data analysis required preprocessing of the raw data, which was performed through several procedures commonly used in data preparation and preprocessing for text mining analysis [40].

Data Preprocessing

Data preprocessing is a data mining technique that transforms raw data into an understandable format. Real-world data are often incomplete, inconsistent, contain a substantial amount of redundant information, and are likely to include many errors [41]. This is a critical and time-consuming process as the output depends on the quality of the data.

Since both the topical n-grams identification and topic modeling approaches have the same preprocessing steps, the same preprocessed dataset was used in both methods. For these tasks, we used the Python programming language in combination with its data science–specific tools (ie, libraries) that made this process possible given the large amount of data. The Python libraries numpy and pandas, which are well known in the data science community, were used extensively throughout the process, along with several other libraries, each specialized for a particular task. The following data preprocessing steps were applied.

First, we removed all non-English reviews. We were only interested in English reviews at this point since our dataset contains reviews in different languages such as Portuguese, Spanish, and German. These reviews make up about 12% of our dataset (9576 reviews), and it was safer to remove them than to translate them into English. A total of 72,084 user reviews in English were identified in this step using the Python library langdetect. These reviews were used for all analyses performed in this study.

We then converted the text to lowercase, performed an extensive spell check of every review, and made necessary corrections using the Speller Python library. Words such as "I," "are," "and," and "the" were considered "stop words" and removed, as such common words tend to dominate the results. We further removed any special characters and numbers from the reviews.

Second, lemmatization was performed, which is a process of grouping the inflected forms of words so that they can be analyzed as a single item. These forms are identified by the lemma of the word (ie, both "tracking" and "tracks" share the same lemma and become "track"). The lemmatization algorithm considers the morphological analysis of the words during data preparation [42]. Finally, we applied part-of-speech tagging, which determines the category of the word (eg, noun, adjective, adverb, verb) based on both its definition and context [43].

After data preprocessing, a new dataset was obtained with cleaned data that could be used for both topic modeling and n-grams identification. This new dataset comprised a collection of arrays of words. For example, the item in the previous dataset ''I love this app and it's easy to use'' is converted into the word array "love app easy use," which was used as such for further analysis.

Topical N-Grams Identification

The use of topical n-grams is common in text and topic mining, as is the NLP approach when tracking word or phrase frequencies [44,45]. For the purpose of this study, we implemented the analysis of the most frequent trigrams (ie, groups of three words used together) occurring in user reviews (textual user evaluation of the app). For example, applying this to our previously mentioned word array from the cleaned dataset "love app easy use," we could extract exactly two trigrams: (love, app, easy) and (app, easy, use).

These two trigrams would then be added to the trigrams extracted from other reviews, resulting in a total of 744,808 trigrams from 72,084 reviews.

Evaluation of the word combination was then used in conjunction with the users' numerical app assessment (ie, rating), which is often used as a proxy for sentiment (eg, [46,47]). User ratings for apps in Google Play Store are scored on a scale from 1 to 5, where 1 is the worst and 5 is the best rating an app can receive. In our study, scores below 3 were associated with a negative app assessment, whereas scores of 4 and 5 were considered positive. This approach is common in studies in this field (eg, [46]). The ratings were averaged by grouping ratings from reviews containing given trigrams.

Topic Modeling

Topic modeling is another text-mining and NLP method that is commonly used to discover latent topics in a corpus of text. Topic modeling has been shown to be useful for clustering documents or text, and is considered a probabilistic statistical technique for semantic structures [48]. In this study, we used the Python Gensim library, which is commonly used in NLP, for topic modeling analysis. This library helped us to build a mathematical model that could classify each review by topic. The list of possible topics was determined during model training, and we predetermined the number of possible topics. To find the most appropriate number of topics, we used the coherence score. Topic coherence measures the degree of semantic similarity between the highly scored words in the topic, which can help to distinguish between topics that are semantically interpretable and topics that are artifacts of statistical inference [49]. This value is given after each model training process and helped us determine the performance of our trained model.

Finding the best number of topics that would give optimal results required several trials, starting with a randomly selected number of topics until we narrowed down to the model with the best score. We would simply select this model and apply it to our dataset. For example, if our model found 11 topics in the dataset, for each review in our dataset, the model would provide us with the probabilities of how likely the review is to belong to each of the 11 topics.

Results

Topic Modeling

Topic Selection Process

Since topic modeling is an unsupervised method, it was not constrained by certain predefined standards (ie, number of topics). Instead, for the first run, we programmed the script to start with only 2 topics, repeat and increase by 4 (since this is a computationally intensive and demanding process, we had to minimize the number of runs) until reaching 30 (ie, finding optimal number of topics anywhere between 2 and 30 topics). This high number was randomly chosen to find the optimal range for our topic number. This analysis revealed that the number of topics with the best coherence score was between 6 and 13 (Figure 1). For the second iteration, we again reprogrammed the script to repeatedly run in this range, this time increasing by 1 to more accurately determine the best score. The best coherence (0.646) was achieved with 11 topics (Figure 2, Table 2).

Figure 1. Topics coherence score (range between 2 and 30 topics). Num: number.

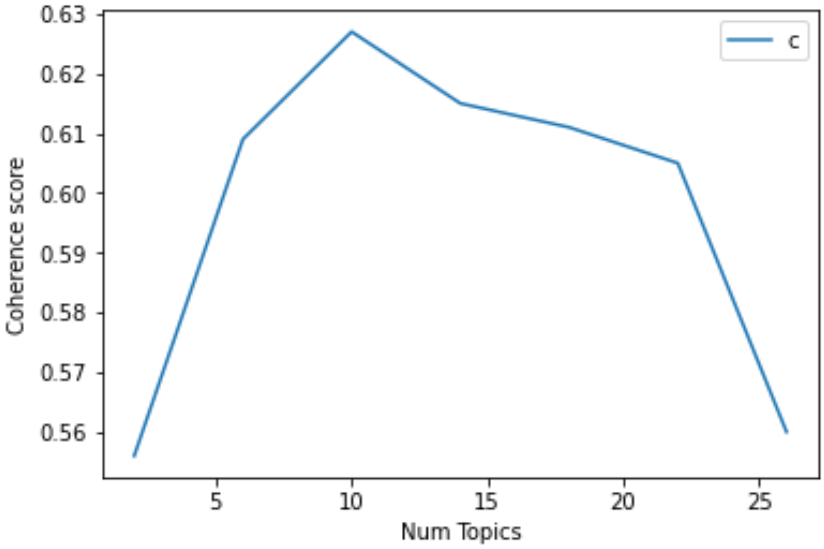

Figure 2. Topics coherence score (range between 6 and 13 topics). Num: number.

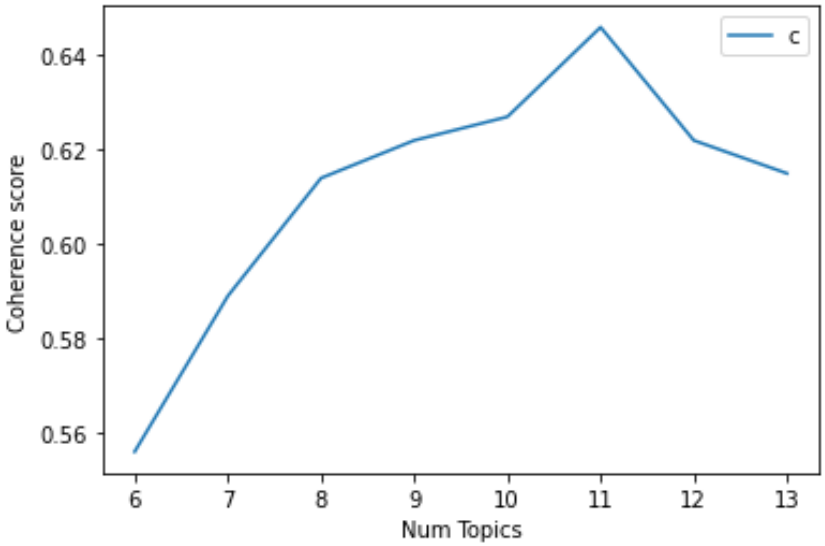

Table 2. Coherence scores for 6 to 13 topics.

Number of topics	Coherence score
6	0.59
7	0.618
8	0.617
9	0.614
10	0.614
11	0.646
12	0.618
13	0.622

Identified Topics

Most of the identified topics included the use of positive words when describing apps in the reviews. In their feedback, users often use words such as “love,” “nice,” “easy,” “good,” and “amaze” to describe the apps. Positively rated topics were more common than negatively rated topics. Users who leave feedback for diet-tracking apps positively rate the possibility to track their

food intake; use food scanners and create/access food databases in the apps; and consider the apps to be user-friendly, convenient, and easy to use overall. Weight loss was another important topic, appearing in 10% of user reviews (Table 3).

By pairing the topics with the average ratings of user reviews from the topic, we found that difficulties with cancellations, payment plans, and charges seem to bother users the most (topic average rating 2.32). One of the users described her experience as follows:

> *Personally I felt company was highly interested in my weight loss journey before I activated plan then no one cares about me, or I noticed they've charged me for another 3 months subscription which I did not authorize. I've made 3 attempts via email to make contact with [app] to end my membership and request a refund and I received an email back stating they'll be in contact in the next 48hrs but I have never heard back from them.*

In addition, technical difficulties appear to create issues in using the app (average topic rating 2.84):

> *Good app when it works. Otherwise, there's too many bugs. It lags too often and takes a long time to load…*
>
> *Stopped working. When I try to add food or search it's a blank screen. Please fix!*

Table 3. Modeling results for 11 selected topics.

Topic	Words	Mean rating	Proportion of reviews (%)
Health and fitness tracking	App, great, work, good, health, step, fitness, tracker, sync, google	4.413731	10.00
Macros tracking	App, great, love, track, awesome, carbs, fat, diet, macro, feature	4.590072	8.13
App praising	App, good, food, thing, lot, find, put, log, info, pretty	4.342717	7.34
App support	Give, room, program, coach, support, day, information, follow, people, plan	4.264332	7.21
App charges	Free, pay, version, plan, premium, cancel, money, charge, month, trial	2.329310	8.96
Weight loss	Weight, lose, week, goal, loss, start, pound, year, month, set	4.697312	10.94
Intake tracking	Calorie, track, exercise, intake, count, daily, day, water, great, burn	4.578164	10.06
Food adding and database	Food, add, meal, option, item, database, recipe, enter, list, search	3.872253	8.77
App “loving”	Easy, love, food, helpful, scan, user, simple, find, scanner, feature	4.709999	12.67
Diet change	Eat, make, change, diet, healthy, recommend, choice, learn, life, habit	4.780649	8.37
Technical issues	Time, work, log, update, day, star, back, phone, issue, problem	2.848619	7.53

Topical Trigrams

Overall Ratings

Similar to the topic modeling results, our overall trigram analysis suggested that, on average, users rate the diet-tracking apps positively in their reviews (Table 4). Trigrams indicating the apps’ ease of use and helpfulness (21/50 top trigrams by frequency of mention), the expression of liking/loving the app (13/50 top trigrams by frequency of mention), and the apps’ tracking option (19/50 top trigrams by frequency of mention) dominated the top 50 trigrams identified from the pool of user reviews. These topics were also frequently associated with high average app ratings; 49 of the top 50 trigrams by frequency attained ratings over 4.

Table 4. Top 50 most frequently mentioned trigrams.

Trigram	Count	Mean rating	Category
(app, easy, use)	948	4.772152	Easy Use/Help
(help, keep, track)	895	4.773184	Easy Use/Help; Tracking
(keep, track, calorie)	591	4.626058	Tracking

(best, app, ever)	142	4.929577	App Liking

[a]N/A: not applicable; no relevant category.

The number of mentions of positive and negative trigrams in user reviews also showed a trend of positive evaluation dominance among users leaving reviews. The top 50 most frequent positive trigrams appeared 12,723 times, while the top 50 most frequent negative trigrams were mentioned 1270 times in our dataset of 72,084 user reviews.

Positively Evaluated App Characteristics

With respect to positively valenced user ratings, we identified a significant presence of reviews praising the apps in general. Most of the top 50 positively rated user reviews refer to the apps' ease of use and helpfulness (21/50 top positive trigrams by frequency of mention), intake and calorie tracking (20/50 top positive trigrams by frequency of mention), and weight loss (6/50 top positive trigrams by frequency of mention) (Table 5). Users generally characterized the apps as "very easy to use and intuitive" and "easy to use and pretty straightforward." The ability to track their intake is described as "keeps me accountable" and "very informative about the diets you choose." Some users also viewed the apps as contributors to their better and healthier food choices:

> *Helps get a better understanding of the different foods calorie loads so I can make better choices.*
>
> *Easy to check total carb, fat and protein content and individual food values so I can make better choices next day.*

Similar comments were found for weight loss:

> *Teaches you how and why you need to change your eating habits;*
>
> *Mind changing weight loss program;*
>
> *This is about sustainable weight loss...*

Table 5. Top 50 “positive” trigrams (most frequently mentioned trigrams with ratings over 4).

Trigrams	Count	Mean rating	Category

Negatively Evaluated App Characteristics

Based on our results, an aggressive approach to advertising premium app options, and unclear policies of subscription charges and cancellations seem to be particularly problematic (15/50 top negative trigrams by frequency of mentions). The reviews also indicate that constant display of ads and reminders about premium app options often lead users to delete the app, as illustrated by the following excerpts from the reviews:

> *Every time I open the app it pushes its premium service at me. I get that they are here to make money, but seriously, just throw a nonintrusive ad window in somewhere and don't pester me.*
>
> *Go for alternatives until these guys stop giving you ads for paid plans.*
>
> *NO MONEY BACK NO MATTER WHAT. This app didn't work for me since I'm not overweight. I tried it to give it a chance thinking it was what I was looking for, but it wasn't. and then found out that NO MATTER what, you can't get your money back once they have charged the subscription even if it's on THE SAME DAY.*

Given the size of the apps in question and their numbers of users, it is easy to see how the ability to upload content could be difficult to manage from a technical perspective. Nevertheless, 14 of the 50 most frequently mentioned negative trigrams refer to technical issues experienced by users (Table 6), which include app crashing, inability to use or open the app, and similar:

> *It freezes every time I try to add food or exercise.*
>
> *Not sure what's going on however ever since paid ads keep popping up the app has just gone down hill. Today in particular has been awful. Screen goes black, freezes. Constant crashing. I've used this app for 3 years now and am seriously looking at using another app.*
>
> *I really wanted to give this app 5 stars, especially since it's helped me to lose more than 20 pounds in the last 6 weeks. Unfortunately, the app itself is so laggy & buggy that I can't give it more than 1-star. Every time I shift between apps, [app] needs 15-60 seconds to start up. The whole app crashes on me at least 10 times a day.*

Some content-related complaints could also be found in reviews, such as "need to be able to add new food with more than the 100 grams" or "needs an option to let users easily add new foods and correct scanned foods that have incorrect nutritional data."

Adding new foods creates additional issues for users (5/50 top frequent negative trigrams). Namely, users' complaints in this area usually refer to the inability to add a product to the database due to technical challenges:

> *There's an option to add a new food item, but no way to save it.*
>
> *Would have been a perfect app but becomes utterly useless when trying to input my own foods. Everyone I enter the nutritional info it changes everything I put in to insane numbers like 2800 calories for cottage cheese.*
>
> *The reason I gave this a 4 is because the app doesn't always keep my information I add about new foods. It constantly says it's downloading the database for days on end.*

Table 6. Top 50 negative trigrams (most frequently mentioned trigrams with ratings lower than 3).

Trigrams	Count	Mean rating	Category

Discussion

Principal Findings

Despite extensive literature on nutrition apps and individual usage patterns in health and nutrition research, the investigation of these apps from the perspective of user-generated content (ie, publicly available user reviews) is in its infancy. Previous research has mainly focused on app development issues and feature evaluation to make apps more accessible and user-friendly (eg, [7,31]). Numerous studies have examined consumer opinions of existing apps through surveys, interviews, and qualitative content analysis. This existing research captured an overall positive assessment/evaluation of the available apps (ie, app liking), as well as users' perceptions of these apps as helpful and easy to use (eg, [8,15,50]). These findings were supported by our results, as was the importance of the diet-tracking feature to users [8] and the deterrent effect of ads [8,15]. In contrast to other studies that have incorporated user reviews to assess user perspectives on diet and nutrition apps using simple research methods to manually evaluate a smaller set of user reviews (eg, [8,50]), this study extends this knowledge, and includes over 70,000 user reviews that were evaluated and classified using text mining and NLP techniques.

In our study, we focused on the user perspective, and aimed to evaluate the diet-tracking apps and their features that are most frequently commented on by users in app reviews. Although users rated the apps they use very highly on average (the overall rating for all apps was 4.4 out of 5, with individual app ratings ranging from 4.1 to 4.7), some features could still be improved to enhance the user experience.

The predominant positivity in comments and reviews left by users online has already been noted in a recent study including 25 online platforms [51]. We can also support these findings for diet-tracking app reviews, as our results suggest that the users leaving reviews for diet-tracking apps generally tend to give positive ratings. The extracted topics show the prevalence of positive words used in reviews to describe apps, as well as the average ratings of user reviews. To provide diet-tracking app users with an even better experience, we recommend paying more attention to the food databases and the features for adding new foods to the app's database. Users are generally satisfied with the apps' functionality, while a richer database would make it easier for them to make choices, and they would likely feel more motivated than if they had to search for substitutes or go through long procedures to add a product. This is especially valid for apps that do not offer the option of adding products by taking a picture. As this is also one of the features associated with several complaints about technical issues (ie, difficulty in adding new, personalized food items or food scanning), working on advanced technological solutions, enriching the database, or working on a stronger network of products within food categories could reduce the negative evaluation of user experience.

Hidden costs and inadequate communication about the cost of using the app are some of the main reasons reported for users to stop using an app [8]. We also identified these issues as a source of numerous complaints from users leaving app reviews, along with the users' inability to get their money refunded. Therefore, to retain users and keep them satisfied and loyal, an app should provide adequate, clear, and respectful communication regarding the costs that may be incurred through app use (eg, paid premium versions, in-app purchases, refund policies).

Limitations

Although this study provides valuable insight into user opinions, it is not without limitations. Owing to feasibility constraints, we focused on available reviews and introduced a set of constraints that allowed us to structure and summarize the otherwise diverse user-generated content in the form of app reviews. Future research could apply other text-mining approaches for data collection, cleaning, and analysis. In performing similar studies, it may be beneficial to differentiate users and their motivations for using the diet-tracking app. This can be done (to a certain extent) by a deeper investigation of the review content and its sentiment.

The use of additional methods (eg, surveys, focus groups, or interviews) would be necessary to include and understand the opinions of users who do not leave feedback in the form of a review and to generalize the findings to the entire population of diet-tracking app users.

In addition, users from different cultures may have different app needs (eg, product availability, serving size differences, religious and other food restrictions). To ensure the generalizability and applicability of such findings to a specific market, the results should also include analysis of additional

apps and reviews (both global and local apps) in the local language.

This study focused on apps that offer their users the ability to count their calories and track their diets (ie, diet-tracking apps). Although these features are present in apps that are widely applicable (ie, nutrition apps), the results obtained in this study cannot be generalized to the entire segment of nutrition apps. The inclusion of additional selection criteria and apps would be necessary to claim broader applicability of the results. Similarly, reviewers (consumers who write reviews) have been shown to differ from other customers in terms of income, education, and purchasing behavior [52]. Since only a small proportion of users provide openly worded text, an analyst should be aware of nonresponse bias and how a reviewer's sentiments can be directly correlated with the sentiments of previous reviews, which affects the corpus in which posts are public [53]. Hence, our results cannot be generalized to the entire population of app users.

In addition, only apps that had the highest download numbers in the market were selected for this study. This selection was made due to their greater impact and ability to influence more individuals. Moreover, these apps make frequent updates to provide better service to their users, support the growing network of users, and avoid technical issues that are usually the subject of user complaints, including those in reviews. Because of these efforts, the apps used in this study were also quite homogenous in terms of their ratings (all 15 apps were rated above 4.1 out of 5). Including a broader range of apps (both in terms of greater variation in ratings and in terms of number of users and downloads) may reveal additional challenges users face when using diet-tracking apps.

Conclusions

Assessment of 72,084 user reviews for diet-tracking apps revealed an overall positive user evaluation. Users highly value the ability to track their food intake and manage their weight. Nonetheless, there is significant room for improvement, particularly in the area of charges associated with app use and features that enable adding food to the apps' databases. The findings of this study provide relevant insights into user opinions and evaluations of diet-tracking apps.

The implications of this study go beyond those for app developers as stakeholders; for example, in cases concerning health and nutrition, public policy and official institutions should be involved. Digital participation of current and future generations is increasing; there is also evidence that mobile apps are a potentially useful tool for shaping and tracking users' diets [8,14]. By exploring users' experiences with apps, along with their suggestions and comments, it is possible to better support the apps they need and improve their eating habits, health and diet management, and nutrition-related well-being.

Abstract

Background: Supported self-management for asthma reduces acute attacks and improves control. The internet of things could connect patients to health care providers, community services, and their living environments to provide overarching support for self-management.

Objective: We aimed to identify patients' and clinicians' preferences for a future internet-of-things system and explore their visions of its potential to support holistic self-management.

Methods: In an exploratory sequential mixed methods study, we recruited patients from volunteer databases and charities' social media. We purposively sampled participants to interview them about their vision of the design and utility of the internet of things as a future strategy for supporting self-management. Respondents who were not invited to participate in the interviews were invited to complete a web-based questionnaire to prioritize the features suggested by the interviewees. Clinicians were recruited from professional networks. Interviews were transcribed and analyzed thematically using PRISMS self-management taxonomy.

Results: We interviewed 12 patients and 12 clinicians in the United Kingdom, and 140 patients completed the web-based questionnaires. Patients expressed mostly wanting a system to log their asthma control status automatically; provide real-time advice to help them learn about their asthma, identify and avoid triggers, and adjust their treatment. Peak flow (33/140, 23.6%), environmental (pollen, humidity, air temperature) (33/140, 23.6%), and asthma symptoms (25/140, 17.9%) were the specific data types that patient most wanted. Information about asthma and text or email access to clinical advice provided a feeling of safety for patients. Clinicians wanted automated objective data about the patients' condition that they could access during consultations. The potential reduction in face-to-face consultations was appreciated by clinicians which they perceived could potentially save patients' travel time and health service resources. Lifestyle logs of fitness regimes or weight control were valued by some patients but were of less interest to clinicians.

Conclusions: An automated internet-of-things system that requires minimal input from the user and provides timely advice in line with an asthma action plan agreed by the patient with their clinician was preferred by most respondents. Links to asthma information and the ability to connect with clinicians by text or email were perceived by patients as features that would provide a sense of safety. Further studies are needed to evaluate the usability and effectiveness of internet-of-things systems in routine clinical practice.

asthma; supported self-management; telehealth; mobile application; internet-of-things

Introduction

Asthma is a chronic disease, affecting 235 million people worldwide [1]. Supported self-management reduces emergency use of health care resources, improves asthma outcomes, and reduces morbidity [2-4]. The PRISMS (Practical Systematic Review of Self-Management Support for Long-term Conditions [5]) taxonomy consists of a 14-item list of strategies that have been used to support self-management in long-term conditions and which readers can select according to applicability to their context. In the context of asthma, these strategies include information about the condition, an action plan agreed upon between the patient and their clinician, self-monitoring of asthma status with feedback, recording of physiological measures, use of equipment, lifestyle, and social support. Technology can help support self-management [6], and many patients are interested in a broad range of self-management support strategies, with a seamless link to their clinician if needed [7]. The internet of things (IoT)[8] and wireless networks such as The Things Network (TTN; [9]), long-range wide area networks (LoRaWAN), Wi-Fi, and mobile networks, enable asthma status to be logged automatically by smart devices (eg, smart inhalers, smart peak flow meters, smart watches). Long-life invisible environmental sensors with embedded intelligence supported by Raspberry Pi [10] and Arduino [11] can measure indoor and outdoor environmental triggers which can be correlated to asthma logs that alert patients to changes status, give real-time advice on self-management, and can share data with health care advisors if necessary.

The IoT is a giant system comprising networks linking web-based services and clouds with online sensors and actuators. Sensors are able to communicate with each other to make distributed intelligent decisions in real time [12-15] An app or webpage can be provided to give users a *door* to interact with the system (eg, to view data dashboards; to receive advice; to receive reminders to collect data, reorder medication, or make appointments with their clinician). The IoT health care network has defined an IoT topology [16], which is an architecture and platform that can be used for diagnosis, personalized medication, emergency service, home rehabilitation, remote surgery remote monitoring, and self-management of conditions such as diabetes [17-20], hypertension [18,21], and asthma [18,22,23]. The implementation of 5G IoT will increase data transmission speed and reduce the transmission latency, allowing a faster and seamless service [16]. IoT interconnectivity between patients and their health care providers, the community services, and their living environment can be used to provide overarching and personalized patient self-management support.

There are many asthma-related smart devices in the market (eg, smart inhalers [24], smart spirometers and peak flow meters [25], respiratory rate sensors, wearable sensors that detect wheezing and sleeping patterns [26-28], and digital fraction of exhaled nitric oxide meters [29]), some of which have laboratory-proven accuracy [24,29,30]. Few, however, are able to be personalized to a patient's clinical profile, social preferences, and environmental context or integrated with a patient's electronic health records. Mobile systems that connect asthma smart devices and pull data from electronic health records [22,23] and apps that support asthma self-management [31] have been developed, but often, technology researchers focus on novelty and ensuring acceptability of their technology [32], rather than exploring the breadth of functionality that could support patients' everyday life of living with a condition and meet the demands of clinicians providing routine clinical care [33]. In contrast, clinical research typically focuses on evaluating older, established digital health technologies and their impact on patient health outcomes [34,35]. To our knowledge, there is no research that explores which IoT features are desired by patients and clinicians in the context of asthma self-management. We, therefore, aimed to explore the perspective of patients and clinicians on which self-management features (as defined by the PRISMS taxonomy) they would want in a future IoT system.

Methods

Ethical Approval

This mixed methods study was conducted between May 2019 and January 2020, with the approval of the National Health Service (NHS) London Fulham Research Ethics committee (ref 19/LO/0703). The study was sponsored by the University of Edinburgh and the NHS Lothian (Academic and Clinical Central Office for Research and Development). All participants were fully informed about the study and provided their consent.

Design

We used qualitative interviews and a web-based questionnaire to explore patients' and professionals' vision for future IoT features. We adopted an exploratory sequential design [36], using qualitative interviews with purposively selected patients and clinicians to identify the preferred IoT features, which in turn were used to inform a web-based questionnaire in a wider asthma patient community enabling triangulation of interview findings.

Patient and Clinician Recruitment

Patient Recruitment

We included UK-based adult patients who were actively using treatment for asthma [37] and excluded anyone who needed carers' support to manage their asthma. We recruited patients from volunteer databases and asthma charities social media. We identified patients in the Scottish Health Research Register (SHARE) [38], Register for Asthma Research (REACH), and Asthma UK volunteer database [39]. People registered in these databases have given consent to be contacted about asthma research. Eligible patients were invited with emails sent by SHARE, REACH, and Asthma UK, which included a recruitment link on behalf of the research team. We also posted advertisements on Asthma UK and Asthma UK Centre for Applied Research (AUKCAR) Facebook and Twitter that included a recruitment link. People who were interested in the

study used the link to register their interest. They were asked to read the information leaflet, confirm their eligibility, provide basic demographics, and give consent to be contacted (via the contact details they provided) in order complete the registration.

Sampling for Qualitative Interviews

We purposively recruited a maximum variation sample of 12 patients to take part in individual interviews. Sampling was based on age (16-25 years, 26-45 years, 16-65 years, 65 years or older); ownership of an action plan (or not); duration of asthma (diagnosed <6 months, 6-12 months, 1-10 years, >10 years); hospital admission in the previous 12 months (or not); confidence with using technology (ability to download apps by themselves, need help, never tried).

Clinician Recruitment

We recruited health care professionals from primary and secondary care through newsletters and social media (the NHS Research Scotland Primary Care Network and professional bodies such as the Primary Care Respiratory Society and the NHS Lothian Respiratory Managed Clinical Network). We also approached individual professionals who were actively involved in clinical care or research through personal networks.

Data Collection

Think-Aloud Qualitative Interviews

We adopted a think-aloud approach [40] to explore patients' and professionals' preferences on the future design and utility of IoT systems to support asthma self-management.

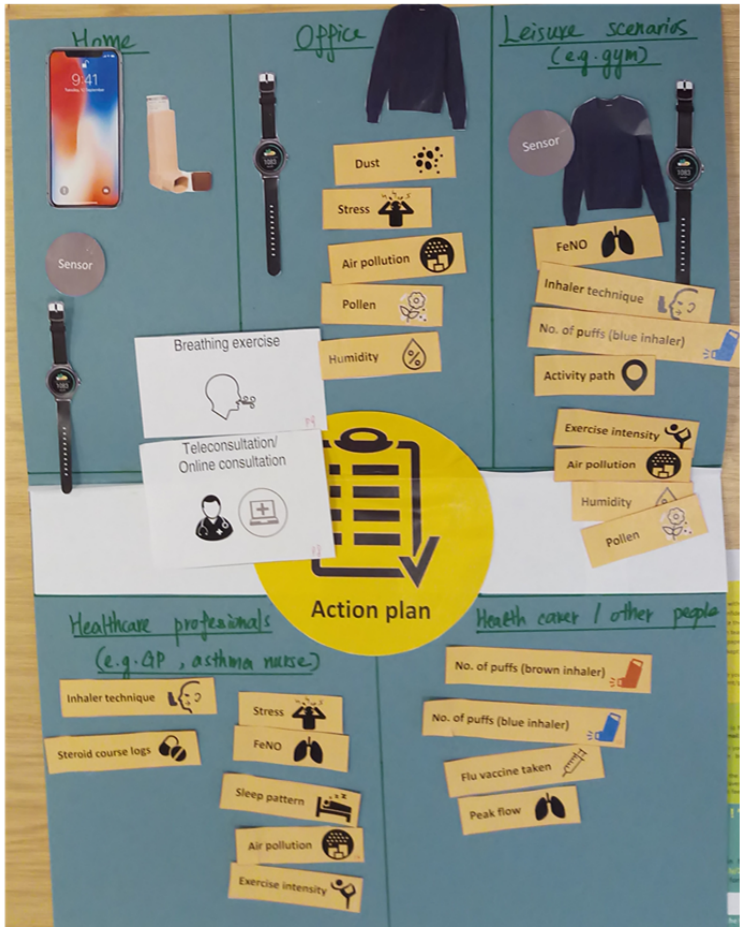
We asked patients to complete 2 tasks in the interview. For task 1, we provided a list of the most wanted app features (Multimedia Appendix 1) identified in our previous study [7] and asked patients to think about their previous usage of asthma apps and their previous asthma self-management experience to decide the features that they would want to be included in a future IoT system, and how often they think they would use them. For task 2, we provided images of current and future potential smart devices in the market (smart inhaler, smart peak flow meter, smart fabric, smart watch, voice assistant, smart purifier, human robot, and robot pet) and available data and asked patients to discuss their future potential. Specifically we asked them to use the images to create a IoT system that they would want to support their daily self-management, and if, how, and when they would use each device for self-monitoring and what data (if any) they would want to be able to send to their health care professionals and their health carers, for example, parents or spouse. (Figure 1 is an example of a task completed by a participant.)

At the end of each task, participants were asked to add any features, data, or smart devices that they thought would be useful but that were not included in the list or images (or were not yet available).

Professionals were asked to think about their previous experiences providing care for people with asthma and select the features from the list [7] that could support self-management and data that they would like to receive in order to assist their consultations with patients.

Finally, we showed participants a prototype app (an interface app which included many wanted features [7]) to stimulate their thoughts on how they would like to interact with a self-management support IoT system (Multimedia Appendix 2).

Figure 1. An example of a task completed by a participant.



Development of the Web-Based Questionnaire

The web-based questionnaire aimed to quantify the features wanted by interviewees and their perceived usefulness enabling us to triangulate the findings. Participants' feedback in the qualitative interview informed the features listed.

The questionnaire (Multimedia Appendix 3) collected basic demographic information (age group and gender) and asked questions regarding what data that they would want an IoT system to collect and where they would want the data to be collected. The flow of questions reflected the sequence that we used in the interviews. To reduce instances of missing data, each question had to be completed before progressing to the next. First, we offered a list of features based on our previous research [7] and the interview responses. Survey participants were asked to select the top 5 types of data that they would like collected by the IoT system and to prioritize them. A free-text option was provided. Second, we asked participants to choose where it would be most useful for the technology to collect these data. The choices were informed by the interviews—"home," "at work/office/school," "the place where they are at leisure activities that they do regularly (eg, gym, running, etc)," and "others." If participants chose the leisure option, we asked the participants to specify which leisure scenario they thought was relevant to that data type. We offered a variety of activities informed by the interviews and a free text option.

Administration of the Web-Based Questionnaire

We used Bristol Online Survey, a secure web-based survey platform that complies with ISO27001 information security standards and the General Data Protection Regulation, to build the web-based questionnaire and collect data. To test content validity and readability, we invited a patient volunteer and an independent researcher to try out the questionnaire independently. Their feedback was incorporated in the questionnaire before it was sent to participants. Potential participants who had not been selected for an interview and who had given permission to be contacted regarding the survey were emailed a participant information sheet and a link to the questionnaire.

Data Analysis and Synthesis

Qualitative Analysis

Interviews were digitally recorded, transcribed, and coded in NVivo (version 12; QSR International). We used PRISMS taxonomy [3] as a framework to categorize the IoT features (themes) that emerged from the interviews. In addition, our thematic analysis explored issues of particular importance to the participants. One reviewer (CYH) coded 2 interviews (patient, professional) independently, and another reviewer (HP) reviewed the coded transcriptions to standardize the coding, which was then applied (by CYH) to all the transcriptions. CYH (reviewed by HP) coded features suggested by patients and professionals separately and extracted the features, which were then combined in tables for comparison. We categorized the

individual assessments of the features as would "always use," "often use," "use when needed," or "less likely to use" according to the words used in the interviews (Table 1). In our previous study [7] on self-management features wanted by patients' and clinicians', no new app features were generated after 15 interviews. We estimated that a sample size of 12 would be likely to achieve data saturation and was within our resources for conducting individual interviews.

Table 1. Defining patients' perceptions of potential future usage.

Usage	Examples of words used by patient interviewees
Always use	"always use," "would always use," "very helpful," "would be good," "more important," "definitely a must"
Often use	"would often use," "would be good," "really/extremely useful," "it might be useful," "something that I'd probably use often, if I could, or if I can"; "once a month," "quite/might be/ useful," "might interest me"
Use it when needed	"safety net," "absolutely need it," but like "rare occurrences," "once a year," "very important just to remind yours occasionally," "it wouldn't be like every day," "a bit of a waste of time if you have that popping up every day," "check in on regularly"
Less likely to use	Unlikely to use because "I know what to do" "the factors do not affect me", "the feature is already provided by the current practice", "no need to have this feature as an extra"; or they "hope not to use this feature very often" or "would not rely on it"; or they "haven't used it before".
Not applicable	"Does not apply to them"; "no point in it"

Quantitative Analysis and Triangulation of Findings

We used descriptive statistics to analyze patients' preference ratings for the data they would like a future IoT system to collect and in which circumstances the system would be most useful. We used data from the survey to quantify the features wanted by interviewees and their perceived usefulness.

Interpretation

The findings, data synthesis, and interpretation were discussed regularly within the multidisciplinary study team, which included a patient representative, technology developer, health care professionals, and researcher. The researcher had an engineering and technology background and clinical research experience with patients and clinicians in asthma app development.

Results

Participants

Patients

Invitations were sent by email to 572 patients (SHARE n=211; Asthma UK n=220; REACH n=141). Advertisements were posted to the Asthma UK's Facebook and Twitter (185,800 followers) and AUKCAR Twitter (1224 followers). Of 362 patients who expressed interest in the study, 297 (82.0%) were from Asthma UK's social media, email, or website; 42 (11.6%) were from the AUKCAR Twitter; 10 (2.8%) were from SHARE; 3 (0.8%) were from REACH, 2 (0.6%) were recommended by their hospital or a relative, 8 (2.2%) received an e-mail invitation from Asthma UK and others responded to our advertising. Of the 362 patients, 12 were selected for an interview, and the remaining 350 were invited to complete the web-based questionnaire: 3 rejected the invitation (2 were no longer available to take part and 1 declined when they realized there was no payment), and 29 were undeliverable emails. Thus, 318 were sent the web-based questionnaire link, of whom 140 (44.0%) completed the questionnaire. Of the 140 participants, 139 participants (99.3%) completed the questionnaire within 15 minutes, and 1 person (0.7%) appeared to take 3 hours and 42 minutes to complete the questionnaire (most likely because the *thank you* page was not closed after completion). There were no instances of missing data.

Of 152 participants (12 interviewees and 140 web-based questionnaire respondents), most (74/152, 49%) were 46 years to 65 years of age, 69.1% (105/152) were female, 54.6% (83/152) had an action plan, 75.0% (114/152) had been diagnosed with asthma for more than 10 years, 12.5% (19/152) had been admitted to hospital in the previous 12 months, and 86.2% (131/152) were confident that they could download apps themselves (Table 2).

Table 2. Characteristics of patient participants.

Patient characteristics	Interviewees (n=12), n (%)	Questionnaire respondents (n=140), n (%)
Age (years)		
16-25	3 (25.0)	2 (1.4)
26-45	2 (16.7)	39 (27.9)
46-65	3 (25.0)	71 (50.7)
>65	4 (33.3)	28 (20.0)
Gender		
Female	8 (66.7)	97 (69.3)
Male	4 (33.3)	42 (30.0)
Prefer not to say	0 (0.0)	1 (0.7)
Action plan ownership		
Yes	4 (33.3)	79 (56.4)
No	3 (25.0)	16 (11.4)
No asthma action plan but I have been told what to do	5 (41.7)	45 (32.1)
Diagnosed with asthma		
Less than 6 months	0 (0.0)	1 (0.7)
Between 6 months and 1 year	0 (0.0)	1 (0.7)
Between 1 year and 10 years	4 (33.3)	32 (22.9)
More than 10 years	8 (66.7)	106 (75.7)
Admission to the hospital because of asthma in the last 12 months		
No	8 (66.7)	125 (89.3)
Yes and now my asthma care is provided by general practitioner/asthma nurse	1 (8.3)	5 (3.6)
Yes and I am still attending the hospital (specialist) clinic	3 (25.0)	10 (7.1)
App download experience		
I download apps by myself	12 (100)	119 (85.0)
I usually ask someone to download apps for me	0 (0.0)	5 (3.6)
I have never downloaded an app	0 (0.0)	16 (11.4)

Professionals

Twelve professionals were recruited from primary, secondary, and tertiary care in the United Kingdom. All provided care for people with asthma, and some had research experience using digital technology to monitor patients' medication use and symptoms for respiratory patients (Table 3).

Table 3. Characteristics of professional participants.

Professional role	n	Experience[a]	Additional description
General practitioner	2	>8 years	Primary care: respiratory lead n=1; accident & emergency experience n=1
Asthma nurse	2	>20 years	General practice asthma-trained nurse n=2
Pharmacist	4	1-20 years	Respiratory pharmacists n=3; community pharmacist n=1 (reviewing patients during asthma admissions or when referred by general practitioner or asthma nurse; checking inhaler technique, choosing devices, addressing medication adherence)
Consultant chest physician	1	__[b]	Secondary and tertiary care (severe asthma center and community lead)
Asthma pediatrician	3	__[b]	Lead consultant in a pediatric asthma service n=1; Using smart inhaler n=1; 30 years of pediatric asthma research experience n=1 (looking after children with a range of asthma severities, conducting face-to-face consultation, determining patients' symptoms, making management plans, offering advice to general practitioners, and reviewing test results)

[a]Experience seeing patients with asthma on a regular basis.

[b]Information not available.

Mixed Methods Assessment: Features and Their Perceived Usefulness

Interview Themes

Perceptions of the 12 patients about the potential usefulness of features were mapped to the PRISMS taxonomy (Table 4; the full version can be found in Multimedia Appendix 4). Features wanted by patients reached saturation within 10 interviews, and we stopped sampling at 12 interviews.

Patients decided the usefulness of potential IoT features based on their own past asthma self-management experiences (eg, ownership or use of action plan and smart peak flow meter, their relationship with their clinicians, medication usage, use of emergency services), their asthma triggers, their curiosity about what affected their asthma, the severity and control of their asthma condition, and what they considered (or had been told by professionals) was best practice for asthma.

Monitoring, supported by feedback advice, was the feature that most patients wanted to see in an IoT system. Information about asthma and an action plan were also priorities. Flexible access to follow-up advice with a general practitioner or asthma nurse by text or email service were "safety net" features that most patients thought would create a sense of "staying connected" with clinicians, although they stated they would only use it when needed. One patient with hearing problems who struggled to communicate during an exacerbation wanted a panic button to automatically text for emergency help. Perceptions on monitoring of control, and feedback are presented in more detail below. Other features were wanted by patients but were lower priority (Multimedia Appendix 4).

Table 4. Summary of the potential usefulness of features mapped to the PRISMS taxonomy [5].

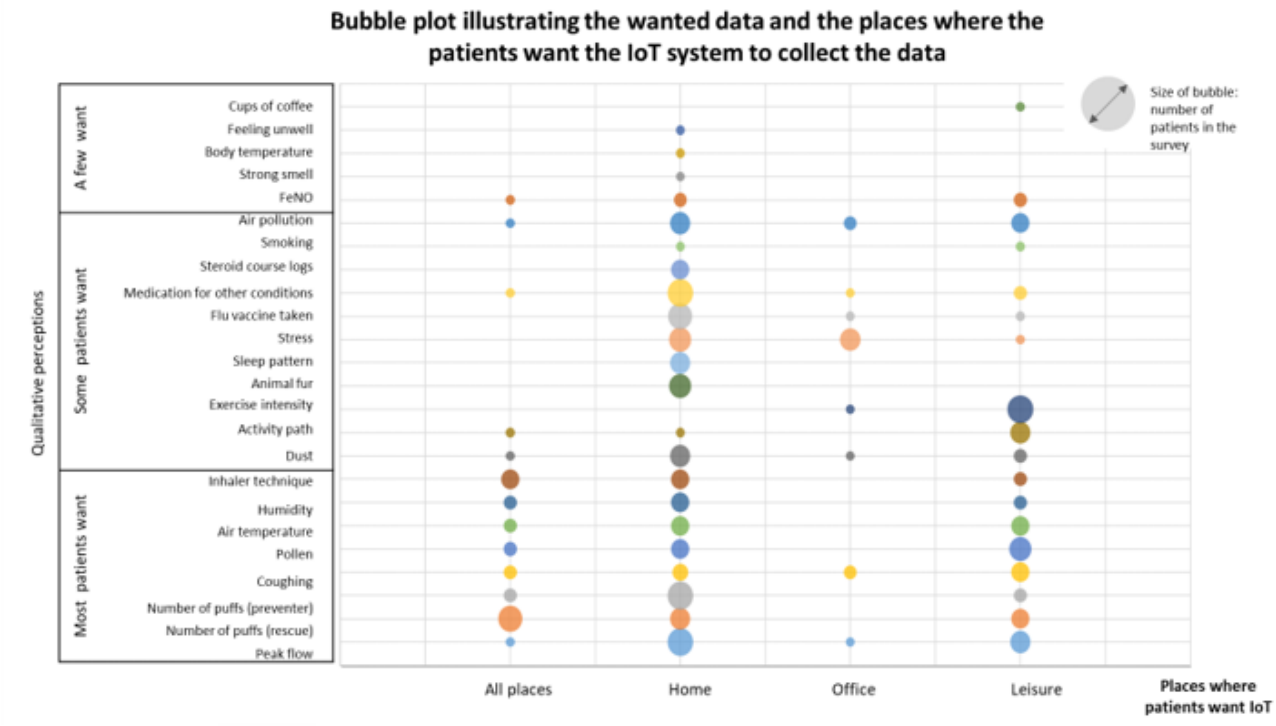
Theoretically based support	Features	Patient	Clinicians
Information about asthma and available resources	Information about asthma management	Online information was of interest, ideally personalized to clinical context and individual situation (eg, broad range of information for newly diagnosed, safety net information for experienced patients)	Professionals considered that reputable information such as inhaler technique videos, treatment information, why and how the medication should be taken were important for patient self-management
Provision of action plan	What to do when condition gets worse	Most patients wanted a (digital) action plan to remind them what to do when they forgot the agreed actions when their conditions were getting worse	Most clinicians suggested an action plan to remind about medication adjustment and agreed actions if patients' condition was getting worse
Regular clinical review	Routine review reminder; remote options.	Most patients wanted reminders for the yearly review. Some preferred web-based or teleconsultation consultation for regular reviews to save travel time	Most professionals thought reminders would encourage attendance, and agreed remote consultations were convenient though not always clinically appropriate
Monitoring condition with feedback	Logging asthma symptoms, peak flow, and medication use.	Most patients wanted automatic logging with intelligent feedback and the facility to transfer data to the hospital or general practitioner practice. Reminders could be useful though ideally only generated when their asthma was bad. Some patients wanted alerts when they had increased use of rescue inhaler	Most clinicians thought objective data would help them assess status and help patients understand their triggers. They were skeptical that reminders would improve adherence to logging. Flagging excess or increasing use of recuse medication could alert patients and professionals to poor control
Practical support with adherence	Medication reminders and support	Some patients thought reminders to take medication were useful if they were busy or forgetful but would not change opinions. Automatic prompting reordering of medication was wanted. Most patients wanted flu vaccine alerts	Clinicians wanted medication adherence logs and agreed with low-medication alerts to facilitate reordering. Warning about overordering were also important. Flu vaccination reminders should pop up in both patients and clinicians' system
Provision of equipment	Smart devices	Most patients wanted to try smart devices (inhalers, peak flows, activity trackers)	Clinicians generally interested in how the whole technology system, as opposed to how individual smart device can support patients
Provision of easy access to support when needed	Panic button for emergency	A few patients suggested this would be helpful because it could be difficult to speak during exacerbations	Clinicians generally considered this was a duplicate emergency system, though might be useful for brittle high-risk asthma
Communication with health care professionals	Emails, texts, and WhatsApp messages	Most patients wanted flexibility to ask quick follow up questions, and a patient with hearing problems found WhatsApp useful	Clinicians agreed with a flexible approach to reviews, including text services for quick follow up questions, though resources would be needed
Training for everyday activities	Air pollution/pollen high alert	Most patients wanted environmental features, and some young patients (16-25 years old) suggested it could identify triggers and help them to plan their day	Clinicians were less interested in these data, though some thought environmental information could help patients to understand (and avoid) triggers
Training for self-management activities	Incorrect inhaler technique alert	Most patients thought it was good to be prompted when their inhaler technique was incorrect	Most clinicians wanted inhaler technique checks with real-time alerts for patients recorded for discussion at a review
Training for psychological strategies	Breathing exercise	Some patients wanted breathing exercises to keep themselves calm and considered it would help their asthma	Most clinicians were keen to encourage patients to do breathing exercises to improve asthma symptoms
Social support	Social media and alerts	One patient wanted a friend alerted when she was admitted to the hospital	One clinician suggested a social media page to enable sharing of experiences
Lifestyle advice and support	Physical activity and weight loss	Some patients wanted to connect asthma logs with their activity tracker, while others would use a weight watching facility	One clinician suggested an individualized fitness program for people with severe asthma, and 2 clinicians wanted individualized weight management plans

Survey Findings and Triangulation With Interview Themes

The responses to the survey are illustrated with a bubble plot (Figure 2). In keeping with the priorities of the interviewees, the largest bubbles represent monitoring of symptoms (prioritized by 25/140, 17.9%) and peak flow measurement (33/140, 23.6%). For most respondents (24/32, 75.0%), this was a task to be undertaken at home, though some considered that symptom monitoring could be useful at home, work, or leisure

locations. Monitoring environmental asthma triggers (pollen, humidity, air temperature) was prioritized by 23.6% (33/140).

Figure 2. Information that patients want internet-of-things system features to capture. FeNO: fractional exhaled nitric oxide.



Qualitative Perceptions of Specific Features

Smart Devices for Monitoring Asthma Control

Some patients explained that a peak flow was "useful" and "needed" to help clinicians assess their asthma. Most professional interviewees agreed with this and thought that a log of peak flows, symptom scores, and medication use would engage patients and could inform assessment of control and management strategies.

> *I see particularly important is logging asthma symptoms and medication use. Peak flow, maybe less so, but the symptoms and medication use I think are very important. although peak flow is far from perfect, it just shows that the patient has engaged to some degree, that they're seeing differences, whether it's in the morning or evening or when they...after exercise and they're engaged with that, so I know when I ask them some questions about their symptom experience that they're thoughtful about it.* [Health care professional 7, general practitioner]

However, in contrast to the priority attached to logging, most patients acknowledged that in reality they checked their peak flow "rarely" or "only when their asthma was getting worse." The reasons for not measuring every day were varied. Some "forgot," while others felt "weird doing it in front of people," but many suggested it was unnecessary as they knew their asthma and could assess status by how they felt.

> *Not very often. I do sometimes, if I get chest infections or if I get tight chested or if it's not, if I just feel there's something wrong, then I test what my peak flow is, just to see what it is.* [Patient 4, 26-45 years old, male]

> *I'm a big believer in logging things so that if you've got a history... I mean to log things, but I forget, so it would be good to have something there.* [Patient 5, >65 years old, male]

Several suggestions were made about how an IoT system could help overcome this discrepancy. A word that was used frequently was "automatic." Most patients wanted an IoT system that could automatically log their asthma condition. They were interested in trying smart devices (eg, smart peak flow meter); some explicitly mentioned that this would enable them to capture data automatically though they were not clear how the devices could capture their asthma status without some effort on their part. A device with an automated data transfer feature still requires the user to blow the air into the meter, and patients acknowledged that to do this regularly would require motivation such as a request from researchers or their clinician. Patients had different opinions on using voice assistants, smart watches, smart fabrics, smart purifiers, human robots, and robot pets to collect additional data automatically:

> *Smart peak flow would be the way forward I think, it really would, because it's recording it (my peak flow). If you say to me record it every day, I would record it every day...I very rarely use it (the current mechanical peak flow). But if this smart peak flow is going to record my peak flow at that particular time each day or twice a day, that's only going to be good to help me and to help my doctor understand, you know.* [Patient 2, >65 year old, male]

> *It would be good to have something that I could just quickly tell it what's happening. Probably not when I'm having an asthma attack because I can't talk.* [Patient 1, 46-65 years old, female]

> *I don't have my inhalers with me and my other sensors in the office, so for me, given I'm going in and out of meetings and various other things and travelling about and stuff, it's probably easier if I just have the watch and any clothing or something with sensors on it that can do it, in an ideal world.* [Patient 4, 26-45 years old, male]

> *(Voice assistant) It's not very secure, I don't like that.* [Patient 5, >65 years old, male]

How the data were used was an important motivator. Most patients said it was "good" or even "essential" that data from smart peak flow meters and inhalers were transferred automatically to the system so these logs could be correlated with other data and displayed graphically on a mobile phone. Some suggested that they would log peak flows if their clinicians asked them to do so.

Clinicians were keen to see a record of medication use to enable assessment of adherence. They favored automated logging of this information via a smart inhaler as that was perceived to be more accurate.

> *It would be very useful if the patient is logging their asthma symptoms and peak flow, medication use...because that's then helping us to adjust on treatment. I would love to know if they were taking it (prescribed medication) every day like they're telling me they are.* [Health care professional 4, prescribing support pharmacist]

Feedback and Advice

Patients in the interviews suggested a broad range of information and advice that could be usefully provided through an IoT system such as a timely alert when their asthma control changed; the amount of medication to be taken according to asthma control to reduce medication side effects; the numbers of doses taken and remaining in the inhaler, ideally with an option to order a repeat prescription when the medication was running low; and correct inhaler technique.

The clinician interviewees concurred with these priorities, especially the need for detecting poor inhaler technique and linking to information about correct use of an inhaler. They also saw value in feedback supporting treatment adjustment according to an action plan.

Environmental Data

Outdoor environmental data such as pollen, humidity, and air temperature were considered "good to know" and "useful" data by many patients. Patients who were newly diagnosed with asthma wanted to learn which environmental factors affected their asthma, whereas those who already knew what triggered their asthma wanted to use daily environmental data to plan their day.

> *(The outdoor environmental data) could maybe suggest like how likely they are to be actual triggers as opposed to me just thinking. Then if it suggests that I'm really triggered by something then I could put more effort to avoid that.* [Patient 10, 16-25 years old, female]

These data were of less interest to clinicians though some suggested that, together with indoor triggers, outdoor pollution, exercise intensity, weight, peak flow, and symptoms, data could provide real-time feedback and help patients understand which factors affected their asthma in order to avoid them.

Discussion

Principal Results

Both patients and clinicians expressed their interest in automated monitoring with real-time feedback within an IoT system that could support a wide range of self-management tasks. In the qualitative interviews, patients mostly wanted the system to log peak flow, asthma symptoms, and environmental triggers (pollen, humidity, air temperature); provide advice on relevant actions or medication adjustment to suit different levels of asthma control; and provide alerts about the number of doses of medication remaining and inhaler technique. The questionnaire responses quantified these preferences with the most wanted features being monitoring peak flow (33/140, 23.6%), environmental asthma triggers (pollen, humidity, air temperature) (33/140, 23.6%), and symptoms (25/140, 17.9%). Clinicians wanted automated objective logs about patient condition that they could access during a consultation. Patients considered that easy access to information and clinical advice, such as text or email communication via the system, provided a feeling of safety, while clinicians appreciated the potential reduction in face-to-face consultations because it would reduce patient travel time and the use of health service resources. Lifestyle logs (fitness regimes or weight control) were wanted by some patents but were of less interest to clinicians.

Strengths and Limitations

Our study identified the preferred IoT features for patients and clinicians and the type of data that they wanted the system to collect; however, there are some limitations. First, due to limited resources and time, we excluded children under 16 years old from patient interviews though we included experienced pediatricians to provide insights on the needs of children with asthma and their carers. Second, we did not manage to interview any patients who were newly diagnosed with asthma (within the previous year) who may well have had specific needs for information and support. Similarly, all our participants were familiar with downloading and using apps, suggesting that our recruitment strategy of using social media reached a technologically experienced population. Although this approach will have resulted in some perspectives being overlooked, the sample included in the study were demographically diverse, with a range of experiences of living with asthma, and could provide a range of perspectives on the potential of technological support. Increasingly, the global population is becoming more familiar with digital communication. However, we reached data saturation [41,42] in the qualitative analysis, and the web-based questionnaire, which attracted a broader range of patients, provided findings that were consistent with the qualitative data.

Third, though the features that participants said that they wanted were related to participants' past experience, we also used images of emerging technologies and stimulated discussion about novel features that could potentially contribute to managing their asthma.

Reflexivity

The researchers had engineering and research experience in developing asthma apps. To reduce the influence on the interview findings of the researcher's background, the coding and interpretation of results were discussed with study team members from different backgrounds and with different experiences, including general practitioners, a patient, and a technology developer. This range of expertise enabled the study to present a balanced interpretation.

Comparison With Published Literature

IoT is an option to support self-management. Asthma action plans, asthma education, and regular consultations with clinicians are core component of effective self-management; which aims to support patients achieve good control by recognizing when their asthma is getting worse and responding promptly and appropriately [43]. The features that patients wanted from the IoT system resonated with these aims (ie, such as facilitating learning about asthma and its triggers, logging asthma status, providing alerts to highlight deterioration and offering feedback advising on treatment adjustment and other actions). Features such as monitoring how much medication is left and inhaler technique can be delivered by smart inhalers that are already on the market.

There is, however, an anomaly. Most patients wanted features that enabled regular monitoring of peak flow and symptoms, but the literature suggests that this is rarely, if ever, achieved in real life [7]. For example, in the context of chronic obstructive pulmonary disease, patients who are more severely affected by their disease (ie, those who might find monitoring most helpful) were less likely to use communication technologies such as mobile phones, text messaging, email, and video chat [44]. Our interviewees acknowledged this discrepancy by explaining that they actually only logged their asthma control when they were concerned about increasing symptoms, but that, most of the time, they did not see the necessity of monitoring because they already knew the status of their asthma. Reminders are unlikely to solve the problem of nonadherence to logging because, when patients did not complete logs, it was typically intentional and not due to forgetfulness [45]. A solution suggested by both patients and professionals was to simplify data collection by automating the process and increase motivation by providing useful graphical feedback or linking with professional advice, though even this requires some input from the patient. Further advances may require the development of systems that that silently monitor use of rescue medication with a smart inhaler that requires no input by the patient and only alerts patients in the event of unusual behavior patterns (eg, increased usage) with advice from their action plan on jhow to regain control.

Monitoring is also influenced by whether the patients' clinician is interested in the results. Home monitoring with feedback has shown promise as a self-management strategy for people with hypertension [46] and diabetes [47]. The sense of having the ongoing interest and support of a clinician is a factor in maintaining motivation to self-manage [48]. Our interviewees felt "safe" if they had an easy way (text or email) to contact clinicians when they had concerns or needed clarifications. A recent review [49] of patients with asthma and chronic obstructive pulmonary disease revealed similar preferences for accessible support. Similarly, patients with type 2 diabetes wanted technology that allowed 2-way text communication with their clinicians.[50]. The professional interviewees in our study considered that, when text and email are offered as options, they have the potential to reduce face-to-face consultations and save health care resources.

Conclusion

An IoT system can encompass the range of components needed to support asthma self-management. Patients and clinicians preferred features that monitor asthma status (preferably using automated silent monitoring), provide timely advice in line with an agreed upon asthma action plan, and allow observation of environmental factors in relation to asthma control. Our technologically literate participants appreciated the ability to connect to asthma information, as well as easy access to clinicians by text or email. Sustained use was acknowledged as a challenge. Large-scale evaluation of usability, health outcomes, and resource implications are needed to realize the potential benefits of silent monitoring connected IoT systems.

Acknowledgments

CYH received funding from (Scotland) Chief Scientist Office and Asthma UK Innovation (grant CSO-AUK-2018-03) to plan and carry out the study. BM and HP received funding from European Institute of Innovation and Technology (grant 18113). The views expressed in this publication are those of the authors and not necessarily those of the Chief Scientist Office or Asthma UK.

We are grateful to patient and professional participants for taking part in this study; Asthma UK, AUKCAR, SHARE, and REACH for help with patient recruitment; the National Health Service Research Scotland Primary Care Network, Primary Care Respiratory Society, and Lothian Respiratory Managed Clinical Network for help with professional recruitment; and AUKCAR Patient Public Involvement group members for advice on the interview materials.

Authors' Contributions

CYH and HP designed the study. CYH extracted data. HP and synthesized the data. HP is the study guarantor. CYH and HP wrote the manuscript. BM reviewed the final manuscript. OF commented on the findings from patient perspective, and MB commented on implications from technology perspective. All authors approved the final version of the manuscript.

Conflicts of Interest

MB is managing director of Tactuum Ltd. OF contributes in a lay capacity to Teva Pharmaceuticals, AstraZeneca, and WEGOHealth.

Abstract

Background: Blockchain technology has the potential to enable more secure, transparent, and equitable data management. In the health care domain, it has been applied most frequently to electronic health records. In addition to securely managing data, blockchain has significant advantages in distributing data access, control, and ownership to end users. Due to this attribute, among others, the use of blockchain to power personal health records (PHRs) is especially appealing.

Objective: This review aims to examine the current landscape, design choices, limitations, and future directions of blockchain-based PHRs.

Methods: Adopting the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) guidelines, a cross-disciplinary systematic review was performed in July 2020 on all eligible articles, including gray literature, from the following 8 databases: ACM, IEEE Xplore, MEDLINE, ScienceDirect, Scopus, SpringerLink, Web of Science, and Google Scholar. Three reviewers independently performed a full-text review and data abstraction using a standardized data collection form.

Results: A total of 58 articles met the inclusion criteria. In the review, we found that the blockchain PHR space has matured over the past 5 years, from purely conceptual ideas initially to an increasing trend of publications describing prototypes and even implementations. Although the eventual application of blockchain in PHRs is intended for the health care industry, the majority of the articles were found in engineering or computer science publications. Among the blockchain PHRs described, permissioned blockchains and off-chain storage were the most common design choices. Although 18 articles described a tethered blockchain PHR, all of them were at the conceptual stage.

Conclusions: This review revealed that although research interest in blockchain PHRs is increasing and that the space is maturing, this technology is still largely in the conceptual stage. Being the first systematic review on blockchain PHRs, this review should serve as a basis for future reviews to track the development of the space.

blockchain; personal health records; electronic health records; distributed ledger; systematic review

Introduction

Background

Personal health records (PHRs) are a form of electronic health records (EHRs). PHRs are unique in that patients themselves can access, manage, and share their health information [1]. The benefits of PHRs include patient empowerment, which leads to improved outcomes and reduced health care costs [2,3]. Although interest in PHRs has been increasing, their adoption remains low [4,5]. One of the oft-cited reasons is related to privacy and security concerns owing to an increasing trend of

health information breaches [6,7]. Another reason is the lack of perceived usefulness to patients [7].

Blockchain technology was introduced through Bitcoin in 2008 [8]. It is considered a general-purpose technology and has since been successfully applied across several different industries [9,10]. In the health care industry, EHRs were found to be the most commonly used case for blockchain applications [11-14]. Compared with conventional data management methods that rely on on-premise data servers or third-party cloud services, blockchain's distributed ledger technology offers a novel alternative. This could potentially address the privacy and security concerns surrounding EHRs [15]. Specifically for application to PHRs, blockchain also has the ability to decentralize control and incorporate incentive mechanisms through smart contracts, which can further entice its general use and increase adoption [16]. These advantages, among others, have motivated efforts to test the feasibility and implement blockchain PHRs [17-19].

The research space in which EHRs and blockchain intersect is still in its infancy, with the first blockchain EHR introduced in 2016 [20]. Systematic reviews covering this space so far have considered EHRs as a collective entity. Mayer et al [21] provided an overview of the ecosystem of blockchain EHRs while also proposing a taxonomy for the space. Shuaib et al [22] looked at the main areas of focus when implementing a blockchain EHR and the remaining issues to be addressed, whereas Vazirani et al [23] assessed the feasibility of blockchain as a method of managing health care records efficiently.

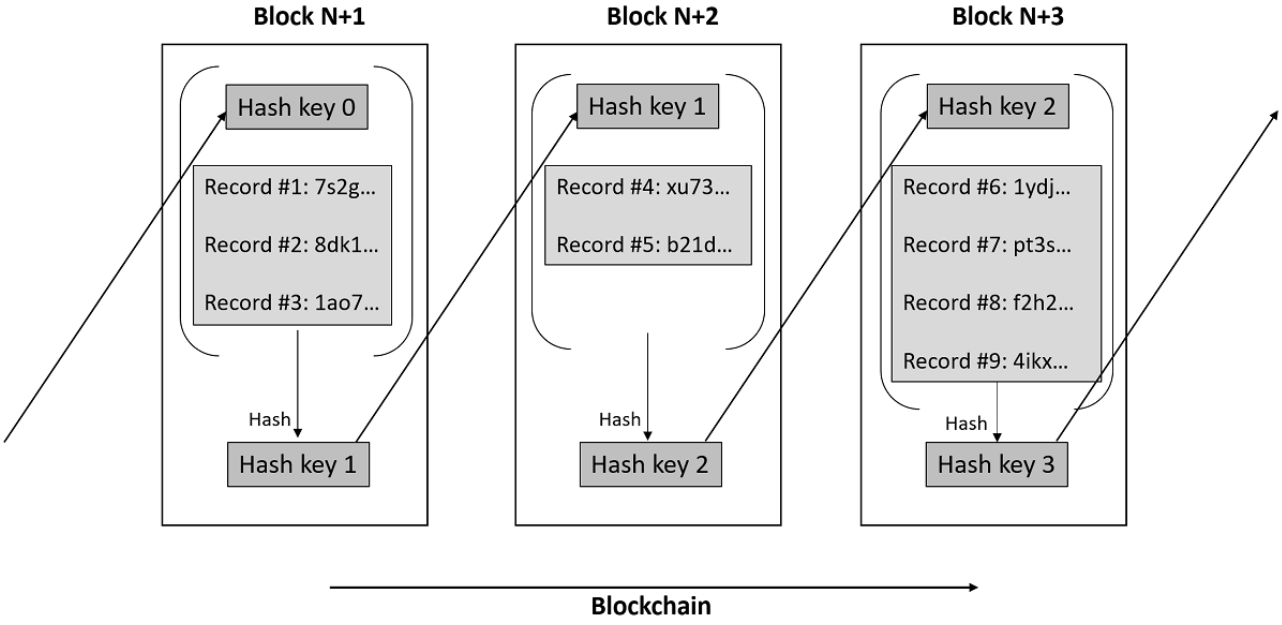
Given that one of the inherent properties of blockchain is its decentralized nature, in which data ownership is placed in the hands of individual users, some have proposed that blockchain may be more suitably applied to PHRs specifically rather than EHRs in general [19,24-26]. In this paper, we aim to systematically review the following: (1) the current landscape and trends of blockchain-based PHRs (blockchain PHRs), (2) the attributes of various blockchain PHRs that have been described, and (3) the current limitations and future directions for blockchain PHRs. To the best of our knowledge, this is the first systematic review examining blockchain with PHRs. We hope that this review will serve as a useful reference, especially for those intending to develop a blockchain PHR and for future reviews in this area.

To provide more context for subsequent sections of this paper, we will first explain pertinent blockchain concepts and take the opportunity to introduce some terminology specific to blockchain. This is by no means an exhaustive explanation of blockchain.

What Is a Blockchain?

A blockchain can be thought of as a shared (or distributed) database that is spread across multiple sites and participants. For new data to be added to a blockchain, they are first compiled into a *block*, which is simply a collection of records to be added to the database. The block is then combined with some data (a *hash key*) from the previous block through a cryptographic technique called *hashing* before it is added. As it combines the previous block's hash key, each new block is tied to all its predecessors in the form of a chain—hence the term *blockchain* (Figure 1).

Figure 1. Illustration of how blocks of data are linked together in a blockchain through hashing. To add a new record (eg, Record #7) to the blockchain, this is first grouped with other records (Records #6, #8, and #9). The group of records is then combined with a hash key from the previous block (hash key 2) and then put through a hashing algorithm to produce a new hash key (hash key 3). The new records, along with hash keys 2 and 3, are now part of a new block (Block N+3) that has been added to the blockchain. This process continues as new records are added.



Types of Blockchains and Their Properties

Before data can be added to a blockchain, its users need to agree or reach *consensus*. This is achieved through a *consensus algorithm*. A well-known consensus algorithm is the proof of work (PoW) algorithm. PoW is used in the Bitcoin and Ethereum blockchain network protocols [8,27]. In the PoW algorithm, users (also known as *miners*) compete in computational tasks to reach consensus. The winning miner of each block's task is usually given a reward [28].

Blockchains can be classified into the following three types, depending on which participants are allowed in the consensus algorithm [28]:

1. Public: anyone can participate in the consensus algorithm. Examples include Bitcoin and Ethereum [8,27].
2. Consortium: a select (or permissioned) group of entities can participate in the consensus algorithm. Examples include Hyperledger Fabric (HF), Quorum, and Corda [29-31].
3. Private: only a single entity operates the consensus algorithm and controls the addition of new data.

Public blockchains are sometimes referred to as permissionless blockchains, whereas consortium and private blockchains are collectively termed permissioned blockchains.

The three types of blockchains differ in the following properties:

1. Decentralization: unlike traditional databases that are owned by a specific entity, a decentralized blockchain can allow every user to own the data collectively. Using the illustration in Figure 1 as an example, a decentralized blockchain would contain all the records, but only one user owns records #1, #3, #4, #6, and #8, and another user separately owns records #2, #5, #7, and #9.
2. Immutability: because of the underlying chain structure, once data have been added to the blockchain, they cannot be tampered with. Changing a record would alter the hash key and effectively cause a break in the chain.
3. Transparency (with privacy): the entire blockchain can be made publicly viewable while preserving privacy by masking each individual record using cryptography. To unmask one's own records, a private key is required.

Table 1 provides a summary of the different types of blockchains and their properties, with an example of each type in the health care setting.

Table 1. Comparison of public, consortium, and private blockchains.

Variables	Type of blockchain		
	Public	Consortium	Private
Participation in consensus protocol	Anyone	Select (or permissioned) group of entities	A single entity
Decentralization	Yes	Partial	No
Immutability	Tamperproof	Could be tampered with	Could be tampered with
Transparency	Public	Can be public or restricted	Can be public or restricted
Example in health care setting	A transnational, open EMR[a] system in which anyone (eg, health care institutions, patients) may choose to contribute their own resources to maintain health records of all patients who use the EMR system	A national EMR system in which selected health care institutions collectively maintain the health care records of their patients	An institution-based EMR system in which only a single institution maintains the health records of its own patients

[a]EMR: electronic medical record.

Scalability and Smart Contracts

Finally, we will briefly explain the two concepts of *scalability* and *smart contracts*, which will be relevant to subsequent parts of this paper.

Scalability refers to the capacity of a blockchain to store and process transactions. It generally relates to the size and frequency of transactions a blockchain can handle. For example, Bitcoin's block size is limited to 1 megabyte, and each block is added every 10 minutes. This translates to a rate of approximately 7 transactions per second. Various solutions have been proposed to improve scalability. One such solution is to store data *off-chain* (instead of on-chain), and another solution is to use *side-chains* (linked to the main chain) to enable larger transaction volumes to be processed in parallel. Given that health care data are estimated to reach as much as 2314 exabytes generated yearly by 2020, it is crucial for almost all blockchain-based health care applications to achieve a certain level of scalability [32].

Smart contracts are programmable computer rules. Blockchain is a digital database that allows for the implementation of smart contracts, which can be automatically triggered to execute when predefined conditions are satisfied. For example, a smart contract can be programmed to issue tokens on the blockchain each time a user records his or her blood pressure. These tokens can then be used to pay for health care services. Such smart contracts can thus potentially be used to enable incentive structures to encourage certain positive user behaviors.

In this systematic review, particularly focused on the blockchain component of blockchain PHRs, we will pay particular attention to the (1) type of blockchain, (2) scalability solutions, and (3) smart contract–based incentive structures.

Methods

Study Design

While conducting and reporting this systematic literature review, the guidelines described in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) statement were adopted [33]. This type of literature review was selected because the goal was to identify articles on blockchain PHRs and to summarize the current landscape, design choices, limitations, and future directions. Unlike a meta-analysis, this review did not require any data synthesis. Quality assessment was not performed because the intention was to achieve a collective understanding of the efforts and ideas rather than judging the quality of various blockchain PHRs.

The presented systematic review was carried out by defining the following activities:

1. Research questions
2. Search strategy
3. Article selection
4. Data abstraction

Research Questions

For this review, there were 3 research questions we aimed to address:

1. What are the current landscape and trends of blockchain PHRs in terms of interest groups, geography, and maturity level?
2. What were the key design decisions made for the blockchain PHRs described?
3. What are the current limitations faced by blockchain PHRs and future directions?

Search Strategy

The following search string was used: “blockchain” AND (“health record*” OR “medical record*” OR “*EHR*” OR “*EMR*” OR “*PHR*”). Articles in the following databases were searched: (1) ACM, (2) IEEE Xplore, (3) MEDLINE, (4) ScienceDirect, (5) Scopus, (6) SpringerLink, (7) Web of Science, and (8) Google Scholar. For databases whose search engines did not enable the use of wildcards, the search was widened to include abstracts and keywords, and Microsoft Excel was subsequently used to filter the returned list by applying the search string to the titles.

As the space is still in its infancy stage, Google Scholar was included as a search database to incorporate relevant gray literature in this review. This decision was supported by systematic reviews by Holbl et al [34] and Kuo et al [35] on blockchain in the health care domain, which had found valuable information residing in gray literature.

Article Selection

Once the articles were obtained, we applied the following inclusion and exclusion criteria to select articles for the final review. The inclusion criteria were as follows: a health record system that had (1) a patient-facing component and (2) used blockchain in its health record system. The exclusion criteria were as follows: (1) duplicate articles, (2) review articles, (3) articles that did not have full text available, and (4) articles whose full text was not in English.

The selection was performed in a stepwise manner. First, duplicate articles returned from multiple databases were excluded. Second, the titles of the articles were reviewed and those that were not relevant to the topic were discarded. Third, the abstracts of the articles were reviewed and those whose main focus was not on blockchains and EHR or PHR and those that were review articles were also discarded. Those that looked at EHRs at this stage were retained because some EHRs would have a patient-facing component but might not have been explicitly mentioned in the title or abstract. Finally, the full text was reviewed and those that did not have a PHR element in the EHR were discarded. At this stage, those that did not have full text available or whose full text was not in English were also excluded.

Data Abstraction

For data abstraction, a standardized data collection form was developed using Microsoft Excel. A full-text review of each selected study was performed independently by 3 reviewers who are knowledgeable about blockchain and health records. For discrepancies in the abstracted data, the reviewers performed a repeat review of the articles together to reach a consensus.

For the interest groups, author affiliations, publishers, and publications were used as a proxy. As this space is situated at the intersection of computer science (CS), engineering, and medicine, we classified the publications into either (1) CS or engineering, (2) medical, or (3) general. For maturity level, the classification used by Chukwu et al [12] was modified, and the projects were classified as *concept/model/framework*, *prototypes*, and *pilots or implementations*. A prototype was considered to have both a working front-end and back-end system, and a pilot or implementation had to be a product that was released for use in the real world. If an article described systems at multiple levels of maturity (eg, a framework and a prototype), only the more mature level described was abstracted.

Many design choices must be made when developing a blockchain PHR. To keep this review manageable, the review focused on high-level design decisions [36]. To ensure a comprehensive list of possible design parameters, the *PHR taxonomy* proposed by Roehrs et al [37] and *EHR in a Blockchain taxonomy* proposed by Mayer et al [21] were used as starting points. Next, through a consensus-driven process of elimination, 10 design parameters were selected for abstraction. These were (1) blockchain type, (2) data storage, (3) scaling solution, (4) incentive smart contract, (5) PHR type, (6) data owner, (7) read and write ability, (8) semantic standards, (9) privacy standards, and (10) user interface (UI).

For limitations and future directions, the issues and areas for improvement brought up across the articles reviewed were identified, consolidated, and presented as a list of unique issues. We did not delve into a more in-depth analysis such as ranking the unique issues because the frequency of mention was not necessarily associated with importance or criticality. Moreover, the articles may not have fully listed all their limitations, as it was not their primary aim.

In total, 23 data elements were extracted from each article. Table 2 provides a complete list of the extracted data elements and a description of each element.

Table 2. List of data elements extracted from the selected articles.

Types of data elements	Description
General	
Author	First author's last name
Title	Title of the article
Year	Publication year of the article
Country	First author's affiliated country
Type	Type of article (eg, journal article, conference paper, book chapter, and whitepaper)
Publisher	Name of publisher of the article
Blockchain	
Name of blockchain PHR[a]	Name of the blockchain PHR (if any)
Maturity	Maturity level of the blockchain PHR described (ie, concept/framework, prototype, and pilot/implementation)
Blockchain type	Type of blockchain (ie, public, consortium, private, or a combination)
Blockchain name	Name of the blockchain used (if any)
Data storage	Type of data storage mechanism (ie, on-chain, off-chain, or hybrid)
Scaling solution	Type of scaling solution used in the blockchain PHR (if any)
Incentive smart contract	Was a smart contract used to incentivize use of the blockchain PHR? (yes or no)
PHR	
PHR type	Type of PHR (ie, standalone or tethered to an existing EMR[b] system)
Data owner	Party that owned the data from the blockchain PHR (ie, patient, provider, or both)
Read-write access (for patients)	Was the patient given read and/or write access in the blockchain PHR? (yes or no)
Read-write access (for providers)	Was the provider given read and/or write access in the blockchain PHR? (yes or no)
Read-write access (for other parties)	Were other parties given read and/or write access in the blockchain PHR? (yes or no)
Semantic standard	Type of semantic standard adopted (eg, HL-7[c] and FHIR[d])
Privacy standard	Type of privacy standard adopted (eg, HIPAA[e] and GDPR[f])
User interface	Modality of accessing the blockchain PHR (ie, web, mobile, or desktop application)
Additional	
Limitations	Current limitations of the blockchain PHR
Future directions	Future directions and opportunities described

[a]PHR: personal health record.

[b]EMR: electronic medical record.

[c]HL-7: health level 7.

[d]FHIR: Fast Healthcare Interoperability Resource.

[e]HIPAA: Health Insurance Portability and Accountability Act.

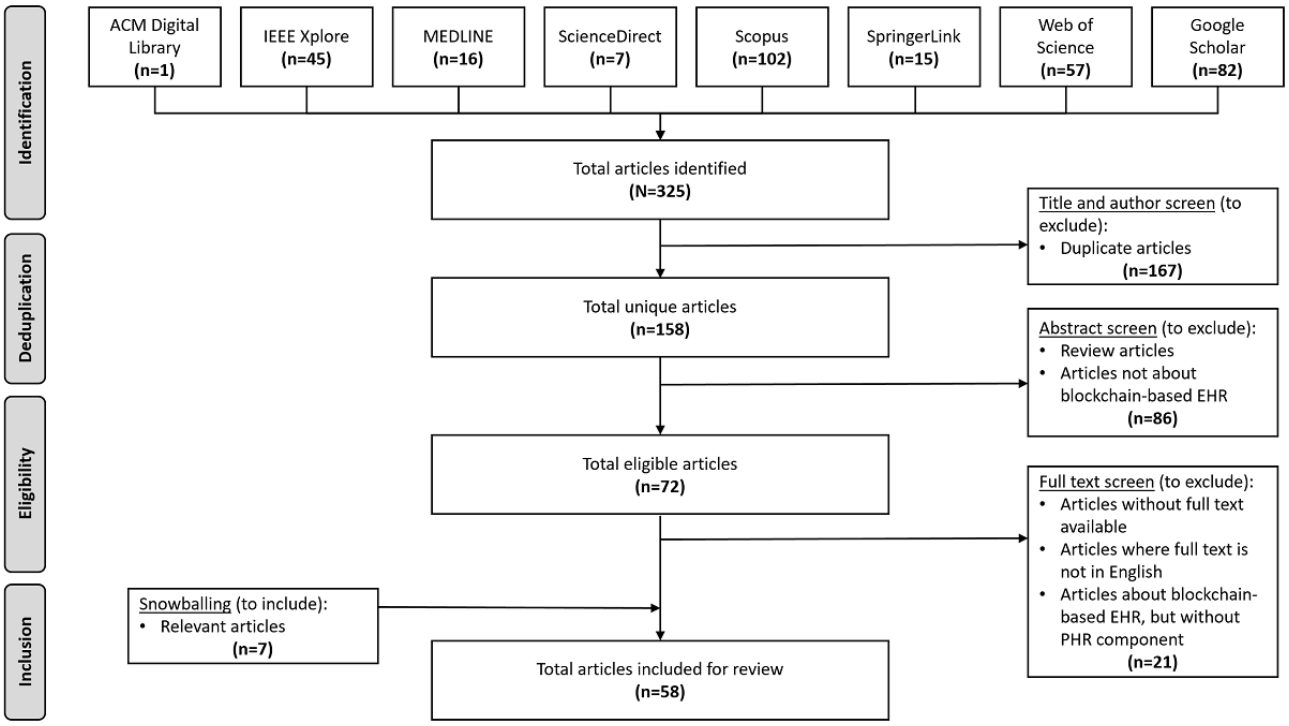
[f]GDPR: General Data Protection Regulation.

Results

Overview of Articles

The search performed on July 6, 2020, yielded 325 articles, of which 158 were unique articles. From the article selection process, 51 articles were selected for review. An additional 7 articles were added via snowballing (review of the references from the included articles) of the full texts screened (Figure 2).

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) flow diagram of the article selection process. The title and author screen involved removing duplicate articles that had the same title and authors. The abstract screen involved reviewing article abstracts to remove review articles and those not related to blockchain and electronic health records. The full text screen involved reviewing the full articles to exclude those that did not meet the inclusion and exclusion criteria, and those whose full text was not available or in English. ACM: Association of Computing Machinery; EHR: electronic health record; IEEE: Institute of Electrical and Electronics Engineers; PHR: personal health record.



A total of 58 studies were included in the final review [17,19,37-92]. The complete list of articles, with identifiers used in this study, are presented in Table 3. The completed data collection form for these articles can be found in Multimedia Appendix 1. An overview of the articles with the publication year, publisher, article type, country, and interest group is presented in Multimedia Appendix 2 [17,19,37-92].

Table 3. List of articles included in the final review.

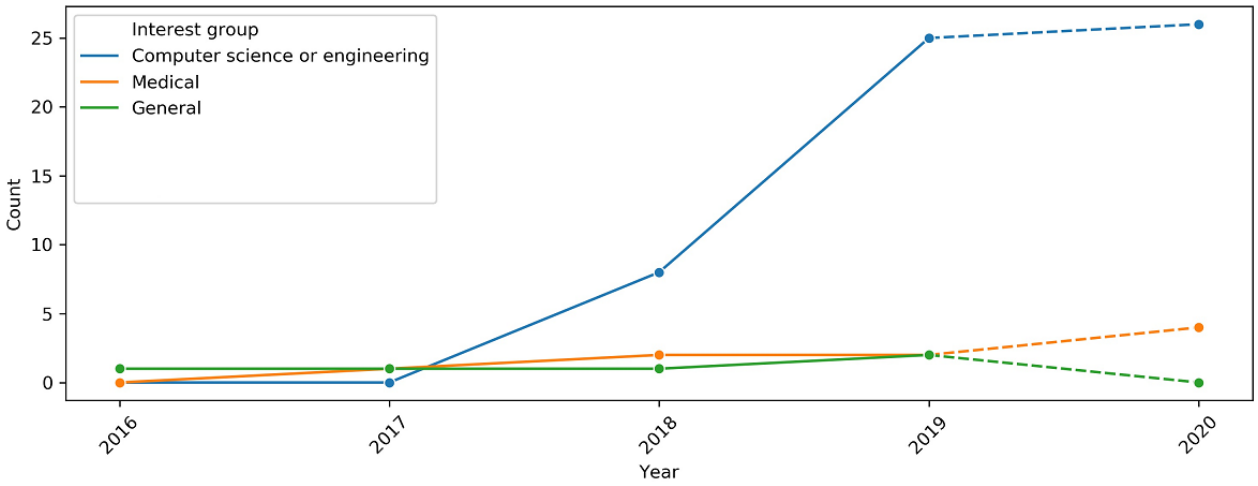
Current Landscape and Trends of Blockchain PHRs

Interest Group

The level of academic interest in the space has been rising, supported by an increasing trend in the number of published articles since 2016. In terms of interest groups, 45 articles were CS-or engineering-related publications or from CS- or engineering-related authors. Seven were published in medical journals, all of which were related to medical informatics. Of the 6 remaining articles that were classified as *General*, 5 were whitepapers. The articles from the CS or engineering interest group showed a sharp rise from 2017 to 2019 and may have started to plateau, whereas those from medical journals have been following a gradual, steady increase since 2016 (Figure 3).

Figure 3. Trend of blockchain personal health record articles by interest group. The trend from 2019 to 2020 (represented by dashed lines) is a projection because only data from the first half of the year 2020 was available at the time of the search. Count refers to the number of articles published in that year.



Geographic Distribution

The articles originated from 23 different countries. The majority were from India (n=13), United States (n=9), China (n=8), and South Korea (n=5), with Canada, Switzerland, Taiwan, and Thailand having 2 articles each and the remaining countries having 1 article each (Figure 4). Although the research interest in blockchain PHR is multinational, there clearly are a few countries that are leading the pack. Among these leading countries, there has been an increasing number of publications from India over the years, whereas China, South Korea, and the United States have shown a slowing trend. Apart from these countries, the aggregated output from the rest of the countries is also increasing (Figure 5).

Figure 4. Distribution of articles published by geography. The number of articles refers to the total number of articles selected for the final review.

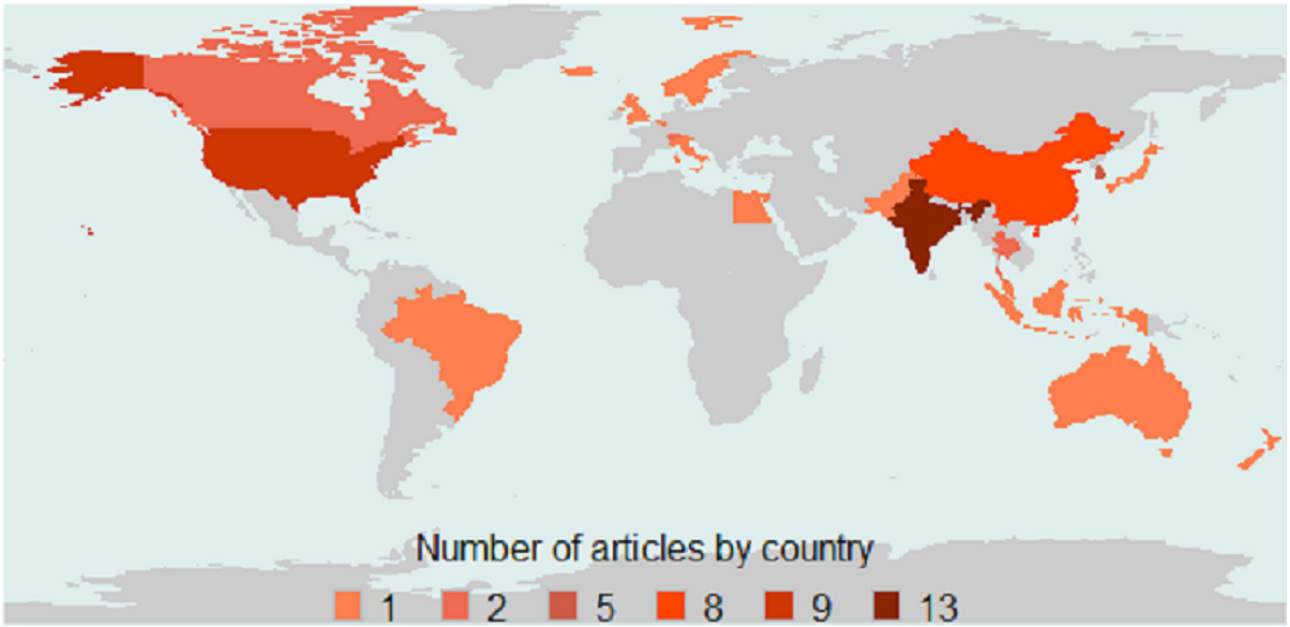


Figure 5. Trend of blockchain personal health record articles by country. Only countries with 5 or more articles in the final review were plotted individually. The other countries were grouped under an Others category. The trend from 2019 to 2020 (represented by dashed lines) is a projection because only data from the first half of the year 2020 was available at the time of the search. Count refers to the number of articles published in that year.

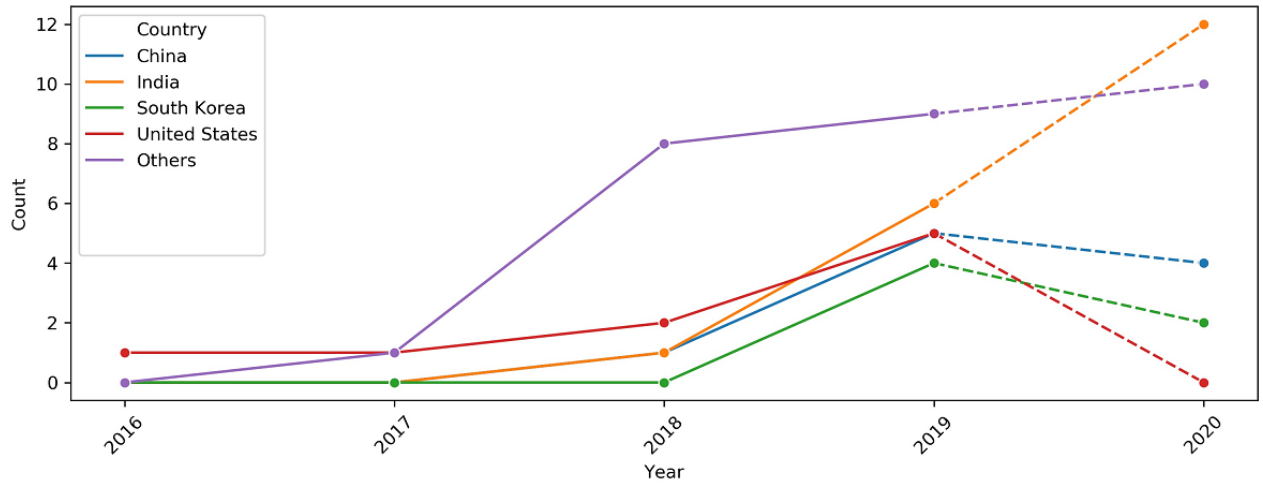
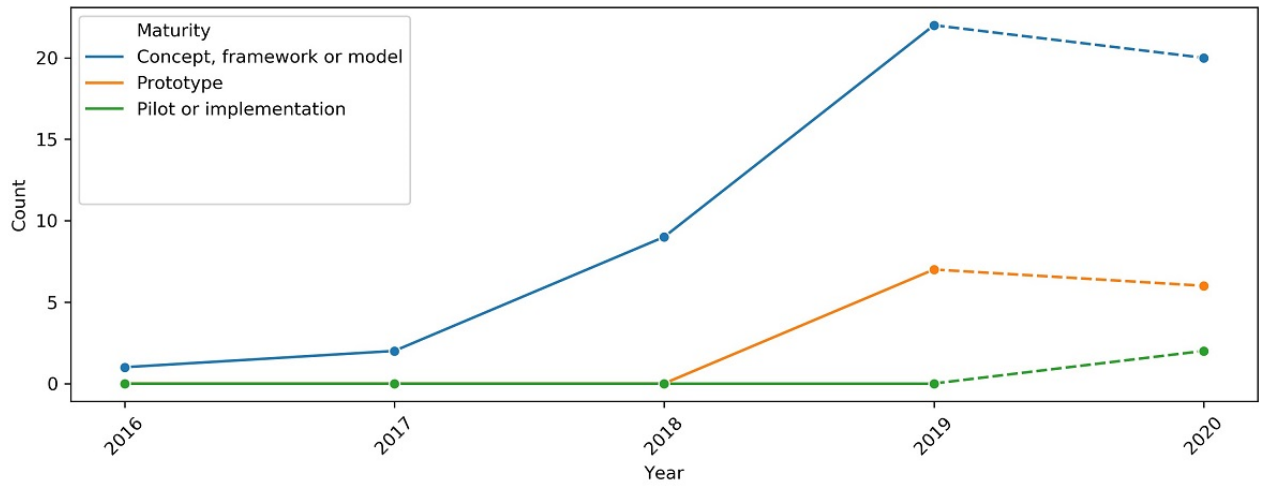


Maturity Level

The blockchain PHR space is maturing, with the proportion of articles describing prototypes showing an upward trend (Figure 6). In addition, the first paper to describe an implementation was also published in the first half of 2020 by Lee et al [19]. Their blockchain PHR implementation was deployed across Southeast Asia via an information network and became the first PHR management platform for cross-regional medical data exchange.

Figure 6. Trend of blockchain personal health record maturity. Note that the trend from 2019 to 2020 (represented by dashed lines) is a projection because only data from the first half of the year 2020 was available at the time of search. Count refers to the number of articles published in that year (2018).



Key Design Choices for Blockchain PHRs

Blockchain Attributes

Most blockchain PHRs are described using a private (n=24) or consortium (n=22) blockchain, whereas 4 others used a public-permissioned hybrid design. Only 4 cases of using a public blockchain were described. In the remaining 4 cases, the blockchain type was not clearly stated. An Ethereum-based blockchain was the most commonly used (n=26), with HF being the next most common (n=20). Among these, 3 articles used both Ethereum and HF.

For data storage, the majority used off-chain data storage (n=40), 14 stored EHR data on-chain, and 4 described hybrid data storage. For off-chain storage, 10 articles, all from 2019 onward, used the Interplanetary File System (IPFS). In terms of other scaling solutions, 9 articles considered new consensus algorithms such as Proof-of-Authority, 4 used a tiered-chain architecture, and 1 used both side-chain and algorithmic methods to improve the blockchain scaling capacity.

Among the articles, 5 described an incentive structure in the blockchain PHR using smart contracts. Four of these were whitepapers, which proposed incentivizing stakeholders through the issuing of tokens (digital currency of value) from smart contracts. In these cases, once an action warranting compensation had taken place, the smart contract automatically triggered the issuance of tokens. Table 4 provides additional

details of the tokens and how they can be earned and used as part of the incentive structure. Unlike the others, Daraghmi et al [56] proposed a novel, nonmonetary incentive. Their system kept score using *degrees* based on the effort in maintaining the quality of records and creating new blocks. Those with higher degrees would have a lower probability of performing the computation task of creating new blocks. In this way, it is meant to achieve fairness and sustainability of the system.

Table 4. Incentive structure proposed by blockchain personal health record systems.

Article identifier	Token name	Party compensated	Compensation	Token use
A02	Patientory issued tokens	Provider	• On the basis of how effective provider ensures improvement in care quality and outcomes	• Renting storage space on the platform • Execution of smart contracts
A11	MedToken	Patients	• Sharing of personal health data on health care data marketplace	• Lower insurance premiums • Payment for use of applications (eg, tele-consultations)
A29	MediBloc coin	Provider	• Performing computational task of producing blocks	• Tradable for monetary value
A30	LOT[a] token	Patients	• Contribute data • Compliance to health care recommendations	• Analytics services (eg, personalized health reports) • Payment to retail and pharmaceutical partners

[a]LOT: token used in the MediLOT system.

PHR Attributes

A total of 18 articles described a tethered blockchain PHR that interfaced with an existing electronic medical record (EMR) system. All of these were of the *Concept/Framework/Model* maturity level. Those that were prototypes, pilots, or implementations were all standalone PHR systems.

In the majority (n=45) of the articles, the patient was the data owner. Of the remaining articles, providers were data owners in 9 of them, whereas 2 had both patients and providers as owners. It was unclear who the data owner was in the last 2 articles.

In most articles, both patients and providers had read and write abilities. Most blockchain PHRs granted providers with both read and write abilities (n=40), and only 4 blockchain PHRs did not grant providers any read or write abilities. Table 5 is a matrix representing the distribution of read and write capabilities for patients and doctors among the various articles and article codes refer to article identifier in Table 3.

Table 5. Matrix of various read and write models among the blockchain personal health records reviewed.

Provider	Patient		
	Read only	Write only	Read and write

[a]Not available.

Most articles did not mention the adoption of any semantic standard. For those that did, the 2 standards mentioned were Fast Healthcare Interoperability Resource (FHIR) and health level 7 (HL-7) in 5 and 2 articles, respectively. Similarly, most did not mention adopting any privacy standards. For those that did, 4 mentioned compliance with the Health Insurance Portability and Accountability Act (HIPAA), 1 with the General Data Protection Regulation (GDPR), and 1 with both the HIPAA and GDPR.

Among the blockchain PHRs that were either prototypes or implementations, 9 developed a web UI, whereas 2 had both a mobile phone application UI and a desktop UI.

Current Limitations of and Future Directions for Blockchain PHRs

Current Limitations

Most of the current limitations can be grouped into 1 of the following 3 main categories: (1) scalability, (2) privacy, and (3) usability. Scalability issues pertained to the inability of

blockchain PHR to store large file sizes such as medical images [44,53,54] or to the slowness in confirming transactions, especially with the incorporation of streaming data from internet of things devices [45,76].

The inability of blockchain PHRs to ensure full privacy has been highlighted in a few articles. Although records on the blockchain are encrypted, there are possible means to infer the information, such as through blockchain analysis [17,43,54]. Another privacy issue raised was the inability to erase one's records, as blockchains are inherently immutable [17,70]. This limitation would make it difficult for blockchain PHRs to comply with privacy regulations such as the GDPR, which stipulates data subjects' right to erasure (Article 17 of the GDPR).

One of the usability limitations was the affordability of the blockchain PHR, as each transaction typically required users to pay a transaction fee [45,71]. Another practical usability issue described by Charanya et al [84] was that, unlike conventional PHRs that had password recovery mechanisms, patients would not be able to access their records if they lost their private keys on blockchain PHRs. Incapacitated or unconscious patients also present a similar problem with blockchain PHRs that do not have built-in access control when emergency health care providers would need permission to access records.

Apart from these 3 main categories, there were other limitations inherent to certain types of popular blockchains such as Ethereum. For example, Gebremedhin [45] highlighted that Solidity (Ethereum's programming language) was unable to implement nested string data types, whereas Kung et al [86] mentioned the need to batch upload data in a certain file format as a limitation of their Ethereum-based PHR.

Future Directions

The current limitations provide direction to some future work areas for blockchain PHRs. Scalability solutions have already been studied and experimented on, such as Proof-of-Authority and the novel Byzanthine fault tolerance (BFT) consensus mechanisms [44,56,67]. Other methods include enhancing the blockchain architecture through tiered-chain [40,64] or side-chain structures [57]. Although privacy solutions were more limited in our review, we came across one by Reen et al [70] who proposed storing InterPlantary Naming System records instead of the conventional hash of the medical records directly on the blockchain. In this way, users may retain the ability to revoke access to the record if desired.

Many suggestions have been made to improve the usability of the system. These suggestions could be grouped into (1) user experience, (2) integration with existing systems, and (3) compliance with regulations and development of governance processes. Table 6 summarizes the suggestions proposed in the articles reviewed.

Table 6. Suggestions for improving blockchain personal health record usability from the selected articles.

Suggestion	Article identifiers
User experience	
Improving user interface of blockchain PHRs[a]	A10, A31, A55
Biometric user authentication	A40
Allowing next-of-kin or caregiver to access records if patient grants access or is incapable of self-access	A40
Incorporating incentives for users	A56
Incorporating analytics capabilities for personal health insights and management	A32, A53
Adding on payment functions for health care services	A37, A55
Integration with existing systems	
Integrating with existing EMR[b] systems	A07, A08, A19, A20, A52,
Adopting health care data standards	A03, A09, A17, A53
Integrating with IoT[c] devices	A32
Integrating with open, public blockchain systems	A17, A18, A33
Compliance with regulations and development of governance processes	
Complying with regulations on health care data privacy	A07, A18
Developing governance processes for the blockchain PHRs	A38

[a]PHR: personal health record.

[b]EMR: electronic medical record.

[c]IoT: internet of things.

Apart from improving usability, another aspect of future work is the validation of blockchain PHRs. Among the areas for validation, several articles suggested data validation when data were transferred to off-chain storage [77], security validation [48,58,79], and real-world validation in terms of cost-effectiveness [52,53,71]. Validating these components

would be relevant to obtain stakeholder and user confidence in deciding where to implement and adopt blockchain PHRs.

Discussion

Principal Findings

In this first ever systematic review on blockchain PHRs, we adopted a broad search strategy across medical and CS and engineering databases and included gray literature. We focused on the scope of blockchain PHRs to allow for more targeted data abstraction. Through our study, we found that there was a growing interest in blockchain PHRs and that the space has been steadily maturing over the past few years, albeit still much in the conceptual stage. As the space is still fairly new, a lion's share of the research and innovation has been happening at the technical level to discover new ways to solve problems. This is evidenced by the overwhelming proportion of articles that have come from the CS and engineering domain.

One of the major areas regarding blockchain PHRs that is still undergoing much research is scalability. We came across a few ideas such as Proof-of-Authority, novel BFT consensus mechanisms, and other modified blockchain architectures such as tiered-chains and side-chains [40,44,56,57,64,67]. Apart from blockchain PHR teams working on this, the space may also benefit from parallel innovations from the larger blockchain ecosystem. As Ethereum is looking forward to a new version release (version 2), it is considering various scaling solutions, of which *rollups* is a strong contender [93]. *Rollups* solution essentially involves keeping transaction data on-chain while pushing the computational load off-chain. If adopted into Ethereum 2.0, this could automatically benefit many Ethereum-based PHRs.

Although some areas are actively evolving, others are beginning to consolidate. As found in other systematic reviews, most blockchain PHR project teams have gravitated toward Ethereum and HF as their blockchains of choice [22]. In addition, in terms of data storage, we see more projects opting for IPFS as a complementary off-chain data store for their blockchain PHRs [68,72,83,92]. Outside of this review, we are also aware that there are efforts happening in other public blockchains. An example is NEO, whose core developers are developing a similarly distributed, decentralized object storage network known as NEO file storage system (NeoFS), which will seamlessly integrate with its native blockchain [94,95]. We did not come across any NEO-based PHRs in this review. NeoFS could potentially be a game changer, so it would be interesting to track its development in this area.

In this review, we also identified some current limitations that blockchain PHRs need to address. We broadly classified them into scalability, privacy, and usability limitations. In addition to identifying the current limitations, this review also revealed some possible solutions. For example, to address the privacy issue of inferring information from chain analysis, Ray Chawdhuri [54] introduced zero-knowledge provable mixing, whereas Park et al [17] proposed the zero-knowledge succinct non-interactive argument of knowledge technique. Another example is the solution of using biometric authentication mentioned by Tian [75] to address the issues of verifiable user authentication and patients losing their private keys. Medicalchain has also described an emergency bracelet that can be scanned, giving access to essential health information in unconscious patients who are unable to access their private keys [47].

The first blockchain PHR has already been piloted, and this will undoubtedly augur a move of the space toward deployment [19]. With this in mind, blockchain PHRs will need to comply with the privacy standards within the jurisdictions they intend to become operational. In addition, to enable integration with existing health care EMR systems, it is necessary to design blockchain PHRs that follow established semantic standards such as HL-7 and FHIR. Looking further ahead, to realize true decentralization, it may be necessary to consider building a PHR atop public blockchains.

Finally, in terms of geographic interest, we found that although interest in blockchain PHR was multinational, there were obvious leaders in this space. Looking deeper among the leading countries, we noticed that since 2018 there has been an increase in publications from India, whereas those from China, South Korea, and the United States started to level off or decrease. A possible reason for this could be that in 2017, in the midst of an initial coin offering (ICO) fever that drove unusually high interest in blockchain, the latter 3 countries' relevant authorities had issued bans or indicated legal restrictions on ICO activities with stiff penalties [96-98]. This may suggest further research into the different factors, including sociopolitical, economic, and cultural factors, which could significantly impact the development of this space. In terms of interest groups, our findings should also provide a sense of where most of the developments are occurring, and this may guide government and private sector funders in their allocation of resources.

Limitations

We acknowledge that this review is not exhaustive and that there are many other areas that were excluded. These areas include other smart contract uses, performance evaluation, and the type of vocabulary standard such as Systematized Nomenclature of Medicine Clinical Terms, 10th revision of the International Classification of Diseases, and Logical Observation Identifiers Names and Codes. We also recognize that greater detail about the read and write models could be studied, such as their validity periods and whether other stakeholders (eg, researchers and insurance companies) were given access. Future reviews should consider delving deeper into these areas.

Furthermore, despite our best efforts to capture as much material available as possible, we are aware that the exclusion of articles whose full text was not in English would have limited the scope of this review. In addition, there may also be other developments in this space that have not been made publicly available for commercial or other reasons.

Conclusions

This cross-disciplinary systematic review on the blockchain PHR space has revealed that as of now, much of the development is still in the conceptual stage. However, there is a trend of growth and maturation. We believe that this provides

consolidated evidence for researchers to continue following this space and, more optimistically, to spur them to contribute ideas and efforts to accelerate its development. Those in the medical informatics community will undoubtedly play an increasingly larger role in the development and implementation of blockchain PHRs, especially when the need to integrate with EMR systems and adopt health care data standards becomes more prominent. In addition, as the first systematic review covering blockchain PHRs, we expect this to be an important basis for subsequent reviews to track how the space has progressed in the future.

Acknowledgments

The authors would like to thank their families and work organizations—SingHealth Polyclinics, SingHealth Community Hospitals, and the National University Hospital—for their support.

Authors' Contributions

AF had the original idea for this study. AF, MT, and CT designed the review. MT obtained the relevant articles. AF, TT, and MT reviewed the articles and abstracted the data. AF wrote the first draft of this paper, and all the authors subsequently assisted in revising the work and have approved the final version.

Conflicts of Interest

The authors did not receive any funding for this work and declare no conflicts of interest. However, the authors would like to highlight that MT is the cofounder of MediLOT, which published one of the articles reviewed in this paper.

Abstract

Background: Despite the prevalent use of geosocial networking dating apps (GNDAs), there is limited research on their impact on sexual health outcomes among young music festivals attendees.

Objective: This study aims to explore the use of GNDAs and risky sexual behaviors of young adults attending a music festival.

Methods: The music festival attendees (N=862) completed a cross-sectional questionnaire study encompassing demographics, dating app use, and risky sexual behaviors in the past year. Associations between these variables were estimated using bivariate and multivariate logistic regression analyses.

Results: Of the respondents, 51.9% (448/862) had used GNDAs in the previous year. Compared with people who had 1 partner, people who had 2-5 sexual partners in the previous year had almost 7 times the odds of using dating apps (odds ratio [OR] 6.581, 95% CI 4.643-9.328) and those who had more than 5 partners had 14 times the odds of using dating apps (OR 14.294, 95% CI 8.92-22.906). Condom users were more likely to be app users (P<.001), as were those who relied on emergency Plan B (P=.002), but people using hormonal contraception were less likely to use dating apps (P=.004). After adjusting for sexual orientation and relationship status, those having casual sex had 3.096 (95% CI 2.225-4.307; P<.001) times the odds of using dating apps and those having multiple sexual partners had 3.943 (95% CI 2.782-5.588; P<.001) times the odds of using dating apps. Similarly, after adjusting for sexual orientation, relationship status, and number of sexual partners, people who had no discussions before having sex about sexually transmitted infections (STIs) or boundaries were more likely to use dating apps (OR 1.755, 95% CI 1.232-2.500; P=.002). Those who perceived the risk of having sex without contraception to be *very high* had 2.486 (95% CI 2.213-5.096; P=.01) times the odds of using dating apps than those who perceived *no risk*. Compared with those who perceived no risk, people who thought that the risk of having multiple sexual partners was *low* to *high* had 1.871 (95% CI 1.024-3.418; P=.04) times the odds of using dating apps. A significant number of app users (389/440, 88.4%) indicated that GNDAs should promote safe sex.

Conclusions: This study identified that festival goers engaging in certain high-risk sexual behaviors, including casual sex, having multiple sexual partners, and having sex without discussion about STI status and boundaries, are more likely to use dating apps. Festival goers who perceived sex without any form of contraception, having sex while drunk, and having multiple sexual partners as risky were more likely to be app users. Policy makers and GNDA developers should acknowledge the vulnerability of their users to adverse sexual health outcomes and use GNDAs as a platform to promote risk-reduction practices.

KEYWORDS

sexual health; mobile apps; young adults; music festival

Introduction

Background

Geosocial networking dating apps (GNDAs) provide users with a web-based platform to make social, romantic, or sexual connections. These apps connect users to potential partners based on their location. Such platforms have become increasingly popular since the launch of Tinder in 2012, which has grown to over 10 million users per day, with similar apps (Bumble and OkCupid) joining the market [1]. In Australia, web-based dating has become the second most preferred way to meet new partners after introductions from family and friends, surpassing more traditional methods of meeting [2]. A Dutch study on the primary motivations for Tinder use showed that in addition to dating, GNDAs may be used to ease communication and obtain self-worth or validation and for excitement or trendiness [1].

Young adults, the primary users of GNDAs [3], have a higher tendency toward risky sexual behaviors. For example, they often lack safe-sex discussions before intercourse [4], a significant risk factor for sexually transmitted infections (STIs). Consequently, in Australia, young adults (15-24 years) account for 50% of newly acquired STIs [5].

GNDA use has been directly associated with risky sexual behaviors. A meta-analysis concluded that GNDA users were more likely to contract STIs [6]. Similarly, Shapiro et al [7] found that Tinder users were more likely to report 5 or more previous sexual partners and a positive STI screen. This is concerning, given the high rate of GNDA use and promotion at music festivals [8]. Furthermore, a recent review of 99 studies on GNDAs and sexual health identified that the most common theme was risky sexual behaviors [9] and tended to focus on the lesbian, gay, bisexual, transgender, and queer (LGBTQ+) community [9].

Music festival attendees have also demonstrated significant risky sexual behaviors. An Australian study found that half of the music festival attendees reported taking illicit drugs in the last 12 months and had engaged in risky sexual behaviors such as sex without condoms, casual sex, and a lack of STI screening [10]. The environment of a music festival is particularly risky for dating app use because of the proximity of hundreds of young people, many of whom use dating apps and do not practice safe sex. Therefore, the proximity of congregated youth creates an environment conducive for increased app use and, in turn, greater potential for risky sexual behavior. There is evidence to suggest that GNDAs can be used for safe-sex health promotion, and several reviews have identified the potential effectiveness of mobile phone (or app based) interventions on delivering safe-sex information among young people [11,12]. Despite this potential, a 2016 study investigated 60 dating apps to determine whether they included any sexual health content. Huang et al [13] found that only 9 dating apps had sexual health content and 7 of these only targeted men having sex with men.

Objective

In summary, GNDA use is prevalent among young adults, and festival goers are a higher risk group, but the association between sexual health and dating app use among young people attending festivals has, to our knowledge, not been investigated yet. Therefore, this study aims to explore GNDA use and risky sexual behavior among young adults attending a music festival.

Methods

Study Design

This study was a cross-sectional survey. People aged 18 years and above attending a music festival in 2019 in New South Wales, Australia, were eligible to participate in the study.

Data Collection

Data were collected at a major 3-day music festival in 2019 in New South Wales, Australia. Recruitment was conducted by 5 of the authors who were on-site during the festival. Attendees who approached a permanent health promotion stall within the campgrounds were invited to take part and people within the target demographic were approached. Those approached were screened by age and given a participant information survey. The information sheet outlined the study aims, what they would be asked to do, the benefits of taking part and potential downsides, how the study was paid for, data storage, an explanation about study withdrawal, and how to contact the ethics committee or researchers. If willing to participate, paper surveys were distributed, completed anonymously, and placed in closed boxes for confidentiality. Survey completion was obtained as consent. Owing to the size, timing, and location of the festival, the data were collected via convenience sampling. The number of individuals who declined to participate was not recorded. No visibly intoxicated people were allowed to complete the study, and no incentives were provided. The data were entered into a Microsoft Excel spreadsheet.

Survey Development

The questionnaire development was guided by public health and sexual health experts and included questions about demographics, sexual behavior, risk perception, and dating apps. Risky sexual behaviors were selected from the Safer Sex Behavior Questionnaire (SSBQ) by Dorio et al [14] and were used to develop questions in relation to dating apps and sexual health. Akin to the SSBQ, the questionnaire covered condom use, impact of intravenous drug use history in a sexual partner, drinking alcohol before sex, and discussion about safe sex with a partner before sexual activity. The SSBQ covered more risky sexual behaviors, such as engagement in anal intercourse and sexual intercourse on the first date. However, these were excluded to reduce survey fatigue, as it was necessary to keep

the survey relatively brief. The survey was piloted (n=13) with university students, representing the target population and refined before being approved by the Western Sydney University Human Research Ethics Committee (H11327). The survey questions used in this study are listed in Multimedia Appendix 1.

Outcome Measures

GNDA use and nonuse were determined by asking whether they had used a dating app in the last 12 months. Dating app users were also asked: "Should dating apps share educational messages about safe sex?"

The survey asked about reasons for use and sexual behavior with partners meeting off GNDAs. However, data were not captured in this study as it did not allow the comparison of users versus nonusers.

All participants were asked about their age, gender, sexual orientation, relationship, whether they had engaged in sexual activity in the last 12 months, and the number of sexual partners in the last 12 months. The survey explained the definition of *sexual activity* to be defined as oral and/or penetrative sex.

Participants were also asked what forms of contraception they used regularly, including *none*; *condoms*; *Plan B (morning-after pill)*; *the pill*; *intrauterine devices(IUDs), such as Mirena and Paragard*; *spermicide*; *Implanon—the rod;pulling out method*; or other methods. These were then categorized as follows for further analyses: *no contraception at all*, *condom use*, *Plan B*, *pulling out*, and *hormonal contraception*, with the latter including *the pill*, *IUD (Mirena and Paragard)*, *spermicide*, and *Implanon—the rod*.

With respect to sexual health behavior, participants were first asked about their actual behavior and then about their risk perception of this behavior. Participants were asked if they had engaged in the following 8 behaviors in the last 12 months: sex without any form of contraception; sex without condom but with other contraception, for example, the pill; casual sex; having sex while drunk; lack of discussion about STI status and sexual boundaries before sexual activity; having multiple sexual partners; having unprotected sex with a partner who has ever injected drugs; and finally having sex with a partner who has an STI. For each behavior, participants were asked to rate their perception of sexual risk on a 5-point Likert scale, ranging from no risk to very high risk.

Data Analysis

Data were analyzed using SPSS, version 25. Bivariate analysis was used to compare categorical demographics, contraception, specific risky sexual behaviors, and related risk perceptions with dating app use. Statistical significance was defined as P=.05. Logistic regression analyses were used to estimate crude odds ratios (ORs) to determine the factors associated with using GNDAs. Contraceptive and specific sexual behavioral variables that were statistically significantly associated with GNDA use in bivariate analyses were then analyzed in a multivariate model, which was adjusted for sexual orientation, relationship status, and number of sexual partners.

Results

Demographics

About half (448/862, 51.9%) of the participants had used GNDAs within the past 12 months. A significant number of dating app users (389/440, 88.4%) indicated that GNDAs should promote safe sex. The study (N=862) was predominantly completed by those between the ages of 21 and 24 years (395/862, 45.8%), closely followed by those aged between 18 and 21 years (383/862, 44.4%; Table 1). The highest proportion of respondents were female (558/860, 64.9%), heterosexual (770/862, 89.3%), and sexually active (813/862, 94.3%). The majority were in exclusive relationships (362/858, 42.2%), whereas the rest were single and not dating (310/858, 36.1%) or casually dating or in open relationships (186/858, 21.7%). Of the sexually active participants (n=812), most had 2 to 5 sexual partners within the past 12 months (341/812, 41.9%), followed by those who had one sexual partner (311/812, 38.3%).

People identified as LGBTQ+ had almost twice the odds (OR 1.846, 95% CI 1.175-2.900; P=.008) of using GNDAs as compared with their heterosexual counterparts. Participants in exclusive relationships had a lower proportion of app usage (109/362, 30.1%) compared with casual daters (141/186, 75.8%) and singles (195/310, 62.9%). Casual daters were 7.273 times (95% CI 4.857-10.891; P<.001) more likely to have used GNDAs within 12 months compared with those in exclusive relationships. Participants who were *single and not dating* were 3.936 times (95% CI 2.853-5.430; P=.003) more likely to use GNDAs.

People who had more sexual partners were more likely to be dating app users. Of the participants with 1 partner, only 21.9% (68/311) were GNDA users, compared with 64.8% (221/341) of those with 2 to 5 partners and 80% (128/160) of those with more than 5 partners. Compared with those with only 1 partner in the last 12 months, participants with 2 to 5 partners had 6.581 times the odds (95% CI 4.643-9.328; P<.001) of using dating apps, whereas people with more than 5 partners had 14 times the odds of using dating apps (OR 14.294, 95% CI 8.92-22.906; P<.001).

Table 1. Logistic regression of geosocial networking dating app users and demographics (N=862).

Risky Sexual Behavior and User Status

Contraception

Table 2 shows that participants who used condoms had 1.914 times (95% CI 1.448-2.531; *P*<.001) the odds of using GNDAs. Participants who relied on emergency contraception as Plan B were more likely to use dating apps (OR 2.357, 95% CI 1.381-4.087; *P*=.002), whereas those who used hormonal contraception such as IUDs, the oral contraceptive pill, and the rod were less likely to use dating apps (OR 0.660, 95% CI 0.496-0.879; *P*=.004).

Table 3 shows that after adjusting for sexual orientation, relationship status, and number of sexual partners, no association was found between any form of contraception use and dating app use.

Table 2. Logistic regression of geosocial networking dating app users and sexual behaviors.

Behavior	Total, n (%)	Users, n (%)	Nonusers, n (%)	Dating app users, crude odds ratio (95% CI)	*P* value
Contraception (n=811)					
No contraception at all	76 (15.7)	44 (57.9)	32 (43.3)	1.334 (0.828-2.162)	.24

[b]Adjusted for sexual orientation and relationship status.

[c]STI: sexually transmitted infection.

[d]PWID: person who injects drugs.

Specific Sexual Behaviors

Table 2 shows that participants who had casual sex (*P*<.001), those who had no discussion about STIs or boundaries before having sex (*P*<.001), those with multiple sexual partners (*P*<.001), those having unprotected sex with a person who injects drugs (*P*=.04), and those having sex with a partner with an STI (*P*=.01) had higher odds of using GNDAs. Table 3 shows that after adjusting for sexual orientation and relationship status, those having casual sex have 3.096 times (95% CI 2.225-4.307;

P<.001) the odds of using dating apps and those having multiple sexual partners have 3.943 times (95% CI 2.782-5.588; *P*<.001) the odds of using dating apps compared with those who have not. Similarly, after adjusting for sexual orientation, relationship status, and number of sexual partners, people who had no discussions before having sex about STIs or boundaries were more likely to use dating apps (OR 1.755, 95% CI 1.232-2.500; *P*=.002). However, no association was found between dating app usage and having unprotected sex with a person who injects drugs or having sex with a person with an STI, after adjusting for sexual orientation, relationship status, and number of sexual partners (Table 3).

Risk Perception of Risky Sexual Behavior and User Status

Table 4 shows that those who perceived the risk of having sex without any form of contraception to be *very high* had 2.486 times (95% CI 2.213-5.096; *P*=.01) the odds of using dating apps than those who saw *no risk*.

Those who felt that the risk of having sex while drunk to be *low to high* had 1.659 times (95% CI 1.067-2.581; *P*=.03) the odds of using dating apps compared with those who saw *no risk*. Similarly, those who felt the risk of having sex when drunk was *very high* were 2.151 times (95% CI 1.087-4.256; *P*=.03) more likely to use dating apps compared with those who felt there was no risk. Finally, people who thought that the risk of having multiple sexual partners was *low to high* had 1.871 times (95% CI 1.024-3.418; *P*=.04) the odds of using dating apps compared with people who thought having multiple partners posed *no risk*.

Table 4. Logistic regression of geosocial networking dating app users and the perceptions of risky sexual behavior.

Behavior and risk perception	Total, n (%)	Users, n (%)	Nonusers, n (%)	Dating app users, crude odds ratio (95% CI)	*P* value

Discussion

Principal Findings

This study explored the link between risky sexual behaviors, risk perceptions, and GNDA use among festival goers. After adjusting for confounders, statistically significant associations existed between GNDA use and lack of discussion about safe sex, engaging in casual sex, and having multiple sexual partners. Festival goers who perceived sex without any form of contraception, having sex while drunk, and having multiple sexual partners as risky were more likely to be app users. A high proportion of dating app users (389/440, 88.4%) also thought that GNDAs should promote safe sex.

Condom users were more likely to use dating apps, which can be seen as a protective factor; however, this was not significant after adjusting for confounders. People having unprotected sex with a person who injects drugs and having sex with a partner with an STI were about twice as likely to use dating apps. After adjusting for confounders, this effect was no longer apparent; however, this may have been because of the relatively small number of people in these categories. Given the prevalence of risky sexual behavior in this music festival population, it would be appropriate for GNDA companies and public health experts to include targeted health promotion interventions on such platforms [1,9,15].

Most participants were heterosexual (770/862, 89.3%), directly reflective of the general Australian population, where 11% identify as LGBTQ+ [16]. The LGBTQ+ group were almost twice as likely to use dating apps, a rate comparable with recent literature [3,4,9]. Rosenfeld et al [17] stated that over 60% of same-sex couples met on the web in 2008 and 2009 in the United States, positing a *thin dating market* for LGBTQ+ individuals. It is not surprising that those who are in an exclusive relationship are less likely to use dating apps, whereas those with multiple sexual partners are much more likely to use dating apps.

This study found that music festival attendees who engage in casual sex, do not discuss safe sex, have multiple partners, have unprotected sex with intravenous drug users, or someone with an STI are more likely to use dating apps. Peter and Valkenburg [18] had a similar finding that individuals who scored highly on *sexual permissiveness*—having more tolerant attitudes and higher engagement in risky sexual behaviors—were more likely to use GNDAs. Chan [19] also demonstrated that GNDA users have more casual relationships and sexual partners.

This high rate of casual sex in GNDA users attending music festivals is significant because of the increased STI risk [20]. In Australia, the rates of notifiable STIs such as gonorrhea and chlamydia have risen significantly in recent years [21], implying that there is a risk involved with having multiple sexual partners. In this study, people with multiple sexual partners were more likely to use dating apps. However, the effective use of barrier protection greatly diminishes the likelihood of STI contraction, with the male condom offering 90% protection against gonorrhea [22]. Those who perceived the risk of sex with no form of contraception to be *very high* were 2.5 times more likely to use dating apps and those using condoms were almost twice as likely to use dating apps, potentially signaling that dating app users are aware of the risks involved. A 2016 study found that young Australians have high rates of condom failures, with 48% experiencing the condom slipping off during intercourse and because of high rates of inconsistent or incorrect use [23]. In addition, the cost of condoms impedes their use, even in developed countries [24]. Therefore, a practical method to minimize STI contraction could be to promote awareness about correct use as opposed to increasing risk perception and the services that offer free condoms such as Aboriginal medical services and Family Planning New South Wales [25].

Furthermore, despite perceiving no contraception use to be at a *very high* risk, GNDA users at the festival had low rates of hormonal contraception and relied on emergency contraception. MacPhail et al [26] found that despite 75% of Australian university students having positive attitudes toward condom use, only 50% used condoms during their last encounter. Thus, an increasing perception of risk may not always translate to safer sexual behaviors. Given that Australia's abortion rates are among the highest in the developed world [27], it is important to have greater health promotion on practical methods of reducing unintentional pregnancies. Those who did not use efficacious hormonal contraceptive options such as the oral contraceptive pill and IUDs [28] had higher odds of using GNDAs. Despite the high uptake of barrier contraception, its efficacy tends to be user dependent, as mentioned earlier [23]. Distributing information encouraging longer-acting contraceptive devices and correct contraceptive use via dating apps may be an effective means of curbing accidental pregnancies [28,29]. In addition, this study found that 37.1% (292/788) of sexually active respondents had multiple sexual partners in the last 12 months and that 48.9% (385/788) reported having not used any form of contraception. This is comparable with the study by Lim et al [30], which was conducted at the Big Day Out festival in 2007, with 48% of respondents reporting multiple partners in the last 3 months and 43% not using a condom because of substance abuse. Thus, it seems that over the past 13 years, no significant reduction in engagement in risky sexual behaviors among Australian music festival populations can be noted, and it remains an area in need of targeted sexual health promotion strategies.

Limitations and Strengths

Study limitations included the use of a binary measure of dating app usage in the last 12 months, self-report, selection bias, and the inability to show causal effects because of the cross-sectional design. A longitudinal study method should be conducted to determine the relationship between GNDA use and sexual health behaviors and outcomes over time. Although the survey used evidence-based, risky sexual behaviors [14], the SSBQ was abridged to ensure respondents remained engaged and avoid survey fatigue. This may be problematic, as the study may not have captured the full breadth of risky sexual behaviors within the target demographic. Respondents were willing to complete the survey because the topic is of interest to the study population; however, we did not record how many people declined to partake.

Another study limitation is the potential influence of relationship status and sexual orientation on dating app usage. Our study found that LGBTQ+ people are twice as likely as heterosexuals to use dating apps. This may influence the results about the performance of risky sexual behaviors, as it has been shown that people of sexual minorities, especially men who have sex with men, engage in risky sexual behaviors. Similarly, an increased number of sexual partners and not being in an exclusive relationship were predictors of GNDA use. However, this was adjusted for in multivariate analyses. It should also be noted that participants could have been under the influence of drugs or alcohol, the data were therefore collected early in the day, and people who were perceived to be under the influence were excluded. Finally, the terminologies *casual sex* and *multiple sexual partners* may be considered vague and interpreted differently between participants. Thus, the results

from questions in which these terms were used need to be interpreted with caution.

Practical Implications

An overwhelming number of festival attendees who were GNDA users (389/440, 88.4%) indicated that safe-sex messaging should be included in GNDAs. Our study also demonstrated that young festival attendees engaging in more high-risk sexual behaviors were more likely to be app users. Therefore, as GNDA use at music festivals is promoted by app companies [8], it is recommended to focus on safe-sex messaging. This provides a platform for health strategists to target at-risk demographics. However, health professionals should be aware that a 2018 Australian survey found that although 88.7% of those aged between 18 and 29 years noticed sexual health promotion, only 40.9% considered it relevant and only 32% felt an increase in knowledge [15]. Therefore, the success of safe-sex messaging relies on whether the material will be relevant to users and increase their knowledge of risky sexual behavior. However, as stated earlier, increasing the perception of risk may not always translate to safer sexual behaviors. Despite relatively high levels of risk perception, health promotion messages to lower risk among music festival patrons should be further explored. Areas of future research include examining which GNDAs have the riskiest user bases and which strategies are most effective for harm reduction in this population. Focus groups with festival participants could be conducted to help ensure that messaging is relevant and targeted.

Major GNDAs such as Tinder and Bumble run web-based promotional subsidiaries, including *SwipeLife* (Tinder) [31], *The Buzz* (Bumble) [32], and blogs that incorporate safe-sex articles. As stated previously, less than 19% of heterosexual app users saw safe-sex messages in dating apps [9], despite existing literature identifying the importance of web-based safe sexual health messages to users [9,15,33]. Safe-sex messages may therefore need to appear more prominently within the apps themselves. This is further confirmed by our study, in which an overwhelming majority of participants were in favor of in-app sexual health resources. The fact that Tinder has released coronavirus safety messages in March 2020 demonstrates their ability and willingness to use health promotion messages [31]. In addition, intervention research for safer dating app use has also emerged [34]. Finally, there is evidence that mobile phone interventions can be successful in delivering safe-sex messages [35,36] and strengthens the argument that safe-sex messaging could appear more prominently within dating apps. However, a recent systematic review on new digital media interventions for sexual health promotion among young people reported that it should be taken into account that the technology itself does not necessarily lead to success [11]. The authors suggest that interventions should use high-quality, evidence-based content that engages with young people. Formative research [37] among Swedish youth on the development of a mobile phone app to promote safe sex identified that the following features would engage youth and therefore useful for the app development: *Condom Obstacles and Solutions; Quiz; Games; Self-Refection; Challenges; Stories by Peers (stories from peers and information from a doctor); Condom Tips, Pep Talk, and Boosting; and Random Facts*. Further guidelines are available for complex messaging in health promotion when developing interactive eHealth apps [38].

Conclusions

This study identified that festival goers engaging in certain high-risk sexual behaviors, including casual sex, having multiple sexual partners, and having sex without discussion about STI status and boundaries, are more likely to use dating apps. Festival attendees who perceived sex without any form of contraception, having sex while drunk, and having multiple sexual partners as risky were more likely to be app users. A high proportion of dating app users support the notion that GNDAs should promote safe sex. The results of this study contribute to the growing body of knowledge surrounding the changing landscape of dating, sexual behaviors, and health impacts in the era of GNDAs. Policy makers and GNDA developers should acknowledge the vulnerability of their users to adverse sexual health outcomes and use GNDAs as a platform to promote risk-reduction practices.

Abstract

Background: Internet hospitals in China are in great demand due to limited and unevenly distributed health care resources, lack of family doctors, increased burdens of chronic diseases, and rapid growth of the aged population. The COVID-19 epidemic catalyzed the expansion of online health care services. In recent years, internet hospitals have been rapidly developed. Ping An Good Doctor is the largest, national online medical entry point in China and is a widely used platform providing online health care services.

Objective: This study aims to give a comprehensive description of the characteristics of the online consultations and inquisitions in Ping An Good Doctor. The analyses tried to answer the following questions: (1) What are the characteristics of the consultations in Ping An Good Doctor in terms of department and disease profiles? (2) Who uses the online health services most frequently? and (3) How is the user experience of the online consultations of Ping An Good Doctor?

Methods: A total of 35.3 million consultations and inquisitions over the course of 1 year were analyzed with respect to the distributions of departments and diseases, user profiles, and consulting behaviors.

Results: The geographical distribution of the usage of Ping An Good Doctor showed that Shandong (18.4%), Yunnan (15.6%), Shaanxi (7.2%), and Guangdong (5.5%) were the provinces that used it the most; they accounted for 46.6% of the total consultations and inquisitions. In terms of department distribution, we found that gynecology and obstetrics (19.2%), dermatology (17.0%), and pediatrics (14.4%) were the top three departments in Ping An Good Doctor. The disease distribution analysis showed that, except for nondisease-specific consultations, acute upper respiratory infection (AURI) (4.1%), pregnancy (2.8%), and dermatitis (2.4%) were the most frequently consulted diseases. In terms of user profiles, females (60.4%) from 19 to 35 years of age were most likely to seek consultations online, in general. The user behavior analyses showed that the peak times of day for online consultations occurred at 10 AM, 3 PM, and 9 PM. Regarding user experience, 93.0% of users gave full marks following their consultations. For some disease-related health problems, such as AURI, dermatitis, and eczema, the feedback scores were above average.

Conclusions: The prevalence of internet hospitals, such as Ping An Good Doctor, illustrated the great demand for online health care services that can go beyond geographical limitations. Our analyses showed that nondisease-specific issues and moderate health problems were much more frequently consulted about than severe clinical conditions. This indicated that internet hospitals played the role of the family doctor, which helped to relieve the stress placed on offline hospitals and facilitated people's lives. In addition, good user experiences, especially regarding disease-related inquisitions, suggested that online health services can help solve health problems. With support from the government and acceptance by the public, online health care services could develop at a fast pace and greatly benefit people's daily lives.

Introduction

Background

Internet hospital is an innovative type of hospital where professional physicians provide health care services on the internet. The online health care services at these hospitals include, but not limited to, health-related consultations, disease diagnoses, medication prescription, and chronic disease management [1].

In this study, internet hospitals generally refer to all applications that provide online health services for disease consultation and treatment through information technology. Services by internet hospitals include a combination of offline medical treatment and online follow-up consultation, telemedicine, online medical consultation, and online health management. Internet hospitals are sometimes referred to worldwide as telehealth [2]. In the United States, each state's laws, regulations, and Medicaid program policies for telehealth differ significantly. However, the common aspect they share is that most states and Washington, DC, provide reimbursement via Medicaid for some form of live video as a fee-for-service [3]. In the European Union, most countries have no formal definition of telemedicine services [4]. There is an online consultation system in South West England that allows adult patients to contact their general practitioner, but evidence indicates that the use of e-consultations is very low [5]. Compared with developed countries, telehealth could be more meaningful in developing countries because of limited medical resources and poor health care services [5,6].

Internet hospitals have been rapidly established in China in recent years [7-9]. As of May 2019, there were 158 internet hospitals in China [10], and as of October 28, 2020, there were about 900 of them operating in China [11]. The expansion of internet hospitals is due to the following five reasons.

First, health care resources are limited and unevenly distributed by geography in China [12]. By 2019, there were only 2.77 licensed physicians per 1000 people [13]; for city residents, there were 4.10 licensed physicians per 1000 people, while that number was 1.96 for rural residents [13]. There are 3-tier health care systems in China [14,15]. Primary health care providers are usually community based and are expected to play the role of general practitioner and to perform health care management. Secondary and tertiary health care providers include more specialists and focus on more complicated clinical problems. However, tertiary health care providers are mainly located in the eastern cities of China where the economies are more developed. The top 100 hospitals in China have mostly been located in big cities, such as Beijing and Shanghai, and provincial capitals [16]. As a result, residents in rural areas or western cities have had limited access to high-quality health care services [16].

Second, family doctor systems in China have been underdeveloped [17,18]. As the family doctor plays a gatekeeping role in developed countries, it is convenient for one to seek health care services for mild problems. Although the Chinese government launched a series of policies and regulations to accelerate family doctors' contracting services during the last decades, family doctor systems are still at an early stage in China [17]. The number of general practitioners was not sufficient due to the large population, wide geographic area, and uneven distribution of health care resources. As a consequence, the effect of family doctor systems was compromised in practice [19]. With low public awareness of diseases, patients with moderate symptoms also visited the tertiary hospitals, putting more stress on health care resources. According to the China Health Statistics Yearbook 2020, tertiary hospitals covered 53.5% of patient visits in China, while primary hospitals only accounted for 6.0% [13]. Internet hospitals are easy to access and serve as a supplement to family doctors. Therefore, internet hospitals meet the population's need for convenient access to professional medical help in China.

Third, clinical data sharing has been hindered by unconnected hospital systems. Such information islands result in patients having to endure repeated examinations when changing to a new hospital. However, with internet hospitals, patients are able to upload their existing examination results, which avoids wasting clinical resources.

Fourth, with the increasing burden of medical insurance, the Chinese government proposed the *Healthy China 2030* plan [20] and put more focus on health-driven management instead of traditional disease-driven treatment. For the increasing aged population, health care providers should intervene at the onset of chronic diseases and take advantage of artificial intelligence technology to manage the disease at the same time.

Last but not least, after the outbreak of COVID-19, offline treatment channels were blocked and the Chinese government had adopted a series of administrative measures to encourage the development of internet hospitals [21]. Unnecessary face-to-face contact was avoided with internet hospitals, providing safer and more convenient health care services than in-person, offline hospitals. As suggested by recent work, internet hospitals helped control the COVID-19 epidemic [22,23] and made access to health care services more convenient [24].

In terms of the types of initiators, internet hospitals in China can be divided into government-led, hospital-led, and enterprise-led services [8]. In 2012, the Guangdong Second Provincial General Hospital built the first internet hospital in China, which belonged to the first type of internet hospital (ie, government-led) [14]. Compared with government-led and hospital-led internet hospitals, enterprise-led internet hospitals have the advantages of stronger capabilities in market

exploration and faster product iterations. Enterprises are more open to advanced technology and pay more attention to improving the efficiency of consultation.

Ping An Good Doctor has been one of the leading companies of enterprise-led internet hospitals [21]. It provides health care services via a mobile app of the same name, *Ping An Good Doctor*. Ping An Good Doctor aimed to create a one-stop, whole-process, online-to-offline service platform and integrated online health service platform with offline health services, such as private clinics, pharmacies, health checkup and test centers, and so on [25]. It was rapidly developed, as there was an urgent need for internet hospitals in China. The use of Ping An Good Doctor was nationwide. There were 346 million registered users, more than 1800 staff members working for in-house medical teams, and about 10,000 external experts by the middle of 2020. There were more than 820 million online consultations and inquisitions in total from 2014 until now, which covered a wide range of departments and diseases. The number of cumulative visits during the COVID-19 epidemic—from the period of January 20 to February 10, 2020—reached 1.11 billion [26]. Besides Ping An Good Doctor, Ali and JD are also major players in internet health care in China [27]. However, Ping An Good Doctor has the largest average daily consultation volume [28-30].

Any user with a cell phone can use the health care services provided by the Ping An Good Doctor app anytime and anywhere. Users can ask any health-related questions or seek health care services whether or not they have a specific health problem. In general, a dialogue in the absence of health problems is referred to as a consultation, while seeking clinical help for specific health problems is called an inquisition. In the latter scenario, users are expected to submit their chief complaint and other clinical materials about their health status; the physician would then make the diagnosis and provide corresponding health care services, including prescriptions if needed. Medications, if needed, would be delivered if the users chose to buy them online. All consultations and inquisitions are documented for further quality examination. At the end of the process, users are also asked to score the consultation, where 1 stands for the least satisfaction and 5 for the most satisfaction.

Study Objectives

Despite the rapid development of internet hospitals in China, there exist limited studies examining the characteristics of the departments and diseases of internet hospitals. To fill this gap, we carried out analyses regarding the nationally utilized Ping An Good Doctor platform, aiming to provide a comprehensive description of online medical care in China. Our primary focus was on answering the following three questions: (1) What are the characteristics of the consultations and inquisitions in Ping An Good Doctor in terms of department and disease profiles? (2) Who most often use the platform's online health services? and (3) How do users experience the online consultations of Ping An Good Doctor?

Methods

Data Collection

To eliminate the influence of seasonal patterns, we analyzed the online consultations and inquisitions of Ping An Good Doctor from the past year (ie, from August 2019 to August 2020). Here, consultation referred to the asking of health-related questions, while inquisition meant being treated online for health problems. For all consultations and inquisitions, four types of information were extracted: (1) demographic information about the clients, (2) health care–related variables, (3) details about the consultation process, and (4) consultation evaluations collected after the consultation finished. A detailed description of all variables involved in this study is listed in Table 1.

Table 1. Variables considered in this study.

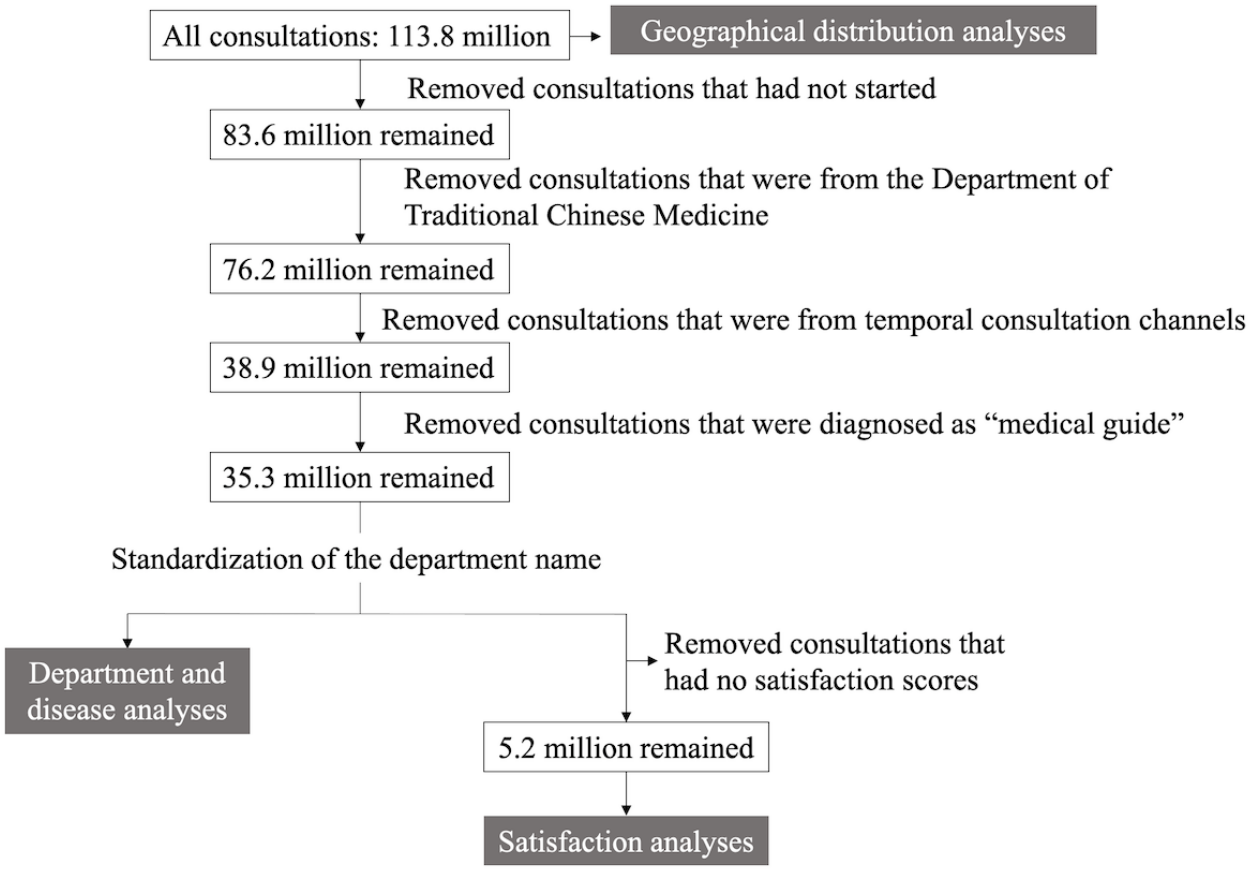
Type of information and variables	Description of variables	Responses (N=113,805,518[a]), n (%)
Demographic information		
Gender	Gender of the user	111,844,894 (98.3)
Age	Age of the user	110,502,135 (97.1)
Province	Province (ie, location) of the user	103,786,537 (91.2)
Health care–related variables		
Diagnosis	Diagnosis as given by the physician	81,574,890 (71.7)
Department	Subentity of the online hospital, such as dermatology	113,805,518 (100)
Details about consultation process		
Dialogue rounds	Number of rounds of dialogue between the user and the physician	113,805,518 (100)
Consultation time	Time of day when the user described their chief complaints	113,805,518 (100)
Consultation evaluation		
Satisfaction score	Scores given by the user after the consultation and/or inquisition	6,879,529 (6.0)

[a]This value represents all consultations and inquisitions combined.

Data Selection

The number of consultations and inquisitions accumulated between August 20, 2019, and August 22, 2020, was around 113.8 million. The detailed process of data selection is illustrated in Figure 1. Four types of consultations and inquisitions were excluded before the analyses of departments and diseases. First, invalid consultations, where the consultations and inquisitions had not started, were removed. Second, consultations from the Traditional Chinese Medicine (TCM) department were excluded since the diagnosis system of TCM is distinct from that of the International Classification of Diseases, Tenth Revision (ICD-10), and is poorly standardized. Third, consultations and inquisitions from some temporal consultation channels, such as the special consulting channel during COVID-19, that would bias the distributions of departments and diseases were also omitted. Lastly, we removed consultations that were labeled as "medical guide," which was an automatic diagnosis label assigned under certain circumstances, such as the unexpected end of a consultation due to the extended nonresponse of the user. After the four data-filtering steps, there were 35.3 million consultations and inquisitions remaining. After standardization of the departments, those data were used for department- and disease-related analyses. To further analyze user satisfaction of the online consultations, data that had no satisfaction scores were filtered out.

Figure 1. The process of data selection and the data sets that were used for different analyses.



Data Preprocessing

The diagnoses from the inquisitions were mainly based on the ICD-10 coding system [31], while consultations were assigned self-defined diagnosis labels, such as *general consultations*, *specific consultations*, and *lifestyle-related questions*. Here, the term *general consultations* was a vague definition referring to asking questions about any nonspecific aspect of health problems, such as how one should take exercise if one has had a stroke. *Specific consultations* referred to asking questions about a specific disease, such as diabetes and cardiovascular diseases. *Lifestyle-related questions* referred to asking questions about how to stay healthy without mentioning specific health problems, such as what tea to drink to protect eyesight.

Generally, the diagnosis labels for inquisitions and consultations were standardized as one-by-one mapping to ICD-10 or self-defined codes.

It should be noted that for 20.2% (7,140,917/35,296,169) of the consultations and inquisitions, there existed multiple diagnoses. In this case, the diagnosis distribution was calculated by splitting the multiple diagnoses of one sample into multiple samples, each sample with a distinct diagnosis. All analyses in terms of diagnoses were based on this splitting approach of diagnosis statistics, such as user experience for each diagnosis.

Statistical Analysis

Data were extracted from the database using Structured Query Language and were preprocessed by the *pandas* library in Python 3.6 (Python Software Foundation).

Results

Overview of the Online Consultations and Inquisitions

The overall statistics of our data set are shown in Table 2. There were 35,296,169 valid consultations and inquisitions in total. During the study period, 12,446,838 users participated in consultations via Ping An Good Doctor. A total of 40.3% of the consultations and inquisitions were made by male users, and the mean age of the users was 27.3 years (SD 17.2). There were, on average, 7.3 (SD 5.3) rounds of conversation between users and physicians. After standardization, there were 76 departments and 1419 diseases covered in the cross section that we studied.

As shown in Figure 2, which was drawn using the *pyecharts* library in Python 3.6, the consultations and inquisitions came from all the provinces, municipalities, and autonomous regions of China. Shandong (19,067,141/113,805,518, 18.4%), Yunnan (16,192,209/113,805,518, 15.6%), Shaanxi (7,439,540/113,805,518, 7.2%), and Guangdong (5,672,425/113,805,518, 5.5%) were the four leading provinces and accounted for 46.6% (48,371,315/113,805,518) of the total consultations and inquisitions in our data set. A city-level rank was also calculated. Table 3 lists the top 10 cities in yearly visits to Ping An Good Doctor. It was interesting to note that big cities such as Beijing and Shanghai only ranked 9th and 5th, respectively, accounting for 34.4% (1,699,251/4,932,918) and 54.7% (2,700,223/4,932,918) of the total visits, relative to the top city, Kunming.

Longitudinally, the COVID-19 epidemic activated the daily visits to Ping An Good Doctor. As shown in Table 4 [32,33], the average daily visits increased by 23.2% during the outbreak of COVID-19 in China. It was encouraging that the average daily visits increased more even after the outbreak of COVID-19 in China.

Table 2. Characteristics of the current data set.

Characteristic	Value
Total consultations and inquisitions, N	35,296,169
Consultations and inquisitions by male users, n (%)	14,063,178/34,904,918 (40.3)
Users of the platform, n	12,446,858
Age of users who submitted consultations and inquisitions (years), mean (SD)	27.3 (17.2)
Rounds of dialogue between physicians and users, mean (SD)	7.3 (5.3)
Departments represented in the data set, n	76
Diseases represented in the data set, n	1419

Figure 2. The number of consultations and inquisitions from all over China out of the original 113.8 million data points. Red dots indicate the capital city of each province and the black dot indicates the city of Kunming. Kunming had the largest volume of consultations and inquisitions in Ping An Good Doctor at the city level.

Table 3. Top 10 cities by visits to Ping An Good Doctor from August 2019 to August 2020.

City	Province	Relative yearly visit amount[a]
Kunming	Yunnan	1
Xi'an	Shaanxi	0.915
Yantai	Shandong	0.835
Qingdao	Shandong	0.559
Shanghai	Shanghai	0.547
Chongqing	Chongqing	0.424
Linyi	Shandong	0.410
Honghe Hani and Yi Autonomous Prefecture	Yunnan	0.385
Beijing	Beijing	0.344
Zhengzhou	Henan	0.305

[a]Values are based on the original 113.8 million data points; relative yearly visits of each city are calculated by setting the yearly visit amount by Kunming as a reference.

Table 4. Average daily visits to Ping An Good Doctor before, during, and after the outbreak of COVID-19 in China.

Phase	Time range	Daily visits, mean (SD)
Before the COVID-19 outbreak	August 20, 2019, to January 22, 2020	74,893.92 (5843.34)
During the COVID-19 outbreak	January 23, 2020[a], to February 29, 2020[b]	92,246.74 (20,411.83)
After the COVID-19 outbreak	March 1, 2020, to August 22, 2020	114,898.50 (11,708.20)

[a]The city of Wuhan closed on January 23, 2020, indicating the start of the outbreak of COVID-19 in China [32].

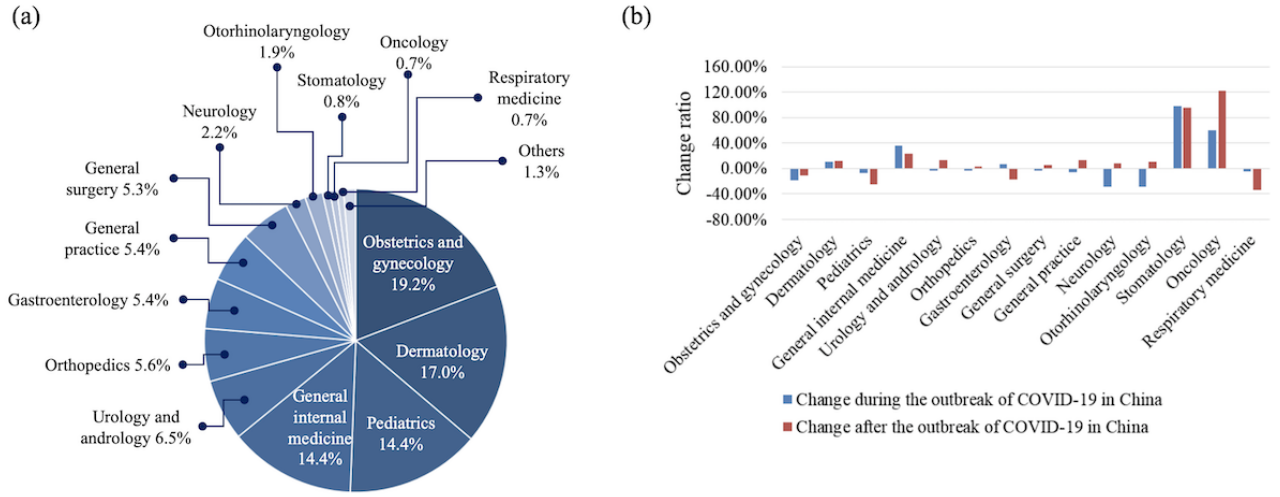
[b]As of February 29, 2020, the number of newly diagnosed COVID-19 cases per day in China was less than 1000 [33].

Characteristics of Departments and Diseases in Online Consultations

Distribution of Departments

Although there were 76 departments represented in our data set, about 14 (18%) departments accounted for more than 99% of the consultations and inquisitions. As shown in Figure 3 (a), the most popular department was gynecology and obstetrics, which was represented in 19.2% (5,868,172/30,579,297) of the consultations, followed by 17.0% (5,204,805/30,579,297) for the dermatology department and 14.4% (4,394,634/30,579,297) for pediatrics. We further analyzed the change ratios of distribution for the top 14 departments during and after the COVID-19 outbreak to investigate the effect of the COVID-19 epidemic on the distribution of departments. The result is shown in Figure 3 (b); for most of the departments, the change ratios were within ±10% during and after the COVID-19 outbreak. It should be noted that the fraction of consultations represented by dermatology increased by more than 10%, both during (from 15. 9% to 17.5%) and after (from 15.9% to 17.7%) the COVID-19 outbreak. In addition, the fraction of consultations represented by general internal medicine increased by 36.5% (from 11.7% to 16.0%) and 22.7% (from 11.7% to 14.4%) during and after the COVID-19 outbreak, respectively. Although the fractions of consultations represented by stomatology and oncology both had a sharp increase, their absolute fractions increased by 0.47% and 0.51% after the COVID-19 outbreak, respectively.

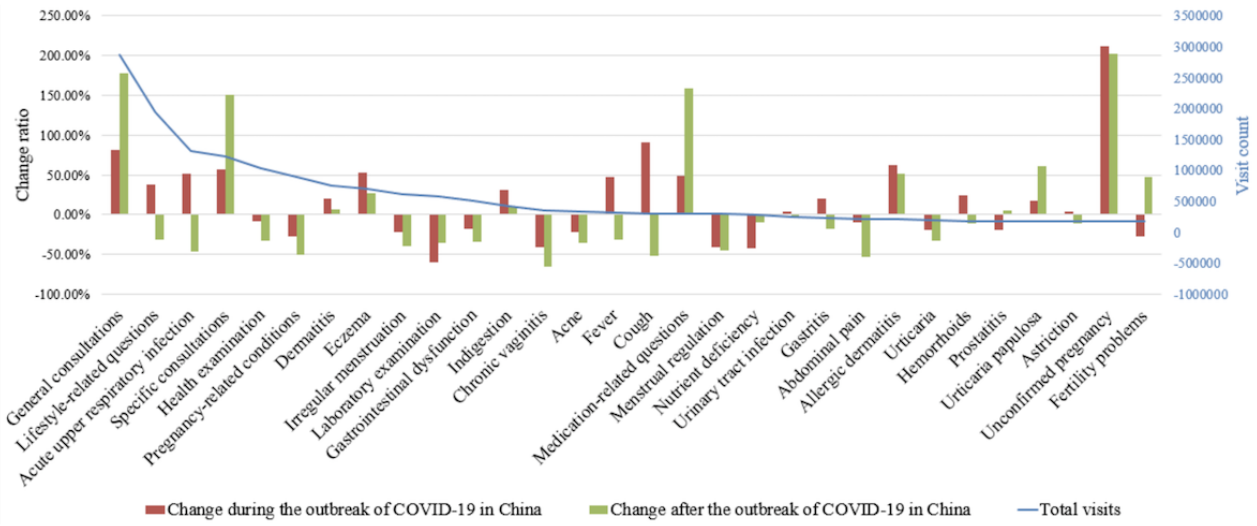
Figure 3. Departments represented in the consultations and inquisitions: (a) distribution of the departments; (b) change ratios of the distribution of the top 14 departments during and after the outbreak of COVID-19 in China.



Distribution of Diseases

There were 1419 diseases represented in our data set, and the top 30 diseases accounted for 53.6% (17,911,125/33,409,879) of the total consultations. As illustrated by the blue line in Figure 4, consultations were the key components in terms of yearly visits to Ping An Good Doctor; these included *general consultations*, *lifestyle-related questions*, *specific consultations*, *health examinations*, and *pregnancy-related conditions*. The change ratios of disease distribution during and after the COVID-19 outbreak were also analyzed. As shown by the red bars in Figure 4, diseases labeled as *unconfirmed pregnancy*, *cough*, *consultations*, and *specific consultations* increased the most during the COVID-19 outbreak. In addition, *eczema* and *allergic dermatitis* also had a significant increase. To summarize, diseases that increased in popularity during the COVID-19 outbreak, as represented in consultations and inquisitions, included those with respiratory or dermatology symptoms. After the COVID-19 outbreak, the inquisitions that included respiratory symptoms decreased, while the inquisitions that included characteristics of other diseases and consultations remained.

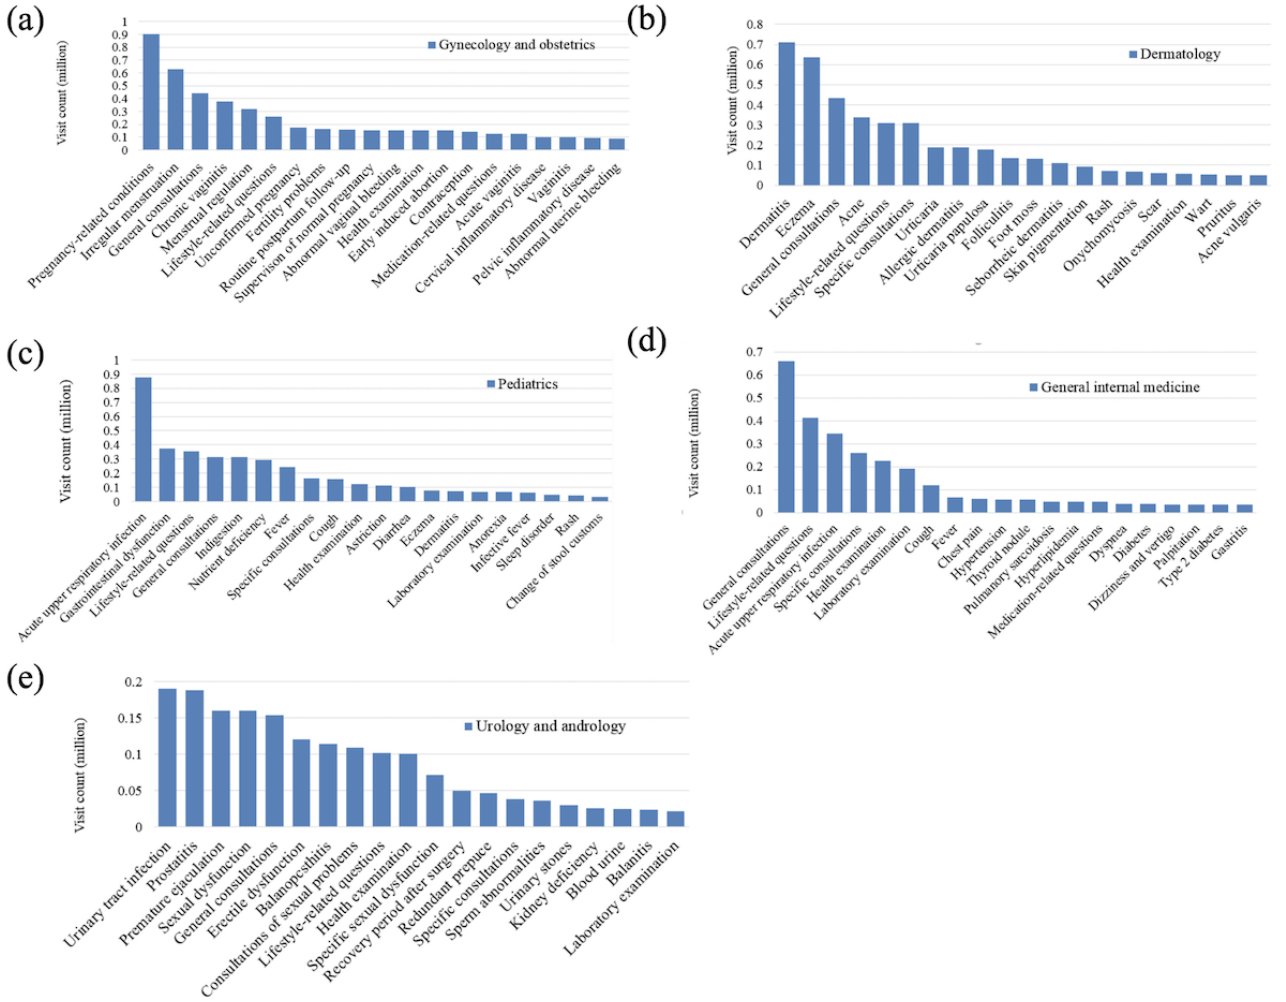
Figure 4. Distribution of the top 30 diseases represented in the yearly visits to Ping An Good Doctor; change ratios of the distribution of diseases during and after the outbreak of COVID-19 in China are also shown.



Disease Profiles for the Most Popular Departments

We further analyzed the disease profiles for the five most popular departments to see if major diseases existed in each department. The results are illustrated in Figure 5; for each department, the top 20 diseases are shown.

Figure 5. Disease profiles of the top five departments: (a) gynecology and obstetrics, (b) dermatology, (c) pediatrics, (d) general internal medicine, and (e) urology and andrology.



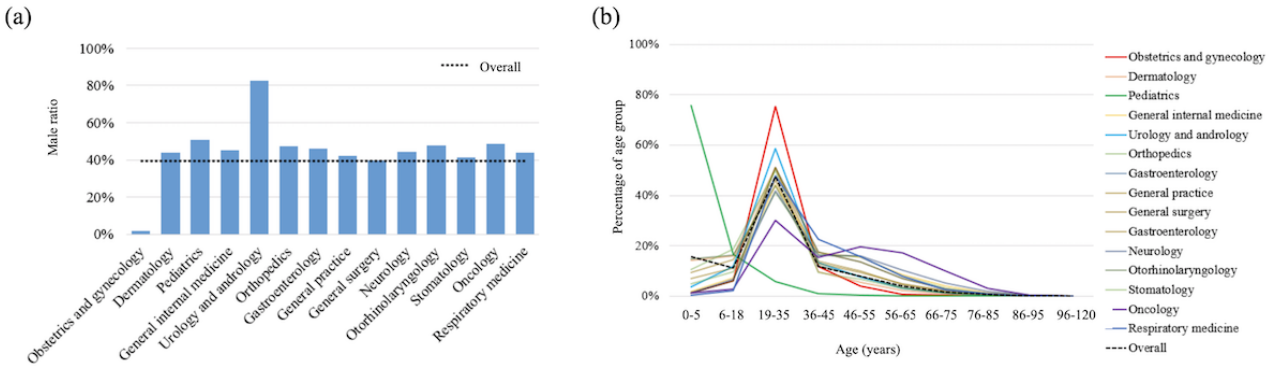
From Figure 5, pediatrics had the most obvious head effect regarding disease profiles, while acute upper respiratory infection (AURI) accounted for 16.5% (876,786/5,074,566) of all the consultations. In addition, urology and andrology had the least head effect regarding disease profiles, suggesting a relatively high degree of disease diversity.

User Profiles

Demographic Characteristics

To better understand the users of Ping An Good Doctor, we analyzed the user profiles for the top 14 departments. Male users accounted for 39.6% (12,098,998/30,579,308) of the consultations; this proportion varied little except for the reproductive-related departments, as shown in Figure 6 (a). For most of the departments, users aged 19 to 35 years constituted the largest proportion of users as compared with other age groups, as listed in Figure 6 (b). For pediatrics, there were many more consultations and inquisitions for children under 6 years of age than for children older than 6 years of age. For the respiratory medicine department , there was a relatively higher proportion of users aged 36 to 45 years as compared with the overall age groups. For oncology, the proportion of users in the senior age ranges increased.

Figure 6. User profiles for the top 14 departments: (a) percentiles of male users by department; (b) age distribution.

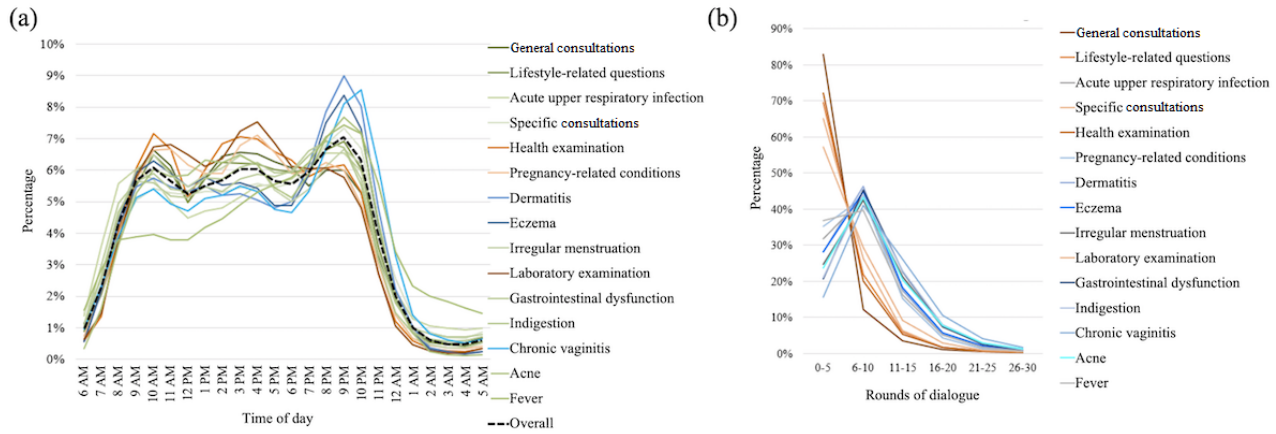


User Behaviors

The user profiles for the top diseases had concordant observations with those for the department analyses. We further investigated user consultation behaviors with respect to different diseases; namely, the times of day when users began to seek consultations and the rounds of dialogue between users and physicians.

As shown in Figure 7 (a), there were three peaks regarding times of day for consultations; these were 10 AM, 3 PM, and 9 PM. The diseases could be roughly divided into three groups according to the relative proportions for different time-of-day peaks as indicated in Figure 7 (a). Figure 7 (b) shows the distribution of rounds of dialogue between the users and physicians. For inquisitions, the number of rounds of dialogue peaked at around the *6 to 10* range; for consultations, at least half of the dialogues went through *0 to 5* rounds.

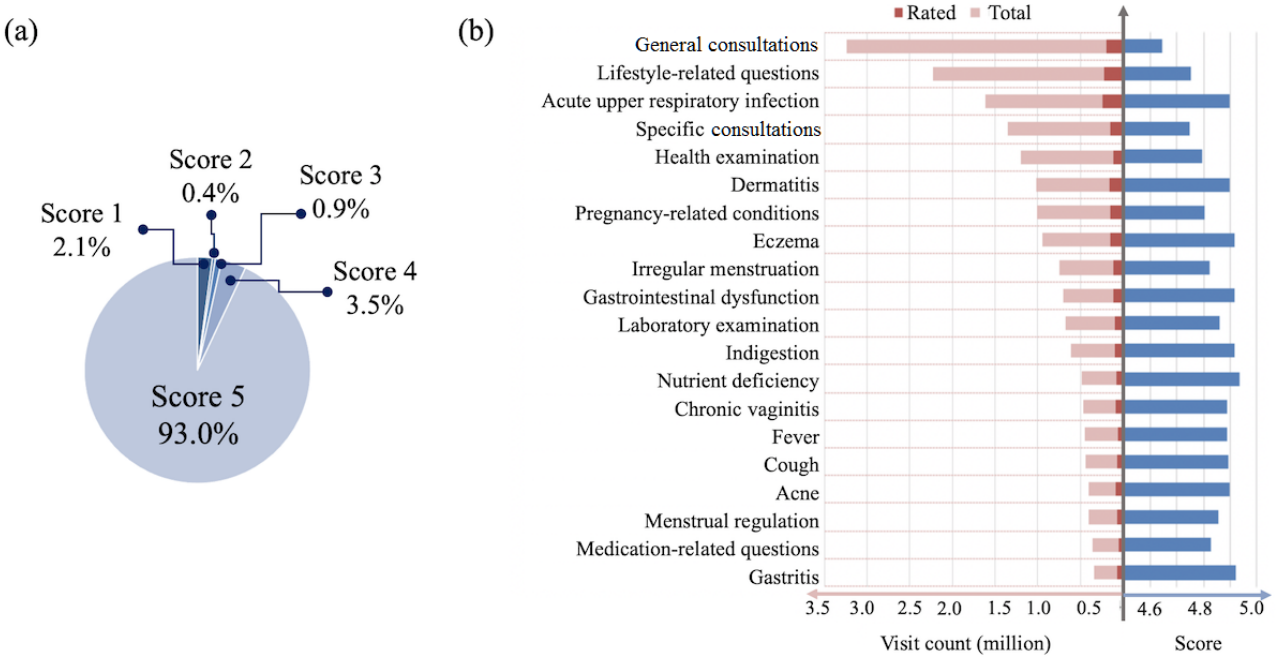
Figure 7. Characteristics of users' behaviors regarding the top 15 diseases: (a) distribution of times of day of consultations; (b) distribution of rounds of dialogue between users and physicians.



Users' Satisfaction With Online Consultations

Among all the 35.3 million consultations, there were 5.2 million that had satisfaction scores. A total of 93.0% (6,408,143/6,879,529) of these satisfaction scores were 5, suggesting that the vast majority of the users had a good experience when using Ping An Good Doctor, as seen in Figure 8 (a). We also analyzed user satisfaction in terms of different diseases. As shown in Figure 8 (b), consultations related to the top 20 diseases all had average satisfaction scores above 4.6. For some specific diseases, the average satisfaction scores were even higher, such as for AURI and dermatitis, which were also popular topics of consultation in our internet hospitals. For *general consultations* and *specific consultations*, the satisfaction scores were relatively low.

Figure 8. Users' satisfaction with the online consultations: (a) the distribution of satisfaction scores; (b) the proportion of users who scored the consultations and inquisitions and the corresponding scores related to the top 20 diseases. Scores range from 1 (least satisfaction) to 5 (most satisfaction).



Discussion

Principal Findings

Analyses in this study answered the three questions proposed in the Introduction section. First, the distributions of departments and diseases in Ping An Good Doctor differed from those of offline hospitals. The gynecology and obstetrics department and the dermatology department were the top two departments in Ping An Good Doctor in terms of number of consultations, which differed from offline hospitals. The popularity of gynecology and obstetrics came from about 22% of the users being female, aged 19 to 35 years, who were in the reproductive age group. The popularity of dermatology suggested that users found it suitable and more acceptable to seek consultations about dermatological diseases online. Consultations and diseases with moderate symptoms were commonly seen in terms of disease profiles. Second, we found that most of the users of Ping An Good Doctor were between 19 and 35 years of age, and females were slightly more highly represented compared to males. The gender distribution was in agreement with previous work by Qiu et al, though their results were based on one city with a much smaller population [34]. Last, the users had a good experience with Ping An Good Doctor, in general. We observed an average satisfaction score of 4.6 out of 5, suggesting that users were comfortable with Ping An Good Doctor as a health care service.

Our results provided the distribution profiles of departments and diseases. By examining those distributions, we could gain an increased understanding about which diseases can be diagnosed and treated online. The user profile analysis described the current user market of internet hospitals; a new strategy to explore the market should be based on this user profile analysis.

Open Attitudes Were the Key Factor for Developing Internet Hospitals

Based on the geographical distribution of the Ping An Good Doctor visits, we found that Shandong, Yunnan, Shaanxi, and Guangdong were the four leading provinces in terms of volume of visits; the reasons for this were four-fold. First, Shandong and Guangdong have large populations. Second, high-quality health care services are limited in these four leading provinces; Shandong, Yunnan, Shaanxi, and Guangdong ranked 17th, 24th, 20th, and 19th, respectively, in terms of number of tertiary hospitals per 100,000 persons, according to the China Health Statistics Yearbook 2020 [13]. Third, Guangdong and Shandong have a relatively high internet penetration rate [35]. Fourth, open attitudes toward internet technology were the key factor for developing internet hospitals. Guangdong was the pioneer in online health care services. The Guangdong government funded the first internet hospital in China [14]. Shandong has the most online physicians in a web-based medical consultation service in China, which suggests an open mind on the part of the physicians [36]. The Yunnan and Shaanxi governments also have an open attitude toward the internet-related industry and the public has a high acceptance of internet technology.

It was interesting to note that the usage of internet hospitals was not centered in big cities. For example, Beijing and Shanghai ranked 9th and 5th, respectively, among all the cities, although these two are megalopolitan cities with populations of more than 20 million. Kunming, the capital of Yunnan province with a population of around 7 million, had more yearly visits than Shanghai. The geographical distribution of yearly visits to Ping An Good Doctor suggested that internet hospitals provided accessible health care services to anyone in need and could relieve the uneven distribution of health care services across China.

Nondisease-Specific Consultations and Moderate Health Problems Were Popular in the Top Five Departments

The top five departments represented in Ping An Good Doctor were gynecology and obstetrics, dermatology, pediatrics, general internal medicine, and urology and andrology. As the characteristics varied across departments, we will discuss them one by one.

In gynecology and obstetrics, the most common consultations and inquisitions were focused on menstruation, vaginitis, and cyesis. These were mild health issues as compared with those in offline hospitals where cancers; cervical disease, such as hysteromyoma and ovarian cyst; and obstetric complications were seen in higher proportions. These profiles were consistent with the highest ratio of users who sought consultations in gynecology and obstetrics being aged 19 to 35 years, as seen in Figure 6 (b).

For dermatology-related concerns, the most common diseases were dermatitis and eczema, as seen in Figure 5 (b). The same pattern was also reported in other work [37]. It was interesting to note that disease inquisitions played a major role as compared with consultations. The most important reason for this was that the online health care service could replicate the offline clinical scenarios to the largest extent. Users were able to upload pictures of their skin, which played a vital role in diagnoses and treatments in the dermatology department. In addition, the efficiency and timeliness of online health services encouraged users to choose online inquisitions when they had dermatological problems. Online consultations also allowed patients to avoid the potential embarrassment of exposing themselves to physicians face-to-face.

In pediatrics, the most common inquisitions were about AURIs as well as growth and development, such as nutrient deficiency. Recent work on a pediatric map of Hangzhou also found that AURI was the top disease discussed in all the outpatient visits they considered. However, the next most popular category of diseases in their study was common symptoms, such as fever, abdominal pain, and vomiting, which was distinct from the pattern we found in the online health service [38]. Internet hospitals provide a way to efficiently and conveniently acquire knowledge about children's growth and development, relieving parents' anxiety. Educated with knowledge about their children's growth and development, parents can make proper and timely decisions when needed. Mild medical cases were able to be resolved online, which reduced unnecessary visits to offline hospitals and also relieved the stress experienced by them.

The diseases that were part of the general internal medicine department were mostly chronic, indicating that health management was in high demand. This was in agreement with previous findings from Di Tommaso et al [39]. Meanwhile, health management was vital for reducing fatality rates and disability rates. The proper management of chronic diseases could reduce the occurrences of complications and acute episodes. Traditionally, physicians mainly focus on chronic diseases at the time of patient in-person, offline visits; they have no time to conduct daily management for patients with chronic diseases. With developments in artificial intelligence and wearable devices, health care data are easy to collect and analyze. With well-educated patients and automatic tracking of physical measures, smart health care management has relieved physicians from tedious work and helped patients to maintain clinical conditions. Meanwhile, patients can benefit from advice on diet, exercise, and medication as given by smart health care management.

In the urology and andrology department, the consultations and inquisitions were focused on sexual function and urinary system infections. The online consultations were private and allowed users to avoid the embarrassment of face-to-face inquiries about sexual function problems. Urinary system infections were also common in both online and offline hospitals, but other frequent diseases seen in offline hospitals, such as cancer, urinary stones, and surgical trauma, were uncommon in online consultations.

To summarize, the common diseases seen in internet hospitals included moderate health problems. In this sense, internet hospitals play the role of general practitioner, which partially fills a gap that exists in the family doctor system in China.

Relationship Between the COVID-19 Epidemic and Internet Hospitals

The COVID-19 epidemic promoted widespread use of internet hospitals in China. From Table 4 and Figure 4, we observed that consultations and inquisitions did not decrease even after the first outbreak of COVID-19, from January 23, 2020, to February 29, 2020. COVID-19 provided people with an opportunity to change their behavior when seeking health care services. With the epidemic under control, the development of internet hospitals has normalized [40]. On the other hand, internet hospitals played a vital role in China's defense against COVID-19, from sharing knowledge on virus control and providing health consultations to follow-up treatment for chronic diseases and drug delivery. Ping An Good Doctor also played a positive role during the COVID-19 pandemic, suggesting that internet hospitals are a valuable resource in dealing with large-scale public health emergencies [41].

More Advantages of Internet Hospitals

In addition to the pros mentioned above, internet hospitals had many other advantages. First, internet hospitals had a positive effect on the physician-patient relationship [42]. Online health services made health information more accessible to patients, reducing the communication barrier between physicians and patients.

Second, for the physicians, providing health care services via internet hospitals was a way to not only increase their income but to widen and deepen their clinical experience of patients. The patients they met were not limited to their local regions. Meanwhile, physicians had the opportunity to inspect the whole disease process for the patients, from the onset to the prognosis.

Finally, internet hospitals could accelerate the reform of government health care insurance in China and possibly the world. Medical insurance costs increase year by year. The total cost reached 2085.4 billion yuan (US $299 billion) in 2019 in China, and had increased by 12.2% compared to 2018 [43]. Internet hospitals could help control four aspects of medical insurance costs. First, because the process of consultations and inquisitions was documented and all data were traced, it is feasible to conduct quality control and fraud detection. Second, equipped with artificial intelligence, standardized diagnosis and treatment procedures were simplified; for example, a robot helps to collect basic information before the consultations begin. Therefore, with increased efficiency, the cost of consultations in internet hospitals would decrease. Third, the whole process of health management in internet hospitals controls the rate of chronic diseases and, in the end, reduces medical insurance costs. China has a large population living with chronic diseases. Until 2019, there were 116.4 million people with diabetes in China [44]. The glucose control rate was 10.2% in China and was 49.9% in America [45]. A higher control rate is related to slower disease progression, lower comorbidity risk, lower disability rate, and lower costs. Efficient health management could help to increase the control rate and reduce medical costs. Fourth, internet hospitals could promote the separation of medical services and medications, which would prevent doctors from receiving rebates from drugs.

Limitations

We described the characteristics of internet hospitals in terms of the distributions of departments, diseases, user profiles, user behaviors, and user experiences. However, treatment—an important aspect of clinical practice—was not investigated and evaluated, but will be targeted in our future work. To deepen our understanding of the characteristics of internet hospitals, our future efforts will include additional comparisons between offline hospitals and internet hospitals.

Conclusions

As the largest entry point to online medical services in China, Ping An Good Doctor provides accessible health care services nationwide, breaking the geographical boundary for high-quality clinical resources. The COVID-19 epidemic accelerated the expansion of online health services. This also provided an opportunity to test the feasibility of such online modes of health care delivery. It should be emphasized that after the outbreak of COVID-19, the number of daily visits kept increasing, suggesting that online health services satisfied peoples' needs for convenient and contactless health services. Our analyses showed that nondisease-specific consultations and moderate health problems accounted for the majority of online visits to Ping An Good Doctor. This indicated that online health services played a similar role as family doctors. The positive feedback received from most users showed that online health services would be their preferred option in many circumstances. The changes in people's attitudes and behaviors, together with

support from the government, would further promote the development of online health services, leading to great benefits for both patients and health care providers.

Abstract

Background: Heart failure (HF) is a major public health problem that places a significant disease burden on society. Self-care is important in the management of HF because it averts disease progression and reduces the number of hospitalizations. Effective nursing interventions promote HF self-care.

Objective: This study aims to explore participants' perspectives on a nurse-led, home-based heart failure self-management program (HOM-HEMP) in a randomized controlled trial conducted in Singapore to gain insight into the effectiveness of the study intervention.

Methods: A descriptive, qualitative approach was used. English- or Chinese-speaking participants from the intervention arms were recruited through a purposive sampling method from January 2019 to July 2019. Individual, face-to-face, semistructured interviews were conducted with 11 participants. All interviews were audio recorded and transcribed verbatim, with the participant identifiers omitted to ensure confidentiality. The thematic analysis approach was used to identify, analyze, and report patterns (themes) within the data.

Results: A total of six themes emerged from the process evaluation interviews and were categorized according to the Donabedian structure-process-outcome framework as *intervention structure*, *intervention process*, and *intervention outcome*. These six themes were manageability of the intervention, areas for improvement, benefits of visiting, personal accountability in self-care, empowered with knowledge and skills in self-care after the intervention, and increased self-efficacy in cardiac care.

Conclusions: The findings of the process evaluation provided additional information on participants' perceptions and experiences with the HOM-HEMP intervention. Although a home visit may be perceived as resource intensive, it remains to be the preferred way of engagement for most patients. Nurses play an important role in promoting HF self-care. The process of interaction with the patient can be an important process for empowering self-care behavior changes.

Introduction

Background

Heart failure (HF) is a major public health problem that places a significant disease burden on society. It is one of the most common causes of hospital admissions and readmissions, leading to an increased demand for hospital beds, staff resources, subsidies, and insurance coverage [1]. Southeast Asians are at particular risk of HF because of the high prevalence of risk factors such as hypertension and diabetes. They also have an earlier onset of HF than Americans and Europeans [2]. Furthermore, the incidence and prevalence of HF are closely related to age. As one gets older, the condition becomes more common [3]. Singapore has one of the fastest aging populations among developed countries worldwide. Therefore, it is expected that the number of people with HF is likely to surge in the near future.

To sustain the health care system, the Ministry of Health in Singapore recently announced three paradigm shifts: beyond hospital to community, beyond quality to value, and beyond health care to health [4]. With this change, more patients with chronic conditions will be managed in the community, and nurses will need to embrace new knowledge and skills that match the care needs of their patients. Simultaneously, as hospital stays become shorter and less frequent, there is a need for patients and families to acquire disease self-care skills to achieve the success of managing their conditions outside the hospital.

In HF, self-care encompasses a range of behaviors, including adhering to medication and treatment, avoiding excessive fluid and salt intake, monitoring daily weight, engaging in exercise, monitoring and identifying exacerbating symptoms, and taking appropriate steps to intervene if symptoms worsen [5]. Self-care is the cornerstone of HF management. Patients who practice constant self-care have been shown to avert 30% of hospital admissions and more than half of the readmissions [6]. Despite its importance, several studies have reported gaps in patients' knowledge and skills regarding HF self-care, with many patients finding HF self-care challenging, especially when transitioning from hospital care to home and community care [7,8]. Traditionally, hospital nurses have provided disease education with information on the value of medication adherence and lifestyle risk modification. Most of these education programs are done as part of discharge instructions and/or as part of inpatient education. However, the severity of symptoms during stressful hospital stays (eg, breathlessness and fatigue) precludes patients from being physically and psychologically ready to absorb any information. As a result, many patients feel underinformed when they return home [8].

We recently conducted a 3-arm stratified randomized controlled trial to evaluate the effectiveness of a newly developed, nurse-led, home-based psychosocial and educational intervention (home-based heart failure self-management program [HOM-HEMP]) for patients with HF in Singapore (ClinicalTrials.gov NCT03108235) [Jiang Y, unpublished data, 2021]. The development of the intervention and its detailed description have been published previously [9]. In brief, the HOM-HEMP intervention is a 6-week, multicomponent self-management program designed to promote HF self-care. It consisted of an HF patient education and self-care toolkit and three biweekly home visits by the research nurse. The toolkit included an HF education manual, a drinking cup marked with fluid volume, picture cards of common local foods and their associated sodium content, a weight scale, a weight monitoring calendar, and a pillbox with an alarm clock that reminded patients to take their medications (Multimedia Appendix 1). The toolkit provided cues (eg, a visual reminder of fluid intake and alarm reminder for medication adherence) of self-care activities in the context of daily life, whereas biweekly home visits provided an opportunity for the research nurse to interact with patients face-to-face, during which the research nurse also employed motivational interviewing to promote patient self-care engagement. In addition, a supplementary smartphone app was developed based on the study intervention (Multimedia Appendix 2), which was only available to participants in the experimental group B (one of the intervention arms). The smartphone app offered features such as educational content; customized scheduled medication and medical appointment reminders; weight, blood pressure, and symptom logs; and a chat room to communicate with the research nurse via text message. The research nurse reviewed the patient's symptoms on the back end through a secured web portal.

The aims of the research project are to evaluate the effectiveness of the HOM-HEMP intervention in improving patients' HF self-care, cardiac self-efficacy, psychological well-being, health-related quality of life, social support, and clinical outcomes. Consenting participants were randomly assigned to a control group, an experimental group A, and an experimental group B. All study participants received usual care provided by the study hospital. Participants in the experimental group A and experimental group B received usual care and the HOM-HEMP intervention. In addition, participants in the experimental group B received a supplemental smartphone app. The purpose of having 2 experimental groups was to explore the effects of the mobile health (mHealth) component on the study outcomes. The findings of this trial are reported elsewhere [Jiang Y, unpublished data, 2021].

Objectives

This study details the process evaluation of the study intervention, which is part of the HOM-HEMP research project [9]. Process evaluations are recommended by the UK Medical Research Council guidance to provide additional information to understand how an intervention might or might not work in a specific context or whether the outcomes of the trial can be reproduced [10]. It is an important step in the evaluation of a complex intervention, as it allows researchers and practitioners to understand whether improvements in outcomes have resulted from the intended intervention process, whether the intervention causes poor outcomes, or even sometimes whether good outcomes are produced by the intervention that is actually less satisfactory [10].

To better understand participants' views and experiences regarding the HOM-HEMP intervention provided to them, the Donabedian structure-process-outcome framework was

employed in the process evaluation [11]. In his model, Donabedian proposed *structure*, *process*, and *outcome* of care as the key aspects of quality of care [12]. The framework recognizes that outcomes are associated with the relationships between the context and actions of patients and care providers and that understanding the implementation of an intervention requires not only what is delivered but also the mechanism through which the intervention is delivered [11]. In this study, *structure* refers to physical components of the intervention and the organization of the intervention, such as the duration and frequency of the intervention; *process* refers to the participants' experiences of interactions and encounters during the study intervention; and *outcome* refers to changes in participants as a result of the intervention and/or interactions with the research nurse during the intervention.

The aim of this process evaluation is to explore participants' views and experiences with regard to the HOM-HEMP intervention and to understand the mechanism by which the intervention had an impact.

Methods

Study Design and Participants

A descriptive, qualitative approach was used. One-to-one semistructured interviews were conducted to elicit participants' responses to their overall experiences with the HOM-HEMP intervention. An interview guide was developed to guide the one-to-one semistructured interviews and to ensure uniform data collection across all participants. The questions in the interview guide were reviewed by the members of the researcher's team, all of whom had experience in conducting qualitative research. The semistructured interview offers some flexibility that allows participants to voice out their views in a naturalistic narrative fashion while ensuring that all question areas were discussed with each participant [13]. Compared with group interviews, the one-to-one interview format provides a less threatening environment for the participants to share their personal views and/or describe their experiences [13].

Participants were recruited through a purposive sampling method from January 2019 to July 2019 at a tertiary public hospital in Singapore. Participants from the intervention arms with either positive or negative differences in any of the study outcomes were included in the process evaluation if they were willing to be audio recorded. The inclusion criteria for the HOM-HEMP research project were patients who were aged ≥21 years, had been clinically diagnosed with HF, were able to read and understand English or Chinese, owned and used a smartphone in their everyday lives, and were able to be followed up at home after discharge from the hospital. The exclusion criteria were patients who had unstable angina, resting tachycardia, or severe arterial hypertension; had a terminal illness other than HF that affects their self-care ability and/or completion of the study, for example, end-stage cancer; had a psychiatric condition or impaired cognitive functioning that affects their understanding of the study intervention; were bed- or wheelchair-bound affecting their mobility and self-care ability; and had no internet access at home. To ensure a diverse sample of participants, participants' ethnicity, age, and socioeconomic status were taken into consideration when choosing the cases in this study to identify important patterns across variations [13].

Sample Size

There is no established rule for sample size in qualitative evaluations. In this study, the sample size was determined based on information needs and the concept of data saturation [13]. Recruitment for the process evaluation interview stopped when no new information emerged and redundancy was achieved.

Data Collection

At the end of the HOM-HEMP study, participants from either experimental group A or experimental group B were approached based on the purposive sampling criteria. Details regarding the interview process and objectives were explained to the participants. In addition, they were informed that the session would be audiotaped. Written informed consent was obtained from the participants before the interviews commenced. Interviews were arranged at a place convenient for the participant.

Qualitative data were obtained from individual, face-to-face, semistructured interviews. All interviews were conducted by a research nurse who delivered the study intervention. Interviews were conducted in either English or Chinese, depending on the participants' language preference. Before the start of the interview, the research nurse reassured the participants that all the information they provided would be kept confidential and that the interview would be like a conversation with no right or wrong answers to the questions asked. Rapport was established by one or two warm-up questions before putting forward the topics on the interview guide. Open-ended questions were used to encourage participants to talk freely on the questions asked. If the participants' family members were present during the process evaluation interview, their role was limited to helping to relay the point the participant was trying to make when the participant had difficulties in explaining his or her point of view clearly. All interviews were audio recorded and transcribed verbatim. The participant identifiers were omitted from the transcripts to maintain confidentiality. The transcripts were cross-checked by a second researcher to ensure accuracy.

Ethical Considerations

Ethical approval was obtained from National Healthcare Group-Domain Specific Review Board (NHG DSRB ref: 2017/00249) before the commencement of the HOM-HEMP research project. Voluntary participation, confidentiality, the right to withdraw, and potential risks and benefits were explained. Informed consent was obtained from each participant before the study commenced. Participants were also reassured that declining to participate in the study would not lead to any penalties or any differences in treatment or care.

Data Analysis

Descriptive data analysis was performed to profile the sample characteristics based on participants' sociodemographic and clinical data. Frequencies and percentages were used to describe the categorical variables, such as gender, race, marital status, highest education level, employment status, types of housing,

smoking status, the New York Heart Association functional classification, and the presence of comorbidities.

The thematic analysis approach was used to identify, analyze, and report the patterns (themes) within the data, as they are not reliant on any theoretical framework and provide sufficient flexibility for data analysis [14]. Specifically, the thematic analysis process involved five different phases, including familiarizing the data, generating initial codes, collating codes into potential themes, reviewing themes, and defining and naming those themes [14]. The transcripts were coded independently by the research nurse and a second researcher. The results were cross-checked for consistency and revised as required. The primary coding and collation of codes into themes were manually performed. To ensure that themes were formed coherently and accurately, the initial themes were reviewed and refined based on discussions with team members. Illustrative quotations were translated into English if they were in Chinese. Repeated words and grammatical errors were edited for ease of understanding, but no substantive changes were made. The translations were cross-checked by two researchers proficient in both English and Chinese.

Trustworthiness

The trustworthiness of the qualitative approach in the process evaluation was established by ensuring the feasibility and adequacy of the semistructured interview guide in eliciting appropriate data to achieve the evaluation objectives. The questions in the interview guide were reviewed by members of the research team and the author's supervisor, all of whom had experience in conducting qualitative research. In addition, to ensure the accuracy and authenticity of the data, the interviews were audio recorded and transcribed verbatim. The transcribed data and data analysis were cross-checked by two researchers, and thematic agreement was reached through discussion. These steps provided a complete and accurate description of the participants' responses, thus ensuring the credibility of the process evaluation. The confirmability was to ensure that the themes were a true representation of the participants' experiences and perceptions [13]. It was established by recording the participants' quotations to support the results. Auditability was established by keeping records of the data analysis process, such as records of the evolution of findings and emergence of themes. Finally, transferability was established by providing a detailed research context to allow readers to relate to the conclusions drawn from this study.

Results

Sociodemographic Data and Clinical Characteristics of the Participants

A total of 11 participants were approached and invited to participate in the process evaluation interview, of which 6 were from experimental group A and 5 were from experimental group B. The average duration of the interviews was 9.24 minutes, ranging from 5 to 17 minutes. Of 11 participants, 7 (82%) were Chinese speaking. The descriptive statistics of the participants' baseline sociodemographic data and clinical characteristics are presented in Table 1. Of the 11 participants, 7 (64%) were male and 4 (36%) were female. Their age ranged from 44 to 85 years (mean 64.45, SD 12.58 years). Of the 11 participants, 6 (55%) participants were still working full time or on a part-time basis. None of the participants drank alcohol, but 9% (1/11) of the participants had smoked in the past 4 weeks. From the 11 participants, 9 (82%) had coronary heart disease, 7 (64%) had diabetes, 6 (55%) had hypertension, and 7 (64%) had high cholesterol.

Table 1. Sociodemographic data and clinical characteristics of the participants (N=11).

Variables	Values
Age (years), mean (SD)	64.45 (12.58)
Gender, n (%)

Qualitative Findings

The findings are organized and presented based on the Donabedian framework. A total of six underlying themes representing participants' overall experience and perceptions of the study intervention were identified. They were grouped under *intervention structure*, *intervention process*, and *intervention outcome* (Table 2). The emerging themes were manageability of the intervention, areas for improvement, benefits of visiting, personal accountability in self-care, empowered with knowledge and skills in self-care after the intervention, and increased self-efficacy in cardiac care.

Table 2. Themes and subthemes.

Themes	Subthemes
Intervention structure	
1. Manageability of the intervention	• Ease of learning • Essential topics were covered • Convenient to participate • Different views on the use of technology
2. Areas for improvement	• Participants' different preferences for frequency and duration of intervention • Intervention format can be more flexible • Some of the self-care tools did not match the participants' usage habits • To include topics related to chronic diseases
Intervention process	
3. Benefits of visiting	• Allow patients to better express themselves • Preferred personalized advice over information from other resources • Felt nurses can better understand patients' problems • Reassurance for family members • Worries and burden are being addressed
4. Personal accountability in self-care	• You have to help yourself first • Self-discipline is required
Intervention outcomes	
5. Empowered with knowledge and skills in self-care after the intervention	• Monitoring inculcated in daily life • Able to sustain effort after intervention
6. Increase self-efficacy in cardiac care	• Increased initiative • Improved self-awareness of health status • Determination to change a certain lifestyle

Intervention Structure

Theme 1: Manageability of the Intervention

Most participants reported that overall, the intervention was easy to manage with no added burden. It covered all the essential topics that participants wanted to know with an adequate amount of information. The most helpful aspects of the intervention included coaching on weight monitoring and controlling fluid and salt intake. One participant mentioned that it was important that the intervention be as simple as possible so that it would help them apply what they had learned easily:

> *...[the programme] is really very good, because I have learnt a lot of things that I did not know last time, like how to read the sodium amount in the food label...* [P2, aged 46 years]

> *...[the most helpful aspects] are weight monitoring, coz it tells me if I have water retention...also controlling my water intake and diet...I try to keep my water intake to 1L/day, and eat less oily and salty food...* [P6, aged 76 years]

> *I think the best is simple and useful...yes...because we need to work, if it is too complex, we feel very troublesome. So, I think the simpler the better...And also, we are not that young now, sometimes we cannot remember so many things.* [P9, aged 59 years]

In addition, home visits reduced the travel needs of the participants. Convenience of participation through home visits encouraged participants to participate in the study. For some participants, the flexibility of scheduled home visits allowed them to plan ahead between different commitments:

> *Look, instead of you asking patients come over [to the hospital], you are visiting them now. So it is more convenient for the patients as well. Rather than you ask them to come to the hospital, you are meeting them halfway at their premises. It is a good thing and I think a lot of patients will like it. It is easier. If you ask me to go down to the hospital I might be like "ah, cannot today, tomorrow cannot." I may want to push the appointment for the later dates.* [P8, aged 58 years]

> *I think it is good because you will call me to confirm home visit appointment before you come, and if I cannot make it, I can also give you a call. This is very good...* [P6, aged 76 years]

In terms of the mHealth component of the study intervention, participants had different views on the usability and acceptability of the technology. Some participants reported that employing the smartphone app in health monitoring increased their awareness of their personal health condition and found it convenient to record and monitor their condition via the app. Importantly, having the nurse and other health care professionals accessing and monitoring the participants' conditions at the backend was especially useful in motivating them to use the app. However, older patients needed to rely on their helper to monitor their health data because of difficulties in using a smartphone:

> *...initially, it was not easy to use, there were some errors in [Chinese] translation...subsequently, this problem has been fixed, we can understand [the meaning], and it becomes very easy to use...app is preferred over paper and pen, because you just need to press a few buttons, if [you] record on paper, you need to first look for a pen, then write it down...* [P6, aged 76 years]

> *...I prefer the app...I really appreciated that. It gives you a purpose that you want to do it every morning to key in whatever information. So that it can be shared all over in the hospital. They are also looking at it. And it's so easy. I think the app is user friendly. No problem.* [P8, aged 58 years]

> *We don't know how to use smartphone, it is difficult for our age, so I have to ask my helper to key in the record.* [P3, aged 83 years]

Theme 2: Areas for Improvement

Participants also made suggestions on intervention frequency, duration, and content coverage for future improvement. A male participant believed that the interval (ie, every 2 weeks) between home visits was too short and the duration of the intervention program (ie, 6 weeks) was too long. In contrast, female participants felt that the frequency and duration of home visits could be increased. The participants also preferred that the disease education and self-care content provided by the research nurse could cover other topics related to chronic disease management and not just HF. Furthermore, one participant wanted the research nurse to relay his information to the doctors so that he did not need to repeat himself during the doctor's consultation, as consultations are usually very short:

> *Personally, I feel that the home visit interval is too close, may be one or two months will be ok...yes, both are ok, if home visit interval increased, give a telephone call in between home visits is also fine...* [P9, aged 59 years]

> *I hope that your programme duration won't be so short, it will be good if you can visit the patient two to three times a month. Or perhaps, visit more frequently at the start, and if patient is stable, can slowly [reduce the frequency]...but will continue to see them...* [P2, aged 46 years]

> *..., but now you can only teach us about heart problems...Sometimes it's inevitable that there will be other diseases, although I hope I won't be so unlucky as to have other diseases after this heart problem...But things like high blood pressure, high cholesterol, and high blood sugar are common and can be discussed...* [P10, aged 58 years]

> *I hope that whatever you saw during home visit, [you] can let my doctor know too...my problems...because doctor's consultation is very short, only have 10 minutes...but during home visit, I can tell you more...* [P3, aged 83 years]

Finally, not all participants used all the tools in the HF self-care toolkit provided by the research team for self-care. Participants felt that some of these tools did not fit their usage habits. The size of the pillbox in the self-care toolkit was too small, and the weight monitoring calendar was too complex to use. Participants preferred to record their weight in their own way, rather than following it on weekly pages, as instructed:

> *...among all the things you gave me, I did not use the table [referring to the weight monitoring calendar], and the pillbox is too small, not big enough to put all my medication in, you should have given me a bigger one...* [P2, aged 46 years]

> *the pillbox in the self-care toolkit is less useful, because if I put my medication inside, I cannot see the medication instructions and the name of the medication, also the size of the box is too small...* [P6, aged 76 years]

> *Basically, everything is ok, but...except for the weight record calendar, it is too complicated, I only need to keep my own record...* [P9, aged 59 years]

Intervention Process

Theme 3: Benefits of Visiting

Participants reported that they preferred a nurse to visit them for a variety of reasons, including better clarity and understanding with face-to-face interaction for both the nurse and participant, enabling increased depth of discussion and the family being reassured with an understanding of their conditions, and that they were well taken care of. Participants also felt that their thoughts and existing problems could be better understood during home visits. Older adult patients stated receiving too much information from the news and internet nowadays, which can confuse them sometimes. However, through face-to-face interactions, the nurse can probe and discover minor problems encountered by the patient that might otherwise go unnoticed:

> *I find it hard to communicate clearly through phone, it is better to talk face-to-face, it is much clearer in this way...[P6, aged 76 years]*

> *I preferred face-to-face interaction, because sometimes, we wanted to clarify something...I mean when you are trying to describe some problems, it is very hard to talk over the phone. Therefore, I think*

> *home visit and face-to-face interaction are much better.* [P9, aged 59 years]
>
> *I think it is very important to talk face-to-face, because you received too much conflicting information from computer...the newspaper said coffee is good for the heart yesterday but now it said [coffee] is not good [for the heart], so you don't know which information is correct...and become very confused...* [P3, aged 83 years]

In addition, some participants, especially those who were staying alone or only with their spouse who is an older adult, identified that the relational component in the intervention process made a difference to them. Perceived caring presence can be as simple as individual attention, understanding of their concerns, or comfortable interactions. During face-to-face home visits, a participant felt that the ability to voice out his problems to a nurse who is knowledgeable about HF was helpful in unloading his burden:

> *...I would love to see you coming...otherwise the house will be so quiet...* [P4, aged 58 years]
>
> *Yes, yes I do. And I really appreciate that because you took your time to come to my home, be there. It wasn't a very formal meeting. It's like talking to friends. So, it is good...we can just talk, not just about medical advice. We can sit down and talk, and have a good conversation.* [P8, aged 58 years]
>
> *When you are talking to somebody, you are putting whatever your problem or whatever elements, you are just voicing out. Just like some help to unload the burden that you've been carrying along. And talking to you, whoever the interviewer is, they know about the subject. So, it helps, you know they might understand. But talking to family member is just the basic, I don't know. They may not understand. So, it is very much helpful.* [P8, aged 58 years]

Theme 4: Personal Accountability in Self-Care

During the intervention process, participants recognized their own personal responsibility in HF self-care and felt that self-discipline was required to benefit from the study intervention:

> *actually, it's very helpful. At the same time when people try to help you, you yourself must help you. You have to be disciplined as well. That means whatever the doctor or the nurse advises you, you have to follow it. But at the same time, you have to gauge all these yourself, to see whether the conditions suit you or not. But most important thing is to discipline yourself. If you don't discipline yourself, nobody can help you.* [P11, aged 57 years]

Intervention Outcomes

Theme 5: Empowered With Knowledge and Skills in Self-Care After the Intervention

A couple of participants mentioned that they will continue to use the intervention materials, such as the measuring cup and weighing scale, to monitor HF even after the intervention ended. They expressed sustained confidence in incorporating changes after the intervention, as regular weight monitoring and control of diet have been inculcated in daily life:

> *I feel my physical health and mood have improved...I used to be less energetic, but now I feel my energy level goes up...and I feel more confident [to manage my condition] after someone taught me these methods...yes, yes, I will definitely continue to maintain healthy diet, control my water intake...will follow the instructions...* [P5, aged 69 years]
>
> *last time, I did not know soup can be salty, so I keep drinking soup and I thought that was good...but now I cut it down totally...when I go to supermarket, I will also look at the food label and pay attention to the sodium content...in the past, I only look at place of production and nothing else...* [P2, aged 46 years]
>
> *...I have been following the instructions on the HF manual...I have done that...see I used the measuring cup you gave me to make tea, with no sugar...I like to use the [measuring] cup, I have been using it and I also keep track of my weight every day, it was 65 point something in the past, now is 62.5, 63.8 and then no further increase...I lost some weights and [feel] less tired...I prefer to keep my current weight, and I am happy about it.* [P4, aged 58 years]

Theme 6: Increased Self-Efficacy in Cardiac Care

Participants reported that one of the biggest changes after the study intervention was the ease of control of symptoms due to a better understanding of the HF condition. They felt that they were gaining more control in managing their HF symptoms. A few of them showed increased initiative to control their symptoms. For example, a participant would control his activity level to reduce dyspnea. Another participant reported that he kept track of his weight to better understand his current health and adjust his diet accordingly. When necessary, they would take the initiative to act quickly:

> *I can control my condition more easily because I have more knowledge about how my condition is right now...I am quite confident...* [P11, aged 57 years]
>
> *I walk, but not very fast...and avoid strenuous exercises. I still practise tai Chi for a while, but not too long...* [P3, aged 83 years]
>
> *...I think after quitting smoking, finally I am getting on my way. And there is a way...* [P8, aged 58 years]
>
> *it is better to record down as it helps me to better understand my current health condition...and I started to pay more attention to my diet, so as not to aggravate my condition...I started to control, so I cook myself...* [P10, aged 58 years]

Discussion

Principal Findings

A total of six themes (manageability of intervention, areas for improvement, benefits of visiting, personal accountability in self-care, empowered with knowledge and skills in self-care

after the intervention, and increased self-efficacy in cardiac care) emerged from the process evaluation and summarized participants' experiences and perspectives after receiving the HOM-HEMP study intervention. Overall, participants expressed more advantages than disadvantages of the study intervention. In addition, participants appeared to be more attuned to the process of the intervention and the experience of interacting with the research nurse than to the content and form of the intervention. Thus, the strengths they expressed were more focused on the intervention process than on the intervention components. This was also reflected in the fact that although the HF self-care toolkit provided by the research team was not perfect, this did not prevent them from using other methods for self-care.

In this study, home visits remained to be the preferred method of engagement for most patients. Although home visits may be perceived as resource intensive, they have intangible values. Face-to-face interactions allowed for more authentic and in-depth exchanges between the participants and the research nurse. Participants felt that they were being listened to, rather than being rushed to end the conversation, and gave the nurse an opportunity to probe and discover problems that might otherwise have gone unnoticed. In addition, human touch and care remain to be important in the healing process. Personal encounters help foster therapeutic nurse-patient relationships that will further enhance their recovery process [15]. This was further demonstrated when some participants reported that the relational component and the perceived caring presence in the intervention process had an impact on them. This finding is consistent with the results of a previous review on the effective mechanisms of disease management interventions in HF [16]. In their review, Clark et al [16] found that studies with effective health professional supports were those with *sufficient* consultation time, who incorporated patient goals into care, providing rapid feedback, and who had a consolidated patient-professional relationship. Conversely, interventions are less effective when health care providers focus too much on mere information giving or prioritizing treatment goals over the patient's own goals [16].

In this study, participants reported that they became more confident in self-care as a result of increased knowledge and understanding of symptom monitoring and interpretation. Effective intervention promoted the understanding of many complex links between HF symptoms and self-care tasks [17]. Although a plethora of accessible health information exists on the internet, in newspapers, and on instant messaging tools such as WhatsApp, a considerable proportion of patients are left with either an incomplete or an incorrect understanding of their condition, as they are not equipped to discern this vast amount of information. Even when they have the right information, guidance in translating their knowledge and skills into pragmatic actions is needed. As such, the consultative role of the nurse has evolved from simply providing health information to helping patients sift through and ascertain the credibility and authority of the informational sources, identify knowledge gaps, dispel confusion, and provide personalized advice. Participants seemed to particularly value this kind of support from health care professionals. This can be seen in the participants who expressed the wish that the research nurse could have also included education topics on other chronic disease management besides HF. Individualized interventions that are responsive to individual learning needs and preferences, with personalized reinforcement of specific salient information, have been shown to be effective in promoting self-care behavior change [17-19].

Although mHealth and telemedicine have great potential to overcome many barriers to health care delivery [19], especially in the context of the current COVID-19 pandemic [20], participants had different views on the use of technology in the study. Some believed that employing a smartphone app in health monitoring was not only convenient but also increased their awareness of personal health. One of the main motivations for participants to use the app was that they knew that their recorded data on the app would be monitored backend by the research nurse. Athilingam et al [21] reported that mHealth apps have the potential to improve self-care by providing patients with real-time access to health care providers. Similar observations were found in an unpublished local study in which postmyocardial infarction patients highlighted that the greatest advantage of telemedicine interventions was the ability to have direct access to their health care providers [22]. Although participants commended the many benefits of using a smartphone app in their health monitoring, older patients needed to rely on their caregivers to monitor their health data because of the difficulties in using a smartphone. Past research has reported that the efficacy of mobile phone–based telemonitoring in improving HF outcomes may depend on the characteristics of the patient population [23,24]. In this regard, further trials are needed to explore the effectiveness of mHealth apps in defined patient subgroups.

In this process evaluation, participants provided a lot of valuable feedback to maximize the study intervention in future studies, particularly on the structure of the intervention. First, interventions should be kept simple and manageable so as not to overwhelm or intimidate the user. Second, there should be some flexibility in the implementation of study interventions. Depending on the patient's progress, the interval between home visits can be extended or shortened. Long intervals between home visits can be augmented by telephone calls to check on the patient. In addition, one interviewee suggested that the intervention duration be extended as needed. Finally, although the HF self-care toolkit was designed to help patients establish a systematic self-care process and provide some tangible help in integrating self-care into their daily lives, not all of the items in the toolkit were user-friendly. Consequently, some participants did not like to follow up on tracking their weight trends and managing their medication in the way they were told.

Limitations

It is inevitable that this study had limitations that may affect the transferability of the research findings. First, as the research nurse for this study delivered both the study intervention and conducted the interviews for the process evaluation, this may have led to bias in the collection of participant feedback because of an established rapport between the participants and the research nurse. However, the development of rapport is not only a limitation but can also be seen as a strength. When participants

are familiar with the interviewer, they will be more open to speaking and sharing their genuine opinions. Moreover, as the interviews were semistructured, in addition to discussing the parts of the intervention that were found to be helpful, we made a point of exploring with participants where the research interventions were least helpful and where future improvements were needed. These measures facilitated a relatively balanced discussion with participants. Second, some participants were very reticent during the interview process; even after much probing, they just answered *everything is fine* or repeated what they had already mentioned. As a result, some of the interviews were very short, which may have affected the authenticity of the data.

Conclusions

Despite these limitations, the findings of the process evaluation provided additional information about participants' perceptions and experiences with the HOM-HEMP intervention. Although a home visit may be perceived as resource intensive, it remains to be the preferred way of engagement for most patients. During the intervention, the nurse played an active and essential role in the individual's healing process, further demonstrating that not only does the value of nursing come from the content of the intervention but that interactions with the patient can be an important empowering process for self-care behavior changes. These findings shed light on why and how the intervention worked and areas for improvement in future studies. It allows researchers and practitioners to better understand the mechanism by which an intervention generates impact. Therefore, future intervention programs can leverage these mechanisms and adapt them to different contexts for better intervention effectiveness.

Acknowledgments

This study was funded by a grant from the Health Services Research Grant of the National Medical Research Council in Singapore (grant NMRC/HSRG/0064/2016). The study funder was not involved in the study design, data collection, data analysis, or writing for publication.

Authors' Contributions

All authors have agreed on the final version and meet at least one of the following criteria: substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data and drafting the paper or revising it critically for important intellectual content.

Abstract

Background: Gender imbalances in academia have been evident historically and persist today. For the past 60 years, we have witnessed the increase of participation of women in biomedical disciplines, showing that the gender gap is shrinking. However, preliminary evidence suggests that women, including female researchers, are disproportionately affected by the COVID-19 pandemic in terms of unequal distribution of childcare, elderly care, and other kinds of domestic and emotional labor. Sudden lockdowns and abrupt shifts in daily routines have had disproportionate consequences on their productivity, which is reflected by a sudden drop in research output in biomedical research, consequently affecting the number of female authors of scientific publications.

Objective: The objective of this study is to test the hypothesis that the COVID-19 pandemic has had a disproportionate adverse effect on the productivity of female researchers in the biomedical field in terms of authorship of scientific publications.

Methods: This is a retrospective observational bibliometric study. We investigated the proportion of male and female researchers who published scientific papers during the COVID-19 pandemic, using bibliometric data from biomedical preprint servers and selected Springer-Nature journals. We used the ordinary least squares regression model to estimate the expected proportions over time by correcting for temporal trends. We also used a set of statistical methods, such as the Kolmogorov-Smirnov test and regression discontinuity design, to test the validity of the results.

Results: A total of 78,950 papers from the bioRxiv and medRxiv repositories and from 62 selected Springer-Nature journals by 346,354 unique authors were analyzed. The acquired data set consisted of papers that were published between January 1, 2019, and August 2, 2020. The proportion of female first authors publishing in the biomedical field during the pandemic dropped by 9.1%, on average, across disciplines (expected arithmetic mean y_{est}=0.39; observed arithmetic mean y=0.35; standard error of the estimate, S_{est}=0.007; standard error of the observation, σ_x=0.004). The impact was particularly pronounced for papers related to COVID-19 research, where the proportion of female scientists in the first author position dropped by 28% (y_{est}=0.39; y=0.28; S_{est}=0.007; σ_x=0.007). When looking at the last authors, the proportion of women dropped by 7.9%, on average (y_{est}=0.25; y=0.23; S_{est}=0.005; σ_x=0.003), while the proportion of women writing about COVID-19 as the last author decreased by 18.8% (y_{est}=0.25; y=0.21; S_{est}=0.005; σ_x=0.007). Further, by geocoding authors' affiliations, we showed that the gender disparities became even more apparent when disaggregated by country, up to 35% in some cases.

Conclusions: Our findings document a decrease in the number of publications by female authors in the biomedical field during the global pandemic. This effect was particularly pronounced for papers related to COVID-19, indicating that women are producing fewer publications related to COVID-19 research. This sudden increase in the gender gap was persistent across the 10 countries

with the highest number of researchers. These results should be used to inform the scientific community of this worrying trend in COVID-19 research and the disproportionate effect that the pandemic has had on female academics.

science of science; gender disparities; research evaluation; COVID-19

Introduction

As of the date of this writing, the COVID-19 pandemic has claimed hundreds of thousands of lives worldwide and disrupted almost all aspects of human society. The socioeconomic impacts of the pandemic are yet to be assessed and the impending economic crisis and recession are becoming evident [1-3]. During recessions, men are more likely to lose their jobs, as men work in industries that are heavily affected by the slowdown in economic activity, such as manufacturing and construction. Compared to previous economic crises, the current crisis has disproportionately affected female workers [4-11]. One of the reasons for such disparity is women's overrepresentation in occupations in industries that are most affected by the closures and movement restrictions imposed by public health policies, such as restaurants and hospitality. Another large part of the gender disparity is related to the unequal division of labor in the household, as women are traditionally expected to continue to devote more time to childcare and domestic chores than their partners [4]. In the case of dual-earner, heterosexual married couples with children, the partners have unequally adjusted their work time during the pandemic. Mothers with young children have reduced their work hours 4 to 5 times more than fathers, which contributes to the increased gender gap in earnings [5]. Working mothers affected by the unequal distribution of working hours and the additional burden of domestic chores have reported lower work productivity and job satisfaction than men [6].

Stay-at-home orders, lockdowns, and school closures have affected scientists as well, especially those caring for children or other family members [12,13]. Female scientists reported that their ability to devote time to their research has been substantially affected, and the impact is most pronounced for female scientists with young dependents [14]. The sudden shift in daily activities makes it hard to balance between increasing professional requirements and childcare.

As a result, the research productivity of female scientists appears to have decreased [15-18]. Early evidence suggests that the proportion of publications with female authors is lower during the pandemic with the evident gendered authorship disparities in journal submissions [19,20]. Reports from journal editors in the fields of international studies, political science, economics, medicine, and philosophy indicate that the proportion of submissions authored by women has dropped in most cases [21]. Even though female academics are still submitting manuscripts for publication during the crisis, they are submitting less of their own work than men [22].

A similar effect has been observed with publications on preprint servers. The proportion of female authors publishing on the most popular economics preprint servers is lower than expected [23,24], with only 14.6% of female authors; comparably, they usually make up about 20% of the authors in these databases. Similarly, women publish less in other disciplines, such as physics, earth science, and sociology [25]. In regard to medical and related sciences, on top of the exacerbated gender disparity in publishing during the pandemic, the proportion of female scientists publishing research specifically about COVID-19 is much lower than expected, by almost 23% [25-27].

Motivated by ongoing research efforts, we expand on the previous research by analyzing a large bibliographic data set in the biomedical field; we also employ different modeling techniques that can further improve our understanding of this phenomenon. The aim of this study is to quantify how the COVID-19 crisis exacerbates the gender gap in scientific publishing in the biomedical field.

Methods

Data

Bibliometric data on published papers were collected from three separate sources:

1. The bioRxiv repository contains 51,171 papers and 225,110 authors; Rxivist is the application programming interface (API) provider for bioRxiv publications [28].
2. The medRxiv repository contains 8845 papers and 52,364 authors; data are scraped directly from medrxiv.org.
3. The Springer-Nature repository contains 19,525 papers and 91,257 authors; data from 62 journals are collected using the Springer-Nature OpenAccess API. Springer-Nature data include high-impact journals, such as Nature Genetics, Nature Medicine, and Nature Immunology, as well as multiple BMC journals, such as BMC Bioinformatics and BMC Genomics.

We included the data from all journals in the biomedical field for which Springer-Nature provides data. A complete list of journals used in the analysis is available in Table S1 of Multimedia Appendix 1. All the papers from the data set were published between January 1, 2019, and August 2, 2020. The earliest publication on medRxiv is from June 25, 2019.

For each source, we collected the relevant metadata. For each paper in bioRxiv and medRxiv, we kept the *date* of publishing. For Springer-Nature journals, we kept the date of manuscript submission, which is the most comparable date to publication dates in bioRxiv and medRxiv. We additionally stored the *title* and the *abstract* of each paper as well as the scientific discipline of each paper. There were a total of 112 scientific disciplines represented in the data, and each paper belonged to a single discipline. The complete list of all disciplines is provided in

Table S2 in Multimedia Appendix 1. For each author, we preserved the *name*, *affiliation*, and the *authorship order*. We removed the papers with group authors, such as scientific consortiums and projects (~0.1% of all papers), as they do not represent individuals. We used socioeconomic data on countries, including their respective gross domestic product (GDP) per capita provided by Our World in Data [29].

Identifying Authors' Genders

To infer each author's gender from their name, we used a state-of-the-art tool, namely the genderize.io API [30]. Given an input name, the model returns a gender and a confidence score between 0.5 and 1. The uncertainty is greater for Asian names, which often are not gender specific [31]. We filtered out all authors for which the confidence scores were lower than 0.8. Overall, 19% of names yielded a score below this threshold, with Chinese and Korean names topping the ranking at 54% and 41%, respectively.

In our data set, we identified the most likely gender of 466,836 authors in total. Out of these, the gender of 348,506 (74.7%) unique authors (214,095 male [61.4%] and 134,411 female [38.6%]) could be inferred with high accuracy, with confidence scores from genderize.io higher than 0.8.

Identifying Authors' Countries

To identify each author's country in the bioRxiv and medRxiv data sets, we first located a toponym in each author's affiliation and assigned to it the most likely country code. If there was no toponym, we queried the Global Research Identifier Database, found the institution with the most similar name, and assigned the institution's country to that author. Additionally, we manually checked the location of the most common affiliation names from the data set that covered most of the authors. The countries of approximately 80% of all authors were determined using this method. The countries of the authors in the Springer-Nature data set were already provided by the API.

Identifying COVID-19 Papers

The papers that dealt specifically with COVID-19 and similar topics were identified by the set of keywords that appeared in their titles or abstracts.

Calculating the Differences Between the Expected and Observed Proportions

To measure the discrepancy between the expected and observed proportions of female authors, we first established baselines, which were the expected proportions of female researchers that appeared as authors of publications. The expected proportions were calculated using the ordinary least squares (OLS) model and historical data from January 2019 to March 2020 (see the Model section). We then calculated the true observed proportions of female authors who published during the COVID-19 pandemic in 2020 and compared it to the expected baselines. The error for the predicted value was the mean standard error of the prediction. The error of the observed value was calculated as the standard error of the mean: $SE = \sigma/\sqrt{n}$. The percentage change is calculated as $diff = (f^{exp} - f^{obs})/f^{exp}$, where f^{exp} is the expected proportion and f^{obs} is the observed proportion. The errors for the percentage change were calculated as the total sum of the errors of predicted and observed values.

Model

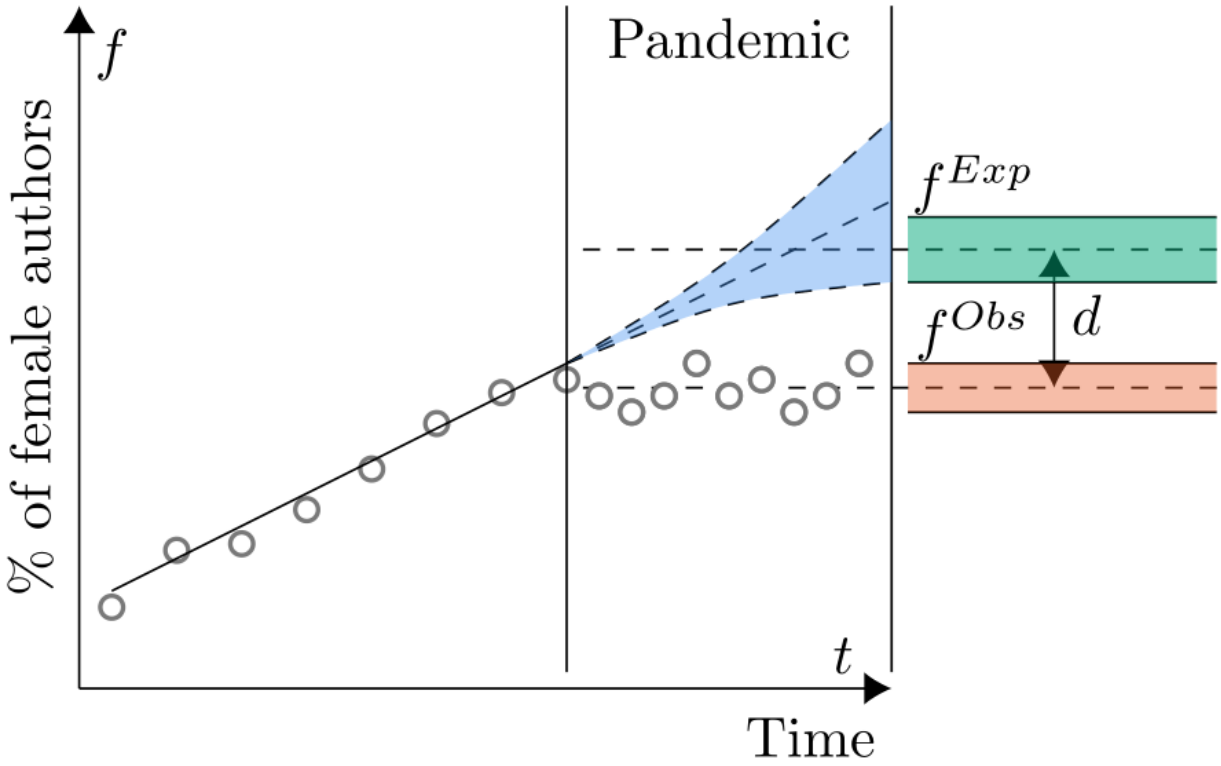
Using historical data from before March 15, 2020, we calculated the proportion of female authors who published each week. We fit an OLS regression model, $f = \beta t + c$, where f is the proportion of female authors, which serves as a response variable; t is the predictor variable—time of publication/submission (to the nearest week); and β and c are the slope and the intercept, respectively. We fit the separate models depending on the level of disaggregation (country, publisher, etc). The model is illustrated in Figure 1. From the model, we derived the expected fraction, $f^{exp} = \sum f/n$, which is the mean fraction of all predicted values for the observed period and $f^{obs} = \sum f_{true}/n$. To estimate the expected number of papers and authors, we used a similar approach, where the response variables were the numbers of papers and authors rather than the proportion of female authors. We used the *statsmodels* [32] package in Python 3.6 (Python Software Foundation) for this purpose.

The OLS model tends to weight all data points equally, regardless of the number of samples. To guarantee the validity of the statistical analysis, we established the conditions under which the data points would be evaluated. The number of data points used to fit the OLS model before March 2020 and the number of data points after March 2020 were at least 10 each. This way, we limited the impact of small-sample observations that could skew the estimate.

We additionally evaluated the model by applying the generalized linear model with binomial errors and a logit link function, as the OLS model could overestimate the proportions in binary variables. Both models performed similarly, and the OLS model did not provide any out-of-norm estimates. For the sake of better interpretability and consistency with modeling the nominal number of authors and papers, we decided to use the OLS model.

To better capture the productivity of the population, we counted each publication from each author separately, effectively modeling the proportion of papers authored by the population of female authors. Considering that multiple authorships in the observed period were relatively rare (<5% of all first authors and <10% of all last authors had >1 paper), we considered each authorship independently.

Figure 1. Statistical model. Schematic illustration of the ordinary least squares model used to calculate the expected numbers and proportions. *d*: difference; f^{exp}: expected proportion; f^{obs}: observed proportion.



Regression Discontinuity Design

To estimate the potential causal effects of the pandemic on the proportion of female researchers, we devised a typical nonparametric regression discontinuity design (RDD) with a local linear regression in time, with the following general form:

$$Y = \alpha + \tau D + \beta_1(X - c) + \beta_2 D(X - c) + \varepsilon$$

where c is the treatment cutoff and D is a binary variable equal to 1 if $X \geq c$. In our case, we assumed that the date c of a policy change was mid-March 2020. For all dates $t > c$, the unit was treated, and for all dates $t < c$, the unit was not. This regression discontinuity setup used time-series data and, in this case, weekly observations, both globally and on a country level. By comparing observations lying closely on either side of the temporal threshold, we estimated the average treatment effect. We made sure to focus on observations not too far in time from the threshold, avoiding potential bias from unobservable confounders [33].

The falsification, or placebo, tests were performed by using fake cutoffs before and after mid-March 2020 and comparing the treatment effect. We identified the optimal cutoff point c_0 as the point in time when the treatment effect was the most prominent, $c_0 = c|\max(|\tau|)$. The RDD was implemented using the *rdd* package in Python [34].

The data and source code for reproducing the results are available at GitHub [35].

Results

The Gender Gap in Research During the COVID-19 Pandemic

Overall, during the pandemic, scientists posted papers on preprint servers at an increasing rate. On average, we observed 31.2% more papers than expected and a 41.6% increase in the number of authors (39.2% increase for females and 42.9% increase for males). Despite the absolute increase in the numbers of papers and authors across publishers (see Figure S1 and Tables S3-S5 in Multimedia Appendix 1), the proportion of female authors was lower than expected.

In biology, medicine, and related disciplines, the most active contributors are usually listed first. The author listed last is the most senior author, typically the head of the lab. To address the high variability of the number of authors on the publications (μ=7.4, σ=9.2), we analyzed the proportion of women, separately, who appeared as the first author, the last author, an author regardless of authorship order, and the solo author. Additionally, we performed a separate analysis on the papers with topics that were directly related to COVID-19 (see Table 1).

Table 1. The expected and observed proportions of female authors disaggregated by the order of authorship and the topic.

Author order and paper topic	Expected proportion		Observed proportion		Drop, %
	y_{est}[a]	S_{est}[b]	y[c]	σ_x[d]	
First					
All	0.389	0.007	0.353	0.004	9.142

Non-COVID-19	0.210	0.030	0.168	0.013	19.802

[a]y_{est}: the arithmetic mean of the estimate.

[b]S_{est}: the mean standard error of the estimate.

[c]y: the arithmetic mean of the observation.

[d]σ_x: the standard error of the mean of the observation.

The aggregate results suggest that the proportion of female authors publishing on all topics as the first author decreased by 9.1% (expected arithmetic mean y_{est}=0.38; observed arithmetic mean y=0.35; standard error of the estimate, S_{est}=0.007; standard error of the observation, σ_x=0.004). The percentage drop became unusually prominent when we analyzed the papers about COVID-19. The proportion of female scientists who wrote on COVID-19-related topics as the first author was lower by 28% (y_{est}=0.38; y=0.27; S_{est}=0.007; σ_x=0.007). When considering the last authors, the proportion of women writing about COVID-19 decreased by 18.8% (y_{est}=0.25; y=0.2; S_{est}=0.005; σ_x=0.007). However, when we focused only on papers that did not deal with COVID-19, we saw a smaller change both for the first author (2.3%) and the last author (4.4%). The proportion of women publishing papers on topics other than COVID-19 on medRxiv increased by 14%, on average. The results are shown in Table 1 and are illustrated in Figure 2. The expected proportions are plotted as the green bars, and the true proportions are plotted in orange. The standard errors were relatively small (see Methods section for details about the error calculation).

Additionally, we focused our analysis on the papers with a single author and discovered an even greater disparity. We observed 34.5% (y_{est}=0.21; y=0.13; S_{est}=0.03; σ_x=0.008) fewer female solo authors during the pandemic who published on all topics across the platforms (see Figure S2 in Multimedia Appendix). A similar disparity appeared in case of the solo authors publishing papers about COVID-19. Note that only 3.2% (2551/79,528) of all papers were authored by a single author, hence, the relatively large standard errors of both the estimate and the observation, especially for papers published on medRxiv. The effect still exists, although much less prominently, when we observed all authors regardless of the order of authorship. More detailed information is provided in Table S3 in Multimedia Appendix 1.

The results suggest that the aggregate gender disparity in academia during the pandemic was due to the increased publication rate of papers about COVID-19 authored by men. To further explore this possibility, we tracked the individual publication records and calculated the probability that the author would publish work about COVID-19. Around 3.7% of men who had publication records in our data set would publish at least one paper about COVID-19, compared to ~2.2% of women. Men who already had a publication before the pandemic were 37% more likely to publish a paper about COVID-19. This suggest that women are getting excluded from critical research about COVID-19.

Figure 2. Comparison of the expected and observed proportions of female authors that published during the COVID-19 pandemic. Green bars represent the expected proportion of female authors, estimated by the ordinary least squares model from the historical data from 2019. Orange bars represent the observed proportion of female authors that published during the COVID-19 pandemic. The standard errors of the aggregate analyses are represented as the vertical lines on top of the bars. The papers are divided by topic into three groups: (1) all papers from the data set, (2) papers that deal directly with COVID-19 and related topics, and (3) papers that are not about COVID-19 or related topics. The first row shows the results from all publishers combined. The following rows represent the results for each publisher separately.

When disaggregated by publisher, the relative drop in the proportion of female first authors for COVID-19-related research was 12.6%, 23.2%, and 2.1% for bioRxiv, medRxiv, and Springer-Nature journals, respectively (see Figure 2). A similar disparity was observed for last authors, with a relative drop of 20.1%, 30.8%, and 23.6%, and for authors regardless of the authorship order, with a relative drop of 2.2%, 10.7%, and 16.1% for bioRxiv, medRxiv, and Springer-Nature journals, respectively. In the case of solo papers, the average drop across the platforms was 34.5%. The proportion of females publishing on topics other than COVID-19 remained within the standard error of the estimate, without strong evidence of decrease. Note the large standard errors in the estimated proportion of women publishing COVID-19-related papers in Springer-Nature journals due to the lack of data. Only published papers have metadata available through the Springer-Nature API, and many papers submitted during the pandemic that will ultimately be published have not yet been accepted and published (see Methods section).

Additionally, we checked whether there was a significant change in the proportion of women authors that occurred in mid-March 2020. To test the hypothesis, we performed an RDD analysis in time (see Methods section). We estimated a vertical discontinuity of the proportion of women over time by the coefficient τ at the cutoff point c_0 = March 15, 2020. For all the papers, regardless of the topic, we obtained τ=–0.008 with P=.03. However, when considering only the papers about COVID-19, the discontinuity became clearer with τ=–0.049 and P<.001. To assert the robustness of our model, we performed a placebo test (see Methods section) to confirm that the discontinuity was likely aligned with the start of the pandemic, and that it happened at or around March 2020 and

not during any time in 2019. When RDD analysis was performed at the country level, we confirmed that, for most countries, the cutoff threshold fell between mid-March and mid-April 2020 (see Table S6 in Multimedia Appendix 1). The RDD analysis suggests that there was a drop in the proportion of female authors at the beginning of April 2020 that was more significant than any other fluctuation that occurred in 2019 or after April 2020.

Further, we checked whether we could confidently use the proportion of women who published before the pandemic as the reference to estimate the proportion of women who published papers specifically about COVID-19. A hypothesis is that before the pandemic, women were less likely to be represented in the scientific disciplines that would produce COVID-19 research. To check this hypothesis, we first performed a chi-square test on the distribution of disciplines involved in COVID-19 research. We discovered that some disciplines, such as infectious diseases, epidemiology, public health, and global health, were overrepresented (P<.001). Then, we tested whether the proportions of women in COVID-19 disciplines were significantly different from non-COVID-19 disciplines. By performing the Kolmogorov-Smirnov test, we compared the distributions of the proportion of women across two groups of disciplines and we obtained P=.84. We conclude that the two groups were sampled from populations with the same distributions, and we can be confident that we can use the data on the proportion of women from before the pandemic to model the proportion of women that publish about COVID-19.

Some Trends During the Pandemic

To assess the temporal trends during the pandemic, we built the linear model $f(t) = \alpha + \beta t + \varepsilon$, where $f(t)$ is the proportion of female scientists, and t is the time in weeks after mid-March 2020. The regression coefficient β is used to quantify the trend. We did not identify a significant change in the proportion of female first authors (see Table 2). However, we observed a small but significant increase in the proportion of female scientists appearing as the last author (β=.001, P=.002) and as an author regardless of authorship order (β=.001, P<.001). An even stronger positive trend was observed for the COVID-19-related research for the last author (β=.003, P<.001) and for an author regardless of authorship order (β=.005, P<.001) (see Table S7 in Multimedia Appendix 1).

Table 2. Parameters of the linear model of the proportion of female authors over time during the pandemic.

Paper topic	First author		Last author		All authors		Solo author	
	β[a]	P value	β	P value	β	P value	β	P value
All	–.002	.08	.002	.002	.001	<.001	.000	>.99
COVID-19	.001	.28	.003	<.001	.005	<.001	–.005	.12
Non-COVID-19	–.002	.02	.001	.03	.000	.17	.004	.13

[a]β is a regression coefficient.

Country-Level Analysis

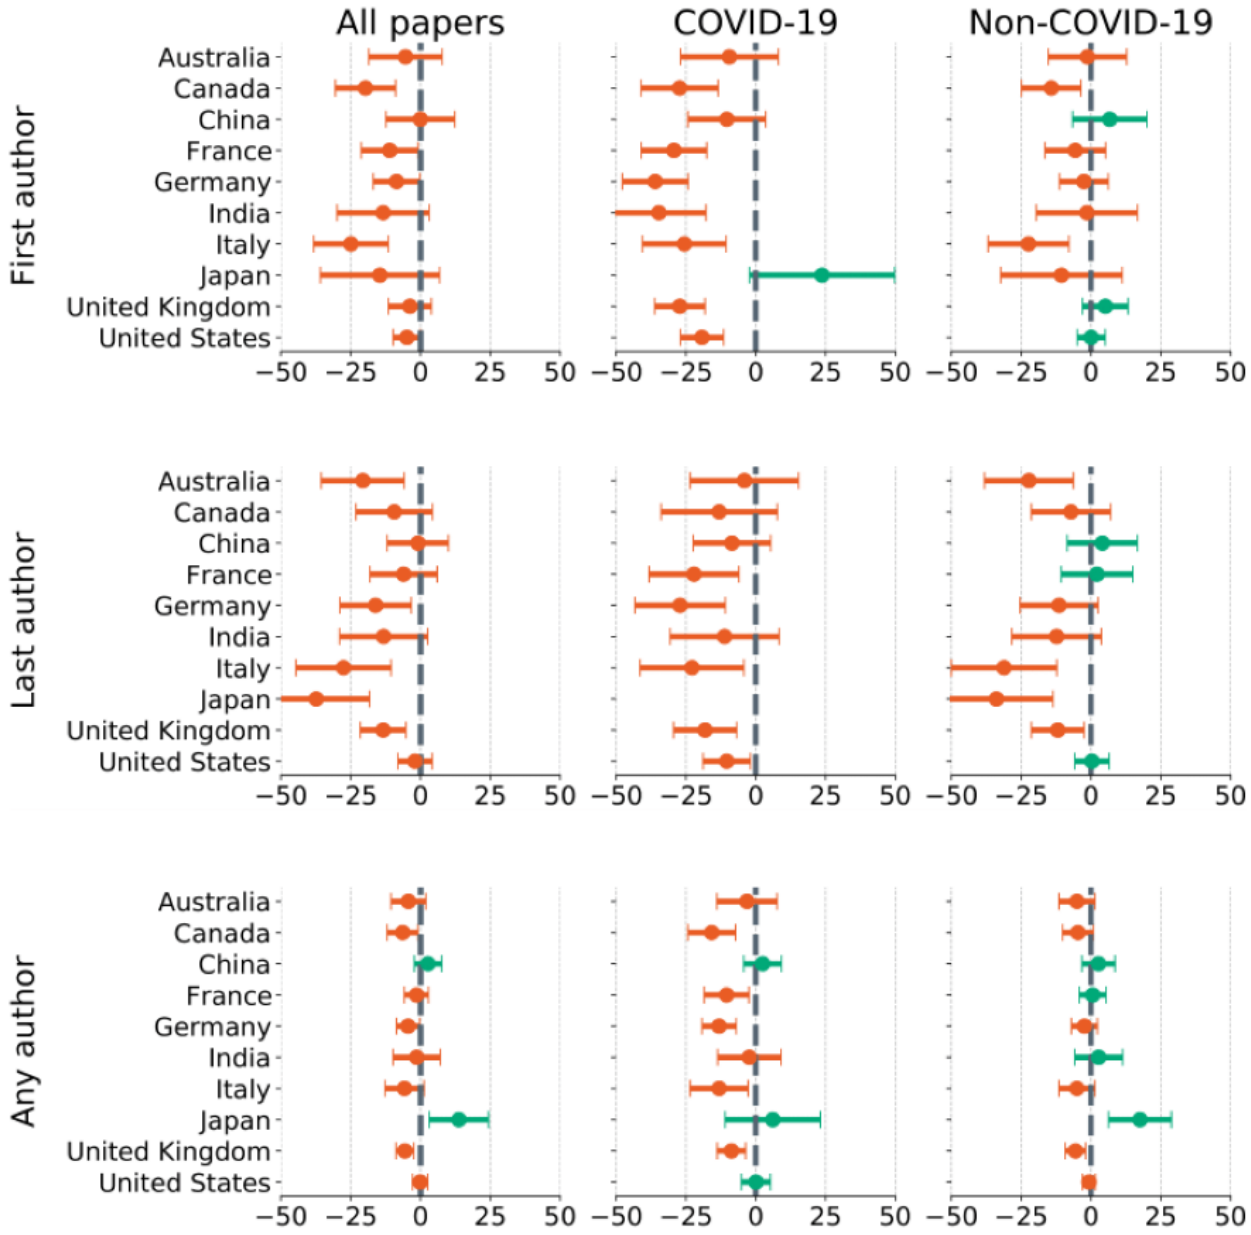
We identified the most likely country of the authors based on their affiliations (see Methods section) and measured the difference between the expected and observed proportions of female authors during the pandemic. Figure 3 shows the pandemic-related gender gap across the countries with the largest share of authors. The values represent percentage differences between the expected and observed fractions of female authors publishing in bioRxiv, medRxiv, and selected Springer-Nature journals between March and August 2020. Points to the left of the midline (orange) represent countries with less than expected fractions of female authors, and points to the right of the midline (in green) represent countries an increase in the fractions of female authors. The left-hand plots are for all papers regardless of topic, the middle plots are only for COVID-19-related papers, and the right-hand plots are only for papers that are not related to COVID-19. More detailed information is provided in Tables S8-S10 in Multimedia Appendix 1.

A significant drop in the proportion of female first authors was consistent across the countries. Regardless of the topic, we observed a 24.9% drop in Italy (y_{est}=0.526; y=0.395; S_{est}=0.046; σ_x=0.024), followed by Canada (19.7%), Sweden (15.9%), Japan (14.5%), India (13.4%), and France (11.1%). For research dealing explicitly with the topic of COVID-19 (see Figure 3, middle panels), we observed a greater gender gap than with papers on other research topics (see Figure 3, right-hand panels). In Germany, for example, the relative drop in the proportion of female first authors was 36% (y_{est}=0.39; y=0.25; S_{est}=0.02; σ_x=0.027), indicating that male scientists affiliated with German institutions are publishing disproportionately more than their female colleagues about COVID-19. Similar considerations applied to India, France, Italy, Great Britain, Canada, and the United States. The opposite was true for Japan, where the proportion of women publishing about COVID-19 as the first author increased by 23.7%. A similar disparity applied to the last authors (see Figure 3, second row). Missing points indicate that there were not enough data from the pandemic period to calculate the observed mean.

When we observed the proportion of female authors regardless of the authorship order, the drop became less prominent but still consistent across the countries. For example, in Canada, a drop in the proportion of female authors for COVID-19-related papers was 15.7% (y_{est}=0.387; y=0.318; S_{est}=0.014; σ_x=0.018), with similar-sized drops for Germany, Italy, Great Britain, and France (see Figure 3, third row). On the other hand, there was an increase of 6% in the proportion of female authors writing about COVID-19 in Japan (y_{est}=0.155; y=0.164; S_{est}=0.010; σ_x=0.017). The increase in the proportion of female authors in China (2.4%) was within the margin of error.

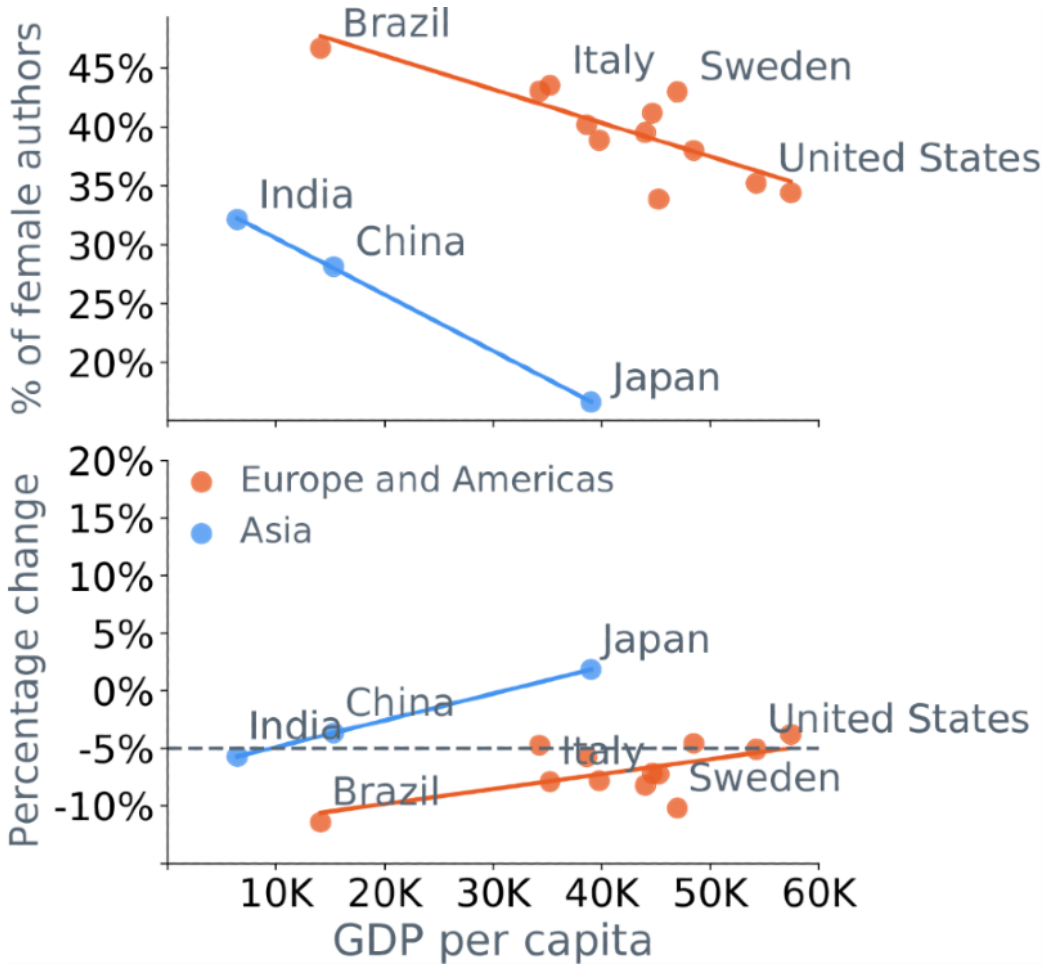
The gender gap for non-COVID-19-related research (see Figure 3, right-hand panels) was found to exist during the pandemic, but it is smaller than for COVID-19 research. Again, we observed stark differences between countries, with the proportion of female first authors publishing during the pandemic significantly decreasing in Italy, Canada, Japan, and France. Note that the plots for the single-author papers are missing, as the samples became too small when disaggregated by country.

Figure 3. Percentage drop in proportion of female authors during the pandemic across countries. Orange points mark the percentage decrease in proportion of female authors; green points mark the increase. Horizontal lines represent standard errors. The analysis is divided by topic into three groups: (1) all papers from the data set, (2) papers that deal directly with COVID-19 and related topics, and (3) papers that are not about COVID-19 or related topics. Missing points indicate insufficient sample size.



Further, we explored whether there were any commonalities among the countries with respect to the participation of women in research. Figure 4 illustrates the proportion of female authors (upper panel) and the percentage change in the proportion of female authors (lower panel) as a function of GDP. When disaggregated by region, we observed that the wealthier countries—those with higher per capita GDP—had proportionally fewer female researchers, with Asian countries exhibiting the most pronounced gender disparity. However, the countries with a higher GDP per capita demonstrated a smaller drop in the proportion of women publishing during the pandemic.

Figure 4. Gender disparity in research and gross domestic product (GDP). The proportion of women active in research is higher in countries with lower per capita GDP (upper). The proportion of female authors of research articles decreased more than expected in countries with lower per capita GDP (lower).



Discussion

Principal Findings

We analyzed bibliographical data from biomedical preprint servers and Springer-Nature journals and showed that the fraction of women publishing during the COVID-19 pandemic dropped significantly across disciplines and research topics. Since the announcement of the global pandemic and the start of lockdowns, we observed a drop of 9.1% in the number of women publishing biomedical scientific papers as the first author. Women were significantly excluded from COVID-19-related research, as we measured a 28% drop in female first authors in that area of research. This confirms some earlier suggestions that female first authors contributed less to COVID-19 studies than to research in other areas [25]. Women remain underrepresented, even though we observed an increased publishing rate for both genders during the pandemic. A similar disparity can be observed for last authors as well as solo-authored papers. The increased gender gap in publishing is persistent across the 10 countries with the highest number of researchers.

For papers on topics other than COVID-19, we did not observe this high discrepancy, and, in the case of medRxiv, we observed more women than projected by the model. The overall gender disparity in research during the pandemic was mostly driven by the higher publication rate of papers on COVID-19 and related topics. It seems that such research is conducted disproportionately by men, as male authors are more likely to appear in first author positions on papers posted on preprint servers and published in peer-reviewed journals.

It appears that the most significant drop in proportion of female authors happened early in the pandemic. The proportion of women has been increasing gradually for some authorship categories. Note that the observed gradual increase is statistically significant but is very slow. One can think that a possible explanation for such a sudden drop and a subsequent gradual increase is that most of the COVID-19 papers published early during the pandemic were various epidemic models focusing on cases and death counts. Many of the authors' affiliations were departments of engineering, mathematics, and physics, which might have a different proportion of women than the population of scientists in biology and medicine. Since research in the biomedical field usually takes longer to conduct and publish, it could lead to a shift in the gender distribution later. However, this argument does not explain the phenomenon entirely, as the base gender gap in science, technology, engineering, and mathematics fields is not higher than in biology [31]; therefore, future publications from biologists are not expected to narrow the gender gap. On the contrary, they might even increase it.

Another likely explanation of a sudden drop in the proportion of female authors is that caregiving demands have exploded during the pandemic, and these have mostly fallen on women [12,36,37]. These include childcare demands [38], elderly care, and other kinds of domestic and emotional labor. Sudden lockdowns and other preventive measures unevenly increased the burden on certain populations, causing the productivity of female scientists to decrease. As the world started fighting off the pandemic, people got used to the "new normal" and scientists started returning to their routines. That can partially explain the gradual increase in the proportion of female authors. Nevertheless, further research and more time is needed to investigate the reasons for such a sudden drop and gradual revival of the proportion of papers published by female scientists during the pandemic.

The global pandemic has touched almost every nation on the planet. Countries, however, responded differently in containing the spread of the disease. The variability of the measures and their timing, combined with differences in cultural norms and outbreak severity, have had a variable impact on researchers across the world. Country-level analysis better reveals global trends, as the aggregate data can be skewed by countries with a disproportionately large number of publications, such as the United States, which represents almost 29% of all authors in the data set (see Table S11 in Multimedia Appendix 1). Additionally, our analysis can reveal regional, political, and cultural differences between the nations. It is known that gender disparities in research are strongly associated with a country's wealth [39]. The wealthier countries—those with higher per capita GDP—have proportionally fewer female researchers, with Asian countries exhibiting the most pronounced gender disparity. However, the countries with higher GDP per capita were more resilient to the effects of COVID-19 on gender imbalance. In addition, wealthier countries showed a smaller pandemic-related drop in women's participation in research than poorer countries, with wealthier Asian countries experiencing an increase in the proportion of active female researchers. This suggests that women experience bigger life disruptions in poorer countries, which affects their productivity. Additionally, women are more excluded from COVID-19 research in poorer nations. This certainly should not imply any purpose or deliberate action, but rather the disproportionate variations in the social environments across nations, caused by the various expectations for the female members of households.

Implications

Gender imbalances in academia have been evident historically and still persist today. Various measures of research output, including the proportion of authors, fractionalized authorships [40], tenure decisions, and number of research grants [41], indicate the significant gender gap that is observed worldwide. For the past 60 years, we have witnessed an increase in participation by women in science across scientific disciplines [31] and lower levels of discrimination [42], demonstrating that the gender gap is shrinking over time [43]. Thus, a sudden drop in women's research output in biomedical research about COVID-19 appears as a surprising reverse trend.

The factors that led to such extreme and consistent differences in the proportion of female scientists can be numerous. The already existing barriers for female participation in science vary across countries. In some nations, men are more favorably placed than women [44-47] and can be more likely to receive quick funding for COVID-19-related research. Additionally, traditional gender norms differ and can affect the genders differently. Caregiving demands have mostly fallen on women. At the same time, new challenges bring new opportunities, and men who are likely to engage in more aggressive self-promotion [48,49] and pursue careers more forcefully [43] can be motivated to push for faster publication. Identifying the exact reasons for an increased gender gap can be an important topic for future studies.

The global pandemic caused this unforeseen crisis that will most certainly affect academia. All the difficulties female scientists faced previously may possibly be exacerbated by the extended lockdowns and sudden shift in work-life dynamics. It is important to understand the impact of such an extraordinary circumstance on the scientific community that will disproportionately affect research outputs as well as prospects for tenure and promotions [21]. Future research evaluation practices should be informed by our findings to account for and mitigate the penalizing effects that COVID-19 is having on female researchers.

Strengths and Limitations of the Study

The strengths of our study include the use of a relatively large and diverse data set from three different publishing platforms. The focus on preprint papers allows for the assessment of the observed effects in a timely manner. We focused on a structured and rigorous statistical analysis, making sure that the results are significant. The data and the code to reproduce the results are available.

Potential limitations warrant consideration. First, the gender of a publication's author can be wrongly identified. Even though we excluded the results that had a low confidence, a small fraction of the authors could have been misgendered. Additionally, we acknowledge that automated gender classifiers do not recognize the various nonbinary gender identities [50], and we assigned the gender label based on the historical distribution of typical male and female names. As awareness of the nature of gender and identity shift, so may the number of researchers who do not identify within the binary categories of male and female. Such researchers face additional layers of discrimination that our study does not consider. While we understand that binary gender can be an oversimplification that can introduce some amount of bias and inaccuracy, the problem that we highlight hopefully can bring some attention to the multifaceted issue of gender, identity, and discrimination. Second, the algorithm that identified the authors' countries relies on recognizing the names of the toponyms in the names of the authors' affiliated institutions. Even though we made sure that the most popular institutions were properly localized and we optimized the localization resolution, some errors are possible. Third, throughout the paper, the word "productivity" was used to refer to the rate of publication output of scientists in terms of publications per week and it did not capture changes to

scientists' other inputs. For example, female scientists appearing less productive in terms of publications per week may simply reflect that they were not able to spend as much time on their research (ie, hours worked were not captured). We are aware that there are other preprint servers and journals that publish papers in the biomedical field. By analyzing the data from the two largest preprint servers and the largest publisher of peer-reviewed papers, we aimed to cover a representative sample of papers and authors from the field. Finally, our analysis was focused on the first 6 months of the pandemic and might not accurately evaluate the effects that can be observed later in the pandemic.

Conclusions

Our findings documented a decrease in the proportion of female authors in the biomedical field who published research papers during the global pandemic. This effect was particularly pronounced for papers related to COVID-19, indicating that women are producing fewer publications related to COVID-19 research. A sudden increase in this gender gap was persistent across the 10 countries with the highest number of researchers. The results should be used to inform the scientific community of this worrying trend in COVID-19 research and the disproportionate effect the pandemic has had on female academics' research outputs.

Abstract

Background: Lifestyle diseases, because of adverse health behavior, are the foremost cause of death worldwide. An eCoach system may encourage individuals to lead a healthy lifestyle with early health risk prediction, personalized recommendation generation, and goal evaluation. Such an eCoach system needs to collect and transform distributed heterogenous health and wellness data into meaningful information to train an artificially intelligent health risk prediction model. However, it may produce a data compatibility dilemma. Our proposed eHealth ontology can increase interoperability between different heterogeneous networks, provide situation awareness, help in data integration, and discover inferred knowledge. This "proof-of-concept" study will help sensor, questionnaire, and interview data to be more organized for health risk prediction and personalized recommendation generation targeting obesity as a study case.

Objective: The aim of this study is to develop an OWL-based ontology (UiA eHealth Ontology/UiAeHo) model to annotate personal, physiological, behavioral, and contextual data from heterogeneous sources (sensor, questionnaire, and interview), followed by structuring and standardizing of diverse descriptions to generate meaningful, practical, personalized, and contextual lifestyle recommendations based on the defined rules.

Methods: We have developed a simulator to collect dummy personal, physiological, behavioral, and contextual data related to artificial participants involved in health monitoring. We have integrated the concepts of "Semantic Sensor Network Ontology" and "Systematized Nomenclature of Medicine—Clinical Terms" to develop our proposed eHealth ontology. The ontology has been created using Protégé (version 5.x). We have used the Java-based "Jena Framework" (version 3.16) for building a semantic web application that includes resource description framework (RDF) application programming interface (API), OWL API, native tuple store (tuple database), and the SPARQL (Simple Protocol and RDF Query Language) query engine. The logical and structural consistency of the proposed ontology has been evaluated with the "HermiT 1.4.3.x" ontology reasoner available in Protégé 5.x.

Results: The proposed ontology has been implemented for the study case "obesity." However, it can be extended further to other lifestyle diseases. "UiA eHealth Ontology" has been constructed using logical axioms, declaration axioms, classes, object properties, and data properties. The ontology can be visualized with "Owl Viz," and the formal representation has been used to infer a participant's health status using the "HermiT" reasoner. We have also developed a module for ontology verification that behaves like a rule-based decision support system to predict the probability for health risk, based on the evaluation of the results obtained from SPARQL queries. Furthermore, we discussed the potential lifestyle recommendation generation plan against adverse behavioral risks.

Conclusions: This study has led to the creation of a meaningful, context-specific ontology to model massive, unintuitive, raw, unstructured observations for health and wellness data (eg, sensors, interviews, questionnaires) and to annotate them with semantic metadata to create a compact, intelligible abstraction for health risk predictions for individualized recommendation generation.

Introduction

Overview

Lifestyle diseases are an economic burden to an individual, household, employer, and government, and lead to financial and productivity risks for poor and rich countries alike [1-3]. The key risk factors behind lifestyle diseases are the excessive use of alcohol, inappropriate food plan, physical inactivity, excessive salt intake, saturated fat consumption, and tobacco use [1-3]. These result in excess weight gain, elevated blood glucose, high blood pressure (BP), elevated total cholesterol in the blood, and social isolation. Obesity is one of the foremost lifestyle diseases that lead to other noncommunicable diseases such as cardiovascular diseases, chronic obstructive pulmonary disease, cancer, diabetes type II, hypertension, and depression [1-3]. eHealth monitoring has become increasingly popular, providing information and communications technology (ICT)–based remote, timely care support to patients and health care providers [1-3]. An eHealth virtual coaching recommendation system can guide people and convey the appropriate recommendations in context with enough time to prevent and improve living with lifestyle diseases. It requires capturing physiological (vital signs such as BP, pulse, lipid profile, glycemic response, BMI), behavioral (sleep, diet, exercise), and contextual data (position, and weather) from secure wearable sensors, manual interactions, feedback, and customized questionnaires over time, to train an artificial intelligence (AI) model for behavior analysis and early prediction of wellness trends and risks [4-6]. However, data collection from heterogenous sources may lead to data interoperability, annotation, and semantization problem.

Background and Problem Description

Health and wellness data collected from heterogeneous sources (eg, multimodal sensors, interviews, questionnaires) are of different format and lead to well-known problems in health informatics, which are related to logical data representation, aggregation, data analysis, data standardization, and data interoperability [7,8]. Targeted personal, habitual, physiological, activity, and nutrition data are generally collected via secure wearable sensors, manual interactions, interviews, web-based interactions, smartphone apps, customized questionnaires, and feedback forms over time. Weather application programming interfaces (APIs) and external weather sensors are useful for the collection of contextual weather data over time. The wearable activity monitors need to connect to a personal smartphone via Bluetooth nearfield communication technology (Bluetooth low energy [BLE]) [9,10]. The device can seamlessly measure and transfer high-resolution raw acceleration data and multiple activity parameters to a secure storage to process the data further with a machine intelligence module [11]. High-end, time-dependent activity data collection with wearable BLE devices has become accessible and feasible for ubiquitous monitoring. Some of the activity data, such as nonwear time or intensive activity details, are questionnaire dependent.

Physiological data are collected either invasively (eg, glycemic response, cholesterol level) or noninvasively (eg, weight, BP, heart rate, body assessment data). The questionnaire-dependent nutrition data are collected either daily or on an alternate day or on a weekly basis. The assessment of nutrition data helps to determine the type of food, amount of food, conceptual information (temporal/spatial), dietary pattern, and intake of alcohol or energy drinks. Some baseline data (medical history, habit, preference, personal details, initial weight and height, initial BP, and initial body assessment data) are collected during the initial recruitment of the participant or every month for either demographic statistics or population clustering or individual goal assessment. Each data have their unit and range following a standard guideline based on the context and domain (eg, data on temperature are applicable for both health and environment domain with a different range, meaning, and context). Therefore, each measurement process owns separate challenges related to logical or semantic data representation, proper usage of data, and improving data reusability. The data usability involves the transformation of data into an understandable computer format. It creates a challenge to systematically and syntactically analyze health and wellness data in aggregation with other clinical data. Incorporation of physical activity, diet as a care procedure, or investigating how it afflicts healthy outcomes involves a more detailed and diverse representation of participant's behavioral level and physiological condition [7,8,12,13].

Furthermore, the challenges of reusing the existing physiological and behavioral data of a participant within the electronic health record remain and include concerns related to opacity and semantic inconsistency [7,8]. Besides, these health and wellness data are still mostly hidden in clinical narratives with highly variable forms of expression. In this regard, ontology can provide a framework to allow the mentioned heterogeneous health and wellness data to be organized, compact, structured, consistent, machine understandable, and queried through high-level specifications. Ontology helps to annotate diverse health and wellness data with semantic metadata to increase interoperability among heterogeneous networks, data integration, discovery, and situation awareness. An eHealth ontology can reuse the concept of existing, proven, well-accepted ontologies (eg, semantic sensor network [SSN] ontology [14], Systematized Nomenclature of Medicine—Clinical Terms [SNOMED CT] ontology [15]) to enhance its vocabularies and better semantic representation.

A rule-based decision support system (DSS) can use such an eHealth ontology model to measure and predict health risks, and to generate useful personalized recommendations following proven clinical rules. If the collected health and wellness data are not annotated accurately with semantic metadata in the

medical domain, then the DSS may fail to deliver accurate decisions to both physicians and patients or participants in the form of incorrect recommendation plan, goal setting, and goal evaluation. DSS decision inaccuracy may appear primarily due to the following effects—improper design of knowledge base (KB), the inadequacy of tools or technologies applied in the execution of DSS, problems related to the ontology reasoning engine, and issues associated with inferring new knowledge.

Aim of the Study

After studying existing ontology models, we found that many ontologies and regulated terminologies cover aspects of obesity and related chronic illness domains, but concept analysis remains incomplete. After reviewing relevant ontologies, we proposed a freshly created OWL-based ontology to deal with different data inputs (internet of things [IoT] sensors, interviews, and questionnaires) and annotate them with semantic data. The proposed ontology will support data interoperability, logical representation of collected health and wellness data in context, and to build a rule-based DSS for health risk prediction related to obesity and afterward generation of lifestyle recommendations for a healthy lifestyle.

We have not evaluated the impact of the suggested recommendations on participants as we executed the complete scenario under a simulated environment. Still, we evaluated the performance of the proposed ontology model. In the proposed ontology, we annotated every participant's data with semantic web language rules and stored the generated OWL file in a triple-store format for better readability (Multimedia Appendix 1). The proposed ontology model allows automatic inferencing, efficient knowledge representation, balancing a trade-off between complexity and eloquence, and reasoning about formal knowledge. The entire study is divided into the following 2 segments: (1) ontology design and development and (2) its verification. This study addresses the following identified research questions:

(RQ-1) How to annotate distributed, heterogenous health and wellness data received from sensors, questionnaires, and interviews into meaningful information to build a future machine learning model for health risk prediction for obesity?

(RQ-2) How to integrate existing IoT and medical ontologies to design and develop proposed eHealth ontology for obesity study case?

(RQ-3) How to verify the proposed ontology with rule-based behavioral recommendation generation?

For this set of semantic data, which will be considered as asserted true facts, the primary goal of the paper is to trigger logical rules of the shape (A IMPLIES B) or trigger rules in a logically equivalent way, that is, (NOT(A) OR B). If some specific variables are inferred to be true, then some recommendations shall be provided to the user from whom the semantic data are originating.

Related Work

This section offers existing background knowledge applicable for this research. It includes (1) a discussion of existing, relevant eHealth ontology models for chronic illness, health monitoring, and ontology-based DSS, (2) ontologies in the IoT domain for modeling sensor data, and (3) ontologies in the medical domain.

Existing eHealth Ontology Models

Different research groups have conducted different studies on eHealth ontology modeling for chronic illness, health monitoring, and ontology-based clinical decision support system (CDSS). For example, Kim et al [16] developed an ontology model for obesity management with the nursing process in the mobile device domain for spontaneous participant engagement and continuous weight monitoring. The scope of the obesity management included behavioral interventions, dietary recommendations, and physical activity, and for this purpose, the study included assessment data (BMI, sex, and hip-to-waist circumference), inferred data for representing diagnosis results, evaluations (cause of obesity, success, or failure of behavioral modifications), and implementation (education, suggestion, intervention). Sojic et al [17] modeled an obesity domain–specific ontology with OWL to design inference patterns to individualize health condition assessment as age and gender specific. The ontology helped classify personal profiles based on the changes of personal behavior or feature over time and infer personal health status automatically, which are important for obesity evaluation and prevention. The ontology rules were written in semantic web rule language (SWRL). Kim et al [18] proposed an ontology model for physical activity (PACO) to support physical activity data interoperability. The ontology was developed in Protégé (version 4.x), and the FaCT++ reasoner verified its structural consistency. Lasierra et al [19] developed an automatic ontology–based approach to manage information in home-based scenarios for telemonitoring services based on the automatic computing paradigm, namely, MAPE (monitor, analyze, plan, and execute). They proposed another 3-stage ontology-driven solution [20] (stage 1: ontology design and implementation; stage 2: ontology application to study personalization issues; and stage 3: software prototype implementation) for giving personalized care to chronic patients at home. The proposed ontology was designed in OWL DL language in Protégé-OWL version 4.0.2 ontology editor and was verified using FACT++ reasoner. The ontology development involved data from heterogeneous sources, such as clinical knowledge, data from medical devices, and patient's contextual data. Yao and Kumar [21] proposed a novel CONFlexFlow (Clinical cONtext based Flexible workFlow) approach using ontology modeling for incorporating flexible and adaptive clinical pathways into CDSS. They developed 18 SWRL rules for practical explanation of heart failure. The model was verified with the Pellet Reasoner Plug-in for Protégé version 3.4. Additionally, they developed a "proof-of-concept" prototype of the proposed approach using the Drools framework. Chi et al [22] constructed a chronic disease dietary consultation system using web ontology language (OWL) and SWRL. The KB involved heterogeneous sources of data and interaction of factors, such as the illness stage, the physical condition of the patient, the activity level, the quantity of food intake, and the critical nutrient constraints. Rhayem et al [23] proposed an ontology-based system (HealthIoT) for patient monitoring with sensors, radiofrequency identification devices, and actuators. They claimed that data obtained from medically connected

devices are enormous, and thereby lack repressibility and understandability, and are manipulated by other systems and devices. Therefore, they proposed an ontology model to represent both the connected medical devices and their data based on a semantic rule, followed by model evaluation with the proposed IoT Medicare system that supports decision making after analyzing the vital signs of the patients. Galopin et al [24] proposed an ontology-based prototype CDSS to manage patients with multiple chronic disorders following clinical practice guidelines. The KB decision rules were based on the "if–then" rules following clinical practice guidelines and patient observation data. Sherimon et al [25] proposed an ontology system (OntoDiabetic) using OWL2 language to support a CDSS for patients with cardiovascular disease, diabetic nephropathy, and hypertension following clinical guidelines and "if–then" decision rules. Hristoskova et al [26] proposed another ontology-driven ambient intelligence framework to support personalized medical detection and alert generation based on the analysis of vital signs collected from the patients diagnosed with congestive heart failure. The DSS system can classify personalized congestive heart failure risk stages, and thereby, notify patients through ambient intelligence's inference engine. Riaño et al [27] proposed an ontology-based CDSS for monitoring and intervening chronically ill patients to prevent critical conditions, such as incorrect diagnoses, undetected comorbidities, missing information, and unobserved related diseases. Jin and Kim [7] designed and implemented an eHealth system using the IETF YANG ontology based on the SSN concept. The approach assisted in the autoconfiguration of eHealth sensors (responsible for collecting body temperature, BP, electromyography, and galvanic skin response) with the help of internet and communication technologies and querying the sensor network with semantic interoperability support for the proposed eHealth system. The proposed eHealth system consisted of 3 main components: SSN (eHealth sensors, patient, unified resource identifier [URI]), internet (eHealth server, KB), and eHealth clients (patient, and professionals). The proposed semantic model used a "YANG to JSON translator" to convert YANG semantic model data to JSON semantic model data for semantic interoperability before storing them in the database (KB). Ganguly et al [28] proposed an ontology-based model to manage semantic interoperability problems in eHealth in the context of diet management for diabetes. The development of the framework included rules of dialogue games, DSS with KB (rule base and database), a dialogue model based on decision mechanism, the syntax of dialogue game, decision mechanism, and translational rules.

Ontologies in the Internet of Things Domain

Ontology [29] provides a framework for describing sensors. SSN-XG (W3C Semantic Sensor Network Incubator Group) developed the SSN ontology to model sensor devices, systems, processes, and observations. SSN annotates sensor data with semantic metadata (semantic sensor web) to increase interoperability among diverse networks, data integration, discovery, and situation awareness. The Sensor Model Language (SensorML) was developed by the Open Geospatial Consortium (OGC), which provides syntactic descriptions using XML to describe sensors, observations, and measurements. While SensorML provides an XML schema for defining sensors, it lacks the repressibility provided by ontology languages such as OWL [30-32]. Semantic sensor web, a combination of sensor and semantic web technologies, helps to annotate spatial, temporal, and thematic semantic metadata for the more artistic representation of sensor data, advanced access, formal analysis of sensor resources, and data standardization. SSN ontology is used to describe sensor devices; sensing; sensor measurement capabilities; and sensor observations, process, and systems [30-32]. SSN allows its network, sensor devices, and data to be installed, structured, managed, queried, and controlled through high-level specifications. Sensors Annotation and Semantic Mapping Language offers XML schema to transfer sensor data and sources into the instances of SSN ontology based on a predefined XML-based document (resource description framework [RDF]), which is achieved automatically with sensor data to RDF mapping algorithm [33]. "M3 Ontology" (machine-to-machine) was developed based on the "SenML" protocol (designed for simple sensor measurement), which is an extension of SSN, to enable the interoperable design of domain-specific or cross-domain-specific applications which are termed as Semantic Web of Things [13]. AeroDAML, KIM, M3 Semantic Annotator, MnM, and SemTag are different available semantic annotators for sensor observations for their corresponding semantic models (DAML, KIMO, M3, Kmi, and TAP) [34]. Like SSN, there are other IoT-based contextual ontologies, such as IoT-Ontology, IoT-Lite, and IoT-O [35]. SCUPA, CoBrA-Ont, CoDAMoS, PalSPOT, the delivery context ontology, and Fuzzy-Onto are different IoT-based ontologies for activity recognition [34]. URI, HTTP, HTML5, REST, SOAP, Web Socket, Web feed, MQTT, CoAP, and AMQP are some standard IoT protocols applicable to Web of Things [14,34,36,37]. In this study, we integrated the concept of SSN ontology to model sensor observations.

Ontologies in Medical Domain

SNOMED CT, 11th edition of the International Classification of Diseases (ICD-11), Unified Medical Lexicon System (UMLS semantic network), Foundational Model of Anatomy, OpenEHR, Gene Ontology, DOLCE, Basic Formal Ontology, Cyc's upper ontology, Sowa's top-level ontology, the top level of GALEN, and Logical Observation Identifiers Names and Codes (LOINC) are biomedical ontologies introduced to deliver semantic interoperability and complete knowledge related to the specific biological and medical domains [38]. Most laboratory and clinical systems send out data using the HL7 (version 2) protocol and in an HL7 message, the LOINC codes represent the "question" for a laboratory test or experiment and the SNOMED CT code represents the "answer." In this study, we have reused the SNOMED CT ontology for modeling the health condition based on health and wellness data, and recommendation generation [8]. SNOMED CT was designed in 1965 as a controlled medical vocabulary licensed and supported by the International Health Terminology SDO. It is an organized list of a wide variety of clinical terminology defined with unique codes (ICD). It covers a wide range of medical terminologies for disorders and findings (what were observed!), procedures (what was done!), events (what happened!), substance/medication (what was consumed or administered!),

and anything related to medical data. It offers a shared language that enables a reliable way of indexing, storing, reclaiming, and accumulating clinical data across fields and care sites. It is a complete, multilingual clinical terminology that gives clinical content and clarity for clinical documentation and reporting [8,38,39].

As described above, most studies have developed ontologies using OWL to solve the data interoperability problem. Still, integration among the electronic health data, semantic rules, semantic annotation, clinical guidelines, health risk prediction, and personalized recommendation generation remains an issue in eHealth. This study addresses it and proposes a prototype ontology model for obesity as a case study, to integrate data from heterogeneous sources (eg, sensor, questionnaire, and interview) in order to enable data interoperability, information search and recovery, and automatic interference. We integrated SSN and SNOMED CT ontologies into our proposed eHealth ontology because of their vast vocabularies, appropriateness, and semantic capabilities as discussed above [40-43].

Methods

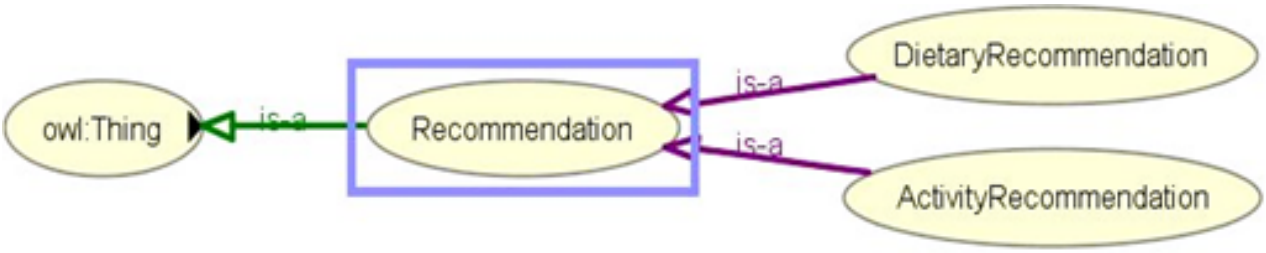
Basics of Ontology

Ontology commenced as a philosophical discipline studying the existence and being and expanded into information technologies. Ontology is a formalized model for specific domains with the following essential elements: individuals/objects, classes, attributes, relations, and axioms. A class diagram of a program written in object-oriented programming [44] is a visual representation of an ontology. Ontology is a philosophy that has been around for thousands of years, and it allows for design flexibility by reusing existing ontologies [45]. It follows the open world assumption knowledge representation style using OWL, RDF, and RDF schema (RDFS) syntaxes. It can be optimized with ontology patterns, and its logical and structural consistency is verified with ontology reasoners.

Overview

The proposed eHealth ontology encompasses the following steps: (1) ontology design approaches and used vocabularies; (2) ontology modeling in Protégé; (3) defining the scope; (4) integrating existing IoT and medical ontologies in the proposed ontology to annotate sensor and clinical observations; (5) ontology implementation (mapping the concepts to the proposed ontology classes and their properties in Protégé); and (6) rule expression (rule base) and basic SPARQL queries as a part of ontology verification. We further discuss how rule-based lifestyle recommendation messages (regarding activity and nutrition) could be delivered to the participants following an asserted hierarchy in the proposed eHealth ontology model, as depicted in Figure 1.

Figure 1. Asserted hierarchy for lifestyle recommendation for obesity management.



Ontology Design Approaches and Used Terminologies

Ontology design approaches can be classified into the following 5 categories: inspirational, inductive, deductive, synthetic, and collaborative [46]. We adopted a combination of inspirational and deductive approaches in our ontology design and development. The inspirational approach helped us identify the need for the ontology (what to design?) and obtain expert views to create the ontology (how to design?). The deductive approach helped us to adopt and adapt general principles to create the intended ontology tailored toward obesity as a study case. It includes the general notions being filtered and refined to be personalized to a specific domain subset (obesity). The overall approaches are divided into 5 phases as follows: in phase 1, we performed a systematic literature review to understand the need for an ontology to support the logical representation of observable and measurable data for healthy lifestyle management targeting obesity as a case study. In phase 2, we consulted experts with a research background in ICT, eHealth, nursing, and nutrition for designing the ontology. In phase 3, we developed the ontology to model and annotate health and wellness data observations with semantic metadata to create a lightweight, intelligible abstraction for health risk predictions for the personalized generation of recommendations based on rule-based decision making. In phase 4, we created rules for SPARQL queries and personalized recommendation generation (rule-based deduction). In phase 5, we verified the ontology with simulated data based on rule-based decision support.

The semantic web is W3C recommended, and it allows the specification of metadata that permit automatic reasoning [47,48]. The W3C-maintained specifications related to this study are XML, URI, RDF, turtle, RDFS, ontology web language (OWL), SPARQL Protocol and RDF Query Language (SPARQL), and SWRL. The following terminologies are relevant for our eHealth ontology representation and processing: propositional variable (an atomic name of a truth value that may change from one model to another), constant (the unique propositional variables TRUE and FALSE such that their truth value cannot be changed), and operators (the set of logical connectors in each logic). Besides, in this case, we use the operators (NOT, AND, OR, IMPLIES, and EQUIV); quantifiers (the set of logical quantifiers in a given logic; FORALL for the universal quantifier and EXISTS for the existential quantifier); quantified clause (a set of propositional variables linked together

by operators and quantifiers); clause (a quantified clause without any quantifiers); formula (a collection of clauses and quantified clauses related together by logical operators); and model of the procedure (a group of assignments for each propositional variable, such that when simplified, it leads the procedure to the constant TRUE).

Protégé, TopBraid Composer ($), NeOn Toolkit, FOAF editor, WebOnto, OntoEdit, Ontolingua Server, Ontosaurus, and WebODE are some popular ontology editors [49]. These ontology editors are open-source ontology development tools with OWL support. A reasoner is a crucial component for working with OWL ontologies. It derives new truths about the concepts that are being modeled with OWL ontology. Practically all querying of an OWL ontology (and its import closure) can be done using a reasoner [50,51]. That is why knowledge in an ontology might not be explicit, and a reasoner is required to deduce implicit knowledge so that the correct query results are obtained. The OWL API includes various interfaces for accessing OWL reasoners. For accessing reasoner via the API, a reasoner implementation is necessary. Reasoners can be classified into the following groups: OWL DL (Pellet 2.0*, HermiT, FaCT++, RacerPro), OWL EL [CEL, SHER, snorocket ($), ELLY], OWL RL [OWLIM, Jena, Oracle OWL Reasoner ($)], and OWL QL (Owlgres, QuOnto, Quill) [50-57]. In this study, we utilized Protégé ontology editor and HermiT reasoner to create and validate the structure of the ontology.

Apache Jena is a Java-based framework used for building semantic web applications. It provides an API to extract data from and write to RDF graphs. A Jena framework includes the following: (1) RDF API to parse, create, and search RDF models in XML, N-triple, N3, and Turtle formats. Triples can be stored in memory or database; (2) ARQ Engine/SPARQL API, which is a query engine for querying and updating RDF models using the SPARQL standards; (3) tuple database engine as a high-performance RDF store on a single machine; (4) ontology API for handling OWL and RDFS ontologies; and (5) Apache Jena Fuseki, which is the SPARQL server for supporting query and update. It is tightly integrated with tuple database to deliver a robust, transactional persistent storage layer. The framework has internal reasoners and an OWL API [58,59]. In this study, we used Apache Jena Fuseki for SPARQL processing with triple database.

Knowledge representation in computer-understandable form is well accepted among AI communities. Knowledge representation with symbols facilitates inferencing and the creation of new elements of knowledge. By contrast, the KB is a database for knowledge management. It provides a means for information to be collected, organized, shared, queried, and utilized for inferring new information. Knowledge engineering helps to obtain specific knowledge about some subject and represents it in a quantifiable form. KB consists of terminology models or TBox (atomic and complex) and assertions model instance or ABox (asserted and inferred). Inferred statements come as a logical outcome of the asserted statements and logical rules [35,60,61]. A KB is a pair (T, A) where T is a TBox and A is an ABox. The idea behind this paper is that the TBox concepts and relations are coming from the freshly created ontology and the ABox is a list of clauses assigning truth values to some variables. The TBox is coming from integration with the SSN Ontology and the SNOMED CT ontology plus additional concepts specific to the recommendation test case considered. The ABox is the semantic data, coming from the different data inputs (IoT sensors, interviews, and questionnaires). The satisfiability of the KB, and thus the model output, is obtained by using the hyper-tableau-based [62] reasoning solver HermiT [55]. The whole approach has been tested with 4 generated test cases to ensure that the whole mechanism can indeed set the propositional variables to true and thus send the corresponding recommendation message when needed.

Ontology Modeling

An ontology can be modeled with the following 2 ways in Protégé: frame based and OWL based. The Protégé frame editor ensures ontology development following the Open Knowledge Base Connectivity Protocol with the help of classes, properties, relationships, and instances of classes (objects). By contrast, the Protégé OWL editor (applied in this study) enables ontology development for the Semantic Web with the help of classes, properties, instances, and reasoning. We have used the steps detailed in Textbox 1 to model our proposed OWL-based eHealth ontology using the Protégé OWL editor.

Textbox 1. Steps to model the proposed OWL-based eHealth ontology.

Step 1

Create a new empty OWL project in Protégé and save it as a local file with “owl” or “ttl” extension (“ttl” signifies the turtle resource description framework [RDF] format).

Step 2

Create named classes under the “owl:Thing” super class following consistency

- Create a group of meaningful and required classes
- Define disjoint classes
- Define subclasses and disjoint subclasses

Step 3

Create OWL properties

- Object properties (associates object to object)
- Data properties (relates object to XML schema datatype or rdf:literal)
- Annotation properties (to add annotation information to classes, individuals, and properties)

Step 4

Define object properties if they are subproperties, inverse properties, functional properties, inverse functional properties, transitive properties, symmetric properties, and reflexive properties.

Step 5

Define property domain and ranges for both object and data properties (it is used as axioms in reasoning).

Step 6

Define property restrictions as follows:

- Quantifier restrictions (existential and universal)
- Cardinality restrictions (one or many)
- hasValue restrictions (eg,, string/integer/double)

Step 7

Ontology processing with a reasoner to check consistency in OWL DL, and to compute the inferred ontology class hierarchy.

- Blue color class in the inferred hierarchy signifies that the class has been reclassified.
- Red color class in the inferred hierarchy signifies an inconsistent class.

Step 8

Remove inconsistencies before importing the ontology file in Apache Jena for further processing, querying (Simple Protocol and RDF Query Language [SPARQL]), and storing it into tuple database for persistence. Tuple database supports the full range of Jena application programming interfaces. It can be used as a high-performance RDF store on a single machine.

Scope of the Proposed Ontology

We have planned to integrate the proposed eHealth ontology into a simulated eCoach system used for automatic rule-based recommendation generation to inspire individuals to manage healthy lifestyles with early health risk predictions. The planned system will have 2 main modules, as depicted in Figure 2: a data collection module and a data annotation module. The data collection module will collect identified fabricated set of habit, baseline, nutrition, personal, contextual, activity, and physiological data over time via a simulator, as depicted in Figure 3.

Figure 2. Proposed eCoach system architecture for data semantization.

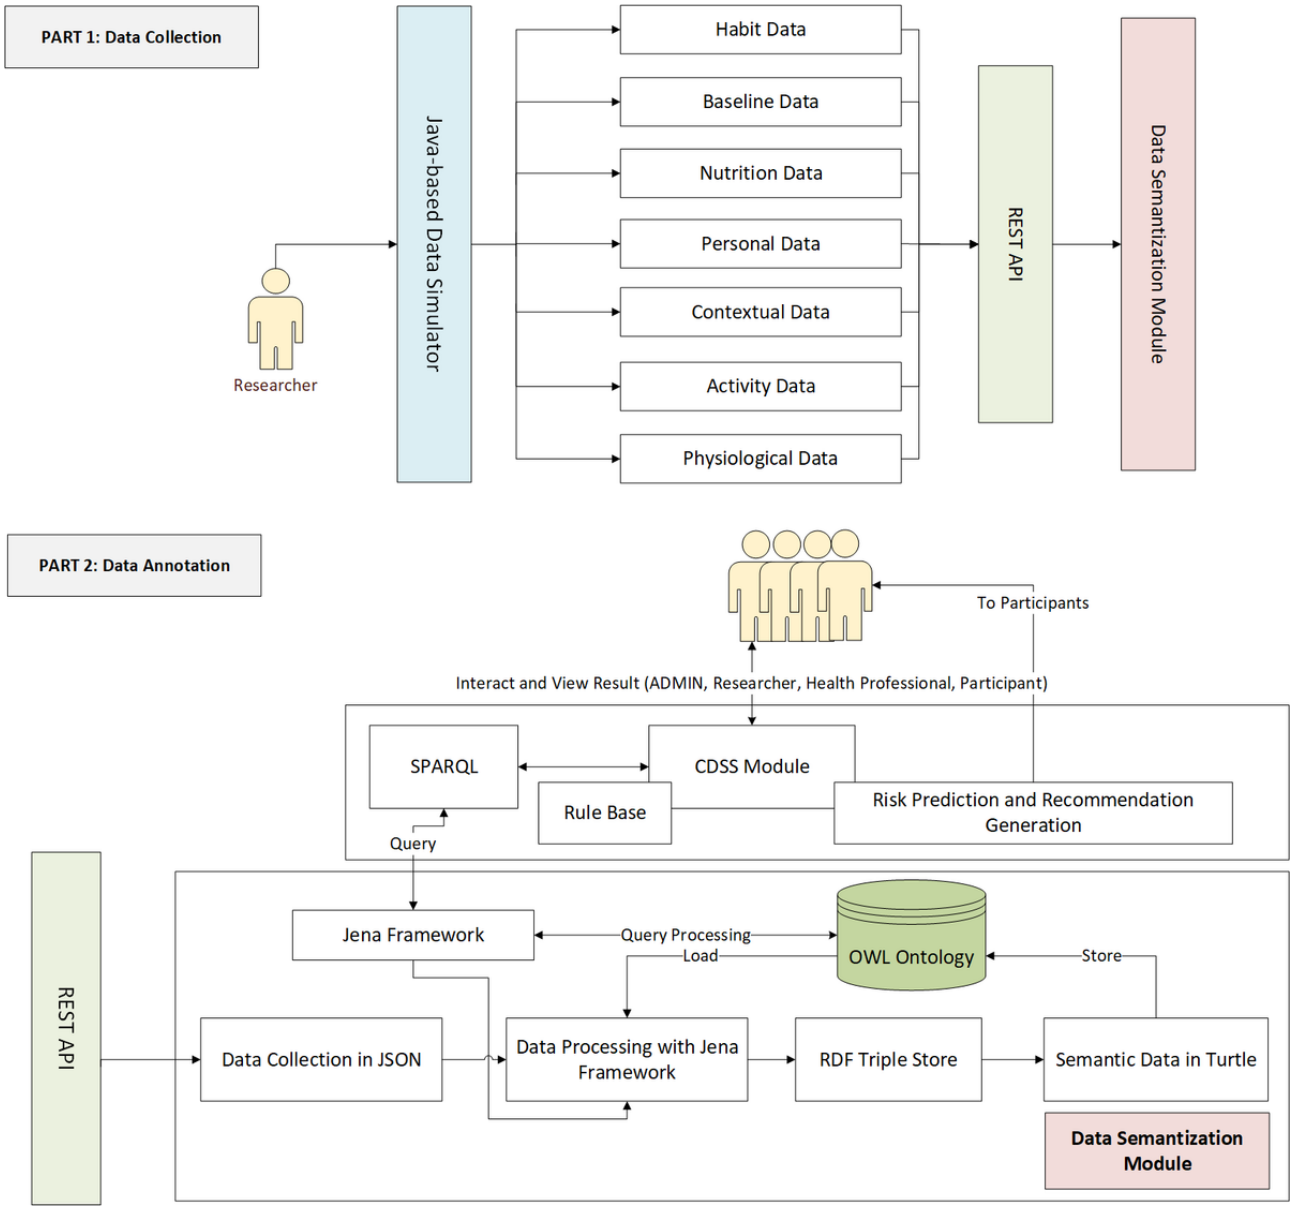


Figure 3. Types of data to be collected from participants.

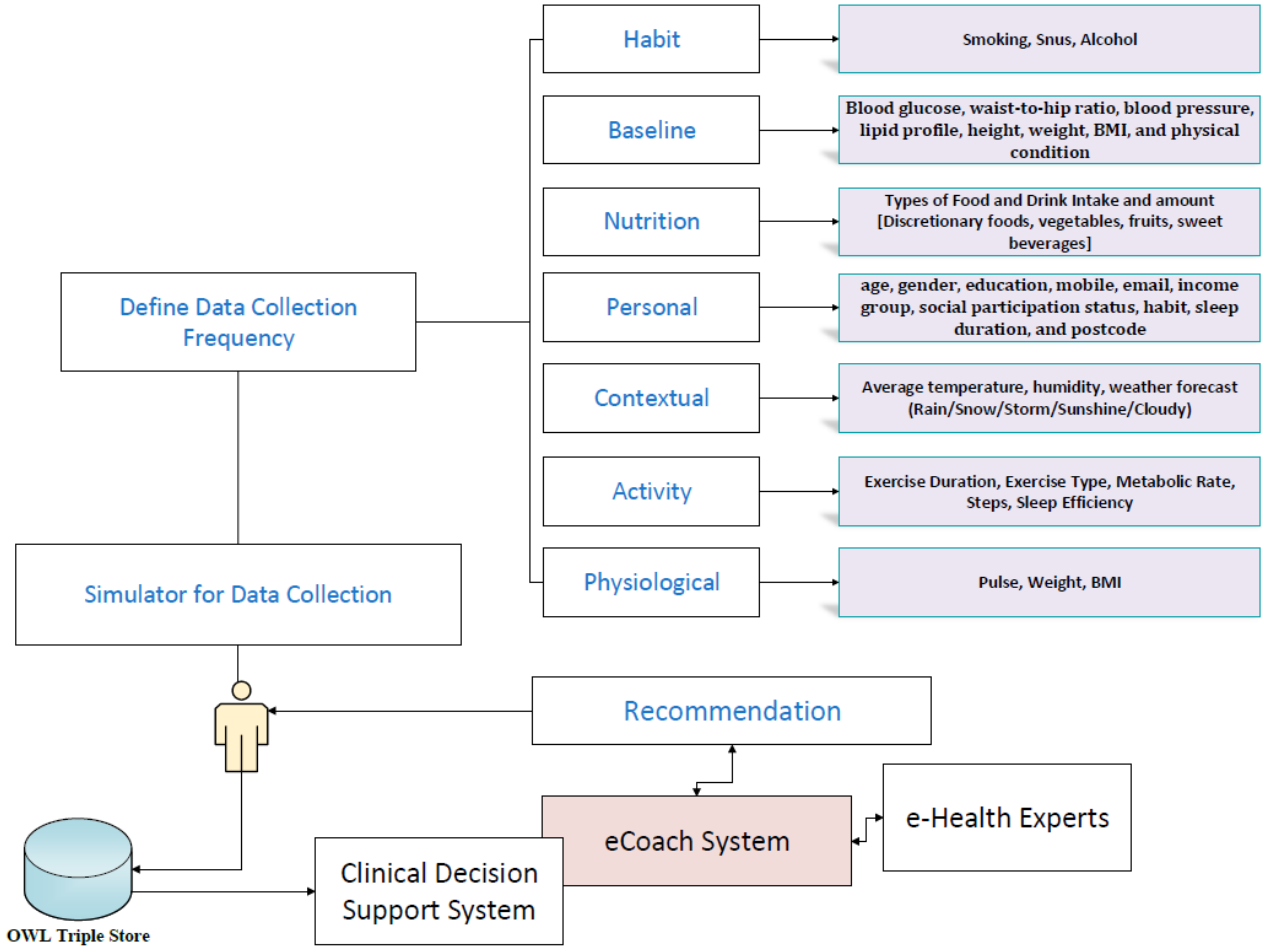
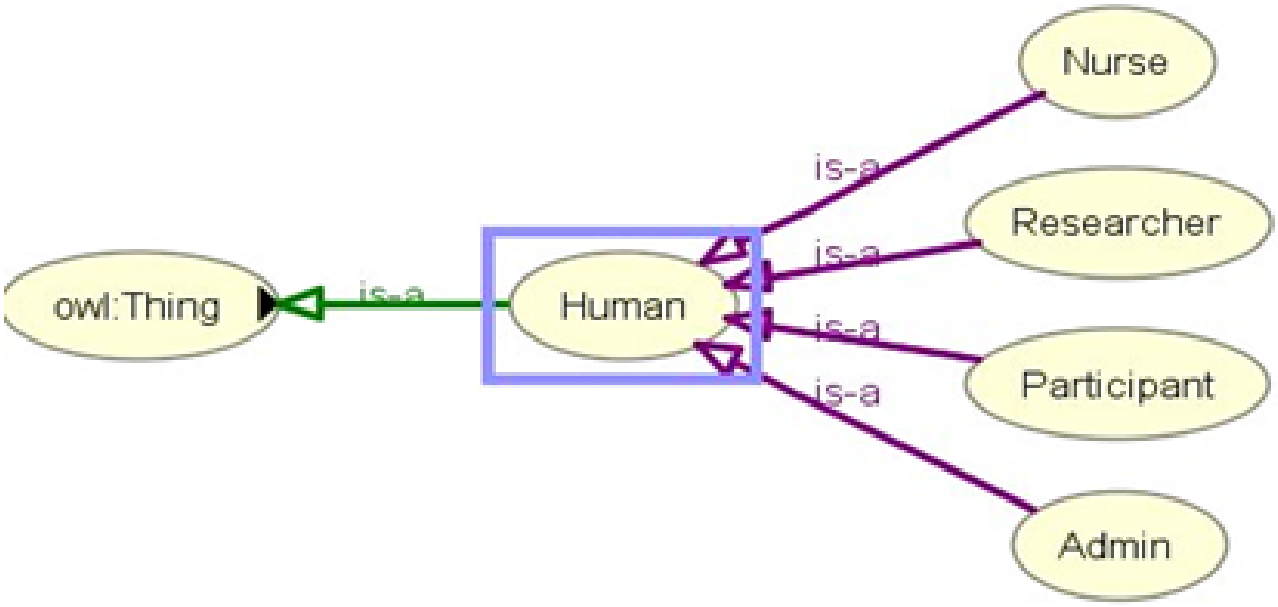


The accumulated data were annotated with semantic metadata (RDF triple store graph) and stored in tuple database in turtle format. The DSS, rule base, SPARQL, risk prediction, and recommendation generation modules are not the core, and they are used for ontology verification as a test engine. The scopes of DSS are as follows: (1) periodic querying of the ontology with Jena framework using preset SPARQL queries [63-65] to assess the health condition; and (2) mapping the query result to preset clinical rules in "rule base" to generate lifestyle recommendations. This study involves 4 different user types: administrator, researcher, participants, and health professionals (eg, nurses; Figure 4). The ontology is protected from personal identity disclosure as no unique identifiers (eg, national identifiers) of participants were collected and stored in the simulated environment in accordance with the Norwegian Centre for Research Data guidelines [66]. Core eCoach and DSS concepts, AI integration for health and wellness data (activity and nutrition) analysis, real-world data collection from actual participants through web applications/mobile apps, real-life personalized recommendation generation, goal evaluation, pregnancy, genetics, child obesity, and obesity in older adults are beyond the scope of this study. This study's primary focus is to design and develop an eHealth ontology for the obesity case and to verify it with artificial data and behavioral recommendation generation with a rule-based DSS. Defined rules for test setup may vary with change in the context and is not the key focus of this paper.

Figure 4. Different types of users involved in the eCoach System.



We simulated habit, nutrition, contextual, activity, and physiological data for 4 dummy participants (2 healthy weight [N] and 2 overweight [O] participants aged between 18 and 40) for the very first day (day-n; n>0); see Multimedia Appendix 2. We assumed all the dummy participants are from the same region, so the contextual information is the same. Rule-based recommendations based on data analysis on "day-n" will be carried out by targeted participants on "day-(n+1)." Recommendations inform individual participants about their daily activity (sedentary or not), dietary intake, and activity/dietary plans. For dietary assessment, we have relied on the daily self-reported questionnaire, rather than on direct calorie calculation for basal metabolic rate. Baseline data help to compare (at the end of each month until the process ends) whether any improvement or deterioration occurred as a result of behavior change based on lifestyle recommendations. For example, reduction in BMI and BP for a person who is obese/overweight, and maintaining safe BMI and BP for a person with healthy weight upon following the behavioral recommendations is a good indication of maintaining a healthy lifestyle. We consulted with 5 experts with a research background in ICT, eHealth, nursing, and nutrition for simulating activity and nutrition data. Obesity-related information and guidelines were obtained from the World Health Organization (WHO) [67], the National Institute for Health and Care Excellence (NICE) [68], and the Norwegian Dietary Guidelines [69].

Integration With SSN Ontology and SNOMED CT

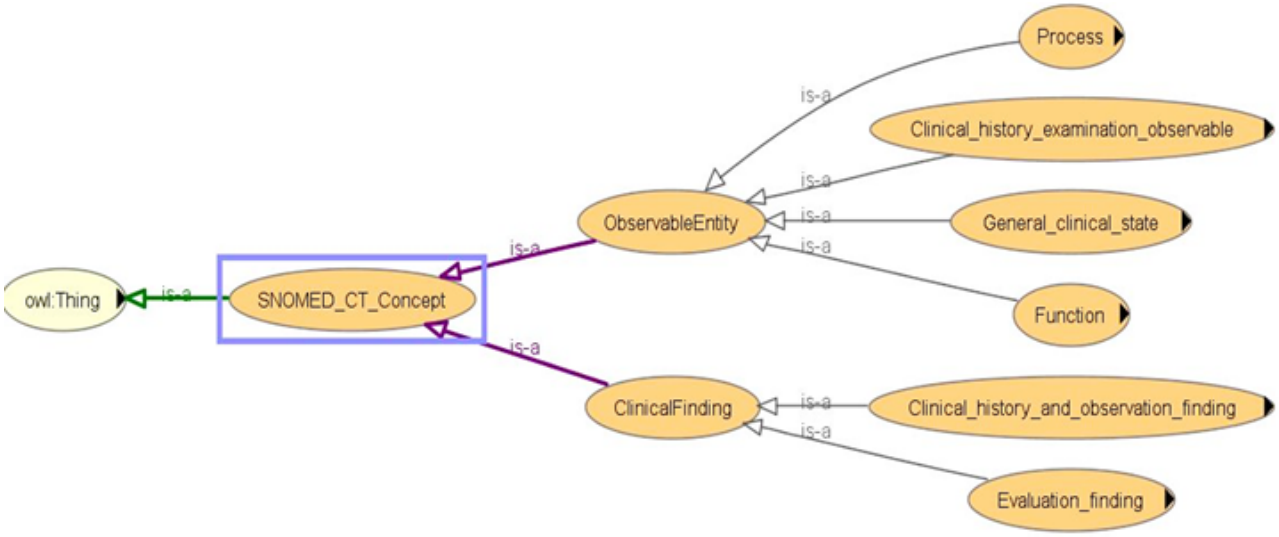
We integrated the SSN ontology [30,36,70-72] into our proposed eHealth ontology to describe sensors (activity sensors and external weather sensors), their observations, and methods adopted for sensing individual activities and context (Figure 5). Observation data related to activity and external weather are annotated with SSN ontology concepts and object properties.

Figure 5. Asserted hierarchy for sensor-based data collection with OWLViz.

Concepts and object properties in the ontology are commented and connected with "rdfs:label," "rdfs:isDefinedBy," "rdfs:seeAlso," "rdfs:comment," "dc:source," "isProxyFor," "has value," "is produced by," "has property," "hasTimeStamp," "isRegionFor," "attached system," "in deployment," "has measurement capability," "detects," "hasOutput," "observes," "implements," "has deployment," "has operating range," "has subsytem," "has survival range," "on platform," "deployment process part," "deployed on platform," "deployed system," "is property of," "feature of interest," "observation result time," "observation sampling time," "observed property," "quality of observation," "sensing method used," "includesEvent," and "observedBy." The SSN ontology is constructed on the foundation of a central ontology design pattern, so-called the stimulus–sensor–observation pattern to describe relationships between sensors, stimulus, and observations [30], and the same concept is reused in our proposed eHealth ontology model. The perspectives of SSN ontology can be classified as follows [30]: a sensor perspective, an observation perspective, a system perspective, and a feature and property perspective. Namespaces for the SSN and DUL ontologies are reused in our ontology prefixing concepts and properties as ssn: and dul:, respectively. "PhysicalDeviceThing" (a class), which behaves as a superclass of classes related to sensor-based observations, is a subclass of "owl:Thing," the universal ontology superclass.

We incorporated selected concepts from SNOMED CT [73] into our proposed ontology model to define how information about the participant's state is to be structured and processed. The SNOMED CT ontology combines hierarchical "is-a" relationships and other related relationships for vital signs, process, body measurements, and observations to describe clinical attributes as depicted in Figure 6. SNOMED CT simplifies the search for respective diseases, process, function, clinical state, measurements, and vital signs, and every concept is identified with an SCTID or SNOMED CT identifier with an object property "hasSCTID" (eg, Obese_finding hasSCTID value "414915002"^^xsd:long) [74].

Figure 6. Asserted hierarchy of SNOMED_CT concept with OWLViz.



Figures 7-9 describe the class hierarchy to process participant's clinical information using the SNOMED CT hierarchy for the vital signs (eg, BP, pulse) and body measurement (eg, obese or overweight) based on the observable entities [75-79]. Observable entities and clinical findings are linked with the objectProperty: isFoundBy. The proposed ontology model can be extended for additional clinical findings [73,74].

Figure 7. SNOMED CT class hierarchy based on selected concepts.

Figure 8. SNOMED CT ontology visualization with OntoGraf based on selected concepts.

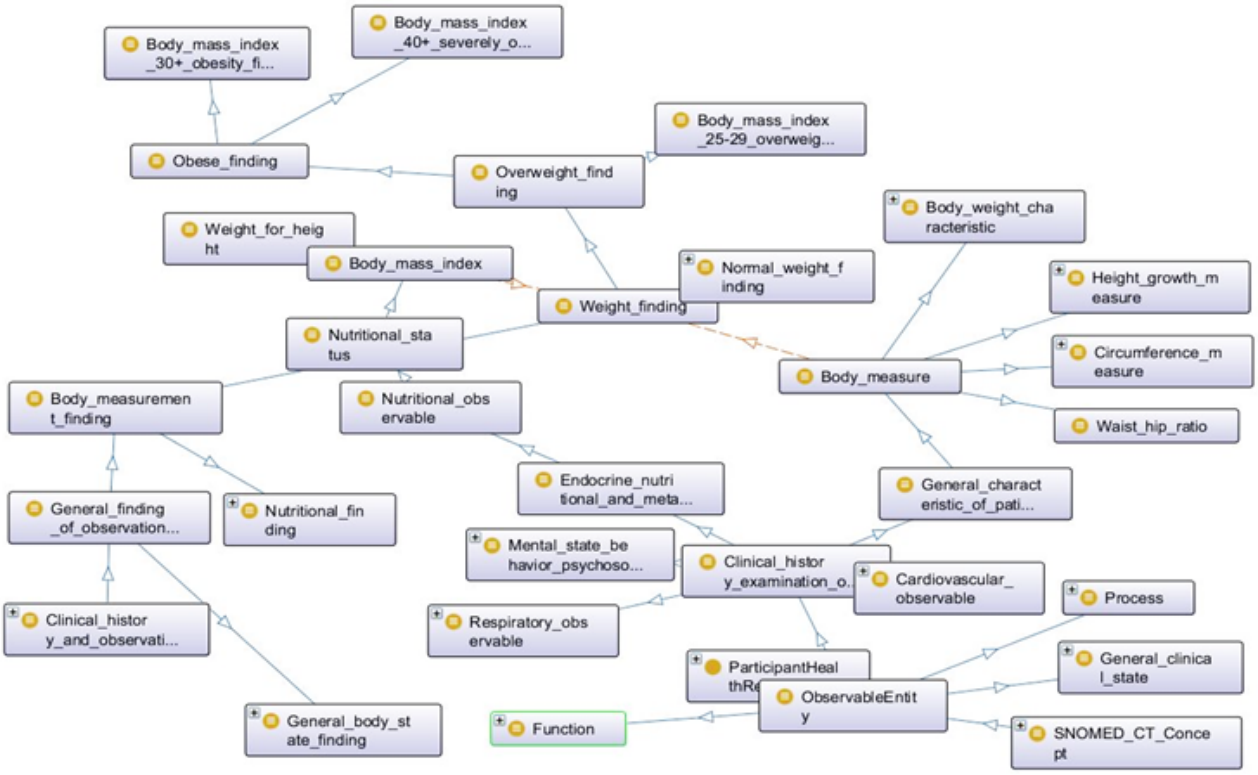


Figure 9. Selected concepts from SNOMED CT Ontology for vital signs, body measurement, and observations.

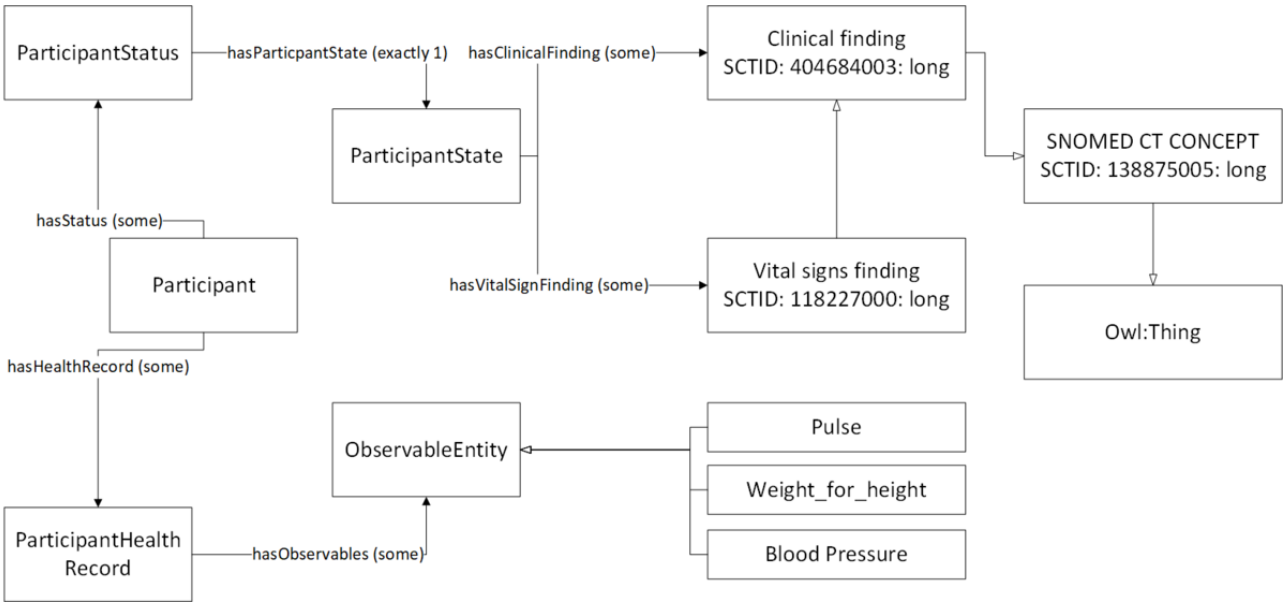

Ontology Implementation

In Figure 10 we describe how we implemented the proposed eHealth ontology for our future eCoach system with required classes, object properties, and data properties to annotate collected data. The administrator, health professionals, researchers, and participants are subclasses of the "Human" class. They have their designated role, password, and userId to authorize themselves in the system with the following associated objectProperties: hasRole, hasPassword, and hasUserId, respectively. Administrator, health professionals, and researchers have their office address (hasOfficeAddress), and personal data (hasPersonalData) to describe themselves. Their office address consists of a phone number, a postcode, and a room number with the following associated dataProperties: hasOfficePhone, hasOfficePostCode, and hasRoomNo, respectively. Their personal data include age, designation, email, first name, last name, gender, and mobile number with the corresponding dataProperties hasAge, hasDesignation, hasEmail, hasFirstName, hasLastName, hasGender, and hasMobile. The "Participant" is an important class and participants are at the core of the system. Participants have their health record, personal data obtained through interview process by trained health professionals, status (active/inactive), and recommendation with

the associated objectProperties hasHealthRecord, hasInterviewPersonalData, hasStatus, and hasReceivedRecommendation as depicted in Figure 11. “ActivityData,” “BaselineData,” “HabitData,” “NutritionData,” “PhysiologicalData” are subclasses of the “ParticipantHealthRecord” class as depicted in Figure 11. Activity data are an observable entity and are planned to be collected via activity sensors (activity bouts, steps, sleep time, activity duration, sedentary bouts, metabolic rate, nonwear time) and questionnaire (duration of intensive activity and nonwear sensor time) daily. Intensive activities are running, weightlifting, cycling, swimming, and skiing. Based on the activity type, participants can be classified into the following 4 groups: sedentary, light active, moderate active, and active. Baseline data (blood glucose, waist-to-hip ratio, BP, lipid profile, height, weight, BMI, and physical condition) are planned to be collected by trained health professionals at the time of recruitment of participants and on a monthly basis following an interview process. Habit data (smoking, snus, and alcohol consumption) and nutrition data (types of foods and drinks with amount) are planned to be collected daily with a pre-set questionnaire. Physiological data (pulse, weight, and BMI) are planned to be collected daily via activity sensors and pre-set questionnaire, as depicted in Figure 12. Personal data (age, gender, education, mobile, email, income group, social participation status, habit, sleep duration, and postcode) of healthy participants are planned to be collected following an interview process by trained health professionals during recruitment. Gender, education, income range, and social participation are essential for demographic classifications. The data properties related to data collection are depicted in Figure 13.

Figure 10. Proposed eHealth Ontology implementation in Protégé 5.x.

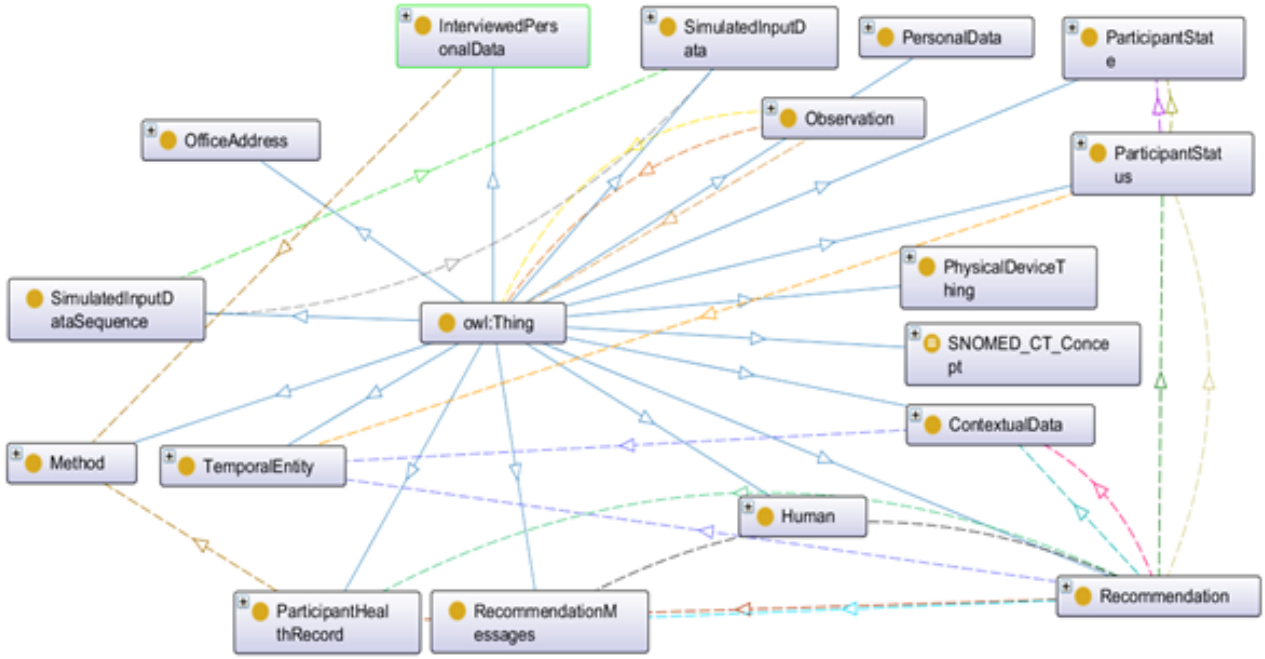

Figure 11. The class hierarchy of the proposed eHealth ontology and the description of participant class.

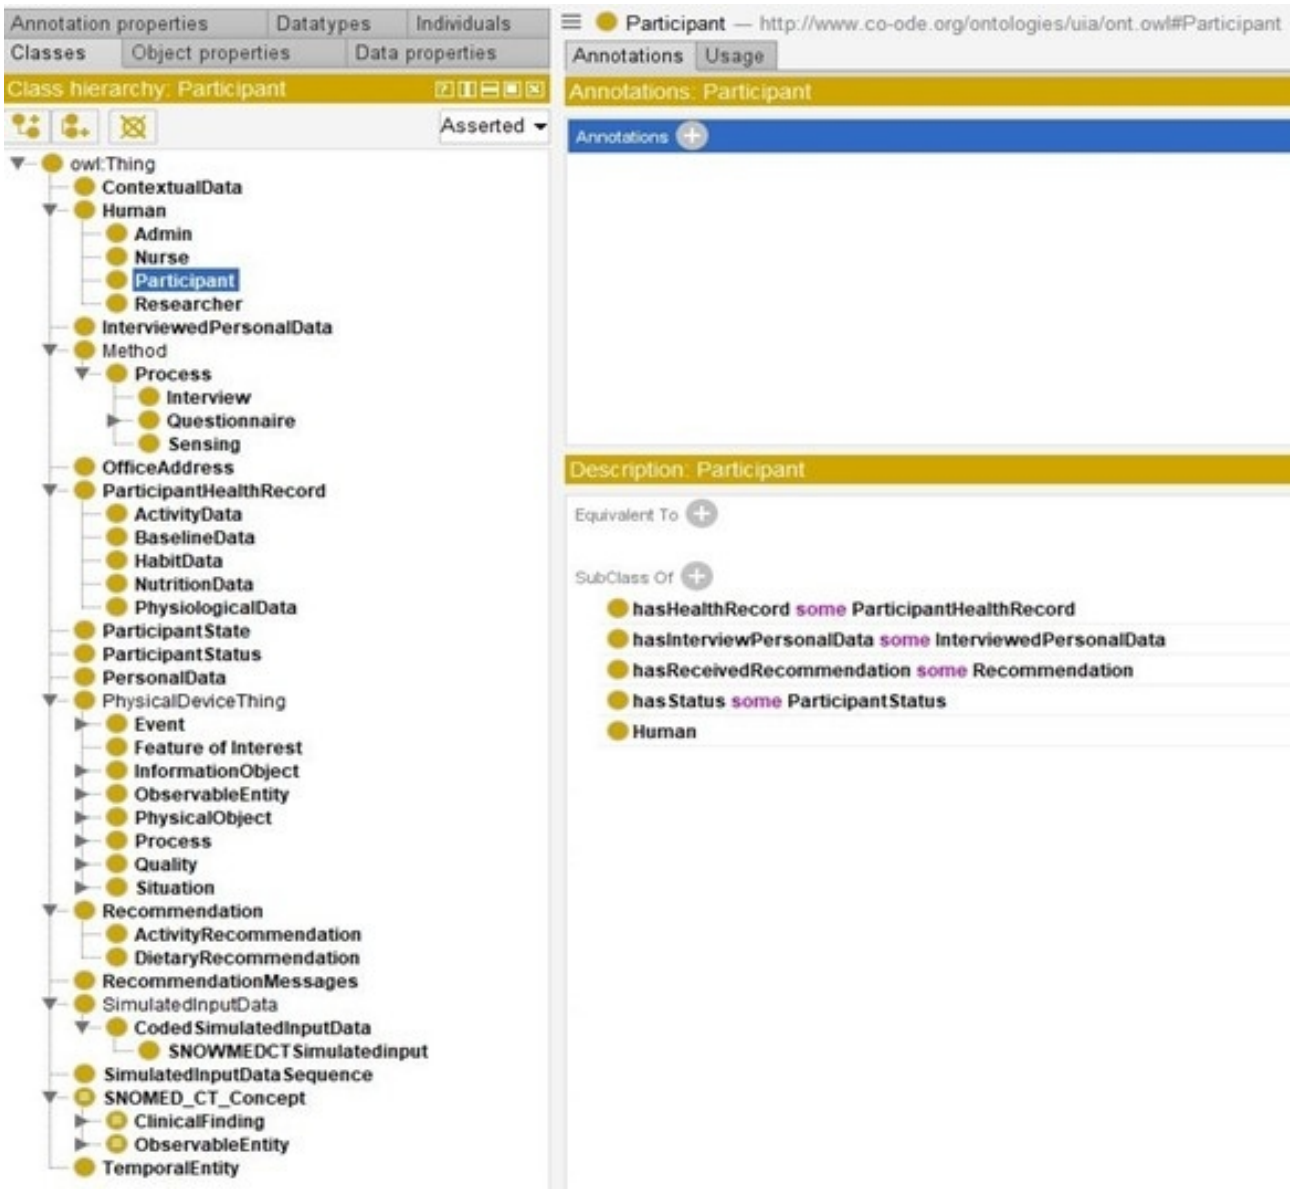

Figure 12. The asserted class hierarchy of participant's health record with OWLViz.

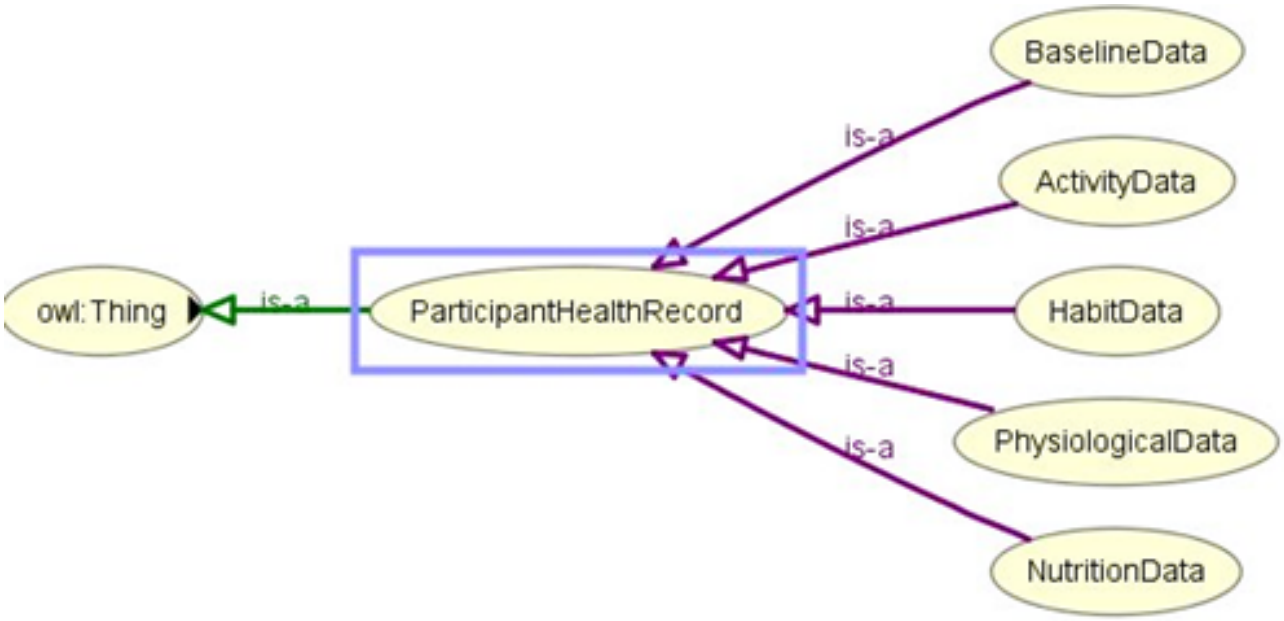

Figure 13. Data properties related to data collection.

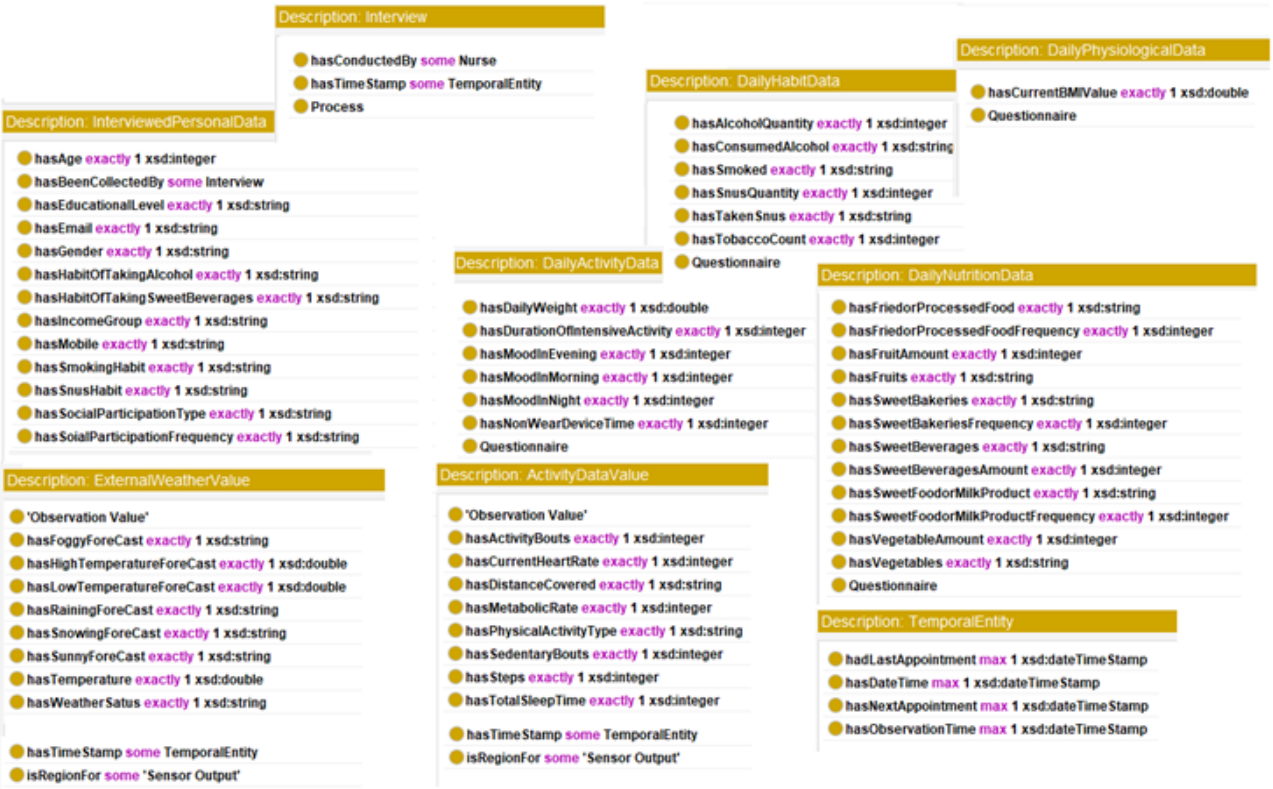

The asserted class hierarchy of the methods used for participant's data collection is depicted in Figure 14. Each method ensures a collection of simulated data sequences, maintaining a timestamp as depicted in Figure 15. Contextual data are observable weather-related data (weather status, current temperature, rain forecast, snow forecast, storm forecast, sunny forecast, high and low temperature forecast, fog forecast), which are planned to be collected daily via sensing devices. The relationship between data and data collection methods are linked with the objectProperty: hasBeenCollectedBy and hasConductedBy (for interview).

Figure 14. The asserted class hierarchy of participant's data collection methods with OWLViz.

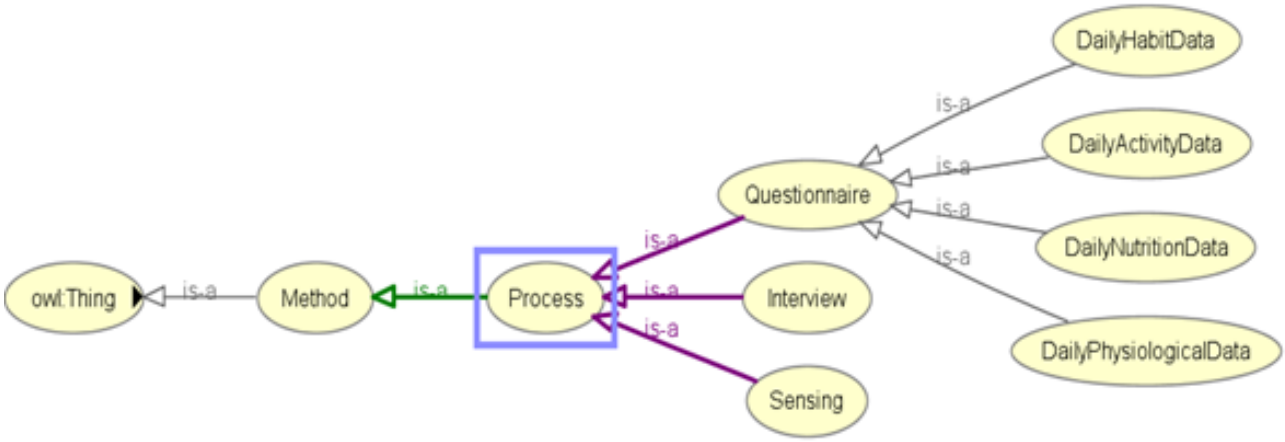

Figure 15. Ontology for data collection from simulated input.

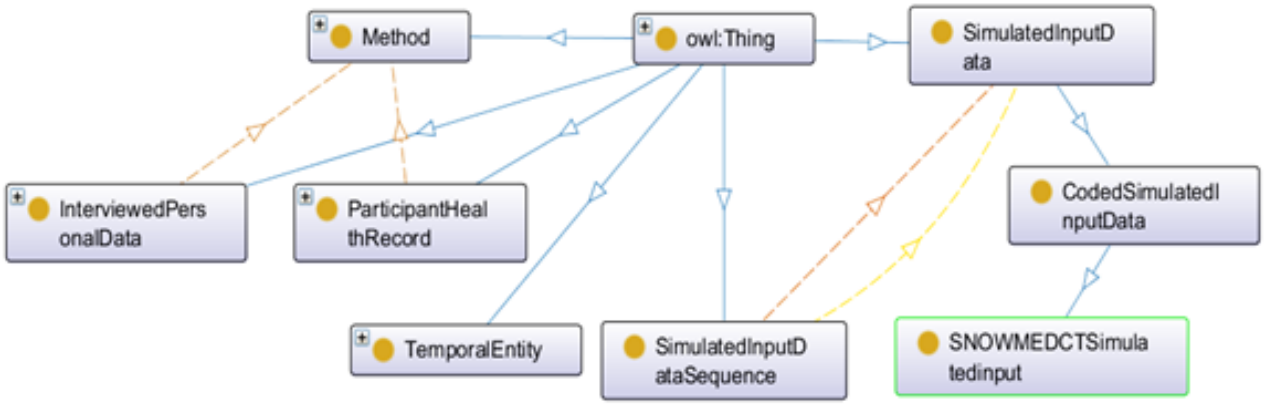
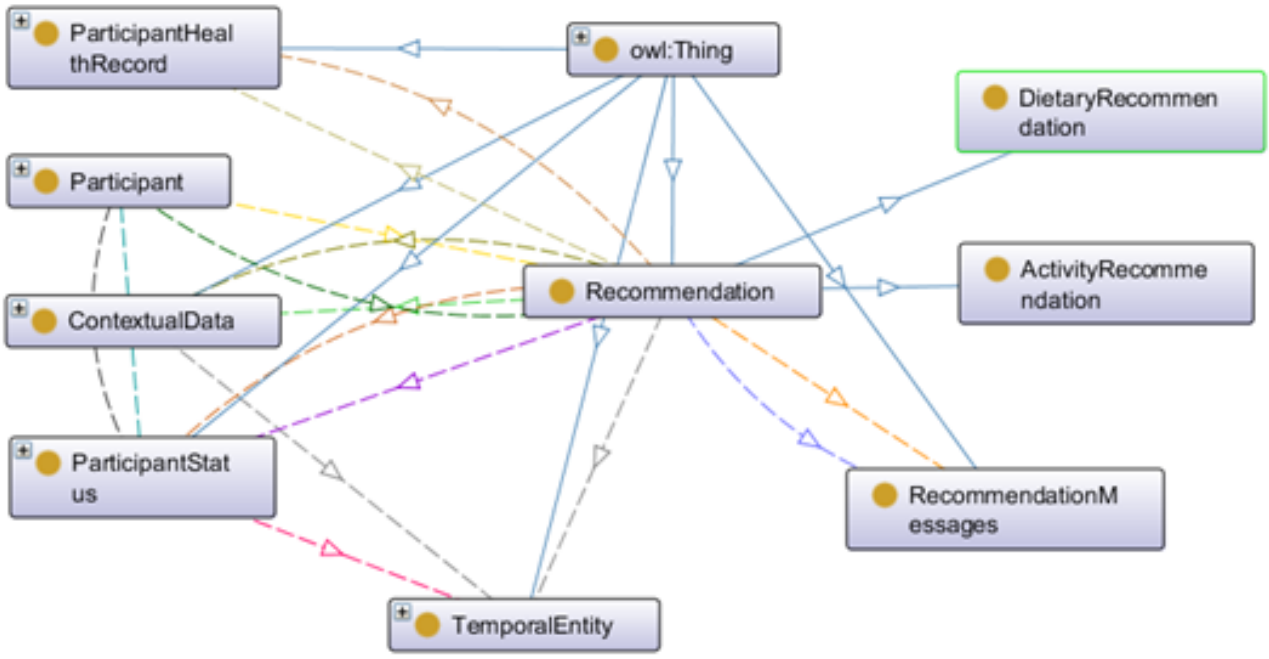


Behavioral recommendations for a healthy lifestyle can be classified in the following 2 categories: activity (A) and dietary (D). Each recommendation is personalized and contextual. Therefore, the recommendation generation depends on evaluating participants' health status (health risk, vital signs, body measurement data) and contextual information. Each generated recommendation consists of a message and the corresponding timestamp (Figure 16). A bad habit (H) has a significant impact on healthy dietary practice. Activities are related to the context (C). Contextual data help recommend participants to plan for indoor/outdoor activities based on the following day's external weather conditions. The data properties of "RecommendationMessages" for activities are "hasActivityMessages" and "hasContextualMessages," whereas those for the diet are "hasDietaryMessages" and "hasHabitRelatedMessages." The identified set of recommendation messages for test setup (ontology verification) is presented in Multimedia Appendix 3, and is prepared based on the positive psychology [79] and the persuasion [80] concept.

Figure 16. Ontology for recommendation generation.

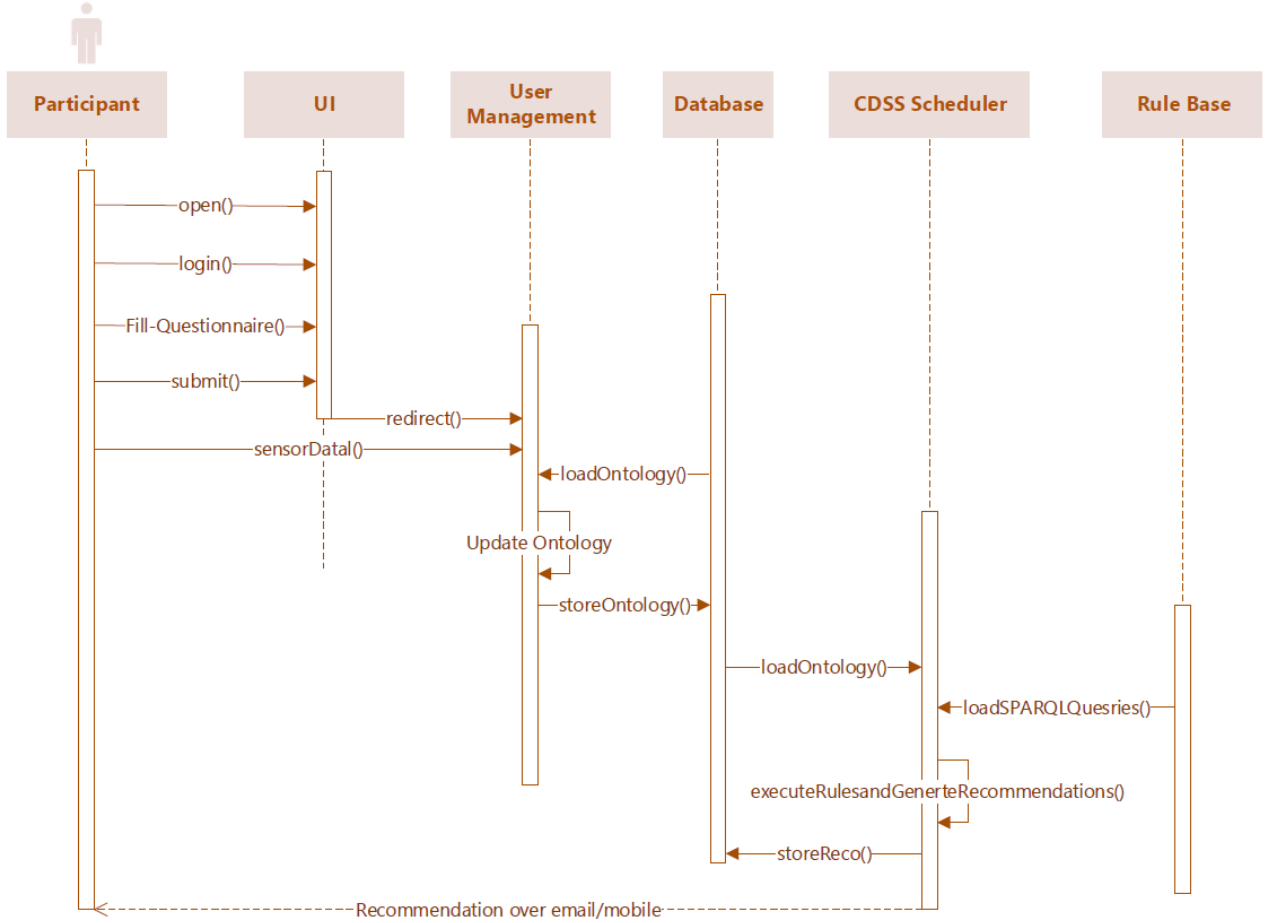


Description logic [35,81] is a formal knowledge representation of the ontology language that offers a good trade-off between expressivity, complexity, and efficiency in knowledge representation and reasoning about structured knowledge. To ensure that the paper is perfectly understood, we have the propositional variables with their linked recommendation messages. Now, we need a set of clauses such that some models will assign these variables to true and thus trigger the sending of a recommendation. The description logic SROIQ [82,83], which is logic providing a formal underpinning of OWL2, has been used as the formal logic to reason in this paper (Multimedia Appendix 4).

Rule Creation for Querying, Recommendation Generation, and Ensuring Satisfiability

A rule consists of a premise (antecedent) and a conclusion (premise). For every condition mentioned in Multimedia Appendix 3, DSS executes SPARQL queries daily to determine what type of recommendation message is to be delivered to each participant as depicted in the unified modeling language sequence diagram (Figure 17). The execution of every predefined semantic rule as specified in Multimedia Appendix 4 relies on the SPARQL query execution, and the rules are created following clinical guidelines, as stated in Multimedia Appendix 5 [62,84-92]. In this study, 20 semantic rules are subdivided into activity-level classification (8), habit-related classification (3), dietary classification (4), weather-level classification (1), obesity-level classification (3), and satisfiability (1) (please also see Multimedia Appendix 4). Moreover, except for the already-existing ontologies used, to ensure some consistency regarding what a participant is, what are the participant health records, etc., the concepts and the rules added are relatively easy to follow, and therefore they will be relatively easy to use.

Figure 17. UML sequence diagram for recommendation generation and delivery.



The observable and measurable parameters associated with activities, habit, nutrition, and context (as described in Multimedia Appendix 4) for individual participants on a timestamp are obtained based on the execution of SPARQL queries by DSS on a daily scheduled interval as specified in Multimedia Appendix 6. The rules 17-19 in Multimedia Appendix 4 assign truth values to variables that ensure consistency with concepts already existing in the SNOMED CT ontology, where the body measurement is defined. We have confirmed with HermiT that for 4 specific cases the correct recommendation messages are triggered. However, one would need to ensure that there is not a combination of variables such that the whole formula is unsatisfiable (ie, no model can satisfy the procedure). One would also need to ensure that only 1 message can be triggered at a time. In this study, we have a formal guarantee that 2 “once-a-day” messages can neither be triggered simultaneously nor for every possible combination of variables, there is, every time, a model output by HermiT. If we put the different variables used in the first 19 rules (Multimedia Appendix 4) into propositional variables, we would have an exponential number of “possible participants.” One formal way to ensure a model’s existence is to negate all our rules and ensure the same. Then, the formula is indeed unsatisfiable. As 2 messages cannot be triggered at the same time, and to satisfy the same, we added a rule (rule 20) on the variables used in the recommendations started “once-a-day.” If rule 20 is false, then the whole set of rules (considered as a large conjunction) will be set to false. It will result in “no execution” of the proposition (see Multimedia Appendix 3) and will help us to debug our defined semantic rules (rules 1-19) as defined in Multimedia Appendix 4. If it is set to true, we have a formal guarantee that no 2 “once-a-day” messages can be triggered at the same time, no matter the truth values we put into our ABox.

Results

The test setup to verify the proposed eHealth ontology’s performance and reliability consisted of a DSS module (health risk prediction and recommendation generation for a healthy lifestyle), SPARQL, and rule base. As an outcome of ontology verification, we generated personalized and contextual recommendations (behavioral) following semantic rules to balance individual weight change with adopting healthy behavior to balance a trade-off between physical activity, healthy habit, and a healthy diet as depicted in Figure 18. We executed all the semantic rules as stated in Multimedia Appendix 4 in the form of SPARQL queries using the Jena ARQ engine on each participant’s simulated data as mentioned in Multimedia Appendix 2. We then determined what type of recommendation messages would be required to be delivered for each participant to manage his/her healthy lifestyle. These findings are detailed in Table 1.

Figure 18. Behavioral recommendation generation (pivot) for the management of healthy lifestyle (a trade-off between physical activity, healthy habit, and healthy diet).

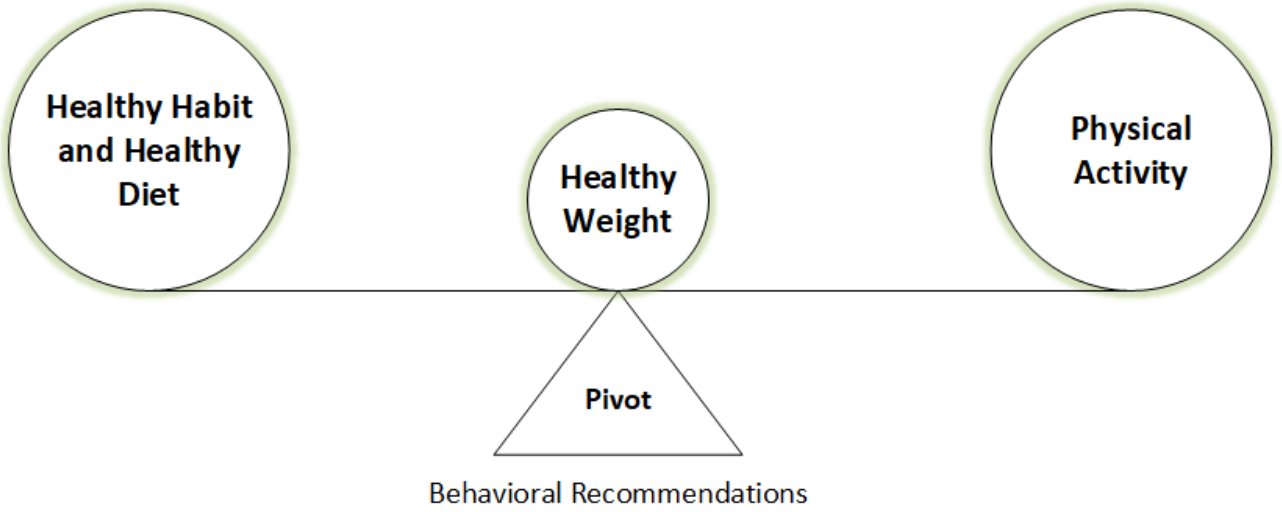


Table 1. Recommendation generation for participants for Day-(n+1) [n>0].

Participant	Profile	SCTID	Healthy habit on Day-n	Healthy diet on Day-n	Physically active on Day-n	Recommendation(s) for Day-(n+1)
Individual_1	Normal weight	43664005	No	No	Yes	H-1, D-2, D-3, A-4, C-1
Individual_2	Normal weight	43664005	No	Yes	No	H-1, H-2, D-4, A-3, C-1
Individual_3	Overweight	162863004	No	No	No	H-2, D-1, D-2, D-3, A-2, A-5, C-1
Individual_4	Overweight	162863004	Yes	No	No	D-1, D-2, A-1, C-1

Discussion

Principal Findings

According to Table 1, “Individual_1” and” Individual_2” are healthy weight participants, and “Individual_3” and “Individual_4” are overweight participants as assessed based on their daily (“Day-n”) BMI (weight/height^2) value. According to Figure 1, a healthy weight is a trade-off between healthy habits, healthy diet, and physical activity. On “Day-n” (n>0), “Individual_1” has been physically active, and this is the reason he has been encouraged to keep up the same activity level (A-4). By contrast, he has shown some addiction toward “snus,” sweet beverages, and fried/processed foods, which might grow negative behavior in the participant and increase his weight. Therefore, he has been recommended to reduce tobacco consumptions (H-1) and to refrain from discretionary food items (D-2 and D-3). The simulated data for “Individual_2” has demonstrated that she is inclined to a healthy diet (D-4), but growing some negative behavior with consumption of alcohol and tobacco (H-1, H-2). She is just one step behind to become physically active (A-3). Hence, she has been recommended to take a healthy dietary plan, refrain from tobacco and alcohol, and increase activity level to become active. “Individual_3” is neither physically active nor adhered to healthy habits or healthy dietary plans. He is addicted to alcohol, fried/processed foods, sweet beverages, sweet food/milk products. His consumed number of vegetables and fruits is not adequate for a healthy diet (<400 g). Therefore, he has been recommended to reduce alcohol consumption (H-1), to follow a healthy dietary habit (D-1, D-2, D-3), and to become more physically active (A-2) with adequate sleeping (A-5). The fabricated data for “Individual_4” has shown that she has an unhealthy diet plan, and she is mostly leading a sedentary lifestyle. Therefore, she has been recommended to stay away from discretionary food items (D-2), to incline on “core-foods” (D-1), and to increase activity level by one step (A-1). The analysis of contextual data reveals that the weather on “Day-(n+1)” is suitable for outdoor activities. The purpose of the individualized recommendation generation is to guide and encourage individual participants to keep up a healthy lifestyle by maintaining a balance between healthy habit, healthy diet, and physical activity. It encourages people with a normal weight to maintain their healthy weight, and those with obesity/overweight to reduce their weight.

The rule-based decision support has generated personalized and contextual recommendations (Table 1) using SPARQL queries, as depicted in Figure 19, based on the proposed ontology without any “false-positive” case. The proposed ontology’s reasoning time has been measured as <30.0 seconds in Protégé with HermiT reasoner without reporting any inconsistencies. The reading time of the ontology after loading it in the Jena workspace was about 2.0-3.5 seconds with the “OWL_MEM_MICRO_RULE_INF” ontology specification in the “TTL” format (OWL full), “in-memory” storage, and “optimized rule-based reasoner with OWL rules.” Then, we queried ontology classes, ontologies, “predicate, subject, and object” of every statement using Jena in <1.5 seconds, <0.5 seconds, and <3.5 seconds, respectively. Each ontology model (complete RDF graph) is related to a document manager (default

global document manager: "OntDocumentManager") to assist with the processing and handling of ontology documents. All the classes in the ontology API that represent ontology values have "OntResource" as a common super-class with attributes (versionInfo, comment, label, seeAlso, isDefinedBy, sameAs, and differentFrom) and methods (add, set, list, get, has, and remove). We used the implementation of the RDF interface, provided by Jena, to store the modeled ontology and its instances persistently in the tuple database and load it back to process further. Jena Fuseki is tightly integrated with tuple database to provide a robust, transactional persistent storage layer (Figure 20).

In the future study, the recommendation process can be automated with the amalgamation of a hybrid DSS system (rule based and data driven) and AI algorithms. The scope of the proposed ontology can be enhanced with the integration of (1) real sensor activity devices; (2) mood assessment of participants; (3) collection of nutrition data on a detailed level through multiple questionnaires (daily, on every alternative day, and weekly); (4) semantic annotation of the recommended messages; (5) weekly suggestion generation after evaluating daily generated recommendations, and followed by a ranking of participants based on their weekly performances; (6) help-desk management for technical support; (7) assessment of baseline data; (8) trend analysis of health risks as a function of habit, diet, and activity with machine intelligence; and (9) automated interview management by trained health professionals (nurses).

Figure 19. Sample SPARQL query for recommendation finding (e.g., "Individual_1").

Conclusions

In health care, with the research advancement on the IoT domain, an increasing number of sensors, actuators, mobile, and web-based health monitoring devices are deployed into our daily life for remote health monitoring. It produces enormous personalized health and wellness observable and measurable data with hidden patterns. Data collected by multichannel sensors or devices demonstrate significant differences in data formats, types, and domains, which might lead to a problem in machine understandability. Therefore, a semantic representation of collected health and wellness data from heterogeneous sources is necessary, and the ontology serves the purpose. In this pilot study, we have proposed an eHealth ontology model in association with SSN and SNOMED CT, to support a semantic representation of collected observable and measurable data to manage a healthy lifestyle focusing on obesity as a case study. The ontology represents collected data with OWL-based web language in RDF triple-store format. The performance of the proposed ontology has been evaluated with the simulated data (eg, sensor, interview, and questionnaire) of 4 dummy participants. The proposed ontology's structural and logical consistency has been evaluated with a Protégé reasoner (HermiT 1.4.3.x). The proposed ontology model has been used by a rule-based DSS to generate personalized and contextual recommendations with the execution of SPARQL queries against a preset rule base (with the help of Apache Jena library) to promote a healthy lifestyle for obesity management. In the future study, we will recruit real participants following inclusion and exclusion criteria and provide them real activity devices to replicate the whole scenario and evaluate the efficacy of the recommendation generation plan. The proposed ontology can be extended to annotate observable and measurable data for other related lifestyle diseases, such as diabetes type II, chronic obstructive pulmonary diseases, cardiovascular diseases, and mental health.

Abstract

Background: Next-generation sequencing (NGS) technology has been rapidly adopted in clinical practice, with the scope extended to early diagnosis, disease classification, and treatment planning. As the number of requests for NGS genomic testing increases, substantial efforts have been made to deliver the testing results clearly and unambiguously. For the legitimacy of clinical NGS genomic testing, quality information from the process of producing genomic data should be included within the results. However, most reports provide insufficient quality information to confirm the reliability of genomic testing owing to the complexity of the NGS process.

Objective: The goal of this study was to develop a Fast Healthcare Interoperability Resources (FHIR)–based web app, NGS Quality Reporting (NGS-QR), to report and manage the quality of the information obtained from clinical NGS genomic tests.

Methods: We defined data elements for the exchange of quality information from clinical NGS genomic tests, and profiled a FHIR genomic resource to enable information exchange in a standardized format. We then developed the FHIR-based web app and FHIR server to exchange quality information, along with statistical analysis tools implemented with the R Shiny server.

Results: Approximately 1000 experimental data entries collected from the targeted sequencing pipeline CancerSCAN designed by Samsung Medical Center were used to validate implementation of the NGS-QR app using real-world data. The user can share the quality information of NGS genomic testing and verify the quality status of individual samples in the overall distribution.

Conclusions: This study successfully demonstrated how quality information of clinical NGS genomic testing can be exchanged in a standardized format. As the demand for NGS genomic testing in clinical settings increases and genomic data accumulate, quality information can be used as reference material to improve the quality of testing. This app could also motivate laboratories to perform diagnostic tests to provide high-quality genomic data.

Introduction

Next-generation sequencing (NGS) technology has been rapidly adopted in clinical practice, with the scope extended to early diagnosis, disease classification, and treatment planning [1-3]. To implement clinical NGS applications, health care providers operate their own NGS laboratories or request genomic tests to external laboratories. The NGS genomic testing reports provide information regarding genomic variations and related data. However, different templates and data elements are used depending on the laboratory, and most reports are provided in text or PDF format [4,5]. As the number of requests for NGS genomic testing increases, considerable efforts have been made to deliver the testing results clearly and unambiguously [6-10]. Moreover, international standards development organizations have developed reporting standards such as the Fast Healthcare Interoperability Resources (FHIR) Genomics Reporting Implementation Guide and International Organization for Standardization (ISO) standards to exchange complex clinical genomic data and interpretations [11-14].

For the legitimacy of clinical NGS genomic testing, the quality information from the process of producing the genomic data should be included within the test results [15-17]. The demand for genomic testing of small tissue samples and needle biopsies is increasing [18], and it remains challenging to determine the reliability of the genomic test results. When testing small quantities or low-quality samples, including low-purity specimens and formalin-fixed paraffin-embedded (FFPE) specimens, quality information can be considered for the interpretation of diagnostic results as evidence. Confirming that there is no specific variation is a particular challenge, especially without quality information. For the validity and utility of clinical NGS genomic testing, the US Centers for Medicare and Medicaid Services regulates all laboratory tests performed on humans through the Clinical Laboratory Improvement Amendments, and the US Food and Drug Administration (FDA) requires information regarding the clinical validity for genomic tests [19,20]. In Korea, the Ministry of Food and Drug Safety (MFDS) has initiated the clinical laboratory accreditation program since 2017 [21]; however, this provides accreditation of the entire NGS process rather than the reliability of individual samples. When a clinician performs NGS genomic testing for diagnostic purposes, quality information can be used to interpret the results for individual samples. In addition, when constructing a reference database using these samples, it is essential to include this quality information.

The successful practice of precision medicine depends on clinical genomic data sharing and knowledge-based interpretations of genomic variant data at the point of care [11]. To improve interoperability as part of precision medicine, health care stakeholders encourage the use of application programming interfaces (APIs) and app-based ecosystems such as SMART on FHIR, CDS Hooks, and SMART Markers [22-26]. These platforms enable easy implementation for health care use cases and facilitate functional extensibility. There are several apps based on clinical genomics use cases on the SMART on FHIR platforms, such as the SMART Precision Cancer Medicine and SMART Cancer Navigator apps [27-29].

In this study, we developed the NGS Quality Reporting (NGS-QR) app to exchange the quality information of clinical NGS genomic testing. To exchange the information in a standardized format, we profiled a FHIR genomic resource based on ISO/TS 22692:2020 Genomics Informatics-Quality Control Metrics for DNA sequencing, which defines the quality-related data for the entire NGS process, including sample preparation, library preparation, sequencing, and data processing [15]. This app enables the performance comparison of clinical NGS genomic testing and monitoring of the quality status of the current sample as the data accumulate.

Methods

Overview

This study describes the development of the NGS-QR app, a FHIR-based web app, to report, manage, and monitor the quality information from the process of producing genomic data. As shown in Table 1, the development was composed of the following phases: (1) requirement analysis, (2) design, (3) implementation, and (4) testing. In the requirement analysis phase, we defined use cases and selected data elements such as DNA purity and integrity, library input amount and size, and sequencing running quality, in accordance with standards and guidelines. In the design phase, we profiled a FHIR resource on the existing genomic resource to exchange quality information in a standardized manner. We also designed user interfaces and functions for the NGS-QR app. In the development phase, we developed the three following components: web app (NGS-QR app), FHIR server, and R Shiny server. The web app includes a FHIR resource handler to generate and parse FHIR resources. Finally, in the testing phase, the NGS-QR app was validated using real-world data collected from the NGS pipeline, a targeted sequencing platform.

Table 1. Overview of development of the next-generation sequencing-quality reporting (NGS-QR) app.

Development phase	Description
Requirement analysis	
Use cases	Define use cases for quality information exchange of clinical NGS[a] genomic testing
Data elements	Select data elements in accordance with standards and guidelines (eg, ISO[b], US FDA[c], ACMG[d])
Design	
FHIR[e] genomic profile	Profile a FHIR resource on the existing genomic resource, MolecularSequence
System components	Design user interfaces and functions of the NGS-QR app
Implementation	
Web app (NGS-QR app)	Develop user interfaces and functions of the web app; develop a FHIR resource handler to generate and parse FHIR resources
FHIR server	Develop a FHIR server and repository; apply the FHIR QcMetrics profile to the FHIR server
R Shiny server	Develop R code for statistical analysis of NGS experimental data
Testing	
Data collection	Collect real-world data generated from the NGS pipeline
Data exchange	Exchange real-world data between the FHIR server and NGS-QR app using FHIR APIs[f]
Quality management	Check the quality information of NGS genomic testing using the dashboard and statistical analysis

[a]NGS: next-generation sequencing.

[b]ISO: International Organization for Standardization.

[c]US FDA: US Food and Drug Administration.

[d]ACMG: American College of Medical Genetics.

[e]FHIR: Fast Healthcare Interoperability Resources.

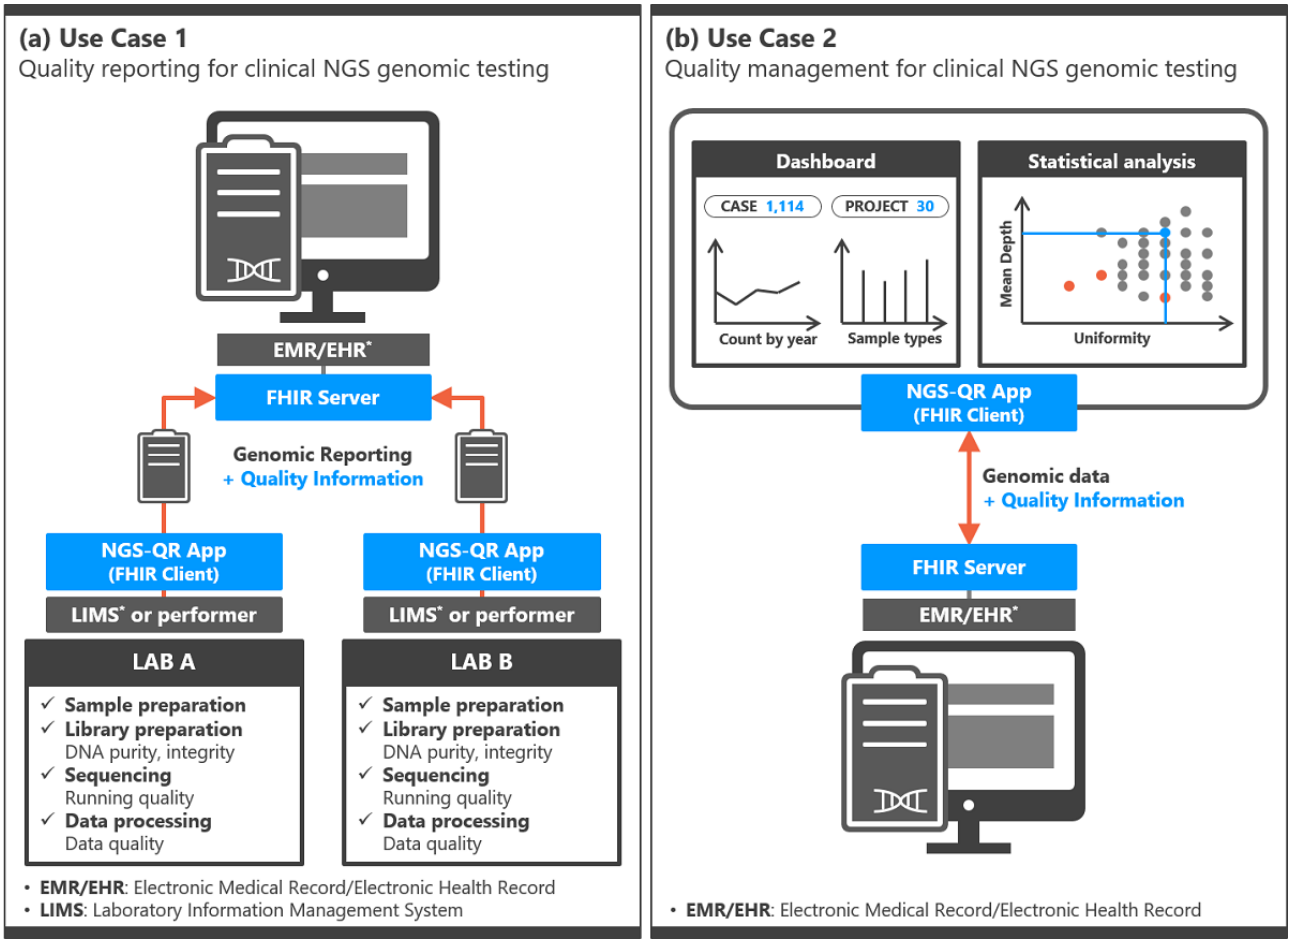
[f]APIs: application programming interfaces.

Use Cases

We defined two use cases: quality information reporting and quality management for clinical NGS genomic testing. The first use case is related to the quality information reporting for clinical NGS genomic testing, as shown in Figure 1a. The laboratory reports the results of NGS genomic testing to the hospital along with quality information. This use case assumes that the hospital information system provides the FHIR APIs. The laboratory requested for the NGS genomic testing sends the results using the NGS-QR app, which acts as an FHIR client. When the user fills out the reporting form in the NGS-QR app, a FHIR resource is created in JSON format and then the resource is sent to the server via the FHIR API. Hospitals that request NGS genomic testing to multiple laboratories can receive information in the same format through this standardized method.

The second use case is related to the quality management for clinical NGS genomic testing, as shown in Figure 1b. Users such as health care providers and performers of NGS testing manage and monitor the quality status of the genomic data received from the laboratories. Through the NGS-QR app, users can retrieve experimental data from the FHIR server and view the summary such as the total number of genomic tests and the number of tests based on the year or specimen type for all genomic test results. Moreover, quality information such as DNA purity, integrity, and data quality for each sample can be compared through statistical analysis. This step can be used to determine the reliability of clinical NGS genomic testing.

Figure 1. Use cases for exchanging the quality information of clinical next-generation sequencing (NGS) genomic testing. (a) Quality reporting for clinical NGS genomic testing. (b) Quality management for clinical NGS genomic testing. FHIR: Fast Healthcare Interoperability Resources.



Data Elements Selection

The NGS workflow involves complex procedures consisting of several steps, which are broadly divided into sample preparation, library preparation, sequencing, and data processing. In this process, various types of experimental conditions and results are generated and captured. As shown in Table 2, we selected data elements based on the ISO 22692 [15] and guidelines such as those of the FDA [20], American College of Medical Genetics [30], and College of American Pathologists [31] for quality management and comparative analysis. For this study, approximately 30 data elements were selected.

Table 2. Next-generation sequencing (NGS) workflow and data elements.

NGS workflow	Data elements
Sample preparation	
Sample sequencing type	sequencing type, target gene
Sample information	specimen type, sampling date
Library preparation	
DNA extraction	DNA extraction kit, DNA purity (eg, OD[a] 260/280, OD 260/230), DNA integrity (eg, DNA median size)
Library construction	library input amount, library input size, library construction kit
Sequencing	
Sequencing information	sequencing instrument, read length, sequencing direction, running mode
Running quality	error rate, percent data quality (>Q30)
Data processing	
Data quality	total reads, mean coverage, uniformity, on-target rate, Q30, PR[b] score
Sequencing alignment	mapping algorithm, sequencing alignment software
Variant calling	variant calling software, quality score, allelic read percentage
Variant filtering and annotation	germline filter criteria, reference database

[a]OD: optical density.

[b]PR: pass rate.

FHIR Genomics Resource Profile

We profiled a FHIR genomic resource by defining constraints and extensions for exchanging quality information with a standardized method. Since the results of NGS genomic testing include genomic variant information and its quality-related data, the FHIR R4 MolecularSequence resource [32] was used for tailoring the NGS data to the use cases in this study. We created a QcMetrics element (a FHIR extension) in the resource and added data elements for each process under QcMetrics. Textbox 1 shows an example of a FHIR genomics resource that includes the QcMetrics profile. We uploaded the profile to the public FHIR registry SIMPLIFHIR.NET [33].

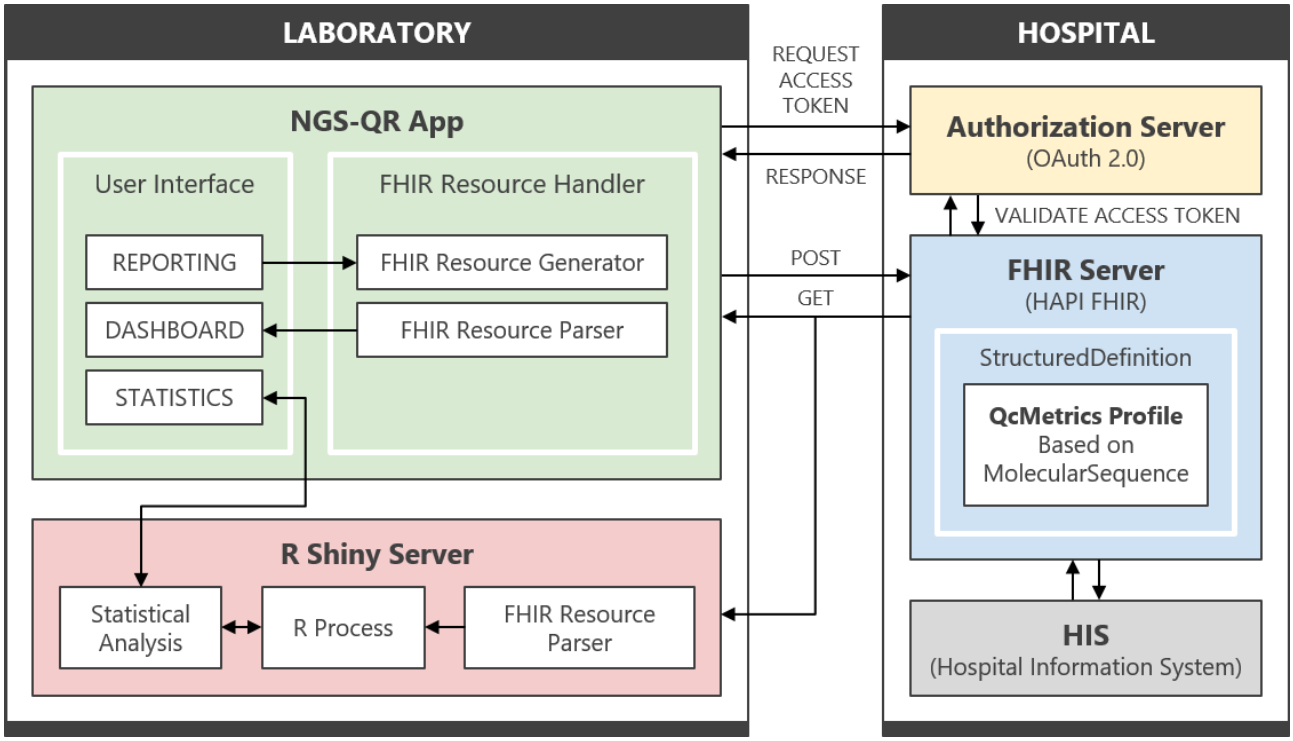
Implementation

We developed the following three major components: the NGS-QR app (FHIR client), FHIR server, and R Shiny server, as shown in Figure 2. The NGS-QR app was developed using Node.js (v12.13.1), which is composed of user interfaces (UIs), a FHIR resource handler, and a REST API module. The app has been deployed to the App Gallery of SMART on FHIR, which is an open platform for substitutable third-party health apps to connect to electronic medical record (EMR)/electronic health record (EHR) systems with appropriate security guarantees [34,35]. The source code of the app is available at GitHub [36]. The FHIR server was locally installed using the HAPI FHIR server (v4.0.0), which is an open-source Java implementation of the FHIR specification. The QcMetrics profile was added to the FHIR server. The source code for operating the R Shiny server was written in RStudio Cloud (R version 3.6.3) and the server was deployed to the R cloud platform, Shinyapp.io [37]. The R Shiny server fetched the data used for statistical analysis from the FHIR server. The R source code is available at GitHub [38].

FHIR has a set of security recommendations that identifies communications security, authentication, authorization, access control, and auditing [39]. We applied Transport Layer Security

(TLS) and OAuth 2.0, which are industry-standard protocols for communications security and authentication [40,41]. The TLS was used for the encryption of FHIR resources transmitted between the NGS-QR app and the FHIR server. The OAuth 2.0 protocol was used to grant the NGS-QR app access to the FHIR server. The NGS-QR app requests an access token by authenticating with the Authorization Server. The Authorization Server authenticates the NGS-QR app and issues an access token. The access token was used for security credentials for the NGS-QR app to make API requests on behalf of a user.

Figure 2. Concept model of the NGS-QR app, FHIR server, and R Shiny server. FHIR: Fast Healthcare Interoperability Resources.



Results

Data Collection

Samsung Medical Center (SMC) has developed and utilized a cancer panel sequencing pipeline, namely CancerSCAN, to determine effective treatment methods for patients based on data from more than 15,000 panel sequencing studies since 2014 [17,42,43]. The SMC received clinical laboratory accreditation by the MFDS in 2017, and CancerSCAN is clinically used for the diagnosis and prognosis of cancer patients [17]. For this study, approximately 1000 data entries were collected from CancerSCAN. They contained the experimental conditions and results for FFPE specimens, fresh cells, and cell lines.

User Interfaces and Functions

In the reporting UI, input data are converted to a FHIR genomic resource in JSON format using the FHIR resource generator, and the resource is sent to the FHIR server using the POST method, as shown in Figure 3. In the dashboard UI, genomic resources in the FHIR server are compiled using the GET method to display the summary of data such as the total number of genomic tests and the number of tests based on the year and specimen type for the complete genomic test results. In the statistics UI, the user can select the group of samples, and view the distribution and threshold of each experimental parameter. The user can also check the current quality status of each sample in the overall distribution, as shown in Figure 4.

Figure 3. Screenshots of the user interface: reporting quality information of clinical next-generation sequencing (NGS) genomic testing.

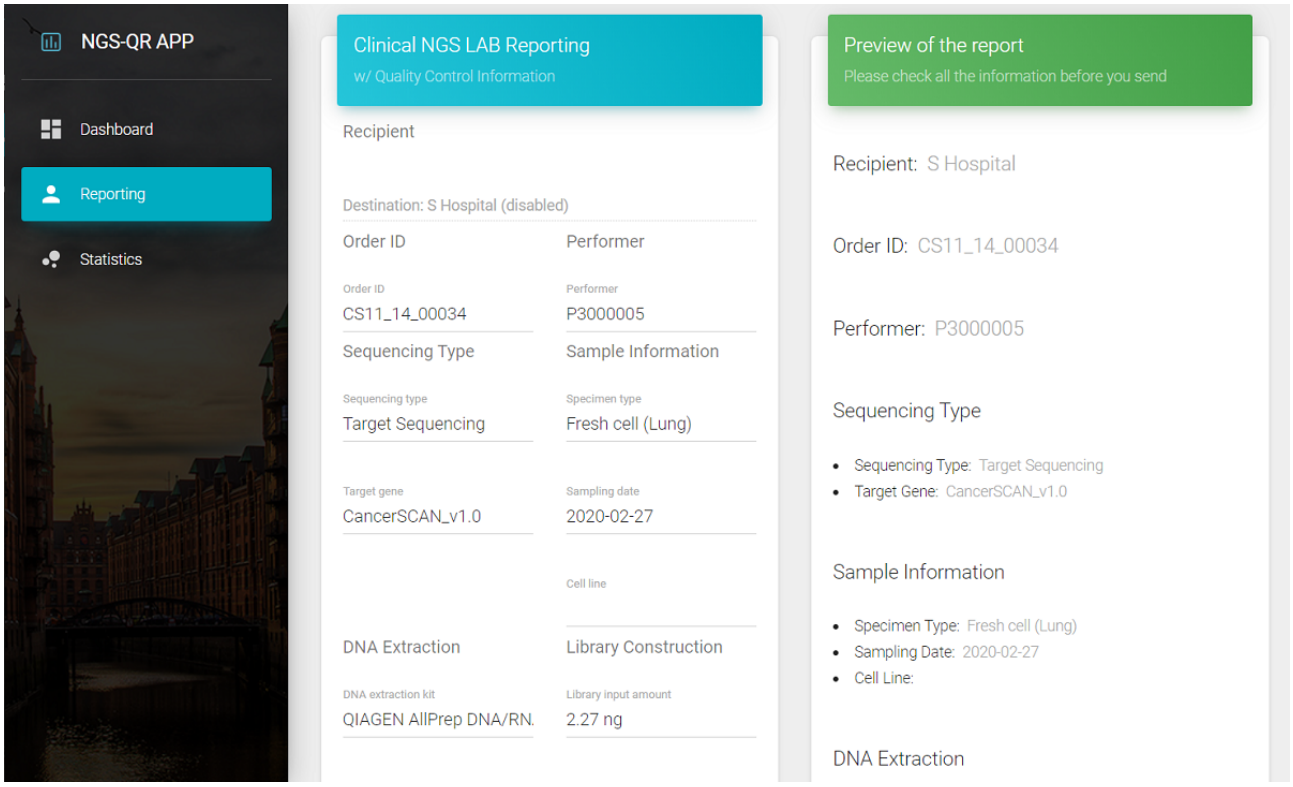


Figure 4. Screenshots of the user interface: quality management of clinical next-generation sequencing genomic testing.

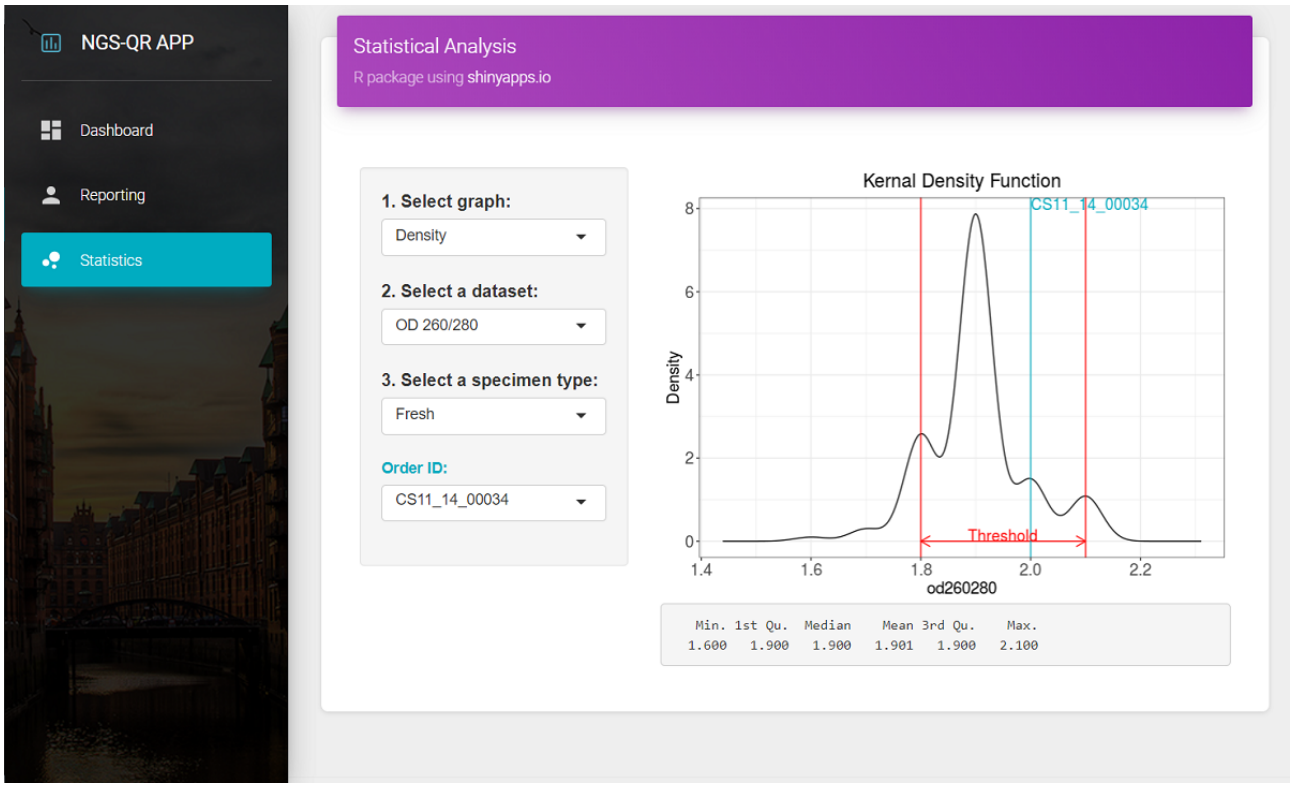
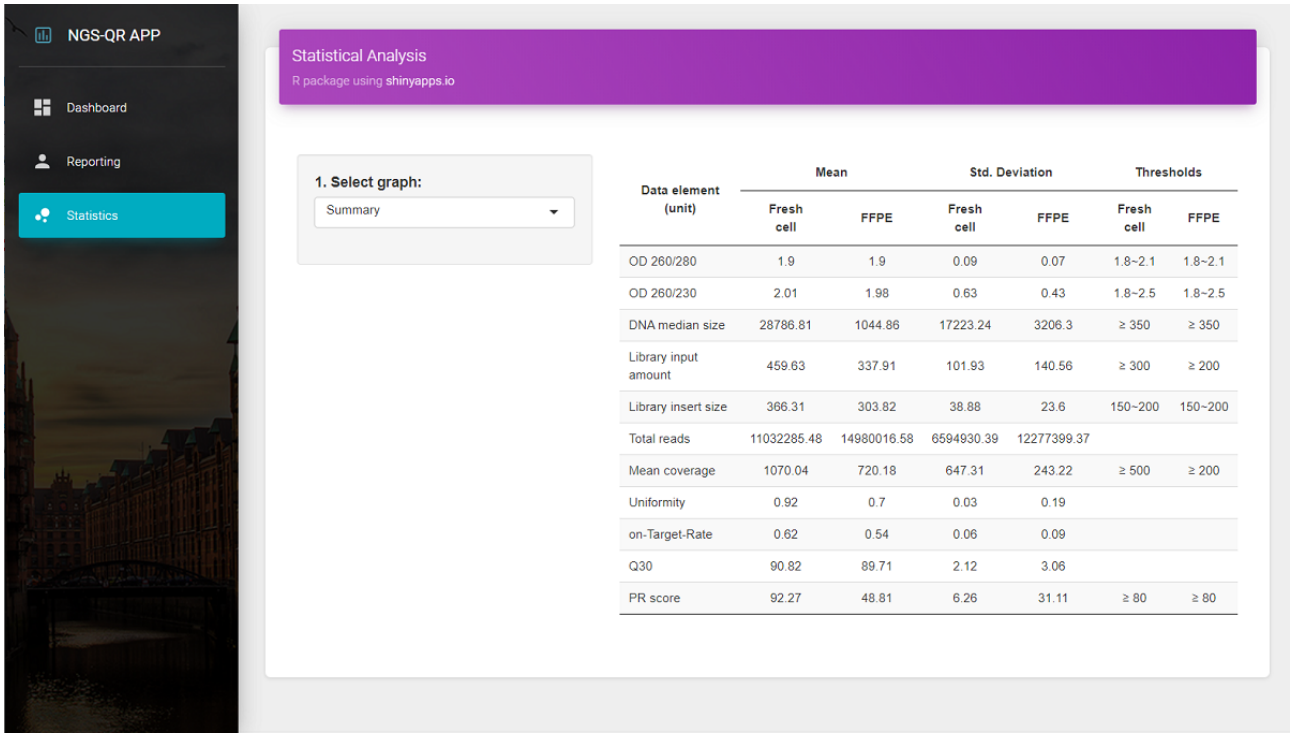


Data Statistics

We validated the utility of the NGS-QR app using real-world data from the NGS pipeline CancerSCAN in SMC. All data were converted to FHIR genomic resources and sent to the FHIR server using the NGS-QR app. Figure 5 shows the statistics of the experimental data used in this study. As expected, fresh cell samples had better quality than FFPE samples in almost every category.

Figure 5. Statistics of the experimental data used in this study. FFPE: formalin-fixed paraffin-embedded; OD: optical density; PR: pass rate.



Data element (unit)	Mean		Std. Deviation		Thresholds

Discussion

Principal Results

NGS technology has been widely adopted in clinical practice, which will play a prominent role in precision medicine. Although many countries and international institutions have developed NGS guidelines to implement clinical NGS applications, the quality criteria for determining the reliability of NGS genomic testing have not yet been standardized due to the complexity of the NGS technology. Since the scope and purpose of NGS applications are very diverse, it remains challenging to evaluate the validity and utility of clinical NGS genomic testing. At present, most individual laboratories have their own processes and criteria; thus, it is important to share quality information from the process of generating genomic data.

In this study, we propose the NGS-QR app to exchange quality information for clinical NGS genomic testing. This study provides the following main contributions to the field. First, we demonstrated that the quality information managed only by individual laboratories could be shared using a standardized format. In the NGS workflow, the experimental conditions change depending on the purpose of the tests and the status of the samples. Thus far, it has been difficult to determine the conditions under which the genome data were generated. This study defined quality-related elements and profiled the FHIR genomic resource to report the experimental conditions and results produced in NGS genomic testing. Since our proposed method is based on ISO/TS 22692 and HL7 FHIR standards to interoperably share the quality-related data of clinical genomic testing, the app can communicate with any EMR/EHR systems that conform to these standards.

Second, this study facilitated the verification of the quality status of each sample as experimental data accumulate. The quality of genome data is determined through comparative analysis based on the characteristics of NGS technology. As shown in Figure 6, the results from different types of specimens cannot be directly compared because this may lead to incorrect conclusions. Therefore, it is important to select the target groups and determine the performance of individual samples within them. The NGS-QR app allows users to select various experimental conditions and compare the produced data with the correct target group to check the exact data quality.

Figure 6. Example of comparative analysis based on specimen type using the NGS-QR app. FFPE: formalin-fixed paraffin-embedded; PR: pass rate.

Conclusions

This study successfully demonstrated how the quality information of clinical NGS genomic testing can be exchanged using a standardized method. As the demand for NGS genomic testing increases and genomic data accumulate, quality information can be used as reference material for improving the quality of testing. This approach can also motivate laboratories to perform diagnostic tests to provide high-quality genomic data.

(J Med Internet Res 2021;23(4):e29452) doi:10.2196/29452

In "Spelling Errors and Shouting Capitalization Lead to Additive Penalties to Trustworthiness of Online Health Information: Randomized Experiment With Laypersons" (J Med Internet Res 2020;22(6):e15171) one error was noted after publication.

One reviewer of this paper, L Sbaffi, was listed twice in the originally published paper due to a system error. The duplicate instance of the reviewer's name has been removed from the corrected version.

The correction will appear in the online version of the paper on the JMIR Publications website on April 13, 2021, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Submitted 07.04.21; this is a non–peer-reviewed article;accepted 07.04.21; published 13.04.21.

(J Med Internet Res 2021;23(4):e29629) doi:10.2196/29629

In "Theory Integration for Lifestyle Behavior Change in the Digital Age: An Adaptive Decision-Making Framework" (J Med Internet Res 2021;23(4):e17127) the authors noted one error.

In the originally published manuscript, the heading "Mapping Digital Intervention Techniques to the Framework" was incorrectly set as a level 3 subheading rather than a level 2 heading. This has been changed to a level 2 heading in the corrected version of the manuscript.

The correction will appear in the online version of the paper on the JMIR Publications website on April 15, 2021, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

(J Med Internet Res 2021;23(4):e29598) doi:10.2196/29598

In "Assessing Public Interest Based on Wikipedia's Most Visited Medical Articles During the SARS-CoV-2 Outbreak: Search Trends Analysis" (J Med Internet Res 2021;23(4):e26331) the authors noted two errors.

Due to a system error, the name of one author, *Wojciech Fendler*, was replaced with the name of another author on the paper, *Dariusz Jemielniak*. In the originally published paper, the order of authors was listed as follows:

> *Jędrzej Chrzanowski; Julia Sołek; Dariusz Jemielniak; Dariusz Jemielniak*

This has been corrected to:

> *Jędrzej Chrzanowski; Julia Sołek; Wojciech Fendler; Dariusz Jemielniak*

In the originally published paper, the ORCID of author 'Wojciech Fendler' was incorrectly published as follows:

> *Wojciech Fendler: 0000-0002-3745-7931*

This has been corrected to:

> *Wojciech Fendler: 0000-0002-5083-9168*

The correction will appear in the online version of the paper on the JMIR Publications website on April 15, 2021, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Submitted 13.04.21; this is a non–peer-reviewed article;accepted 13.04.21; published 15.04.21.

Correction of: https://jmir.org/2021/4/e25468

(J Med Internet Res 2021;23(4):e29790) doi:10.2196/29790

In “Potential Correlates of Internet Gaming Disorder Among Indonesian Medical Students: Cross-sectional Study” (J Med Internet Res 2021;23(4):e25468) the authors noted two errors.

Due to a system error, the name of one author, *Andree Kurniawan*, was replaced with the name of another author on the paper, *Ryan Yudistiro*. In the originally published paper, the order of authors was listed as follows:

> *Kristiana Siste; Enjeline Hanafi; Lee Thung Sen; Petra Octavian Perdana Wahjoepramono; Ryan Yudistiro; Ryan Yudistiro*

This has been corrected to:

> *Kristiana Siste; Enjeline Hanafi; Lee Thung Sen; Petra Octavian Perdana Wahjoepramono; Andree Kurniawan; Ryan Yudistiro*

In the originally published paper, the ORCID number of author *Ryan Yudistiro* was incorrectly published as follows:

> *0000-0002-5219-9029*

This has been corrected to:

> *0000-0003-1418-2661*

The correction will appear in the online version of the paper on the JMIR Publications website on April 21, 2021, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Submitted 20.04.21; this is a non–peer-reviewed article;accepted 20.04.21; published 21.04.21.

(J Med Internet Res 2021;23(4):e29877) doi:10.2196/29877

In "Health Care Cybersecurity Challenges and Solutions Under the Climate of COVID-19: Scoping Review" (J Med Internet Res 2021;23(4):e21747) the authors noted one error.

In the originally published manuscript, a footnote was erroneously displayed in the authorship list noting equal contribution only for author Cunjin Luo.

This footnote has been removed from the corrected manuscript, as no equal contribution should be noted in the authorship list.

The correction will appear in the online version of the paper on the JMIR Publications website on April 28, 2021, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Correction of: https://www.jmir.org/2020/8/e21366/

(J Med Internet Res 2021;23(4):e29069) doi:10.2196/29069

In "Work-Related and Personal Factors Associated With Mental Well-Being During the COVID-19 Response: Survey of Health Care and Other Workers" (J Med Internet Res 2020;22(8):e21366) the authors noted two errors in the reference list.

In the originally published paper, the following reference was omitted from the reference list:

> *Wu AW, Connors C, Everly GS. COVID-19: Peer Support and Crisis Communication Strategies to Promote Institutional Resilience. Annals of Internal Medicine 2020 Jun 16;172(12):822-823. [doi: 10.7326/m20-1236]*

This citation has been inserted as Reference 3 in the corrected version of the paper.

In addition, References 20 and 21 were duplicate references in the originally published paper. In the corrected version, this reference (McGinty et al) remains as Reference 21. The remaining references have been renumbered accordingly to adjust for these changes. The corrected and renumbered list of references appears below and in the corrected paper.

The correction will appear in the online version of the paper on the JMIR Publications website on April 9, 2021, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Abstract

Background: COVID-19 cases resurged worldwide in the second half of 2020. Not much is known about the changes in public responses to containment measures from the initial outbreak to resurgence. Monitoring public responses is crucial to inform policy measures to prepare for COVID-19 resurgence.

Objective: This study aimed to assess and compare public responses to containment measures during the initial outbreak and resurgence of COVID-19 in China.

Methods: We curated all COVID-19–related posts from Sina Weibo (China's version of Twitter) during the initial outbreak and resurgence of COVID-19 in Beijing, China. With a Python script, we constructed subsets of Weibo posts focusing on 3 containment measures: lockdown, the test-trace-isolate strategy, and suspension of gatherings. The Baidu open-source sentiment analysis model and latent Dirichlet allocation topic modeling, a widely used machine learning algorithm, were used to assess public engagement, sentiments, and frequently discussed topics on each containment measure.

Results: A total of 8,985,221 Weibo posts were curated. In China, the containment measures evolved from a complete lockdown for the general population during the initial outbreak to a more targeted response strategy for high-risk populations during COVID-19 resurgence. Between the initial outbreak and resurgence, the average daily proportion of Weibo posts with negative sentiments decreased from 57% to 47% for the lockdown, 56% to 51% for the test-trace-isolate strategy, and 55% to 48% for the suspension of gatherings. Among the top 3 frequently discussed topics on lockdown measures, discussions on containment measures accounted for approximately 32% in both periods, but those on the second-most frequently discussed topic shifted from the expression of negative emotions (11%) to its impacts on daily life or work (26%). The public expressed a high level of panic (21%) during the initial outbreak but almost no panic (1%) during resurgence. The more targeted test-trace-isolate measure received the most support (60%) among all 3 containment measures in the initial outbreak, and its support rate approached 90% during resurgence.

Conclusions: Compared to the initial outbreak, the public expressed less engagement and less negative sentiments on containment measures and were more supportive toward containment measures during resurgence. Targeted test-trace-isolate strategies were more acceptable to the public. Our results indicate that when COVID-19 resurges, more targeted test-trace-isolate strategies for high-risk populations should be promoted to balance pandemic control and its impact on daily life and the economy.

Introduction

In December 2019, COVID-19 emerged in Wuhan, and propagated rapidly across China and worldwide [1]. In response, many countries implemented stringent large-scale containment measures such as lockdowns, quarantines, and suspension of mass gatherings. Following these containment measures, the number of new COVID-19 cases decreased significantly from its peak in the first half of 2020 [2-6]. In China, the government adopted a rapid nationwide lockdown in late January 2020 during the Chinese New Year holiday, which included stay-at-home orders, transportation block, closure of shops and schools, suspension of gatherings, and suspension of work after the national Spring Festival holiday (the Chinese New Year), when most individuals in China would travel across cities or provinces for family gatherings. The lockdown measure aimed to prevent movement and mass gatherings in order to limit community transmission of COVID-19. As the then epidemic was under control, many provinces lifted containment measures from late February 2020 [7].

Although very few COVID-19 cases were thereafter reported in China [7], smaller-scale resurgences occurred. On June 11, 2020, a confirmed case, not linked to international travel, was reported in Beijing, ending the city's almost 2-month span of zero incidence of local infections [8-10]. During the resurgence, Beijing adopted a more targeted response strategy instead of the city-level lockdown that was implemented during the initial outbreak. This targeted response strategy, namely "test-trace-isolate," principally consisted of nucleic acid testing of individuals who had contact with known cases, tracing of close contacts of confirmed or suspected cases, and isolation of vendors and customers of Xinfadi Market (the epicenter of COVID-19 resurgence in Beijing). By rapidly identifying Xinfadi Market as the disease epicenter, most businesses and schools in Beijing were allowed to remain operational. Furthermore, instead of suspending all modes of transport, restrictions were promptly applied to passengers or goods entering or leaving Beijing, which prevented the virus from spreading outside Beijing. Moreover, the health code system was widely used to identify the exposure risk within the population [11]. One month later, no new cases were reported, with a total of 335 confirmed cases, and on July 19, 2020, Beijing lifted its response strategy. Worldwide, there has also been a resurgence of COVID-19 since August 2020, and evidence-based response strategies are thus needed to fully prepare for yet another resurgence [6,12-15].

The public response may change from that during the initial outbreak to resurgence and hence needs to be monitored. Previous studies have reported that the public frequently discussed the containment measures on social media, including lockdown, test-trace-isolate strategies, suspension of gatherings, personal protection, social distancing, travel restrictions, and workplace closures [16-18]. At the early stage of the COVID-19 pandemic, the public complied with containment measures in many countries, but their compliance gradually weakened as the pandemic progressed [19]. Studies also reported that both Weibo and Twitter users expressed more negative sentiments in the early stage of the COVID-19 pandemic [20-22]. In late 2020, many countries faced a COVID-19 resurgence and restarted containment measures. In India, Twitter users held a positive viewpoint to the second lockdown, but the majority held a negative opinion regarding the third lockdown [23]. In the Philippines, the negative sentiments increased owing to food shortage and helplessness during the lockdown [24]. Prolonged containment measures may lead to decreased risk perception, increased negative sentiments, and fatigue with sustaining containment measures [25-27]. Therefore, it is necessary to continuously monitor the public's response to containment measures and design effective public communication strategies. Previous studies have reported that public risk perception and negative sentiments (such as depression, anxiety, and frustration) were highly correlated with the implementation of containment measures [16,26,28,29]. However, to our knowledge, none of these studies has assessed public responses to containment measures during COVID-19 resurgence and compared them across different stages of the pandemic.

With the protraction of pandemics, containment measures need to be adjusted accordingly, and it is imperative to gain timely feedback on containment measures from the public. Social media has been increasingly recognized as a platform for social surveillance [7,30]. Compared to surveys, social media not only allows for the monitoring of fluctuations in public sentiment and responses over a longer period but also is limited by a low recall bias. Using a machine learning approach based on social media data, this study aimed to assess and compare public responses to containment measures during the initial outbreak and resurgence of COVID-19 in China, including the level of public engagement, sentiments expressed, and frequently discussed topics. This study presents primary data on the evolution of public responses toward the progression of the COVID-19 pandemic, which would help inform adjustments in containment measures. Understanding the shifts of public responses could be essential for policymakers to prepare for future resurgence of COVID-19 globally.

Methods

Study Design

This is a comparative study based on social media data. With over 500,000,000 users, Sina Weibo (China's version of Twitter) is the most influential social media platform in China [31]. Weibo allows users to share information and opinions in real time through posts and has been widely used to identify public concerns during the COVID-19 pandemic. We compared the public response to containment measures between the initial outbreak and resurgence on the basis of the following indicators: (1) the number of relevant Weibo posts, (2) the prevalence of negative sentiments in Weibo posts, and (3) the proportion of frequently discussed topics on Weibo. All data in this study are

publicly available, and this study is exempt from ethical approval.

Data Collection

Weibo posts that contain specific words can be retrieved through Sina Weibo's keyword search function. We programmed a crawler in Python to curate publicly available Weibo posts through a keyword search. Since COVID-19 spread across China during the initial outbreak and only propagated in Beijing during resurgence, we retrieved all COVID-19–related Weibo posts in China for the initial outbreak and posts in Beijing for resurgence. For both surges of the pandemic, we curated Weibo posts from 1 week before the outbreak to the time when affected areas began to lift their responses (January 13 to February 28, 2020, for the initial outbreak and June 4 to July 20, 2020, for resurgence). In total, we curated 8,985,221 Weibo posts, and the data set is available on GitHub [32].

Data Preprocessing

The initial pool of Weibo posts was preprocessed using a Python script to exclude duplicates, remove hashtags, links, uniform resource locators, and user handles from each post to clean the text [33,34]. We extracted the last user's comment if it was a repost, and we excluded Weibo posts that were irrelevant to the public's response by matching patterns with Python [35]. Finally, keyword matching was carried out from all COVID-19–related Weibo posts to extract Weibo posts targeting 3 primary containment measures: lockdown, the test-trace-isolate strategy, and suspension of gatherings (Table 1). A flowchart of data collection and preprocessing is shown in Multimedia Appendix 1.

Table 1. Keywords related to containment measures associated with the COVID-19 pandemic.

Containment measure	Keywords
Lockdown	"封城"(city lockdown), "封村"(village lockdown), "封路"(block road), "封闭"(close), "响应"(public health response), "停运"(stop traffic), "暂时关闭"(temporarily closed)
Test-trace-isolate strategy	"体温监测"/"测温"(body temperature monitoring), "检测"(test), "排查"(trace), "隔离"(isolate), "强制"(enforce/enforcement), "控制"(control)
Suspension of gatherings	"暂停"(suspension of gathering), "停止"(call off), "取消"(cancel), "推迟"(put off school opening or returning to work), "延期"(postpone), "延长"(prolong vacation)

Data Analysis

We analyzed public engagement, sentiments, and frequently discussed topics related to each of the 3 containment measures and compared them between COVID-19 resurgence and the initial outbreak. Public engagement toward containment measures was assessed on the basis of the daily number of related Weibo posts, which was compared with the daily number of new COVID-19 cases locally reported by the National Health Commission of China and Beijing Municipal Health Commission. Public sentiment toward containment measures was analyzed using the Baidu open-source sentiment analysis application programming interface and measured from the proportion of Weibo posts with negative sentiments. Frequently discussed topics regarding containment measures on social media were identified through latent Dirichlet allocation (LDA) topic modeling combined with manual annotation.

Topic modeling is an unsupervised machine learning technique that can automatically identify underlying topics or clusters by identifying groups of words that often co-occur in a textual data set (ie, Weibo posts) [9,17,36]. LDA is a widely used topic modeling algorithm to identify the most common topics across social media platforms [36,37]. In LDA, each document (ie, a Weibo post) is assumed to contain different topics, and each topic can be captured from a set of words. This helps map the given documents to the set of topics, such that the words in each document can be mostly captured by those topics. We applied LDA topic modeling by separating all documents into 30 machine-generated topics, and every Weibo post was assigned to a topic that it most likely belonged to according to the LDA model. LDA outputs provide keywords of the 30 LDA-generated topics for each containment measure during the initial outbreak and resurgence (Multimedia Appendix 2).

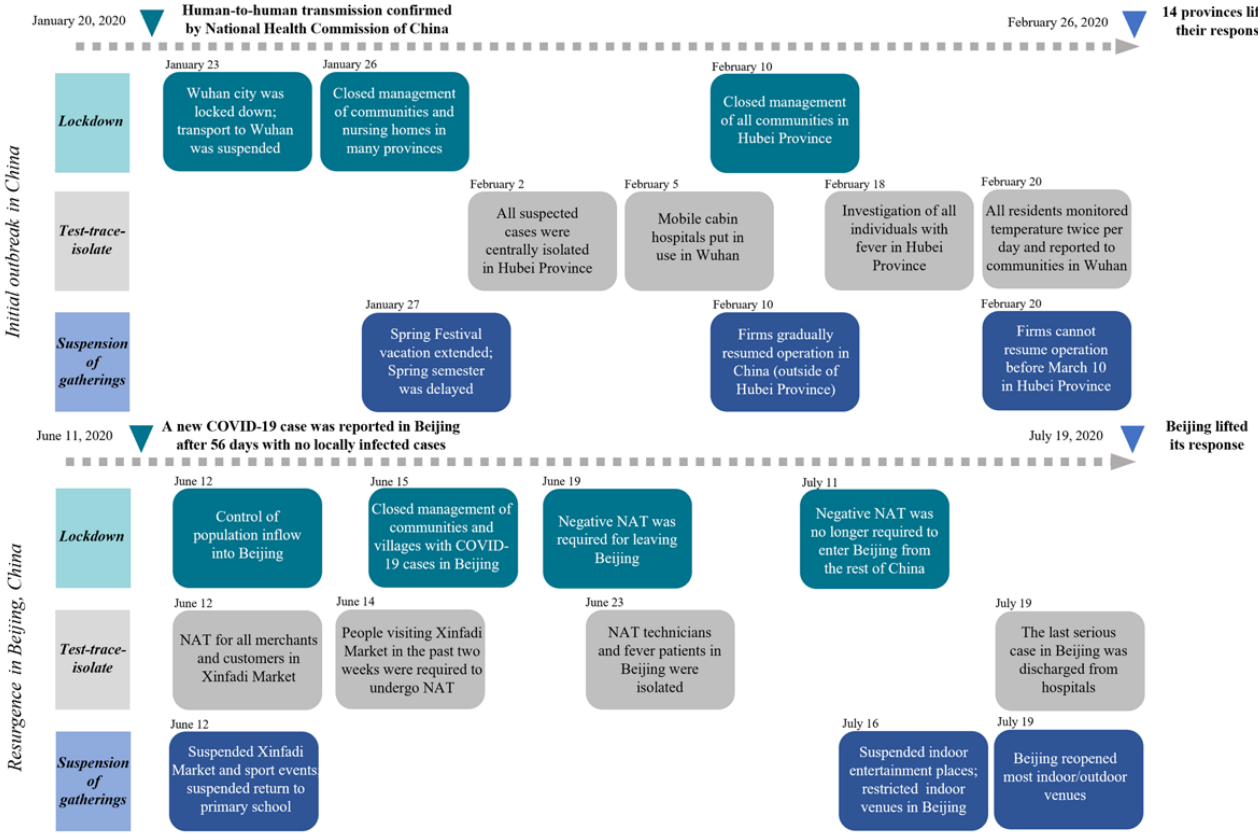
Since LDA is an unsupervised text classification algorithm based on the "bag-of-words model" [38], it may sometimes misclassify documents or misidentify topics [39-41]; therefore, it is important to manually assess representative documents (in our case, Weibo posts). In this study, LDA outputs was verified and improved by 2 independent researchers (YS and QW) to analyze key words generated by the LDA model and manually review sample posts for each topic. If the Weibo posts in one of the machine-generated 30 topics were found to contain several exclusive subtopics, that topic was manually reviewed. Finally, a random sample of Weibo posts (>10%) and their assigned topics were reviewed by 2 independent researchers (YS and QW) for quality control.

Results

Findings Overview

We compared the public sentiment to 3 containment measures during the initial COVID-19 outbreak in China and resurgence in Beijing (Figure 1): lockdown, the test-trace-isolate strategy, and suspension of gatherings. Generally, these measures evolved from a complete lockdown for the general population during the initial outbreak to a more targeted response strategy for high-risk populations during resurgence.

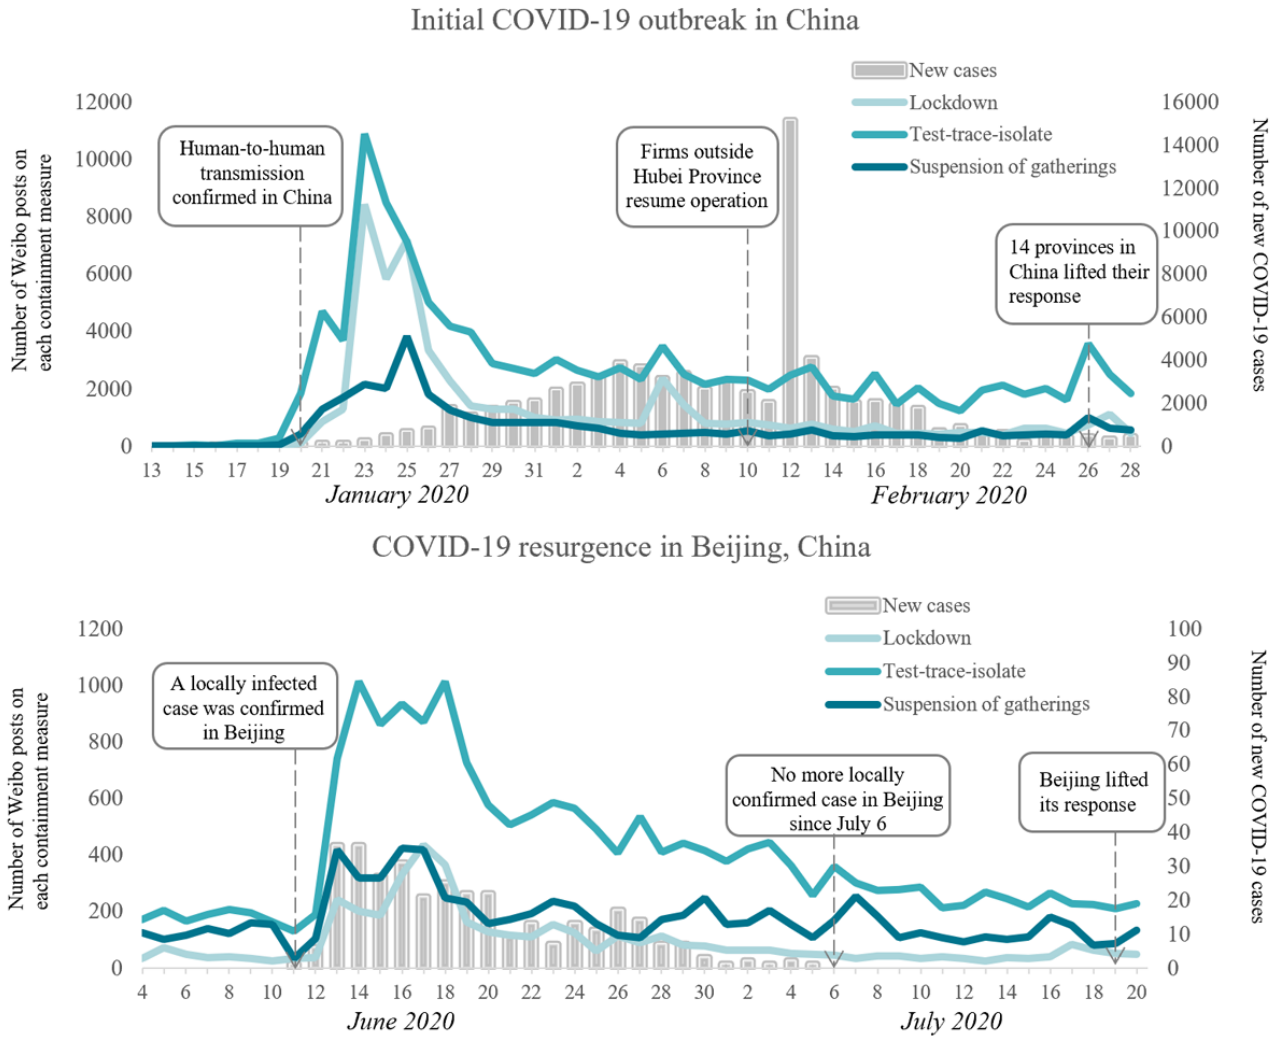
Figure 1. Timeline of containment measures during the initial outbreak and the resurgence of COVID-19 in China. Containment measures relevant to the lockdown, the test-trace-isolate measure, and suspension of gatherings are shown in chronological order. NAT: nucleic acid testing.



Public Engagement With Containment Measures

The COVID-19 pandemic received marked engagement from the public nationwide. During both the initial outbreak and resurgence in China, test-trace-isolate measures had the most engagement from the public, and suspension of gatherings had relatively low engagement; one difference between these 2 periods is that lockdown measures had high engagement during the initial outbreak but the lowest engagement during resurgence (Figure 2). In both periods, the number of Weibo posts related to containment measures increased drastically after outbreak announcement and the implementation of containment measures, remained high for approximately 1-2 weeks, and then plummeted. From 1 week before to 1 week after the confirmation of human-to-human transmission (on January 20, 2020) in China, the average daily number of Weibo posts increased from 14 to 4168 for the lockdown measure, 69 to 2003 for the suspension of gatherings, and 340 to 6298 for the test-trace-isolate measure. Similarly, the average daily number of Weibo posts during the week before resurgence (on June 11, 2020) were 41 for the lockdown measure, 118 for the suspension of gatherings, and 179 for the test-trace-isolate measure. In comparison, this number approached 256 for the lockdown measure, 321 for the suspension of gatherings, and 803 for the test-trace-isolate measure in the week after resurgence. Furthermore, Weibo activity peaked approximately 1-2 weeks before the peak in COVID-19 cases, which indicated that Weibo seemed to track policy changes (eg, lockdown) rather than the actual number of cases.

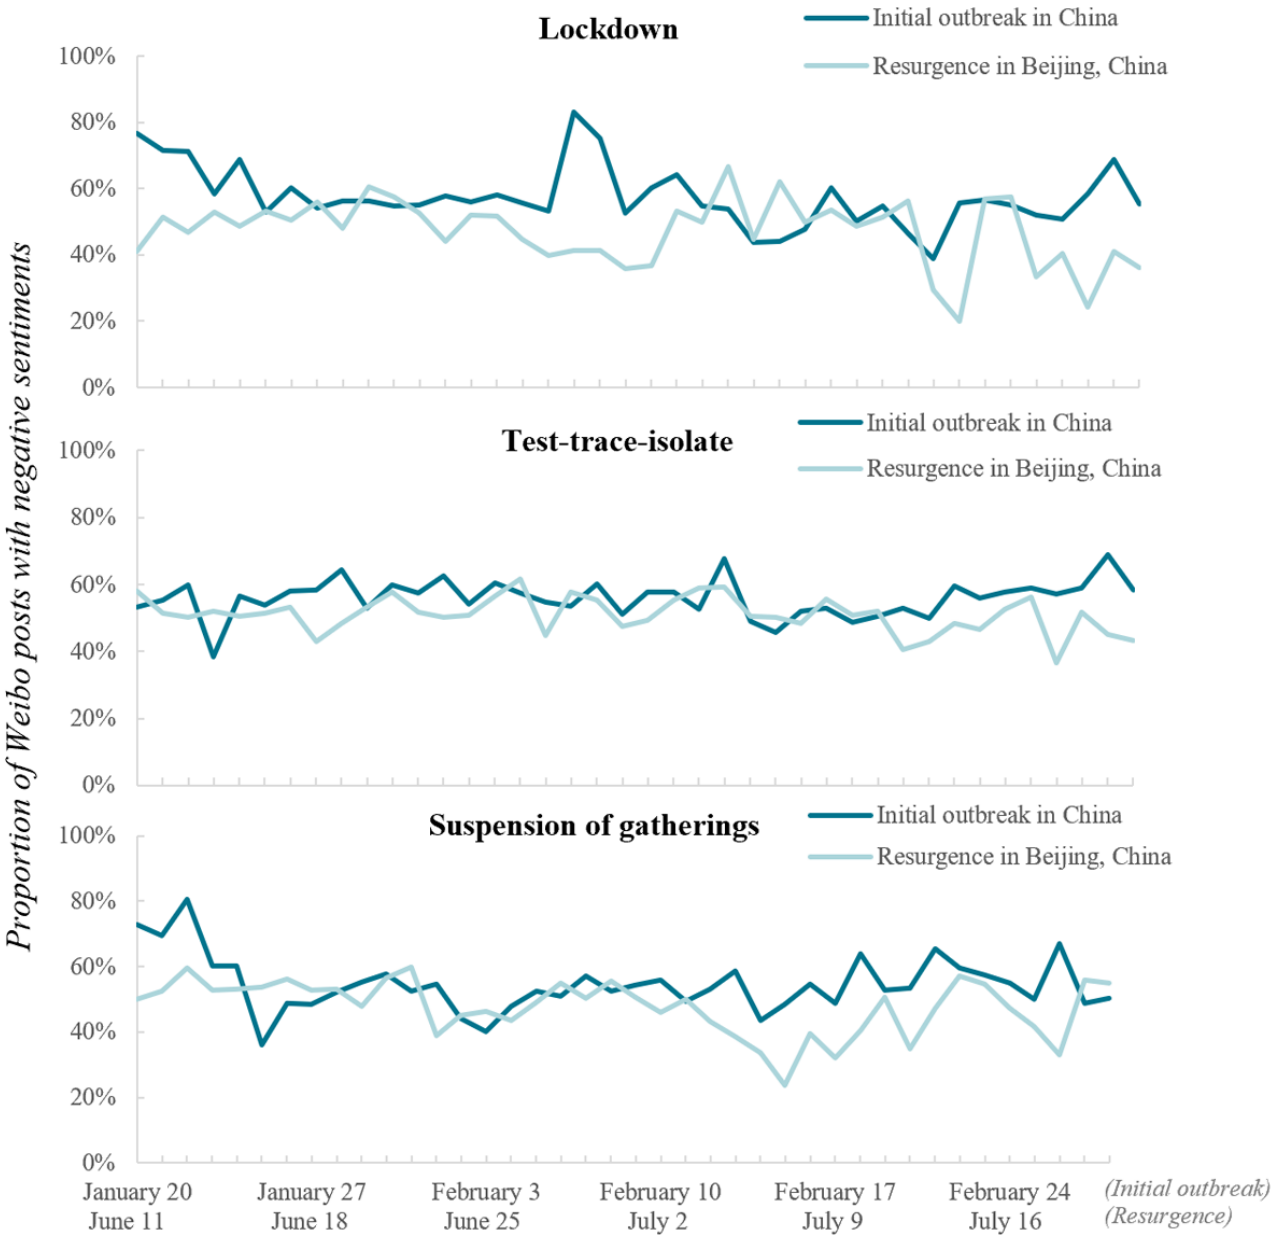
Figure 2. Number of Weibo posts on containment measures and new COVID-19 cases during the initial outbreak and the resurgence of COVID-19 in China. The lines show the daily number of Weibo posts on the lockdown, test-trace-isolate measure, and the suspension of gatherings. The bars show the daily number of new confirmed COVID-19 cases in China and Beijing.



Public Sentiment Toward Containment Measures

The overall negative sentiment toward all 3 containment measures during resurgence (average daily proportion of Weibo posts with a negative sentiment: 47% for the lockdown, 51% for the test-trace-isolate measure, and 48% for the suspension of gatherings) was lower than that during the initial outbreak (average daily proportion: 57% for the lockdown, 56% for the test-trace-isolate measure, and 55% for the suspension of gatherings) (Figure 3). During the initial outbreak, approximately 80% of the public immediately expressed negative sentiments toward the lockdown and suspension of gatherings after a lockdown was imposed in Wuhan, and approximately 60% of people expressed negative sentiments toward the test-trace-isolate measure. Thereafter, negative sentiments rapidly started to decrease for approximately 1 week and fluctuated surrounding a low level. However, for the test-trace-isolate measure, the proportion of negative sentiments varied through a smaller range than that for the other 2 containment measures. One exception is the spike in negative sentiments toward the lockdown on February 6, 2020, which might be related to concerns regarding the lack of medications or treatments for patients with other diseases; this accounted for a large proportion of posts expressing a negative sentiment on that day. During COVID-19 resurgence in Beijing, the negative sentiment toward containment measures was relatively lower and displayed lesser variation than that during the initial outbreak.

Figure 3. Proportion of Weibo posts with negative sentiments on containment measures during the initial outbreak and the resurgence of COVID-19 in China.



Frequently Discussed Topics Related to Containment Measures

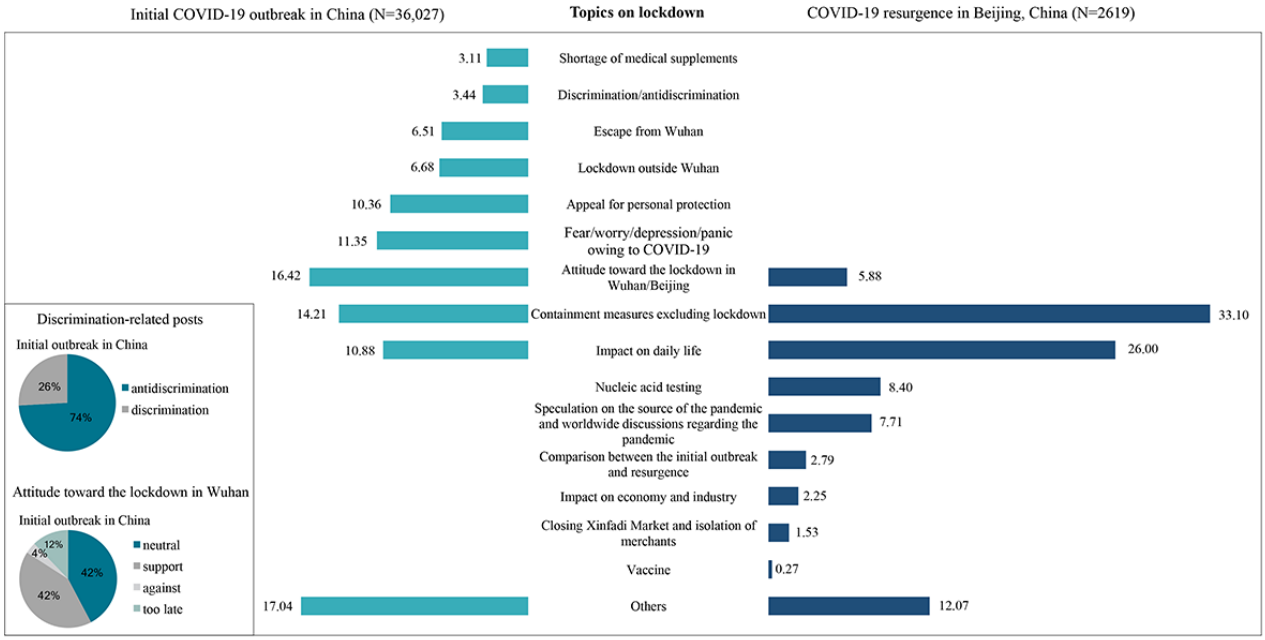
Weibo posts during the first two weeks of the initial outbreak and COVID-19 resurgence were used to identify frequently discussed topics on each containment measure.

Topics Related to the Lockdown Measure

For the initial outbreak, the top 3 topics related to the lockdown measure were attitudes towards the lockdown in Wuhan (n=5915/36,027, 16.42%), discussions on containment measures other than the lockdown (n=5120/36,027, 14.21%), and expressions of negative sentiments owing to the pandemic, such as fear, worry, depression, and panic (n=4090/36,027, 11.35%) (Figure 4). Among posts related to attitudes toward the lockdown in Wuhan, 2473 of 5915 (42%) posts expressed support for the policy, while 220 (4%) expressed opposition toward the policy, along with 720 (12%) posts that indicated that the lockdown should have been implemented earlier. Regarding resurgence in Beijing, the leading 3 topics were public containment measures (n=867/2619, 33.10%), impacts on daily life (n=681/2619, n=26.00%), and nucleic acid tests for COVID-19 (n=220/2619, 8.40%). Since more targeted responses had been used during the resurgence, containment measures excluding lockdown became the main focus of Weibo posts, whereas posts related to the lockdown decreased from 16.42% to 5.88%. After the resumption of work, people paid more attention to how containment measures would affect their daily lives or work, and thus the proportion of relevant posts increased from 10.88% to 26.00%. Consequently, there were discussions about the impact of containment measures on the economy and industry. Noticeably, people expressed more biases by ascribing the emergence and spread of the pandemic

to Wuhan residents during the initial outbreak; in contrast, this was barely mentioned during resurgence in Beijing. Other topics during the initial outbreak included an appeal for personal protection (10.36%), lockdowns outside Wuhan (6.68%), people leaving Wuhan (6.51%); shortages in the supply of medical equipment, including masks, were not widely discussed (3.11%). Topics such as vaccines and nucleic acid tests only emerged during resurgence.

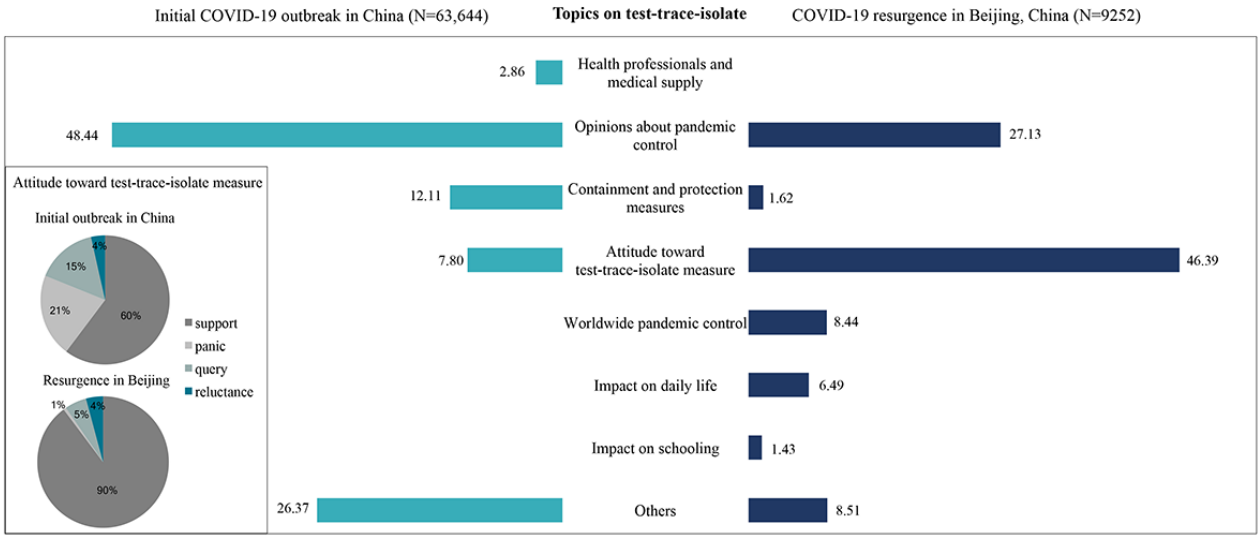
Figure 4. Proportion of posts related to frequently discussed topics on the lockdown measure during the initial outbreak and the resurgence of COVID-19 in China. The columns show the proportion of posts on each topic among all posts related to the lockdown measure. Pie charts show the proportion of various attitudes toward some topics during the initial outbreak.



Topics Related to the Test-Trace-Isolate Measure

During the initial outbreak, 30,826 of 63,644 (48.44%) posts related to the test-trace-isolate measure were opinions on pandemic control, which expressed hope or trust in rapid control of the pandemic and contained suggestions about specific containment measures and descriptions of the status of its spread (Figure 5). During resurgence, the percentage of posts expressing opinions on pandemic control decreased to 27.13% owing to public confidence in effective response measures. The second-most popular topic during the initial outbreak was quarantine and protective measures, which were only indicated in 1.62% of posts during resurgence. In the initial outbreak, 7.8% of posts expressed public attitudes toward the test-trace-isolate measure, while during resurgence, 46.39% of users expressed their attitudes. This further illustrates how the discussion's focus shifted from the status of pandemic control to targeted response measures. Interestingly, public attitudes toward the test-trace-isolate measure differed between these 2 periods of the pandemic in China. In the initial nationwide outbreak, only 3921 of 6506 (60%) posts supported the test-trace-isolate strategy. However, during resurgence in Beijing, the proportion of posts supporting the test-trace-isolate policies increased to 90% (n=3853/4292). Posts indicating panic decreased from 21% to 1%, and those related to queries decreased from 15% to 5%. Users expressing reluctance to be tested or quarantined accounted for 4% of posts during these 2 periods. Furthermore, different topics emerged during these 2 periods. During the initial outbreak, some posts (2.86%) discussed medical equipment and health professionals, while during resurgence, people discussed the impact of the test-trace-isolate measure on schooling, work, daily lives, and the status of the pandemic worldwide.

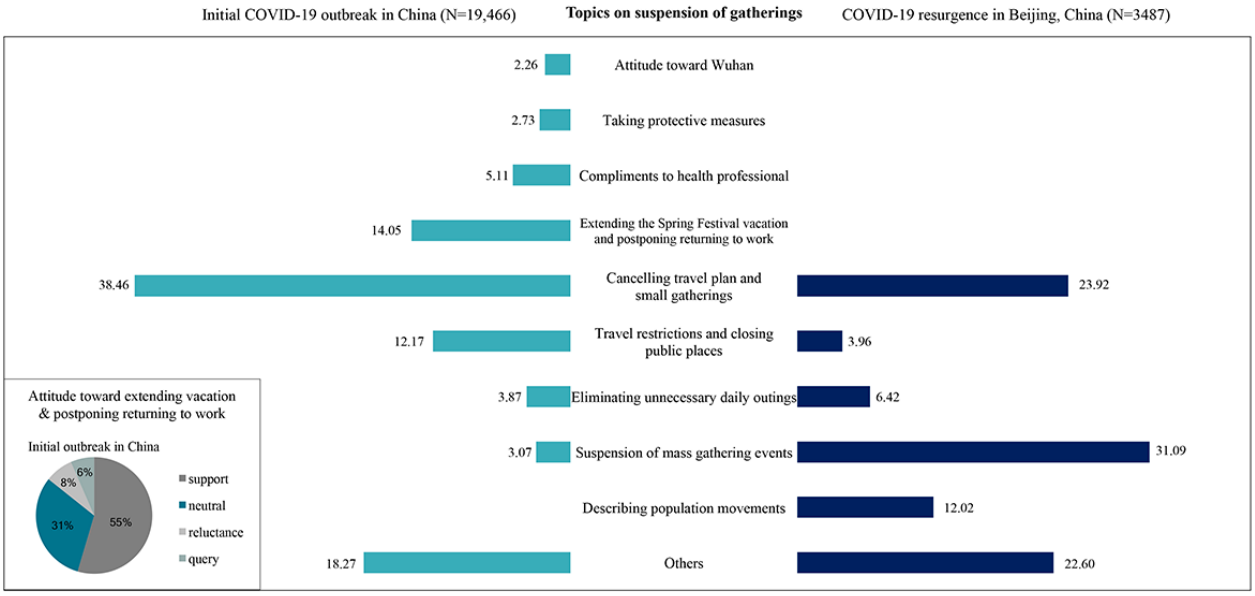
Figure 5. Proportion of posts related to frequently discussed topics on the test-trace-isolate measure during the initial outbreak and the resurgence of COVID-19 in China. The columns show the proportion of posts on each topic among all posts related to the test-trace-isolate measure. Pie charts show the proportion of various attitudes toward the test-trace-isolate measure between the initial outbreak and resurgence.



Topics Related to the Suspension of Gatherings

Among posts on the suspension of gatherings, 7487 of 19,466 (38.46%) and 834 of 3487 (23.92%) posts indicated the cancellation of travel plans and small-scale gatherings during the initial outbreak and resurgence, respectively (Figure 6). The proportion of posts describing the suspension of mass gathering events increased drastically from 3.07% during the initial outbreak to 31.09% during resurgence, which indicates that the public response was much more sensitive to the suspension of mass gathering events such as sports and concerts, during resurgence. Other common topics during these 2 periods included travel restrictions, closure of public places, and elimination of unnecessary daily outings. In addition, 2735 of 19,466 (14.05%) posts discussed the extension of the Spring Festival holiday and postponing of the return to work during the initial outbreak, among which, 55% of users supported the extension of the holiday. During resurgence, discussions on issues regarding population movement emerged, such as visas and immigration.

Figure 6. Proportion of posts related to frequently discussed topics on the suspension of gatherings during the initial outbreak and the resurgence of COVID-19 in China. The columns show the proportion of posts on each topic among all posts related to the suspension of gatherings. Pie charts show the proportion of various attitudes toward some topics during the initial outbreak.



Discussion

Principal Findings

Through social media surveillance, we analyzed and compared the level of public engagement, sentiment expressed, and frequently discussed topics related to 3 primary containment measures during the initial outbreak and the resurgence of COVID-19 in China. As the pandemic control strategy switched from lockdown to a targeted response during resurgence, public responses became more rational. During the initial outbreak,

the number of Weibo posts escalated drastically after the lockdown in Wuhan, a high proportion of posts indicated a negative public sentiment toward all 3 primary containment measures, and topics related to discrimination emerged. During resurgence, however, the public showed less engagement and less negative sentiments, were more supportive towards containment measures, and shifted their focus to the impacts of containment measures on their daily lives or their work.

Monitoring of public responses for pandemic control strategies is crucial for obtaining rapid feedback and informing strategy adjustments during a pandemic. Previous studies have reported that social mobilization and community engagement were central to the Ebola response in West Africa [42-44]. During the COVID-19 pandemic, especially during the initial outbreak, Weibo users in China raised questions regarding the pandemic's source, shortage of medical equipment, and discrimination against Wuhan residents. A considerable number of Weibo posts expressed panic or queries regarding containment measures. This is worth noting, since previous studies have reported that panic and queries regarding containment measures and discrimination may inhibit community engagement and dampen pandemic control [19]. During resurgence, public concerns regarding containment measures changed to focus on their impact on daily life. Policymakers should pay close attention to these changes in the public response to track the most vital needs of the population during the different stages of the pandemic and to address public concerns through timely and effective communication [45,46]. This can improve public compliance and engagement with containment measures and facilitate their implementation [47,48].

During COVID-19 resurgence in Beijing, a more targeted response strategy was applied for the high-risk population, and the general population was less impacted. Frequently discussed topics on Weibo during resurgence suggested that the lives of the public were returning to normal; there were no longer topics regarding discrimination and the shortage of supplies, and the overall negative sentiment toward all containment measures was lower during resurgence than during the initial outbreak. The shifts in discussed topics and the public sentiment might also be related to the reduced stringency of these containment measures. Concurrent with previous reports, stricter measures were followed by a more marked negative sentiment [16]. The public may become fatigued to containment measures when the pandemic resurges. In our study, public responses were more sensitive to the suspension of mass gathering events during resurgence than during the initial outbreak. Therefore, governments should balance the benefits of containment strategies to their impacts on daily life and the economy to formulate tailored response strategies during COVID-19 resurgence.

As more information on COVID-19 and its control has become available, governments have found alternatives to tailor their response strategies to its resurgence. Using the test-trace-isolate measure for high-risk populations, Beijing flattened the contagion curve and gained control over the pandemic within 1 month. Our study indicates that this targeted response strategy better matches public concerns. With the normalization of the pandemic, people cared more about their life and the economy. during the pandemic, such as the return to school or work, going to concerts, traveling, immigration, and sports events. The targeted response strategy focuses on high-risk populations and has less restrictions on most people's lives, which might help reduce the negative public sentiment during resurgence. A modeling study predicted that, compared with the community-wide lockdown strategy, the targeted response strategies would be less costly [49] and could help revive industries and the economy. China's economy data revealed that its gross domestic product decreased by 6.8% in the first quarter of 2020 during the complete lockdown but increased by 3.2% and 4.9% in the second and third quarters of 2020, respectively, with the test-trace-isolate measure targeting high-risk populations [50]. Therefore, more targeted response strategies should be promoted during subsequent COVID-19 resurgence.

Overall, the public reaction to the initial outbreak indicated a drastic escalation in public engagement, as evident from the increased number of negative sentiments after implementation of the lockdown, and, in comparison, targeted containment measures during resurgence gained more rational responses and greater support. The public expressed a high level of panic (21%) during the initial outbreak but virtually no panic (1%) during resurgence. Only 4% of the public expressed reluctance to be tested or quarantined during both the initial outbreak and resurgence, which is an important consideration for public health efforts to achieve universal compliance. The targeted test-trace-isolate measure received the greatest support among all 3 containment measures during the initial outbreak, and its support rate approached approximately 90% during resurgence. The evolution of public responses toward containment measures indicated that targeted test-trace-isolate strategies were more acceptable to the public. Governments should take public responses on social media into consideration, and develop more targeted test-trace-isolate strategies to prepare for the future resurgence of COVID-19.

Limitations

This study has several limitations. First, Weibo is more widely used by younger people, and some users simply read Weibo posts but do not post their own content. Therefore, caution should be exercised when interpreting our findings in the context of the general public. We used Python to curate all relevant Weibo posts for analysis; therefore, our data are valid enough to reflect the opinions and responses of the Weibo users. Second, as an unsupervised text classification algorithm based on the "bag-of-words model" [38], LDA may lead to misclassification of Weibo posts. However, such misclassification is random; that is, it does not specify a certain direction (positive or negative) [51]. Therefore, it does not cause an interpretation bias in a comparative study. To control for this potential bias, we randomly sampled and manually classified Weibo posts to rectify for misclassification and improve accuracy. Future studies should perform real-time social media surveillance with more advanced machine learning techniques (eg, bidirectional encoder representations from transformers), and conduct long-term, multilingual, and multiplatform public response surveillance for the COVID-19 pandemic.

Conclusions

Compared to the initial outbreak, the public became more rational during COVID-19 resurgence. The public expressed less engagement and less negative sentiment on containment measures, were more supportive towards containment measures, and shifted their focus to the impact of containment measures on their daily life or work during resurgence. Targeted test-trace-isolate strategies were more acceptable to the public. This study indicates that pandemic control strategies should be more targeted during subsequent COVID-19 resurgence, such as test-trace-isolate strategies targeting high-risk populations, to balance pandemic control and its impact on daily life and the economy.

Abstract

Background: Global efforts toward the development and deployment of a vaccine for COVID-19 are rapidly advancing. To achieve herd immunity, widespread administration of vaccines is required, which necessitates significant cooperation from the general public. As such, it is crucial that governments and public health agencies understand public sentiments toward vaccines, which can help guide educational campaigns and other targeted policy interventions.

Objective: The aim of this study was to develop and apply an artificial intelligence–based approach to analyze public sentiments on social media in the United Kingdom and the United States toward COVID-19 vaccines to better understand the public attitude and concerns regarding COVID-19 vaccines.

Methods: Over 300,000 social media posts related to COVID-19 vaccines were extracted, including 23,571 Facebook posts from the United Kingdom and 144,864 from the United States, along with 40,268 tweets from the United Kingdom and 98,385 from the United States from March 1 to November 22, 2020. We used natural language processing and deep learning–based techniques to predict average sentiments, sentiment trends, and topics of discussion. These factors were analyzed longitudinally and geospatially, and manual reading of randomly selected posts on points of interest helped identify underlying themes and validated insights from the analysis.

Results: Overall averaged positive, negative, and neutral sentiments were at 58%, 22%, and 17% in the United Kingdom, compared to 56%, 24%, and 18% in the United States, respectively. Public optimism over vaccine development, effectiveness, and trials as well as concerns over their safety, economic viability, and corporation control were identified. We compared our findings to those of nationwide surveys in both countries and found them to correlate broadly.

Conclusions: Artificial intelligence–enabled social media analysis should be considered for adoption by institutions and governments alongside surveys and other conventional methods of assessing public attitude. Such analyses could enable real-time assessment, at scale, of public confidence and trust in COVID-19 vaccines, help address the concerns of vaccine sceptics, and help develop more effective policies and communication strategies to maximize uptake.

Introduction

The imminent availability of COVID-19 vaccines poses a pressing need to continually monitor and better understand public sentiments in order to develop baseline levels of confidence in them among the general public and enable the identification of early warning signals of loss in confidence [1]. This will help address the concerns of vaccine sceptics [2-4] and develop the required public trust in immunization [5,6] to realize the goal of generating herd immunity [7].

Traditionally, governments use surveys to understand public attitude; however, these typically have limitations including small sample sizes, closed questions, and limited spatiotemporal granularity. In order to overcome these limitations, we argue that social media data can be used to obtain more, real-time insights into public sentiments and attitudes with considerable spatiotemporal granularity. Over half of the worldwide population, including approximately 70% the populations of the United Kingdom and the United States, are active social media users, and social media usage has significantly increased during the pandemic; for instance, Facebook usage increased by 37%. Since social media data are largely unstructured, they are amenable to the application of established artificial intelligence (AI) techniques such as machine learning, deep learning (DL) [8], and natural language processing (NLP) [9] to extract topics and sentiments from social media posts.

Sentiment analysis involves categorizing subjective opinions from text, audio, and video sources [9] to determine polarities (eg, positive, negative, and neutral), emotions (eg, anger, sadness, and happiness), or states of mind (eg, interest vs disinterest) toward target topics, themes, or aspects of interest [10]. A complementary approach, termed stance detection [11], assigns a stance label (favorable, against, and none) to a post on a specific predetermined target, which in itself may not be referred to or be the target of opinion in the post. Such approaches are currently underutilized in health care research. In particular, there is significant untapped potential in drawing on AI-enabled social media analysis to inform public policy research.

Methods

Ethics

Since the data analyzed in this study were completely in the public domain, no ethics review was necessary. We conducted a thorough assessment of the privacy risk that our study posed to individuals, in accordance with previous reports [12,13], to ensure compliance with relevant sections of the General Data Protection Regulation. We strived to comply with best practices for user protection [14,15], ensuring that nonpublic material is not included in our data set. Further, to comply with privacy laws and social network policies in accordance with the General Data Protection Regulation to collect data from Twitter [16] and Facebook CrowdTangle [17] platforms, we have not shared or published direct tweets or posts by individuals, quotes from individuals, or names or locations of users who are not public organizations or entities.

Data Sources

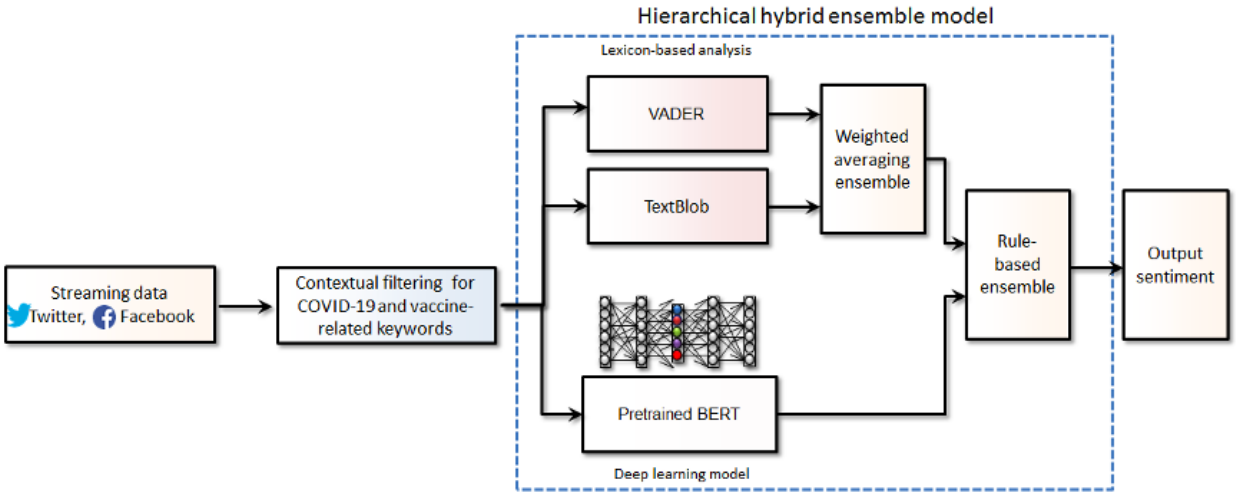
We used data from both Facebook and Twitter, two of the most popular and representative social media platforms [16]. We used Facebook posts and tweets that were posted in English in the United Kingdom and the United States from March 1 to November 22, 2020. Facebook posts were obtained through the CrowdTangle platform [17] and Twitter posts from a publicly available Twitter API. We used hydrated tweets from the global COVID-19 data set [18], which collects up to 4,400,000 tweets per day (including retweets) and up to 1,100,000 cleaned tweets without retweets. The total number of tweets hydrated and used in this study was >158,000,000. Facebook posts and tweets were thematically filtered for both COVID-19– and vaccine-related keywords and then geographically filtered for the United Kingdom and the United States. The first step in filtering COVID-19–related keywords involved widely used terms from the data set of Banda et al [18] (Multimedia Appendix 1). Vaccine-related terms used for second step filtering were selected by our team: “vaccine,” “vaccination,” “immunise,” “immunize,” “immunisation,” and “immunization.” A 2-step thematic filtering process was applied using these keywords before processing and analysis.

Analysis

The filtered data set was initially preprocessed (eg, removing links, hashtags, and stop words) and a new hierarchical hybrid ensemble–based AI model was developed for thematic sentiment analysis. This utilized an average weighting ensemble [19] of 2 lexicon-based methods: Valence Aware Dictionary for Sentiment Reasoning (VADER) [20] and TextBlob [21]. These were combined with a pretrained DL-based model, Bidirectional Encoder Representations from Transformers (BERT) [22], using a rule-based ensemble method (Figure 1).

A random 10% sample of Facebook posts and tweets was then manually annotated by the team and screened against our hybrid ensemble AI model’s sentiment classifications for refinement and validation. The hybrid ensemble model was optimized on the basis of the validation results, with sensitivity and specificity analysis revealing that the lexicon-based methods provided generally better accuracy for positive sentiments, and the BERT model generally provided better accuracy for neutral and negative sentiments, as illustrated using normalized confusion matrices (Multimedia Appendix 1).

Figure 1. Hierarchical hybrid-ensemble–based artificial intelligence model and data pipeline for thematic sentiment analysis. BERT: Bidirectional Encoder Representations from Transformers, VADER: Valence Aware Dictionary for Sentiment Reasoning.



VADER and TextBlob were combined though weighted averaging (VADERx0.45 + TextBlobx0.55), with TextBlob assigned a marginally higher weight of 0.55 owing to its performance. The weighted averaged output from the lexicons was combined with the output of the BERT model, using a final rule–based ensemble. The final output was combined through "If" and "Else" statements on the basis of the model's output sentiments.

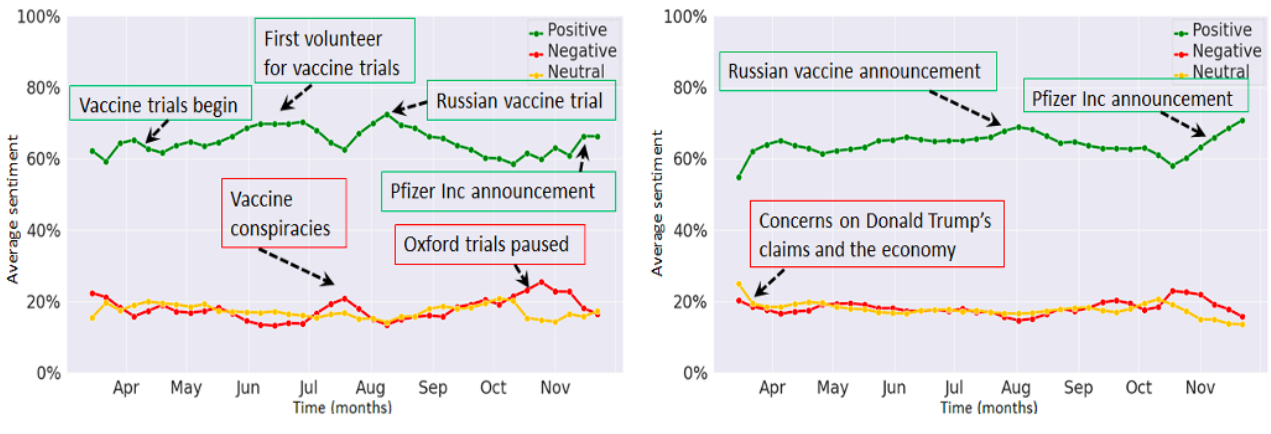
A number of established NLP techniques were used to analyze the processed data (Multimedia Appendix 1). Specifically, in addition to analyzing averaged sentiment trends and their geospatial mappings in the United Kingdom and the United States, we statistically analyzed the trends with Pearson correlation coefficient (r) and compared the findings with those of independent surveys. Sentiment word cloud and N-gram analyses were performed for specific periods of interest, around points of inflexion on sentiment trend graphs, to identify topics of discussion and to gain insight into the positive and negative content of online discourses. The analysis was also carried out over the entire study period to identify underlying themes and topics. Findings were validated, and further insights were obtained through manual reading of randomly selected posts around target points of interest by our team. Relevant social media data sets and outputs were anonymized, and statistical aggregates were made openly accessible for transparency and reproducibility (additionally through a publicly available dashboard [23]).

Results

Temporal Sentiment Trends

Monthly volume trends of the filtered Facebook posts and tweets in the United Kingdom and the United States for the target study period are shown in Multimedia Appendix 1. Figure 2 shows the averaged (weekly) positive, negative, and neutral Facebook sentiments in March-November 2020 in the United Kingdom and the United States. We identified topics of discussion on points of interest in the graphs. These are referred to in our descriptive analysis of the graphs below, and some are highlighted in Figures 2 and 3. It was interesting to note that the difference between the averaged positive and negative sentiment trends was more pronounced on Facebook than on Twitter.

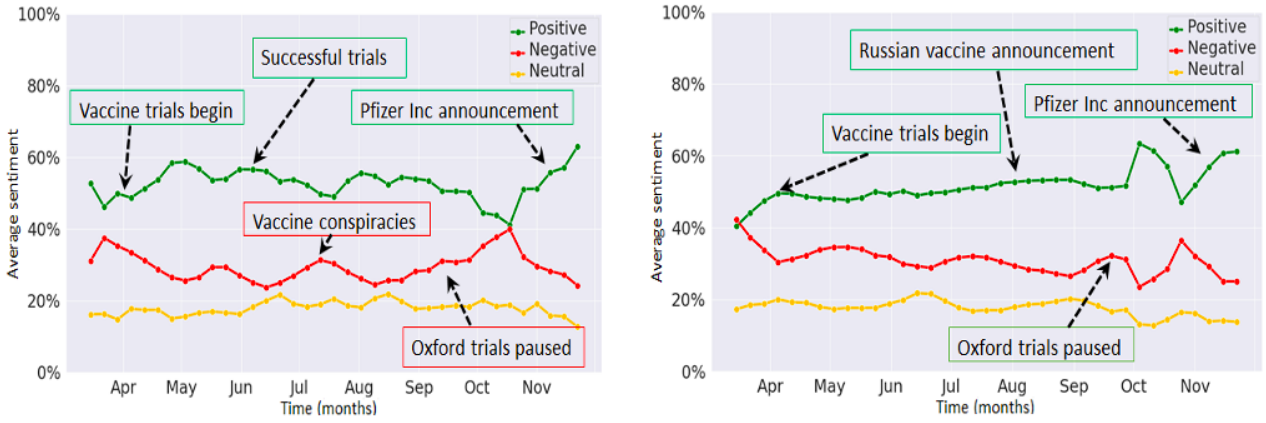
Figure 2. Averaged weekly trends in Facebook sentiments for (A) the United Kingdom and (B) the United States.



(A) The United Kingdom

(B) The United States

Figure 3. Average weekly trends in Twitter sentiments for (A) the United Kingdom and (B) the United States.



(A) The United Kingdom

(B) The United States

For the United Kingdom, positive sentiments on Facebook displayed the most prominent trend (Figure 2A), showing a steady increasing trend since May 2020, corresponding to the initiation of vaccine trials and the recruitment of the first trial volunteer. We observed a peak in mid-August 2020, which was potentially associated with news on vaccine development in the United Kingdom and Russia. Negative sentiments on Facebook displayed an inverse trend to that of positive sentiments, and discourse was centered around vaccine conspiracies and halting of trials. For the United States, positive sentiments on Facebook displayed the most prominent trend, showing a small peak in August 2020, which was associated with posts relating to research on the COVID-19 vaccine in Russia. Moreover, negative sentiments on Facebook displayed a slight increase in mid-September 2020, which was associated with posts relating to the accelerated development of the COVID-19 vaccine (Figure 2B). More recently, from mid-October 2020, the trend of positive sentiments on Facebook in the United Kingdom and the United states increased, partly because of announcements from Pfizer Inc and Moderna Inc on successful vaccine trials [24].

Figure 3 illustrates the positive, negative, and neutral sentiments on Twitter from March to November 2020 for the United Kingdom and the United States. Figure 3A shows that in the United Kingdom, positive sentiments on Twitter displayed the most prominent trend, showing a small peak at the end of April and July of 2020, the former related to the first human vaccine trial. The negative sentiment trend on Twitter displayed peaks in July and October of 2020, simultaneously with the United Kingdom opting out of the European Union vaccination scheme and halting of the phase III vaccine trials at the University of Oxford owing to safety concerns [25]. Figure 3B shows that in the United States, positive sentiments on Twitter displayed the most prominent trend, showing major peaks from end-September to end-November of 2020, which was related to claims by ex-President Donald Trump regarding a vaccine being ready in a few weeks and an increase in Twitter discourse due to his reference to the "herd mentality." We observed a small peak in the negative trend graph in mid-September 2020, which was related to halting of the phase III vaccine trial at the University of Oxford.

For both the United Kingdom and the United States, we observed a marked increase in the positive sentiment trend, since end-October 2020, which was related to recent breakthrough announcements by Pfizer Inc and Moderna Inc. Analysis of social media conversations indicated public optimism, with trial results being hailed as "good" and "amazing" and with "hope" prevailing for the "new year" (Multimedia Appendix 1). A notable peak in the negative sentiment trends for both countries, in approximately mid-October 2020, was associated with the growing antivaccination movement and with concerns regarding "fake news" and "misinformation."

Statistical Analysis of Sentiment Trends

Statistical analysis (results detailed in Multimedia Appendix 1) involved the assessment of the strength of the association between the predicted sentiment in the trend graph and the accuracy of the labeled data. Overall, regarding COVID-19 vaccines, we observed stronger sentiments on Twitter for the United States, with both positive and negative sentiments displaying stronger increasing and decreasing trends, respectively, compared to the United Kingdom. Public sentiments on Facebook reflected a reduction in positive sentiments and an increase in neutral sentiments in both the United Kingdom and the United States, with positive sentiments displaying a slightly stronger decreasing trend in the United Kingdom than in the United States.

Sentiment Word Clouds and Text N-Gram Analysis

We performed sentiment word cloud and text N-gram analyses for the entire study period to identify and analyze notable events that were of interest to social media users, and the findings are summarized in Multimedia Appendix 1 (some of these were also identified in the aforementioned analysis, on the sentiment trend graphs).

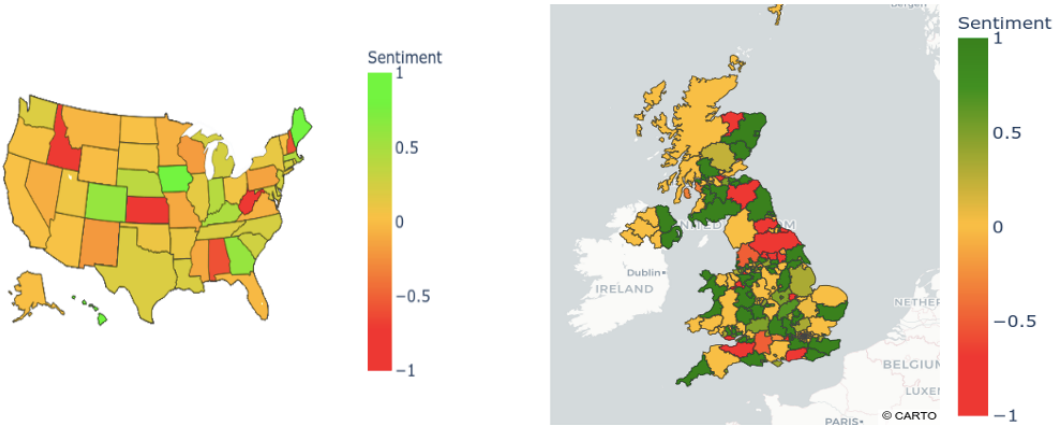
Geospatial Sentiment Analysis

A geospatial map of overall (averaged) sentiments at the state level in the United States is shown in Figure 4 (left), and it indicates that most states had a negative sentiment. The states with an overall negative sentiment toward COVID-19 vaccines were concentrated in the West and Midwest regions,

namely Idaho, Kansas, New Hampshire, West Virginia, and Alabama. The states with an overall positive sentiment were in the East, namely Maine, Colorado, Georgia, and Hawaii.

A geospatial map of averaged sentiments toward COVID-19 vaccines at the county level in the United Kingdom is shown in Figure 4 (right). In contrast with the United States, most counties in the United Kingdom had an overall positive sentiment toward COVID-19 vaccines. The counties with the most positive sentiments included Cornwall, Kent, East Sussex, Surrey, and Dorset in England and Aberdeenshire, Angus, and Stirlingshire in Scotland. Furthermore, the counties with the most negative sentiments were West Sussex, Somerset, North Yorkshire, and Durham in England.

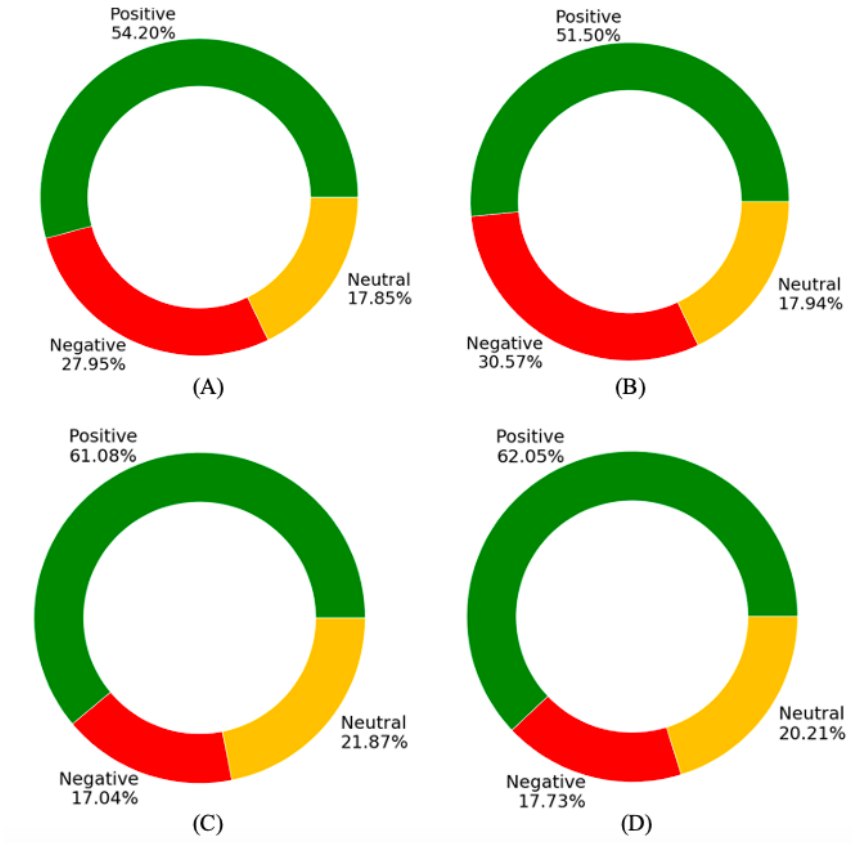
Figure 4. Geospatial mapping of averaged social media public sentiments in the United States (left) and the United Kingdom (right) toward COVID-19 vaccines (1 or green: positive sentiments, 0: neutral sentiments, and -1 or red: negative sentiments).



Overall Averaged Sentiments

Overall averaged sentiments in the United Kingdom and the United States on Facebook and Twitter are shown in Figure 5 and in Multimedia Appendix 1.

Figure 5. Overall averaged sentiments: (A) Twitter sentiments in the United Kingdom, (B) Twitter sentiments in the United States, (C) Facebook sentiments in the United Kingdom, and (D) Facebook sentiments in the United States.



Discussion

Principal Findings

We analyzed temporal variations in public sentiments toward COVID-19 vaccines in the United Kingdom and the United States. We identified, evaluated, and mapped the key events impacting positive, negative, and neutral sentiments to the temporal trends. We also mapped spatial variations in public sentiment to regions in the United Kingdom and states in the United States. Our geospatial maps can help identify areas with more negative sentiments toward COVID-19 vaccines, which can be further studied for potential interventions, to allay the underlying public fears and concerns.

Our findings indicate that online public discourse on Facebook and Twitter across the United Kingdom and the United States is evolving, with both complementary and contrasting insights obtained from the 2 popular platforms. Comparative analysis revealed that over the 9-month study period, averaged public sentiment toward COVID-19 vaccines has been mostly positive and similar in both the United Kingdom and the United States across both platforms (57.70% average across both platforms for the United Kingdom vs 56.80% for the United States). Positive sentiments were related to public opinions on vaccine development, related trials, and news related to vaccine availability.

On both platforms, overall averaged negative sentiments were found to be similar for the United Kingdom (22.50%) and the United States (24.10%). It is interesting to note that Twitter sentiments appeared more negatively biased, with the proportion of negative sentiments being almost 2-fold those on Facebook, for both the United Kingdom (27.95% vs 17.04%) and the United States (30.57% vs 17.73%), which potentially reflects their respective user demographics. This finding appears consistent with those of Waterloo et al [16], who reported that public opinions were often more negatively biased on Twitter than on Facebook, with public opinions being more positively biased on Facebook. Negative sentiments in our study were related to public apprehensions and concerns regarding delays or pauses in vaccine trials, vaccine safety, corporations, and governments influencing vaccine availability and rights exclusivity for economic benefits.

A comparative analysis with independent surveys was carried out. Our findings related to trends of averaged positive and negative sentiment across the United Kingdom and the United States were found to correlate broadly. In the United States, during the early stages of the pandemic, polling indicated that a significant minority had low trust in a vaccine; for example, a Yahoo News/YouGov survey in May 2020 [26] reported that only 55% of people in the United States intended to get vaccinated against COVID-19, while almost 1 in 5 (19%) individuals would not get vaccinated. A similar survey in July 2020 [27] reported that 42% of people in the United States would get vaccinated (27% would not get vaccinated), while a survey in September 2020 [28] reported that only 36% of people in the United States were certain they would get vaccinated (32% would not get vaccinated). More recently, an Axios-Ipsos survey in November 2020 reported, consistent with the findings of our social media analysis, a marked increase in the proportion of individuals who are likely to get vaccinated (51% were "very" or "somewhat" likely to take the first-generation vaccine; this proportion would increase to 70% if the vaccine was proven safe and effective by public health officials) [29].

In the United Kingdom, a YouGov survey in June 2020 [30] reported that 41% of respondents would "probably" or "definitely" get vaccinated, while 1 in 6 (16%) respondents would "definitely" or "probably" not get vaccinated. The survey also reported that individuals who used social media more than traditional media as their source of news were 9% less likely to be in favor of being vaccinated. A more recent YouGov survey in the United Kingdom in November 2020 [31], related to the Pfizer COVID-19 vaccine, reported that 67% of individuals were "very" or "fairly" likely to take the vaccine when available, and approximately 1 in 5 (21%) individuals were unlikely to take it. While there has been a slight increase in the proportion of individuals unlikely to take the vaccine, the proportion of those likely to get vaccinated has increased, indicating a reduction in the number of individuals who were previously unsure. This could be attributed in part to the recent announcements by vaccine manufacturers, and our results corroborate this finding with a marked increase in positive sentiments since mid-October 2020, in both the United Kingdom and the United States, across the 2 social media platforms. Further studies on changes in sentiments could further the current understanding of factors that have contributed to this, with particular focus on the impact of government education programs.

Limitations

It is important to consider the limitations of our data sources and techniques and the related challenges and opportunities they present for future research. While we attempted to gauge nationwide public sentiments in the United Kingdom and the United States by analyzing posts in English on both Facebook and Twitter, our data may not be representative of the broader population of both countries. Users are known to differ in their usage and preferences regarding social media platforms on the basis of their sociodemographics (eg, age, socioeconomic status, and political affiliation). Vaccines are likely to be preferentially targeted at older populations and possibly ethnic minorities, communities with historically lower rates of vaccine uptake [32,33]. Further exploration is therefore imperative to increase our understanding of the public perception toward vaccines and their underlying behavioral determinants [34]. Social network analysis [35,36] can be performed in conjunction with DL methods to effectively identify sources of fake news or misinformation and their social networks to help deal with infodemic challenges [37,38]. Demographic data including age, gender, race, and geographic origin can also be inferred from social media profiles of users by using AI techniques [39]. This can help categorize distinct groups and inform the development of demographic-level engagement and tailored communication strategies to promote diversity and inclusion in vaccination campaigns. These can also effectively account for the fact that there are genuine knowledge voids being filled by misinformation [34].

The technical limitations of our approach include challenges in determining the geographic location of users and issues relating to the accuracy of the AI techniques (eg, interpreting sarcasm and implicit context). Alternative deep neural networks [40-42] and fuzzy-based approaches [43,44] can be explored and potentially integrated as part of our ensemble model in an attempt to further refine the present findings. The 2-step keyword-based thematic filtering process and the use of geotagged posts in this study resulted in relatively small sample sizes. This could be improved by using more sensitive filtering and data-driven search mechanisms, network metadata (such as likes and retweets), and additional social media and web-based platforms. On account of the current study limitations, our approach should only be used in conjunction with other techniques for understanding public sentiments, such as focus groups, input from civil society organizations, surveys, and public consultations.

Future studies could consider conducting periodic public surveys over the period of interest being explored through social media analysis. This would ensure that both methodologies were informed by each other over the course of the study to enable more granular spatiotemporal analysis, thus allowing more robust comparisons from reciprocal findings and deeper insights for policymakers. These could also complement other qualitative methods, such as in-depth interviews and ethnographic studies, as part of mixed-study approaches. Manual annotation or labeling of datasets is imperative when training AI models for NLP tasks to ensure accuracy and generalizability. These can be affected by the skill of annotators and the proportion of the data set that is labeled. Confounding factors, such as political affiliations, should also be included in future studies, by applying further filters to screen strategies and through targeted demographic analysis, to further the current understanding of the underlying determinants of public sentiments. Attitudes toward different vaccine manufacturers could also be explored to identify and assess effective public engagement strategies to build support for ethical principles and maximize the uptake of the imminently available vaccines.

Conclusions

One of the main threats to the resilience of vaccination programs globally is the rapid and global spread of misinformation. Public confidence in COVID-19 vaccines can be exacerbated by unproven concerns regarding vaccine safety, which seed doubt and distrust. Furthermore, there have been cases where vaccine debates have been purposefully polarized, thus exploiting the doubting public and system weaknesses for political purposes, while waning vaccine confidence elsewhere may be influenced by a general distrust in the government and scientific elites. Recent surveys and polls in the United Kingdom and the United States have indicated the fragility of support for vaccination, which furthers the requirement for a better understanding of underlying public concerns and attitudes, both at scale and in real time. Retrospective analysis of 2 popular and most representative social media platforms in this study demonstrates the potential of AI-enabled real-time social media monitoring of public sentiments and attitudes to help detect and prevent such fears and also to enable policymakers to understand the reasons why some social groups may be reluctant to be vaccinated against COVID-19. This can inform more effective policy-making and promote participatory dialogue on complex vaccine deployment issues, under conditions of uncertainty, including decisions on prioritization and equitability, to help maximize the uptake of imminently available vaccines.

Acknowledgments

This study was funded by the Chief Scientist Office of the Scottish Government under its COVID-19 priority research program (COV/NAP/20/07) and is jointly led by co-Principal Investigators AH and AS. AS was supported by BREATHE - The Health Data Research Hub for Respiratory Health [MC_PC_19004], which is funded by the UK Research and Innovation Industrial Strategy Challenge Fund and delivered through Health Data Research UK. AH was supported by the UK Government's Engineering and Physical Sciences Research Council grants (EP/T021063/1, EP/T024917/1). This study does not represent the views of the Scottish or UK Governments.

Conflicts of Interest

AS is a member of the Chief Medical Officer's COVID-19 Advisory Group of the Scottish Government and the UK Government's New and Emerging Respiratory Virus Threats Risk Stratification Subgroup.

Abstract

Background: Limited information is available about the present characteristics and dynamic clinical changes that occur in patients with COVID-19 during the early phase of the illness.

Objective: This study aimed to develop and validate machine learning models based on clinical features to assess the risk of severe disease and triage for COVID-19 patients upon hospital admission.

Methods: This retrospective multicenter cohort study included patients with COVID-19 who were released from quarantine until April 30, 2020, in Korea. A total of 5628 patients were included in the training and testing cohorts to train and validate the models that predict clinical severity and the duration of hospitalization, and the clinical severity score was defined at four levels: mild, moderate, severe, and critical.

Results: Out of a total of 5601 patients, 4455 (79.5%), 330 (5.9%), 512 (9.1%), and 301 (5.4%) were included in the mild, moderate, severe, and critical levels, respectively. As risk factors for predicting critical patients, we selected older age, shortness of breath, a high white blood cell count, low hemoglobin levels, a low lymphocyte count, and a low platelet count. We developed 3 prediction models to classify clinical severity levels. For example, the prediction model with 6 variables yielded a predictive power of >0.93 for the area under the receiver operating characteristic curve. We developed a web-based nomogram, using these models.

Conclusions: Our prediction models, along with the web-based nomogram, are expected to be useful for the assessment of the onset of severe and critical illness among patients with COVID-19 and triage patients upon hospital admission.

KEYWORDS

clinical decision support system; clinical characteristics; COVID-19; SARS-CoV-2; prognostic tool; severity

Introduction

COVID-19, an infectious disease, is currently spreading at an unprecedented pace. The World Health Organization declared COVID-19 a public health emergency of worldwide concern on January 30, 2020, and subsequently a pandemic on March 11, 2020. The COVID-19 pandemic has posed challenges to public health systems worldwide [1,2].

The clinical spectrum of SARS-CoV-2 infection ranges from asymptomatic to fatal, requiring mechanical ventilation [3]. According to initial data from China, the clinical spectrum of COVID-19 is broad, with most infected individuals experiencing only mild or subclinical illnesses, especially in the early phase of the disease [4]. However, a recent study reported that approximately 14%-30% of hospitalized patients diagnosed with COVID-19 develop a severe respiratory failure that requires intensive care [5-7]. The wide range of outcomes observed, ranging from subpopulations that are mainly asymptomatic to those with substantial fatality rates, calls for risk stratification.

Although dexamethasone and remdesivir have recently been considered a preferred treatment strategy, it is still difficult to use them universally for all patients with COVID-19 [8]; hence, supportive treatments to protect multiorgan functions are a major resource for reducing mortality [9,10]. Several promising innovative drugs and treatment strategies are under investigation; however, until they become commercially available, the capacity of the medical system remains limited, prompting the need for making rationing decisions [10,11]. We argue that early identification of patients at the risk of severe respiratory failure would facilitate better resource planning and help set up effective organizational and clinical interventions, including early pharmacotherapy to prevent admission to the intensive care unit.

Since COVID-19 is a pandemic, many studies have assessed regional clinical features among patients. Pandemic preparedness and strategies differ among countries, and the clinical characteristics of patients admitted to medical facilities seem to vary in different cohorts.

We obtained data on 5628 confirmed patients with COVID-19 admitted to hospitals in Korea and analyzed their clinical features and clinical findings upon admission. Therefore, the objectives of this study are to (1) develop models that predict which individuals are at a high risk of severe disease and their duration of hospitalization in a cohort of hospitalized patients with a confirmed diagnosis of COVID-19 and (b) generate a web-based nomogram based on these models. Our results are expected to provide clinicians with a better understanding of the clinical course of COVID-19 and a guideline for critical care rationing.

Methods

Data Source and Study Design

This is a retrospective, multicenter cohort study conducted in Korea. The data used in this study were public data provided by the Korea Disease Control and Prevention Agency (KDCA) in Korea. Data were collected by the KDCA from physicians at multiple centers. The study cohort included 5628 patients with COVID-19 confirmed through the RT–PCR test and hospitalized or released from quarantine upon recovery by April 30, 2020.

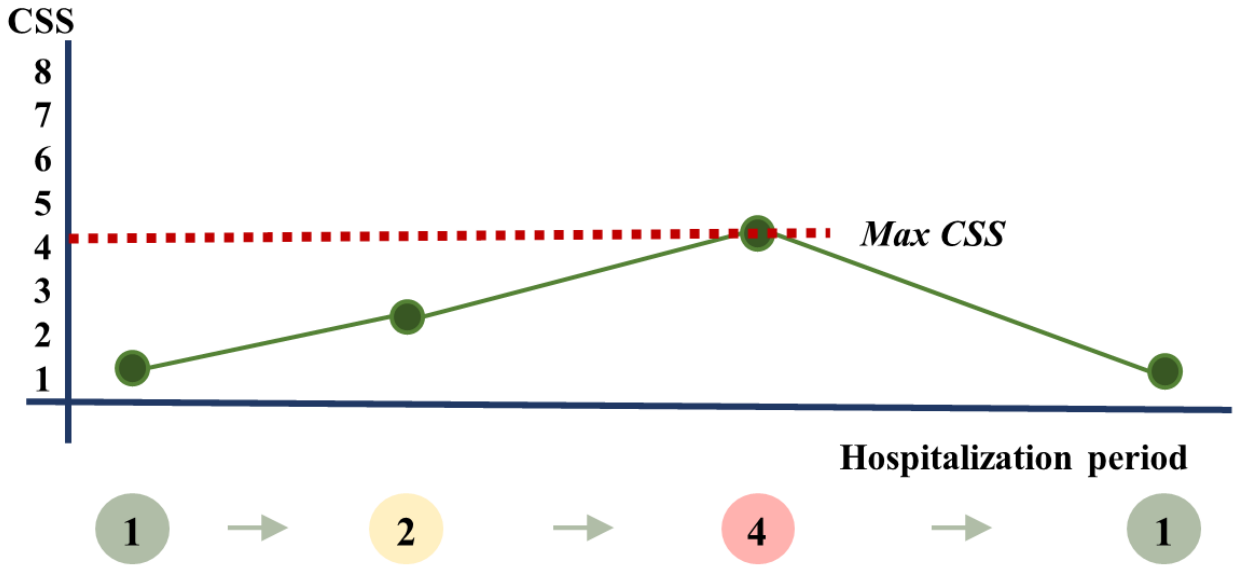
A total of 41 variables were recorded for each patient. These 41 variables are classified into 7 types (Multimedia Appendix 1, Table S1). Among the 41 variables provided by KDCA, 35 were used as predictors, including demographics, physical measurements, initial vital signs, comorbidities, and laboratory findings collected upon admission. We excluded 6 pregnancy-related variables because they were applicable only to women. This study was approved by the institutional review board of Seoul National University (protocol# E2008/003-004).

Definitions of the Primary and Secondary Outcomes

In this study, the primary outcome of interest is the maximum clinical severity score (CSS). The original CSSs provided by the KDCA have 8 levels (Multimedia Appendix 1, Table S2). The CSSs contain ordered information about the clinical severity of patients with COVID-19. For example, the lowest level (ie, level 1) represents no activity restrictions and the highest level (ie, level 8) represents death. As shown in Figure 1, each patient may go through different CSS levels during the course of hospitalization. For each patient, the “max CSS” was defined as the maximum level of CSS reported through their hospital duration (Figure 1). Instead of the original 8 levels, the severity was reclassified into 4 levels depending on the patient’s condition to determine the appropriate treatment in our study. Accordingly, the modified CSS (mCSS) was defined as mild, moderate, severe, and critical (Multimedia Appendix 1, Table S2). The mild group included patients with no activity restrictions, which corresponded to 1 in the original CSS levels. The moderate group displayed limited activity but did not require oxygen therapy. This group corresponded to the original CSS level of 2. Patients who received oxygen therapy were classified under the severe group and those who received ventilation or extracorporeal membrane oxygenation or those who died were classified under the critical group. The severe group corresponded to original CSS levels of 3 and 4, and the critical group corresponded to original CSS levels of 5, 6, 7, and 8.

The secondary outcome was the total duration of hospitalization from the time of admission to discharge. In Korea, once a patient tests positive for COVID-19 on the RT–PCR test, he/she would be admitted to hospital or an isolation facility immediately. Our data set contains data on only the hospitalized patients with COVID-19 having clinical findings such as blood test results.

Figure 1. Diagrammatic representation of the definition of the maximum clinical severity score. CSS: clinical severity score.



Data Preprocessing

Among 35 predictor variables, 7 variables including body temperature, heart rate, and 5 laboratory results were continuous variables, while all the other variables were categorical variables. Among the 7 continuous variables, body temperature and heart rate were recategorized. Specifically, body temperature was divided into 2 categories with 37.5°C considered the threshold, and the heart rate was divided into 3 groups of <60 beats/min, 60-100 beats/min, and ≥100 beats/min. Among the 28 original categorical variables, age, body mass index (BMI), systolic blood pressure (SBP), and diastolic blood pressure (DBP) were recategorized. Age was originally grouped into 10-year-old intervals: <10 years, 10-19 years, 20-29 years, 30-39 years, 40-49 years, 50-59 years, 60-69 years, 70-79 years, and ≥80 years. Of these groups, the values of the age groups of 0-9 years and 10-19 years were merged into 1 group. For BMI, 5 groups were formed: <18.5 kg/m^2, 18.5-22.9 kg/m^2, 23-24.9 kg/m^2, 25-29.9 kg/m^2, and ≥30 kg/m^2. Of these groups, values ranging 25-29.9 kg/m^2 and ≥30 kg/m^2 were merged into 1 group. For SBP, 5 groups were initially formed: <120 mmHg, 120-129 mmHg, 130-139 mmHg, 140-159 mmHg, and ≥160 mmHg. For DBP, 4 groups were initially formed: <80 mmHg, 80-89 mmHg, 90-99 mmHg, and ≥100 mmHg. SBP and DBP were divided into 2 groups based on the values of 140 mmHg and 90 mmHg, respectively.

To analyze the primary outcome (ie, mCSS), 5601 samples were used, excluding missing observations. To analyze the secondary outcome (ie, the duration of hospitalization), 5387 samples were used after excluding patients who died through the course of hospitalization. The median duration of hospitalization was 24 days. Accordingly, we classified the duration of hospitalization into two treatment groups: short-term and long-term.

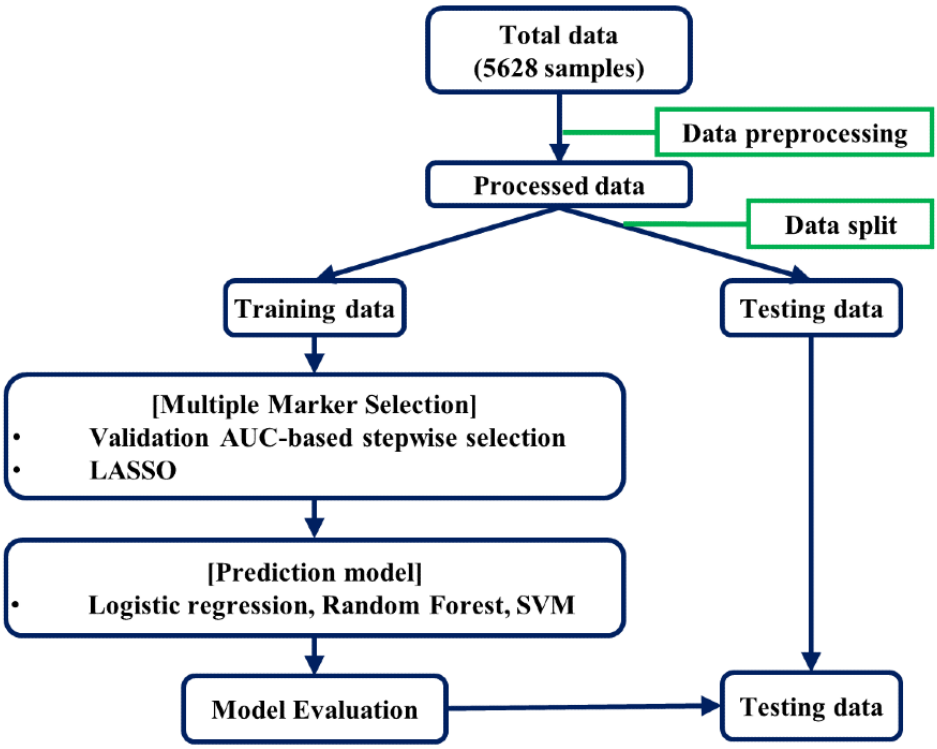
Predictive Marker Selection Through Univariate Analysis

To identify candidate predictive markers related to the primary and secondary outcomes, univariate analysis was first performed. On univariate analysis, mCSS was considered a continuous variable. We performed correlation analysis between mCSS and continuous predictors using the Pearson, Spearman, and Kendall rank correlation tests [12,13], two-tailed *t* test for binary predictors, and analysis of variance for multilevel categorical predictors. Furthermore, we performed the Cochran–Armitage Trend test [14] to identify predictors with a linear trend of mCSS. For the duration of hospitalization, we used a Cox proportional hazards (CoxPH) model to identify candidate predictive markers [15].

Development and Evaluation of the Prediction Model

Figure 2 shows the workflow for model development and evaluation. To avoid overfitting, we evaluated testing errors by splitting the total data set into training and testing data sets in a ratio of 2:1 in a stratified manner, by considering the ratio of the max CSS 4 levels and the long- or short-term group. To maintain the same scale for predictor variables, we standardized each predictor variable.

Figure 2. Workflow for model building and evaluation. AUC: area under the curve, LASSO: least absolute shrinkage and selection operator, SVM: support vector machine.



In order to develop models that predict the max CSS, the 4-level mCSS was combined into two levels in three ways such as (1) y_1: mild (mCSS=1) vs above moderate (mCSS≥2), (2) y_2: below moderate (mCSS≤2) vs above severe (mCSS≥3), and (3) y_3: below severe (mCSS≤3) vs critical (mCSS=4). We fit 3 logistic regression models for binary responses. For multiple marker selection, stepwise variable selection was performed on the basis of the area under the receiver operating characteristic curve (AUC) [16], and we used the least absolute shrinkage and selection operator (LASSO) regression method [17,18]. For both stepwise and LASSO variable selections, 5-fold cross-validation was performed. For prediction models, we considered logistic regression, random forest (RF) classification, and a support vector regression machine [19,20]. Each prediction model was fit using markers selected through stepwise and LASSO regression analyses. The performance of each model was evaluated on the basis of the AUC, sensitivity, and specificity. The optimal threshold for sensitivity and specificity was selected as the threshold value with the maximum balanced accuracy. All analyses were implemented in the R package (version 3.6.1, The R Foundation).

Results

Demographics and Clinical Characteristics

The demographics and clinical characteristics of the 5628 patients, with particular focus on the risk predictors for mCSS or the duration of hospitalization, are presented in Table 1. A complete list of all predictors is provided in Multimedia Appendix 1, Table S3. Among them, 1785 (31.8%) patients were aged over 60 years, and 2320 (41.2%) were male. In total, 1299 (29.4%) patients were overweight or obese by Asia-Pacific BMI criteria. At the time of initial admission, 1936 (35.3%) patients had an SBP of ≥140 mmHg, and 887 (15.9%) had a body temperature of ≥37.5°C. At the time of diagnosis, the patients experienced the following symptoms: fever (n=1305, 23.2%), sputum production (n=1619, 28.8%), shortness of breath (SOB) (n=666, 11.8%), and altered consciousness or confusion (ACC) (n=35, 0.6%).

The patients had the following underlying comorbidities: diabetes mellitus (DM) (n=691, 12.3%), hypertension (HTN) (n=1201, 21.4%), heart failure (HF) (n=59, 1.0%), asthma (n=128, 2.3%), and chronic obstructive pulmonary disease (COPD) (n=40, 0.7%). Initial mean laboratory values were 13.3 (SD 1.8) g/dL for hemoglobin, 39.2% (SD 5%) for hematocrit, 29.1% (SD 11.7%) for the proportion of lymphocytes, 236,733/μL (SD 82,921/μL) for the platelet count, and 6126/μL (SD 2824/μL) for the white blood cell (WBC) count.

[a]*P* values were obtained through Pearson correlation analysis for the modified clinical severity score and with the Cox proportional hazards model for the duration of hospitalization.

[b]N/A: not applicable.

The Severity of COVID-19

Based on the severity of COVID-19, determined from the mCSS, patients were divided into four levels: mild (n=4455, 79.5%), moderate (n=330, 5.9%), severe (n=512, 9.1%), and critical (n=304, 5.4%). Among patients aged >60 years, 1157 (64.8%) 1567 (87.8%) belonged to the severe and critical levels, respectively. Specifically, patients in the severe and critical levels and aged ≥60 years accounted for 135 (26.4%) and 58 (19.1%), respectively, of the mCSS cohort. Patients in the severe and critical levels and aged ≥70 years accounted for 125 (24.4%) and 89 (29.3%), and those aged ≥80 years accounted for 72 (14.1%) and 120 (39.5%), respectively. Furthermore, with respect to the duration of hospitalization, patients aged >60 years were more frequently found in the long-term treatment group than in the short-term treatment group.

Univariate Analysis

Table 2 shows the association between the 30 key prediction markers and the mCSS, determined through univariate analysis at a 5% significance level. Patients with an older age; high BMI; SBP of ≥140 mmHg; high heart rate; body temperature of ≥37.5°C; 6 subjective clinical findings including fever, sputum, fatigue or malaise, SOB, ACC, and vomiting or nausea (VN); or 10 comorbidities including DM, HTN, HF, chronic cardiovascular disease (CCD), asthma, COPD, chronic kidney disease, cancer, chronic liver disease, and dementia were likely to have a higher risk of severe disease. Men were found to be at a higher risk of having a high mCSS than women (*P*<.001). Furthermore, patients with a high WBC count or low values of 4 laboratory findings (hemoglobin, hematocrit, lymphocytes, and platelets) tended to be at a higher the risk of severe disease (*P*<.001).

[a]For each test, a variable with positive coefficient represents the predictor positively associated with an increase in clinical severity.

[b]N/A: not applicable.

[c]Sex: Female=1, Male=0; clinical findings or comorbidities; Yes=1, No=0.

The results of univariate analysis for the duration of hospitalization are shown in Multimedia Appendix 1, Table S4. We identified 20 key prediction markers associated with the duration of hospitalization. Patients with an older age; SBP of ≥140 mmHg; body temperature of ≥37.5°C; 7 subjective clinical findings including fever, cough, sputum, muscle aches or myalgia, SOB, ACC, and VN; 6 comorbidities including DM, HTN, HF, CCD, COPD, and dementia; or low values of blood parameters including hemoglobin, hematocrit, lymphocytes, and platelets tended to have a long duration of hospitalization.

Development and Evaluation of the Prediction Model

To develop prediction models for mCSS and the duration of hospitalization, we selected multiple markers using AUC-based stepwise selection and the LASSO method. For the application of statistical and machine learning models, we defined three binary response variables by regrouping the 4 levels of mCSS into two levels as follows; (1) y_1: mild (mCSS=1) vs above moderate (mCSS≥2), (2) y_2: below moderate (mCSS≤2) vs above severe (mCSS≥3), and (3) y_3: below severe (mCSS≤3) vs critical (mCSS=4). Table 3 shows the results of variable selection and evaluation for each y. Details regarding the selected variables are provided in Multimedia Appendix 1, Table S5. For each case, we aimed to develop a parsimonious model with higher predictive power. Variables selected through the LASSO method were determined as the final model for each y. For y_1, predictors including older age, high body temperature, SOB, low lymphocyte value, and low platelet count were selected as risk factors. The prediction model with these 5 predictors had an AUC of ≥0.83 (ie, AUC=0.830, sensitivity=0.710, and specificity=0.843 for the RF model). For y_2, older age, high body temperature, SOB, low hematocrit and lymphocyte values, and low platelet count were selected as risk factors. The prediction model with these 6 predictors yielded an AUC of ≥0.865 (ie, AUC=0.865, sensitivity=0.772, and specificity=0.842 for the RF model). For y_3, older age, SOB, high WBC count, low hemoglobin and lymphocyte values, and low platelet count were selected as risk factors. The prediction model with these 6 predictors yielded an AUC of ≥0.933 (ie, AUC=0.933, sensitivity=0.895, and specificity=0.865 for the RF model).

Based on these 3 prediction models, we developed a prognostic nomogram to predict the mCSS for each patient. The nomogram is available on the internet for clinical use [21]. Figure 3 shows an example of the developed nomogram. The fitted results of the logistic model used to develop the nomogram are shown in Multimedia Appendix 1, Table S6. Based on the standardized β coefficients of the fitted results, we ranked the importance of the predictors for each model (Figure 4) [22]. In Figure 4, the x-axis represents the standardized β coefficient, and the relative importance of the predictors is shown in descending order for each model. In all 3 prediction models, the SOB ranked first. The temperature selected in the 2 prediction models ranked second in both models, y_1 and y_2. In all 3 prediction models, lymphocytes ranked third.

We performed similar analyses for the duration of hospitalization. The results of variable selection and evaluation are summarized in Multimedia Appendix 1, Table S7. The prediction model selected 13 predictors through stepwise selection, including age, hematocrit, cough, FM, platelets, muscle aches or myalgia, dementia, asthma, VN, lymphocytes, WBC count, diarrhea, and body temperature. This model yielded an AUC of ≥0.601. With the LASSO method, only age was selected, and the prediction model yielded a performance of up to 0.571.

Table 3. Prediction model and performance for the modified clinical severity score.

Discussion

Principal Findings

In this study, we retrospectively assessed the characteristics of 5628 patients with COVID-19 from multiple hospitals in Korea and identified the risk factors for predicting the maximum clinical severity and duration of hospitalization. Older patients aged >60 years accounted for 31.8% of the total, and patients with mild disease accounted for 79.5% of the total. Through univariate analysis for each outcome, we identified 30 risk factors for mCSS and 20 risk factors for the duration of hospitalization. Common risk factors between mCSS and the duration of hospitalization included age, SBP, body temperature, fever, sputum, SOB, ACC, VN, DM, HTN, HF, CCD, COPD, dementia, hemoglobin, hematocrit, lymphocytes, and platelets.

We successfully developed 3 prediction models for mCSS by combining mCSS with 4 levels into 2 levels and developed a web-based nomogram [21] by using these models. Our results indicate that age, body temperature, SOB, lymphopenia, a low hematocrit, low hemoglobin, a low platelet count, and a high WBC count were risk factors positively associated with the maximum clinical severity of COVID-19. These 8 variables have been reported as important predictor variables in the medical literature [23-28]. Specifically, age, shortness of breath, body temperature, lymphocytes, and hemoglobin have been reported as variables for predicting admission to the intensive care unit [23,25], critical illness [24,29], or severe disease [26,27,30]. In particular, Wu et al [26] reported that the severe group had a significantly lower platelet and higher WBC counts than the nonsevere group. Furthermore, Zhang et al [28] reported that hematocrit was significantly lower in the severe group than in the nonsevere group. Our study provides a list of useful risk predictors that can be widely used in a large health care organization during the pandemic.

With an increase in the number of confirmed patients, the number of severely symptomatic patients is also increasing, thus posing a challenge to the management of severe patients during COVID-19 outbreaks. The wide range of outcomes observed, ranging from subpopulations that are mainly asymptomatic to those with markedly high fatality rates, calls for risk stratification. Timely identification of patients at a high risk of developing acute respiratory distress syndrome or multiple organ failure and performing risk stratification management can facilitate more personalized treatment plans and optimized use of medical resources and help prevent further deterioration. To define identify individuals at a high risk of severe disease, the Centers for Disease Control and Prevention defined the following criteria for a high risk of severe disease: age ≥65 years, living in nursing homes, and having at least one underlying comorbidity including chronic lung disease, serious heart conditions, severe obesity, diabetes, chronic kidney disease, liver disease, or an immunocompromised status.

Age and the male gender identified as risk factors of severe COVID-19 in our study have been previously confirmed as risk factors in other countries [31,32]. An elevation in the body temperature is the result of the progression of the infection; hence, if the body temperature is high (≥37.5°C), the prognosis is likely to be poor. In addition, shortness of breath can be considered a symptom that occurs in the course of the disease, since COVID-19 is a type of respiratory disease [33,34]. Among the hematologic abnormalities we observed, we shall consider 2 variables: lymphocytes and platelets. Because lymphopenia and immune dysregulation may impact disease severity, especially because SARS-CoV-2 can directly infect T-lymphocytes, which may be the underlying mechanism of lymphopenia [35]. Regarding the finding of platelet abnormalities, it can be explained that the development of autoimmune antibodies or immune complexes induced by viral infection may play an important role in inducing thrombocytopenia. In addition, SARS-CoV-2 can also directly infect hematopoietic stem or progenitor cells, megakaryocytes, and platelets to inhibit growth and induce apoptosis; furthermore, increased platelet consumption or decreased platelet production in damaged lungs is a potential alternative mechanism that may contribute to thrombocytopenia in severe critical pulmonary conditions [36].

Limitations

Wynants et al [34] reviewed 50 COVID-19 prediction models and reported that most of the models have a high risk of bias when evaluated with the prediction model risk of bias assessment tool [37]. They found that 2 common causes of bias

in prediction models for COVID-19 were the lack of external validation and selection bias. Our study also has these limitations. Since the cohort of patients with COVID-19 in this study includes those whose clinical course has not yet been completed and those who may still potentially develop severe disease, there is a chance that discharged patients without any indication of severe disease during hospitalization would later develop severe disease outside of hospital. In addition, our model was not validated with an external cohort (including foreign data), even though we divided the cohort into a training and testing set to evaluate the predictive power of the developed models. This limitation is mainly due to the limited research environment and the time provided by KDCA to prevent data leakage. Another study limitation is that the data did not include smoking status, which is a very important aspect of an individual's lifestyle, and medication history, especially their history of taking corticosteroids, was not identified. This is an important factor that is closely associated with the exacerbation of the clinical course of COVID-19. The KDCA did not provide information on the smoking status of these individuals because these data were largely missing. In the future, it is expected that more variables from a larger set of patients with COVID-19 be included in the data set to increase the accuracy of the analysis [38,39].

Recently, these prediction tools have been presented in various ways worldwide, but variables with predictive power are identified slightly differently depending on the characteristics of the study population, including nationality and race. In addition, these prediction models can be updated in the current situation where the number of patients continues to rise. Therefore, to develop a model with higher predictive power, it is necessary to constantly compare and validate the results of various studies.

Conclusions

In this study, we developed models that predict the clinical severity of patients with COVID-19. Compared to previous studies that focused on predicting admission to the intensive care unit [23,25], critical illness [24,29], or severe disease [26,27,30], our model used the largest cohort and showed higher performances, even with a limited number of laboratory variables. Specifically, in the case of the model for predicting the critical group, the predictive power was >0.93. Furthermore, we developed a web-based nomogram [21] that can be easily applied visually.

These models are expected to be used as decision supporting tools at the initial stage of treatment; that is, they can be used to predict patients who might need intensive care owing to deterioration among most patients hospitalized with mild or asymptomatic conditions. They can also help hospitals that manage in-patients acquire and use facilities such as negative pressure beds, mechanical ventilation systems, and extracorporeal membrane oxygenation equipment that must be provided to patients with severe symptoms. If further validated through a prospective study, our prediction model might serve for both rationing decisions at health care levels and selecting patients for randomized controlled trials on new treatment options.

Acknowledgments

We thank the members of the Korea Centers for Disease Control and Prevention who provided valuable COVID-19 data during the study. This study was supported by a grant for COVID-19 from the Korea Centers for Disease Control and Prevention (grant# 2020061277D).

Authors' Contributions

BO, SH, TJ, and TP conceived and designed the study. SH and TJ contributed to data analysis and generated the tables and figures. CL developed the web-based nomogram. BO and SH drafted the manuscript and contributed to the literature search. BO, SH, TJ, SK, and TP interpreted the data. All authors critically reviewed and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The dynamics of the COVID-19 pandemic vary owing to local population density and policy measures. During decision-making, policymakers consider an estimate of the effective reproduction number R_t, which is the expected number of secondary infections spread by a single infected individual.

Objective: We propose a simple method for estimating the time-varying infection rate and the R_t.

Methods: We used a sliding window approach with a Susceptible-Infectious-Removed (SIR) model. We estimated the infection rate from the reported cases over a 7-day window to obtain a continuous estimation of R_t. A proposed adaptive SIR (aSIR) model was applied to analyze the data at the state and county levels.

Results: The aSIR model showed an excellent fit for the number of reported COVID-19 cases, and the 1-day forecast mean absolute prediction error was <2.6% across all states. However, the 7-day forecast mean absolute prediction error approached 16.2% and strongly overestimated the number of cases when the R_t was rapidly decreasing. The maximal R_t displayed a wide range of 2.0 to 4.5 across all states, with the highest values for New York (4.4) and Michigan (4.5). We found that the aSIR model can rapidly adapt to an increase in the number of tests and an associated increase in the reported cases of infection. Our results also suggest that intensive testing may be an effective method of reducing R_t.

Conclusions: The aSIR model provides a simple and accurate computational tool for continuous R_t estimation and evaluation of the efficacy of mitigation measures.

Introduction

The COVID-19 pandemic is currently underway. As of September 2, 2020, over 6,000,000 individuals in the United States have been reported positive for COVID-19. Modeling studies are key to understanding the factors that drive the spread of the disease and for developing mitigation strategies. Early modeling efforts forecasted very large numbers of infected individuals, which would overwhelm health care systems in many countries [1-3]. These forecasts served as a call to action for policymakers to introduce policy measures including social distancing, travel restrictions, and eventually lockdowns to avoid the predicted catastrophe [4-6]. The mitigating policy measures have been successful in changing the dynamics of the pandemic and in "flattening the curve," such that fewer people have needed to seek treatment at any given time, and this has prevented the health care system from getting overwhelmed.

One of the most fundamental metrics that describes the pandemic's dynamics is the reproduction number R_t, which is the expected number of secondary infections spread by a single

infectious individual [7]. In 1906, Hamer [8] speculated that the course of an epidemic is determined by the rate of contact between susceptible and infectious individuals. Later, Kermack and McKendrick [9] reported that epidemics end not when there are no susceptible individuals left, but rather when each infectious individual can infect, on average, <1 more individual. The R_t depends on three factors: (1) the likelihood of infection per contact, (2) the period during which infectious individuals freely interact with susceptible individuals and spread the disease, and (3) the rate of contact. The likelihood of infection per contact (factor 1) is determined on the basis of pathogen virulence and protective measures such as social distancing or wearing masks. Free interactions between infectious and susceptible individuals (factor 2) occur until the infectious individual is self-quarantined or hospitalized, either when the individual tests positive or experiences severe symptoms. Finally, the rate of contact (factor 3) is strongly affected by public health measures to mitigate risk [10], such as lockdowns during the COVID-19 pandemic. Thus, R_t is determined on the basis of the biological properties of the pathogen and multiple aspects of social behavior. When $R_t>1$, the number of cases is expected to increase exponentially. The pandemic is considered to have been contained when R_t decreases and remains at <1. Real-time R_t estimation is critical for determining the effect of implemented mitigation measures and future planning.

We propose a method for continuous estimation of the infection rate and R_t to investigate the effect of mitigation measures and immunity acquired by those who recover from the disease. We estimated R_t with a Susceptible-Infectious-Removed (SIR) model [9] that describes the dynamics of population compartments as follows: individuals are initially "susceptible," contract the viral infection and become "infectious," and are then moved to the "removed" compartment once they are quarantined or hospitalized, recover, or die. The SIR model is one of the simplest epidemiological models that still captures the main properties of an epidemic [11,12], and it has been widely used in epidemic modeling studies. In most SIR modeling studies, the model parameters were constant. An SIR model with constant parameters, however, cannot be applied for the COVID-19 pandemic because various mitigating measures were introduced during pandemic progression. The effect of policy changes on COVID-19 dynamics has been modeled using the combination of an SIR model and Bayesian inference [13,14]. In these modeling studies, the rate of infection spread was assumed to be piece-wise linear among the 3 dates of the implementation of policy changes. In another approach, continuous estimation of R_t and an assessment of the effect of mitigation measures were carried out on the basis of estimates of the distribution of the serial intervals between symptom onset in the primary and secondary cases [15-17]. Bayesian inference and methods based on estimations of the serial interval include multiple parameters whose values are not estimated from the data. In contrast, we propose an adaptive SIR (aSIR) model in which only one parameter—the removal rate—is determined from the literature, while the second parameter—the infection rate—is continuously estimated from the data through a sliding window approach. A continuous R_t estimate is then obtained using the infection rate estimate. The SIR model is described as a system of differential equations, and the key idea in our proposed method is that the initial conditions for each window are considered as values estimated for the previous window. The only additional hyperparameter is the length of the sliding window. The proposed method retains the conceptual and computational simplicity of SIR-type models and can be easily extended through the introduction of additional compartments supported by data.

Methods

Data

Data on daily and cumulative confirmed cases between February 29 and September 2, 2020, were obtained from John Hopkins University (JHU), and the dates of interventions by state (eg, state of emergency and stay-at-home orders) were obtained from Wikipedia. The JHU data were available at 2 levels of aggregation: county and state. JHU considers many sources for reporting these data; county-level information was extracted from the websites of the states' departments of health, and state-level data were extracted directly from the website of the Centers for Disease Control and Prevention.

Model

The SIR model is a system of ordinary differential equations:

Here, S is the number of susceptible individuals, I is the number of infectious individuals who freely interact with others and can transmit the infection, R is the number of individuals excluded from the other 2 compartments because they are quarantined or hospitalized, have recovered and acquired immunity, or have died. Several sources of government data on COVID-19 provide the daily number of newly confirmed cases and a cumulative number of confirmed cases. Careful consideration is required to determine whether these numbers should be attributed to the I or R compartment. In the United States, once an individual has been confirmed positive for COVID-19, he/she is expected to be either self-isolated or hospitalized. Therefore, we assigned the data on confirmed cases to the R compartment, and we fit the model to the cumulative number of confirmed cases.

The infection rate is determined as follows:

$$\beta = p \times c \qquad \textbf{(2)}$$

where p is the probability of being infected upon contact with an infectious individual, and c is the average number of contacts per day. We have no data that would allow us to estimate p and c separately; hence, we directly estimated β, as is usually performed when using SIR models.

The removal rate γ determines the rate at which infected individuals are moved from the I to the R compartments. In the context of the COVID-19 pandemic, γ is determined from the time taken for the appearance of severe symptoms, such that the individual can be tested and is self-quarantined or hospitalized, as required. Therefore, we assumed the duration of the infectious period as the average time taken for the infected

individual to be isolated, not the overall time for recovery. We assumed that an individual is infectious from the day he/she contracts the infection before symptom onset [18-20]. The average time to symptom onset is 5-6 days [21-23]. We assumed that the infectious period before the development of severe symptoms is 6 days; hence, $\gamma=1/6$.

Time-Variant Parameter Estimation

The aSIR model contains two parameters, β and γ, with $\gamma=1/6$ obtained from the literature, and β estimated from the reported data for each region of interest. The time-variant $\beta(t)$ was estimated using a sliding window of $\tau=7$ days and step of $s=1$ day, with the estimated values for S and I obtained from the previous window used as the initial conditions for the next window.

The reproduction number was calculated as follows:

$$R_t(t) = \beta(t)/\gamma \quad \textbf{(3)}$$

For the first window, we determined the date when the number of confirmed cases began to increase exponentially. This is important because for many states or counties, very few confirmed cases were initially reported for a number of days or even weeks, which suggests that either the epidemic had not started or the true number of infected individuals was unknown. It is not reasonable to apply an SIR model for this initial period. We considered the onset of the pandemic as the first of the 4 consecutive days in which the number of reported confirmed cases increased in at least 3 days. The initial conditions for system (1) for window 0 were as follows:

$$S_0(0) = N \quad \textbf{(4)}$$

where N is the population in the region of interest, $I_0(0)=1$, and $R_0(0)=0$. The infection rate β_i and $S(t)$, $I(t)$ for t $[0, \tau—1]$ were estimated from the initial conditions and actual R.

The window was slid by $s=1$ point. For the new $i+1$ window, the initial conditions were considered as the estimated values from the previous window $S_{i+1}(0)=S_i(s)$, $I_{i+1}(0)=I_i(s)$, and actual $R_{i+1}(0)=R(s)$. The actual values of $R(t)$ were used, and the infection rates β_{i+1} and $S_{i+1}(t)$, and $I_{i+1}(t)$ were estimated.

For each window, the $R_{t.i}$ was determined as follows:

$$R_{t.i} = \beta_i/\gamma \quad \textbf{(5)}$$

The $R_{t.i}$ was assigned to the last time point of the window. To obtain a smooth estimate of R_t, we used a rolling average of 5 points.

Results

We fit the model for each state and county in the United States. Model performance was evaluated by calculating the quality of fit as the root mean squared error between the actual and fitted R data for all windows concatenated (wRMSE). The fit was excellent with wRMSE<6 across all states. Furthermore, we calculated 1-day, 3-day, and 7-day forecasts of R after each window (Figure 1A). The mean absolute prediction error for the forecasts is provided in Table 1. The 1-day forecast error did not exceed 2.6% across all states, while the 7-day forecast error was large and approached 16.2% for New York. In particular, the 7-day forecast strongly overestimated the number of cases when R_t was rapidly decreasing (Figure 1).

Figure 1. (A) Estimated Infectious and forecast Removed. (B) Estimated reproduction number R_t. The shaded region indicates the dates of the lockdown. While the 1-day and 3-day forecasts are accurate, the 7-day forecast exhibits marked errors when R_t>1 and is rapidly decreasing.

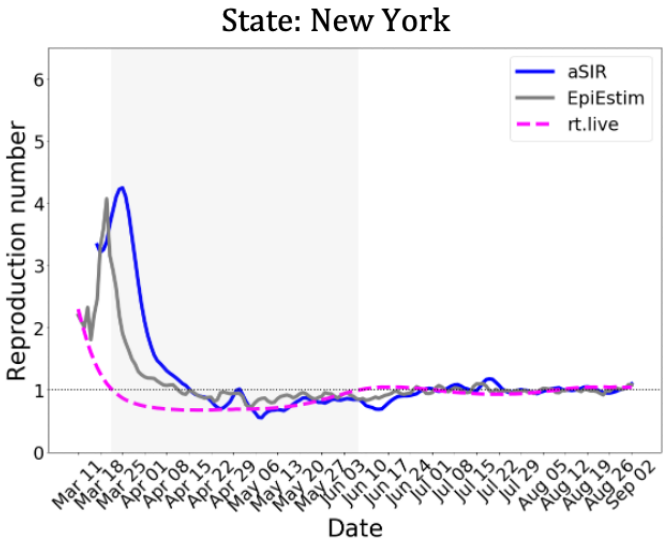
[a]R_t: reproduction number.

[b]MAPE: mean absolute prediction error.

The estimated time course of R_t for New York and Nassau county, one of the most affected counties since the beginning of the COVID-19 pandemic, are shown in Figure 1. The estimated daily number of infectious individuals rapidly increased and then gradually declined after the lockdown was implemented on March 22, 2020 (Figure 1A). The estimated R_t also declined upon implementation of the lockdown (Figure 1B). The time course of R_t exhibits weekly seasonality, which likely reflects the effect of social interactions and possibly the effect of fluctuations in case reporting on weekdays vs weekends. For New York and Nassau county, R_t initially increased, which may reflect the fact that the pandemic in New York was continuously seeded by travelers arriving at John F Kennedy International Airport until a ban on international travel was implemented on March 12, 2020. This may also reflect the fact that not all severe cases were initially recognized and reported as COVID-19 cases. In Florida, R_t decreased to almost 1 by mid-April but then began increasing at the end of May (Figure 1B). In June 2020, Florida authorities introduced more stringent measures to control the pandemic, which is reflected in the reduction in R_t in the second half of July 2020. The opening of multiple states since June 2020 has been accompanied by an increase in R_t beyond 1 (data not shown), and close monitoring of R_t is needed to contain another wave of the pandemic.

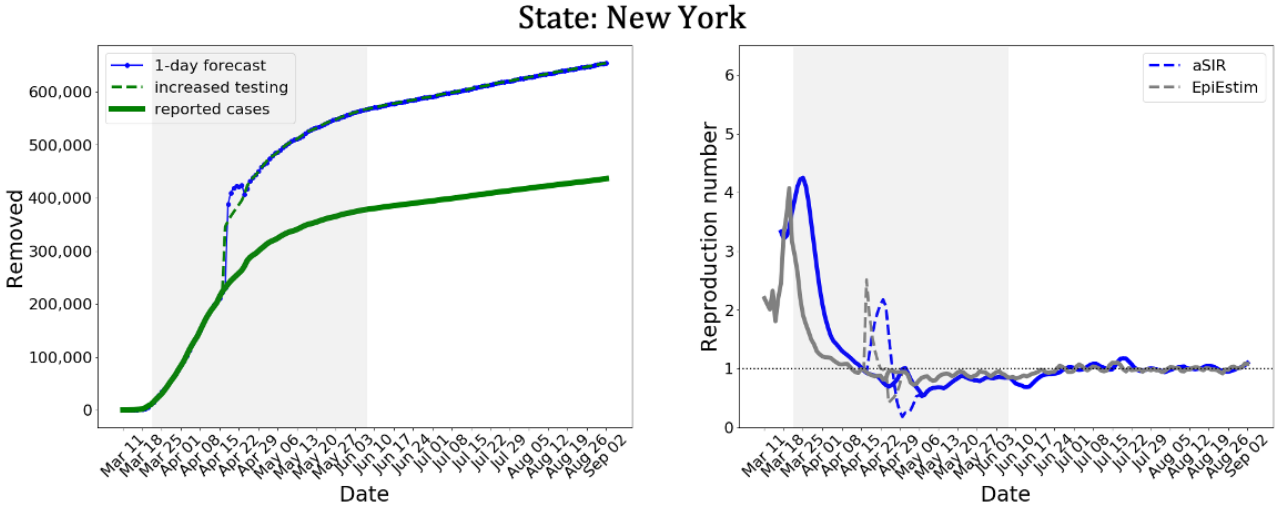
Next, we compared aSIR with the model developed by Cori et al [15], implemented as R package EpiEstim, and a model implemented by Systrom, Vladeck, and Krieger in rt.live [24] (Figure 2). In EpiEstim, we assumed an equal probability of infection within the infectious period of 6 days, the R_t estimate was smoothed with a 7-point rolling average window, same as that in aSIR. While all 3 models show similar estimates when R_t approaches 1, their estimates differ considerably in the beginning of the pandemic. In particular, the rt.live model [24] returned a lower maximum R_t than the other 2 models and estimated that R_t already decreased to 1 by the time the lockdown was announced in New York on March 22, 2020 (Figure 2, shaded region). The EpiEstim and aSIR models estimated similar peak values of R_t, and both models estimated that R_t decreased and approached 1 in the first week of April 2020. Although both models show a rapid reduction in R_t in March, the aSIR model shows a lagged change. However, we are not aware of the ground truth data to determine which model yields a more accurate estimate.

Figure 2. Comparison of models that generate continuous R_t estimates. The three R_t estimates differ widely in the beginning of the COVID-19 pandemic. In particular, the R_t estimated using the rt.live model of Systrom, Vladeck, and Krieger [24] decreased to 1 at the onset at the lockdown on March 22, 2020 (shaded region). aSIR: adaptive Susceptible-Infectious-Removed.



Finally, we investigated the effect of an abrupt increase in testing on the estimated R_t (Figure 3). We assumed a step-wise 50% increase in testing, which persisted after April 12, 2020 (Figure 3, left panel). Both aSIR and EpiEstim models exhibited a spike in R_t. However, an increase in testing would help identify and quarantine infectious individuals sooner, resulting in a shorter infectious period and larger removal rate γ, in turn decreasing R_t. We did not model a potential increase in γ. Instead, we assumed that the underlying dynamics of the pandemic did not change, and within 2 weeks both models returned to the R_t time course estimated without an increase in testing.

Figure 3. Effect of a step-wise 50% increase in testing (left panel, dashed line). The 1-day forecast by the aSIR model adapts within a week. For the Rt estimate, both EpiEstim and our aSIR models produced a spike, followed by a reduction (right panel, dashed lines) before returning to the unperturbed Rt time course (solid lines). aSIR: adaptive Susceptible-Infectious-Removed.



Discussion

Principal Findings

We developed a simple approach to adaptively estimate the time-varying parameters of the SIR model, using reported data on the number of confirmed COVID-19 cases. This approach adds to the already large literature on COVID-19 modeling in 2 ways. First, we estimate the parameters of the SIR model with a sliding window of a limited duration (7 days) to account for rapid changes in transmissibility and contact patterns in response to changes in social behavior and government mitigation measures. The window duration is a hyperparameter that can be changed as needed, the trade-off being the accuracy of the parameter estimates versus the rapid reaction to changes in the underlying pandemic. Because the proposed model is so simple, a number of scenarios can be explored as needed.

Second, we attribute the data on reported cases to the Removed compartment rather than the Infectious compartment. This modeling decision is based on the realities of the COVID-19 pandemic in the United States, where individuals with confirmed COVID-19 are supposed to self-isolate or be hospitalized. Although these individuals remain infectious and can infect

other family members or caregivers even when self-isolated or hospitalized, they would not freely interact with the susceptible population, as would be required to attribute them to the *I* compartment. The addition of a new X compartment in the SIR model has been proposed to model symptomatic quarantined infectious individuals [25]. However, we have no data to independently estimate this additional parameter of quarantine rate. For the same reason, we did not use the Susceptible-Exposed-Infected-Removed (SEIR) model because we are not aware of reliable data on the duration of the exposure period during which an infected person is not yet infectious. Moreover, it has been reported that the SIR model performed better than the SEIR model in representing the information contained in the confirmed-case data on COVID-19 [26].

The reported number of positive COVID-19 cases represents a fraction of infected individuals because of the limited testing capacity in March and April 2020; consequently, only those who developed severe symptoms were tested. Up to 80% of infected individuals may have been asymptomatic or may have experienced mild symptoms [27] and were not tested; hence, for that period, our model applies only to the small subpopulation with severe symptoms. However, this subpopulation is of particular interest because it represents those who are at the greatest risk, and R_t estimated from these limited data can be used to guide policy decisions aimed at protecting the most vulnerable population [28]. As the number of the tested individuals increases, the short sliding window approach makes our model adaptable to an increasing proportion of the population (Figure 3).

Across all US states, the maximal R_t values were estimated for New York (4.4) and Michigan (4.5) (Table 1), which is similar to the mean value of 4.34 estimated for Italy [29] but higher than that obtained with a stochastic transmission model [30,31]. The wide range of maximal values of R_t of 2.0-4.5 (Table 1) likely reflects the differences in contact rates owing to the population density [32,33]. Increased social distancing is required to contain the spread of the pandemic [34,35], with more stringent mitigation measures, including lockdown, considered necessary to decrease the contact rate in high-density states and counties. Another measure to decrease R_t is to increase the removal rate γ through intensive testing and quarantining of individuals who test positive. This targeted intervention would strongly decrease the interaction between infectious and susceptible individuals and maintain an R_t of <1 until a vaccine is available and while vaccination efforts are ramping up. Intensive testing combined with social distancing and mask wearing, followed by the isolation of individuals confirmed with COVID-19, are key features of reopening strategies for schools and universities [36-38]. Our model allows researchers and policymakers to monitor R_t in different geographic regions of the United States, better understand the effect of government policies on the dynamics of the pandemic, and develop further mitigation strategies as we continue to battle COVID-19 [39,40].

Limitations

The SIR model is perhaps the simplest model that captures the dynamics of a pandemic. It is based on several assumptions that are valid only to some degree as we consider real-life scenarios. The 2 main limitations of the original SIR model are that it has constant parameters and it is deterministic. Our proposed aSIR model allows us to estimate time-varying parameters and thus removes the first limitation. The other limitation remains, however. It is assumed that infectious individuals freely interact with the susceptible population. The infection rate β encompasses both the probability of transmission and the average number of contacts per day. The SIR model does not reflect interaction dynamics that are stochastic in nature and are described by stochastic epidemiologic models [15-17,41]. In its simplest form, the SIR model does not reflect the heterogeneity of viral transmission reflected in overdispersion or superspreading where few numbers of infected individuals infect a large number of susceptible individuals [42-44]. The removal rate γ is an average number of days until an infectious individual is excluded and does not reflect the variability of this interval, nor does it allow one to model a possibility of a subsequent, albeit reduced transmission to caregivers or other susceptible individuals as may happen in a real-life scenario. Consequently, R_t, which is calculated using constants β and γ rather than their distributions, does not reflect the stochastic nature of the dynamics of the pandemic. Parameter distributions can be obtained by applying Bayesian methods to SIR modeling [45]. Moreover, a single value of R_t estimated for a large population does not reflect differences in subpopulations, such as age groups, which is especially relevant for COVID-19 [46-48]. The generation of a bank of aSIR models for each subpopulation or region can provide a more realistic insight into the dynamics of the pandemic across a larger population [49,50]. Another critical assumption is that once an individual is infected and recovers, he/she is no longer susceptible to repeated infection; however, this assumption does not appear strongly violated. Although some cases of repeated infection with SARS-CoV-2 have been reported [51-53], the risk of re-infection is considered low [54,55]. Overall, the SIR model is a trade-off between the computational simplicity and veracity of describing the real-life complexities of a pandemic.

Conclusions

SIR type models, particularly the proposed time-variant aSIR model, have an advantage over more complex models in the initial stages of a pandemic when critical public policy decisions need to be made while the empirical data on interaction dynamics, transmission rates, and the disease progression and contagiousness from the moment of infection are not yet readily available. Our model provides a simple and efficient method to assess the efficacy of interventions as the pandemic progresses.

Abstract

Background: Controlling the COVID-19 outbreak in Brazil is a challenge due to the population's size and urban density, inefficient maintenance of social distancing and testing strategies, and limited availability of testing resources.

Objective: The purpose of this study is to effectively prioritize patients who are symptomatic for testing to assist early COVID-19 detection in Brazil, addressing problems related to inefficient testing and control strategies.

Methods: Raw data from 55,676 Brazilians were preprocessed, and the chi-square test was used to confirm the relevance of the following features: *gender*, *health professional*, *fever*, *sore throat*, *dyspnea*, *olfactory disorders*, *cough*, *coryza*, *taste disorders*, and *headache*. Classification models were implemented relying on preprocessed data sets; supervised learning; and the algorithms multilayer perceptron (MLP), gradient boosting machine (GBM), decision tree (DT), random forest (RF), extreme gradient boosting (XGBoost), k-nearest neighbors (KNN), support vector machine (SVM), and logistic regression (LR). The models' performances were analyzed using 10-fold cross-validation, classification metrics, and the Friedman and Nemenyi statistical tests. The permutation feature importance method was applied for ranking the features used by the classification models with the highest performances.

Results: *Gender*, *fever*, and *dyspnea* were among the highest-ranked features used by the classification models. The comparative analysis presents MLP, GBM, DT, RF, XGBoost, and SVM as the highest performance models with similar results. KNN and LR were outperformed by the other algorithms. Applying the easy interpretability as an additional comparison criterion, the DT was considered the most suitable model.

Conclusions: The DT classification model can effectively (with a mean accuracy≥89.12%) assist COVID-19 test prioritization in Brazil. The model can be applied to recommend the prioritizing of a patient who is symptomatic for COVID-19 testing.

Introduction

Overview

In modern medical systems, health care professionals, managers, and governments use information and data analysis to make decisions [1]. Data is stored, enabling rapid access and sharing during the diagnosis, monitoring, and treatment of patients. Therefore, there are propositions of eHealth and mobile health (mHealth) systems to assist health care professionals and policy makers with decision making [2,3]. Such systems are relevant to provide decision support advice based on patients' data,

helping health care professionals and policy makers address problems related to inefficient COVID-19 testing and control strategies (eg, limited testing resources) in low- and middle–income countries [4]. For example, people who live in low- and middle–income settings, remote settings, and hard-to-reach settings are the most affected by precarious health care. Such a situation is even more critical in a pandemic scenario.

COVID-19 is a disease caused by SARS-CoV-2 [5]. In December 2019, the first cases of COVID-19 appeared in Wuhan, Hubei Province, China [6]. Due to the high growth of COVID-19 confirmed cases worldwide, on January 30, 2020, the World Health Organization considered the COVID-19 outbreak a Public Health Emergency of International Concern [7].

Motivation and Problem Statement

As the number of COVID-19 confirmed cases continuously increases, health care professionals and policy makers need to define guidelines to prevent the disease, delaying the transmission rates. Such guidelines are relevant due to the high probability of collapse in health services and shortages of medical supplies (eg, testing resources) [8]. Confirmation of the first COVID-19 case in Brazil was in March 2020, and since then, there has been an upward trend in confirmed cases and deaths. Unfortunately, the Brazilian government has reported more than 13 million cases, with more than 333,000 deaths. Currently, Brazil is one of the most affected countries by COVID-19, with insufficient control measure implementation. Controlling the COVID-19 outbreak in Brazil is a challenge of continental proportions due to the population's size and urban density, inefficient maintenance of social distancing and testing strategies, and limited availability of testing resources [9].

This study addresses the COVID-19 testing prioritization for patients who are symptomatic to assist early COVID-19 detection in Brazil. Addressing this problem is relevant due to the need for prioritization guidelines to improve testing and control strategies' efficiency. Therefore, the main research question (RQ) is can demographic characteristics and symptoms that do not require expensive exams effectively assist the test prioritization for early COVID-19 detection in Brazil? From the main RQ, the four secondary RQs are (1) what demographic characteristics are relevant to conduct the test prioritization? (2) what symptoms are suitable to drive the test prioritization? (3) what is the most suitable classification model for test prioritization? and (4) what are the impacts of the reduction of reported symptoms in the test prioritization?

Aim of the Study

The study relied on preprocessing a raw data set with information on 55,676 patients, aiming to provide a classification model that effectively recommends or not the prioritization of patients who are symptomatic for COVID-19 testing (ie, a binary classification problem). The implementation of classification models also relied on supervised learning and the algorithms multilayer perceptron (MLP), gradient boosting machine (GBM), decision tree (DT), random forest (RF), extreme gradient boosting (XGBoost), k-nearest neighbors (KNN), support vector machine (SVM), and logistic regression (LR). The algorithms were trained and tested using preprocessed data sets composed of demographic characteristics and reported symptoms that do not require expensive exams [10]. Use of such symptoms is a relevant strategy for COVID-19 test prioritization due to the majority of the Brazilian population's high poverty levels [11].

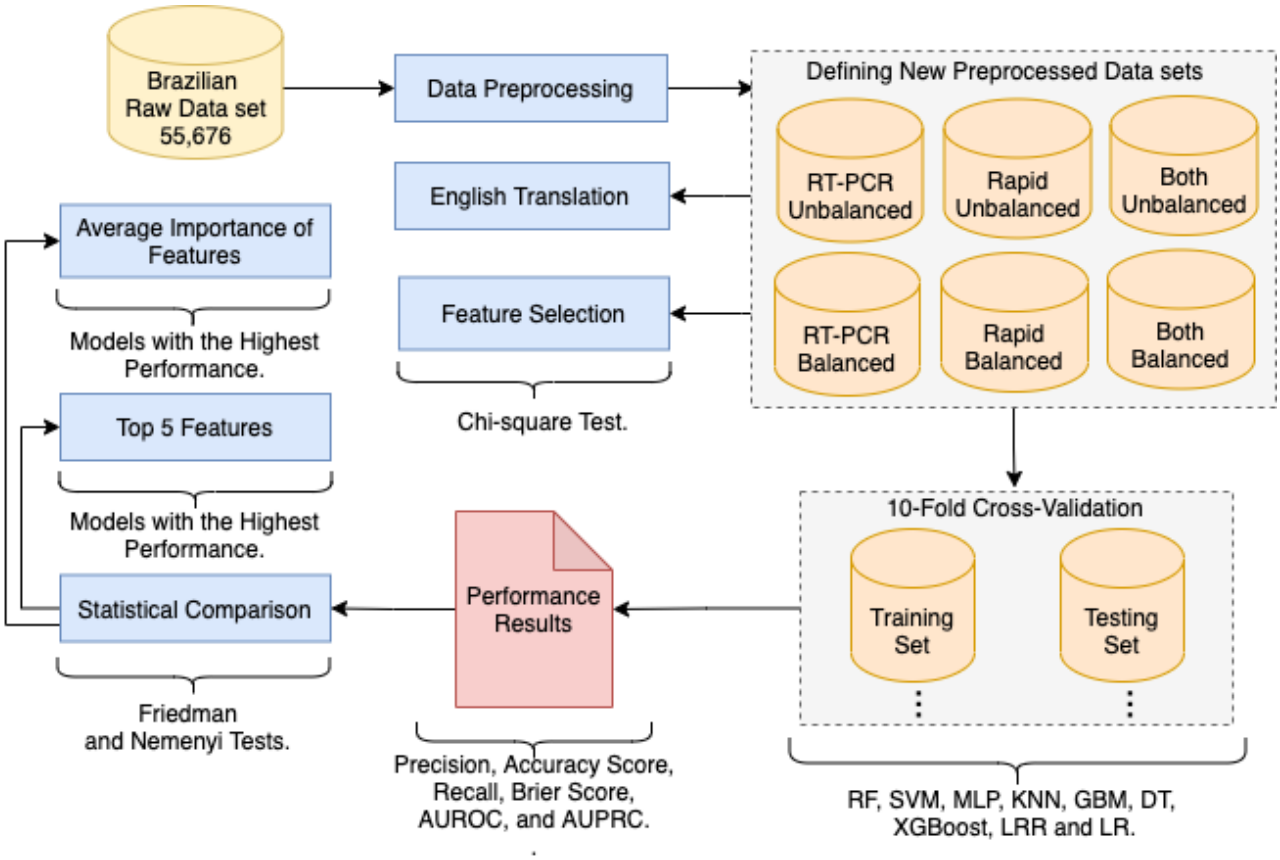
Our findings also provide insights for developers of eHealth and mHealth systems when choosing the most suitable classification model for COVID-19 testing prioritization. Such insights are also relevant for health care professionals and policy makers who envision applying a classification model to prioritize patients who are symptomatic for testing. The study enhances the state of the art by providing three main contributions: (1) the preprocessing of raw data from 55,676 Brazilians, with the availability of data related to patients who are symptomatic [10]; (2) the implementation of classification models, along with reports of feature ranking, to support COVID-19 test prioritization [12]; and (3) a comparative analysis of the classification models.

Methods

Overview

This study's research methodology consists of data preprocessing, the definition of new data sets, English translation, feature selection, 10-fold cross-validation, statistical comparisons, and feature ranking (Figure 1). The raw data from 55,676 Brazilians were preprocessed to define new data sets with information about patients who are symptomatic tested for COVID-19 using reverse transcriptase polymerase chain reaction (RT-PCR) and rapid tests (antibody and antigen). The textual descriptions of six preprocessed data sets (ie, *RT-PCR unbalanced*, *RT-PCR balanced*, *rapid unbalanced*, *rapid balanced*, *both unbalanced*, and *both balanced*) were translated from Portuguese into English for public data availability. The chi-square test was applied in the new data sets to support the feature selection with a $P<.01$, verifying the relevance of features for the classification task by dependence and independence relations [13]. The chi-square test for independence compared two variables in a contingency table to verify if they relate to each other.

Figure 1. Overview of the research methodology applied for the study. The methodological steps consist of data preprocessing, the definition of new data sets, English translation, feature selection, 10-fold cross-validation, statistical comparisons, and feature ranking. AUPR: area under the precision-recall curve; AUROC: area under the receiver operating characteristic curve; DT: decision tree; GBM: gradient boosting machine; KNN: k-nearest neighbors; LR: logistic regression (weak regularization); LRR: logistic regression (strong regularization); MLP: multilayer perceptron; RF: random forest; RT-PCR: reverse transcription polymerase chain reaction; SVM: support vector machine; XGBoost: extreme gradient boosting.



We applied the 10-fold cross-validation method, with five repetitions, to validate the MLP, GBM, DT, RF, XGBoost, KNN, SVM, and LR (weak/strong regularization) classification models using the six data sets. We selected such algorithms because they have different characteristics such as using neural layers, tree combinations, and calculating the distance between data. The mean results for classification metrics were also calculated: precision, accuracy score, recall, Brier Score, area under the receiver operating characteristic curve (AUROC), and area under the precision-recall curve (AUPRC). The recall results were further analyzed using the Friedman and Nemenyi statistical tests to improve the classification models' comparisons. We used the Friedman test to verify the differences between classification models. We applied the Nemenyi test to group classification models based on the verification of differences using multiple comparisons. Finally, we conducted features' ranking for each classification model with the highest performance using the permutation feature importance method, providing average importance and SD. The source code for replication is available in a GitHub repository [12].

Data Collection

The raw data from 55,676 Brazilians included information on tested patients in a spreadsheet format. However, the data collection is not a contribution of this study. The raw data was collected by the public health agency of the city of Campina Grande, Paraíba State in Northeast Brazil. Such a public agency is informed by all the COVID-19 exams performed in the city of Campina Grande. The health agency employees removed patient identification, and the data made available were reused to enable this study. The raw data set comprises categorical features such as *health professional*, *security professional*, *ethnicity*, *test type*, *fever*, *sore throat*, *dyspnea*, *olfactory disorders*, *cough*, *coryza*, *taste disorders*, *headache*, *additional symptoms*, *test result*, *comorbidities*, *test status*, and *symptoms description*.

Data Preprocessing

We conducted the data preprocessing using the Python programming language. The raw data set was preprocessed by applying string matching algorithms to correct inconsistencies. One example of inconsistency was the occurrence of empty columns of symptoms; however, the same symptoms were in a column for the general description of symptoms.

Furthermore, the following instances from the total 55,676 sample were removed due to our exclusion criteria: patients with uncompleted tests or undefined final classifications (n=12,929, 23.22%), duplicated instances (n=251, 0.45%), outliers related to input errors (n=10,408, 18.69%), test types that are not RT-PCR or rapid (n=771, 1.38%), undefined gender (n=27, 0.05%), and patients who were asymptomatic (n=11,269, 20.24%). Patients who were asymptomatic were removed because the inputs for the algorithms rely on demographic characteristics and symptoms.

Removing the feature related to the symptoms' descriptions provides dimensionality reduction in the raw data set feature space. For example, fatigue was removed because the symptom was reported by 228 (0.41%) of the 55,676 patients. Given the main focus on symptoms, the data sets did not include comorbidities and the remaining features (eg, *ethnicity*). As inclusion criteria, the most frequently reported symptoms (ie, fever, sore throat, dyspnea, olfactory disorders, cough, coryza, taste disorders, and headache) and relevant demographic characteristics (ie, gender and health professional) were selected as features of unbalanced and balanced data sets (Table 1). Health care professionals were considered relevant due to the frequency of exposure to SARS-CoV-2. However, for gender, there is no consensus if there is a difference in the proportions of males and females infected with SARS-CoV-2 (usually a relatively even distribution) [14,15].

Table 1. Demographic and symptoms from patients who are symptomatic of both test type data sets.

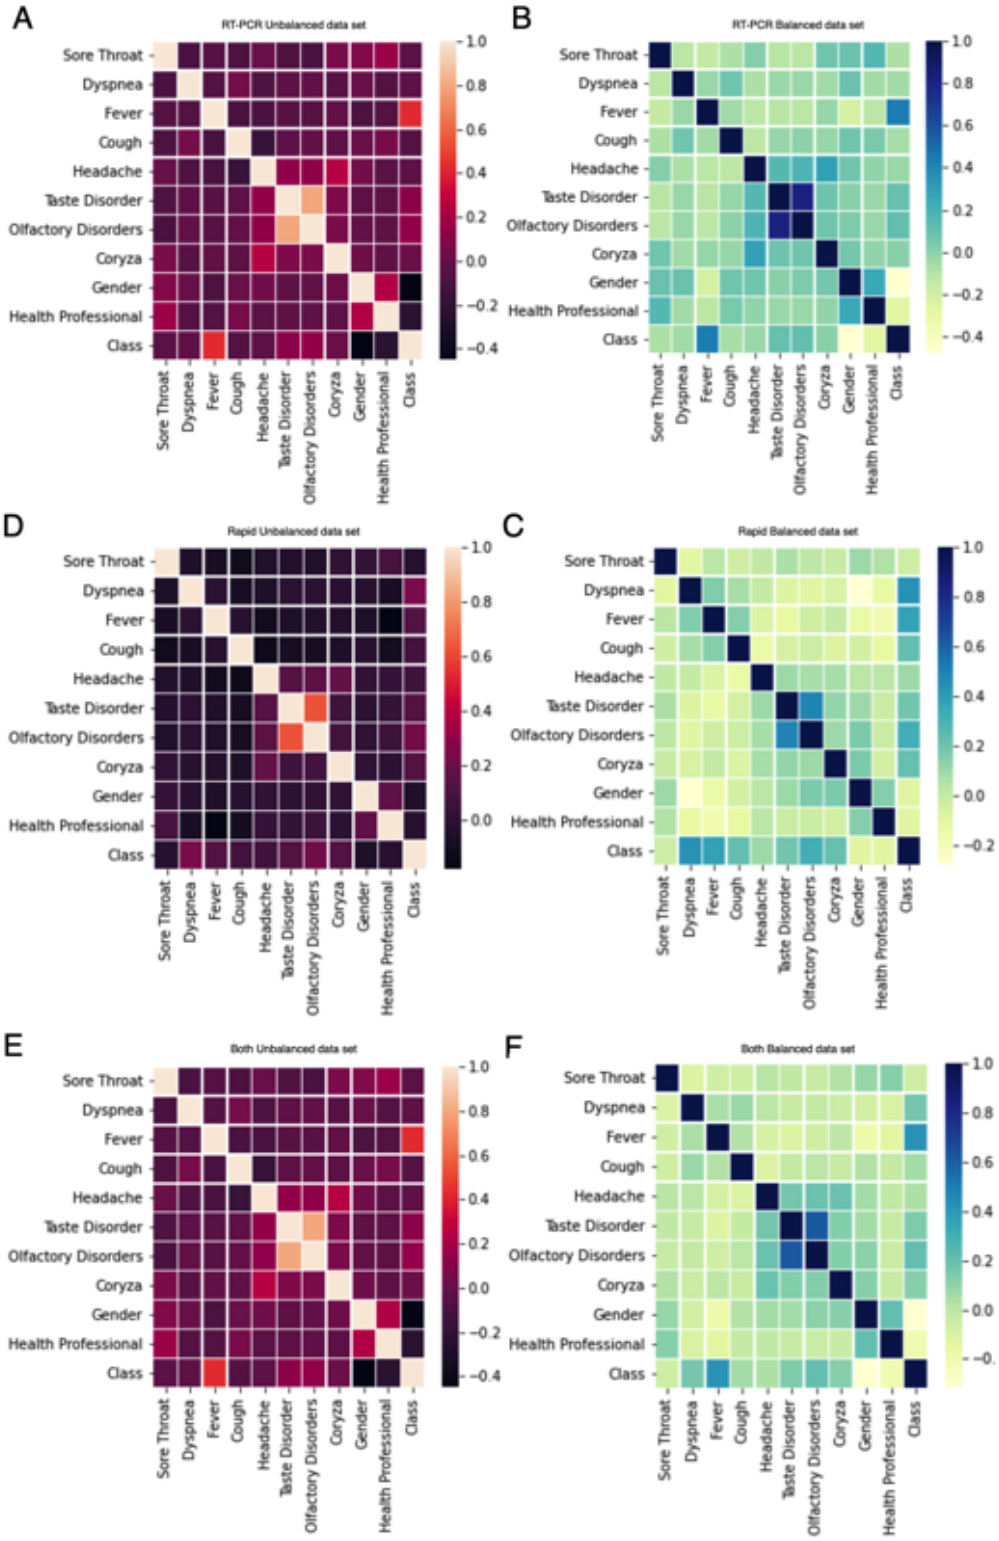
Features	Unbalanced (n=20,021)	Balanced (n=3128)
Demographic characteristics		
Gender: male, n (%)	8919 (44.55)	1639 (52.40)
Health professional, n (%)	2485 (12.41)	475 (15.19)
Symptoms		
Fever, n (%)	9169 (45.80)	1856 (59.34)
Sore throat, n (%)	5976 (29.85)	848 (27.11)
Dyspnea, n (%)	3704 (18.50)	1082 (34.59)
Olfactory disorders, n (%)	1967 (9.82)	522 (16.69)
Cough, n (%)	11,641 (58.14)	1944 (62.15)
Coryza, n (%)	1159 (5.79)	266 (8.50)
Taste disorders, n (%)	1596 (12.37)	387 (12.37)
Headache, n (%)	4034 (20.15)	577 (18.45)

The categorical data were converted into binary representations during the preprocessing. For the feature *gender*, the number 0 represents a female patient, and 1 represents a male. For the features *health professional*, *fever*, *sore throat*, *dyspnea*, *olfactory disorders*, *cough*, *coryza*, *taste disorders*, and *headache*, the number 0 represents a positive response, and 1 represents a negative response. For each data set, the *test result* was the class that can be labeled as 0 for recommending a patient who is symptomatic for COVID-19 test prioritization or 1 for not recommending such patient's prioritization.

The preprocessing included undersampling using the near-miss technique [16], considering COVID-19 positive and negative cases. Undersampling was applied instead of oversampling to prevent the use of synthetic data in training and testing sets. However, as stated, unbalanced data were also considered, without undersampling, to improve the experiments' representativity and to achieve a scenario closer to a real-world setting, with more negative than positive COVID-19 cases.

Using the chi-square test for the *both unbalanced* and *both balanced* data sets, the independence hypothesis was only confirmed for *headache*. For the *RT-PCR unbalanced* data set, the independence hypothesis was confirmed for *sore throat*, *dyspnea*, *headache*, and *coryza*. In the *rapid unbalanced* data set, the independence hypothesis was confirmed for *sore throat* and *health professionals* features. For the *RT-PCR balanced* data set, the independence hypothesis was confirmed for *dyspnea*, *cough*, *headache*, and *coryza*; while for the *rapid balanced* data set, the hypothesis was only confirmed for *sore throat*. Such information was used for feature selection during the experiments, presenting scenarios with different numbers of symptoms to implement classification models. Furthermore, we used a correlation matrix to analyze the correlation coefficients between the features for each data set (Figure 2). For example, *fever* was among the features with the highest correlation coefficients for all data sets.

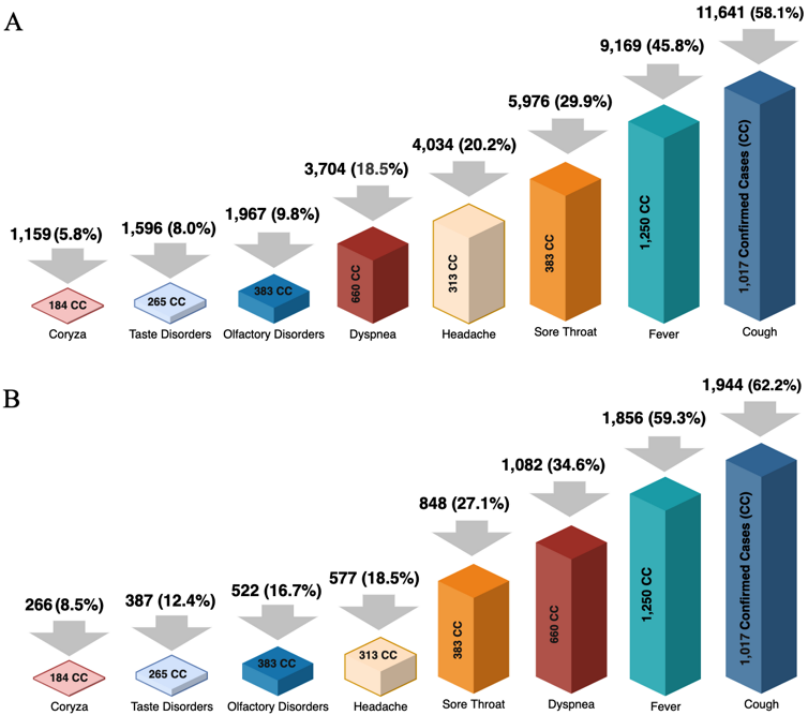
Figure 2. Correlation matrix for (A) RT-PCR unbalanced data set, (B) RT-PCR balanced data set, (C) rapid unbalanced data set, (D) rapid balanced data set, (E) both unbalanced data set, and (F) both balanced data set. RT-PCR: reverse transcription polymerase chain reaction.



The *both unbalanced* data set was composed of 20,021 patients tested by both RT-PCR and rapid tests. The reduction in the number of patients occurred due to the uncompleted tests, duplicated instances, outliers related to input errors, test type, and patients who were asymptomatic. The *both unbalanced* data set contained 1564 (7.81%) positive and 18,457 (92.19%) negative COVID-19 cases, while the balanced one included 1564 cases of each class. From the female patients, 496 (2.48%) were positive and 10,606 (52.97%) were negative cases. For male patients, 1068 (5.33%) were positive and 7851 (39.21%) were negative cases. Cough was the most frequent symptom (n=11,641, 58.1%). Fever was the second most common symptom (n=9169, 45.8%). The remaining symptoms were reported by at most 5976 (29.9%) patients who were symptomatic (Figure 3A).

The *both balanced* data set contained 3128 patients tested by RT-PCR and rapid tests. The near-miss technique reduced the number of negative cases to be equal to positive cases; 496 (15.86%) were positive and 993 (31.75%) were negative cases from the female patients. For males, 1068 (34.14%) were positive and 571 (18.25%) were negative cases. Cough and fever continued to be the first and second most frequently reported symptoms, respectively. The remaining symptoms were also reported by at most 1082 (34.6%) patients (Figure 3B).

Figure 3. (A) The frequency of symptoms for the 20,021 patients who were symptomatic of the both unbalanced data set and the number of CCs. Top values are frequencies; numbers on the geometric forms are the CC for frequency. (B) The frequency of symptoms for the 3128 patients who were symptomatic of the both balanced data set and the number of CCs.



Finally, the *RT-PCR unbalanced* data set included 916 (32.96%) positive and 1863 (67.04%) negative COVID-19 cases, while the balanced one included 916 cases of each class. The *rapid unbalanced* data set included 648 (3.76%) positive and 16,594 (96.24%) negative COVID-19 cases, while the balanced one included 648 of each class. The six scenarios' presentations aim to compare the classification models' results using various test types. Thus, there was no requirement to implement different clinical protocols or select patients with specific profiles for testing based on the results related to the six scenarios presented in this paper.

Algorithms

We implemented the classification models using supervised learning and the MLP, GBM, DT, RF, XGBoost, KNN, SVM, and LR algorithms. An MLP machine learning (ML) algorithm [17] of one hidden layer learns the function:

where W_1 represents the weights of the input layer, W_2 represents the hidden layer, b_1 is the bias added to the hidden layer, b_2 is the output layer, and g is the activation function.

The GBM is a fixed-size DT that uses a boosting strategy [18]. This ML algorithm has a built-in feature selection and aims to provide the estimation or approximation  or the function $F^*(x)$ that maps x to y, minimizing the expected value using a loss function $L(y, F(x))$ over the joint distribution [19], given by:

$$F^* = arg\ min_F E_{y,x} L(y,F(x)) = arg\ min_F E_x [E_y (y,F(x)) \mid x] \quad \textbf{(2)}$$

A DT is an ML algorithm that usually uses a divide and conquer strategy to generate a directed acyclic graph by applying division rules based on information gain [20]. The algorithm has a built-in feature selection, and the information gain is guided by the concept of entropy H, which measures the randomness of a discrete random variable A (with domain $a_1, a_2, ..., a_n$), given by:

where p_i is the probability of observing each value $a_1, a_2, ..., a_n$. This algorithm enables a straightforward interpretation of results by following the decision rules of a unique tree.

The RF is an ML algorithm that relies on classification and regression trees, following specific tree growing rules, tree combination, self-testing, and postprocessing [21]. The algorithm has a built-in feature selection, assessed by the Gini impurity criterion index. The binary split of a node n is given by:

where p_j is the relative frequency of class j. This algorithm also enables a straightforward interpretation of results by following the decision rules of the trees.

As a variant of the GBM, the XGBoost is a regression tree with the same decision rules as a DT [22]. If the XGBoost ML algorithm consists of K DTs, the optimization objective function is given by:

where f_k is an independent tree with leaf scores, and F is the space of a regression tree. Both algorithms enable a straightforward interpretation of results.

The KNN is a distance-based ML algorithm that identifies a new instance based on a neighbor's distance [23]. An instance represents a point in the space, and the algorithm calculates the distance between two points using a metric such as the Euclidean distance, given by:

where x_i and x_j are vectors representing objects in the space, and  and  are the *l-th* elements of the vectors.

The SVM is a ML algorithm that handles binary data using a line to achieve the maximum distance between the data. The algorithm comprises four basic concepts: separation hyperplane, maximum margin hyperplane, soft margin, and kernel function [17]. For instance, the maximization of the margin hyperplane is given by:

where y_i are the output variables, x_i are input vectors, b is the bias, K is a dot products function (Kernel), and α_i is calculated by the maximization of:

where x_j are the named support vectors when α_i is greater than 0.

Finally, the LR is an extension of linear regression that estimates relations between variables using a sigmoid function during probabilistic classifications [24], given by:

where z is the weighted sum of the evidence of a class. Regularization can also be used to prevent overfitting. We applied the LR algorithm to compare a compact and linear model's performance with the previous ML approaches.

We used the Python programming language and the SciPy library [25] to implement and validate the classification models based on such algorithms. We applied the random search method to configure the algorithms' hyperparameters to improve performance carefully. The configurations can be verified in the GitHub repository [12].

Classification Metrics

We calculated the precision, accuracy score, recall, Brier Score, AUROC, and AUPRC for the classification models [26]. The precision represents the proportion of classifications that are true positives and is given by:

where TP is the true positives and FP is the false positives. The accuracy score presents fractions of correct classifications and is given by:

where A is the accuracy score,  is the classified value of a sample, y_i is the corresponding true value, n is the number of samples, and $I(x)$ is the indicator function.

The recall calculates the actual positives that are correctly positives and is given by:

where FN is the number of false negatives. It is relevant for evaluating classifications related to diagnosis due to the highly undesired impacts of false negatives.

The Brier Score provides the mean squared difference between predicted probabilities and expected results, given by:

where f_t is the predicted value, o_t is the expected value, and n is the number of samples.

Finally, the AUROC provides an overview of the diagnostic abilities of the models. However, the use of the AUPRC is usually recommended when handling problems using unbalanced data.

Results

The implementations of classification models using the MLP, GBM, DT, RF, XGBoost, KNN, SVM, and LR algorithms are available in the GitHub repository [12]. Using 10-fold cross-validation with five repetitions, the mean values of precision, accuracy score, recall, and Brier Score of the DT-based classification models were among the best results (Table 2). Such models presented similar results using the six data sets. For the *RT-PCR unbalanced/balanced* and *both unbalanced/balanced* data sets, the LR algorithm was outperformed by the other models. In the results, LR and LRR stand for models with weak and strong regularization, respectively.

Table 2. Results of 10-fold cross-validation for the classification models using the unbalanced and balanced data sets.

Data sets and models	Precision (%)	Accuracy score (%)	Recall (%)	Brier Score
RT-PCR[a] unbalanced and balanced				
MLP[b], unbalanced (balanced)	97.33 (95.86)	96.24 (95.81)	97.08 (95.80)	0.04 (0.04)
GBM[c], unbalanced (balanced)	97.32 (95.95)	96.30 (95.70)	97.17 (95.47)	0.04 (0.04)
RF[d], unbalanced (balanced)	97.42 (96.06)	96.55 (96.00)	97.46 (95.97)	0.04 (0.04)
DT[e], unbalanced (balanced)	97.49 (96.50)	96.33 (95.91)	97.04 (95.32)	0.04 (0.04)
XGBoost[f], unbalanced (balanced)	97.36 (95.94)	96.30 (95.52)	97.13 (95.10)	0.04 (0.04)
KNN[g], unbalanced (balanced)	97.38 (95.92)	96.55 (95.48)	97.50 (95.04)	0.03 (0.05)
SVM[h], unbalanced (balanced)	97.17 (95.84)	96.19 (95.58)	97.18 (95.34)	0.04 (0.04)
LRR[i], unbalanced (balanced)	86.97 (76.86)	86.72 (81.70)	94.37 (90.93)	0.13 (0.18)

[a]RT-PCR: reverse transcription polymerase chain reaction.

[b]MLP: multilayer perceptron.

[c]GBM: gradient boosting machine.

[d]RF: random forest.

[e]DT: decision tree.

[f]XGBoost: extreme gradient boosting.

[g]KNN: k-nearest neighbors.

[h]SVM: support vector machine.

[i]LRR: logistic regression (strong regularization).

[j]LR: logistic regression (weak regularization).

When removing features according to the chi-square results, there was a considerable decrease in the classification models' performances (Multimedia Appendix 1). However, in general, the classification models continued presenting good

performances. For example, the KNN classification model presented the lowest accuracy score (77.42%) using the *RT-PCR balanced* data set. The remaining classification models, considering all data sets, presented accuracy scores between 80.15% and 97.58%. Depending on the preprocessed data set, the LR (weak/strong regularization) continued to be outperformed by the other algorithms. Presenting such scenarios is relevant to analyze how the algorithms behave when models are implemented with reduced reported symptoms.

In addition, by computing the AUROC using the RT-PCR, rapid, and both test scenarios, the trade-offs between sensitivity (true-positive rate) and probability (false-positive rate) were identified, evidencing the diagnostic abilities of the classification models when the discrimination threshold is varied (Figure 4). The classification models presented high discriminatory power for all scenarios, with the curves closer to each graphic representation's upper left corner. However, for such scenarios, the KNN and SVM classification models presented the lowest discriminatory power.

Given the three unbalanced data sets, there were more negative than positive COVID-19 cases. We computed the AUPRC to verify the classification models when handling the minority class, analyzing the trade-off between precision and recall for different decision thresholds (Figure 5). The AUPRC was summarized using the average precision (AP), as a weighted mean of precision. The *RT-PCR unbalanced* data set was mildly unbalanced, with a baseline AUPRC of 0.33. The *rapid unbalanced* data set was highly unbalanced, with a baseline AUPRC of 0.04. This was also the case for the *both unbalanced* data set, with a baseline AUPRC of 0.08. The DT and XGBoost achieved the best AP value (65%) using the *RT-PCR unbalanced* data set. For the remaining scenarios, the classification models presented AP values between 80% and 96%.

We also applied the Friedman and Nemenyi tests to improve confidence in evaluating the classification models, observing that the experiments' results were statistically significant. The classification models were compared over the 6 data sets using the Friedman test [27]. This comparison focused on the recall results due to the highly undesired impacts of false negatives in the COVID-19 application scenario (Figure 6). The null hypothesis was that all classification models are equivalent and have equal mean ranks. The tests resulted in a $P<.001$ for the *RT-PCR unbalanced* (t=307.16), *RT-PCR balanced* (t=328.72), *rapid unbalanced* (t=247.43), *rapid balanced* (t=239.20), *both unbalanced* (t=226.98), and *both balanced* (t=343.10) data sets. The results showed that the difference between the mean recall values was probably real ($P\leq.1$). The Friedman test ranked the classification models for each data set, resulting in an average rank for each classification model.

Based on the Friedman test results, the Nemenyi test [27] was applied to compare the classification models using the mean ranks. The critical difference (CD) between the classification models was verified using the Nemenyi test, with α=0.1. The CD is relevant to highlight if the classification models are separated by an interval less than the CD, meaning that the classification models were statistically indistinguishable. Thus, for most of the data sets, the difference between LRR/LR (statistically indistinguishable) and the other classification models was highlighted by the CD using the mean recall results (Multimedia Appendix 2). Depending on the data set, MLP and GBM were also statistically indistinguishable, as was the case of DT, RF, XGBoost, KNN, and SVM.

From the classification metrics results and the Friedman and Nemenyi tests (Figure 6), the top five features of the classification models with the highest performances (ie, MLP, GBM, DT, RF, XGBoost, and SVM) were ranked using the permutation feature importance method. Each average importance and SD values were presented for the DT-based classification models and the RT-PCR, rapid, and both types scenarios (Table 3). The average importance and SD information relate to reducing the feature importance when a feature is not considered. For example, according to the frequency of symptoms and the number of confirmed cases (Figure 3), *fever* showed higher average importance values for almost all scenarios than other reported symptoms. We also applied the permutation feature importance method for the unbalanced data sets (Multimedia Appendix 3).

We also present the results achieved using the permutation feature importance method for detailing the feature ranking for classifications with MLP and SVM models (Table 4). For example, similar to the DT-based classification models, *fever* presented higher average importance values for almost all test scenarios than other symptoms reported by patients. For such algorithms, we also present the average importance and SD for the unbalanced data sets (Multimedia Appendix 3).

Therefore, the top five most significant features vary depending on the algorithm used to implement the classification model (Table 5). For the *RT-PCR balanced* data set, all algorithms prioritized the same top two features (ie, *fever* and *gender*), slightly differing in the top three and top five, while, for the *rapid balanced* data set, all algorithms prioritized the same top two features (ie, *dyspnea* and *olfactory disorders*), also slightly different in the top three, top four, and top five. For the *both balanced* data set, the algorithms prioritized the top two features similar to the classifications with the *RT-PCR balanced* data set. We also applied the permutation feature importance method to rank features using the unbalanced data sets (Multimedia Appendix 3).

In addition, to improve the experiments conducted to assist the COVID-19 test prioritization, we combined the classification models to define voting ensemble models using the majority voting strategy (Multimedia Appendix 4). Two combinations of classification models were considered for each data set: DT-based models (ie, GBM, DT, RF, and XGBoost) and non-DT models (ie, MLP, SVM, KNN, LRR, and LR). In general, for the voting ensemble models implemented with the six data sets, the mean results of classification metrics using 10-fold cross-validation were similar to those of the MLP, GBM, DT, RF, XGBoost, KNN, SVM, LRR, and LR models (Table 2).

Figure 4. The models' ROC curves with (A) RT-PCR unbalanced, (B) RT-PCR balanced, (C) rapid unbalanced, (D) rapid balanced, (E) both unbalanced, and (F) both balanced. AUC: area under the receiver operating characteristic curve; GBM: gradient boosting machine; KNN: k-nearest neighbors; LR: logistic regression (weak regularization); LRR: logistic regression (strong regularization); Mlp: multilayer perceptron; ROC: receiver operating characteristic; RT-PCR: reverse transcription polymerase chain reaction; SVM: support vector machine; XGBoost: extreme gradient boosting.

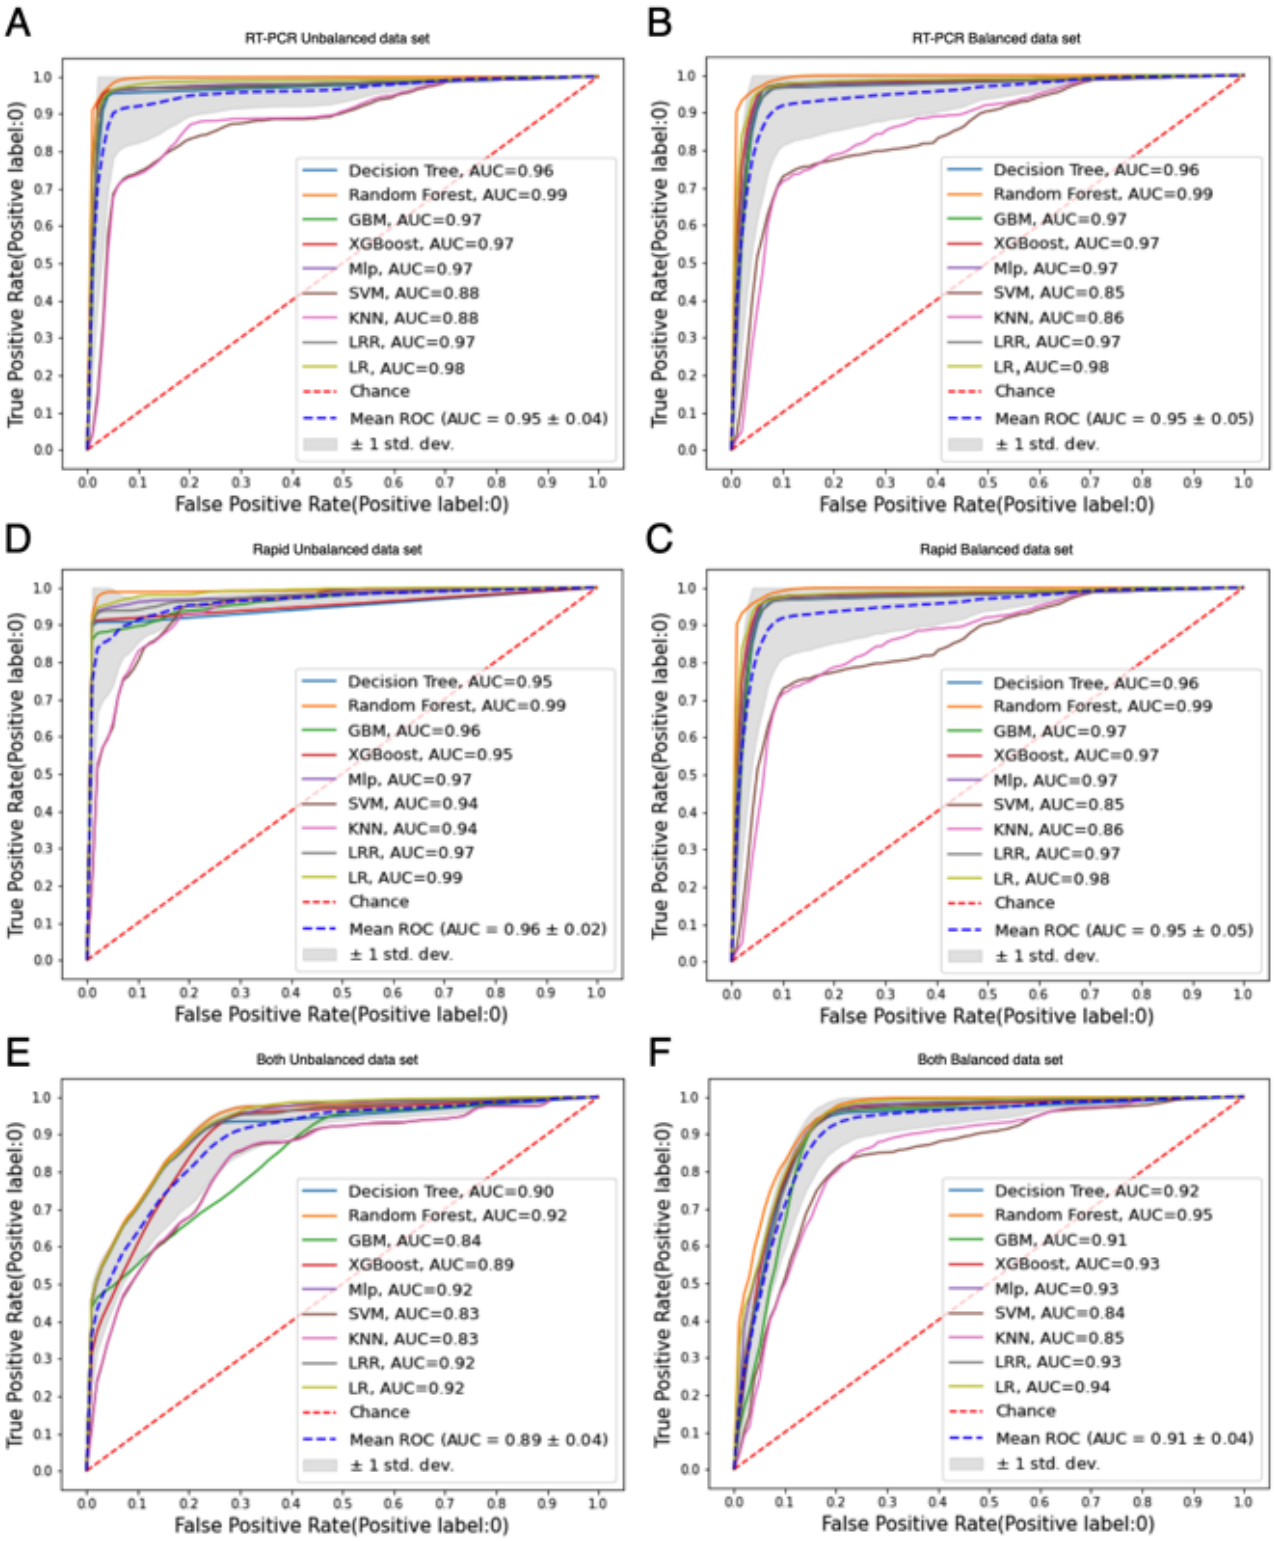

Figure 5. Models' precision-recall curve with (A) RT-PCR unbalanced data set, (B) rapid unbalanced data set, and (C) both unbalanced data set. AP: average precision; GBM: gradient boosting machine; KNN: k-nearest neighbors; LR: logistic regression (weak regularization); LRR: logistic regression (strong regularization); Mlp: multilayer perceptron; PR: precision-recall; RT-PCR: reverse transcription polymerase chain reaction; SVM: support vector machine; XGBoost: extreme gradient boosting.

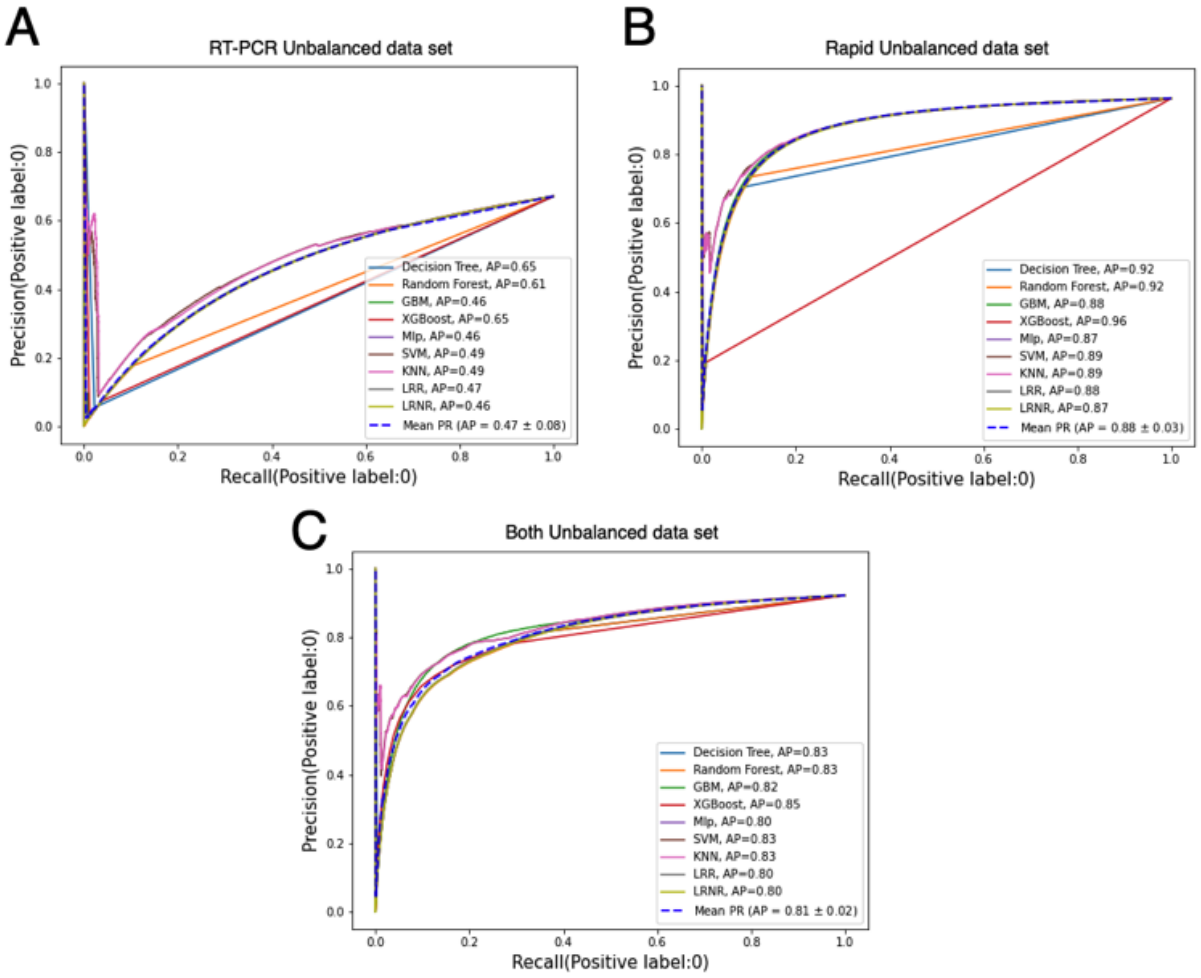

Figure 6. (A) The mean recall for the MLP, GBM, RF, DT, XGBoost, KNN, SVM, LRR, and LR classification models using the unbalanced data sets for RT-PCR, rapid, and both types. (B) The mean recall for the MLP, GBM, RF, DT, XGBoost, KNN, SVM, LRR, and LR classification models using the balanced data sets for RT-PCR, rapid, and both types. DT: decision tree; GBM: gradient boosting machine; KNN: k-nearest neighbors; LR: logistic regression (weak regularization); LRR: logistic regression (strong regularization); MLP: multilayer perceptron; RF: random forest; RT-PCR: reverse transcription polymerase chain reaction; SVM: support vector machine; XGBoost: extreme gradient boosting.

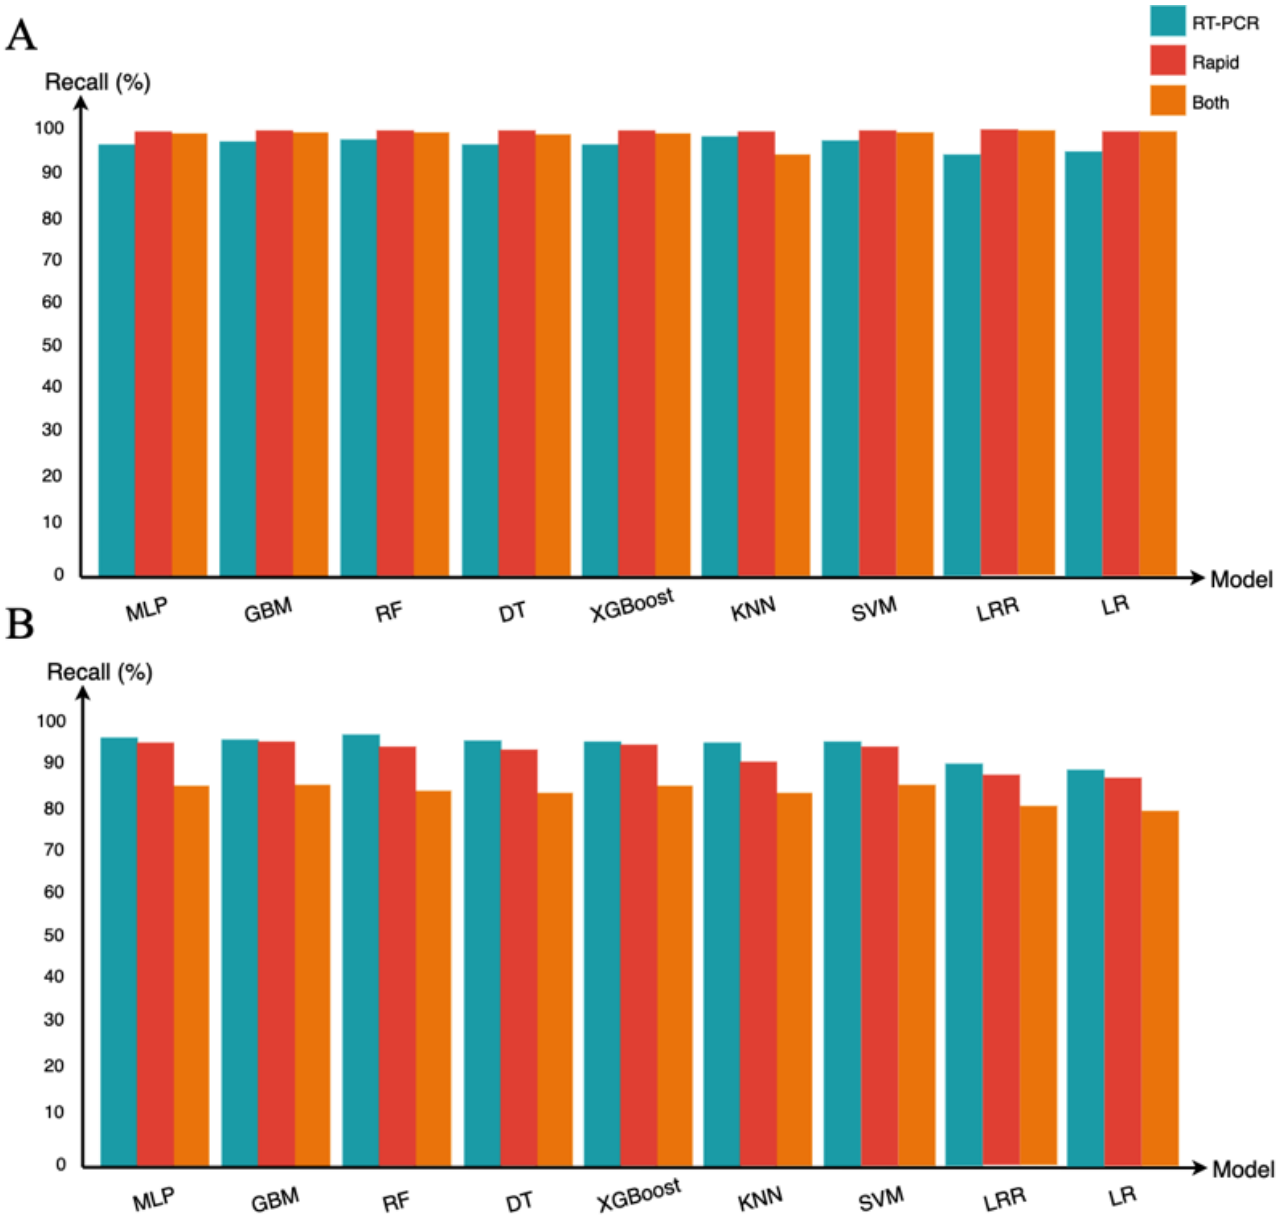

Table 3. The average importance and SD values for each feature for the decision tree–based classification models using the balanced data sets.

Data sets and features	GBM[a], mean (SD)	DT[b], mean (SD)	RF[c], mean (SD)	XGBoost[d], mean (SD)
RT-PCR[e] balanced				
Gender	0.233 (0.013)	0.245 (0.013)	0.238 (0.013)	0.233 (0.013)

Discussion

Principal Findings

The raw data set's data preprocessing enabled the implementation, validation, and comparison of classification models with different characteristics such as using neural layers, tree combinations, and calculating the distance between data. The preprocessing also resulted in the public data availability of patients who were symptomatic tested using RT-PCR and rapid tests [10]. Thus, the data sets can be reused by other studies to improve the state of the art.

The algorithms were trained and tested using the unbalanced and balanced data sets, improving data representativity. The best classification metrics results were related to the RT-PCR and rapid tests scenarios using unbalanced and balanced data. Although the classification models' performance was similar for the RT-PCR and rapid tests scenarios, the RT-PCR test scenario is the most clinically relevant one due to the RT-PCR testing's high confidence. The RT-PCR test's precision increases confidence in the diagnosis, even if the patient was tested in the first days after symptoms onset. For both test scenarios with unbalanced data, although presenting a low Brier Score and high precision, accuracy score, and recall, the classification models presented a lower AUROC because of the higher negative than positive COVID-19 cases. For both test scenarios with balanced data, the Brier score continued to be low. The precision, accuracy, and AUROC were higher; however, the recall results were slightly decreased if compared to the unbalanced data results.

The recall metric is relevant due to the undesired impacts of false negatives in clinical practice. Thus, we improved the classification models' quality of comparisons by applying the Friedman and Nemenyi tests based on the six data sets' recall.

We used such statistical comparison results for defining the MLP, GBM, DT, RF, XGBoost, and SVM as the classification models with the highest performances for COVID-19 test prioritization in Brazil.

Given the classification models with the highest performances and the five most significant features for COVID-19 test prioritization, the fever's importance as one of the top two features is according to the aforementioned statistics (Figure 3). The statistics showed that fever was the second most frequent symptom reported by patients who were symptomatic, confirmed as COVID-19 cases. *Gender* and *dyspnea* were also among the highest-ranked features used by classification models. For example, for the *RT-PCR balanced* data set, observing the DT model's decision rules to get an overview of the role of gender in classifications, positive or negative decisions for males and females differed based on reported symptoms and the *health professional* feature. However, further investigation about the role of gender in classifications is recommended for future works.

Therefore, secondary RQ 1 was answered by showing that *gender* and *health professional* features are related to relevant demographic characteristics to support the COVID-19 test prioritization in Brazil (Tables 4 and 5). Secondary RQ 2 was also answered, showing that fever, sore throat, dyspnea, olfactory disorders, cough, coryza, taste disorders, and headache are relevant symptoms.

All DT-based classification models considered in this study are among the classification models with the highest performances, grouped based on the results of classification metrics and statistical tests. This fact is relevant due to the high levels of DTs' interpretability, positively impacting health care professionals' final decision making. In clinical practice, ML-based applications' acceptance increases when health care professionals can easily understand and interpret classification models' outputs to track decision-making logic [28]. Given the grouping of models with similar performances, we used the criterion of easy interpretability to answer secondary RQ 3. Thus, the DT classification model was considered the most suitable for COVID-19 test prioritization in Brazil. We configured the model with the Gini impurity criterion, best split strategy, no maximum depth, a minimum number of two samples split and one sample leaf, no minimum weighted fraction leaves and no impurity decrease and split, unlimited number of features and leaves, global random state instance, no class weight, and no pruning. As one of the classification models with the highest performances, DT provides a simple tree representation of the decision making, enabling a unique tree's straightforward interpretation by health care professionals.

To answer secondary RQ 4, we analyzed the DT model's classification results, observing that a considerable fraction of the incorrectly classified instances occurred when patients reported only one, two, or three symptoms. Furthermore, we conducted an experiment to verify the impacts of reducing features in the performance of the implemented classification models (Multimedia Appendix 1). For example, with the *both RT-PCR balanced* data set, when the symptoms of sore throat, dyspnea, headache, and coryza were not considered to implement the DT classification model, the performance results decreased considerably. This reduces the ability of the model to distinguish between positive and negative cases.

Although the DT is considered the most suitable model, all the other classification models that presented high performance were relevant to address COVID-19 test prioritization. In Brazil, due to other epidemics (eg, dengue fever [29]), many people report symptoms that may or may not be related to COVID-19. As a limited-income country, Brazil also has inefficient testing strategies such as shortages of COVID-19 tests. One of the available classification models can be applied for COVID-19 test prioritization during primary health care, with a mean accuracy score of at least 88.63%.

Comparison With Prior Work

The relevance of research addressing viral infection outbreaks is evidenced from the public administration (eg, surveillance systems) to the diagnosis viewpoint. For example, Son et al [30] used a South Korean time series of influenza incidence for early outbreak detection, aiming to assist the definition of control policies. Chatterjee et al [31] analyzed COVID-19 data sets to identify risks of spreading, identify correlated factors associated with the disease's spread, identify the impact of social isolation, and experiment with univariate long short-term memory models for forecasting of total cases and total deaths. In general, infectious disease research is guided by trends in data analytics [32].

Indeed, the COVID-19 pandemic is an example of a problematic scenario. Kumar [33] applied cluster analysis to study and improve the monitoring of SARS-CoV-2 infections in India, providing insights on clusters of affected Indian states and union territories. Besides aiming to improve the management of available resources, Khakharia et al [34] developed outbreak classification models for COVID-19 using data sets with information about patients who live in India, Bangladesh, the Democratic Republic of Congo, Pakistan, China, Philippines, Germany, Indonesia, Ethiopia, and Nigeria. Vaid et al [35] implemented and validated models (eg, XGBoost) to predict mortality and critical events using electronic health records of patients who tested positive for COVID-19 in New York City.

To assist COVID-19 detection, Brinati et al [36] validated models implemented using DT, extremely randomized trees, KNN, LR, naive Bayes, RF, and three-way RF algorithms. The authors considered COVID-19 detection using routine blood exams, gender, and age. The accuracy of the models ranged between 82% and 86%. However, the large number of required blood exams (ie, 13) was a limitation, which may compromise this approach's feasibility in low- and middle–income countries.

Ahamad et al [21] used a Chinese data set to assist the COVID-19 detection considering symptoms (ie, fever, cough, pneumonia, lung infection, coryza, muscle soreness, and diarrhea), gender, age, travel history, and isolation. The authors validated the XGBoost, SVM, DT, RF, and GBM models. XGBoost presented the highest accuracy with more than 85%, varying according to age. However, lung infection use, detected by chest images, increases costs and may limit the disease's rapid screening.

Aiming to improve confidence in screening COVID-19, Mei et al [37] used computerized tomography (CT) images along with symptoms (ie, fever, cough, and cough with sputum), exposure history, laboratory testing (ie, white blood cells, neutrophils, percentage neutrophils, lymphocytes, and percentage lymphocytes), age, gender, and temperature. They applied the deep convolutional neural network to analyze images, besides comparing the performance of SVM, RF, and MLP models, showing that MLP presented the highest accuracy score. Afterward, the authors combined images and clinical information. Similarly, requiring images increases costs and may limit the rapid screening of COVID-19 in low- and middle–income countries.

Finally, Zoabi et al [4] used gender, age, symptoms (eg, cough, fever, sore throat, shortness of breath, and headache), and contact with a confirmed case to classify positive and negative COVID-19 cases. The authors implemented a GBM model based on data reported by the Israeli Ministry of Health. The GBM model presented an AUROC of 86% and 90% using a reduced set of features and the complete set, respectively. Similar to our study, the authors reported the high importance of gender during the classifications. We also improved the state of the art by presenting a comparison of other implementations of classification models. Besides cough, fever, sore throat, shortness of breath, and headache, we used the symptoms of olfactory disorders, coryza, and taste disorders to improve the results.

In contrast to such prior works, we focused on raw data from 55,676 Brazilians and used features that do not require expensive exams such as CT images and blood tests. Symptoms included fever, sore throat, dyspnea, olfactory disorders, cough, coryza, taste disorders, and headache. The *gender* and *health professional* features were the additional information required to conduct the COVID-19 test prioritization using the classification models. *Gender* was also used as a feature by prior works [4,20,36,37]. The use of exams such as CT images and blood tests limits classification models' application scenarios because it is necessary to prioritize patients who are symptomatic for testing in the first days after symptoms onset.

Limitations

By preprocessing the 55,676 raw data, the *RT-PCR balanced* data set only included 1832 patients who were symptomatic, the *rapid balanced* data set included 1296 patients who were symptomatic, and the *both balanced* data set included 3128 patients who were symptomatic. However, to improve the strength of results and decrease size limitation, we also considered 3 unbalanced data sets. For example, the *both unbalanced* data set was composed of 20,021 patients who were symptomatic and tested for COVID-19.

Furthermore, in a real-world scenario, the number of patients who were asymptomatic with COVID-19 can also be considered a limitation to the classification models' applicability. In this case, this study continues to be relevant due to the remaining symptomatic cases that also require health care professionals and the government's attention. The evaluation of patients who are symptomatic is also relevant to prevent the unplanned use of COVID-19 testing resources due to other disease outbreaks in Brazil caused by other viral infections (eg, dengue, Zika, and chikungunya). Such viral infections present similar symptoms that may complicate health care professionals' decision on the adequate testing type needed.

The reduced number of symptoms reported by a patient who is symptomatic can also negatively impact the reuse classification models. Nevertheless, the feature ranking and other information (eg, contact with infected people) are relevant to complement the classification models during the decision making conducted by health care professionals and policy makers. We verified the impacts of reducing features in the performance of implemented classification models (Multimedia Appendix 1).

Finally, the number of classification models implemented, validated, and compared is another limitation of our study, given the wide variety of available algorithms and ensemble strategies. This limitation was reduced by selecting well-known algorithms based on trees, linear regression, statistical learning, distance, and the concept of neurons.

Clinical Practice Context

The availability of eHealth and mHealth systems is relevant to assist decision making in different scenarios. One such scenario is detecting COVID-19 in patients who reside in remote and hard-to-reach locations (eg, Amazonia or Latin America) [38]. Developers can integrate eHealth and mHealth systems with services that enable health care professionals to be alerted when the risk of disease is detected. The use of eHealth and mHealth systems should be encouraged, considering that the early detection of COVID-19 is essential in clinical practice to enable early medical attention, possibly reducing the negative impacts of late treatments. This type of eHealth and mHealth system can also benefit public health systems when factors related to the human condition (eg, fatigue and lack of experience) and the collapse of health services negatively influence health care professionals' decision making during patients' evaluation. Such scenarios are authentic in the context of the COVID-19 pandemic [39].

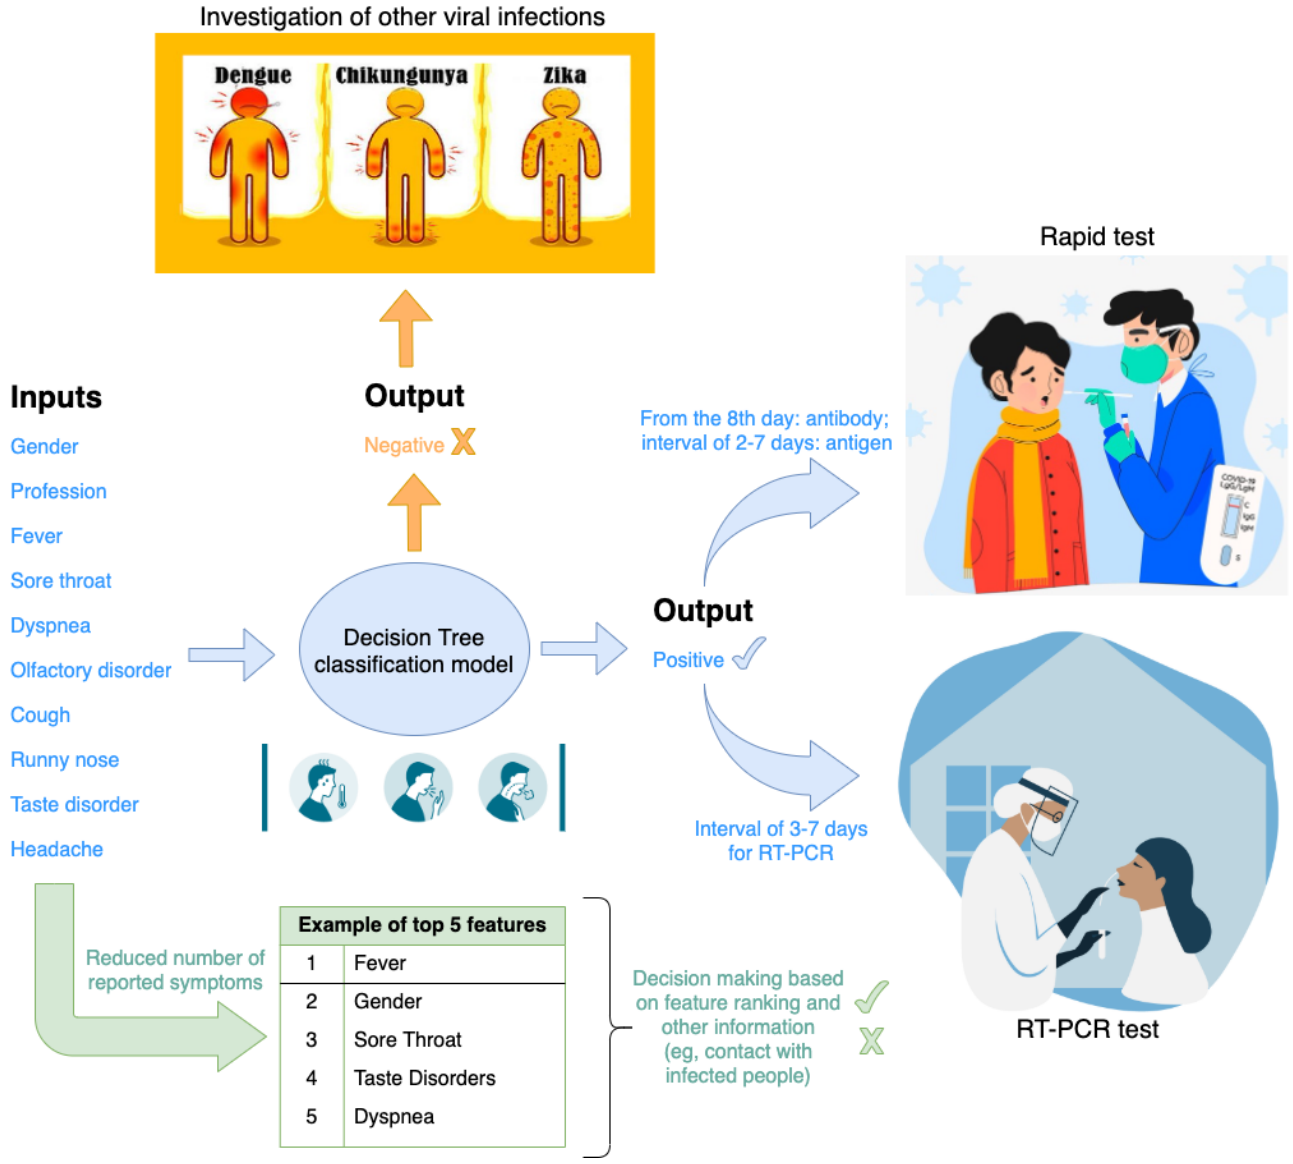
Therefore, the implemented classification models can be the basis for eHealth and mHealth systems to support health care professionals and policy makers during the COVID-19 test prioritization. To be applied in clinical practice and integrated with the current clinical workflow, the availability of the DT classification model and the use of feature ranking information through web services to be consumed by an eHealth or mHealth system is recommended. Such a system shall present classification results for health care professionals in a user-friendly manner. The straightforward interpretation of classification models is relevant to increase health care professionals' confidence in classification results. For example, the web services can be integrated with Brazilian public health facilities' systems to prioritize the reduced COVID-19 testing resources.

We present an application scenario integrating a clinical workflow and the DT classification model (Figure 7). The DT is used to prioritize patients who are symptomatic for COVID-19 testing. However, when the number of reported symptoms is too low, the classification models cannot distinguish between

positive and negative cases. In this case, health care professionals can reuse the feature ranking and other information (eg, contact with infected people) to make decisions about COVID-19 testing. Thus, the use of feature ranking information is guided by the answer of secondary RQ 4. If the result is not prioritized, the patient's clinical condition should be further investigated in regard to other viral diseases.

For the application scenario, there are five possible flows: (1) confirmed case with classification model and rapid test result, (2) confirmed case with classification model and RT-PCR test result, (3) confirmed case using feature ranking and rapid test result, (4) confirmed case using feature ranking and RT-PCR test result, and (5) negative case with the recommendation of investigation of other viral diseases. It is relevant to consider the days between the onset of symptoms and COVID-19 testing: closed interval of 3-7 days for RT-PCR test, from the eighth day for the rapid antibody test, and closed interval of 2-7 days for the rapid antigen test [40-42].

Figure 7. An application scenario to connect the decision tree classification model with a clinical workflow. The model guides the test prioritization of patients who were symptomatic suspected of COVID-19. RT-PCR: reverse transcription polymerase chain reaction.



Conclusions

The results showed the relevance of using classification models for COVID-19 test prioritization in Brazil, mainly based on the symptoms that do not require expensive exams. By comparing the classification models using raw data from 55,676 Brazilians, the 10-fold cross-validation method, classification metrics, and the Friedman and Nemenyi tests, the MLP, GBM, DT, RF, XGBoost, and SVM presented the highest performances with similar results.

DT-based classification models' high performances are relevant for our application scenario due to the high levels of DTs' interpretability, positively impacting health care professionals' final decision making. Therefore, applying the easy interpretability as an additional comparison criterion, DT was considered the most suitable classification model, effectively assisting in the decision making for prioritizing patients who are symptomatic for testing. Information about the features *gender*, *health professional*, *fever*, *sore throat*, *dyspnea*, *olfactory disorders*, *cough*, *coryza*, *taste disorders*, and

headache enable the COVID-19 test prioritization for patients who are symptomatic. The use of symptoms that do not require expensive exams contributes to assisting patients who live, for example, in needy and hard-to-reach communities. The results of feature ranking reported in this paper are also relevant to support a more detailed analysis in a scenario where a patient reports a reduced number of symptoms.

To improve testing prioritization, we plan to investigate the relationship between the symptoms reported by patients with COVID-19 and other widespread diseases in Brazil, such as dengue fever, Zika fever, and chikungunya. Thus, we aim to include implementing and validating classification models and developing and validating an eHealth system to support health care professionals and policy makers in decision making for testing strategies.

Abstract

Background: COVID-19 has plagued the globe, with multiple SARS-CoV-2 clusters hinting at its evolving epidemiology. Since the disease course is governed by important epidemiological parameters, including containment delays (time between symptom onset and mandatory isolation) and serial intervals (time between symptom onsets of infector-infectee pairs), understanding their temporal changes helps to guide interventions.

Objective: This study aims to characterize the epidemiology of the first two epidemic waves of COVID-19 in Hong Kong by doing the following: (1) estimating the containment delays, serial intervals, effective reproductive number (R_t), and proportion of asymptomatic cases; (2) identifying factors associated with the temporal changes of the containment delays and serial intervals; and (3) depicting COVID-19 transmission by age assortativity and types of social settings.

Methods: We retrieved the official case series and the Apple mobility data of Hong Kong from January-August 2020. The empirical containment delays and serial intervals were fitted to theoretical distributions, and factors associated with their temporal changes were quantified in terms of percentage contribution (the percentage change in the predicted outcome from multivariable regression models relative to a predefined comparator). R_t was estimated with the best fitted distribution for serial intervals.

Results: The two epidemic waves were characterized by imported cases and clusters of local cases, respectively. R_t peaked at 2.39 (wave 1) and 3.04 (wave 2). The proportion of asymptomatic cases decreased from 34.9% (0-9 years) to 12.9% (≥80 years). Log-normal distribution best fitted the 1574 containment delays (mean 5.18 [SD 3.04] days) and the 558 serial intervals (17 negative; mean 4.74 [SD 4.24] days). Containment delays decreased with involvement in a cluster (percentage contribution: 10.08%-20.73%) and case detection in the public health care sector (percentage contribution: 27.56%, 95% CI 22.52%-32.33%). Serial intervals decreased over time (6.70 days in wave 1 versus 4.35 days in wave 2) and with tertiary transmission or beyond (percentage contribution: –50.75% to –17.31%), but were lengthened by mobility (percentage contribution: 0.83%). Transmission within the same age band was high (18.1%). Households (69.9%) and social settings (20.3%) were where transmission commonly occurred.

Conclusions: First, the factors associated with reduced containment delays suggested government-enacted interventions were useful for achieving outbreak control and should be further encouraged. Second, the shorter serial intervals associated with the composite mobility index calls for empirical surveys to disentangle the role of different contact dimensions in disease transmission. Third, the presymptomatic transmission and asymptomatic cases underscore the importance of remaining vigilant about COVID-19. Fourth, the time-varying epidemiological parameters suggest the need to incorporate their temporal variations when depicting the epidemic trajectory. Fifth, the high proportion of transmission events occurring within the same age group supports the ban on gatherings outside of households, and underscores the need for residence-centered preventive measures.

Introduction

The novel coronavirus (SARS-CoV-2), which causes COVID-19, first appeared in Wuhan, China, in late December 2019 and quickly plagued the globe. The World Health Organization declared COVID-19 a pandemic on March 12, 2020. As of September 27, 2020, there have been 32.7 million cases and almost one million deaths worldwide [1]. Countries are experiencing the resurgence of COVID-19. For example, in the week of September 21-27, 2020, there were about 420,000 new cases in Europe [1], triggering another round of lockdown measures [2]. Researchers promptly summarized the case epidemiology during the early phase of the pandemic [3,4]. However, the enactment of nonpharmaceutical interventions and the presence of multiple genetic SARS-CoV-2 clusters [5] hint at important changes in the epidemiology of COVID-19.

Hong Kong is no exception with regard to COVID-19. The first epoch of the first wave of COVID-19 in Hong Kong took off after the first imported case reported on January 23, 2020 [6,7]. Initially, the epidemic was under control after prompt bundled public health interventions [8]. With the number of infections surging worldwide in mid-March 2020, Hong Kong faced the second epoch of the first wave of infection. Compulsory laboratory tests for all arriving passengers followed by 14-day compulsory quarantine spurred overseas residents to return, resulting in a small influx of imported cases. After peaking in March 2020, the number of cases remained low until a surge of local cases in July 2020, signifying the second wave of the epidemic in Hong Kong. This second wave represented the largest local outbreak in Hong Kong, which was likely attributable to initiation by imported cases coupled with the easing of social-distancing measures in July 2020.

The disease course of COVID-19 is governed by important epidemiological parameters, including containment delay and serial interval. The former has been shown to be associated with the infection source and number of doctor consultations [6], which in turn vary as the epidemic progresses, whereas the latter varies by virus type and subtype [9,10], the contact patterns between susceptible and infectious individuals [10], and the implementation of nonpharmaceutical interventions during epidemics [11].

Parameterization of mathematical models that account for the temporal variation of epidemiological characteristics would improve decisions regarding mitigation strategies. Moreover, containment delay increases opportunities for transmission and affects the effectiveness of control measures, whereas investigating ways to reduce containment delay could enhance control measures [12]. As such, we analyzed laboratory-confirmed COVID-19 case series in Hong Kong between January 2020 and August 2020 to quantify and identify the factors associated with the containment delay and serial interval.

Methods

Data Retrieval

We analyzed the case series provided by the Hong Kong Centre for Health Protection (HKCHP) from January 23, 2020, to August 2, 2020, from which we extracted the following: demographics, case classification, travel history, epidemiological links among cases, date of symptom onset, date of isolation, and the report date. Based on the order of settings embedded in a cluster and the case classification (cases, or close contact of cases), we compiled a line-list database of infector-infectee pairs (hereafter denoted as “paired data”).

Definitions

A laboratory-confirmed case (hereafter denoted as “a case”) and a cluster were defined previously [6]. In short, a case refers to an individual with SARS-CoV-2 detected in a clinical specimen, and a cluster refers to at least two cases that are epidemiologically linked. Further, a local cluster is defined as a cluster that consists of at least one local case. A cluster encompasses one or more orders of settings, referred to as primary, secondary, tertiary, and quaternary settings.

Containment delay and serial interval were defined previously [6]. In short, containment delay is the time elapsed between the first onset of symptoms and mandatory isolation of a case [6], and serial interval is the time interval between the symptom onset of an infector and an infectee [13]. Further, secondary transmission refers to the first generation of infections induced by a case, and infections caused by infectees of a secondary transmission are referred to as tertiary transmission. Accordingly, subsequent orders of transmission are named based on the aforementioned rationale. Effective reproductive number (R_t) is the average number of secondary cases generated by a primary case at any given time. It measures real-time

transmissibility in response to control measures. The epidemic will shrink if R_t is consistently smaller than 1, and vice versa.

Classifications of Cases

The HKCHP classified cases into six types according to their likely source of infection: imported cases, local cases, possibly local cases, and cases with epidemiological linkage with imported, local, or possibly local cases. Based on their travel history during the 14 days preceding the first symptom onset and their involvement in local clusters, the latter four types of cases were reclassified (Table 1) such that there were only three types of cases: (1) imported, (2) local, and (3) unclassified.

Table 1. Reclassification regime of cases.

Original classification	Reclassified classification	Number of cases (N=3512)
Imported cases	Imported cases	1045
Local cases	Local cases	901
Possibly local cases	Local cases[a]	2
Possibly local cases	Imported cases[b]	71
Possibly local cases	Unclassified cases[c]	30
Close contact of imported cases	Local	31
Close contact of local cases	Local	1370
Close contact of possibly local cases	Local	62

[a]Cases without travel history during the 14 days before their first symptom onset.

[b]Cases that had travel history during the 14 days before their first symptom onset and were not involved in any local cluster.

[c]Cases who either had travel history during the 14 days before their first symptom onset and were linked to a local cluster or did not have an onset/arrival date.

Symptom Profile

Symptoms manifested by cases, if any, were grouped based on the International Statistical Classification of Diseases and Related Health Problems (ICD-10) and the national ambulatory medical care survey [14] into 8 categories (Table S1 in Multimedia Appendix 1), including general (such as fever and headache) and respiratory (such as cough and sore throat) symptoms.

Mobility Index

The index is generated by Apple Maps, and represents the relative volume of routing requests (walking) for directions in Hong Kong compared to the baseline volume on January 13, 2020 [15]. The higher the index value is from the baseline, the higher the level of mobility. For ease of presentation, this index was further normalized with the value on January 18, 2020, set as 100.

Statistical Analysis

Characteristics of cases and epidemiological parameters were summarized with mean, standard deviation, percentage, frequency, and bootstrapped confidence interval. Missing isolation dates were replaced by rounding up the mean of available isolation days in a stratum, which was made up of cases that had the same likely source of infection, asymptomatic indicator, quarantine status, mode of detection, and report dates. If there was no available isolation date in a stratum, the mean day differences between report dates and isolation dates were calculated, and the missing isolation dates were imputed as follows: the corresponding report dates minus the mean day difference. For containment delay, only local cases who were neither quarantined nor under medical surveillance and had nonnegative containment delay were analyzed. For serial intervals, only settings that linked 2-4 cases, had identifiable infectors, and were related to local transmission were used to generate infector-infectee pairs for analysis. For R_t, only symptomatic local cases were considered.

A Markov chain Monte Carlo with doubly interval-censored likelihood [16] was adopted to fit the empirical containment delay and serial interval with four candidate distributions (gamma, lognormal, weibull, and normal) with credible intervals computed. The smallest value of the leave-one-out cross-validation information criterion (LOOIC) [17] indicates the best fitted distribution. Assuming the best fitted distribution for serial intervals as the weighted infectivity function, incidence data of local cases by dates of symptom onset with an 8-day window (to reflect the time between exposure to SARS-CoV-2 and symptom onset) were fitted by a novel and statistically robust tool for estimating R_t [18].

Assuming the respective best fitted distributions as the likelihood function, multivariate linear regression models were used to examine the associated factors for containment delays and serial intervals. The effect of each factor was measured in terms of percentage contribution as previously described [19], which is defined as the percentage change in the predicted value of the outcome (from the regression models) relative to a comparator set of covariate values (referred to as “the comparator”). The comparator refers to a transmission event fulfilling these conditions: the case (for containment delay) or the infector (for serial interval) was female, aged 0-30 years, free of chronic diseases, free of general and respiratory symptoms; the transmission happened in a household, during wave 1, and is of the secondary generation; and (for serial interval only) the mobility index being the baseline value on the onset date of the infector. Specifically, $\ln(\alpha_i + j + 1)$ and

$\ln(\beta_i + k + 1)$ were defined as the response variables for the multivariable regression analyses, where α_i and β_i are the containment delay and serial interval of the i^{th} case, respectively, and j and k are the maximum absolute values for the nonpositive containment delays and the nonpositive serial intervals, respectively.

A statistical significance of .05 was specified. All analyses were performed in R (version 3.6.3; R Foundation for Statistical Computing) [20] with the RStan package (version 2.19.3).

Ethical Statement

This study was approved by the Survey and Behavioral Research Ethics Committee of The Chinese University of Hong Kong (reference: SBRE-19-595).

Data Statement

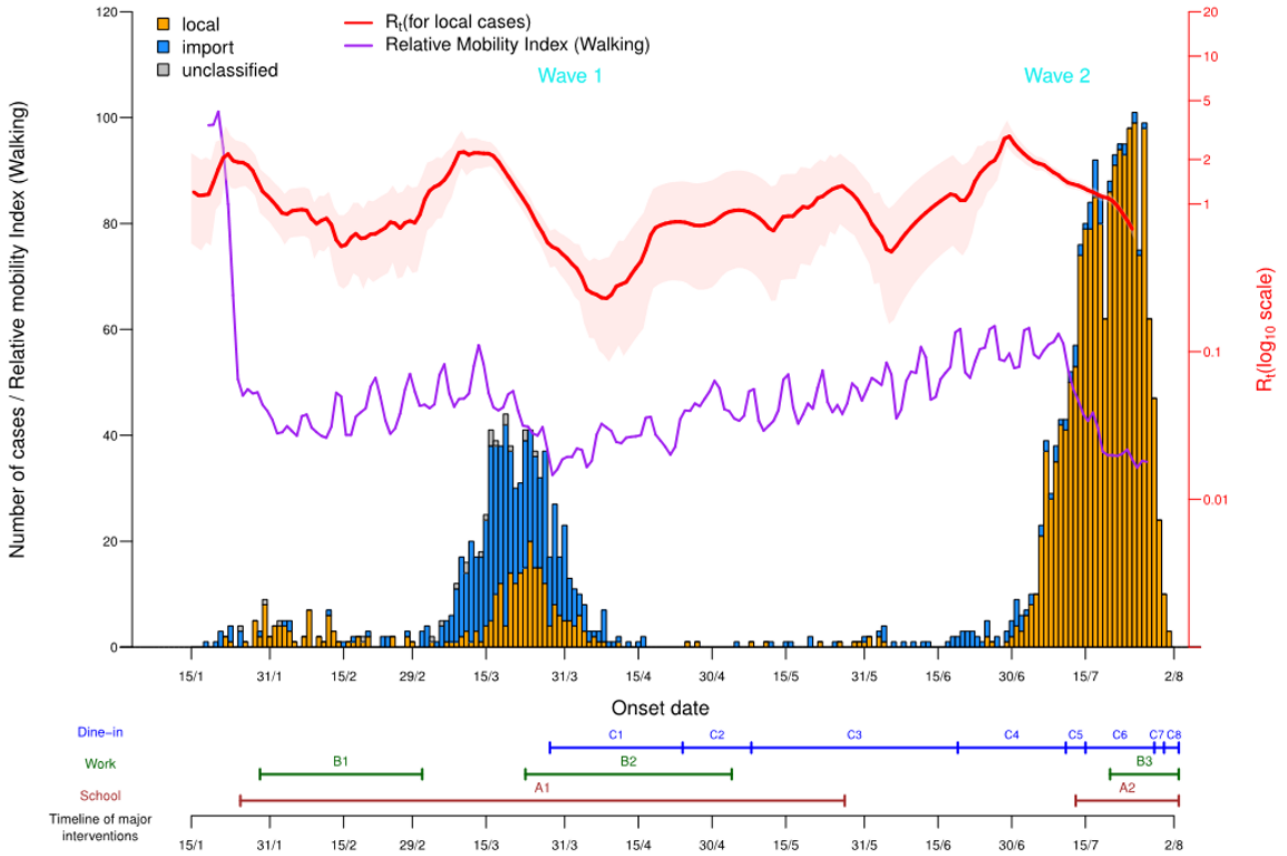
The availability of the data set is subject to approval from HKCHP and relevant government departments.

Results

Characteristics of the Two Epidemic Waves

The report date, June 14, 2020, defined two epidemic waves in Hong Kong: (1) January 23-June 14, 2020 (wave 1) and (2) June 15-August 2, 2020 (wave 2). This cut-off date separated the clusters in both waves without overlap. Two epochs were further defined within wave 1: (1) January 23-February 29, 2020 (epoch 1) and (2) March 1-June 14, 2020 (epoch 2). Wave 1 was initially dominated by imported cases from mainland China and local cases (epoch 1) and subsequently by imported cases from Europe and the Americas (epoch 2), whereas wave 2 was composed mainly of local cases (Figure 1).

Figure 1. Epidemic curve of COVID-19 and timeline for major interventions in Hong Kong. A1: School closure, January 25-May 26, 2020. A2: School closure, July 13, 2020 to ongoing as of August 2, 2020. C6: Regulations imposed on dine-in services, July 15-July 28, 2020: (1) tables ≥1.5 meters apart, (2) ≤4 persons per table, (3) number of customers ≤50% of capacity, and (4) no dine-in service from 6 PM to 4:59 AM every day. C7: No dine-in service at any time, July 29-July 30, 2020. C8: Regulations imposed on dine-in services, July 31, 2020 to ongoing as of August 2, 2020: (1) tables ≥1.5 meters apart, (2) ≤2 persons per table, (3) number of customers ≤50% of capacity, and (4) no dine-in service from 6 PM to 4:59 AM every day.



The government of Hong Kong has enacted multipronged interventions, and the major ones include school closures, work-from-home arrangements, and limiting customer flow and time for dine-in services (Figure 1). In addition, the public

voluntarily reduced their mobility substantially, such that the mobility index dropped from 100.2 initially to as low as 28.0 as the epidemic progressed (Figure 1).

R_t was generally below 1 throughout the epidemic, but it peaked at 2.39 in wave 1 and 3.04 in wave 2. This elevated R_t, coupled with the short doubling time of the epidemic size in wave 2 (Figure S1 in Multimedia Appendix 1), suggested that Hong Kong was on the verge of an uncontrolled outbreak during wave 2.

Characteristics of Cases

As of August 2, 2020, 3512 cases were reported. The mean age of cases was 43.91 (SD 20.27) years, with half of them being male (1748/3512). In addition, 6.2% (216/3512) had consulted with a doctor before case confirmation, and 9.7% (339/3512) had chronic conditions (Table S2 in Multimedia Appendix 1). Most cases (2649/3512, 75.4%) were symptomatic, with fever (929/2649, 35.1%) and cough (805/2649, 30.4%) being the most common symptoms (Table S3 in Multimedia Appendix 1). The proportion of asymptomatic cases decreased from the younger age groups to the older ones (0-9 years: 34.9%; 10-19 years: 34.9%; 20-29 years: 21.7%; 30-39 years: 22.4%; 40-49 years: 18.7%; 50-59 years: 16.1%; 60-69 years: 12.7%; 70-79 years: 21.7%; and ≥80 years: 12.9%). In terms of the probable source of infection, 67.4% (2366/3512) were locally acquired cases (Table 1), among whom 1575 cases were symptomatic and neither quarantined nor under medical surveillance (Table 2).

Table 2. Classification of 3512 cases in Hong Kong, as of August 2, 2020.

Case classification	Wave 1 (n=1110), n (%)	Wave 2 (n=2402), n (%)	Total (n=3512), n (%)
Imported case			
Symptomatic	554 (49.9)	94 (3.9)	648 (18.5)
Asymptomatic	189 (17)	231 (9.6)	420 (12)
Missing	0 (0)	48 (2)	48 (1.4)
Local case			
Symptomatic			
Quarantine[a]	31 (2.8)	158 (6.6)	189 (5.4)
Nonquarantine			
Medical surveillance	91 (8.2)	125 (5.2)	216 (6.2)
Others[b]	176 (15.9)	1399 (58.2)	1575 (44.8)
Asymptomatic	39 (3.5)	246 (10.2)	285 (8.1)
Missing	0 (0)	101 (4.2)	101 (2.9)
Unclassified	30 (2.7)	0 (0)	30 (0.9)

[a]This included home/hotel confinee cases, camp/center quarantine cases, and cases released from home/hotel quarantine before getting infected.

[b]This included cases with these modes of case detection: enhanced lab surveillance, enhanced surveillance in private, enhanced surveillance at general outpatient clinics and accident and emergency departments, meeting reporting criteria, diagnosed in private clinic, test at private clinic, and being under Tier 7 classification.

Containment Delay

After excluding one case with negative containment delay, 1574 cases were included in the estimation. Log-normal distribution (mean 5.18 [SD 3.04] days) fitted the empirical containment delay best (LOOIC: 7525.6; Table S4 in Multimedia Appendix 1), which ranged from 4.38 days (95% empirical CI [eCI] 3.80-4.95) for cases belonging to the secondary settings or beyond in a cluster to 6.48 days (95% eCI 6.15-6.82) for cases identified through a private mode of detection (Table 3).

Table 3. Estimates of and factors associated with containment delay based on 1574 cases.

Factors	Cases, n (%)	Subgroup-specific estimates (95% empirical CI)	Percentage contribution (95% CI)
Age group (years)

[a]Private mode includes diagnosis in private, enhanced surveillance in private, and private test.

[b]Public mode includes enhanced lab surveillance, enhanced surveillance at general outpatient clinics and accident and emergency departments, meeting reporting criteria, Tier 6, and Tier 7.

[c]The reference is a common comparator across all variables.

Containment delay varied by several factors (Table 3; Figure S2A in Multimedia Appendix 1). Notably, the percentage contribution (relative to the comparator) significantly increases with older age (≥61 years) by 11.29% (95% CI 3.05%-20.09%). On the contrary, the percentage contribution decreases with the following: (1) the presence of general symptoms (12.45%, 95% CI 7.27%-17.39%); (2) the transmission event originating from a primary setting of a cluster (10.08%, 95% CI 4.43%-15.44%); (3) the transmission event originating from a secondary setting or beyond of a cluster (20.73%, 95% CI 10.93%-29.61%); and (4) private mode of case detection (27.56%, 95% CI 22.52%-32.33%). The containment delay was shorter in wave 2 than in wave 1, though not statistically significant; the percentage contribution by wave 2 was –7.23% (95% CI –15.58% to 1.82%).

Serial Interval

Initially, there were 847 settings linking at least two cases. After removing 144 settings consisting of solely imported cases, 72 settings with ≥5 cases (as the simultaneous presence of a large number of cases in a setting obscures the transmission link between cases), and 104 settings in which the infectors could not be identified (for example, there was no, or more than one, index case), 528 settings remained. From these 528 settings, 757 infector-infectee pairs were generated. After further removing 4 pairs with duplicated infectees and 195 pairs with missing onset dates of infectors/infectees, 558 paired data were included in the analysis. The mean number of infectees per infector was 1.46.

There were 17 negative serial intervals (range: –5 to –1 days). Log-normal distribution (mean 4.74 [SD 4.24] days) fitted the

overall empirical serial intervals best (LOOIC: 3095.5; Table S4 in Multimedia Appendix 1). The serial intervals were 6.70 days (95% eCI 5.45-7.95) and 4.35 days (95% eCI 4.00-4.70) in waves 1 and 2, respectively. Further, the subgroup estimates of serial intervals ranged from 2.18 days (95% eCI –0.52 to 4.88) for quaternary transmission or beyond to 5.85 days (95% eCI 4.57-7.13) among the infector-infectee pairs with infectors with chronic conditions (Table 4).

Table 4. Estimates of and factors associated with serial interval based on 558 infector-infectee pairs.

Factors	Pairs, n (%)	Subgroup-specific estimates (95% empirical CI)	Percentage contribution (95% CI)

Relative mobility index[a,b,c]	N/A[d]	N/A	0.83 (0.32, 1.33)

[a]An 8-day lag was assumed to account for the time between exposure to SARS-CoV-2 and the first symptom onset, based on the estimated 7.76-day incubation period [21].

[b]The original mobility index was further adjusted relative to January 18, 2020, which has a value of 100.

[c]The reference is a common comparator across all variables.

[d]N/A: not applicable.

Serial intervals varied by several factors (Table 4; Figure S2B in Multimedia Appendix 1). They were significantly shorter in wave 2 than in wave 1: the percentage contribution by wave 2 was –33.9% (95% CI –45.08% to –21.63%). Serial intervals

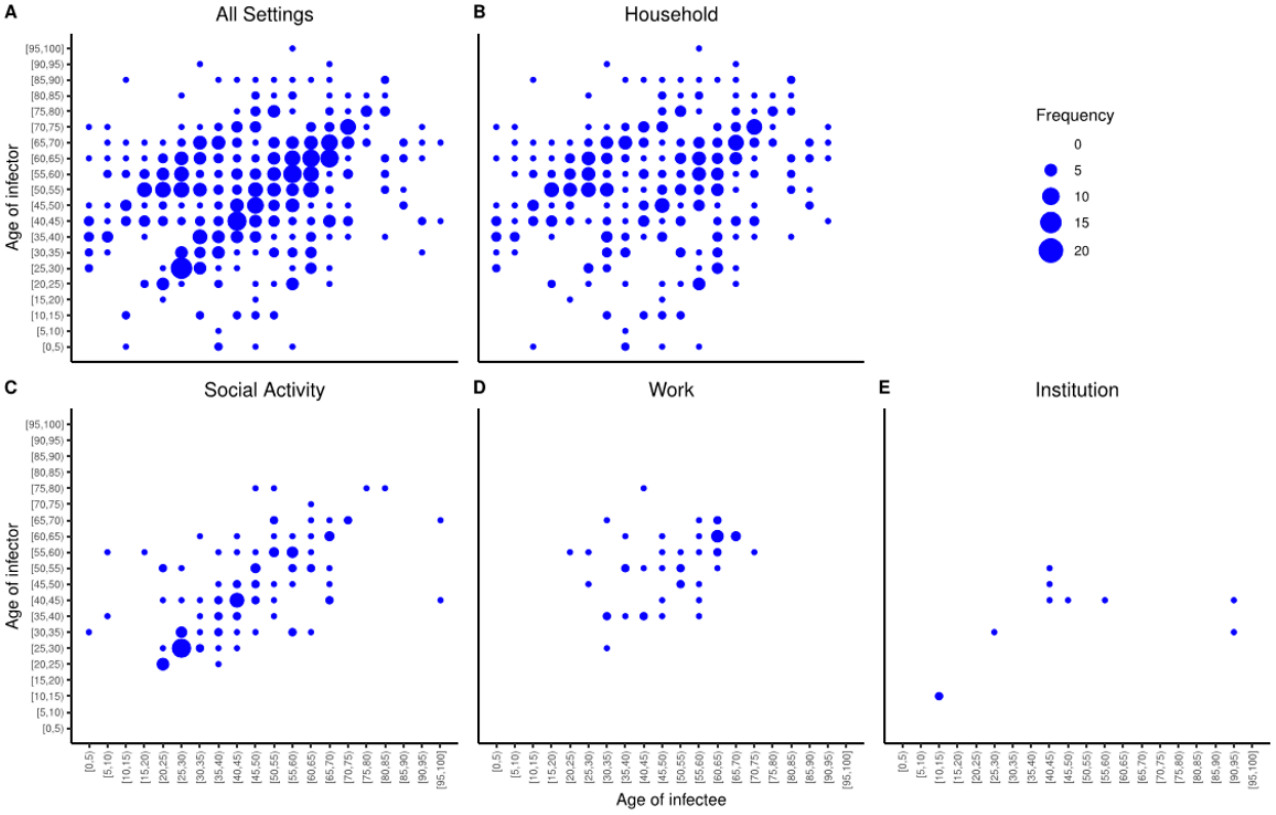
also decreased with a tertiary transmission (percentage contribution: –17.31%, 95% CI –28.84% to –4.75%), and a quaternary transmission or beyond (percentage contribution: –50.75%, 95% CI –72.53% to –23.45%). On the other hand, the 8-day lagged relative mobility index (assuming an incubation period of 7.76 days [21], which reflected the possible exposure date for each infector-infectee pair) lengthened the serial interval (percentage contribution: 0.83%, 95% CI 0.32%-1.33%).

Transmission Events

Transmission events that occurred within the same age band were high (101/558, 18.1%) when using 5-year age bands (Figure 2A). Similar age transmission patterns were also observed in households (Figure 2B) and in social settings (Figure 2C), but were less obvious in work (Figure 2D) and institutional (Figure 2E) settings. In the household setting, transmission from infectors in older age groups (50-70 years) to infectees in younger age groups (15-40 years) was commonly observed (Figure 2B). The age transmission matrix asymmetry in all settings well reflected this phenomenon as well as the lack of transmission from younger age groups to older ones (Figure 2A).

Importantly, households (390/558, 69.9%) and social settings (113/558, 20.3%) were the two most common settings for transmission in Hong Kong (Table 4) in both epidemic waves (Table S5 in Multimedia Appendix 1).

Figure 2. Age-specific transmission events in (A) all settings, (B) households, (C) social settings, (D) work settings, and (E) institutions.



Discussion

Summary of Study Findings

Understanding the evolving epidemiology of an infectious disease is vital for guiding infection control policies. From the case series between January 23, 2020, and August 2, 2020, we identified two waves of epidemics. R_t was in general below the outbreak threshold, suggesting that interventions, whether adopted voluntarily by the community [22] or institutionalized by the government [8], successfully interrupted the transmission of COVID-19. As the epidemic grew in Hong Kong, containment delays and serial intervals were shortened over time. The shortening of the former was associated with the manifestation of general symptoms, involvement in clusters, and public mode of case detection, whereas that of the latter was associated with later transmission generations and lower mobility. The occurrence of intra–age group transmission is more common than inter–age group transmission, and households and social settings together account for 90.14% of all identified transmission events.

Result Implications

Our results have five implications. First, the factors associated with a reduction in containment delay suggested that government-enacted interventions were useful in achieving COVID-19 outbreak control in Hong Kong and should be further encouraged. Containment delay played a major role in determining whether an outbreak was controllable; assuming 80% of contacts can be traced, the chance of controlling an outbreak fell from 89% to 31% if the containment delay increased from 3.43 days to 8.09 days [23]. The difference in containment delay experienced by cases detected by different modes (private: 6.48 days; public: 4.80 days) pinpointed the worthiness of continual investment in public modes of case detection, including setting up community testing centers and

mobile specimen collection stations. Further, as reflected by the percentage contribution by cases involved in a cluster (–20.73% to –10.08%), contact tracing and the follow-up quarantine of individuals with epidemiological links with cases were useful in reducing containment delay; contact tracing should involve a high tracing ratio (preferably ≥80%) and should be done when there are only a few initial cases [23].

Second, the association between decreasing serial intervals over time and lower mobility aligned with the contention that serial intervals are shortened by nonpharmaceutical interventions [11]. Reduced serial intervals indicated faster case generation replacement, which may be attributable to the institutionalized social-distancing policies (Figure 1) that diminished the geographical reach of citizens. This is a tradeoff between time spent in a place versus number of places visited in a limited time, such that citizens may stay in confined locations (eg, home) longer. Although the underlying mechanisms remain undetermined, we hypothesize that confined geographical movement would, in reality, intensify the proximity of contacts between successive case generations. This hypothesis is in line with earlier findings that more time spent in close proximity to the index case shortened serial intervals of influenza [10]. Although the adopted mobility index remained composite, empirical contact surveys—such as the ones by Mossong and colleagues [24] and Kwok and colleagues [19]—that disentangle the interplay of contact dimensions will advance research in the area of evolving epidemiology. On one hand, it is of interest to dissect the role of different contact dimensions on disease transmission; on the other, the potential of other composite social mobility measures—such as the Twitter Social Mobility Index [25]—in estimating epidemiological parameters should be explored.

Third, the presence of negative serial intervals, suggestive of presymptomatic transmission and asymptomatic cases, is a reminder for the community to stay on guard against the resurgence of COVID-19. Infections happening before symptom onset would impede the effectiveness of control measures. This presymptomatic fraction appeared to be low in this study (17/558; 3.05%), but it can be as high as 12.6% [26]. Meanwhile, the proportion of asymptomatic local cases was 12.0% (285/2366) and the number of accumulated infections so far (ie, 3512 cases among more than 7 million people in Hong Kong) is not high enough to confer herd immunity when compared with the conservative 5.66% previously suggested [27]. Together, coupled with the fact that vaccinations will take some time, these results suggest that the community should remain vigilant against any resurgence.

Fourth, temporal variations of key epidemiological parameters should be considered. It is common to assume that the empirical data (of the epidemiological parameters) resembles theoretical distributions. However, the correlation of lower mobility (as proxy to voluntary or compulsory social distancing en masse), involvement in local clusters (as proxy to early government actions on case tracing), and government-level case identification with either containment delay or serial interval observed in this study suggests that epidemiological parameters are dynamic throughout the epidemic. Furthermore, with SARS-CoV-2 transcending international borders, it has mutated into different clusters or subtypes [28-30]. These subtypes differ by their intrinsic properties, exhibiting variations in COVID-19 epidemiology [30]. Therefore, caution must be taken to interpret findings from infectious disease models that assume static epidemiological parameters.

Fifth, the high proportion of transmission events within the same age group supports the ban on gatherings outside of households. The observed intra–age group transmission of COVID-19 echoed the contact assortativity by age of the Hong Kong population [19], and is in line with earlier research [31]: social contact should be considered together with age when it comes to determining the driving force of the incidence of respiratory infections. Further, the asymmetric age transmission matrix revealed that children rarely infected others in the first two epidemic waves. This phenomenon may be attributable to the continual school closure, resulting in fewer social interactions than usual among children in Hong Kong. With the reopening of schools, and hence more social mixing among children, transmission chains branching from children are possible; therefore, older adults who are frequently in contact with children should be prioritized to receive the COVID-19 vaccine, as older adults have a higher risk of COVID-19–related mortality [32]. In addition, the abundance of transmission events in households underscores the need for residence-centered preventive measures, as per the lesson learned from aerosol transmission (through defective plumbing) of the 2003 severe acute respiratory syndrome virus in the Amoy Gardens housing complex in Hong Kong [33].

Study Limitations

There are two study limitations that bear mentioning. First, the data in this study, including self-reported symptoms and contact history, were subject to recall bias. However, the medical surveillance in place to monitor the contacts of cases may lessen the data uncertainties. Second, some cases might not have been captured by the present surveillance system in Hong Kong due to the underdiagnosis of mild cases and asymptomatic individuals, who might play a role in the transmission chain involving unlinked local cases.

Acknowledgments

This study is funded by Direct Grant for Research (number: 2019.020) from The Chinese University of Hong Kong, and by the Centre for Health Systems and Policy Research which is supported by the Tung Foundation. The authors would like to thank Hong Kong Centre for Health Protection and Food and Health Bureau for providing the data, and Margaret Tsoi for technical support. KOK also acknowledges support from Health and Medical Research Fund (reference numbers: INF-CUHK-1, 17160302,

Abstract

Background: COVID-19 is an emerging infectious disease that has created health care challenges worldwide. Pregnant women are particularly affected by this disease.

Objective: The aims of this study are to assess the levels of perceived threat (susceptibility, severity, impact), negative emotions (fear, worry), and self-efficacy of pregnant women in China related to COVID-19 and to examine their associations with mental health (depression and anxiety) and personal protective behavior (wearing a face mask).

Methods: A total of 4087 pregnant women from China completed a cross-sectional web-based survey between March 3 and 10, 2020.

Results: The prevalence of probable depression and anxiety was 48.7% (1989/4087) and 33.0% (1347/4087), respectively; 23.8% participants (974/4087) reported always wearing a face mask when going out. Of the 4087 participants, 32.1% (1313) and 36.4% (1490) perceived themselves or their family members to be susceptible to COVID-19 infection, respectively; 3216-3518 (78.7%-86.1%) agreed the disease would have various severe consequences. Additionally, 2275 of the 4087 participants (55.7%) showed self-efficacy in protecting themselves from contracting COVID-19, and 2232 (54.6%) showed efficacy in protecting their family members; 1303 (31.9%) reported a high level of fear of the disease, and 2780-3056 (68.0%-74.8%) expressed worry about various aspects of COVID-19. The results of the multivariate multinominal logistic regression analyses showed that perceived severity, perceived impact, fear, and worry were risk factors for probable depression and anxiety, while self-efficacy was a protective factor. The results of the multivariate logistic regression analysis showed that perceived susceptibility was associated with always wearing a face mask.

Conclusions: Chinese pregnant women showed high levels of mental distress but low levels of personal protective behavior during the COVID-19 pandemic. Interventions are needed to promote the mental health and health behavior of pregnant women during the pandemic.

Introduction

COVID-19 as an Emerging Infectious Disease

In December 2019, a cluster of viral pneumonia cases of unknown cause, later named COVID-19, were detected in Wuhan, Hubei Province. After that, more cases of new infections and deaths were reported across cities in China. Due to the highly contagious nature of the disease, the COVID-19 outbreak spread worldwide in less than three months. As of February 1, 2021, a total of 102,339,513 confirmed cases of COVID-19 and 2,217,005 deaths were reported worldwide [1]. The outbreak of COVID-19 represents a public health emergency of international concern.

Measures to Prevent the Spread of COVID-19 in China

Following the initial outbreak of COVID-19 in Wuhan, numerous measures were enacted to prevent further spread of the disease to other parts of China. On January 23, 2020, the Chinese government shut down Wuhan and two additional cities (Wenzhou and Shenzhen) by suspending all modes of transportation to and from these cities. Other measures included cancelling or postponing large public events (ie, Chinese New Year celebrations), prohibition of attendance at school and work, and closure of public amenities. These measures were part of the social distancing policies, which aimed to limit social contacts and human-to-human transmission [2]. Moreover, public information and education campaigns that encouraged personal protective behaviors were promoted through social media marketing and traditional media. A number of protective measures were also implemented to prevent the spread of COVID-19 among members of the workforce who wished to return to work [3]. These measures included enhancing the practice of hand hygiene and wearing a face mask, as well as organizational measures such as improvement of workplace hygiene; tracking the physical health status of employees; and dissemination of facts about COVID-19 prevention [3]. On February 2, 2020, the National Health Commission of China issued a new notice proposing a list of guidelines and recommendations for pregnant women and health care professionals in response to COVID-19. This notice urged strengthening of health counselling, screening, and follow-ups for pregnant women. Recommendations on personal protective measures, including social distancing, hand hygiene, and the use of a face mask when going out, were also stated in the notice [4].

Possible Impact of COVID-19 on Pregnant Women

Due to the immunological changes that occur during pregnancy, pregnant women are generally susceptible to respiratory pathogens and the development of severe pneumonia. Therefore, it is believed that pregnant women may be more susceptible to COVID-19 [5]. Recent reviews found that the most commonly reported symptoms of COVID-19 in pregnant women were fever and dry cough, followed by fatigue, diarrhea, dyspnea, lymphocytopenia with elevated C-reactive protein, sore throat, and myalgia [6-8]. These clinical characteristics of COVID-19 are similar to those of nonpregnant adult patients [6-8]. More complications were observed in symptomatic pregnant women, including intensive care unit admissions, mechanical ventilation, and death [9,10]. Moreover, studies have shown that infected pregnant women are at significantly higher risk for caesarean delivery and preterm birth than the general pregnant population [6,7,11], which is associated with increased risk and complications in both mothers and neonates. A number of fetal and neonatal complications, such as stillbirth, neonatal death, low birth weight, fetal distress, thrombocytopenia accompanied by abnormal liver function, neonatal asphyxia, and death, were also reported [7,12]. Although some reviews reported a low risk of vertical transmission [8,13], it is important to note that most studies to date have found no conclusive evidence of vertical transmission of COVID-19 [6,7,10,11,14]. According to the World Health Organization, mothers with suspected or confirmed COVID-19 are recommended to initiate and continue breastfeeding and mother-infant contact because the benefits of breastfeeding and mother-infant contact substantially outweigh the potential risks of transmission of COVID-19 to the child [15]. As the situation of COVID-19 is constantly changing worldwide, understanding the effect of COVID-19 on pregnancy would be important and beneficial for the development of treatment and management to reduce the morbidity and complications of COVID-19 in both mothers and neonates. Very few studies to date have examined the perceptions, emotions, and mental and behavioral responses to COVID-19 of pregnant women in China.

Mental Health and Personal Preventive Behavior During the COVID-19 Period

The uncertainty of COVID-19 has caused substantial psychological distress to the public. In studies among Chinese people, it was found that during the COVID-19 epidemic, 53.8% of respondents rated the psychological impact of the COVID-19 outbreak as moderate or severe [16], between 16.1% and 20.1% Chinese people scored higher than the cutoff for depression [12,17], and between 20.4% and 35.1% scored higher than the cutoff for anxiety [12,17,18]. Recent studies have revealed that females experience much greater levels of anxiety, depression, and stress than their male counterparts during the COVID-19 pandemic [19-21]. Studies have also shown that pregnant women experienced greater psychological distress than the general population during the COVID-19 epidemic [22,23], as they may face difficulties in accessing health care services due to suspension of transportation and other nonemergency services. Health services for pregnant women may also become limited as the health system is strained by the increasing number of infections. Furthermore, visiting clinics and hospitals for medical checkups may place pregnant women at increased risk of infection. Given the potential risk of COVID-19 infection in pregnancy, pregnant women may feel anxious visiting these facilities and worry about being infected during antenatal checkup. Furthermore, other studies that examined the effect of lockdown and quarantine on the mental health of pregnant population demonstrated a higher prevalence of symptoms of

psychological distress (ie, anxiety, depression, posttraumatic stress symptoms, and insomnia [24,25]). As antenatal stress and mental health problems are associated with multiple adverse outcomes for the child [26,27], it would be pertinent to examine the prevalence and associated factors of mental distress among pregnant women during the COVID-19 period so that early interventions could be designed.

The virus of COVID-19 can be transmitted through respiratory droplets and contacts. From the experience of past epidemic outbreaks, personal protective behaviors such as wearing a mask are recommended to offer protections against virus infection. A recent study reported that the frequency of always wearing a face mask in the past week was 76.1%-85.5% among participants in Wuhan and Shanghai during the COVID-19 period [18]. Research has shown that countries with higher proportions of citizens that used face masks had fewer COVID-19 cases and controlled the epidemic much earlier than countries that discouraged the use of face masks [28]. The frequent use of face masks was found to be associated with a lower number of COVID-19 cases; the perceived benefits of wearing a face mask (eg, effectiveness in preventing virus spread from asymptomatic patients) also boosted confidence and reduced the risk of adverse mental health among Chinese people [28]. Studies among pregnant women during the severe acute respiratory syndrome (SARS) outbreak in Hong Kong found that approximately 70% wore a mask all or most of the time [29]. It was expected that the frequency of wearing a face mask among pregnant women would be high during the COVID-19 pandemic.

Factors Related to Mental Health and Personal Protective Behavior

Cognitions are important determinants of health behaviors and mental health. Protection motivation theory is a prominent theory that highlights the important role of cognition in health [30]. Protection motivation theory posits that two parallel cognitive processes function to predict an individual's motivation to perform a health behavior: threat appraisal and coping appraisal. Threat appraisal focuses on perceived susceptibility (ie, estimation of the possibility of harm from a threat) and perceived severity (ie, estimation of the degree of harm resulting from the threat), while coping appraisal focuses on self-efficacy (ie, level of confidence in coping with the threats) and other factors that may increase or decrease the adaptive response. The perception that the pandemic has caused a significant impact on one's life may decrease the probability of the adaptive response. According to protection motivation theory, increased levels of threat and coping appraisal increase individuals' protection motivation, leading to the performance of a health behavior. Protection motivation theory has been applied to COVID-19 preventive behavior among health care workers and the general public [31,32]. A meta-analysis also confirmed that increases in perceived susceptibility, perceived severity, and self‐efficacy facilitated adaptive intentions or behaviors [33].

Consistent with protection motivation theory, extensive studies have also demonstrated the important role of perceived threats on behavioral and psychological responses to a disease. A review by Bish and Michie [34] identified perceived susceptibility to the disease and perceived severity of the disease as important predictors of protective behaviors during a pandemic. A recent study revealed that individuals' perceived severity of the COVID-19 outbreak is related to an increased level of mental health problems in the Chinese public [35]. Studies from other countries, such as the Philippines, Vietnam, and Turkey, also supported the findings that the perceived impact, perceived susceptibility, and perceived severity of COVID-19 are related to increased levels of mental health problems and preventive behaviors [20,21,36].

The literature has also suggested self-efficacy as an important determinant of mental health and behavior. Studies on epidemic outbreaks, such as SARS and H1N1, have found that self-efficacy was associated with better mental health [37] and higher levels of protective behaviors [38,39], while a lower level of self-efficacy was associated with higher fear related to the disease [40]. Studies during the COVID-19 epidemic also demonstrated that stronger self-confidence, stronger confidence in one's health care providers, and having a good perception of one's health status were significantly associated with lower risks of anxiety, depression, and stress as well as with a lower psychological impact of the pandemic [18,20].

The literature has also highlighted the importance of emotional factors in mental health and behavior. According to the appraisal tendency theory, emotions guide specific cognitive response or appraisal, leading to an effect on mental and behavioral outcomes [41]. Negative emotions, such as fear and worry, are associated with a tendency to perceive a situation as uncertain and less controllable, which prompts individuals to engage in precautionary behaviors. Furthermore, negative emotions may impair individuals' cognitive processes in coping with stressful encounters [42], which drives them to perform a range of precautionary behaviors regardless of their scientific value. Supporting this notion, studies conducted during pandemics, such as H1N1 [43-45] and COVID-19 [36], have shown that negative emotions, such as fear of the pandemic, are associated with the practice of protective behaviors. Negative emotions related to epidemic outbreaks have also been consistently found to be detrimental to mental health [40,46]. It is therefore conjectured that during the COVID-19 pandemic period, pregnant women who showed negative emotions toward COVID-19 may have poorer mental health but be more likely to adopt protective behaviors.

This Study

This study examined the prevalence and identified factors for depression, anxiety, and frequency of face mask wearing during the COVID-19 period among pregnant women in China. Based on the protection motivation theory and the appraisal tendency theory, the roles of perceived susceptibility, perceived severity, perceived impact of COVID-19, self-efficacy, and negative emotions (ie, fear and worry about COVID-19) were examined. It was hypothesized that perceived threat and negative emotions would be risk factors for depression and anxiety, while self-efficacy would be a protective factor. Furthermore, perceived threat, negative emotions, and self-efficacy were

hypothesized to be protective factors of the frequency of wearing a face mask.

Methods

Participants

The target participants were pregnant women who were currently using health care services from maternal health care institutions in Mainland China. Pregnant women who intended to continue the pregnancy were eligible for the study, and those who planned to terminate their pregnancy were excluded.

Procedure

A web-based cross-sectional survey was conducted from March 3-10, 2020. Participants were recruited from maternal health care centers in various provinces of China (ie, Beijing, Chongqing, Guangdong, Guangxi, Hainan, Shandong, Tianjin, and Xinjiang). These maternal health care centers provided antenatal health services to all pregnant women within the region, they contained a record and contact details of those women who were using their health services. Eligible women were first identified from the record and were invited to take part in the survey through WeChat. A quick response (QR) code and link to the web-based survey was provided; interested participants could directly access the web-based survey through scanning the QR code or clicking the link. Information about the purpose and procedure of the survey was provided on the first page of the web-based survey. Participants were assured that no direct identifiers (eg, name, email address, ID number) were collected, all data collected would remain confidential, and only the research team would have access to the data. Refusal to take part in the survey would not affect the services they would obtain at the health care center. Women who agreed to take part in the survey were asked to provide informed consent by clicking the "I agree" button before starting the web-based survey. The survey took 15-20 minutes to complete. Participants received no incentive for their participation. Ethical approval was obtained from the Survey and Behavioral Research Ethics Committee of The Chinese University of Hong Kong (SBRE-19-395). Approximately 5540 invitation messages were sent out, and a total of 4087 completed responses were collected (response rate: 73.8%).

Measures

Sociodemographic Characteristics

Participants were asked to report their age, education level, and employment status.

Pregnancy-Related Characteristics

Participants were asked to report their parity, gestational age, and whether they had any pregnancy-related complications.

Perceived Susceptibility to COVID-19

The participants' perceived susceptibility to COVID-19 was measured by 2 items on the likelihood of oneself and one's family members contracting COVID-19. Items were rated on a 4-point Likert scale from 1, very little, to 4, very much, with a higher score indicating a higher level of perceived susceptibility. The internal reliability of the items was satisfactory (Cronbach α=.94).

Perceived Severity of COVID-19

The participants' perception of the severity of COVID-19 was measured by 3 items (eg, "Would maternal infection with COVID-19 affect the health of the newborn?"). These items were rated on a 4-point Likert Scale from 1, very little, to 4, very much, with a higher score indicating a higher level of perceived severity. The internal reliability of the items was satisfactory (Cronbach α =.92).

Perceived Impact of COVID-19

Participants were given a checklist and were asked to rate whether COVID-19 had affected any part of their daily lives (ie, work, financial income, family relationship, social interactions, others). The number of items endorsed reflected the level of impact. The possible score ranged from 0 to 5, with a higher score indicating a higher level of perceived impact of COVID-19.

Self-efficacy

Self-efficacy was measured by 2 items. Participants were asked to rate their level of confidence of protecting themselves and their family members from contracting COVID-19. Items were rated on a 4-point Likert scale from 1, very little, to 4, very much, with a higher score indicating a higher level of self-efficacy. The internal reliability of the items was satisfactory (Cronbach α=.94).

Fear

Fear was measured by a single item. Participants were asked to rate their level of fear of COVID-19 on a 4-point Likert scale from 1, very little, to 4, very much, with a higher score indicating a higher level of fear.

Worry

Worry was measured by 4 items. Participants were asked to rate their level of worry regarding different aspects related to COVID-19 (eg, "You will be infected with COVID-19 when you attend the prenatal check-up"). Items were rated on a 4-point Likert scale from 1, very little, to 4, very much, with a higher score indicating a higher level of worry. The internal reliability of the items was satisfactory (Cronbach α=.92).

Frequency of Face Mask Wearing

Participants were asked to report their frequency of wearing a face mask when going out on a 4-point Likert scale from 1, never, to 4, always. A cutoff of always wearing a face mask was set in this study; this cutoff has been used in previous studies [44,47].

Depression

Depression was measured by the 9-item Patient Health Questionnaire (PHQ-9) [48]. The Chinese version has been validated and used in the Chinese population [49,50]. Participants were asked to rate how often they have been bothered by symptoms in the past 2 weeks on a 4-point Likert scale from 0, not at all, to 3, almost every day. The total score ranges from 0 to 27, with a higher score indicating a higher

level of depression. Scores of 0-4, 5-9, 10-14, 15-19, and 20-27 represent minimal, mild, moderate, moderately severe, and severe depression, respectively.

Anxiety

Anxiety was assessed by the 7-item General Anxiety Disorder scale (GAD-7) [51]. It is a brief, self-reported scale for identifying probable cases of generalized anxiety disorder (GAD). The Chinese version has been validated and used in the Chinese population [52,53]. Participants were asked how often they experienced each symptom in the past 2 weeks on a 4-point Likert scale from 0, not at all, to 3, nearly every day. The GAD-7 total score ranges from 0 to 21, with a higher score indicating a higher level of anxiety. Scores of 0-4, 5-9, 10-14, and 15-21 represent minimal, mild, moderate, and severe anxiety, respectively.

Analysis

Descriptive statistics on the participants' sociodemographic and pregnancy-related characteristics, perceived threat, self-efficacy, negative emotions, and prevalence of depression, anxiety, and frequency of face mask wearing are presented. To identify significant factors of depression and anxiety, univariate multinominal logistic regressions were first conducted to examine the association between all factors with depression and anxiety, and respective odds ratios derived from univariate logistic regression (ORus) and 95% confidence intervals are presented. To control for the potential effect of sociodemographic and pregnancy-related characteristics, all sociodemographic characteristics, pregnancy-related characteristics, and independent variables with $P<.05$ in the univariate multinominal regression models were then subjected to multivariate multinominal logistic regression analysis; the resulting multivariate odds ratios (ORms) are reported.

To identify significant factors of always wearing a face mask when going out, univariate logistic regressions were first conducted to examine the association between all factors and the outcome, and the respective ORus and 95% confidence intervals are presented. To control for the potential effect of sociodemographic and pregnancy-related characteristics, all sociodemographic characteristics, pregnancy-related characteristics, and independent variables with $P<.05$ in the univariate logistic regressions were then subjected to a multivariate logistic regression analysis, and the resulting ORms were reported. Data analyses were performed using SPSS version 21.0 (IBM Corporation), with a P value of <.05 being considered statistically significant.

Results

Descriptive Statistics of the Participants

Slightly more than two-thirds (2743/4087, 67.1%) of the participants were aged 30 years or less. Nearly half of the participants (1989/4087, 48.7%) had received a postsecondary level of education. Approximately half of the participants (2022/4087, 49.5%) were nulliparous, and a similar number (1860/4087, 45.5%) were in their third trimester. A small number of participants (6.6%) reported having some pregnancy-related complications (Table 1).

Moderate (10-14)	504 (12.3)
Moderately severe (15-19)	227 (5.6)
Severe (20-27)	95 (2.3)
Anxiety (measured by GAD-7[b])	

Characteristic	Value, n (%)
Minimal (0-4)	2740 (67.0)
Mild (5-9)	919 (22.5)
Moderate (10-14)	318 (7.8)
Severe (15-21)	110 (2.7)

[a]PHQ-9: 9-item Patient Health Questionnaire.

[b]GAD-7: 7-item General Anxiety Disorder Scale.

Prevalence of Depression, Anxiety and Frequency of Wearing a Face Mask

The prevalence of mild to severe depression (PHQ score >5) and mild to severe anxiety (GAD-7 score >5) was 48.7% (1989/4087) and 33.0% (1347/4087), respectively. Less than a quarter of the participants (974/4087, 23.8%) reported always wearing a face mask when going out (Table 1).

Perceived Threats, Negative Emotions, and Self-Efficacy

One-third of the 4087 participants perceived that they (1313, 32.1%) or their family members (1490, 36.4%) were likely to be infected with COVID-19 (ie, perceived susceptibility), and a sizable number of participants (3216, 78.7%, to 3518, 86.1%) agreed that the disease would have various severe consequences, such as mother-to-child transmission (ie, perceived severity; Table 2). Approximately one-fifth of respondents (894/4087, 21.9%) reported a score of 3 or above on perceived impact (Table 3). Slightly more than half were confident that they could protect themselves (2275/4087, 55.7%) or their family members (2232/4087, 54.6%) from contracting COVID-19. Approximately one-third (1303/4087, 31.9%) reported a high level of fear of the disease, and more than two thirds (2780/4087, 68.0%, to 3056/4087, 74.8%) showed worry about various aspects of COVID-19 (Table 2).

Table 2. Perceived threats, negative emotions, and self-efficacy of pregnant women during the COVID-19 period (N=4087).

Variable	Value, n (%)			
	Very little	Little	Much	Very much
Perceived susceptibility				
Likelihood of oneself contracting COVID-19	788 (19.3)	1986 (48.6)	944 (23.1)	369 (9.0)
Likelihood of one's family members contracting COVID-19	713 (17.4)	1884 (46.1)	1052 (25.7)	438 (10.7)
Perceived severity				
COVID-19 will be transmitted from mother to child	261 (6.4)	610 (14.9)	2114 (51.7)	1102 (27.0)
Maternal infection of COVID-19 will be more difficult to cure than in the general population	212 (5.2)	479 (11.7)	2074 (50.7)	1322 (32.3)
Maternal infection of COVID-19 will affect the health of the child	203 (5.0)	366 (9.0)	1944 (47.6)	1574 (38.5)
Self-efficacy				
Confidence of protecting oneself from contracting COVID-19	478 (11.7)	1334 (32.6)	1588 (38.9)	687 (16.8)
Confidence of protecting family members from contracting COVID-19	443 (10.8)	1412 (34.5)	1601 (39.2)	631 (15.4)
Fear				
Level of fear of COVID-19	666 (16.3)	2118 (51.8)	991 (24.2)	312 (7.6)
Worry				
Worry about being infected with COVID-19 when attending a prenatal checkup	258 (6.3)	773 (18.9)	1983 (48.5)	1073 (26.3)
Worry about one's hospital delivery arrangement being affected due to COVID-19	371 (9.1)	936 (22.9)	1841 (45.0)	939 (23.0)
Worry that accompanied delivery will not be available due to COVID-19	398 (9.7)	865 (21.2)	1844 (45.1)	980 (24.0)
Worry that child health services will be affected after delivery due to COVID-19	339 (8.3)	746 (18.3)	1957 (47.9)	1045 (25.6)

Table 3. Scores of perceived impact of COVID-19 (N=4087).

Total score of perceived impact	Value, n (%)
1	2138 (52.3)
2	1055 (25.8)
3	592 (14.5)
4-5	302 (7.4)

Multinominal Logistic Regression Models for Depression

The results of the univariate multinominal logistic regression analyses showed that among all the background characteristics, being multiparous was a protective factor for mild depression (ORu 0.63, 95% CI 0.45-0.88) and being a farmer was a protective factor for moderately severe depression (ORu 0.72, 95% CI 0.53-0.96) (Table 4). Among the cognitive and psychological variables, perceived susceptibility (ORu 1.17-1.26), perceived severity (ORu 1.14-1.52) and fear (ORu 1.46-2.12) were risk factors for all levels of depression, and perceived impact was a risk factor for mild, moderate, and moderately severe depression (ORu 1.14-1.32). On the other hand, self-efficacy (ORu 0.89, 95% CI 0.82-0.96) was a significant protective factor for moderately severe depression (Table 4). The results of the multivariate multinominal regression analyses showed that after adjusting for significant background variables, perceived severity (ORm 1.08 and 1.09 for mild and moderate depression, respectively), perceived impact (ORm 1.08 and 1.12 for mild and moderate depression, respectively), fear (ORm 1.26-1.70 for all levels of depression), and worry (ORm 1.05 and 1.27 for moderate and severe depression, respectively) were significant risk factors, while self-efficacy was a protective factor (ORm 0.79-0.87 for moderate to severe depression) to different levels of depression (Table 5).

Multinominal Logistic Regression Models for Anxiety

Results from univariate multinominal logistic regressions showed that among all the background characteristics, being multiparous was a risk factor (ORu 2.51, 95% CI 1.32-4.75), while being a farmer was a protective factor (ORu 60, 95% CI 0.40-0.90) for severe anxiety. Education level (ORu 0.32 to 0.46 for matriculation and undergraduate level) was a protective factor for moderate anxiety. Among the cognitive and psychological variables, perceived susceptibility (ORu 1.20-1.24), perceived severity (ORu 1.19-1.52), fear (ORu 1.62-3.03), and worry (ORu 1.16-1.41) were risk factors for all levels of anxiety, and perceived impact was a risk factor for mild and moderate anxiety (ORu 1.16-1.29). On the other hand, self-efficacy (ORu 0.90-0.93) was a significant protective factor for moderate and severe anxiety (Table 6). The results from the multivariate multinominal regression analysis showed that after adjusting for significant background variables, fear (ORm 1.36-2.88) and worry (ORm 1.09-1.22) were risk factors, while self-efficacy was a protective factor (ORm 0.77-0.90) for all levels of anxiety. Furthermore, perceived severity (ORm 1.07, 95% CI 1.02-1.13) was a risk factor for mild anxiety, and perceived impact (ORm 1.22, 95% CI 1.09-1.37) was a risk factor for moderate anxiety (Table 7).

Logistic Regression Models for Always Wearing a Face Mask When Going Out

Results from the univariate logistic regression analyses showed that among all the background characteristics, being in the third trimester (ORu 0.64, 95% CI 0.53-0.77) and pregnancy-related complications (ORu 0.69, 95% CI 0.50-0.95) were risk factors for always wearing a face mask when going out. Having a postgraduate level of education or above was a protective factor for always wearing a face mask (ORu 2.78, 95% CI 1.53-5.05) (Table 8). Among the cognitive and psychological variables, perceived susceptibility (ORu 1.07, 95% CI 1.02-1.11), perceived severity (ORu 1.05, 95% CI 1.02-1.09), and worry (ORu 1.03, 95% CI 1.00-1.05) were associated with always wearing a face mask. The results of the multivariate logistic regression analysis showed that after adjusting for significant background variables, perceived susceptibility was the only significant factor (ORm 1.05, 95% CI 1.00-1.10) for always wearing a face mask (Table 8).

Discussion

Principal Findings

The COVID-19 pandemic is an emerging and rapidly evolving situation. People receive information from various sources may form different perceptions about COVID-19. In this study, between 32.1% (1313/4087) and 36.4% (1490/4087) of the participants perceived that they or their family members were susceptible to the disease, and between 78.7% (3216/4087) and 86.1% (3518/4087) believed that the disease would have various serious consequences. Participants also reported that the disease has affected various parts of their lives. The perceived susceptibility and severity of COVID-19 were considerably higher compared to those observed in a study conducted among residents of Wuhan and Shanghai, which showed that 12.5%-18.6% of participants perceived that they were likely to be infected with COVID-19 and 12%-19.9% rated the disease as serious [18]. The figures were also higher compared with those in studies conducted during other epidemics, such as SARS (eg, approximately 20% of pregnant women considered themselves likely to contract SARS during the SARS epidemic period) [29]. Our findings suggest that a substantial number of pregnant women overestimated their risk of contracting COVID-19 and the severity of infection. Furthermore, slightly more than half of the participants reported high levels of self-efficacy. However, this figure was significantly lower than that in the study conducted in Wuhan and Shanghai, which showed that 86.8% to 87.8% of participants perceived a high level of confidence in taking measures to protect themselves from COVID-19 [18].

Negative emotions towards COVID-19 were commonly documented in this study. Approximately one-third of the 4087 participants (1303, 31.9%) showed high levels of fear towards the disease, and more than two thirds (2780, 68.0%, to 3056, 74.8%) reported different worries related to the COVID-19 pandemic, including worries of contracting the infection when attending antenatal checkups and worries that their delivery and child health services would be affected due to the epidemic. The level of negative emotions is comparable to that documented among pregnant women and the general public during the SARS period in Hong Kong, for which studies found that more than half of the participants worried about themselves or their family members contracting SARS and two-thirds of the women were scared of going to the hospital for antenatal visits [29,54]. Due to the high level of transmissibility of COVID-19 and the disruptions that the pandemic has caused in daily life, it is not surprising that high levels of fear and worry related to the disease were reported in this study. The psychological impact of an epidemic outbreak on pregnant women warrants immediate attention.

It is important to note that nearly half of this sample (1989/4087, 48.7%) scored above the cutoff for probable depression, and one-third (1347/4087, 33.0%) scored above the cutoff for probable anxiety. The prevalence was significantly higher than that reported in the general population of pregnant women [55] as well as that reported among the general public during the COVID-19 period [12,17,18]. These findings were also in line with those conducted in countries such as Canada and Japan, which also showed elevated depression and anxiety among pregnant women during the COVID-19 pandemic [56,57]. Our findings suggest that mental health problems were heightened among pregnant women during the COVID-19 pandemic. Furthermore, it is surprising that although a high level of perceived susceptibility, perceived severity, and perceived impact were reported, less than a quarter of the sample (974/4087, 23.8%) reported always wearing a mask when going out. The prevalence of wearing a face mask was substantially lower compared to that reported in studies among pregnant women and the general public during the SARS epidemic (ie, approximately 70%) [29,54], and the one reported in Wuhan and Shanghai during the COVID-19 pandemic [18]. Our findings show that pregnant women reported poor mental health and personal protective behavior during the COVID-19 epidemic. Efforts should be made to provide education to this specific at-risk group.

This study also identified some factors associated with mental health and protective behavior. The results of the multivariate analyses showed that among the cognitive variables, perceived severity and perceived impact of COVID-19 were associated with higher levels of depression and anxiety. These findings are in line with those of previous studies of epidemic outbreaks such as SARS, in which individuals who had a negative appraisal of the disease reported mental health problems [40,46]. Individuals who endorsed higher levels of negative impact of COVID-19 on their daily lives and perceived that they would experience serious consequences of the disease may have been more likely to exhibit negative emotional responses. Furthermore, perceived susceptibility was associated with higher likelihood of wearing a face mask when going out. These findings are consistent with the extant theories, such as protection motivation theory, that higher perceptions of risk and threat are associated with higher levels of engagement in health behaviors [33].

Consistent with previous studies that documented a positive association between self-efficacy and mental health outcomes [37,58], this study found that self-efficacy was associated with lower levels of depression and anxiety. Individuals with higher level of self-efficacy may have better ability to regulate the distress and negative mental health impact of the COVID-19 pandemic. They may be more likely to use more positive coping strategies to manage their emotions when encountering adversities associated with the disease. Surprisingly, despite

the extensive evidence on the positive role of self-efficacy in explaining a range of health behaviors, self-efficacy had no significant association with wearing a face mask when going out in this study. In this study, self-efficacy was conceptualized as the perceived capability of protecting oneself or one's family members from being infected with COVID-19; it was not behavior-specific in nature and may therefore have failed to predict face mask–wearing behavior.

Consistent with the literature that documented the negative impact of negative emotions and mental health [59,60], fear and worry were associated with higher levels of depression and anxiety in this study. However, no significant association between fear and worry with always wearing a mask when going out was found in this study. The findings suggest that the current sample of pregnant women may be more likely to regulate their negative emotions through mental health rather than behavioral response. More research is needed to elucidate the association between negative emotions and mental and behavioral outcomes under different contexts.

Implications

The findings of this study provide implications for health care professionals and policy makers to address the threats posed to pregnant women by COVID-19 and by any possible future incidences of epidemic outbreaks. As poor health of pregnant women will lead to undesirable outcomes of both the mother and child, interventions to mitigate the negative effects of COVID-19 in this population is highly essential. First, this study found that cognitive perceptions on perceived threats of COVID-19 were associated with wearing a mask. To promote realistic risk perceptions and effective precautions of COVID-19, communication through various channels is essential. There is a need for governments and health care professionals to provide scientific information on the transmissibility and consequences of the disease and the efficacy of protective measures. However, because perceived threats are also associated with worse mental health outcomes, it is important to aim these health messages at increasing individuals' threat-related beliefs while at the same time reducing misconceptions and adverse emotional and mental health outcomes.

Increasing self-efficacy should also be considered, as it has been found to be associated with better mental health. This increase can be achieved through cognitive restructuring of perceived capability in self-care and reappraisal of stressors related to the COVID-19 epidemic, as well as by providing encouragement and role modelling of positive behaviors. Digital psychotherapy, namely internet cognitive behavioral therapy (iCBT), has been demonstrated to be effective in combating the growing prevalence of mental health problems related to COVID-19 [61]. Previous studies have found that iCBT is efficacious in treating depression, anxiety, and insomnia [61,62]. In the context of COVID-19, iCBT could be a useful means for pregnant women to obtain mental health support without concern about contracting the disease from face-to-face contact [63]. As health care professionals are well-placed to recognize potential mental health problems at an early stage, routine screening for depression and other mental health conditions in pregnant women should be considered in obstetrical settings during the COVID-19 pandemic. Moreover, support from family, friends, and health care professionals can also promote the mental health of pregnant women by enhancing their perceived efficacy in coping with the disease.

Finally, the negative associations between negative emotions and mental health also suggest that health education should seek ways to disseminate a realistic level of risk that will not induce excessive worry and fear. It has also been shown that uncertainty can cause fear during pregnancy [64]. It is important to equip women with adequate knowledge about COVID-19 to reduce their fear and worry regarding the disease. Emotion regulation training can also be offered to improve their skills in regulating negative emotions.

Limitations

The study was cross-sectional in nature, so causality cannot be assumed. Data were collected in a few cities; therefore, the findings may not be representative of the entire population of pregnant women in China. This study mainly used self-reported questionnaires to measure psychiatric symptoms and did not make clinical diagnoses. The standard for establishing a psychiatric diagnosis involves a structured clinical interview and functional neuroimaging [65,66]; therefore, the prevalence of mental health problems might have been overestimated. In addition, as participation was voluntary, the provinces that agreed to take part might have provided better services and support to pregnant women during the pandemic, leading to bias in the mental health and protective behaviors of the sample. Caution is needed when generalizing the findings to the population of pregnant women in China. In addition, the income levels of the pregnant women were not recorded. Lastly, as no validated scale on measuring perceptions of COVID-19 is available, variables were assessed by self-developed items with references to previous studies on other epidemics (eg, SARS), and some variables (ie, level of fear) were measured by a single item. The reliability of the items should be interpreted with caution.

Conclusion

This study provided important insights on pregnant women's perceptions of and emotional reactions to COVID-19 as well as their potential influence on behavioral and mental health. This study demonstrated that pregnant women reported a high level of perceived threat towards COVID-19; however, the frequency at which they wore a mask when going out was suboptimal. Most of the women showed negative emotions and mental responses. Our findings provide an important guide for health care professionals and policy makers to develop strategies to alleviate the negative effects of the COVID-19 epidemic.

Abstract

Background: In the current era of widespread access to the internet, we can monitor public interest in a topic via information-targeted web browsing. We sought to provide direct proof of the global population's altered use of Wikipedia medical knowledge resulting from the new COVID-19 pandemic and related global restrictions.

Objective: We aimed to identify temporal search trends and quantify changes in access to Wikipedia Medicine Project articles that were related to the COVID-19 pandemic.

Methods: We performed a retrospective analysis of medical articles across nine language versions of Wikipedia and country-specific statistics for registered COVID-19 deaths. The observed patterns were compared to a forecast model of Wikipedia use, which was trained on data from 2015 to 2019. The model comprehensively analyzed specific articles and similarities between access count data from before (ie, several years prior) and during the COVID-19 pandemic. Wikipedia articles that were linked to those directly associated with the pandemic were evaluated in terms of degrees of separation and analyzed to identify similarities in access counts. We assessed the correlation between article access counts and the number of diagnosed COVID-19 cases and deaths to identify factors that drove interest in these articles and shifts in public interest during the subsequent phases of the pandemic.

Results: We observed a significant (P<.001) increase in the number of entries on Wikipedia medical articles during the pandemic period. The increased interest in COVID-19–related articles temporally correlated with the number of global COVID-19 deaths and consistently correlated with the number of region-specific COVID-19 deaths. Articles with low degrees of separation were significantly similar (P<.001) in terms of access patterns that were indicative of information-seeking patterns.

Conclusions: The analysis of Wikipedia medical article popularity could be a viable method for epidemiologic surveillance, as it provides important information about the reasons behind public attention and factors that sustain public interest in the long term. Moreover, Wikipedia users can potentially be directed to credible and valuable information sources that are linked with the most prominent articles.

KEYWORDS

COVID-19; pandemic; media; Wikipedia; internet; online health information; information seeking; interest; retrospective; surveillance; infodemiology; infoveillance

Introduction

After the COVID-19 pandemic outbreak began, a new concern for public health emerged—predicting and preventing the spread of the disease. The increased media coverage on the COVID-19 pandemic focused the public's attention and likely affected the most popular internet search terms, thus altering people's behavior worldwide [1,2]. The public consumption of COVID-19 information in digital media is directly associated with preventive behaviors, including regularly washing hands with soap and water, staying away from crowded places, and wearing face masks in public [3]. Bragazzi et al [4] have suggested that internet search trend data can be used to build predictive models of disease spread and help with containing the pandemic. Bento et al [5] has shown that the internet search term "coronavirus" increased in popularity immediately after the day of the first COVID-19 case announcement. However, the term's popularity returned to the baseline level in less than 1-2 weeks. After this period, other terms that pertained to community-level policies (ie, quarantine, school closures, and COVID-19 tests) or personal health strategies (ie, masks, grocery delivery, and over-the-counter medications) emerged as the most-searched terms [5]. Other studies have shown that public interest in specific search terms is more associated with reported deaths and media coverage than with real epidemiologic situations [6]. Moreover, it has been observed that people quickly experience information overload, which results in information avoidance [7]. Therefore, it seems logical to identify the most credible and reliable sources and use them to inform the public during the "information-hungry" period of any subsequent pandemics that may occur.

Wikipedia is considered a key web-based source of health information, and people are more willing to seek information that is published in Wikipedia than information from any other health websites [8]. Wikipedia's quality has been a highly debated topic, and many researchers are highly skeptical of the platform [9]. Nevertheless, in 2005, a comparative study that was published in *Nature* reported that Wikipedia was competing head-to-head with Britannica [10]. Since then, many different studies on Wikipedia's accuracy have shown that it is quite on par with published professional sources, as it provides reliable information [11,12]. Studies have reported that the quality of medical information that is available in Wikipedia is consistently high [13,14]. It has also been reported that Wikipedia is more reliable than several published sources, despite its low readability [15]. Medical articles in Wikipedia are based on reliable sources and mainly skew toward the most prominent academic journals [16]. More and more scholars have embraced the use of Wikipedia in the classroom [17,18]. The wide acceptance of Wikipedia is also related to institutional recognition. The American Psychological Association and the Association for Psychological Science have encouraged their members to edit Wikipedia articles [19,20].

With regard to medical information, Wikipedia's popularity exceeds that of the National Health Service, WebMD, Mayo Clinic, and World Health Organization (WHO) websites combined. This is mostly due to the highly accurate information that is provided by the editors of Wikiproject Medicine [21]. Wikiprojects are edited by self-organized groups of volunteers who are involved in curating information on a specific topic [13]. Since their reliability in providing medical information is so high, the WHO has partnered with the Wikimedia Foundation to expand access to trusted COVID-19–related information on Wikipedia [22]. Several studies have indicated that medical students who use Wikipedia to prepare for their exams receive better grades than students who only rely on textbooks [23]. Wikipedia has become a vital tool for global public health promotion [24].

The quality and popularity of Wikipedia's medical content make analyzing the most popular medical articles extremely interesting from a medical professional's point of view. Additionally, changes in viewership and peaks in interest are of high relevance to public health specialists. Given that Wikipedia has over 300 language variations that differ significantly in terms of rules, culture, and the presentation of knowledge [25], it is also interesting to compare changes in the popularity of Wikipedia medical articles across languages. Hence, to better understand public interest in high-quality health information during the COVID-19 pandemic, we conducted an analysis of daily visits to Wikipedia articles that were published from 2015 to 2020 and sought to identify possible factors for attracting public attention.

Methods

Detecting and Quantifying the Surge in COVID-19–Related Searches

We collected a list of 37,880 articles that were curated by the English Wikipedia Medicine Project. We derived the daily access counts (ie, from July 1, 2015, to September 13, 2020) of these articles by using ToolForge (ie, a pageview analytics tool). Daily access was defined as each visit to a given article on a given date. These data did not contain user-specific information.

We limited our selection to the 100 most accessed English Wikipedia Medicine Project articles that were published from July 1, 2015, to September 12, 2020. No other filters were applied to included Wikipedia articles. By using an interwiki mechanism (ie, cross-references for different language versions of Wikipedia), we identified articles that reported on the same subject in nine other language versions of Wikipedia (ie, French, German, Swedish, Dutch, Russian, Italian, Spanish, Polish, and Vietnamese). The articles were matched, and their daily access counts from July 1, 2015, to September 13, 2020 were obtained. These data were stored in an Excel sheet that used English Wikipedia article names. Extracted daily access data are provided in Multimedia Appendix 1.

To provide additional context with regard to the ongoing COVID-19 pandemic, we also obtained pandemic-related data. We decided not to use reports on the total number of daily confirmed SARS-CoV-2 infection cases due to the possible influencing effect of introducing different public testing schemes. Other factors, such as the total number of daily deaths, are less likely to be altered by regional politics and health care discrepancies. Thus, we decided to measure the effect of the COVID-19 pandemic by analyzing the total number of global deaths and region-specific deaths, which were defined as the cumulative number of deaths resulting from SARS-CoV-2 infection for all reported countries and language-specific countries, respectively. These data were obtained from standardized public information in the Our World in Data University of Oxford initiative website [26].

The preprocessing of Wikipedia article access data was performed in Python 3.8, Excel version 2011 (Microsoft Corporation). Due to the influences of day-to-day differences in Wikipedia access and absolute differences in access to the different language versions of Wikipedia, we standardized access data by calculating daily article access as percentages of language-specific access to Wikipedia on a given day.

To identify deviations in the stability of article visits, we chose articles that exhibited the least altered access patterns throughout the investigated period. Articles were selected based on their relative stability (ie, the SD of percent article access in a 30-day moving window divided by the 30-day moving average [ie, mean] of percent article access), which was calculated for the full duration of investigated period. Relative stability was assessed to identify articles that exhibited relatively unchanged access patterns throughout the studied period. Reference articles were defined as the 20 most stable articles across all languages. These articles provided the highest mean daily access percentages for all evaluated periods. As such, a reference article could be used for direct comparisons with other highly accessed articles. They also provided metrics that were the least affected by changes in Wikipedia use.

Statistical Analysis

A statistical analysis was conducted to identify access patterns in Wikipedia and Wikipedia Medicine Project articles that were published in 2020 and to determine these patterns' association with the COVID-19 pandemic. First, we investigated the association between Wikipedia access before and during the COVID-19 pandemic. Second, we determined whether there were specific articles of interest before and during the COVID-19 pandemic (ie, excluding the years that were associated with other epidemics that were covered in media). We also investigated whether the total number of global and regional deaths resulting from SARS-CoV-2 were associated with increased access to articles of interest during the COVID-19 pandemic.

We also investigated whether there was a difference between navigation to Wikipedia articles of interest before and during the COVID-19 pandemic. To this end, we determined the minimum number of links required to navigate between two articles within Wikipedia (ie, the degree of separation [DOS]). The statistical analysis was conducted in Python 3.8 and Statistica 13.3 (Statsoft, TIBCO Software Inc, Dell Inc). The DOS was assessed by using the PHP (hypertext preprocessor) language and jQuery library, which were implemented in the Degrees of Wikipedia tool [27]. To facilitate the straightforward representation of DOS results, we provided the DOSs of articles of interest that were found across the highest number of Wikipedia language versions. Due to the observed lack of a normal distribution in article access, we used nonparametric methods. We considered a P value of <.05 to be statistically significant.

Abnormalities in Wikipedia access patterns that occurred from July 1, 2015, to September 13, 2020, were investigated by using the Chi-square goodness-of-fit test. To identify the qualitative changes in the annual top 10 most accessed Wikipedia Medicine Project articles, we used word clouds as graphical representations of access patterns.

Identifying Shifts in Search Patterns Before and During the COVID-19 Pandemic

We determined whether the COVID-19 pandemic altered temporal article access patterns. This was achieved by using a k-nearest neighbor (kNN) unsupervised clustering method for analyzing selected Wikipedia language versions. As we were interested in the patterns of access to articles that were of increased user interest in a given period, we performed separate unsupervised clustering analyses for the 2017-2019 and 2020 periods. We excluded the 2015-2016 period due to the possible influence of the Zika virus epidemic, which could have promoted interests in the general population that were similar to interests during the COVID-19 pandemic. As such, we were able to identify articles of user interest during the 2017-2019 and 2020 periods.

We provided a tabular representation of kNN-recognized articles that were associated with increased access before and during the COVID-19 pandemic. The weights that were detected by the kNN algorithm were used to analyze monthly changes in the public's interest in overrepresented articles during the COVID-19 pandemic and these articles' relation to the total number of global and regional deaths resulting from SARS-CoV-2 infection. This correlation was tested by performing a Spearman rank correlation analysis. We further divided the data by month (ie, March to September 2020) to evaluate whether the correlation changed between months.

We compared navigation patterns between articles of interest that were published before and during the COVID-19 pandemic by using the DOSs of reference articles. These patterns were tested with the Kruskall-Wallis test, Dunn posthoc test, and U Mann-Whitney test.

Results

Characteristics of Wikipedia Medicine Project Articles

We analyzed visits to Wikipedia Medicine Project articles that were published in 10 language versions of Wikipedia from 2015 to 2020. These languages included English, French, German, Swedish, Dutch, Russian, Italian, Spanish, Polish, and

Vietnamese. We analyzed 100 articles from English Wikipedia after mapping the other language versions of Wikipedia (ie, 100 articles from French Wikipedia, 98 from Dutch Wikipedia, 98 from Spanish Wikipedia, 97 from Russian Wikipedia, 96 from Italian Wikipedia, 95 from German Wikipedia, 94 from Polish Wikipedia, and 93 from Vietnamese Wikipedia). Due to its low coverage (ie, <90 matched articles, as determined via the interwiki mechanism), Swedish Wikipedia was removed from the analysis. Wikipedia articles without coverage across all languages included the following: “Bed bug” (25% coverage), “Coronavirus” (50% coverage), “Adderall” (62.5% coverage), “Bubonic plague” (62.5% coverage), “Chronic traumatic encephalopathy” (62.5% coverage); “Plantar fasciitis” (75% coverage), “Alprazolam” (87.5% coverage), “Cancer” (87.5% coverage), “Elizabeth Holmes” (87.5% coverage), “Escitalopram” (87.5% coverage), “Ketogenic diet” (87.5% coverage), “Lorazepam” (87.5% coverage), “Project MKUltra” (87.5% coverage), “Psychopathy” (87.5% coverage), and “Trypophobia” (87.5% coverage). Full lists of articles that are available for each language are provided in Multimedia Appendix 2, Supplementary Table S1.

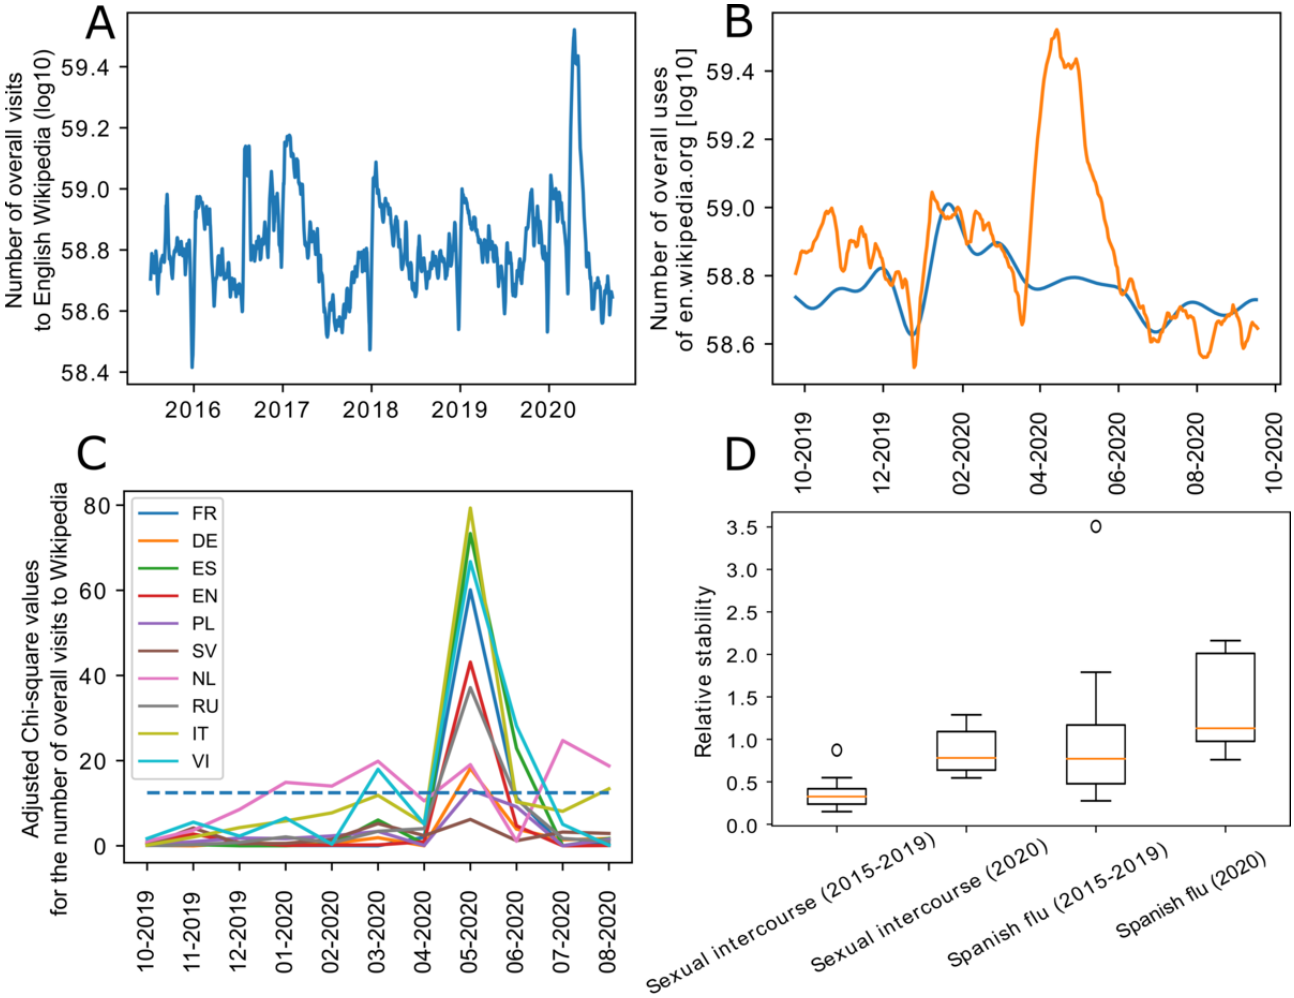
In the 2015-2020 period, there were a total of 2,258,621,012 Wikipedia entries in the top 100 most accessed articles and 775,791,941,485 overall visits to Wikipedia across all selected languages (Wikipedia access across all languages: median 0.41%; range 0.29%-0.46%). Annual access to Wikipedia significantly and gradually decreased from 2015 to 2020 (r=−0.0513; P=.03). Significant increases in use (P<.001) were observed for the English (r=0.0619), Polish (r=0.1237), Dutch (r=0.0481), Italian (r=0.2197), and Vietnamese (r=0.7480) versions of Wikipedia. Significant decreases in use (P<.001) were observed for the German (r=−0.2654), Spanish (r=−0.1085), and Russian (r=−0.4338) versions of Wikipedia. For the top 100 most accessed Wikipedia medical articles, we observed a 1.5-fold to 3.8-fold increase in access across all language versions of Wikipedia in 2020 (ie, compared to access in previous years).

Surge in Article Visits During Early 2020

To determine the effect of the COVID-19 pandemic on Wikipedia use, we used a graphical representation of total daily Wikipedia access (Figure 1). Due to the suspected increase in Wikipedia use during 2020, we constructed a generalized additive model by using a limited-memory Broyden-Fletcher-Goldfarb-Shanno fitting algorithm that was implemented in the FBProphet tool to predict Wikipedia use in 2020 based on previous access patterns. We based the model on data from the 2015-2019 period to identify expected behaviors in 2020 and compare them to observed access patterns. The global pattern for Wikipedia access was indicative of seasonal behaviors (Figure 1). This pattern changed across all language versions of Wikipedia in March 2020, and it returned to normal in September 2020, as predicted by our models. The Chi-square goodness-of-fit test values for monthly Wikipedia access had P values of <.001 across all eight languages (Figure 1).

To determine how abnormal Wikipedia access altered the relative search stability of articles, we needed to pick a point of reference. We determined that the “Sexual intercourse” article demonstrated high yet stable monthly access within the evaluated period. By comparing the “Sexual intercourse” article to the “Spanish flu” article, we were able to determine that the relative access to these articles before the COVID-19 pandemic changed during the pandemic (“Spanish flu” article: P<.04; “Sexual intercourse” article: P<.001; Figure 1).

Figure 1. The disruption in annual Wikipedia visit patterns. (A) The pattern of general English Wikipedia access from 2015 to 2020 (Multimedia Appendix 3). Data for other language versions of Wikipedia are provided in Multimedia Appendix 4, Supplementary Figures S1a-S9a. (B) The FBProphet prediction model was created based on data from the 2015-2019 period. The model compared expected behaviors in 2020 (ie, the blue line) to observed access (ie, the orange line). Data for the other language versions of Wikipedia are provided in Multimedia Appendix 4, Supplementary Figures S1b-S9b. (C) A summary of monthly general access to Wikipedia across all Wikipedia language versions from September 2019 to September 2020. Solid lines represent Chi-square goodness-of-fit values and the dashed line represents the cutoff value. (D) The stability of the two reference Wikipedia articles across all languages in the 2015-2019 and 2020 periods (ie, the moving SD divided by mean percent access across a 30-day window). DE: German; EN: English; ES: Spanish; FR: French; IT: Italian; NL: Dutch; PL: Polish; RU: Russian; SV: Swedish; VI: Vietnamese.



Effects of the COVID-19 Pandemic on the Annual Top 10 Most Commonly Accessed Articles in Wikipedia

We provided a graphical representation of the annual top 10 most accessed articles by creating word clouds for articles that were published from 2015 to 2020 (Multimedia Appendix 3, Multimedia Appendix 4, Supplementary Figures S10-S17). English Wikipedia word clouds are shown in Multimedia Appendix 3, and those for other language versions of Wikipedia are shown in Multimedia Appendix 4, Supplementary Figures S10-S17. We investigated how the 10 most viewed articles changed each year. In the 2015-2019 period, we observed a set of articles that were constantly among the top 10 most accessed articles each year. These articles were as follows: “Leonardo da Vinci” (appearance frequency: 37/45), “Asperger syndrome” (appearance frequency: 36/45), and “Bipolar disorder” (appearance frequency: 28/45). Compared to previous years, there was a distinctive difference in the top 10 most accessed articles in 2020; the “Pandemic” (appearance frequency: 9/9), “COVID-19 pandemic” (appearance frequency: 9/9), “Coronavirus disease 2019” (appearance frequency: 8/9), and “Spanish flu” (appearance frequency: 8/9) articles became the most frequently accessed articles. We found 8 new articles among the top 10 most accessed articles in 2020 that have never appeared in this list. Of these articles, 2 were created after the SARS-CoV-2 pandemic (ie, the “COVID-19 pandemic” and “Coronavirus disease 2019” articles), while the other 6 were present within Wikipedia before the pandemic (ie, the ”Pandemic,” “Spanish flu,” “Coronavirus,” “Bubonic plague,” ”Influenza,” and “World Health Organization” articles).

Identifying Cross-Language Similarities in Article Access Prior to and During the COVID-19 Pandemic via Unsupervised Clustering

The across-language abnormality that was observed in Wikipedia and Wikipedia Medicine Project access frequency in 2020 was further investigated. By conducting an unsupervised analysis, we identified differences between article access before and during the COVID-19 pandemic. Articles that were published in 2020 and recognized by the kNN algorithm were

considered COVID-19–related articles. These included the following eight articles: “Coronavirus,” “Spanish flu,” “Coronavirus disease 2019,” “COVID-19 pandemic, “Influenza,” “Pandemic,” “Virus,” and “Black Death.” The group of articles that were unrelated to COVID-19 included 25 articles. We selected the four articles from this group that were present in most language versions of Wikipedia (ie, the “Sexual intercourse,” “Leonardo da Vinci,” “Bipolar disorder,” and “Borderline personality disorder” articles).

We compared the DOSs of COVID-19–related articles to the DOSs of articles that were unrelated to COVID-19. We used the “COVID-19 pandemic” article as a point of reference for COVID-19–related articles and the “Sexual intercourse” article as a point of reference for articles unrelated to COVID-19. The analysis showed that the DOSs between articles unrelated to COVID-19 and the “Sexual intercourse” article were significantly higher than the DOSs between COVID-19–related articles and the “COVID-19 pandemic” article (Kruskall-Wallis test and posthoc Dunn test: $P<.001$; Table 1). This indicated that COVID-19–related articles were more closely connected, which we suspected due to the observed similarities in themes.

We performed a Spearman rank correlation analysis on articles to provide additional context. We observed that articles unrelated to COVID-19 had higher median correlation values across languages than those in the COVID-19–related article group (Table 1). In the COVID-19–related article group, the highest median correlation value (ie, across all languages) was found between the “COVID-19 pandemic” and “Coronavirus disease 2019” articles (R=0.7022), and the lowest median correlation value was found between the “COVID-19 pandemic” and “Influenza” articles (R=0.0330). In the group of articles unrelated to COVID-19, correlation values were higher. The highest median correlation value was found between the “Sexual intercourse” and “Bipolar disorder” articles (R=0.8657), and the lowest median correlation value was found between the “Sexual intercourse” and “Leonardo da Vinci” articles (R=0.4631).

We also compared the DOSs between all articles that were analyzed in detail and the “COVID-19 pandemic” article. COVID-19–related articles had significantly lower DOSs compared to articles unrelated to COVID-19 (*U* Mann-Whitney test: $P<.001$; Table 1).

Finally, we investigated how the patterns in articles access (ie, those identified by unsupervised clustering) were associated with the total number of global and region-specific deaths resulting from SARS-CoV-2 infection. To this end, we standardized each measure. We used ordinary least squares linear regression to identify correlations across each month in the March to September 2020 period (Figure 2, Multimedia Appendix 2, Supplementary Table S3).

Upon further investigation, we found that the kNN-derived pattern in COVID-19–related articles’ access was significantly associated with both the total number of global and region-specific deaths resulting from SARS-CoV-2 infection for articles across all Wikipedia language versions (Figure 2). There was a notable difference in the correlation between article access and the total number of deaths resulting from SARS-CoV-2 infection, which appeared linear for region-specific deaths and negatively exponential for global deaths (Figure 2). This was also reflected by the low absolute Spearman rank coefficients between article access and the total number of global deaths resulting from SARS-CoV-2 infection for the months after June 2020 (Figure 2).

Table 1. Degrees of separation (DOSs) between investigated articles and reference articles within and across article clusters for the 2016-2019 and 2020 periods.

Wikipedia articles	Prevalence[a], %	Spearman R[b] (within groups)	DOSs within groups[c] (IQR)	DOSs across articles[d] (IQR)
COVID-19–related article group				
Coronavirus	80	0.2770	1 (1-1)	1 (1-1)
COVID-19 pandemic	77.8	Reference[e]	Reference[e]	Reference[e]
Spanish flu	55.6	0.4451	2 (1.75-2)	2 (1.75-2)
Coronavirus disease 2019	55.6	0.7022	1 (1-1.25)	1 (1-1.25)
Pandemic	44.4	0.4341	1 (1-1)	1 (1-1)
Black death	33.3	0.4332	2 (2-2)	2 (2-2)
Virus	11.1	0.3851	2 (1-2)	2 (1-2)
Influenza	11.1	0.0330	1.5 (1-2)	1.5 (1-2)
Group of articles unrelated to COVID-19				
Sexual intercourse	88.9	Reference[e]	Reference[e]	3 (2-3)
Leonardo da Vinci	88.9	0.4631	2 (1.5-2)	2 (2-2.5)
Bipolar disorder	77.8	0.8657	3 (2-3)	3 (2.75-3)
Borderline personality disorder	77.8	0.8352	2.5 (2-3)	3 (3-3)

[a]Refers to the presence of an article in k-nearest neighbor–determined groups across all available languages.

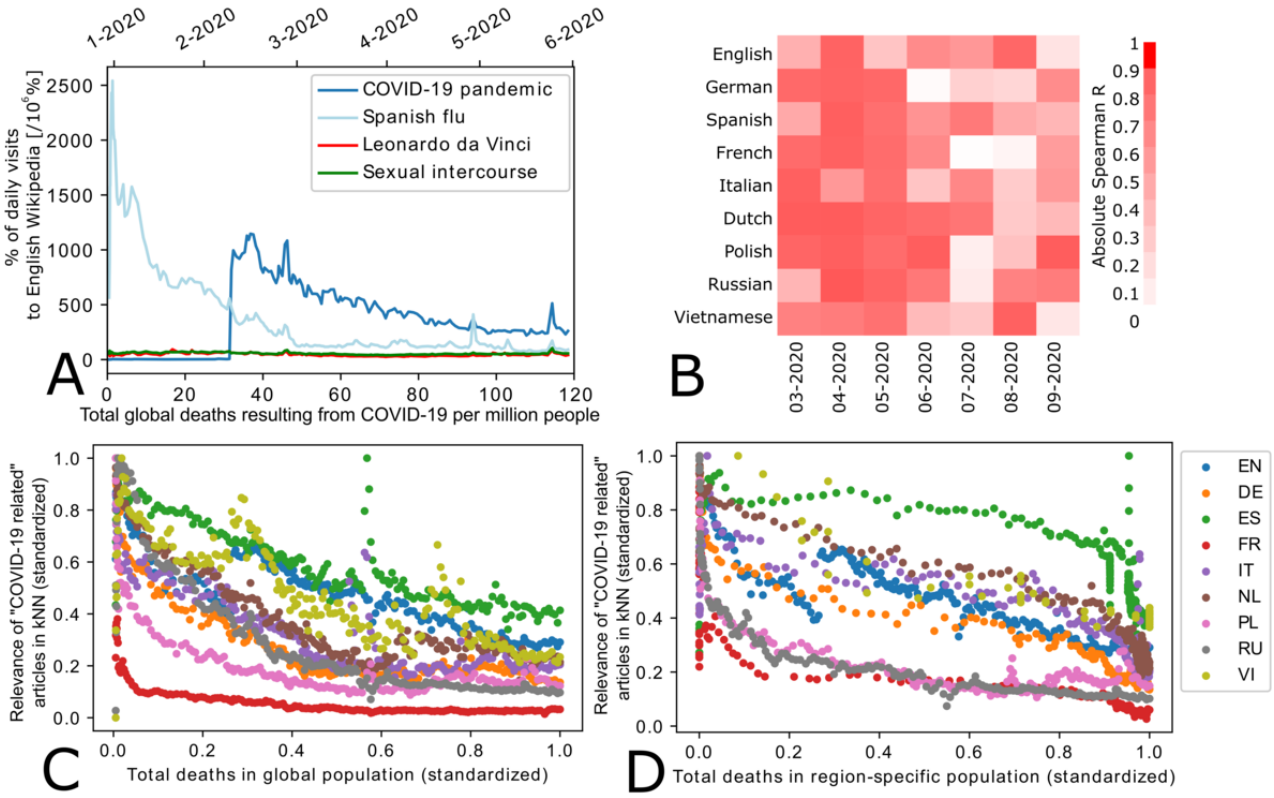
[b]The Spearman R value for an article.

[c]The DOS of an article within a k-nearest neighbor–determined group.

[d]The DOS across all articles that were investigated in detail.

[e]The article of reference for calculating DOSs.

Figure 2. Access to COVID-19–related Wikipedia articles in 2020 and the total number of deaths resulting from SARS-CoV-2 infection. (A) The percentage of daily article access (ie, the "COVID-19 pandemic," "Spanish flu," "Leonardo da Vinci," and "Sexual intercourse" articles) to English Wikipedia and total number of global deaths resulting from SARS-CoV-2 infection (ie, per 1 million people). Data for other language versions of Wikipedia are provided in Multimedia Appendix 4, Supplementary Figures S18-S25. (B) Heatmap of Spearman absolute regression coefficients for COVID-19–related articles and the total number of global deaths resulting from SARS-CoV-2 infection across languages and months. (C) Access to COVID-19–related articles (ie, the kNN-determined relevance values across selected Wikipedia language versions) versus the total number of region-specific deaths resulting from SARS-CoV-2 infection. The graph shows correlations between region-specific deaths and COVID-19–related articles. (D) Access to COVID-19–related articles (ie, the kNN-determined relevance values across selected Wikipedia language versions) versus the total number of global deaths resulting from SARS-CoV-2 infection. DE: German; EN: English; ES: Spanish; FR: French; IT: Italian; kNN: k-nearest neighbor; NL: Dutch; PL: Polish; RU: Russian; SV: Swedish; VI: Vietnamese.



Discussion

Principal Results

Our study shows that the pandemic has significantly influenced patterns in Wikipedia access. There was an apparent surge in interest for infectious disease, which somewhat surprisingly and quickly declined despite the mounting death toll. This is the first study on the impact of the previously recognized change in society's interest, which resulted from the COVID-19 pandemic. In this study, this impact was reflected by changes in Wikipedia access patterns. Moreover, the analysis of different Wikipedia language versions allowed us to confirm that the observed effect of these changes is reflected by both the regional and global impacts of the COVID-19 pandemic. Our study provides proof that an unsupervised clustering method for analyzing data on daily access to medical information could be used to identify interests in global health issues.

Recent studies have indicated that the global lockdown is a possible reason for the change in internet use [28]. We noticed a pronounced increase in the total number of visits to Wikipedia in March 2020. Not only did we observe more frequent visits to Wikipedia, but we also observed a distinctive change in searched topics. The list of the top 10 most accessed articles in 2020 included articles that have not appeared in such lists during previous years. Moreover, the DOS between most of the articles of interest was low, suggesting that navigation was relevant to the observed change. This finding, combined with the correlations between article access, indicated that during the pandemic, people had an increased interest in topics that were not directly related to COVID-19 but were related to pandemics in general. Correlations in access to the "Spanish flu," "Black Death," and "Bubonic plague" articles show that the general public has rapidly gained interest in the topic of previous infectious disease–related health crises. We suspect that these observed correlations are associated with the COVID-19 Wikiproject, which curates articles to provide users with valuable information. The COVID-19 Wikiproject, which is managed by 1200 editors, has resulted in the addition of more than 6500 entries to Wikipedia [29].

Our study shows that similar changes in public interests have already occurred in recent years. We noticed an increase in access to the 2016 "Zika virus" article in 5 of the 9 investigated language versions of Wikipedia. This could be associated with the epidemic that was announced by the WHO in November 2016. This association was also confirmed in the Bragazzi et al [30] and Hickmann et al [31] studies on H1N1-related and Zika virus–related articles and these viruses' respective outbreaks.

Other studies have focused on the increased amount of searches for terms related to anosmia (ie, a characteristic symptom of COVID-19) and have shown its correlation with the SARS-CoV-2 outbreak in many countries [32]. Moreover, trends in the amount of searches for the terms “wash hands,” “hand sanitizer,” and “antiseptic” have successfully predicted the rising number of COVID-19 cases in many countries, which indicates that search trends can potentially be used in epidemiologic surveillance [33]. In our analysis, we noticed an increase in the popularity of a Wikipedia article about the WHO. This result may indicate that the general public has decided to learn more about the organization, making the WHO a focal point for the outbranching of searches. Conversely, this increase in popularity could be linked with President Donald Trump’s attempts to discredit the WHO for the way that they handled the COVID-19 outbreak. These attempts were highly amplified by mainstream media and Twitter [34].

We were interested in identifying the aspect of the pandemic that specifically drove people’s growing interest in COVID-19 from March to June 2020. Our unsupervised clustering analysis showed that the total number of global deaths significantly correlated with the temporal increase in the number of searches for COVID-19–related articles (ie, from March to June 2020). Interestingly, despite the continuous rise in the number of global deaths, the number of visits to COVID-19–related articles decreased after June 2020. This could be interpreted as a gradual decline in global interest toward the pandemic. Data on interest in COVID-19–related articles suggest that there is an increased interest in contagious diseases and that an opportunity to raise awareness through Wikipedia-centered strategies will arise during future outbreaks of infectious diseases. However, the stable correlation between the region-specific number of deaths and the frequency of searches for COVID-19–related articles that persisted until September 2020 is a noteworthy finding. A study by Gozii et al [35] showed that public attention and response are mostly driven by media coverage instead of disease spread. Interestingly, they also showed that the media sharply shifted their focus toward domestic situations as soon as the first death was confirmed in a person’s home country [35]. Therefore, we conclude that reporting about region-specific death reshapes individuals’ perceptions of risk and significantly impacts public interest, thereby affecting the information-seeking behaviors of people from affected areas.

Our study's limitations include the fact that our analysis was restricted to article access data, which did not contain detailed information on user-specific article access patterns or users’ demographic characteristics (eg, age, gender, and educational status). However, we refrained from performing such analyses to maintain the privacy of Wikipedia users. Our study proves that it is possible to identify the global and regional effects of a health crisis on people's behavior. The in-depth analysis of users’ behaviors can be unethical due to its potential for targeting region-specific populations and spreading disinformation, which are ever-present concerns due to the malicious spread of fake news.

Language bias may have also slightly skewed our results, as preferences for English may have resulted in an underreporting of native language–specific searches. Moreover, several idiomatic phrases that are specific to the English vocabulary—“black death” being the prime example—may not directly translate to other languages. To mitigate this bias, we assumed that analyzing data from English Wikipedia would account for most of the global population’s language preferences. Further, we used search data from the other language versions of Wikipedia to validate our results. This strategy yielded a cohesive and surprisingly uniform sample of COVID-19–related search data.

Conclusions

Our results support the idea that Wikipedia can be used as a tool for successfully surveilling trends in public interest. The increase in interest toward COVID-19–related articles was followed by a progressive decline. This shows that the potential optimal window for efficient information dissemination via Wikipedia is the early phase of a pandemic. Wikipedia articles that directly link to major articles about a major health crisis can contribute to the spread of global anxiety and the promotion of prevention behaviors. Therefore, Wikipedia articles should be carefully selected.

Abstract

Background: With the approval of two COVID-19 vaccines in Canada, many people feel a sense of relief, as hope is on the horizon. However, only about 75% of people in Canada plan to receive one of the vaccines.

Objective: The purpose of this study is to determine the reasons why people in Canada feel hesitant toward receiving a COVID-19 vaccine.

Methods: We screened 3915 tweets from public Twitter profiles in Canada by using the search words "vaccine" and "COVID." The tweets that met the inclusion criteria (ie, those about COVID-19 vaccine hesitancy) were coded via content analysis. Codes were then organized into themes and interpreted by using the Theoretical Domains Framework.

Results: Overall, 605 tweets were identified as those about COVID-19 vaccine hesitancy. Vaccine hesitancy stemmed from the following themes: concerns over safety, suspicion about political or economic forces driving the COVID-19 pandemic or vaccine development, a lack of knowledge about the vaccine, antivaccine or confusing messages from authority figures, and a lack of legal liability from vaccine companies. This study also examined mistrust toward the medical industry not due to hesitancy, but due to the legacy of communities marginalized by health care institutions. These themes were categorized into the following five Theoretical Domains Framework constructs: knowledge, beliefs about consequences, environmental context and resources, social influence, and emotion.

Conclusions: With the World Health Organization stating that one of the worst threats to global health is vaccine hesitancy, it is important to have a comprehensive understanding of the reasons behind this reluctance. By using a behavioral science framework, this study adds to the emerging knowledge about vaccine hesitancy in relation to COVID-19 vaccines by analyzing public discourse in tweets in real time. Health care leaders and clinicians may use this knowledge to develop public health interventions that are responsive to the concerns of people who are hesitant to receive vaccines.

Introduction

The approval of the Pfizer-BioNTech and Moderna vaccines sent waves of excitement and relief across the world. However, some people remain hesitant about receiving a vaccine for COVID-19 [1,2]. The World Health Organization noted in 2019 that one of the greatest threats to global health was vaccine hesitancy [3]. Emerging international evidence on COVID-19 vaccine hesitancy suggests that there is a range of reasons for this reluctance, including doubts about the safety and efficacy of the vaccine, political or pharmaceutical mistrust, belief in natural immunity, and the belief that the virus is mild or not life-threatening [4-6].

For herd immunity to any communicable disease to be effective, a considerable portion of the population needs to be vaccinated or have antibodies present from being recently infected. Achieving herd immunity is difficult when a large portion of the public is not vaccinated. For herd immunity to be effective for measles and polio, 95% and 80% of the population need to be vaccinated, respectively [7]. The exact percentage required for herd immunity to COVID-19 is difficult to estimate [7].

A Statistics Canada survey conducted in September 2020 (before a vaccine was approved) indicated that 75% of Canadians were either likely or somewhat likely to receive a vaccination [8]. An Angus Reid Institute [4] study conducted between December 8 and 11, 2020 found that 48% of Canadians sampled wanted to be vaccinated immediately if a vaccine was available, and 31% wanted to be vaccinated but preferred to wait. Additionally, 7% of respondents indicated that they were unsure if they would receive a vaccination, and 14% indicated that they would not get vaccinated [4].

In the context of influenza vaccinations, there remains a broad, ethical imperative to respect others' agency over personal health decisions (eg, choosing to not get vaccinated). However, from a public health ethics perspective, the decision to not be vaccinated creates a conflict between population safety and personal liberty [9]. As of yet, COVID-19 vaccination has not been deemed mandatory by any nation, but conversations about whether such a public mandate should exist are emerging [10]. Whether vaccines are mandated, it is worthwhile for public institutions to understand how to change behaviors concerning vaccine hesitancy to ensure that informed decision-making practices are being exercised.

Previous research has suggested that behavioral change interventions are more successful when they are grounded in theory [11]. Thus, we selected a behavioral change framework to guide this study. The Theoretical Domains Framework (TDF) was selected because of its ability to help identify the barriers and facilitators to behavior change while taking into account social and environmental factors [12]. Other public health interventions have used the TDF. For example, Garbutt et al [13] used this framework to improve human papillomavirus vaccine uptake in primary care settings. The use of such theories can facilitate the development of comprehensive health education programs [11], but this requires correctly identifying the attributes of individuals and their surroundings, which influence behavioral patterns [14]. As Bandura [15] and other behavioral theorists have posited, social norms, social relationships, and social networks have a substantial and persistent influence on behaviors [15]. It is worth understanding public discourse about vaccine hesitancy in order to develop interventions that are responsive to the needs of the population and effectively address their concerns.

In the past decade, there has been a particular interest in the utility of Twitter as a tool for monitoring and surveilling public health [16], detecting trends [17], conducting research, and disseminating information [18,19]. A systematic review of using Twitter data for health research found that most studies were in the overlapping fields of public health (23%) and infectious disease (20%) [18]. With 187 million active users worldwide as of January 2021 [20], Twitter has become a powerful social network for disseminating important public health information.

Since the start of the COVID-19 pandemic, social networking platforms like Facebook and YouTube have become stricter with their oversight of the spread of COVID-19 misinformation by deleting false information and providing hyperlinks to government websites containing credible and validated information on COVID-19. Twitter took a similar screening approach in May 2020 [21], yet the scale, spread, and speed of information sharing has made this process challenging. Further, at the start of the pandemic, Twitter introduced a system for verifying COVID-19 experts (indicated with a blue checkmark), including physicians, epidemiologists, scientists, and academics, to provide credible information concerning COVID-19 [22]. Yet, there continues to be influential individuals who have also been verified by Twitter and have enough public credibility to contradict expert opinions or present false information.

We can combat the spread of misinformation by creating targeted approaches to changing behaviors and promoting the understanding of vaccines. Thus, the purpose of this study was to identify the reasons behind vaccine hesitancy among people in Canada by conducting a content analysis of tweets through the lens of behavioral science. Our findings can be used to develop behavior change strategies and policies that are responsive to target populations.

Methods

Study Design

Twitter is a social media platform that allows users to microblog and socially network. Each user is allowed up to 280 characters in a post (called a tweet). Users can post text, pictures, videos, or links to websites. Users who have registered for an account can tweet, like, and comment on another user's tweet and repost tweets (called a retweet). Registered users can also follow accounts and send private messages to each other. Unregistered users can read tweets, retweets, and comments but cannot engage in any interactions [23].

Twitter was selected because of its ability to capture real-time data [19]. Other studies have used Twitter to capture data on vaccine hesitancy. One study compared survey results about vaccine hesitancy in 2018 (before the COVID-19 pandemic) to data captured from Twitter and found that the data were similar to each other [24]. The study argued that Twitter could

potentially be used instead of surveys in some contexts and similar results would be obtained [24]. Another study went as far as saying that Twitter is a "sentinel tool" for identifying public opinions on vaccinations [25]. Thus, Twitter was selected as the site of data collection because it offers a publicly available repository of discourse data (ie, tweets) that are captured in a specific point in time for a specific geographic area.

This study did not require research ethics approval, as it was based on data that were publicly available. Other Canadian-based studies [26] have forgone ethical review by using publicly available Twitter data, as some sources are anonymous or unidentifiable. Only the Twitter user's username (ie, handle), city or town, and tweet content were extracted. This paper only presents aggregated data. Moreover, no interaction occurred between the authors of this study and any of the Twitter users.

Data Collection

After the researcher (JG) was approved for a developer account on Twitter, she received credentials for accessing Twitter's application programming interface. By using a Jupyter environment, the researcher created a Python program to access Twitter's application programming interface. Twitter allows access to tweets up to 1 week after they are posted. Thus, the researcher collected data from two time periods (December 18 and 23, 2020) to access 2 weeks' worth of tweets. Tweets that contained the words "COVID" and "vaccine" were extracted. Similar to a library search, tweets were returned based on variations of these words, such as "COVID-19," "COVID19," "vaccination," and "vaccinate."

Data were extracted from tweets from December 10, 2020, to December 23, 2020. These dates were selected because they followed the Pfizer-BioNTech vaccine approval announcement in Canada (December 9, 2020) and included the dates for the first vaccine administration in Canada (December 14, 2020) and the approval of the Moderna vaccine in Canada (December 23, 2020). This date range also accounted for the time frame when the highest number of searches for terms that included both "COVID" and "vaccine" occurred on Google, which perhaps indicated a spike in interest [27]. Thus, our data reflects a time period when receiving a COVID-19 vaccine was close to becoming a reality. Figure 1 provides a graph that shows when data were extracted and when COVID-19–related events occurred in Canada.

To only include tweets from Canada, the researchers used five geographic radiuses that covered most of Canada. However, several small areas were unintentionally omitted (Figure 2). It was not possible to know how many tweets were missed.

Demographic data beyond users' locations (ie, city or town) were not collected. It was possible to obtain estimates for other demographic information, such as age and gender, from third-party companies. However, this study was operating within the confines of publicly available data so as to disseminate the findings sooner.

Figure 1. A graph depicting Google Trends data for the combined search terms "covid" and "vaccine" aligning with vaccine approval and administration dates in Canada. Tweets that were posted between December 10 and 23, 2020 were eligible for analysis. This date range aligned with the time when the highest peaks in related Google search activity occurred in Canada. This figure indicates that the number of searches on Google for the combined words "COVID" and "vaccine" was highest in December 9, 2020. All other searches were relative to this highest peak. For example, on December 14, 2020, roughly 70% of related searches occurred in December 9, 2020 [28]. It was not possible to obtain more detailed numbers.

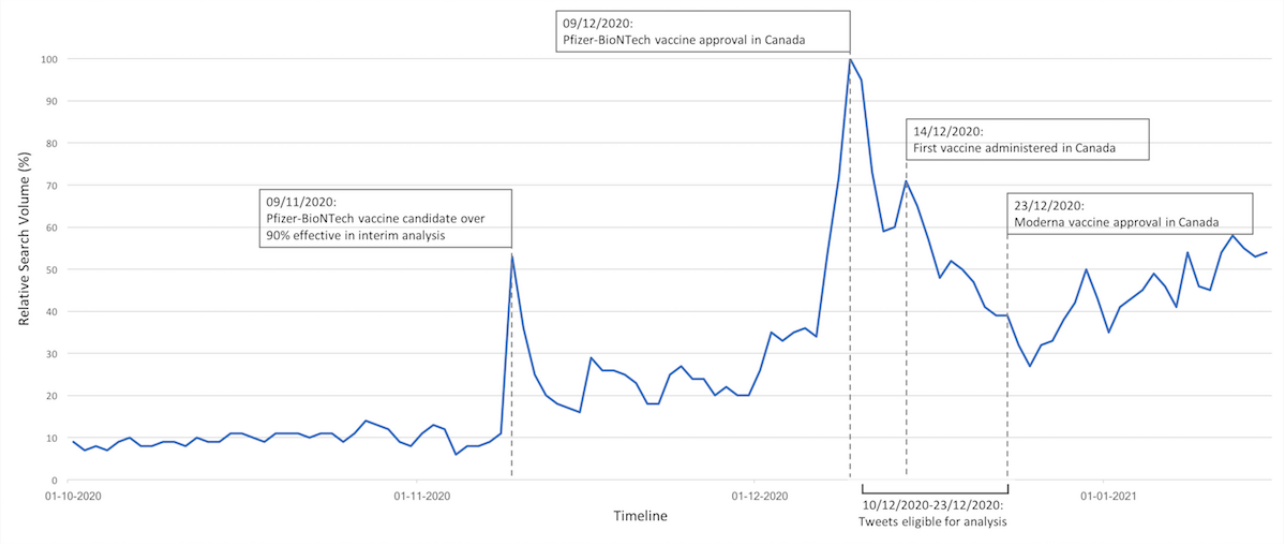

Figure 2. A map of where Twitter users were located. Tweets from outside of Canada (ie, those from the United States) were excluded.

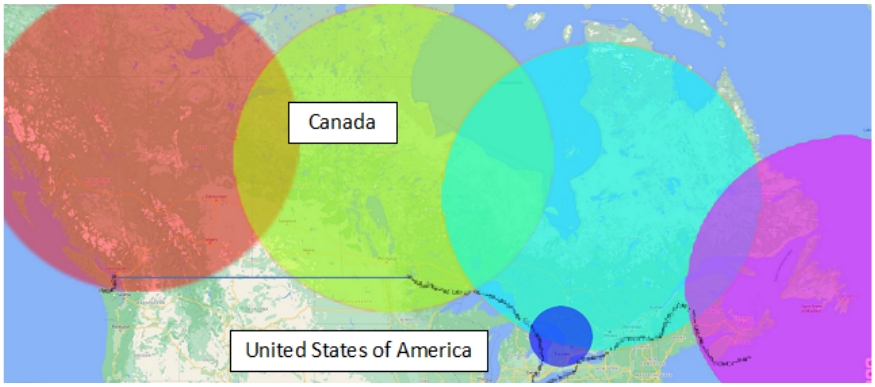


Data Analysis

The results were exported to a comma-separated values file and were analyzed in Microsoft Excel. Tweets were randomized (ie, reordered) in Excel so that tweets were not included based on date. As we expected, the number of tweets extracted was insurmountably high for manual analysis. Therefore, we randomly selected 20% of the tweets to be screened for eligibility. This exceeded the number of randomly selected tweets in other studies, which only included 10% of returned tweets for screening [28]. Double screening was performed for 10% of the tweets to ensure consistency. Manual analysis was selected because this study was exploratory in nature; it was unclear what themes might emerge a priori. As such, training an automated analysis program was unfeasible.

Eligible tweets included any tweets from a Canadian location that contained an expression of hesitancy toward COVID-19 vaccines. These included tweets that provided links to articles or other media that expressed hesitancy toward any COVID-19 vaccine. Eligible tweets also included those with graphics that expressed sentiments of COVID-19 vaccine hesitancy. Tweets that expressed positive or unclear sentiments toward COVID-19 vaccines were excluded. Tweets captured from the United States (given the country's geographic proximity to Canada) were also excluded. As data were extracted on two dates, several duplicate tweets were present. These were identified and deleted in Excel.

All tweets that were deemed eligible after screening were analyzed (ie, qualitatively coded) by 2 authors (JG and HMVM). These researchers had expertise in qualitative coding. Additionally, 10% of the eligible tweets were double-coded to ensure consistency.

In Excel, a content analysis was performed on all eligible tweets. The majority of health studies that use Twitter data (56%) have conducted content analyses [18]. Content analysis was performed as described by Sutton et al [28]; the content of each tweet was systematically reviewed by at least 1 researcher. The researcher(s) then coded the content of tweets according to their meaning. The resulting codes were then organized into thematic categories. Each eligible tweet could be coded into one or more themes.

Once themes emerged from the content analysis, they were mapped onto the TDF. The TDF was selected because it applies a theory-based approach to understanding behavior and has been used extensively in implementation science research. The TDF consists of the following 14 domains: knowledge; skills; social and professional roles and identities; beliefs about capabilities; optimism; beliefs about consequences; reinforcement; intentions; goals; memory, attention, and decision processes; environmental context and resources; social influences; emotion; and behavioral regulation. It has been used in other research pertaining to seasonal flu [29] and human papillomavirus vaccine hesitancy [13] to identify barriers to vaccine uptake and plan for implementation interventions.

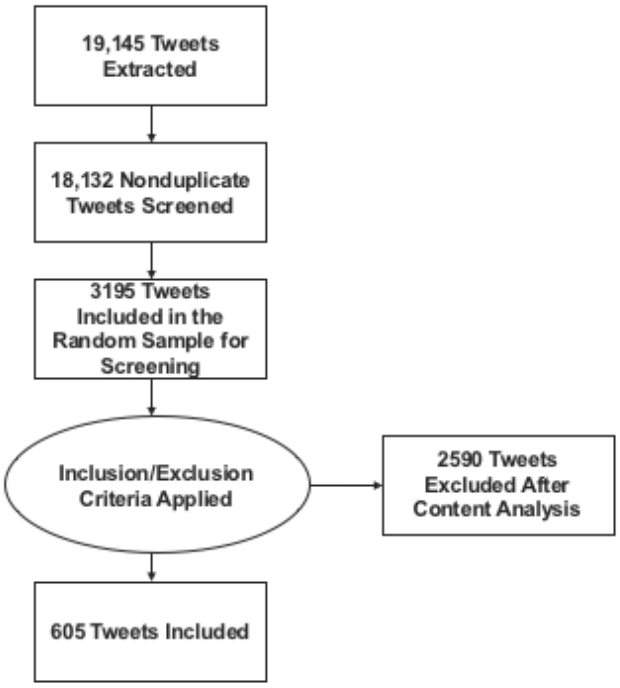
Results

Tweet Characteristics and Themes

In total, 18,132 tweets were returned as search results. Overall, 3915 tweets were screened for eligibility. These tweets represented 21.6% of the total number of tweets. It took approximately 1 hour to manually screen 100 tweets. The 10% (400/3915) of tweets that were double-screened resulted in a Cohen κ coefficient of 0.89, indicating an almost perfect agreement. After screening, 605 tweets met the inclusion criteria. This was represented in a modified PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram (Figure 3).

Through content analysis, the included tweets were grouped into the following major themes concerning vaccine hesitancy: safety, political skepticism, influence from authority figures, a lack of knowledge, and legal liability. The final theme included medical legacies. This theme was different from the other categories of vaccine hesitancy. The themes were not mutually exclusive. Examples of tweets were not provided with the presentation of the themes to preserve the anonymity of Twitter users. In the following subsections, each theme will be described.

Figure 3. Modified PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram of the data extraction process.



Safety

Overall, 48.3% (292/605) of tweets were about safety. These were largely centered around the worry that the vaccine would cause more harm than good. These tweets also expressed concerns that the COVID-19 vaccine was developed more quickly than other vaccines and that the COVID-19 vaccine was not tested to the same rigorous extent as other vaccines. Apprehension over severe side effects was also noted from tweets, including those that reported on nurses fainting and vaccine trial participants experiencing Bell palsy.

Political Skepticism

Another major theme found in 32.4% (196/605) of tweets was skepticism toward the political motivations behind vaccine development. Several Twitter users presented conspiracy theories about the COVID-19 vaccine being a vehicle for exerting political control over citizens. Other participants felt that the vaccine was not tested enough due to political pressures to reopen the economy. Several Twitter users in Canada were also highly influenced by politics in the United States; they cited rumors about the White House threatening the leadership of the US Food and Drug Administration to rush vaccine approval or face forced resignation. Tweets also indicated concern over the influence of big, government-backed pharmaceutical companies ("Big Pharma") that were motivated by profits instead of the desire to help people.

Deficits in Medical and Epidemiologic Literacy Concerning the Benefits of Vaccination

Many tweets (159/605, 26.3%) indicated a lack of knowledge about vaccines among Twitter users. For example, several users expressed the idea that if those who contracted COVID-19 had a ≥99% survival rate, then they should not have to receive a vaccine that is said to be 95% effective. Additionally, Twitter users questioned why anyone else should be concerned if they do not receive the vaccine, indicating a lack of understanding of herd immunity. Twitter users also reported concerns about how the vaccine would alter human DNA. Several Twitter users also felt that a lack of a vaccine for cancer, heart disease, and AIDS was proof that a new virus could not be cured. Additionally, Twitter users viewed COVID-19 as a mild disease; therefore, their interest in undergoing vaccination was low.

Authority Figures

Another theme we found was mistrust toward the COVID-19 vaccine resulting from Canadian and international authority figures not taking the vaccine (51/605, 8.4%). For example, several tweets highlighted users' mistrust toward the CEO of Pfizer and political figureheads in Canadian politics like Doug Ford (the elected provincial leader of Ontario), as they were not taking the vaccine. However, later tweets criticized public figures such as Dr Bonnie Henry (the Provincial Health Officer of British Columbia) and Alexandra Ocasio-Cortez (a member of the US House of Representatives) for receiving the vaccine before frontline workers and older adults.

Legal Liability

To a smaller extent (19/605, 3.1%), Twitter users also expressed mistrust toward vaccines that was based on reports of not being able to take legal action against drug companies if a person experiences any side effects. Additionally, news of the Federal Vaccine Injury Compensation Program in Canada resulted in further skepticism toward vaccine safety.

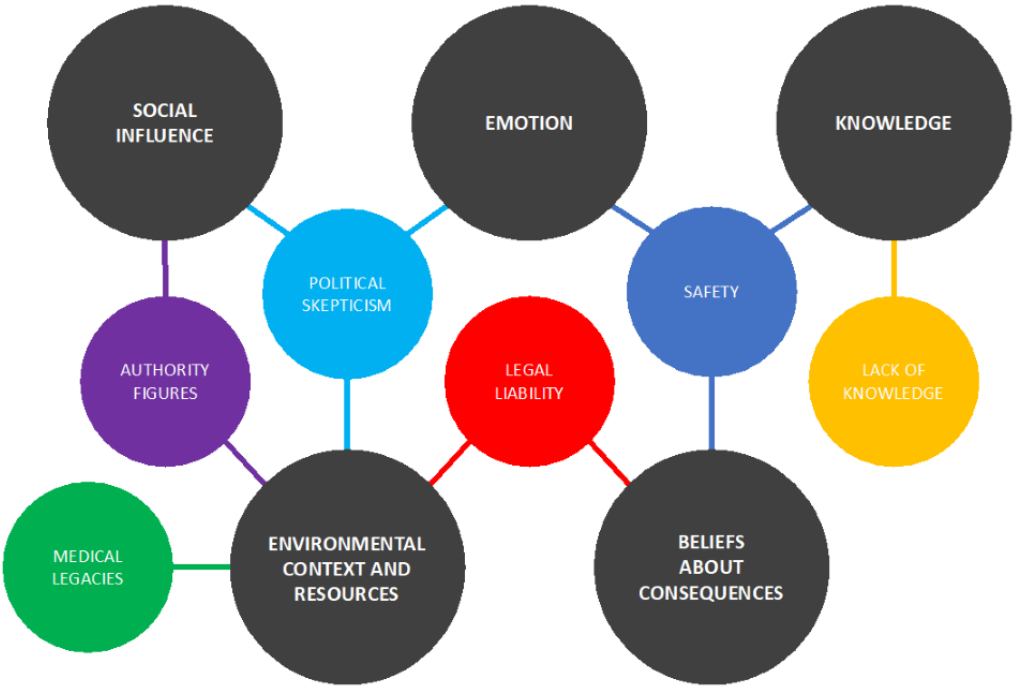
Medical Legacies

The final theme was unlike all of the other themes of vaccine hesitancy in this paper—the legacy of harm caused by health care institutions that have traditionally targeted the Black, Indigenous, and people of color (BIPOC) community and the lesbian, gay, bisexual, transgender, queer+ (LGBTQ+) community. Tweets (24/605, 4%) in this theme highlighted the lack of trust toward the COVID-19 vaccine resulting from how marginalized groups, such as the BIPOC and LGBTQ+ communities, have been historically targeted by the medical community. For example, the Tuskegee syphilis experiments were referenced in several tweets. Moreover, the first people who were vaccinated in the United States were Black health care workers, and several Twitter users viewed this as forced participation in medical experiments. Additionally, a poster promoting COVID-19 vaccination was viewed as paralleling the stigmatization of people who take pre-exposure prophylaxis, a medication for people living with HIV.

Theoretical Domains Framework

Themes were mapped to the TDF and categorized into the following five domains: knowledge, beliefs about consequences, environmental context and resources, social influence, and emotion. The mapping of themes to TDF domains was an interpretive and consensus-driven exercise that was conducted by two study authors (JG and HM). Disagreement was reconciled by a third study author (HMVM). Figure 4 displays a representation of the themes that were mapped to the TDF. We provide insight into this framework in the *Discussion* section. Overall, themes were not mutually exclusive; themes were classified according to several TDF domains.

Figure 4. Themes were categorized based on the TDF. The TDF domains are represented by the dark-gray circles. The themes from the content analysis (smaller colored circles) were mapped to relevant TDF domains. TDF: Theoretical Domains Framework.



Discussion

Principal Results

Through content analysis and TDF application, this study identified the reasons behind vaccine hesitancy among Twitter users in Canada. The major themes that emerged included concerns over safety, suspicion about political or economic forces driving the COVID-19 pandemic or vaccine development, a lack of knowledge about the COVID-19 vaccine, messages from authority figures, and a lack of legal liability from vaccine companies. An additional theme regarding the historical impact of medical mistrust among marginalized communities was also presented. These themes were categorized into the following five TDF constructs: knowledge, beliefs about consequences, environmental context and resources, social influence, and emotion. Thus, efforts to overcome vaccine hesitancy should focus on targeting these constructs.

Although evidence concerning vaccine hesitancy toward the COVID-19 vaccine is still emerging, our findings are consistent with previous studies. A study from Israel found that COVID-19 vaccine hesitancy was related to concerns about safety and efficacy and the belief that the disease is mild [5]. This was similar to our study, wherein concerns about safety was the top reason for vaccine hesitancy. The efficacy of the vaccine and the belief that the virus is mild were grouped into the lack of knowledge theme, which was another top reason for vaccine hesitancy in our study. Another study surveyed individuals from Canada and the United States in May 2020 and reported that vaccine hesitancy correlated with a lack of trust about a vaccine's benefit, concerns about safety (ie, unknown future health consequences), commercial profiteering, and a belief in natural immunity [6]. Of note, these respondents were more likely to receive a vaccine if there was evidence of rigorous testing and safety measures [6]. Both of these studies were

conducted prior to the development and implementation of a COVID-19 vaccine. As such, their results were hypothetical.

This study identified the particular reasons why people in Canada may be hesitant to receive a vaccine, so that implementation scientists who are responsible for vaccine rollouts can become responsive to these concerns. Although the analyzed tweets were from Canada, we believe that the tweets' themes may be generalizable to other contexts. To our knowledge, no other study has analyzed tweets to determine the reasons behind COVID-19 vaccine hesitancy. This study's contribution is especially important because the timing of our study coincided with the approval of the first two vaccines (ie, the Pfizer-BioNTech and Moderna vaccines) and the first vaccine administration in Canada.

Our results relate to vaccine hesitancy in general (ie, past research on non–COVID-19 vaccines), as prior related research has provided similar findings. For example, the influence of the media and people's knowledge about vaccines, past experiences, perceptions of risk, and trust have all been documented [30]. However, hesitancy toward the COVID-19 vaccines presents new, unprecedented challenges; namely, the global COVID-19 pandemic is unlike any pandemic that has been experienced in the past century, herd immunity depends on vaccine participation on a global scale, and new SARS-CoV-2 strains can emerge if the virus has opportunities (ie, time and vectors) to mutate. Additionally, the long-term health consequences of COVID-19 are unknown [31].

Our recommendation for the organizations responsible for implementing vaccination programs is to create behavioral interventions that are responsive to the concerns presented in this study. The mapping of these themes to the TDF provided us with preliminary insights into how to best target these behavioral interventions. For example, safety was a top concern that was found in the tweets, and we mapped safety to both knowledge and beliefs about consequences. Thus, targeting vaccine literacy may be beneficial, and this can be done by explaining how vaccines work, why they are safe, and how no steps were missed in the expedient process of COVID-19 vaccine development. However, trust in politicians and pharmaceutical companies is a vaccine hesitancy factor that is difficult to target because both groups are necessarily involved in vaccine rollouts. One approach to targeting this concern might be to have trusted physicians speak to their patients about why it is important to be immunized. This approach falls under the domain of emotion in the TDF.

Although providing details on interventions for responding to vaccine hesitancy was beyond the scope of this study, Table 1 provides example suggestions for interventions based on each TDF domain.

More research is necessary to determine whether addressing these concerns is effective in overcoming vaccine hesitancy.

Table 1. Reasons for vaccine hesitation fell under several Theoretical Domains Framework (TDF) constructs (left column). The rightmost column provides examples of intervention suggestions for responding to vaccine hesitancy in relation to the TDF construct.

TDF constructs	Content analysis theme	Example suggestions
Knowledge	Lack of knowledge	• Introduce campaigns that educate the public about using clear language in media that are commonly used to digest content (eg, social media).
Social influence	Authority	• Have nonpolitical, respected older adult Canadian celebrities take the vaccine as an example. • Such celebrities could be retired athletes or musicians.
Environmental context and resources	Political skepticism	• Emphasize that vaccines are rooted in science and not politics. This is a difficult quality to understand. • In action, this could be done by having messages come from trusted physicians instead of politicians.
Emotion and beliefs about consequences	Safety	• Highlight examples of instances when the vaccine has worked. • Reiterate the safety of the vaccine. • Reiterate the fact that the steps in the scientific development of the vaccine were not missed.

Limitations

As of January 2021, roughly 6.45 million (~17%) Canadians use Twitter [32]. Therefore, the perspectives on vaccine hesitancy presented in this paper are not wholly representative of the perspectives of all people in Canada. All users included in this study represent people in Canada with broadband internet access, which, as the COVID-19 pandemic has illustrated, is an important determinant of health [33]. As such, we likely missed the perspectives of those who face challenges when accessing the internet. It is also possible that nonhuman Twitter users (bots) were represented in our sample. Previous research has found that Twitter bots have manipulated public opinion and fueled cascades of negative emotions related to topics about COVID-19 [34]. Without any way to systematically identify and exclude these tweets, we suspect that several such tweets were included in our analysis. We also searched for English-only tweets due to limitations in language expertise among this study's authors. A more comprehensive content analysis that is representative of all people in Canada should include tweets that are written in other languages. This limitation may have

resulted in themes not being identified, including those related to culturally specific concerns.

It was not possible to collect demographic data such as age, gender, and ethnicity while also preserving users' anonymity. Thus, we were unable to analyze the demographic characteristics of Twitter users who expressed vaccine hesitancy.

Although the search strategy could have been expanded to include many more terms related to vaccination (eg, "shot," "jab," "immunization," etc), the search results would have been insurmountable for conducting our manual analysis process. Additionally, terms related to hoax beliefs were not included; the inclusion of such terms would have likely produced more results. Although saturation was achieved for our search, we may have missed themes that used alternative language to express vaccine hesitancy.

Of note, the examples of interventions presented in Table 1 are merely suggestions. A behavioral scientist may have more informed suggestions about how to combat vaccine hesitancy according to the TDF.

Finally, the tweets related to the medical legacies discussed in this paper should not be viewed as tweets about vaccine hesitancy or conflated with those under the categories of safety, a lack of knowledge, political skepticism, messages from authority figures, and legal liability. As Mosby and Sridrovich [35] have emphasized, health care providers need to understand the history of "racially segregated health care and medical experimentation." Additionally, Boyd [36] stated that the "hyper-focus on hesitancy implicitly blames Black communities for their undervaccination, and it obscures opportunities to address the primary barrier to COVID-19 vaccination: access." Building trust in the medical system goes far beyond the suggestions presented in this paper.

Conclusions

Overall, this study identified the reasons why people in Canada may feel hesitant toward receiving a COVID-19 vaccine. These reasons fell under the following themes: safety concerns, suspicions about political or economic forces, a lack of knowledge, messages from authority figures, and a lack of legal liability from vaccine companies. Additionally, other tweets revealed the historical impact of medical mistrust among marginalized communities, which should not be viewed as hesitancy or as the result of the reasons identified in this paper. Overall, behavioral, implementation, and public health scientists can use theory-based approaches like the TDF to design interventions that are tailored to address the concerns that people have and improve the uptake of the COVID-19 vaccine, thereby increasing the chances of achieving the threshold necessary for herd immunity.

Acknowledgments

JG conceived the study idea and was involved in all study activities, including study data extraction and analysis and manuscript preparation. HM supported the literature extraction and manuscript preparation. HMVM supported the coding of tweets and manuscript revision. This study was conducted without financial support.

Abstract

Background: Population mobility is closely associated with COVID-19 transmission, and it could be used as a proximal indicator to predict future outbreaks, which could inform proactive nonpharmaceutical interventions for disease control. South Carolina is one of the US states that reopened early, following which it experienced a sharp increase in COVID-19 cases.

Objective: The aims of this study are to examine the spatial-temporal relationship between population mobility and COVID-19 outbreaks and use population mobility data to predict daily new cases at both the state and county level in South Carolina.

Methods: This longitudinal study used disease surveillance data and Twitter-based population mobility data from March 6 to November 11, 2020, in South Carolina and its five counties with the largest number of cumulative confirmed COVID-19 cases. Population mobility was assessed based on the number of Twitter users with a travel distance greater than 0.5 miles. A Poisson count time series model was employed for COVID-19 forecasting.

Results: Population mobility was positively associated with state-level daily COVID-19 incidence as well as incidence in the top five counties (ie, Charleston, Greenville, Horry, Spartanburg, and Richland). At the state level, the final model with a time window within the last 7 days had the smallest prediction error, and the prediction accuracy was as high as 98.7%, 90.9%, and 81.6% for the next 3, 7, and 14 days, respectively. Among Charleston, Greenville, Horry, Spartanburg, and Richland counties, the best predictive models were established based on their observations in the last 9, 14, 28, 20, and 9 days, respectively. The 14-day prediction accuracy ranged from 60.3%-74.5%.

Conclusions: Using Twitter-based population mobility data could provide acceptable predictions of COVID-19 daily new cases at both the state and county level in South Carolina. Population mobility measured via social media data could inform proactive measures and resource relocations to curb disease outbreaks and their negative influences.

KEYWORDS

COVID-19; mobility; incidence; South Carolina

Introduction

Since the first confirmed case of COVID-19 in the United States on January 21, 2020, countrywide COVID-19 outbreaks have surged. As of March 5, 2021, there were 28,580,198 cumulative confirmed cases and 517,224 COVID-19–related deaths in the United States [1]. South Carolina, a state located in the southeastern United States, had its first confirmed cases on March 6, 2020. From March to May 2020, the trend of daily new cases was flat, with an average daily increase in cases of less than 500. However, the daily new cases in South Carolina have risen sharply since June 2020. On July 14, 2020, COVID-19 cases in South Carolina surpassed 60,000, with more than 2200 daily new cases, the second highest increase in one day in the United States [2]. Between August and October 2020, the transmission rate slowed down with the further implementation of nonpharmaceutical interventions (NPIs), such as dine-in service restrictions and face-covering requirements, but increased steadily after October. By March 5, 2021, there were 448,275 reported cases and 7697 deaths in South Carolina [3].

Given the rapid transmission of COVID-19 and limited options in terms of medical interventions, forecasting is of critical importance as it could predict the spread of disease, estimate the impacts of NPIs, and inform further decision making regarding public health interventions [4]. During the COVID-19 pandemic, decision makers in the United States need to balance the net losses arising from social interruptions, economic damage, and indirect effects on health caused by NPIs with the direct health benefits of disease control [5]. Accurate and reasonable forecasting of COVID-19 could minimize the disease burden in health care settings and the loss of health and life in different phases of reopening plans [5,6].

Existing literature has suggested that population mobility may reflect the influences (both positive and negative) of NPIs, reopening actions, and public holidays [7-9]. For instance, in the early stages of the COVID-19 pandemic, the governor of South Carolina issued a series of NPIs, such as shelter-in-place and the closure of schools and nonessential businesses, to reduce social interaction. These NPIs showed positive effects in suppressing the statewide spread of COVID-19. Later, in May 2020, reopening policies and public holidays diluted the implementation of NPIs, leading to increased social interactions and statewide COVID-19 spread [10,11]. At present, it may be difficult to directly measure the real-time impact of reopening policies, public holidays, and NPI implementation fidelity. Therefore, population mobility may be a proximal indicator allowing for real-time COVID-19 transmission forecasting.

Social media platforms, such as Twitter, collect geospatial information and closely monitor changes in population mobility [12,13]. Indeed, the tremendous volume of user-generated geoinformation from social media enables the real-time or near real-time surveillance of population mobility and provides timely data on how population mobility changes in response to different phases of the COVID-19 outbreak, policy reactions, and public holidays [14-16]. Several studies have leveraged mobility data from social media (eg, Google, Facebook, Twitter) to investigate the relationship between population mobility and COVID-19 transmission [9,11,17-19]. These studies identified a consistently positive relationship between population mobility and COVID-19 incidence. However, few studies used population mobility as a predictor to forecast further outbreaks and to evaluate prediction accuracy in addition to performing correlation analysis. A study by Wang and Yamamoto [19] predicted COVID-19 daily new cases in Arizona using disease surveillance data, the Google Community Mobility report, and partial differential equations. They found an acceptable prediction accuracy for the next 3 days, but the time window of prediction did not cover the duration of viral incubation (ie, 14 days). Furthermore, this study only split Arizona into three regions (ie, central, northern, and southern) rather than examining prediction accuracy at both the state and county level. In fact, there may be geospatial differences in population mobility due to the plausible differential implementation fidelity of NPIs and reactions to reopening policies by county [20,21]. Additionally, there may be geospatial differences in the estimation of population mobility on social media as the number of users and their demographic characteristics may differ by county. All these differences may result in variations in prediction accuracy at the county level, and further studies are needed in this regard.

Prior research has predicted COVID-19 incidence using disease surveillance data and several different time series methods. Most of the studies successfully incorporated the association of the current incidence with the previous incidence using time series methods such as autoregressive, moving average, autoregressive integrated moving average (ARIMA), and Holt-Winters [22]. Some studies used generalized linear regression with continuous outcomes (eg, rate and count), without including time series [23]. However, there were few studies that simultaneously considered time-varying population mobility. Recently, Liboschik and colleagues [24] suggested that count time series following generalized linear models could overcome the limitations of classic time series methods. Based on the generalized linear model methodology, a suitable distribution for count data and appropriate link function could be specified, and the effect of the time-varying covariate could be tested and integrated into forecasting. In this study, we adopted the Poisson count time series model and time-varying population mobility data extracted from Twitter, which may increase the accuracy of COVID-19 prediction.

To address these knowledge gaps, by leveraging disease surveillance data and Twitter-based population mobility, this study aimed to construct Poisson count time series models of COVID-19 daily new cases, investigate the relationship between them, and evaluate the prediction accuracy of daily new cases for the next two-week window at both the state and county level in South Carolina.

Methods

COVID-19 Incidence Data

Cumulative confirmed cases of COVID-19 through November 11, 2020, at both the state and county level in South Carolina were collected from The New York Times data set, which was deposited in GitHub [25]. The data set was compiled using data from state and local governments and health departments, ensuring its accuracy. Within the study period (March 6, 2020 [date of first COVID diagnosis in South Carolina] to November 11, 2020 [251st day]), daily new cases were calculated by subtracting the cumulative confirmed cases of the previous day from the total cases for the entire state and its five counties with the largest numbers of cumulative confirmed cases (ie, Charleston, Greenville, Horry, Spartanburg, and Richland). The study protocol was approved by the Institutional Review Board at the University of South Carolina.

Population Mobility

Population mobility was determined using the number of people (Twitter users) with a moving distance greater than 0.5 miles per day in South Carolina and the selected counties. The methodology of extracting daily population movement (origin-destination flows) from geotagged tweets is discussed elsewhere [26,27]. Briefly, geotagged tweets during the study periods were collected and used for calculation. Only users who posted at least twice per day or posted tweets on at least two consecutive days were included in the calculation. Daily travel distance was calculated for each user based on the derived origin-destination flows and used to generate a variable of how many people moved each day (with a travel distance greater than 0.5 miles). This method of capturing population mobility using Twitter has been previously validated [16,26].

Statistical Analysis

First, daily new cases of COVID-19 and population mobility at both the state and county level were described using line charts in R (version 3.6.3; R Foundation for Statistical Computing; “ggplot” package). Daily new cases and mobility were also described using five quantiles (ie, minimum, 25th percentile, 50th percentile, 75th percentile, and maximum) for each month.

Second, a Poisson count time series model was used to model the impact of population mobility on the daily new cases of COVID-19 at the state level. Time series models were built at various time windows. For the first-round selection, a total of 17 time windows (by 7-day increments) were considered, including 1-7 days, 1-14 days,…, and 1-119 days. The daily new cases from the first to the 234th day were used as the training data set, and those from the next 3 days (days 235-237) were used as a testing data set for the purpose of model evaluation. With the smallest prediction error (equation 1) and good interpretation, the predictive model with the best time window was selected. After the best time window in the first round selection was determined, second- and third-round selections were conducted to narrow down the time window and obtain the final model with the smallest prediction error. The final model was used to predict the COVID-19 daily new cases for the next 3, 7, and 14 days (days 238-251). The cumulative difference (equation 2) between observed and predicted cases and mean absolute percentage accuracy (equation 3) for each time frame were reported [19]. The equations used are as follows:

In equations 1-3, *d* represents the day; *n* is the next 3, 7, or 14 days; *o* is the observed value, *p* is the predicted value, and *x* represents the daily new cases.

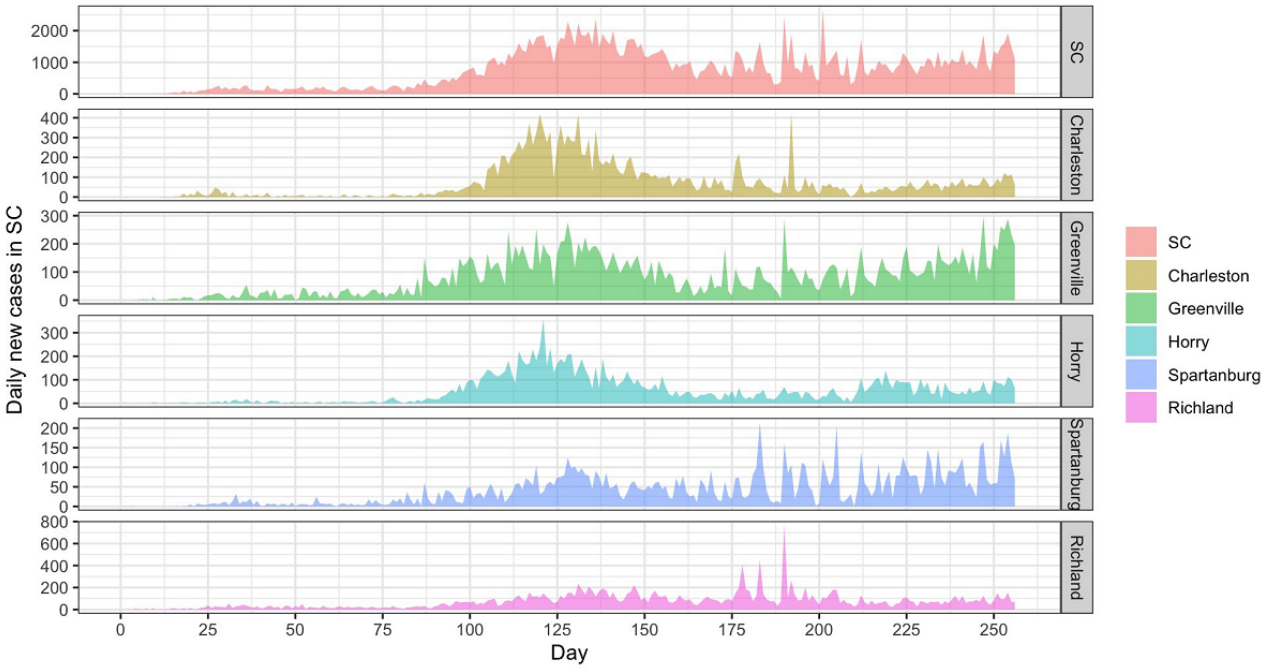
Finally, a similar analytic procedure was performed to construct the final model at the county level for each of the top five counties (ie, Charleston, Greenville, Horry, Spartanburg, and Richland) in South Carolina. A Poisson count time series model was conducted using an R package (“tscount”). Table S1 in Multimedia Appendix 1 provides a detailed description of the data acquisition process, scripts for analysis and figures, and a link to data resources.

Results

Descriptive Statistics

Figure 1 shows the changes in COVID-19 daily new cases at both the state and county level. By October 31, 2020, there were 176,612 cumulative confirmed COVID-19 cases in South Carolina. The cumulative confirmed cases in Charleston, Greenville, Horry, Spartanburg, and Richland were 17,384, 18,021, 12,591, 9290, and 17,531, respectively. At the state level, the daily new cases from March to the end of May were less than 500. From June to the middle of July, the number of daily new cases rose, with 2217 new patients with confirmed COVID-19 on July 14. After that, the transmission rate decreased, with most daily new case counts staying under 1500. However, since October 2020, the daily new cases have steadily increased.

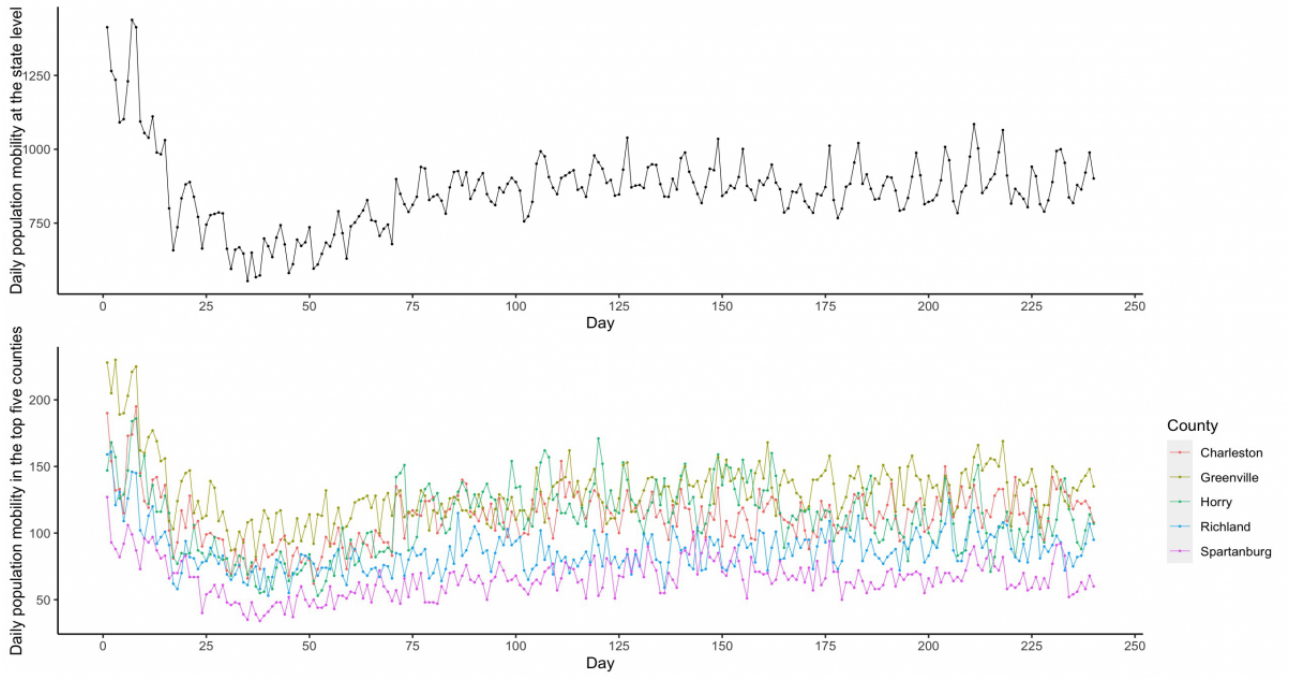
Figure 1. Daily COVID-19 new cases at both state and county level in South Carolina. SC: South Carolina.



At the county level, the top five counties showed a similar trend of COVID-19 outbreaks and accounted for more than 40% of the total cases in South Carolina. The daily new cases increased earlier in Greenville than in the other four counties (ie, Charleston, Horry, Spartanburg, and Richland).

Trends for population mobility at both the state and county level were similar. The number of people in South Carolina (Twitter users in our data) with a moving distance of more than 0.5 miles decreased from 1400 to 550 between March 6 and April 9, 2020. Although there were slight increases from the middle of April to that of June, the numbers were consistently around 1000 after this timeframe. At the county level, each of the five counties had less than 200 people with a moving distance greater than 0.5 miles after the middle of March. Figure 2 shows the changes in population mobility at both the state and county level. Table S2 in Multimedia Appendix 1 presents the descriptive statistics of population mobility and COVID-19 new cases at both the state and county level.

Figure 2. Daily population mobility at both state and county level in South Carolina.



Model Selection of Time Series Analyses

Following the model selection procedure, a Poisson count time series model of COVID-19 incidence at the state level was constructed using daily new cases and population mobility. Population mobility was positively associated with state-level COVID-19 daily new cases (β=.818, 95% CI .761-.876), and the model using the past 7 days (1-7 days) as the time window had the smallest prediction error (Table 1). The prediction error of new cases in the next 3 days (days 235-237) was 0.294.

At the county level, a similar modelling procedure was employed. Population mobility was consistently and positively associated with new cases of COVID-19 across the top five counties. The best time windows for Charleston, Greenville, Horry, Spartanburg, and Richland were 9, 14, 28, 20, and 9 days, respectively. Table 1 displays the detailed results of the final model, the correlation analysis, and the 3-day prediction error at both the state and county level.

Table 1. The impacts of population mobility on COVID-19 outbreaks in South Carolina.

Parameters	State level	County level				
		Charleston	Greenville	Horry	Spartanburg	Richland
Model training						
Time windows (days)	1-7	1-9	1-14	1-28	1-20	1-9
Coefficient of population mobility (95% CI)	0.818 (0.761-0.876)	0.486 (0.338-0.634)	0.278 (0.165-0.390)	0.395 (0.275-0.515)	0.270 (0.118-0.422)	0.157 (0.067-0.246)
Model evaluation (3-day prediction error)	0.294	2.032	0.214	3.146	0.427	0.396
3-day forecasting						
Cumulative difference	42	30	28	40	66	81
Accuracy (%)	98.7	85.1	93.3	69.0	76	72.2
7-day forecasting						
Cumulative difference	670	110	147	45	175	144
Accuracy (%)	90.9	76.7	85.2	85.9	68.3	76.8
14-day forecasting						
Cumulative difference	2858	272	541	217	452	329
Accuracy (%)	81.6	72.1	74.5	72.6	60.3	73.6

COVID-19 Daily New Cases Forecasting

Table 1 also presents the results of forecasting and prediction accuracy. Using the final models with the selected time windows, COVID-19 daily new cases were forecasted for the next 14 days at both the state and county level. At the state level, the 3-day cumulative difference and prediction accuracies were 42 and 98.7%, respectively. As compared to the 3-day prediction accuracy, the 7- and 14-day accuracies reduced to 90.9% and 81.6%, respectively. At the county level, among the top five counties, the 3-day prediction accuracy ranged from 69.0%-93.3%. The prediction accuracy deceased in Charleston, Greenville, and Spartanburg with increased time span. In contrast, the prediction accuracy in Horry and Richland increased in the 7-day prediction but decreased in the 14-day prediction. The 14-day prediction accuracies for Horry and Richland were closer to their values in the 3-day prediction. Table S2 in Multimedia Appendix 1 presents the predicted and observed cases of COVID-19 in the final models.

Discussion

Principal Findings

This study leveraged disease surveillance data and Twitter-based population mobility data to test the relationship between mobility and COVID-19 daily new cases and forecast transmission during the next 14 days at both the state and county level in South Carolina. Results revealed that population mobility was significantly and positively associated with new daily COVID-19 cases. Using the selected models to forecast COVID-19 transmission, we found that although the prediction accuracy at the state level and most of the selected counties decreased as the time span increased, the prediction accuracy remained acceptable. To the best of our knowledge, this is the first study that combined correlation analysis and forecasting together to investigate the impacts of population mobility on COVID-19 transmission at both the state and county level.

Population mobility could reflect the impacts of NPIs, reopening policies, and public holidays, and estimate social movement during the current COVID-19 pandemic. It is closely related to COVID-19 outbreaks, which is in accordance with the findings of prior research [9,11,17-19]. This study adds value to previous studies by examining the impacts of population mobility on COVID-19 incidence at both the state and county level in South Carolina. The results revealed a positive association of population mobility with daily new COVID-19 cases. However, it should be noted that the population mobility data used in our study only reflected the mobility of people who used Twitter, although such mobility data have been validated to be a good proxy of actual human movement during the pandemic

[16,26,27]. Additionally, those Twitter users tended to be young, which might influence how much and what they tweet. The sociodemographic characteristics of Twitter users may be potential confounders, which were not controlled for in our study. Thus, caution is needed when interpreting our findings. Future studies are needed to consider and control for the sociodemographic characteristics of Twitter users.

Using Twitter-based mobility data to predict daily new COVID-19 cases could yield acceptable accuracy, which could also justify the prediction efficacy of this indicator. The high prediction accuracy at the state level was consistent with Wang's finding in Arizona [19]. However, such a high prediction accuracy was not found at the county level. One possible explanation for this finding is that we did not capture or account for the influences of contextual factors (ie, population density) and the roles of mitigating factors (eg, wearing a face mask, practicing social distancing) [18,19,28]. Additionally, the Twitter-based mobility data did not differentiate between social movement at different locations, such as parks, workplaces, and retail locations, which have different impacts on COVID-19 incidence [9]. Finally, in this study, we only captured population mobility at the state and county level, while population mobility at the zip code level might provide a more accurate prediction. Nevertheless, the findings generated from our study confirmed the spatial-temporal relationship between Twitter-based mobility and COVID-19 outbreaks in South Carolina and the acceptable prediction efficacy of population mobility.

Our findings provide empirical evidence to support the application of Poisson count time series and time-varying population mobility data in improving the accuracy of COVID-19 forecasting. Compared with the existing literature, our models yielded acceptable prediction accuracy for two-week forecasting at both the state and county level. Time-varying population mobility could be incorporated into other forecasting models, such as classic time series methods and machine learning [22,24]. Since we are particularly interested in count data, we preferred the Poisson count time series model. When modelling rate, ARIMA and Holt-Winters are more appropriate than the Poisson count time series model. Regarding machine learning, most models are applied to the prediction of binary or categorical variables, and future studies are needed to apply them to predicting the count outcome with time-varying population mobility.

The use of population mobility data has potential implications for future research and practices to curb COVID-19 outbreaks. From a research perspective, research on mobility and COVID-19 could be studied at the state, county, and/or zip code level. In addition, mobility around different locations could provide detailed information regarding COVID-19 transmission, identify the most relevant mobility associated with daily new cases, and inform tailored interventions on social distancing by location to control disease outbreaks. Furthermore, the geospatial difference in the prediction accuracy of population mobility for daily new cases by county suggested that contextual factors—such as demographic characteristics and the implementation fidelity of NPIs at the county level—should be accounted for in future research. Finally, since the incubation and transmission of COVID-19 are closely associated with time-varying factors, such as temperature and weather, such impacts should be accounted for in forecasting studies [29]. Regarding the practice of disease control and prevention, leveraging social media platforms to monitor daily population mobility could improve predictions of further COVID-19 transmission, inform proactive NPIs, and guide the allocation of health care resources to reduce disease morbidity and mortality [30,31].

Conclusions

Population mobility was positively associated with COVID-19 transmission at both the state and county level in South Carolina. Using Twitter-based mobility data could enable acceptable predictions of COVID-19 daily new cases. The use of social media data to monitor population mobility and predict COVID-19 spread could inform proactive measures to curb disease outbreaks and plan coordinated responses.

Abstract

Background: The COVID-19 pandemic is probably the greatest health catastrophe of the modern era. Spain's health care system has been exposed to uncontrollable numbers of patients over a short period, causing the system to collapse. Given that diagnosis is not immediate, and there is no effective treatment for COVID-19, other tools have had to be developed to identify patients at the risk of severe disease complications and thus optimize material and human resources in health care. There are no tools to identify patients who have a worse prognosis than others.

Objective: This study aimed to process a sample of electronic health records of patients with COVID-19 in order to develop a machine learning model to predict the severity of infection and mortality from among clinical laboratory parameters. Early patient classification can help optimize material and human resources, and analysis of the most important features of the model could provide more detailed insights into the disease.

Methods: After an initial performance evaluation based on a comparison with several other well-known methods, the extreme gradient boosting algorithm was selected as the predictive method for this study. In addition, Shapley Additive Explanations was used to analyze the importance of the features of the resulting model.

Results: After data preprocessing, 1823 confirmed patients with COVID-19 and 32 predictor features were selected. On bootstrap validation, the extreme gradient boosting classifier yielded a value of 0.97 (95% CI 0.96-0.98) for the area under the receiver operator characteristic curve, 0.86 (95% CI 0.80-0.91) for the area under the precision-recall curve, 0.94 (95% CI 0.92-0.95) for accuracy, 0.77 (95% CI 0.72-0.83) for the F-score, 0.93 (95% CI 0.89-0.98) for sensitivity, and 0.91 (95% CI 0.86-0.96) for specificity. The 4 most relevant features for model prediction were lactate dehydrogenase activity, C-reactive protein levels, neutrophil counts, and urea levels.

Conclusions: Our predictive model yielded excellent results in the differentiating among patients who died of COVID-19, primarily from among laboratory parameter values. Analysis of the resulting model identified a set of features with the most significant impact on the prediction, thus relating them to a higher risk of mortality.

Introduction

The COVID-19 pandemic is one of the most prominent health catastrophes of the modern era. This is not exclusive to the health field, as the far-reaching economic and social consequences of this crisis are still unquantifiable [1]. The disease primarily affects the respiratory system, causing respiratory failure, and in certain patients, results in severe inflammatory syndrome. This is mediated by proinflammatory cytokines and can lead to marked systemic complications, which may be fatal in many cases [2].

The lack of knowledge of this virus led the World Health Organization, together with the US Center for Disease Control and Prevention, to define a profile of high-risk patients; this included factors such as age over 65 years, living in nursing homes, and having at least one of the following health problems: chronic lung disease, severe heart disease, obesity, diabetes, kidney failure, liver disease, or an immunocompromised status. The result has been a highly uneven response to the pandemic, both with respect to treatment and the diagnostic and prognostic criteria for the disease [3].

The exponential increase in COVID-19 cases over a short period, lack of experience and knowledge of the virus, and the shortcomings in health resources and health care personnel (many of whom were infected) have caused hospitals to become saturated, especially intensive care units, which have received a very high number of patients every day, many of whom required long stays. Pressure on the health care system after the first wave of the pandemic led to a search for different resources in order to help understand and accurately predict how each patient would react on interacting with the virus. The availability of tools to enable us to classify at-risk patients is crucial because microbiological diagnostics are slow, the PCR test takes more than 4 hours, and emergency physicians do not usually receive the results for up to 24 hours after collecting the sample. Furthermore, the treatments are based on vital support that is not always effective, and potentially gives rise to a large number of adverse events; furthermore, drug availability is sometimes limited. Developing tools that allow us to classify patients at the risk of complications, such those with a prothrombotic status, or an increase in the number of inflammation parameters in a blood sample, would help alleviate the saturation of the health system, optimize resources, and save time in resolving clinical complications [4].

Hence, we developed a model to predict the mortality risk from the laboratory parameters obtained during patients' hospital stay [5]. With this model, we aimed to evaluate how laboratory parameters are related to the risk of a more (or less) severe disease, so that when a patient presents at the emergency department at a hospital, the mortality risk can be predicted on the basis of the blood parameters.

Methods

Data Description

This study is based on anonymized clinical data obtained from a private hospital group in Spain (HM Hospitales), with centers primarily in the Autonomous Communities of Madrid and Galicia and in Barcelona. This group made its data available to the scientific community for research purposes. Using these electronic case histories, we accessed data on individuals suspected with COVID-19 admitted to their centers between March and June 2020. From all the data tables provided, we selected the following: (1) a main table containing specific data on hospitalization and patients (2547 records) and (2) a laboratory data table with the results of the various tests requested for each patient during hospitalization and those presenting at the emergency department (584,136 records).

In the table, an "Outcome" feature is present, with 5 possible values: "Death," "Home," "Transfer to hospital," "Transfer to sociosanitary center" and "Voluntary discharge." This Outcome feature is the aim of the predictive model developed in this study.

Data Preprocessing

Before developing the model, and as a prior step in any machine learning procedure, the information in the 2 tables was preprocessed as follows:

1. Only those patients with a confirmed diagnosis of COVID-19, and whose "Outcome" feature was either "Home" or "Death," were selected.
2. Data from both tables were combined in accordance with the patient ID. Since the patients can present a variable number of measurements for each laboratory parameter, the mean value was calculated and assigned to each of them.
3. Owing to the large number of missing values, we decided to filter records and features in order to handle data without missing values. Some machine learning algorithms can function by directly using data with missing values, and imputation methods can also be used. In this study, for the sake of uniformity and simplicity, the following procedure was used: first, those features having missing values in >10% of all records were eliminated; thereafter, only those records that had value in all the remaining features were selected.
4. Features such as "Sex" and "Outcome" were properly encoded as binary values. No other preprocessing such as normalization or scalarization was applied to the data.

Machine Learning Techniques

A range of machine learning methods to obtain predictive models have been developed, such as those based on logistic regression, linear discriminant analysis, instance-based learning, artificial neural networks, decision trees, and ensemble learning. This study applied the gradient boosting method to develop a predictive model.

Gradient Boosting

Gradient boosting is a machine learning technique used to resolve regression and classification problems and yields a predictive model through an ensemble of weak prediction models, usually decision trees. As in other boosting methods, it builds the model incrementally by incorporating weak prediction models, but it optimizes an arbitrary differentiable loss function. Finally, the prediction for a new case is obtained

by aggregating the predictions of all the individual decision trees that constitute the model. By combining many trees, nonlinearity and interactions between predictor features are achieved [6].

Extreme gradient boosting (XGBoost) is a relatively new gradient boosting implementation that has achieved excellent results in many classification tasks. It is an open-source software library that provides a gradient boosting framework designed to be highly efficient and flexible [7]. It has also been successfully applied in medicine; for example, for the prediction of diabetes risk [8], hypertension [9], drug responses [10], or kidney injury [11].

Shapley Additive Explanations

A fundamental feature of studies performed with machine learning techniques is the interpretability of the results. In medicine, this feature is essential for health care professionals to draw conclusions and take decisions based on the results obtained from machine learning algorithms. Doshi-Velez and Kim [12] defined interpretability as the "ability to explain or to present in understandable terms to a human." This renders interpretability in machine learning a favorable model characteristic.

Recently, the Shapley Additive Explanations (SHAP) framework has been applied to interpret derived machine learning models [13]. SHAP is based on the game theory [14] and helps evaluate feature contributions toward model prediction, identifying the features that most prominently influence the prediction. SHAP values are associated with each feature's marginal contribution when aggregated to the model. The XGBoost method has an additional advantage when SHAP is used, in that being based on decision trees we can use TreeSHAP, a fast variant of SHAP for tree-based machine learning [15].

Model Training and Evaluation

In order to obtain a mortality predictive model ("Outcome" feature), a gradient boosting model was trained using previously described data. Input features were "Age," "Sex," and each of the laboratory values (mean values) in accordance with the data preprocessing described above. For this, the XGBoost model was developed using the existing implementation for Python.

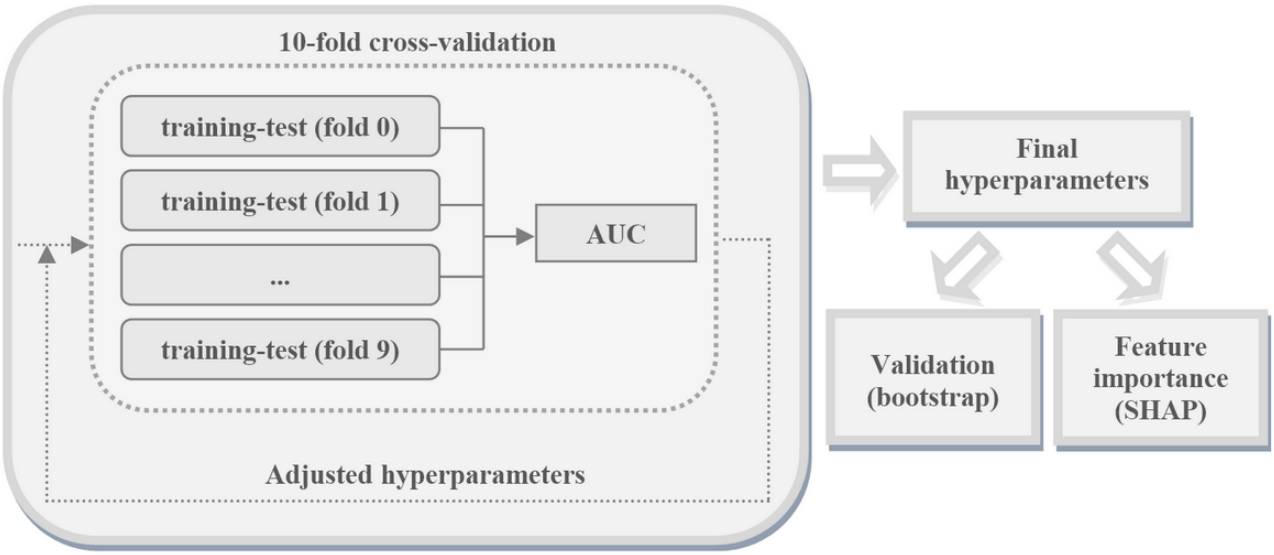
To initially assess the performance of the XGBoost algorithm in relation to other models in the literature, a comparison was made with 8 representative classifiers in machine learning: decision tree, K-nearest neighbors, linear discriminant analysis, logistic regression, multilayer perceptron, Gaussian naive Bayes, random forest, and support vector machines. For this, the corresponding implementation in the Python Scikit-learn library [16] was used. The metrics analyzed were the area under the receiver operator characteristic curve (AUROC), the area under the precision-recall curve (AUPRC), accuracy, and F-score (F1). To assess a value for these metrics, bootstrap validation was used.

For each classifier, the most relevant model parameters (hyperparameters) were adjusted by selecting the best values after an iterative tuning procedure, and leaving the rest with their default values. Hyperparameter values were identified using hyperopt, a Python library for distributed hyperparameter optimization [17]; the metric and the algorithm used in the optimization were AUROC and the 3-structured Parzen estimator. To estimate the AUROC value, k-fold stratified cross-validation (k=10) was employed. Thus, each tuning cycle involved 10 training-test executions using different nonoverlapping test data (each with 10% of the total records). Through cross-validation, the variance of the estimates can be reduced, and the estimation of the generalization performance was improved [18].

Once the results were analyzed, suitable behavior was confirmed in most of the metrics obtained using XGBoost. To further improve its performance, the final model parameters were adjusted using a more exhaustive tuning procedure. Among the variety of parameters available in XGBoost, the ones considered more relevant were selected for tuning. The 6 selected parameters influence the number of gradient boosted trees and their structure (n_estimators, max_depth, and min_child_weight), and the learning process (learning_rate, subsample, and colsample_bytree).

Following this parameter tuning phase, the final model was assessed through bootstrapping. The performance metrics were as follows: AUROC, AUPRC, accuracy, F1, Youden's index, sensitivity, and specificity. Finally, the relative importance of the features in the model was obtained using SHAP (Figure 1).

Figure 1. Procedure for obtaining the model parameters, validation, and feature importance. AUC: area under the curve, SHAP: Shapley Additive Explanations.



Results

Study Population and Features

Following the initial data preprocessing phase, the combination of the data in the 2 tables produced a data set composed of 1823 records and 33 features. All the data correspond to patients with a confirmed diagnosis of COVID-19. Tables 1 and 2 show prevalence and clinical laboratory values, respectively. The median age of all patients was 68 (IQR 57-79) years, and 1114 (61.1%) were male. The "Death" outcome had a prevalence of approximately 14% in the resulting subset of patients after data preprocessing.

Table 1. Prevalence for the "Age," "Sex," and "Outcome" features.

Feature	Patients, n (%)
Age (years)	
0-25	7 (0.4)
25-50	235 (12.9)
50-75	942 (51.7)
75-100	635 (34.8)
100-125	4 (0.2)
Sex	
Male	1114 (61.1)
Female	709 (38.9)
Outcome	
Home	1561 (85.6)
Death	262 (14.4)

Table 2. Clinical laboratory values for the features in the data set.

Feature (units)	Median (IQR[a])	Reference value
Alanine transaminase (U/L)	31.7 (19.2-55.7)	<40
Aspartate transaminase (U/L)	31.8 (22.2-47.3)	<40
Anisocytosis coefficient (%)	13.0 (11.9-14.1)	11.5-14.5
Basophils (%)	0.3 (0.2-0.5)	0-1
Basophil count (10^{-3}/μL)	0.02 (0.01-0.03)	0-0.1
C-reactive protein (mg/L)	52.8 (24.1-94.0)	<5
Creatinine (mg/dL)	0.8 (0.7-1.0)	0.6-1.0
D-Dimer (ng/mL)	885 (492-1883)	<500
Eosinophils (%)	0.8 (0.2-1.6)	2-7
Eosinophil count (10^{-3}/μL)	0.05 (0.01-0.10)	0.1-0.6
Glucose (mg/dL)	110 (97-132)	70-105
Hematocrit (%)	39.5 (36.5-42.5)	40-54
Hemoglobin (g/dL)	13.3 (12.1-14.3)	13.5-17.5
Lactate dehydrogenase (U/L)	507 (402-654)	120-230
Leukocyte count (10^{-3}/μL)	7.0 (5.5-9.2)	4.4-11.3
Lymphocytes (%)	18.4 (12.1-25.5)	20-48
Lymphocyte count (10^{-3}/μL)	1.2 (0.9-1.6)	1.2-3.4
Mean corpuscular hemoglobin (pg)	29.7 (28.6-30.8)	28-33
Mean corpuscular hemoglobin concentration (g/dL)	33.5 (32.7-34.2)	33-36
Mean corpuscular volume (fL)	88.4 (85.5-91.5)	80-95
Mean platelet volume (fL)	10.3 (9.7-11.0)	7.4-10.4
Monocytes (%)	8.1 (6.0-10.5)	1-11
Monocyte count (10^{-3}/μL)	0.6 (0.4-0.7)	0.1-1
Neutrophils (%)	71.0 (62.5-80.1)	40-75
Neutrophil count (10^{-3}/μL)	4.9 (3.6-7.1)	1.5-7.5
Platelet count (10^{-3}/μL)	250 (195-317)	150-450
Potassium (mmol/L)	4.3 (4.0-4.6)	3.5-5.1
Erythrocyte count (10^{-6}/μL)	4.5 (4.1-4.9)	4.1-5.9
Sodium (mmol/L)	138 (136-140)	135-145
Urea (mg/dL)	38 (29-54)	5-50

[a]IQR: Q1-Q3 values.

Model Performance

In the initial evaluation of XGBoost's performance, a comparison with several well-known classifiers was carried out. Table 3 shows the results of this comparison. XGBoost yielded the best results for 3 measures and the second-best results for the F1. These results reaffirm the choice of XGBoost as the predictive method for this study. Figure 2 displays the resulting receiver operator characteristic and precision-recall curves for XGBoost, and Multimedia Appendix 1 shows the corresponding ones for the other methods.

Table 3. Comparison of the outcomes of methods after bootstrap validation.

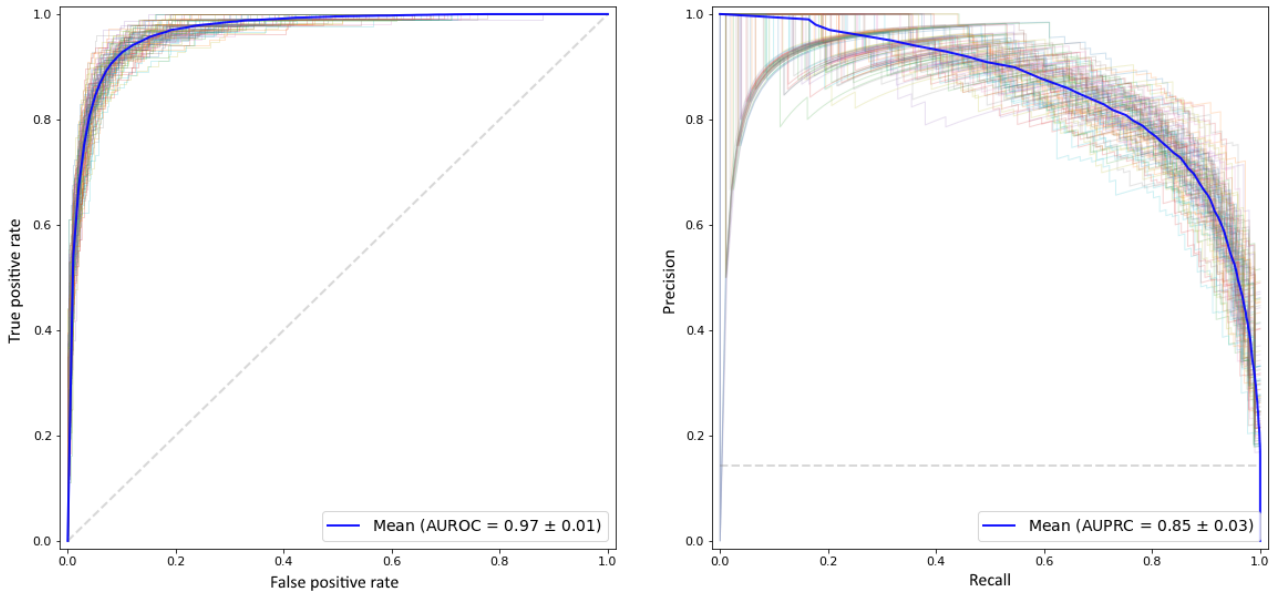
Method	AUROC[a], mean (95% CI)	AUPRC[b], mean (95% CI)	Accuracy, mean (95% CI)	F1[c], mean (95% CI)
Decision tree	0.89 (0.84-0.92)	0.67 (0.58-0.74)	0.89 (0.85-0.92)	0.60 (0.52-0.68)
K-nearest neighbors	0.87 (0.85-0.90)	0.55 (0.46-0.64)	0.88 (0.86-0.90)	0.41 (0.29-0.50)
Linear discriminant analysis	0.96 (0.94-0.97)	0.85 (0.80-0.90)	0.94 (0.92-0.95)	0.75 (0.70-0.82)
Logit	0.96 (0.94-0.98)	0.84 (0.79-0.89)	0.94 (0.92-0.95)	0.76 (0.70-0.82)
Multilayer perceptron	0.95 (0.93-0.97)	0.79 (0.71-0.86)	0.93 (0.91-0.94)	0.73 (0.65-0.79)
Naive Bayes	0.94 (0.91-0.96)	0.74 (0.66-0.82)	0.91 (0.89-0.92)	0.68 (0.62-0.76)
Random forest	0.96 (0.95-0.98)	0.84 (0.76-0.90)	0.93 (0.91-0.95)	0.73 (0.67-0.79)
Support vector machines	0.91 (0.88-0.94)	0.62 (0.53-0.71)	0.87 (0.85-0.88)	0.21 (0.11-0.31)
XGBoost	0.97 (0.96-0.98)	0.85 (0.79-0.91)	0.94 (0.92-0.95)	0.76 (0.71-0.81)

[a]AUROC: area under the receiver operating characteristic curve.

[b]AUPRC: area under the precision-recall curve.

[c]F1: F-score.

Figure 2. The receiver operator characteristic curve (left) and precision-recall curve (right) in the XGBoost model after bootstrap validation. AUROC: area under the receiver operator characteristic curve, AUPRC: area under the precision-recall curve, XGBoost: extreme gradient boosting.



In an attempt to improve XGBoost's performance, the final model parameters were adjusted through a more exhaustive tuning procedure using the Python hyperopt library. Setting the number of iterations (max_eval) at 8000 yielded the hyperparameter values presented in Table 4. The remaining hyperparameters retained their default values. The model used 110 decision trees, with a maximum depth of 3.

Table 4. Final values of the tuned hyperparameters in the extreme gradient boosting model.

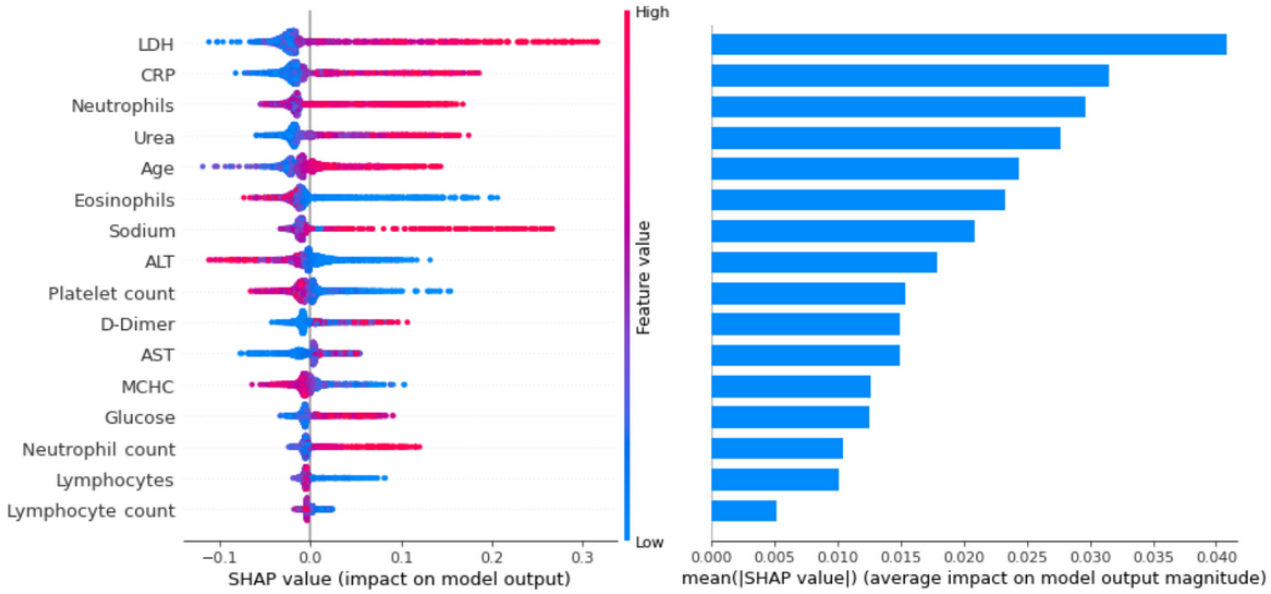
Hyperparameter	Value
Number of gradient-boosted trees	110
Maximum tree depth	3
Minimum sum of instance weight needed in a child	5
Boosting learning rate	0.094
Subsample ratio of the training instances	0.928
Subsample ratio of columns	0.474

With these hyperparameter values, bootstrap validation was again used to obtain model results for the performance metrics, after 300 bootstrap iterations. Through this process, the values obtained were 0.97 (95% CI 0.96- 0.98) for AUROC, 0.86 (95% CI 0.80- 0.91) for AUPRC, 0.94 (95% CI 0.92-0.95) for accuracy, and 0.77 (95% CI 0.72- 0.83) for the F1. We observed a slight improvement owing to more processing in the hyperparameter search process (8000 vs 1000 iterations). Furthermore, the associated sensitivity and specificity values were calculated using the receiver operator characteristic curve values to determine the cut-point that maximizes the Youden index. These calculations yielded a value of 0.85 (95% CI 0.80-0.90) for the Youden index, 0.93 (95% CI 0.89-0.98) for sensitivity, and 0.91 (95% CI 0.86-0.96) for specificity.

Feature Importance

After applying the tuned XGBoost model to the total data set, the SHAP values associated with this model were calculated. Each feature's overall performance can be determined on the basis of these SHAP values in accordance with their average impact on model output. Figure 3 shows SHAP summary plots for the 16 most important features. Based on the mean absolute SHAP values, 5 features, including lactate dehydrogenase, C-reactive protein, neutrophil (%), urea, and age, had a greater average impact on model output. Among these, the feature's highest values (red) are generally associated with a higher SHAP value and, by extension, to a greater likelihood of the "Death" outcome. In other cases, for example eosinophil (%) and alanine aminotransferase, the feature's lowest values (blue) are associated with a greater risk of the "Death" outcome.

Figure 3. SHAP summary plots for the 16 most important features in accordance with their mean absolute values. Beeswarm plot (left), where each dot corresponds to an individual patient, showing the impact of the feature on the model's prediction for that patient. The graph on the right shows the average impact on model output. ALT: alanine transaminase, AST: aspartate transaminase, CRP: C-reactive protein, LDH: lactate dehydrogenase, MCHC: mean corpuscular hemoglobin concentration, SHAP: Shapley Additive Explanations.



Plots developed using SHAP values are displayed in Multimedia Appendix 1; these highlight the relationship between these features and the mortality risk. Every dot represents an individual patient. Furthermore, Multimedia Appendix 1 contains boxplots that describe value distribution between recovered and dead patients for the same features.

Discussion

Principal Findings

COVID-19 mortality is strongly linked to 2 events. There are patients who develop a severe inflammatory syndrome, which results in uncontrolled activation of the immune system and a massive release of proinflammatory cytokines, which translates into an increase in acute-phase reactants such as C-reactive protein, interleukin-6, ferritin, cell destruction markers such as lactate dehydrogenase, and an increase in proinflammatory cells such as neutrophils. This severe inflammatory syndrome has been described as a cause of mortality in most patients with complications arising from a SARS-CoV-2 infection. In such patients, lactate dehydrogenase is associated with an increase in cell destruction, which results in a reduction in lymphocytes, rupture of the lung parenchyma due to inflammation, cell damage, cell remodeling, and lung fibrosis [19,20]. Our study data are concurrent with this trend, with lactate dehydrogenase, C-reactive protein, and neutrophils having the greatest impact on mortality among these patients. Another important complication described in these patients is acute renal failure [21]; our data show that the laboratory parameter that most influences mortality in relation to renal function is urea, a marker of renal function at the prerenal level, which indicates whether renal filtering is effective. Urea levels tend to increase when patients are dehydrated or experience excessive fluid loss [3].

From among clinical laboratory findings, it is essential to establish a biochemical panel of acute-phase reactants that facilitate the identification of patients susceptible to an acute inflammatory syndrome. In this case, we propose lactate dehydrogenase and C-reactive protein as the best candidates

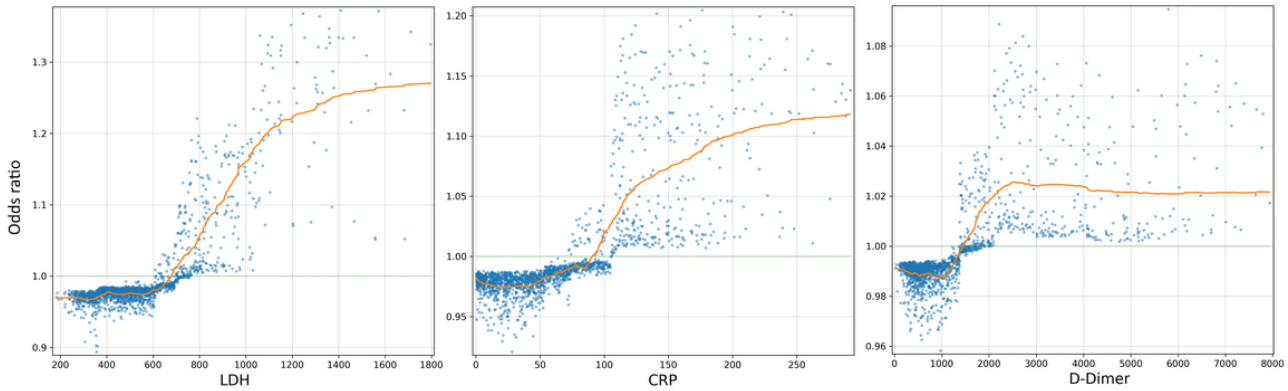
according to the data obtained, to which interleukin-6 ferritin should be added, at the very least.

Another complication that results in high mortality in these patients is coagulation disorders. COVID-19 results in a systemic hypercoagulation state, producing pulmonary thromboembolisms, ischemic strokes, and other disorders, and a markedly large number patients experience severe complications. This complication can be assessed on the basis of 2 laboratory parameters: D-Dimer and platelets. As a degradation product of a previously formed clot, the increase in this parameter will thus be proportional to the number of previously formed clots. In the first step of the coagulation process, a reduction in the number of platelets would indicate that clots are being formed. Accordingly, a risk factor would be an increase in D-dimer levels and a reduction in the platelet count [22].

Approximately 30% of patients with COVID-19 complications have hypercoagulation disorders; hence, it is important to be able to predict these complications in order to establish prophylactic anticoagulant treatment as early as possible in patients in whom this blood disorder is identified. Some studies have compared the hypercoagulation status resulting from COVID-19 to that appearing in patients with an antiphospholipid syndrome, who present with the same complications and in whom the treatment is identical [23]. Of note, we have established a strong relationship between coagulation parameters and mortality in the predictive model we developed in this study.

Figure 4 shows the most interesting parameters—from the clinical point of view—and their relation to mortality. The 3 graphs have a common relationship; that is, from a certain value, the curve that relates the value of the variable to mortality increases significantly. At this point, the medical intervention could change the clinical course of patients since, as seen in the graph, very high values in these tests represent a higher mortality risk, while low levels relate to a more favorable prognosis.

Figure 4. Plots developed using SHAP values, displaying the relationship between laboratory values—including LDH, CRP, and D-Dimer—and mortality risk. Every dot represents an individual patient. Higher values of these features indicate an increase in the mortality risk, and lower ones are associated with a more favorable prognosis. CRP: C-reactive protein, LDH: lactate dehydrogenase, SHAP: Shapley Additive Explanations.



At the beginning of the pandemic, one of the main risk factors by which patients were classified was age; as expected, higher morbidity and mortality rates prevail among older individuals. In our predictive model, age ranks in fifth position, which is important, but mortality is still more prominent among those patients who develop a severe inflammatory syndrome. Therefore, if we relate age as an independent variable to the main biochemical markers of severe inflammation, we can estimate patient mortality on the basis of their age and a clinical laboratory value (Figure 5). On the other hand, Figure 6 shows the difference in different clinical laboratory values from among patients who die or are discharged from hospital. We observed a clear difference between different laboratory values depending on each group.

Figure 5. Partial dependence plots representing the model output associated with age and other features (LDH, CRP, and urea). Red zones indicate a greater influence on mortality risk. CRP: C-reactive protein, LDH: lactate dehydrogenase.

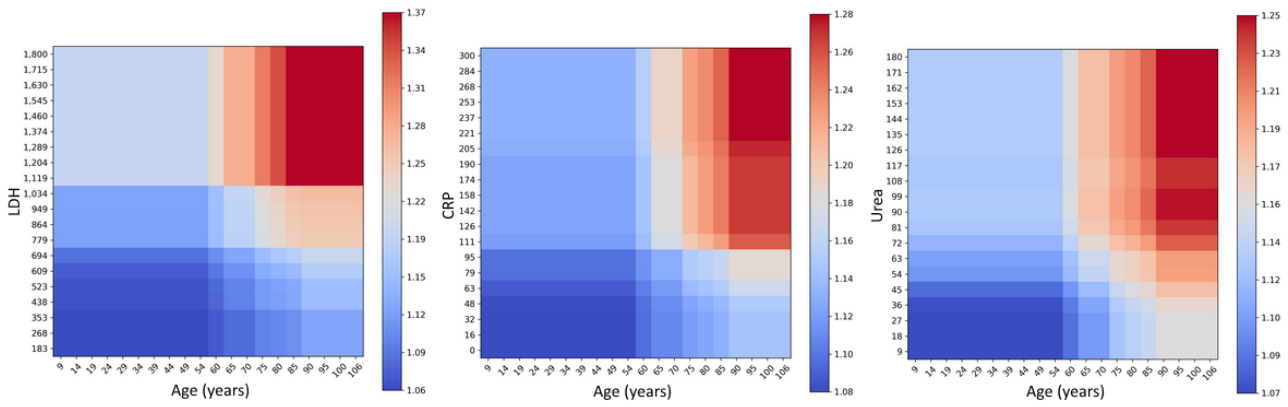


Figure 6. Boxplots describing value distribution between recovered and dead patients on the basis of the laboratory values of LDH, CRP, Urea, and D-Dimer. CRP: C-reactive protein, LDH: lactate dehydrogenase.

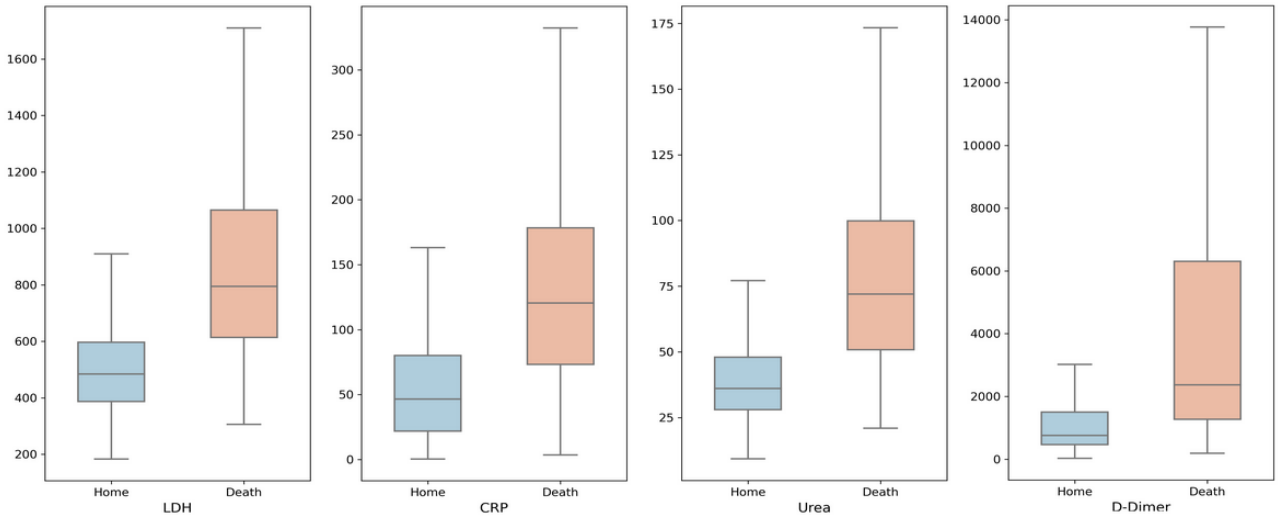

It is not easy to establish strict criteria for mortality in patients with COVID-19, as they are influenced by other unquantified variables and environmental factors. The comorbidities in these patients prior to them contracting COVID-19 are very important when managing these patients and predicting complications [24]. Patients with chronic pathologies such as hypertension or diabetes have a higher number of complications and rate of mortality than those who do not; however, the underlying reason remains unclear. It has been hypothesized that these patients have higher expression levels of angiotensin-converting enzyme 2 receptors through which the virus penetrates the cells to replicate; such patients are candidates for a stronger and more severe disease. Furthermore, Fang et al [25] reported that polymorphisms in the gene that encodes this receptor increases the severity of the disease.

Carrasco-Sánchez et al [26] collected data from approximately 20,000 patients in Spain and reported that mortality can be predicted among those patients who arrive at an emergency department and are then found to have high blood glucose levels, during their hospital stay, provided they are not in a critical condition. Blood glucose is thus one of the most prominent predictors of patient mortality, which is concurrent with our hypothesis. Therefore, glycemic control among patients before and during their hospital stay is essential to increase their survival.

Limitations

Clinically, this study has a series of limitations. First, this study has a small patient cohort; previous similar studies have included a markedly larger patient cohort [21,26]. Second, we did not record the comorbidities of these patients; therefore, we cannot assess their role in relation to other variables and their potential to predict a patient's mortality. Finally, it is very important to perform a battery of laboratory tests, which facilitates the evaluation of an inflammatory syndrome with more parameters, such as interleukin-6 and ferritin.

Conclusions

This study aimed to develop a model to predict the mortality of patients with COVID-19, which can assess mortality from laboratory values with a high degree of accuracy. The use of machine learning techniques, in this case the XGBoost predictive method, has yielded excellent results for several performance metrics. The analysis of the resulting model enables us to identify a set of features with a markedly high prediction potential, which can be useful for improving care decisions and increasing patient survival.

Abstract

Background: Accompanying the rising rates of reported mental distress during the COVID-19 pandemic has been a reported increase in the use of digital technologies to manage health generally, and mental health more specifically.

Objective: The objective of this study was to systematically examine whether there was a COVID-19 pandemic–related increase in the self-reported use of digital mental health tools and other technologies to manage mental health.

Methods: We analyzed results from a survey of 5907 individuals in the United States using Amazon Mechanical Turk (MTurk); the survey was administered during 4 week-long periods in 2020 and survey respondents were from all 50 states and Washington DC. The first set of analyses employed two different logistic regression models to estimate the likelihood of having symptoms indicative of clinical depression and anxiety, respectively, as a function of the rate of COVID-19 cases per 10 people and survey time point. The second set employed seven different logistic regression models to estimate the likelihood of using seven different types of digital mental health tools and other technologies to manage one's mental health, as a function of symptoms indicative of clinical depression and anxiety, rate of COVID-19 cases per 10 people, and survey time point. These models also examined potential interactions between symptoms of clinical depression and anxiety, respectively, and rate of COVID-19 cases. All models controlled for respondent sociodemographic characteristics and state fixed effects.

Results: Higher COVID-19 case rates were associated with a significantly greater likelihood of reporting symptoms of depression (odds ratio [OR] 2.06, 95% CI 1.27-3.35), but not anxiety (OR 1.21, 95% CI 0.77-1.88). Survey time point, a proxy for time, was associated with a greater likelihood of reporting clinically meaningful symptoms of depression and anxiety (OR 1.19, 95% CI 1.12-1.27 and OR 1.12, 95% CI 1.05-1.19, respectively). Reported symptoms of depression and anxiety were associated with a greater likelihood of using each type of technology. Higher COVID-19 case rates were associated with a significantly greater likelihood of using mental health forums, websites, or apps (OR 2.70, 95% CI 1.49-4.88), and other health forums, websites, or

apps (OR 2.60, 95% CI 1.55-4.34). Time was associated with increased odds of reported use of mental health forums, websites, or apps (OR 1.20, 95% CI 1.11-1.30), phone-based or text-based crisis lines (OR 1.20, 95% CI 1.10-1.31), and online, computer, or console gaming/video gaming (OR 1.12, 95% CI 1.05-1.19). Interactions between COVID-19 case rate and mental health symptoms were not significantly associated with any of the technology types.

Conclusions: Findings suggested increased use of digital mental health tools and other technologies over time during the early stages of the COVID-19 pandemic. As such, additional effort is urgently needed to consider the quality of these products, either by ensuring users have access to evidence-based and evidence-informed technologies and/or by providing them with the skills to make informed decisions around their potential efficacy.

Introduction

Background

On March 11, 2020, the World Health Organization designated the COVID-19 outbreak a global pandemic, which, among other things, has led to unprecedented hazards to mental health globally [1]. Individual states within the United States began to implement measures to contain the spread of the virus, including limiting travel, mandating physical distancing, and limiting nonessential medical visits. By April 2020, nearly 200,000 cases of COVID-19 and more than 5000 deaths had been reported in the United States [2].

In addition to the unpredictability and uncertainty of the pandemic itself, policy efforts to mitigate risk, such as stay-at-home orders and/or social distancing, introduced a number of additional stressors including social isolation, inactivity, loss of income, and lack of access to basic services, to name but a few [3]. This may be why, mirroring the increase in COVID-19 cases and deaths, there has been an increase in mental distress [1,4-6]. For example, data from the US Census Bureau reported that adults assessed as part of a nationally representative survey in April and May 2020 were more than three times as likely to screen positive for depressive disorders, anxiety disorders, or both, relative to a comparable sample in 2019 [7]. In a similar vein, the Centers for Disease Control and Prevention reported significantly elevated levels of adverse mental health conditions, substance use, and suicidal ideation resulting from the COVID-19 pandemic, with these mental health conditions disproportionately affecting specific populations, such as young adults, Hispanic persons, Black persons, essential workers, unpaid caregivers of adults, and those receiving treatment for preexisting psychiatric conditions [8].

As medical organizations and hospital systems, including those that address mental health, quickly pivoted to digital platforms such as videoconferencing/teleconferencing and patient-provider SMS text messaging [9], the documented growth in and reliance on eHealth/telehealth use emerged as a viable solution to continue providing health and mental health services [10-12]. Indeed, it has been suggested that the COVID-19 pandemic is serving as a "black swan" moment for mental health care—an unforeseen event that will permanently shift mental health care provision toward online prevention, treatment, and care [12]. Given the increase in mental health issues resulting from the pandemic, digital platforms also offer the potential to provide scalable, nonconsumable mental health resources, as they may be less reliant on trained providers [13]. A nonconsumable treatment is one that, once used, retains its therapeutic potential. Unlike a dose of medication, which will not benefit another person once used, digital resources can be used by many people and continue to be helpful [14].

In tandem with this increase in the use of telehealth services and digital platforms, technology companies have also reported increased demand for digital mental health products and therapeutics since the start of the COVID-19 pandemic [15]. However, there have been no empirical studies examining rates of use of these digital mental health products and therapeutics during the COVID-19 pandemic. Examination of marketplace trends through app analytics platforms (eg, App Annie) indicate that downloads and engagement have increased since the onset of COVID-19 [16]. However, it is unclear if reported rates of growth relate to the pandemic or represent an already documented gradual trend of engagement [17]. In light of the transformative changes that have occurred in the delivery of health and mental health care resulting from the COVID-19 pandemic, understanding potential changes in consumer behavior pertaining to the use of digital mental health tools and other technologies during the COVID-19 pandemic is needed.

Current Study

To this end, this study examined the following questions:

1. To what extent was the likelihood of having symptoms indicative of clinical depression and anxiety associated with the county COVID-19 case rate and time?
2. Were individuals with moderate to high self-reported depressive or anxious symptomatology more likely to use digital mental health tools and other technologies compared to individuals who endorsed low depression or anxiety symptom experiences?
3. If so, did the differences in use of these digital mental health tools and other technologies among those with high versus low symptom endorsement vary according to the COVID-19 case rate?

Methods

Participants and Procedures

Participants were recruited from Amazon Mechanical Turk (MTurk), an online crowdsourcing platform commonly used in behavioral science studies [18]. Survey data collection occurred across all 50 states and Washington DC during 4 one-week periods in April, May, June, and July 2020, starting on approximately the 6th of each month. At the first time point, we aimed to recruit approximately 1250 people. At each of the following time points, we aimed to recruit approximately 1750 people.

MTurk allows researchers to collect a large amount of quality data quickly and for relatively little cost [19-21]. On MTurk, requesters are people who post or request tasks (eg, surveys) to be completed, whereas workers are people who are paid for task completion. Requesters can customize the tasks to be available to certain MTurk workers. MTurk workers are able to read descriptions of tasks and select the tasks they are interested in.

For the purpose of this study, study participants had to meet three eligibility criteria: (1) be at least 18 years old, (2) currently reside in the United States, and (3) not have completed the survey in a prior wave. If eligible, participants completed the survey via Qualtrics and received US $6 via MTurk as compensation upon completion. The protocol was approved by the Institutional Review Board (IRB#2019-5406) at the University of California, Irvine.

Measures

Symptoms Indicative of Clinical Depression and Anxiety

The Patient Health Questionnaire-9 (PHQ-9) [22] is a self-report measure used to assess depressive symptoms. It consists of the nine criteria upon which the diagnosis of major depressive disorder is based, according to the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV). The questionnaire uses a 4-point Likert scale (0=not at all, 1=several days, 2=more than half the days, 3=nearly every day) to gauge responses to questions about participants' mental health over the previous 2-week period. Scores on the PHQ-9 can range from 0-27, with 0-4 suggesting no depression symptoms, 5-9 mild symptoms, 10-14 moderate symptoms, 15-19 moderately severe symptoms, and 20-27 more severe depression [23], with a cut-off score of 10 or above being used in this study to indicate the presence of clinically elevated levels of depression symptoms (0=minimal or mild depressive symptomatology and 1=moderate to severe depressive symptomatology). This cut-off has been shown to have high sensitivity (88%) and specificity (88%) [22]. In the present sample, reliability was strong (unweighted α=.92).

The Generalized Anxiety Disorder-7 Questionnaire (GAD-7) [24] was used to assess generalized anxiety disorder. Respondents rate answers (0=not at all, 1=several days, 2=more than half the days, 3=nearly every day) to 7 questions assessing anxiety symptoms experienced over the past two weeks, with the total score ranging from 0-21; scores from 0-4 suggest minimal symptoms, 5-9 mild symptoms, 10-14 moderate symptoms, and 15-21 severe symptoms. A cut-off score of 10 or above was used in this study to indicate the presence of elevated levels of anxiety symptoms (0=minimal to mild anxiety symptomatology and 1=moderate to severe anxiety symptomatology). This cut-off has high sensitivity (89%) and specificity (82%) [24]. Reliability in the present study was high (unweighted α=.92).

Digital Mental Health Tools and Other Technologies to Support Mental Health

Participants were asked how frequently (never, rarely, sometimes, often, or always) they used 20 different types of technology in the last 7 days to manage or support their mental health. Responses were dichotomized (0=never, rarely, sometimes and 1=often or always). The 20 technology types included the following: (1) mental health online forums or communities (eg, Mental Health Forum, BeyondBlue), (2) mental health websites (eg, NAMI, StudentsAgainstDepression.org), (3) mental health apps (eg, 7 Cups, Headspace, Moodpath), (4) phone-based or text-based crisis lines (eg, Crisis Text Line, Suicide Prevention Lifeline), (5) other health online forums or communities (eg, MyFitnessPal forum), (6) other health websites (eg, WebMD, WHO), and (7) other health apps (eg, LoseIt, MapMyRun, Sleep Cycle, Flo). Additionally, participants were also asked about their use of the following technologies to manage their mental health: (8) social media (eg, Facebook, Instagram, Twitter, Snapchat), (9) blogs, (10) online, computer, or console gaming/video gaming, (11) online calendar, checklist, or planner, (12) Word, Notepad, or Google Docs, (13) spreadsheet or Google Sheets, (14) email, (15) texting or messaging software, and (16) video conferencing software. Participants were also able to select the following options: (17) other general online forums or communities, which may include mental health communities (eg, Reddit); and writing in (18) other types of websites, (19) other apps, and (20) other types of technologies not listed [25].

The technologies were collapsed into seven categories by theme: (1) mental health forums, websites, or apps, (2) phone-based or text-based crisis lines, (3) other health forums, websites, or apps, (4) social media and blogs, (5) online, computer, or console gaming/video gaming, (6) online calendar, checklist, planner, Word, Notepad, Google Docs, spreadsheet, or Google Sheets, and (7) email, texting or messaging software, or video conferencing software [25].

County COVID-19 Case Rate

The COVID-19 Data Repository maintained by the Center for Systems Sciences and Engineering at Johns Hopkins University has provided the COVID-19 case count of each county in the United States on a daily basis since January 22, 2020 [2]. Using participants' zip codes, the case count in each participant's county on the date each participant began the survey was merged with the data collected from MTurk. The county case count was converted into the rate of cases per 10 people by dividing the count by each county's total population and multiplying this number by 10. Total county population was obtained from the US Census Bureau's American Community Survey 2018 5-year estimates [26].

Survey Time Period

Survey response windows that reflected the states' population sizes were made available during 4 week-long periods in April, May, June, and July of 2020. As such, this variable also serves as a proxy indicator of time. The time point variable was treated as a continuous variable in the analyses.

Covariates

Additional variables were included as covariates. These encompassed standard demographic characteristics, including age, sex (1=male, 2=female), race/ethnicity (1=non-Hispanic White, 2=Latino, 3=non-Hispanic Asian, 4=non-Hispanic Black or African American, 5=other), marital status (1=married or living with a partner, 2=single or not living with a partner, 3=separated, divorced, or widowed), employment status (1=no change in employment status due to COVID-19, 2=reduced hours due to COVID-19, 3=lost job due to COVID-19), income level, and education level (1=completed high school or less, 2=some college or more). Covariates also included a variable representing state fixed effects.

Analytic Sample

A total of 6704 survey responses were collected. After omitting ineligible people due to duplicate or missing MTurk worker identification numbers, the total sample included 5907 participants. Of this group, 2.22% had missing data for at least one question from the PHQ-9 and 1.64% had missing data for at least one question from the GAD-7. Participants' average PHQ-9 and GAD-7 scores were imputed if at least 50% of the scale questions were answered. Less than 5.51% of sociodemographic data was missing. Binary and continuous variables underwent mean imputation. An additional category for missing data was created for all other sociodemographic covariates. Where participants had a missing zip code, but provided their state of residence, the average county case count and the average county population in the participant's state were used to calculate the county case rate per 10 people. After mean imputation was executed and missing county case rates were replaced with average rates, the analytic sample included 5899 individuals.

Statistical Analyses

Summary statistics were calculated to describe the sociodemographic characteristics of and prevalence of anxiety and depression symptoms in the sample. The use of digital mental health tools and other technologies in the sample was also described. Means, standard errors, and proportions were reported.

To examine the extent to which the likelihood of having symptoms indicative of clinical depression and anxiety was associated with the county COVID-19 case rate and time, we estimated two separate logistic regression models, one for each mental health outcome. Adjusted models included age, sex, race/ethnicity, marital status, employment status, income level, education level, and state fixed effects.

To evaluate whether individuals with moderate to high self-reported depressive or anxious symptomatology were more likely to use digital mental health tools and other technologies compared to individuals who endorsed low depression or anxiety symptom experience, we estimated seven different logistic regression models, one for each of the technology types defined above. Symptoms of anxiety, symptoms of depression, county case rate per 10 people, and time point were the independent variables. Adjusted models included age, sex, race/ethnicity, marital status, education level, income level, and state fixed effects. To descriptively assess the use of digital mental health tools and other technologies over time, the predicted probabilities of employing each type of tool or technology were plotted at each time point, while holding the covariates at their mean values. We also plotted the total number of respondents using each type of technology at each time point.

Finally, to understand if differences in use among those with high versus low symptom endorsement varied according to the rate of COVID-19 cases, we further tested the inclusion of two interactions examining the following in these adjusted models: (1) county-level COVID-19 case rate with depression and (2) county-level COVID-19 case rate with anxiety.

Probability weights were generated to account for oversampling and undersampling of participants in each state. Use of probability weights allowed for the proportion of participants from each state to reflect the proportion of the US population that each state population comprises. Weights were generated using data from the American Community Survey 2018 5-year estimates of US state populations. Survey weights were employed when estimating summary statistics and multivariable regression. Additionally, a Šidák-corrected cut-off P value (P<.0037) was employed to identify significant findings and account for the increased type I error rate that resulted from the use of multiple models [27]. All analyses were conducted in Stata 16 (StataCorp LLC) [28].

Results

Table 1 shows the weighted means and standard errors for continuous variables, as well as the weighted proportions of individuals within each categorical variable group. Overall, the average age was 36.99, and most of the sample was male, non-Hispanic White, and married or living in a marital-like relationship. Most of the sample did not experience a change in employment status due to the COVID-19 pandemic, had an income level greater than US $50,000, and had greater than a high school education. Close to half of the sample experienced symptoms indicative of clinical levels of depression (45.45%) or anxiety (40.04%).

Table 1. Characteristics of analytic sample (N=5899).

Sociodemographic characteristics	Values[a]
County case rate per 10 people, mean (SE)	0.069 (0.0023)
Age, mean (SE)	36.99 (0.17)
Symptoms of depression, %	45.45
Symptoms of anxiety, %	40.04
Sex, %	
Male	57.58
Female	42.42
Race/ethnicity, %	
Non-Hispanic White	61.07
Latino	11.69
Asian	6.54
Black/African American	7.85
Other	12.85
Marital status, %	
Married/living in a marital-like relationship	62.20
Single/never married	31.76
Separated, divorced, or widowed	6.04
Employment status, %	
No change in employment status due to COVID-19	64.42
Reduced hours due to COVID-19	26.88
Lost job due to COVID-19	8.70
Income level (US $), %	
0-10,000	4.67
10,001-20,000	7.42
20,001-30,000	11.71
30,001-40,000	11.91
40,001-50,000	11.85
50,001-60,000	12.14
60,001-70,000	8.75
70,001-80,000	8.60
80,001-90,000	5.24
90,001-100,000	6.14
>100,000	11.56
Education level, %	
High school or less	19.35
More than high school	80.65
Use of digital mental health tools and other technologies to manage mental health, %	
Mental health forums, websites, or apps	27.39
Phone-based or text-based crisis lines	17.74
Other health forums, websites, or apps	34.48
Social media or blogs	47.73
Online, computer, or console gaming/video gaming	33.55

Sociodemographic characteristics	Values[a]
Online calendar, checklist, planner, Word, Notepad, Google Docs, spreadsheet, or Google Sheets	44.55
Email, SMS texting or messaging software, or video conferencing software	55.50

[a]The proportion of missing data ranged from 0.0%-5.51%.

Table 2 shows the results of the two adjusted models regressing the prevalence of clinically meaningful symptoms of depression and anxiety, respectively, on the county COVID-19 case rate per 10 people, time point, and the covariates. As shown, COVID-19 case rate was significantly associated with an increase in the likelihood of experiencing clinically meaningful symptoms of depression (odds ratio [OR] 2.06, 95% CI 1.27-3.35), but not anxiety (OR 1.21, 95% CI 0.77-1.88). Additionally, the likelihood of experiencing symptoms of depression or symptoms of anxiety increased over time (OR 1.19, 95% CI 1.12-1.27 and OR 1.12, 95% CI 1.05-1.19, respectively). Results associated with each covariate are shown in Multimedia Appendix 1.

Table 2. Association between symptoms indicative of clinical levels of depression and anxiety and rates of COVID-19 cases and time: estimates based on two separate logistic models (N=5899)[a].

Variables	Model 1: Symptoms of depression, odds ratio (95% CI)	Model 2: Symptoms of anxiety, odds ratio (95% CI)
County-level COVID-19 case rate per 10 people	2.06[b] (1.27-3.35)	1.21 (0.77-1.88)
Survey time point	1.19[c] (1.12-1.27)	1.12[c] (1.05-1.19)

[a]Models adjusted for the following covariates: age, sex, race/ethnicity, marital status, employment status, income level, education level, and fixed state effects.

[b]$P<.0037$ (Šidák-corrected P value).

[c]$P<.001$.

The adjusted association between depression, anxiety, county case rate per 10 people, time point, and use of each of the seven categories of digital mental health tools and other technologies is presented in Table 3. Results pertaining to each covariate are shown in Multimedia Appendix 1. Both symptoms of depression and anxiety were significantly associated with the likelihood of using each type of tool and technology. Those with depressive symptoms were three to six times more likely to use digital mental health tools than those without depressive symptoms. Those with symptoms of anxiety were two to three times more likely to use digital mental health tools than those without symptoms of anxiety. Specifically, those with depressive symptoms or symptoms of anxiety were more likely than those without symptoms to use mental health forums, websites, or apps (OR 6.01, 95% CI 4.70-7.70 and OR 2.95, 95% CI 2.37-3.66, respectively), phone-based or text-based crisis lines (OR 4.98, 95% CI 3.66-6.77 and OR 2.85, 95% CI 2.22-3.66, respectively), and other health forums, websites, or apps (OR 3.44, 95% CI 2.81-4.20 and OR 2.55, 95% CI 2.11-3.10, respectively).

The findings pertaining to digital mental health tools mirrored the results from models assessing use of other technologies not necessarily related to health. Specifically, those with symptoms indicative of depression and anxiety were more likely, as compared to those without symptoms, to engage in use of social media and blogs (OR 1.56, 95% CI 1.31-1.86 and OR 1.80, 95% CI 1.51-2.14, respectively); online, computer, or console gaming/video gaming (OR 1.63, 95% CI 1.36-1.95 and OR 1.67, 95% CI 1.40-1.99, respectively); online calendar, checklist, planner, Word, Notepad, Google Docs, spreadsheet, or Google Sheets (OR 1.91, 95% CI 1.60-2.28 and OR 2.09, 95% CI 1.75-2.50, respectively); and email, texting or messaging software, or video conferencing software (OR 1.66, 95% CI 1.39-1.98 and OR 1.82, 95% CI 1.52-2.17, respectively). However, in general, even though significant, the odds ratios for these other technologies tended to be much smaller, with the largest being 2.09 and all others below 2.00, while all the odds ratios for the mental health technologies were well above 2.00, ranging from 2.55 to 6.01.

With regard to the association between county-level COVID-19 case rate and digital mental health tool and other technology use, a higher county case rate per 10 people was associated with increased likelihood of using digital mental health tools, specifically mental health forums, websites, or apps (OR 2.70, 95% CI 1.49-4.88) and other health forums, websites, or apps (OR 2.60, 95% CI 1.55-4.34). Additionally, over time, there was an increase in the likelihood of using mental health forums, websites, or apps (OR 1.20, 95% CI 1.11-1.30); phone-based or text-based crisis lines (OR 1.20, 95% CI 1.10-1.31); other health forums, websites, or apps (OR 1.12, 95% CI 1.05-1.20); and online, computer, or console gaming/video gaming (OR 1.12, 95% CI 1.05-1.19). The predicted probabilities of using each type of technology at each time point while holding the covariates at their mean values are graphed in Multimedia Appendix 2. Multimedia Appendix 3 shows the total number of respondents using each type of technology at each time point.

Table 3. Associations between use of digital mental health tools and other technologies and prevalence of mental illness symptoms and the rate of COVID-19 cases: estimates based on seven separate logistic models[a].

Variables	Model 1: Mental health forums, websites, or apps (n=5849)	Model 2: Phone-based or text-based crisis lines (n=5831)	Model 3: Other health forums, websites, or apps (n=5854)	Model 4: Social media and blogs (n=5788)	Model 5: Online, computer, or console gaming/video gaming (n=5866)	Model 6: Online calendar, checklist, planner, Word, Notepad, Google Docs, spreadsheet, or Google Sheets (n=5835)	Model 7: Email, texting or messaging software, or video conferencing software (n=5849)
	OR[b] (95% CI)	OR (95% CI)	OR (95% CI)	OR (95% CI)	OR (95% CI)	OR (95% CI)	OR (95% CI)
Symptoms of depression	6.01[c] (4.70-7.70)	4.98[c] (3.66-6.77)	3.44[c] (2.81-4.20)	1.56[c] (1.31-1.86)	1.63[c] (1.36-1.95)	1.91[c] (1.60-2.28)	1.66[c] (1.39-1.98)
Symptoms of anxiety	2.95[c] (2.37-3.66)	2.85[c] (2.22-3.66)	2.55[c] (2.11-3.10)	1.80[c] (1.51-2.14)	1.67[c] (1.40-1.99)	2.09[c] (1.75-2.50)	1.82[c] (1.52-2.17)
County-level COVID-19 case rate per 10 people	2.70[d] (1.49-4.88)	1.81[e] (1.02-3.19)	2.60[c] (1.55-4.34)	1.49 (0.95-2.36)	1.65[e] (1.07-2.56)	2.04[e] (1.26-3.30)	1.77[e] (1.09-2.89)
Survey time point	1.20[c] (1.11-1.30)	1.20[c] (1.10-1.31)	1.12[d] (1.05-1.20)	1.08[e] (1.02-1.15)	1.12[c] (1.05-1.19)	1.08[e] (1.01-1.15)	1.08[e] (1.02-1.14)

[a]Models adjusted for the following covariates: age, sex, race/ethnicity, marital status, employment status, income level, education level, and fixed state effects.

[b]OR: odds ratio.

[d]*P*<.0037 (Šidák-corrected *P* value).

[e]*P*<.05.

Lastly, models assessing the interaction of county-level COVID-19 case rate and symptoms indicative of anxiety or depression did not yield significant findings (analyses available on request). For this reason, interaction terms were not subject to further analyses.

Discussion

To our knowledge, this is the first study to examine rates of use of digital mental health tools and other technologies to manage one's mental health among a sample of people during the early stages of the COVID-19 pandemic. Similar to other studies [29], rates of COVID-19 cases were associated with increased rates of depressive symptoms. Both depressive and anxiety symptoms and COVID-19 county case rates were associated with the largest increased likelihood of using digital mental health tools, specifically mental health forums, websites, and apps; phone-based/text-based crisis lines; and other health forums, websites, and apps, reflecting the greatest increase in likelihood of use for products designed specifically for health and mental health. Interestingly, we also found a general increase in the likelihood of using other technologies to support one's mental health, including gaming and work products, among those experiencing symptoms of mental illness. This increase in the use of other technologies may reflect the transition to working from home that occurred for many people.

We also sought to examine if the likelihood of using these tools and technologies was the highest among people who were both living in counties with high COVID-19 case rates *and* exhibiting symptoms indicative of clinically meaningful levels of depression or anxiety. The findings suggested, in fact, that there was no additional significant likelihood of increased use among respondents with depressive or anxious symptoms living in counties with high COVID-19 case rates compared to individuals with similar symptom levels in counties with low COVID-19 rates. Of course, it is likely that other factors, such as the impacts of policy measures aimed at mitigating risks (eg, physical distancing, working from home, or school closures) may have had a greater impact on mental health symptoms, resulting in people turning to digital tools for mental health support. In the absence of in-person connections or services, digital tools appear to play an important role in combatting the mental health impact of the pandemic.

We also found that the odds of having used these technologies generally increased over time. This increase in use of digital mental health tools and other technologies may be due, in part, to increased access to some of these technologies. For example, cities like New York City [30] have made technologies freely available to their residents and/or shared recommendations for particular products that have been vetted. Additionally, health insurance companies, such as Kaiser Permanente and others, have also made mental health products freely available for their enrollees [31]. It might also be due to the fact that people are spending more time interacting with technologies and these may be convenient ways to receive mental health support.

Our findings that people are increasingly using various technologies—both those specifically designed for mental health support as well as those that are not—are consistent with studies that explore the various ways people use technology to self-manage their mental health [32-34]. These findings also support recent calls for understanding how the technology

ecosystem might impact mental health and lead to opportunities for prevention and intervention tools [35]. Some efforts, such as Google's integration of mental health screening into their search engine, have been launched [36]. In light of our findings, it appears as though there is consumer interest for such resources. Furthermore, an important consideration for future work is to ensure that consumers find effective and safe resources, and have the proper support for using such resources appropriately.

Indeed, despite this increased use and interest, evidence-based and safe resources are rarely available for consumers. One study has suggested that only 2.08% of publicly available psychosocial wellness and stress management mobile apps have published, peer-reviewed evidence of feasibility and/or efficacy [37]. Furthermore, few products provide sufficient information to gauge their safety and privacy [38], and even among those that do, many share information with third parties in ways that might not be disclosed in those policies [39]. Although various efforts have been launched that either evaluate or offer evaluative frameworks for mental health apps (including One Mind PsyberGuide [40], ORCHA [41], and the American Psychiatric Association app evaluation framework [42]), no widely accepted or coordinated effort at regulation and evaluation exists in the United States, despite multiple calls for such models (see National Institutes of Health, National Advisory Work Group [43]). Indeed, better regulation and better access to information at point-of-access could be a significant improvement in helping guide consumers [44], who are demonstrating a clear interest in such resources, and might serve an important need in light of the COVID-19 pandemic.

Several study limitations should be noted. First, this survey was completed by MTurk workers who regularly use the computer, and therefore have the necessary technology, mobility, and digital literacy to participate [45]. This might contribute to the rates of technology use reported and the ability to use technologies—both those designed for mental health and otherwise—to support their mental health. Additionally, it is likely that people with the lowest socioeconomic status, those that are the most isolated, and those with limited access to technology were omitted from the study. These individuals may represent those most affected by COVID-19 and thus may have the greatest mental health needs [46]. Second, the survey was only available in English, and thus the findings may not hold among groups with limited English proficiency who also might be less likely to use these technologies, especially because many are not designed for diverse populations [47]. Third, this study only included people living in the United States, and thus, findings cannot be generalized to other countries [1]. Fourth, there exist a number of scales pertaining to examining the self-reported impact of COVID-19 on mental health [48-51]. These works were primarily published during the development and implementation of this survey, and as such, they were not included in this study. Fifth, there exists the possibility that at least some of the survey responses were bot-generated. To test for the potential influence of bots, we executed post hoc diagnostics previously suggested by Chmielewski and Kucker [52]. Removing those responses suspected to be bot-generated did not substantially change the findings. Thus, we reported on those findings generated from the full analytic sample. However, we also have included the results garnered after removing tagged responses (Multimedia Appendix 4).

Finally, this study focused on examining the extent to which people used mobile health technologies throughout the early period of the pandemic. The findings do not shed light on the effectiveness of these particular strategies for managing mental health. For many, engagement in digital mental health tool and other technology use has been critical for enhancing social connectedness, managing stress and anxiety, and providing greatly needed entertainment [53]. Although the vast majority of the increase in digital technology use is adaptive, it is important to note that there are likely negative impacts of this growth, including the spread of false information [54-56]. Furthermore, there exist subgroups of vulnerable individuals that are at risk of developing problematic usage patterns [53]. Excessive engagement in specific online activities such as video gaming, social media use, and shopping has been linked with severe problems and can elevate the risk of disordered or addictive use [57,58].

In conclusion, this study provides an important description of the prevalence of symptoms of anxiety and depression and digital mental health tool and other technology use during the early stages of the COVID-19 pandemic. Specifically, we found evidence of an increased likelihood of experiencing depressive symptoms both when considering differences between county COVID-19 case rates and changes over time. Furthermore, COVID-19 case rate and time were generally associated with an increased likelihood of using digital mental health tools and other technologies. Lastly, those experiencing symptoms of depression or anxiety were more likely than those without such symptoms to use tools and technologies to manage their mental health.

As the pandemic is expected to continue well into the spring and summer of 2021, and as depression [59,60], anxiety [7,61], and suicidal ideation rates continue to climb [1,8,62], the importance of providing easy access to tools and technologies to manage one's mental health will become even more important. The current shortage of mental health professionals demands the need to explore more scalable solutions that might be able to be adapted and deployed to meet the needs of various populations. The findings from this study—as well as future research that may address more specific issues designed to understand how digital mental health tools and other technologies can be more accessible and effective for the populations who need them—could inform public health efforts.

Abstract

Background: The number of deaths from COVID-19 continues to surge worldwide. In particular, if a patient's condition is sufficiently severe to require invasive ventilation, it is more likely to lead to death than to recovery.

Objective: The goal of our study was to analyze the factors related to COVID-19 severity in patients and to develop an artificial intelligence (AI) model to predict the severity of COVID-19 at an early stage.

Methods: We developed an AI model that predicts severity based on data from 5601 COVID-19 patients from all national and regional hospitals across South Korea as of April 2020. The clinical severity of COVID-19 was divided into two categories: low and high severity. The condition of patients in the low-severity group corresponded to no limit of activity, oxygen support with nasal prong or facial mask, and noninvasive ventilation. The condition of patients in the high-severity group corresponded to invasive ventilation, multi-organ failure with extracorporeal membrane oxygenation required, and death. For the AI model input, we used 37 variables from the medical records, including basic patient information, a physical index, initial examination findings, clinical findings, comorbid diseases, and general blood test results at an early stage. Feature importance analysis was performed with AdaBoost, random forest, and eXtreme Gradient Boosting (XGBoost); the AI model for predicting COVID-19 severity among patients was developed with a 5-layer deep neural network (DNN) with the 20 most important features, which were selected based on ranked feature importance analysis of 37 features from the comprehensive data set. The selection procedure was performed using sensitivity, specificity, accuracy, balanced accuracy, and area under the curve (AUC).

Results: We found that age was the most important factor for predicting disease severity, followed by lymphocyte level, platelet count, and shortness of breath or dyspnea. Our proposed 5-layer DNN with the 20 most important features provided high sensitivity (90.2%), specificity (90.4%), accuracy (90.4%), balanced accuracy (90.3%), and AUC (0.96).

Conclusions: Our proposed AI model with the selected features was able to predict the severity of COVID-19 accurately. We also made a web application so that anyone can access the model. We believe that sharing the AI model with the public will be helpful in validating and improving its performance.

KEYWORDS

COVID-19; artificial intelligence; blood samples; mortality prediction

Introduction

The COVID-19 pandemic has had a major impact on health care systems globally. Since early 2020, COVID-19 has spread rapidly around the world, exceeding 100 million cases and 2 million deaths [1]. In the COVID-19 pandemic situation, the most important issue in the management of COVID-19 patients is to triage patients at high risk of mortality and provide tailored treatment, so that medical costs and mortality rates can be reduced.

Several models have been proposed to predict the severity or mortality of COVID-19 patients using artificial intelligence (AI) techniques. The majority of them have been developed based on limited information or variables, such as medical images [2-7], blood and/or urine information [8,9], clinical characteristics [10-12], individual-level epidemiological data sets [13], and electronic health records (ie, demographics, laboratory results, medical history, and vital signs) during hospitalization [14]. However, most of them were developed based on relatively small samples from limited data sources, which makes their generalization problematic. More specifically, the numbers of patients used for training of some models were 375 [15], 443 [16], 548 [17], and 663 [18].

To overcome the generalization issue, we aimed to develop an AI prediction model based on confirmed nationwide patient data obtained from the South Korean government, which included 5601 patients from more than 100 hospitals. In this model, we used comprehensive data sets composed of 37 factors, including basic demographic information, vital signs, physical examination results, clinical symptoms and severity, comorbid diseases, and general blood test results. To the best of our knowledge, this is the first attempt to develop an AI model to predict the severity of COVID-19 based on a nationwide cohort and comprehensive data set in South Korea.

Methods

Data Sets

This study was approved by the Korea Disease Control and Prevention Agency (KDCA) in South Korea. Informed consent was waived. The KDCA has been managing comprehensive data from COVID-19–confirmed patients in Korea obtained from approximately 100 hospitals. The KDCA discloses this data to few selected researchers during a specific study period. Thus, we investigated this data between September 15 and October 5, 2020, under the approval of the KDCA.

Table 1 describes the KDCA data set. The basic patient information includes the patient's ID, age, gender, outcome, quarantine period, pregnancy status, and pregnancy week. The physical index includes body mass index. The initial examination findings include systolic and diastolic blood pressure, heart rate average, and body temperature at the hospital admission stage. The clinical findings include the status of fever, cough, sputum production, sore throat, rhinorrhea, myalgia, malaise, dyspnea, headache, confusion, nausea, and diarrhea. The current or previous comorbid diseases include diabetes mellitus, hypertension, heart failure, chronic heart disease, chronic obstructive pulmonary disease, chronic kidney disease, cancer, chronic liver disease, rheumatism or autoimmune disease, and dementia. The clinical severity has two categories: low and high severity. The conditions of patients in the low-severity group correspond to no limit of activity, oxygen support with nasal prong or facial mask, and noninvasive ventilation. The conditions of patients in the high-severity group correspond to invasive ventilation, multi-organ failure with extracorporeal membrane oxygenation required, and death. The general blood test results include levels of hemoglobin, hematocrit, lymphocytes, platelets, and white blood cells.

Out of 5628 COVID-19 patient records, the clinical severity information was missing in 27 patient records, so we excluded them from our study. Thus, we used 5601 patient data records to develop the AI prediction model for clinical severity. For each patient data record, we used 37 variables as model inputs; these variables are summarized in Table 1 without ID, outcome, quarantine period, and clinical severity. As the model output, we used clinical severity, which is a binary component composed of low and high severity.

Table 2 summarizes the clinical features from the high-severity group (271/5601, 4.8%) and the low-severity group (5330/5601, 95.2%). Notably, in the high-severity group, 241 out of 271 patients were deceased (88.9%), while no patients died in the low-severity group.

Table 1. Description of COVID-19 patient data.

Item category and data	Type	Description
Basic patient information		
ID	Number	Anonymous
Age (years)	9 categories	0-9 (0), 10-19 (1), 20-29 (2), 30-39 (3), 40-49 (4), 50-59 (5), 60-69 (6), 70-79 (7), ≥80 (8)
Gender	2 categories	Male (0), female (1)
Outcome	2 categories	Survived (0), deceased (1)
Quarantine period	Continuous	Days (0 if confirmed after death)
Pregnancy	2 categories	No (0), yes (1)
Pregnancy week	Number	Weeks (0 if not pregnant)
Physical index: BMI (kg/m^2)	5 categories	<18.5 (0), 18.5-22.9 (1), 23.0-24.9 (2), 25.0-29.9 (3), ≥30 (4)
Initial examination findings		
Systolic blood pressure	5 categories	<120 (0), 120-129 (1), 130-139 (2), 140-159 (3), ≥160 (4)
Diastolic blood pressure	4 categories	<80 (0), 80-89 (1), 90-99 (2), ≥100 (3)
Heart rate	Number	Heart rate
Temperature	Number	Temperature
Clinical findings		
Fever	2 categories	No (0), yes if higher than 37.5 °C (1)
Cough	2 categories	No (0), yes (1)
Sputum production	2 categories	No (0), yes (1)
Sore throat	2 categories	No (0), yes (1)
Runny nose or rhinorrhea	2 categories	No (0), yes (1)
Muscle aches or myalgia	2 categories	No (0), yes (1)
Fatigue or malaise	2 categories	No (0), yes (1)
Shortness of breath or dyspnea	2 categories	No (0), yes (1)
Headache	2 categories	No (0), yes (1)
Altered consciousness or confusion	2 categories	No (0), yes (1)
Vomiting or nausea	2 categories	No (0), yes (1)
Diarrhea	2 categories	No (0), yes (1)
Current or previous comorbid diseases		
Diabetes mellitus	2 categories	No (0), yes (1)
Hypertension	2 categories	No (0), yes (1)
Heart failure	2 categories	No (0), yes (1)
Chronic cardiac disease	2 categories	No (0), yes (1)
Asthma	2 categories	No (0), yes (1)
Chronic obstructive pulmonary disease	2 categories	No (0), yes (1)
Chronic kidney disease	2 categories	No (0), yes (1)
Cancer	2 categories	No (0), yes (1)
Chronic liver disease	2 categories	No (0), yes (1)
Rheumatism or autoimmune diseases	2 categories	No (0), yes (1)
Dementia	2 categories	No (0), yes (1)

Item category and data	Type	Description
Clinical severity	2 categories	Low severity, including no limit of activity, oxygen support required with nasal prong or facial mask, and noninvasive ventilation (0); high severity, including invasive ventilation, multi-organ failure, extracorporeal membrane oxygenation, and death (1)
General blood test results		
Hemoglobin	Number	g/dL
Hematocrit	Number	%
Lymphocytes	Number	%
Platelets	Number	10^9/L
White blood cells	Number	10^9/L

Table 2. Statistical summary of clinical features from the low-severity group and high-severity group (N=5601).

Participant data	Low-severity group (n=5330)	High-severity group (n=271)	*P* value
Basic patient information

[a]Age categories were as follows (years): 0-9 (0), 10-19 (1), 20-29 (2), 30-39 (3), 40-49 (4), 50-59 (5), 60-69 (6), 70-79 (7), ≥80 (8).

[b]N/A: not applicable; there were no pregnant participants in the high-severity group.

[c]BMI categories were as follows (kg/m^2): <18.5 (0), 18.5-22.9 (1), 23.0-24.9 (2), 25.0-29.9 (3), ≥30 (4).

[d]Systolic blood pressure categories were as follows (mm Hg): <120 (0), 120-129 (1), 130-139 (2), 140-159 (3), ≥160 (4).

[e]Diastolic blood pressure categories were as follows (mm Hg): <80 (0), 80-89 (1), 90-99 (2), ≥100 (3).

Imputation and Standardization

In the data set, some features were missing (Table S1 in Multimedia Appendix 1). To handle the missing data, we calculated the mean value from the training data set for each feature and replaced the missing data with the mean value in both the training and testing data sets. We then performed standardization of the data set, which is a common requirement for machine learning algorithms. The standardization changes the data distribution of each feature with a mean of zero and standard deviation of one:

where *mean*(*train*) and *SD*(*train*) are the mean and standard deviation values, respectively, for each feature from the training data set. We applied the standardization to both the training and testing data sets.

Data Split

For the feature importance analysis and the AI prediction model development, we performed a grid search with a 5-fold cross-validation and 10-time repetition. For that, we divided the 5601 records into training (4480/5601, 80.0%) and testing (1121/5601, 20.0%) data sets in a stratified fashion (Table 3). We used 4480 records as the training data set (4260/4480, 95.1% low severity and 220/4480, 4.9% high severity) and 1121 records as the testing data set (1070/1121, 95.5% low severity and 51/1121, 4.5% high severity). The testing data set was isolated and used only for evaluating the performance of the proposed model.

The training data set (n=4480) was randomly shuffled and partitioned into 5 equal folds in a stratified manner: each fold included 433 low-severity records and 15 high-severity records. Of the 5 folds, a single fold was retained as the validation data set for testing the model, and the remaining 4 folds were used as the training data. We repeated the process 10 times, with each of the 10 folds used exactly once as the validation data. Here, since the number of low-severity records was much higher than the number of high-severity records, we up-sampled the high-severity data by randomly copying the data to prevent the model's bias toward the low-severity data by balancing the amount of data in the two groups.

Table 3. Summary of training and testing data sets.

Data set	Records, n (%)	
	Low-severity group	High-severity group
Training (n=4480)	4260 (95.1)	220 (4.9)
Testing (n=1121)	1070 (95.5)	51 (4.5)
Total (N=5601)	5330 (95.2)	271 (4.8)

Feature Selection

In order to select important features that influence clinical severity, we first investigated the contribution of each of the 37 input variables on severity via feature importance analysis using AdaBoost [19,20], random forest [21], and eXtreme Gradient Boosting (XGBoost) [22] algorithms. After analyzing the feature importance values from each classifier algorithm, we normalized and averaged the values to calculate the combination feature importance values.

By repeating the 5-fold cross-validation 10 times, we found the best hyperparameters. For AdaBoost, we set the hyperparameters as follows: the number of tree estimators was set to 50 and the learning rate was set to 0.4. For random forest, we set the number of tree estimators to 100, the maximum depth to 4, and the maximum features to 5. For XGBoost, we set the maximum depth to 2, the learning rate to 0.2, the number of tree estimators to 100, the value of the regularization parameter α to 1.0, the fraction of observations to 0.9, and the fraction of columns to 0.9.

The 10-time repeated 5-fold cross-validation provided 50 sets of feature importance values for each classifier (ie, AdaBoost, random forest, and XGBoost). We then averaged the 50 sets of importance values and normalized them so that the importance values from each classifier were in the range from 0 to 1. Finally, we averaged the importance values for the final ranked feature importance value. Moreover, we determined the optimal number of top features to incorporate into the AI prediction model based on the cross-validation results.

AI Prediction Model Development

To develop the final AI model for severity prediction, we used a deep neural network (DNN). In the DNN approach, we investigated up to 5 hidden layers and each layer depth (ie, node) up to the previous layer depth (ie, node). For the input layer, we first ranked the features according to their importance and increased the number of top features used in the input layer from 1 to 37. For the fully connected (FC) layers as hidden layers, we applied dropouts by changing the dropout rate from 0 to 0.5 with 0.1 increments. The last FC layer was fed into a sigmoid layer, which is an output layer providing the probabilities for the patient severity. We trained the models with the Adam optimizer and binary cross-entropy cost function with a learning rate of 0.0001 and batch size of 64. We implemented the models using R, version 4.0.2 (The R Foundation), with TensorFlow, version 1.13.1, for DNN; scikit-learn, version 0.22.1, for machine learning algorithms; and xgboost, version 0.6.4, for the XGBoost algorithm.

For each set of top features, we found the best cross-validation accuracy using the metrics of area under the curve (AUC) and balanced accuracy:

Given the cross-validation accuracy analysis, we finally modeled with the 5-layer DNN using the top 20 features. The 5-layer DNN comprised an input layer, 3 FC layers as hidden layers, and an output layer. The input layer was fed into a series of 3 FC layers consisting of 20, 16, and 8 nodes, respectively. In the first 2 FC layers, we used a dropout rate of 0.5. Then, the last FC layer was fed into a sigmoid layer.

Performance Evaluation

We evaluated the prediction performance of our proposed 5-layer DNN model with the isolated testing data set (n=1121). To compare the prediction performance of the DNN model with those of other external AI models, we separately trained the following models: logistic regression, decision tree, random forest, support vector machine, XGBoost, AdaBoost, GradBoost, and HistBoost. We evaluated the prediction performance of these AI models as single models as well as ensemble models.

Results

Feature Selection

Figure 1 shows the results of the ranked feature importance analysis from AdaBoost, random forest, XGBoost, and their combination. Results from AdaBoost indicate that platelet count had the highest importance value, followed by lymphocyte level, age, and body mass index (Figure 1, a). Results from random forest indicate that age had the highest importance value, followed by lymphocyte level, shortness of breath or dyspnea, and platelet count (Figure 1, b). Results from XGBoost indicate that platelet count had the highest importance value, followed by age, lymphocyte level, and temperature (Figure 1, c). By averaging the values obtained from the three models, age had the highest importance value, followed by lymphocyte level, platelet count, and shortness of breath or dyspnea (Figure 1, d). On the other hand, cancer, fatigue or malaise, chronic obstructive pulmonary disease, sputum production, chronic cardiac disease, heart failure, asthma, rheumatism or autoimmune diseases, pregnancy, and pregnancy week rarely contributed to the predictive model. The normalized feature importance values from AdaBoost, random forest, and XGBoost, as well as the combined ranked feature importance values with those averages, are summarized in Table S2 in Multimedia Appendix 1.

We investigated the cross-validation performance with the metrics of AUC and balanced accuracy (Figure 2). The results show that both AUC and balanced accuracy reached the highest values when the top 20 features from the combination of AdaBoost, random forest, and XGBoost were used for the input layer. Therefore, we incorporated the top 20 features into the AI prediction model, which yielded a sensitivity of 88%, specificity of 90%, accuracy of 90%, balanced accuracy of 89%, and AUC of 0.96 (Table 4).

Figure 1. Results of normalized feature importance analysis from (a) AdaBoost, (b) random forest, and (c) eXtreme Gradient Boosting (XGBoost) as well as (d) the combined average ranked feature importance. ACC: altered consciousness/confusion; BMI: body mass index; CCD: chronic cardiac disease; CKD: chronic kidney disease; CLD: chronic liver disease; COPD: chronic obstructive pulmonary disease; DBP: diastolic blood pressure; DEMEN: dementia; DIARR: diarrhea; DM: diabetes mellitus; FM: fatigue/malaise; HCT: hematocrit; HEADA: headache; HF: heart failure; HGB: hemoglobin; HR: heart rate; HTN: hypertension; LYMPHO: lymphocyte; MAM: muscle aches/myalgia; PLT: platelets; Preg: pregnancy; PregWk: pregnancy weeks; RDAD: rheumatism/autoimmune disease; RNR: runny nose/rhinorrhea; SBP: systolic blood pressure; SOB: shortness of breath/dyspnea; SPUTUM: sputum production; ST: sore throat; Temp: temperature; VN: vomiting/nausea; WBC: white blood cells.

Table 4. Cross-validation results.

Model	Cross-validation measures (n=448), mean (SD)				
	Sensitivity	Specificity	Accuracy	Balanced accuracy	Area under the curve
5-layer deep neural network	0.88 (0.06)	0.90 (0.02)	0.90 (0.02)	0.89 (0.04)	0.96 (0.01)

Performance of the AI Prediction Model

With the isolated testing data set (n=1121), our proposed 5-layer DNN showed a sensitivity of 90.20%, specificity of 90.37%, accuracy of 90.37%, balanced accuracy of 90.28%, and AUC of 0.96. Table 5 shows the prediction performances on the testing data set. First, we compared the accuracy metrics when the synthetic minority oversampling technique was applied, and we found that both balanced accuracy and AUC were slightly lower. Second, we compared the accuracy metrics when principal component analysis (PCA)–based feature reduction was applied with eight dimensions, and we found that both balanced accuracy and AUC were also slightly lower. Table 5 [19-28] also shows the prediction performances of various AI models; it can be seen that our proposed 5-layer DNN method provided higher accuracy, balanced accuracy, and AUC values than the other external AI models (ie, logistic regression, decision tree, random forest, support vector machine, XGBoost, AdaBoost, GradBoost, and HistBoost).

Furthermore, we investigated the prediction performance of ensemble AI models (ie, combination of AI models); none of the ensemble AI models outperformed our proposed 5-layer DNN model (Table 6).

Discussion

Principal Findings

Our proposed AI model, the 5-layer DNN using the selected top 20 features, was able to predict the severity of COVID-19 patients at the hospital admission stage with excellent prediction performance: 90.2% sensitivity, 90.4% specificity, and 90.4% accuracy. The model has several unique characteristics. First, it was developed based on nationwide confirmed COVID-19 patient data obtained from the KDCA. In South Korea, all confirmed cases must be reported to the KDCA; thus, the KDCA data are very accurate and updated on a daily basis [4]. The Korean government designated more than 100 general hospitals, including 20 tertiary hospitals, as specialized infection control hospitals equipped with isolation and negative pressure rooms. These designated hospitals should report important clinical information about COVID-19 patients to the KDCA, especially for patients who are admitted to hospitals or show severe conditions. When we were allowed to access the KDCA data sets in September 2020, there were data from 5601 patients with comprehensive clinical information that we could use to develop an AI prediction model. This is the largest cohort with a sufficient amount of data to develop reliable and generalizable AI prediction models.

Second, our AI prediction model development started with feature importance analysis of the 37 features in the comprehensive data set. Of these, 20 were selected based on ranked feature importance analysis results in order to develop an accurate AI prediction model. The cross-validation demonstrated that the AI prediction model showed higher accuracy using the selected 20 features compared to using all 37 features. In addition, the selected 20 features (ie, age, lymphocyte level, platelet count, shortness of breath or dyspnea, temperature, hemoglobin level, white blood cell count, body mass index, hematocrit level, heart rate, systolic blood pressure, dementia, hypertension, altered consciousness or confusion, diabetes, gender, cough, sore throat, chronic liver disease, and runny nose or rhinorrhea) can be easily acquired from patient history, basic physical examinations, and routine laboratory tests. Thus, our AI prediction model can be easily incorporated into routine clinical practice. Furthermore, we observed that PCA-based feature selection also provided as good of a performance as did the feature importance analysis. In particular, we expect that many researchers will be able to flexibly diversify the model for predicting the severity of COVID-19 patients, in that a similar level of accuracy could be obtained with only eight features.

In terms of our feature selection process, we combined AdaBoost, random forest, and XGBoost machine learning algorithms to rank the important features. The AdaBoost algorithm is part of the family of boosting algorithms and sequentially growing decision trees as weak learners [19]. It is

well known that it rarely overfits in low-noise data sets [20]. The random forest algorithm is based on a bagging approach, which is based on the aggregation of a set of weak learners [21]. XGBoost is a recently introduced algorithm with optimized gradient boosting [22]. In low-dimensional or highly separable data, all of the classifiers generally provide reasonably good performance. However, they may provide different performances depending on various factors, such as feature dimension, data separability, data balancing, and feature correlation. That is the reason we have combined the three algorithm results.

We named our proposed AI prediction model KOVIDnet, indicating the deep learning algorithm for Korean COVID-19 patients. Owing to its high accuracy and generalizability in Korea, we expect that KOVIDnet will be able to provide treatment priority guidance at the time of admission regarding who should be treated intensively. Although most patients with COVID-19 showed mild and self-limiting illness, some patients became severely and critically ill, showing the rapid progression to acute respiratory failure, sepsis, septic shock, multi-organ failure, and eventual death [29-32]. The mortality rate of severe cases is about 20 times higher than that of mild cases [30,33]. This indicates that early identification of patients at risk of mortality is important for the management of COVID-19 patients.

Limitations and Future Work

In our earlier study, we grouped the patients into eight subgroups. Subgroup 1 patients had no limits to their activity. Subgroup 2 patients had limits to their activity, but did not need oxygen. Subgroup 3 patients needed oxygen with a nasal prong. Subgroup 4 patients needed oxygen with a facial mask. Subgroup 5 patients needed noninvasive ventilation. Subgroup 6 patients needed invasive ventilation. Subgroup 7 patients had multi-organ failure or underwent extracorporeal membrane oxygenation. Subgroup 8 patients died. For the multiclass classification, we also trained the model through the same procedure as mentioned above, but the accuracy when using the testing data was not satisfactory (Table S3 in Multimedia Appendix 1). It may be because there was no distinct difference in features according to each subgroup or because the number of training data values was insufficient. In addition, the data were extremely imbalanced: the imbalance ratio was 405 (Table S4 in Multimedia Appendix 1). After analyzing the results from the eight-subgroup multiclass classification problem, we considered the binary classification problem, where the low-severity group included subgroups 1 to 4 and the high-severity group included subgroups 5 to 8. Not only was the binary classification problem the most realistic in training the predictive model based on our current data, but it was also useful to convey clinically important implications. We believe that we can extend our model to the multiclass classification problem based on more extensive data.

Our study also has additional limitations. First, our proposed AI prediction model was validated with an isolated test data set (n=1121), which was a data set that was split from the entire data set. It may be necessary to validate our AI model with external data sets, such as prospectively collected data. To validate and update KOVIDnet, we made a web application [34] so that anyone can access the model. We believe that sharing the AI model with the public will be helpful in validating and improving its performance. Second, our data did not include patients of other races, such as Caucasian or Middle East Asian. In the near future, we have a plan to apply our AI model to various data sets, including data from patients of other races. To realize this goal, we will establish a real-time training framework that can train our model using prospectively collected data from all over the world. We believe that we can improve KOVIDnet for better generalization based on the extended data.

Conclusions

In conclusion, we developed our AI model with 20 selected features based on a large nationwide data set, and it was able to predict the severity of COVID-19 accurately. We believe that our model can help health care providers to effectively treat COVID-19 patients at an early stage and ultimately reduce deaths.

Acknowledgments

We acknowledge all the health care workers involved in the diagnosis and treatment of COVID-19 patients in South Korea. We also thank the KDCA, the National Medical Center, and the health information managers at the hospitals for their efforts in collecting the medical records. This study was supported by the Basic Science Research Program through the National Research Foundation of Korea (NRF), funded by the Ministry of Science, ICT, and Future Planning (grants 202012B04 and NRF-2020R1A2C1014829), and by the Korea Health Industry Development Institute (grant HI18C1216).

Authors' Contributions

HC and HK carried out the machine learning and deep learning simulation for hyperparameter search and modeling. CP performed data validation to be applied to COVID-19 patients. KWK, H-OS, T-YC, and JHS validated and confirmed the simulations and helped to draft the manuscript. HL developed and maintained the web application. JL and WSK conceived of the study, participated in the study’s design and coordination, and wrote the initial manuscript. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: During the COVID-19 pandemic, health professionals have been directly confronted with the suffering of patients and their families. By making them main actors in the management of this health crisis, they have been exposed to various psychosocial risks (stress, trauma, fatigue, etc). Paradoxically, stress-related symptoms are often underreported in this vulnerable population but are potentially detectable through passive monitoring of changes in speech behavior.

Objective: This study aims to investigate the use of rapid and remote measures of stress levels in health professionals working during the COVID-19 outbreak. This was done through the analysis of participants' speech behavior during a short phone call conversation and, in particular, via positive, negative, and neutral storytelling tasks.

Methods: Speech samples from 89 health care professionals were collected over the phone during positive, negative, and neutral storytelling tasks; various voice features were extracted and compared with classical stress measures via standard questionnaires. Additionally, a regression analysis was performed.

Results: Certain speech characteristics correlated with stress levels in both genders; mainly, spectral (ie, formant) features, such as the mel-frequency cepstral coefficient, and prosodic characteristics, such as the fundamental frequency, appeared to be sensitive to stress. Overall, for both male and female participants, using vocal features from the positive tasks for regression yielded the most accurate prediction results of stress scores (mean absolute error 5.31).

Conclusions: Automatic speech analysis could help with early detection of subtle signs of stress in vulnerable populations over the phone. By combining the use of this technology with timely intervention strategies, it could contribute to the prevention of burnout and the development of comorbidities, such as depression or anxiety.

Introduction

In December 2019 in the Chinese city of Wuhan, a new coronavirus pneumonia, COVID-19, emerged. The pathogen involved is SARS-CoV-2. Here, we will refer to the pathology as COVID-19. COVID-19 has spread very rapidly in China but also in many other countries [1]. On March 11, 2020, the World Health Organization declared that the COVID-19 outbreak had become a pandemic [2].

According to previous studies on SARS or Ebola epidemics, the onset of a sudden and immediately fatal disease could put extraordinary pressure on health care professionals [3]. Increased workloads, physical exhaustion, inadequate personal equipment, nosocomial transmission, and the need to make ethically difficult decisions about rationing care can have dramatic effects on their physical and mental well-being. Their resilience may be further compromised by isolation and loss of social support, risk or loss of friends and relatives, and radical, often worrying changes in working methods. Health care workers are, therefore, particularly vulnerable to mental health problems, including fear, anxiety, depression, and insomnia [4,5]. Initial results estimate that 23% and 22% of health care workers experienced depression and anxiety, respectively, during the COVID-19 pandemic [6].

Paradoxically, health care workers do not tend to seek professional help, and stress-related symptoms are often not immediately reported: “burnout, stress, and anxiety will have to wait.” Most of the time there will not even be a demand for care. Early implicit stress detection is of great importance in this population and would allow for timely intervention strategies in order to prevent escalation and complete occupational burnout.

To measure stress in clinical practice, various scales and questionnaires are available, such as the Perceived Stress Scale (PSS) [7], the Stressful Life Event Questionnaire [8], the Stress Overload Scale [9], and the Trier Inventory for Chronic Stress [10]. However, the present health crisis pushed research teams to investigate the use of new technological tools in this specific population. One possible avenue is the use of automatic speech analysis allowing extraction of voice features during standard consultation or over a simple phone call.

Psychological stress induces multiple effects on the body, including increased muscle tension, increased breathing rate, and changes in salivation rate, which may, in turn, affect vocal production [11,12]. Under psychological stress, voice pitch (ie, the acoustic correlate of fundamental frequency [F0]) usually increases, as it is inversely related to the rate of vocal fold vibration, which stretches under stress and becomes tenser together with an increase in subglottal pressure and vocal intensity [13,14]. Indeed, an increase in voice pitch is the most commonly reported finding in studies examining speech under stress. However, stress can also affect other voice parameters, such as an increase in speech prosody [11,13]. In depression, the analysis of speech characteristics has recently attracted considerable research attention [15-17]. Studies revealed that patients show flattened affect, reduced speech variability, monotonicity in pitch and loudness, increased pause duration, and reduced speech rate [18-20]. A recent study investigated the use of speech parameters extracted from audio recordings to differentiate patients suffering from posttraumatic stress disorder from healthy controls [21].

Thus, the detection of subtle events in the voice may offer a window into assessing the impact of stress in situations where circumstances make it difficult to monitor stress directly but need to be addressed urgently [22].

In this work, we aim to investigate the use of a rapid and remote measure of stress levels in health professionals working during the COVID-19 outbreak, utilizing the automatic analysis of their speech behavior during a short phone call conversation.

Firstly, speech samples of health care professionals were collected over the phone during the COVID-19 pandemic, and various voice features were extracted and compared with classical stress measures. Secondly, based on the extracted features, scores from the completed stress scale that were obtained by participants were predicted. The purpose of this pilot study was to assess whether this technological method could be of interest to support early screening of subtle signs of stress.

Methods

Participants

Health care professionals were recruited through outreach telephone calls. They worked during the COVID-19 outbreak in the local university hospital center of Nice, France, in either private practices or as independent workers in the Provence-Alpes-Côte d’Azur region. They could occupy any function in these structures. The only criterion for noninclusion was the subjects’ refusal to participate in the study. Inclusion of participants was carried out from May 5 to June 7, 2020.

The study was approved by the Ethical Board for noninterventional studies of the University Côte d’Azur, France (approval 2020-58). Participants were given all the information about the study prior to the call so they could give informed consent. For those interested, the option for a follow-up call with a clinician was provided.

Procedure

The telephone calls were made by psychiatrists (n=3) or psychologists (n=1) belonging to the Cognition Behavior Technology research team and the memory clinic of the University Côte d’Azur. Calls lasted about 15 minutes and were composed of the following:

1. An informative part explaining the reasons for the call and its structure and how the study is conducted. The participant’s consent was requested to continue and to proceed with a recording of his or her voice.
2. The Motivation Stress Affect (MSA) questionnaire. The MSA questionnaire is a self-administered questionnaire composed of 11 questions that must be answered by “yes” or “no.” The first five questions assess motivation [23], the next two questions assess depression, and the last four questions assess stress [24].

3. Three open standardized questions: neutral, positive, and negative storytelling. In order to capture natural speech, but within a limited time frame, the participant was asked to talk about something emotionally neutral (ie, describe where he or she is), to talk about a negative event in his or her life, and, finally, to talk about a positive event in his or her life. Each answer should have lasted about 1 minute and was recorded in a secure and encrypted way. It was not specified whether the event had to be experienced during COVID-19; thus, it was open to the participant to recall whatever event first came to mind. These free-speech tasks were used in previous studies [18,25] and allowed for a greater range of induced emotional effects, potentially sensitive to signs of stress and depression. The comparison of speech features between neutral and emotionally loaded questions may give insight into the affective state of participants.
4. The PSS. This scale [7] is a hetero-questionnaire composed of 10 questions to be answered by "never," "almost never," "sometimes," "quite often," or "often."
5. An open listening part aimed at exploring certain points in greater depth in order to refine the clinical needs.
6. Decision and advice. Following the above steps, the psychiatrist or psychologist offered or did not offer psychological follow-up depending on whether he or she considered that the patient was at risk of developing or had a mood or anxiety disorder. He or she may also have offered advice on intervention strategies (eg, relaxation, yoga, physical activity, and national call platform for psychological support for caregivers).

Materials

To perform the phone calls for this study, the phone version of the DELTA application [26] was used. The DELTA solution allows for the use of a dedicated interface in the form of an iOS app to make phone calls and locally record these calls on the internal memory of an iPad. The phone calls were made directly with the iPad and through its internal microphone.

These recordings were then automatically transmitted—the iPad had to be connected to the internet—to the DELTA application programming interface (API) for analysis of acoustic and semantic parameters. Once the analysis was complete, the results were displayed directly on the DELTA interface. The recordings were made locally on the phone, the connection between the interface and the DELTA API was secure and encrypted, and the recordings were destroyed from the DELTA servers once the analysis was complete and the results sent to the experimenter.

Analysis

Audio features were extracted directly and automatically from the recorded audio signals of the three open standardized questions (see item #3 in the Procedure section). Characteristics were extracted from four main areas:

1. Prosodic characteristics, on long-term variations in perceived stress and speech rhythm. Prosodic features also measure alterations in personal speech style (eg, perceived pitch and speech intonation).
2. Formant characteristics represent the dominant components of the speech spectrum and convey information about the acoustic resonance of the vocal tract and its use. These markers are often indicative of articulatory coordination problems in motor speech control disorders.
3. Source characteristics that are related to the source of voice production, the airflow through the glottal speech production system. These features make operational irregularities in the movement of the vocal fold (eg, voice quality measurements).
4. Temporal characteristics include measures of the proportion of speech (eg, duration of pauses and duration of speech segments), speech segment connectivity, and overall speech rate.

Features were extracted using Python 3.7 (Python Software Foundation) [27] and free and publicly available packages. For the temporal features, the My-Voice Analysis [28] package was used. This package was built off of the speech analysis research tool praat [29]. Temporal features were actualized as the speech rate, syllable count, rate of articulation, speaking duration, total duration, and ratio of speaking to nonspeaking. This package was also used to extract prosodic features, namely the F0 values: mean, standard deviation, minimum, maximum, and upper and lower quartiles. The F0 value is the representation of what is known as the pitch.

Formant features were calculated using the Python Speech Features library [30]. To characterize this aspect of speech, the original sound recording was refit according to a series of transformations commonly used for speech recognition that yield a better representation of the sound called the mel-frequency cepstrum (MFC). From this new representation of the sound form, the first 14 coefficients of the MFC were extracted. The MFC values were extracted given that they describe the spectral shape of the audio file, generally with diminishing returns in terms of how informative they are, which is why we only considered the first 14 coefficients. If we were to select a greater number of MFC values, it would result in a potentially needlessly more complex machine learning model using less informative features.

From each of these waves, the mean, variance, skewness, and kurtosis were calculated for the energy (static coefficient), velocity (first differential), and acceleration (second differential).

The Librosa package [31] was used to calculate the mean, maximum, minimum, and standard deviation of the root mean square value, centroid, bandwidth, flatness, zero-crossing rate, loudness, and flux of the spectrogram, or the visualization of the recording.

The source characteristics were extracted using the Signal_Analysis package, version 0.1.26, to extract the micromovements of the sound wave: harmonics-to-noise ratio (HNR), jitter, shimmer, and glottal pulses. Jitter and shimmer are two features of vocal signals that describe the frequency variation from cycle to cycle of the sound wave and the waveform amplitude, respectively [32,33]. While jitter rises with the growing lack of control of vocal cord vibration, higher shimmer is coupled with increased breathiness. HNR is the ratio between periodic components and nonperiodic components that

constitute a voiced speech segment [34]. These components correspond to the vibration from vocal cords and glottal noise, respectively.

Speech features vary naturally between males and females due to differences in the length of the vocal tract. These differences have been leveraged in gender classification through speech analysis based on pitch and formant frequencies [35], HNR [36], linear predictive components, and mel-frequency cepstral coefficients (MFCCs) [37]. Previous work found differences in speech depending on gender in the effects of depression and the effectiveness of classifiers for its detection [38]. This is why this study considers males and females separately.

Statistical Analysis

The data collected were described using mean and standard deviation for quantitative variables, and frequency and percentage for qualitative variables. Demographic characteristics, such as age and gender, were compared between different groups of caregivers using a chi-square test for qualitative variables (eg, gender) and an analysis of variance performed for quantitative variables (eg, age). Similarly, the data measured for voice and scores were compared between different groups of caregivers. The normality of the collected data was tested using a Shapiro test. In order to test the relationship between the different voice measures and the measured scores, Spearman correlations were used. In addition, to test the link between the voice measures and the therapist's decision, Student *t* tests or Wilcoxon-Mann-Whitney tests were performed. A *P* value of less than .05 was considered significant. The analyses were performed using the free statistical software RStudio 4.0.0 [39]. Further, regression analyses were performed with the extracted vocal features to determine the error rate for predicting the participants' stress scores.

Results

Participants

In total, 89 French-speaking health professionals, aged between 20 and 74 years, accepted the outreach phone calls and their speech samples were recorded and analyzed. Their demographic characteristics are presented in Table 1.

The mean age of the participants was 40.53 years (SD 14.19). The mean stress score on the PSS was 22.43 (SD 7.16) and on the MSA questionnaire was 2.92 (SD 2.09). The majority of the participants scored below 26 on the PSS but above 0 on the MSA questionnaire. Results on the PSS and on the MSA stress scale were proportional. We found that 27% (24/89) of the recorded health professionals experienced intense stress, and 28% (25/89) experienced occasional stress. Only 16% (14/89) of the participants requested a follow-up. The stress level was gender dependent, with females reporting higher stress levels. For males, stress levels tended to drop with age. Figure 1 shows a distribution of the total stress scores across genders. The total stress scores in the female group are more dispersed than in the male group and are generally higher. A total of 14 out of 88 (16%) participants (11/57, 19% of all females; 3/31, 10% of all males) asked for a follow-up call. Their mean PSS score (mean 31.78, SD 7.40) and mean MSA scale score (mean 5.57, SD 1.34) were significantly higher than for those who did not ask for a follow-up, whose mean PSS score was 20.60 (SD 5.63) and mean MSA scale score was 2.38 (SD 1.8).

Table 1. Descriptive statistics for participant characteristics (N=89).

Characteristic	Participants, n (%)			*P* value[a]
	Total (N=89)	Male (n=31)	Female (n=58)

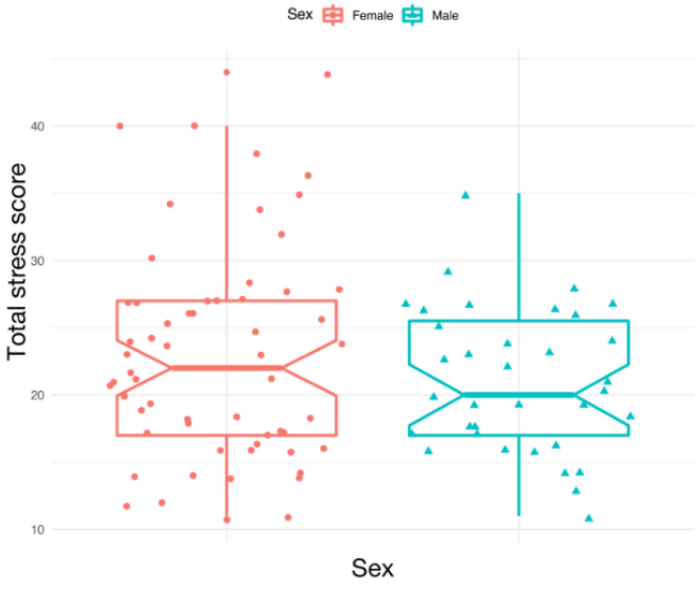
[b]N/A: not applicable; the *P* value was not calculated for gender.

Figure 1. Stress score distribution across genders.



Correlations

First, vocal and nonvocal features were analyzed in relation to the stress level. The data set was quite small and, therefore, rather than training a classifier, we performed correlation analysis between the features computed for each speech task and the reported stress level. Further, only extracted speech features were considered; a priori, nonmeaningful features, like ID, were removed.

We performed a selection of the top k features based on their descriptive power for the target variable *total stress score*. Vocal features might be gender dependent. Therefore, we performed a selection of top features for male and female data sets separately. We used Spearman correlation, since we had both ordinal and continuous features: the target *total stress score* is ordinal. Since Spearman correlation uses only the ranks of the variables and not their raw values, we could omit the normalization step. We considered absolute values of the correlation coefficient for feature scoring. Results are presented in Table 2.

The main speech parameters correlating with stress levels in both genders were spectral (ie, formant) features, namely the MFCCs. These features characterize the spectrum of speech, which is the frequency distribution of the speech signal at a specific time. MFCCs were derived by computing a spectrum of the log-magnitude mel-spectrum of the audio segment. The lower coefficients represent the vocal tract filter and the higher coefficients represent periodic vocal fold sources [18]. Moreover, in males' prosodic characteristics, such as the F0, and in females with the positive storytelling, pitch ranges were associated with stress levels.

Table 2. Correlation between stress levels and speech features.

Top 10 features for each data set	Task	Spearman correlation
Female data set		
MFCC[a]3 acceleration skewness	Positive story	0.49
MFCC2 mean	Neutral story	0.44
Pitch range	Positive story	0.44
MFCC3 acceleration skewness	Negative story	0.43
MFCC2 mean	Positive story	0.44
MFCC5 acceleration kurtosis	Negative story	–0.42
MFCC2 mean	Negative story	0.43
MFCC5 velocity kurtosis	Negative story	–0.40
MFCC3 acceleration skewness	Neutral story	0.39
MFCC5 velocity kurtosis	Negative story	0.39
Male data set		
Upper quartile F0[b]	Neutral story	–0.54
Pronunciation posteriori probability score percentage	Positive story	–0.50
Energy acceleration mean	Positive story	0.52
Mean F0	Neutral story	–0.51
MFCC9 kurtosis	Positive story	0.41
MFCC9 variance	Positive story	–0.44
Upper quartile F0	Negative story	–0.47
MFCC4 acceleration mean	Positive story	–0.40
Upper quartile F0	Positive story	–0.47
MFCC12 acceleration skewness	Neutral story	–0.42

[a]MFCC: mel-frequency cepstral coefficient; the numbers following MFCC are part of the feature names presenting their location on a spectrum.

[b]F0: fundamental frequency.

For female participants, correlation analyses between negative, positive, and neutral features and the target feature *total stress score* were performed. Among the top 5 features, we have MFCC acceleration skewness, which correlates with the stress level by 0.45 and 0.37 in the positive and neutral tasks, respectively. The other features among top 5 features are task specific. Thus, for each task there is a different set of features associated with stress level.

For male participants, the selection was performed analogously. The top features are task specific as well, and they differ from the features for the female data set. In this sample, we obtained more negatively correlating features than for the female data

set; this meant that features, for instance, related to F0 of low value (mean F0 in the neutral story with –0.51, upper quartile F0 in the negative and positive story with –0.47, and upper quartile F0 in the neutral story with –0.54) are associated with high stress scores. In general, low values represent a smaller pitch range.

Regression

Stress scores were regressed against measurements for positive, neutral, and negative tasks. Similarly, the regression for tasks of different sentiments was performed for groups of female and male participants to allow for possible impacts of gender on stress levels. For the regressors, we used linear, support vector machine (SVM), and random forest regressors to predict the stress scores.

The first regression approximated the stress score by estimating coefficients for each feature in the training data, where greater coefficients indicate a greater influence over the predicted value. Linear regression models are fast, highly interpretable, and commonly used for prediction of stress scores from audio features and speech analysis, according to previous studies [40-42]. The random forest regressor created a number of decision trees that were constructed based on random sampling from the training data; each tree then attempted to determine the best way to predict the scores given the data it received. Each decision tree outputted a predicted value and the mode value was selected. Decision tree methods have shown high accuracy with good interpretability in similar studies where vocal and linguistic features were employed for detection of emotions, social signals, and mental health problems [43-45]. The SVM regressor took each set of features and projected them as a vector onto a space and attempted to find the optimal way to separate the data. The stress score was then based on the distance from that separator. Stress modeling with inputs from physiological sensors or audio sources using SVM has also been previously reported to give high model performance [46-48]. In recent studies, both SVM and random forest provided notably high prediction and classification strength for stress detection using various speech features [49-51].

The caret package from R, version 3.4.2 (The R Foundation), was used for data training and validation. A 10-fold cross-validation was performed and performance was evaluated using the mean absolute error (MAE): the average of the absolute difference between the predicted and actual values from our models for all participants. The score ranges from 0 to infinity, where a score closer to 0 indicates a better-fitting model.

The prediction of total stress scores using all or a subset of tasks among male or female subjects was carried out using various baseline regression models, whose performances were evaluated by the plots in Figure 2, where the MAE values are presented on the y-axis. Overall, the prediction strength in males was better than in females for all sentiments, as shown by a trend of lower errors (lowest MAE for males was 3.84; lowest MAE for females was 5.56). It is notable that stress score regression models based on negative tasks in males and neutral tasks in females performed relatively poorly compared to other tasks. For both male and female participants, using positive tasks for regression yielded equivalent or better results than using all tasks, suggesting that a subset of tasks could be employed for accurate and less time-consuming prediction of stress scores. An overview of the lowest scores for each testing scenario is presented in Table 3.

All regression models outperformed their respective baseline MAE values (4.46 and 6.35 in males and females, respectively). Linear models and the SVM regressor were the most precise for the prediction of total stress scores in general.

Figure 2. Performances of different computerized regression models in predicting stress levels based on vocal features. Boosted: boosted linear model; ElasticNet: mix of L1 and L2 regularized linear regression; MAE: mean absolute error; Poly: support vector machine with polynomial basis function kernel; Quantile: quantile regression forest; Radial: support vector machine with radial basis function kernel; SVM: support vector machine.

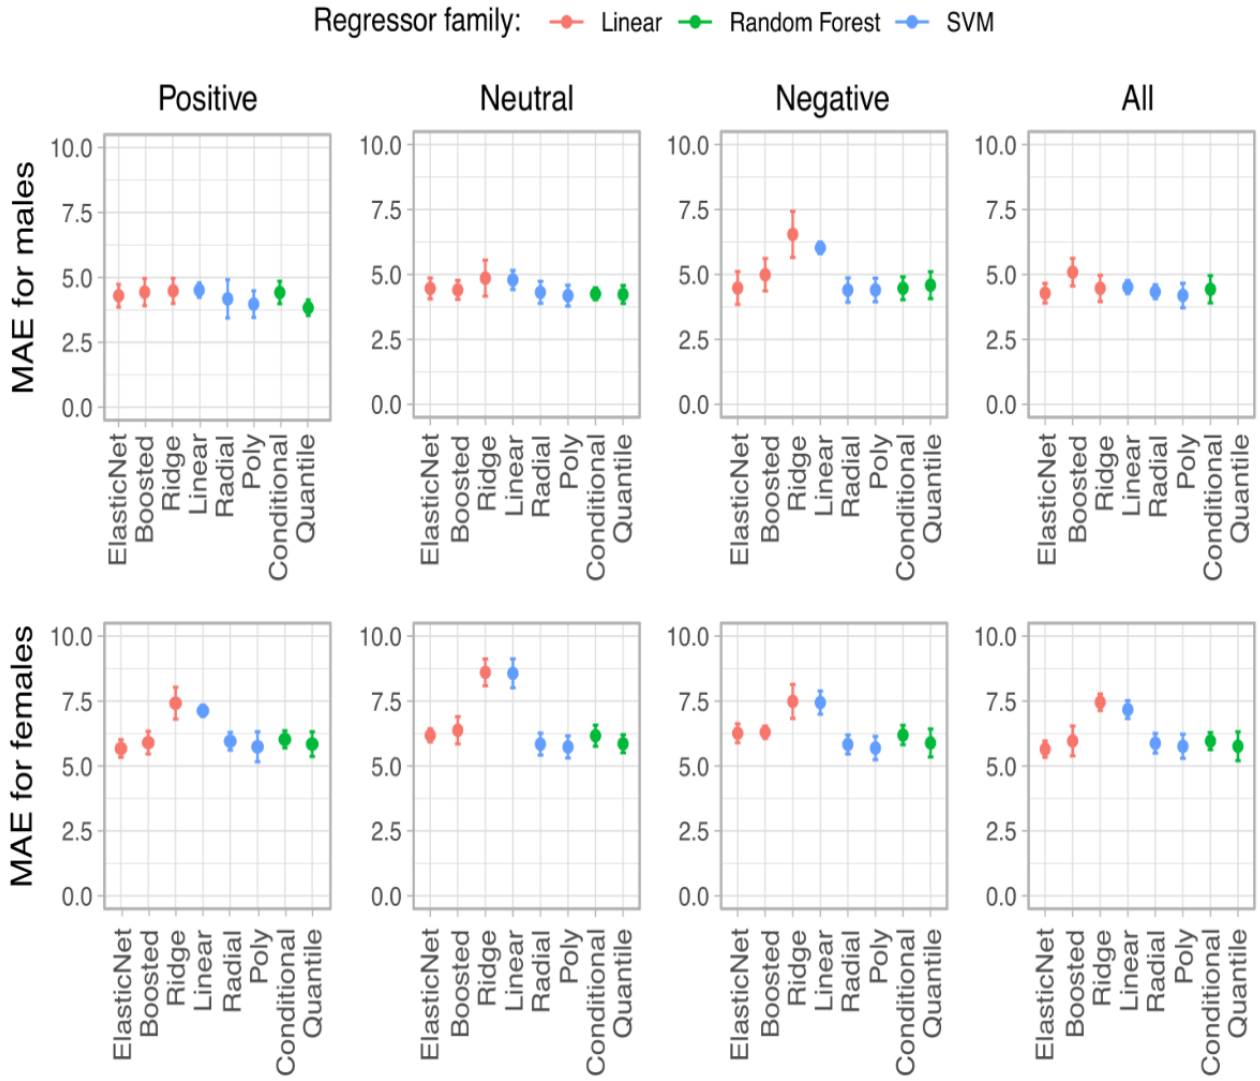


Table 3. The lowest scores for each testing scenario.

Participant group	Positive tasks		Neutral tasks		Negative tasks	
	MAE[a] (SD)	Model	MAE (SD)	Model	MAE (SD)	Model
All	5.31 (0.25)	ElasticNet[b]	5.25 (0.28)	QuantileRF[c]	5.34 (0.35)	PolySVM[d]
Male	3.84 (0.43)	QuantileRF	4.40 (0.37)	BoostedLM[e]	4.37 (0.43)	PolySVM
Female	5.56 (0.41)	ElasticNet	5.84 (0.42)	RadialSVM[f]	5.68 (0.45)	PolySVM

[a]MAE: mean absolute error.

[b]ElasticNet: mix of L1 and L2 regularized linear regression.

[c]QuantileRF: quantile regression forest.

[d]PolySVM: support vector machine with polynomial basis function kernel.

[e]BoostedLM: boosted linear model.

[f]RadialSVM: support vector machine with radial basis function kernel.

Discussion

Principal Findings

The purpose of this study was to investigate the potential of using automatic speech analysis for the detection of stress in health care professionals during the current COVID-19 pandemic. This would potentially lead to earlier and timely prevention among this high-risk population. Firstly, speech samples were collected over the phone, and various voice features were extracted and compared with classical stress measures. Secondly, based on the extracted features, scores obtained by participants on the completed stress scale were predicted.

The main outcome of this study was the demonstration of this approach's feasibility under the given context, as all participants were cooperative and appreciated the initiative of rapidly applying this existing technology to this specific use case. Moreover, from phone call recordings, a number of vocal correlates of stress have been identified, namely in the area of spectral features (ie, MFCC) as well as prosodic features such as F0, which seem to be the most commonly reported features in well-controlled trials [11]. Stress scores could be predicted based on speech features with relatively small errors.

Spectral features characterize the speech spectrum; the frequency distribution of the speech signal at a specific time indicates information in some high-dimensional representation [18]. The features capture information regarding changes in muscle tension and control and have consistently been observed to change with a speaker's mental state. A few depression studies reported a relative shift in energy with increasing depression severity [52,53].

Another result we obtained was that most identified vocal features were task dependent as well as gender dependent. Interestingly, in the female group, MFCC features seemed to be associated with stress levels during all tasks, meaning that it did not matter what participants were talking about; as long as sufficient speech was captured, meaningful information could be extracted and subtle signs of stress level could be detected. On the other hand, in the male data set, the upper quartile F0 appeared as a task-independent feature sensitive to stress levels. Overall, in the male data set, we observed more features with a negative correlation than we did for the female data set.

Voice production can be divided into three processes: breathing, phonation, and resonance stress [54]. For the second process, phonation, the vocal folds must close and open again to create vibration. The frequency rate of these pulses determines the F0 of the vocal source contributing to the perceived pitch of the sound.

Previous research showed that increased muscle tension tends to be caused by stress [55,56], resulting in a tensing of the vocal folds, which, in turn, most likely causes a raising of F0. A recent review on voice analysis in stress [22] stated that the parameter F0 has been considered as a "universal stress indicator," whereas increased levels of F0 might be linked with acute bottom-up processes of sympathetic arousal. Similar studies of analysis of phone call recordings during situational stress situations revealed an increase in F0 and intensity with presumed levels of stress [55,57,58]. Our findings seem consistent with the majority of acoustic studies, pointing to F0 as one important marker of stress levels.

However, most correlations we found were with resonance (ie, formant) parameters, which are involved in the quality of sound shaping and vowel and consonant pronunciation and are produced by the muscle activity involved in the shaping of the resonant cavities of the vocal tract system [59]. These parameters are less documented in regard to stress. The MFCC, in particular, can be indicative of breathiness in the voice [60]. Interestingly, one study found a circadian pattern in MFCCs due to sleep deprivation. For this, voice perturbations were compared with classical sleep measures [61] and correlations were found between fatigue scores and MFCCs. This might eventually explain our results, as most participants also reported signs of fatigue during the interviews.

Another study examined speech in students under exam stress and a few days later; in this case, heart rate was measured to control for the actual stress levels. Under stress, students' heart rates increased, F0 and F0 SD increased, first formant (F1) and second formant (F2) frequencies increased, and MFCCs decreased in relation to baseline levels [62].

It can be hypothesized that given our recorded population who reported relatively mild to moderate levels of stress, rather subtle changes in voice parameters were found and, therefore, weaker correlations were observed. However, it is important to underline that changes in features that we found to be sensitive to stress levels were gender dependent but not necessarily task dependent. They were most likely too small to be detectable by the human ear but were captured by the automatic speech analysis. We assume that by applying this technology to regular check-up calls with people experiencing high stress levels, such as health care professionals, very early signs of stress can be detected in their voices, allowing for timely preventive strategies.

Regression models using vocal features performed relatively well in predicting stress scores, namely in the positive story task for both genders (MAE of 5.31). It shows that the technology could capture indicative patterns from even a short amount of time, possibly even from one task, to recognize tendencies of stress levels in a fragile but healthy population; this represents a promising rapid tool for prediction of stress scores.

Strengths of This Study

This study is a first step into the early identification of stress in an at-risk population, such as caregivers, who do not directly express their psychological suffering. We can imagine extending this technique to other fragile populations for early screening of stress, such as teenagers who are victims of school harassment or women who are victims of abuse, where timely management could potentially prevent the development of comorbidities, such as depression and anxiety. Moreover, patient populations who have difficulty expressing their problems, such as those with autism spectrum disorder or dementia, could benefit from this technology.

Generally, remote psychological counseling is controversial. Nevertheless, it is becoming necessary due to current economic, social, and health constraints, but has been received by professionals and patients with mixed feelings. Indeed, the nonverbal part of communication is lost and the dynamics of interaction are not the same. However, contrary to these preconceived ideas, we have noticed during this work that it is easier for certain participants to open up and speak about personal issues during these interviews in a liberating manner, similar to a confessional. Not being in the physical presence of the listener may facilitate personal expression, with less fear of being judged. This aspect is very interesting during a screening because it considerably accelerates the process of detection and diagnosing of psychological symptoms.

Weaknesses of the Study

This project has been rapidly implemented, initially with an approach of qualitative and quantitative data analysis, that should contribute to the early and timely assistance of health professionals during the COVID-19 pandemic. The staff members available to participate in the study were limited. Patient selection was done on a voluntary basis. It is conceivable that the population studied were more concerned about their state of psychological suffering and, therefore, potentially had a selection bias.

Although the voice recordings were made in the middle of the interview without this time being precisely stated, it is possible that some patients may have suspected this, which could have been anxiety provoking and skewed our results. Recording throughout the interview for parameters not affected by the tasks would provide more data and more robust results.

Finally, the obtained correlations can be considered as rather moderate, which makes it difficult to draw any strong conclusions. A larger data set, ideally of a longitudinal nature, with more precise characterization of the speakers is needed in order to verify whether the correlating features represent real markers of stress.

Future Perspective

For future work, we propose to perform this analysis on a larger data set and to build a prediction model. In case of an insufficient number of observations per stress level, the number of stress levels can be reduced by binning. Binning can also be carried out on characteristic values.

Further studies with acoustic measurements and stress questionnaires at regular time intervals would allow for the analysis of the kinetics of the markers and a better perception of their sensitivity and specificity. In addition, adding clinical measurements of psychiatric symptoms, such as the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition [63], would make it possible to perceive whether one of the markers is predictive of an anxiety or depression disorder. The use of the tool could be combined with the delivery of preventive strategies, such as physical exercises, adaptation of diet, psychotherapy, meditation, or the use of symptomatic treatments, and it could be employed at the same time for the evaluation of the obtained effects. However, in order to produce a real-world application of this technology, larger validation studies have to be performed to demonstrate clinical meaningfulness by comparing its performance to standardized measurement tools.

Acknowledgments

This research was supported by a grant from the Fondation GSF (Groupe Services France) Jean Louis Noisiez and the Association Innovation Alzheimer. Thanks to all of the professional health care workers who agreed to participate in this study.

Authors' Contributions

AK, KR, JE, and PR designed and conducted the study. AD contributed as technical support to this study. NL, HL, and RF analyzed the data. KR, AK, NL, HL, and PR drafted the manuscript. All authors have read and agreed to the published version of the manuscript.

Abstract

Background: During the COVID-19 response, nonclinical essential workers usually worked overtime and experienced significant work stress, which subsequently increased their risk of mortality due to cardiovascular diseases, stroke, and pre-existing conditions. Deaths on duty, including deaths due to overwork, during the COVID-19 response were usually reported on web-based platforms for public recognition and solidarity. Although no official statistics are available for these casualties, a list of on-duty deaths has been made publicly available on the web by crowdsourcing.

Objective: This study aims to understand the trends and characteristics of deaths related to overwork among the frontline nonclinical essential workers participating in nonpharmaceutical interventions during the first wave of COVID-19 in China.

Methods: Based on a web-based crowdsourced list of deaths on duty during the first wave of the COVID-19 response in China, we manually verified all overwork-related death records against the full-text web reports from credible sources. After excluding deaths caused by COVID-19 infection and accidents, a total of 340 deaths related to overwork among nonclinical essential workers were attributed to combatting the COVID-19 crisis. We coded the key characteristics of the deceased workers, including sex, age at death, location, causes of death, date of incidence, date of death, containment duties, working area, and occupation. The temporal and spatial correlations between deaths from overwork and COVID-19 cases in China were also examined using Pearson correlation coefficient.

Results: From January 20 to April 26, 2020, at least 340 nonclinical frontline workers in China were reported to have died as a result of overwork while combatting COVID-19. The weekly overwork mortality was positively correlated with weekly COVID-19 cases (r=0.79, P<.001). Two-thirds of deceased workers (230/340, 67.6%) were under 55 years old, and two major causes of deaths related to overwork were cardiovascular diseases (138/340, 40.6%) and cerebrovascular diseases (73/340, 21.5%). Outside of Hubei province, there were almost 2.5 times as many deaths caused by COVID-19–related overwork (308/340, 90.6%) than by COVID-19 itself (n=120).

Conclusions: The high number of deaths related to overwork among nonclinical essential workers at the frontline of the COVID-19 epidemic is alarming. Policies for occupational health protection against work hazards should therefore be prioritized and enforced.

Introduction

The first wave of the COVID-19 epidemic in China was brought under control within 3 months—from mid-January 2020 (when human-to-human transmission of COVID-19 was confirmed) to the end of April 2020 [1]. The effective containment of the initial wave of COVID-19 in China was credited to not only the frontline medical response but also swift, massive, and aggressive nonpharmaceutical interventions (NPIs) [2]. Implementation of such interventions was time-sensitive and labor-intensive, demanding the continuous efforts of staff from all sectors to meet community health care and logistical needs, such as setting up checkpoints for temperature screening, conducting travel history inquiries to screen for suspected cases, and protecting incarcerated people in prisons and detention houses. However, although COVID-19 cases and related deaths among medical professionals have been well acknowledged [3], the health of nonclinical essential workers engaged in NPIs to contain the spread of COVID-19 should not be overlooked.

In China, these frontline workers have suffered from high levels of psychological and physical stress, and they have worked long hours without sufficient rest for weeks, even months, due to the rapid acceleration of the epidemic and understaffing [4]. It has long been recognized that "overwork" can kill [5], as prolonged working hours and heightened psychological stress increase the risk of coronary heart disease and stroke by inducing increased catecholamine secretion, eventually leading to increased mortality risk [6-8]. However, the hidden casualties of these deaths from overwork have not been studied. Deaths on duty during the COVID-19 response were usually reported by web-based news platforms for reasons of public recognition and solidarity, but there are no official statistics concerning these casualties. Fortunately, a list of on-duty deaths in the combat against the COVID-19 crisis has been made publicly available on the social media platform Weibo [9] by crowdsourcing and has been recognized by the Chinese public. This study aims to conduct a comprehensive search of web-based news reports to describe the trends and characteristics of deaths from overwork in the fight against the COVID-19 epidemic in China.

Methods

Based on a widely recognized list of on-duty deaths in the fight against COVID-19 in China, from January 20 to April 26, 2020, a total of 496 deaths on duty were included in this study, with no duplication [9]. All records of deaths in the line of duty were verified with the corresponding full-text, reports on the web from credible news platforms such as Xinhua News Agency, People's Daily, Sohu.com, and Sina.com, as well as official government websites (detailed sources are presented in Multimedia Appendix 1). If the on-duty death reports explicitly mentioned *overwork* and the deaths were not attributed to COVID-19 or accidents, then those deaths would be identified as *deaths related to overworks*. After excluding the deaths caused by COVID-19 or accidents, we found that 340 of the 496 (68.5%) deaths related to overwork among nonclinical essential workers were attributed to combatting the COVID-19 crisis.

We coded the key characteristics of the 340 deceased workers, including sex, age at death, location, causes of death, date of incidence, date of death, containment duties, working area, and occupation (see Table S1 in Multimedia Appendix 1). The date of incidence refers to the date when the frontline worker's health condition deteriorated suddenly due to overwork, and they could no longer perform their duties, whereas the date of death refers to the date when the overwork-related death occurred. If a frontline worker died from overwork immediately or was found dead, the date of incidence and the date of death would be the same. However, if the frontline worker's health condition deteriorated suddenly due to overwork, but they died only after several days of rescue and treatment at the hospital, then the date of incidence and date of death would be different. This study only used the date of incidence to analyze the trends and correlation of deaths from overwork and COVID-19 incidence, as it reflected the timely physical and psychological stress caused by the severity of the epidemic.

In addition, the number of daily deaths from overwork and daily COVID-19 incidences were aggregated into weekly COVID-19 incidence to reflect the time trends of deaths from overwork and COVID-19 incidence [10]. The temporal correlation between weekly overwork mortality and COVID-19 incidence and the spatial correlation between provincial deaths from overwork and COVID-19 case counts were also examined using Pearson correlation coefficient (r); the correlation was considered statistically significant at $P<.05$. As a sensitivity analysis, we analyzed cases in which the death occurred within 2 days of the date of incidence to examine the correlation. This study was approved by the institutional review board of Research Center for Public Health, School of Medicine, Tsinghua University, Beijing, China (THUSM/PHREC 2020400-009).

Results

The earliest deaths from overwork occurred on January 24, 2020, and during the 14 weeks from January 20 to April 26, 2020, at least 340 nonclinical frontline workers in China were reported to have died due to overwork in the fight against the COVID-19 epidemic. Both the number of COVID-19 cases (n=30,396) and the number of deaths from overwork (n=53) reached the peak in the fourth week after January 20 (Figure 1). Weekly overwork mortality was positively correlated with weekly COVID-19 cases (r=0.79, $P<.001$). A total of 86.5% (294/340) of cases died within 2 days of the incidence. As indicated by the sensitivity analysis, if only considering the deaths within 2 days of incidence, the temporal correlation between weekly overwork mortality and weekly COVID-19 cases would increase to 0.81 ($P<.001$).

Among those individuals who died due to overwork (Table 1), the mean age at death was 49.50 (SD 9.13) years, with two-thirds (230/340, 67.6%) of them under 55 years old. Two of the major specified underlying causes of death were cardiovascular diseases (138/340, 40.6%), including myocardial infarction and sudden cardiac arrest, and cerebrovascular

diseases (73/340, 21.5%), including stroke. A majority of the deaths from overwork were among men (324/340, 95.3%) in China; this reflected that the epidemic containment responsibilities were carried out by village leaders (111/340, 32.6%), police (96/340, 28.2%), and civil servants (58/340, 17.1%), which are traditionally male-dominated occupations in China. Most deceased workers were involved in community mobilization and support (217/340, 63.8%), including community closure and access control, temperature screening, travel history collection, and delivery of daily necessities, followed by public security (77/340, 22.6%). Apart from working in rural (156/340, 45.9%) and urban (132/340, 38.8%) settings, 15.3% (52/340) of the deceased workers used to work at traffic checkpoints on expressways and in prisons and detention houses.

In addition, 32 of the 340 (9.4%) deaths from overwork occurred in Hubei province, which reported the highest prevalence of COVID-19 in China. Among the remaining 308 (90.6%) deaths reported outside Hubei province, provincial deaths related to overwork were positively correlated with the number of COVID-19 cases (r=0.55, P=.002). If only considering the deaths that occurred within 2 days of incidence, the correlation coefficient remains nearly the same (r=0.55, P=.002).

Figure 1. Trends of weekly overwork-related deaths and COVID-19 incidence between January 20 and April 26, 2020, in China.

[a]Other working areas include prisons, detention houses, and traffic checkpoints at the expressway.

[b]Other causes of death include acute hepatic failure, acute pancreatitis, and pre-existing conditions.

[c]Other epidemic containment duties include logistics, electricity or telecommunication maintenance, and health communication.

[d]Other public sectors include schools and institutions funded by the government.

Discussion

Principal Findings

This study utilized the manually verified crowdsourced data available on the internet to illustrate the trends and characteristics of deaths from overwork, which were casualties of the effort to contain the COVID-19 epidemic in China. The 340 deaths from overwork reveal a hidden "epidemic within the epidemic" that has not been documented thus far and has further sounded the alarm of fatigue and occupational burnout among nonclinical frontline workers. The severity of the epidemic presented a considerable health burden to those who were involved in the battle against COVID-19, and it explains why the peak of deaths from overwork was synchronized with the peak of the COVID-19 pandemic. Notably, outside Hubei province, there were over 2.5 times as many deaths caused by COVID-19–related overwork (308/340, 90.6%) than deaths caused by the disease itself (n=120) [10], and these provincial deaths related to overwork were correlated with COVID-19 case counts, signaling the high intensity of NPIs to curb the COVID-19 epidemic.

This epidemic embodies the health threats that all nonclinical essential workers faced. First, nonclinical essential workers had mental distress due to the fear of contracting COVID-19. Unlike ordinary residents under home quarantine, nonclinical essential workers had to work outside to perform their duties, especially screening for suspected COVID-19 cases. During the early stages of the epidemic in China, all personal protective equipment (PPE) was prioritized for clinical staff [11]; thus, nonclinical workers faced a shortage of PPE, which may have heightened their fears of COVID-19 infection. Second, most of the containment strategies were implemented by public sector employees, and they were accountable by the law and regulation for containing the epidemic. Thus, they experienced considerable work stress and workload due to understaffing, especially in provinces other than Hubei. The Chinese central government dispatched many clinical and nonclinical workers from other provinces to support Hubei province [12], whereas for other provinces, they had to manage to contain the transmission of COVID-19 largely on their own. Nonclinical essential workers worked overtime at the peak of the epidemic, which may have increased the risk of death due to cardiovascular and cerebrovascular diseases [6,7]. Third, due to understaffing, many workers with pre-existing conditions joined the workforce in the intensive battle against COVID-19. Those workers did not have enough time to rest and recover, and their pre-existing poor health conditions may have deteriorated and contributed to the observed deaths from overwork.

The high number of deaths from overwork among essential workers serving at the frontline during the COVID-19 epidemic is alarming. Although protection for health care workers in the line of duty against COVID-19 has been a global focus [11,13], policies for occupational health protection against work hazards such as adequate training, sufficient PPE, and proper working shifts, should be prioritized and enforced. Counseling services should also be provided to mitigate the psychosocial impacts. The possibility of a second wave of COVID-19 cannot be ruled out [14], so NPIs will likely remain in place until there is a breakthrough in treatment or a vaccination becomes widely available.

Limitations

Our study also has some limitations. First, the deaths related to overwork were identified based on news reports on the web, not from the hospital health records; hence, some misclassification of data may exist. We verified the full-text reports of all deaths from overwork by using credible and official sources to minimize this misclassification. Second, the length and details of the individual death reports varied and, as such, some characteristics could not be retrieved and coded. Finally, the number of deaths from overwork was likely to be underestimated, as not every incident was reported on the internet.

Conclusions

This cross-sectional study based on web-based crowdsourced data emphasizes that deaths related to overwork among nonclinical essential workers should be acknowledged. Corresponding policies for occupational health protection against deaths due to overwork should be implemented. Nonclinical essential workers are the unsung heroes, and their safety and well-being should be prioritized as they constitute society's frontline of defense against COVID-19.

Acknowledgments

We would like to thank Jianing Ren, Xinran Qi, Jie He, Yu Wang, Chunyu Liu, Siyu Zou, Chunxiao Peng, Luoqi Yuan, Jiashu Shen, Zhao Jin, Yiqian Xin, and Fan Yang for their diligent work on the full-text verification of reports on deaths related to overwork. This study has been funded by National Nature Science Foundation of China (72074130) and Spring Breeze Foundation of Tsinghua University (20203080035).

Abstract

Background: A central component of the public health strategy to control the COVID-19 pandemic involves encouraging mask wearing and social distancing to protect individuals from acquiring and transmitting the virus.

Objective: This study aims to understand the psychological factors that drive adoption or rejection of these protective behaviors, which can inform public health interventions to control the pandemic.

Methods: We conducted an online survey of a representative sample of 1074 US adults and assessed three novel potential predictors of COVID-19 behaviors: trait reactance, COVID-19 conspiracy beliefs, and COVID-19 apocalypse beliefs. Key outcomes (dependent variables) included an index of COVID-19 protective behaviors, the number of trips taken from the home, and COVID-19 knowledge.

Results: In bivariate analyses, all three predictors were significantly correlated in the hypothesized direction with the three COVID-19 outcomes. Specifically, each predictor was negatively (P<.01) correlated with the COVID-19 protective behaviors index and COVID-19 knowledge score, and positively correlated with trips taken from home per week (more of which was considered higher risk). COVID-19 protective behaviors and COVID-19 knowledge were significantly lower in the top median compared to the bottom median for all three predictors. In general, these findings remained significant after adjusting for all novel predictors plus age, gender, income, education, race, political party, and religiosity. Self-identified Republicans (vs other political affiliations) reported the highest values for each of the novel predictors.

Conclusions: This study can inform the development of health communication interventions to encourage the adoption of COVID-19 protective behaviors. Interestingly, we found that higher scores of all three novel predictors were associated with lower COVID-19 knowledge, suggesting that lack of an accurate understanding of the virus may be driving some of these attitudes; although, it is also possible that these attributes may interfere with one's willingness or ability to seek and absorb accurate health information. These individuals may be particularly immune to accepting new information and yielding their beliefs. Health communication professionals may apply lessons learned from countering similar beliefs around climate change and vaccine hesitancy. Messages designed for individuals prone to reactance may be more effective if they minimize controlling language and emphasize the individual's independence in adopting these behavioral recommendations. Messaging for those who possess conspiracy beliefs should similarly not assume that providing evidence contrary to these beliefs will alone alter behavior. Other communication techniques such as *rolling with resistance*, a strategy used in motivational interviewing, may be helpful. Messaging

for those with apocalyptic beliefs may require using religious leaders as the message source and using scripture that would support the adoption of COVID-19 protection behaviors.

Introduction

A central component of the public health strategy to control the spread of the COVID-19 pandemic and the associated morbidity and mortality is to encourage behaviors that protect individuals from acquiring and transmitting the virus. Key protective behaviors that have been recommended by US and global health organizations such as the World Health Organization and the Centers for Disease Control and Prevention include consistent wearing of a facial mask, social distancing, handwashing, and avoiding large gatherings [1]. Until a vaccine or more effective treatments become widely available, behavior change will remain the core of the public health strategy.

Understanding individual-level attributes that are associated with adoption of these behaviors is critical to controlling the spread of COVID-19. To date, most of the research on COVID-19 protective behaviors has focused on demographic variables such as gender and race as well as social cognitive variables such as perceived risk and knowledge regarding the virus [2-5]. Less attention has been given to personality factors and constructs beyond the traditional models of health behavior (eg, perceived risk). Understanding the psychological traits that drive adoption of these protective behaviors can inform social marketing campaigns and behavior change interventions.

To address these gaps in understanding about what drives individual protective behavior choices, we identified three novel predictors based on both theoretical and empirical considerations. Psychological *reactance* theory, originally proposed by Brehm and Brehm [6] posits that when an individual's sense of behavioral freedom is threatened, the individual is motivated to restore the perceived loss of freedom by psychologically and behaviorally rejecting the behavior, even if the behavior may be in their best interest. *Conspiracy beliefs* can be defined as unsubstantiated, implausible assertions that malevolent and hidden forces control our social institutions, and these nefarious forces secretly plot major events such as 9/11; covering up alien visitations; and, in the case of this study, the creation and spread of COVID-19. Often these beliefs reject other simpler explanations that are more probable and plausible [7]. Conspiracy beliefs have previously been found to be associated with lower adoption of protective behaviors such as vaccination and condom use [7-11]. With regard to COVID-19, a few studies have found a negative association between conspiracy beliefs, both measured as a global trait and specific to COVID-19, and positive attitudes toward and adoption of COVID-19 protective behaviors [4,10,12-14]. Finally, we were interested in the potential impact of *apocalyptic beliefs*. Apocalypticism is the generally religious belief that the end of the world is imminent [15], and civilization will soon come to a tumultuous end due to some catastrophic global event such as war, famine, or disease and more recently global warming and the COVID-19 pandemic. These beliefs often include some sense of divine punishment for immorality or disobedience and spare the *righteous* who obey God's rules. For some Christians, these beliefs include the rapture, when both living and dead believers will ascend in to heaven to meet Jesus Christ at the Second Coming. Our underlying assumption is that individuals who believe in the apocalypse will be less likely to adhere to public health recommendations around COVID-19, in part because they welcome the end of days and the Second Coming of Christ. Although we could find no studies reporting the association between apocalyptic beliefs and COVID-19 protective behaviors, conceptual and empirical work has shown that such beliefs may impact behaviors related to climate change and violence [16,17], and we suspected it might play a role in the adoption of COVID-19 protective behaviors.

We conducted a national online survey and report here the association between these three potential novel predictors—(1) trait reactance, (2) COVID-19 conspiracy beliefs, and (3) COVID-19 apocalypse beliefs—and COVID-19 protective behaviors.

Methods

Sampling

Surveys were completed online using a sample provided by Dynata [18] between May 19-22, 2020. Dynata's research panel comprises an opt-in list of over 60 million individuals worldwide. For this study, we requested a nationally representative sample of 1000 US adults 18 years or older. Quotas were used to approximate national rates for age, gender, race, income, and region for the overall US population. Our survey was conducted as open enrollment, whereby eligible panel members who log in to the Dynata website were offered a chance to partake in this survey. Surveys were completed using the Qualtrics online platform. Participants received a modest payment from Dynata for completing their survey. Dynata incentives vary based on individual preferences and include cash, frequent traveler or customer loyalty points, or a donation to a charity. The reward value is based on the amount of effort required and the population surveyed. Regardless of the type of incentive, the value is the same for every respondent in a given study. In this study, the value was US $1.00. The full survey assessed a range of individual and household characteristics and attitudes and behaviors related to the COVID-19 pandemic as well as demographics. Other than screener items, no survey items were required to progress (ie, no strict validation was used). After excluding implausible

values (<10 minutes and >2 hours), the mean minutes to complete the survey was 25.3 (range 10.1-117.1) minutes.

A total of 2272 individuals clicked on the invitation link, 187 did not complete the age screener or consent, and 609 were ineligible or refused consent. This yielded 1476 surveys from age-eligible consenting individuals. To ensure the quality of the respondent data, we excluded 402 of the 1476 surveys based on two criteria. First, we excluded 375 surveys from individuals who completed the full survey in less than 10 minutes. We considered 10 minutes the minimum time required to complete a valid survey. Second, we excluded 27 surveys for individuals who answered all items within a 16-item block of items assessing attitudes toward the pandemic with an identical response. This is the equivalent of clicking down an entire column (eg, all strongly agree or disagree) for all items. Because some of the 16 items in this section were worded in the positive direction (eg, social distancing has slowed the spread of COVID-19) and others in the negative direction (eg, social distancing is not really doing much good), we considered these *response set* patterns contradictory and therefore an indication that the validity of that survey was suspect. After applying these exclusions, 1074 surveys remained for the present analyses.

Measures

Primary Predictor Measures (Independent Variables)

Trait Reactance

We selected 5 items from the widely used Hong Reactance scale [19-23]. The scale measures trait reactance rather than reactance specific to COVID-19 recommendations. Each item was answered along a five-point continuum ranging from strongly disagree to strongly agree. Internal consistency in our sample was 0.87. The five items, averaged to create a mean scale, were:

1. I become angry when my freedom of choice is restricted.
2. Regulations trigger a sense of resistance in me.
3. When something is prohibited, I usually think, “That’s exactly what I am going to do.”
4. It disappoints me to see others submitting to society’s standards and rules.
5. Advice and recommendations usually induce me to do just the opposite.

COVID-19 Conspiracy Beliefs

We developed a brief, three-item scale based on prior studies of COVID-19 and other health issues [7,14]. The scale is intended to measure conspiracy beliefs regarding COVID-19 rather than a generalized conspiracy trait or worldview [14]. Each item was answered along a five-point continuum ranging from definitely false to definitely true. Internal consistency in our sample was 0.74. The three items, averaged to create a mean scale, were:

1. The real truth about COVID-19 is being kept from the public.
2. People in power are using COVID-19 as an excuse to monitor and control the public.
3. The media is making COVID-19 seem more dangerous than it really is.

COVID-19 Apocalypse Beliefs

We developed a new brief scale informed by theological definitions and prior related work [15,17]. Each item was answered along a five-point continuum ranging from strongly disagree to strongly agree. Internal consistency in our sample was 0.92. The three items, averaged to create a mean scale, were:

1. The COVID-19 pandemic is a sign that the apocalypse is coming.
2. The COVID-19 pandemic is a sign that Jesus will soon be returning.
3. The COVID-19 pandemic is a sign that the rapture is coming.

Outcomes Measures (Dependent Variables)

Adoption of Positive COVID-19 Protection Behaviors

We examined the frequency of five self-reported behaviors over the past week, all of which are recommended for reducing the risk of transmitting or acquiring COVID-19 [1]. For each item the responses were: rarely or never (coded 1), some of the time (coded 2), most of the time (coded 3), almost all of the time (coded 4), and all of the time (coded 5). The values of 1-5 for each item were summed to form an index score with a range of 5-25. The alpha value for the five behaviors was .84 in this sample.

1. Staying home as much as possible.
2. Wearing a mask or face covering when I go out of the house.
3. Staying at least 6 feet (about 3 steps) away from people I do not live with.
4. Avoiding gatherings or groups of other people.
5. Keeping my hands clean.

COVID-19 Knowledge

We created a seven-item scale, with each item answered definitely false to definitely true. A response was coded as correct by answering definitely or probably false for items 4, 5, 6, and 7, and definitely or probably true for items 1, 2, and 3. Correct scores were summed, yielding a total score from 0 to 7. Internal consistency for the seven items was 0.77.

1. A vaccine is not yet available for COVID-19.
2. COVID-19 can be easily spread from one person to another.
3. Many thousands of people have died from COVID-19.
4. Most people already have immunity to COVID-19.
5. Symptoms of COVID-19 are always visible.
6. There are effective treatments for COVID-19 that can cure most people.
7. Having COVID-19 is about as dangerous as having the flu.

Trips Leaving the Home

We assumed that a higher number of trips from home indicated higher risk behavior. We queried leaving the home in the past week across various types of trips. For each, we asked, “In the last seven days, how many times did you go out of your home for each of the following reasons?” Responses ranged from none to five or more times. The reasons included going to work; the grocery store or market; to get takeout from a restaurant or

fast-food location; eat at a restaurant or fast-food location; the drug store or pharmacy; seek health care; check on or help care for a vulnerable person; visit friends, family, or neighbors; take a child or minor to day care or some activity, exercise, or some other outdoor activity; and attend a gathering of 10 or more. Items were summed to create a trips leaving home index with an observed range of 0-39.

Demographic Variables (Covariates)

Gender was initially assessed with five categories: male, female, transgender (identify as male), transgender (identify as female), and other. Transgender and other were collapsed.

Political party was assessed with four categories: Republican, Democrat, Independent, and something else.

Race and ethnicity were coded as White, Black, Hispanic, multiracial, and other, which included American Indian, Asian, and other.

Income was initially assessed with 9 strata that, for ease of presentation, were collapsed into three categories: less than US $30,000; US $30,000 to US $74,999; and US $75,000 and greater.

Education was initially assessed with 10 strata that were collapsed into four categories for ease of presentation: none through high school or General Educational Development, postsecondary (trade school, some college, or associate's degree), bachelor's degree, and advanced degree (master's degree, doctoral degree, or professional degree).

Religiosity was measured with a single item: "How religious are you?" Responses ranged from not at all religious, which was coded as 1, to very religious, coded as 7.

Analyses

We first present sample demographic frequencies and means for key continuous independent and dependent variables. Next, bivariate correlations between the three novel predictors and the correlation of the predictors with the three COVID-19 outcomes are presented. For ease of presentation, a dichotomous variable was created using the median split for each of the three predictors. Using the median split for the three novel predictors, we next presented means for the three COVID-19 outcomes (which are all continuous), first unadjusted, with only the novel predictor in the model, then using a general linear model, adjusted for the other novel predictors along with age, gender, income, education, political party, and religiosity. Income, education, political party, and race, all categorical variables, were all dummy coded prior to entry into the multivariate model. All analyses were performed using SPSS version 25 (IBM Corp) [24]. This survey was approved by the University of Michigan's Institutional Review Board.

Hypotheses

The first hypothesis was that individuals that score higher on trait reactance will report fewer COVID-19 protective behaviors, higher daily excursions from their home, and lower COVID-19 knowledge.

The second hypothesis was that individuals that score higher on conspiracy beliefs regarding COVID-19 will report fewer COVID-19 protective behaviors, higher daily excursions from their home, and lower COVID-19 knowledge.

The third hypothesis was that individuals that score higher on COVID-19 apocalypse beliefs will report fewer COVID-19 protective behaviors, higher daily excursions from their home, and lower COVID-19 knowledge.

Results

Sample Description

The 1074 sample was 55% (n=573) female, 70% (n=723) White, 8% (n=84) Black, 9% (n=95) Hispanic, and 6% (n=65) multiracial. About 22% (n=225) of the sample had high school or lower education, and 47% (n=482) had at least a bachelor's degree. Income distribution was about even across the three strata. With regard to political party, 29% (n=297) identified as Republican, 38% (n=395) as Democrat, 27% (n=283) as Independent, and 6% (n=61) as other. The mean for trait reactance, COVID-19 conspiracy beliefs, and COVID-19 apocalypse beliefs were 2.4, 2.9, and 2.2, respectively. Assuming a mean value of 4 or higher (corresponding to a response of agree for reactance and apocalypse items or probably true for conspiracy items) indicates a high presence of the attribute. The prevalence was 9.8% (102/1041) for apocalypse beliefs, 20.3% (214/1052) for conspiracy beliefs, and 6.9% (72/1041) for trait reactance (Table 1).

Range	1-5

[a]GED: General Educational Development.

Correlations

All three predictors were significantly (P<.01) correlated in the hypothesized direction with the three COVID-19 outcomes. Specifically, each predictor was negatively correlated with the COVID-19 protective behaviors index (range –0.10 to –0.39) and COVID-19 knowledge (range –0.42 to –0. 57). All three predictors were positively correlated with trips from home per week (range 0.27-0.31; see Table 2). The three predictors were all positively correlated (P<.001). Specifically, apocalypse beliefs were correlated 0.31 and 0.33 with conspiracy beliefs and reactance, respectively. Conspiracy beliefs and reactance were correlated 0.51 (data not shown).

Table 2. Pearson correlations of novel predictors and COVID-19 outcomes (N=1074).

Variable	COVID-19 protective behaviors	Trips leaving home per week	COVID-19 knowledge score
Trait reactance	–0.38[a]	0.31	–0.54
COVID-19 conspiracy beliefs	–0.32	0.21	–0.57
COVID-19 apocalypse beliefs	–0.09[b]	0.27	–0.42

[a]All correlations were significant with a P of <.001, unless otherwise indicated.

[b]P=.002

Bivariate Means

Using the median split for the three predictors, the differences between the top and bottom half of participants were statistically significant across all three variables for each of the three COVID-19 outcomes (ie, protective behaviors index, trips from home, and COVID-19 knowledge). Specifically, the mean for the COVID-19 protective behaviors index and the COVID-19 knowledge scale were significantly lower in the top median compared to the bottom median for all three predictors. The mean trips from home was significantly higher in the top median compared to the bottom median for all three predictors. This model does not adjust for covariates or other novel predictors (see the unadjusted mean columns in Table 3).

In analyses accounting for all novel predictors simultaneously, plus age, gender, income, education, race, political party, and religiosity, the adjusted means remained significantly different for the top and bottom median for all outcomes except for apocalypse beliefs and the COVID-19 protective behaviors index. Thus overall, these findings were generally consistent with a priori hypotheses (see the adjusted mean columns in Table 3).

Table 3 also presents results by political affiliation. In adjusted analyses, respondents identifying as Democrat had the highest mean for the protective behaviors index and COVID-19 knowledge, whereas for trips from home, Republicans had the highest number. For all three predictors, values were highest among those identifying as Republican and lowest among those identifying as Democrat (data not shown).

Finally, we previously reported the means, using the median split of each of the three novel predictors, for each of the three outcomes. We also examined the outcome means using a threshold of 4 or higher compared to those scoring less than 4, for each of the predictors. For individuals with an average score of 4 or higher on the reactance scale, the means were 17.5, 11.2, and 22.0 for the protective behaviors index, trips from home, and knowledge score, respectively. For individuals with an average score of 4 or higher on the COVID-19 conspiracy scale, the means were 18.0, 7.8, and 23.2 for the protective behaviors index, trips from home, and knowledge score, respectively. For individuals with an average score of 4 or higher on the COVID-19 apocalypse scale, the means were 20.4, 11.0, and 23.5 for the protective behaviors index, trips from home, and knowledge score, respectively. Thus, in general, the pattern of results using the threshold of 4 or higher for the three predictors was similar to results using the median split (data not shown).

Table 3. Bivariate and adjusted means of COVID-19 protective behaviors, leaving home episodes, and COVID-19 knowledge by novel predictors (N=1074).

Variable	COVID-19 protective behaviors				Trips leaving home per week				COVID-19 knowledge score			
	Bivariate unadjusted, mean (SD)	*P* value	Adjusted[a], mean (SE)	*P* value	Bivariate unadjusted, mean (SD)	*P* value	Adjusted, mean (SE)	*P* value	Bivariate unadjusted, mean (SD)	*P* value	Adjusted, mean (SE)	*P* value

Discussion

Primary Findings

Our findings indicate that three psychological factors—trait reactance, COVID-19 conspiracy beliefs, and COVID-19 apocalypse beliefs—were associated with key COVID-19 outcomes, all in the hypothesized direction. In unadjusted analyses, individuals scoring higher on trait reactance, COVID-19 conspiracy beliefs, and COVID-19 apocalypse beliefs reported lower protective behaviors and lower COVID-19 knowledge. With the exception of apocalypse beliefs and the protective behaviors index, all of these bivariate associations remained significant after adjustment for age, gender, race, income, education, religiosity, and political party. Although the three novel predictors were all correlated (ranging from 0.31 to 0.51), the magnitude of these correlations suggest that they tap largely independent dimensions of personality and attitude.

These findings have significant implications for both understanding who may adopt COVID-19 protective behavior and how intervention messages might be tailored to accommodate or counter these beliefs. With regard to reactance, our findings indicate that a subset of the US population reflexively rejects the adoption of COVID-19 protective behaviors due to a general predisposition to act in the opposite direction of authority or resist any rules or public health recommendations they feel infringe upon their personal freedom. Individuals with this trait are prone to feeling their autonomy is being threatened by government regulations or public health recommendations and will restore their freedom by rejecting the recommended behavior or counterarguing with the content and source of related messages.

With regard to conspiracy beliefs, our findings indicate that a subset of the US population believes that government officials and the media inaccurately portray the *truth* about the COVID-19 epidemic, and those who possess these beliefs are less likely to adopt COVID-19 protective behaviors. Although

we did not specifically query this, it is likely this group would consider much of the mainstream media as *fake news*, making any data reports or behavioral guidelines suspect. Our findings are consistent with those of a recent study of 2501 British adults [14], which found that endorsement of COVID-19 conspiracy beliefs were significantly associated with lower self-reported adherence to recommended protective behaviors. These beliefs were also associated with general mistrust of government and authority, paranoia, vaccination conspiracy beliefs, religiosity, and climate change denial. There is a growing body of work showing an association between patterns of media consumption and endorsement of misinformation, including conspiracy beliefs. There is therefore a need to enhance media use skills and eHealth literacy in particular to help counter COVID-19–related misinformation [25,26].

Finally, individuals who believe that the COVID-19 epidemic is a signal that the end of times is nigh are less likely to adopt COVID-19 protective behaviors. Although the mechanism for this association merits elucidation, it seems plausible that individuals who believe in a coming apocalypse, particularly for those who believe they will be spared, might be less likely to adopt COVID-19 protective behaviors because, for this group, the ultimate outcome is viewed in a more positive light.

Intervention Implications

Designing tailored communication campaigns to encourage adoption of COVID-19 protective behavior for individuals who possess the beliefs we assessed poses substantial challenges. These individuals may be particularly immune to accepting new information and yielding their beliefs. The persistence of these beliefs may in part be due to having roots in deeper psychological attributes such as paranoia, mistrust, religious fundamentalism, or hostility. Health communication professionals may apply lessons learned from countering similar beliefs around climate change and vaccine hesitancy. One lesson learned from countering antivaccination beliefs is that simply providing corrective information not only may be ineffective but also could instigate further reactance, leading to entrenchment of antivaccine attitudes [27]. Thus, messages designed for individuals prone to reactance that minimize controlling language (eg, you must or you have to) and emphasize the individual's independence in adopting these behavioral recommendations may be more effective [28,29]. Messaging for those who possess conspiracy beliefs should similarly not assume that providing evidence contrary to these beliefs will alone alter behavior [29]. Other communication techniques such as *rolling with resistance*, a strategy used in motivational interviewing [30], which may manifest as agreeing or empathizing with some aspects of their belief system (eg, "the government is not always honest with the American people") should be considered. Messaging for those with apocalyptic beliefs may require using religious leaders as the message source and using scripture that would support the adoption of COVID-19 protection, perhaps as an act of kindness, respect, or following God's will. Interestingly, we found that higher scores of all three novel predictors were associated with lower COVID-19 knowledge, suggesting that lack of an accurate understanding of the virus may be driving some of these attitudes; although, it is also possible that these attributes may interfere with one's willingness or ability to seek and absorb accurate health information. Thus, efforts to improve COVID-19 knowledge among these subgroups, in particular designing messages that mitigate inherent resistance to absorbing and yielding to new information, may be an important part of the public health messaging strategy.

This paper provides insight that may inform public health communication efforts to reduce the transmission of COVID-19 among segments of the population that may not respond to general audience messages but whose adherence to recommendations are nonetheless needed to control the pandemic.

Limitations and Future Studies

Our data were cross-sectional, limiting directional inference. It is possible, for example, that behaviors might influence attitudes rather than the inverse. The sample was accrued entirely online, which introduces several potential sampling and response biases [31,32]. For example, our sample had a slightly lower percentage of non-Whites and a greater percentage of females and Democrats than the US population. Sample bias poses a lower threat to the validity of our findings, as we were primarily interested in exploring the association between variables rather than establishing the true prevalence of the attitudes and behaviors under study.

Our survey was administered on May 19-22, 2020. Late May appears to represent the high point of optimism about the pandemic in the United States compared to both the initial period of March and April and the second and third wave that occurred in October and November 2020. For example, according to the Gallup COVID Panel survey conducted late May 2020, the percentage of Americans who felt the COVID-19 situation was getting better was 42% [33]. Gallup had asked this question on several occasions between April and November, and this was approximately the peak for this variable for that period. The percentage feeling the situation was getting better began to drop sharply shortly after, hitting just 19% in June and remaining around only 20% through November 2020 [33]. Gallup similarly reported that, in early June, only 46% of Americans said they were very or somewhat worried about getting the virus compared to 58%-59% in July and August 2020 [34]. These data likely reflect optimism over what turned out to be short-lived falling infection and death rates during this period. These temporal patters are also reflected in data reported by the Pew Research Center, which found that in June 2020, 59% of Americans reported that they think the worst of the outbreak was still to come [35], compared to 73% who believed the worst was yet to come in April and 71% who reported the worst was yet to come in November 2020. Moreover, according to the Pew Research Center, the percent of Americans who reported wearing a mask or face covering all or most of the time when in stores and businesses over the past month was only 65% in June 2020 compared to 85% in August and 87% in November of 2020 [35]. How these background contextual factors and the specific timing of our survey administration might have impacted our results is difficult to determine. We acknowledge, however, that the pattern of our findings might have differed had we conducted our survey during times of greater overall

concern about COVID-19, higher rates of mask wearing, or more stringent lockdown restrictions. For example, during periods of greater perceived risk and more strict lockdowns, it is possible that the impact of the correlates we identified might have been attenuated, as they may have been overwhelmed by a greater concern of catching the disease. Alternatively, the strength of association might have been stronger in response to the increase in perceived risk and greater restrictions. We anticipate that future studies conducted during the COVID-19 period will elucidate the generalizability of our findings across the pandemic period.

There are other potential personality and attitudinal predictors of COVID-19 protective behaviors we did not measure including trait conspiracy orientation (we measured only COVID-19 conspiracy beliefs), mistrust of government, mistrust of science, paranoia, autonomy needs, independence, hostility, intelligence, media literacy, and vaccine hesitancy. How these constructs may relate to the three we focused on merits investigation. We did not query intentions regarding uptake of a potential future COVID-19 vaccine. Understanding how the factors identified here may also be associated with COVID-19 vaccine intentions merits investigation. Future studies are needed to replicate and extend our findings, including examination of how other psychosocial and demographic factors may interact with the three predictors we studied. Additionally, work is needed to determine how best to tailor messages, both on the group and individual level, based on these constructs.

Abstract

In the wake of the COVID-19 pandemic, the information stream has overflowed with accurate information, misinformation, and constantly changing guidelines. There is a great need for guidance on the identification of trustworthy health information, and official channels are struggling to keep pace with this infodemic. Consequently, a Facebook group was created where volunteer medical physicians would answer laypeople’s questions about the 2019 novel coronavirus. There is not much precedence in health care professional–driven Facebook groups, and the framework was thus developed continuously. We ended up with an approach without room for debate, which fostered a sense of calmness, trust, and safety among the questioners. Substantial moderator effort was needed to ensure high quality and consistency through collaboration among the presently >200 physicians participating in this group. At the time of writing, the group provides a much-needed service to >58,000 people in Denmark during this crisis.

Introduction

The world is currently facing a COVID-19 infodemic, and the immense information load complicates the identification of trustworthy health information [1]. The substantial growth of media sources has resulted in a dilution of relevant and reliable information. Because of the novelty and worldwide spread of COVID-19, we learn more about the virus every day and witness almost daily changes to the clinical recommendations. This is confusing for the public and for health care professionals. In April 2020, Limaye et al [2] called for health care professionals to accommodate this issue by building trust on social media. This viewpoint describes a novel eHealth literacy project in Denmark, where we have built a network of >200 volunteer medical physicians who provide up-to-date knowledge to a broad audience in a Facebook group with thousands of members.

Health Information on Social Media

The Internet has become the primary source of health information for many people despite difficulties in verifying the reliability of web-based clinical evidence [3,4]. The emergence of Web 2.0 has further reoriented advancements from top-down information distribution to platforms for collaboration, dialogue, and content-sharing. One of the most

significant components of Web 2.0 is social media platforms such as Facebook with approximately 2.4 billion users [5]. Since Facebook launched its community pages function in 2010, it became possible for people to create health-related groups, which have become larger interactive communities [6]. Web-based communities provide a space for social support, sharing of experiential data, and a collective voice [7]. Layperson-friendly explanations of medical terms help patients have more positive experiences when visiting their health care providers, thus improving the physician-patient relationship [8]. However, negative reactions from health care professionals toward patients' social media activity might negatively affect patient-physician symmetries [9]; this underlines the need for health care professionals to engage on social media platforms to facilitate a positive physician-patient dynamic.

Owing to the COVID-19 pandemic, many new communities have been established on Facebook; however, this is accompanied with the risk of large-scale sharing of misinformation. The bombardment of emotionally evoking information makes it difficult for individuals to distinguish between accurate information and misinformation [10]. Although Facebook is mainly a lay-driven platform, health institutions, patients' societies, and health care professionals are increasingly creating their own groups to interact with patients on the internet. As this is a rather new phenomenon, few studies have investigated the effect of Facebook groups created and moderated by health care professionals. Initial experiences indicate difficulties in establishing, disseminating, and scaling such networks on Facebook [11].

The Facebook Group

In response to the infodemic, the Facebook group "Spørg en Læge om Coronavirus," which literally translates to "Ask a Doctor About Coronavirus," was created on March 15, 2020, by authors EBO and AP (Figure 1) [12]. This group was conceived owing to the sudden rise in waiting times on acute-care telehealth services. The continuously expanding group contains 57,000 members (approximately 1% of the entire population of Denmark) at the time of writing.

Figure 1. A screenshot from the Facebook group, "Spørg en læge om coronavirus," which literally translates to "Ask a doctor about coronavirus.".

The rules of the group are conservative. Group members can post a question, and physicians with administrator privileges can either reject or accept the request and answer the question. Questions are of different types, spanning from basic knowledge on, for example, the biological, statistical, and epidemiologic aspects of the practical applications of the proposed guidelines to more complex existential questions on fear, the future, and hope. Approximately 30% of the incoming questions are rejected because they violate the group rules, such as those on politically motivated comments, weblinks to misinformation, and personalized health information. Rejections to requests are typically accompanied by an explanation. In parallel to the main group, where laypeople ask questions and physicians provide answers, we have a closed administrative physicians-only group to debate and share guidelines, news, and warnings against popular myths.

Running a group with >200 volunteer physicians takes active management. Early on, we realized that rules and structure were essential for all member physicians to feel safe. We selected a narrow approach without room for discussion related to the answers; when a physician has answered a question, the thread is closed for further commenting and unauthorized answers are deleted. This approach was selected owing to logistic reasons: it would be too time consuming for physicians to ensure the validity and relevance of the information posted freely in a

thread. Surprisingly, the response from the users has been overwhelmingly positive. The calm and safe nature of the short threads of only physician-validated answers has proven a valuable factor, indicating the need for authoritative sources as a supplement to existing peer groups on Facebook. Unfortunately, the very rigid format of the group limits dialogue with the questioner. Furthermore, the practice has caused accusations of censorship. In the second wave of the COVID-19 pandemic, an increasing number of coronavirus skeptic members, verified through simultaneous membership in known government-critical or coronavirus skeptic groups, have joined the group and accused the group of censoring critical voices when closing threads and rejecting questions violating the rules; specifically those questions that are rejected because they contain weblinks to misinformation.

The ongoing stream of new questions provides us with a fine-tuned barometer of trending topics including circulating misinformation. Insecure members ask the group about the reliability of these topics before official information channels respond to the misinformation. We noticed that the users are highly perceptive to any inconsistency in the answers from different physicians, and we quickly identify any disruption in the sense of safety and security among the users. Fear and insecurity are directly articulated in the questions and comments, which confirms that feeling safe and in control is key to being eHealth-literate [13].

Meeting this need with consistency, empathy, and patience in our answers demands a considerable degree of active community building among the volunteer physicians. Key administrators are easily approachable for debriefing and conflict resolution among member physicians. In addition, a closed forum is used to discuss news and challenging questions and for a more unrestricted and informal conversation; this creates a safe space for critical feedback. The closed forum and personal messages among the volunteer physicians contribute to a supportive peer interaction and foster genuine interpersonal connections. We have witnessed the evolution of close relationships between physicians, even though they have never met.

The quality of the answers provided in the group is ensured largely by the community of the volunteer physicians and the approximately 30,000 daily active users. All answers are provided by named physicians, and supervision is accessible at all hours in the closed forum. Furthermore, physicians read one another's answers and users are quick to notice errors or inconsistencies in the answers. Lastly, other professionals such as pharmacists, nurses, and engineers have contributed with nuance or correction to answers related to their respective fields. This informal web of quality control has proven to ensure a generally high quality, although this has not been formally validated.

Volunteer physicians were recruited mainly via already established Facebook communities for only physicians with Danish authorization and through snowballing recruitment. Once the workflow was established and the legal implications were clarified, we had a running proof of concept. This, in turn, made recruitment of doctors easier as many of them were hesitant to participate before seeing a working setup. We recruited physicians with all experience levels and specialties. All were subsequently verified through the Danish Authorization Registry and internal Facebook relations with other physicians. We have mobilized not only working physicians, but also those excluded from contributing to the COVID-19 workforce owing to sick leave, maternity or paternity leave, pregnancy, or quarantine, all of whom worked from home on their own conditions. This provides an indispensable workforce for the group and is meaningful to physicians marginalized in this crisis.

Users were recruited through sheer diffusion. We do not have any control over the outreach of our group. We initially shared our group in our personal networks, and the group has naturally grown since then. Some answers have been shared in public and private networks, in closed groups, or on Twitter, and some have even been shared by Instagram influencers, thus expanding the awareness of the group and the service we provide. This positively reflects the degree of trustworthiness our group has achieved; however, this also highlights a point of consideration among all physicians that for all answers they provide, they should withstand publication out of context.

Especially in the beginning of the COVID-19 pandemic, a large proportion of the questioners presented with insufficient eHealth literacy to navigate the information environment of the pandemic [13]. Answers to many questions are accessible on public information websites, but the ability to obtain proper and updated information and to apply the guidelines for activities of daily life has been inadequate. As the pandemic has progressed, the difficulty level of questions has risen, which suggests that public information sources have succeeded in further disseminating basic information on the novel coronavirus among the general public.

At the other end of the spectrum, we noticed that many questioners show a high degree of health and science literacy. Their questions on complex preliminary scientific discoveries are embellished with distortionary "clickbait" headlines, indicating their limitations in interpreting such complex data. Such diversity in the questions underlines a need for physicians of different backgrounds to answer different questions in different tones and temperaments. Consequently, the challenge of maintaining consistency in the answers coexists with the large diversity in the group of physicians.

Future Perspectives

The Facebook group, "Spørg en Læge om Coronavirus," was created to counteract misinformation and foster a feeling of safety during a stressful time. The group has received no funding; nonetheless, 57,000 unique members have joined, which indicates a need for this type of health service. This group demonstrates classic one-to-one counseling in combination with one-to-many communication where answers are visible to all members, thereby illustrating the current discourse of health communication. Currently, a news article can stimulate a personal discussion in the comments section (one-to-many communication becoming one-to-one communication), while a recording of an individual consultation can be distributed on social media platforms (one-to-one communication becoming one-to-many communication). One can thus argue that we here

illustrate a future health communication premise that awaits almost every physician.

This group provides a proof of concept of a new way for health professionals to communicate and interact with the general public on social media platforms. The group is inspired by other Facebook groups and provides a template replicable in other similar or related initiatives. The Faroe Islands have already created the group, “Spyr ein Lækna um Korona,” which emulates the original initiative [14].

Our growing experience provides unique insights into the potential of Facebook in health communication; however, we cannot ignore the possibility of the distinctive information-seeking environment of the COVID-19 pandemic providing a favorable foundation for dissemination and upscaling of information. The extent and the validity of research on a health professional–driven social media platform should be further explored, preferably through a multidisciplinary approach and with an array of methodologies. Such studies could investigate developments in behavior, eHealth literacy, professional identity, and impact on physician-patient-relationships. Such a platform could also provide insights into patient adherence, navigation of health services, experiences with new treatments, management of common and rare diseases, and peer collaboration and communication. Therefore, further studies in this area would be highly relevant, and insights from this group should be further explored.

On World Patient Safety Day (September 17, 2020), the group "Spørg en læge om coronavirus” received the Danish Patient Safety Award 2020 in recognition of its effort to promote health understanding and a sense of safety through knowledge. This group was never intended to be a research study; the research potential was only recognized months after its launch. This group is part of a spontaneous health professional–driven emergency response at a unique time point where all community members have stepped up to contribute to their community in any way they can. This would limit the research potential of the data but adds a distinctive value of authenticity.

Acknowledgments

This study was made possible by the more than 200 volunteer medical physicians who contribute on a daily basis, with thousands of answers now accessible to the general public in the Facebook group “Spørg en læge om coronavirus.” The group functions solely on a volunteer basis without having received any funding. JS has sponsored the article processing fee for this viewpoint article.

Authors' Contributions

EBO, AP, and DF are core administrators and initiators (EBO and AP) of the Facebook group and conceived this viewpoint. EBO, AP, NK, and DF drafted the manuscript. JS provided insights on the direction of the content. All authors critically revised and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: COVID-19 has challenged the resilience of the health care information system, which has affected our ability to achieve the global goal of health and well-being. The pandemic has resulted in a number of recent cyberattacks on hospitals, pharmaceutical companies, the US Department of Health and Human Services, the World Health Organization and its partners, and others.

Objective: The aim of this review was to identify key cybersecurity challenges, solutions adapted by the health sector, and areas of improvement needed to counteract the recent increases in cyberattacks (eg, phishing campaigns and ransomware attacks), which have been used by attackers to exploit vulnerabilities in technology and people introduced through changes to working practices in response to the COVID-19 pandemic.

Methods: A scoping review was conducted by searching two major scientific databases (PubMed and Scopus) using the search formula "(covid OR healthcare) AND cybersecurity." Reports, news articles, and industry white papers were also included if they were related directly to previously published works, or if they were the only available sources at the time of writing. Only articles in English published in the last decade were included (ie, 2011-2020) in order to focus on current issues, challenges, and solutions.

Results: We identified 9 main challenges in cybersecurity, 11 key solutions that health care organizations adapted to address these challenges, and 4 key areas that need to be strengthened in terms of cybersecurity capacity in the health sector. We also found that the most prominent and significant methods of cyberattacks that occurred during the pandemic were related to phishing, ransomware, distributed denial-of-service attacks, and malware.

Conclusions: This scoping review identified the most impactful methods of cyberattacks that targeted the health sector during the COVID-19 pandemic, as well as the challenges in cybersecurity, solutions, and areas in need of improvement. We provided useful insights to the health sector on cybersecurity issues during the COVID-19 pandemic as well as other epidemics or pandemics that may materialize in the future.

health care; security incidents; root causes; cybersecurity challenges; cybersecurity solutions; COVID-19; pandemics

Introduction

Background

COVID-19 has been an unprecedented challenge for the global health care system. It has further challenged the resilience of the health information system, which has affected our ability to achieve the global goal of health and well-being. The sector has become a primary target of adapted cybersecurity attacks [1,2]. To manage the pandemic and this extraordinary situation, the health sector has shifted its focus from the security of their systems and practices to their primary duty of delivering health care in order to save lives, placing themselves in a vulnerable situation. Attackers are taking advantage of the COVID-19 pandemic and have launched a number of cyberattacks against health care organizations [3-8]. Recent cyberattacks have impacted health care organizations such as Brno University Hospital [3], the US Department of Health and Human Services [4], the World Health Organization (WHO) [5], Gilead Sciences, Inc [6], hospitals in Romania [7], as well as the general supply chain of the health sector [8]. The health sector must be prepared to counteract cyberattacks in order to protect the availability of essential health care services as well as the confidentiality and integrity of health care information.

Cybercrime adapts to changes in the world situation very quickly. At the beginning of an escalation in the COVID-19 pandemic, malware cyberattackers identified common vulnerabilities and adapted their attacks to exploit these vulnerabilities. The current situation in the United Kingdom and worldwide provides a fertile breeding ground for various cyberattacks [9]. Cyberattackers are leveraging the increased reliance on remote working, decreased mobility, and the closure of borders between different countries, and the heightened demand for personal protective equipment (PPE) such as masks and gloves. The complex health care supply chain is also a target [10]. As a result, greater fear, uncertainty, and doubt is being experienced by the general population.

Rationale

There is some research reviewing the literature on cybersecurity in the health sector. Jalali et al [11] performed a systematic review of the literature on cybersecurity response plans in health care. Coventry et al [12] conducted a narrative review on trends in cyber threats and ways forward in the health sector. Kruse et al [13] systematically reviewed health care–related cyber threats and trends. Offner et al [14] reviewed cyber threats and mitigation strategies among Australian health care organizations. Sardi et al [15] performed a systematic review of cyber risk in health facilities. However, there is limited research on an in-depth review and analysis of key cybersecurity challenges and solutions, specifically in the health sector, in the context of a pandemic situation such as COVID-19.

Objective

Through a scoping review, this paper aims to identify the most prominent and significant methods of attack and threats that have affected the health sector during the COVID-19 pandemic, cybersecurity challenges, solutions, and areas that require further improvement. This research covers not only security-related matters as a result of the COVID-19 pandemic but also discusses inherent security challenges in health information systems that can be potentially exploited by attackers during the COVID-19 pandemic. It has implications for the whole spectrum of the health sector as a result of the increase in cybersecurity risks such as phishing, ransomware, and distributed denial-of-service (DDoS) attacks during the coronavirus crisis and in the long term.

Methods

Protocol and Registration

The review was performed according to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist, proposed by the Joanna Briggs Institute [16]. The aim of this review is to identify health sector cyberattacks, security challenges, and solutions. Before undertaking this review, a protocol was created detailing sources of information, search strategies, eligibility criteria, source selection, and data charting processes. The PRISMA-ScR checklist is presented in Multimedia Appendix 1.

Information Sources

A search of two major scientific databases (PubMed and Scopus) was performed to identify relevant articles. These include both original research articles and review articles.

Search

The search formula “(covid OR healthcare) AND cybersecurity” was used to search for articles. The articles identified should have either a COVID-cybersecurity core or a healthcare–cybersecurity core.

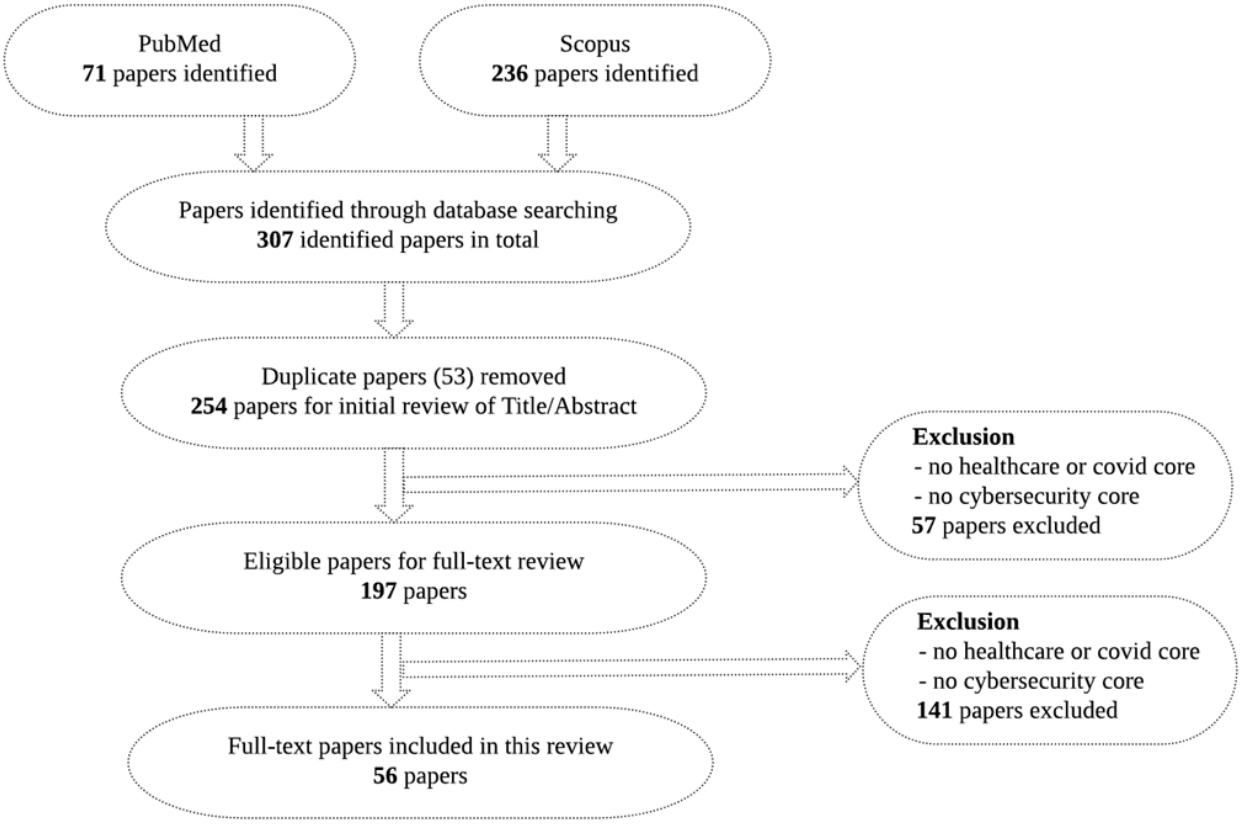
Eligibility Criteria

Only articles in English published in the last decade were included (ie, 2011-2020) in order to focus on current issues, challenges, and solutions. Reports, news articles, or websites were also included only when they are related directly to previously published work, or they were the only currently available information source at the time of manuscript preparation. Inclusion criteria were as follows: (1) relevance to health care cybersecurity and (2) coverage of well-discussed cybersecurity issues, challenges, and solutions.

Selection of Sources of Evidence

The selection process is illustrated in Figure 1. The results of the search were exported to the EndNote library. The title and abstract of each paper were analyzed by 2 of the authors to assess eligibility. In cases in which this was not obvious, all 4 authors examined the paper and, when necessary, read it to assess relevance. A total of 307 identified papers were screened and 53 duplicates were removed. An additional 57 papers were excluded for not focusing on the healthcare–cybersecurity core or the COVID-cybersecurity core in the abstract. Another 197 papers were excluded for lacking these cores in the full text. In total, 56 papers were included in the review.

Figure 1. Flowchart showing the article identification and selection process.



Data Charting Process

The data were extracted and stored in a standardized Microsoft Excel (Microsoft Corp) form. This was an iterative process whereby the charting table is continually updated. Data charting was carried out both independently and collectively by at least two authors to ensure the quality of the extracted key findings from the literature before being used in the analysis.

Data Items

Key data items, including title, abstract, authorship, aims, key findings related to the review objectives, evidence document, document type, year of publication, and location, were extracted.

Critical Appraisal Within Sources of Evidence

Although the Joanna Briggs Institute suggests that the critical appraisal is usually not needed for a scoping review, we had at least 2 authors check the quality of the source of evidence to ensure they were relevant, up to date, and from reputable sources. In cases in which this was not obvious, all 4 authors assessed the sources.

Synthesis of Results

By aggregating information from the selected literature, the results were analyzed and qualitatively presented in both tabular and descriptive formats (grouped into themes), which aligned with the objective and scope of the review.

Results

Four themes were observed across the selected literature: (1) health sector condition changes due to COVID-19, (2) health care cyberattacks during the COVID-19 pandemic, (3) health care cybersecurity challenges, and (4) health care cybersecurity controls.

Health Sector Condition Changes Due to COVID-19

The findings pertaining to changes in conditions in the health sector as a result of COVID-19 are summarized in Table 1. The main changes to health services caused by the COVID-19 pandemic include decreased mobility, border closures, and the increasing reliance on remote work, often carried out with little previous experience and planning. These conditions have made the health sector more vulnerable to potential cyberattacks [1,2,17].

Table 1. Health sector condition changes due to COVID-19.

Changes	Reference
The decreased mobility and border closures, and the increasing reliance on remote work, create challenges to health sector	Hakak et al [1], Williams et al [2], Schneck [17]
New technologies such as eConsultation services for patients and electronic multidisciplinary teams leave users open to a variety of attacks	Weil and Murugesan [18]
Health service staff often have limited experience in working remotely, leaving the sector vulnerable to cyberattacks, such as malwares	Boddy et al [9], Offner et al [14], Jalali et al [19], Hoffman [20], Ronquillo et al [21]
The health care industry significantly lags behind other industries in terms of cybersecurity and digital literacy is lacking among staff working from home, making it a prominent target	Sardi et al [15], Kim et al [22]
The increase in demand for certain goods such as PPE[a] makes health services and governments exposed to digital scams such as luring emails with the intention of stealing sensitive information	Schneck [17]

[a]PPE: personal protective equipment.

As health staff and patients are restricted in terms of movement due to the lockdown, the decrease in mobility and border closures make individuals and organizations turn to technology to provide essential health services such as appointments, diagnosis, and even operations. Examples are the use of eConsultation (electronic consultation) services for patients and electronic multidisciplinary teams. Although these technologies have their advantages, they leave users and receivers of these technologies open to a variety of attacks such as phishing campaigns and ransomware attacks [18].

Furthermore, health services staff often have limited previous experience with remote working and with planning for this change, which leaves the sector vulnerable to cyberattacks [9,14,19]. As health services make use of a variety of medical devices, interconnectivity and interoperability create issues as they are now being accessed from outside health services' internal network perimeter. The medium and mode of access creates problems as access to the sensitive parts of health services can be reached via unsecured network connections or unpatched systems by staff working remotely [19]. In addition, some medical devices use off-the-shelf software, such as commercial operating systems (eg, older versions of Windows). These systems are vulnerable to a large variety of threats such as malware, ransomware, etc [20,21]. Overall, the health care industry significantly lags behind other industries in terms of cybersecurity and coupled with a lack of digital literacy among staff mostly working from home, makes it a prominent target [15,22].

Additionally, the increase in demand for certain goods such as PPE and other protective merchandise such as masks, gloves, etc, are exposing health services and even governments to digital scams, especially in the form of phishing attacks. As health services are in need of these essential items, they can be targeted by adversaries via luring emails with the intention of stealing sensitive information [17].

Health Care Cyber Attacks During the COVID-19 Pandemic

Multiple cyberattacks occurred at the beginning of the global COVID-19 pandemic (early 2020) in the health sector. We selected well-documented cyberattacks with detailed information available, including root causes and consequences. The main findings are summarized in Table 2.

Table 2. Security incidents during the COVID-19 pandemic.

Security incidents	Type of attack	Impact
Brno University Hospital [3]	Ransomware	Postponement of surgeries, appointments, etc
US Department of Health and Human Services [4]	Distributed denial of service	Disruption to COVID-19 pandemic responses
World Health Organization [5]	Ransomware/phishing	Defacement and misinformation
Gilead Sciences, Inc [6]	Phishing	Impersonation and exfiltration
Hospitals in Romania [7]	Phishing/ransomware	Disruption and exfiltration
Health care supply chains [8]	Malware	Disruption of activities

Brno University Hospital in the Czech Republic, which is one of the country's main COVID-19 testing centers, was struck by ransomware, resulting in the postponement of surgeries. The ransomware infection was confirmed in the early hours of the day when the hospital decided to disconnect all computer networks. It was noticed that the ransomware infection was gradually replicating, and all the individual systems were failing. As a result, all computers had to be shut down. The hospital is reported to be still recovering capabilities, as it is not yet fully operational due to the attack [3]. The attack had an impact on the activities of the hospital as there was no database systems, that is, means of storing data; hence, staff have had to write and transfer their notes manually. This leads to slow processes and can potentially endanger lives in these trying times.

The US Department of Health and Human Services experienced a DDoS attack intended to disrupt the organization's responses to the COVID-19 pandemic. This attack targeted its servers by overloading it with millions of hits over several hours [4]. It was reported as a campaign of disruption aimed at hindering the response to the coronavirus pandemic as the targeted agency was tasked with protecting the health of citizens and delivering essential human services. Although the agency claimed the attack was not successful, and that the attackers did not infiltrate the internal network nor steal any data, this demonstrates that attacks like these can cause damage not just to the services of health agencies but also to the lives that depend on it, especially in times of emergencies.

Increased phishing website hacking attempts on the WHO and its partners led to the WHO putting out a warning to the general public to be more careful [5], as it has been reported that over 4000 coronavirus-related domains (ie, domains that contain words like "corona" or "covid") have been registered since the beginning of 2020. These registered domains were used by adversaries for phishing-related activities. Thus, the WHO incident was orchestrated by hackers in order to steal passwords. It was reported that a group of hackers created a malicious website posing as an email login portal for WHO employees in an attempt to steal their passwords. Although the WHO claims the attack was not successful, it still shows that phishing attacks can be leveraged to target health organizations.

Coronavirus vaccine manufacturer Gilead Sciences, Inc, was also targeted by hackers [6]. Staff at this pharmaceutical company were targeted via a fake email login page that was designed to steal passwords. It was reported that the attack was an attempt to compromise the email accounts of staff at the company using messages that impersonated journalists.

Hospitals in Romania experienced ransomware attacks by hackers as well [7]. The hackers were planning to use COVID-19–themed emails to infect these hospitals with ransomware. Their motivation was the protest against the COVID-19 quarantine measures of the country. The hackers owned malwares (eg, remote access trojans, ransomware, website defacements, and SQL injection tools) that can be used to bring down servers and steal information. It was reported that they intended to send emails about COVID-19 to hospitals to infect computers, encrypt files, and disrupt hospital activities. However, the attack was not as successful as the hackers were tracked down and arrested by Romanian law enforcement.

It has been reported that Interpol has cautioned agencies around the world about a significant rise in the global number of ransomware attacks explicitly targeting hospitals and health institutions [8]. It discovered that there was an increase in the number of attempted ransomware attacks on organizations in the 194 member countries. Additionally, a cyber warning was issued for key health care organizations involved in the coronavirus response both in the United Kingdom and the United States. A joint statement by the United Kingdom's National Cyber Security Centre (NCSC) and US Cybersecurity and Infrastructure Security Agency revealed that malicious cyber campaigns had been uncovered, with large-scale "password spraying" campaigns directed at health care bodies and medical research organizations in both nations [23].

Health care supply chains have not been omitted from these attacks; the US Federal Bureau of Investigation (FBI) issued a warning about a malware targeting this sector. The malware is called Kwampirs, a remote access Trojan that exploits network vulnerabilities of targeted organizations across the United States, Europe, Asia, and the Middle East [24]. The infected supply chain components included cyber-physical systems assets in health care organizations. The FBI alerted the health care sector against future cyberattacks, as Kwampirs have been historically targeting health care organizations.

The analysis of the above-mentioned incidents indicate that the health sector has become a primary target of cybersecurity attacks. Attackers are taking advantage of the COVID-19 pandemic and launching attacks, which are mainly ransomware, DDoS, phishing, and other type of malwares. The health care supply chain can be more vulnerable to cyberattacks especially during pandemics. The cyberattacks have resulted in negative impacts on the availability of essential health care services and challenged health care organizations in the protection of the confidentiality and integrity of health care information.

Health Care Cybersecurity Challenges

Selected papers discussing the main challenges of cybersecurity in the health sector were reviewed, and the main findings are summarized in Table 3.

Table 3. Key health sector security challenges and associated vulnerabilities.

Key challenges and published vulnerabilities	Reference
Remote work security assurance	
There are known security vulnerabilities with remote desktop protocols and virtual private networks	Argaw et al [10]
There are known attacks on health care system such as distributed denial-of-service attacks, malware, etc	Offner et al [14]
Cyberattacks target innumerable wireless connected devices in health care	Boddy et al [9]
Endpoint device management	
An endpoint device can provide an entry point to larger health care networks	Coventry et al [12]
The integration of new endpoint devices with outdated, legacy, or unsupported operating systems compromises interoperability and increases cybersecurity vulnerability	Kruse et al [13], Naidoo [25]
The health sector relies heavily on perimeter defense (antivirus, firewalls) for protection against cyber risk	Reagin and Gentry [26]
The factor that most influences cybersecurity in a hospital is endpoint complexity	Jalali and Kaiser [27]
Human factors in cybersecurity	
The majority of information security incidents are related to human error	Evans et al [28], Evans et al [29]
There is a statistically significant positive correlation between workload and the probability of health care staff opening a phishing email	Jalali et al [19]
The health sector lacks root cause analysis and cybersecurity incident prevention, especially those through unintentional human error	Evans et al [28], Evans et al [29]
Although some effort has been made to analyze human error (eg, use of IS-CHEC[a]), such approaches have not been widely adopted	Evans et al [30]
Lack of security awareness	
There is low awareness in the health sector of cyber risks	Gordon et al [31]
The most common action taken in response to breaches or attacks is additional staff training or communication	Furnell and Shah [32]
Health staff has poor awareness of consequences of behavior, and there is a lack of policies and reinforcement of secure behavior	Coventry et al [33]
There is a lack of pandemic-specific cybersecurity training campaigns, documented procedures, and guidance on revised procedures and technologies	Kaplan [34]
Inadequate board-level risk assessment communication	
There is a need for a matrix that can translate the strategic requirements of a health care system into prioritized cyber improvement needs	Barad [35]
There is a lack of understanding of security risks and its impact on organization-wide risk management	Tully et al [36]
There is a lack of appreciation among health care executive management of the business risk impact associated with cyber breaches	Jones and Katzis [37]
Inadequate business continuity plans	
Risks will continue to grow if cybersecurity is not designed into the product from the beginning of the product or project life cycle	Coventry and Branley [12]
The key security risks challenging business continuity are vendor dependence, inappropriate encryption configurations, and the inability to handle health information sharing and exchange with third-party and cross-border partners	Frontoni et al [38], Bhatia and Ibrahim [39], Natsiavas et al [40], Nalin et al [41]
The health sector lacks sophisticated data security tools compared to other industries	Walker-Roberts et al [42]
Cybersecurity capability is a strategic asset that every health organization must adopt, along with the concepts of building organizational resilience and the capacity to learn from mistakes	Jalali et al [11], Reagin and Gentry [26]
Lack of coordinated incident response	
The health sector tends to have a time lag between an attack occurring and detection of the breach	Coventry and Branley [12]
Current health care cyber defense is often reactive and undertaken after malicious attacks	Akinsanya et al [43]

Key challenges and published vulnerabilities	Reference
There is a lack of a coordinated incident response capacity to actively counteract constantly emerging and evolving malware threats	Chen et al [44]
Cybersecurity should be a team effort, from board members to front-line employees, with all being held accountable for cybersecurity	Pullin [45]
Limited budget and the need to deliver health care services without disruption	
There is a lack of experienced cybersecurity experts in the health care industry	Argaw et al [46]
There is a lack of a value-based system to weigh and balance benefits and risks in aspects of security, privacy, and adoption of technology	Boddy et al [9]
Vulnerable MCPS[b]	
Limited MCPS capability makes the health sector vulnerable to compromises	Almohri et al [47]
The reliance on the health care network increases cybersecurity risks to health care systems	Zheng et al [48]
Cyber threats can be introduced to the MCPS though vulnerable IoT[c] devices	Jimenez et al [49]

[a]IS-CHEC: Information Security Core Human Error Causes.

[b]MCPS: medical cyber-physical systems.

[c]IoT: internet of things.

The analysis shows that the main cybersecurity challenges of the health sector are remote work security assurance, endpoint device management, human errors, the lack of security awareness, inadequate senior-level security risk assessment, inadequate business continuity plans, the lack of coordinated incident response, constrains on budget and resources, and vulnerability of medical systems. These challenges cover not only the security-related matters as a result of the COVID-19 pandemic but also the inherent security challenges in the health sector that can be potentially exploited by attackers during the COVID-19 pandemic. It is imperative for the health care organizations to identify these challenges and take actions for prevention.

Remote Working Security Assurance

As remote working is now an integral element of health care service delivery, health staff are relying on enterprise remote desktop protocols and virtual private networks (VPN) to access internal networks. However, these come with certain risks that adversaries are looking to exploit. For example, the remote desktop protocol has a history of security issues and generally should not be publicly accessible without additional protections such as firewall, whitelist, and multifactor authentication [10]. Likewise, VPNs also have some known and unknown vulnerabilities, both on the client and server side, which have been exploited for years by cybercriminals [19]. The DDoS attacks on health care systems [14] and the innumerable wireless connected devices [9] have created further challenges to a remote work environment.

Endpoint Device Management

A number of endpoint devices, which comprises various patient-monitoring equipment that either connects to the internet or legacy-dispersed networks, are often unpatched [12]. This risk further increased during the pandemic as a result of organizations competing to procure internet of things (IoT) devices during the COVID-19 pandemic for their staff, which resulted in more employees than before using personal devices to perform work from home. From an enterprise architecture perspective, having tighter integration across the information technology (IT) environment is positive in terms of the organization being more agile; however, it makes the network vulnerable to cyberattacks such as email phishing, ransomware, DDoS, and network data breaches [13]. The integration of new endpoint devices with outdated legacy systems can increase vulnerabilities [13,25]. However, organizations overly rely on perimeter defense (antivirus, firewalls) and other forms of basic protection against cyberattacks [26]. By interviewing 19 C-Suite cybersecurity professionals, Jalali et al [27] also confirmed the factor that most influences cybersecurity in a hospital setting is endpoint complexity.

Human Factors in Cybersecurity

Existing research has shown that the majority of information security incidents are related to human error [28]. There is a tendency for human error when staff are busy focusing on saving lives and adjusting to new work environments and technologies. With sudden changes in working practices, being under stress for an extended period of time makes employees vulnerable to falling into malicious trickery and making mistakes [28]. According to Jalali at al [19], there is a statistically significant positive correlation between workload and the probability of a health care staff opening a phishing email. Naidoo et al [25] developed a multilevel influence model to explore how cybercriminals exploited the COVID-19 pandemic using social engineering techniques. However, the health sector lacks root cause analysis [28] to prevent human error related security incidents, especially those through unintentional human error [29]. Although some efforts have been made in applying the human reliability analysis technique in the context of information security (eg, Information Security Core Human Error Causes [IS-CHEC] [30]) to analyze human error, such approaches have not been widely adopted.

Lack of Security Awareness

Cybercriminals are exploiting people's anxieties during the COVID-19 pandemic. Gordon et al [31] identified that there is low awareness in the health sector of risks. Furnell et al [32] identified that the most common action taken in response to the most disruptive breaches or attacks is additional staff training or communication. Coventry et al [33] reported that health staff had poor awareness of the consequences of certain behaviors, and there is a lack of policies and reinforcement of secure behavior. However, increased cybersecurity awareness is required for the health sector to protect themselves and their patients from potential cyber threats such as phishing and ransomware. Due to the lack of prior planning and training to work under pandemic situations, health care staff require more training and support, such as pandemic-specific cybersecurity training campaigns, documented procedures, and guidance on revised procedures and technologies [34]. For example, health sector staff should be made aware of and able to flag phishing emails containing buzzwords during a pandemic, such as "WHO" or "donation." They should also be advised on how to validate trustworthy information sources in order to avoid ransomware attacks [1].

Inadequate Board-Level Risk Assessment Communication

There is a lack of understanding of security risks and its impact on organization-wide risk management, such as impacts on patient care and clinical outcomes [36]. The health sector lacks a matrix that can translate the strategic improvement needs of a health care system into prioritized information/cyber improvement needs [35]. Schwartz et al [37] identified that there is a lack of appreciation among health care executive management staff of the business risk impacts of cyber breaches.

Inadequate Business Continuity Plans

The health sector does not have enough data protection mechanisms; Walker-Roberts et al [42] confirmed that the health sector lacks sophisticated data security tools compared to other industries. Security is not built into its supply-chain and third-party vendors. Existing research shows that the key security risks challenging business continuity are vendor dependence, inappropriate encryption configurations, and the inability to handle health information sharing and exchange with third-party and cross-border partners [38-41]. Risks will continue to grow if cybersecurity is not integrated into the project life cycle from the beginning [12]. Cybersecurity capability is a strategic asset that every health organization must adopt, along with the concepts of building organizational resilience and the capacity to recover from incidents and learn from mistakes in order to maintain business continuity [11].

Lack of Coordinated Incident Response Involving Different Parties

As highlighted by Coventry and Branley [12], the health care sector has a exhibited a trend of having a time lag between the occurrence of an attack and its detection. In fact, this aids attackers by giving them more time to explore the network and conduct lateral movement, which increases the damage inflicted by security breaches. Current health care cyber defense response is often reactive and undertaken after malicious attacks [43], lacking a coordinated incident response capacity to counteract constantly emerging and evolving malware threats [44]. The failure of health care organizations in having a successful and secure backup mechanism in place makes it frail in terms of incident response and recovery [12]. Pullin et al [45] also confirmed that cybersecurity should be a team effort, with everyone from board members to front-line employees being held accountable for cybersecurity.

Limited Budget and the Need to Deliver Health Care Services Without Disruption

Although health care services are spending funds to become more integrated to deliver health care services without disruption [9], the necessary emphasis is not given to the security aspect in terms of upkeep (eg, keeping software updated and systems secure). However, this is reported to be due to a shortage in experienced cybersecurity experts within health care organizations with the required skills and experience to enable health care organizations to change their business operations at significant pace without undertaking the "usual" levels of cybersecurity assurance [46]. Boddy et al [9] identified the needs of a value-based system to weigh and balance the benefits and risks in aspects of security, privacy, and adoption of technology.

Vulnerable Medical Cyber-Physical Systems

Cybersecurity measures such as vulnerability scans or patch management are often not available or only possible by manufacturers [49]. Their basic limited capability makes them vulnerable to compromise [47]. Cybersecurity measures such as vulnerability scans or patch management are often not available or only accessible for manufacturers. Moreover, their connection and reliance upon the health care network significantly increase the cybersecurity risk to the entire health care system [48]. With the widespread use of IoT medical devices, cyber threats can be introduced to medical cyber-physical systems though vulnerable IoT devices [44].

Health Care Cybersecurity Controls

Selected papers discussing cybersecurity solutions present within the health sector were reviewed, and the main findings are summarized in Table 4.

Table 4. Crucial health sector security solutions.

Solution	Reference
Apply endpoint device management tools	
Apply perimeter-based defense (antivirus, firewalls) for protection against cyberattacks	Reagin and Gentry [26]
Restrict the technologies and devices used by health staff to remain compliant with security regulations such as HIPAA[a] during pandemics	Hoffman [20]
Adapt the NIST[b] approach to manage security IoT[c] medical devices	Kelly et al [50]
Secure the remote work environment	
Apply multifactor authentication	Argaw et al [10]
Apply a chaotic map–based authenticated security framework for remote point of care	Deebak et al [51]
Apply remote access monitoring such as the NHS[d] attack surface reduction rules	Zorz [52]
Apply perimeter security solution such as NHS Secure Boundary to enable secure access	NHS Digital [53]
The health care sector needs to ensure data protection mechanisms for securing system access and transmitting data	Rezaeibagha et al [54]
Raise security awareness	
Apply a holistic, integrated approach to improve staff awareness, competence, and mitigation of threats	Pullin [45], Sedlack [55]
Implement cybersecurity training programs and cybersecurity awareness campaigns	Gordon et al [56]
Apply the NCSC's[e] Board Toolkit to raise board-level security awareness	NHS Digital [57]
Provide comprehensive employee training and education to enable the identification and assessment of risks	Alzahrani [58]
Implement a positive organizational climate to influence people's behavior	Kessler et al [59]
Ensure business continuity	
Apply a self-assessment tool such as the NHS Data Security and Protection Toolkit	NHS Digital [60]
Embrace cybersecurity and a develop strong culture of cyber vigilance	Dameff et al [61]
Ensure business continuity through data backups, intrusion detection, and prevention systems	Rezaeibagha et al [54]
Apply a systematic risk assessment of the impacts on health care business operations	Kim et al [22]
Consider cybersecurity insurance in health care	Kabir et al [62]
Apply technical controls	
Apply network segmentation to isolate network traffic	Hakak et al [1]
Apply general technical controls including encryption, authentication, and authorization	Yaseen et al [63]
Apply homomorphic encryption that ensures strong security and privacy guarantees while enabling analysis of encrypted data and sensitive medical information	Raisaro et al [64]
Apply blockchain to facilitate health care interoperability	Narikimilli et al [65]
Apply cryptographic security to address data sharing and storage of patient information across network systems	Pussewalage and Oleshchuk [66]
Policies and legislations	
Laws and regulations can help to combat the issues of medical cyber-physical systems	Raisaro et al [64]
Security instructions and control designs should be tailored	Wang and Jones [67]
Regulatory changes or manufacturers should become more security-minded in the medical device design phase	Department of Health and Social Care, UK Government [68]
Policymakers may need to alter policies to allow new technological innovations to be applied to health care	Bhuyan et al [69]
The US Congress passed the 21st Century Cures Act to promote patient control over their own health information while protecting privacy and cybersecurity	Hoffman [20]
Incident reporting and cyber threat intelligence support	
NHS Digital issued two high-severity CareCERT alerts (BlueKeep and DejaBlue) and developed a high-severity alert process handbook to facilitate incident reporting and sharing	Department of Health and Social Care, UK Government [68]

Solution	Reference
Apply an evidence-based approach, such as the generic security template, for incident reporting and exchange	He and Johnson [70], He and Johnson [71]
Establish an international workforce to facilitate cyber threat reporting and exchange to combat pandemic-themed cyber threats	Hakak et al [1]
Cybersecurity guidance specific to COVID-19	
The NHS has added guidance on working from home securely in the context of COVID-19	NHS Digital [72]
The United Kingdom's Information Commissioner's Office created an information hub to assist individuals and organizations to manage data protection during the COVID-19 pandemic	Information Commissioner's Office [73]

[a]HIPAA: Health Insurance Portability and Accountability Act.

[b]NIST: National Institute of Standards and Technology.

[c]IoT: internet of things.

[d]NHS: National Health Service.

[e]NCSC: National Cyber Security Centre.

Apply Endpoint Device Protection

During the COVID-19 pandemic, health staff working from home may adopt telehealth technologies or IoT devices. This increases cybersecurity risks, as it expands the footprint for cyberattack to the use of new devices outside of the service providers' network [50]. Health staff are advised to restrict the technologies and devices they used to remain compliant with security regulations such as Health Insurance Portability and Accountability Act during the pandemics [20]. However, health care organizations mainly reply on perimeter defense (eg, antivirus, firewalls) for protection against the potential cyberattacks [26]. The National Institute of Standards and Technology (NIST) has recently released a draft security guide and recommendations for managing the security IoT devices, but it is unclear whether it will be enforced across the health sector [50].

Secure Remote Work Environment

Existing solutions include the use of multifactor authentication and the monitoring of the log activity of user accounts and revoking account access if no longer needed [10]. Deebak et al [51] proposed a chaotic map–based authenticated security framework for remote point of care. Health organizations such as those in the United Kingdom have started using services to monitor their remote access infrastructure constantly and to investigate anomalies. For example, the National Health Service (NHS) has employed attack surface reduction rules (eg, block macros, executable content, process creation) [52]. Furthermore, a more recent NHS Digital service, Secure Boundary, was introduced as a perimeter security solution to enable secure access for NHS staff and to provide security monitoring [53].

Raise Security Awareness

Health care organizations already have cybersecurity programs in place to increase levels of security awareness [45,55]. Existing solutions include the use of cybersecurity training programs and cybersecurity awareness campaigns [56]. In a cybersecurity campaign, the IT department sends out fake phishing emails to their staff and provides further training to those who fail to identify these emails [56]. In the United Kingdom, more than 100 NHS boards have completed cybersecurity training accredited by the Government Communications Headquarters since the WannaCry attack. Furthermore, the NCSC's Board Toolkit for the NHS provides additional information on ransomware and backups. NHS Digital also runs a cyber awareness campaign called the Keep I.T. Confidential campaign. Over 340 organizations have downloaded the materials since its launch in September 2019 [57]. However, there is not enough work on training programs tailored to the pandemic such as COVID-19–themed social engineering, although the world is realizing the importance of raising the awareness of COVID-19–related cyberattacks [58]. Existing research shows that positive organizational climate can influence people's behavior [59].

Ensure Business Continuity

Health care leadership must embrace cybersecurity and develop strong cultures of cybervigilance [61]. The health sector already has business continuity solutions in place such as data backups and intrusion detection and prevention systems [54]. NHS trusts have been asked to follow and meet the Cyber Essentials and government standards. NHS Digital has launched a Data Security and Protection Toolkit [60], a self-assessment tool for organizations that need to access NHS patient information and systems. The toolkit must be applied to ensure that organizations practice good cyber hygiene. Security risk assessment is essential to ensure business continuity. Kim et al [22] systematically assessed the impacts of cybersecurity threats on remote health care. Cybersecurity insurance in health care [62] should also be considered as a solution to ensure business continuity management, but it has not been widely adopted.

Apply Technical Controls

General technical controls applied by the health sector include encryption, authentication, and authorization to protect data from cyber threats [63]. Cryptographic security is used to address data sharing and storage of patient information across network systems [66]. Homomorphic encryption is applied to ensure robust security and privacy guarantees while enabling analysis of encrypted data and sensitive medical information [64]. Blockchain is also applied to facilitate health care interoperability due to its immutability, transparency, and decentralization [65]. Network segmentation and isolation also

need to be considered by the health sector [1]. With network segmentation, network traffic can be isolated and/or filtered to limit and/or prevent access between network zones. For example, in case of systems compromise, one should freeze any activity in the system, disconnect the infected machines from any external drive or medical device, and go offline from the network.

Policy and Legislation

The health sector already has security policies and legislation in place for cybersecurity management. Laws and regulations are available to protect medical cyber-physical systems [64]. Security controls need to be tailored according to regulation [67]. Manufacturers are also required to consider these regulations to design medical devices [68]. However, policymakers may need to alter policies to allow new technological innovations to be applied to health care [69]. The US Congress passed the 21st Century Cures Act to promote the interoperability of electronic health records and promote more patient control over one's own health information while protecting privacy and cybersecurity [20]. However, more efforts are needed on security policies or legislations in handling cybersecurity-related matters during pandemics like COVID-19.

Incident Reporting and Cyber Threat Intelligence Support

The health sector is required to report cybersecurity incidents to a supervisory authority, such as the national Computer Security Incident Response Team in the European Union. In the United Kingdom, there is government-approved support from the NCSC. NHS Digital has issued two high-severity CareCERT alerts in 2019 (BlueKeep and DejaBlue). After developing a high-severity alert process handbook, remediation went from 18 weeks for BlueKeep down to 3 weeks for DejaBlue [68]. He and Johnson [70,71] proposed a generic security template, which is an evidence-based argumentation approach to facilitate incident reporting and exchange. This approach was applied to a health care organization but has not been widely adopted. Hakak et al [1] identified the needs of establishing an international workforce to facilitate threat reporting and cyber threat intelligence (eg, attack vectors and countermeasures) exchange to combat pandemic-themed cyber threats. The health sector will benefit from such practices during pandemics in order to avoid similar incidents.

Cybersecurity Guidance Specific to COVID-19

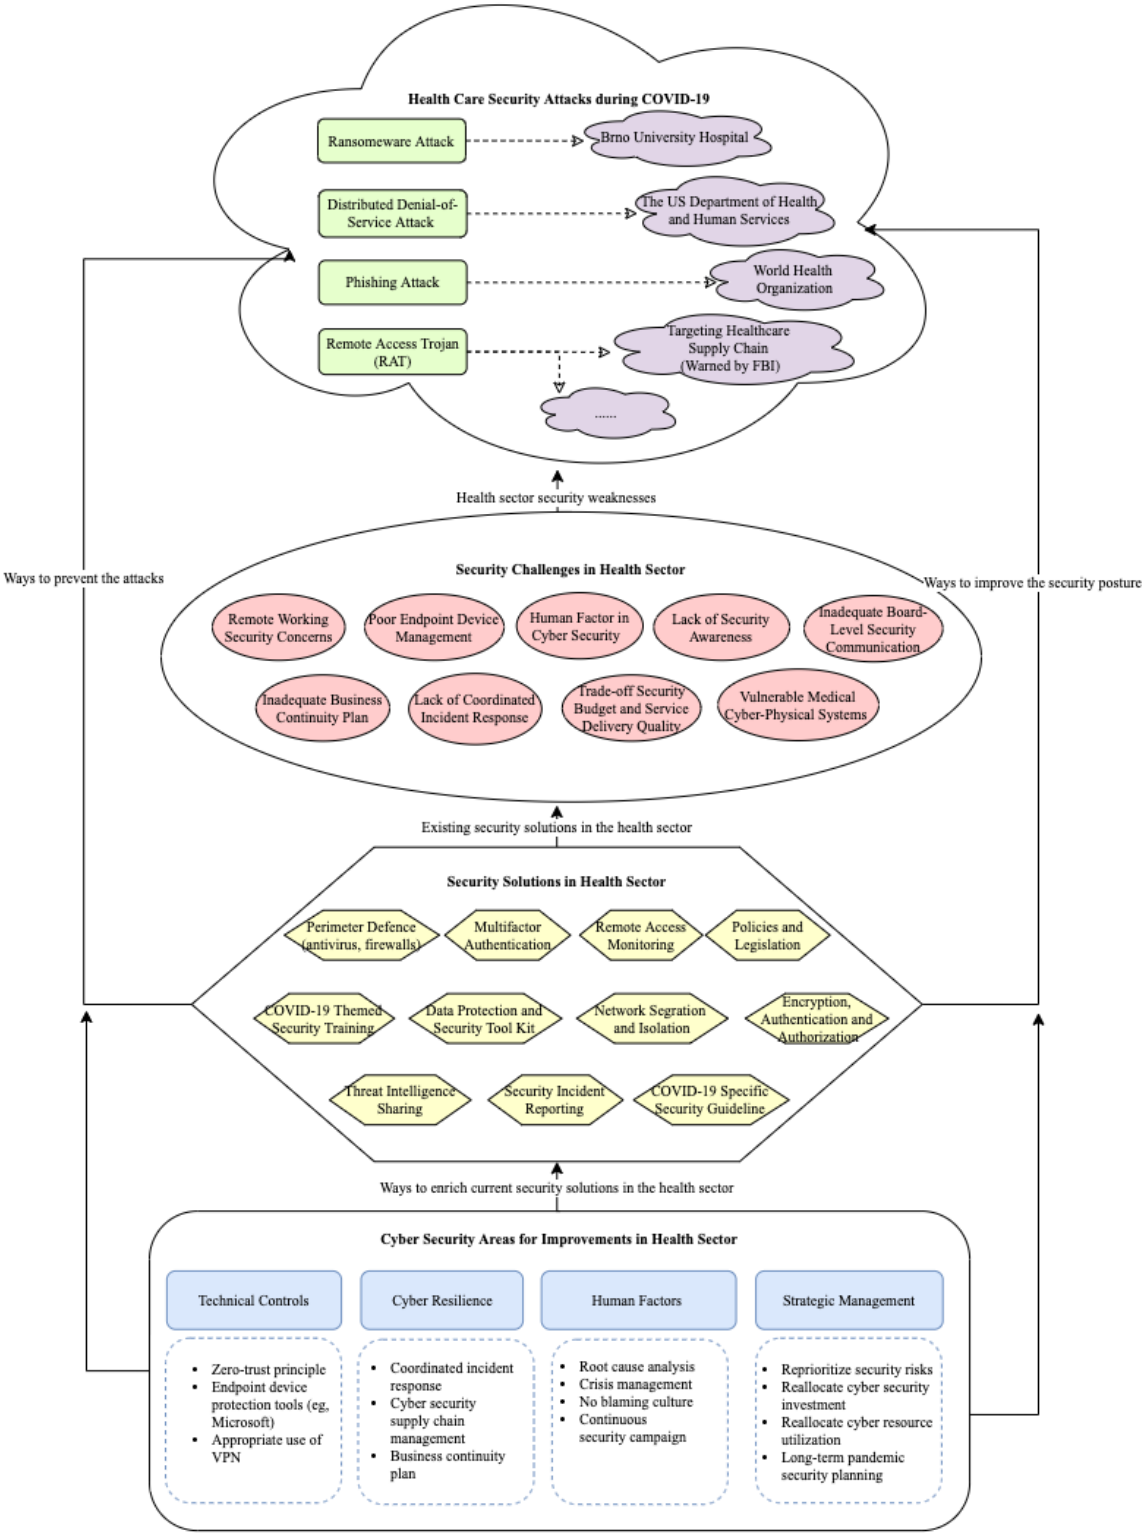
Some health care organizations have started providing security guidance specific to COVID-19 for their staff. For example, NHS Digital has added guidance on working from home security, ramping up its on-site support for trusts on risk mitigations, data backup, and threat response. They also offer the NHS the NCSC's Protective Domain Name Service free of charge [72]. Furthermore, governments also provide cybersecurity guidance to both individuals and organizations. For example, the United Kingdom's Information Commissioner's Office created an information hub in order to assist individuals and organizations to protect data during the COVID-19 pandemic [73].

Discussion

Summary of Evidence

Through a scoping review, this research identified key cybersecurity challenges, solutions adapted by the health sector, and areas to be improved in order to counteract the cyberattacks introduced through changes to working practices in the face of the COVID-19 pandemic. This review identified 9 main challenges in cybersecurity and 11 key solutions that health care organizations adapted to address these challenges. Based on our findings and analysis, we can conclude that the main challenges that the health sector faces due to the COVID-19 pandemic include increased reliance on remote working by staff, high demand for PPE by staff on the first line of defense, and decreased mobility due to the lockdown. Indeed, these changes have made the health sector vulnerable to potential cyberattacks. For example, remote work was taken up by users with little previous experience, and there was also no planning and cybersecurity-associated assurance prior to the shift. Furthermore, evidence can be seen from the security incidents that took place during the lockdown period such as those of Brno University Hospital, hospitals in Romania, etc. The health sector continues to face security challenges [1,17]. Challenges such as remote working security assurance, endpoint device management, inadequate business continuity plans, lack of security awareness, etc, are apparent in the health sector. There are some existing solutions employed by health care organizations, especially in the United Kingdom, such as remote access monitoring. Figure 2 summarizes the main findings from the literature review and highlights the gaps and vulnerabilities that were exploited during the cyberattacks that took place during the COVID-19 pandemic. However, there are still challenges and gaps to be addressed, as discussed below.

Figure 2. Security attacks, key security challenges, solutions, and areas to improve. FBI: Federal Bureau of Investigation; VPN: virtual private network.



Implications for Future Research

Although the health sector has made some efforts to address these challenges, more research is required in some domains.

Technical Controls

The health sector has applied some technical solutions to tackle cybersecurity challenges in order to secure the remote work environment and monitor endpoint applications. These include but are not limited to network security (eg, network segmentation), multifactor authentication, password protection, patching systems, and the use of intrusion detection and prevention systems. There are also innovative security solutions such as the zero-trust principle (ie, to treat all devices as untrustworthy before access or authorization can be considered). The use of VPNs is a popular technique in the remote work environment but is not always required. Health care organizations should avoid the abuse of VPNs and ensure it is

applied to specific tasks, such as for system admin use and medical diagnosis purposes through access to legacy systems (eg, patient records management systems) stored on private data servers. Future research should explore innovative solutions such as blockchain as it can facilitate health care interoperability due to its immutability, transparency, and decentralization. In general, the health sector significantly lags behind other sectors in terms of cybersecurity. Future research should borrow experience from general cybersecurity practices (eg, NIST guidelines) and adapt them according to the needs of the health sector, especially in the context of pandemics.

Cyber Resilience

In order to improve system resilience, health organizations have some business continuity planning in place for data protection and recovery but lack a systematic way to maintain cyber resilience [18]. The vulnerabilities in the cyber supply chain makes it difficult to recover from an incident caused by third parties [38-41]. In the case of impact on medical devices or clinical information systems, incident response should be coordinated with device manufacturers and vendors. Health care organizations have realized the importance of having a comprehensive view of cybersecurity management in order to prevent cyberattacks [18] but have not built this coordinated capacity. There is a lack of a cyber resilience program to evaluate vendors' capabilities around threat protection, particularly across email servers (phishing and ransomware), breadth of portfolio coverage in addressing cloud architecture, and endpoint security. Future research should focus on building a coordinated cybersecurity capacity in order to systematically assess vulnerabilities and respond to cyber threats.

Human Factors in Cybersecurity

People are likely to make mistakes, especially in the context of changes in their traditional way of working. Health care organizations are required to adopt a nonblaming culture in reporting incidents. The health sector should focus on root cause analysis [28] and prevent incidents from happening especially through unintentional human error. Published research has shown that the majority of information security incidents relate to human error [28,29], which is a vulnerability that attackers will look to exploit. A human error analytical approach such as IS-CHEC could be deployed both reactively, through integration within incident management practices [29,30], and proactively, through simple interaction with operational personnel [29], to detect current human error areas of weaknesses and apply associated remedial and preventative measures. Moreover, health care staff in the organization need to be educated and build awareness of the ongoing security situation during the COVID-19 pandemic. For example, in the case of infection, staff are required to disconnect from the network to contain the spread. Organizations should continuously raise awareness internally by launching campaigns even during a time of crisis (ie, to inform health staff not to open suspicious emails). Future research should focus on creating pandemic-themed security awareness campaigns. Moreover, a positive and empowering culture is also required (eg, by sharing the rate of people who did not click on phishing-negative emails during a training campaign). Experience can be borrowed from the organizational climate literature to positively influence people's behavior [59].

Strategic Cybersecurity Management

Although health care organizations have invested in cybersecurity to counteraction security attacks, further efforts are needed to reprioritize cybersecurity risk assessment during the COVID-19 pandemic, reallocate security investment, and optimize resource utilization to obtain adequate assurances. According to Argwa et al [46], health care organizations are advised to allocate more resources and funding to cybersecurity. Strategic cybersecurity investment is still an immature research area in health care largely due to boards' inability to fully understand and anticipate the direct and indirect impact on their health services. Further, there are language barriers between the technical team and the board [27]. Another reason is that the board finds it difficult to estimate the costs of investing and balancing these against potential benefits procured or impacts mitigated [8] as cybersecurity investments prevent potential losses but may not generate business benefits directly. Moreover, organizations should not only create security guidelines specific to the COVID-19 pandemic but also plan for the long term for remote working and spend efforts on strengthening their security mechanisms and cybersecurity crisis management capabilities. More research efforts are needed to support the top management teams of the health sector to understand the threat landscape and make better-informed decisions to allocate resources not just to provide services to staff and patients but also for protection and resilience, in order to continuously serve even in times of emergency such as the current pandemic and beyond.

Limitations

Contrary to systematic reviews, scoping reviews are used to identify knowledge gaps, scope a body of literature, and clarify concepts. However, some limitations should be considered. Scoping reviews usually provide descriptive information in order to address the objectives of the review, which often leads to less defined searches. This review mitigated this limitation by clearly defining the search terms and search formula. Scoping reviews are also at risk of bias from different sources. All 4 authors were involved in the article identification, selection, and analysis processes in order to reduce the risks of bias. Because of variability when conducting a scoping review, there is a need for methodological standardization to ensure the strength of evidence. This review followed the PRISMA-ScR to standardize the process and improve the strength of evidence. Another limitation is that this review included exact terms used to search the titles or abstracts of existing publications. Any articles that used different terms, (eg, "computer security") would not have been included. In addition, publications that were not written in English were excluded. Moreover, although this scoping review focused on health care, the solutions identified could be applied to other industries.

Conclusions

The COVID-19 pandemic has challenged the resilience of the health care information system. This research was motivated by the urgency of counteracting the cyberattacks that have recently happened to hospitals, pharmaceutical companies, the

US Department of Health and Human Services, and the WHO and its partners, etc. We performed a review on security challenges of the health sector and the solutions employed during COVID-19. We identified the root causes of the security incidents that have impacted the health sector during the COVID-19 pandemic, cybersecurity challenges, solutions, and areas in need of improvement. The results show that the main root causes of the security incidents that happened during the COVID-19 pandemic are mainly from phishing, ransomware, DDoS attacks, and malware. The main challenges faced by health care organizations are inadequate endpoint device management, lack of security awareness, insecure remote work environment, inadequate business continuity plans, lack of coordinated incident response, and difficulty in trading off security investment and service delivery quality. Needless to say, another major challenge is human error, both from the perspective of the health care worker at the frontline and those working from home. As the COVID-19 pandemic has shifted our priorities, there is a greater tendency for human error to occur when staff are preoccupied with saving lives, working in a strange or different environment, and using new or various technologies. With little or no experience and a lack of prior planning and training to work in such situations, health care workers require more than training and support, such as adequate time, documented procedures, and guidance on revised procedures and technology.

Although the health sector has made some efforts to address these challenges by applying technical measures, raising security awareness, enforcing policies, and developing COVID-19–specific guidelines, more research efforts are still required in some domains. Future research should focus on exploring enhanced technical controls through the adaption of general cybersecurity practices (eg, NIST guidelines); improving cyber resilience by building a coordinated cybersecurity capacity to systematically assess vulnerabilities of the complex health care supply chain and respond to cyber threats; reducing human-related security incidents by exploring human error reduction approaches and pandemic-themed awareness campaigns; and enhancing strategic cybersecurity management by exploring crisis management planning, security risks reprioritization, and the optimization of cybersecurity budget and resource reallocation.

Many health care organizations are applying a temporary solution to counteract cyber threats during the COVID-19 pandemic. These organizations should plan for the long term, provide adequate levels of cybersecurity resources to deal with fast-changing situations, and offer the required assurance within these changes. This paper provides useful insights for the health sector on their cybersecurity issues during the COVID-19 pandemic or other epidemic or pandemic situations in the future. Moreover, cybersecurity experience in other sectors can be borrowed and applied in the health sector.

Abstract

Background: Due to the influence of the COVID-19 pandemic, conventional face-to-face academic conferences have been restricted, and many of these conferences have moved onto the internet.

Objective: The aim of this study was to investigate the virtual conferences in the field of urology during the COVID-19 pandemic and provide suggestions for better organization of such conferences.

Methods: A cross-sectional survey was conducted from May 30 to June 15, 2020, in China. Our team designed a 23-item questionnaire to investigate the conferences attended by urologists during the COVID-19 pandemic. SPSS 22.0 (IBM Corporation) was applied to analyze the data collected.

Results: A total of 330 Chinese urologists participated in our survey, and the response rate was 89.7% (330/368). Among the participants, 40.9% (135/330) were associate chief physicians. The proportion of participants who took part in conventional face-to-face academic conferences decreased from 92.7% (306/330) before the COVID-19 pandemic to 22.1% (73/330) during the pandemic (P<.001). In contrast, the proportion of urologists who took part in virtual conferences increased from 69.4% (229/330) to 90% (297/330) (P<.001). Most urologists (70.7%, 210/297) chose to participate in the virtual conferences at home and thought that a meeting length of 1-2 hours was most appropriate. Among the urologists, 73.7% (219/297) reported that their participation in the virtual conferences went smoothly, while the remaining respondents reported that they had experienced lags in video and audio streaming during the virtual conferences. When comparing conventional face-to-face conferences with virtual conferences, 70.7% (210/297) of the respondents thought that both conference formats were acceptable, while 17.9% (53/297) preferred virtual conferences and 11.5% (34/297) preferred conventional face-to-face meetings.

Conclusions: Virtual conferences are increasing in popularity during the COVID-19 pandemic; however, many aspects of these conferences could be improved for better organization.

(J Med Internet Res 2021;23(4):e24369) doi:10.2196/24369

KEYWORDS

virtual conference; COVID-19; survey

Introduction

Since the first case of COVID-19 was reported in Wuhan, China, the disease has spread worldwide rapidly [1]. To prevent the spread of COVID-19, many mass gathering events have been canceled or postponed, including the annual meetings of the European Association of Urology (EAU) and the American Urological Association [2,3]. In this condition, the role of virtual conferences is expanding [4], and many academic conferences moved onto the internet, such as the EAU20 Virtual Congress [5].

However, to our knowledge, there is no study investigating virtual conferences in the field of urology. In this study, we aimed to investigate the virtual meetings during the COVID-19 pandemic in China and provide advice on organizing efficient and high-quality virtual conferences according to the results of our survey.

Methods

Our team designed a structured questionnaire after reviewing the current relevant literature. A total of 23 items were finalized for this survey, covering demographics (2 items), traditional academic conferences (5 items), virtual (video) conferences (11 items), comparison between traditional and virtual conferences (3 items), and topics of academic conferences (2 items). We have provided the questionnaire in Multimedia Appendix 1.

We collected the data through the *Wenjuanxing* website [6] from May 30 to June 15, 2020. All participants accessed the questionnaire by clicking on the survey link. Participants were able to submit the questionnaires only when all the items were completed. To avoid repetition, IP restriction was applied, which meant that the survey could only be completed once from a single IP address.

Data are presented as number (percentage) for categorical variables, and chi-square tests were used to compare the distributions of categorical variables. All the statistical analyses were conducted using SPSS 20.0 (IBM Corporation).

Results

From May 30 to June 15, 2020, we sent the web-based questionnaire to 368 Chinese urologists; 330 of them completed the survey, resulting in a response rate of 89.7%. Among the participants, 96.4% (318/330) were based at secondary grade A hospitals and above. Regarding their academic titles, most of the participants were associate chief physicians (135/330, 40.9%), followed by attending physicians (113/330, 34.2%), chief physicians (61/330, 18.5%), and residents (21/330, 6.4%) (Table 1).

Table 1. Baseline information about the survey participants (N=330).

Characteristic	Value, n (%)
Hospital level[a]	
Tertiary grade A	168 (50.9)
Tertiary grade B	97 (29.4)
Secondary grade A	53 (16.1)
Secondary grade B	6 (1.8)
Primary and others	6 (1.8)
Academic title[b]	
Chief physician	61 (18.5)
Associate chief physician	135 (40.9)
Attending physician	113 (34.2)
Resident	21 (6.4)

[a]In China, hospitals are classified as primary, secondary, or tertiary institutions. Typically, primary hospitals contain less than 100 beds and secondary hospitals contain 100-500 beds, while tertiary hospitals have a bed capacity exceeding 500. According to their medical quality, etc, each hospital level is further subdivided into three subsidiary grades of A, B, and C, which results in a total of 9 levels.

[b]For the physicians' hierarchy in China, there are four levels in total, namely chief physician, associate chief physician, attending physician, and resident, from senior to junior.

The proportion of urologists participating in conventional face-to-face conferences decreased from 92.7% (306/330) before the COVID-19 pandemic to 22.1% (73/330) during the pandemic (P<.001). Generally, 89.5% (274/306) of the urologists were satisfied with the traditional conferences, while others (32/306, 10.5%) thought that live conferences were time-consuming (27/32, 84%,) and expensive (20/32, 62.5%).

The proportion of urologists participating in virtual conferences increased from 69.4% (229/330) before the COVID-19 pandemic to 90% (297/330) during the pandemic (P<.001). Of the participants, 99.0% declared that they were "very satisfied" or "satisfied" with the virtual conferences.

Most of the urologists (70.7%, 210/297) chose to take part in the virtual conferences at home. In terms of the length of the virtual conferences, most participants (62.3%, 185/297) reported that they usually spent 0.5-1.5 hours per meeting, and 66.3% (197/297) thought that 1-2 hours is the most appropriate duration for a meeting.

Regarding the software, Tencent Meeting, DingTalk, and Zoom were the most commonly used platforms in China. Of the urologists, 73.7% (219/297) reported that their participation in the virtual meetings went smoothly, while the remaining urologists said that due to limited bandwidth or unstable web-based platforms, they experienced lags in video and audio streaming during the virtual conferences. According to our survey, the urologists thought that a good web-based platform should provide on-demand video and should be stable and interactive.

When comparing conventional face-to-face conferences with virtual conferences, 70.7% (210/297) of the participants thought that both formats were acceptable, while 17.9% (53/297) preferred virtual conferences and 11.5% (34/297) preferred conventional face-to-face meetings. Compared with conventional face-to-face meetings, the urologists reported that virtual conferences were time-effective, less expensive, and more convenient; however, they also lacked interaction, body language, and Continuing Medical Education (CME) credits.

For the different topics of urological conferences, stones (286/330, 86.7%), laparoscopy (84.9%, 280/330), urological oncology (84.6%, 279/330), and prostatic diseases (74.9%, 247/330) were the four most popular topics, followed by andrology (177/330, 53.6%), female urology (140/330, 42.4%), reconstructive urology (130/330, 39.4%), and kidney transplantation (17/330, 5.2%). When the participants were asked about what they expected to learn about during urological conferences, clinical experience and surgical techniques were selected by 95.8% (316/330) and 94.2% (311/330) of participants, while the methodology of medical research and basic research progress were only chosen by 46.4% (153/330) and 39.1% (129/330) of the participants. Further analysis showed that there was no significant difference among the different levels of hospitals for interest in clinical experience (Figure 1), surgical technique (Figure 2), or basic research progress (Figure 3), while fewer urologists based at secondary grade A hospitals and below were interested in the methodology of medical research (Figure 4).

Discussion

Principal Findings

As far as we know, this is the first survey to investigate urological conferences during the COVID-19 pandemic. A total of 330 Chinese urologists, with different academic titles and from different levels of hospitals, were included in our survey. Our study revealed that although virtual conferences are increasing in popularity during the COVID-19 pandemic, the organization of these virtual conferences needs further improvement.

During the COVID-19 pandemic, traditional face-to-face meetings have been restricted, and it is more important than ever to maximize virtual meetings. In our survey, the proportion of urologists who took part in virtual conferences increased from 69.4% before the COVID-19 pandemic to 90.0% during the pandemic, indicating a sharp increase in virtual conference participation. Additionally, due to the development of efficient

telecommunication networks, technological capabilities are no longer a hindrance, and these networks have been used in various areas [7,8]. Recently, the Human Genome Meeting, Global Genomic Medicine Collaborative, and Trans Tasman Radiation Oncology Group Annual Scientific Meeting were delivered virtually and achieved great success, with 97% of the participants being "very satisfied or satisfied" with the virtual style [9,10]; this was similar to our 99.0% proportion of satisfied participants, indicating that virtual conferences were well accepted by urologists. As a result, we should maximize the use of virtual conferences to ensure communication in the medical community during the COVID-19 pandemic.

When preparing for virtual conferences, the first task is to define the target audience, as different audiences may have different appetites. For example, in our study, the urologists who worked at secondary grade A hospitals and below had lower enthusiasm for the topic of medical research methodology. Second, according to our survey, most people chose to take part in conferences at home; therefore, avoiding early morning and late evening meetings would provide them with a better experience [11]. Web-based platform selection is another essential aspect of the success of virtual conferences. In our survey, Tencent Meeting, DingTalk, and Zoom were the most commonly used platforms. In addition to these platforms, webinar technology [12], Twitter [13], journal clubs, podcasts, *Intouch Vita*, etc, were used for virtual meetings [14]. However, regardless of which platform is chosen, it should ensure a smooth and stable video experience; this was what people were most concerned about according to our survey.

During virtual conferences, the duration of the sessions should be controlled, as the average attention span for adults is only approximately 15-20 minutes [15]. In our study, most of the urologists thought that 1-2 hours was the most appropriate length. Salomon and their team [16] designed each session at their virtual conference to last 2 hours, and this schedule was appreciated by most of the participants (135/181, 74.6%), which was in accordance with our respondents' preference of 1-2 hours. As a result, the duration of an academic meeting should be controlled within approximately 2 hours. Additionally, as mentioned before, one of the limitations of virtual conferences is the lack of interaction. To solve this problem, organizers could increase the time allotted to question-and-answer periods [10], permit attendees to turn on their cameras, provide virtual open discussion chat rooms [16], etc.

When a virtual conference has ended, the organizer should provide on-demand content such as video on the virtual platform. On-demand video is important for people in different time zones and is valuable for all participants to catch up on missed talks. Over 90% of the urologists in our survey thought that on-demand video was essential for their learning. Additionally, the physicians who attend virtual conferences should be provided with CME credits. In the era of information explosion, to enable physicians to remain current with their medical knowledge, CME has been implemented in many countries worldwide, and a variable number of CME credits is required [17,18]. Normally, CME credits can be earned through attendance at in-person academic conferences, workshops, symposiums, etc. However, according to our survey, some urologists reported that during virtual conferences, CME credits were not made available to participants, which in our view may reduce the enthusiasm of urologists to take part in these conferences. As a result, in the future, we believe that virtual conferences should also provide CME credits.

In terms of the comparison between virtual conferences and conventional face-to-face conferences, as mentioned before, both formats have their advantages and disadvantages. As a result, some researchers have proposed a new type of meeting called a hybrid meeting, which combines aspects of virtual and live conferences. In a survey conducted by Forrest et al [10], 85% of the delegates reported that they preferred hybrid meetings compared with virtual or physical meetings only. Additionally, Gomez Rivas et al [19] shared their preliminary experience of hybrid meetings that included both onsite and web-based participants. Moreover, we believe that this type of meeting would be the best choice for academic conferences in the future, as it combines the advantages of both formats.

Limitations

There are several limitations to our survey. First, our survey had a relatively small sample size. Second, most of the participants in this study were from tertiary hospitals. Despite these two limitations, our study provides a preliminary report of virtual conferences during the COVID-19 pandemic and provides many suggestions on how to organize an efficient and satisfying virtual conference, which is timely and useful.

Conclusion

Virtual conferences are increasing in popularity during the COVID-19 pandemic; however, many aspects of these conferences could be improved for better organization.

Abstract

Background: COVID-19 was declared a pandemic by the World Health Organization on March 11, 2020, and as of this writing, Texas, United States, has reported >675,000 cases with over 14,000 deaths. Many of the preventive measures implemented during the pandemic can increase sedentary lifestyles, which can lead to the development of chronic diseases, including obesity, among the general population and cause serious threats to people's physical health and overall quality of life. Individuals with pre-existing comorbidities are at an increased risk of COVID-19 and may hence have higher levels of stress.

Objective: This study aimed to investigate the relationship between physical activity levels and mental health status on an individual level and to compare them between those with and those without comorbidities in a cohort of Texas residents, before and after COVID-19 was declared a pandemic.

Methods: An electronic survey was disseminated throughout various regions of Texas. In total, 160 individuals were asked questions about their demographic characteristics, time spent on daily physical activities, and daily mental health status before and after COVID-19 was declared a pandemic. Frequency distributions and descriptive statistics were analyzed.

Results: Overall, 94 (58%) participants reported having ≥1 medical condition, and 31 (13.1%) had >3 medical conditions. Physical activity levels among participants with ≥1 pre-existing comorbidity drastically—but not significantly—decreased, as evident from a 10% increase in sedentary lifestyles after COVID-19 was declared a pandemic. On the contrary, we observed a 9% increase in the number of individuals without a pre-existing comorbidity who reported 30-60 min of physical activity per week. There was a 2-fold increase in the number of participants reporting more frequent feelings of nervousness, too much worry, trouble relaxing, and the fear of something awful happening after the pandemic. More specifically, individuals with pre-existing medical conditions reported, on average, a 10% higher incidence of feelings of stress, anxiety, and sadness compared to their healthy counterparts after COVID-19 was declared a pandemic.

Conclusions: Stressful life conditions and chronic comorbidities are risk factors that can affect mental health and reduce the ability to perform activities of daily life. Therefore, when implementing pandemic protocols, municipalities should consider providing mental health support to their citizens to protect them from this rather inconspicuous adverse effect.

KEYWORDS

anxiety; COVID-19; descriptive study; mental health; pandemic; physical health; quality of life; stress

Introduction

COVID-19 was declared a pandemic by the World Health Organization on March 11, 2020 [1], and Texas has reported >675,000 cases and 14,000 deaths as of this writing. The routines of individuals have been impacted since the beginning of the pandemic owing to the implementation of restrictions and preventative measures such as social distancing, self-isolation, stay-at-home orders, and closure of businesses and recreational facilities. Many of these protocols can have a negative effect, promoting a sedentary lifestyle and decreasing physical activity levels, which can lead to the development or exacerbation of chronic diseases and mental health issues [2-5]. This study aimed to explore the relationship between physical activity levels and mental health status at an individual level in a cohort of Texas residents before and after COVID-19 was declared a pandemic. We hypothesize that the declaration of COVID-19 as a pandemic, which led to the implementation of social distancing and self-isolation protocols, would negatively impact mental health, increase stress and anxiety, and decrease physical activity levels among all study participants.

Methods

Recruitment

Texas residents aged ≥18 years were recruited through social media and email, using convenience and snowball sampling over a 2-week period in July 2020. Respondent identities were anonymized, and the study was exempt from ethics review for the use of human subjects by the institutional review board of the University of Texas Health Science Center at San Antonio.

Survey Instrument

A shortened survey instrument initially developed by Flanagan et al [6] was used to capture respondent demographics, medical history, and physical and mental health status. Questions related to physical and mental health were constructed in a manner to determine health status before and after the implementation of COVID-19 quarantine protocols. Study data were collected and managed using Research Electronic Data Capture (REDCap) [7] tools hosted at the University of Texas Health Science Center at San Antonio. REDCap is a secure web-based software platform designed to support data capture for research studies, providing (1) an intuitive interface for validated data capture, (2) audit trails for tracking data manipulation and export procedures, (3) automated export procedures for seamless data downloads to common statistical packages, and (4) procedures for data integration and interoperability with external sources.

Demographics and Medical History

Data on the participants' gender (male, female, or no response), age, marital status, employment status, household number, ethnicity, and race were collected. Participants were asked to indicate whether they have been diagnosed with any chronic medical conditions, including cardiovascular, respiratory, gastrointestinal, genitourinary, kidney, hematologic, infectious, dermatological, ophthalmologic, endocrine, musculoskeletal, oncologic, or neurologic disease. The demographic characteristics of the survey participants are presented in Table 1.

Table 1. Demographic characteristics of the survey participants (N=160).

Characteristic	Number of participants, n (%)
Race	
American Indian or Alaskan native	0 (0)
Asian	10 (6.3)
Black or African American	3 (1.9)
Native or Pacific Islander	3 (1.9)
White	134 (83.8)
Not reported	8 (5.0)
Unknown	2 (1.3)
Ethnicity	
Hispanic or Latino	65 (40.9)
Not Hispanic or Latino	86 (53.9)
Not reported	7 (4.5)
Unknown	2 (1.3)
Gender	
Female	138 (86.3)
Male	20 (12.5)
Not reported	2 (1.3)
Age (years)	
18-25	17 (10.9)
26-35	44 (27.6)
36-45	30 (18.6)
46-55	34 (21.2)
56-65	28 (17.3)
66-75	7 (4.4)
Pre-existing diagnosed medical conditions (n=94; percentages reported considering a sample of 160 participants)	
1	52 (32.5)
2	21 (13.1)
3	13 (8.1)
≥4	8 (5.0)

Questions on Physical Activity

Participants were asked to provide details regarding their physical activity levels before and after COVID-19 was declared a pandemic. Specifically, they were asked to provide details regarding their physical activity or exercise minutes per day. Participants were provided the following categorical variables as choices: 0-30 minutes, 30-60 minutes, 60-90 minutes, 90-120 minutes, or >120 minutes of daily physical activity.

Questions Related to Psychological Status and Mental Health

Participants were asked if they were worried about their physical health with respect to the COVID-19 pandemic. They were also asked about generalized stress, anxiety, and sadness before and after the COVID-19 pandemic. Furthermore, 8 questions were related to the participants (1) feeling nervous, anxious, or on edge; (2) not being able to stop of control worry; (3) worrying too much about different things; (4) having trouble relaxing; (5) being restless and finding it difficult to sit still; (6) becoming easily annoyed or irritable; (7) feeling afraid that something awful might happen; and (8) having difficulty getting things done because of these mental health issues. Participants selected either (1) not at all, (2) several days, (3) over half the days, or (4) nearly every day. Each response was converted to a numerical score for analysis.

Statistical Analysis

Descriptive statistics were calculated to summarize the response frequency. Respondents who declined to answer a question were considered missing and excluded from the calculated proportions. We report all summary statistics. For paired testing

of questions that asked for pre– and post–COVID-19 comparisons, we used a paired samples *t* test to analyze mean values. The significance level was set at Cronbach α=.05, and all tests were 2-sided. All data were processed using SPSS for Windows (version 23.0, SPSS Inc).

Results

Participant Demographics

In total, 160 individuals responded to the social media posts. The vast majority of respondents were married, white, non-Hispanic or -Latino females. Overall, 65 (41%) respondents identified themselves as Hispanic or Latino (Table 1), which was more than the 31% estimated census of Hispanic or Latinos in Texas. More than half of the respondents (n=91, 57%) were aged <45 years and had full-time jobs (n=117, 73%), while 30 (19%) indicated that they were unemployed.

Furthermore, 94 (58%) participants reported having ≥1 pre-existing medical condition, and 21 (13.6%) respondents had >3 pre-existing medical conditions. Medical conditions with the highest frequency included hypertension (22.3% of all responses), respiratory problems (14.0%), endocrine disorders (13.4%), and gastrointestinal problems (12.7%). Participant responses to questions on pre-existing medical conditions are presented in Table 2.

Table 2. Distribution of the responses of participants with pre-existing medical conditions (N=160).

Pre-existing medical condition	Number of responses, n (%)[a]
Cardiac or heart disease	6 (3.8)
Respiratory problems	22 (14.0)
Gastrointestinal problems	20 (12.7)
Genitourinary or kidney disease	5 (3.2)
Hematologic condition	10 (6.4)
Infectious disease	1 (0.6)
Dermatologic condition	13 (8.3)
Ophthalmologic condition	7 (4.5)
Endocrine conditions	21 (13.4)
Diabetes	10 (6.4)
Musculoskeletal conditions	8 (5.1)
Hypertension	35 (22.3)
Cancer	6 (3.8)
Neurologic or psychiatric condition	14 (8.9)

[a]Among 160 respondents, 94 reported having ≥1 pre-existing medical condition. Individuals were asked to mark all medical conditions they have been diagnosed with, allowing them to select >1 response. Percentages are in relation to the total sample of 160 survey responses.

Slight Reduction in Physical Activity in Response to the Declaration of COVID-19 as a Pandemic

No significant differences in self-reported physical activity were observed for the entire cohort of respondents. Similarly, no significant differences were observed in the subgroups of individuals with (*P*=.81) or without (*P*=.91) pre-existing medical conditions. Physical activity was slightly—but not significantly (*P*=.81)—reduced among participants with ≥1 pre-existing condition, as evident from a 10% increase in sedentary lifestyles after COVID-19 was declared a pandemic. On the contrary, we observed a 9% increase in the number of individuals without a pre-existing conditions reporting 30-60 min of physical activity per week.

Negative Effect of the COVID-19 Pandemic on Psychological Health

Respondents were asked how the quarantine protocols in Texas impacted their psychological health (Table 3). We observed significant increases in feelings of fear, annoyance, restlessness, worry, nervousness, sadness, anxiety, and stress (*P*<.001) among the survey respondents. Specifically, participants reported more frequently feeling nervous, worrying too much, having trouble relaxing, and feeling afraid something awful might happen after the pandemic. This negative impact on psychological well-being interfered with their ability to accomplish their work, tasks, or interact with other people. Similar results were obtained among individuals with and those without pre-existing medical conditions. The only exception is that individuals without pre-existing medical conditions reported that the COVID-19 pandemic had no significant impact on their ability to relax (*P*=.08).

Table 3. Changes in psychological health resulting from the COVID-19 pandemic.

Items	All respondents			Respondents with pre-existing medical conditions			Respondents without pre-existing medical conditions		
	Pre–COVID-19, mean (SD)	Post–COVID-19[a], mean (SD)	*P* value	Pre–COVID-19, mean (SD)	Post–COVID-19, mean (SD)	*P* value	Pre–COVID-19, mean (SD)	Post–COVID-19, mean (SD)	*P* value
Feeling nervous, anxious, or on edge	1.78 (0.77)[b]	2.36 (0.91)	<.001	1.88 (0.77)	2.53 (0.98)	<.001	1.63 (0.75)	2.13 (0.74)	<.001

[a]After COVID-19 was declared a pandemic by the world Health Organization on March 11, 2020.

[b]Participants selected either of the following responses: (1) not at all, (2) several days, (3) over half the days, or (4) nearly every day. Each response was converted to a numerical score for analysis. For the question on difficulty level, participants selected either of the following responses: (0) I did not experience any of the conditions, (1) not difficult at all, (2) somewhat difficult, (3) very difficult, and (4) extremely difficult.

Discussion

Principal Findings

After COVID-19 was declared a pandemic, quarantine and social distancing protocols were implemented to help mitigate disease spread in Texas. The implementation of these protocols was accompanied by several adverse effects on quality of life, which were independent of the SARS-CoV-2 infection. With the requirement for more individuals to stay at home and in isolation from friends, family, and colleagues, physical and mental health can depreciate. Mental health was drastically affected in our respondents owing to social isolation measures implemented by local municipalities in Texas. Overall, our survey respondents reported feeling more stress, anxiety, and sadness after COVID-19 was declared a pandemic. However, the long-term implications of quarantine protocols on mental health remain unknown. However, evidence from natural disasters suggest that mental health symptoms peak in the following months and can persist for years [8]. For example, 5% of the population of Texas affected by hurricane Ike met the criteria for major depressive disorder in the months following the storm [9]. Therefore, while a significant impact is demonstratable approximately 4 months into the quarantining protocol, there is potential for even greater impacts in the subsequent months.

Quarantine protocols can have a serious impact on physical health, leading to the development and progression of chronic diseases [10]. The American College of Sports Medicine recommends that most adults engage in moderate-intensity exercise training for more than 30 minutes for more than 5 days a week [11]. Contrary to Tinson et al [2], participants with no pre-existing medical conditions increased their physical activity after COVID-19 was declared a pandemic, with more individuals meeting or exceeding the recommended physical activity guidelines of the American College of Sports Medicine [11]. In this study, physical activity levels slightly—but not significantly—decreased among participants with pre-existing medical conditions, which indicates a potential risk of decreased overall health, potentially resulting in the exacerbation of medical conditions. Given that the risk of COVID-19 is significantly higher in subgroups of the population, which have pre-existing medical conditions, such subgroups are expected to decrease the time they spend outside of home in fear of unintended exposure to the virus.

Limitations

Our study is limited by the self-reported nature of our survey and the convenience and snowball sampling method used to recruit participants. Further, without the use of geocoding, including zip codes, we are limited in our ability to generalize our results to different regions in Texas. Finally, our survey was

distributed only in English, although Spanish is also a dominant language in several areas of Texas.

Conclusions

The quarantine protocols implemented in Texas led to significant levels of stress and anxiety in our survey respondents. Physical activity can be considered a coping mechanism to alleviate the psychological distress people may feel. Psychological distress experienced during the COVID-19 pandemic is likely to have long-term clinical implications.

Acknowledgments

DIP received support in the form of grants from the Mays Cancer Center at University of Texas Health Science Center at San Antonio (National Cancer Institute grant# P30CA054174), the Department of Education (grant# P031S150048), San Antonio Claude D. Pepper Older Americans Independence Center (National Institute on Aging grant# P30 AG044271), and Molecular Transducers of Physical Activity Consortium Adult Clinical Center (grant# U01AR071150).

Authors' Contributions

DIP conceptualized the study. DIP, LS, and JP developed the survey questions. YG developed the web-based survey database. DIP and YG performed the data analysis. All authors contributed significantly to the study. DIP and YG drafted the manuscript, and LS and JP revised the manuscript. All authors approved the final version of this manuscript.

Abstract

Background: The year 2020 was the year of the global COVID-19 pandemic. The severity of the situation has become so substantial that many or even most of the patients with mild to moderate symptoms had to self-isolate without specific medical treatments or even without being tested for COVID-19. Many patients joined internet membership groups to exchange information and support each other.

Objective: Our goal is to determine the benefits and limits of using social media to understand the symptoms of patients with suspected COVID-19 with mild to moderate symptoms and, in particular, their symptoms of anosmia (loss of the sense of smell) and ageusia (loss of the sense of taste). The voluntary reports on an internet website of a membership group will be the platform of the analyses.

Methods: Posts and comments of members of an internet group known as COVID-19 Smell and Taste Loss, founded on March 24, 2020, to support patients with suspected COVID-19 were collected and analyzed daily. Demographic data were collected using the software mechanism called Group Insights on the membership group website.

Results: Membership groups on social media have become rare sources of support for patients with suspected COVID-19 with mild to moderate symptoms. These groups provided mental support to their members and became resources for information on COVID-19 tests and medicines or supplements. However, the membership was voluntary, and often the members leave without notification. It is hard to be precise from the free voluntary reports. The number of women in the group (6995/9227, 75.38% as of October 12, 2020) was about three times more than men (2272/9227, 24.62% as of October 12, 2020), and the peak age of members was between 20-40 years in both men and women. Patients who were asymptomatic other than the senses comprised 14.93% (53/355) of the total patients. Recovery of the senses was higher in the patients who were asymptomatic besides having anosmia and ageusia. Most (112/123, 91.06%) patients experienced other symptoms first and then lost their senses, on average, 4.2 days later. Patients without other symptoms tended to recover earlier (P=.02). Patients with anosmia and ageusia occasionally reported distorted smell and taste (parosmia and dysgeusia) as well as experiencing or perceiving the smell and taste without the sources of the smell or taste (phantosmia and phantogeusia).

Conclusions: Our analysis of the social media database of suspected COVID-19 patients' voices demonstrated that, although accurate diagnosis of patients is not always obtained with social media–based analyses, it may be a useful tool to collect a large amount of data on symptoms and the clinical course of worldwide rapidly growing infectious diseases.

Introduction

Recent outbreaks of COVID-19, caused by SARS-CoV-2, have escalated into a worldwide pandemic. Over 29.4 million people in the United States alone have contracted the virus, causing over 532,000 deaths as of March 13, 2021.

According to the World Health Organization (WHO), "serious symptoms" are defined as "difficulties in breathing or shortness of breath, chest pain or pressure, loss of speech or movement" [1]. The Centers for Disease Control and Prevention (CDC) reported that over 80% of patients with COVID-19 have mild to moderate levels of illness [2] and 20% of the patients develop severe to critical conditions. Although there have been a number of studies published regarding the symptoms and their clinical course for COVID-19, most of them have focused on the patients with severe symptoms, and there have been few reports on patients with COVID-19 with mild to moderate conditions. Depending on the country, especially where the numbers of cases have been high and beds at hospitals are limited, most of the patients with mild to moderate symptoms of suspected COVID-19 have been self-isolating themselves with minimum access to medical treatments due to the large number of patients with severe conditions. Previously there were criteria that were required to be present (fever and coughs) to get tested, although later it became clearer that the symptoms vary largely and that made many suspected patients with various symptoms not be allowed to get tested. The patients with COVID-19 with mild to moderate symptoms are thus the most invisible population of patients who have received the least attention from the public and from medical care facilities.

Recently it has been shown that there is a high percentage (40% to as high as 96%) of asymptomatic [3-6] or presymptomatic [7] COVID-19 positive patients. In addition, more recently, there have been reports on the loss of the senses of smell (anosmia) and taste (ageusia) in COVID-19 positive patients with otherwise asymptomatic to mild levels of other symptoms [8-11] and as one of the early stage symptoms [9]. The ability to sense smell and taste showed a correlation with the severity of other symptoms as well, and odors related to chemesthesis were also found to be impaired by contraction of SARS-CoV-2 [12,13]. Studies have shown that 98% of patients with COVID-19 showed some smell dysfunction [14], indicating that smell dysfunction is a major biomarker of COVID-19. In a survey comparing COVID-19 positive and negative participants, smell dysfunction was found to be the best predictor of COVID-19 [15,16]. There are also papers reporting that asymptomatic patients with COVID-19 stay contagious longer than patients with symptoms [17]. These studies suggest that there is an urgent need to understand the asymptomatic to mild and moderate symptoms of patients with COVID-19 with anosmia and ageusia. Asymptomatic conditions sometimes mean that the patients actually have symptoms but did not realize or notice them because they are mild or because these symptoms were not included in the list of well-known symptoms like coughs and fevers. Understanding of the symptoms and the progression of COVID-19, especially in the mild cases of COVID-19, may help the subjectively asymptomatic patients notice any subtle symptoms that others have previously ignored. This includes the symptoms of anosmia and ageusia. The understanding of the onset and progression of anosmia and ageusia in otherwise asymptomatic patients and that of patients with mild or moderate symptoms may contribute to containment of the virus by enabling the detection of patients with COVID-19 at an earlier stage after contracting SARS-CoV-2.

Near the start of the pandemic, a group to support patients who lost their senses of olfaction or taste due to contraction of COVID-19, known as *COVID-19 Smell and Taste Loss*, was founded on a social media site. The posts from the members were recorded at that time to provide *precision advice*, which was based on the concept of the *Precision Medicine Initiative*. *Precision Medicine* is an approach for disease treatment that considers individual variability. In the case of a social media group, one of the ways to provide *precision advice* is to take into consideration the history of each person's previous posts on their symptoms and progress. The record of the posts at the early stage after the group was founded was conducted with the purpose of understanding the symptoms of the new disease in each person, which became the base of this study. To understand the new disease, COVID-19, we recorded all the posts on symptoms whether they were related to the senses or not.

The aim of this study was to analyze the posts and comments on this social media membership group to establish the benefits and limits of using social media to understand COVID-19 and to investigate the symptoms of mild to moderate COVID-19 patients, especially focusing on anosmia and ageusia. As earlier studies reported, these symptoms are highly observed in patients with COVID-19 [14]. They are early signs of COVID-19 [9], and in some SARS-CoV-2 infected patients, they were the only symptoms of COVID-19 [9,11]. There are only a few papers so far using the reports of patients obtained from social media [18,19]. This is one of the few reports on the mildly to moderately affected patients, many of whom did not have enough symptoms to receive COVID-19 tests and medical treatment, and therefore, clinical information is limited.

Methods

Recording of Cases

A membership group called *COVID-19 Smell and Taste Loss* was established on March 24, 2020, by the charity organization AbScent, which is based in England, United Kingdom. Polls were occasionally conducted to determine various aspects of the members, for example, hospitalization for COVID-19. The information on the age, sex, and the countries and cities where the members were located was obtained through the software mechanism called *Group Insights*. The reports posted were recorded daily as they were in Excel (Microsoft Corporation) spreadsheets with the records of the dates posted and the names, COVID-19 test results if available, a short summary of the symptoms, starting dates of anosmia and ageusia symptoms if available, and recovery dates from these symptoms if available. When the same person posted on a separate day, the posts were recorded under the name of the person with the records of the dates they were posted. Recording of the posts and comments for this study lasted from March 24 to July 1, 2020. Posts and comments without specific content related to their own

symptoms were not recorded (eg, expressing their sympathy, excitement, or approval saying "Yes," "congratulations!" "Thank you," or "nobody knows").

Institutional Review Board

The study is approved as exempt (Institutional Review Board protocol number 10082020-1, Exempt Category #3)

Case Studies

Because, in this group, members freely reported their cases, the level of detail for each member was not consistent. We classified the reports by whether the patient had other symptoms than anosmia and ageusia, and whether they recovered their senses, and then selected several reports that described their symptoms in detail.

Statistical Analysis

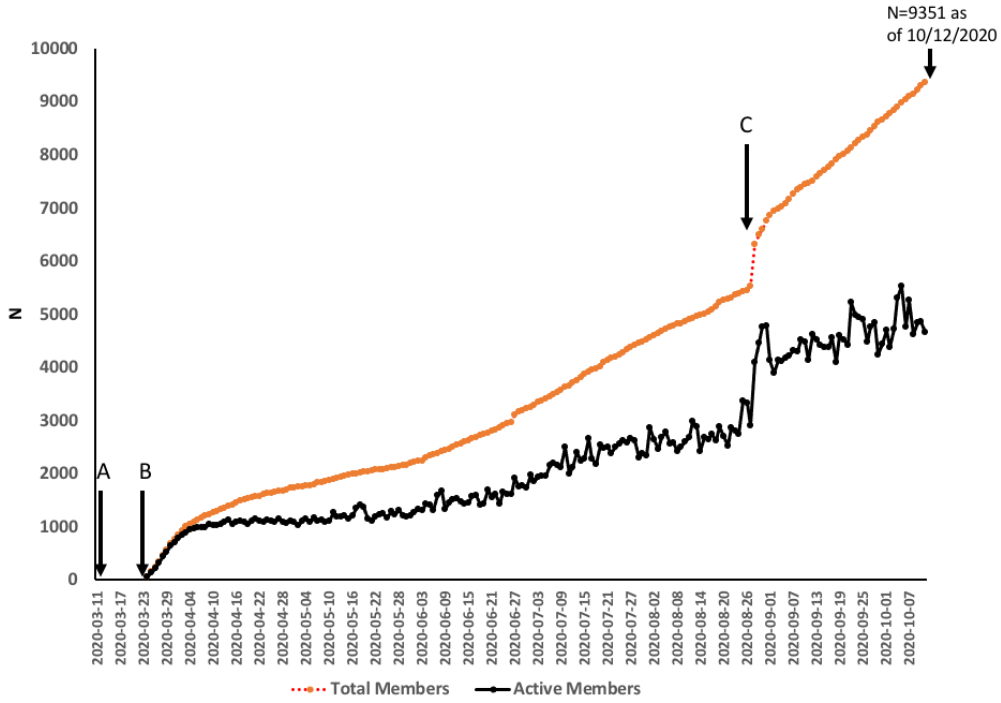
Fisher exact test was used to statistically evaluate the recovery rate among groups.

Results

Demographic Data

Figure 1 shows the time course since the pandemic started. On March 11, 2020, the WHO declared the rapidly spreading SARS-CoV-2 virus a pandemic and warned that it might spread to many countries around the world (Figure 1A). The disease caused by the virus, COVID-19, was first considered to cause fever and coughs as the main symptoms. However, soon it was discovered that there were more symptoms, including the loss of the senses of smell (anosmia) and taste (ageusia). The membership group on social media studied in this project was founded on March 24 (Figure 1B), and the number of members reached about 1000 during the first week (Figure 1). This immediate increase of the members indicates the rapid spread of the disease and the large number of people who suddenly lost their senses of smell and taste at the early stage of the pandemic. The increase in the number of members showed another surge around the time when the second wave in the number of cases started in the autumn of 2020. This may be due to both the increased publicity after the introduction of the group in the media (Figure 1C) and the large number of people with COVID-19–induced anosmia and ageusia. This suggests the existence of a large number of patients who lost their senses during this pandemic.

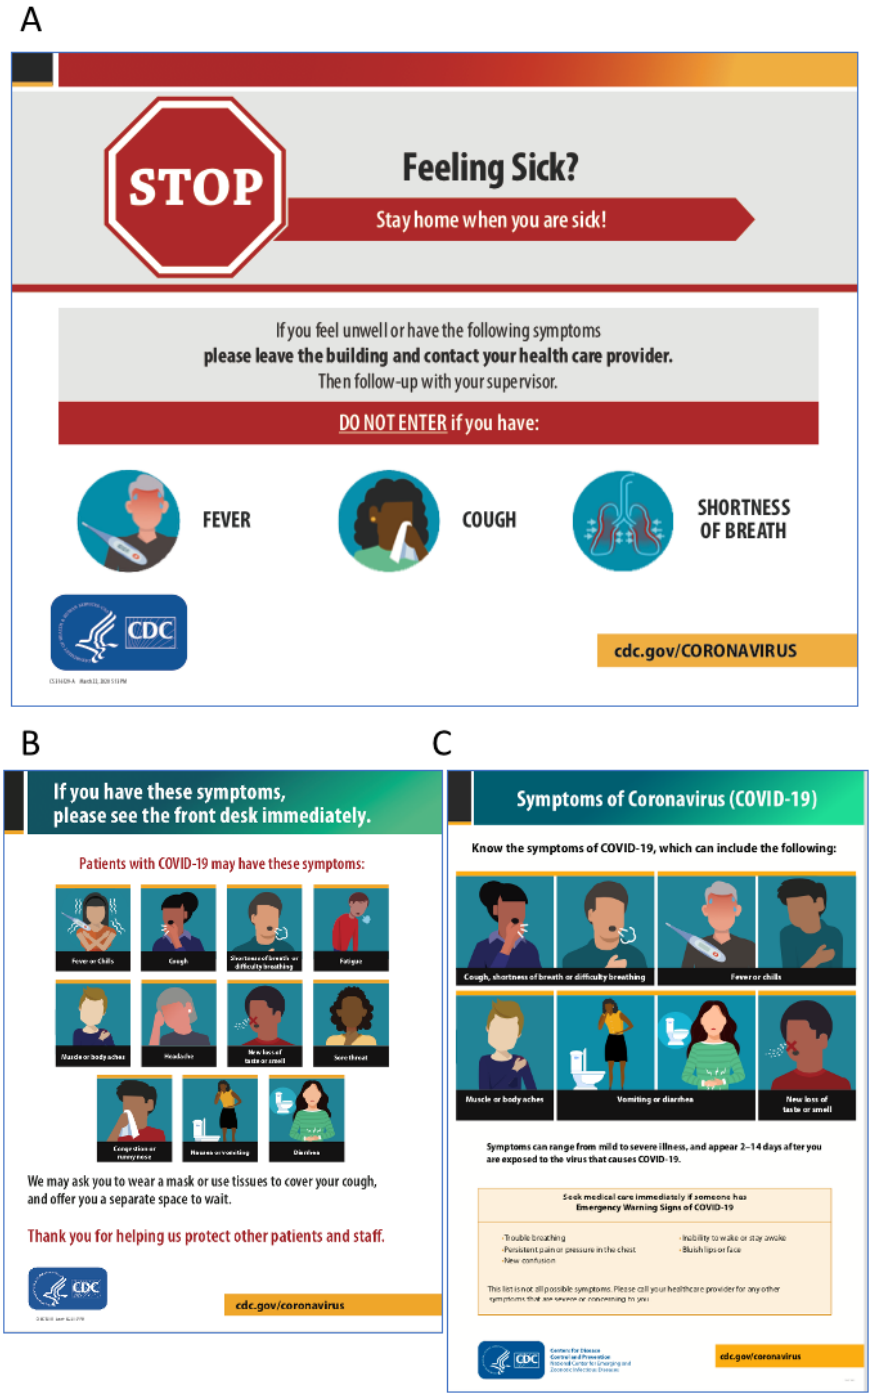
Figure 1. Increase in the number of members (red) and active members who make posts or comments to other posts (black). A: Date of the World Health Organization announcement on the pandemic; B: COVID-19 Smell and Taste Loss membership group founded; C: increase of over 1000 members within a few days following the interview of the founder of the group on the BBC.



What were considered the symptoms of COVID-19 have changed from the earlier stage of the pandemic in spring 2020 to summer and fall 2020. Figure 2 shows the outdoor and indoor signs made by the CDC in March, June, and July [20]. In the sign generated in March (Figure 2A), only the symptoms of fever, coughs, and shortness of breath are described, whereas in the June and July signs, the variety of symptoms has increased by more than double, and now it is well known that not every COVID-19 positive patient has fever, coughs, or shortness of breath (Figure 2B and C). In the poll asking if they got the COVID-19 tests immediately after the onset of symptoms, about 70% (n=259) of the 705 people answered that they could not get tested at all or could not get tested immediately and received the antibody tests later (Figure 3A; could not get tested: n=259, 36.74%; antibody test later: n=247, 35.04%). Analyses of the people who added comments (n=54) to the poll revealed that

most of the patients with COVID-19 who could get tested immediately after the onset of symptoms was due to their jobs (essential workers, mostly) or those who contracted the virus after June when the criteria to get tested expanded (compare Figure 2A and 2B; Figure 3B bottom; job: n=12, 22.22%; after June: n=26, 48.15%). The comments by the people who replied that they could not get tested immediately and received antibody tests later or could not get any test revealed that they were mostly the people who had an onset of symptoms before June (Figure 3B, top two bars).

Figure 2. Indoor and outdoor signs released by the CDC as free to be printed and used. CDC: Centers for Disease Control and Prevention.



Thus during the early stage of the pandemic, there were many people who got sick and self-diagnosed themselves with COVID-19 (suspected COVID-19 patient). This inability to get a COVID-19 test immediately after the onset of symptoms also resulted in the inability to get immediate medical treatments because medicines were not prescribed without an official diagnosis. We asked a question about the way they spent time after the onset of symptoms and found that about 90% (n=204,) of the 221 members who replied either stayed at home with generic medicines and supplements (n=162, 73.73%) or stayed at home without any medicines (n=40, 18.10%; Figure 4). Only 6.79% (n=15) replied that they stayed at home with medicines prescribed by doctors. Although there were some responses showing that there were members who experienced hospitalization in a separate poll (see Figure 3), none of them responded to the poll on the medical treatments, and thus, the

option of medical treatment following hospitalization is not shown in Figure 4. Although there is some missing information on the hospitalized people in the results, Figure 4 clearly shows the invisible nature of the patients with mild to moderate symptoms, which also suggests that the number of cases worldwide in the countries where availability of COVID-19 tests was limited or had criteria to get tested is highly likely to be far more than the officially reported numbers.

Figure 3. Summary of the reply to the question "were you able to get tested immediately after the onset of the symptoms of COVID-19" (A) and classification of the comments related to their selection. (B) Most often listed reasons that they could or could not get tested were the time of onset (before June or after June when the Centers for Disease Control and Prevention announced changes in the typical symptoms and included more symptoms), their jobs as essential workers or supervisors' arrangements, pre-existing health conditions, and hospitalization because of symptoms.

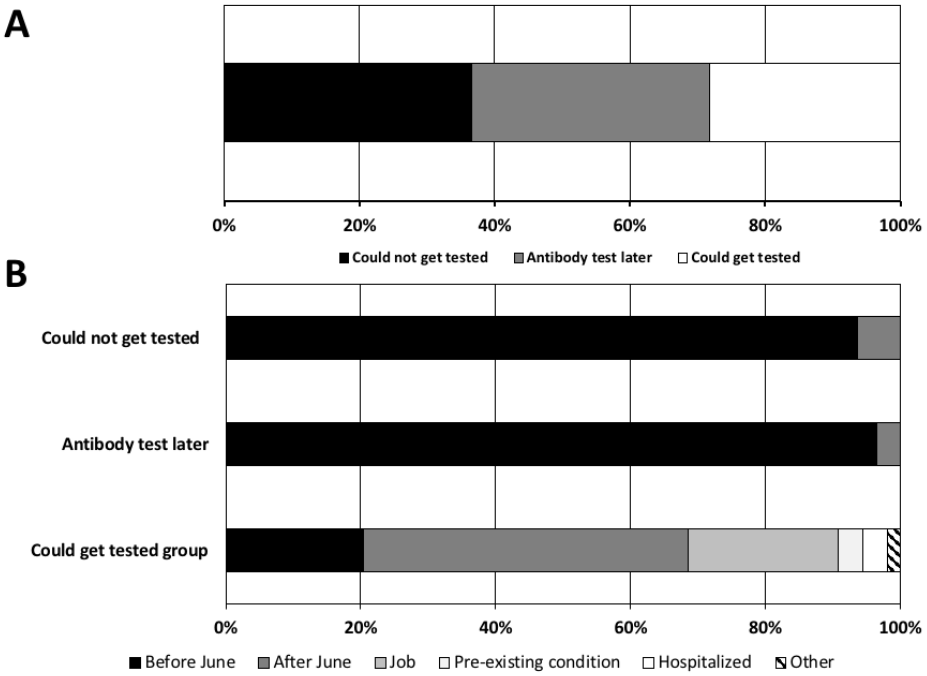


Figure 4. Availability of medical treatments. The result of another choice "hospitalized and then stayed at home with medicines prescribed by the doctors" is not shown as no one selected the option.

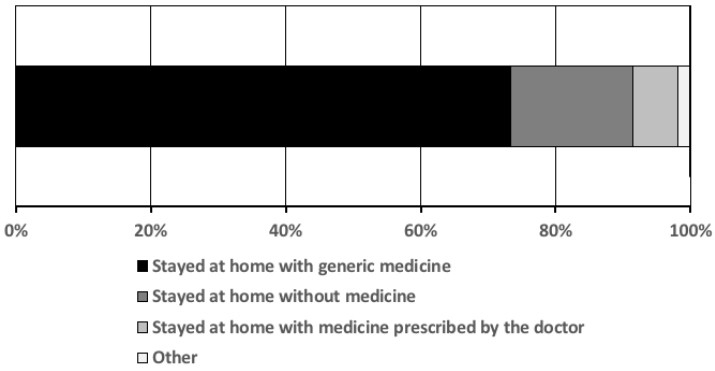
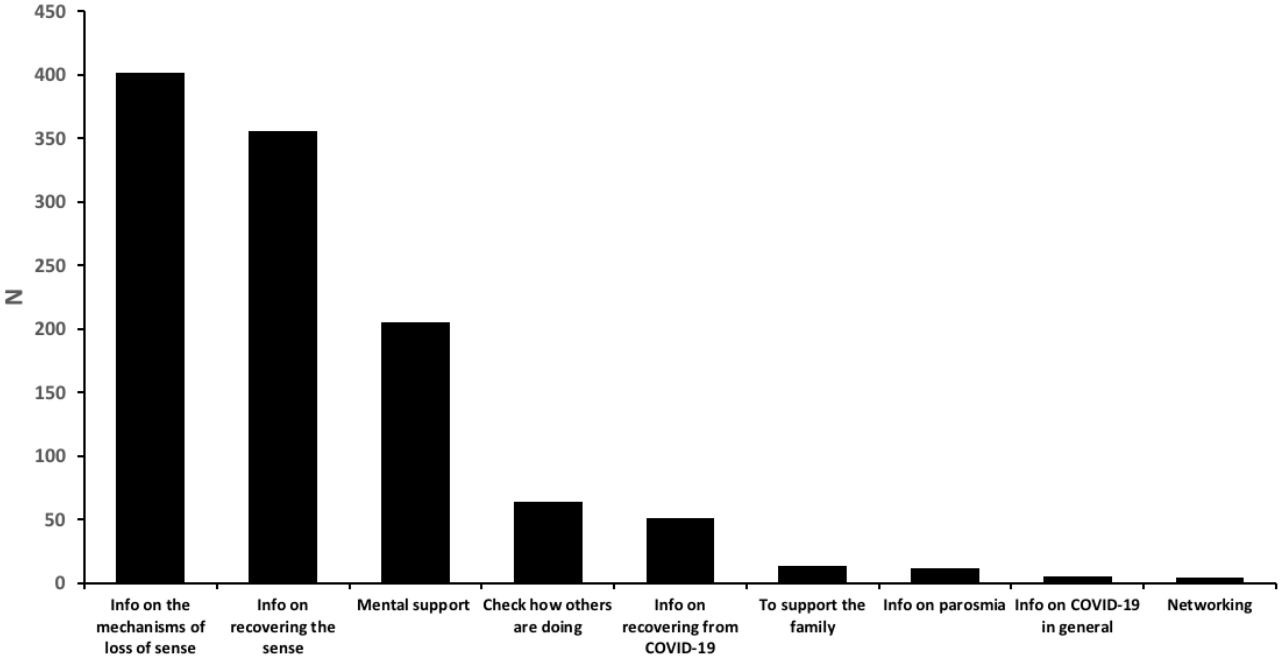


The self-isolation situation, staying at home, itself can cause anxiety. With symptoms of suspected COVID-19 and without a COVID-19 test and medical treatment, it is not hard to imagine that this situation causes high anxiety. It is possible during self isolation to obtain information from the internet and, if available, to join a patient group to exchange information. We asked the members the reasons that they joined the group. We found that the top three reasons were *to obtain the information about the mechanisms of sense loss* (n=401), *information on how to recover the senses* (n=355), and *mental support* (n=205), which accounted for 86.65% (n=961) of the 1109 responses (Figure 5). The sum of the responses related to information (5 out of 9 options; n=823, 74.21%) and mental support of themselves or their family (2 out of 9 options; n=218, 19.66%) accounted for over 93% of the reasons to join the group. If we consider that the two other options, *networking* and *checking how others are doing*, are relatively similar to mental support, it is possible to say that obtaining information and mental support are the two major reasons for joining the group.

Figure 5. Reasons to join the membership group. Multiple selections allowed and adding options was allowed.



Demographic data for the registered members (n=9227 as of October 12, 2020) of the social media site is shown in Figure 6. The number of women in the group (n=6995, 75.38%) was about three times more than men in the group (n=2272, 24.62%). This number included the members who were administrators of the group or scientists, and not patients, although the estimated percentage of these nonpatient members in the group was minimal. There was a peak in the number of members in the age range between 25-34 years in both men and women (Figure 6). This high number in the rather young ages could be due to the use of social media, although there are multiple other reports on patients with COVID-19 with anosmia and ageusia, which are not using social media, that show the same tendency [6]. On the other hand, in other membership groups of AbScent on social media, the average age is higher, which also suggests that this is specific to COVID-19 and not due to the use of social media. We do not know yet if this is due to the tendency that older-aged people develop severe conditions when they contract COVID-19 and are hospitalized or reach a severe condition such that they are unable to use the internet, or if the symptoms of the senses are specific to patients of younger ages.

Figure 6. Number of members of the COVID-19 Smell and Taste Loss group sorted by age and sex.

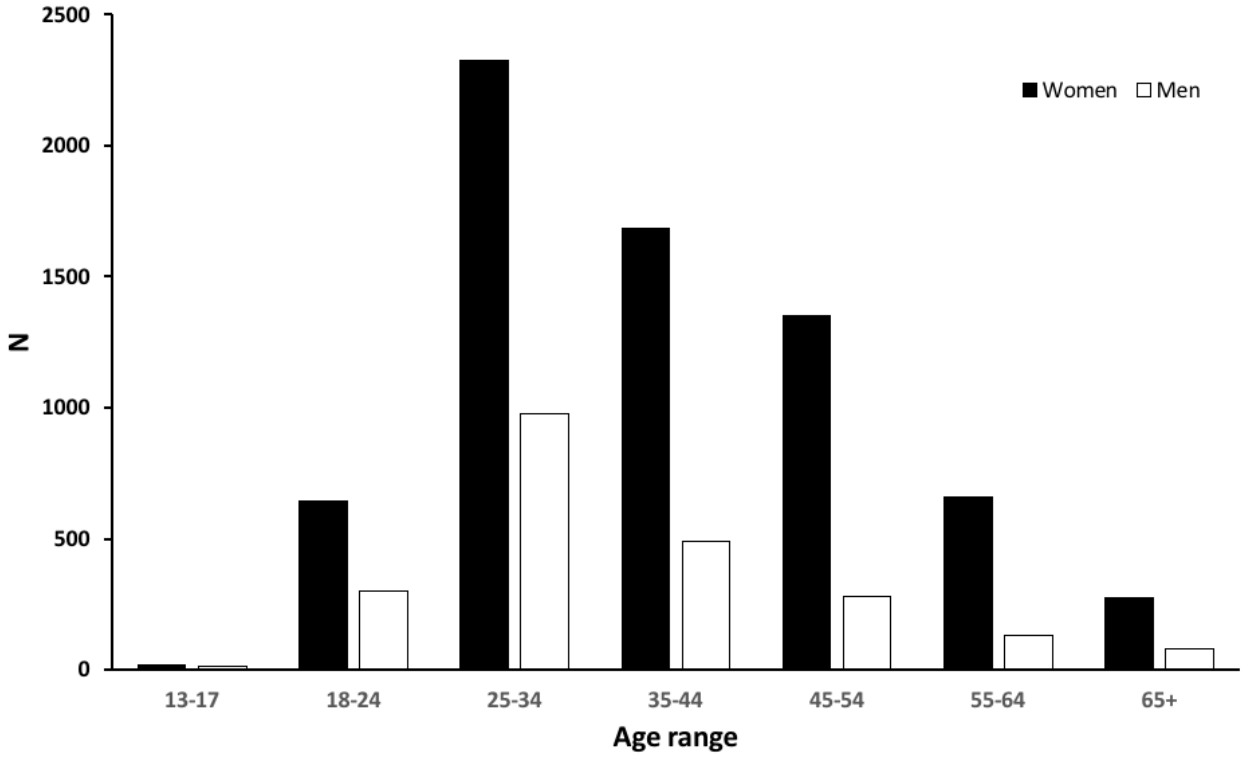


Figure 7 shows the top 20 countries of the members as of October 12, 2020. Where the patients were located may have had some influence on the symptoms, considering the mutation of the reported virus [21,22]. There were a total of 99 countries that had members in the group. The fact that it was possible to join the group from anywhere the internet was available, if there was no federal restriction on joining a social media group, was one of the benefits for suspected patients staying at home without medical treatments. The top 2 countries, however, were the United Kingdom and the United States, comprising 75.7% (United Kingdom: n=3744; United States: n=2809; total of the 20 countries: n=8654 members) of the number of members of the top 20 countries. This suggests that it is easy for the people in the countries where English is used to join the social media group. This may explain the names of the third and fourth top countries as well. The Philippines and South Africa are the third and fourth countries, respectively, in the number of members, and English is one of the official languages in these countries. There were rather few members from the countries in Europe even though the pandemic was severe there (eg, Italy: n=68, 0.79%), which could be due to the language barrier.

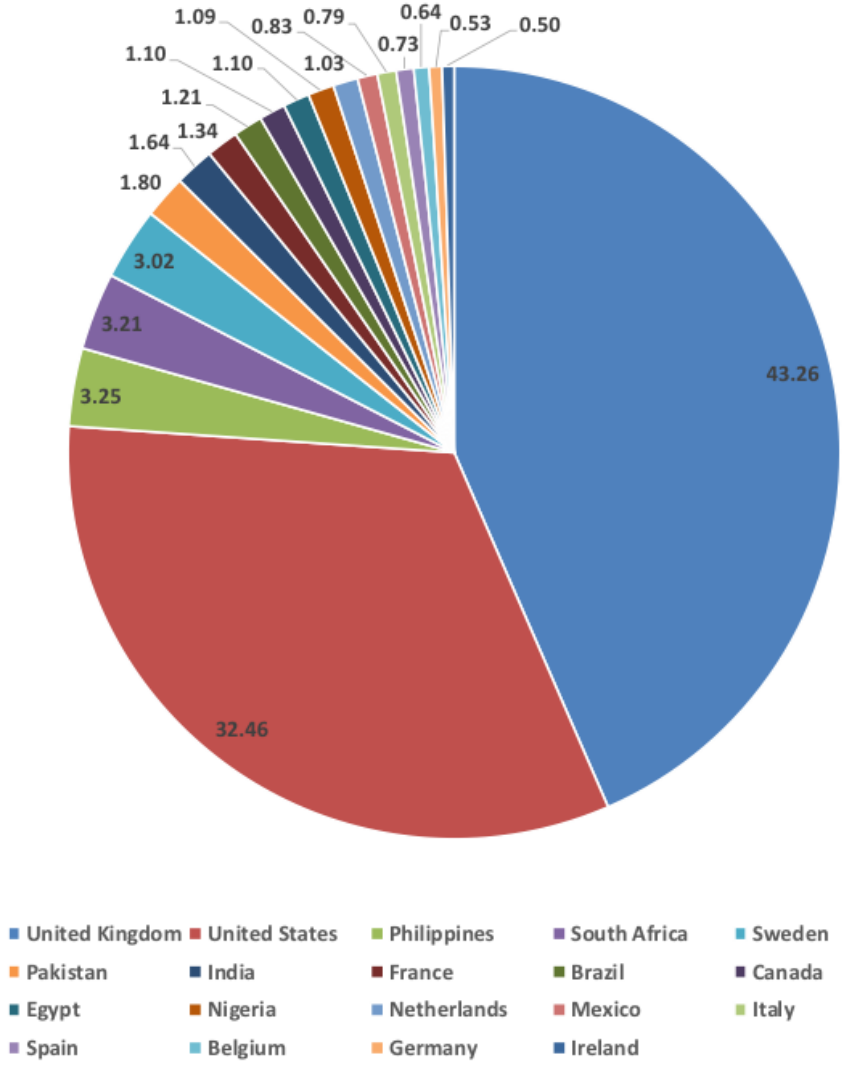
Figure 7. Top 20 countries with a large number of members. Total number of members in these 20 countries was 8654 as of October 12, 2020. The numbers shown inside or outside of the figure indicate the percentage of members of each country.



Symptoms

In December 2019, when the first reports on the outbreak started in Wuhan, China, the major symptoms reported were shortness of breath, cough, fever, and diarrhea. However, it has become clear that many patients who contracted the virus are asymptomatic yet contagious [3-5]. In addition, the symptoms of the symptomatic patients are more varied than first reported (Figure 2). Many patients reported symptoms that suggested encephalitis (headaches, foggy brain, memory loss, hallucinations, pain in the upper end of the nose suggesting inflammation in the olfactory bulb, ear pain, and pain in the back of eyes; Table 1). In addition, some patients also reported a skin rash and tingling in the legs (Table 1), which also has been reported by other recent publications [23].

Table 1. Symptoms other than anosmia or ageusia reported by COVID-19–induced anosmia or ageusia patients.

Region and symptoms	Patients, n

During the time period that the posts from the members were recorded (March to the end of June 2020), there were 355 members who posted reports of their smell or taste dysfunction and other symptoms they had. Of these 355 members, the percentage of patients without other symptoms comprised 14.93% (n=53), and 85.07% (n=302) of them had other symptoms than the loss of their senses. Almost 10% had recovered their senses by the time this report was summarized (recovered vs not recovered: n=34, 9.58% and n=321, 90.42%). The percentage of patients who recovered their senses was higher in the patients who did not have other symptoms besides anosmia and ageusia (recovered with other symptoms vs without other symptoms: 25/302, 8.28% and 9/53, 16.98%).

There were 123 members who reported that they had other symptoms and reported the timing of the onset of the loss of senses and other symptoms. Of the 123 members, 112 (91.06%) members reported that other symptoms started first. The average difference of the days between the onset of other symptoms and the onset of the loss of senses was 4.2 days. There were 6 (4.9%) members who reported that the onset of the loss of senses occurred on the day other symptoms started, and 5 (4.07%) members who reported that the loss of senses occurred before other symptoms started. The average difference of the days between the onset of the loss of senses and other symptoms was 1.6 days when the loss of senses preceded the onset of other symptoms.

The duration of time until recovery varied largely, with some people regaining their senses within a week and some people who lost their senses at the beginning of the pandemic and still had not recovered their senses at the end of June 2020. As we found the tendency that patients without other symptoms had a rather higher recovery rate, we examined if these differences correlated with the duration to recover their senses as well. Table 2 shows the 34 patients who recovered their senses in the order of the days until recovery. When the 34 patients were divided into the top 50% and the bottom 50% (fast recovery group and slow recovery group; n=17 for both), the average days to recover was 12.9 days for the fast recovery group and 41.3 days for the slow recovery group. In the fast recovery group (n=17), there were 8 (61.54%) patients without other symptoms, whereas in the slow recovery group (n=17), there was only 1 (7.69%) patient who did not have other symptoms, and there was a statistically significant difference in the duration to recovery (Fisher exact test was used: P=.02; Figure 8). These results indicate that patients without other symptoms than the loss of the senses had the tendency to recover earlier. This, however, did not indicate that patients without other symptoms will always recover their senses faster. Of the 321 patients who reported they had not recovered their senses by the time we

summarized this report, there were 44 (13.71%) patients who reported they did not have other symptoms. This suggests that there may be several causations in the loss of senses (ie, one of these could be the severity of the overall COVID-19–related symptoms and some other factors could also be involved, affecting the recovery process).

Patients with anosmia and ageusia occasionally reported distorted smell and taste (parosmia and dysgeusia) as well as the smell and taste without the sources of the smell or taste (phantosmia and phantogeusia). Table 3 summarizes the reports from the patients. Although there are various ways to describe the nature of phantosmia and phantogeusia, a smell and taste of smoke and burnt material was most frequently reported.

Table 2. Days until the recovery of senses sorted by the days and the symptoms.

Order	Until recovery of senses (days)	Symptoms other than anosmia and ageusia
1	5	Low grade fever, fatigue, insomnia
2	9	No other symptoms
3	9	No other symptoms
4	11	Fatigue, chest pain, short breath, no fever, no cough
5	12	No other symptoms
6	13	No other symptoms
7	13	No other symptoms
8	14	Cough, nausea
9	14	No other symptoms
10	14	Slight fever, runny nose
11	14	Fever, aches, chills, sore throat, headaches, rash
12	14	No other symptoms
13	14	No other symptoms
14	15	Nose pain, fatigue, headaches
15	15	Fatigue
16	17	Cold, runny nose, fatigue, sore eyes, congestion
17	17	Fatigue, cough
18	21	Burning nose, fatigue, eye pain, shiver
19	21	Fatigue, sore throat
20	23	Fever
21	27	Dizziness, disorientation, foggy brain, insomnia, ear congestion
22	28	No other symptoms
23	30	Back pain, sore throat
24	31	Burning nose, headache, fatigue, sinus infection
25	32	Nose is super dry and inflammation is high
26	35	Backache, low fever, very mild nasal congestion and mild difficulty breathing.
27	38	No fever, chills, coughs, headache, muscle ache, fatigue
28	42	Fatigue, feverish, cough
29	42	unwell, sore throat, breathless, headaches, fatigue, nausea, tinnitus
30	47	Fever, headache, fatigue, sore skin
31	56	Cough, fever, muscle ache, lethargy
32	69	Fatigue, headaches, fizzy, burning nose
33	77	Fatigue, headaches
34	83	Fatigue, headache, nasal pain

Figure 8. Recovery of senses. Earliest 50%: patients who lost their senses and recovered; longer 50%: patients who lost their senses and took a longer time to recover.

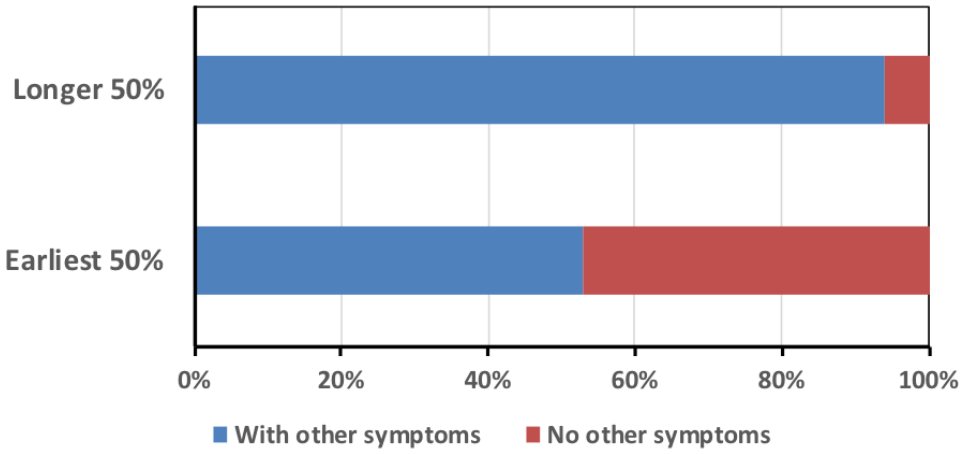

Table 3. Types of phantosmia and phantogeusia.

Types of phantosmia and parosmia	Reported cases, n
Smoke, ashtray, cigarette, burnt, fire, dusty	43
Chemical	7
Ammonia, vinegar	6
Metallic	5
Garbage, rotten	3
Skunk	1
Other expressions: weird, strange, distorted	6

Case Studies

Here, we show several examples of reports from the patients. In selecting the examples, we first classified the 355 members who posted reports of their smell or taste dysfunction during March and June 2020 into the patients who recovered (fast recovery group and slow recovery group) and had not recovered, and those with or without other symptoms than anosmia and ageusia.

Case 1 represents a fast recovery group patient who recovered early and did not have other symptoms. The length of time until recovery of smell and taste was 9 days. This patient was not tested for COVID-19. The dates shown in Textbox 1 were added when they were recorded in Excel.

Textbox 1. Case 1: fast recovery group without other symptoms (original posts).

April 7, 2020 (Tuesday)

- "Woke up and Lost all sense of smell on Thursday. Can't taste can only taste salt or sweet. Smell seems to be coming back it's now at about 10% maybe lower because I can only smell garlic and onion powder. Can't smell perfume at all. I am day 6. I am praying it's returning. Brother in law lost his smell for 11 days and it's returned fully"

April 8, 2020 (Wednesday)

- "I woke this morning and I can smell my toast in the toaster and also zoflora cleaning product can also taste the toast as well I would say it's come back 30% so happy it's improving daily thank god."
- "Quick update lost all sense of smell last Thursday complete loss no taste or smell. Yesterday i could smell spices on close inspection. This morning I could smell my toast in the toaster and also taste it it's still not 100% but I would say it's now at about 30% smell 50% taste it is getting better each day I'm now on day 7 since losing it so the general time frames are generally 7-14 days but if yours isn't then don't panic it will come back in time."
- "It came back together once my smell returned yesterday taste returned but can taste more than I can smell it's 40% smell 60% taste which am hoping will improve daily I'm On day 7 too."

April 9, 2020 (Thursday)

- "Hi all update to help anyone currently feeling scared and alone try and not to panic it will come back mine is now back 75% I'm day 7 I cried tonight when I ate dinner because I could taste and smell it very scary when all sense goes but the joy when it returns we often take this sense for granted please don't worry it will return"

April 11, 2020 (Saturday)

- "100% back"

Here is another example from the fast recovery group, but the patient had other symptoms. The patient reported recovery of the senses in 13 days (however, at the time point of summarizing this report, we have heard that this patient started to experience parosmia starting from about 2 months after the recovery of the senses). The dates shown in Textbox 2 were added when they were recorded in Excel.

Textbox 2. Case 2: fast recovery group with other symptoms (original posts).

March 28, 2020 (Saturday)

- "I've noticed this other weird phenomenon and wanted to see if you all were experiencing it too. Since I got my first possible CV19 symptom 13 days ago (slight cough), whenever I shower my skin on my hands wrinkle up super fast...like within 5 minutes of being in the shower. It usually take a good 30 minutes for that to happen to me. Now I barely shampoo and my hands are all wrinkled. My wife noticed it happening to her too although she has had no symptoms. Anyone else notice this weird thing? Ps...my smell is coming back! It's about 40-50% today and I'm on day 7. I hope it continues!!!"

March 29, 2020 (Sunday)

- "I'm on day 8 and yesterday was the weirdest day. I had the strange sense of a smell whenever I inhaled, like you, but mine was like a burning sour smell. And I got a slight metallic taste when I was eating food. Not going to lie, it was pretty awful. In fact, at the end of the day I started feeling sick to my stomach with the feeling that I had been smelling sour milk for hours and hours. Luckily today, that's completely gone. Now I'm back to smelling things about 50%. I think it's called Phantosmie. I don't know, I'm going to do more research today."

April 3, 2020 (Friday)

- "I just wanted to write a positive post for those who are feeling anxious and scared. I've got my smell and taste back! It is GLORIOUS. Everything is so flavorful and the smells are incredible. I lost both senses 13 days ago and had absolutely no improvement for 5-6 days. I was so scared that it might never come back and it was very depressing. On day 5 or 6 I could just get a wiff of a few things that I passed by maybe at about 5%. It stayed there for a couple days and then slowly started to get better. I personally had a lot of ups and downs where one day it might be at 60% and then the next day back at 30%. I was feeling rather frustrated because I couldn't tell if I was really getting better or not. Well I'm happy to say that the last two days I've been able to taste everything I've eaten and smelled things I haven't smelled in almost two weeks!! I know it might drop again before being at 100% consistently but I feel hope that I will fully heal for the long haul. Those of you who are where I was a week or so ago...don't give up. Try to stay hopeful even though it's hard. I want this to encourage anyone who feels nervous right now. It's a possibly that things will be ok.

  "PS...I'm pretty sure I had CV19 but couldn't get tested because I got don't fit the criteria."
- "I had a dry cough and then a full head cold and I lost my senses once my cold started to get better. I did have one day of burning nose and chemical taste right before I started really getting better with my smell and taste."

The next example is a patient of the slow recovery group who recovered after 42 days and had other symptoms. The dates shown in Textbox 3 were added when they were recorded in Excel.

Textbox 3. Case 3: slow recovery group with other symptoms (original posts).

April 8, 2020 (Wednesday)

- "I started getting covid symptom April 1st and on day 4 my sense of smell and taste suddenly 100% dissapeared. Now this was only 4 days ago but it already feels like a lifetime...I can't even remember what it's like to taste food. I'm just wondering, I've seen that this could be caused by a zinc deficiency? Coincidently I had just started taking zinc when the covid symptoms started so I was taking it, but now that I've actually started researching it apperently a certain form of zinc (I believe it was a nasal spray) had caused permenant loss of smell for many people so now I'm kindof hesitant to even take the pills...So confusing!!!"

May 16, 2020 (Saturday)

- "just wanted to share my story before I leave this group to provide hope to people. I got COVID symptoms April 1st (weakness, fatigue, feverish, dry cough) and woke up April 4th with zero taste or smell. I was never actually tested. I had 5 days with absolutely nothing (which was absolutely horrible, I can't even imagine people who have to deal with that for more than a month it was literally all I thought about) then I was finally able to get a tiny whiff of one of my essential oils (lemon grass haha) which gave me hope that it was not permenant. It was soooo slow coming back, like I would say it only improved max 2% a day. It is only yesterday that I realized I think I am finally at 100% back to normal, so I would estimate it took a month to slowly come back. Throughout that month I would wake up almost every day with that phantom "chemically plasticy burning" smell/sensation which gradually reduced in strength, I do remember smelling it only a few days ago. Now I guess my recovery is sort of on the fast side, which I would attribute to my healthy lifestyle. I generally eat a plant focused diet, with minimal meat, dairy and processed foods. Since I was sick I have had barely any alcohol and obviously no smoking. In the beginning I was taking vitamins daily such as vit C, D, zinc and oil of oregano. I also tried to incorporate many anti-inflammatory foods into my diet such as tumeric, garlic, ginger. Who knows how much this actually helped but I'm sure it didn't hinder."

The last example is of a patient who has not recovered their senses yet. The dates shown in Textbox 4 were added when they were recorded in Excel.

Textbox 4. Case 4: not recovered, with other symptoms.

March 29, 2020 (Sunday)

- "March 13th - sudden and complete loss smell and taste. Before that date I have been suffering some headaches. March 16 to 18 – fatigue and dizziness. Now I feel ok physically but smell and taste is still gone. After 12-13 days later I was able to smell coffee grains but faintly. My testers are coffee, vicks, perfume for sniffing. I'm about 10% and it comes and goes back. Taste was completely gone I could not even identify salty, spicy etc. Now I can identify them but flavor is missing. I feel 15-20% improvement but not so sure."

April 2, 2020 (Thursday)

- "I could smell Vicks around day 15-16. Now in day 20. Coffee, garlic, mint etc. are OK but rest is not good"

April 14, 2020 (Tuesday)

- "Day 32 still weak. It comes and goes even during the day. Early mornings and evenings are worse. Still need to get close to be able to smell and taste is way behind."

April 24, 2020 (Friday)

- "Hi all! It has been around 10 weeks for me and I cannot even say the percentage :) How do you define it? For example, I feel 100% for mint, coffee or other strong things but 0% for basil interestingly - once upon a time it was my fav :D Besides, all bad smells are totally gone. Sometimes I can smell strong smells in the air - if there is garlic in the food for example. And as many others I'm experiencing fluctuations hour by hour and day by day. Still feel improving but sometimes I feel quite desperate and it's really diffucult to stay always postive! Good luck to all of us!"

Discussion

Benefits and Limits of Social Media

The year 2020 has become a tragic year with the pandemic that has over 67 million cases and over 1.54 million deaths worldwide as of December 6, 2020. At the early stage of the pandemic, many suspected COVID-19 patients could not get tested because of the overwhelming number of patients with severe conditions at the hospitals. This suggests that the actual number of patients with COVID-19 could be far more than the officially reported number. Many of the suspected COVID-19 patients with mild to moderate symptoms self-isolated themselves without medical treatment. These suspected COVID-19 patients had to depend on the internet to obtain information, and many of them joined membership groups on social media, which were founded to support patients with COVID-19.

In this study, we analyzed the information in the social media database of suspected COVID-19 patients, with particular attention to their olfactory and gustatory dysfunction. About 70% of them could not get tested at all or could not get tested immediately and received the antibody tests later. Furthermore,

about 90% of them either stayed at home with generic medicines or supplements, or stayed at home without any medicines. These results suggest the limited access of the patients with mild to moderate symptoms to medical services. In the aspect of olfactory and gustatory dysfunction, it was demonstrated that patients who were asymptomatic other than the senses comprised about 15% of patients. Recovery of the senses was higher in the patients who were asymptomatic besides having anosmia and ageusia. Most patients experienced other symptoms first and then lost their senses, on average, 4.2 days later. Patients without other symptoms tended to recover earlier (P=.02). Patients with anosmia and ageusia occasionally reported distorted smell and taste (parosmia and dysgeusia) and experiencing or perceiving the smell and taste without the sources of the smell or taste (phantosmia and phantogeusia). Olfactory dysfunction of a large portion of patients with COVID-19 persisted at least several weeks to months.

Through the analyses of the reports, we have noticed the benefits and limits of using social media (Textbox 5). There are many benefits for patients, which suggest that these membership groups can be a beneficial system for patients to provide information and mental support. For researchers, there are some limits that require improvements to use social media membership groups to enhance understanding of the COVID-19 symptoms and conditions of the patients. These limits are due to the free nature of the involvement in the activities of the group, which causes difficulties in following up with each patient, and control of the conditions. The reports are based on each patient's subjective experience that the same symptom at similar severity could be experienced as a difficult experience by one person and as an easy experience by another. Some modifications in the way of organizing these membership groups may be able to reduce these limits for the researchers in the future. Demographic data revealed that there were about three times more women than men, and the range of age showed a peak in the age group of 25-34 years. The number of members in each age group decreased in the groups of higher age. These results on the demographic trends may reflect the trends that the symptoms of the younger people are milder compared to older people, and thus, they stayed home without medical treatments. However, there are also possibilities that women used social media more than men and that younger people used social media more than older people to obtain information on COVID-19. There were, in fact, a few cases that wives who joined the group instead of the husbands with suspected COVID-19 and mothers who joined the group instead of their small children who were suspected COVID-19 patients. These are the possible aspects of the social site structures that can skew the information.

Textbox 5. Benefits and limits of using social media.

Benefits

- (Patient) Possible to post *immediately* without waiting, compared to doctor visits, which usually require appointments
- (Patient) Patients who have mild/moderate symptoms can obtain and exchange *information*
- (Patient) Patients who have mild/moderate level of symptoms can *mentally support* each other
- (Patient) Possible to join from anywhere in the world if there is access to internet
- (Researcher) If the number of members increase, it is possible to obtain large numbers of data
- (Researcher) Possible to understand the patients' conditions, emotional responses, their experiences with their doctors from their posts

Limits

- (Patient) Possibility to join is limited to the areas where there is access to internet and to countries without federal restrictions to join internet groups
- (Researcher) There is no control group
- (Researcher) Some people are tested for COVID-19 and some are not, and we do not know which person is tested by the reports unless the person writes this each time
- (Researcher) Cannot get the same people to respond to each poll
- (Researcher) Everything is based on self-reporting and it is difficult to get precise information on the symptoms to diagnose
- (Researcher) Members often leave without notification and it is difficult to follow up

Symptoms

Among the symptoms, we especially focused on smell and taste dysfunction, which is now known as one of the major biomarkers of COVID-19. The use of social media allowed members to join the group from around the world. Although there is a limit in the range of information that can be obtained through social media (eg, accurate diagnosis of the patients), the use of it enabled us to obtain the symptoms and the progression of these symptoms from the patients who did not or could not visit the hospitals.

The current analysis demonstrated that about 90% of the 355 patients in the *COVID-19 Smell and Taste Loss* group that reported their subjective smell or taste disturbance did not recover, at least completely, for months. These results are in sharp contrast to the previously reported findings that 80% of smell and taste dysfunction in patients with COVID-19 is recovered within a few weeks [9,24-26]. This discrepancy may

be due to several reasons: the differences in the patient populations (ie, the patients in the previous studies were mostly in-patients whereas over 99% of the patients of this report had never been hospitalized and most of them did not or could not have access to medical treatments at a hospital), this is a self-selected group who joined because of their smell loss, and one limit of social media, which is the inability to confirm the recovery unless the patients post their recovery to the group.

The pathophysiology of human olfactory dysfunction is divided into three major categories. One is an airflow problem, where the airflow toward the olfactory cleft is blocked by mucosal swelling or mucus hypersecretion [27-29]. The second is a sensorineural problem, where the perception of odorants is disturbed due to damage to the olfactory mucosa, such as olfactory neural degeneration, downregulation of the odorant molecules on the olfactory neurons, or impaired transport of the odorant molecules to the olfactory receptors due to secretory dysfunction of Bowman glands [27-29]. The third is a central nervous problem, in which the olfactory pathway from the olfactory bulb to the olfactory cortex is damaged [27-29]. Airflow problems could be resolved in a relatively short time as mucosal swelling by viral infection decreases in several days to weeks, and usually the smell problem could fluctuate in its severity during the time course, depending on the nasal condition. In contrast, sensorineural and central nervous problems are usually severe, do not fluctuate, and take a longer time (months to years) for recovery. Postviral olfactory disorder, an olfactory problem developing after an upper respiratory viral infection, is usually considered as a combination of a sensorineural and central nervous system problem [27-29]. In contrast to such current concepts, previous studies reported that a large portion of patients with COVID-19 recovered from their olfactory dysfunction within a few weeks [9,24-26], suggesting that the problem was due to an airflow problem. In fact, a case report of olfactory dysfunction in a patient with COVID-19 showed mucosal swelling in a restricted area of the olfactory cleft on magnetic resonance images [30]. However, our analysis, as well as some more recent studies [31], demonstrated that a larger number of those with olfactory dysfunction were not resolved in such short time frames, suggesting that a neural problem could be also involved in COVID-19–induced olfactory dysfunction. Previous reports suggest that the virus may migrate along the peripheral and central nervous system. Studies using animal models have shown that human coronaviruses can make axonal transports enabling neuron-to-neuron propagation [32]. Development of parosmia, a sign of neural olfactory dysfunction, supports this hypothesis.

Our analysis also demonstrated that the smell problem of patients with COVID-19 tends to recover sooner when the patients only have smell dysfunction, not multiple COVID-19 symptoms. The reason for this finding is unclear, but one possible explanation is that, for the outpatients without access to medical treatments, recovery from olfactory dysfunction is faster if the patients have a lower viral load and therefore fewer symptoms. In other words, olfactory dysfunction may be one of the most sensitive indicators of SARS-CoV-2 infection. In fact, the percentage of patients showing anosmia or ageusia was especially high in the asymptomatic to mild level patients [9]. This indicates that anosmia and ageusia are several of the important symptoms to diagnose COVID-19 in the early stages, and to detect patients who are asymptomatic or have mild symptoms [12,15]. The official classification of the levels of illness is based on the ability to breathe, chest pain, and ability to talk or move [1], although often the ability to breathe becomes the major criteria. The level called *mild* refers to the lack of these signs of severity, although often the pains and severity of symptoms in patients classified to have mild or moderate symptoms are not mild or moderate (Table 1). Some patients with mild symptoms have fatigue and pain in various parts of the body for a prolonged length of time [33]. This indicates that patients with COVID-19 need to be diagnosed as soon as possible to enable immediate treatment not only to avoid the symptoms turning into a severe condition but also to avoid the prolonged time of these symptoms.

As described in this study, social media can become an important platform to collect data from outpatients, especially in the era of infectious disease pandemics, when hospitals are overwhelmed with patients that have severe conditions and patients with mild or moderate symptoms are often overlooked. Following the outbreak of COVID-19, virtual visits to doctors have started to become more popular, which can provide medical service without in-person visits. The benefits of social media are that patients can post their symptoms and questions whenever they are in need without appointments and can receive responses from the public, either patients, nurses, or doctors, through the internet, which enables real-time monitoring of the infected condition, patient symptoms, and the clinical course. In the United States, there is a project called DETECT, which uses a smartphone and a wristband to sense changes in the heart rate, which can be an indicator of changes in health conditions [34]. This device also allows the movement of people to be tracked, providing epidemiologically useful data. However, DETECT cannot distinguish between changes due to COVID-19 or other causes. The use of social media in addition to these other media (ie, virtual doctor visits and portable tracking devices) can become a strong monitoring method in the era of infectious disease pandemics. What is necessary to further strengthen the merits of social media could be the establishment of a system that serves as a route from the social media to, for example, virtual doctors or clinics nearby. At the current stage, obtaining enough information to provide diagnosis and treatments through social media sites contains challenging aspects for medical professionals. A system that guides patients from social media to the adequate medical support they need, to counselling, to other types of support systems, and the establishment of the rules in detail to organize such systems will help social media to become one of the new tools for the medical system in the near future.

Principal Results

Our analysis of a social media database of COVID-19 patients' posts demonstrated that olfactory dysfunction of a large portion of patients with COVID-19 persisted at least several weeks to months. This information is important in understanding the pathophysiology of COVID-19–induced anosmia. Although accurate diagnosis of patients is not always obtained with social media–based analysis, it may be a useful tool to collect a large

amount of data on symptoms and the clinical course of worldwide, rapidly growing, infectious diseases.

Limitations

Our study explores the benefits and limits of using social media membership groups in studying the symptoms of COVID-19. The patients are suspected COVID-19 patients and not all of them have been tested for COVID-19, but all have experienced loss of the senses of smell and taste.

Comparison With Prior Work

This is the first study to determine the benefits and limits of using social media in studying the symptoms of COVID-19.

Conclusions

Social media membership groups can function as a source of information and mental support for patients with COVID-19. Although some improvements in the system are necessary for its use for research purposes, it is a rare source of a large amount of data for researchers as well.

Acknowledgments

SK would like to express her special gratitude to Dr Amy Poehlman who edited the English of the paper and provided comments. SK would like to thank Christine Kelly, the founder of the social media membership group *COVID-19 Smell and Taste Loss* for her comments to the draft. The authors also wish to thank the members of *COVID-19 Smell and Taste Loss* who participated in this project. This study was partially supported by MSD Life Science Foundation, Public Interest Incorporated Foundation.

Abstract

Background: Web-based analysis of search queries has become a very useful method in various academic fields for understanding timely and regional differences in the public interest in certain terms and concepts. Particularly in health and medical research, Google Trends has been increasingly used over the last decade.

Objective: This study aimed to assess the search activity of pain-related parameters on Google Trends from among the most populated regions worldwide over a 3-year period from before the report of the first confirmed COVID-19 cases in these regions (January 2018) until December 2020.

Methods: Search terms from the following regions were used for the analysis: India, China, Europe, the United States, Brazil, Pakistan, and Indonesia. In total, 24 expressions of pain location were assessed. Search terms were extracted using the local language of the respective country. Python scripts were used for data mining. All statistical calculations were performed through exploratory data analysis and nonparametric Mann–Whitney *U* tests.

Results: Although the overall search activity for pain-related terms increased, apart from pain entities such as headache, chest pain, and sore throat, we observed discordant search activity. Among the most populous regions, pain-related search parameters for shoulder, abdominal, and chest pain, headache, and toothache differed significantly before and after the first officially confirmed COVID-19 cases (for all, $P<.001$). In addition, we observed a heterogenous, marked increase or reduction in pain-related search parameters among the most populated regions.

Conclusions: As internet searches are a surrogate for public interest, we assume that our data are indicative of an increased incidence of pain after the onset of the COVID-19 pandemic. However, as these increased incidences vary across geographical and anatomical locations, our findings could potentially facilitate the development of specific strategies to support the most affected groups.

COVID-19; data mining; Google Trends; incidence; internet; interest; pain; research; trend

Introduction

Eysenbach [1] in 2002 defined Infodemiology as the "science of distribution and determinants of information in an electronic medium, specifically the Internet, or in a population, with the ultimate aim to inform public health and public policy." Since then, web-based sources have been suggested to be valuable in various academic fields for understanding timely and regional differences in the public interest in certain terms and concepts [2].

Especially in health and medical research, infodemiological studies using Google Trends have increased over the last decade [3]. Recently, several studies have used Google Trends data to elucidate the progression of the COVID-19 pandemic. For example, Husain et al [4] used Google Trends to track public interest in COVID-19 [4] and reported that in the United States, when containment and mitigation strategies were first implemented, public interest was very low. However, the search volume of COVID-19–related terms increased and correlated with the increase in positive findings on COVID-19 tests nationwide. Furthermore, Walker et al [5] correlated the search activity for the term "loss-of-smell," an early symptom of COVID-19, to the number of daily confirmed cases and COVID-19 deaths. Similarly, Jimenez et al [6] correlated searches for different symptoms of COVID-19 with daily incidences. Another study used Google Trends to identify mental health consequences related to physical distancing during the lockdown. Notably, Knipe et al [7] reported a reduction in search activity related to suicide and depression after the announcement of the pandemic.

The use of internet searches to gather information about patients experiencing pain has been insufficiently studied. Of 2 studies on populations of people with chronic pain, 1 reported that 24% of the population searched the internet for pain-related information, and the other reported that 39% of the population performed internet searches [8,9]. However, both studies are more than 10 years old. Considering the recent growth of the usage of online media, it is reasonable to suppose that the proportion of individuals searching for pain-related information on the internet increased during the last decade.

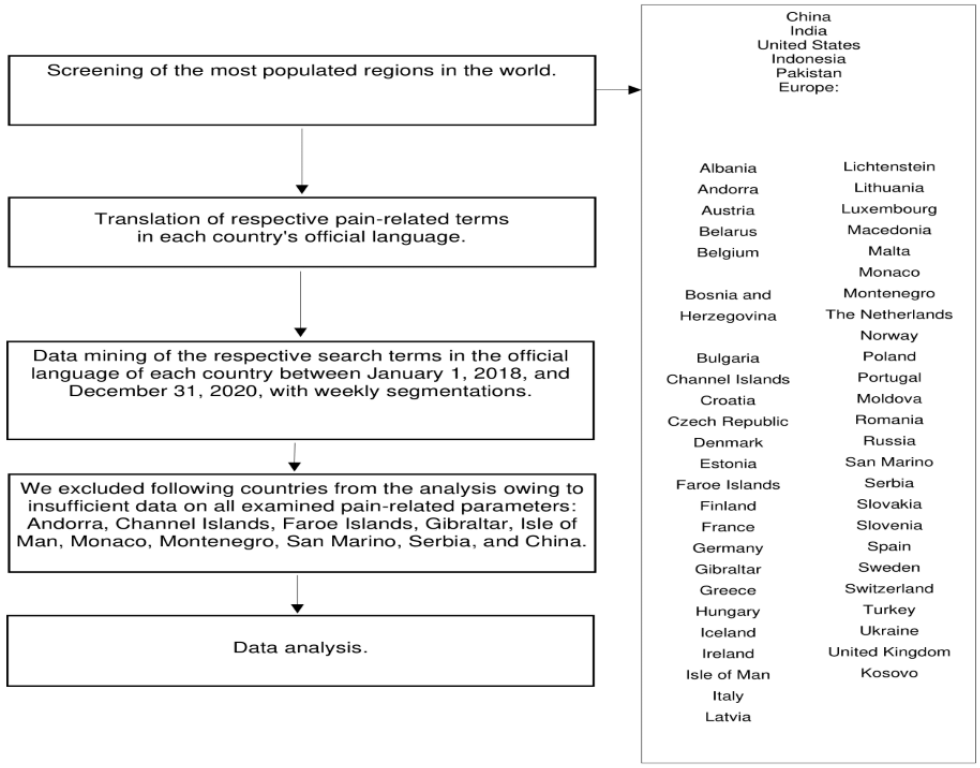
The COVID-19 pandemic has affected the health condition and quality of life of people with chronic pain in 2 ways. First, several changes have led to increased susceptibility to and a higher risk of pain exacerbation. Specifically, the availability of health care was significantly reduced and an atmosphere of fear and isolation was developed [10]. Previous experiences with epidemics have shown a latent, but long-term, deterioration of psychosocial problems [11]. Therefore, it has also been postulated that chronic pain, as a biopsychosocial phenomenon, exacerbates in response to the COVID-19 situation [12]. Second, acute stress can alleviate chronic pain [13,14]. Indeed, acute stress in response to disasters alleviates pain [15]. One could therefore hypothesize that the COVID-19 situation alleviates chronic pain, at least at the onset of the pandemic. To date, no studies have examined changes in the experience of chronic pain after the onset of the COVID-19 pandemic in large patient populations. To bridge this knowledge gap, search activity can be used as a surrogate for the public interest in pain. This does not necessarily reflect the incidence or the burden of pain in the general population; however, acute changes can be interpreted as a momentary shift of attention and thus highlight the importance of these symptoms.

This study aimed to assess the Google search activity of pain-related expressions in the most populated regions worldwide and to use them as markers of the social importance of pain before and during the first wave of the COVID-19 pandemic.

Methods

This infodemiological study was designed and carried out at Graz Medical University in cooperation with the Graz University of Technology and Fraunhofer Austria. The workflow of this study is presented in Figure 1. The temporary popularity of pain-related search terms was assessed using Google Trends [16]. Google Trends delivers data on web-based search queries for specified timeframes and countries. Google Trends offers 2 analysis modes: one with "terms" and the other with "topics." In contrast to the analysis with "terms," Google Trends analysis with "topics" corresponds to a fuzzy search. The difference is that "topics" include all search terms related to a particular aspect, whereas "terms" are specific, and the results will only show the relative volume of the corresponding term. Since different types of pain are related to one another—for example, neck pain and shoulder pain or dysmenorrhea and pelvic pain—a fuzzy search that includes related terms is not adequately discriminative. Furthermore, it is unclear which terms are summarized in a specific "topic." Hence, smaller, discriminative trend analysis with "terms" was preferred. Data are presented as relative popularity, normalized to the region and period and scaled from 0 to 100. Subsequently, the data were exported for further calculations [17]. The study followed the methodology framework developed by Mavragani and Ochoa [18].

Figure 1. Workflow for data retrieval and processing pipeline in this study.



The search terms used in this study were based on a recent study of global internet searches associated with pain [19]. In total, 24 expression entities based on anatomical regions were used: “abdominal pain,” “back pain,” “breast pain,” “chest pain,” “dysmenorrhea,” “dyspareunia,” “ear pain,” “epigastric pain,” “eye pain,” “groin pain,” “headache,” “knee pain,” “low back pain,” “neck pain,” “odynophagia,” “pelvic pain,” “penile pain,” “podalgia,” “rectal pain,” “shoulder pain,” “sore throat,” “testicular pain,” “toothache,” and “wrist pain.” The results for 3 of these terms (“penile pain,” “podalgia,” and “rectal pain”) were excluded from further analysis because of insufficient data. Weekly data sets were downloaded from January 1, 2018, to December 31, 2020. Google Trends analysis was carried out in February 2021.

Our intention was to provide an overview of the development of the aforementioned pain-related search parameters in the most populated regions worldwide. The most populous areas worldwide were extracted from the recommendations of the United Nations and a web-based population database [20,21]. Europe, consisting of individual European countries, is defined as a single region in this study. Figure 1 shows all the selected regions and the individual European countries. We identified the following as the most populated regions: Europe, the United States, China, India, Pakistan, Brazil, and Indonesia. Search terms were extracted in the respective language of each country. The data set of Europe is accumulated; it consists of all available nationwide data sets of the European countries weighted by their population. Details including the complete list of countries, their population sizes, the corresponding weighting factors, and the date of the first officially reported COVID-19 case of the country were provided by the European Centre for Disease Prevention and Control. Using this list of European countries, we retrieved a data vector for each country and pain type in the respective language of each country. Thereafter, the individual vectors were weighted with the country’s population and accumulated to a European vector (Multimedia Appendix 1). Since the weighted summation with sum 1 is an affine map, the result is also normalized. Calculations with the European vector thus correspond to stratified sampling; that is, individual characteristics of the target group deemed relevant for the study are transferred to the sample in approximately the same proportion as those in the population.

Data from China could not be extracted adequately, and data extraction yielded numerous error parameters. Therefore, China had to be excluded from our analysis.

We assumed that the occurrence of biological and psychosocial effects of the pandemic correlated with the first appearance of the virus in a certain region. Accordingly, we defined the beginning of the “COVID-19 period” for each geographic region with the first officially confirmed case for each country on the basis of reports from the European Centre for Disease Prevention and Control [22]. The date of the first officially reported COVID-19 case for each country was used as the independent variable for our calculations.

For data extraction, we used Python scripts. The Google Trends analysis data were obtained with the software libraries pytrends and pandas [23,24] using Python. The number of COVID-19 cases were obtained from the European Centre for Disease Prevention and Control on February 9, 2021. Results from countries with erroneous data or insufficient cases and subsequently inconsistent data are excluded from the study (Figure 1).

IBM SPSS Statistics (version 26, IBM Corp), Microsoft Office 365, and LibreOffice 7.1 were used for the statistical

calculations. Explorative data analysis and nonparametric Mann–Whitney *U* tests were performed. The level of significance was not corrected for multiple comparisons. These corrections are necessary for multiple tests carried out with the same samples: the greater the number of hypotheses tested on 1 data set, the higher the probability that 1 of them is (incorrectly) assumed to be true. As the data were collected separately by country and pain type, the precondition for test corrections (all tests on 1 data set) was not met; that is, Bonferroni corrections or similar methods were not required and hence not applied.

Additionally, we performed a visual analysis to illustrate the difference between significant and nonsignificant changes in the time series data (Figures 2 and 3) and to plot a side-by-side comparison of the progression of pain-related search criteria with the so-called waves of COVID-19 outbreaks (Figure 4). This analysis has been performed for "headache," as this query term increased significantly in all geographic regions, and for "wrist pain," as this query term did not show any significant changes.

For both terms, the analysis involved a seasonal autoregressive model whose parameters have been determined using Google Trends vectors retrieved for 2018 and 2019. Using these models, weekly differences between the model values for 2018-2019 and 2020 were calculated and plotted (Figures 2 and 4).

Figure 2. Trends for headache.

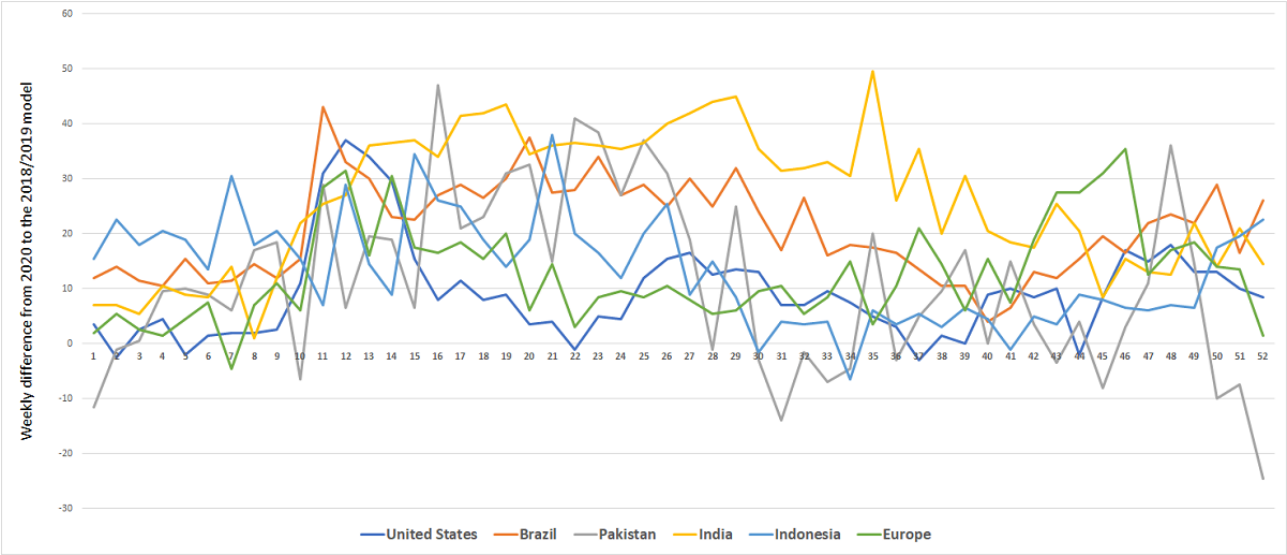


Figure 3. Trends for wrist pain.

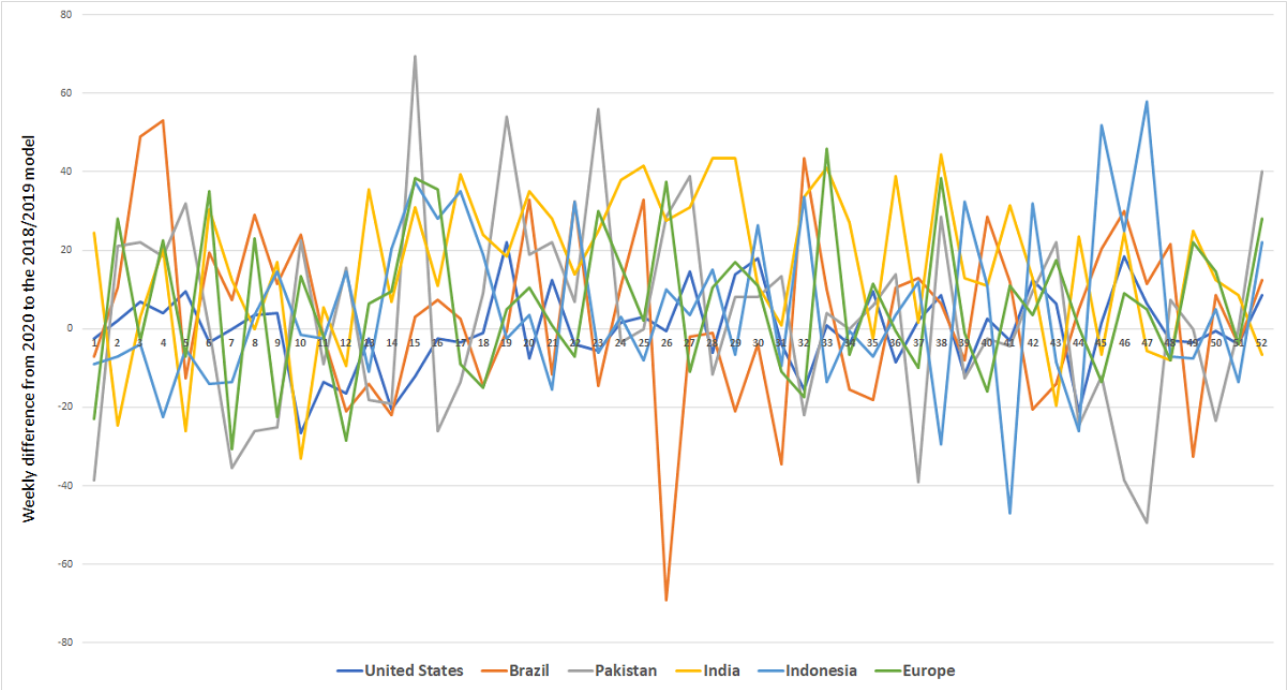

Figure 4. An overview of the 5 most populous countries (last row) and European countries in an arrangement that corresponds to the geography of Europe. Only countries for which sufficient data were available are included; data on China and Serbia were inadequate. Each chart consists of 4 rows, each used by a subchart, and 4 vertical columns, each covering 1 quarter of 2020.

Results

Our results demonstrate significant differences in pain-related search queries by comparing quantities before and after the first confirmed COVID-19 case. We observed a peak in the incidence of pain-related search parameters in March and April 2020 (Figure 5). Abdominal pain, dysmenorrhea, dyspareunia, groin pain, eye pain, knee pain, low back pain, and pelvic pain were the only pain types with a significantly decreased frequency of search relevance in some of the most populous geographic regions since the COVID-19 outbreak (Table 1). In contrast, the frequency of searches related to back pain, breast pain, chest pain, ear pain, headache, odynophagia, neck pain, shoulder pain, sore throat, testicular pain, toothache, and wrist pain

significantly increased after the first confirmed case of COVID-19 was reported (Table 1, Figure 4).

Figure 5. Summation trends of pain-related search parameters in the most populated regions worldwide (Europe, the United States, Brazil, Pakistan, India, and Indonesia).

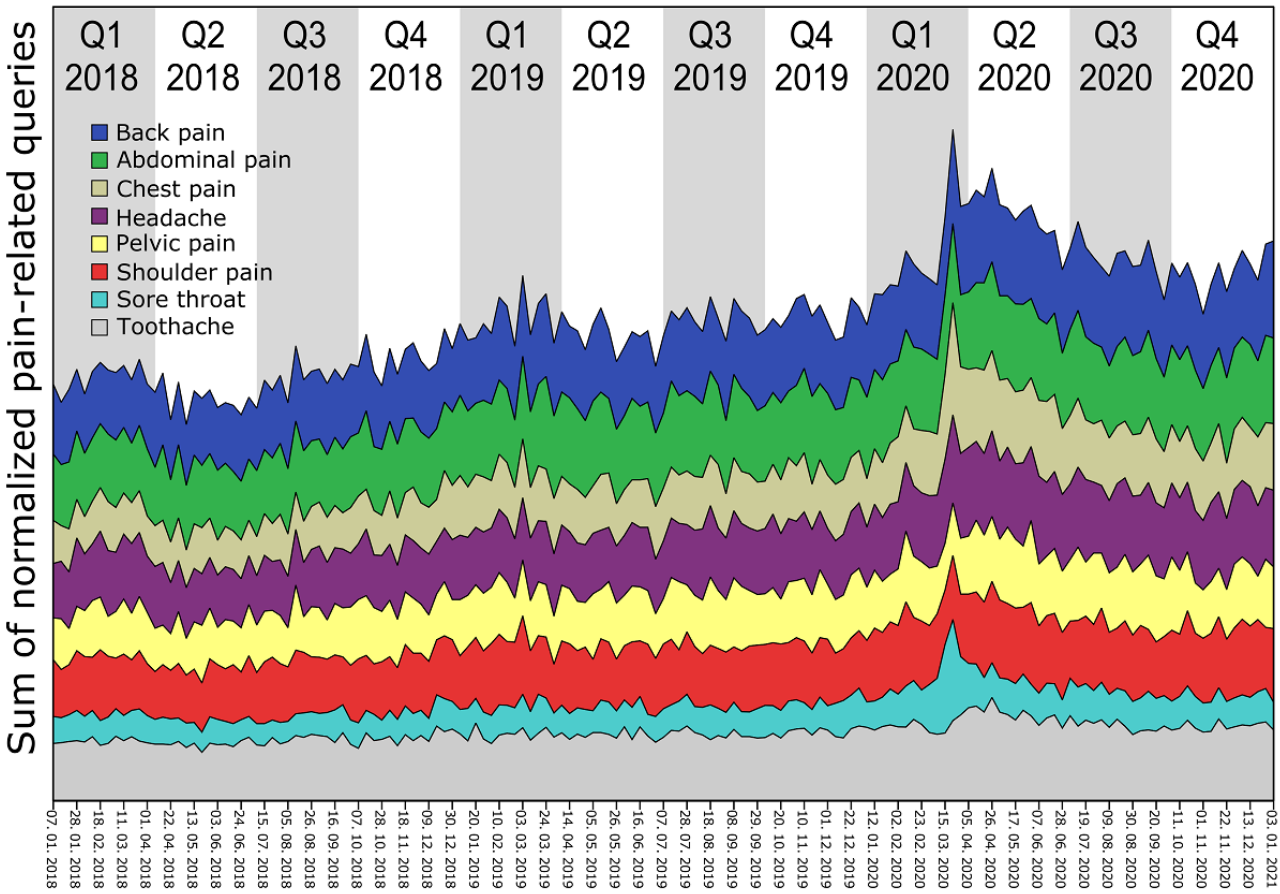

Table 1. Comparison of search trends between January 1, 2018, and December 31, 2020, for pain-related terms before and after the first officially confirmed COVID-19 case in in Europe, the United States, Brazil, Pakistan, India, and Indonesia (China was excluded from the data set owing to insufficient data).

Pain type	Europe (*P* value)	United States (*P* value)	Brazil (*P* value)	Pakistan (*P* value)	India (*P* value)	Indonesia (*P* value)	Overall (*P* value)

Toothache	<.001[a]	.31[b]	<.001[a]	<.001[a]	<.001[a]	<.001[a]	<.001[a]
Wrist pain	.08[b]	.94[b]	.11[b]	.77[b]	<.001[a]	.04[a]	<.001[a]

[a]Relevance of the pain-related search parameter increased significantly after the first confirmed COVID-19 case was reported.

[b]No significant changes.

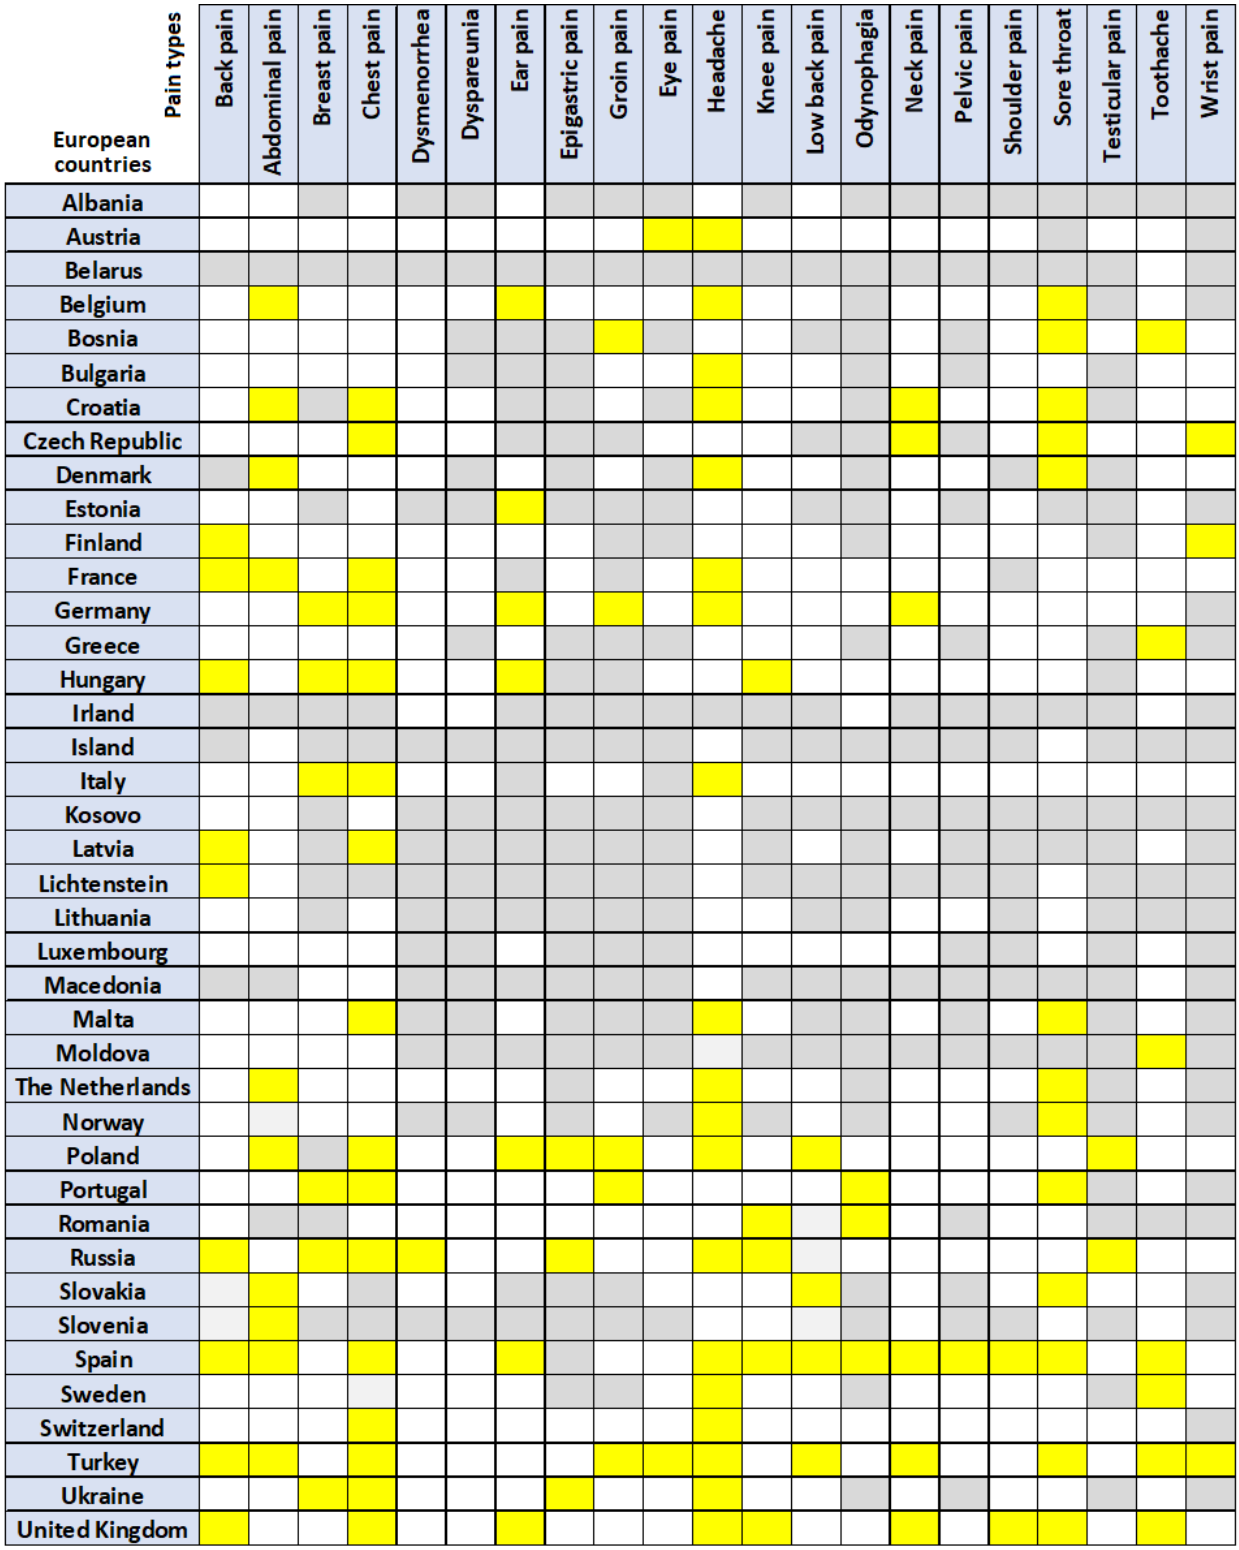
[c]Relevance of pain-related search parameter decreased significantly after the first confirmed COVID-19 case was reported.

[d]N/A: not applicable; no data available/inadequate number of cases.

Our data show that in Europe, Brazil, Pakistan, and India, all pain entities listed above increased significantly or remained unchanged after the first confirmed COVID-19 case was reported. In contrast, in the United States, we observed an inhomogeneous trend, with the frequency of some pain-related search terms decreasing significantly after the first confirmed COVID-19 case was reported, whereas that of the others increased or remained unchanged (Table 1).

A comparison among individual European countries revealed that the most frequently observed significant differences among countries were noted for headache, chest pain, sore throat, abdominal pain, and back pain since the COVID-19 outbreak. With respect to individual European countries, Spain displayed the most frequent significant pre– and post–COVID-19 discrepancies in the frequency of pain-related search queries (Figures 3 and 6).

Figure 6. Summation trends of pain-related search parameters in European countries. Yellow=relevance of pain-related search parameters changed significantly after the report of the first confirmed COVID-19 case, white=no significant changes, and gray=no data available or inadequate data.



The analysis of the difference plots for the term "headache" revealed that the weekly differences between the 2020 and the 2018-2019 models were more often significantly positive than negative; in other words, the number of queries for "headache" increased. As the Google Trends data are normalized with a range of 0 to 100, the 2018-2019 model was normalized accordingly (Figure 2).

If the search frequency of a term did not increase significantly, the differences would be expected to be as often positive as negative. Consequently, the difference plots would resemble random noise; for example, the search term "wrist pain" displayed no significant change in most geographic regions and its plots illustrate random noise around 0.

Furthermore, on assessing country-specific developments in pain-related search parameters, which have significantly

increased in relevance since the COVID-19 pandemic outbreak, it becomes apparent that the relevance of pain-related search parameters increased in almost all countries before the peak of the first wave of the COVID-19 pandemic. “Headache” was consistently high in relevance, especially in Belgium, Brazil, Germany, Indonesia, Italy, Russia, Turkey, and the United States. The relevance of “chest pain” and “sore throat” seemed to resonate with the first wave of the COVID-19 pandemic, as seen in several countries including Belgium, Croatia, France, Italy, the Netherlands, and the United Kingdom. In contrast, the frequency of “abdominal pain” appeared highly dynamic compared to that of COVID-19 cases (Figure 4).

Discussion

Principal Findings

Our results indicate that for most pain entities, the frequency of pain-related search queries significantly increased after the official report of the first confirmed COVID-19 case (Table 1). In particular, search queries for “chest pain” and “headache” significantly increased in all of the world's most populous regions included in this study.

On assessing the trends for the most populated regions, we found that the incidence of pain-related search criteria increased for back pain, breast pain, chest pain, ear pain, headache, neck pain, shoulder pain, sore throat, and toothache after the COVID-19 outbreak. With the exception of the United States and Indonesia, we observed a significant increase in pain-related search parameters for almost all the pain types (Table 1).

Part of our findings of increased numbers of searches of pain-related terms may reflect symptoms attributed to COVID-19. For example, sore throat [25] and headache [26] are frequent symptoms of COVID-19 and have been often discussed as signs of COVID-19 in the news media [27]. Consequently, an increased interest in this search term was expected. This may also apply to chest pain. Similar to sore throats and headaches, “chest tightness” was a term that was frequently used in the news media in connection with COVID-19 [27]. However, since chest pain is also a key symptom of major cardiac events, our data should be interpreted with caution as other studies have reported a drastic increase in heart attacks and cardiovascular deaths during the first wave of the COVID-19 pandemic [28]. This is postulated to be associated with delays in seeking help. Compared with other pain-related terms, the increase in searches for “toothache” was delayed but persisted at a higher level. The changes in search behavior for toothache may be explained by the fact that many patients had no opportunity or were too afraid to visit a dentist during the lockdown [29]. The number of dental visits decreased to less than one-fifth that before the onset of the COVID-19 pandemic [30]. Therefore, painful dental conditions may have remained untreated or may have developed over time. The variation in the search pattern of eye pain in response to the COVID-19 pandemic has been previously reported [31]. However, it remains unclear if this can be attributed to a direct effect of the virus or is the effect of changes in lifestyle during the lockdown (eg, more time spent in closed rooms and increased screen time). The same argument could hold true for neck pain; as internet usage for private purposes, remote working, and education increased, one can assume that problems with posture also became more prevalent [32].

It remains unclear why the search frequency for groin and knee pain decreased in certain populous regions before to after the onset of the COVID-19 pandemic. Each of these pain entities was associated with physical activity [33,34]. Owing to the potential consequences of a lockdown, decreased physical activity can be anticipated as a possible effect.

In Pakistan, India, Brazil, and Indonesia, the frequency of most pain-related keywords increased after the first confirmed COVID-19 case. Furthermore, Europe displayed a predominant increase in search queries across almost all pain types. On further inspection of individual European countries, we found that similar to the overall picture, that COVID-19–related symptoms dominate the increase in searches, such as “headache,” “sore throat,” or “chest pain” (Figure 6). On the contrary, in the United States the frequencies for most pain-related searches decreased.

Owing to our study design, we can only speculate the reasons for this geographically heterogeneous pattern. We assume that except for those symptoms (chest pain, headache, neck pain, sore throat, and toothache) that showed the same direction of change in all geographic regions, there are no direct or indirect biological effects of COVID-19 on pain. Thus, the reasons for the observed regional differences are most likely attributed to psychosocial dimensions. Differences in social systems and cultures are evident in various fields of health [35]. Especially in the more developed regions, the overall satisfaction with the health care system is generally high [36,37]. One could speculate that these differences contribute to the impact of the COVID-19 pandemic on people with chronic pain on an individual level.

A special situation was observed in the United States, in that we observed a reduction in the frequency of most search terms. This may be explained by the fact that the exposure to COVID-19 was time-shifted for different areas in the United States. Only the third wave of the pandemic encompassed the country simultaneously and its entirety.

Limitations

This study has limitations, which need to be addressed. Some of these limitations are related to our study design. It is evident that analyzing online searches may only reflect the behavior of internet users, thus potentially excluding relevant groups; for example, older or uneducated individuals [38]. Other demographic groups are potentially overrepresented. Younger individuals and women displayed a higher prevalence in health-related information searches on the internet [39].

Similarly, one can only speculate the reasons for the individual searches. Generally, internet searches are considered a surrogate for public interest. This does not necessarily imply that searches are carried out by patients experiencing a certain symptom. In our case, relatives, advocates, or researchers may also search for pain-related terms.

Figure 4 shows high fluctuations in the Google Trends data set. According to Google, only a sample is used for the trend

analysis and not the complete data set of all search queries [40]. Google does not disclose which sampling strategy is used. However, Figure 4 suggests that the population size has an influence on the sampling rate considering the number of search queries. The lower the sampling rate (ie, lesser data on which the data calculation is based), the greater the inaccuracies that are reflected in the fluctuations in the graphs [41].

Some limitations are specific to our study. For instance, our study only uses Google data and therefore represents the search behavior of only Google users. However, as Google has a nearly 70% worldwide market share, it is representative of the majority of internet users [42]. In our study, we excluded China as we did not obtain adequate data from this origin. The use of other sources including Baidu could have provided more details; however, as these data would not be comparable to Google Trends data, we decided against this approach.

We have summarized the data of European countries. In doing so, the exact timepoint of the "first official case" was not defined at the national level but rather on the continental level in in Europe. It can be assumed that the inaccuracy of these statistics for the temporal delimitation for the local onset of the pandemic is of the same order of magnitude as for the individual country data sets provided by Google Trends. The problem also exists in these data sets as outbreaks of the pandemic did not occur homogenously (eg, in all US states or in all provinces of China) simultaneously.

The definition of search terms is crucial when extracting information from search databases [38]. Our keywords represent anatomical locations instead of certain diagnoses (eg, fibromyalgia and migraine). This approach was previously introduced by Kamiński et al [19]. As we have not been aware of another already established search strategy for pain-related keywords in an infodemiological study, we decided to follow the method of Kamiński et al.

Conclusions

Our results indicate considerable changes in internet search behavior related to pain-related keywords for the most populated regions worldwide. There are many possible reasons for these changes in internet search behavior. As expected, we found that certain search terms that are closely related to COVID-19 symptoms are increasing, such as the pain entities of headache, chest pain, or sore throat. Our study describes the analysis of the trends in pain-related search parameters on the Google search network, as developed over a 2-year period.

In summary, apart from COVID-19–related pain symptoms, the frequency of search parameters related to pain across the most populated regions worldwide was observed to change over time before and after the onset of the COVID-19 pandemic. As internet searches are a surrogate for public interest, we assume that our data are indicative of an increased incidence of pain after the onset of the COVID-19 pandemic. However, as these increased incidences vary across both geographical and anatomical locations, our data could potentially facilitate the development of specific strategies to support the most affected groups.

Abstract

Background: Communicating scientific uncertainty about public health threats such as COVID-19 is an ethically desirable task endorsed by expert guidelines on crisis communication. However, the communication of scientific uncertainty is challenging because of its potential to promote *ambiguity aversion*—a well-described syndrome of negative psychological responses consisting of heightened risk perceptions, emotional distress, and decision avoidance. Communication strategies that can inform the public about scientific uncertainty while mitigating ambiguity aversion are a critical unmet need.

Objective: This study aimed to evaluate whether an "uncertainty-normalizing" communication strategy—aimed at reinforcing the expected nature of scientific uncertainty about the COVID-19 pandemic—can reduce ambiguity aversion, and to compare its effectiveness to conventional public communication strategies aimed at promoting hope and prosocial values.

Methods: In an online factorial experiment conducted from May to June 2020, a national sample of 1497 US adults read one of five versions of an informational message describing the nature, transmission, prevention, and treatment of COVID-19; the versions varied in level of expressed scientific uncertainty and supplemental focus (ie, uncertainty-normalizing, hope-promoting, and prosocial). Participants then completed measures of cognitive, emotional, and behavioral manifestations of ambiguity aversion (ie, perceived likelihood of getting COVID-19, COVID-19 worry, and intentions for COVID-19 risk-reducing behaviors and vaccination). Analyses assessed (1) the extent to which communicating uncertainty produced ambiguity-averse psychological responses; (2) the comparative effectiveness of uncertainty-normalizing, hope-promoting, and prosocial communication strategies in reducing ambiguity-averse responses; and (3) potential moderators of the effects of alternative uncertainty communication strategies.

Results: The communication of scientific uncertainty about the COVID-19 pandemic increased perceived likelihood of getting COVID-19 and worry about COVID-19, consistent with ambiguity aversion. However, it did not affect intentions for risk-reducing behaviors or vaccination. The uncertainty-normalizing strategy reduced these aversive effects of communicating scientific uncertainty, resulting in levels of both perceived likelihood of getting COVID-19 and worry about COVID-19 that did not differ from the control message that did not communicate uncertainty. In contrast, the hope-promoting and prosocial strategies did not decrease ambiguity-averse responses to scientific uncertainty. Age and political affiliation, respectively, moderated the effects of uncertainty communication strategies on intentions for COVID-19 risk-reducing behaviors and worry about COVID-19.

Conclusions: Communicating scientific uncertainty about the COVID-19 pandemic produces ambiguity-averse cognitive and emotional, but not behavioral, responses among the general public, and an uncertainty-normalizing communication strategy reduces these responses. Normalizing uncertainty may be an effective strategy for mitigating ambiguity aversion in crisis communication efforts. More research is needed to test uncertainty-normalizing communication strategies and to elucidate the factors that moderate their effectiveness.

Introduction

Public health crises such as the COVID-19 pandemic pose difficult communication challenges, due in large part to the substantial scientific uncertainty surrounding the nature and management of all new and emerging health threats [1]. This uncertainty is a defining feature of public health crises [2,3] and is important to communicate in order to foster public accountability and trust [3-5]. The communication of scientific uncertainty in public health crises is also important because it promotes more realistic expectations about the benefits of risk-reducing actions and allows people to prepare for different potential outcomes. Uncertainty communication in crisis situations has thus been a central focus of expert guidance, such as the Crisis and Emergency Risk Communication (CERC) guidelines issued by the US Centers for Disease Control and Prevention. CERC guidelines recommend that communicators both acknowledge uncertainty by clarifying what is known, what is not known, and what is being done to reduce the uncertainty, and avoid promoting excess certainty about future outcomes that cannot be controlled [6].

The challenge, however, is that uncertainty can have negative psychological effects. As CERC guidelines also acknowledge, the communication of uncertainty can heighten perceptions of risk and promote fear, panic, anxiety, emotional distress, and feelings of hopelessness and helplessness, which can prevent people from taking action [6]. These aversive psychological responses have been empirically documented by a large body of research showing that uncertainty caused by a lack of reliability, credibility, or adequacy of risk information—features of information that constitute what decision theorists have termed *ambiguity* [7]—produces a set of cognitive, emotional, and behavioral responses [8-10]. These include heightened risk perceptions, pessimistic appraisals of risk-reducing actions, fear and anxiety, and avoidance of decision making. These responses, collectively known as *ambiguity aversion*, have been demonstrated in numerous decision-making settings, including health care [7,10,11].

These effects are not universal; individuals vary in their tolerance of ambiguity as well as uncertainty arising from other causes [10-12]. Furthermore, communicating uncertainty can increase, rather than decrease, individuals' confidence and trust in information when they expect such uncertainty to exist [13-15]. Nevertheless, the predominance of aversive responses to uncertainty for most individuals and situations makes the communication of scientific uncertainty in public health crises challenging [16]. Furthermore, although expert guidelines recommend adjunctive strategies, such as expressing empathy as a means of mitigating the negative psychological effects of uncertainty [5,6], empirical evidence for this or other strategies is lacking, and the optimal methods for communicating uncertainty in public health crises remain unknown [2]. Consequently, available empirical evidence suggests that in these situations scientific uncertainty is rarely communicated in a clear, explicit manner, either by experts or journalists [17-19].

One promising theory-based strategy, however, may be to normalize uncertainty; that is, to emphasize that existing uncertainty is an expected experience that does not indicate an unusual deficit in people's abilities. A leading theoretical account of ambiguity aversion, the *competence hypothesis*, suggests that ambiguity is aversive because it lowers people's perceptions of their own competence in decision making [20]. An extension of this account, the *comparative ignorance hypothesis*, posits that aversion to ambiguity about a given prospect is driven by an implicit comparison with a less ambiguous prospect or the state of mind of more knowledgeable individuals [21]. Winkler has posited that ambiguity aversion may also arise from an erroneous belief in the existence of a single ''true'' objective probability for individual events and a discomfort with not knowing this probability [22]. Together, these theories suggest that ambiguity aversion will be heightened if decision makers' perceived competence is decreased and their comparative ignorance increased (eg, when they are made aware that relevant risk information is unavailable to them but available to others). In contrast, ambiguity aversion will be diminished if perceived competence is increased and comparative ignorance decreased. Chow and colleagues obtained experimental evidence supporting these effects by showing that individual decision makers' ambiguity aversion—manifested by their reluctance to bet on an uncertain outcome—diminished when they were made aware that the risks at hand are unknown not only to them but to all individuals; that is, they are *unknowable* [20,23,24].

Normalizing uncertainty as an expected state, therefore, may be a potentially effective strategy for reducing negative psychological responses to the communication of scientific uncertainty in public health crises. The overarching objective of this study was to evaluate this possibility in the real-life context of the COVID-19 pandemic. In a previous experimental study of public responses to uncertainty about a hypothetical viral pandemic [25], we found that an uncertainty-normalizing strategy did not reduce ambiguity-averse cognitive, emotional, and behavioral responses (ie, heightened risk perceptions and worry and diminished vaccination intentions) to scientific

uncertainty about the pandemic. However, the generalizability of these findings was limited by the hypothetical nature of the study. In the current study, we addressed this limitation by evaluating the effects of an uncertainty-normalizing strategy in a real public health crisis. Its specific objective was to test whether normalizing uncertainty reduces ambiguity-averse responses, compared to commonly used strategies aimed at promoting either (1) hope or (2) prosocial values [26-28]. These alternative strategies have been broadly implemented in public information campaigns about COVID-19, and focus on mitigating hopelessness, helplessness, and stigmatization—important adverse responses to public health crises [3,5,6]. However, because these strategies do not directly target perceptions of, or responses to, uncertainty, they should be less effective in reducing ambiguity aversion than an uncertainty-normalizing strategy.

To evaluate this possibility, we conducted an online survey–based experiment comparing alternative approaches to communicating scientific uncertainty about multiple aspects of the COVID-19 pandemic, including its controllability, prognosis, and severity. The experiment tested the following hypotheses:

- Hypothesis 1 (H1). The communication of uncertainty about the COVID-19 pandemic will result in ambiguity-averse psychological responses—consisting of greater perceived likelihood of developing COVID-19, greater worry about COVID-19, and lower intentions for COVID-19 risk-reducing behaviors—compared to the noncommunication of uncertainty.
- Hypothesis 2 (H2). Ambiguity-averse responses to the communication of uncertainty about the COVID-19 pandemic will be reduced by uncertainty-normalizing language but not by either hope-promoting or prosocial language.

As an exploratory objective, we also evaluated the extent to which individual differences, including sociodemographic characteristics (ie, age, gender, and education), political affiliation, health literacy, trait-level risk aversion, trait-level ambiguity aversion, and dispositional optimism—all factors that might influence people's responses to medical uncertainty [11,12,25,29,30]—might moderate the effects of these different uncertainty communication strategies.

Methods

Study Design and Experimental Manipulation

The study was part of a larger online experiment, hosted by the internet survey vendor Qualtrics, designed to test different strategies, including language aimed at promoting hope and prosocial values, for communicating to the general public about the nature and prevention of COVID-19. This study focused specifically on strategies for communicating about uncertainty surrounding the COVID-19 pandemic. All alternative strategies were created by adding language to basic information on the nature, transmission, prevention, and treatment of COVID-19, reproduced from a public website produced by a government public health department [31]. This basic information contained no explicit communication of scientific uncertainty and served as the *control* strategy. Supplementing this basic information with additional language resulted in a total of five alternative uncertainty communication strategies, which constituted separate experimental conditions to which participants were randomly assigned: (1) control, (2) uncertainty, (3) uncertainty + uncertainty-normalizing, (4) uncertainty + hope-promoting, and (5) uncertainty + prosocial.

The *uncertainty* condition highlighted the existence of scientific uncertainty about the controllability, prognosis, and severity of the COVID-19 pandemic. The *uncertainty + uncertainty-normalizing* condition combined expressed uncertainty with language emphasizing the unknowability of these various aspects of COVID-19 and the expected nature of scientific uncertainty. The *uncertainty + hope-promoting* condition combined expressed uncertainty with language conveying optimism about future advances in knowledge and control over the pandemic. The *uncertainty + prosocial* condition combined expressed uncertainty with language encouraging awareness of obligations to other community members and concern for the collective good. The alternative uncertainty communication strategies varied in length from 940 to 1273 words; the full text of all strategies is presented in Multimedia Appendix 1.

Study Population and Recruitment

The study population consisted of a national sample of adult members (aged ≥18 years) of the US public belonging to a voluntary opt-in web survey panel professionally managed by the internet survey vendor Qualtrics. Panel members have experience and interest in completing online surveys for marketing purposes, for which they are provided modest monetary incentives. Qualtrics maintains sociodemographic and geographic data on panel members, which provides the capacity to target recruitment to prespecified quotas in order to achieve a sociodemographically diverse study sample. This study employed quotas aimed at obtaining a balanced distribution by age, gender, race, geographic region of the United States, education level (ie, ≥20% high school diploma or less), and income (ie, ≥50% annual income of US $50,000 or less), and to exclude participants who reported a current or prior diagnosis of COVID-19. To ensure data quality, we excluded participants who gave logically inconsistent responses to two screener questions about participants' attitudes toward risk-reducing behaviors or whose survey completion time was below 12 minutes—the time cut point accounting for the majority of inconsistent responses in preliminary fielding of the study.

The study was approved by the MaineHealth Institutional Review Board. The survey was fielded from May 7 to June 11, 2020; during this time, the number of total coronavirus infections in the United States increased from >1.2 million to >1.6 million, and total deaths increased from >77,200 to >98,000 [32].

Measures

After reading their randomly assigned informational vignettes, participants completed a survey questionnaire consisting of the measures summarized below.

Outcome Variables

Perceived uncertainty about COVID-19 served as the manipulation check for the study and was assessed using a 6-item scale (α=.71) developed for this study (see Multimedia Appendix 2). This measure assessed participants' perceptions of uncertainty arising from various sources (ie, probability, ambiguity, and complexity) and pertaining to various issues (ie, controllability, prognosis, and severity of the COVID-19 pandemic) raised in the experimental vignettes. Example items include "There are conflicting estimates of how long the COVID-19 pandemic will past." Likert scale response options ranged from 1 (*strongly disagree*) to 7 (*strongly agree*).

Perceived likelihood of getting COVID-19 was assessed with a single item used in prior studies [25,33,34]: "How likely does it feel that you will get COVID-19 within the next month?" Likert scale response options ranged from 1 (*not at all*) to 7 (*very*).

Worry about COVID-19 was assessed with a single item used in prior studies [25,33,34]: "How worried are you about getting COVID-19 within the next month?" Likert scale response options ranged from 1 (*not at all*) to 7 (*very*).

Intentions for COVID-19 risk-reducing behaviors was assessed by measuring participants' willingness to follow 14 recommended COVID-19 risk-reducing behaviors (eg, handwashing, avoiding social gatherings, and wearing masks) (see Multimedia Appendix 2). Likert scale response options ranged from 0 (*I am not planning to follow this guideline at all*) to 100 (*I am planning to follow this guideline fully*). Participants' responses were averaged to create a composite score (α=.95).

Intentions for vaccination was assessed with a single item used in prior studies [25,33,34]: "If a vaccine becomes available for COVID-19, how likely would you be to get vaccinated against COVID-19?" Likert scale response options ranged from 1 (*definitely would not get vaccinated*) to 7 (*definitely would get vaccinated*).

Covariates and Potential Moderators

Sociodemographic characteristics included age (ie, <30, 30-39, 40-49, 50-59, 60-69, and ≥70 years), gender, race, and political affiliation (ie, Democrat, independent or other, and Republican).

Subjective health literacy was assessed using an abbreviated, single-item version of a validated health literacy screening measure [35]: "How often do you have someone (like a family member, friend, hospital/clinic worker, or caregiver) help you read instructions, pamphlets, or other written health materials from your doctor or pharmacy?" Likert scale response options ranged from 1 (*never*) to 5 (*always*).

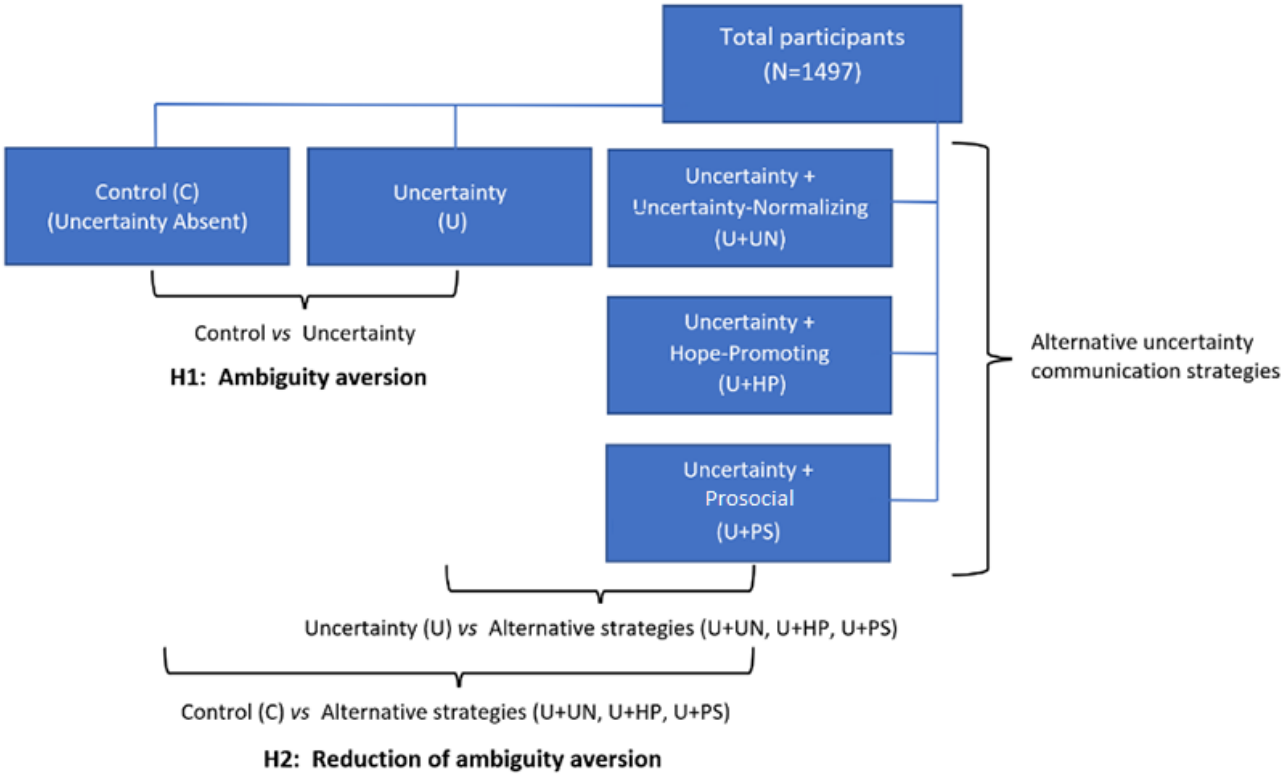
Data Analysis

To compare the effectiveness of alternative uncertainty communication strategies in reducing cognitive, emotional, and behavioral manifestations of ambiguity aversion, we fit analysis of variance models with perceived likelihood of getting COVID-19, worry about COVID-19, and intentions for both risk-reducing behaviors and vaccination as dependent variables and communication strategy as the independent variable. For each dependent variable, we used prespecified contrasts to assess the following: (1) the extent to which the communication of uncertainty produced ambiguity-averse responses, compared to the noncommunication of uncertainty (H1), and (2) the extent to which the three alternative uncertainty communication strategies (ie, uncertainty-normalizing, hope-promoting, prosocial) reduced ambiguity-averse responses (H2) (see Figure 1).

H1 was assessed by the contrast between the *uncertainty* and *control* conditions, while H2 was assessed by contrasts between each of the alternative uncertainty communication strategies and both the *uncertainty* and *control* conditions. For each contrast, we estimated the effect size by calculating Cohen *d*, which represents the standardized mean difference between two groups [36].

To explore potential moderating effects of sociodemographic characteristics (ie, age, gender, race, and political affiliation) and subjective health literacy, we fit separate models with perceived risk of COVID-19, worry about COVID-19, and intentions for both risk-reducing behaviors and vaccination as dependent variables and communication strategy as the independent variable; we entered relevant interaction terms one at a time. All analyses were conducted using SPSS, version 27.0 (IBM Corp).

Figure 1. Study design. Alternative uncertainty communication strategies and between-group comparisons. H1: Hypothesis 1; H2: Hypothesis 2.



Results

Overview

In our primary conditions, we received data from 1524 respondents. We excluded 2 respondents who gave inconsistent responses and another 25 individuals who reported current or previous COVID-19 illness, leaving a final sample of 1497 respondents (see Table 1). Data were assumed to be missing at random; thus, we utilized a listwise deletion strategy for participants with missing data on any of the outcome measures.

On average, participants took 27.82 (SD 34.59) minutes to complete the study. There were no significant between-group differences in time of completion of the experimental task ($F_{7,2386}$=0.479; P=.85), suggesting that the cognitive effort required by the task was similar across conditions.

Table 1. Sample population characteristics.

Characteristic	Value (N=1497), n (%)
Age (years)	
<30	306 (20.4)
30-39	229 (15.3)
40-49	209 (14.0)
50-59	183 (12.2)
60-69	227 (15.2)
≥70	343 (22.9)
Gender	
Male	743 (49.6)
Female	748 (50.0)
Other or prefer not to say	6 (0.4)
Race	
White	1003 (67.0)
Black or African American	178 (11.9)
Asian	147 (9.8)
Multiracial or other	169 (11.3)
Education	
Less than high school	264 (17.6)
High school graduate	242 (16.2)
Some college or trade school	396 (26.5)
College graduate or higher	595 (39.7)
Income (US $)	
0-24,999	394 (26.3)
25,000-49,999	371 (24.8)
50,000-99,999	370 (24.7)
100,000-149,999	235 (15.7)
≥150,000	127 (8.5)
Political affiliation	
Democrat	540 (36.1)
Republican	438 (29.3)
Independent or other[a]	519 (34.7)

Manipulation Check

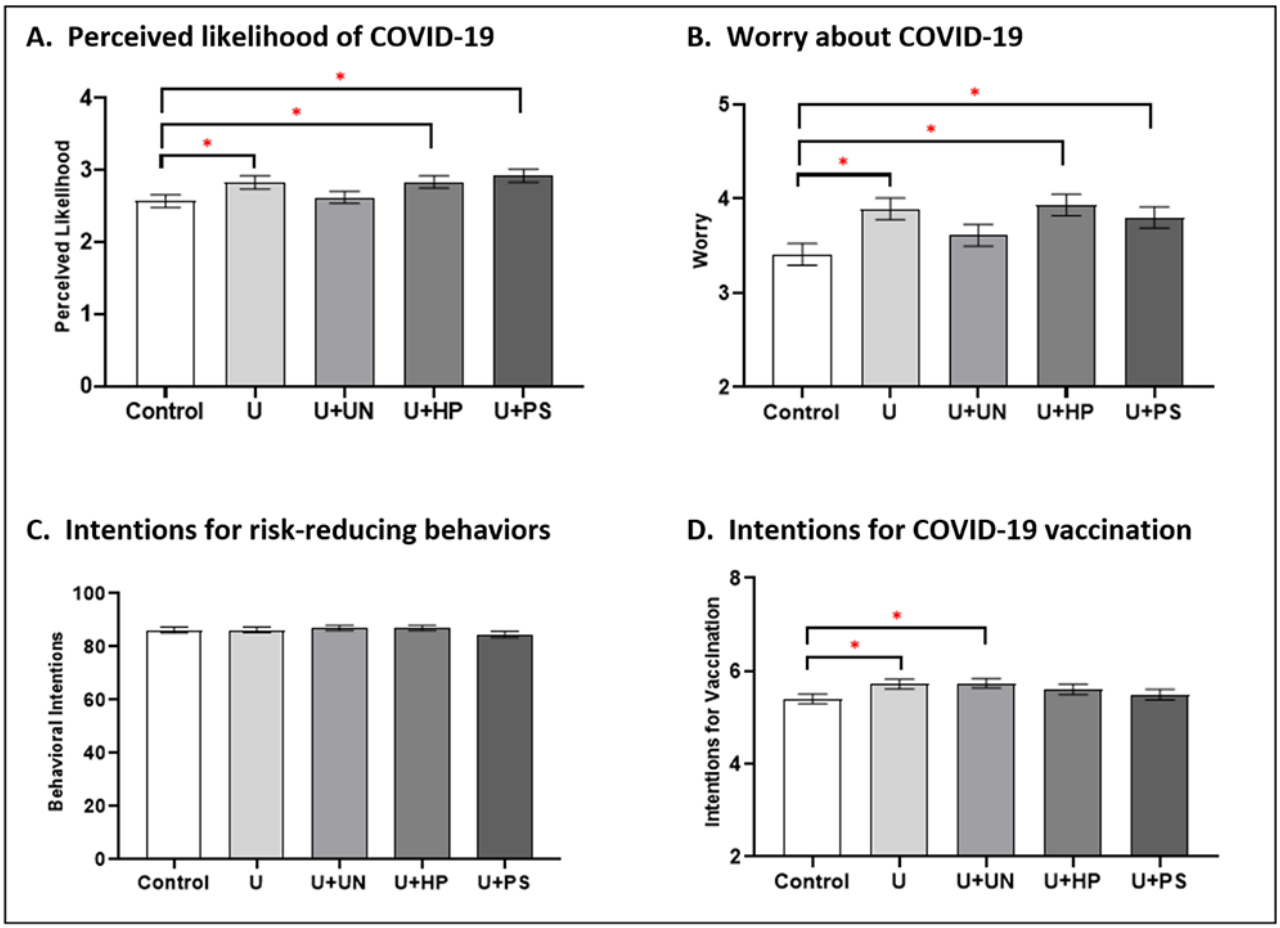
Supporting the intended effect of the experimental manipulation, perceived uncertainty about COVID-19 was significantly higher in all experimental conditions containing uncertainty ($F_{4,1492}$=3.52; η^2=0.009; *P*=.007)—that is, *uncertainty* (*d*=–0.28; *P*=.001), *uncertainty + uncertainty-normalizing* (*d*=–0.23; *P*=.006), *uncertainty + hope-promoting* (*d*=–0.20; *P*=.01), and *uncertainty + prosocial* (*d*=–0.22; *P*=.007)—compared to the *control* condition containing no uncertainty. These differences were in the small effect-size range.

Perceived Likelihood of Getting COVID-19

Consistent with an ambiguity-averse cognitive response to the communication of uncertainty (H1), perceived likelihood of getting COVID-19 was significantly higher in the *uncertainty* condition than in the *control* condition ($F_{4,1492}$=2.95; η^2=0.008; *P*=.02) (see Figure 2A). Supporting the effectiveness of the uncertainty-normalizing strategy in reducing ambiguity aversion (H2), perceived likelihood of getting COVID-19 was not significantly different for the *uncertainty + uncertainty-normalizing* condition compared to the *control* condition (*d*=–0.04; *P*=.66). However, this ambiguity aversion–reducing effect was not seen for the *hope-promoting*

(*d*=–0.18; *P*=.03) or *prosocial* (*d*=–0.23; *P*=.005) communication strategies; perceived likelihood remained significantly higher for these conditions than for the *control* condition.

Figure 2. Effects of uncertainty and uncertainty communication strategies on cognitive, emotional, and behavioral manifestations of ambiguity aversion. Asterisks indicate statistically significant pairwise differences (*P*<.05); error bars indicate standard error. U: uncertainty; U+HP: uncertainty + hope-promoting; U+PS: uncertainty + prosocial; U+UN: uncertainty + uncertainty-normalizing.



Worry About COVID-19

Consistent with an ambiguity-averse emotional response to the communication of uncertainty (H1), worry about COVID-19 was significantly higher in the *uncertainty* condition than in the *control* condition ($F_{4,1492}$=3.65; η^2=0.01; *P*=.006) (see Figure 2B). Supporting the effectiveness of the uncertainty-normalizing strategy in reducing ambiguity aversion (H2), worry was not significantly different for the *uncertainty + uncertainty-normalizing* condition compared to the *control* condition (*d*=–0.10; *P*=.21). However, this ambiguity aversion–reducing effect was not seen for the *hope-promoting* (*d*=–0.27; *P*=.001) or *prosocial* (*d*=–0.20; *P*=.02) communication strategies; worry remained significantly higher for these conditions than for the *control* condition.

Intentions for COVID-19 Risk-Reducing Behaviors and Vaccination

Inconsistent with an ambiguity-averse behavioral response to uncertainty, intentions regarding COVID-19 risk-reducing behaviors (η^2=0.002; *P*=.49) and vaccination (η^2=0.005; *P*=.14) showed no significant differences between any of the experimental conditions (see Figure 2C and D). However, prespecified contrasts revealed higher vaccination intentions in both the *uncertainty* (*d*=–0.17; *P*=.04) and the *uncertainty + uncertainty-normalizing* (*d*=–0.18; *P*=.03) conditions compared to the *control* condition, suggesting that the communication of uncertainty itself motivated vaccination intentions and that the addition of uncertainty-normalizing language preserved this motivation (see Figure 2D).

Moderating Effects

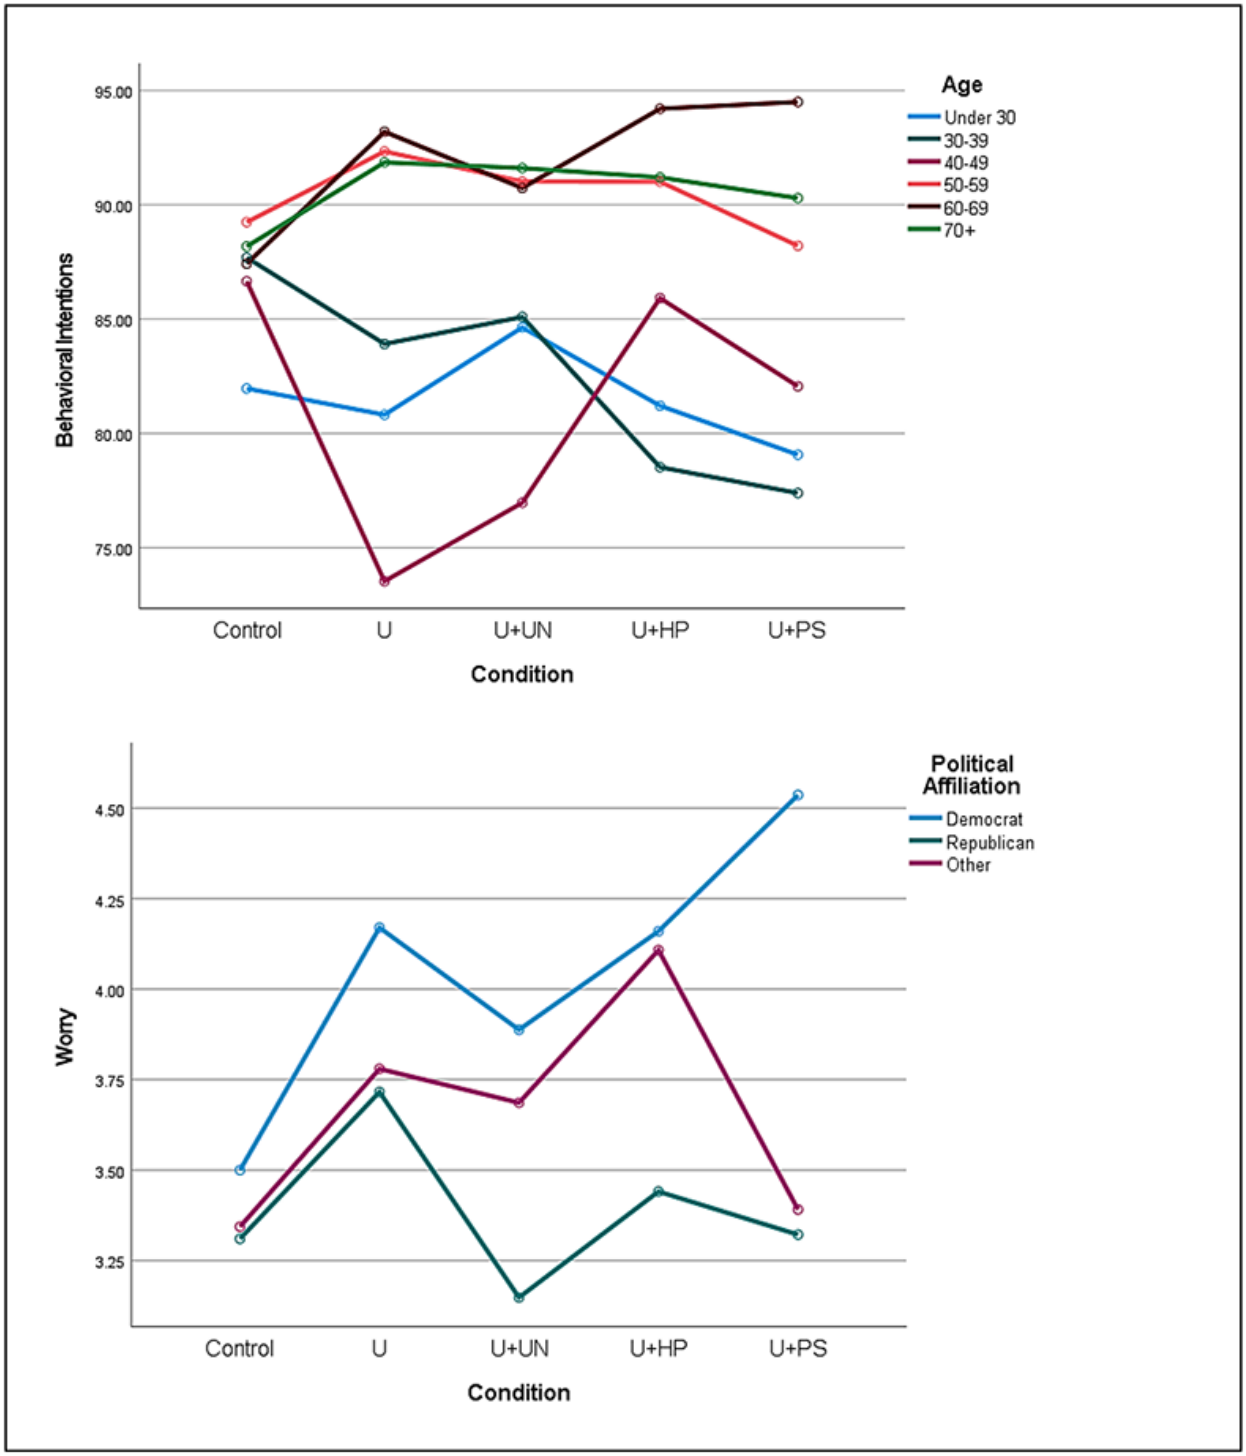
Two factors, age and political affiliation, were found to moderate the effects of uncertainty communication strategy on different ambiguity-averse responses to the communication of uncertainty. Age moderated the effect of communication strategy on intentions for COVID-19 risk-reducing behaviors ($F_{20,1445}$=1.86; $\eta\rho^2$=0.025; *P*=.01), such that older participants (ie, aged 50 years and older) generally reported higher intentions in all of the supplementary uncertainty communication conditions compared to the *control* condition, while younger participants (ie, less than 50 years of age) generally reported lower intentions (see Figure 3, top plot).

Political affiliation showed a weaker interaction with uncertainty communication strategy on worry about COVID-19 ($\eta\rho^2$=0.010; *P*=.06), such that self-reported Republicans had lower worry in

the *uncertainty + uncertainty-normalizing* condition compared to the *control* condition, while self-reported Democrats and independents had higher worry (see Figure 3, bottom plot). In other words, the uncertainty-normalizing strategy reduced ambiguity aversion to a greater extent for Republicans than for Democrats. Democrats also had higher worry in the *prosocial* condition compared to the *control* condition, while Republicans and independents had lower worry.

No significant moderating effects were noted for other sociodemographic factors or subjective health literacy.

Figure 3. Moderators of the effects of uncertainty communication strategy on manifestations of ambiguity aversion: age and political affiliation. U: uncertainty; U+HP: uncertainty + hope-promoting; U+PS: uncertainty + prosocial; U+UN: uncertainty + uncertainty-normalizing.



Discussion

This experimental study evaluated the comparative effectiveness of different communication strategies in reducing ambiguity-averse cognitive, emotional, and behavioral responses to uncertainty in information about the COVID-19 pandemic. We believe its findings have several implications for future efforts to understand and improve the communication of uncertainty in public health crises.

Consistent with predictions, a strategy aimed at normalizing uncertainty as an expected state of affairs was effective in reducing at least some aversive psychological responses to the communication of uncertainty, whereas widely used alternative strategies aimed at promoting hope and prosocial values had no such effect. A major barrier to open, explicit communication of the uncertainties that inevitably exist during public health crises is a real concern about exacerbating both the perception of vulnerability as well as feelings of fear and panic among the general public [2,3,5,6]. Our findings suggest, however, that language aimed at normalizing these uncertainties can reduce aversive cognitive and emotional responses to them. When uncertainty-normalizing language was added to a message that communicated scientific uncertainty about the COVID-19 pandemic, levels of COVID-19 risk perceptions and worry did not differ from those produced by a message that did not communicate scientific uncertainty. In other words, uncertainty-normalizing language neutralized ambiguity aversion. The overall size of this effect was relatively small, and although uncertainty-normalizing language resulted in lower levels of COVID-19 risk perceptions and worry than those produced by a message that communicated uncertainty alone, this difference was not statistically significant. Nevertheless, even small effects in reducing aversive psychological responses to uncertainty may be beneficial in large-scale efforts to communicate with the general public about health crises. If our findings can be replicated and validated, they suggest a promising new approach to inoculating people against the vulnerability and fear that typically accompany the communication of uncertainty in these situations.

Contrary to predictions, uncertainty-normalizing language had no effect on intentions for COVID-19 risk-reducing behaviors or vaccination. Notably, however, the communication of uncertainty itself also had no effect; it neither decreased nor increased behavioral intentions. In other words, ambiguity aversion in this study was manifest cognitively and emotionally, but not behaviorally. This pattern may be attributable to several factors. Potential negative effects of scientific uncertainty about COVID-19 on intentions for risk-reducing behaviors may have been attenuated by the legally mandated nature of several of these behaviors (eg, mandatory quarantines and regulations requiring social distancing and use of masks). Furthermore, uncertainties about the controllability, prognosis, and severity of the COVID-19 pandemic may have mixed, opposing effects on behavioral intentions. They may decrease intentions by fostering skepticism about the benefits of risk-reducing behaviors, thereby promoting a tendency toward inaction, which is consistent with ambiguity aversion. At the same time, these different uncertainties may also increase intentions by promoting fear about the consequences of avoiding risk-reducing behaviors, thereby promoting a tendency toward action, which is consistent with ambiguity tolerance. More research is needed to understand the factors that moderate people's behavioral responses to different uncertainties and favor either inaction or action.

Our study sheds light on at least some of these factors. Age moderated the effect of communication strategy on intentions for COVID-19 risk-reducing behaviors. For adults over 50 years of age, all active uncertainty communication strategies resulted in higher behavioral intentions compared to the control (ie, no uncertainty) strategy, while for younger adults, all active uncertainty communication strategies resulted in lower intentions. This moderating effect may be attributable to several factors. Older adults have been identified as being at higher risk for complications of COVID-19 and may, thus, be more motivated to take action in the face of uncertainty. Political affiliation also appeared to partially moderate the effect of communication strategy on worry about COVID-19; the uncertainty-normalizing strategy was more effective in reducing ambiguity aversion for Republicans than for Democrats. This moderating effect is intriguing, and its causes are unclear. Political party affiliation has been shown to influence COVID-19 risk perceptions and intentions for risk-reducing behaviors; Republicans generally demonstrate lower risk perceptions and behavioral intentions than Democrats [37-39]. The differential worry-reducing effect of uncertainty normalization for Republicans versus Democrats suggests the existence of respectively opposing propensities toward either minimizing feelings of vulnerability in the face of uncertainty (for Republicans) or else maximizing them (for Democrats). Political affiliation may be a proxy for numerous factors, including ideologies, values, and worldviews, that may predispose people to more optimistic or pessimistic appraisals of uncertain threats [40]. More research is needed to elucidate how these and other factors produce differential responses to different uncertainty communication strategies and to identify other important moderators.

Our study had several limitations that qualify its findings. The sample consisted of web survey panel members who, by virtue of their willingness to participate regularly in market research and other studies, may not be representative of the general population. However, the sample was large and both geographically and sociodemographically diverse, providing support for the external validity of its findings. Nevertheless, more research is needed to assess the reproducibility of our findings and their generalizability to other populations. The alternative uncertainty communication strategies tested in this study varied modestly in length; however, the absence of significant between-group differences in study completion time suggests that our findings are not attributable solely to differences in cognitive burden or effort. The uncertainty-normalizing language tested in this study was also novel and unvalidated, and it may have contained unintended hope-promoting or prosocial messages. We believe the significant between-group differences observed in our study argue against this possibility; however, further research is needed to ascertain the precision and efficacy of our uncertainty-normalizing language in conveying the normal, expected nature of uncertainty. We also conducted multiple exploratory analyses to identify potential moderators of the effects of different communication strategies; the two significant interactions identified could thus have resulted from chance, and further research is needed to confirm these findings. Finally, some key constructs (ie, perceived uncertainty about COVID-19 and intentions for COVID-19 risk-reducing behaviors) were assessed using new measures that have yet to be validated. Other constructs were assessed using existing single-item measures;

however, similar measures have been used in prior studies and shown to have predictive validity [25,30,41-43].

In spite of these limitations, this study yields important new insights on the nature and extent of aversion to ambiguity in the context of the COVID-19 pandemic and on a new and potentially effective uncertainty communication strategy that can minimize this aversion. It remains for future research to confirm our findings and to develop more effective strategies for communicating the unavoidable and irreducible scientific uncertainties that complicate all public health crises.

Acknowledgments

This work was supported by a Pilot Project Program Award to PH from the Northern New England Clinical & Translational Research Network (1U54GM115516-01). The funding agreement ensured the authors' independence in designing the study, interpreting the data, and in writing and publishing the report.

Authors' Contributions

PH conceived and designed the study, developed the experimental conditions and measures, conducted the experiments, analyzed the data, and drafted and revised the manuscript. ES, AS, AT, CL, LW, AF, and ND contributed to the development of the experimental conditions and measures, provided input on data analysis, and revised the manuscript. ES also programmed the survey and analyzed the data. All authors approved the final version.

Abstract

Background: National governments worldwide have implemented nonpharmaceutical interventions to control the COVID-19 pandemic and mitigate its effects.

Objective: The aim of this study was to investigate the prediction of future daily national confirmed COVID-19 infection growth—the percentage change in total cumulative cases—across 14 days for 114 countries using nonpharmaceutical intervention metrics and cultural dimension metrics, which are indicative of specific national sociocultural norms.

Methods: We combined the Oxford COVID-19 Government Response Tracker data set, Hofstede cultural dimensions, and daily reported COVID-19 infection case numbers to train and evaluate five non–time series machine learning models in predicting confirmed infection growth. We used three validation methods—in-distribution, out-of-distribution, and country-based cross-validation—for the evaluation, each of which was applicable to a different use case of the models.

Results: Our results demonstrate high R^2 values between the labels and predictions for the in-distribution method (0.959) and moderate R^2 values for the out-of-distribution and country-based cross-validation methods (0.513 and 0.574, respectively) using random forest and adaptive boosting (AdaBoost) regression. Although these models may be used to predict confirmed infection growth, the differing accuracies obtained from the three tasks suggest a strong influence of the use case.

Conclusions: This work provides new considerations in using machine learning techniques with nonpharmaceutical interventions and cultural dimensions as metrics to predict the national growth of confirmed COVID-19 infections.

Introduction

Background

In response to the COVID-19 pandemic, national governments have implemented nonpharmaceutical interventions (NPIs) to control and reduce the spread in their respective countries [1-5]. Indeed, early reports suggested the potential effectiveness of the implementation of NPIs to reduce the transmission of COVID-19 [2,4-8] and other infectious diseases [9-11]. Many epidemiological models that forecast future infection numbers have therefore suggested the role of NPIs in reducing infection rates [2,4,7,12], which can aid the implementation of national strategies and policy decision-making. Recent research incorporates publicly available data with machine learning for use cases such as reported infection case number forecasting [13-16]. Although these studies have used various features, such as existing infection statistics [13], weather [14], media and internet activity [15], and lockdown type [16], to predict infection case numbers, no study has yet examined the combination of NPIs and cultural dimensions in predicting infection growth. In this paper, we include the implementation of NPIs at the national level as features (ie, independent variables) in predicting the national growth of the number of confirmed infection cases. Based on recent studies that identify cultural dimensions as having influence in the effectiveness of NPIs [17-19], we also incorporate cultural dimensions as features. Prior work has focused on NPI variations in different regions of specific countries [2,5,6,20,21]. In contrast, our study involves 114 countries.

Various metrics may provide different perspectives and insights on the pandemic. In this study, we focus on one: confirmed infection growth (CIG), which we define as the 14-day growth in the cumulative number of reported infection cases. Other common metrics to measure the transmission rates of an infectious disease are the basic reproduction number, R_0, which measures the expected number of direct secondary infections generated by a single primary infection when the entire population is susceptible [3,22] and the effective reproduction number, R_t [2], which accounts for immunity within a specified population. Although such metrics are typically used by epidemiologists as measures of the transmission of an infectious disease, these metrics are dependent on estimation model structures and assumptions; therefore, they are application-specific and can potentially be misapplied [22]. Furthermore, the public may be less familiar with such metrics as opposed to more practical and observable metrics, such as the absolute or relative change in cumulative reported cases.

Related Work

Mathematical modelling of the transmission of infectious disease is a common method to simulate infection trajectories. A common technique for epidemics is the susceptible-infected-recovered (SIR) model, which separates the population into three subpopulations (susceptible, infected, and recovered) and iteratively models the interaction and shift between these subpopulations, which change throughout the epidemic [23,24]. Variations of this model have since been introduced to reflect other dynamics expected of the spread of infectious diseases [25-27]. These variations of the SIR model have also been applied to the ongoing COVID-19 pandemic [28-31].

The recent increase in data availability through advances in the internet and other data sources has enabled the inclusion of other factors in epidemiology modelling [32,33]. Since the early months of the COVID-19 pandemic, Johns Hopkins University has managed the COVID-19 Data Repository by the Center for Systems Science and Engineering (CSSE), which aggregates daily statistics of reported infection and mortality numbers across multiple countries [34]. Data sets related to governmental policies and NPIs have also been released publicly on the web. Notable COVID-19–related data sets include the Oxford COVID-19 Government Response Tracker (OxCGRT) [1], Complexity Science Hub COVID-19 Control Strategies List [35], CoronaNet [36], county-level socioeconomic data for predictive modeling of epidemiological effects (US-specific) [37], and CAN-NPI (Canada-specific) [20]. Additional COVID-19 data sets relate to social media activity [38-41], scientific publications [42-44], population mobility [45-48], and medical images [49-52]. In this work, we focus on the use of NPIs in the forecast of COVID-19 infection growth. Specifically, we selected the CSSE data set for infection statistics and the OxCGRT for NPI features due to their global comprehensiveness. Although features can be extracted from additional COVID-19 data sets in our models, we limited the scope of this study to COVID-19 NPI features.

Recent research has also linked the effect of cultural dimensions in responses to the COVID-19 pandemic. Studies suggest that cultural dimensions may affect individual and collective behavior [53-57] and the effectiveness of NPIs [17-19], and that cultural dimensions should be considered when implementing NPIs [17]. Although these studies identify the importance of cultural dimensions in controlling the COVID-19 pandemic, to our knowledge, this work is the first to complement cultural dimensions with NPIs to forecast future COVID-19 infection growth. We recognize that various cultural dimension models exist, such as the six Hofstede cultural dimensions [58], Global Leadership and Organizational Effectiveness (GLOBE) [59], and the Cultural Value Scale (CVSCALE) [60], and that each model has their advocates and criticisms [61]. In this work, we selected the 2015 edition of the Hofstede model [62] due to the relevance of its cultural dimensions in the mentioned studies [17-19,55-57].

Machine learning has been used in applications to combat the COVID-19 pandemic, such as in patient monitoring and genome sequencing [63-66]. Recent studies have also used various statistical and machine learning techniques for short-term forecasting of infection rates for the COVID-19 pandemic [13,15,16,30,33] using reported transmission and mortality statistics, population geographical movement data, and media activity. Pinter et al [13] combined multilayer perceptron with fuzzy inference to predict reported infection and mortality numbers in Hungary with only case number features from May to August 2020. Although reported infection and mortality case numbers aligned with their predictions for May 2020, comparison of the predictions with actual reported numbers from June to August 2020 suggest inaccuracies. Liu et al [15]

used internet and news activity predictors within a clustering machine learning model for reported COVID-19 case numbers within Chinese provinces. However, the predictors used within this work are heavily limited to Chinese populations (eg, Baidu search and mobility data, Chinese media sources), and they only predicted cases 2 days ahead. Malki et al [14] used weather, temperature, and humidity features as predictors for COVID-19 mortality rates in regressor machine learning models. Their results suggest that these predictors are relevant for COVID-19 mortality rate modelling. Similar to our work, Saba et al [16] implemented multiple machine learning models to forecast COVID-19 cases based on NPI implementation. However, their work differs in that it only includes lockdown type as an NPI feature (and does not consider cultural dimensions), the study is limited to 9 countries, and the reported case numbers are predicted instead of the change in case numbers. To our knowledge, no other studies have combined NPI and cultural dimension features to predict the growth of reported COVID-19 cases using machine learning. Furthermore, only this work forecasts COVID-19 growth as a measure of CIG (ie, 14-day growth in the cumulative number of reported cases at a national level) across 114 countries via three validation methods, each of which is applicable to a different use case of the model.

Description of the Study

Due to its direct inference from the number of reported cases, the CIG is a verifiable metric, and it may have a greater impact on the public perception of the magnitude of the COVID-19 pandemic than the actual transmission rate. In this work, CIG reflects the growth in the total number of reported cases within a country in 14 days relative to the total number of previously reported infections, including recoveries and mortalities. We selected 14 days as a suitable period for measuring the change in reported cases because of the expected incubation period of COVID-19. Researchers have found that 97.5% of reported patients with identifiable symptoms developed symptoms within 11.5 days, and 99% developed symptoms within 14 days [67]. We therefore propose the use of 14 days, or 2 weeks, as a suitable period to observe changes in reported case numbers occurring after the implementation of NPIs. A shorter period may lead to the misleading inclusion of reported infections that occurred prior to the implementation of an NPI. Results for a longer period may be misleading as well, given the higher likelihood of change in NPIs within this period that will not be accounted for during prediction. We propose that the CIG over 14 days is a suitable metric that enables inference of the effect of NPIs while being within a relevant period for short-term epidemiology forecasting. We emphasize that the reported number of infections may not necessarily be correlated with the actual transmission rate due to factors such as different testing criteria and varying accessibility in testing over time.

We deployed five machine learning models to predict the CIG for individual countries across 14 days. Explicitly, this value was the label (ie, dependent variable) we sought to predict. We used features (ie, independent variables) representing the implementation levels of NPIs and the cultural dimensions of each country. We obtained daily metrics for the implementation of NPIs at the national level from the OxCGRT data set [1]. Although different countries may implement similar NPIs, researchers have suggested that cross-cultural variations across populations lead to different perceptions and responses toward these NPIs [53,54,68]. We intended to capture any effects due to national cross-cultural differences by complementing the OxCGRT data set with national cultural norm values from the Hofstede cultural dimensions [58]. Our non–time series deep learning models predicted the expected future national CIG using both NPI implementation and cultural norm features. Although time series deep learning models (eg, recurrent neural networks or transformers) may also provide CIG predictions, these models generally require greater amounts of accurately labeled trajectory data and assume that past trajectory trends are readily available representatives of future trajectories. Instead, our non–time series models were trained on more granular data that did not necessarily need to be temporally concatenated into a trajectory. We also opted for less complex non–time series models due to indeterminacies in acquiring and verifying sufficient trajectory data, especially due to the lack of reliable data at the onset of the COVID-19 outbreak.

Our results suggest that non–time series machine learning models can predict future CIG according to multiple validation methods, depending on the user's application. Although we do not necessarily claim state-of-the-art performance for infection rate prediction given the rapidly growing amount of parallel work in this area, to the best of our knowledge, our work is the first to use machine learning techniques to predict the change in national cumulative numbers of reported COVID-19 infections by combining NPI implementation features with national cultural features.

Our implementation uses publicly available data retrieved from the internet and relies on the open-sourced Python libraries Pandas [69] and Scikit-Learn [70].

Methods

Data and Preprocessing

Candidate features at the national level were extracted from three data sets for input into our machine learning models: NPIs, cultural dimensions, and current confirmed COVID-19 case numbers.

OxCGRT provides daily level metrics of the NPIs implemented by countries [1]. This data set sorts NPIs into 17 categories, each with either an ordinal policy level metric ranging from 0 (not implemented) to 2, 3, or 4 (strictly enforced) or a continuous metric representing a monetary amount (eg, research funding). The value of each national NPI metric is assigned daily from data in publicly available sources by a team of Oxford University staff and students using the systematic format described in [1]. We limited our candidate features to the 13 ordinal policy categories and 4 computed indices, which represent the implementation of different policy types taken by governments, based on the implemented NPIs. This data set contains data starting from January 1, 2020.

To represent cultural differences across populations of different countries, the 2015 edition of the Hofstede cultural dimensions [62,71] was tagged to each country. Although these dimensions are rarely used in epidemiology studies, they have been used

frequently in international marketing studies and cross-cultural research as indicators of the cultural values of national populations [61,72]. Multiple studies have also linked cultural dimensions to health care–related behavior, such as antibiotic usage and body mass index [73-76]. Because the 2015 edition of this data set groups certain geographically neighboring countries together (eg, Ivory Coast, Burkina Faso, Ghana, etc, into Africa West), we tagged all subgroup countries with the dimension values of their group. Although we recognize that this approach is far from ideal and will likely lead to some degree of inaccurate approximation in these subgroup countries, we performed this preprocessing step to include those countries in our study. The dimension values for each country were constant across all samples. Six cultural dimensions were presented for each country or region [71]:

- Power distance index: the establishment of hierarchies in society and organizations and the extent to which lower hierarchical members accept inequality in power
- Individualism versus collectivism: the degree to which individuals are not integrated into societal groups, such as individual or immediate family (individualistic) versus extended families (collectivistic)
- Uncertainty avoidance: a society's tendency to avoid uncertainty and ambiguity through use of societal disapproval, behavioral rules, laws, etc
- Masculinity versus femininity: Societal preference toward assertiveness, competitiveness, and division in gender roles (masculinity) compared to caring, sympathy, and similarity in gender roles (femininity)
- Long-term versus short-term orientation: Societal values toward tradition, stability, and steadfastness (short-term) versus adaptability, perseverance, and pragmatism (long-term)
- Indulgence versus restraint: The degree of freedom available to individuals for fulfilling personal desires by social norms, such as free gratification (indulgence) versus controlled gratification (restraint)

We extracted the daily number of confirmed cases, n_t, for each country from the COVID-19 Data Repository by the CSSE at Johns Hopkins University [34]. We used a rolling average of the previous 5-day window to smooth fluctuations in n_t, which may be caused by various factors, such as inaccurate case reporting, no release of confirmed case numbers (eg, on weekends and holidays), and sudden infection outbreaks. We refer to the smoothed daily number of confirmed cases for date t as  .

We computed the CIG for a specified date, τ, as:

The CIG represents the expected number of new confirmed cases from date $\tau - 13$ to date τ as a percentage of the total number of confirmed infection cases up to date $\tau - 14$.

Our goal was to predict the CIG 14 days in advance (ie, $CIG_{\tau+14}$) given information from the current date τ for each country. Available candidate features included all ordinal policy metrics and the four computed indices from OxCGRT, the six cultural dimension values from the Hofstede model, the CIG of the current date CIG_τ, and the smoothed cumulative number of confirmed cases  , for a total of 25 candidate features. Neither the date nor any other temporal features were included.

We trimmed samples with fewer than 10 cumulative confirmed infection cases and with the highest 2.5% and the lowest 2.5% of $CIG_{\tau+14}$ to remove outliers in the data. Because the lowest 2.5% of $CIG_{\tau+14}$ were all 0.0%, we removed the samples with $CIG_{\tau+14}$=0.0% by ascending date.

Our data range from April 1 to September 30, 2020, inclusively. We excluded all countries from our combined data set that had missing feature values. In total, our combined data set and our experiments applied to 114 countries: Algeria, Angola, Argentina, Australia, Austria, Bahrain, Bangladesh, Belgium, Benin, Botswana, Brazil, Bulgaria, Burkina Faso, Burundi, Cameroon, Canada, Central African Republic, Chad, Chile, China, Colombia, Comoros, Croatia, Czech Republic, Denmark, Djibouti, Egypt, El Salvador, Eritrea, Estonia, Ethiopia, Finland, France, Gabon, Gambia, Germany, Ghana, Greece, Guinea, Hong Kong, Hungary, India, Indonesia, Iran, Iraq, Ireland, Italy, Japan, Jordan, Kenya, Kuwait, Latvia, Lebanon, Lesotho, Liberia, Libya, Lithuania, Luxembourg, Madagascar, Malawi, Malaysia, Mali, Mauritania, Mauritius, Mexico, Morocco, Mozambique, Namibia, Netherlands, New Zealand, Niger, Nigeria, Norway, Oman, Pakistan, Palestine, Peru, Philippines, Poland, Portugal, Qatar, Romania, Russia, Rwanda, Saudi Arabia, Senegal, Serbia, Seychelles, Sierra Leone, Singapore, Slovenia, Somalia, South Sudan, Spain, Sudan, Sweden, Switzerland, Syria, Taiwan, Tanzania, Thailand, Togo, Trinidad and Tobago, Tunisia, Turkey, Uganda, United Arab Emirates, United States, Uruguay, Venezuela, Vietnam, Yemen, Zambia, and Zimbabwe.

The mean, standard deviation, and range of each candidate feature value for the above countries are shown in Table 1.

The data preprocessing procedure is shown in Figure 1.

Table 1. Statistical measurements of candidate feature values.

Candidate features	Mean (SD)	Range
Nonpharmaceutical interventions		
School closure	2.23 (1.01)	0.00 to 3.00
Workplace closure	1.67 (0.92)	0.00 to 3.00
Cancellation of public events	1.64 (0.65	0.00 to 2.00
Restrictions on gatherings	2.89 (1.27)	0.00 to 4.00
Closure of public transport	0.71 (0.77)	0.00 to 2.00
Stay-at-home requirements	1.17 (0.90)	0.00 to 2.00
Restrictions on internal movement	1.15 (0.88)	0.00 to 2.00
International travel controls	3.13 (1.00)	0.00 to 4.00
Income support	1.04 (0.79)	0.00 to 2.00
Debt/contract relief	1.23 (0.76)	0.00 to 2.00
Public information campaigns	1.97 (0.23)	0.00 to 2.00
Testing policy	1.84 (0.82)	0.00 to 2.00
Contact tracing	1.50 (0.64)	0.00 to 2.00
Stringency Index	63.02 (20.57)	0.00 to 100.00
Government Response Index	61.43 (15.03)	0.00 to 95.54
Containment Health Index	62.91 (16.50)	0.00 to 98.96
Economic Support Index	52.53 (28.93)	0.00 to 100.00
Current infection numbers		
Current cumulative number of confirmed cases:	113,302.24 (505,170.50)	4.00 to 7,155,220.00
CIG_{τ} [a]	0.85 (3.83)	–0.423 to 228.00
Hofstede cultural dimensions		
Power distance	66.74 (17.34)	11.00 to 104.00
Individualism	38.52 (18.71)	12.00 to 91.00
Masculinity	48.32 (14.06)	5.00 to 95.00
Uncertainty avoidance	64.17 (17.42)	8.00 to 112.00

Feature Selection and Processing

We selected features to input into our machine learning models from our candidate feature pool using mutual information [77]. Mutual information is a measure of the dependency between an individual feature (ie, the independent variable) and the label (ie, the dependent variable), and it captures both linear and nonlinear dependencies. However, mutual information does not capture multivariate dependencies or indicate collinearity between features. To include both linear and nonlinear dependencies, features are selected if they achieve substantially nonzero mutual information (ie, greater than 0.10). Feature selection was conducted prior to training with the training set in all validation methods. Similar feature filtering and selection techniques have been used in other machine learning applications [70,78]. The candidate features considered for input and their respective mutual information are listed in Table 2 for the in-distribution and out-of-distribution validation methods. Mutual information was also computed for each of the ten folds of the cross-validation method.

All selected features were then normalized to the range [0,1] using standard min-max normalization.

Table 2. Mutual information of candidate features for the in-distribution and out-of-distribution validation methods. In the cross-validation method, the 10 folds have varying mutual information.

Candidate feature	Mutual information	
	In-distribution	Out-of-distribution

Model Training and Validation

We trained the machine learning models by performing a grid search over the combinations of hyperparameters listed in Table 3 [70,79-82]. We optimized the models using the mean squared error (MSE) criterion and selected the model hyperparameters with the lowest mean absolute error (MAE) as the optimal configuration of the model. The MSE heavily penalizes large residual errors disproportionately, while the MAE provides an absolute mean of all residual errors [83]. The MAE of the training data acts as a measure of the goodness-of-fit of the model, while the MAE of the validation and testing data acts as a measure of the predictive performance [84].

Table 3. Machine learning models and hyperparameter combinations used in the grid search.

Model	Hyperparameters
Ridge regression	
α	0.00, 0.25, 0.50, 0.75, 1.00, 1.25
Decision tree regression	
Depth	5, 10, 15, 20, 25, 30
Minimum sample split	2, 5, 10
Minimum sample leaves	1, 2, 4, 8, 10
Random forest regression	
Depth	5, 10, 20, 25, 30
Estimators	3, 5, 10, 15, 20, 30, 50, 75, 100, 125, 150
Minimum sample split	2, 5, 10
Minimum sample leaves	1, 2, 4, 8, 10
AdaBoost[a] regression	
Weak learner	Decision tree (maximum depth: 2)

[a]AdaBoost: adaptive boosting.

To validate in-distribution and out-of-distribution, we split our samples into 70-15-15 training-validation-test sets. For cross-validation [85,86], we split our samples into 10 folds (ie, 90-10). These three methods of validation each represent a different definition of performance for the machine learning models.

In-Distribution Validation

We randomly split the samples into training, validation, and test sets. Consequently, the models were trained from samples distributed across the entire date range available in our data. This is critical, as it is generally expected that model performance is best when training and test data are drawn from the same distribution. Because the COVID-19 infection numbers naturally constitute a time series, this method ensures that validation and test samples are indeed from the same distribution as the training samples. Because the samples are disassociated from their dates and all other known temporal features, the prediction of the validation and test samples using the training samples is unordered. This method may be applicable to use cases in which the date-to-predict is expected to be in a similar distribution as the training samples, such as predicting $CIG_{\tau+14}$ when data up to the current date τ are available.

Out-of-Distribution Validation

Although the in-distribution method can ensure that the training, validation, and test data are all sampled from the same distribution, it may not necessarily be the most practical method. Generally, the goal of long-term infection rate forecasting is to anticipate future infection rates, and it should not be represented as an in-distribution task, where we trained it with data from near or later than the date-to-predict. Therefore, we also validated the performance of our models by training on the earliest 70% of the samples. The validation and test sets were then randomly split between the remaining 30% of the samples. This setup ensures that all training samples occurred earlier than the validation and testing samples and that no temporal features (known or hidden) were leaked. However, due to the changing environment related to COVID-19 infections (eg, the introduction of new NPIs, seasonal changes, new research), the validation and testing distributions are likely different from that of the training set. This method may be applicable for use cases in which the date-to-predict is in the far future and not all data up to 14 days prior to the date-to-predict are available.

Country-Based Cross-Validation

As a compromise between the above two methods, we also used a cross-validation method in which we split the available countries into 10 folds. The aim was to evaluate validation samples from the same date range as the training samples, but not the same country trajectory. That is, only data from countries not in the validation set are included in the training set. Although the samples from the training and validation sets are therefore sampled from different distributions (ie, different countries), we anticipate that features from the Hofstede cultural dimensions [58] may assist in identifying similar characteristics between countries, thus reducing the disparity between the training and validation distributions. This method may be applicable in

predicting the CIG of countries for which previous associated data is unavailable or unreliable.

Results

Feature Selection

For both the in-distribution and out-of-distribution training sets, we observed that most candidate features met our requirement of nonzero mutual information (≥0.10) (see Table 2).

In both training sets, the candidate features that did not meet the requirements were international travel control (0.099, 0.099), debt/contract relief (0.043, 0.053), public information campaigns (0.020, 0.023), testing policy (0.056, 0.064), and contact tracing (0.030, 0.038). Additional candidate features that did not meet the requirements for the in-distribution training set were workplace closure (0.098) and cancellation of public events (0.089). Overall, the in-distribution and out-of-distribution data sets contained 17 and 20 features, respectively.

CIG_{τ} had the highest mutual information out of all features, suggesting similarities between the feature CIG_{τ} and the label $CIG_{\tau+14}$. Further analysis showed a correlation of r=.309 between CIG_{τ} and $CIG_{\tau+14}$. This may be due to similar trends in the CIG when the implementation of NPIs is consistent within a 14-day period. We also observed that all candidate features for the six Hofstede cultural dimensions had higher mutual information than all individual NPI candidate features, aside from the aggregated indices. This finding suggests a high statistical relationship between each cultural dimension feature and the label we sought to predict. Although the cultural dimension values may not fully represent the cultural differences of each country (see Limitations), there is sufficient information between each cultural dimension feature and the label for them to be relevant predictors of the label.

Comparison of Machine Learning Models

Out of all the available configurations (ie, hyperparameter combinations) of each model, we selected the model configurations with the lowest validation errors and computed the test errors. The parameters for these selected models are listed in Table 4. The mean training, validation, and test errors are included in Table 5, Table 6, and Table 7, respectively, for the in-distribution, out-of-distribution, and cross-validation methods. We also include the median percent error [87], which is the percentage difference of the prediction $f(x^{(i)})$ and the label $y^{(i)}$ for each instance $\{x^{(i)}y^{(i)}\}$, computed as:

We observed that random forest regression had the lowest mean test error in the interpolation method (0.031) and adaptive boosting (AdaBoost) regression had the lowest mean test errors in the extrapolation and cross-validation methods (0.089 and 0.167, respectively) (see Table 5, Table 6, and Table 7). For all models aside from ridge regression, the in-distribution method had the lowest mean test errors and the lowest median percent error.

Analysis of Best-Performing Models

Intercepts near 0.0 and slopes near 1.0 are the linear calibration measures that indicate a perfect calibration relationship between the predictions and the labels [84]. For the optimal models in all the validation methods, we observed slopes close to 1.0 and intercepts close to 0.0 (see Table 8). Due to the large sample sizes, statistical significance testing indicated that several slopes and intercepts are significantly different from 1.0 and 0.0, respectively. However, the small mean differences (standardized to the standard deviation, ie, the z score) indicate that these differences have no practical significance. High correlations (r>0.70) and moderate-to-high R^2 values (R^2>.50) [88,89] between the predictions and labels were observed in all three validation methods (see Figure 2, Figure 3, and Figure 4).

To assess the fine-grained model performance, we discretized both the true labels and model predictions into bins of size 0.5 for all three validation methods (see Figure 5, Figure 6, and Figure 7). Comparing the resulting empirical distributions, it can be seen that the resulting distributions are extremely similar in both the in-distribution and out-of-distribution methods. In the cross-validation method, the predictions skew slightly higher than the labels in the 0.0-1.0 range, showing a general tendency of the model to slightly overestimate the CIG within this range.

Further analysis shows that the performance of the models varies with the values of the labels. In both the in-distribution and cross-validation methods, the test MAE is lowest for samples with labels of 0.0 (see Table 9 and Table 10), followed by the label range of 0.0-0.5. In the out-of-distribution method, the test MAE is lowest for samples with labels from 0.0-0.5 (see Table 11). For all validation methods, the mean MAE and

median percent errors also increase with label bins greater than 1.0, showing a decrease in accuracy for a larger CIG.

Discussion

Principal Results

Our results suggest that traditional, non–time series machine learning models can predict future CIG to an appreciable degree of accuracy, as suggested by the moderate-to-high R^2 values (R^2>0.50) and strong linear calibration relationships (r>0.70) [88,89] between the labels and predictions in all the validation methods.

A comparison of our results for all the validation methods suggests differences in the predictive performance of the machine learning models across the varying use cases. The in-distribution method has the highest R^2 value and the lowest test mean error and median percent error; this is to be expected, as the test samples were obtained from the same distribution as the training samples. Intuitively, although the samples in the in-distribution method are unordered (ie, no temporal features are included), the availability of samples across the entire temporal range in the training set enables the validation and test samples to interpolate between these training samples.

The out-of-distribution method achieved a higher test mean error and a lower R^2 value than the in-distribution method. This is expected, as the evolving COVID-19 infection trajectories observed in most countries give distributions of training samples from earlier dates that may differ greatly from those of validation and test samples from later dates (ie, data shift), which machine learning models are often ill-equipped to handle [90].

Conversely, although the cross-validation method contained the training and validation sets within the same date range, the cross-validation method also separated countries across these sets (ie, the 10 folds) such that no country had samples in both the training and validation sets. This difference led to higher test mean errors and median percent errors than the other two methods and a similar R^2 value to that of the out-of-distribution method, suggesting that including training samples from the same country as the validation samples is more important than ensuring temporal overlap. We speculate that this result occurs because the unique cultural dimensions per country may potentially act as categorical rather than continuous features for each country. In such cases, the cultural dimensions observed in the training set would be considered irrelevant to the cultural dimensions within the validation set.

The performance also varied depending on the value of the label (see Table 9, Table 10, and Table 11), which may be due to the imbalanced frequency of the training samples. That is, the rareness of samples with higher CIG compared to lower CIG in the training set may be the cause of their comparatively poor performance.

In Figure 3 and Figure 4, we also show constraints of the trained AdaBoost regression models. The discretization of the prediction values may be due to the low number of estimators used in the lowest mean test error configuration, as shown in Table 4. The low number of estimators in these configurations may also restrict the predictions to a maximum of 1.5 selected to the relatively low number of samples with labels greater than 1.5 (see Figure 6 and Figure 7). The label ranges with the most samples are selected over underrepresented ranges as candidates for prediction values in the discretized AdaBoost regression models. Although additional estimators in the AdaBoost regression models may result in less discrete prediction values, they may also cause over-fitting by increasing the complexity of the models.

Limitations

First, the scores in the OxCGRT and Hofstede cultural dimensions data sets are imprecise. NPI enforcement levels and definitions may vary even between countries with the same scores, while countries sharing similar cultural dimension scores may have unobserved differences in terms of cultural practices due to low representation of their cultures with only six dimensions. Although the Hofstede model is convenient for the goal of our work, it does not identify intracountry cultural differences. Furthermore, distinct countries may be grouped within specific geographical regions (eg, Africa West). We also acknowledge that there are trade-offs between different cultural models and different definitions of culture [61]. We encourage further exploration of appropriate cultural dimensions in addition to the Hofstede model, such as GLOBE [59] and CVSCALE [60]. Second, by predicting the CIG 14 days in advance of the current date, the models do not account for information regarding changes in NPIs between the current date and the date-to-predict. Third, the CIG is a measure of the change in the cumulative number of confirmed infections and may not necessarily be correlated with the change in the daily number of confirmed infections or the actual transmission rate of COVID-19. For example, differences in testing and reporting policies of different jurisdictions (eg, prioritizing high-risk patients, performing more tests per capita, and obfuscating test

results) may lead to a misleading representation of the infection growth.

Conclusion

In this study, we trained five non–time series machine learning models to predict the CIG 14 days into the future using NPI features extracted from the OxCGRT data set [1] and cultural norm features extracted from the Hofstede cultural dimensions [58]. Together, these features enabled the prediction of near-future CIG in multiple machine learning models. Specifically, we observed that random forest regression and AdaBoost regression resulted in the most accurate predictions out of the five evaluated machine learning models.

We observed differences in the predictive performance of the machine learning models across the three validation methods; the highest accuracy was achieved with the in-distribution method and the lowest with the cross-validation method. These differences in performance suggest that the models have varying levels of accuracy depending on the use case. Specifically, predictions are expected to have higher accuracies when existing data from the same country in nearby dates are available (ie, in-distribution method). This enables applications such as predicting the CIG over the upcoming 14 days from the current date. The decrease in accuracy when data from nearby dates are unavailable (ie, the out-of-distribution method) suggests weaker performance in predicting the CIG over 14 days for relatively distanced future dates. We observed the greatest decrease in performance when data from the same country were unavailable (ie, the cross-validation method). However, with all validation methods, we observed appreciable calibration measures between the predictions and labels of the test set.

This study adds to the rapidly growing body of work related to predicting COVID-19 infection rates by introducing an approach that incorporates routinely available data on NPIs and cultural dimensions. Importantly, this study emphasizes the utility of NPIs and cultural dimensions for predicting country-level growth of confirmed infections of COVID-19, which to date have been limited in existing forecasting models. Our findings offer a new direction for the broader inclusion of these types of measures, which are also relevant for other infectious diseases, using non–time series machine learning models. Our experiments also provide insight into validation methods for different applications of the models. As the availability of this data increases and the nature of the data continues to evolve, we expect that models such as these will produce accurate and generalizable results that can be used to guide pandemic planning and other infectious disease control efforts.

Abstract

Background: Holding conspiracy beliefs regarding the COVID-19 pandemic in the United States has been associated with reductions in both actions to prevent the spread of the infection (eg, mask wearing) and intentions to accept a vaccine when one becomes available. Patterns of media use have also been associated with acceptance of COVID-19 conspiracy beliefs. Here we ask whether the type of media on which a person relies increased, decreased, or had no additional effect on that person's COVID-19 conspiracy beliefs over a 4-month period.

Objective: We used panel data to explore whether use of conservative and social media in the United States, which were previously found to be positively related to holding conspiracy beliefs about the origins and prevention of COVID-19, were associated with a net increase in the strength of those beliefs from March to July of 2020. We also asked whether mainstream news sources, which were previously found to be negatively related to belief in pandemic-related conspiracies, were associated with a net decrease in the strength of such beliefs over the study period. Additionally, we asked whether subsequent changes in pandemic conspiracy beliefs related to the use of media were also related to subsequent mask wearing and vaccination intentions.

Methods: A survey that we conducted with a national US probability sample in March of 2020 and again in July with the same 840 respondents assessed belief in pandemic-related conspiracies, use of various types of media information sources, actions taken to prevent the spread of the disease and intentions to vaccinate, and various demographic characteristics. Change across the two waves was analyzed using path analytic techniques.

Results: We found that conservative media use predicted an increase in conspiracy beliefs (β=.17, 99% CI .10-.25) and that reliance on mainstream print predicted a decrease in their belief (β=–.08, 99% CI –.14 to –.02). Although many social media platforms reported downgrading or removing false or misleading content, ongoing use of such platforms by respondents predicted growth in conspiracy beliefs as well (β=.072, 99% CI .018-.123). Importantly, conspiracy belief changes related to media use between the two waves of the study were associated with the uptake of mask wearing and changes in vaccination intentions in July. Unlike other media, use of mainstream broadcast television predicted greater mask wearing (β=.17, 99% CI .09-.26) and vaccination intention (β=.08, 95% CI .02-.14), independent of conspiracy beliefs.

Conclusions: The findings point to the need for greater efforts on the part of commentators, reporters, and guests on conservative media to report verifiable information about the pandemic. The results also suggest that social media platforms need to be more aggressive in downgrading, blocking, and counteracting claims about COVID-19 vaccines, claims about mask wearing, and conspiracy beliefs that have been judged problematic by public health authorities.

Introduction

At the outset of the COVID-19 pandemic in the United States, various conspiracy theories about the origins and prevention of COVID-19 began to circulate on social media and some conservative media outlets [1-4]. The study of conspiracies as explanations for major events achieved notice in Hofstadter's classic and influential 1966 volume *The Paranoid Style in American Politics* [5]. In his analysis, conspiracy beliefs presupposed a "vast, insidious, preternaturally effective international conspiratorial network designed to perpetrate acts of most fiendish character" [5]. Conspiracy beliefs, including those claiming the US government's responsibility for the assassination of John F Kennedy and the 9/11 terrorist attack [6,7], have been a focus of study in the political science literature, which regards such beliefs as ones "in which the ultimate cause of an event is believed to be due to a plot by multiple actors working together with a clear goal in mind, often unlawfully and in secret" [8]. In psychology, the focus has been on understanding what draws individuals to conspiracies [7,9], while in public health, the concern has been about their role in minimizing the likelihood of preventive behavior [10], and their creation of unfounded fears of interventions such as fluoridation and vaccination [11]. As with all conspiracy theories, it is difficult to determine the validity of those related to COVID-19 because the putative actors work in secret [12]. Although stigmatized as paranoid by some [5], such beliefs have a surprising ability to attract adherents [6], and their influence has increasingly been observed in response to COVID-19 public health recommendations, such as vaccination and social distancing [13,14].

A notable characteristic of conspiracy beliefs is the tendency for belief in any one to be associated with acceptance of others [2,15-17]. In the United States, three such beliefs prevalent early in the pandemic [1,2,4] concerned suspicions that the pandemic was the result of malign actions by either the Chinese government or the pharmaceutical industry or that some in the US government were exaggerating the danger of COVID-19 to undermine the president of the United States. A national probability sample of the US population in March and again in July of 2020 [18] found that belief in any one of the conspiracies was highly related to belief in the others and that those beliefs were stable over time. Furthermore, belief in a composite of the three conspiracies in March predicted unwillingness in July to obtain a vaccine for the virus should one become available. The beliefs also predicted a lower likelihood of reporting wearing a face mask outside the home when exposed to other people [18]. Although belief in pandemic conspiracies increased from March to July 2020, our earlier analysis did not identify potential sources of that increase or their possible effects on preventive behavior.

Previous research has found that both misinformation [19] and conspiracy beliefs are resistant to change [6,7,20,21] and that holding conspiracy beliefs related to COVID-19 is associated with lower levels of behaviors known to prevent its spread [13,22]. In addition, single cross-sectional studies have found a positive relationship between social media use and COVID-19 misinformation [1] and conspiracy beliefs [14,23,24] and found that mainstream media consumption is associated with greater rejection of them [25,26]. However, such cross-sectional data cannot determine whether persistent use of these sources is related to change in these beliefs across time or whether efforts undertaken between the two surveys by media outlets to decrease the amount of conspiracy content about COVID-19–related topics is associated with a decrease in these beliefs.

Using a longitudinal study design, we tested the possibility that exposure to different types of media sources might be responsible for change in COVID-19 conspiracy beliefs in the United States. Where our earlier work found that conspiracy beliefs were positively related to use of social and conservative media and negatively related to use of mainstream television and print [18], we sought to determine whether those media sources were also associated with subsequent change in the strength of conspiracy beliefs from March to July 2020.

In examining the role of the media, it is important to recognize that different types of outlets follow different norms when communicating information even in ordinary times. According to normative models of news reporting [27,28], journalists draw on reliable, predictable sources, such as government agencies and other accounts that can be independently verified through standard fact-checking procedures. In the case of conspiracy theories, such evidence is not available [29]. At the same time, their imperviousness to disconfirmation reduces the likelihood that mainstream news sources will feature them except to debunk them. However, commentators on conservative cable and talk radio, and those who post on social media are not bound by such conventions [27]. As one example, Tucker Carlson of Fox News noted that there was "a lot of speculation" that COVID-19 "is not a naturally occurring virus; that it was somehow created by the Chinese government" [30]. Rush Limbaugh alleged that "the coronavirus is being weaponized as yet another element to bring down Donald Trump" and that "it probably is a ChiCom laboratory experiment that is in the process of being weaponized" [31].

Misleading information percolated through social media as the pandemic unfolded [14,23]. On March 3, 2020, NewsGuard [32] raised an alarm due to the following finding:

> *Over the last 90 days, posts from the websites of the U.S. Centers for Disease Control and Prevention and the World Health Organization received 364,483 'engagements,' or likes, shares, and comments on social media. In that same period, 74 U.S. sites that NewsGuard found to have published coronavirus misinformation received a combined 52,053,542 'engagements'—more than 142 times the engagement of the two major public health institutions providing information about the outbreak.*

A video on a YouTube channel named the Next News Network was viewed nearly 7 million times before it was taken down by YouTube [33]. It claimed that the COVID-19 pandemic was the result of a deceptive plot that sought to impose "mandatory vaccines" on the public.

Unlike conservative cable and talk radio, the major social media platforms took active measures to interdict COVID-19–related misinformation and conspiracies by removing misleading and potentially harmful content, inserting warnings where appropriate, and featuring articles that refuted the widespread misinformation. In March 2020, Twitter announced that it would "prioritize removing content when it has a clear call to action that could directly pose a risk to people's health or well-being" [34] and in May announced that it would "put labels and warning messages on some tweets that contain disputed or misleading information related to Covid-19" [35]. In addition, in anticipation of the release of a COVID-19 conspiracy film, "Pinterest had its moderators run proactive searches for terms that might have been associated with the movie, deleting them to nip any problematic content in the bud" [36]. In early March, Facebook announced that it "was removing false claims and conspiracy theories flagged by global health organizations and the company is blocking people from running ads that try to exploit the fears of the public by pitching snake oil cures" [37]. In mid-April, Facebook began "showing messages in News Feed to people who have liked, reacted or commented on harmful misinformation about COVID-19 that we have since removed. These messages will connect people to COVID-19 myths debunked by the WHO including ones we've removed from our platform for leading to imminent physical harm" [38]. At the same time, it announced that it had "added a new section to [its] COVID-19 Information Center called Get the Facts. It includes fact-checked articles from [Facebook's] partners that debunk misinformation about the coronavirus." In August 2020, Facebook reported that it had removed "7 million posts pushing covid-19 misinformation from its main social media site and Instagram between April and June" and "put warning notes on 98 million covid-19 misinformation posts on Facebook" in the same period [39]. In December 2020, YouTube reported that it had removed more than 700,000 misleading COVID-19 videos to date [40].

Despite their efforts, the range of social media and the capacity of misinformation purveyors to repost interdicted content means that conspiracy theories about COVID-19 often gain substantial audiences before they are blocked or addressed [19,38,41,42]. For example, before YouTube removed a video asserting that the pandemic had been bioengineered, 570,000 subscribers to the website SGT Report had potentially been exposed to it [43]. Additionally, the 26-minute viral video, "Plandemic," which was also eventually removed in May 2020, nevertheless claimed that "vaccines kill millions, the flu vaccine contains the coronavirus, and that the virus was 'manipulated'" [44], and was viewed "more than eight million times on YouTube, Facebook, Twitter and Instagram, and had generated countless other posts," in a little over a week after its release [45]. If exposure to those media is partly responsible for the dissemination and credibility of conspiracy beliefs, we would expect that ongoing exposure would intensify the beliefs between March and July 2020. If the social media efforts to blunt the effects of the content were successful, we would expect that the beliefs reported in March by users of those media would not have intensified by July.

We also were interested to see whether mainstream media use predicted declines in conspiracy beliefs, as cross-sectional analyses of the relations between media sources and conspiracy beliefs in March found [1,18]. If the mainstream news media are a source of substantiated information rather than speculation about conspiracies, then one would expect that exposure to them would result in a decline in conspiracy beliefs regarding the pandemic. Such a finding would suggest that news media can play a role in reducing the strength of conspiracy beliefs, despite their resistance to refutation.

To further investigate the role of conspiracy beliefs on preventive behavior, we asked whether increased belief in COVID-19–related conspiracies from March to July 2020 was related to changes in either preventive behavior (mask wearing) or willingness to accept a COVID-19 vaccine when a safe and effective one becomes available. Furthermore, to the extent to which ongoing use of any media sources was associated with strengthened belief in the same pandemic conspiracies, we were also interested to see if patterns of media exposure might not only predict change in conspiracy beliefs, but also whether those changes were associated with changes in vaccination intentions or with uptake of mask wearing.

In summary, we explored whether use of different media that span the liberal to conservative political spectrum, including mainstream media, predicted change in the acceptance of conspiracy theories that were found to be prevalent at the start of the COVID-19 pandemic in the United States [1,2,4]. In particular, we tested our major hypothesis (H1) that use of mainstream news media such as broadcast television and newspapers that abide by journalistic norms of reporting would predict reduction in conspiracy belief. With regard to social media, which are not constrained by such norms and have been found to be associated with belief in conspiracy theories about the pandemic [14,23], we explored whether their use might have strengthened conspiracy beliefs or alternatively, consistent with efforts by major platforms to remove misinformation and conspiracies, have reduced the strength of those beliefs over time. Our prior analysis of the role of conservative media suggested our second major hypothesis (H2) that use of conservative media would strengthen conspiracy beliefs. Finally, to the extent that media use predicted continued growth or decline in conspiracy beliefs, we asked whether such changes were associated with changes in accepting a vaccine when one became available or with adopting the newly recommended preventive action of mask wearing.

Methods

Survey Sample

A sample of US residents (N=840) that was recruited from a national probability panel by Qualtrics completed two waves of an online survey as part of their participation in NORC (National Opinion Research Center) at the University of

Chicago's AmeriSpeak Panel [46]. The first survey was conducted in March 2020 and the second approximately four months later in July. We restricted our analysis to the respondents who completed both surveys (see [18]). The sample that remained at the second wave was very similar to that from the first wave and missingness was only slightly related to intention to vaccinate at wave 1. The study was deemed to be exempt from institutional review board review in as much as no personally identifiable information was retained from the survey firm.

NORC also provided demographic survey weights to enable projection to the US population according to age, gender, race/ethnicity, education, and Census Division based on the Current Population Survey of February 2020. Those weights were applied for descriptive purposes in describing belief in conspiracy theories, but all multivariate analyses were conducted with unweighted data and demographic differences controlled.

A power analysis conducted prior to the study indicated that a sample size of approximately 800 would enable us to detect standardized mediated relationships of .04 or greater at the 99% CI [18], which was regarded as sufficiently sensitive for direct relationships as well.

Survey Content

Conspiracy Beliefs

We assessed belief in three conspiracy theories circulating in social media and other venues at the time of the first wave [47], which were found to be accepted by at least 10% of the US population [1,2,4]:

1. "The pharmaceutical industry created the coronavirus to increase sales of its drugs and vaccines."
2. "The coronavirus was created by the Chinese government as a biological weapon."
3. "Some in the U.S. Centers for Disease Control and Prevention, also known as CDC, are exaggerating the danger posed by the coronavirus to damage the Trump presidency."

Belief in each conspiracy theory was registered on a 4-point scale ranging from "Definitely false" to Definitely true." Belief in conspiracies is distinguishable from endorsement of other forms of misinformation (eg, that taking vitamin C protects one from contracting COVID-19) that were also prevalent during the early phase of the pandemic in the United States [48]. We operationalized strengthening of conspiracy belief as a movement toward either "definitely" or "probably true" and weakening as movement toward "definitely false." These ratings were correlated within respondents with values ranging from .40 to .54 at both waves and high levels of reliability (α values=.71 and .74 and ω values=.67 and .74). The mean of these ratings increased from 1.75 (SD 0.85) to 1.90 (SD 1.08), $P<.001$, at the second wave. Belief in the conspiracies in March was inversely related to taking preventive action and accepting an eventual vaccine [18]. In addition, conspiracy belief in March prospectively predicted both action taken and change in vaccination intention assessed in July. In the analysis reported here, we determined whether change in conspiracy belief associated with media use was also related to prospective prediction of those outcomes.

Mask Wearing and Other Preventive Actions

We also developed an index encapsulating adoption of seven recommended actions to prevent the infection at wave 1 (eg, frequent hand washing) [18]. The index was the sum of the actions taken in the past few days (Yes or No). This index did not include mask wearing, which was not recommended until after the first wave was completed. At the second wave, we used this outcome as a measure of compliance with recommended action since it had become recognized as critical to halting the spread of the virus through the air as well as preventing contact between the hands and face [49]. At the second wave, 79% (n=668) of the sample reported wearing a mask every day they went to public places where they "might encounter other people." The two outcomes were positively correlated across the two waves (r=.23), indicating that the index at wave 1 was sensitive to willingness to comply with recommended behavior, and so we used the index at wave 1 to assess change in this tendency over time.

Vaccination Intentions

We also assessed intentions to accept a vaccine should one become available in the future with a 4-point scale going from "not at all likely" to "very likely." The proportion who reported either not at all likely or not very likely increased from 14.5% (n=121) at the first wave to 25.8% (n=215) at the second wave, $P<.001$.

Media Use

To determine whether media use predicted change across time in conspiracy beliefs, we assessed reliance on six sources of news and commentary in the media from across the political spectrum [11]. Our use of conservative, mainstream, and liberal media categories was consistent with classifications that are commonly used to categorize media in the United States [27,50-52].

For each source, respondents rated "How much information do you get from sources such as…" on a 6-point scale from "no information" to "a lot of information" (see Table 1 for each list of sources). The modal response was "no information" except for mainstream broadcast television news, for which the mode was the highest level of information. We refer to the use of major national newspapers and news services that have users both online and in traditional print as mainstream print. As seen in Table 1, the reported amount of information that respondents received from each source tended to decline from March to July and did so reliably for all but liberal news and aggregators. Nevertheless, individual use of each media category was highly stable across time, as evidenced by the correlations between the two time points. In addition, correlations between use of each media and belief in COVID-19 conspiracies ranged from a high of .37 for conservative media to –.28 for mainstream print.

Table 1. Use of six media (with examples of each) as sources of information in both March (T1) and July (T2) of 2020 and relations with political ideology (unweighted).

Media use	March 2020 (T1), mean (SD)	July 2020 (T2), mean (SD)	*t* value of paired difference, T1-T2	Probability of *t* value	Correlation over time	Correlation with T1 Conspiracy Belief Index
Mainstream television (eg, ABC News, CBS News, NBC News)	2.94 (1.77)	2.61 (1.73)	6.13	<.001	.62	–.18
Conservative media (eg, Fox News, Rush Limbaugh, Breitbart News, One America News, The Drudge Report)	1.49 (1.83)	1.39 (1.74)	2.19	.029	.71	.37
Liberal media (eg, MSNBC, Bill Maher, Huffington Post	1.35 (1.53)	1.31 (1.51)	0.69	.49	.57	–.10
Aggregators (eg, Google News, Yahoo News)	2.00 (1.63)	1.94 (1.59)	1.22	.22	.54	.06
Social media (eg, Facebook, Twitter, YouTube)	1.80 (1.71)	1.67 (1.63)	2.23	.026	.54	.16
Mainstream print (eg, Associated Press, New York Times, Washington Post, Wall Street Journal)	1.85 (1.75)	1.80 (1.71)	2.26	.026	.61	–.28

We controlled for the partisanship of the respondent as an alternative explanation for effects, using a measure of political ideology registered on a 5-point scale ranging from "very conservative" to "very liberal." As expected, self-identified liberals reported greater use of liberal media (r=.30), while conservatives reported greater use of conservative media (r=–.42).

We also assessed various demographic differences that could be associated with media exposure and therefore might explain changes between the two waves in relation to conspiracy beliefs and media use. The relations between these characteristics and belief in coronavirus conspiracies are described in the Results section. The text of the survey is located in Multimedia Appendix 1.

Analysis

We used the program Mplus [53] to test path models for the relation between media use in March 2020 and changes in conspiracy beliefs in July 2020. For any media use that predicted such change, we examined whether the change in conspiracy belief mediated changes in either preventive action (mask wearing) or intention to vaccinate. Less than 3% of the data was missing for any analysis, and Mplus imputed those scores using maximum likelihood estimation. We used bootstrap procedures with 1000 samples to construct 99% and 95% CIs for all tests of direct and mediated paths. We report standardized coefficients for all paths in the models that had CIs excluding zero. To avoid overfitting, paths with values that did not lie outside of at least 90% CIs were dropped from the models and fixed at a value of zero. We used standard measures of goodness of fit for all models [54].

Results

Overview

Table 2 shows the percentages of respondents at each wave who reported belief in the three conspiracy theories by various demographic characteristics and media use (weighted to national demographics). Overall, each belief received greater endorsement at the second wave, and this occurred across most of the demographic and media use characteristics. In total, belief that China had created the virus as a weapon was the most widely endorsed (38.1%), with belief that some within the Centers for Disease Control and Prevention (CDC) were using the pandemic to undermine the president was close behind (32.2%). The belief that the pharmaceutical industry was benefiting from the pandemic and possibly helped to create it was the least accepted (17.4%).

Table 2. Percentages of sample believing that each conspiracy belief was either "definitely true" or "probably true" by demographic characteristics and news use in March and July 2020 (N=840, weighted).

Characteristic	Percentage of sample	Pharmaceutical industry created the virus, %		Centers for Disease Control and Prevention wants to damage the Trump presidency, %		Chinese government created the virus, %

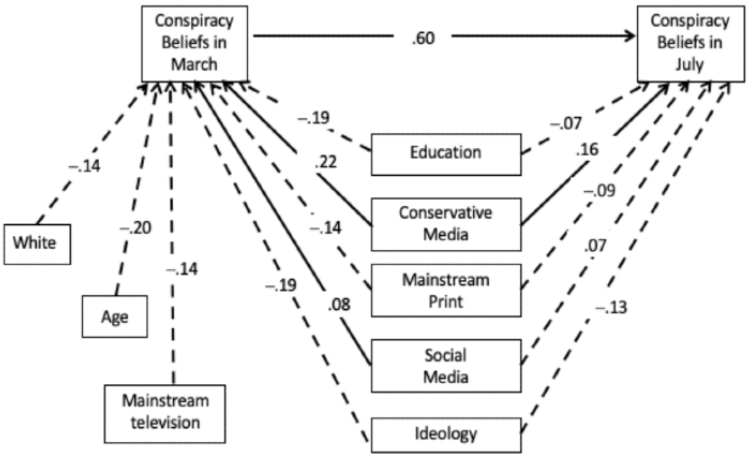
[a]Response distributions that are significantly different within each time period ($P<.05$) either across demographic groups or within each media use.

Figure 1 shows the results of the path model that tested our hypotheses regarding mainstream and conservative media as predictors of change in support of pandemic conspiracies and our exploration of social media as a continued influence. The model provided an excellent fit to the data, with a root mean square error of approximation (RMSEA) of .032, 90% CI .000-.068; comparative fit index (CFI)=.99; Tucker-Lewis Index (TLI)=.99, and standardized root mean square residual (SRMR)=.007. As seen in Figure 1, holding constant the relation between conspiracy beliefs across time, our first hypothesis (H1) regarding the effects of mainstream news was only partially supported, while H2 regarding the effects of conservative and social media was fully supported: both conservative (.159, 99% CI .089-.231) and social media use (.072, 99% CI .018-.123) predicted increased belief in the conspiracies. However, while mainstream television and print were inversely related to conspiracy belief in March, only mainstream print predicted a decline in conspiracy belief in July (–.090, 99% CI –.150 to –.029). No other media use predicted subsequent conspiracy belief.

Figure 1. Standardized predictors of conspiracy beliefs in March and again in July with all coefficients falling within 99% CIs, except for social media and conspiracy beliefs in March.

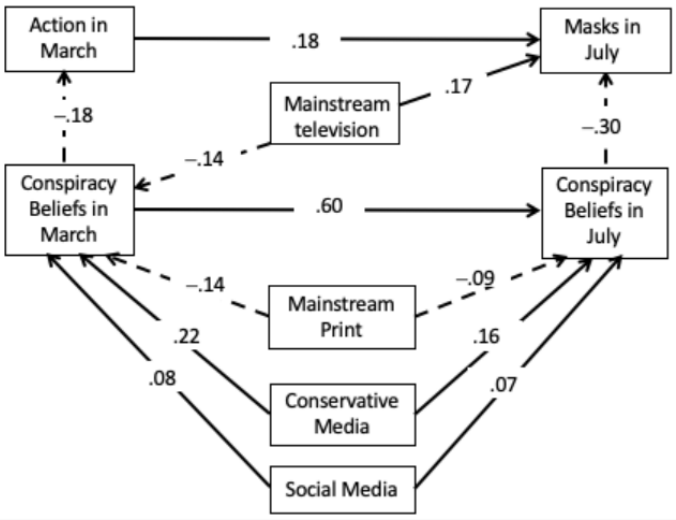


As seen in Figure 1, the media sources remained predictive despite controls for other factors, such as education and liberal political ideology, which predicted declines in conspiracy beliefs.

Relations With Mask Wearing in July

Figure 2 shows the results of the analysis for changes in action taken, with mask wearing specifically assessed at the second wave. This model also fit the data well, with an RMSEA of .036, 90% CI .021-.051; CFI=.98; TLI=.97; and SRMR=.019. Use of masks in July was inversely related to conspiracy belief in July (–.30, 99% CI –.38 to –.22), controlling for demographic differences and political ideology (not shown in the figure). Interestingly, use of mainstream television in March was a positive predictor of mask wearing in July (.17, 99% CI .09-.26), but this relation was direct and not mediated by conspiracy belief in July. This was in contrast with conservative media use in March, which indirectly predicted lower mask wearing in July with an overall relation of –.093, 99% CI –.132 to –.061. Importantly, about half of this mediated relation (–.047/–.093=51%) was attributable to change in conspiracy beliefs (–.047, 99% CI –.076 to –.024). The rest of the relation went through the carryover of conspiracy belief from March to July (–.039, 99% CI –.061 to –.021) and the carryover of preventive action in March to mask wearing in July (–.007, 99% CI –.015 to –.003). Thus, these indirect paths show that use of conservative media in March predicted less mask wearing as mediated by increases in conspiracy belief in July apart from any change attributable to previous actions taken.

Figure 2. Standardized relations between media use in March and subsequent conspiracy beliefs and action taken to prevent spread of COVID infection in July. All paths within 99% CIs, except between social media and conspiracy beliefs in March, which excluded zero with a 95% CI.



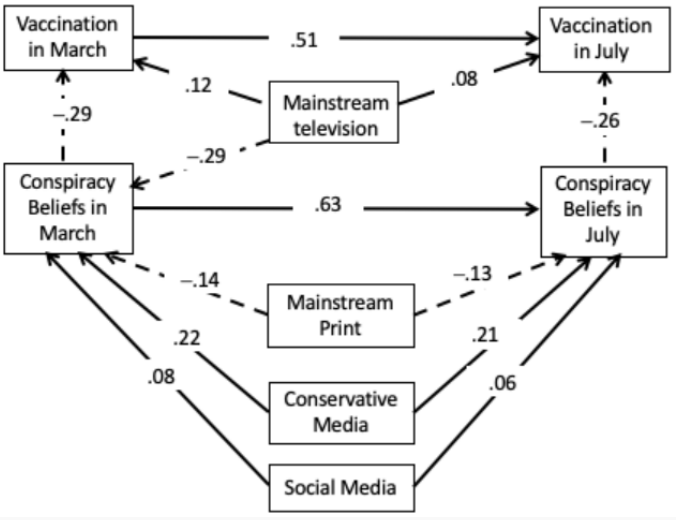
With regard to use of mainstream print in March, the overall relation with mask wearing in July was positive (.057, 99% CI .030-.086), indicating that it was associated with greater use of this behavior. In addition, in contrast with conservative media use, its relationship with mask wearing as mediated by change in belief in pandemic conspiracy theories was positive (.027, 99% CI .008-.042). This amounted to about 47% (.027/.057) of the relation between use of mainstream print in March and mask wearing in July. The rest of the relation was mediated by carryover in conspiracy belief from March to July (.026, 99% CI .008-.043) and through action taken in March (.005, 99% CI .001-.010).

Social media use in March also predicted less mask wearing in July with a total indirect relation of –.039, 99% CI –.067 to –.018. Here more than half of this relation (–.022/–.039=56%) was attributable to change in conspiracy beliefs (–.022, 99% CI –.040 to –.006).

Relations With Vaccination in July

Figure 3 shows the model that explored the role of various media uses in March as predictors of change in vaccination intentions and associated change in conspiracy beliefs. This model also fit the data well, with an RMSEA of .058, 90% CI .046-.072; CFI=.97; TLI=.94, and SRMR=.021.

Figure 3. Standardized relations between media use in March and conspiracy beliefs and vaccine intentions in July. All paths within 99% CIs, except between social media and conspiracy beliefs in March and July, which excluded zero at the 95% CI.



As with mask wearing, vaccination intentions in July were inversely related to conspiracy beliefs in July apart from demographic variables and political ideology (–.26, 99% CI –.34 to –.17). Again, use of mainstream television was a positive predictor in July even though its relation was independent of belief in pandemic conspiracies (.075, 95% CI .016-.135). In the case of vaccination, mainstream television was also associated with greater intention to vaccinate in March (.124, 99% CI .031-.211).

Use of conservative media in March predicted reduced intentions to vaccinate in July as mediated in total by conspiracy beliefs and carryover in vaccination intentions (–.120, 99% CI –.165 to –.083). Use of conservative media in March was specifically

related to change in vaccination intentions stemming from changes in conspiracy beliefs in July (–.054, 99% CI –.083 to –.031). This indicates that about 45% (–.054/–.120) of the overall relation was attributable to conservative media's association with increased belief in pandemic conspiracies from March to July. The rest of the relation was attributable to carryover in conspiracy beliefs from March to July (–.035, 99% CI –.059 to –.019) and carryover from vaccination intention in March to July (–.031, 99% CI –.050 to –.018).

As with mask wearing, use of mainstream print had an overall positive relation with vaccination intention in July (.078, 99% CI .037-116). About 44% (.034/.078) of this relation was due to mainstream print's association with change in conspiracy belief (.034, 99% CI .017-.055). The rest of the mediation was attributable to carryover in conspiracy beliefs from March to July (.023, 99% CI .007-.040) and carryover in vaccination intentions from March to July (.021, 99% CI .007-.036).

Use of social media in March was also predictive of vaccination in July, with an overall negative indirect relation of –.041, 99% CI –.071 to –.014. However, this relation as mediated by change in conspiracy beliefs was weaker than for the other media, with only about 39% (–.016/–.041) attributable to this source (–.016, 99% CI –.035 to –.001). The rest of the relation was attributable to carryover in conspiracy beliefs and vaccination intentions from March to July.

Discussion

Principal Findings

Despite the characterization of conspiracy beliefs as paranoid [5] and stigmatized by some in public discourse [6], they remain robust sources of skepticism regarding important public health recommendations able to prevent the spread of COVID-19. In our analysis of the prevalence of three conspiracy beliefs regarding the COVID-19 pandemic, we found that acceptance of those beliefs ranged from 17% for belief that pharmaceutical companies created the virus to 38% for belief that the Chinese government did so. These levels of acceptance grew over the period from March to July. As with many conspiracies, these beliefs can be accepted by the same person despite their logical incompatibility [55,56]. Scholars have argued that it is the underlying distrust of governments rather than the consistency of their content that appears to motivate their acceptance [57,58].

We found that reliance on different types of media for information during the early months of the COVID-19 pandemic in the United States predicted changes in the strength of belief in the three prevalent conspiracy theories. In particular, use of conservative media, such as Fox News and the talk radio program hosted by the late Rush Limbaugh, was associated with increased acceptance of the three conspiracy beliefs, while use of mainstream print—such as the New York Times and the Wall Street Journal—was associated with increased rejection of them. Although mainstream broadcast television news was negatively associated with conspiracy beliefs in March, there was no direct relation in July. Despite the efforts of the platforms to interdict such content, there was also a small but reliable increase in the perceived truth of the three theories among users of social media in July.

We found partial support for the hypothesis (H1) that use of mainstream news outlets would reduce belief in conspiracy theories because those media tend to follow traditional journalistic norms of reporting based on substantiated information backed by credible sources [27,28]. Conspiracy theories are by their nature spread by questionable sources whose assertions are difficult to verify [29]. As a result, those theories are less likely to be covered in the news, except to undercut them (eg, NBC news coverage of the QAnon conspiracy [59]). This hypothesis was supported in regard to mainstream print, but not broadcast television. We also found support for the hypothesis (H2) that use of conservative media would sustain and strengthen conspiracy beliefs because the commentators on these venues discussed those theories as plausible causes of the pandemic and explanations for failures of the Trump administration to cope with the crisis [60]. As one would expect, we found that, regardless of media use patterns, politically conservative more so than liberal or independent respondents endorsed the conspiracy beliefs at both times. Early in the pandemic, a Republican member of Congress wore a gas mask to a vote on emergency relief for the pandemic, in an apparent attempt to poke fun at the need for such action [61]. Moreover, President Trump opined that the virus was no more serious than the seasonal flu [62], suggested that it was created at the Wuhan Institute of Virology [63], characterized a finding by the Department of Veteran Affairs that hydroxychloroquine was not effective as a "Trump enemy statement" [64], and alleged that the "deep state" was delaying progress on a vaccine to thwart his reelection [65]. These moves to downplay the seriousness of the pandemic, blame its origins on a Chinese lab, and dismiss inconvenient science as the work of his enemies are consistent with two of the conspiracy beliefs on which we focused. Indeed, both the belief that some in the CDC were exaggerating the seriousness of the pandemic in order to undermine his presidency and that the Chinese created the virus as a weapon were endorsed by 63% and 55% of conservative respondents at the second wave, respectively. Conservatives were previously found to be more disposed to accept the COVID-19 conspiracy belief that "powerful people intentionally planned the COVID-19 outbreak" [66].

We did not make a directional prediction about the influence of social media on continued belief in conspiracy theories because, as we noted earlier, during the period between our two surveys, considerable effort was expended by major platforms to remove or downgrade misleading information about the pandemic [40,41]. In addition, a recent survey of content on Twitter concluded that despite the large amount of misinformation on social media, there is also a great amount of science-based information that circulates on those sites [67]. However, our findings suggest that these efforts did not remove the influence of the three theories on which we focused. This finding is consistent with evidence from a study conducted in April 2020 that found considerable evidence of tweeted comments supporting a conspiracy theory about the pandemic [68] and other work suggesting that conspiracy claims that are interdicted quickly reappear elsewhere [17,45]. Although

experience in China suggests that rapid refutation of pandemic rumors can be successful in reducing transmission of misinformation on social media [69], the expanse, variety, and decentralized nature of US media make such efforts more challenging than in countries whose media are largely government controlled. We also found that acceptance of conspiracy theories was associated with less action to prevent the spread of the disease, such as mask wearing. Similar patterns were observed in willingness to accept a vaccine. In both cases, use of conservative and social media were related to reductions in preventive behavior associated with changes in conspiracy beliefs.

Although it is difficult to debunk conspiracy theories, we did find that use of mainstream print predicted a subsequent decrease in the three beliefs. In addition, persons with greater education were more likely to move away from belief in those theories by July. Nevertheless, despite the potential ability of mainstream print to reduce belief in pandemic conspiracies, its influence appeared to be weaker than that of conservative and social media, which together predicted more than twice the effect size of mainstream print (.23 versus –.09). If this pattern of influence were to persist, it could lead to further increases in conspiracy belief among users of social and conservative media and, because of the smaller influence of print, a net increase in those beliefs in the US population at large.

On a positive note, the influence of mainstream television news, which also reaches a more sizeable audience than social and conservative media, appeared to outweigh their potentially negative effects on mask wearing and future vaccination. Indeed, mainstream television was the most used source of information in our sample. Despite the greater *change* in conspiracy beliefs associated with conservative and social media use, when the direct relations with vaccination intentions (.08) and mask wearing (.17) are included, the difference between social and conservative versus mainstream media use was negligible for vaccination (–.161 versus .158, respectively) and weaker for mask wearing (–.132 versus .227, respectively). Considering the larger reach of mainstream news, the overall potential effects of those news sources could well have outweighed the effects of conservative and social media use on the public's acceptance of vaccination and mask wearing.

Some have suggested that use of mainstream news is so dominant in the United States that disinformation transmitted through the internet and social media is unlikely to exert much influence [70]. Our findings are consistent with the conclusion that although mainstream news use is extensive and correlated with positive protective behaviors, the influence of social and conservative media is nonetheless significant. The three conspiracy beliefs that we studied are associated with media use outside of mainstream news, suggesting that these sources have a worrisome influence on the US public, despite their smaller share of the media market.

It is notable that use of mainstream television news was associated with greater mask wearing and intentions to vaccinate whether one accepted the three conspiracies or not. Use of broadcast television was also associated with taking recommended action in the United Kingdom [26] and Canada [25]. This pattern suggests that this popular source of information enhances compliance with recommended behavior by means other than dispelling conspiracy theories. Through its wide reach and its audiovisual capacities, it may provide direct exposure to persons wearing masks and taking vaccines, actions that would increase the normative acceptance of these behaviors. It is also likely that mainstream news sources such as television transmit more public health recommendations than are routinely accessed on social media [25] or conservative cable and opinion sites [60]. Trust in mainstream news is also associated with greater rejection of conspiracy theories [71].

It is noteworthy as well that some individual characteristics were no longer directly related to increased belief in COVID-19 conspiracies in July despite being associated with them in March. Although both Black and Hispanic respondents reported more belief in those theories than white respondents in March, Black and Hispanic respondents did not increase their belief by the second wave in July. This suggests that they were not exposed to greater sources of COVID-19 conspiracy information in the media during the intervening period. Importantly, neither Black nor Hispanic respondents were more likely to consume information on conservative media (*r* values ranging from –.015 to .057) and were only somewhat more likely to use information on social media (*r* values ranging from .017 to .099). At the same time, Black respondents were more likely to use mainstream television than others at both time points (*r* values=.167 and .144), while Hispanic respondents exhibited no differential use of information on any of the two remaining media groupings over the two time points. Nevertheless, despite the absence of an increase in conspiracy belief among Black and Hispanic respondents, their greater overall endorsement of such beliefs is still related to their unwillingness to accept vaccines.

Limitations

Although our two-wave panel study provides more sensitive evidence of the role of media use in the persistence of conspiracy beliefs regarding the COVID-19 pandemic, there are limitations that need to be recognized. We use a national probability sample to generalize to the US population, but the survey was conducted online, which restricted the sample to those with online access and experience. As a result, older citizens were underrepresented. Additionally, because we rely on self-reports of behavior, such as mask wearing, we cannot confirm that those reports reflect actual behavior. Our results also are only applicable to changes that occurred between March and July of 2020 in the United States. The effects of media use on pandemic conspiracy beliefs beyond that period remain to be studied. Finally, despite the ability to observe changes in conspiracy beliefs associated with media use, we cannot make strong causal claims because it still remains possible that characteristics other than those for which we controlled drove the changes in those beliefs. Nevertheless, our controls for a wide range of demographic differences as well as for political ideology increase our confidence that media use predicts changes in conspiracy beliefs regarding the pandemic.

Conclusions

Exposure to conservative and social media during the period from March to July 2020 predicted greater belief in three COVID-19 conspiracy beliefs in the United States, and these beliefs were related to less intention to vaccinate in the future and lower reported use of masks in the present. Public health agencies tasked with communicating the need for effective action to prevent the spread of the virus should seek opportunities to present accurate information about the pandemic to users of those media. At the same time, reaching users of mainstream media is also important in that they were either less likely to subscribe to conspiracy beliefs (in the case of print) or more likely to adopt protective behavior (in the case of mainstream broadcast television news). Although social media platforms have attempted to remove misinformation and conspiracy theories related to the COVID-19 pandemic, users of these platforms were more likely to exhibit increases in the strength of such beliefs in July. This finding suggests that those venues need to exert even greater efforts to counteract exposure to problematic COVID-19–related content.

Abstract

Background: In the face of the current COVID-19 pandemic, the timely prediction of upcoming medical needs for infected individuals enables better and quicker care provision when necessary and management decisions within health care systems.

Objective: This work aims to predict the medical needs (hospitalizations, intensive care unit admissions, and respiratory assistance) and survivability of individuals testing positive for SARS-CoV-2 infection in Portugal.

Methods: A retrospective cohort of 38,545 infected individuals during 2020 was used. Predictions of medical needs were performed using state-of-the-art machine learning approaches at various stages of a patient's cycle, namely, at testing (prehospitalization), at posthospitalization, and during postintensive care. A thorough optimization of state-of-the-art predictors was undertaken to assess the ability to anticipate medical needs and infection outcomes using demographic and comorbidity variables, as well as dates associated with symptom onset, testing, and hospitalization.

Results: For the target cohort, 75% of hospitalization needs could be identified at the time of testing for SARS-CoV-2 infection. Over 60% of respiratory needs could be identified at the time of hospitalization. Both predictions had >50% precision.

Conclusions: The conducted study pinpoints the relevance of the proposed predictive models as good candidates to support medical decisions in the Portuguese population, including both monitoring and in-hospital care decisions. A clinical decision support system is further provided to this end.

Introduction

Background

COVID-19 is a disease caused by the novel coronavirus SARS-CoV-2, transmissible from person to person and associated with acute respiratory complications in severe cases [1,2]. The main symptoms of patients infected are fever, cough, and fatigue; others are asymptomatic [3]. The COVID-19 pandemic presents a substantial threat to global health and has been directly responsible for many deaths. Since the first

outbreak in December 2019 in Wuhan, China, the number of confirmed infected patients worldwide has exceeded 55 million cases, and nearly 1.3 million people have died from COVID-19 [4]. Current literature has shown that infected patients with specific comorbidities or preconditions (eg, hypertension, respiratory problems, diabetes) and of old age are expected to develop a more severe response to the infection and may consequently need longer hospitalizations and intensive care [5-7]. Strict social confinement measures have been implemented to decrease the COVID-19 R_0 value (average number of individuals infected by each infected person) and guarantee the optimal use of equipment and beds at normal, continuous, and intensive care units (ICUs). However, although public health responses aim to delay the spread of the infection, several countries such as the United States, Brazil, Italy, and India have faced severe health care crises.

Without effective antiviral drugs and a vaccine, prognostic tools related to COVID-19 are required. Statistical and computational models could assist clinical staff in triaging patients at high risk for respiratory failure to better guide the allocation of medical resources. Recently, several predictive models ranging from statistical and score-based systems to more recent machine learning models have been proposed in response to COVID-19. Guan et al [8] proposed a Cox regression model to infer potential risk factors associated with serious adverse outcomes in patients with COVID-19. Univariate and multivariate logistic regression models have been used to determine risk factors associated with mortality [9]. Scoring systems have been proposed to predict COVID-19 patient mortality but are limited by small sample sizes, with a poor discriminatory ability [10-12]. Other statistical approaches have also been emerging to aid prognostics [13,14]. Complementarily, machine learning methods offer the possibility to model more complex data relationships, generally yielding powerful capabilities to predict outcomes of infectious and noninfectious diseases in medical practice [15-17]. To this end, classification and regression models have been proposed for risk stratification of patients and to screen the spread of COVID-19 [18-20]. Despite the inherent potentialities of ongoing efforts, studies in the context of COVID-19 are limited by either the size of available cohorts or the lack of a systematic comparison of different models [21-24], and generally neglect the predictability of medical needs (instead the focus is commonly placed on measurable disease factors, early detection of infection, and mortality risk prediction [25-28]). None of these studies have comprehensively targeted the Portuguese population at the present time.

This Study

This study provides a structured view on the predictability of hospitalizations, ICU admissions, respiratory assistance needs, and survivability outcomes using a retrospective cohort encompassing individuals with a SARS-CoV-2–positive result in Portugal as of June 30, 2020.

To this end, and considering demographic, comorbidity, and care provision variables collected for the infected individuals, an assessment methodology was conducted, whereby state-of-the-art predictive models were hyperparameterized and robustly evaluated in order to assess the upper bounds on the predictive performance for each one of the targeted variables. In addition, whenever applicable, this analysis was extended toward the various stages of a patient's cycle: prehospitalization (at the time of testing), after hospitalization, and after ICU admission.

This study offers a solid methodology for the robust assessment of the predictability guarantees of future care needs of infected individuals, contrasting with the dominant correlation-based guarantees in literature. As comparable studies demonstrated in other populations, it lays a solid ground to compare type-I and type-II predictive errors and assess population-wise differences.

Methods

Overview

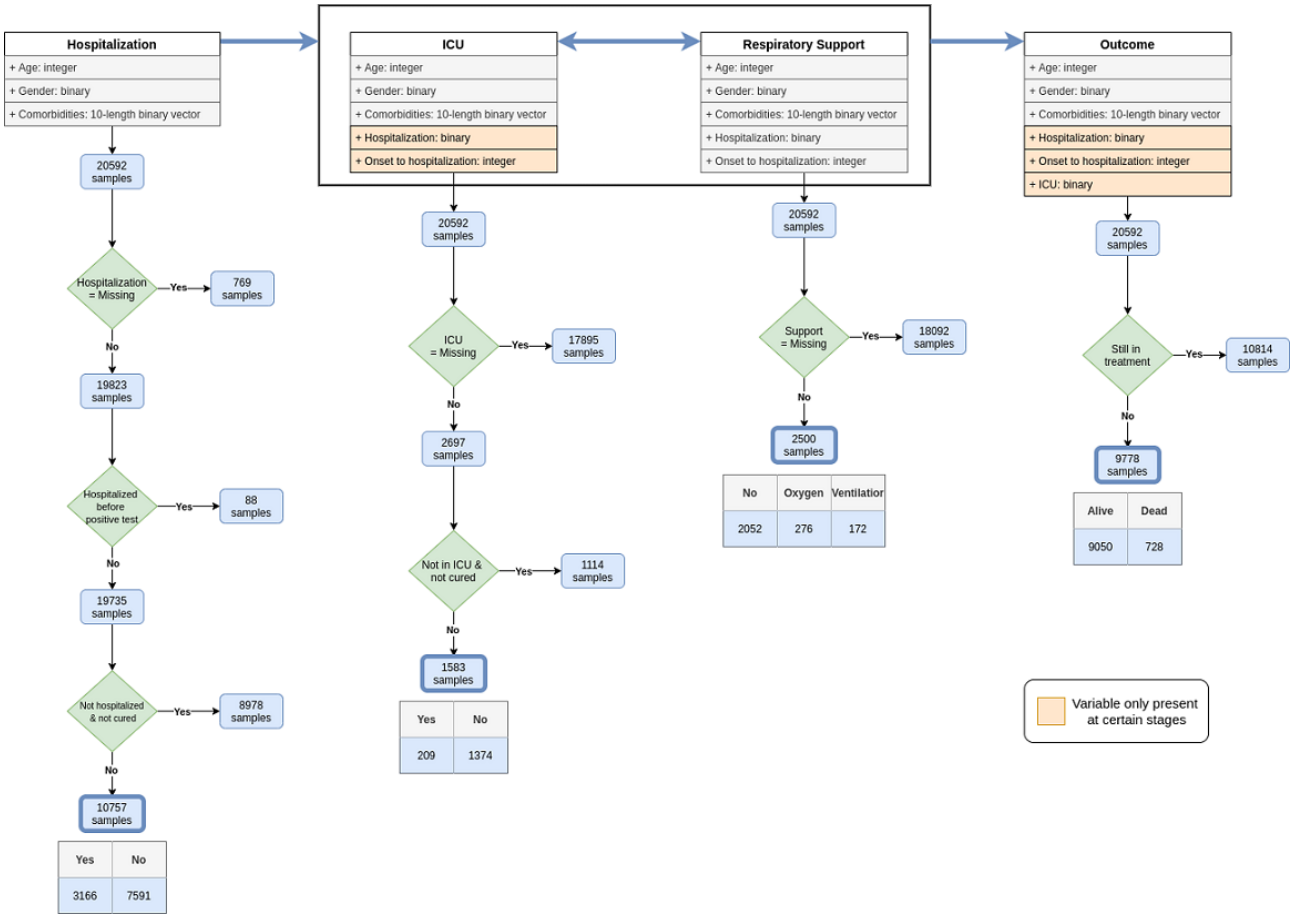
Complete subpopulations from the target cohort were identified for each output (Figure 1), guaranteeing the presence of all individuals undertaking the target forms of care (hospitalization, ICU admission, respiratory support) with a recovery-or-death outcome.

After the sampling and data curation steps (Figure 1), we proceeded to the optimization of data preprocessing options and classifiers' parameterization for each of the target variables separately. To this end, we applied a nested 10-fold cross-validation assessment methodology, whereby we first create train-test partitions (outer cross-validation) to assess the performance of an optimized classification method, and within each training fold we further create train-test partitions (inner cross-validation) for hyperparameterizing the predictive model under assessment. This methodology guarantees that all observations are used to assess the final performance and prevents biases as hyperparameterization takes place within each training folds.

Within each inner train-test fold, Bayesian optimization [29] was applied to find the hyperparameters that best fit the pipeline. The optimization measures are:

- F1 score and 0.7 × recall + 0.3 × precision for binary classes. These two views generate two sets of classifiers: one that equally weights recall-and-precision views, and other that, similar to the F2 score (F_β, where $\beta=2$), prioritizes the optimization of the true-positive rate (recall) at the cost of a lower positive predictive value (precision);
- Cohen kappa and average class recall for target variables with more than 2 classes (respiratory support).

Figure 1. Exclusion and inclusion criteria for composing the outcome-conditional cohorts: hospitalization, respiratory assistance support, intensive care unit (ICU) admission, and survivability. Blank/unknown cells in the Direcção-Geral da Saúde data set are classified as missing values.



Hospitalization, UCI admission, respiratory support, and recovery-or-death outcomes for SARS-CoV-2–infected individuals are considerably imbalanced, hence, the relevance of the placed recall-precision and multiclass recall views. In particular, considering both a balanced recall-precision optimization and recall-oriented optimization is relevant for clinical decisions. When the allocated teams have capacity to remotely monitor SARS-CoV-2–infected patients, the predictive models optimized with a schema that prioritizes recall should be pursued to guarantee that no vulnerable patient is left out. Nevertheless, when monitoring capacity is limited, greater attention to precision is necessary, and only more vulnerable patients (as suggested by the predictive models optimized with balanced recall-precision views) should be attemptively monitored.

The allowed preprocessing options are as follows: imputation of missing values using median-mode imputation, KNNImputer, or none; class balancing using subsampling, oversampling, SMOTE (Synthetic Minority Oversampling Technique), or none; and normalization of real-valued variables using standardization, scaling, or none. The selected classifiers are as follows: Bernoulli naive Bayes, Gaussian naive Bayes, k-nearest neighbors (KNN), decision tree (DT), random forest, XGBoost (XGB), logistic regression, Light Gradient Boosting Machine (LightGBM), Super Learner, and multilayer perceptron (MLP). Super Learner uses folding to hyperparameterize models and selects predictors for out-of-fold predictions from individual performance estimates per fold. In this context, Super Learner's performance is generally coincident with the best predictive model and thus not always disclosed in the *Results* section to allow the identification of the best underlying predictors. We considered the implementations provided in the *scikit-learn* [30] and *xgboost* [31] packages in Python (Python Software Foundation). For each classifier, all supported parameters in scikit-learn were subjected to hyperparameterization. Regarding the MLP, we placed upper limits on the number of hidden layers (3) and nodes per layer (20) given the low-dimensionality nature of the target data set. The hyperparameters were subjected to a total of 50 iterations. Multimedia Appendix 1 displays the optimized parameters for the best-performing predictive models per outcome.

Differences in performance from the paired-error estimates collected per fold were statistically tested using *t* tests when estimates passed the Shapiro–Wilk normality test. When this condition was not satisfied, Wilcoxon signed-rank tests were applied.

In addition to the conducted analysis, the best predictors trained on the whole data set were made available within a clinical decision support system built using flask technology and dash facilities in Python [32], which can run as an offline web application.

Data Source

A retrospective cohort (from March 1 to June 30, 2020) of patients with confirmed COVID-19 in Portugal was used in this

study. The anonymized data set was provided by the Directorate General of Health (Direcção-Geral da Saúde, DGS), the Portuguese health authority. The gathered data, called the *covid19-DGS* database, contains information pertaining to the demographic and clinical patient characteristics as well as preexisting conditions.

Data are available upon reasonable request.

Ethical Considerations

The COVID-19 data set is provided by the DGS under the collaborative *score4COVID* research project proposal. The tasks conducted in the *score4COVID* project were further validated by the Ethical Committee of the NOVA School of Science and Technology.

Results

Results on the predictability of hospitalization needs, ICU admissions, respiratory assistance, and outcome of infected individuals living in Portugal, as of June 30, 2020, are discussed below.

Cohort Characteristics

The target cohort comprised 38,545 individuals who were SARS-CoV-2 positive: 17,046 recoveries (SARS-CoV-2 negative after positive testing) and 1155 deaths. Four individuals were excluded from the data set due to inconsistent recordings related to age and pregnancy-gender variables. Table 1 provides essential statistics. Figure 2 further describes sex and age distributions in deaths, hospitalizations, ICU admissions, and average number of days from symptom onset (traced by the public health line for COVID-19) to a positive test result and hospitalization.

Within the target population, there were 4326 hospitalizations (11.2% of population base) and 253 admissions to the ICU (5.8% of hospitalizations). Among ICU internments, there were 82 recoveries and 61 deaths. In terms of respiratory support, a total of 180 individuals undertook assisted ventilation, 292 submitted to oxygen therapy, and 9 underwent alternative modes of respiratory support such as extracorporeal membrane oxygenation.

The major classes of comorbidities monitored were neoplasm, diabetes, asthma, pulmonary, hepatic, hematological, renal, neurological, neuromuscular, and immune deficiency conditions. The representativity of individuals with one or more comorbidities, as well as their impact on survivability, is depicted in Figure 3.

Table 1. Characteristics of SARS-CoV-2–infected patients in the target cohort.

Characteristic	Value
Numeric variables, mean (SD); range

[a]ICU: intensive care unit.

Figure 2. Cohort statistics: (A-C) demographic distribution of infected individuals with known outcome (death and recovery) and stage in the care life cycle (hospitalization and intensive care unit [ICU] admission); (D) average number of days between care stages (the plotted negative bin [ie, negative occurrences] corresponds to hospitalizations before SARS-CoV-2 testing).

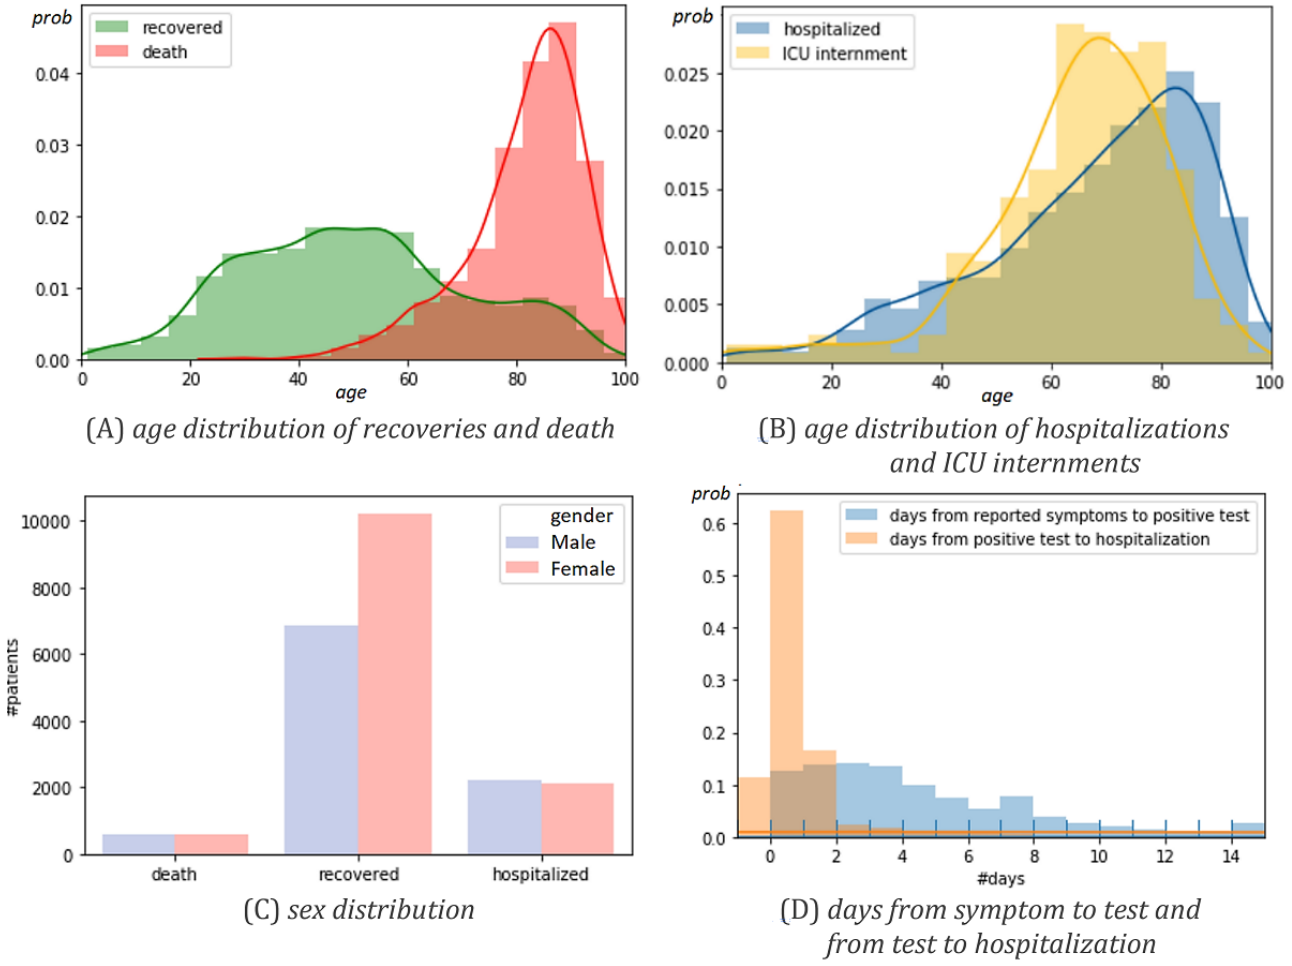

Figure 3. Cohort statistics: (A) distribution of individuals with one or more comorbidities among deaths, recovered cases, and hospitalizations; and (B) association between individual comorbidities and survivability outcomes.

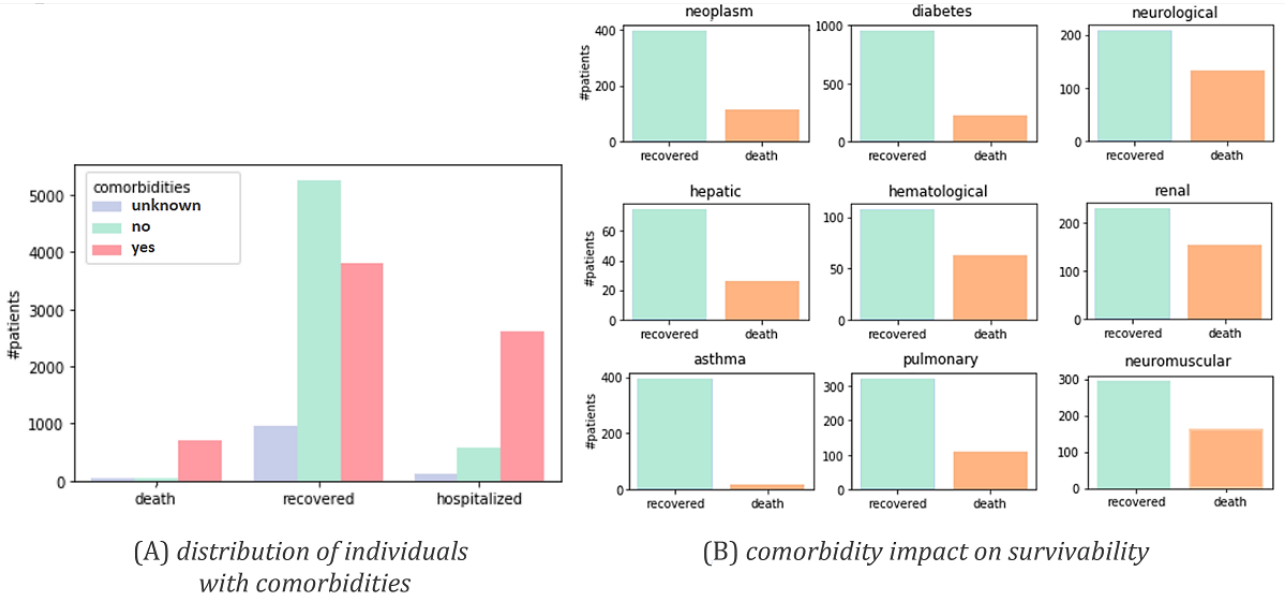

Hospitalization

Figure 4 and Table 2 provide results pertaining to the models' ability to predict the need for individuals to be hospitalized once they are tested as SARS-CoV-2 positive given their (1) demographic group (age and gender) and (2) comorbidity factors. Comorbidity factors were categorized in accordance with the presence or absence of kidney, asthma, lung, cancer,

neuromuscular, diabetes, HIV, cardiac, and pregnancy conditions. Nonhospitalized individuals without a clear outcome (recovery or death) were excluded from this analysis. Figure 5 provides the receiver operating characteristic curve per predictor for each optimization setting.

Generally, we observed that nearly 90% of hospitalization needs could be identified at the time of SARS-CoV-2 testing. This level of recall/sensitivity was observed at the expense of an approximate 55% precision, meaning that more than half of the predicted hospitalization needs were in fact observed. Logistic regression and MLP were the best-performing classification models according to F1-score and recall, respectively. Statistical superiority was verified for logistic regression but not MLP against peer models (at =.05). These results provide empirical evidence toward the role of these predictors in supporting individual remote monitoring decisions.

Figure 4. Predictability of hospitalizations for individuals testing SARS-CoV-2 positive. Recall, precision, and F1 for the best predictors in F1 (left) and recall-oriented (right) scores on the validation set after nested cross-validation. MPL: multilayer perceptron.

ICU Admissions

Figures 6 and 7 and Table 3 assess the ability to anticipate intensive care needs for infected individuals at two stages: before hospitalization and after hospitalization. To this end, the proposed methodology was pursued considering demographic factors, comorbidity factors, and the time to hospitalization for hospitalized individuals. Individuals without a SARS-CoV-2–negative test result after infection were excluded.

[h]LGBM: LightGBM.

The predictability of ICU needs is less satisfactory than hospitalization needs, particularly for the prehospitalization stage. We hypothesize that this difficulty was partially related to the smaller number of individuals with ICU internments, together with the presence of missing values associated with ICU internment needs for most individuals. Even though we can achieve recall levels over 90% with gradient boosting (XGBoost) in a posthospitalization setting, it comes at the cost of a considerably low precision (with one-third of predictions seen in practice). Still, the best-performing predictive models are suggested to support monitoring decisions at the hospital bedside, as their recall and specificity are considerably high.

Respiratory Support

Figure 8 and Table 4 assess respiratory assistance needs for hospitalized individuals with SARS-CoV-2, considering three assistance modes: (1) ventilation support, (2) oxygen therapy, and (3) combined ventilation and oxygen therapies. Demographic, comorbidity, and time-to-hospitalization factors were used as input variables.

Individuals without a SARS-CoV-2–negative test result after infection were excluded from this analysis. As respiratory support is a multiclass variable, we considered a different performance evaluation by focusing on (1) the recall for each major class (ventilation, oxygen, and nonrequired support), (2) the precision of individuals with oxygen or ventilation assistance, and (3) the Cohen kappa coefficient.

XGBoost, LightGBM, and random forests attained a satisfactory identification of hospitalized individuals who may require respiratory support in the future, generally providing recalls for each assistance mode around 60% at the cost of a 40% precision. According to the conducted methodology, they are thus pinpointed as good candidates to support in-hospital care decisions.

Figure 8. Predictability of respiratory support needs—assisted ventilation, oxygen therapy, and combined support—for hospitalized individuals with SARS-CoV-2. Performance of the best F1 predictor (right) and recall-oriented predictor (left) is shown. XGB: XGBoost, LGBM: LightGBM.

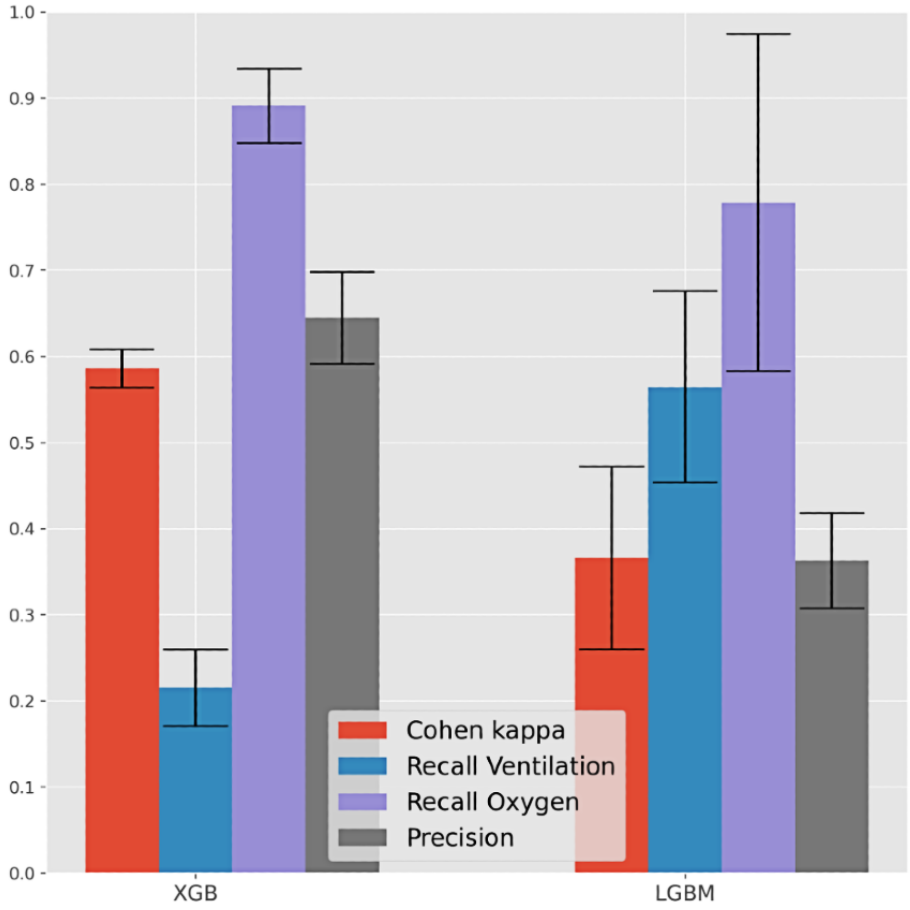

Table 4. Predictability of respiratory needs per predictive model.

Model	Kappa optimization, kappa, mean (SD)	Recalls optimization average, kappa, mean (SD)
KNN[a]	0.324 (0.050)	0.162 (0.022)

Survivability (Outcome)

Finally, Figures 9 and 10 and Table 5 provide an analysis of the ability of the models to predict recovery-or-death outcomes for individuals with SARS-CoV-2 infection at three time points: (1) before hospitalization (at the time of testing), (2) after hospitalization, and (3) after ICU admission when applicable. To this end, we preserved the input variables and validation

methodology (see *Methods* section) considered in previous scenarios.

Our results showed a high ability to identify death outcomes. However, at the SARS-CoV-2 testing stage, this comes at a cost of incorrectly classifying two-thirds of individuals susceptible to death. In the posthospitalization scenario, we achieved more balanced results, with both precision and recall around 75% using gradient boosting (XGBoost and LightGBM). The introduction of the intensive care variable hampered the results since it restricted the analysis of deaths to individuals with acute needs and dependent on continuous care instruments.

Figure 9. Predictability of the survivability (outcome) of infected individuals at 3 stages. Results for the best F1 predictor (left) and recall-optimized predictor (right) per stage are shown. XGB: XGBoost, LGBM: LightGBM.

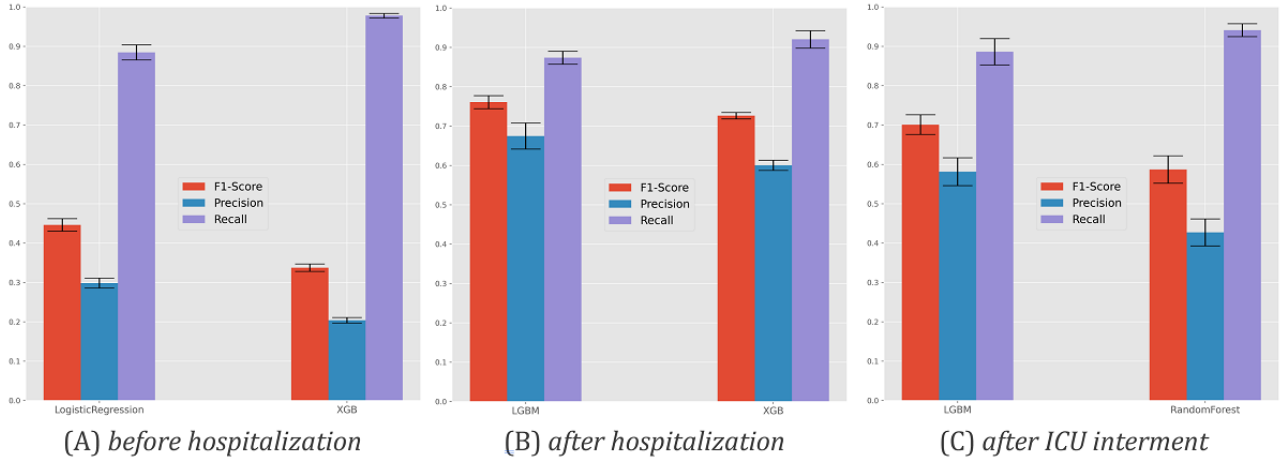

Figure 10. Receiver operating characteristic curves with the predictive behavior of the selected classifiers in asserting patient survivability at the time of hospitalization. XGB: XGBoost, MLP: multilayer perceptron, LGBM: LightGBM.

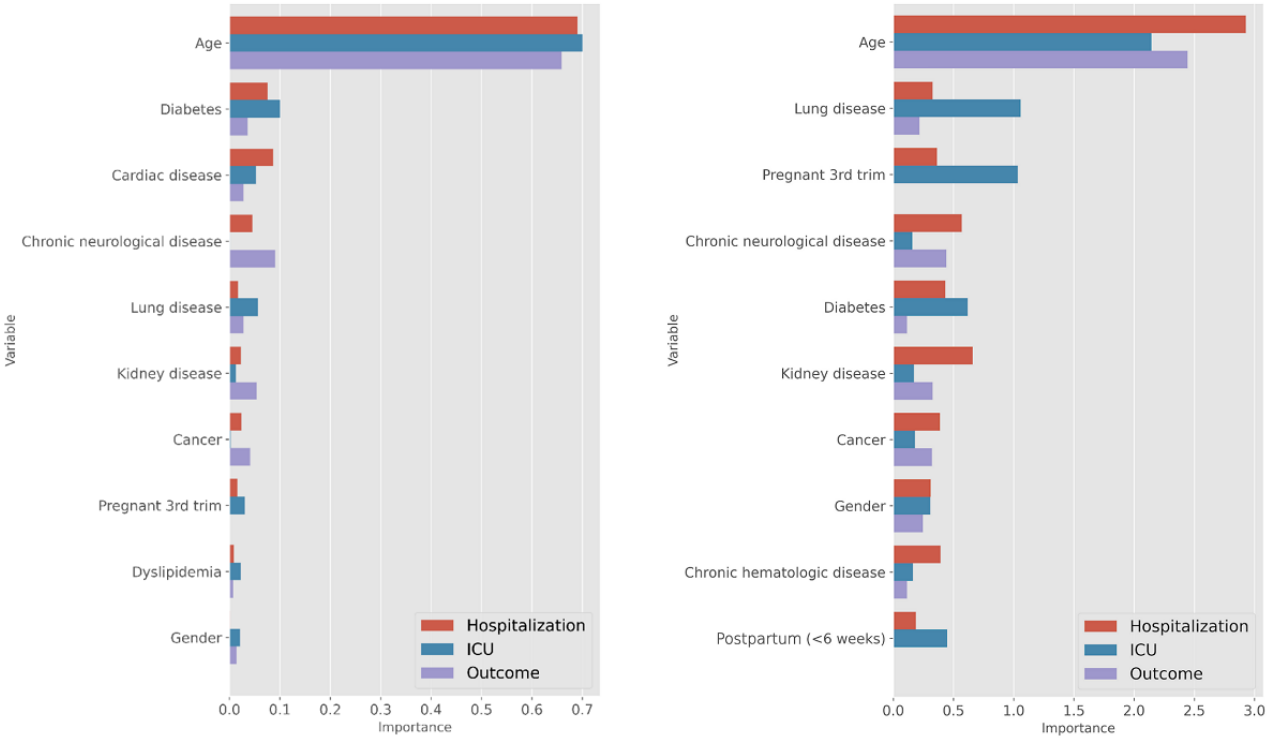
Determinants of Predictability

To assess the determinant factors underlying the achieved predictability levels, we first statistically tested the correlation between input and output variables using chi-square tests, ANOVA (analysis of variance), and their nonparametric counterparts, yielding results similar to those by Nogueira et al [33]. For a more in-depth understanding of the feature relevance for the assessed predictive models, Figures 11 and 12 illustrate the importance of the top features. To this end, we considered relevance outputs from gradient boosting (XGBoost) due to its competitively high performance across all outcomes, as well as the logistic regression for the hospitalization outcome by computing the Wald statistic to assess the significance of the coefficients for predictions.

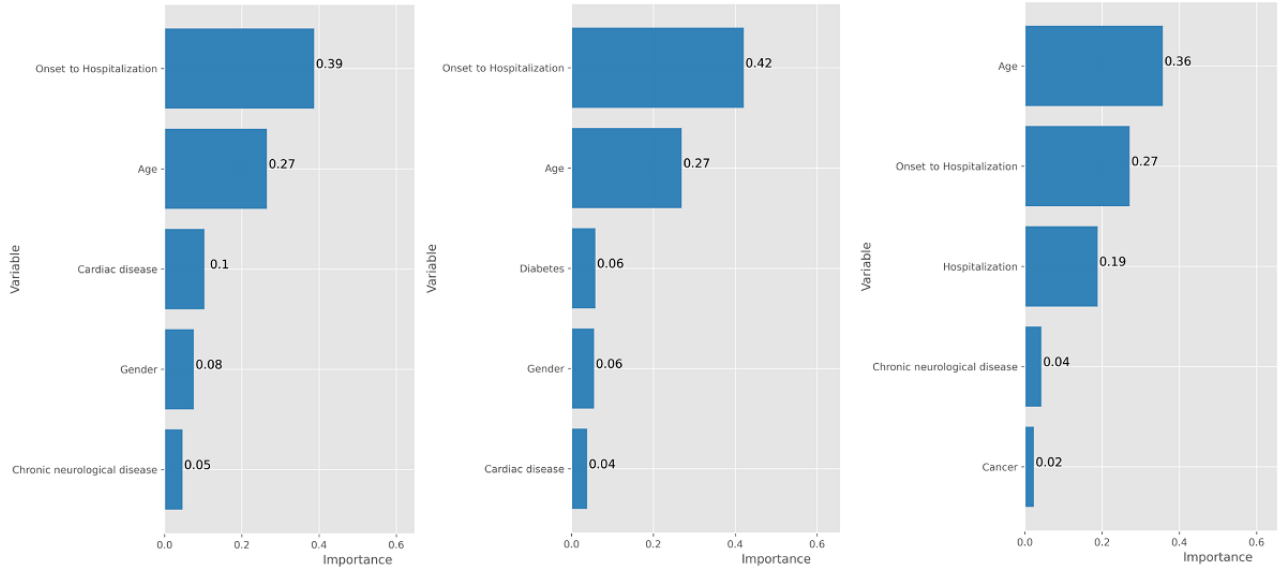
Figure 11. Top features and their importance for each target variable at the time of SARS-CoV-2 testing (prehospitalization). ICU: intensive care unit, LR: logistic regression.



(A) *XGBoost importance* (B) *LR importance (Wald statistic)*

We can observe that XGBoost distinguishes the relevance of different comorbidities for the target variables along each stage of the care process. In addition to the age variable, the onset period to hospitalization in days was also found to be a critical factor affecting the decisions (Figure 12). The high relevance of this variable consistently had top rank among associative models—XGBoost, random forests, and decision trees—pinpointing the importance of its collection for computer-aided predictions of ICU internment and respiratory needs.

Figure 12. XGBoost top features and their importance for the different outcomes at posthospitalization. ICU: intensive care unit.

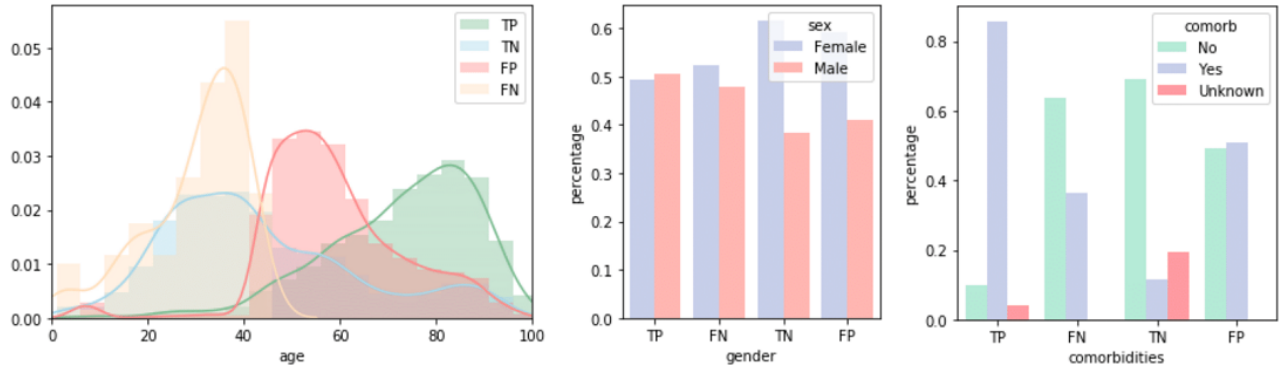


(A) ICU *admission* (B) *respiratory needs* (C) *survivability*

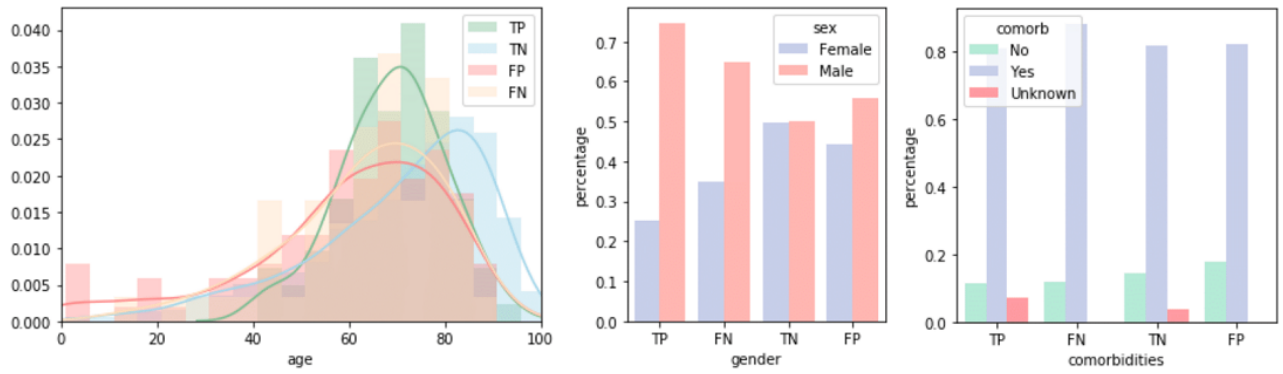
Complementarily, Figure 13 offers additional insights into the target predictive tasks by plotting some of the characteristics of the correctly classified individuals against incorrectly classified individuals with XGBoost. Particular attention should be paid to the differences between true positives and false negatives, that is, to the individuals requiring care, in order to guarantee their timely and proper assistance. The susceptibility

to false negatives is higher for individuals within the 40-60-year age category and without comorbidities.

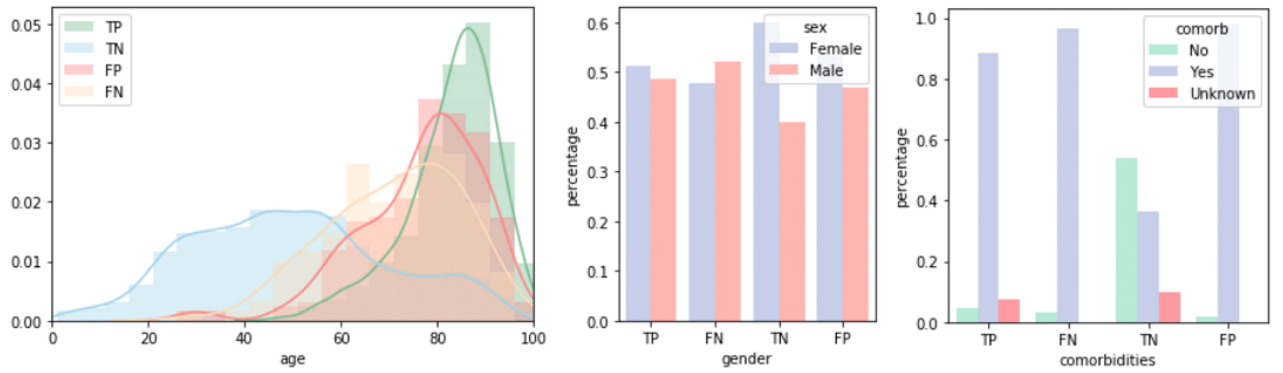
Figure 13. The characteristics of incorrectly predicted individuals with XGBoost. Particular attention should be paid to the differences between true-positive and false-negative individuals given their clinical relevance. ICU: intensive care unit.



(A) *Hospitalizations: profile of false-positive* (FP) *and false-negative* (FN) *individuals*



(B) ICU *admissions* (*posthospitalization*): *profile of false-positive* (FP) *and false-negative* (FN) *individuals*

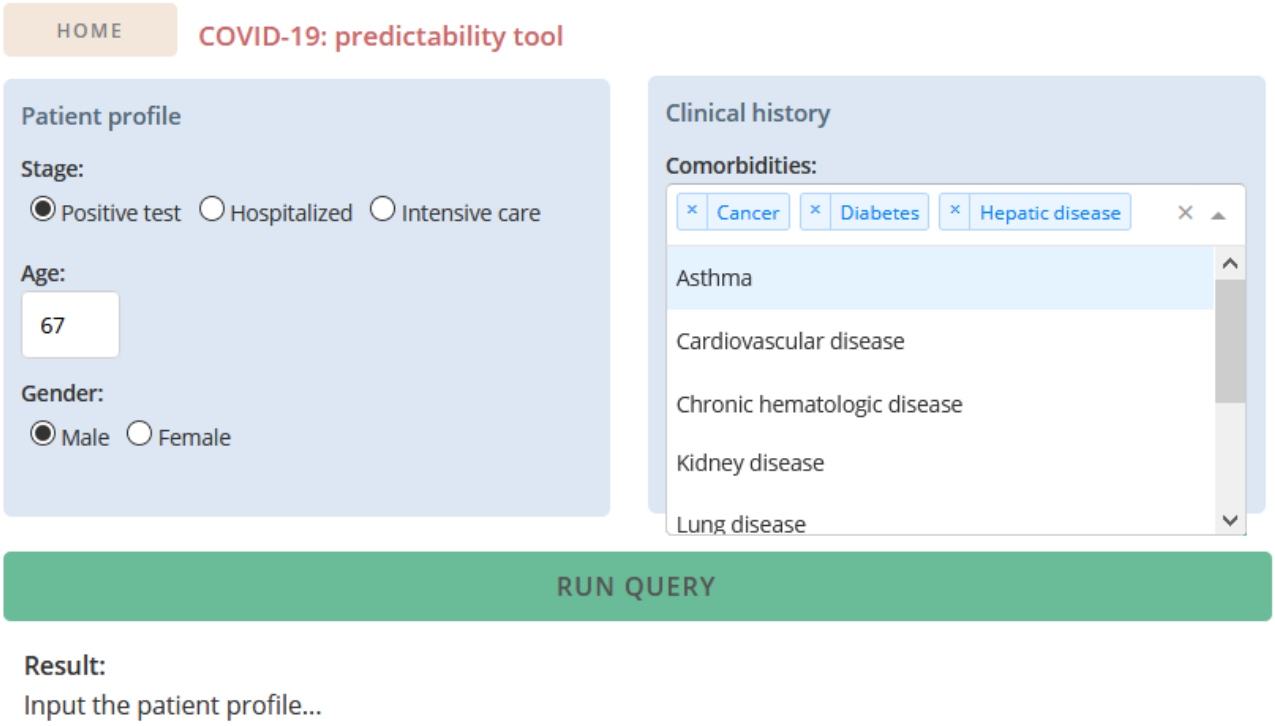


(C) *Survivability: profile of false-positive* (FP) *and false-negative* (FN) *individuals*

Clinical Decision Support System

The learned predictive models based on simple variables (stage, age, gender, and comorbidities) have been made available to health care providers within a recommendation system with graphical facilities. The serialized predictive models are used for the efficient testing of individuals at the different stages of the care cycle (testing, hospitalization, ICU admission) for the different outcome variables (care needs) after inserting essential demographic and comorbidity features. The output provides a bounded statistic based on the estimation returned by the predictive models achieving better recall and F1-measure for each outcome variable. Figure 14 provides a visualization of the graphical interface.

Figure 14. Snapshot of the provided clinical decision support system.



The variables required for each outcome score calculation are usually available at hospitals, and the tool is easy to use. Although recommendations are provided within a statistical frame, the tool does not categorize the risk into low- or high-risk patients as clinical experts are more informed to approximate this risk. In addition, we advise caution for clinicians who intend to use this tool as a predictive guide, especially for survivability analysis. Clinicians must balance the predictions from this tool against their practical experience.

In collaboration with DGS, our predictors are expected to be provided within public hospitals and care contact centers of the Portuguese Health Service (Serviço Nacional de Saúde), particularly to support remote care monitoring decisions.

The decision support system is available as a software tool on GitHub [34].

Discussion

Principal Findings

This work offers a discussion on the predictability of hospitalization needs, ICU admissions, respiratory assistance, and survivability outcome in individuals infected with SARS-CoV-2 in Portugal as of June 30, 2020. A retrospective cohort with all confirmed COVID-19 cases since March, encompassing demographic and comorbidity variables, was considered as the target population in this study.

The results for the given cohort reveal that (1) over 75% of hospitalization needs can be identified at the time of SARS-CoV-2 testing (with >50% precision); (2) ICU needs are generally less predictable at both the pre- and posthospitalization stages in the given cohort; (3) respiratory assistance needs (including ventilation support, oxygen therapy, and combined ventilation-oxygen support) achieved recall levels above 60% (with >50% precision); (4) death risk along different stages (testing time, after hospitalization, and after ICU admission) had the highest degree of predictability.

The predictive models yielding better accuracy performance were associative classifiers, particularly XGBoost and RandomForests, neural networks with hyperparameterized architectures, and logistic regressors, with the optimal choice varying in accordance with the target variable and evaluation measure.

Publications on COVID-19 using machine learning models for different outcomes have been rapidly increasing. Gao et al [35] developed a model that includes the mortality risk prediction and reported an F1 ranging from 0.65 to 0.69 (κ=0.61-0.65), in line with our findings. Alternative studies [28,36,37] offer additional results for generalizing results and identifying population-specific differences. Yet, most of these studies do not comprehensively assess models' performance or the cohort characteristics, impeding solid cross-population findings.

Limitations

This study has some inherent shortcomings that should be noted: (1) the number of clinical variables for the outcomes of interest were limited (eg, BMI and clinical symptoms were missing); (2) further external validation of the selected models is required; and (3) although some inconsistencies (listed in the *Cohort Description* section) and missing/unknown entries in the original DGS data set were excluded, data acquisition problems may still persist and influence the outcomes of this work. The fully autonomous and parameter-free nature of the proposed computational approach/models allows it to be dynamically retrained with updated data.

Concluding Remarks

In this work, we developed a web-based clinical decision support tool without biological variables as input that can be used by clinicians. The conducted work pinpoints the relevance of the proposed predictive models to aid medical decisions for the Portuguese population, including both remote monitoring and in-hospital care decisions. Predicting the most probable outcomes along the life cycle of a SARS-CoV-2–infected individual can identify patients who are expected to develop severe illness, thus optimizing the allocation of health care resources and supporting more vulnerable patients.

Abstract

Background: With the growing stress on hospitals caused by the COVID-19 pandemic, the need for home-based solutions has become a necessity to support these overwhelmed hospitals.

Objective: The goal of this study was to compare two nonpharmacological respiratory treatment methods for home-isolated COVID-19 patients using a newly developed telemanagement health care system.

Methods: In this single-blinded randomized clinical trial, 60 patients with stage 1 pneumonia caused by SARS-CoV-2 infection were treated. Group A (n=30) received oxygen therapy with bilevel positive airway pressure (BiPAP) ventilation, and Group B (n=30) received osteopathic manipulative respiratory and physical therapy techniques. Arterial blood gases of PaO_2 and $PaCO_2$, pH, vital signs (ie, temperature, respiratory rate, oxygen saturation, heart rate, and blood pressure), and chest computed tomography scans were used for follow-up and for assessment of the course and duration of recovery.

Results: Analysis of the results showed a significant difference between the two groups (P<.05), with Group A showing shorter recovery periods than Group B (mean 14.9, SD 1.7 days, and mean 23.9, SD 2.3 days, respectively). Significant differences were also observed between baseline and final readings in all of the outcome measures in both groups (P<.05). Regarding posttreatment satisfaction with our proposed telemanagement health care system, positive responses were given by most of the patients in both groups.

Conclusions: It was found that home-based oxygen therapy with BiPAP can be a more effective prophylactic treatment approach than osteopathic manipulative respiratory and physical therapy techniques, as it can impede exacerbation of early-stage COVID-19 pneumonia. Telemanagement health care systems are promising methods to help in the pandemic-related shortage of hospital

beds, as they showed reasonable effectiveness and reliability in the monitoring and management of patients with early-stage COVID-19 pneumonia.

Trial Registration: ClinicalTrials.gov NCT04368923; https://clinicaltrials.gov/ct2/show/NCT04368923

Introduction

COVID-19 has become a global pandemic that has had a gross dramatic impact on hospitals and health care systems worldwide [1-3]. Therefore, home isolation may become the only available option to stop the spread in most countries [4-6]. A worldwide shortage of medical devices, protective equipment, and pharmacological treatment with growing stress on hospital resources have led to an obvious drop in the performance of the majority of frontline health care workers [7-9]. Therefore, introducing telemanagement approaches has become a necessity for coping with the exponential increase in the number of people infected with SARS-CoV-2 [10-12].

Home care isolation can be considered for COVID-19 patients with mild illness when inpatient isolation is unavailable. However, advice and precautions regarding respiratory hygiene, environmental ventilation, hand hygiene, shared space confinement, and optimal nutritional intake should be followed as a part of the management process [13,14].

Current evidence suggests that the application of noninvasive bilevel positive airway pressure (BiPAP) can reduce pulmonary complications and raise pulmonary oxygen pressure by activation of collapsing alveoli and reduction of the degree of shunt [15]. However, noninvasive positive pressure ventilation is usually considered the last line of treatment in the initial management of hospitalized COVID-19 patients, as it is considered an aerosol-generating procedure that can increase the risk of infection in a hospital setting [16,17]. Yet, there is an apparent lack of research on its impact on COVID-19 patients, despite evidence from several previous studies that confirm its beneficial effects in different types of pneumonia.

COVID-19 disease progression and complications have been found to be unpredictable. Patients' deterioration has been commonly reported to be a result of pulmonary edema due to interstitial fluid accumulation from pulmonary capillary leakage, cytokine storms, and microvascular thrombosis. Pulmonary edema is characterized by acute onset and rapid progression [18]. Noninvasive BiPAP may prevent this deterioration if applied at an early stage by impeding the consequent pulmonary edema via positive pressure [19].

Recent studies indicate that osteopathic manipulative respiratory and physical therapy techniques can improve pulmonary function in both chronic and acute pulmonary conditions [20]. These techniques are directed toward the respiratory musculoskeletal components inducing thoracic pressure changes, which are essential for effective respiratory processes. Additionally, these techniques have enormous potential in the alleviation of pulmonary disease complications through increasing mobility of chest wall muscles and the diaphragm [21].

Osteopathic manipulative respiratory and physical therapy techniques have an important advantage of being low cost with the ability to be modified for home or self-application, which can reduce the risk of infection and overcome the shortage in pharmacological treatments and medical devices [22].

In the presence of COVID-19, telepractice has transformed physical therapy, as communication-based platforms beyond telerehabilitation, telemedicine, telemanipulation, and telehealth are utilized to advance remote access to therapy [23].

Recent evidence supported the use of self-directed web-based physical therapy over traditional outpatient physical therapy. Moreover, web-based physical therapy at home has gained interest owing to its interactive nature, which offers a more formal structure and direction for the patients [24]. Consequently, self-directed web-based physical therapy with remote supervision can be considered as an effective solution to offset the risks associated with infection among COVID-19 patients without compromising outcomes [24-26].

Noninvasive ventilation (NIV) has been utilized as an adjunct to physical therapy in patients with respiratory diseases. Several studies have demonstrated the positive effects of NIV and supplemental oxygen as adjuncts to physical therapy [27]. NIV was found to unload the ventilatory muscles and reverse the neural drive of fatigue through reducing the amount of necessary patient effort as well as reducing the muscle load during an assisted interactive breath [28]. Thus, investigation of these two treatment modalities among COVID-19 patients would be a great benefit.

Evidence has reported that real-time telemedicine in patients with acute respiratory infections showed similar rates of clinical management when compared to traditionally treated patients. Furthermore, the frequency of follow-up visits in real-time telemedicine was higher than in traditional follow-up visits [29].

Preliminary regulations have been issued regarding the control of infection, diagnosis, and monitoring of COVID-19 patients, while there is limited and unclear guidance on the effect of starting care management of these patients from an early stage [30-33]. The divergence of results in the majority of research studies on this topic and the need for high-quality randomized clinical trials that follow the recommended standards of reporting were the reasons for implementing this study.

Advances in information and communication technologies (ICTs) have turned the world into a connected village. Remarkable challenges have been addressed by ICTs in various health care sectors [34-36].

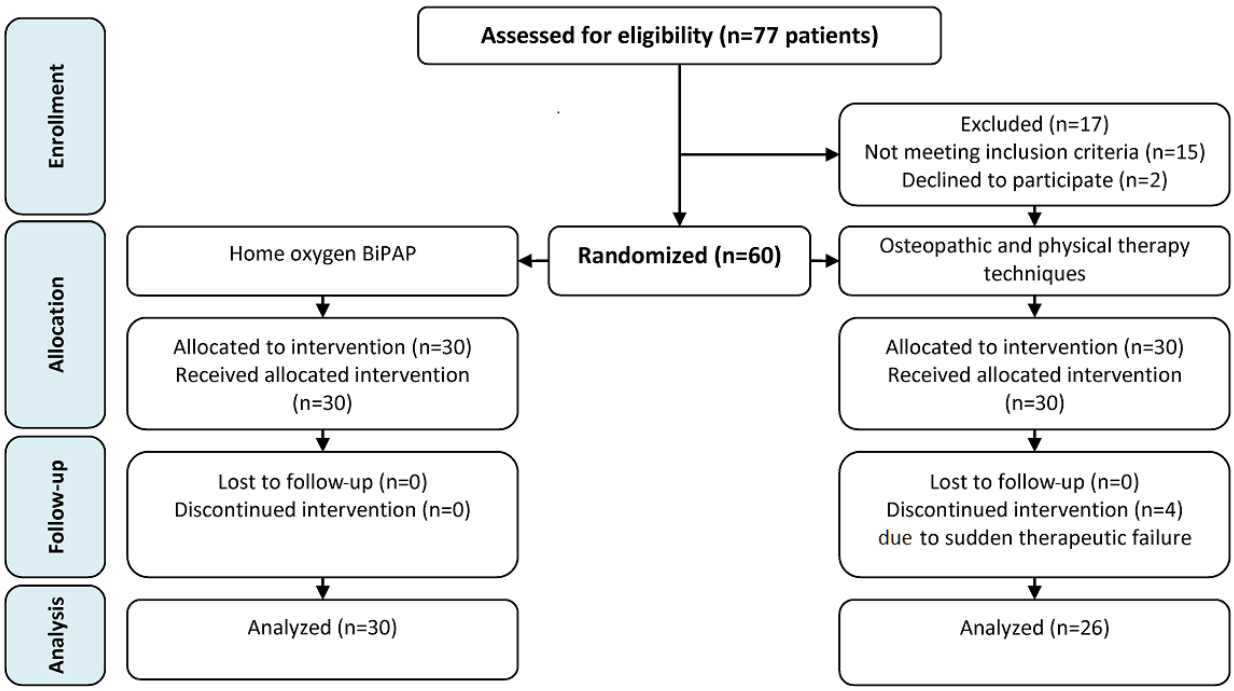
Thus, the aim of this study was to assess and compare oxygen therapy combined with noninvasive positive pressure ventilation with osteopathic manipulative respiratory and physical therapy techniques using a telemanagement health care system, which was applied to home-isolated COVID-19 patients. We also assessed patient satisfaction with the COVID-19 telemanagement system.

Methods

Overview

This single-blinded, parallel-group, randomized clinical trial was approved by the Research Ethics Committee of Cairo University and was registered at ClinicalTrials.gov (NCT04368923). The study was performed in accordance with the ethical standards of the Declaration of Helsinki and followed CONSORT guidelines for conducting randomized trials (see Figure 1).

Figure 1. CONSORT flow diagram. BiPAP: bilevel positive airway pressure.



Patient recruitment was realized through social media using the snowball subject recruitment technique. Initially, invitations were targeted to patients who met the study's eligibility criteria through the health professionals' social media networks. Then, those patients were requested to distribute invitations through their individual social media networks; no restrictions were made on what social media platform they should use. The participants were obligated to send the required data online in order to be assessed for eligibility.

A total of 60 patients were randomized into two groups in a 1:1 allocation ratio using the computer-generated randomization software StatsDirect, version 2.7.7 (StatsDirect Ltd); the allocation was done by a blinded and independent coworker to ensure that the randomization process was totally concealed. This study was conducted with a sample of home-isolated patients. Informed consent was obtained from all patients who were included in this study.

The inclusion criteria for patients were as follows:

- American Society of Anesthesiologists Class I patient before the onset of COVID-19
- History of close contact to a confirmed positive COVID-19 case as defined by the national guidelines for public health units [37]
- SARS-CoV-2 infection determined by chest computed tomography (CT) scan showing typical ground-glass abnormalities with the onset of two or more clinical symptoms and the patient condition classified as stage 1 pneumonia according to Pan et al [38]
- Patient indicated for home isolation.

Patients were excluded if they demonstrated the following characteristics:

- Not being consistent with home-isolation regimen, including nutritional supplementation, proper hygiene, and room aeration
- Inability to deal with the telemanagement system provided
- Therapeutic failure during the study, which is characterized by severe respiratory distress with respiratory rate that is more than or equal to 30 breaths per minute, oxygen saturation less than or equal to 93% in room air, and a requirement of intubation or mechanical ventilation [39].

Patients were divided equally into two groups, with 30 patients in each group. The first group received oxygen therapy with BiPAP ventilation (Group A), and the second group received osteopathic manipulative respiratory and physical therapy techniques (Group B). All patients received the same nutritional supplementation, including multivitamins and adequate supportive diets.

Regarding Group A, an oxygen concentrator with BiPAP was given using an AirFit F30 face mask (ResMed) with inspiratory positive airway pressure/expiratory positive airway pressure of 15/3 cm H_2O and 5 L/min oxygen flow by an oxygen flow meter, which was done for 4 hours per day [40]. Procedures for oxygen administration were consistent across all patients, clarified in detail, and accomplished via a teleconference for each patient that was supervised by an expert respiratory physiotherapist.

Group B received osteopathic manipulative respiratory and physical therapy techniques in the form of the following:

- Prone reverse Trendelenburg positioning for 4 hours/day [41,42]
- Cephalic traction with approximate duration of 1 minute/day [43]
- Muscle energy technique for scalene muscles 5 times/day [43]
- Rib raising technique (5 cycles for each rib group with a total of 15 cycles and approximately 5 minutes' duration) [44]
- Suboccipital area intermittent rhythmic pressure (according to each patient sensitivity) [45]
- Osteopathic lymphatic thoracic pump techniques with respiratory assist for 4 minutes [46]
- Pedal lymphatic pump for 1 minute [47]
- Thoracic inlet myofascial release for 1 minute [48]
- Diaphragmatic doming for 3 to 5 sequential respiratory cycles [49-52].

A real-time videoconference was established between the patient and the physiotherapist for training, directing, and supervising the patient during self-application. All techniques were given on a daily basis. The total duration of each therapeutic session was approximately 4 hours and 30 minutes.

In both groups, therapy ended after the assessment of all the outcome values, making sure that all of them fell within the normal range and continued to be stable for three consecutive outcomes without any clinical symptoms, which indicated recovery.

Evaluation procedures included the following:

- Recording of arterial blood gases for both oxygen (PaO_2) and carbon dioxide ($PaCO_2$) in addition to pH for each patient in both groups every 48 hours [53]
- Telemonitoring of vital signs (ie, temperature, respiratory rate, oxygen saturation, heart rate, and blood pressure) for each patient in both groups every 24 hours [54]
- Pretreatment and 14 days' posttreatment chest CT scans.

All evaluation procedures were recorded, monitored, and analyzed with an application developed by the authors, which was used for management of the patients' data and tracking of their therapeutic progress. Continuous online support with comprehensive supervision was done via videoconferencing by expert respiratory physiotherapists whenever requested by the patient.

The primary outcome measures for this study were the times to reach normal levels of both PaO_2 and $PaCO_2$ in addition to pH, which were assessed every 48 hours. Secondary outcome measures were temperature, respiratory rate, oxygen saturation, heart rate, and blood pressure, which were evaluated every 24 hours.

The participants were provided with wearable devices that have been used for telemonitoring of the required vital signs. The devices were capable of transmitting vital signs data via Bluetooth connection to the authorized gateway (ie, mobile, tablet, or any other gateway).

Collection and reporting of the primary outcome measures were done by three laboratory technicians who were blinded to the groups of study; they were then analyzed via the system. The technicians were assigned to take the samples from patients' homes for analysis. Interrater reliability was assessed using the intraclass correlation coefficient, which was 0.97; intrarater reliability was assessed using the Pearson correlation coefficient and was found to be 0.99.

Secondary outcome measures were collected and reported by the patient himself or herself, and the evaluation of these readings was done by a single clinician who was also blinded to the groups under study. All patients were instructed to be observed for another 14 days after ending therapy; chest CT scans were then performed.

Method for Telemanagement of COVID-19 Patients

A telemanagement system was developed by the authors, which followed the Health Level Seven Version 3 Standard in order to simplify its integration and facilitate receiving and/or retrieving information from other sources and applications, as well as to enable the usage of Internet of Things. This system was able to support live transmission of the vital signs data and allowed for incorporation of different medical sensors through wireless connections. The patient was able to access the system via mobile phone, tablet, or any web platform.

The major components of the platform included (1) a thorough monitoring plan, (2) the patient-specific interventions, (3) definitions of alarms and indicators, (4) the user-environment configurations of the therapist's device, and (5) the user-environment configurations of the patient's device.

Additionally, the system was able to provide an efficient, flexible, scalable integrated solution that incorporates artificial intelligence to provide support in planning, predicting, and decision making. The platform was specifically designed for managing and providing teletherapeutic services to home-isolated COVID-19 patients. It also covered the services of therapists and managing staff while coordinating the work of all the involved professionals. The system was also able to allow the patients to receive an individualized therapeutic program. It also allowed the therapists to set up a plan and

thresholds that could be personalized in accordance with each patient's profile.

In addition, it provided the option to create combined alerts via several variables. The system provided the patient with step-by-step written instructions as well as precautions about each procedure, along with a video that explained how to perform the procedures. Another advantage of this system was the auto-reminder feature to help patients with sending their data on time.

After outcome data were collected for each patient, the results were sent immediately to a server so they would be available for analysis. The system included a decision support option, which provided tailored feedback for each patient. Depending on the progress of the outcome variables, the system provided an alerting option when certain outcomes were reached or when patient performance required in-person counseling. At the end of the therapy, the system enabled each patient to answer posttreatment questions to assess patient satisfaction with the quality of this novel telemanagement service.

The decision support engine entailed workflow management routines that were used for coordinating reception of the inputs and managing their interactions, in addition to handling decision support outputs by means of tasks or actions.

The alert messages were sent to the intended devices with features that could be adjusted, such as color-coded displays, preferred choices for creating alerts, and interface personalization options. The system presented the information in meaningful medical-related ways, where it first presented the alerts followed by their related information, which was gradually presented in a more detailed manner.

With the goal of adapting the designed platform in line with the specific needs of COVID-19 patients, we conducted consecutive meetings with the patients and the therapists. The platform took into consideration the normal values of the outcome measures according to their follow-up schedule. Furthermore, we incorporated a group of educational elements for improving patients' knowledge of COVID-19, which was strengthened via interactive materials.

Analysis began after the reception of data, or was periodically scheduled, in accordance with decision support requirements. The input-module functions were dependent on the routines of feature extraction for the characterization of the data patterns.

Data sets were generated through the collection of questionnaires and clinical measurements; these measurements were assessed as being a function of time in order to detect sudden deviations, which can indicate health deterioration. The feature extraction routines for the distribution analysis and thresholding were implemented as separated modules; processed data were then retrieved and the notable clinical data patterns were fed back into a decision support engine.

For proper identification of the significant downward or upward values over the analysis window period, an identification analysis routine was used. In addition, a threshold analysis routine was used for comparing the values to the adaptive thresholds. The data in the outer ranges were defined through the confidence intervals, and any detected deviation was flagged as being an abnormal measurement. Furthermore, we designed the system to have the ability to predict the probability that a future patient would experience therapeutic failure using deep learning; however, a sufficient training data set is yet to be obtained in order for the system to provide accurate results.

Deep learning was based on feed-forward multilayer artificial neural networks that used back-propagation processes for updating the weights among the hidden layers and the output; a back-propagation of the resulting error was then applied. For the predictions, the mean square error, as well as the R^2 error, were calculated.

Statistical Analysis

The sample size was calculated with a power of 80% and level of significance of 5% (α=.05). The analysis was based on post hoc power analyses utilizing G*Power software, version 3 (Heinrich-Heine-Universität Düsseldorf) [55], accounting for 15% missing data, and based on the minimal meaningful effect size. This analysis showed that the sample size was adequate. Differences between the two groups were assessed by means and standard deviations. Comparison between the two groups was done using Student *t* test. Nominal data were summarized as frequencies and percentages. All data were statistically analyzed by an independent statistician, who was blinded to the interventions, using SPSS statistical software, version 20 (IBM Corp).

Results

A total of 60 patients (22 males [37%] and 38 females [63%]) were included in this study. Their ages ranged from 21 to 40 years with a mean age of 31.6 (SD 5.8) years. The characteristics that presented most frequently were fever (56/60, 93%) and dyspnea (55/60, 92%), as shown in Table 1.

Table 1. Demographics and baseline characteristics of patients.

Characteristic	Total (N=60)	Group A (n=30)	Group B (n=30)
Age (years), mean (SD)	31.6 (5.8)	32.2 (5.4)	30.9 (6.2)
Gender, n (%)			
Male	22 (37)	10 (33)	12 (40)
Female	38 (63)	20 (67)	18 (60)
Clinical symptom, n (%)[a]			
Fever	56 (93)	27 (90)	29 (97)
Tachypnea	51 (85)	29 (97)	22 (73)
Tachycardia	29 (48)	17 (57)	12 (40)
Hypertension	19 (32)	11 (37)	8 (27)
Dyspnea	55 (92)	27 (90)	28 (93)
Cough	43 (72)	17 (57)	26 (87)
Chest tightness	12 (20)	5 (17)	7 (23)

[a]Percentages in this category add up to greater than 100% because patients could report multiple symptoms.

A significant difference was observed between the two groups regarding the mean number of days needed for recovery (P<.05), with Group A showing a lower recovery period than Group B (mean 14.9, SD 1.7 days, and mean 23.9, SD 2.3 days, respectively), as shown in Figures 2 and 3. The unpaired t test (df=58) value was 16.55 with a mean difference of –9.056 between Group A and Group B.

Figure 2. Number of days needed for Group A and Group B to recover. Values and whiskers on bars are means and SDs, respectively. BiPAP: bilevel positive airway pressure.

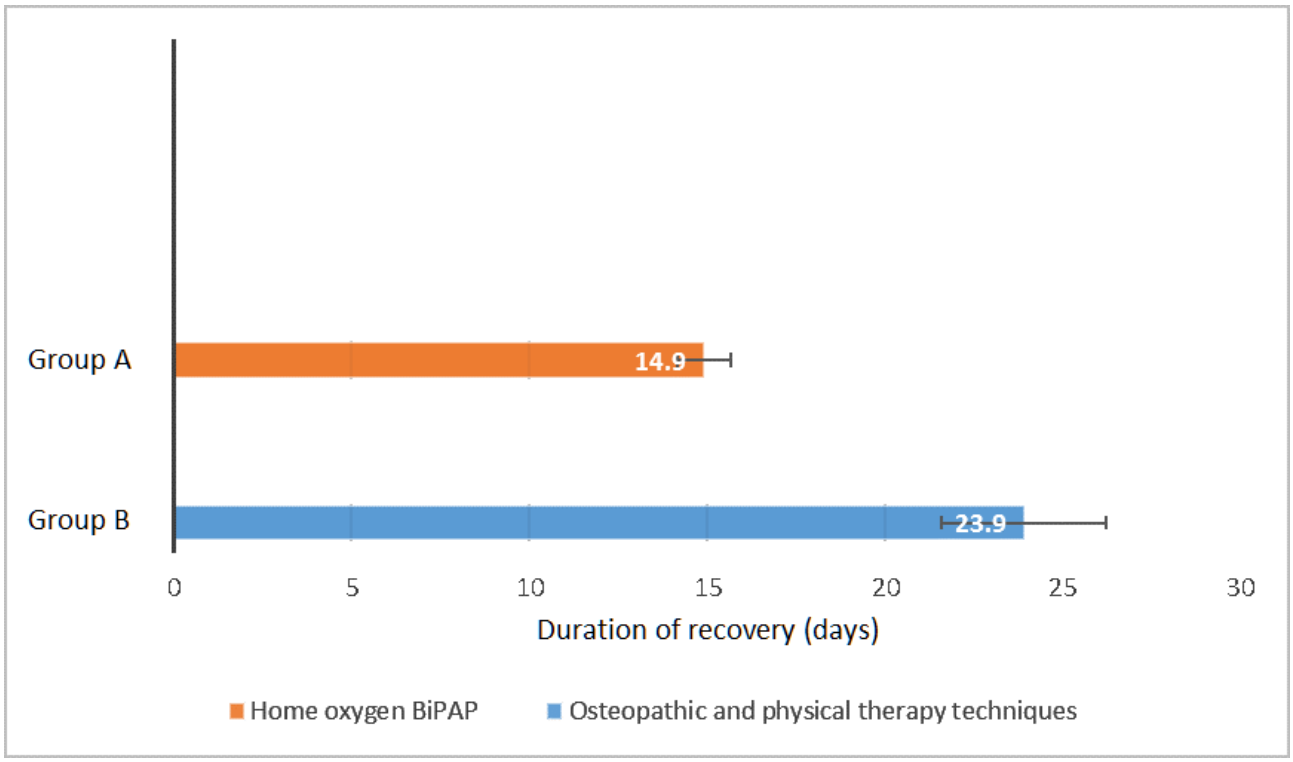


Figure 3. Patient outcome recovery rates.

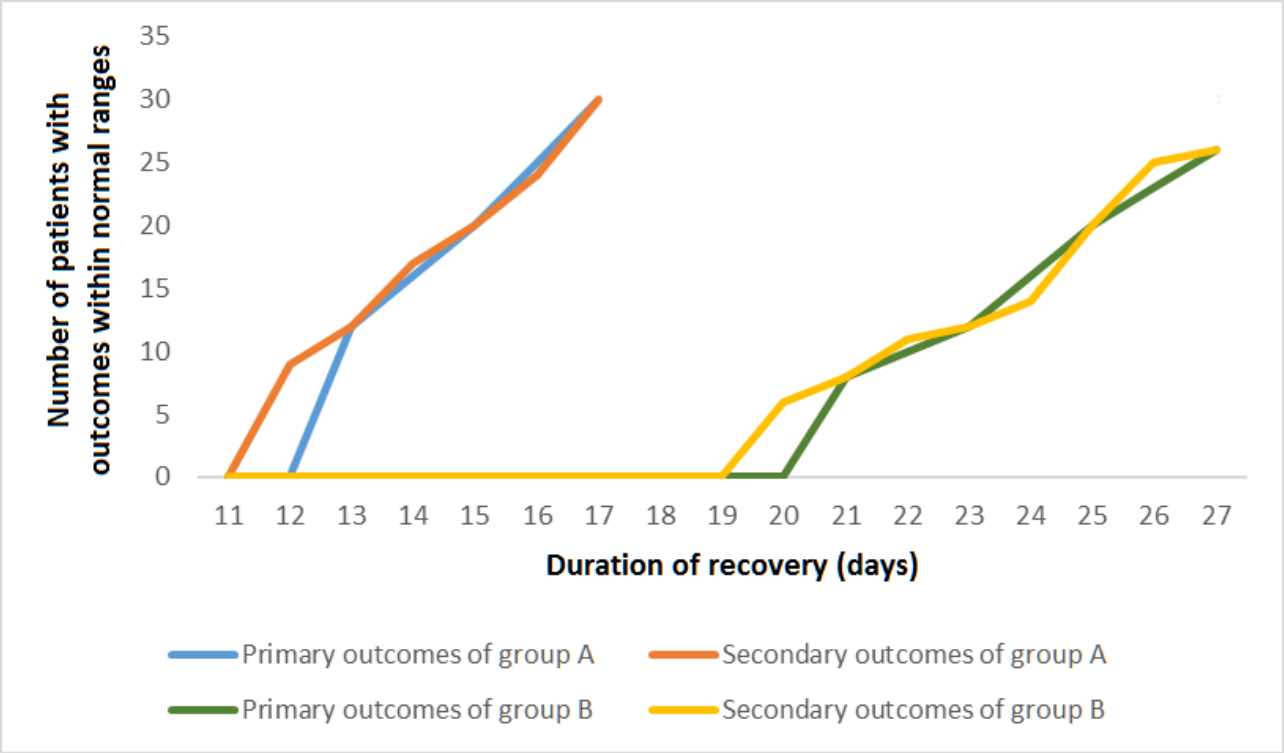

A total of 4 patients out of 30 (13%) from Group B were excluded because of sudden therapeutic failure during the course of osteopathic manipulative respiratory and physical therapy techniques, as these patients required hospitalization and/or intubation.

All patients who were included in the analysis underwent chest CT scans two times, one before starting therapy and the other 14 days after ending therapy. Early-stage COVID-19 pneumonia mainly appeared as minor subpleural, bilateral, or, less commonly, unilateral ground-glass opacities in the lower lobes.

A total of 51 of the 60 patients (85%) had bilateral lung pneumonia, while 9 of the 60 patients (15%) had unilateral lung involvement. The unilateral lung involvement cases were comprised of 6 patients who had right lung involvement and 3 patients who had left lung involvement.

A total of 2 weeks after ending therapy, the CT scans showed complete resolution in Group A patients; however, in Group B patients, the lesions were mostly absorbed compared with images from before therapy in 23 out of 30 patients (77%), while 3 patients (10%) showed no worsening compared to the previous CT scan results. The 4 patients who were excluded from the study due to therapeutic failure were instructed to be admitted to the hospital.

The data sets from the study were based on the daily reports. These reports included analysis of arterial blood gases and vital signs. The data set consisted of 1735 daily records. After filtering the data set by removing the records of the excluded patients, the final analyzed data set included 1686 records. The parameters of the submitted records for each attribute are shown in Table 2.

Table 2. Parameters of the submitted records.

Attribute	Duration	Total submitted records for Group A, n	Total submitted records for Group B, n
PaO_2	Every 48 hours	238	324
$PaCO_2$	Every 48 hours	238	324
pH	Every 48 hours	238	324
Temperature	Every 24 hours	476	648
Respiratory rate	Every 24 hours	476	648
Oxygen saturation	Every 24 hours	476	648
Heart rate	Every 24 hours	476	648
Blood pressure	Every 24 hours	476	648

Our system predictions showed an R^2 of 0.965 with a mean square error of 0.27, which means that more than 96% of the variations were predicted.

The posttreatment patient satisfaction questions focused on a group of technical aspects—simplicity, effectiveness, acceptability, usability, reliability, and level of confidence—as well as the system's ability to assess a patient's status remotely. The results of the satisfaction questions were very promising and most of the patients responded positively to the questions, as shown in Table 3.

Table 3. Posttreatment patient satisfaction questions for the telemanagement system.

Question	Response (n=56), n (%)[a]		
	Yes	No	No answer
Were the telemanagement procedures simple?	41 (73)	12 (21)	3 (5)
Were the telemanagement treatment procedures useful?	54 (96)	0 (0)	2 (4)
Were the telemanagement procedures well tolerated?	56 (100)	0 (0)	0 (0)
Were educational elements and interactive materials useful?	56 (100)	0 (0)	0 (0)
Did you regret using this telemanagement system and, instead, prefer admission to the hospital?	1 (2)	52 (93)	3 (5)
Did the auto-reminder option in this system help you in sending data on time?	55 (98)	0 (0)	1 (2)
Do you think that the time spent by therapists with you was adequate?	38 (68)	13 (23)	5 (9)
Do you think that this telemanagement system was consistent?	49 (88)	2 (4)	5 (9)
Do you think that this telemanagement system is an acceptable way to receive treatment services?	56 (100)	0 (0)	0 (0)
Overall, are you satisfied with the quality of the services provided by this telemanagement system?	55 (98)	1 (2)	0 (0)
Would you recommend this telemanagement system to anyone?	51 (91)	1 (2)	4 (7)
Any comments? (Comments added to a free-text field are shown below) • I regret not being admitted to the hospital as I think that I would not have transmitted the infection to my wife. • This telemanagement system saved efforts, costs, and time. • I think that the time spent with the therapist needs to be more frequent. • The system could be more helpful if it would send periodic information often about my status by informing me if I am getting better or worse.	4 (7)	48 (86)	4 (7)

[a]Percentages may not add up to 100% due to rounding.

The telemanagement system showed positive satisfaction responses from the patients for most categories, including simplicity (41/56, 73%), effectiveness (101/112, 90.2%), acceptability (56/56, 100%), usability (110/112, 98.2%), reliability (162/168, 96.4%), level of confidence (55/56, 98%), and ability for remote assessment (38/56, 68%).

Discussion

Principal Findings

Our study explores the feasibility of oxygen therapy with noninvasive positive pressure ventilation therapy versus osteopathic manipulative respiratory and physical therapy techniques in COVID-19 patients.

Only 56 of the 60 patients (93%) completed the treatment until recovery and achieved all of the required outcomes. The therapeutic procedures were well tolerated, and the clinical symptoms significantly improved over a relatively short time.

The telemanagement application addressed variance in the clinical outcomes and maximized the benefits from the specialists' expertise. Telemanagement and telemedicine applications have a wide range of implementations, and there has been robust evidence about their clinical benefits, cost-effectiveness, simplicity, and positive impact on critical care safety and quality [56].

The telemanagement decision support option provided many potential benefits by reducing the specialist's workload caused by regular revision of all the results; this option allowed patients' measurement patterns to indicate health status deteriorations and the identification of patients with higher priorities for revision.

Regardless of the broad usage of smart devices in health telemanagement and the collection of data, medical applications of deep learning approaches for making predictions are still considered to be challenging [57]. In this study, depending on the prevailing health conditions, deep learning was used to assist in defining the essential features, predictions, and contextual detections of patterns.

Deep learning was also used as a recognized candidate to predict the probability that a future patient would experience therapeutic failure; this was due to its ability to exploit the intramodality correlations efficiently that would allow for extraction of the hierarchical representations of the data, as well as its ability to perform feature extractions.

The results obtained from this study clearly demonstrated that noninvasive BiPAP was able to significantly improve the clinical

status of patients infected with SARS-CoV-2. Patients' PaO_2 and oxygen saturation were elevated over a relatively short time. Patients' respiratory frequency and heart rate decreased. Furthermore, 100% (30/30) of Group A patients did not require any hospitalization or intubation and did not experience any complications.

The results of this study suggest that the application of home-based oxygen BiPAP therapy could improve the respiratory status of patients with COVID-19 pneumonia. It could also significantly improve the arterial blood gas status of the patients without any negative influence on hemodynamics.

It was also found that the application of oxygen with BiPAP at an early stage could reduce the need for intubation along with its related complications. The respiratory complications of COVID-19 can be attributed to a rise in the capillary alveolar membrane permeability, which can lead to pulmonary edema. Thus, noninvasive BiPAP may have contributed to prevention of deterioration by impeding the consequent pulmonary edema via positive pressure [19].

Nevertheless, some side effects of BiPAP were noticed in this study, such as facial skin and eye irritation, mild oropharyngeal dryness, mild abdominal gaseous distention, and stomach pain. Using appropriate face masks with good compatibility, along with avoiding mouth respiration and guiding nasal respiration, have been found to be effective in decreasing these side effects.

Regarding the group treated with osteopathic manipulative respiratory and physical therapy techniques, the improvement in chest CT scans was not significantly different from baseline but seemed to be clinically relevant, while there was a significant improvement in the rest of the outcomes. The clinical symptoms had also improved over a relatively short time. The osteopathic manipulative respiratory techniques that were used with this group have been reported in several studies to have beneficial effects in treating pneumonia [58]. Our main motives for the use of these techniques were focused on immunity improvement, blood clotting prevention, as well as the absence of any noticeable side effect.

Although NIV was found to be more effective, combining the reverse Trendelenburg with prone positioning can be beneficial as well. In our study, it was reported to be tolerable and comfortable by the patients. Some studies investigated the effects of each position [41,42]; one of those studies demonstrated that prone positioning contributed to improvement of the ventilation perfusion mismatch in COVID-19 patients by inducing dorsal lung region recruitment, alveolar shunt reduction, tidal volume, and end-expiratory lung volume improvement [41]. However, we found that prone positioning can induce abdominal push on the diaphragm, especially with patients that have a protruded abdomen, which can limit diaphragmatic excursion. In another study, reverse Trendelenburg positioning by tilting the patient's head up by 25 degrees showed a decrease in abdominal push on the diaphragm; therefore, an increase in functional residual capacity and lung compliance were observed [42]. Thus, we combined the two positions to avoid any limitations in diaphragmatic movement.

While the group treated with physical therapy showed less-significant results, most of the patients in our study reported relaxation effects immediately after application of cephalic traction and muscle energy techniques for scalene muscles. Similarly, another study demonstrated that these techniques had an effective role in improving vital capacity, increasing respiratory muscle efficiency, increasing cervical flexibility, and decreasing fatigability levels [43]. This study also revealed that the more the lengths of the scalene muscles changed per unit volume, the lower the alveolar pressure became. Thus, the ventilation volume through thoracic expansion increases when the scalene muscles maintain reasonable lengths. Likewise, the rib-raising technique was reported to be relaxing to the patients, which is consistent with another study that found this technique to have an immediate reduction in the activity of the sympathetic nervous system without causing any alteration in parasympathetic activity or in the hypothalamic-pituitary-adrenal axis [44].

The patients' feelings of arousal that were reported after having intermittent pressure to the suboccipital area can be attributed to the ability of this technique to cause arterial vasomotion at rates usually associated with the cranial rhythmic impulse, as demonstrated in another study [45].

In our study, osteopathic lymphatic thoracic pump techniques with respiratory assist, myofascial release to the thoracic inlet, and the pedal lymphatic pump technique also indicated good tolerability; they were also reported in another study to be advantageous for treating pneumonia by targeting the lymphatic flow, activating autonomic-mediated intrinsic lymphatic contractility, improving respiratory function, and improving circulation. In addition, the thoracic lymphatic pump techniques and thoracic inlet release have been shown to increase chemokines and cytokines in the thoracic vessels as well as in the intestinal lymph vessels, while the pedal lymphatic pump technique improves flow into the lymphatic systems [59]. The outcomes of the lymphatic pump techniques, including improvement in serum interferon levels [46], were carefully directed toward our study sample as we have taken into consideration that COVID-19 induces hyperactivation of the immune system in the severe stages, while it usually induces impairment of the immune system in the early stages. Therefore, immune response suppression may be targeted in the severe stages, while in the early stages, which was the case in our study, reduction of the viral load by stimulating type I interferon should be targeted [60].

It was also observed that in the first group, NIV promoted a significant increase in chest wall volumes directly after application, which could be due to passive expansion. On the other hand, manual diaphragmatic releasing techniques in the second group contributed to positive outcomes of our study by improving the mobility of the chest wall immediately after the intervention, which was in accordance with several studies [49-52].

Compared to physical therapy techniques, BiPAP therapy outcomes were confirmed by this study to be much more effective and promising. Even though physical therapy

techniques do not require equipment, those techniques need to be investigated further in order to be considered promising.

Overall, regarding posttreatment satisfaction with our proposed telemanagement health care systems, positive responses were given by most of the patients, even in the group treated with physical therapy, despite longer recovery periods. This was attributed to the advantage of the second group's costs being lower than those of the first group.

Limitations

Our study had some limitations. The study included a relatively small number of patients. Thus, further large randomized controlled trials with larger sample sizes are recommended. In addition, osteopathic manipulative respiratory and physical therapy techniques may have a role in elevating recovery rates and improving outcomes of patients with COVID-19. Therefore, further randomized controlled trials with larger sample sizes would be required to determine the therapeutic extent of these techniques.

Conclusions

From this study, it was found that in the early stages of SARS-CoV-2 pneumonia, home-based oxygen BiPAP ventilation can reduce the need for endotracheal intubation. It can also be an effective prophylactic treatment approach to avoid exacerbation of this disease and the need for hospitalization. Home-based oxygen BiPAP ventilation was more effective than osteopathic manipulative respiratory and physical therapy techniques, as it was associated with shorter recovery periods. A home-based COVID-19 telemanagement system with decision support services showed satisfying outcomes and may be recommended in certain cases as an effective solution for the extreme shortage of hospital beds caused by this pandemic. Further investigations are still required to determine the effectiveness of the osteopathic manipulative respiratory and physical therapy techniques in the management of COVID-19 patients in the early stages.

Abstract

Background: The COVID-19 pandemic has caused an abrupt reduction in the use of in-person health care, accompanied by a corresponding surge in the use of telehealth services. However, the extent and nature of changes in health care utilization during the pandemic may differ by care setting. Knowledge of the impact of the pandemic on health care utilization is important to health care organizations and policy makers.

Objective: The aims of this study are (1) to evaluate changes in in-person health care utilization and telehealth visits during the COVID-19 pandemic and (2) to assess the difference in changes in health care utilization between the pandemic year 2020 and the prepandemic year 2019.

Methods: We retrospectively assembled a cohort consisting of members of a large integrated health care organization, who were enrolled between January 6 and November 2, 2019 (prepandemic year), and between January 5 and October 31, 2020 (pandemic year). The rates of visits were calculated weekly for four settings: inpatient, emergency department (ED), outpatient, and telehealth. Using Poisson models, we assessed the impact of the pandemic on health care utilization during the early days of the pandemic and conducted difference-in-deference (DID) analyses to measure the changes in health care utilization, adjusting for the trend of health care utilization in the prepandemic year.

Results: In the early days of the pandemic, we observed significant reductions in inpatient, ED, and outpatient utilization (by 30.2%, 37.0%, and 80.9%, respectively). By contrast, there was a 4-fold increase in telehealth visits between weeks 8 (February 23) and 12 (March 22) in 2020. DID analyses revealed that after adjusting for prepandemic secular trends, the reductions in inpatient, ED, and outpatient visit rates in the early days of the pandemic were 1.6, 8.9, and 367.2 visits per 100 person-years (P<.001), respectively, while the increase in telehealth visits was 272.9 visits per 100 person-years (P<.001). Further analyses suggested that the increase in telehealth visits offset the reduction in outpatient visits by week 26 (June 28, 2020).

Conclusions: In-person health care utilization decreased drastically during the early period of the pandemic, but there was a corresponding increase in telehealth visits during the same period. By end-June 2020, the combined outpatient and telehealth visits had recovered to prepandemic levels.

Introduction

The COVID-19 pandemic has caused an abrupt reduction in the use of in-person health care, which has been accompanied by a corresponding surge in the use of telehealth services [1,2]. Health care visits such as inpatient visits, emergency department (ED) visits, and outpatient visits have significantly decreased since the start of the pandemic [3-6]. Two major factors have contributed to these changes. First, patients have chosen not to seek in-person health care owing to the fear of exposure to SARS-CoV-2 [3,7-9]. Second, in the early days of the pandemic, the Centers for Disease Control and Prevention (CDC) and Centers for Medicare and Medicaid Services (CMS) recommended delaying elective care to reduce the risk of SARS-CoV-2 transmission in health care facilities and to reduce the burden on health care systems [10]. Specifically, on March 4, 2020, the governor of California declared a state of emergency after the first official COVID-19 death in the state. On March 19, 2020, a stay-at-home order was enacted in California to slow the spread of SARS-CoV-2.

The CDC also encouraged the use of telehealth services to deliver care [11]. Telehealth is a health care provider's technology of choice to communicate information regarding the delivery of clinical and nonclinical care services. In addition to providing care for some medical conditions, telehealth has helped protect both providers and patients from the risk of exposure to SARS-CoV-2. It has also helped preserve critical personal protective equipment that was in short supply in the early days of the pandemic.

In response to this, Kaiser Permanente Southern California (KPSC) reported a drastic decline in in-person health care visits, coupled with an immediate increase in telehealth visits. The objectives of this study are to (1) evaluate changes in in-person health care utilization and telehealth visits at one of the largest integrated health care systems in the United States during the COVID-19 pandemic year 2020 and (2) assess the difference in changes in health care utilization between the pandemic year 2020 and the prepandemic year 2019.

Methods

Study Population and Study Period

We retrospectively assembled a cohort consisting of members from a large integrated health care system, KPSC. The KPSC serves 4.7 million members at 15 medical centers with at least 50% of its members belonging to racial or ethnic minorities, and 55% living in neighborhoods with a median annual household income of ≤US $75,000 [12]. The study period included the first 43 weeks in the pandemic year (January 5 to October 31, 2020) and the first 43 weeks in the prepandemic year 2019 (January 6 to November 2, 2019). In all analyses, health care utilization was considered for all members of the KPSC enrolled in this study during a given week. Because of data lags in inpatient and ED visits revealed from claims, we only included inpatient and ED visits in the first 35 weeks in the following analyses.

Data Source and Identification of Visits

We used electronic health record (EHR) data and claims data to identify visits in four settings: inpatient, ED, outpatient, and telehealth. Most of the encounters (approximately 90%) were from EHR data. While EHR data clearly indicated the encounter setting, for claims data, we used place-of-service and hospital revenue codes to determine the encounter setting. Multiple claims were consolidated to resemble a similar visit in the EHR. For example, a consolidated inpatient visit from claims data could include both institutional and professional claims. When a patient was admitted to the ED and then transferred to the hospital, both the ED visit and the hospital visit were considered. For encounters in the outpatient setting, we required a direct interaction between the provider and the patient and a documented diagnosis or procedure code. Encounters for a laboratory test or a procedure only were not included.

For telehealth encounters, telephone appointment visits and video visits were conducted synchronously using real-time telephone or live video-audio interaction, and they were billable and had a diagnosis or procedure code. Thus, telephone appointment visits and video visits were considered telehealth visits in this study. On the other hand, e-visits and message-only encounters were for patient self-triage and for communications without a real-time provider evaluation component. They were not considered telehealth visits in this study. Claims with a telehealth place-of-service code or with the 95 modifier, indicating that the services were delivered through telehealth, were considered telehealth visits in accordance with the CMS billing rules [13].

Rates of Health Care Utilization During the Pandemic and Prepandemic Years

The rates of visits from these 4 care settings were calculated weekly (Sunday to Saturday) for the prepandemic year and the pandemic year. The numerator was the visit counts of each type, and the denominator was 100 person-years of membership during a given week.

Statistical Analyses

We first plotted monthly KPSC member enrollment in 2019 and 2020. We examined the demographic characteristics of the cohort, including age, gender, race and ethnicity, and mean Charlson comorbidity index (CCI) of KPSC members in June 2019 and June 2020. CCI scores were calculated only for individuals aged ≥18 years. The visit rates by week during the prepandemic and pandemic years were plotted separately for inpatient, ED, outpatient, and telehealth visits.

In addition to plotting the trends, we used Poisson models to assess the significance of changes in health care utilization after versus before the onset of the pandemic in 2020 relative to

changes across the same time periods in 2019, using a difference-in-difference (DID) analysis. To achieve this goal, we selected week 8 (February 23, 2020) as the timepoint before the pandemic because the governor of California declared a state of emergency on March 4, 2020. We also chose week 12 (March 22, 2020) as the timepoint after the start of the pandemic because a stay-at-home order was enacted in California on March 19, 2020. We then selected the 2 corresponding time points during the prepandemic year. In Poisson models, the number of visits was the dependent variable, and an indicator variable for the 2 time points (ie, t=0 for week 8 and t=1 for week 12), an indicator variable for the year (2019 and 2020), and an interaction between the 2 variables were the independent variables. The interaction term was included in the DID analysis to directly assess the significance of the difference in the changes in the visit rates across the 2 years. In these Poisson models, we also included the natural log of person-years as an offset and adjusted for overdispersion of the count data. Because weekly visit data of the entire population were analyzed, individual-level covariates were not included in the analyses.

Results

Results Overview

Although the member enrollment number in the KPSC slightly decreased from July to October 2020 (4.57 million to 4.55 million), it remained steady during the pandemic year with a range of 4.55-4.57 million, slightly higher than 4.47-4.48 million in 2019 (Figure 1).

Similarly, the characteristics of KPSC members, such as age, gender, race and ethnicity, and mean CCI did not differ between June 2019 and June 2020 (Table 1). The impact of the pandemic on health care utilization in the KPSC was observed after week 8 (February 23) in 2020 (Figures 2-6).

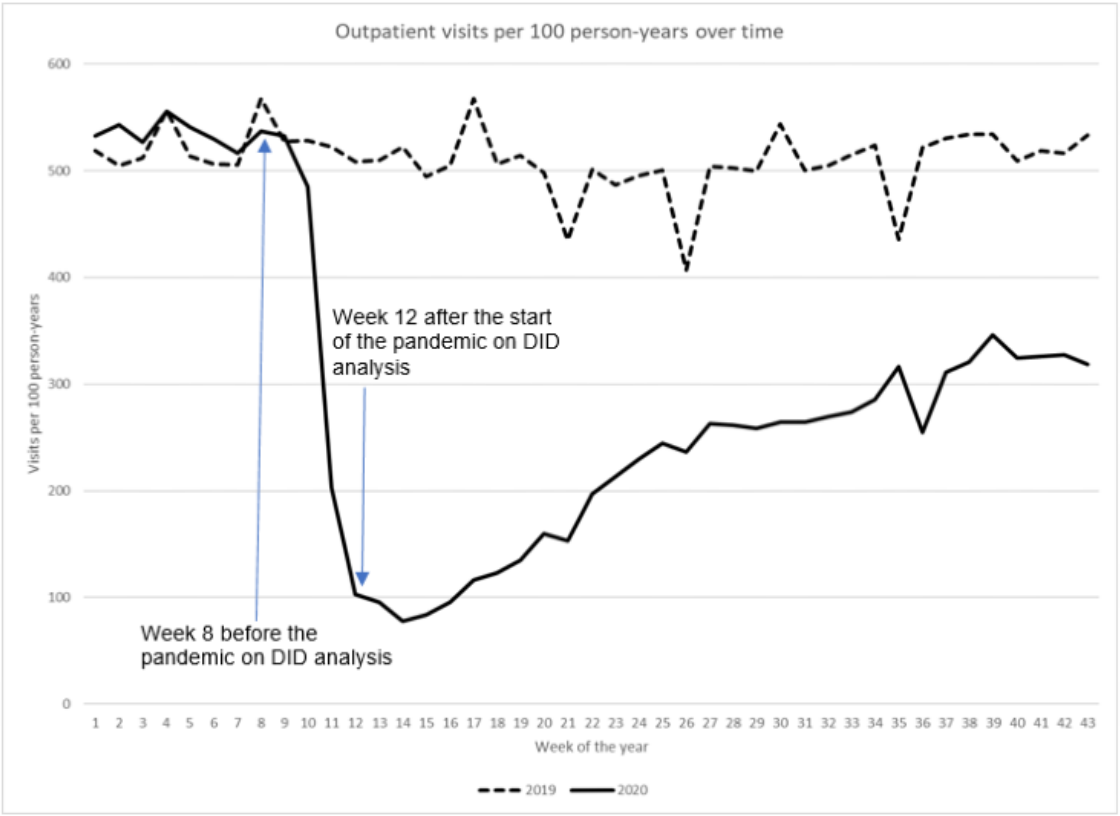

Figure 5. Telehealth visit rate over time. DID: difference in difference.

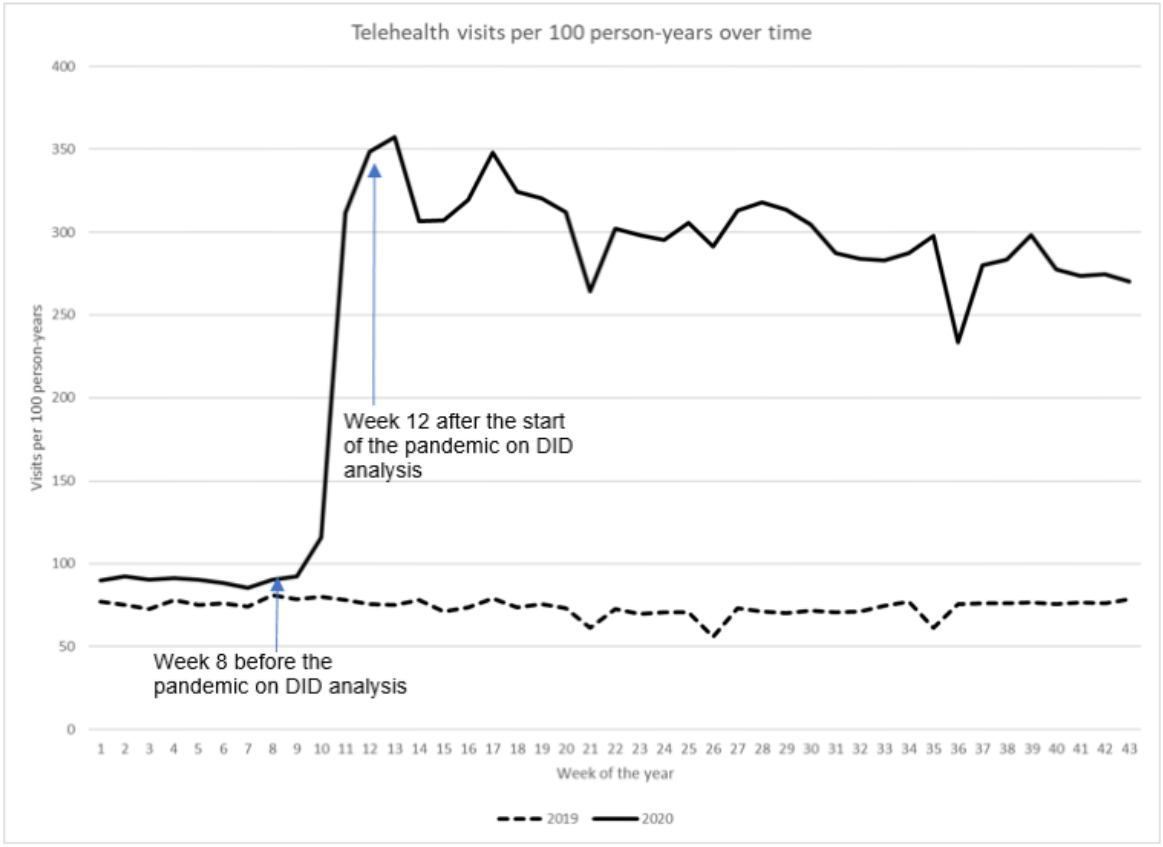

Figure 6. Combined outpatient and telehealth visit rate over time. DID: difference in difference.

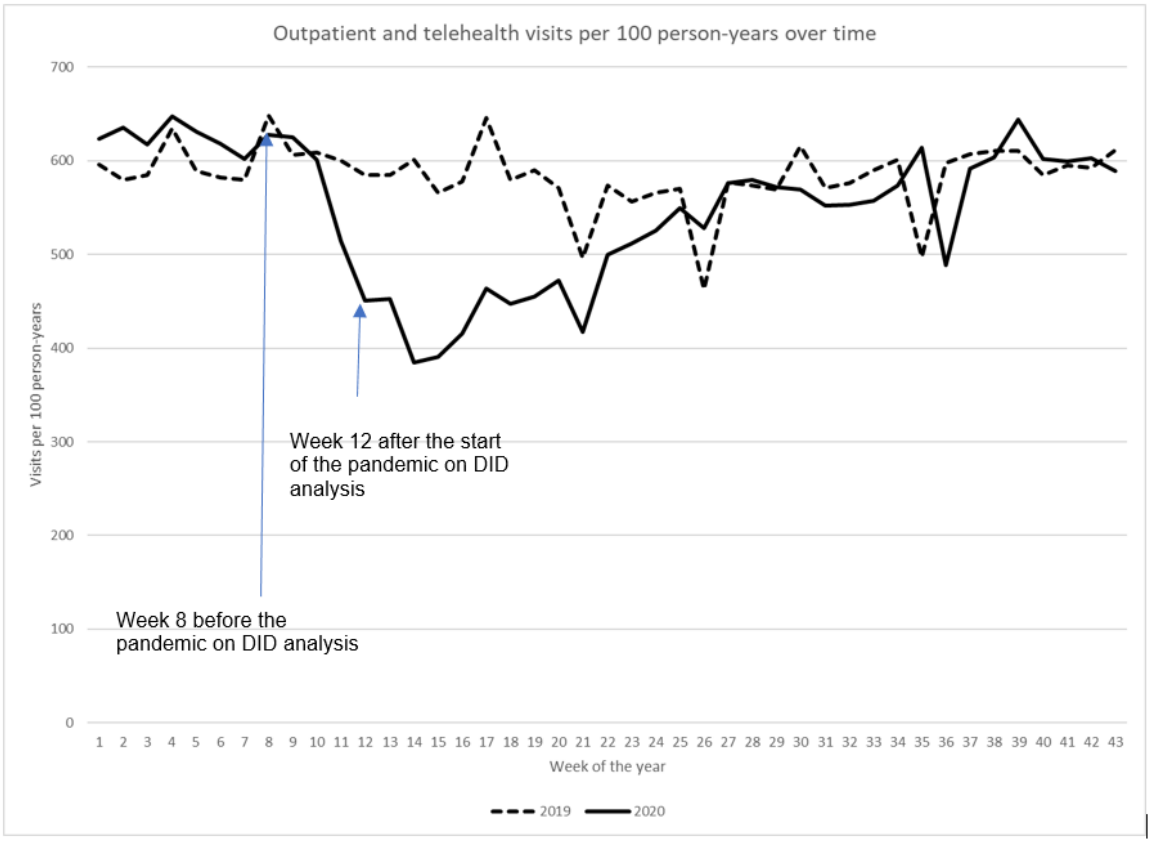

Inpatient Visits

The inpatient visits per 100 person-years significantly decreased from 6.3 in week 8 (February 23) to 4.4 in week 12 (March 22) during the pandemic year (P<.001), thus displaying a 30.2% reduction, while the inpatient visit rate only slightly decreased from 6.7 to 6.4 between the same weeks in 2019 (Figure 2). DID analysis revealed that after adjusting for prepandemic secular trends, the reduction in inpatient visit rates from weeks 8-12 during the pandemic was 1.6 visits per 100 person-years (P<.001). After week 12 in the pandemic year, the inpatient visit rate increased until week 30 (July 26) but did not approach prepandemic levels (week 8 in 2020); the inpatient visit rate decreased again after week 30. In contrast, during the prepandemic year, the inpatient visit rate remained at approximately 6 per 100 person-years after week 12.

ED Visits

ED visits per 100 person-years significantly decreased from 26.2 in week 8 (February 23) to 16.5 in week 12 (March 22) during the pandemic year (P<.001), thus displaying a 37.0% reduction, while the ED visit rate slightly decreased from 27.3 in week 8 to 26.6 in week 12 during the prepandemic year (Figure 3). DID analysis revealed that after adjusting for prepandemic secular trends, the reduction in ED visit rates from week 8 to week 12 during the pandemic year was 8.9 visits per 100 person-years (P<.001). After week 12 during the pandemic year, the ED visit rate plummeted in week 14 (12.8) and increased to 21.6 in week 27 (July 5), but did not approach prepandemic levels. ED visit rates remained largely unchanged afterwards. In contrast, the average ED visit rate throughout the prepandemic year was 25.5 (range 24.0-27.3) per 100 person-years. The ED visit rates during February 24 to April 6, 2019, were slightly higher than those in the rest of 2019.

Outpatient Visits

The outpatient visits per 100 person-years drastically decreased from 537.3 in week 8 (February 23) to 102.8 in week 12 (March 22) during the pandemic year (P<.001), thus displaying a 80.9% reduction, while the outpatient visit rate slightly decreased from 567.2 to 508.9 for the same period during the prepandemic year (Figure 4). DID analysis revealed that after adjusting for prepandemic secular trends, the reduction in outpatient visit rates from week 8 to week 12 during the pandemic was 367.2 visits per 100 person-years (P<.001). After week 12 during the pandemic year, the outpatient visit rate decreased to 77.8 in week 14 and increased to 346.0 in week 39 (September 27), amounting to only 64.4% of the outpatient visit rate in week 8. In contrast, outpatient visit rates fluctuated during the prepandemic year with an average of 502.3 (SD 45.9) per 100 person-years and did not decrease abruptly as it did in 2020.

Telehealth Visits

In contrast with in-person visits, telehealth visits increased drastically after the onset of the pandemic (Figure 5). While the trend of the telehealth visit rate remained relatively steady during 2019, we observed an approximately 4-fold increase in the telehealth visit rate during the early days of the pandemic year: 90.4 visits per 100 person-years in week 8 (February 23) to 348.3 in week 12 (March 22). Although these rates decreased after week 13, the weekly rate at the end of the study period (October 25) was still almost 3-fold that in week 8. DID analysis revealed that after adjusting for prepandemic secular trends, the increase in telehealth visit rates from week 8 to week 12 was 272.9 visits per 100 person-years (P<.001) during the pandemic year.

Outpatient and Telehealth Visits

To determine whether the increase in telehealth visits offsets the reduction in outpatient visits, we calculated the rate of combined telehealth and outpatient visits (Figure 6). Although not as drastic as the rate of outpatient visits alone, the rate of combined telehealth and outpatient visits decreased from 627.7 visits per 100 person-years to 451.1, thus displaying a 28.1% reduction from week 8 (February 23) to week 12 (March 22) during the pandemic year. After week 12, the rate of combined telehealth and outpatient visits increased, having approached that in week 26 (June 28) in the prepandemic year.

Discussion

Principal Findings

In this study, we observed significant reductions in in-person medical visits as the pandemic progressed. The greatest reduction was observed in outpatient visits in the early days of the pandemic (80.9%). Although of lesser magnitude, inpatient and ED visits also decreased by 30.2% and 37.0%, respectively, during the early days of the pandemic. By contrast, we observed an approximately 4-fold increase in telehealth visits in weeks 8-12 in the pandemic year. Further analyses suggest that the increase in telehealth visits did not offset the reduction in outpatient visits during the early days of the pandemic; however, it did compensate for the reduction in outpatient visits by week 26 (June 28). In addition to the CDC recommendation for the use of telehealth services [11], federal and state governments have issued changes in reimbursement policies for these services [14,15]. Even though the pandemic continues to progress with periodic surges in COVID-19 cases and hospitalizations, these policy changes have helped providers deliver health care in telehealth settings.

Our study sheds light on the impact of the pandemic on health care utilization. With approximately 10 months' data during 2020, this study provides insights into patterns of health care utilization during the pandemic. By using visit rates as our outcomes, we could account for the changes in the underlying population denominator during the pandemic. We observed that KPSC membership generally remained stable during the pandemic, largely owing to the KPSC's decision to not cancel health coverage for groups or individuals who could not pay for most of the study period. By comparing health care utilization during the pandemic year to that in the prepandemic year through DID analyses, we show that these findings did not result from simply an exacerbation of seasonal effects. Robinson et al [16] recently described the transition to virtual care at the KPSC, but in contrast to our study, they used counts of visits instead of rates as outcomes; hence, they did not adjust for population size. In addition, they included all types of virtual care (including those intended for communication), did not use data from the prepandemic year, and did not conduct a DID

analyses. Furthermore, our study included data for 3 additional months.

Limitations

Some potential limitations in this study must be recognized. First, in addition to the COVID-19 pandemic, other factors such as civil unrest due to racial injustice and the wildfires on the West Coast may have influenced how patients sought health care. We could not differentiate the impact of these factors on health care utilization. Second, these results were derived from a large integrated health care organization that might have been able to change practices quickly, thus potentially not reflecting patterns in other health care systems. Third, while we studied the impact of the pandemic on health care utilization, we did not address the quality of care and population health.

Conclusions

In conclusion, in-person health care utilization decreased drastically during the early period of the pandemic, but there was a corresponding increase in telehealth visits during the same period. By the end of June 2020, the rate of combined outpatient and telehealth visits reverted to prepandemic levels.

Acknowledgments

The study was supported by internal funds of the KPSC.

Abstract

Background: A detailed understanding of the public's knowledge and perceptions of COVID-19 could inform governments' public health actions in response to the pandemic.

Objective: The aim of this study was to determine the knowledge and perceptions of COVID-19 among adults in China and its variation among provinces and by sociodemographic characteristics.

Methods: Between May 8 and June 8, 2020, we conducted a cross-sectional online survey among adults in China who were registered with the private survey company KuRunData. We set a target sample size of 10,000 adults, aiming to sample 300-360 adults from each province in China. Participants were asked 25 questions that tested their knowledge about COVID-19, including measures to prevent infection, common symptoms, and recommended care-seeking behavior. We disaggregated responses by age; sex; education; province; household income; rural–urban residency; and whether or not a participant had a family member, friend, or acquaintance who they know to have been infected with SARS-CoV-2. All analyses used survey sampling weights.

Results: There were 5079 men and 4921 women who completed the questionnaire and were included in the analysis. Out of 25 knowledge questions, participants answered a mean and median of 21.4 (95% CI 21.3-21.4) and 22 (IQR 20-23) questions correctly, respectively. A total of 83.4% (95% CI 82.7%-84.1%) of participants answered four-fifths or more of the questions correctly. For at least one of four ineffective prevention measures (using a hand dryer, regular nasal irrigation, gargling mouthwash, and taking antibiotics), 68.9% (95% CI 68.0%-69.8%) of participants answered that it was an effective method to prevent a SARS-CoV-2 infection. Although knowledge overall was similar across provinces, the percent of participants who answered the question on recommended care-seeking behavior correctly varied from 47.0% (95% CI 41.4%-52.7%) in Tibet to 87.5% (95% CI 84.1%-91.0%) in Beijing. Within provinces, participants who were male, were middle-aged, were residing in urban areas, and had higher household income tended to answer a higher proportion of the knowledge questions correctly.

Conclusions: This online study of individuals across China suggests that the majority of the population has good knowledge of COVID-19. However, a substantial proportion still holds misconceptions or incorrect beliefs about prevention methods and recommended health care–seeking behaviors, especially in rural areas and some less wealthy provinces in Western China. This study can inform the development of tailored public health policies and promotion campaigns by identifying knowledge areas for which misconceptions are comparatively common and provinces that have relatively low knowledge.

KEYWORDS

COVID-19; knowledge; perception; risk; public health; China; cross-sectional; survey

Introduction

COVID-19 has taken a large toll on public health and economic growth worldwide [1-4]. Assessing the perception and knowledge among the public during infectious disease outbreaks is essential to inform public health campaigns. Research has shown that governmental policies can have a substantial impact on community transmission of SARS-CoV-2 [5-8]. It is likely that the more detailed an understanding governments have of their population's knowledge and perceptions of COVID-19, the more effectively they can design policies to contain COVID-19 in their population, whether this is on the national, regional, or local level.

A cross-sectional survey conducted in late February 2020 that assessed the public's perceptions of COVID-19 in the United States and the United Kingdom found that a considerable proportion of adults had misconceptions about infection prevention methods and care-seeking behaviors [9]. For example, over a third of survey participants selected at least one of the following options when asked whether they are effective prevention measures: using a hand dryer, rinsing your nose with saline, taking antibiotics, or gargling with mouthwash. Reasons for these false beliefs are unclear but could be different for populations in East Asian countries like China or Singapore, which were affected by the severe acute respiratory syndrome outbreak in 2002-2004.

Assessing the population's perceptions and knowledge of COVID-19 is not only essential to understanding and comparing different behaviors and policy decisions retrospectively but also vital for informing postlockdown policies since it will be crucial that people follow infection prevention methods as they start to interact more [10,11]. As of November 2020, China appears to have been successful in containing the spread of COVID-19 and has reported low case numbers [12]. However, further waves of COVID-19 may emerge in parts of China over the coming months. Therefore, collecting data about the knowledge and perception of COVID-19 across China is imperative.

Several studies have assessed the perception of COVID-19 within China. However, they have either focused on specific subgroups, such as pregnant women [13] or patients with mental health disorders [14], or assessed risk perception within particular contexts such as tourism [15]. To our knowledge, our study is the first large-scale survey that assessed COVID-19 perception and knowledge among the public in all provinces of China. This study aims to inform Chinese policy makers on the knowledge and perceptions of their population with regard to COVID-19 to facilitate effective policy design during future waves of the pandemic.

Methods

Sampling Process

The survey was implemented by KuRunData, an online private survey company that maintains a database of potential survey participants and delivers surveys. KuRunData recruits members through its own platform [16], partnerships with other websites, and encouraging registered members to recruit new members through the popular mobile app Wechat Mini. KuRunData verifies that members have access to mobile phones and the internet, and are capable of navigating online surveys. For this study, we used KuRunData to sample 300-360 participants in each of China's 31 provincial-level administrative units, with the total sample size goal being 10,000 adults. Potential participants were unable to access the questionnaire as soon as this sample size goal was reached. Within each province, KuRunData aimed to sample a proportion of participants that was reflective of the demographic composition of the province's population (as per the 2019 China Statistical Yearbook [17]) by sex and urban-rural residence. Adults in the survey pool were invited to participate in the survey by KuRunData's own platform. They were informed that they would receive ¥5 (US $0.77) for completing the questionnaire. Before filling in the questionnaire, participants had to provide their informed written consent with signature confirmation. The informed consent page described the project's background and purpose, the possible risks, the payment after completing the questionnaire, and the

confidentiality of information and records. To be able to access the questionnaire, the participants must have read the informed consent description for at least 15 seconds and self-declared understanding of the purpose and risks of the study before signing. The survey was administered between May 8 and June 8, 2020.

Questionnaire

The questionnaire was built in the KuRunData platform and had 25 questions partitioned into the following sections: introduction, perceived risk of death from COVID-19, mode of transmission of COVID-19, recognizing and acting upon an infection, sociodemographic characteristics, and specific questions about possible misconceptions or falsehoods on COVID-19 prevention and symptoms that were drawn from the World Health Organization's "myth busters" website [18]. The questionnaire was written in Standard Chinese and is shown in Text A1 in Multimedia Appendix 1. Participants had to answer a question to reach the next question. Numerical entry questions did not allow for nonsensical inputs (eg, percentage questions were restricted to inputs between 0 and 100).

Data Quality Checks

Three types of data quality checks were performed. First, we verified the time taken to complete the questionnaire and excluded participants who took less than 2 minutes to complete the questionnaire under the assumption that these participants did not read the questions. Second, we plotted the distribution of the time taken to complete the questionnaire. If some respondents used random clicking to complete the questionnaire as fast as possible, then a bimodal distribution in the time taken to complete the survey might be expected (with one study population clicking as quickly as possible and one reading the questions). Third, participants were asked whether they looked up any answers online and, if so, for which questions. Those who self-reported having looked up the answer online for a particular question were excluded from the analysis for that question in the supplementary analyses shown in Multimedia Appendix 1.

Data Analysis

We excluded participants who answered less than half of the questions in the questionnaire. All analyses used sampling weights to account for the complex survey design. The sampling weights were the inverse of the probability of selecting participants given the following variables: gender, rural versus urban residence, and province. These probabilities were calculated using population counts from the 2019 China Statistical Yearbook within each province. For binary and categorical response options, we computed the percentage of participants who selected each response to summarize the survey findings. For binomial proportions, we constructed two-sided 95% CIs using the Wilson score interval. In addition, we computed a total score for participants, which consists of the number of COVID-19 knowledge questions that were answered correctly. We henceforth refer to this score as the *overall knowledge score*. To examine how knowledge and perceptions varied by participants' characteristics, we used ordinary least squares regression to regress this overall score and the response to each question onto age (10-year age group); sex; educational attainment; province; rural versus urban residence; vocation; household income; and whether or not a participant had a family member, friend, or acquaintance who they knew to have been infected with SARS-CoV-2. All regressions included only one of these variables plus a binary indicator for each province (province-level fixed effects). We show regression results that we additionally adjusted for 10-year age group and sex in Multimedia Appendix 1.

Ethics

This research was considered to not involve human participants by the institutional review board of the Heidelberg University Hospital because all authors only had access to deidentified data.

Results

Sample Characteristics

A total of 14,493 adults agreed to take the online survey. After excluding participants who did not complete the whole survey or who took less than 2 minutes to complete the questionnaire, 10,000 participants (all of whom completed all survey questions) were included in the analysis. There was no evidence of a bimodal distribution in the time taken to complete the questionnaire (Multimedia Appendix 1 Figure A1). A total of 3643 participants reported looking up the answer online on a median of 2 questions (IQR 1-3).

There were 5079 males and 4921 females from 31 provinces that completed the questionnaire. Their sociodemographic characteristics are shown in Table 1. Around one-tenth of the 10,000 participants (n=900, 9.0%) were aged 18 or 19 years, 16.5% (n=1645) were aged 20-29 years, 19.0% (n=1895) were aged 30-39 years, and 16.8% (n=1675) were 60 years or older. A total 37.3% (n=3733) of the participants had received high school or technical secondary school education, and one-third (n=3369, 33.7%) had completed an undergraduate degree. Only 4.4% (n=438) and 4.8% (n=475) of participants had never been to school or had been to elementary school only, respectively. The majority of participants (n=5935, 59.3%) lived in urban areas. The number of participants per province ranged from 300 to 360. About half (n=5007, 47.0%) of participants reported to have an annual total household income between ¥60,000 (US $9180) and ¥119,999 (US $18,360).

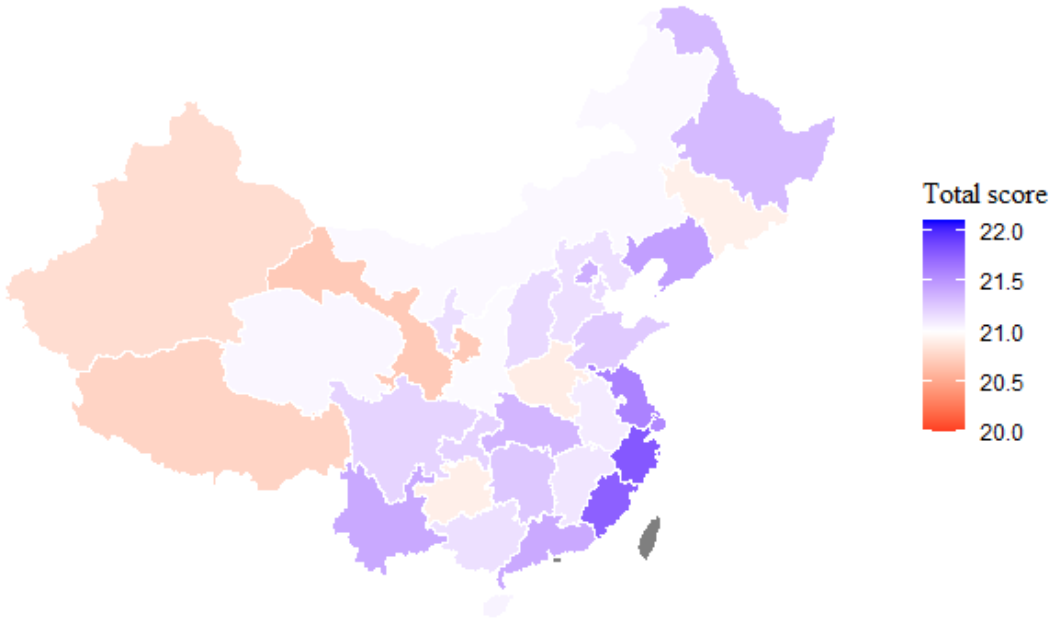
[c]Data not available.

Overall Knowledge Score

A total 83.4% (95% CI 82.7%-84.1%) of participants answered 80% or more (ie, 20 or more out of 25 questions) of the questions correctly, and almost all (98.4%, 95% CI 98.1%-98.6%) participants answered more than 60% of the questions correctly (Figure 1). The mean and median overall knowledge score was 21.4 (95% CI 21.3-21.4) and 22 (IQR 20-23), respectively. The distribution of the overall knowledge score is shown in Figure A2 in Multimedia Appendix 1.

Participants residing in the eastern provinces tended to have marginally higher overall knowledge scores. For instance, the mean knowledge score in the eastern province of Fujian was 21.9 (95% CI 21.6-22.1), whereas it was 20.9 (95% CI 20.6-21.2) in the western province of Gansu.

Figure 1. Map showing the mean overall knowledge score by province.



Perceived Risk of Death From a SARS-CoV-2 Infection

Survey participants' median estimate of the infection-fatality rate of COVID-19 was 3.2% (IQR 1.0%-3.6%; Table 2). When asked to estimate the percentage of patients infected with the common flu who die from the flu, participants' median response was 0.75% (IQR 0.10%-1.00%). Almost all (96.4%, 95% CI 96.0%-96.8%) participants identified that older adults were the age group most likely to die from COVID-19.

Table 2. Summary of survey findings.

Survey question and response[a]	Proportion or median estimate[b]
Perceived risk of death from a SARS-CoV-2 infection	
"What percent of individuals infected with the new coronavirus experience a fatal disease course?" (%), median (IQR)	
Continuous variable	3.2 (1.0-3.6)
"When they have been infected, what age groups are most likely to die from the illness caused by the new coronavirus?" % (95% CI)	
Children	25.0 (24.2-25.9)
Young adults	12.0 (11.4-12.6)
Older adults	96.4 (96.1-96.8)
"Are those with other health problems more likely to die from an infection with the new coronavirus disease than those without any other health problems?" % (95% CI)	
Yes	92.5 (92.0-93.0)
"What percent of people who get infected with the common flu end up dying from the common flu?" (%), median (IQR)	
Continuous variable	0.75 (0.10-1.00)
Transmission of SARS-CoV-2, % (95% CI)	
"Only older adults can become infected with the new coronavirus."	
False	98.3 (98.0-98.5)
"Is there currently a vaccine available that protects against infection with the new coronavirus?"	
No	78.9 (78.1-79.7)
"Which of the following actions help prevent catching an infection with the new coronavirus?"	
Selected all of the following: avoiding touching eyes, nose, and mouth with unwashed hands; washing your hands; and avoiding close physical contact with people who are sick	86.3 (85.6-86.9)
Selected at least one of the following: using a hand dryer, regularly rinsing your nose with saline, taking antibiotics, and gargling mouthwash	68.9 (68.0-69.8)
"Consistently wearing a face mask is highly effective in protecting you from getting infected with the new coronavirus."	
True	89.5 (88.9-90.1)
"What is the main way in which people are currently getting infected with the new coronavirus?"	
Droplets of saliva that land in the mouths or noses of people who are nearby when an infected person sneezes or coughs	82.2 (81.5-83.0)
Symptoms of COVID-19 and recommended health care–seeking behavior, % (95% CI)	
"What are common signs or symptoms of an infection with the new coronavirus?"	
Nose bleeds	9.7 (9.1-10.2)
Cough	98.2 (97.9-98.5)
Fever	99.5 (99.4-99.6)
Skin rash	8.7 (8.2-9.3)
Constipation	7.4 (6.9-7.9)
Shortness of breath	91.5 (91.0-92.1)
Frequent urination	4.5 (4.1-4.9)
"If you have a fever and new persistent cough that started today, what would you do?" % (95% CI)	
Go directly to a hospital	36.9 (35.9-37.8)
Call the official hotline	38.6 (37.7-39.6)
Continue my daily routine	10.9 (10.3-11.6)

[a]Response options are grouped to summarize categorical variables into a dichotomous measure.

[b]For dichotomous outcomes, data are expressed as percentage with correct response (95% CI). For continuous outcomes, data are expressed as median (IQR).

Transmission of SARS-CoV-2

A total 98.3% (95% CI 98.0%-98.5%) of participants correctly identified that COVID-19 does not only afflict older adults. When asked to identify the primary mode of transmission from a list of multiple choices, 82.2% (95% CI 81.5%-83.0%) of participants correctly selected a description of droplet transmission. A total 89.5% (95% CI 88.9%-90.1%) of participants answered that wearing a face mask was highly effective in protecting against infection, and 86.3% (95% CI 85.6%-86.9%) of participants selected correct behavioral prevention measures. However, 68.9% (95% CI 68.0%-69.8%) of participants answered that at least one of the following measures helps prevent SARS-CoV-2 infection: using a hand dryer, regular nasal irrigation, gargling mouthwash, and taking antibiotics.

Symptoms of COVID-19 and Recommended Health Care–Seeking Behavior

Most participants correctly identified the common symptoms of COVID-19: fever (99.5% answered correctly, 95% CI 99.4%-99.6%), cough (98.2% answered correctly, 95% CI 97.9%-98.5%), and shortness of breath (91.5% answered correctly, 95% CI 91.0%-92.1%). Conversely, when asked about symptoms that are not characteristic of COVID-19, participants correctly answered that these were not expected symptoms of the disease: relatively few participants believed that nose bleeds (9.7%, 95% CI 9.1%-10.2%), skin rash (8.7%, 95% CI 8.2%-9.3%), constipation (7.4%, 95% CI 6.9%-7.9%), or frequent urination (4.5%, 95% CI 4.1%-4.9%) were symptoms of COVID-19.

When asked what they should do if they developed new symptoms of fever and cough, 36.9% (95% CI 35.9%-37.8%) stated they would go directly to a hospital or contact their community health worker or other official contact person, 38.6% (95% CI 37.7%-39.6%) said they would call the official hotline, and 10.9% (95% CI 10.3%-11.6%) reported that they would continue their usual daily routines.

Variation in Knowledge and Perceptions of COVID-19 by Sociodemographic Characteristics

Participants who were male, were middle-aged (we found the highest knowledge score among the age group 40-49 years), were living in an urban area, and had a higher annual household income were more likely to answer knowledge questions correctly (Table 3). On average, participants living in urban areas answered an additional 1.33 (95% CI 1.22-1.44) questions correctly compared to participants living in rural areas. Men answered an additional 0.42 (95% CI 0.32-0.52) questions correctly compared to women.

Although there was relatively little variation in knowledge between provinces for prevention methods, common misconceptions, and the main mode of SARS-CoV-2 transmission (Figure 2), a higher proportion of participants in eastern coastal provinces answered the question on recommended care-seeking behavior correctly than in western inland provinces. The range in the proportion of correct responses for this question varied from 47.0% (95% CI 41.4%-52.7%) in Tibet to 87.5% (95% CI 84.1%-91.0%) in Beijing.

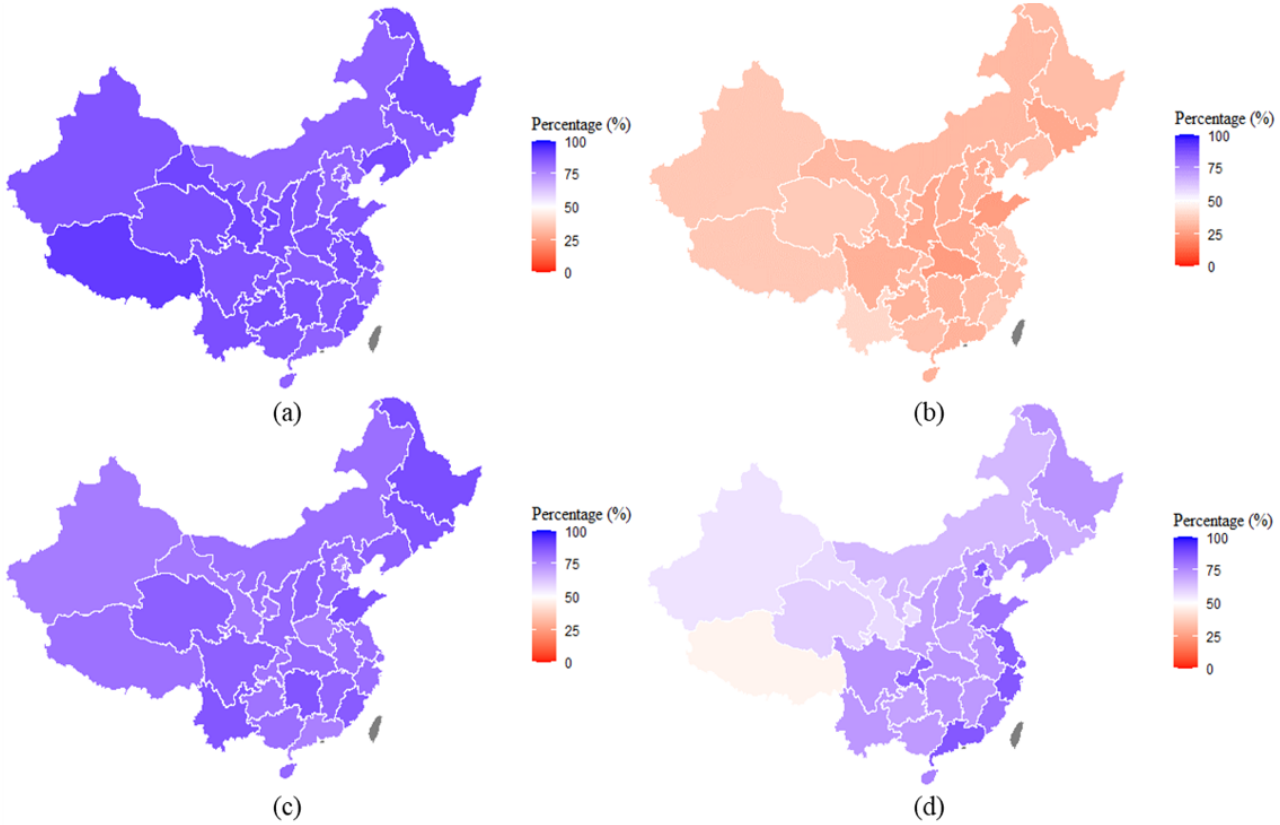
Friend	–2.55 (–6.7 to 1.59)	.23

[a]All regressions included only one of the variables (sex; age group; education; place of residence; income; vocation; whether or not a participant has a family member, friend, or acquaintance who they know to have been infected with SARS-CoV-2) shown in the table and a binary indicator for each province (province-level fixed effects).

[b]N/A: not applicable.

Figure 2. The proportion of the population by province with correct responses to questions about (a) prevention methods, (b) common misconceptions, (c) transmission channels, and (d) recommended actions after infection.



Discussion

On average, participants in our survey answered 21.4 (95% CI 21.3-21.4) out of 25 questions correctly. Higher knowledge scores were associated with being middle-aged, higher household income, male sex, and living in urban areas. Knowledge about prevention methods, common misconceptions, and transmission modes of SARS-CoV-2 infection did not vary markedly across provinces. However, knowledge about appropriate measures upon the appearance of suspicious symptoms showed a decreasing trend from the eastern wealthier coastal provinces to the western less wealthy inland provinces.

A significant proportion of participants in all provinces held misconceptions about prevention methods and recommended health care–seeking behaviors, such as beliefs that regular nasal saline rinses or gargling mouthwash are effective at preventing a SARS-CoV-2 infection. Moreover, 10.0% (95% CI 9.4%-10.6%) of participants reported that, if they had symptoms suggestive of a possible SARS-CoV-2 infection, they would continue with their daily routine. It is important for these false and potentially dangerous beliefs to be addressed in public health campaigns. These findings could inform campaigns focused on the dissemination of misinformation on the internet and on social media, both of which have been identified as platforms to circulate such misinformation [19]. It may also be useful to inform Chinese health care professionals about common misconceptions held by the public so that these misconceptions can be addressed in consultations.

Although the majority of participants demonstrated a high proportion of correct responses to knowledge questions, there was nonetheless important variation in knowledge by knowledge domain. Questions that assessed knowledge of who is at increased risk of severe COVID-19 and common symptoms of SARS-CoV-2 infection were answered correctly over 90% of the time. Questions about how SARS-CoV-2 is primarily transmitted and what precautions are effective against transmission had correct response rates between 81% and 84%. The areas of lowest knowledge were identifying ineffective measures for, or misconceptions about, prevention of SARS-CoV-2 transmission and recommended care-seeking behavior when developing a fever or new persistent cough. This suggests that public health campaigns in China can most efficiently improve the public's knowledge about COVID-19 by dispelling misconceptions about ineffective prevention

measures and developing clear, consistent, and widely distributed instructions on what individuals should do if they develop symptoms suggestive of COVID-19.

Our study results are comparable with those of studies from other countries that assessed knowledge and perceptions of COVID-19. In comparison to a similar survey in the United States and the United Kingdom [9], the majority of the results were similar across the three countries. However, we also observed differences in the beliefs about the effectiveness of masks between these countries. Nearly nine-tenths of Chinese participants reported to believe wearing a face mask was effective in preventing a SARS-CoV-2 infection, whereas only about 40% and 30% of the US and UK participants, respectively, expressed this belief, suggesting that Chinese participants were more likely to accept and select masks as a prevention measure against infections. This comparison is limited, however, as it is important to note that beliefs in the effectiveness of mask wearing in the United States and the United Kingdom have likely increased since that survey was conducted in February-March 2020. In Australia, an online survey undertaken between March 18-24, 2020, found that understanding and adoption of hygiene-related behaviors was high [20]. Surveys conducted in Nepal, Egypt, and Malaysia found that participants had good general knowledge about COVID-19, including modes of transmission and recommended prevention measures [21]. However, several misconceptions were common, such as avoidance of eating poultry and meat to reduce the chance of SARS-CoV-2 infection or that wearing masks in public does not reduce infections [21-23]. The prevalence of misinformation and misconceptions about COVID-19 worldwide underscores our recommendation that public health authorities should continue campaigns that dispel widespread misinformation and focus on consistent messaging about the importance of following a combination of evidence-based infection prevention methods and behaviors.

A key strength of our study is that we sampled a large number of individuals across China's provinces, allowing us to assess how knowledge and perceptions vary across regions, and specifically to compare perceptions in provinces that have been less impacted by COVID-19 to those in more impacted areas like Hubei, the most severely affected province in China so far.

This study, however, also has several limitations. First, participants were selected from a pool of adults who were registered with KuRunData and who agreed to take the survey. It is possible that these individuals differ in important ways from the general population of China, as ability and willingness to register with an online survey company and participate in this survey might be related to literacy, education level, and perspectives on or experience with COVID-19, to name a few. Second, an important demographic limitation is the relatively small number of older adults in our sample. Although we used sampling weights to adjust for this pattern, our estimate for the oldest age groups had a small sample size and thus a large degree of uncertainty. Third, as answers were self-reported responses to hypothetical situations, they might not reflect what individuals would do in reality. Similarly, social desirability bias could have influenced participants to answer in ways that they thought they should, rather than how they truly felt. Finally, it must be noted that this survey was administered between May 8 and June 8, 2020, and consequently reflects knowledge and perceptions at that time.

In conclusion, although general knowledge about COVID-19 was comparatively high across China, a substantial proportion of the population was found to hold important misconceptions about some prevention methods and recommended health care–seeking behaviors. Chinese policy makers should address this misinformation, as it will be important that people have accurate knowledge and practice correct prevention measures to avoid a resurgence of infections.

Abstract

Background: The increasing incidence of COVID-19 infection has challenged health care systems to increase capacity while conserving personal protective equipment (PPE) supplies and minimizing nosocomial spread. Telemedicine shows promise to address these challenges but lacks comprehensive evaluation in the inpatient environment.

Objective: The aim of this study is to evaluate an intrahospital telemedicine program (virtual care), along with its impact on exposure risk and communication.

Methods: We conducted a natural experiment of virtual care on patients admitted for COVID-19. The primary exposure variable was documented use of virtual care. Patient characteristics, PPE use rates, and their association with virtual care use were assessed. In parallel, we conducted surveys with patients and clinicians to capture satisfaction with virtual care along the domains of communication, medical treatment, and exposure risk.

Results: Of 137 total patients in our primary analysis, 43 patients used virtual care. In total, there were 82 inpatient days of use and 401 inpatient days without use. Hospital utilization and illness severity were similar in patients who opted in versus opted out. Virtual care was associated with a significant reduction in PPE use and physical exam rate. Surveys of 41 patients and clinicians showed high rates of recommendation for further use, and subjective improvements in communication. However, providers and patients expressed limitations in usability, medical assessment, and empathetic communication.

Conclusions: In this pilot natural experiment, only a subset of patients used inpatient virtual care. When used, virtual care was associated with reductions in PPE use, reductions in exposure risk, and patient and provider satisfaction.

Introduction

The COVID-19 pandemic presents unprecedented challenges to infection control in hospitals worldwide. These challenges are particularly urgent given the potential exposure risk for both health care personnel and uninfected patients amid shortages of personal protective equipment (PPE).

The health care–associated spread of COVID-19 to patients and health care workers is well documented. In Wuhan, China, presumed hospital-related transmission of COVID-19 was suspected in 41% of patients [1]. In Italy, 20% of health care professionals in one health system became infected with COVID-19 [2]. In Washington state, lack of sufficient PPE use in a skilled nursing facility is thought to have contributed to the

spread of infection to 101 residents, 34 staff members, and 14 visitors [3]. As of September 2, 2020, nearly 570,000 health care providers in the Pan-American region have been infected with COVID-19 and more than 2500 have died [4]. Although health care providers may be infected outside their job duties, health care–associated COVID-19 infections are potentially avoidable, cause direct morbidity and mortality, and lead to a reduction in workforce capacity as many health care workers are quarantined. Addressing these risks, the World Health Organization and Centers for Disease Control and Prevention both recognize PPE as one of the most effective preventive measures to reduce transmission of COVID-19. Unfortunately, there is currently a global shortage due to a surge in demand and disruptions to the global supply chain [5,6]. Although strategies have been developed to mitigate these shortages and infection risks, they will continue to present challenges as the pandemic continues.

Telemedicine has been proposed as a potential innovative solution to reduce the infection risk associated with COVID-19 [7-9]. Telemedicine, including delivery in a hospital-based setting, has the capacity to facilitate communication and a visual examination of a patient without entering the room. This in turn has the potential to decrease PPE use and health care–associated COVID-19 transmission. More than 50 US health systems already have existing telemedicine programs [7], which have been used in ambulatory [10], triage [11], inpatient [12], and intensive care unit settings [13]. These programs are associated with high patient and provider satisfaction and noninferior clinical outcomes [12,14,15]. Furthermore, telemedicine has been shown to be feasible in the context of the COVID-19 pandemic [16-19]. To date, however, telemedicine in the hospital-based setting has typically centered on using this technology to increase coverage to critical access hospitals—often for specialist services not available locally (eg, intensivists)—or for consultants as opposed to a more ubiquitous care modality for inpatient care.

To our knowledge, telemedicine in the hospital has not been extensively used and studied with the explicit purpose of reducing infection exposure and PPE use. If intrahospital telemedicine (virtual care) is an option, providers and patients have a choice on whether to conduct an in-person evaluation or virtual evaluation for a given interaction. This creates a unique environment to test the impact of a novel use for telemedicine technology on communication, in addition to evaluating its impact on exposure risk and PPE use and patient experience.

We built an in-house virtual care system at a large academic medical center in the midwestern United States with a dedicated COVID-19 service. The primary objective of this study was to evaluate if virtual care for hospitalized patients with confirmed COVID-19 could reduce overall exposures to patients with COVID-19. Secondary outcomes included patient and provider satisfaction.

Methods

The study was a prospective cohort study conducted in three general medicine units at an urban university hospital solely dedicated to treating patients with a confirmed positive test for COVID-19. The chart review portion of the study was approved by the University of Minnesota Institutional Review Board.

Patients

All patients were confirmed to have a positive polymerase chain reaction test result indicating infection with COVID-19 prior to transfer to the COVID-19–specific hospital to one of three medicine units. Only adult patients over 18 years of age were included in the evaluation.

Intervention

We conducted a natural experiment of an intrahospital telemedicine program (termed virtual care) on three medical units in a dedicated COVID-19 hospital. All rooms were equipped with an iPad (Apple Inc) with third-party videoconferencing software (Polycom) assigned to the patient's room. Patients and providers were given the option to opt out of the use of this virtual technology on a daily basis if deemed inappropriate based on mental status, illness severity, technical issues, or individual preference. If accepted for use, providers and nurses could conference into the patient's room using a device at the nursing station or an enterprise-associated phone or tablet. The virtual evaluation process required the patient to opt in by either leaving a virtual room open or turning on the camera and microphone. We present an analysis of a convenience sample of consecutively collected patients during a 6-week evaluation period.

Measures

Age, race, gender, interpreter use, and comorbidities were extracted from the electronic health record (EHR). Comorbidities were characterized by the Elixhauser Comorbidity Index using diagnosis codes collected in the year prior to hospitalization [20]. In addition, iPad use was reported in a standardized EHR note template, which was tracked on a daily basis prospectively. We measured PPE use on even number days by extracting daily PPE usage logs that were placed on each patient's door and filled out by all staff entering the room. Admission days, discharge days, and days where the patient was transferred between units were excluded. We specifically report face shield, mask, and gown use rates. We also report PPE breach rates, which were recorded on the same sheet. Finally, we report physical exam rates, which is the number of in-person exams conducted by physicians and nurses documented in the chart or sign-in sheet.

Survey Deployment

We developed a multidisciplinary workgroup to assess patient, nurse, and physician satisfaction. The goals were to assess comfort with the technology, usefulness in supporting communication, disruptiveness, and perceptions of safety using a modified Likert scale. Questions were designed to adhere loosely to the Technology Acceptance Model [21], assessing perceived usefulness, perceived ease of use, and attitude toward use. Clinicians serving dedicated COVID-19 units were contacted with both paper and electronic surveys. Patients were contacted virtually via the iPad or by phone if they had at least one documented use of virtual care and were felt to be close to discharge by the patient's medical team. Surveys were continually applied to patients as they approached discharge,

and were distributed to providers and nurses at week 3 and week 6. At week 6, an additional survey was distributed to providers and nurses to address usability and capture reasons inpatient virtual care was not used.

Statistical Analysis

Continuous variables are displayed as median and IQR for skewed variables or otherwise mean and SD and binary or categorical variables as a count and percentage. An ordinal variable was generated related to survey responses as measured by 5-point Likert scale, with 0 being strongly disagree and 4 being strongly agree. Mean and SD for each group (patients, clinicians) were calculated. Between-group comparisons between patients who opted in and opted out were performed using Mann-Whitney and chi-square tests where appropriate.

To adjust for repeated measures, daily PPE use rates were converted into panel data. Gown, face shield, and mask use were evaluated using Poisson regression adjusting for clustering by patient. Physical exam rate was evaluated by negative binomial regression. Two comparisons were performed. First, we evaluated the impact of virtual care by evaluating per-patient daily PPE use against all control patient days. Since patients were not reported to use virtual care every day, we performed a subsequent sensitivity analysis comparing PPE use on days where virtual care was used against days it was not, among a cohort that used it at least once. All statistical analysis was completed in STATA (version 16; StataCorp LLC).

Results

Overview

A convenience sample of 137 patients admitted to the COVID-19 inpatient unit was evaluated, accounting for a total of 483 patient days during the 6-week evaluation period. This included 43 patients who used virtual care at least once (Table 1). On average, patients who opt out versus opt in to virtual care are not statistically different with respect to age (mean 66.6 years versus 65.1 years, P=.62), gender (46% male versus 49% male, P=.79), racial make-up (62% White versus 49% White, P=.15), or comorbidity rates. Although proportionally more White patients opted out of virtual care than Black or Asian patients, there was not a statistically significant difference. Use of interpreters was lower in the opt-in population (12% versus 20%, P=.09), but this did not reach statistical significance. On average, those patients who opted in had a longer length of stay (11.8 days versus 9.9 days, P=.09) but this was also not statistically significant. Similarly, there were no significant differences in mortality in those who opted in versus opted out (7% versus 10%, P=.62) or maximum oxygen requirements (maximum oxygen requirement 4.5 liters per minute versus 6 liters per minute, P=.68).

Table 1. Patient demographics, comorbidities, and hospital utilization among patients with and without virtual care.

Variables	Opt-out group (n=94)	Opt-in group (n=43)	*P* value
Demographics			
Age years, mean (SD)	66.6 (18)	65.1 (19)	.62
Male, n (%)	46 (49)	20 (46)	.79
White, n (%)	58 (62)	21 (49)	.16
Black, n (%)	14 (15)	8 (19)	.58
Asian, n (%)	10 (11)	4 (9)	.81
Other/missing, n (%)	12 (13)	10 (23)	.12
Comorbidities			
Congestive heart failure, n (%)	26 (28)	7 (16)	.08
Chronic obstructive pulmonary disease, n (%)	15 (16)	5 (12)	.50
Obesity, n (%)	26 (28)	16.9 (37)	.26
Depression, n (%)	27 (29)	16 (37)	.32
Hypertension, n (%)	68 (72)	30 (70)	.76
Diabetes mellitus, n (%)	29 (31)	17 (40)	.32
Elixhauser Comorbidity Index score, median (IQR)	5 (3-8)	5 (3-7)	.49
Hospital utilization			
Maximum oxygen requirement (liters per minute), median (IQR)	6 (3-10)	4.5 (3-7)	.68
Discharged, n (%)	70 (74)	31 (72)	.77
Length of stay (days, if discharged), median (IQR)	9.9 (6.5-14.9)	11.8 (7.0-24.9)	.09
In-hospital mortality, n (%)	9 (10)	3 (7)	.62
Interpreter use, n (%)	19 (20)	5 (12)	.09

Use of PPE

Distribution of daily PPE use is displayed in Figure S1 in Multimedia Appendix 1. As shown in Table 2, daily gown use (median 5, IQR 4-5 versus median 3, IQR 2-3; *P*<.001), face shield use (median 5, IQR 4-5 versus median 3, IQR 2-3; *P*<.001, *P*=.001), and mask use (median 5, IQR 4-5 versus median 3, IQR 2-3; *P*<.001) were all reduced on days where virtual care was reported to be used. Similarly, physical exam rates (median 1, IQR 1-2 versus median 0, IQR 0-1; *P*<.001) were reduced on days where virtual care was used. There was no significant difference in the recorded PPE breach rate; breaches were rare for both groups. Similar differences were found when comparing days where virtual care was used and not used among patients who opted in (Table 2).

Table 2. Daily personal protective equipment use rates among patients with and without virtual care.

Variables	Opt-out group	Opt-in group	Coefficient (95% CI)	*P* value
All patients				
Number of days	401	82	N/A[a]	N/A
Face shields, median (IQR)	5 (4-6)	3 (2-3)	–0.54 (–0.65 to –0.43)[b]	<.001
Masks, median (IQR)	5 (4-6)	3 (2-3)	–0.54 (–0.65 to –0.43)[b]	<.001
Gowns, median (IQR)	5 (5-6)	3 (2-3)	–0.54 (-0.65 to –0.43)[b]	<.001
Physical exam, median (IQR)	1 (1-2)	0 (0-1)	–0.84 (–1.12 to –0.57)[c]	.001
Personal protective equipment breach, n (%)	4 (1)	3 (4)	1.65 (0.33 to 8.30)[d]	.55
Patients who opted in at least once				
Number of days	116	82	N/A	N/A
Face shields, median (IQR)	5 (4-6)	3 (2-3)	–0.54 (–0.69 to –0.41)[b]	<.001
Masks, median (IQR)	5 (4-6)	3 (2-3)	–0.54 (–0.69 to –0.41)[b]	<.001
Gowns, median (IQR)	5 (5-6)	3 (2-3)	–0.54 (–0.69 to –0.41)[b]	<.001
Physical exam, median (IQR)	1 (1-2)	0 (0-1)	–0.85 (–1.31 to –0.56)[c]	.001
Personal protective equipment breach, n (%)	2 (2)	5 (6)	1.65 (0.33 to 8.30)[d]	.55

[a]N/A: not applicable.

[b]Poisson regression adjusting for clustering by patient.

[c]Negative binomial regression adjusting for clustering by patient.

[d]Logistic regression adjusting for clustering by patient.

Patient Experience

We then investigated patient attitudes and perceptions on use and usability. The overall response rate was 40% (42/105), and 65% (27/41) for providers. Among patients surveyed, 8 of 15 (53%) reported common use of videoconferencing and 5 (33%) reported not using it at all. Overall, the patients' perceptions of virtual care were positive (Table 3). Furthermore, 8 (53%) respondents reported virtual care improved communication with the care team; however, only 7 (46%) felt emotionally supported through virtual communication. Patients reported improvements in sense of isolation with use (11/15, 73%), felt that it reduced exposure risk (n=15, 100%), and felt that overall continuing the project was a good idea (n=14, 92%). Importantly, patients largely felt that providers remained responsive to patient needs (n=14, 92%), and 10 (67%) disagreed with the idea that virtual care would cause doctors to miss something.

Table 3. Patient satisfaction: means and distributions of survey responses of patients with COVID-19.

Survey questions	Mean (SD)[a]
I use Facetime or other video chat programs in my daily life	2.13 (1.50)
The purpose and use of the iPad was explained to me	2.53 (1.12)
My doctor and nurses primarily communicated with me virtually	1.73 (1.10)
Virtual visits improved my ability to communicate with my care team	2.73 (0.96)
I felt that use of virtual communication reduced the risk of exposing my medical team to COVID-19	3.60 (0.51)
My care team was able to emotionally support me through virtual communication	2.27 (0.96)
Being able to use virtual communication allowed me to feel less isolated	2.93 (0.80)
My care team was responsive to my needs including visiting me in person when I needed it	3.67 (0.62)
I feel that my care team was more likely to miss something when relying on virtual communication	1.33 (0.82)
I think continuing to use virtual visits in the hospital is a good idea	3.13 (0.52)

[a]Modified Likert scale was converted to a 0-4 scale, with 0 denoting strongly disagree and 4 denoting strongly agree. Scores above 2 are significantly more positive.

Health Care Worker Experience

Results of the provider survey are shown in Table 4. Two areas identified as potential barriers for provider acceptance of this technology were lack of prior use of telemedicine with patients (Likert mean 1.65, SD 1.44) and concern that virtual care does not allow for adequate assessment of patient disease severity (Likert mean 1.92, SD 1.02; responses less than 2 indicated disagreement). Benefits of virtual care included reduced exposure risk and PPE use for providers (Likert mean 3.19, SD 0.85) and interest in expansion of virtual care visits (Likert mean 3.09, SD 0.7). Providers on average were less confident in virtual care's ability to allow effective evaluation of disease severity (n=7, 26% responding positively) and empathetic communication (n=11, 41% responding positively).

Table 4. Provider satisfaction: means and distribution of surveys to health care workers caring for patients with COVID-19.

Survey questions	Mean (SD)[a]
I am familiar with telemedicine technology	2.69 (0.93)
I had personally used telemedicine with a patient prior to this initiative	1.65 (1.44)
Using the iPad/remote assessment improves my job effectiveness and performance	2.38 (1.06)
Using the iPad/remote assessment makes me feel safer	2.65 (0.98)
Using the iPad/remote assessment reduced my exposure risk and use of personal protective equipment	3.19 (0.85)
Using the iPad/remote assessment is disruptive to my normal workflow	1.84 (1.00)
Using the iPad/remote assessment improves my ability to communicate with patients under isolation	2.69 (0.97)
Using the iPad/remote assessment allows for adequate assessment of patient disease severity	1.92 (1.02)
Using the iPad/remote assessment allowed me to effectively show empathy to patients under isolation	2.15 (1.12)
iPad/Remote assessment should be expanded to other patients with COVID-19	2.84 (0.96)

[a]Modified Likert scale was converted to a 0-4 scale, with 0 denoting strongly disagree and 4 denoting strongly agree.

Finally, we investigated barriers among providers who were not successful in using virtual care (Table S1 in Multimedia Appendix 1). Sentiment for virtual health remained positive in regard to improving communication, family involvement, and reducing exposure risk (Table S2 in Multimedia Appendix 1) even among providers who reported difficulty with use. Respondents reported language (n=7, 58% reported frequent occurrence) and usability issues (n=8, 67% reported frequent occurrence) were the most common barriers to use. The virtual care also did not appear to detract significantly from providers' efficiency; most disagreed with the statement that the iPad/remote assessment was disruptive to normal workflow (Likert mean 1.84, SD 1.0). Patient and provider preference as a barrier to use was also rare (Table S1 in Multimedia Appendix 1).

Discussion

Principal Findings

In the era of COVID-19, hospitals have necessarily become testing grounds for innovation. Inpatient wards under duress need to adapt to patient surges, minimize health care worker exposure, prevent nosocomial transmission, and streamline patient flow. Despite these pressures, however, the human core of medical care—effective communication, empathy, and clinical expertise—should not be sacrificed. We took a mixed

methods approach to evaluate the degree to which an inpatient telemedicine program (virtual care) could reduce COVID-19 exposure risk and PPE use while maintaining effective communication. Although telehealth programs have rapidly expanded in the context of COVID-19, direct evaluation of patient and provider experience and overall utility remain understudied. This is particularly true for inpatients where choice between a virtual encounter and in-person encounter exists continuously. We provide several contributions to the literature that have important implications.

We provide a structured evaluation of virtual care for patients with COVID-19 and find important limitations. Patients and providers had the ability to opt out of use based on usability, preference, and medical appropriateness. As such, it was used a minority of the time even when it was available for all patients. Even among patients who used virtual care, it was relied upon less than half the days. Providers found use was of limited utility for risk assessment and providing empathetic communication.

Concerns regarding empathetic communication echo the findings that the digitization of health care can lead to a corresponding decrease in the expression of empathy by providers [22]. For example, in at least one study, empathy and praise utterances were observed less in telemedicine consultations compared to face-to-face consultations [23]. This is of particular importance because empathy is a fundamental determinant of quality in medical care [24]. Techniques have been suggested to overcome these barriers during the COVID-19 pandemic, such as finding a private place for videoconferencing, looking directly at the camera, ensuring proper lighting, and paying close attention to subtle comments and body language [16,25]. However, it is not yet clear whether these or other measures can fully bridge the digital empathy gap.

These observations highlight the importance of patient and provider engagement in the implementation of new technology, especially during a crisis. In this natural study, implementation was guided by efficiency to address a rapidly emerging health crisis. Development of a more patient-centered telemedicine program could build upon this work, improving accessibility by integrating translation services, addressing the needs of those who are hard of hearing or have vision loss, and integrating other health services to promote multidisciplinary virtual rounding. Without a patient-centered approach, there is also a risk that the digital health divide could exacerbate health disparities even within the confines of the hospital [26]. It is estimated that in the United States, not only may 13 million older adults have trouble accessing telemedical services during the COVID-19 pandemic, but also a disproportionate number of those may be among the already disadvantaged [27]. This study thus provides a first step toward understanding what is needed for a more patient-centered system.

Despite these limitations, providers and patients were generally positive regarding their experience with inpatient virtual care in two domains: supporting patient-provider communication and reducing risk of exposure. Both patients and providers supported the value of a virtual rounding program for COVID-19, with all patients and 73% (19/26) providers surveyed agreeing with program continuance. This is consistent with prior literature, which has found adequate patient satisfaction with telemedicine interventions, including during the COVID-19 pandemic [9,11,15,16,25,28,29].

Importantly, virtual care was also associated with significantly reduced PPE usage and potential exposure. Given critical shortfalls in PPE supply and distribution, efficient management of “burn rate” is an important factor in maintaining safety in our health care system [5,6]. This observation was corroborated by survey data in which both providers and patients agree that virtual care reduced exposure and PPE use. Understanding predictors of use and identifying factors that can improve efficiency of PPE use will be an important future area of study in adapting to the COVID-19 pandemic [30]. It is not known, however, whether the reduced exposure alone led to a subsequent decrease in health care–associated COVID-19 transmission because health care–associated infections were not reported as part of this study.

There are several further limitations to this study as a single-center natural experiment on the use of inpatient telemedicine. First, the sample size is small and as such we may not be able to capture the full variation in PPE use pattern or patient experience. Future work with larger sample sizes should elucidate in which ways patient satisfaction varies based on demographic groups. Second, this was not a randomized trial and there are numerous possible sources for bias. Associations can be confounded by unobserved factors such as policy changes in PPE use (such as approaches to reuse) and patient characteristics. One alternative explanation for our findings, for example, is that the differences in PPE use could be related to changes in illness severity during times in which inpatient telemedicine was felt to not be medically appropriate. Although a survey of clinicians who reported usability barriers suggested this was a minority of episodes, such a relationship could still be present. A critical next step will be understanding how PPE use rates correlate with patient factors and how they change temporally, while also determining how they correlate with outcomes.

Similarly, as this experiment used new technology, lack of use may be highly practitioner dependent and less dependent on patient-related factors. Thus, observed PPE differences and patient experiences could be attributed to the providers that tended to use virtual care more often. More structured evaluation of use to eliminate some of these inherent biases with our observational experience, such as a cluster randomized controlled trial with structured use protocols, would be better designed to overcome these shortfalls. Finally, we only surveyed patients who used virtual care at least once. The primary reason for this design was to get perspectives based on direct experience. As such, we did not obtain perceptions for patients who did not choose to use virtual care, resulting in an additional source of potential bias, and limitation to generalizability of our study findings.

Importantly, this program was built upon pre-existing technology available to our health care system, including iPads, an enterprise network, and Health Insurance Portability and Accountability Act–compliant videoconferencing technology. To other health care systems without existing telemedicine

infrastructure, this intervention may be more expensive and difficult to put into place. Furthermore, in the setting of this study, a direct in-person evaluation was always immediately available. In such circumstances, intrahospital telemedicine may not be directly comparable to a fully remote telemedicine model where in-person consultation is not possible.

Indeed, the psychological effects of virtual care possibilities in light of COVID-19 warrant further investigation. We found gaps in the ability to deliver empathetic care, but there were also anecdotal stories of success. For example, an additional use case that was used was the ability to hold remote family conversations for patients in isolation. Additionally, we had multiple family members hospitalized in separate rooms in this study who could stay continually connected through this technology, for which they expressed gratitude during our survey collection.

Ultimately, we suggest that an individualized, prudent selection process for the use of virtual care may offer an appropriate use model in response to COVID-19. This can be based on evolving and unique patient and provider characteristics. In times of clinical stability and when used in the right population, virtual care may enhance communication, reduce PPE use, and reduce exposure risk. However, during periods where diagnostic evaluation, direct communication, or empathy are paramount, in-person care remains preferable. The future of telemedicine must be individualized and patient centered.

Conclusions

In summary, our experience suggests that intrahospital telemedicine is feasible and well received. It can be used by a select subpopulation and effectively reduces infectious exposure and PPE usage, and can support communication, though with the caveat of a more limited capability for empathetic support and need to improve usability in a patient-centered manner.

Abstract

Background: On January 30, 2020, the World Health Organization's Emergency Committee declared the rapid, worldwide spread of COVID-19 a global health emergency. Since then, tireless efforts have been made to mitigate the spread of the disease and its impact, and these efforts have mostly relied on nonpharmaceutical interventions. By December 2020, the safety and efficacy of the first COVID-19 vaccines were demonstrated. The large social media platform Twitter has been used by medical researchers for the analysis of important public health topics, such as the public's perception on antibiotic use and misuse and human papillomavirus vaccination. The analysis of Twitter-generated data can be further facilitated by using Twitter's built-in, anonymous polling tool to gain insight into public health issues and obtain rapid feedback on an international scale. During the fast-paced course of the COVID-19 pandemic, the Twitter polling system has provided a viable method for gaining rapid, large-scale, international public health insights on highly relevant and timely SARS-CoV-2–related topics.

Objective: The purpose of this study was to understand the public's perception on the safety and acceptance of COVID-19 vaccines in real time by using Twitter polls.

Methods: We developed 2 Twitter polls to explore the public's views on available COVID-19 vaccines. The surveys were pinned to the Digital Health and Patient Safety Platform Twitter timeline for 1 week in mid-February 2021, and Twitter users and influencers were asked to participate in and retweet the polls to reach the largest possible audience.

Results: The adequacy of COVID-19 vaccine safety (ie, the safety of currently available vaccines; poll 1) was agreed upon by 1579 out of 3439 (45.9%) Twitter users. In contrast, almost as many Twitter users (1434/3439, 41.7%) were unsure about the safety of COVID-19 vaccines. Only 5.2% (179/3439) of Twitter users rated the available COVID-19 vaccines as generally unsafe. Poll 2, which addressed the question of whether users would undergo vaccination, was answered affirmatively by 82.8% (2862/3457) of Twitter users, and only 8% (277/3457) categorically rejected vaccination at the time of polling.

Conclusions: In contrast to the perceived high level of uncertainty about the safety of the available COVID-19 vaccines, we observed an elevated willingness to undergo vaccination among our study sample. Since people's perceptions and views are strongly influenced by social media, the snapshots provided by these media platforms represent a static image of a moving target. Thus, the results of this study need to be followed up by long-term surveys to maintain their validity. This is especially relevant due to the circumstances of the fast-paced pandemic and the need to not miss sudden rises in the incidence of vaccine hesitancy, which may have detrimental effects on the pandemic's course.

Introduction

On January 30, 2020, the World Health Organization's Emergency Committee declared the rapid, worldwide spread of SARS-CoV-2 and COVID-19 a global health emergency [1]. Since then, tireless efforts have been undertaken in order to mitigate disease spread and its impacts on many different areas of public health, which range from the amount of patient and health care personnel to nationwide public health measures that mostly rely on nonpharmaceutical interventions [2-5]. Several of these measures have already been associated with the reduced transmission of COVID-19 in geographic, region-wide studies [6,7]. By December 2020, the first COVID-19 vaccine candidates were proven to be safe and efficacious in protecting against COVID-19 and were approved by regulators [8-11], and more vaccine candidates are still under development [12]. Consequently, medical societies and experts all over the world have advocated that vaccination against COVID-19 should be prioritized for high-risk groups, especially older people and people with underlying chronic medical conditions that place them at an increased risk of severe outcomes resulting from SARS-CoV-2 infection [13,14].

Since the beginning of the COVID-19 pandemic, traditional media coverage and information distribution via social media channels have been shaping public opinions and international public health strategies [15]. Although this may have positive effects on public health attitudes related to mitigation measures, one should also be aware of the detrimental effects of misinformation in media [16-20]. Misinformation should be of special consideration in the context of social media platforms such as Twitter, since false claims regarding COVID-19 appear to propagate faster on such platforms, as demonstrated in a recent study by Shahi et al [21]. However, even before the COVID-19 "infodemic," the spread of misinformation on social media platforms, on e-commerce platforms (eg, Amazon [22]), and by prominent celebrities in the United States has led to the emergence of an antivaccine movement, which has detrimental effects on national vaccine programs [23]. The resulting increased incidence of vaccination hesitancy is partly responsible for the re-emergence of measles in the United States almost 20 years after its elimination [24].

The potential implications of social media for public health are becoming increasingly clear, and the medical community was using Twitter as a tool for public health research long before the onset of the COVID-19 pandemic. The primary purposes of its use, as reported in previous health-related studies, are content analysis, surveillance, engagement, recruitment, intervention, and network analysis, and most related studies are being published in the areas of public health and infectious diseases [25]. Such Twitter-based analyses involve important public health topics that are often related to the themes of infectious diseases, such as the public's perception on antibiotic use and misuse or human papillomavirus vaccination [26,27].

Twitter—a social media platform with about 353 million monthly active users [28]—allows registered users (possible for anyone aged over 13 years) to share short, 280-character texts (also known as tweets) with other users. These tweets may be further categorized into different topics to start discussions. This is done by the use of tagging symbols, such as the hashtag symbol (#). Such discussions may be further facilitated by incorporating Twitter's built-in and anonymous polling tool. This tool has the potential to obtain insight into public health topics and real-time feedback on an international scale [29].

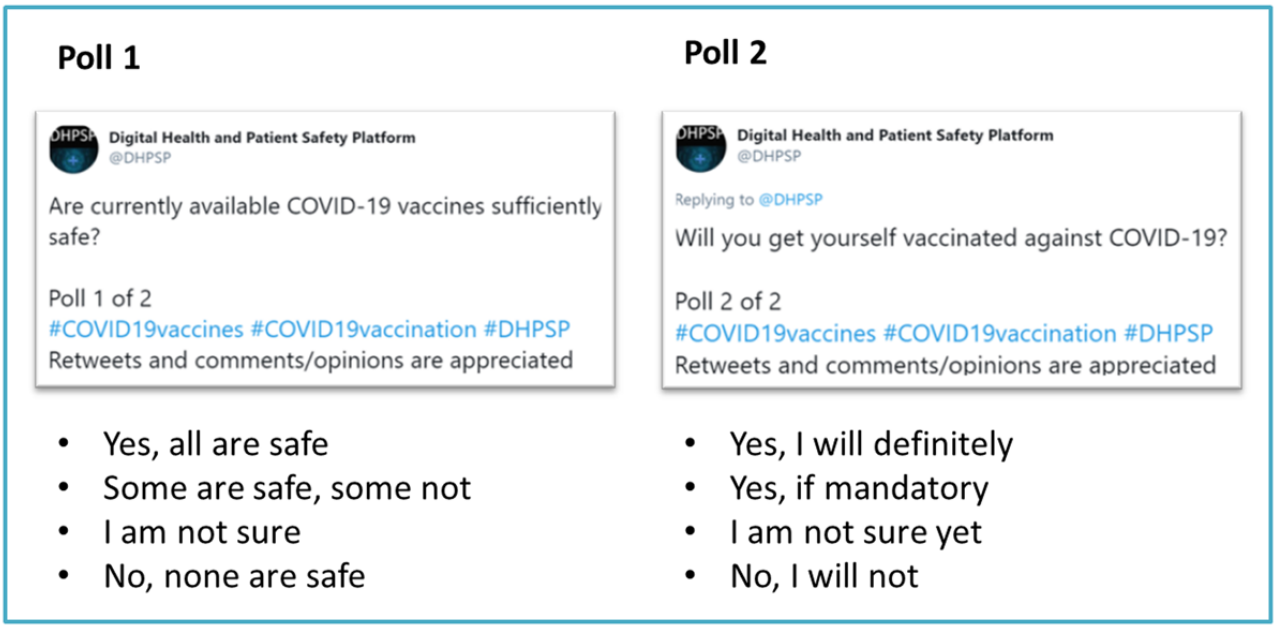
Surveying public attitudes toward COVID-19 vaccination is of high importance, since it might provide a better understanding of the reasons behind vaccine hesitancy and how to better design vaccine awareness strategies. Given the fast-paced dynamic of the COVID-19 pandemic, the Twitter polling tool seems to be a reasonable instrument for gaining immediate, large-scale, international public health insights on SARS-CoV-2–related topics. We therefore used this opportunity to rapidly collect and analyze international public health data on COVID-19 vaccines by using the Twitter polling tool. Through these efforts, we aimed to explore the potential benefits and limitations of using such a highly relevant digital health tool to investigate a highly important and broadly discussed topic.

Methods

In 2019, the Ludwig Boltzmann Institute for Digital Health and Patient Safety in Vienna, Austria was launched with the major aim of empowering patients and health care professionals with digital tools and promoting innovative research and the development of digital health and patient safety tools. One of these innovations was the initiation of the Digital Health and Patient Safety Platform (DHPSP) [30], which provides subscribers with an overview of recent scientific publications regarding digital health and patient safety.

For this study, we used the Twitter account of the DHPSP (Twitter handle: @DHPSP) to distribute two polls regarding COVID-19 vaccine safety and acceptance. The polls were developed by the authors and posted on Twitter under the @DHPSP Twitter handle between February 12 and February 19, 2021. Poll 1 addressed the perceived safety of the available (at the time of polling) COVID-19 vaccines ("Are currently available COVID-19 vaccines sufficiently safe?"), whereas poll 2 addressed the confidence or hesitancy of the respondents with regard to undergoing vaccination against COVID-19 ("Will you get yourself vaccinated against COVID-19?"). Both polls were linked (poll 2 was posted as a comment below the tweet for poll 1) and pinned at the top of the DHPSP Twitter timeline during the polling period. The poll questions, which included hashtags for categorization, were limited (by Twitter) to 280 characters. Twitter allows up to 4 answers with a limit of 25 characters (including spaces) for each poll. Therefore, both polls included 4 answers that ranged from total agreement ("Yes, all are safe" and "Yes, I will definitely") to total disagreement ("No, none are safe" and "No, I will not") and were presented in the manner of a 4-point response scale. Both polls were categorized using the following hashtags to promote better visibility and facilitate analysis: #COVID19vaccines, #COVID19vaccination, and #DHPSP. Figure 1 displays the detailed construction of both polls on Twitter.

Figure 1. Structure of the two Twitter polls.



After launching the polls, the first people who could see them on their Twitter timelines were the DHPSP Twitter followers. Twitter poll votes are anonymous and do not allow for the evaluation of respondents' characteristics (eg, gender). Therefore, in order to at least obtain some data on the characteristics of the audience that was first exposed to the polls, we aimed to analyze the follower characteristics of @DHPSP via the web-based tool Followerwonk [31] on February 20, 2021 (Table 1). In total, the @DHPSP Twitter account had 526 followers at the time of the analysis. Of these, 121 (23%) were male, 69 (13.1%) were female, and 336 (63.9%) did not state their gender on Twitter. A total of 66 (12.6%) @DHPSP followers had more than 5000 followers, 152 (28.9%) had between 500 and 5000 followers, and 308 (58.6%) had less than 499 followers.

Table 1. @DHPSP's Twitter follower characteristics (N=526).

Characteristics	Value, n (%)
Gender	
Male	121 (23)
Female	68 (13)
Not stated	337 (64)
Follower count	
<499	305 (58)
500-5000	153 (29)
>5000	68 (13)

The polls' body message encouraged people to retweet the polls ("Retweets and comments/opinions are appreciated"; Figure 1), and with each new retweet, the polls gained a bigger audience (consisting of the followers of the retweeting accounts). Moreover, to achieve greater visibility, members and email list subscribers of the DHPSP [30] were asked to support the polls by voting; retweeting the polls; and disseminating them via diverse networking approaches, including direct emails or direct social media messages. The website of the DHPSP and diverse social media accounts of DHPSP members were also used to post hyperlinks to the polls. Additionally, information for the polls was shared through the DHPSP Facebook [32] and LinkedIn [33] accounts.

To characterize the population of users that retweeted the studied polls, we performed a hashtag analysis by using the web-based tool Symplur Signals [34]. We therefore analyzed the number of retweets, users, locations, and languages of all tweets that contained our unique combination of hashtags (#COVID19vaccines, #COVID19vaccination, and #DHPSP) by the end of this study. This was done on the day after the polls were closed (February 20, 2021). To ensure accuracy and to limit interference bias from other Twitter discussions related to our topic, we conducted a Twitter search prior to launching the polls (February 11, 2021), and we confirmed that our combination of hashtags was never used.

Ethical approval was not required for this study, as it was outside the scope of the medical ethics law in Austria. Participation in the studied polls was completely anonymous. Therefore, the collected data were outside the scope of the General Data Protection Regulation [35]. Excluding the poll votes, analyzed parameters such as the number of followers and retweets were based on data that were publicly available on the internet.

Results

Both of our Twitter polls were pinned to the Twitter timeline of the @DHPSP Twitter account for 7 days, beginning on February 12, 2021. Pinning a tweet permanently places it at the top of a Twitter user's account. Therefore, any new visitors will see this tweet at the top of the visited user's timeline.

Poll 1 ("Are currently available COVID-19 vaccines sufficiently safe?") received a total of 3439 votes (194,695 views), whereas poll 2 ("Will you get yourself vaccinated against COVID-19?") received a total of 3457 votes (246,814 views). The analysis of the poll retweets that contained our unique combination of hashtags (#COVID19vaccines, #COVID19vaccination, and #DHPSP) revealed a total of 930 tweets from 375 users. Overall, 262 (69.9%) users posted 1 retweet, 67 (17.9%) users posted 2 retweets, and 46 (12.3%) posted ≥3 retweets. The polls, including all retweets, had a total of 15,446,703 views on Twitter. The top 3 locations of Twitter users who retweeted the polls were the United States of America (n=64, 17.1%), the United Kingdom (n=19, 5.1%), and Canada (n=16, 4.2%). A summary of these details is provided in Table 2. The other top locations (rank 4-10) were India (13 users), Mexico (8 users), Argentina (5 users), Spain (5 users), Australia (4 users), United Arab Emirates (4 users), and Italy (3 users).

Table 2. Analysis of poll retweets that contained our unique combination of hashtags (#COVID19vaccines, #COVID19vaccination, and #DHPSP).

Characteristics	Value, n (%)
Top locations[a,b]	
United States of America	64 (17.1)
United Kingdom	19 (5.1)
Canada	16 (4.2)
Number of retweets[b]	
1	262 (69.9)
2[c]	67 (17.9)
≥3[c]	46 (12.3)
Top languages[d,e]	
English	802 (86.2)
Spanish	6 (0.6)
Indonesian	5 (0.5)

[a]Determined based on data derived from the users who indicated their location in their account information on Twitter. During the interpretation of the data, readers should be aware that 50.5% (189/375) of Twitter users did not provide location information on their profiles.

[b]Percentage is based on the number of Twitter users who retweeted the polls (N=375).

[c]Includes regular retweets, retweets with comments, and quote retweets (in which a hyperlink to the original tweet is inserted in a newly composed tweet).

[d]Only the most used languages are indicated. All other tweet languages each accounted for less than 0.5% (5/930) of the retweets.

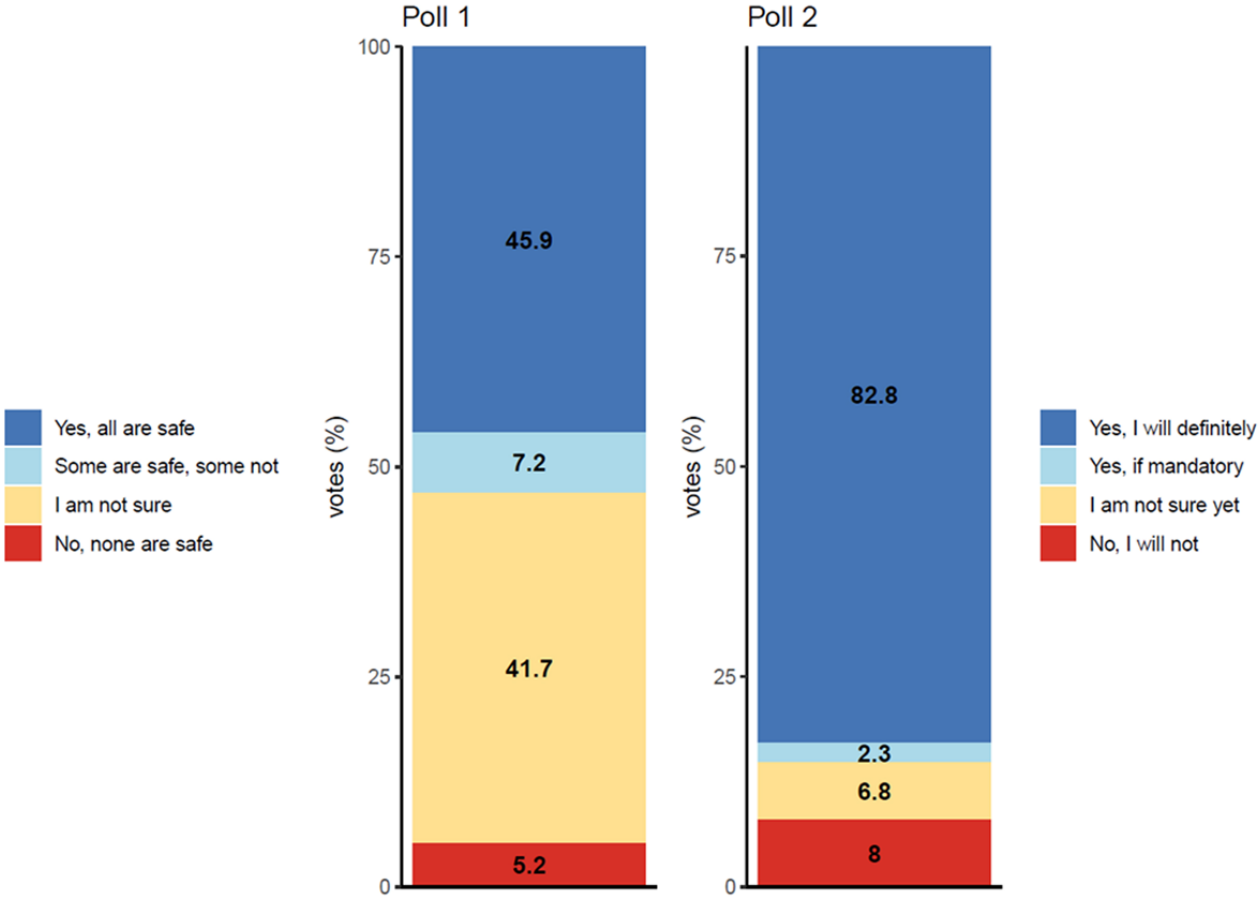
[e]Percentage is based on the number of retweets (N=930).

In total, 45.9% (1579/3439) of Twitter users who responded to poll 1 (“Are currently available COVID-19 vaccines sufficiently safe?”) voted with total agreement (“Yes, all are safe”), meaning that the users considered all currently available COVID-19 vaccines to be safe. However, almost as many Twitter users (1434/3439, 41.7%) were not sure about the safety of the available COVID-19 vaccines (voted with “I am not sure”). Interestingly, only 5.2% (179/3439) of the respondents in this poll felt that the available COVID-19 vaccines were generally unsafe (“No, none are safe”). In addition, a total of 7.2% of Twitter users (248/3439) advocated for the safety of some vaccines but felt that not all of them were safe.

Poll 2 explored Twitter users’ confidence or hesitancy toward undergoing vaccination against COVID-19 (“Will you get yourself vaccinated against COVID-19?”). A majority (2862/3457, 82.8%) of the respondents stated, “[y]es, I definitely will [get vaccinated].” In total, 6.8% (235/3457) of Twitter respondents were not yet sure (voted with “I am not sure yet”) about undergoing vaccination, and 8% (277/3457) categorically rejected vaccination at the time of polling (“No, I will not”). Only a minor percentage (80/3457, 2.3%) of Twitter users stated that they would undergo vaccination if it was mandatory.

A detailed summary of the answers to both polls is provided in Figure 2.

Figure 2. Twitter users' answers to poll 1 ("Are currently available COVID-19 vaccines sufficiently safe?"; respondents: n=3439) and poll 2 ("Will you get yourself vaccinated against COVID-19?"; respondents: n=3457).



Discussion

In the context of the fast-paced dynamic of the COVID-19 pandemic, we used the rapid, progressive environment of social media (ie, Twitter) to gain international insights into the public's opinion on COVID-19 vaccination. We followed a methodological approach that was outlined in a previous study on public attitudes toward telemedicine, which was conducted by Vidal-Alaball et al [29]. They suggested that the Twitter polling tool for quick surveys on timely topics should be used to obtain prompt feedback for new questionnaires before their validation. In this study, by using the DHPSP's Twitter handle and gaining the support of the retweeting accounts, we were able to validate the Twitter polling approach on a large scale. We obtained a 30-fold higher poll response rate and view rate (impressions) and an 18-fold higher retweet rate compared to those of Vidal-Alaball et al [29]. In the previously mentioned study regarding attitudes toward telemedicine, Vidal-Alaball et al [29] only used the Twitter handle of one of the authors, whereas in our study, an established Twitter network (the DHPSP) was used to achieve a greater reach and higher response rates. Therefore, we were able to not only validate the previously published approach on a larger scale but also demonstrate the definitive advantage of an established user network that is less dependent on single users for achieving a wider reach and higher response rates.

Although this study involves the first scientific Twitter poll analysis of the perceived safety of available (at the time of polling) COVID-19 vaccines and the confidence or hesitancy of respondents with regard to undergoing vaccination against COVID-19, it is not the first survey on this topic in medical literature. In this study, despite the insecurities about the sufficient safety of the available (at the time of polling) COVID-19 vaccines (BNT162b2 by Pfizer-BioNTech, mRNA-1273 by Moderna, ChAdOx1 by AstraZeneca, and Gam-COVID-Vac by the Gamaleya Research Institute of Epidemiology and Microbiology of the Russian Federation), which was observed in 54.1% (1861/3439) of the poll's respondents, a surprisingly large group of respondents (2863/3457, 82.8%) voted that they would definitely undergo vaccination.

Although this is a positive result, due to the Twitter poll's anonymous nature, there is no reassurance that the Twitter users who answered the first poll also answered the second poll. In contrast to this study, in a large-scale international analysis of 13,426 participants from 19 countries that was conducted via multiple international, web-based panel providers (Dynata, Opinion Access, Survey Monkey, and Amazon MTurk), Lazarus et al [36] found that only 46.8% of participants agreed to accept a COVID-19 vaccine if it was generally available; 24.7% somewhat agreed; and 14% and 34.1% completely and somewhat agreed to accept a COVID-19 vaccine if it was recommended by their employer, respectively. However, the data from the Lazarus et al [36] study were collected in June

2020. At that time, none of the currently available COVID-19 vaccines were approved by regulatory authorities. Other studies that were conducted during an earlier pandemic phase reported higher rates of willingness to undergo vaccination once a vaccine against COVID-19 became available, ranging from 59% to 75% [37].

Our study may be limited in terms of interpretability. This is due to the fact that the visibility of the polls was widely promoted by the DHPSP, which has a follower base that consists of highly educated individuals with scientific backgrounds or strong interests in science. Since the DHPSP account exclusively posts science-based content, it is reasonable to assume that it attracted followers with interests in science. This assumption is in line with a recent study by Schwarzinger et al [38], which revealed that COVID-19 vaccination hesitancy was highly prevalent among people with low educational levels in the French population. These findings are in line with other, more recent studies that were conducted in France, the United States of America, and Australia [39-41]. As reported and discussed by Kreps et al [42], several factors associated with willingness, hesitancy, advice, and recommendations to vaccinate against COVID-19 are consistent with those in past studies on other vaccines, whereas other factors may be more complex due to the fast-paced dynamic and unpredictable course of the pandemic as well as difficult political and public health actions and communications.

The number of surveys on confidence and hesitancy toward vaccinating against COVID-19 that have been conducted over the course of the pandemic has demonstrated the importance of regular reviews on the public's opinion toward the effectiveness and safety of vaccines. Such reviews are needed in order to instill public confidence [36]. Lazarus et al [36] also concluded that one of the most important factors for initiating positive health behaviors is credible and culturally informed health communication. With this in mind, health authorities could reach out to the public via rapid, low-barrier, and easy-to-access media platforms, such as Twitter, in order to monitor and instill positive health behaviors through the provision of clear information and credible sources that are tailored to the cultural backgrounds of target populations. As Twitter polls provide the necessary anonymity for confident and large-scale participation and allow for rapid and concise questioning, we propose that this tool is useful for reaching out to the public and addressing public health issues.

The strengths of this tool and this study lie in rapid assessment, the large-scale dissemination of information, and the expeditious retrieval of concise information. The possible strengths of using a preformed network to disseminate information and surveys in order to reach a broad target audience are shown in this study, especially in our comparison of single-user promotion and our promotion method. The very tight restrictions of Twitter polling, including question and answer character limits as well as limits on the total number of answers, might serve as strengths for constraining poll creators to the development of concise and well-formulated surveys, which might result in higher response rates than those of traditional surveys. However, these restraints may also impede the formulation of more complex questions and the clarification of questions and answers. This might interfere with poll results, as a lack of clarity may result in different interpretations among poll participants. Therefore, Twitter polling is better suited for clear, concise, and close-ended questions instead of open-ended and semistructured questions that leave room for interpretation.

The pinning and promoting of Twitter polls by specific accounts may also interfere with sample selection and result in biases that may be challenging to mitigate because of the lack of data on the baseline characteristics (eg, gender, age, and socioeconomic status) of participants. However, this challenge can be easily overcome by promoting Twitter polls for a longer period of time across multiple accounts and groups. Nevertheless, it should be noted that complete anonymity can result in the manipulation of votes in the polling tool due to people exploiting multiple usership, as outlined in the study by Vidal-Alaball et al [29]. Even though the analysis of Twitter network followers is made possible by third-party web-based tools, the geographical distribution of the @DHPSP follower network (Figure 3) might not be representative of our polls' responders, as random Twitter users were able to participate in these polls. The Twitter polls did not undergo a formal validation process. Future studies (eg, those that pilot polling tools) should address the validation of the questions used in this study. However, we were able to gain a better perspective of the users who responded to the polls by using a novel approach, which involved a unique combination of hashtags and a hashtag analysis, to gain insights on the population of users who retweeted the Twitter polls.

In conclusion, despite the high levels of uncertainty regarding the safety of available COVID-19 vaccines in the study sample, the respondents had a high willingness to undergo vaccination. The public's perceptions and views on health issues are strongly influenced by social media. This underscores the importance of using social media polling tools to understand public health perspectives in real time. Such information can be used to inform public health messaging and communication efforts. Regular surveys on public health issues that use social media platforms may aid in the early discovery of sudden rises in the incidence of COVID-19 vaccination hesitancy among the public before the detrimental effects of the pandemic can manifest.

Figure 3. Main locations of the DHPSP's Twitter followers. These data cover only a fraction of the DHPSP followers who indicated their location in their account information on Twitter. DHPSP: Digital Health and Patient Safety Platform.

Abstract

Background: The COVID-19 pandemic has led to worldwide school closures, with millions of children confined to online learning at home. As a result, children may be susceptible to anxiety and digital eye strain, highlighting a need for population interventions.

Objective: The objective of our study was to investigate whether a digital behavior change intervention aimed at promoting physical activity could reduce children's anxiety and digital eye strain while undergoing prolonged homeschooling during the COVID-19 pandemic.

Methods: In this cluster randomized controlled trial, homeschooled grade 7 students at 12 middle schools in southern China were recruited through local schools and randomly assigned by the school to receive (1:1 allocation): (1) health education information promoting exercise and ocular relaxation, and access to a digital behavior change intervention, with live streaming and peer sharing of promoted activities (intervention), or (2) health education information only (control). The primary outcome was change in self-reported anxiety score. Secondary outcomes included change in self-reported eye strain and sleep quality.

Results: On March 16, 2020, 1009 children were evaluated, and 954 (94.5%) eligible children of consenting families were included in the intention-to-treat analysis. Children in the intervention (n=485, 6 schools) and control (n=469, 6 schools) groups

were aged 13.5 (SD 0.5) years, and 52.3% (n=499) were male. The assigned interventions were completed by 896 children (intervention: n=467, 96.3%; control: n=429, 91.5%). The 2-week change in square-root–transformed self-reported anxiety scores was greater in the intervention (–0.23, 95% CI –0.27 to –0.20) vs control group (0.12, 95% CI 0.09-0.16; unadjusted difference –0.36, 95% CI –0.63 to –0.08; *P*=.02). There was a significant reduction in square-root–transformed eye strain in the intervention group (–0.08, 95% CI –0.10 to 0.06) compared to controls (0.07, 95% CI 0.05-0.09; difference –0.15, 95% CI –0.26 to –0.03; *P*=.02). Change in sleep quality was similar between the two groups.

Conclusions: This digital behavior change intervention reduced children's anxiety and eye strain during COVID-19–associated online schooling.

KEYWORDS

homeschooling; children; anxiety, digital eye strain; peer to peer; live streaming; digital health; intervention; health information; physical activity; COVID-19; online learning; behavior; app; mobile phone

Introduction

COVID-19 has spread worldwide, with more than 24 million confirmed cases as of August 29, 2020 [1]. UNESCO (United Nations Educational, Scientific and Cultural Organization) announced that at least 188 countries have closed schools nationwide as of August 2020, which has resulted in the unprecedented adoption of online homeschooling [2]. An estimated 1.5 billion children are learning at home without direct access to school activities [2].

Prolonged adoption of homeschooling has important implications for children's mental health. Although the long-term mental health consequences of the COVID-19 pandemic on children have not been systematically explored [3-5], it has been suggested that quarantined children have an average posttraumatic stress score 4 times higher than nonquarantined children [6]. Given that school isolation and stay-at-home orders could further worsen anxiety and other mental health problems, there is a critical need for novel interventions to safeguard the well-being of students in this regard [7-9].

In addition to its psychological impacts, the COVID-19 pandemic can take a toll on children's vision as many schools move online. The expanded use of digital devices and increased screen time may result in worsening symptoms of eye strain and pose greater risk for myopic progression [10]. The American Academy of Ophthalmology has recommended the 20-20-20 rule, which calls for taking a visual break every 20 minutes by looking at an object 20 feet away for 20 seconds. While it is important to deliver such health information, it is equally necessary to study effective ways to promote behavior change, motivate eye relaxation exercises, and test effectiveness in reducing eye strain.

Digital behavior change interventions have been considered as an effective approach to promote physical activity and/or reduce sedentary behavior [11]. Furthermore, physical activity may be a useful target for strategies to handle stress, anxiety, sleeping problem, and eye relaxation, given previous reports regarding the associations of a lower level of physical activity with anxiety [12], depression [13], sleep disorder [14], and dry eye disease [15]. We have therefore hypothesized that a digital behavior intervention aimed at promoting physical activity could improve outcomes in anxiety, sleeping, and eye strain. This issue is critically important, given the magnitude of the COVID-19 pandemic. While this manuscript was under review, it was reported that individuals with inadequate physical activity reported a greater level of psychological distress during the COVID-19 pandemic [16].

The advent of digital technology has provided new opportunities to deliver digital behavior interventions on a population scale [17]. More than 90% of American teenagers are online every day (averaging more than 6.5 hours daily), where they spend much of their time interacting with friends and family through social media [18]. More than 40% of adolescents in grades 7 to 9 in China report at least 2 hours of exposure to digital screens per day [19]. In particular, live-streaming apps have become a popular form of social entertainment for children. However, despite the increasing adoption of live-streaming apps among children and teenagers, their use in public health interventions has yet to receive wide attention in clinical trials.

In light of this gap, we developed a novel digital behavior change intervention that encourages children to engage in regular physical activity and relaxation of accommodation (near focusing) during online school recess periods. The aim of this study is to evaluate the effectiveness of this digital intervention in reducing anxiety syndrome (main outcome) and eye strain, compared to a conventional educational intervention among Chinese children during a recent period of home confinement occasioned by the COVID-19 pandemic.

Methods

Study Design and Participants

This cluster randomized controlled trial was conducted in the Duanzhou district of Zhaoqing City, Guangdong Province, in southern China. This setting was chosen because Zhaoqing, one of southern China's major cities, is readily accessible from Guangzhou, the provincial capital. The 2016 national census shows that Zhaoqing has a relatively stable population of 4,084,600, which is representative of the Chinese national urban population in terms of demographic and socioeconomic characteristics [20]. Smartphone use is very widespread in this area, as throughout the rest of China, where the number of

mobile phone subscribers in December 2019 (1.6 billion) exceeded the total population of 1.43 billion [21]. China has mandated 9 years of compulsory education since 1986, and the enrollment rate for the 7th grade (12-14 years) is nearly 100% in Zhaoqing. Thus, the school-going cohort is representative of children in the general population.

The research protocol was approved by the Institutional Review Board of the Zhongshan Ophthalmic Center, Sun Yat-sen University, and the study was performed in accordance with the Declaration of Helsinki. Written informed consent was obtained from at least one parent or guardian of all participating children. The date of registration of the clinical trial was March 16, 2020.

The COVID-19 outbreak was recognized in China during the nationwide winter school vacation. On January 27, 2020, China's Ministry of Education announced the postponement of the 2020 spring semester, and all schools were asked to recommend that students stay at home, avoiding group activities and large gatherings. As the outbreak continued, the Guangdong Education Department announced in February 2020 that secondary schools would begin formal online education beginning March 2, 2020. Teachers at the 14 public secondary schools in Duanzhou district (Figure S1 and Table S1, Multimedia Appendix 1) formulated an online curriculum for homeschooling, with standardized content and schedules for all students in the area (Table S2, Multimedia Appendix 1).

After excluding 2 secondary schools owing to an insufficient number of students per cluster, permission to conduct the study was requested from the remaining public secondary schools (n=12) in the district (Figure S1, Multimedia Appendix 1). Inclusion criteria were as follows: (1) grade 7 (12-13 years old) students in Duanzhou district and (2) under home confinement and enrolled in online learning courses during the COVID-19 outbreak. Exclusion criteria included the presence of disorders such as autism, pervasive developmental delay, and schizophrenia, which might interfere with participation in the intervention. The study followed the CONSORT (Consolidated Standards of Reporting Trials) guideline [22] (Multimedia Appendix 2). The reporting of the mobile-phone–based questionnaires followed the CHERRIES checklist (Checklist for Reporting Results of Internet E-Surveys) [23] (Multimedia Appendix 3).

Randomization, Concealment, and Masking

Cluster randomization with schools as the cluster was adopted in order to maximize peer-to-peer support while avoiding contamination in the use of social media between study groups. A total of 12 schools with a block size of 4 were assigned (1:1) to receive either health education + download of the peer-to-peer live-streaming app (intervention group) or health education only (control). The randomization sequence was generated by an independent statistician using an online random number generator. In each school, 2 classes (on average, 40 students per class) were further randomly selected for participation.

Due to the nature of the intervention, students were not masked. However, masking of investigators was achieved through the exclusive use of electronic, self-administered questionnaires and masking the statistician to group allocation until completion of all analyses. In addition, participating students were informed that their responses to questionnaires would not be made available to their parents or teachers. Qualitative feedback on the app was not obtained from participants.

Procedures

Recruitment and enrollment were assisted by trained teachers, who described the study in detail to participants and their parents over the phone. Participants and their parents were offered the opportunity to ask questions about participation. Before randomization, online seminars for parents were conducted through all 12 participating schools, during which the investigators answered questions and collected consent forms. Teachers were trained and were provided with a manual of operations, which included the study protocol and standard operating procedures for the study.

During the period of home confinement, the Chinese government had already issued a policy recommending a specific schedule for recess and physical activity breaks for students. In the control group, teachers delivered an online health information session covering the following topics and health advice to students: (1) an outline was provided on the recommended 20-20-20 rule during study and viewing of on-screen content; (2) during recess (15 mins for each recess; 4 times per day), participants in the control group received SMS text message prompts (≤50 characters) to participate in broadcast exercise programs at home, eye relaxation, or to stretch for 10 minutes. Students had access to at-home workout videos developed by exercise physiologists. Breaks were part of the online curriculum, and students were instructed by teachers (who were not aware of the study allocation) to rest and take exercise breaks according to government-issued recommendations.

Students in the intervention group received the identical health information session, online curriculum, workout videos, and breaks as described above. Additionally, at the beginning of the study, students in the intervention group were asked to log on and download a peer-to-peer live-streaming app (the Recess and Exercise Advocacy Program [REAP]). REAP is a live-streaming platform that allows users to capture short videos and photographs with their smartphones related to their physical exercise or eye relaxation activities (eg, looking outdoors through the window). The app has been optimized for both iOS (Apple) and Android operating systems. During each recess from homeschooling (15 mins for each recess; 4 times per day), participants in the intervention were prompted by SMS text messaging (≤50 characters) to log in to the REAP app to participate in live streaming or posting their workouts and outdoor videos and photographs (Supplementary Method S1, Multimedia Appendix 1).

The outcomes were measured by a self-assessed survey through mobile-phone–based questionnaires after signing the informed consent form. The questionnaires were surveyed at the beginning of the study and at the 2-week follow-up. At the start of the questionnaire, participants were given the following information: the purpose of the study, the expected length of time of the mobile phone survey, the names of the investigators, and the way and duration the data were stored. To ensure completeness

checks, the participants were asked to complete the mandatory items before the questionnaire was submitted. The study investigators ensured that the confidentiality of the participants' data was preserved. Individual participant data will not be disclosed to outside personnel and will not appear in any publications. Data assistants entered the questionnaires into a database and pseudonymized the data before it passed to the study statistician.

Outcome Measures

The primary study outcome was a change in self-reported anxiety score between baseline and the 2-week follow-up, as measured using the 45-item Chinese version of the Spence Children's Anxiety Scale (SCAS). In addition to the total SCAS score, this measure assesses 6 domains of anxiety: panic/agoraphobia, separation anxiety, social phobia, fears of physical injury, obsessive compulsive problems, and generalized anxiety. Details relating to the SCAS can be found in Multimedia Appendix 1 [24]. This instrument has been well validated in Chinese children [25]. A higher total score (range 0-114) summing the point values of all items indicates greater anxiety.

Secondary outcomes included changes from baseline to the 2-week follow-up in the following items: children's self-reported eye strain, sleep quality, and time spent on different near-work activities. Eye strain was measured with the self-reported Computer Vision Syndrome Questionnaire (CVS - Q), which evaluates the frequency (never, occasionally, or often/always) and intensity (moderate or intense) of 16 symptoms. Details relating to the CVS-Q scale are available in Multimedia Appendix 1 [26]. The 4-item Patient-Reported Outcomes Measurement Information System (PROMIS) pediatric sleep disturbance questionnaire was used to assess sleep disturbance (Multimedia Appendix 1) [27]. Self-reported information regarding the average daily time spent on near-work activities was collected, including each of the following: reading; writing; and use of computers/tablets, smartphones, television, and video games (Multimedia Appendix 1).

In addition, parentally reported anxiety scores on behalf of children were obtained using the SCAS for Parent (SCAS-P) questionnaire (Multimedia Appendix 1). This variable was not prespecified but was used to assess the reliability of self-reported scores from children.

Statistical Analysis

The sample size was calculated based on a cluster randomized design, assuming that children's self-reported raw anxiety score in the intervention group would be reduced by 2.5 points, with a standard deviation of 5 points, and the anxiety score of the control group would not change. The average cluster size was about 80, and an intracluster correlation coefficient of 0.02 was estimated based on the Refractive Error Studies in Children [28]. A sample size of 8 schools (4 in each group) at a two-sided significance level of .05 would give a power of 90%. Assuming a participation rate of 90% and attrition of 20%, a total of 12 schools was required. The sample size was calculated using PASS 16.0 (NCSS, LLC).

The distribution of baseline characteristics was presented as the mean (SD) for continuous variables and frequency (percentage) for categorical variables. The unadjusted mean differences between study groups in 2-week change and the 95% CI for primary and secondary outcomes were calculated using linear regression. The adjusted intervention effect on the primary outcome and 95% CI were estimated using linear regression models, adjusting for baseline measures. The study group and all variables with $P<.20$ in univariable regression analyses were included in the multivariable regression analysis. Histograms and quantile-quantile plots were used to verify the normality assumptions of the *t* test and linear regression models. Square-root transformation was applied to all outcomes due to lack of normality. To satisfy intention-to-treat criteria, we conducted missing data imputation. Multiple imputation was used to create 20 copies of the data, and final results were obtained by averaging these data sets using the rules developed by Rubin [29]. A two-sided *P* value less than .05 was considered statistically significant. All analyses were performed using Stata 15.0 (Stata Corp). The study protocol was registered at ClinicalTrials.gov (NCT04309097) prior to enrollment of the first participant and is available for online access.

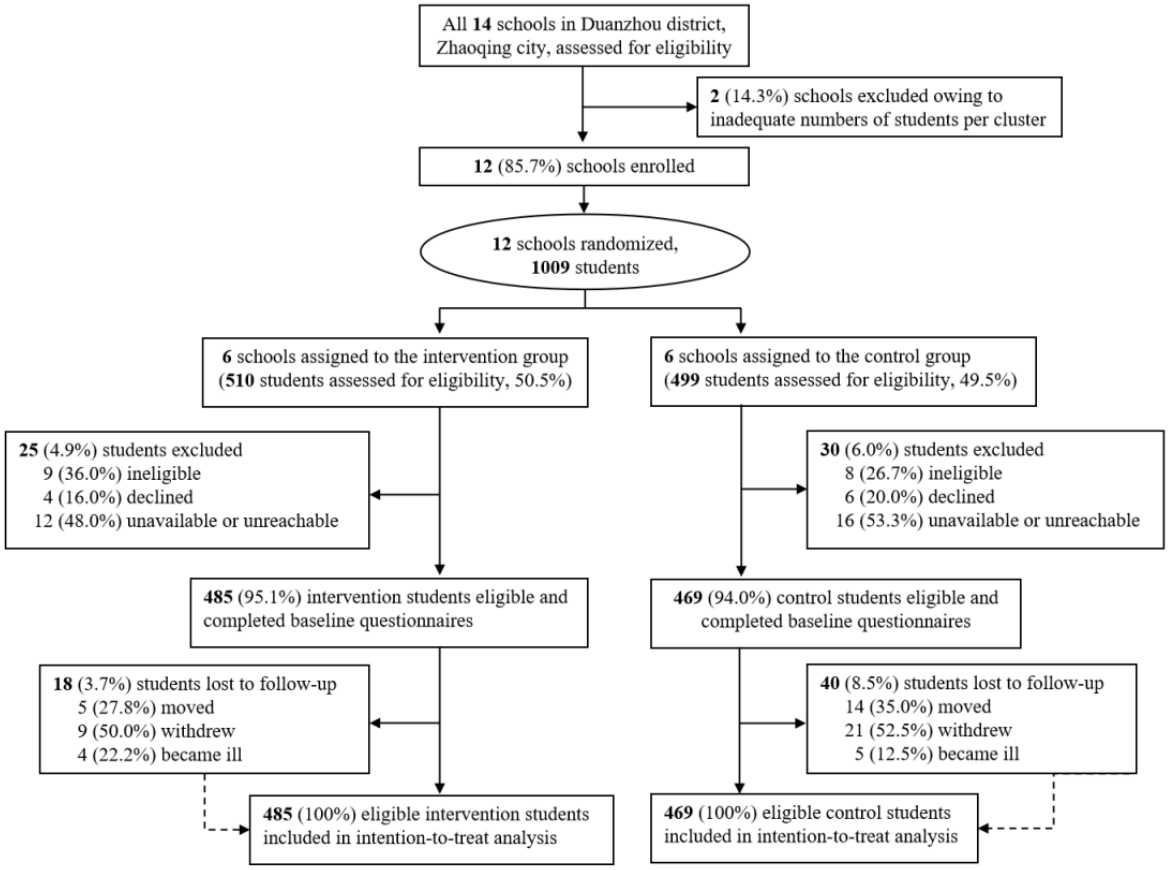
Data-Sharing Statement

Requests for anonymized individual participant data and study documents will be considered on a case-by-case basis and on scientific merit by the principal investigators and approved by the relevant institutional review boards.

Results

A total of 12 schools were randomized (6 to the intervention group and 6 to the control group; Figure 1). Of the 1009 grade 7 students assessed for eligibility (intervention group: n=510, 50.5%; control group: n=499, 49.5%), 55 (5.45%) were unreachable, ineligible, or declined to participate, leaving 954 (94.5%) eligible students, with 485 (95.1%) in the intervention group and 469 (94.0%) as controls. Rolling recruitment occurred on March 16, 2020. During the 2-week follow-up period, 18 (3.7%) and 40 (8.5%) students withdrew from the intervention and control groups, respectively (Figure 1).

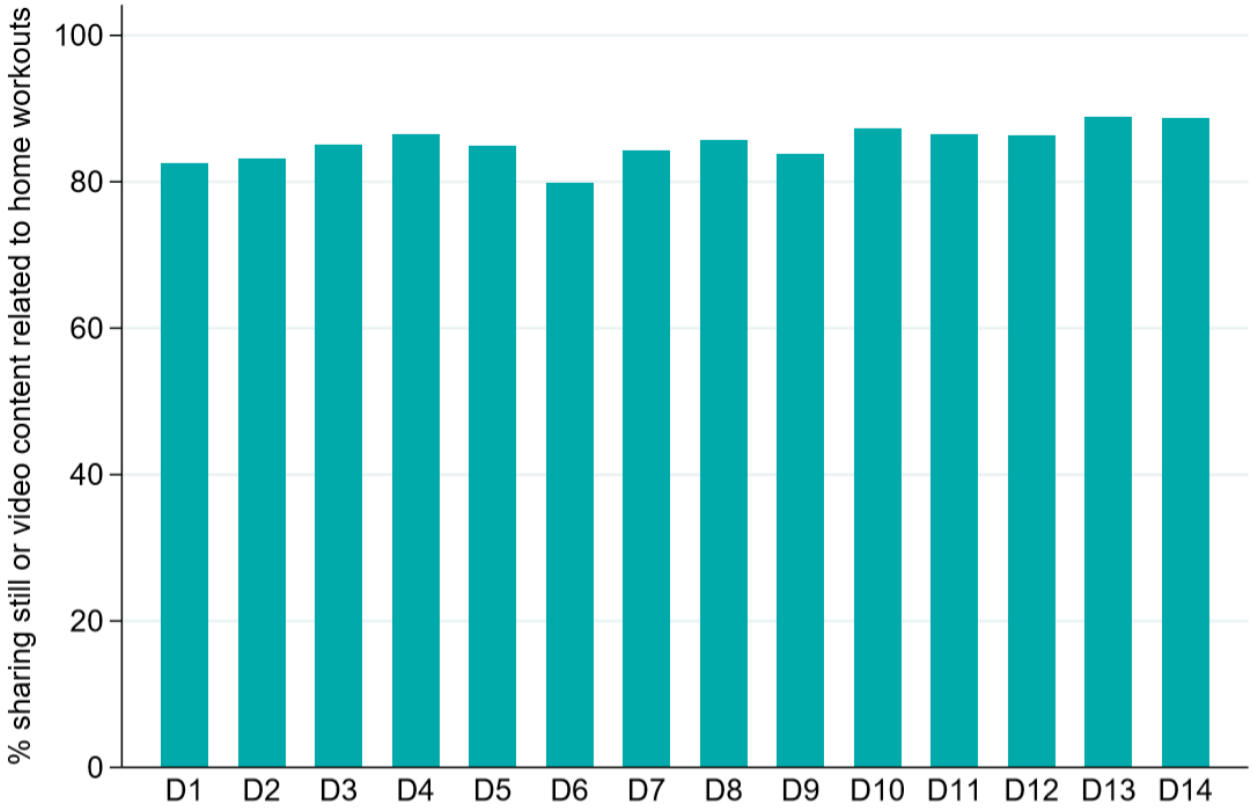
Figure 1. Flow diagram for the trial.



The baseline characteristics of students in the study groups were similar (Supplementary Table S4, Multimedia Appendix 1). The mean age was 13.5 (SD 0.50) years in both groups, and there were no significant baseline differences in sex, use of glasses, parental education and smoking, and family income.

Intervention compliance was monitored using the Cloud platform of the live-streaming app. An average of 1.91 (SD 0.32) videos and photographs of stay-at-home workouts and eye relaxation activities per intervention group student per day were uploaded to the live-streaming app (1.63, SD 0.31, during weekdays; 2.14, SD 0.80, on weekends). All students uploaded at least one video or photograph per day in the intervention group. The app includes the essential feature of a data-monitoring system, and detailed utilization data are presented in Figure 2.

Figure 2. The proportion of participants sharing photos or video content related to home workouts in the intervention group.



The square-root–transformed self-reported anxiety score (main study outcome) fell by –0.23 (95% CI –0.27 to –0.20) in the intervention group and rose (worsened) by 0.12 (95% CI 0.09-0.16) in the controls by the end of the study (Table 1). The change in anxiety score was significantly greater in the intervention group compared to the controls (difference –0.36, 95% CI –0.63 to –0.08; *P*=.02). Significant associations were also found between changes in many SCAS subscale scores and the intervention (Supplementary Table S9, Multimedia Appendix 1). Change in self-reported eye strain was also significantly greater in the intervention vs the control group (intervention group: –0.08, 95% CI –0.10 to 0.06; control group: 0.07, 95% CI 0.05-0.09; difference –0.15, 95% CI –0.26 to –0.03; *P*=.02). The changes in sleep disturbance score (*P*=.23), screen time (*P*=.84), and reading time (*P*=.47) during the 2-week follow-up did not differ significantly between study groups (Table 1).

Table 1. Comparisons of change between study groups in self-reported anxiety, eye strain, sleep score, and time spent on different near-work activities between baseline and the 2-week follow-up (intention-to-treat analysis).

Variable	Intervention group (n=485), mean (95% CI)	Control group (n=469), mean (95% CI)	Difference in change between groups, mean (95% CI)	*P* value[a]
Anxiety score[b,c]				
Baseline	3.72 (3.69 to 3.76)	3.67 (3.64 to 3.70)		
2-week follow-up	3.49 (3.46 to 3.52)	3.79 (3.76 to 3.83)		
Change (follow-up – baseline)	–0.23 (–0.27 to –0.20)	0.12 (0.09 to 0.16)	–0.36 (–0.63 to –0.08)	.02[d]
Eye strain score[b,c]				
Baseline	1.21 (1.19 to 1.23)	1.08 (1.06 to 1.10)		
2-week follow-up	1.13 (1.11 to 1.15)	1.15 (1.12 to 1.18)		
Change (follow-up – baseline)	–0.08 (–0.10 to 0.06)	0.07 (0.05 to 0.09)	–0.15 (–0.26 to –0.03)	.02[d]
Sleep disturbance score[b,c]				
Baseline	2.51 (2.50 to 2.52)	2.53 (2.53 to 2.54)		
2-week follow-up	2.57 (2.56 to 2.58)	2.55 (2.54 to 2.56)		
Change (follow-up – baseline)	0.06 (0.05 to 0.07)	0.01 (0.002 to 0.02)	0.05 (–0.03 to 0.13)	.22
Average daily time spent in near work, hours				
Screen time[b]				
Baseline	2.68 (2.67 to 2.69)	2.69 (2.68 to 2.70)		
2-week follow-up	2.61 (2.60 to 2.62)	2.61 (2.60 to 2.63)		
Change (follow-up – baseline)	–0.07 (–0.08 to –0.05)	–0.08 (–0.09 to –0.06)	0.01 (–0.10 to 0.12)	.84
Reading time[b]				
Baseline	1.37 (1.35 to 1.38)	1.29 (1.28 to 1.30)		
2-week follow-up	1.34 (1.32 to 1.35)	1.21 (1.20 to 1.22)		
Change (follow-up – baseline)	–0.03 (–0.05 to –0.01)	–0.08 (–0.09 to –0.06)	0.05 (–0.09 to 0.18)	.47

[a]Linear regression models adjusting for cluster effects within schools.

[b]Square root transformed.

[c]Higher score indicates greater severity.

[d]Significant.

In linear regression models, randomization to receive the peer-to-peer live-streaming intervention was associated with a significant reduction in self-reported anxiety compared to the controls (β=–0.36, 95% CI –0.63 to –0.08; *P*=.02), after adjusting for sex and household income (Supplementary Table S5, Multimedia Appendix 1). Results based on parentally reported anxiety scores were consistent (Supplementary Table S6, Multimedia Appendix 1).

Discussion

Principal Results

Our findings from a geographically representative region in urban China showed that a digital behavior change intervention effectively reduced anxiety and eye strain during children's homeschooling, without increasing overall screen time. This digital tool might be useful during the COVID-19 pandemic, which has led to widespread school closures, with over a billion children around the world receiving online homeschooling, potentially increasing risk of anxiety and eye strain [10,30,31].

Comparison With Prior Work

A recent review suggested that children's mental and visual health may suffer during home confinement and online schooling [32]. These effects may result from reduced face-to-face social interaction, persistent and intense screen exposure, prolonged time spent on near-work activities, and the disruption of normal life rhythms, all of which may contribute to increased anxiety, eye strain, and sleep disturbance [33]. Children with preexisting mental health conditions such as depression may be especially susceptible to such problems [7].

The app only permitted users to post content related to exercise and activities promoting eye relaxation. This focus on activities highly relevant to both parents and children during the COVID-19 lockdown may explain the high study participation rate of over 95% and the large counts of children who shared photos or video content on a daily basis (Figure 2). We did not

record any adverse events related to our intervention, nor did we observe any significant increase in screen time in the intervention group (Table 1). This latter finding is significant in view of concerns that children's use of smartphones and social media may increase the risk of attention-deficit disorder, sleep disturbance, obesity, and other conditions [18,34,35]. Further studies are needed to investigate the long-term impacts of our digital intervention on children's social media behavior.

Strengths and Limitations

Strengths of the current study include the fact that participants were recruited from a population-representative sample of schools in a typical Chinese urban region, allowing our findings to be generalized to a wider range of Chinese children affected by the COVID-19 lockdown. Second, because of social media's reliance on peer support, our protocol followed a cluster randomized design, which minimized the risk of cross-contamination in social media use between study groups. Thirdly, children in both study groups received the same online courses, ensuring intergroup homogeneity except with respect to the intervention. Finally, the results of primary, secondary, and sensitivity analyses were in full agreement; for example, there was concordance between self- and parentally reported anxiety scores (Supplementary Table S7, Multimedia Appendix 1), indicating the robustness and reliability of our findings.

Study limitations must also be acknowledged. First, masking of participants was not feasible due to the nature of the intervention, so the possibility of placebo effects cannot be excluded. However, good agreement between parental and self-report of anxiety makes this somewhat less likely. Second, data for the main outcome were obtained by questionnaires and were thus based on an evaluation of symptoms, rather than a clinical diagnosis of anxiety disorder. Regardless, the reproducibility of this questionnaire has been well validated [21], and, as mentioned above, parental and self-reported scores were in accord (Supplementary Table S7, Multimedia Appendix 1). Third, the study design allowed for only 2 weeks of follow-up. Previous studies have shown that interventions of this length can be effective [36-38], and such brief periods of engagement may be particularly applicable to unpredictable, short-term school closures [39], which may become more common in the future with additional waves of the COVID-19 pandemic. For example, a brief (2-3 week) lay counsellor–delivered, problem-solving intervention was found to be effective for adolescents with diverse mental health problems [38]. Nevertheless, it is certain that a longer follow-up will provide additional information on the robustness and stability of this intervention effect. Fourth, only Chinese children were included in the study, and the effectiveness of live-streaming interventions to reduce children's anxiety and eye strain must be validated in other settings. Fifth, due to the nature of our behavior intervention, we could not exclude the possibility that the changes in children's anxiety and eye strain may have been caused by other factors (eg, the increased interactions between children and parents), rather than a change in the behavior itself. In addition, the questionnaires were not fully validated for online use, which is the only means that can be used during COVID-19–related home learning. Finally, the urban sample used in the study may not be representative of China, not only because of the lack of smartphones in less developed parts of China but also due to the higher probability of separation between children and their parents due to labor migration. Our results therefore need to be interpreted with caution.

Conclusions

In summary, this study demonstrated that a novel digital behavior change intervention can significantly reduce anxiety and eye strain in homeschooled children. Further work is needed to determine whether these results can be extended to other aspects of pediatric and adult health, and to different geographic and cultural settings.

Authors' Contributions

Y Zheng, NC, WW, and Y Zhong had full access to all of the data in the study and take responsibility for the integrity of the data and the accuracy of the data analysis. YL, NC, and Y Zheng were responsible for concept and design. All authors were involved in acquisition, analysis, and interpretation of data. Y Zheng, NC, and WW drafted the manuscript. All authors were involved in

critical revision of the manuscript for important intellectual content. LJ conducted statistical analysis. YL was responsible for securing funding. Y Zhong, LX, ZZ, and HL provided administrative, technical, or material support. Y Zheng, NC, and YL were responsible for supervision. All authors approved the final version.

Conflicts of Interest

YL reports receiving grants from the National Natural Science Foundation of China. Y Zheng has served on the digital advisory board for Novartis and is the owner of the REAP app. NC is the director of research for Orbis International, a nongovernmental organization that carries out children's eye health work in China. The remaining authors have no disclosures to report.

Abstract

Background: The COVID-19 pandemic has disrupted human societies around the world. This public health emergency was followed by a significant loss of human life; the ensuing social restrictions led to loss of employment, lack of interactions, and burgeoning psychological distress. As physical distancing regulations were introduced to manage outbreaks, individuals, groups, and communities engaged extensively on social media to express their thoughts and emotions. This internet-mediated communication of self-reported information encapsulates the emotional health and mental well-being of all individuals impacted by the pandemic.

Objective: This research aims to investigate the human emotions related to the COVID-19 pandemic expressed on social media over time, using an artificial intelligence (AI) framework.

Methods: Our study explores emotion classifications, intensities, transitions, and profiles, as well as alignment to key themes and topics, across the four stages of the pandemic: declaration of a global health crisis (ie, prepandemic), the first lockdown, easing of restrictions, and the second lockdown. This study employs an AI framework comprised of natural language processing, word embeddings, Markov models, and the growing self-organizing map algorithm, which are collectively used to investigate social media conversations. The investigation was carried out using 73,000 public Twitter conversations posted by users in Australia from January to September 2020.

Results: The outcomes of this study enabled us to analyze and visualize different emotions and related concerns that were expressed and reflected on social media during the COVID-19 pandemic, which could be used to gain insights into citizens' mental health. First, the topic analysis showed the diverse as well as common concerns people had expressed during the four stages of the pandemic. It was noted that personal-level concerns expressed on social media had escalated to broader concerns over time. Second, the emotion intensity and emotion state transitions showed that *fear* and *sadness* emotions were more prominently expressed at first; however, emotions transitioned into *anger* and *disgust* over time. Negative emotions, except for *sadness*, were significantly higher (P<.05) in the second lockdown, showing increased frustration. Temporal emotion analysis was conducted by modeling the emotion state changes across the four stages of the pandemic, which demonstrated how different emotions emerged and shifted over time. Third, the concerns expressed by social media users were categorized into profiles, where differences could be seen between the first and second lockdown profiles.

Conclusions: This study showed that the diverse emotions and concerns that were expressed and recorded on social media during the COVID-19 pandemic reflected the mental health of the general public. While this study established the use of social media to discover informed insights during a time when physical communication was impossible, the outcomes could also contribute toward postpandemic recovery and understanding psychological impact via emotion changes, and they could potentially inform health care decision making. This study exploited AI and social media to enhance our understanding of human behaviors in global emergencies, which could lead to improved planning and policy making for future crises.

Introduction

Overview

The COVID-19 pandemic continues to devastate the world, with more than 80 million infections and more than 1.7 million deaths [1]. It is an unprecedented public health emergency that has prompted most governments to enforce hard borders, strict social distancing, and rigorous quarantine restrictions. The impact and aftermath of these public health emergency measures have resulted in a severe psychological burden for all individuals. The economic and social fallout has affected individuals and communities alike, resulting in mental health disorders and emotional distress that adds to already overwhelmed health care systems and services worldwide [2-4]. Although researchers and authorities are readily investing in vaccinations, social distancing regulations, and health care facilities to eliminate the virus, long-term mental health impacts will also require undivided attention and action to minimize the detrimental effects. Given this context, developing an understanding of the psychological and emotional burden will aid and accelerate postpandemic recovery and enable policy making for future emergencies of this scale.

Social restrictions and physical distancing measures during this pandemic have led to increased use of social media as a medium of communication by individuals and communities [5]. Expressions on social media during such crises are critical and representative of public opinion, as it has become the primary medium of communication for the exchange of information, experiences, and emotions with others who are facing similar challenges [6-8]. Identification of such opinions in the form of topics enables identification of people's past and ongoing concerns throughout the pandemic [9]. Recent studies have shown a rapid growth of social media content focused on informational and emotional sharing as means of emotion regulation, avoiding mental health issues, and adjustments to the quality of life in lockdown [10,11]. This phenomenon has been described as the *social sharing of emotion*, which postulates that individuals who experience emotions are often eager to share and talk about their emotions [12]. Crises similar to the current pandemic may lead to the amplification of expression of emotions within a community or group of people [13-15]. The extent and frequency of sharing depend on the intensity of the emotional episode, and such social sharing occurs as a means of regulating one's emotions. Thereby, the social sharing of emotions during a crisis creates a spreading and escalation of emotions within the group or community impacted by the event, which, in turn, reflect the mental health status of the community.

Given the volume and variety of content being shared on social media, online behaviors have been investigated as a *proxy* for offline human behaviors, with several studies reporting conclusive results and outcomes [16-18]. A massive number of social media conversations represents a cross-section of society that encompasses people's opinions across different demographic dimensions. These emotions and opinions create a pool of untapped self-reported information. Therefore, it is relevant and useful to study the emotions and concerns voiced over such internet-mediated communication to better understand the mental health and emotional well-being during a time of crisis. Several recent studies have investigated the use of social media during the COVID-19 pandemic to discover topics, emotions, and sentiments from social media conversations [19-21] as well as different information sharing behaviors [22]. While the use of social media to understand public opinion is well established, studies suggest that more focus should be given to showcase how social media can be used to improve health knowledge [23].

On this premise, this study aims to investigate concerns and emotions expressed over social media to infer insights on people's mental health as the pandemic progresses. It has been shown that emotions and concerns expressed on social media represent and relate to people's underlying mental health [24-27]. This establishes social media as a lens through which to comprehend people's mental health during a constrained situation such as the current pandemic, where conducting clinical trials is challenging.

We selected Twitter as the test bed social media platform for our experiments, given that it provides fast-paced, frequent, current affairs–focused end-user engagement, in comparison to other social media platforms [28]. We extracted tweets related to the pandemic that were posted from January to September 2020 and specifically focused on an Australian context based on the following reasons. First, Australia was one of the countries where distinct phases of the lockdown and their impact were clearly visible. This enables the temporal analysis of emotions and concerns in each phase to gauge insights into how citizens react and change their emotion-related behaviors as the pandemic progresses. The four phases are (1) prepandemic—when the outbreaks were yet to be declared a global pandemic and no positive cases have been reported in Australia, (2) the first lockdown—social restrictions following the first wave of positive cases locally, (3) easing restrictions—relaxation of social restrictions when the case numbers were brought under control, and (4) the second lockdown—following the emergence of new cases. Next, as Australia is one of the few countries with a sizeable population to successfully suppress both first and second waves of the pandemic [29,30], it was pertinent to study the emotions related to COVID-19 as experienced by the Australian public. Despite the successful management, a recent study mentions that mental health problems were widespread among Australians during the lockdown periods, where one-quarter of the participants in the study showcased mild to moderate symptoms of anxiety or depression [31,32]. The use of social media among the

Australian public is well established for being representative of a broad cross-section of society [33-35], especially during emergencies as a powerful communication tool [36,37]. This allows us to investigate the emotions expressed via virtual platforms in order to determine similar behaviors related to Australian citizens' mental health.

In this study, we focus on the application of artificial intelligence (AI) approaches that have been validated across several studies [18,27,38] to analyze human emotions. The algorithms are used to quantify emotion intensities, detect emotion state transitions, and identify profiles of impacted individuals based on the concerns they have expressed on social media to provide a holistic view of people's mental health. This approach can be described as an ensemble of machine learning algorithms and natural language understanding (NLU) techniques that establish an end-to-end pipeline to extract, process, normalize, analyze, and aggregate self-reported information in its unstructured format into topics and emotions expressed during the key phases of the pandemic. We have also compared the two lockdown periods and the social media expressions in response to restrictions imposed during each lockdown to capture changes in temporal emotions and related concerns.

The rest of the paper is organized as follows. The Methods section presents an overview of the methodology used in this study and the Results section presents the outcomes of the analysis. The paper concludes with the Discussion section, which outlines the implications of the study, limitations, and potential avenues for future research.

Background

The current literature reports many research studies that detect sentiment and emotions from social media using a variety of techniques. Sentiment analysis has been explored using lexical and statistical approaches [39-42] and recent research studies have extended this by using advanced deep learning models that can detect the bipolarity of social media conversations [43-46]. While sentiment analysis classifies posts into negative and positive categories, emotion detection extends this categorization by detecting granular variants of emotions [47]. Many emotion models, such as Ekman's basic emotion model [48], the valence and arousal model [49], and Plutchik's emotion model [50], are being used as the basis for emotion detection. Most of the approaches of emotion detection rely on prelabeled data via crowdsourced annotations and semantics to develop machine learning models [51-53]. Current research studies report the use of many deep learning models, such as word embedding models [46,54], convolutional neural networks [55], and recurrent neural networks [56-58], for emotion classification. Emoticons and emojis have also been used in studies to infer emotions from social media as they represent user-annotated labels for emotion classification [56,59]. In addition to the emotion classification, emotion intensity is also captured via the annotated data sets [52]. A more recent research study reports on the use of the stacked ensemble method for emotion intensity detection that enables the identification of expressions that denote the emotion intensity [60].

However, these approaches are focused on detecting sentiment or emotion from a social media post but do not focus on emotion modeling, which makes it possible to explore underlying changes of intensity, shifts, and patterns of change in emotions and to generate insights by linking to associated human behaviors [61]. The lack of labeled data for emotion detection is also a major drawback in using supervised machine learning approaches. Therefore, it requires a robust method to explore emotions in unstructured, voluminous social media data that does not require prior knowledge about the data. In this study, we use an ensemble of word embedding and NLU techniques to derive emotions from unlabeled social media conversations. As the foundation of the emotion analysis, we use Plutchik's model [50], which comprises eight basic emotions: anger, sadness, joy, trust, anticipation, fear, disgust, and surprise. The emotion classification is based on these eight emotions, and their intensities are mapped to show the strength of each emotion.

Methods

Data

Twitter conversations that were posted from January to September 2020 within Australia or an Australian context were extracted. Popular hashtags related to COVID-19 in Australia were used to query the data sources. Content by news channels and bots was identified by examining an unusual volume of data generated by each user and was eliminated from the analysis. This process yielded 73,000 public conversations by Twitter users in Australia. The extracted data were cleaned, preprocessed, and anonymized before being used in the analysis.

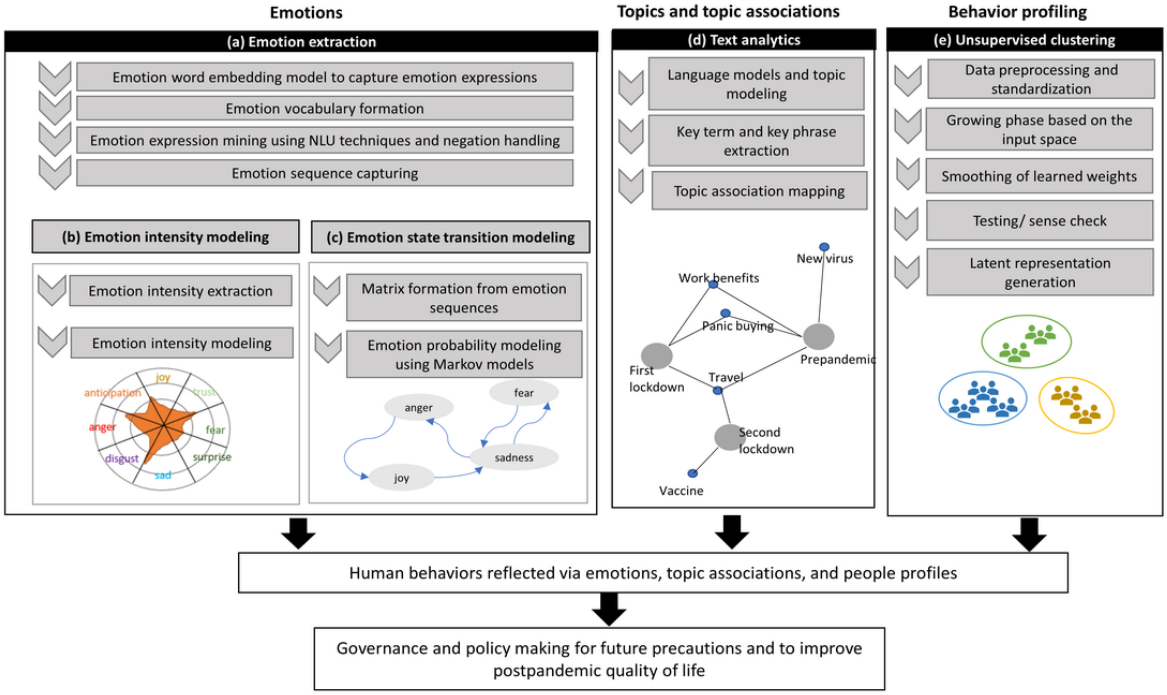
In order to identify different phases of the pandemic, the stages from Table 1 were formed to align with the timeline of the pandemic experience in Australia [62].

Figure 1 presents the high-level view and the workflow of the framework with the respective components.

Table 1. The four main phases of the COVID-19 pandemic from January to September 2020.

Time period (in 2020)	Phase
January to February	Prepandemic
March to May	First lockdown
June	Easing restrictions
July to September	Second lockdown

Figure 1. The high-level view and workflow of the artificial intelligence framework. NLU: natural language understanding.



Emotion Analysis

The emotion extraction, intensity generation, and emotion transition modeling process is shown in the emotions component of the architecture diagram in Figure 1 (a). The emotion analysis was conducted to represent the emotions of each stage as well as the temporal changes in emotions over time. The emotion extraction was carried out on chronologically ordered social media conversations in order to represent emotions over a conversation as a sequence of individual, single-post emotions. First, we trained a word2vec [63] word embedding model, which is a deep learning technique to create vector representations of textual data. This allows the positioning of semantically similar terms together, thereby enabling the finding of closely associated terms for each basic emotion. This querying process yielded a rich vocabulary for representing each emotion, from the basic emotions, which was used as the basis for emotion extraction.

Next, emotion negation was handled to fine-tune the extracted emotions. This process resulted in a sequence of emotions that denoted the chronologically ordered emotions and change of emotions over a conversation. The intensity of emotions in the four stages was used to model an intensity profile for each stage. We have used a modified intensity-capturing algorithm presented in Adikari et al [16] that accommodates the frequency and the presence of expressions that increase or inhibit the valence of the emotion. This allowed for the identification of prominent emotions and their differences in each stage, as seen in Figure 1 (b).

The temporal emotion analysis was conducted by modeling emotion transition models, which models the probabilities of emotion state changes over a course of time. Affective computing research suggests that basic emotions at a particular instance—represented by one post of a tweet in this application—can be regarded as discrete states, and the interactions among these can be modeled to represent the likelihood of the change in the state of emotions [64]. For this purpose, a mathematical model can be used to model the interactions between the emotion states. We have used the sequence of emotions at each stage to generate respective emotion transition models using Markov models [65,66], as seen in Figure 1 (c). The use of emotion transitions to capture individual and group emotions using social media conversations has been successful in a smart city context [17] and for analysis of mental health via online data sources [16]. We have applied this to model the emotion state transitions of each stage, which reflect the flow of emotions as the pandemic progressed.

Topic and Topic Association Analysis

The topic analysis was conducted based on a series of NLU techniques to capture topics of discussions from social media data, as seen in Figure 1 (d). The topics represent people's concerns and, therefore, encompass useful insights on their discourse patterns related to COVID-19 concerns. Outcomes of this analysis help in better interpreting the outcomes of the emotion analysis by providing contextual information for different emotion changes.

To conduct the topic analysis, the data set was first cleaned and processed in order to remove weblinks, stop words, news links, and repeating content generated by bots. This cleaned data set was then split into each stage and taken for the topic analysis. Given the large amount of content, an unsupervised topic modeling technique was used, which groups similar terms based on latent Dirichlet allocation [67]. Once the prominent topic clusters were identified, a trained word2vec embedding model and an automated keyphrase extraction algorithm [68] were used to identify similar topics and subtopics. The outcomes generated the most frequently mentioned terms as well as semantically prominent terms, which allowed us to understand a discrete topic from the terms. The analysis was conducted

separately for the four stages to understand which topics were prominent in each stage; thereafter, a topic association map was created to identify common topics across stages to demonstrate people's continuing concerns.

Behavior Profiling

Behavior profiling was conducted to identify different groupings of citizens in the community based on their emotions and concerns expressed over social media. Identification of such profiles can form a visualization of different profiles that exist in society. This representation is useful to better understand different citizen needs and can inform decision making for relevant authorities.

For profiling, we used an improved variant of the growing self-organizing map (GSOM) algorithm [69]. The GSOM presents a map topography that self-structures by adapting its size and shape based on the attributes and variations of input data. The GSOM algorithm utilizes competition and correlative learning based on the data provided. As input data are presented, nodes of the network compete among each other for ownership of the input, and the winners strengthen their relationships with this input. The competitive learning process is repeated for the complete data set for several cycles, and ultimately the map associates output nodes with patterns in the input data set. The GSOM acts as a knowledge map and can discard outdated information and overfitting of knowledge during the knowledge acquisition process [70,71] that allows the retention of relevant information only. The primary reason to incorporate such mature self-structuring AI was to discover hidden representations of behavior profiles based on their discourse and emotion patterns, which is otherwise challenging to interpret from a large amount of data. The ability of the GSOM algorithm to uncover patterns among data without prior training or supervision makes it possible to detect different groups of behaviors present among the citizens.

Ethics Statement

We have obtained ethics approval for this research from the La Trobe University Human Ethics Committee.

Results

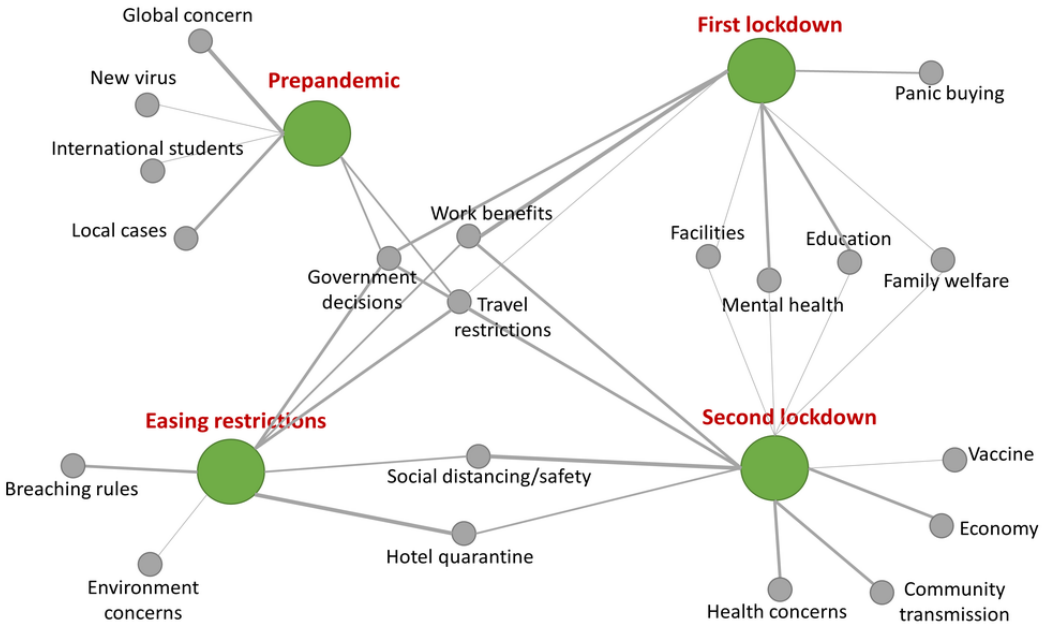
Topics and Topic Associations

Social media contains a high volume of expressions by individuals and groups alike. However, most of these expressions can be aggregated into a finite number of themes and topics [72]. We conducted a topic analysis and a topic association analysis to explore the distinct and common themes across the four stages of the pandemic. Table 2 presents the topics discussed during the four stages of the pandemic, from January to September 2020. The most prominent topics in each stage are presented in Table 2, where the quantitative measure indicates the weight of each topic based on the volume. The topics were also associated across stages as depicted in Figure 2. Key observations are that *government decisions* and *travel restrictions* were discussed during all four stages, and both lockdown stages expressed similar topics oriented toward lifestyle factors. These common topics included *education*, *mental health*, *family welfare*, and *facilities*. *Panic buying* was only mentioned during the first lockdown and was entirely absent during the second lockdown. During the easing restrictions stage, people mostly talked about *social distancing and safety* as well as *hotel quarantine*, which were common topics during the second lockdown as well. Apart from the common topics, the second lockdown mainly focused on *health care*, *community transmission*, *economy*, and *vaccine*. These denote that the conversations were more informed and regulated by the second lockdown. It should be noted that only conversations with prominent topics were included in the analysis and that general conversations have been omitted from the topic analysis. The outcomes of this analysis also aid in comprehending the emotions by providing contextual information related to each stage.

Table 2. Topics of discussion across the four stages of the pandemic.

Pandemic stage and main themes	Volume of conversations, n (%)
Prepandemic (n=15,302)	
Global concern	6021 (39.35)
Local cases	3522 (23.02)
Travel restrictions	2518 (16.46)
Government decisions	2127 (13.90)
International students	588 (3.84)
New virus	526 (3.44)
First lockdown (n=23,201)	
Work benefits	6116 (26.36)
Education	5832 (25.14)
Government decisions	3765 (16.23)
Travel restrictions	3069 (13.23)
Mental health	2568 (11.07)
Family welfare	1176 (5.07)
Facilities	413 (1.78)
Panic buying	262 (1.13)
Easing restrictions (n=11,801)	
Government decisions	2811 (23.82)
Travel restrictions	2700 (22.88)
Hotel quarantine	2294 (19.44)
Breaching rules	1554 (13.17)
Work benefits	1184 (10.03)
Social distancing and safety	925 (7.84)
Environment concerns	333 (2.82)
Second lockdown (n=16,198)	
Social distancing and safety	2910 (17.96)
Health care	2112 (13.04)
Work benefits	2046 (12.63)
Government decisions	1902 (11.74)
Community transmission	1793 (11.07)
Facilities	897 (5.54)
Economy	886 (5.47)
Hotel quarantine	867 (5.35)
Education	841 (5.19)
Family welfare	829 (5.12)
Mental health	489 (3.02)
Vaccine	381 (2.35)
Travel restrictions	245 (1.51)

Figure 2. Topic associations between the four stages of the pandemic.



Emotion Classification and Intensities

The AI approach used for the study of emotions expressed during the pandemic began with the classification of emotions, based on the widely cited psychological emotion model proposed by Plutchik [50]. Classification of emotions was followed by the quantification of the intensity of each of the eight emotions as they were expressed during the four stages.

The outcomes of the emotion analysis suggested that both *sadness* and *fear* emotions were the most intense during the prepandemic stages. This is indicative of the central emotional response during a pandemic being *fear* [2]. In addition, it is said that given the instinctive defensive systems for combating ecological threats, humans experience negative emotions resulting from a threat that can be contagious. The high intensity of *sadness* and *fear* identified during the announcement stage of the pandemic exhibits this emotional pattern. This behavior was also confirmed by the emotion transition model in this stage, where higher probabilities were observed for these emotions. Furthermore, *fear* is also associated with *panic*, where people act blindly and excessively out of self-preservation, possibly endangering the survival of others [2]; this was experienced via incidents like *panic buying*, where people unreasonably stocked up on essential items for impending self-isolation. The surfacing of fear and sadness emotions represents increased anxiety, which impacts people's mental health [73].

The temporal emotion analysis showed that, out of the negative emotions, *anger* and *disgust* were more strongly expressed toward the latter part of the pandemic due to the security breaches and restrictions. Terms such as "covidiot," "quarantine issues," "restrictions," and "another lockdown" were mostly mentioned in the Twitter conversations related to these emotions. This indicates that starting from the negativity of fear and sadness, public emotions have transferred to more anger and disgust at a later stage.

Positive emotion expressions were also captured by the analysis. It was noted that *joy* was more strongly expressed during the easing restriction stage and least during the second lockdown stage. This behavior aligned with real-world behaviors, as it was expected that people would express disappointment for having to experience another lockdown. The emotions *trust* and *anticipation* demonstrated higher intensities during the first lockdown and easing restriction stages; however, they have subsided over time (Figure 3).

We conducted a comparative study based on the two lockdown stages to identify the differences in emotion intensity (Table 3). The differences were compared using the Pearson chi-square test [74,75], and the confidence intervals were calculated based on the recommended method given by Altman et al [76]. A significance level of $P<.05$ was used to determine if the differences in the intensities were significant.

The comparison of negative emotions shows that, except for *sadness*, all other negative emotion intensities were significantly higher in the second lockdown ($P<.05$). This evidently demonstrates the increased disappointment and negativity of having to experience a second lockdown. The emotion *sadness* was persistent in both lockdowns.

The positive emotion comparison shows that, apart from *anticipation*, all other positive emotions were strongly expressed in the first lockdown ($P<.05$). This suggests that people had elicited more positive thoughts during the first lockdown compared to the second. The increase in the intensity of negative emotions and the reduction of positive emotions with further lockdowns confirm the increased levels of distress and deterioration of mental health. Based on this, relevant strategies should be initiated in order to eliminate the spread of negativity among people in further lockdowns.

Figure 3. Emotion intensity fluctuations over time.

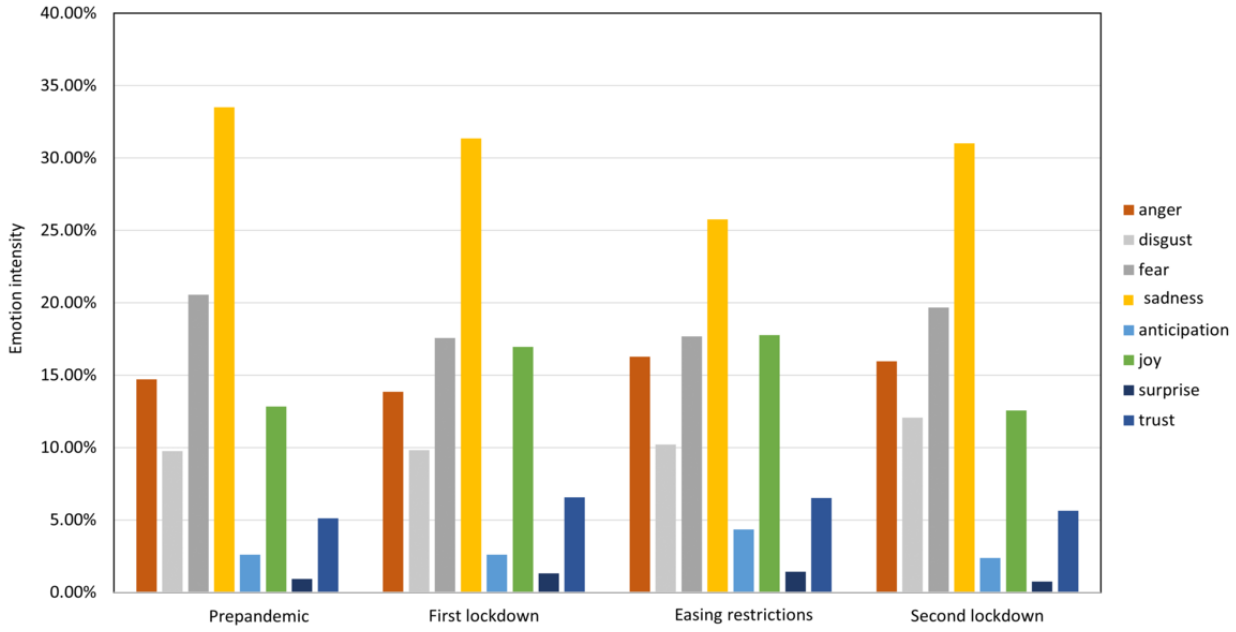


Table 3. Comparison of emotion intensities between the first and second lockdowns.

Emotion	Normalized emotion intensity during the first lockdown (n=36,317), %	Normalized emotion intensity during the second lockdown (n=10,604), %	Difference, % (95% CI)	*P* value
Negative emotions				
Anger	13.84	15.97	2.13 (1.3567 to 2.9218)	<.001
Sadness	31.36	31.01	0.35 (–0.6563 to 1.3461)	.49
Disgust	9.81	12.06	2.25 (1.5691 to 2.9518)	<.001
Fear	17.58	19.66	2.08 (1.2365 to 2.9399)	<.001
Positive emotions				
Joy	16.94	12.56	4.38 (3.6308 to 5.1097)	<.001
Surprise	1.32	0.74	0.58 (0.3662 to 0.7708)	<.001
Trust	6.56	5.63	0.93 (0.4108 to 1.4260)	<.001
Anticipation	2.59	2.37	0.22 (–0.1257 to 0.5406)	.21

Emotion Transitions

Mapping and quantifying the transition of emotions over conversations can be useful to predict the likelihood of emotion state changes as well as to observe temporal change in emotions and intensities over time. In a social media setting, this represents collective emotions in a community over time. The emotion state transitions were modeled separately for each stage, which enabled temporal analysis of emotions from the prepandemic stage to the second lockdown stage. For generating emotion transitions, the emotion space was defined as a set of discrete emotions—anger, fear, sadness, disgust, joy, anticipation, trust, and surprise—from the emotion extraction described earlier. Based on the temporal emotion sequence extracted from the emotion extraction module, a matrix was formed with the frequency of transitions of emotions from one state to another, and the matrix was used to create the emotion state transition diagrams shown in Figure 4; the shift and emergence of emotions are demonstrated via the arrows connecting the emotion states. The probabilities denote the likelihood of changed emotion states (Table 4).

Transitions at each stage demonstrate the temporal analysis of emotions during the pandemic. This emotion flow is useful when determining how people's emotions have changed over time. Health care practitioners and the government can use this information and analysis to understand the mental health status of the population.

Regarding the outcomes, it was observed that most of the emotion transitions involved the *sadness* state in the prepandemic stage. *Sadness to fear* was also prominent relative to other emotion changes. By the first lockdown, there was a shift toward positive emotions, as the emotion states *anticipation* and *joy* were seen to be prominent. This pattern deviated slightly

in the third stage, where positive emotions had amplified and negative emotions had reduced. The emotion propagation made a drastic change in the second lockdown, where positive emotion behaviors had decreased and negative emotions had been amplified, eliciting more tendencies toward *sadness*, *fear*, and *disgust*. This propagation of emotions denoted the emotion flow among people as they voiced their thoughts on social media.

The emergence and shift of emotions over different points in time were seen to be associated with the different stages across different time points in the COVID-19 pandemic. It is apparent that people experienced diverse emotions and had expressed them on social media reflecting their individual interests, opinions, and priorities. Further analysis was conducted using profiling techniques to investigate the intensity (ie, valence) of these emotions and the variation across different stages, which provided insights into who these people were and their priorities and opinions during the pandemic.

Figure 4. Emotion transitions of the four stages of the pandemic. Each arrow represents a transferring of one emotional state to another. The numbers on the arrows represent the likelihoods (ie, probabilities) of changed emotion states.

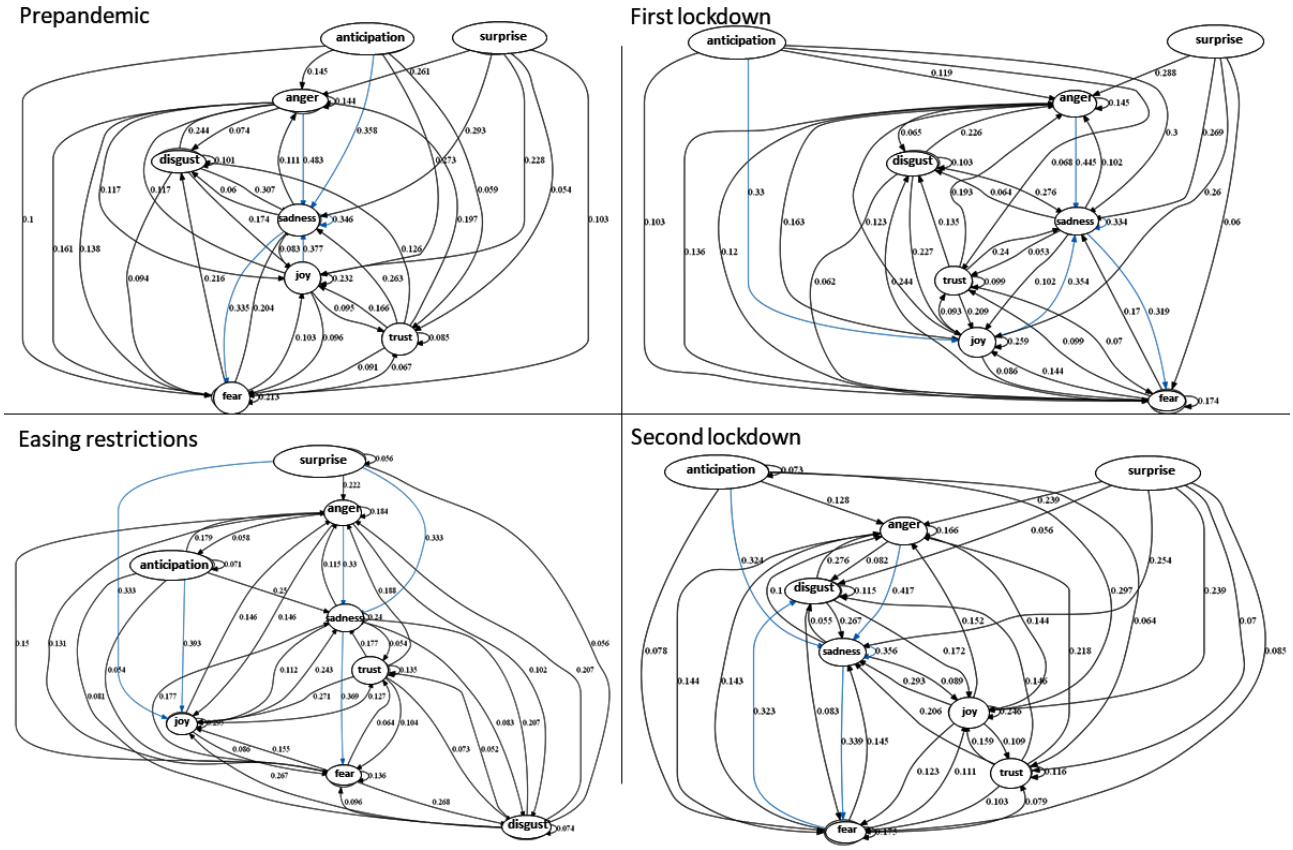

Table 4. Top five emotion transitions and probabilities for each pandemic stage.

Emotion transition	Probability
Prepandemic	
Anger → sadness	0.483
Joy → sadness	0.378
Anticipation → sadness	0.358
Sadness → sadness	0.346
Sadness → fear	0.335
First lockdown	
Anger → sadness	0.445
Joy → sadness	0.354
Sadness → sadness	0.334
Anticipation → joy	0.329
Sadness → anticipation	0.288
Easing restrictions	
Anticipation → joy	0.393
Surprise → joy	0.389
Sadness → fear	0.362
Anger → sadness	0.340
Joy → joy	0.295
Second lockdown	
Anger → sadness	0.417
Sadness → sadness	0.357
Sadness → fear	0.341
Anticipation → sadness	0.324
Fear → disgust	0.322

Group Profiles Based on Topics and Emotions

The GSOM algorithm was used to generate profiles of individuals based on topics and emotions. This enabled the identification of different clusters of citizens that existed within the community in terms of their concerns and emotions. Figures 5 and 6 illustrate the profiles identified for the period of the first and second lockdowns, respectively. Seven profiles were identified for the first lockdown based on the topics and emotions expressed by individuals, and they were labeled based on the most prominent topics that have been discussed. The profiles were (1) children's education, (2) family-oriented discussions, (3) work concerns, (4) panic buying, (5) lifestyle-oriented discussions, (6) travelers and traveling, and (7) higher education–focused discussions.

These profiles demonstrated a distinct focus in their conversations, which resulted in grouping those individuals together. Among these profiles, the *panic buying* cluster demonstrated higher levels of *fear*, whereas *sadness* was prominent in all clusters. In addition, the *family* cluster demonstrated more *joy*, which can be aligned with spending more time with family.

The second lockdown profiles shifted slightly from the profiles identified in the first lockdown. The identified behavior profiles were (1) government decisions, (2) health and mental health concerns, (3) community transmission, (4) safety measures, and (5) work concerns.

Compared to the first lockdown, the profiles of the second lockdown exhibited more negative emotions, where increased levels of negative emotions can be seen in health and mental health concerns. It is noteworthy to observe that the profiles formed in the second lockdown were more focused toward broader aspects of the pandemic when compared to the more lifestyle-oriented profiles in the first lockdown. This difference indicates that as the pandemic progressed, people's concerns shifted more toward broader aspects than concerns at the early stages, which may have been normalized with time.

Figure 5. Behavior profiles in the first lockdown. The mean strength of each concern is denoted as a blue line. GSOM: growing self-organizing map.

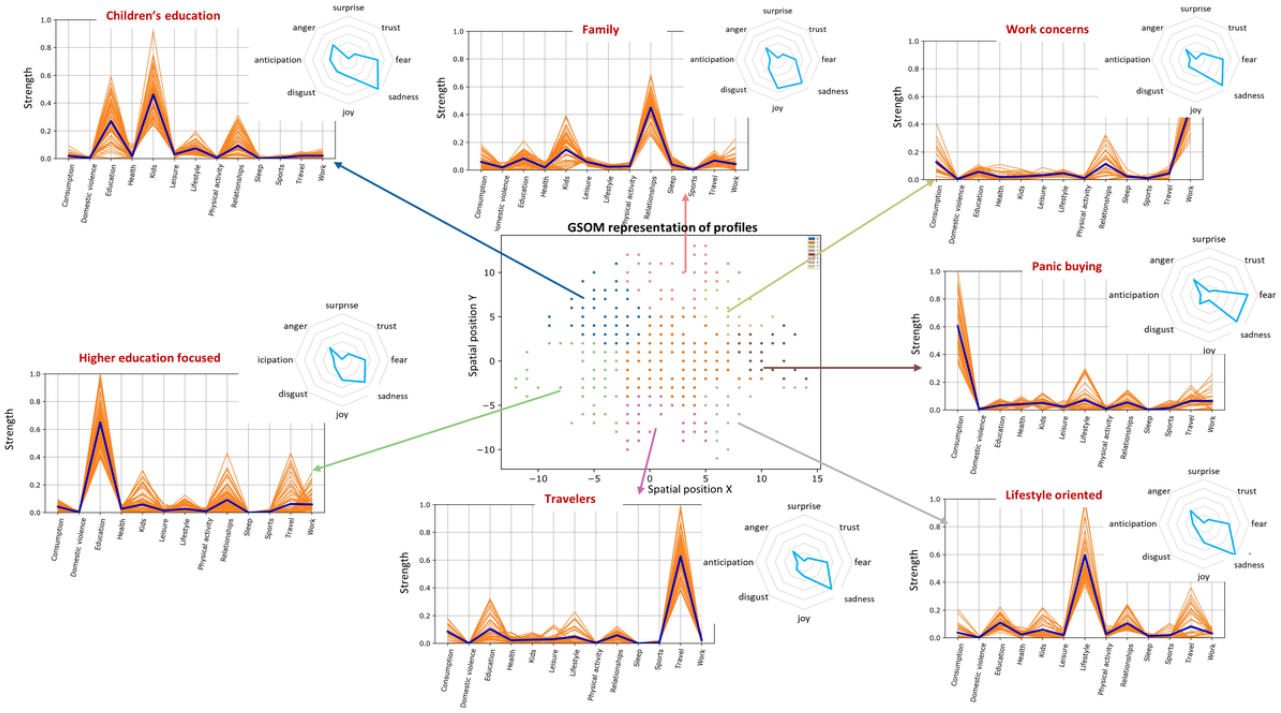

Figure 6. Behavior profiles in the second lockdown. The mean strength of each concern is denoted as a blue line. GSOM: growing self-organizing map.

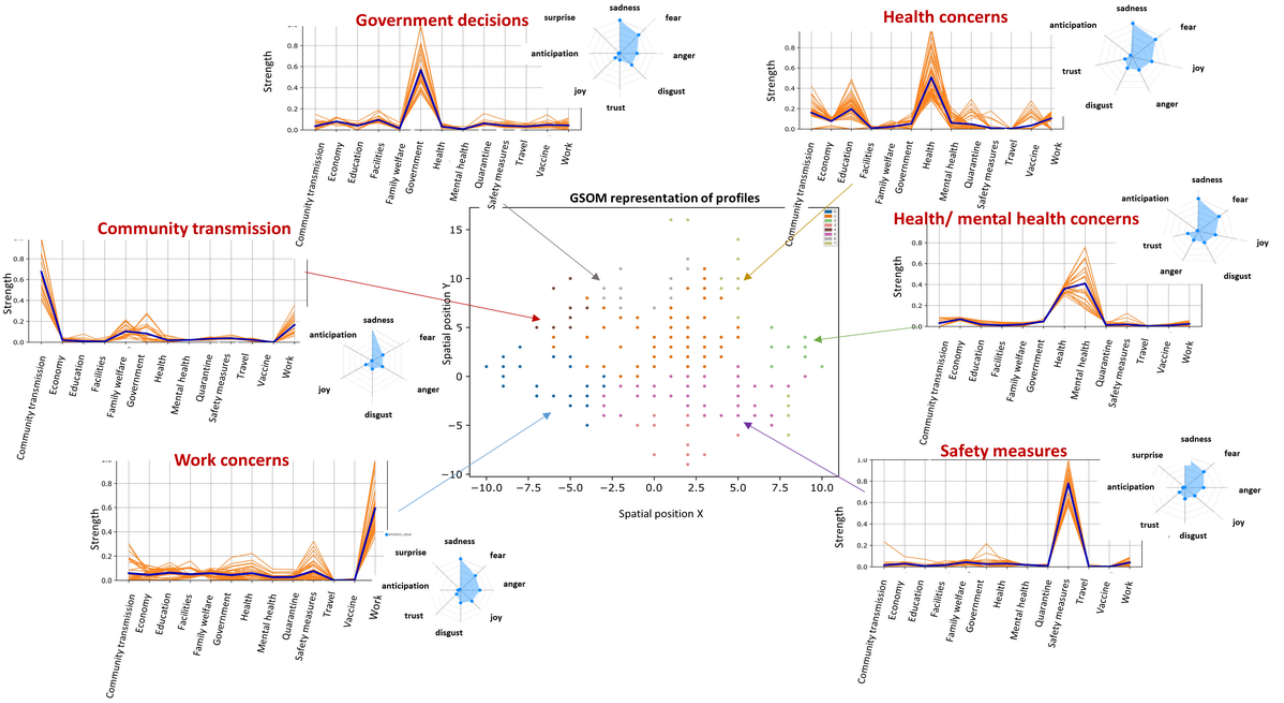

Discussion

Principal Findings and Implications

At a high level, the themes and topics that were seen at the individual level in the first stages of the pandemic had cascaded into broader and informed topics during the second lockdown. Individuals frequently discussed matters related to family, panic buying, and facilities during the first stage and transitioned into generic topics, such as the vaccine and economy, in the latter stages. Besides, several common concerns persisted over the course of time. Identification of such behaviors related to topics and topic associations from social media conversations can inform public health authorities regarding necessities and the issues that disrupt people's quality of life during this global pandemic. However, it is crucial to investigate the underlying emotions in these conversations to gauge the status of people's mental health.

Limitations and Future Work

One of the limitations of this study is the use of a single data source. As Twitter users are not representative of the whole of Australia, we believe that this could pose a limitation when modeling the emotions and concerns of the Australian population. However, given the importance of Twitter as a social media platform and the substantial amount of data retrieved (73,000 conversations), we were able to capture a broad cross-section of the community. As future work, the study could be extended by using multiple data sources, such as online forums and other social media channels. This will create a holistic view of the community. Moreover, the investigation could be conducted using data from another country, as this would provide different insights into how people have reacted toward different restriction measures and pandemic stages.

Comparison With Prior Work

Our findings regarding emotions are consistent with and align with public health studies related to the COVID-19 pandemic. The emergence of the *sadness* and *fear* emotions during the initial stages resemble the increased anxiety and depression faced by Australians in the first few months of the pandemic [31,32]. Past research indicates that public health emergencies often trigger negative emotions, as people tend to develop aversion, anxiety, and fear [77,78]. The emotion *fear* is often associated with such emergencies and pandemics, as it is one of the core emotions linked with survival. It has been reported that the human mind's instinctive defensive systems for combating ecological threats are often wired with negative emotions resulting from a threat that can be contagious [78]. Moreover, fear is also associated with panic behaviors, where humans act egoistically, endangering others' lives as well. These behaviors were captured via the emotion and topic analysis of this study, demonstrating that social media reflected people's underlying emotions and mental health concerns.

Studies investigating social media sentiments and topics during the pandemic align with our study [20,79,80]. In addition, our study provides an extension to the current body of COVID-19 social media research by modeling the emotion state transitions over time to represent the shift of emotions over time. The profiling of citizens based on emotions and concerns also enables the identification of clusters in the community during different stages of the pandemic. Recent research related to identifying the role of social media in the COVID-19 pandemic suggested further exploration of how social media can be utilized to inform health care practices [23]. We believe that our study contributes to providing outcomes that can enhance health care practices related to community understanding and uplifting of mental health care during a similar crisis.

Conclusions

As the entire world is still grappling with the direct or indirect effects of the COVID-19 pandemic, it is pertinent that we explore and analyze human emotions and related expressions in order to aid postpandemic recovery, as well as to prepare for future crises. Given the current social isolation settings, people are experiencing increased mental health issues and emotion changes that are affecting their quality of life [81,82]. During times of social isolation, the abundance of data available in digital spaces provides a reflection of people's behaviors, which is otherwise challenging to assess via clinical trials or interviews. This enables emotion analysis using digital spaces to act as an adjunct to real-world behavior analysis [83].

This study focused on capturing human emotions and concerns, which were reflected through social media conversations as the COVID-19 pandemic progressed. Our work is targeted at detecting and helping to understand the underlying mental health– and well-being–related issues via emotions expressed and topics discussed on social media by different segments of society. Although prevention of spread with social distancing and masking, as well as attempts at the elimination of COVID-19 with vaccine programs, have been widely discussed, less attention has been paid to the less visible issue of emotional distress and mental health. Governments and health care organizations are now realizing the deep and long-term effects of these issues; funding is being allocated to address these issues and programs for understanding the implications are now being established [81]. The work described here is focused on this less discussed area. We proposed an AI-based approach and designed and developed a supporting technical framework to learn about the emotion and content representations from unstructured, voluminous social media data, which are otherwise challenging to assess manually. The outcomes from this study aligned with theories of social sharing, emotional responses during pandemics, and collective emotion theories, and they represent insights that can be used to improve the mental health of citizens.

The outcomes of the emotion analysis demonstrated a high intensity of fear and sadness emotions during the announcement stage of the COVID-19 pandemic, and the emotion transition model also demonstrated higher probabilities of expressing fear and sadness during the prepandemic stage among Australian citizens. Noteworthy insights were produced as the outcomes of the temporal emotion analysis. The emotion transition models across the pandemic demonstrated how the emotions had changed over time. It was noted that, although fear and sadness emotions were more prominent over the first few months, they had eventually transitioned into anger and disgust as people expressed their dissatisfaction and frustration with the continuing pandemic and restrictions. The temporal emotion analysis during the pandemic using emotion transition models was one of the main contributions of this study, as it demonstrates how people's emotions change over time. On the other hand, positive emotions such as trust and anticipation were observed in the first lockdown and easing restrictions stages; however, they had diminished over time as the pandemic progressed. This *emergence and shift* of different emotions is a strong indicator of people's varying emotions, and it signals the underlying mental health of the population. The decreased intensity of sadness and fear in the latter stage showed the normalization of emotions as people tended to realize the nature of the pandemic. However, the increased emotion transitions toward anger and disgust as well as broader concerns represented the dissatisfaction toward the management of the pandemic. These emotion behaviors presented insights into people's emotions, which were challenging to quantify and measure using

traditional surveys or clinical trials, given the social isolation settings. Social media has been effective in helping us understand human emotion expressions during times of crisis, and it can be utilized to improve health care practices in similar crises.

On the other hand, emotions expressed on social media can be contagious, as negative content attracts more attention and propagation on social media [84,85]. The increased intensity of negative emotions and the persistence of negativity over time that was captured across different stages in this study aids this phenomenon. Negative emotions were observed in both first and second lockdowns and were significantly higher during the second lockdown. Therefore, it is crucial to observe this negative content to avoid further escalation. These swirls of emotions generated at one point in time have the ability to propagate through time using social media as the medium, as social media holds the potential for cascading and going viral to transmit emotional content more rapidly and broadly than other media [86,87]. These behaviors can also be aligned with the social sharing of emotion, which states that collective emotional events are anticipated to trigger a social process of emotion propagation [12]. It has been stated that emotion strength, presence, and valence can affect and influence citizen engagement through social media; therefore, it is imperative to moderate and monitor such emotional behaviors on digital platforms [88]. As potential implications, the proposed emotion behavior analysis in the study can be used to moderate online negativity and even detect distress among people during the pandemic to uplift their mental health as well as in postpandemic times as measures of precautions.

Another key observation of this study was the profiling of people based on similar emotions and thematic expressions on social media. It was observed that while certain groups of people were more enthused about family matters, some groups expressed more concerns related to employment issues. The deviation of profiles from the first lockdown to the second lockdown also shows how the identified profiles took different shapes depending on the concerns at that point in time. Such behavior profiling enables the understanding of different groups of people with different concerns and emotions. Such groups elicit significant insights and enable us to look at the community from different perspectives. Based on these behavior changes, governance and health care policy-making practices could be tailored to consider different groups of concerns emerging from different sectors within the community. Insights can also inform future planning to uplift citizens' mental health during disastrous events similar to the current pandemic.

Apart from the aforementioned implications, one of the key outcomes of this study was to showcase the applicability and capability of using social media conversations to identify, analyze, and understand human behaviors at scale during a global crisis. Digital avatars created in social media have become a derivative of reality. This study showcases that in the age of social media, it is helpful, or even essential, to study human behaviors and emotions using their digital representations.

Abstract

Background: With the rapid growth of the older adult population worldwide, car accidents involving this population group have become an increasingly serious problem. Cognitive impairment, which is assessed using neuropsychological tests, has been reported as a risk factor for being involved in car accidents; however, it remains unclear whether this risk can be predicted using daily behavior data.

Objective: The objective of this study was to investigate whether speech data that can be collected in everyday life can be used to predict the risk of an older driver being involved in a car accident.

Methods: At baseline, we collected (1) speech data during interactions with a voice assistant and (2) cognitive assessment data—neuropsychological tests (Mini-Mental State Examination, revised Wechsler immediate and delayed logical memory, Frontal Assessment Battery, trail making test-parts A and B, and Clock Drawing Test), Geriatric Depression Scale, magnetic resonance imaging, and demographics (age, sex, education)—from older adults. Approximately one-and-a-half years later, we followed up to collect information about their driving experiences (with respect to car accidents) using a questionnaire. We investigated the association between speech data and future accident risk using statistical analysis and machine learning models.

Results: We found that older drivers (n=60) with accident or near-accident experiences had statistically discernible differences in speech features that suggest cognitive impairment such as reduced speech rate (P=.048) and increased response time (P=.040). Moreover, the model that used speech features could predict future accident or near-accident experiences with 81.7% accuracy, which was 6.7% higher than that using cognitive assessment data, and could achieve up to 88.3% accuracy when the model used both types of data.

Conclusions: Our study provides the first empirical results that suggest analysis of speech data recorded during interactions with voice assistants could help predict future accident risk for older drivers by capturing subtle impairments in cognitive function.

Introduction

As the world's older adult population increases, car accidents involving older adults have become an increasingly serious social problem. While it has been reported that older drivers have an increased risk of car accident involvement per unit distance travelled [1-4], they also showed a substantially higher rate of serious injury than that of middle-age car drivers [5,6].

Even in normal aging, there is a decline in many cognitive abilities related to driving, and this cognitive decline is known to be one of the risk factors for older adults being involved in car accidents [7-9]. Associating cognitive assessment scores with either self-reported car accidents, crash records, or on-road driving measures has been investigated to identify predictors of driving safety (in previous empirical studies [7]). In particular, cognitive abilities such as visual attention, short-term memory, and executive functions (evaluated with neuropsychological tests) were consistently shown to have associations with driving safety [7,10-12]. In this respect, if cognitive impairments relevant to driving safety in older adults can be inferred solely from behavior data in everyday situations in a passive way, this would be beneficial for accident prevention.

Speech in daily life can be used a potential data sources for determining cognitive impairments related to driving safety. Speech involves multiple interacting cognitive abilities including attention, memory, and executive functions [13,14]. Many empirical studies have used speech data to identify cognitive impairments resulting from aging and diseases such as Alzheimer disease [15-18] and characterized speech changes related to cognitive impairments by extracting linguistic and paralinguistic features from speech data [19-25]. For example, difficulties with word finding and word retrieving have been quantified by tallying pronoun frequency and pause durations [19,20,24,26-28]. A reduction in speech expressiveness has also been quantified by measuring lexical diversity and speech rate [19,23,29-31]. Using a combination of these features, previous studies [19-25,29] have succeeded in differentiating individuals with cognitive impairments from healthy controls. Although no study has investigated the relationship between speech data and driving safety, it is reasonable to explore the possibility that speech data could be used for inferring ability to drive safely from changes in cognitive functioning in older drivers.

At the same time, there is growing interest in using speech data that can be collected in everyday situations for applications in health care owing to the popularity of voice-based interaction systems such as voice assistants in smart speakers and smartphones [32-34]. One approach is to provide various types of voice-based tests via a smart-speaker platform. For example, previous studies [35,36] have used mobile apps for collecting speech responses to neuropsychological tasks such as verbal fluency and picture description tasks; they showed accurate classification rates in detecting patients with Alzheimer disease [35] and dementia [36]. Another approach is to analyze health-related insights from speech data collected during daily voice-based interactions. For example, vocal characteristics in speech data during typical tasks on smart speakers appeared to be associated with neuropsychological test scores [37], while linguistic features extracted from phone conversation data were significant indicators for differentiating patients with Alzheimer disease from older adults with normal cognition [38]. This approach, focusing on speech data that can be collected in everyday situations, would increase opportunities for frequent assessment by facilitating passive and unobtrusive monitoring.

In this study, we aimed to investigate the relationship between speech data and future driving experiences related to car accidents in healthy older adults by collecting speech data during interactions with a voice assistant with simulated tasks on smart speakers and smartphones. We hypothesized that these speech data could be used for predicting accident risk for older drivers.

Methods

Participants

We recruited healthy older adults aged 60 years or older through recruiting agencies and advertisements in the local community in Ibaraki, Japan. All examinations were conducted in Japanese. Older adults met the inclusion criteria if they were in good physical and mental health and had no serious diseases, disabilities, mental illness (eg, major depression, bipolar disorder, and schizophrenia), or neurodegenerative diseases (eg, Parkinson disease and dementia). This study was conducted with the approval of the University of Tsukuba Hospital Ethics Committee (H29-065). All participants provided written consent after the procedures of the study had been fully explained.

A total of 71 older individuals participated in the cognitive assessments and speech data collection (women: 38/71, 53.5%; age: range 61-80 years, mean 71.1, SD 4.9). Of the original 71 participants, 60 consented to the follow-up study about their driving experiences (women: 33/60, 55.0%; age: range 61-80 years, mean 70.8, SD 5.1; Table 1). They were contacted again approximately one-and-a-half years after the speech data collection (mean 17.3 months, SD 2.7) and answered a questionnaire on their driving experiences within the past year. The questionnaire included free-form questions about accidents and near accidents; *near accidents* were described as infractions and any other incidents while driving that they deemed to be dangerous regardless of severity and culpability.

Table 1. Demographic and assessment data for study participants.

Variable	Total (N=60)	Individuals without accident or near-accident experiences (n=34)	Individuals with accident or near-accident experiences (n=26)	*P* value
Age (years), mean (SD)	70.8 (5.1)	70.5 (4.9)	71.3 (5.3)	.45
Education (years), mean (SD)	13.7 (2.2)	13.7 (2.2)	13.6 (2.1)	.93
Sex, n (%)				.53
Men	27 (45)	17 (50)	10 (38)	
Women	33 (55)	17 (50)	16 (62)	
Mini-Mental State Examination[a], mean (SD)	27.6 (1.8)	27.4 (1.8)	27.9 (1.8)	.28
LM IA[b], mean (SD)	9.6 (3.8)	9.1 (3.7)	10.2 (4.0)	.43
LM IIA[c], mean (SD)	7.5 (3.6)	7.3 (3.7)	7.6 (3.6)	.74
Frontal Assessment Battery[d], mean (SD)	13.7 (2.7)	13.4 (2.7)	14.2 (2.7)	.45
Trail making test-part A (seconds), mean (SD)	33.2 (9.8)	33.6 (9.7)	32.6 (10.1)	.72
Trail making test-part B (seconds), mean (SD)	89.5 (49.7)	95.7 (60.9)	81.3 (28.2)	.71
Clock Drawing Test[e], mean (SD)	6.7 (0.8)	6.7 (0.7)	6.7 (1.0)	.36
Geriatric Depression Scale[f], mean (SD)	2.9 (2.4)	2.8 (2.4)	3.1 (2.4)	.62
Severity scores for atrophy in medial temporal structures, mean (SD)	0.9 (0.6)	0.8 (0.4)	0.9 (0.7)	.86

[a]The total possible score ranges from 0 to 30.

[b]LM IA: immediate recall of the logical memory-story A of the Wechsler memory scale-revised for episodic memory; the total possible score ranges from 0 to 25.

[c]LM IIA: delayed recall of the logical memory-story A of the Wechsler memory scale-revised for episodic memory; the total possible score ranges from 0 to 25.

[d]The total possible score ranges from 0 to 18.

[e]The total possible score ranges from 0 to 7.

[f]The total possible score ranges from 0 to 15.

Cognitive Assessments

Cognitive assessments and examinations were those typically used for the diagnosis of dementia and comprised 12 variables: age, sex, education, 7 neuropsychological test scores (Mini-Mental State Examination for global cognition; immediate and delayed recall of the logical memory-story A of the Wechsler memory scale-revised for episodic memory; the Frontal Assessment Battery for executive function; the trail making test-part A and B for executive function and attention; and the clock drawing test for visuospatial function), and 2 clinical scores (Geriatric Depression Scale and the severity of medial temporal lobe atrophy). The severity of medial temporal lobe atrophy was evaluated using structural magnetic resonance imaging (MRI) scans—1.5 T, T1-weighted images and a 3D gradient-echo sequence—with the following parameters: sagittal orientation with 1.2-mm thick sections; time repetition/time echo: 2400/3.52 milliseconds; flip angle: 8°; field of view: 192×192. We expressed the severity of medial temporal lobe atrophy as a *Z* score relative to cognitively healthy adults by using a standalone, voxel-based specific regional analysis system for Alzheimer disease [39]. Two psychiatrists (KN and TA) reviewed the results of the cognitive assessments and confirmed that participants did not meet the criteria for dementia based on those of the National Institute on Aging and Alzheimer's Association and Alzheimer disease Neuroimaging Initiative 2 [40].

Speech Data Collection

We simulated conversations with a voice assistant on modern smart speakers and smartphones and collected the speech data while performing 3 typical task scenarios: information retrieval (asking for tomorrow's weather), shopping online (booking a movie ticket), and personal schedule management (creating a calendar event). The tasks began with a simple scenario and then advanced to the more complicated ones. Each task started with an initiating question from the system ("what can I help you with?"), with follow-up questions that asked for detailed information related to the task. The follow-up questions were presented in a fixed order. The questions consisted of four categories—open-ended, to which participants responded with a free-form sentence (Multimedia Appendix 1: Table S1); multiple choice, to which participants responded by choosing one of the options stated in the question; prepared input, to which participants responded with information (eg, passcode) specified by the experimenter; and confirmation, to which participants responded by accepting or rejecting a statement made by the system. The system presented at least 22 questions in total to each participant for the 3 tasks.

To simulate conversations, we took a Wizard-of-Oz [41] approach, in which the participants were told that they were talking with a computer system, though in fact the interaction was mediated by an experimenter (ie, the wizard). We chose this approach so that we could avoid uncertain factors such as errors in automatic speech recognition. During the tasks, the experimenter made the system present a question. After the participant responded, the experimenter prompted the system to move onto the next question if the response contained the necessary information corresponding to the question; otherwise, they would repeat the same question. Each open-ended, multiple choice, and prepared input question presented by the system was scripted in advance and the same for all participants. For confirmation questions, we prepared several variations for each question and the experimenter chose one, depending on the participant's previous response. For example, the experimenter chose "you are purchasing one ticket, is it OK?" or "you are purchasing two tickets, is it OK?" to have the participant confirm the number of tickets to book.

The interface for speech data collection was implemented as a tablet-based app on an Apple iPad Air 2. In the experiment, participants sat down in front of the tablet and talked with the system (Figure 1a). During the tasks, the tablet showed a screen indicating whether it was speaking (Figure 1b) or listening (Figure 1c). The experimenter sat behind the participant and operated the system by using a separate interface hidden from the participants. Speech data were recorded in raw format with a sampling rate of 44.1 kHz through the embedded microphone in the tablet. Each experimental session took approximately 30 minutes per participant, including instructions and wrap-up. Additional details about our apparatus and procedure have been previously published [37].

Figure 1. Overview of experimental setup: (a) setup for collecting speech data, (b) screen showing participant's turn, and (c) screen showing the tablet's turn.

Data Analysis

From each participant's speech data, we automatically extracted 84 paralinguistic speech features used in previous studies on inferring cognitive impairments and detecting early signs of Alzheimer disease [19,20,23,27-29,31,42,43]. They consisted of 56 acoustic features and 28 prosodic features.

The acoustic features consisted of features related to mel-frequency cepstral coefficients (MFCCs), jitter, and shimmer. We used the mean and first-order derivatives of the first 12 MFCCs, which represent the short-term power spectrum of the speech signal. Jitter and shimmer features measure cycle-to-cycle variations of fundamental frequency and amplitude [44]. Prosodic features included speech rate, pitch variability, phonation time, number of phonemes needed for completing tasks, response time, total pause duration, and proportion of long pauses (pauses >0.8 seconds). Both acoustic and prosodic features were extracted from each task's speech data separately. We used Python (version 3.8) audio-processing libraries (librosa, version 0.8.0 [45]; Signal_Analysis, version 0.1.26 [46]).

Statistical analyses were performed using Statistics and Machine Learning Toolbox (version 11.1) for MATLAB (version R2017a, The MathWorks Inc) environment. To assess the differences in each variable between participants with and without accident or near-accident experiences, we used 2-sided Mann-Whitney tests for continuous data and chi-square tests for categorical data. We did not correct for multiple comparisons, and *P* values <.05 were considered significant.

The prediction models for differentiating individuals with and without accident or near-accident experiences were built using multiple types of binary classifiers with automatic sequential forward selection of features. Model performance was evaluated with both leave-one-subject-out cross validation and 100 iterations of 10-fold cross-validation methods. The classifiers included *k*-nearest neighbors [47], random forest [48] and support vector machine [49]. The parameters that we studied were as follows: the number of neighbors for the *k*-nearest neighbors; the number and the maximum depth of trees for random forest; kernel functions, penalty parameter, and the parameter associated with the width of the radial basis function kernel for the support vector machine. We performed an exhaustive grid search to determine these parameters. The algorithms were implemented using the Python scikit-learn package (version 0.23.2).

Results

For speech data collection (the 30-minute sessions), we obtained an average of 23.8 responses within 100.2 seconds (SD 28.6) from each participant. The average response duration of each task scenario ranged from 17.4 to 59.6 seconds (mean 33.41, SD 9.5). The average duration of a single response for each participant ranged from 1.1 to 7.6 seconds (mean 4.2, SD 1.1). At follow-up, 26 of the 60 participants (43.3%) reported car accident or near-accident experiences within the previous year.

Of those, 23 participants reported a near-accident experience, 2 reported accidents, and 1 reported both. The near-accidents consisted of near-misses with a car or pedestrian resulting in a sense of fear and anxiety (eg, from failure to notice a crossing pedestrian), errors in operation (eg, stepping on the accelerator instead of the brake), and unintentional violations (eg, entering the opposite lane).

In comparisons between individuals with and without accident or near-accident experiences, there were no significant differences in any cognitive assessment variables (age: P=.45; education year: P=.93; sex: P=.53; Mini-Mental State Examination: P=.28; immediate and delayed recall of the logical memory-story A of the Wechsler memory scale-revised: P=.43, P=.74; the Frontal Assessment Battery: P=.45; the trail making test-part A and B: P=.72, P=.71; the clock drawing test: P=.36; Geriatric Depression Scale: P=.62; severity scores for atrophy in medial temporal structures: P=.86; Table 1); however, we found 10 speech features with significant differences—$\Delta MFCC_1$: P=.005, $\Delta MFCC_4$: P=.043, $\Delta MFCC_5$: P=.011, $\Delta MFCC_7$: P=.035, $\Delta MFCC_{12}$: P=.023; jitter: P=.034; response time: P=.040; proportion of long pauses: P=.044; speech rate: P=.048; and number of phonemes needed for completing tasks: P=.049 (Figure 2; Multimedia Appendix 1: Table S2). Those with accident or near-accident experiences showed decreased speech rate and jitter as well as increased response time and long pauses. These speech features were reported in previous studies as significant indicators of changes in cognitive function, and the trends in their changes were consistent with those observed in individuals with cognitive impairments and patients with Alzheimer disease and mild cognitive impairment (for speech rate [23,27,31]; for jitter [42,43]; for response time [20,27]; for proportion of long pause [27,28]).

To visualize whether the variance seen among a variable set is capable of discriminating between individuals with and without potential future accident or near-accident experiences, we performed principal component analysis on 2 variable sets: the 12 cognitive assessment variables and 10 speech features (Figure 3). The cognitive assessment variable set had little capability to differentiate the groups; there was considerable overlap and no clear separation. In contrast, the speech variable set enabled some separation of the groups.

Input variables for the classification models were either or both the 12 cognitive assessment variables and 10 speech features. When model performance was evaluated with leave-one-subject-out cross-validation, with only the cognitive assessment variables, we obtained 75.0% accuracy (65.4% sensitivity, 82.4% specificity, and 69.4% F1 score; Figure 4a), with only the speech features, the model accuracy increased to 81.7% accuracy (65.4% sensitivity, 94.1% specificity, and 75.6% F1 score; Figure 4b), and with speech features and cognitive assessment variables combined, performance improved further (88.3% accuracy, 88.5% sensitivity, 88.2% specificity, and 86.8% F1 score; Figure 4c). When we evaluated the model using 10-fold cross validation, the results showed similar trends (Multimedia Appendix 1: Table S3): the model using the cognitive assessment variables achieved 75.5% accuracy (95% CI 75.1-75.9), the model using speech features achieved 80.1% accuracy (95% CI 79.7-80.5), and the model using both types of features achieved 85.5% accuracy (95% CI 85.1-85.9).

Figure 2. Box plots (line and diamond represent median and mean, respectively) for speech features with significant differences between individuals with and without accident or near-accident experiences—jitter: P=.034; response time: P=.040; speech rate: P=.048.

Discussion

Principal Results

In light of the increasing demand for preventing car accidents involving older adults, we investigated the possibility that future accident risk related to cognitive impairments could be automatically predicted with passive unobtrusive monitoring. To this end, we focused on speech data because many previous studies have succeeded in quantifying and detecting cognitive impairments from speech data [19,20,23,27-29,31,42,43], speech data are becoming more accessible, and voice-based interaction systems such as voice assistants are becoming more popular [32-34].

The statistical analysis showed that the speech data collected during typical tasks on smart speakers and smartphones had statistically discernible speech features between older drivers with and without accident or near-accident experiences. These speech features indicated that older drivers with these experiences tended to show decreased speech rate and jitter as well as increased response time and long pauses. These changes in speech features were reported as statistically significant signatures for cognitive impairments by previous studies on patients with Alzheimer disease and mild cognitive impairment [19,20,23,27-29,31,42,43]. The results suggest that speech features could capture subtle impairments of cognitive function in older drivers. On the other hand, we found no differences in any cognitive assessment variables, but this could be explained by the criteria for driving risks that differed from those in previous studies [7,10,12,50-53]. While previous studies compared older drivers with and without car-accident experiences regardless of having near-car-accident experiences and reported significant differences in cognitive assessment scores between them [7,10,12,50-53], we focused on both accident and near-accident experiences, and the majority of the high-risk group in our study were individuals with near-accident experiences but without actual car accidents. Speech data and cognitive assessment results suggest that eliciting discernible changes relevant to future near-accident experiences may require cognitive assessment for subtle impairments, such as, test batteries used for screening preclinical Alzheimer disease [54,55]. Even so, if speech data during interactions with voice assistants can be used for predicting future accident risk, it would greatly increase the accessibility of early screening with a relatively low burden.

The classification model using speech features achieved 81.7% accuracy, which is 6.7% higher than that using cognitive assessment data, and models achieved up to 88.3% accuracy with both combined. Dimensional reduction and visualization using principal component analysis, an unsupervised method, showed that the feature space with speech data was better able to separate those with and without accident or near-accident experiences than the feature space with cognitive assessment variables. These results and those of the statistical analysis indicate that speech data during typical tasks with voice assistants could have comparable (or possibly more) information for predicting future accident risks of older drivers compared with the standard cognitive assessments.

Our results show paralinguistic speech characteristics were useful for predicting future accident risks of older drivers. Previous user-interface studies reported that voice input was effective and was preferable as an input modality for older adults [56-58], while other studies reported that the performance of automatic speech recognition tended to be worse in older adults than in other age groups [59,60]. From this perspective, our results suggest that models for predicting future accident risks of older drivers can be made robust against errors of automatic speech recognition by exploiting paralinguistic features.

Our results highlight the possibility that cognitive impairments related to future car accident risks could be detected using speech data collected in everyday life. Assistive and automated driving systems are promising technologies that may help older adults with cognitive challenges to safely continue driving [61]. Recent studies suggested the importance of individual differences in cognitive abilities for assistive and automated driving technologies for older adults [62,63] because literature has suggested that cognitive abilities affect both performance with automated technology and perceptions of automation (ie, trust) [64,65]. Hence, our approach to detect cognitive impairments associated with driving risks might provide useful information for the personalization of assistive and automated driving systems based on the cognitive abilities of older adults.

Limitations

Our work had several limitations. First, we collected speech data in a lab setting. The controlled setting might affect the way people interact with a voice assistant. In future work, data collection in free-living situations using voice assistants would be needed along with additional interaction scenarios. Second, the sample size was limited. In spite of this limitation, our statistical analysis of speech features showed consistent trends indicating subtle cognitive impairments in older adults with future accident or near-accident experiences, and the prediction performance (to predict independent future accidents) using speech features was as high as 88%, even when the classifier was trained on a subsample. From these perspectives, we believe

that our results can be confirmed by future studies. Third, our definition of future car accident risks was based on self-reports of accident and near-accident experiences. In future work, we need to consider obtaining more objective measures for accident risks by combining self-reports with on-road driving assessments, informant reports, or drive recorder videos.

Conclusion

Given the increasing demand for car accident prevention involving older adults, we explored the possibility of predicting future accident risks associated with cognitive impairments by using behavioral data that can be collected in everyday life. To this end, we focused on speech data collected during interactions with voice assistants in smart speakers and smartphones and investigated the associations with future accident risks by following up with older drivers. We found that (1) older drivers with accident or near-accident experiences had statistically discernible changes in speech features, implying cognitive impairments, and (2) the machine learning model using speech features could predict future accident or near-accident experiences with up to 88.3% accuracy. Although further studies with speech data collected in everyday life and objective data for near-accidents are needed, our study provides the first empirical results suggesting that speech data during interactions with voice assistants in smart speakers and smartphones could help predict future accident risks of older drivers by capturing subtle impairments in cognitive function. We believe that our results can be used in future efforts toward preventing driving accidents of older adults through continuous passive unobtrusive monitoring.

Abstract

Background: Voice-controlled intelligent personal assistants (VIPAs), such as Amazon Echo and Google Home, involve artificial intelligence–powered algorithms designed to simulate humans. Their hands-free interface and growing capabilities have a wide range of applications in health care, covering off-clinic education, health monitoring, and communication. However, conflicting factors, such as patient safety and privacy concerns, make it difficult to foresee the further development of VIPAs in health care.

Objective: This study aimed to develop a plausible scenario for the further development of VIPAs in health care to support decision making regarding the procurement of VIPAs in health care organizations.

Methods: We conducted a two-stage Delphi study with an internationally recruited panel consisting of voice assistant experts, medical professionals, and representatives of academia, governmental health authorities, and nonprofit health associations having expertise with voice technology. Twenty projections were formulated and evaluated by the panelists. Descriptive statistics were used to derive the desired scenario.

Results: The panelists expect VIPAs to be able to provide solid medical advice based on patients' personal health information and to have human-like conversations. However, in the short term, voice assistants might neither provide frustration-free user experience nor outperform or replace humans in health care. With a high level of consensus, the experts agreed with the potential of VIPAs to support elderly people and be widely used as anamnesis, informational, self-therapy, and communication tools by patients and health care professionals. Although users' and governments' privacy concerns are not expected to decrease in the near future, the panelists believe that strict regulations capable of preventing VIPAs from providing medical help services will not be imposed.

Conclusions: According to the surveyed experts, VIPAs will show notable technological development and gain more user trust in the near future, resulting in widespread application in health care. However, voice assistants are expected to solely support health care professionals in their daily operations and will not be able to outperform or replace medical staff.

Introduction

Overview

With their expanding capabilities, voice-controlled intelligent personal assistants (VIPAs), such as Amazon Echo and Google Home, profoundly change the way people interact with technology [1]. Using natural language processing (NLP) or natural language understanding (NLU), as well as cloud data storage, VIPAs can process nearly any human request in real time, mimicking natural human communication [2]. Following the recent *Dr Google* phenomenon [3], conversational agents

have quickly become a source of knowledge for health-related requests, providing information on various physical and mental health conditions [4]. Over the past years, advances in machine learning, particularly in neural networks, have enabled voice-based technologies to assist health professionals during medical consultation [5], provide diagnostic support [6], assist elderly people in their daily routines [7,8], and promote an overall healthier lifestyle [9]. Furthermore, intelligent assistants show potential in recognizing emotions and developing robot-human relationships with users [10,11], which can open a wide range of new applications for mental health patients, after-diagnosis support, and treatment of chronic conditions [12]. In particular, the current COVID-19 pandemic might trigger telemedical approaches involving VIPAs [13].

However, the potential to improve treatment efficiency and save costs comes with possible safety and privacy risks [5,14]. Incomplete or incorrect health-related information, such as first-aid instructions or medication recommendations, may lead to patient harm, especially when users blindly follow the instructions of VIPAs without understanding the limitations of the technology [15]. Serious privacy concerns about the use, disclosure, and protection of personal health data may also keep users from sharing health information and therefore have a large impact on customer acceptance of online health care applications [16].

Such conflicting influences on the adoption of VIPAs make it difficult to foresee their further development. At the same time, the disruptive potential of the technology in health care urges companies to innovate to be able to meet consumer requirements in the future [17]. The necessity to respond to market changes creates a need for an insightful technological forecast, which could support decision making within organizations, facilitate smooth innovation processes, and help companies to maintain or even advance their competitiveness [18]. Despite a wide selection of literature on intelligent voice assistants and their use in health care, the majority of studies have focused on specific therapy areas or functions, such as health coaching [19,20], disease detection [21], applications in psychotherapy [22,23], and others. The overall state and current progress of the field were recently examined by Laranjo et al and Montenegro et al [5,24]. However, studies using widely recognized foresight or forecasting methods, such as a Delphi study, that can shed light on the further development of conversational agents in health care do not exist to date. This paper aimed to fill this gap and present a comprehensive future scenario of the adoption of VIPAs in health care, based on a two-round expert online survey. In particular, the main technology trends, customer acceptance development, promising use cases, and possible regulation changes in the next 5 years have been examined.

With our findings, we contribute to ubiquitous health-related computing services (uHealth) and more specifically VIPAs by forecasting their further development in regard to technology, consumer acceptance, potential use cases, and privacy and data protection regulations, and by drawing practical conclusions for health care providers.

The remainder of the paper is organized as follows. The next section provides a brief technical background of VIPAs and covers the main factors affecting adoption in health care. The methodology section provides details on the Delphi technique and the main steps carried out during the study. Conclusively, the research findings are presented, followed by a discussion of research limitations and suggestions for future research.

Background

A voice assistant is an artificial intelligence–powered computer system that aims to imitate human intelligence while engaging in realistic conversations with users [25]. The current most popular examples are Amazon Alexa, Google Assistant, Apple Siri, Microsoft Cortana, and Samsung Bibxy [26]. As of 2020, VIPAs are integrated in numerous devices, like smartphones, speakers, smartwatches, smart televisions, cars, headphones, game consoles, and household appliances [26]. Unless the system is deactivated by the user, the software always listens for trigger keywords, such as “Alexa” and “Hey Siri,” and automatically starts audio recording when awakened [2]. The request is then transmitted to the cloud, processed using NLU, and assigned to a specific intention. Depending on the inquiry, the server will provide relevant information for the voice assistant to be presented to the user or execute tasks with numerous voice applications and connected devices [2].

Unlike previous intelligent systems, VIPAs can respond to much larger numbers of requests owing to the constant internet connection and access to rapidly growing amounts of services developed directly by VIPA providers or external companies like Uber, McDonalds, and Disney [2]. Because voice built-in capabilities (eg, “Alexa Skills” and “Google Actions”) are stored in the cloud, there is no need for users to download or install them in contrast to smartphone apps. Third-party voice extensions can be published for the general public in a voice app store like *Alexa Skills Store* or used exclusively within an organization, which provides a great opportunity for companies to use VIPAs for their specific needs [27].

Petrock highlights that 33.8% of people from the total US population are currently using a voice assistant at least monthly for various requests [26]. This number is predicted to increase to 36.6% in 2021 [26]. Constantly improving, VIPAs can execute over 100 different tasks, covering the ability to control home appliances, answer numerous questions, set reminders for medications or tasks, shop online, and others [7,28]. In the health care field, various research trials using virtual assistants have shown major advancements in physical training, diet adjustments, accessibility to health information, etc [5,29,30]. However, according to the number of applications already available on the market, the use of voice assistants in the health care context is in its early days in comparison to entertainment, information search, navigation, and calling [26]. Several innovative health care providers, like Mayo Clinic, Boston Children’s Hospital, Atrium Health, and Deloitte, have introduced their voice solutions for Alexa ranging from first aid help and home care treatment to medical appointment scheduling and patient communication [31]. Still, most health care companies are hesitant to adopt VIPAs, primarily due to legal compliance and privacy concerns. At present, given that

private health care data may be shared by a patient using a virtual assistant, health care providers have the option of getting access to Amazon's Health Insurance Portability and Accountability Act–compliant solution for US-based Alexa Skills or building their own voice assistant [31].

Another important barrier for the adoption of VIPAs in health care is privacy concerns. Amazon, Apple, Google, Facebook, and Microsoft have all been using third-party human contractors who listen to user audio recordings to improve the quality of NLU [31]. Since private consumer data had been shared without user consensus, major data privacy concerns can arise from the user side.

Methods

Delphi Study

To generate a plausible scenario for the use of VIPAs in health care, a two-stage Delphi study was conducted online. The Delphi method is a forecasting technique that relies on experts in a particular field to identify technology developments and trends [32]. According to research guidelines, experts anonymously provide their answers to a standardized questionnaire over at least two rounds [33]. The interim results of each round are summarized and fed back to the experts during the next stage to narrow the statistical spread and facilitate concurrence among the participants [34-38].

As Wright et al described, a Delphi study is especially suitable in cases requiring human judgmental input owing to missing historical or technical data, such as forecasting the development of emerging technologies [39]. In contrast to causal-deterministic natural development processes, such as the weather, societal changes are based on human intentions, social interactions, and coincidence [40]. Therefore, societal forecasts can be deduced from subjective expert knowledge and experience-based assessments [41]. The Delphi method surpasses similar interactive group techniques regarding accuracy and efficacy [42-44], and has been frequently used in various fields. In their bibliometric analysis, Flostrand et al found 175 Delphi-related papers in the business field and 1462 papers in the health care field in the period between 1975 and 2017 [45]. Although health care research often aims to find a consensus in general, without a future focus, it has also been applied to examine future developments and tendencies [46-49]. Therefore, the Delphi technique is appropriate to support health care providers' strategic decision making in regard to VIPA implementation.

Formulation of Projections

The topic under investigation is the future of VIPAs in health care within the next 5 years. This timeframe was used owing to the rapid development of the technology, which complicates forecasting the further development regarding VIPAs within a wider time span. Furthermore, the given time period serves the purpose of this study to provide health care organizations with clear guidance regarding the necessity and application of VIPAs in the near future.

According to our knowledge, the future of VIPAs in health care has not been examined in other studies yet. Hence, an exploratory approach was applied to achieve a broad rather than deep scenario. We determined four thematic sections (technology, consumer acceptance, potential use cases, and privacy and data protection regulations) that were supposed to be investigated. As a consequence of this multisection approach, we omitted deeper investigations of each topic in greater detail to ensure an appropriate length of the questionnaire and thus to avoid a low response and high dropout rate from the experts. We considered 20 projections as appropriate for the questionnaire. An equal number of projections per section was not considered necessary.

The formulation of the projections followed a systematic process. First, we conducted desk research (based on academic journals; publications by relevant health associations, consultancies, and state authorities; news articles; and social media posts) and brainstormed to identify relevant issues for the four sections. Second, a small expert panel consisting of two information technology (IT) and two health care experts reviewed the list of issues, without adding or removing items. Third, the issues were transformed into projections. We aimed to formulate the projections in a plausible way such that they could be agreed to. However, implausible statements could also be incorporated into a Delphi study, since both the acceptance of a plausible projection and the rejection of an implausible projection represent the same general trend and can equally contribute to the resulting scenario [50]. Fourth, the list of projections was forwarded to the small expert panel again for review. As a consequence, some formulations became more precise and concise. The final list of projections is presented in Textbox 1.

Textbox 1. Delphi projections (within the next 5 years).

Cluster 1: Technology

1. Voice-controlled intelligent personal assistants (VIPAs) will be able to give solid medical advice based on personal medical information, instructions, and plans.

2. VIPAs will be able to hold a human-like conversation.

3. VIPAs will be able to take into account patients' emotions, moods, and traits.

4. VIPAs will outperform humans in the quality of anamnesis and the ability to have the complete medical history available.

Cluster 2: Consumer Acceptance

5. From a patient's perspective, VIPAs will provide a frustration-free user experience.

6. A high number of patients will regularly use VIPAs for health-related inquiries.

7. Owing to simple use, a high share of elderly people will use VIPAs.

8. The majority of patients will prefer human communication over VIPA communication when in need of psychological support.

9. The majority of patients will prefer VIPAs owing to time and cost savings.

10. Patients will consider trust in content providers (owners of voice applications, such as hospitals and pharmaceutical companies) as more important than trust in VIPA providers (eg, Amazon and Google).

Cluster 3: Potential Use Cases

11. VIPAs will be widely used as remote and in-house real-time anamnesis tools.

12. VIPAs will be widely used as diagnostic support tools for diseases that can be detected through speech characteristics.

13. VIPAs will be widely used as hands-free instruction tools for medical staff (eg, in sterile environments).

14. VIPAs will be widely used as communication tools between medical staff and patients.

15. VIPAs will be widely used as self-therapy tools for patients outside the clinic.

Cluster 4: Privacy and Data Protection Regulations

16. The majority of VIPAs will be compliant with the applicable regulations regarding protected health information.

17. The majority of VIPA providers will discontinue the use of subcontractors to increase trust in data security.

18. Government privacy concerns will greatly decrease.

19. The majority of customers will deliberately share sensitive health information with VIPAs.

20. Too strict regulations will inhibit VIPAs to provide reliable high-quality medical help services.

Panelists

Expert selection is essential for the quality of the resulting forecast [36,51-54]. Following a purposive sampling approach [55], the experts were chosen based on their expertise in the field [33,54,56]. For this study, we searched for the following expert groups: (1) managers from VIPA manufacturers or developers (with job titles such as business development manager and product manager), (2) IT experts from VIPA manufacturers and developers (with job titles such as data scientist, software development engineer, and UX designer), (3) managers from hospitals (with job titles such as executive director, chief innovation officer, and chief technology officer), (4) physicians from hospitals, (5) researchers (especially professors) working in the academic fields of health care management, health care economics, or health care law, (6) representatives of state authorities related to health care and nongovernmental health care associations, and (7) health care consultants. Eligible participants were identified through scholarly publications, conference presentations, and field-specific expert awards related to VIPAs, and job descriptions or posts on the professional social network *LinkedIn*.

Overall, 154 experts were invited to complete the survey. Of these, 35 experts participated in the first round and 27 remained in the second round. The dropout rate of 22.9% is below the 30% rate that is considered acceptable [57,58]. The majority of Delphi panels involve 15 to 35 participants [57], acknowledging seven [59] to 10 [58] as the minimum. Especially in regard to the infancy of the field, the panel selection in this study is considered adequate to achieve the research goal. The panel structure is presented in Table 1. Unfortunately, we were unable to recruit participants from state authorities related to health care or from nongovernmental health care associations, as well as health care consultants. The low proportion of female participants represents the gender distribution in the field of artificial intelligence. Similarly, the prevalence of experts from the North, Central, and South America (AMER) region mirrors the relatively high level of voice technology development and VIPA application in health care in the United States.

Table 1. Panel demographics.

Characteristic	First round (n=35), n (%)	Second round (n=27), n (%)
Gender		
Male	25 (71)	17 (63)
Female	9 (26)	9 (33)
Other	1 (3)	1 (4)
Age (years)		
<30	3 (9)	1 (4)
30-40	10 (29)	9 (33)
41-50	9 (26)	7 (26)
51-60	10 (29)	8 (30)
>60	3 (9)	2 (7)
Affiliation		
Information technology expert (VIPA[a] firm)	5 (14)	4 (15)
Manager (VIPA firm)	9 (26)	8 (30)
Manager (hospital)	8 (23)	5 (19)
Physician (hospital)	7 (20)	3 (11)
Researcher (academia)	6 (17)	7 (26)
Representative (authorities or association)	0 (0)	0 (0)
Health care consultant	0 (0)	0 (0)
Region		
AMER[b]	17 (49)	17 (67)
EMEA[c]	14 (40)	9 (30)
APAC[d]	4 (11)	1 (4)

[a]VIPA: voice-controlled intelligent personal assistant.

[b]AMER: North, Central, and South America.

[c]EMEA: Europe, Middle-East, and Africa.

[d]APAC: Asia Pacific.

Data Collection

The questionnaire covered the 20 projections presented in Textbox 1. The experts were asked to provide their level of agreement with the future statements, using a 4-point Likert scale ("do not agree," "somewhat disagree," "somewhat agree," and "agree"). An even-numbered Likert scale was used to avoid neutral responses [41]. Further, demographic data, such as gender, age, profession, and location, were collected from the participants (Table 1).

To minimize the possibility of misinterpretation of the statements and prevent technical problems with the survey tool, pretests were conducted prior to each round. The first survey round was executed between September 18 and 29, 2020, followed by the second round between October 7 and 14, 2020.

Results

Descriptive Statistics

According to Delphi study guidelines, the most probable future scenario is generated from the accumulation of the group consensus on each projection. The panel's agreement on each statement is concluded from the aggregation of individual assessments. The following numerical values were assigned to the response options to enable the calculation of statistical distribution: "do not agree," 1; "somewhat disagree," 2; "somewhat agree," 3; and "agree," 4.

Considering resistance toward outliers and the potential risk of statistical biases, the median is favored over the mean as the statistical average for Delphi studies [36,41]. Scattering of the responses is evaluated by IQR, which is the difference between the upper quartile ($x_{0.75}$) and the lower quartile ($x_{0.25}$). A low IQR indicates a high level of agreement, whereas a high IQR reflects a high level of discord [41].

Table 2 depicts the detailed results for both rounds. In the second round, no projection received strong agreement (median 4). The experts somewhat agreed (median 3) with most of the projections, namely projections 1, 2, 6, 7, 8, 10, 11, 13, 14, 15, 16, and 19. They somewhat disagreed with projections 3, 4, 5, 9, 12, 17, and 20, and even strongly disagreed with projection 18.

During the second round, only slight changes occurred. The median did not change for the majority of the projections. For projections 3 and 5, the experts revised their assessment from partial agreement to partial disagreement. Further, the median changed from slight to strong disagreement for projection 18. The IQR did not rise for any projection except for projection 9, showing increased insecurity in the panel, but reduced (as aimed) for eight projections, namely projections 2, 4, 7, 10, 13, 16, 17, and 18. Generally, the IQR evaluation shows a high level of consensus among participants. Additionally, to measure the level of consensus, Kendall *W* coefficient of concordance was calculated for both rounds [60]. The value can vary from 0 to 1, but is somewhat difficult to interpret, as it does not depict a linear rise. However, closer proximity to 1 reflects stronger agreement [61,62]. Kendall *W* equaled 0.1188 (χ^2_{19}=78.9689, P<.001) for the first round and 0.2948 (χ^2_{19}=151.2496, P<.001) for the second round of the Delphi study. As expected, the level of consensus among panelists increased in the course of the study. In light of the level of consensus and only minor variations between the rounds, no further iterations were required.

Table 2. Descriptive statistics.

Cluster and projection	First round (n=35)				Second round (n=27)				Difference			
	$X_{0.25}$[a]	$X_{0.5}$[b]	$X_{0.75}$[c]	IQR	$X_{0.25}$	$X_{0.5}$	$X_{0.75}$	IQR	$X_{0.25}$	$X_{0.5}$	$X_{0.75}$	IQR

[b]$X_{0.5}$: median quartile.

[c]$X_{0.75}$: upper quartile.

Scenario

According to the surveyed experts, VIPAs will show notable technological development and gain more trust among users in the next 5 years, resulting in their widespread utilization in health care. However, voice assistants are expected to only support health care professionals in their daily operations and will not be able to outperform or replace medical staff.

Within the next 5 years, the respondents expect a high percentage of patients to use VIPAs for health-related inquiries on a regular basis. Remarkably, a large proportion of elderly people will use voice assistants owing to their screen-free simple interface. Although experts agreed on the ability of VIPAs to hold a human-like conversation in the next 5 years, the given timeframe is still assessed as too short for the technology to be able to provide a frustration-free user experience.

Anticipating extensive use of voice assistants in health care, experts mentioned communicational, anamnesis, and self-therapy tools for patients and medical staff as the most promising use cases. Still, questioning the ability of VIPAs to recognize and take patients' emotions, moods, and traits into consideration, wide application of conversational assistants as diagnostic tools is not expected by 2025.

Pursuant to the survey outcome, the majority of voice assistants will be compliant with the applicable health information regulations within the time span of 5 years. Furthermore, data compliance together with trust in content providers, such as hospitals and pharmaceutical companies, might result in higher user willingness to share sensitive health information with VIPAs. While experts strongly rejected the possibility of a decrease in governmental privacy concerns, strict regulations capable of preventing VIPAs from providing medical help services are not expected.

Discussion

Discussion of the Results

In the technology section, the experts expressed discordant opinions about three of four projections. While the majority of responders agreed with the ability of VIPAs to provide solid medical advice based on patients' medical information, instructions, and plans within the next 5 years, 48% of the panelists rejected the statement. Hence, no clear group opinion could be derived for projection 1. Since not only technological development but also a comprehensive legal framework is required to enable voice assistants to provide medical help, some participants might reject the projection taking into account broad legal and privacy concerns. The presence of expert preoccupation with legal issues was confirmed in the fourth cluster of this study.

Likewise, projection 2 was accepted by the majority (52%) of panelists. Still, 48% of panelists expressed doubt about the potential of VIPAs to have a human-like conversation within the next 5 years. The group skepticism regarding the ability of VIPAs to accurately imitate human skills is reinforced in projections 3, 4, 5, 8, and 9. In detail, 81% of the interviewees believed voice assistants will not be able to outperform humans in the quality of anamnesis in the next 5 years. Projection 5, which stated that VIPAs can provide a frustration-free user experience, was also rejected. Furthermore, 66% of the panel expected patients to prefer humans over voice assistants when in need of psychological support.

Questioning the likelihood of the interchangeability between voice assistants and medical staff in the near future, the experts agreed with the widespread use of VIPAs as support tools. With a high level of consensus, 85% of the panel members anticipated a high number of patients to regularly use VIPAs for health-related inquires. Notably, no expert strongly disagreed with the projection.

Examining the most promising use cases, the panelists agreed on the application of VIPAs by medical staff (eg, in sterile environments, with a majority of 74%). Accordingly, 70% of the group expected extensive use of conversational agents among elderly people and 73% believed patients and health care professionals will use voice assistants for communication. Projection 15 suggesting the use of voice assistants as self-therapy tools was accepted by 59% of the experts. The fact that 41% of the responders expressed doubt about the given use case might reflect the general trend of expert skepticism toward the employment of voice assistants without the presence of health professionals.

The assumption of a potential decrease in the government's privacy concerns was strongly rejected. Only one expert somewhat agreed with the statement, with the rest of the group showing slight or strong disagreement. Furthermore, 85% of the panelists declared they do not expect VIPA providers to stop using subcontractors who listen to user audio files to improve the quality of NLU. Thus, data concerns might remain in place, requiring a new set of regulations. Further research is required to obtain a better understanding of the available tools and the amount of time it would take to address regulatory issues.

From the scenario, several practical implications for health care providers can be concluded, which have been summarized in Textbox 2.

Textbox 2. Practical implications for health care providers (within the next 5 years).

- Voice-controlled intelligent personal assistant (VIPA) technology will be mature.
- VIPAs will be accepted by patients, including elderly people.
- VIPAs will be used for regular anamneses, medical staff support, staff-patient communication, and self-therapy.
- Privacy and data protection issues will not harm the dissemination of VIPAs.

Limitations and Future Research

As this study involves early research on the future use of VIPAs in health care, several limitations apply to this study, which could also provide guidance for future research. First, the Delphi technique develops the most probable future scenario based on experts' present knowledge. Thus, although the method outperforms comparable interactive group forecasting techniques [42-44], the Delphi study cannot guarantee the exact realization of the forecast. Second, the range of addressed questions was limited to keep a sufficient length of the survey and avoid low response rates from the experts. Therefore, only existing features and use cases, which are currently in the early days of their implementation, were examined. The probability of the emergence of new technologies and applications for VIPAs was not investigated.

This study aimed to provide clear guidance for health care companies regarding the current necessity to focus their efforts on voice technology. Thus, a relatively short time frame of 5 years was chosen. Especially for the Europe, Middle-East, and Africa (EMEA) and Asia Pacific (APAC) regions, where the use of voice assistants in health care is in its infancy, the given time span could potentially interfere with the experts' future assumptions.

Currently, the use of voice assistants in health care varies widely across countries. The quality of NLP/NLU in English greatly outperforms other languages. Further factors, including the total user base, tools available for third-party developers, data protection regulations, and cultural differences, determine the adoption of VIPAs in general and in particular in health care. During this study, no large differences were detected comparing AMER, EMEA, and APAC expert assessments. Still, a study covering a specific region might provide more insightful forecasts of VIPA development in a particular geographical area.

Despite the widespread use of the Delphi technique, a number of claims have been made regarding its methodology. First, anonymity is one of the central characteristics of the Delphi technique, which aims to encourage experts to provide true and not socially likeable assessments. However, Sackman points out that anonymity can lead to hasty judgments as a result of experts' assurance that there is no necessity to defend their responses [63]. Second, the Delphi technique requires disclosure of the interim results of each round to generate a group opinion that can be claimed to be representative [64]. Some scholars argue that independent judgement is violated once the panelists know how others have evaluated each item [64]. Further, this disclosure can encourage outliers to revise their assessments owing to group pressure and not because of a changed opinion. Hence, a reduced IQR rate in Delphi studies can correspond to the problem of group thinking rather than higher consensus among experts [36,64,65].

Conclusion

We conducted an international Delphi study and derived a plausible scenario of the future of voice assistants in health care within the next 5 years. Twenty projections were designed and evaluated by an internationally recruited panel consisting of voice experts, as well as medical professionals and representatives of academia, health authorities, and nongovernmental health associations having broad experience with voice technology.

With a high level of consensus, the experts anticipate widespread application of VIPAs in various health care domains in the next 5 years. Although conversational assistants are not expected to replace medical workers, their use as operational supporting tools for health care professionals has strong potential in the industry. In detail, the panelists agreed with the capability of VIPAs to support elderly people and to be widely used as anamnesis, informational, self-therapy, and communicational tools by patients and health care professionals. Although users' and governments' privacy concerns are not expected to decrease in the near future, the panel members believe that strict regulations capable of preventing VIPAs from providing medical help services will not be imposed. To be able to meet consumer expectations and withstand competition within the next 5 years, health care companies are advised to carefully observe current research and development activities in the field of conversational artificial intelligence and allocate resources to optimize business processes using VIPAs.

This was an exploratory study on the future of voice assistants in health care. Hence, a broad rather than deep scenario approach was applied. Further studies might take a deeper look at one of the four clusters examined in this study or focus on a specific geographical area to provide more detailed insights.

Conflicts of Interest

None declared.

Abstract

Background: Chest pain is one of the most common chief complaints in emergency departments (EDs). Collecting an adequate medical history is challenging but essential in order to use recommended risk scores such as the HEART score (based on history, electrocardiogram, age, risk factors, and troponin). Self-reported computerized history taking (CHT) is a novel method to collect structured medical history data directly from the patient through a digital device. CHT is rarely used in clinical practice, and there is a lack of evidence for utility in an acute setting.

Objective: This substudy of the Clinical Expert Operating System Chest Pain Danderyd Study (CLEOS-CPDS) aimed to evaluate whether patients with acute chest pain can interact effectively with CHT in the ED.

Methods: Prospective cohort study on self-reported medical histories collected from acute chest pain patients using a CHT program on a tablet. Clinically stable patients aged 18 years and older with a chief complaint of chest pain, fluency in Swedish, and a nondiagnostic electrocardiogram or serum markers for acute coronary syndrome were eligible for inclusion. Patients unable to carry out an interview with CHT (eg, inadequate eyesight, confusion or agitation) were excluded. Effectiveness was assessed as the proportion of patients completing the interview and the time required in order to collect a medical history sufficient for cardiovascular risk stratification according to HEART score.

Results: During 2017-2018, 500 participants were consecutively enrolled. The age and sex distribution (mean 54.3, SD 17.0 years; 213/500, 42.6% women) was similar to that of the general chest pain population (mean 57.5, SD 19.2 years; 49.6% women). Common reasons for noninclusion were language issues (182/1000, 18.2%), fatigue (158/1000, 15.8%), and inability to use a tablet (152/1000, 15.2%). Sufficient data to calculate HEART score were collected in 70.4% (352/500) of the patients. Key modules for chief complaint, cardiovascular history, and respiratory history were completed by 408 (81.6%), 339 (67.8%), and 291 (58.2%) of the 500 participants, respectively, while 148 (29.6%) completed the entire interview (in all 14 modules). Factors associated with completeness were age 18-69 years (all key modules: *P*s<.001), male sex (cardiovascular: *P*=.04), active workers (all key modules: *P*s<.005), not arriving by ambulance (chief complaint: *P*=.03; cardiovascular: *P*=.045), and ongoing chest pain (complete interview: *P*=.002). The median time to collect HEART score data was 23 (IQR 18-31) minutes and to complete an interview was 64 (IQR 53-77) minutes. The main reasons for discontinuing the interview prior to completion (n=352) were discharge from the ED (101, 28.7%) and tiredness (95, 27.0%).

Conclusions: A majority of patients with acute chest pain can interact effectively with CHT on a tablet in the ED to provide sufficient data for risk stratification with a well-established risk score. The utility was somewhat lower in patients 70 years and older, in patients arriving by ambulance, and in patients without ongoing chest pain. Further studies are warranted to assess whether CHT can contribute to improved management and prognosis in this large patient group.

KEYWORDS

chest pain; computerized history taking; coronary artery disease; eHealth; emergency department; health informatics; medical history; risk management

Introduction

Chest pain is one of the most common chief complaints in emergency departments (EDs) worldwide [1,2]. Aside from electrocardiogram (ECG) and cardiac biomarkers, the medical history is regarded as central for management [3,4]. However, collecting an adequate medical history is a challenge for the physician due to limited time and is seldom done in a systematic, standardized way [5]. To improve chest pain management, emphasis has been put on developing new algorithms and advanced examinations [6-11].

Self-reported computerized history taking (CHT) is a method to collect a structured medical history by direct interaction between patients and a digital device. The concept of standardized history taking with structured paper questionnaires had already appeared in the 1940s [12]. The first software for CHT emerged in the 1960s [13]. Numerous CHT software programs have been developed and shown to collect more detailed data, as compared with conventional questionnaires [14]. CHT has the benefit of being reliable, as it never forgets to pose a question or diverges from what it is programmed to do [5]. As well, it can interpret the data instantly [15], which could aid the physician with complex information processing in a hectic environment (eg, triage in the ED). In several studies, CHT software collected more documented information than the physician (eg, in psychiatric history taking [16], outpatients with gastrointestinal symptoms [17] or dyslipidemia [18]). For the patient, highlighted benefits are that there is good acceptance of the software [14,16]; the patient is more likely to share sensitive information [14]; and consultation can be focused on identifying concerns and problems, rather than history taking [19]. The main disadvantages raised are irrelevant questioning, technical issues, and the programs' lack of empathy and inability to interpret body language [5,19].

Despite promising results, CHT is rarely used in clinical practice [5]. In 2007, a small feasibility study [20] including 64 patients showed that CHT was well accepted, that it collected an appropriate medical history of the various ED chief complaints, and that the concept could successfully be integrated with the process. However, there are only occasional studies on CHT in the acute cardiology setting or for ED patients with an acute complaint [20,21]. Indeed, the authors of a recent review for CHT in the management of cardiovascular disease concluded that there is a need to develop an evidence base for the use of CHT in this area of practice [22].

The overall aim of the Clinical Expert Operating System Chest Pain Danderyd Study (CLEOS-CPDS; ClinicalTrials.gov identifier: NCT03439449) is to determine the value of self-reported CHT for acute chest pain management [23]. This substudy is a utility study among the first 500 patients included, aimed to evaluate whether chest pain patients can effectively interact with CHT in the ED. Effectiveness was assessed as the proportion of patients completing the CHT interview and the time required to collect a medical history sufficient for cardiovascular risk stratification with an established risk score (ie, HEART [history, ECG, age, risk factors, and troponin] score; see below).

Methods

Setting

The CLEOS-CPDS study is an ongoing prospective cohort study recruiting consecutive patients presenting at the ED at Danderyd University Hospital (Stockholm, Sweden) from October 1, 2017, to December 31, 2023 (preliminary). The study has been described elsewhere [23] and has been approved by the Stockholm Regional Ethical Committee (now Swedish Ethical Review Authority) (reference number 2015/1955-1).

Study Population

Clinically stable women and men (Rapid Emergency Triage and Treatment System [RETTS] level orange, yellow, green, and blue [24]) aged 18 years and older with a chief complaint of chest pain, fluency in Swedish, and a nondiagnostic first ECG or serum markers for acute coronary syndrome (ACS) were eligible for inclusion after providing informed consent. Patients unable to carry out an interview with CHT (eg, inadequate eyesight, confusion, or agitation) were excluded.

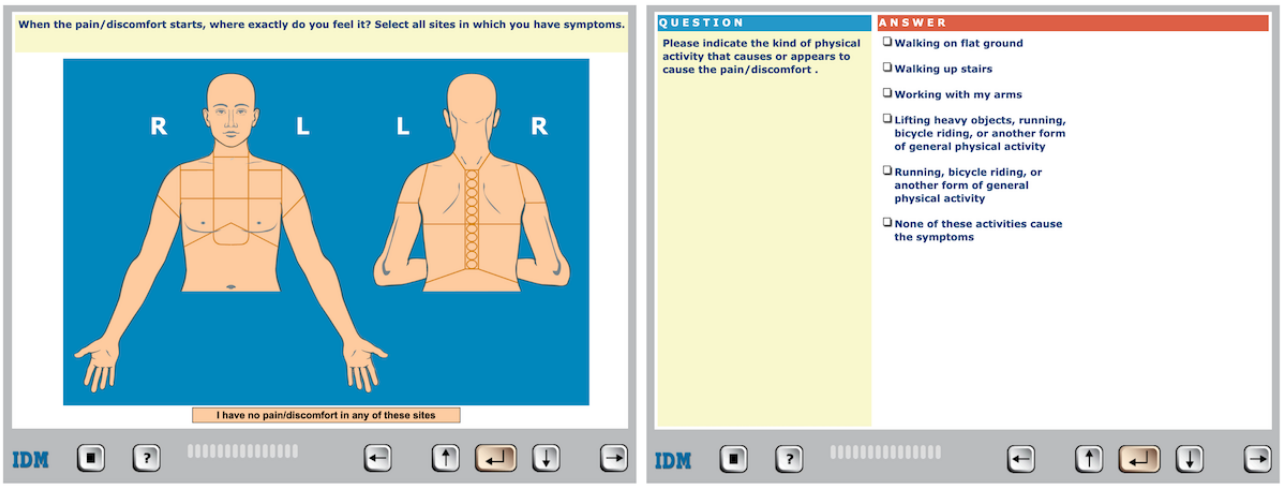
This study included the first 500 consecutive patients recruited (from October 1, 2017, to December 2, 2018). Danderyd University Hospital serves a population of approximately 600,000, and the ED had approximately 100,000 annual visits at the time of the study. The cardiology unit manages about 20% of the acute visits with about two-thirds walk-in patients and one-third patients arriving by ambulance. The average time spent in our ED for patients with a chief complaint of chest pain and RETTS level orange, yellow, green, or blue is 4 hours and

10 minutes, based on all 6920 visits from January through November 2018.

Interventions

Self-reported CHT was conducted with the CLEOS software. CLEOS has been described in detail elsewhere [18,23,25]. In brief, the patient interacts with CLEOS on tablets (iPad, Apple Inc) by answering sets of questions for different medical modules starting with the patient's chief complaint. Questions are mainly given in structured text format, such as yes/no or multiple-choice questions (one or many answers possible), but many questions display images, for instance asking the patient to click on an image of the upper body to indicate where pain is located (Figure 1).

Figure 1. User interface of the Clinical Expert Operating System software with examples of a clickable image and multiple-choice question.



The CLEOS software collects an in-depth history including demographics, present illness, organ systems review, medical history, prescription and over-the-counter medications, socioeconomic status, lifestyle, and family history. First, the software collects information on demographics and then reviews the major medical modules (Table 1). As this study specifically concerns chest pain management, questions regarding established risk factors for ACS were asked in the very first part of the interview. The interview is individually tailored by the software, where each question is determined on the basis of prior questions and a set of rules that interpret the clinical significance of prior answers. In total, the software has >17,000 decision nodes and can collect >40,000 data elements. The interview can be paused at any time when needed (eg, for physician encounter, lab test, or diagnostic imaging) and can be resumed whenever the patient has the opportunity.

Table 1. Consecutive order of medical modules in the interview.

9.	Obstetrics and gynecology
10.	Neurology
11.	Hematology/oncology
12.	Mental health
13.	History of medical/surgical events
14.	Family history

Data Collection

All patients presenting to the ED with a suspected cardiac condition were triaged by a cardiology consultant or senior resident (office hours) or by a trained nurse (out-of-office hours) using the triage protocol RETTS, where a targeted medical history is included. For chest pain patients, ECG and biomarkers were collected before admission to the cardiology unit or to the inpatient day-care unit. If further workup was not indicated, the patients could also be sent home directly from the triage. Less than 0.5% of the patients were sent home directly after triage. If there were signs of ST-elevation myocardial infarction on ECG or if the patient was clinically unstable, the patient was immediately admitted and not included in the study. For patients with a nondiagnostic first ECG, the physician in the cardiology unit or the inpatient day-care unit conducted a more thorough examination and standard history taking. For risk stratification, a combination of a modified HEART score [26], high-sensitivity cardiac troponin assays [10], and the 0/1 hour rule-in and rule-out algorithm [9] is recommended, according to regional guidelines. In the original HEART score, the History component is based on the physician's subjective assessment. In this study, as well as recommended by regional guidelines, the traditional clinical classification of suspected anginal symptoms was used, that is, (1) central chest pain, (2) precipitated by physical or emotional exertion, and (3) relieved by rest or nitrates [27]. Depending on the number of characteristics met, the history was classified as highly (three characteristics met), moderately (two characteristics met), or slightly suspicious (none or one characteristic met) for angina pectoris.

The patients were offered the choice to participate in the CLEOS-CPDS study by a member of the research staff. Standardized oral and written information regarding the study was given, and the patients were given opportunity to ask questions before giving their informed consent by signing a consent form, all according to the procedures approved by the appropriate ethical committee (Multimedia Appendix 1). To ensure that the patient could navigate the CHT software, the research staff supervised the patient as the first page on demographics was answered. If the patient could not navigate the CHT software, the patient was not included. CHT was only performed during waiting times and did not interfere with routine work flow or care in the ED. CHT could occur before, after, or both before and after being seen by a physician, and the staff at the ED was not aware of the information collected by CLEOS at any time. The interview was discontinued either when it was fully completed, if the patient chose to stop for any reason, or if the patient was discharged from the ED or admitted for in-hospital evaluation and treatment. Reasons for not including patients who were considered eligible, the cause for noninclusion, and the cause of discontinuation were registered by the research staff.

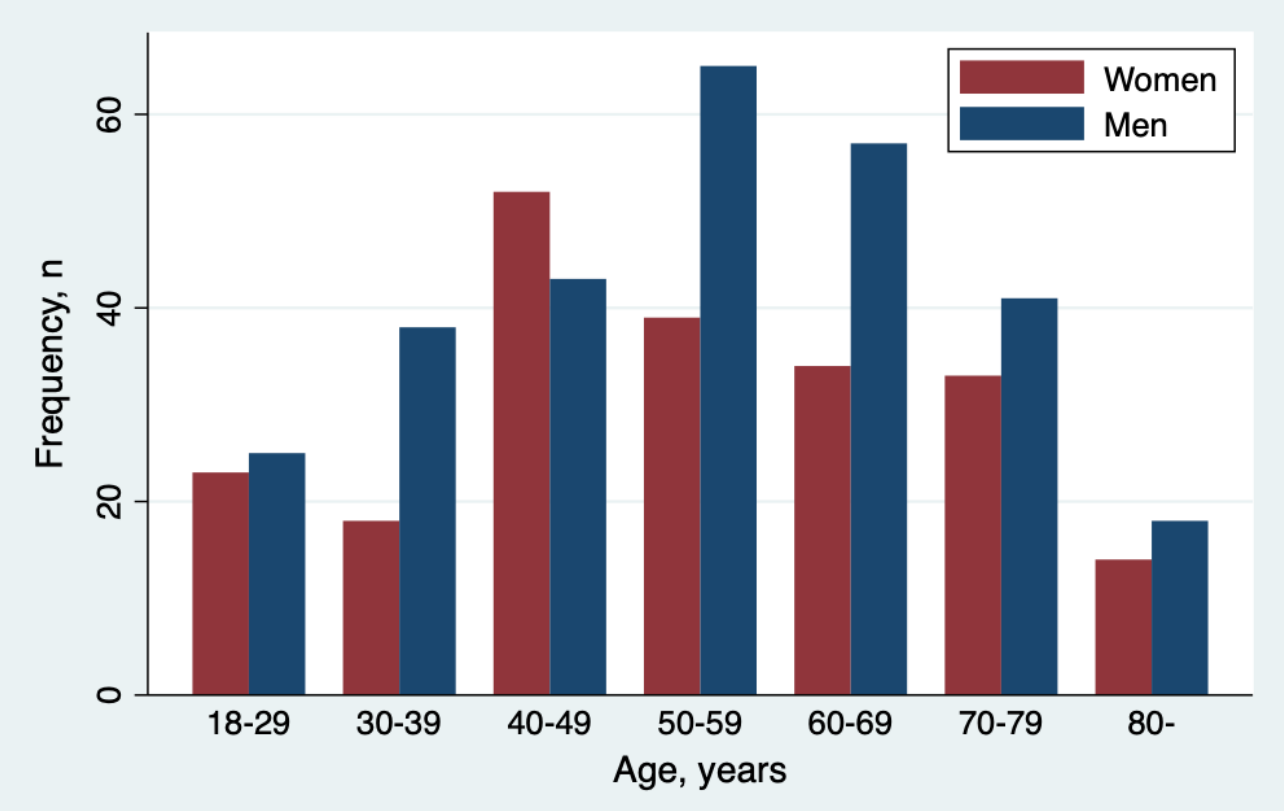
Self-reported descriptive data, medical history data and demographics, and time stamps for completion of each question were collected from the CHT software. All pauses lasting more than 2 minutes were assumed to be interruptions in the interview and excluded when calculating durations. Data on arrival type, arrival time, and admission for the study population were extracted manually by research staff from the electronic health record (TakeCare, CompuGroup Medical Sweden AB). Demographic data and time spent in the ED for the general ED chest pain population during the study period were collected with QlikView, Version 12.10 (QlikTech International AB).

Statistical Analysis

Study outcomes were (1) representativeness of the study population actually included (ie, age and gender of the study participants as compared with the general ED chest pain population), (2) the extent of interview completeness, overall and with regard to demographics, (3) the duration of interview segments, including completed modules, completed interview, and pauses, and (4) effectiveness, assessed as the proportion of patients completing the CHT interview to collect medical history sufficient for cardiovascular risk stratification with the established HEART score.

Descriptive statistics (mean values and standard deviations, median values and IQRs, or proportions, as appropriate) were used for patients' baseline characteristics and to summarize completion and duration of key modules, HEART score data, and completed interview. Pearson χ^2 tests (with 2 degrees of freedom) were used to compare the extent of completeness for binary variables. Wilcoxon rank sum tests were used to compare the median duration for completing the modules. Patients were stratified into 7 age groups (Figure 2), and time of arrival was grouped as morning (7 AM–noon), afternoon (noon–5 PM), evening (5 PM–10 PM), and night (10 PM–7 AM). To test for differences in completion for categorical variables with more than two groups (age groups, occupational status, and time of arrival), the Kruskal-Wallis test with a Dunn pairwise comparison with Bonferroni adjustments as post hoc analysis was used. All statistical analyses were performed using Stata, release 14 (StataCorp).

Figure 2. Age and sex distribution of the study population (n=500). Total number of patients in each age group—18-29: 48, 30-39: 56, 40-49: 95, 50-59: 104, 60-69: 91, 70-79: 74, 80 years or older: 32.



Results

Study Population and Their Characteristics

A total of 9532 patients presented at the ED with a chief complaint of chest pain during the entire study period. During the periods with research staff on duty (ie, when active inclusion was performed), 500 patients who met all inclusion criteria but no exclusion criteria were consecutively enrolled in the study.

The study population (Table 2) had a similar age and sex distribution (mean 54.3, SD 17.0 years, and 213/500, 42.6% women, respectively) as compared with the general chest pain patient population (mean 57.5, SD 19.2 years, and 49.6% women). For patients who were considered eligible for the study but were not included, the most common causes were that they had language issues (182, 18.2%, mostly nonfluent in Swedish), that they felt too tired (158, 15.8%), or that they were unable to use a tablet (152, 15.2%) (Multimedia Appendix 2).

Not at work (unemployed, on sick leave)	38 (7.6)	
Retired	142 (28.4)	
Arrived at ED[d] by ambulance, n (%)	92 (19.9)	463
Arrival time, n (%)		495
Morning (7 AM–noon)	244 (49.3)	
Afternoon (noon–5 PM)	180 (36.4)	
Evening (5 PM–10 PM)	47 (9.5)	
Night (10 PM–7 AM)	24 (4.8)	
Reporting any ongoing chest discomfort/pain, n (%)	264 (58.5)	451
Admitted (to the ward or day-care unit), n (%)	225 (46.0)	489

[a]Data from 500 patients are presented as mean values (SD) or n (%), as appropriate.

[b]CABG: coronary artery bypass grafting.

[c]PCI: percutaneous coronary intervention.

[d]ED: emergency department.

Age and sex distributions of the study population are presented in Figure 2. Self-reported patient characteristics and ED data are presented in Table 2. Mean age was about the same for women as for men (53.8 vs 54.6 years, respectively). Self-reported key clinical characteristics included known coronary artery disease (ie, angina pectoris, history of myocardial infarction, or history of coronary artery bypass grafting or percutaneous coronary intervention) in 16.9% (74/437), diabetes mellitus in 6.6% (27/412), hypertension in 40.1% (163/406), and lipid-lowering medication in 19.6% (69/352) (Table 2).

About one-fifth of the participants arrived by ambulance. Nearly half of the population presented to the ED during the morning (7 AM–noon) and about one-third in the afternoon (noon–5 PM). A majority of the patients (264/451, 58.5%) reported ongoing chest pain. Nearly half of the participants (225/489, 46.0%) were eventually admitted, either to a ward or an inpatient day-care unit (Table 2).

Extent of Completeness

The number of participants who carried on with the interview decreased during the course of the interview (Table 3; Multimedia Appendix 3). Sufficient data to calculate HEART score (ie, clinical presentation and risk factors derived from a complete chief complaint module and the initial part of the cardiovascular module) were collected in 352 (70.4%) of the patients (Table 3). Of the 500 participants, the chief complaint (CC) module was completed by 408 (81.6%), the cardiovascular (CV) module by 339 (67.8%), and the Respiratory module by 291 (58.2%), while 148 (29.6%) completed the entire interview (Figure 3 and Table 3). Men completed the CV module and provided sufficient data to calculate the HEART score to a slightly greater extent than women (71.4% vs 62.9%, *P*=.04; 73.9% vs 65.7%, *P*=.049).

Table 3. Summary table for completion and duration of key modules, HEART score, and completed interview.[a,b]

Characteristic by sex	Chief complaint	Cardiovascular	Respiratory	Completed	HEART[c] score
Women (n=213)					
Completers, n (%)	170 (79.8)	134 (62.9)	117 (54.9)	54 (25.4)	140 (65.7)
Duration (min), median (IQR)	15 (12-20)	24 (20-35)	30 (24-39)	66 (53-75)	21 (18-30)
Duration (min), range	1-42	12-82	15-93	41-182	2-66
Men (n=287)					
Completers, n (%)	238 (82.9)	205 (71.4)	174 (60.6)	94 (32.8)	212 (73.9)
Duration (min), median (IQR)	17 (13-23)	27 (21-35)	32 (25-42)	63 (54-78)	24 (19-32)
Duration (min), range	1-77	11-88	14-97	32-121	2-85
All (n=500)					
Completers, n (%)	408 (81.6)	339 (67.8)	291 (58.2)	148 (29.6)	352 (70.4)
P value (completion)	.37	.04	.18	.07	.049
Duration (min), median (IQR)	16 (12-21)	26 (21-35)	31 (25-41)	64 (53-77)	23 (18-31)

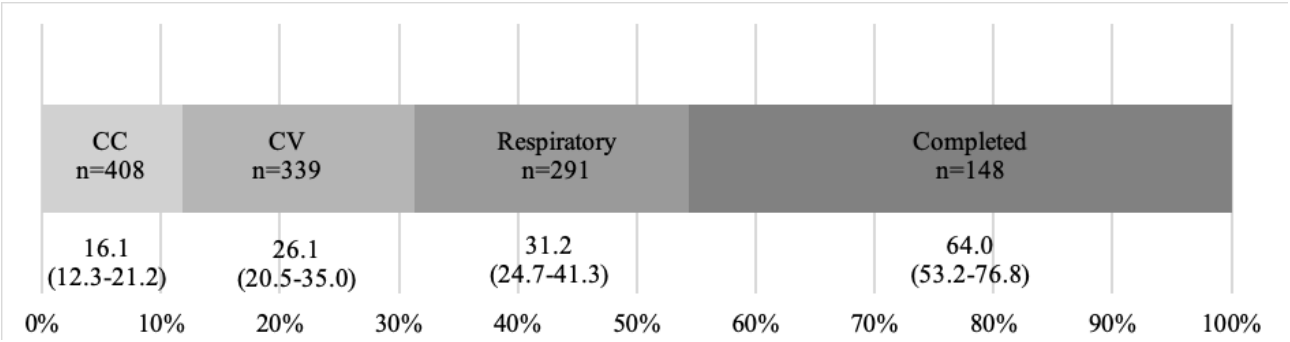
P value (duration)	.12	.15	.43	.25	.08

[a]Number (n) and proportions (%) of participants presented for completed modules, completed interview, and data sufficient for calculating HEART score before discontinuing the interview.

[b]No significant difference between sexes for duration, but significant difference for completion of cardiovascular module and complete HEART score.

[c]HEART: history, electrocardiogram, age, risk factors, and troponin.

Figure 3. Median durations with IQRs (in minutes) for completed modules and complete interview, excluding pauses >2 minutes. CC: chief complaint module; Completed: completed interview; CV: cardiovascular module; Respiratory: respiratory module.



The proportion of the participants who completed the key modules in this context (CC, CV, and Respiratory modules) and the complete interview was lower in the age groups 70-79 years and 80 years or older, as compared with younger age groups (*P*s<.001 for all key modules and completed interview; Figure 4). No other significant differences in rates of completion were found between the age groups. Active workers completed the key modules and the complete interview more often than retired participants (CC: *P*=.004, CV: *P*=.002, Respiratory: *P*<.001, and complete interview: *P*<.001) (Figure 5). Patients not at work completed the Respiratory module to a slightly greater degree than retired participants (*P*=.03). No other significant differences were found by occupational status.

Figure 4. Fractions (with 95% CIs) of completed key modules and completed interviews, stratified by age.

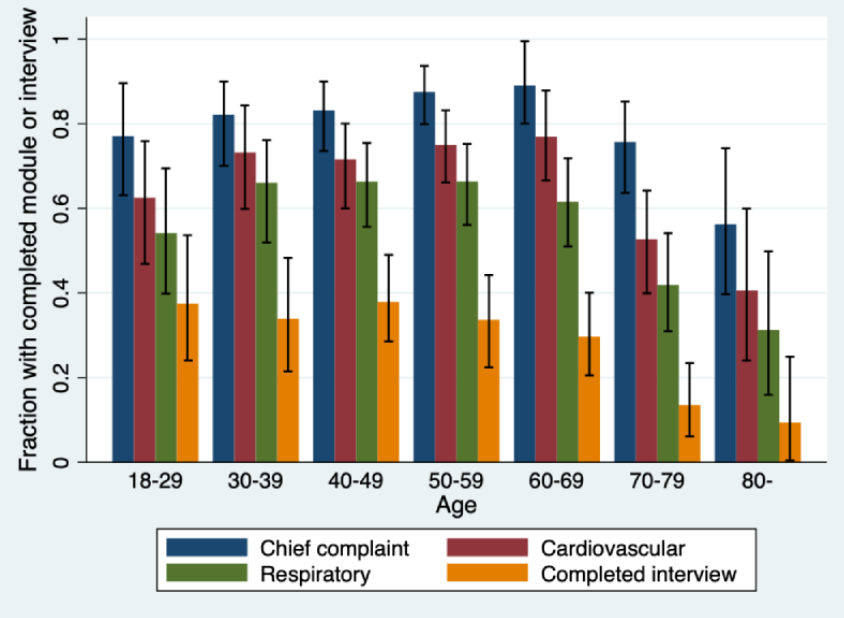


Figure 5. Fractions (with 95% CIs) of completed key modules and completed interviews, stratified by occupational status (320 active workers, 38 not at work, 142 retired). Active worker: employed or student; not at work: unemployed or on sick leave.

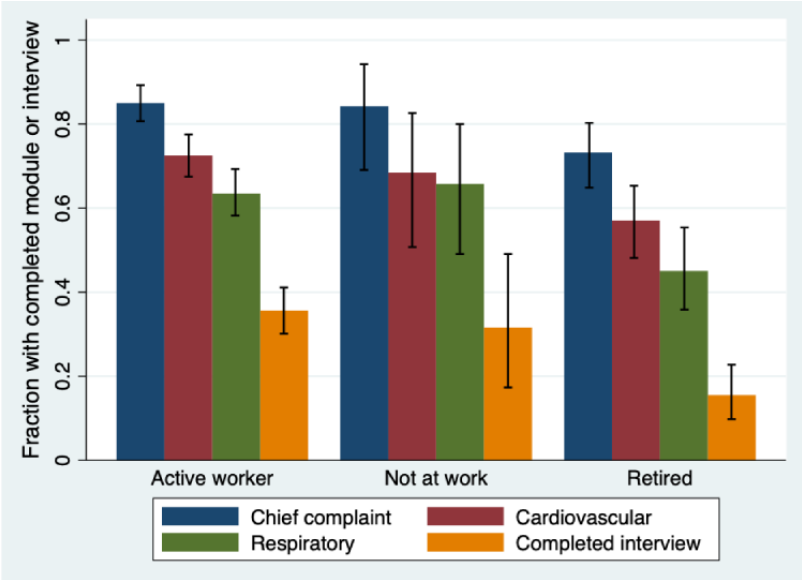
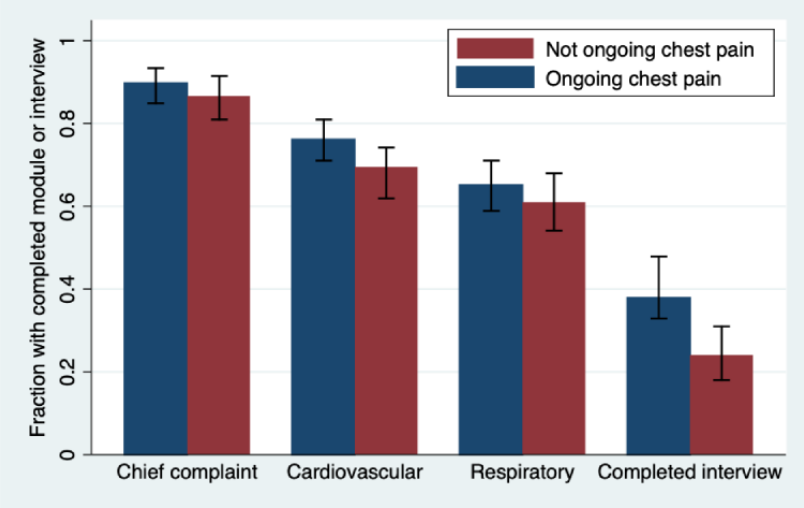


Patients arriving by ambulance completed the CC and CV modules to a slightly lesser extent compared with those not arriving by ambulance (79% vs 88%, *P*=.03 and 63% vs 74%, *P*=.045, respectively). Participants who reported ongoing chest pain completed the interview to a greater extent than those not reporting ongoing chest pain (38% vs 24%, *P*=.002; Figure 6). No other significant differences in the completion of modules, for example, relation to the time of day the participant presented to the ED or by admission (hospital admission vs discharged home), were found.

Figure 6. Fractions (with 95% CIs) of completed key modules and completed interviews, stratified by ongoing chest pain or not (264 with ongoing chest pain and 187 without).



Duration of CHT Session

The median duration (excluding pauses longer than 2 minutes) to collect HEART score data was 23 (IQR 18-31) minutes, to complete the CC module 16 (IQR 12-21) minutes, to complete the CV module 26 (IQR 20-35) minutes, to complete the Respiratory module 31 (IQR 25-41) minutes, and to complete an entire interview 64 (IQR 53-77) minutes (Figure 3 and Table 3). No difference for duration by sex was found. The number and proportions of patients who ended the interview within a certain time and mean pauses stratified by interview duration are presented as supplementary material (Multimedia Appendices 4 and 5).

In the group of 352 participants who did not complete the full interview, the main reasons for discontinuing were discharge from ED (101, 28.7%) and that the participant felt tired (95, 27.0%) (Table 4). When comparing the age groups 18-69 years (n=259) and ≥70 years (n=93) to participants of all ages, discharge from ED was more frequent in the first group (28.7% vs 12.9%, *P*<.001), and difficulty using the tablet was reported more often in the second group (4.5% vs 14.0%, *P*<.001) (Table 4).

Table 4. Reasons for discontinuing the interview.[a]

Reasons	Age groups (years), n (%)			*P* value
	All	18-69	≥70	
Discharge from ED[b]	101 (28.7)	89 (34.4)	12 (12.9)	<.001
Tired	95 (27.0)	69 (26.6)	26 (28.0)	.81
Missing/not stated	61 (17.3)	48 (18.5)	13 (14.0)	.32
Admission/transfer	22 (6.3)	13 (5.0)	9 (9.7)	.11
Difficulty to use tablet	16 (4.5)	3 (1.2)	13 (14.0)	<.001
Clinical examination	15 (4.3)	11 (4.2)	4 (4.3)	.98
Technical issues	11 (3.1)	8 (3.1)	3 (3.2)	.94
End of research staff work shift	10 (2.8)	6 (2.3)	4 (4.3)	.32
Perceived not relevant/too many questions	9 (2.6)	5 (1.9)	4 (4.3)	.21
Acute medical condition/measure	7 (2.0)	3 (1.2)	4 (4.3)	.06
Other	5 (1.4)	4 (1.5)	1 (1.1)	.75

[a]Number (n) and proportions (%) of all 352 participants who did not complete the full interview, according to age group.

[b]ED: emergency department.

Discussion

Principal Results

Although the utility of CHT has been studied in primary care settings [28,29] and general acute settings [20,21], this appears to be one of the first studies of CHT in an acute cardiology setting. We show that a majority (70.4%) of acute chest pain patients can interact with CHT to collect medical history adequately to provide a HEART score for chest pain management. Given the large proportion of people presenting to the ED with chest pain, our results suggest that CHT could potentially contribute to safer management with improved risk

stratification in this patient group, particularly during periods with high workload and crowding, which are associated with worse outcomes [30]. This could eventually reduce unnecessary, expensive, and potentially risky examinations. However, our study only shows the utility of this specific strategy for patient interview. Further studies are needed to validate the information provided by the CLEOS CHT program against information in the electronic health record obtained by an interview performed by a physician and to evaluate the results to prospective outcome data.

The interview was arranged so that the most important factors for assessing chest pain were asked in the very first part, in order to collect medical history sufficient for cardiovascular risk stratification in the ED setting. Subsequently, data was collected for all organ systems with, in the CLEOS developers' opinion, lesser significance for the assessment of chest pain the longer the interview went on. As expected, the proportion of patients who continued with the interview decreased the longer it went on. More importantly, however, the median duration for sufficient data to calculate the HEART score was only 23 minutes. This is comparable to the reported time for taking a standard history in an acute setting [31,32]. However, the CHT can make use of the waiting time in the ED and provide the patient with time to think through their answers more carefully, which could add to more reliable answers and improved diagnostic results.

Premature discontinuations were mainly due to patients being sent home or getting too tired to continue the interview. Only 30% went through a complete interview, with a median duration of 64 minutes, which is longer than a standard interview by a physician in an ED setting [31,32]. However, it is important to consider the context and the intention of data collection when assessing the duration of the interview. Reaching a fully completed interview is of importance to identify an unclear diagnosis or for research purposes, but for risk stratification in acute chest pain patients, it is more important to rapidly populate the elements included in an established risk score. Of note, in the current study of patients with mostly low-intermediate risk (ie, RETTS level orange, yellow, green, and blue), median time spent in the ED was about 4 hours. Thus, the somewhat longer time for the CHT would not prolong the time spent in the ED, as compared to using a standard history taking by the attending physician. Nevertheless, it would be of benefit in future development of CHT if the extent of an interview could be adjusted to the context of the visit and medical urgency.

The extent of completion was lower in the age group 70 years and older, a finding not previously observed in the few studies available [15,17,18,20]. Our data suggests that this was due to difficulties using tablets and to somewhat more frequent hospitalizations than in the younger (18-64 years) age group (Table 4). Patients reporting ongoing chest pain also completed the interview to a slightly greater extent, which raises the question of whether one is more inclined to complete the interview due to concerns about a present complaint. As well, the group of patients arriving by ambulance completed two key modules of the interview (CC and CV) to a lesser extent than walk-in patients, possibly due to a larger proportion of older people in this group.

There are some strengths of this study. First, this is a large sample of patients from a study population representative of a general chest pain population, CLEOS-CPDS, with a prospective cohort study design and a published study protocol. Second, a generic layout of the CHT software may allow the results to be generalized to other complaints and care settings. Finally, this is an academically initiated and driven study where the CHT software is owned by a public university. There are no commercial interests within the research project.

There are also important limitations to this study. First, although patients were recruited consecutively, this occurred mainly during office hours and evenings (due to research staff working hours) and when a sufficient number of tablets was available. This entails a risk of selection bias, and the results may not apply to patients presenting to the ED at other times of the day. However, the proportion of chest pain patients arriving at night was small, and the demographics were similar to the total ED chest pain population. Second, there may also be confounding by a selection of patients with good tablet skills. This potential confounding warrant further study. As well, a number of patients were not eligible; patients with language difficulties or inability to carry out CHT on the tablet were not included. These groups accounted for 18.2% and 15.8% of patients who were asked to participate but did not. However, this compares to results found by others, where no complete basic medical history could be obtained in the ED setting for 25% of the patients [31]. Thus, it is important in future CHT implementations to identify these patient groups and their characteristics, so they can be offered standard history taking. In addition, developing simpler and more user-friendly software in these patient groups is needed. Third, patients sent home directly from the physician triage (potentially healthier and younger) were not eligible for the study. Many EDs do not have physician triage, and the assessment may vary between physicians [33]. This may affect the generalizability of the study. However, a negligible fraction of patients were sent home directly from the medical triage, and we consider it unlikely to have affected the study results. Finally, our results may not be applied for critically ill patients, who should be seen by a physician immediately according to the RETTS triage protocol, as the CHT was not intended for use in these patients.

Conclusions

A majority of acute chest pain patients can interact effectively with CHT on a tablet in the ED to provide sufficient data for risk stratification with a well-established risk score (ie, HEART score). The utility was somewhat lower in patients 70 years and older, in patients arriving by ambulance, and in patients without ongoing chest pain. Further studies are warranted to assess whether CHT can contribute to improved management and better risk stratification for one of the most common chief complaints in the ED.
