Journal of Medical Internet Research

Journal Impact Factor (JIF) (2023): 5.8
Volume 23 (2021), Issue 5 ISSN 1438-8871 Editor in Chief: Gunther Eysenbach, MD, MPH

Contents

Reviews

Information and Communication Technology Use in Suicide Prevention: Scoping Review (e25288)
Jessica Rassy, Cécile Bardon, Luc Dargis, Louis-Philippe Côté, Laurent Corthésy-Blondin, Carl-Maria Mörch, Réal Labelle. 11

Machine Learning and Natural Language Processing in Mental Health: Systematic Review (e15708)
Aziliz Le Glaz, Yannis Haralambous, Deok-Hee Kim-Dufor, Philippe Lenca, Romain Billot, Taylor Ryan, Jonathan Marsh, Jordan DeVylder, Michel Walter, Sofian Berrouiguet, Christophe Lemey. 31

Impact of Asynchronous Electronic Communication–Based Visits on Clinical Outcomes and Health Care Delivery: Systematic Review (e27531)
Oliver Nguyen, Amir Alishahi Tabriz, Jinhai Huo, Karim Hanna, Christopher Shea, Kea Turner. 51

Electronic Tools to Bridge the Language Gap in Health Care for People Who Have Migrated: Systematic Review (e25131)
Frédérique Thonon, Swati Perrot, Abhijna Yergolkar, Olivia Rousset-Torrente, James Griffith, Olivier Chassany, Martin Duracinsky. 65

The Challenge of Integrating eHealth Into Health Care: Systematic Literature Review of the Donabedian Model of Structure, Process, and Outcome (e27180)
Rosian Tossaint-Schoenmakers, Anke Versluis, Niels Chavannes, Esther Talboom-Kamp, Marise Kasteleyn. 79

Social Media Use for Health Purposes: Systematic Review (e17917)
Junhan Chen, Yuan Wang. 102

Maximizing Participant Engagement, Participation, and Retention in Cohort Studies Using Digital Methods: Rapid Review to Inform the Next Generation of Very Large Birth Cohorts (e23499)
Joanna Nkyekyer, Susan Clifford, Fiona Mensah, Yichao Wang, Lauren Chiu, Melissa Wake. 169

Mobile Apps to Improve Medication Adherence in Cardiovascular Disease: Systematic Review and Meta-analysis (e24190)
Shahd Al-Arkee, Julie Mason, Deirdre Lane, Larissa Fabritz, Winnie Chua, M Haque, Zahraa Jalal. 200

Digital Health Strategies for Cervical Cancer Control in Low- and Middle-Income Countries: Systematic Review of Current Implementations and Gaps in Research (e23350)
Andrea Rossman, Hadley Reid, Michelle Pieters, Cecelia Mizelle, Megan von Isenburg, Nimmi Ramanujam, Megan Huchko, Lavanya Vasudevan. 218

The Use of Social Media for Health Research Purposes: Scoping Review (e25736)
Charline Bour, Adrian Ahne, Susanne Schmitz, Camille Perchoux, Coralie Dessenne, Guy Fagherazzi. 234

XSL•FO
RenderX

Theories Informing eHealth Implementation: Systematic Review and Typology Classification (e18500)
Milena Heinsch, Jessica Wyllie, Jamie Carlson, Hannah Wells, Campbell Tickner, Frances Kay-Lambkin. 248

Effectiveness of eHealth Nutritional Interventions for Middle-Aged and Older Adults: Systematic Review and Meta-analysis (e15649)
Caroline Robert, Mojisola Erdt, James Lee, Yuanyuan Cao, Nurhazimah Naharudin, Yin-Leng Theng. 384

Information Quality Frameworks for Digital Health Technologies: Systematic Review (e23479)
Kayode Fadahunsi, Siobhan O'Connor, James Akinlua, Petra Wark, Joseph Gallagher, Christopher Carroll, Josip Car, Azeem Majeed, John O'Donoghue. 855

Agent-Oriented Goal Models in Developing Information Systems Supporting Physical Activity Among Adolescents: Literature Review and Expert Interviews (e24810)
Kerli Mooses, Kuldar Taveter. 878

Priority Given to Technology in Government-Based Mental Health and Addictions Vision and Strategy Documents: Systematic Policy Review (e25547)
Shalini Lal, Lyna Siafa, Hajin Lee, Carol Adair. 955

Original Papers

Effectiveness of Digital Interventions for Reducing Behavioral Risks of Cardiovascular Disease in Nonclinical Adult Populations: Systematic Review of Reviews (e19688)
Natalie Gold, Amy Yau, Benjamin Rigby, Chris Dyke, Elizabeth Remfry, Tim Chadborn. 118

Understanding Public Perceptions of COVID-19 Contact Tracing Apps: Artificial Intelligence–Enabled Social Media Analysis (e26618)
Kathrin Cresswell, Ahsen Tahir, Zakariya Sheikh, Zain Hussain, Andrés Domínguez Hernández, Ewen Harrison, Robin Williams, Aziz Sheikh, Amir Hussain. 277

Initial Outcomes of Transdiagnostic Internet-Delivered Cognitive Behavioral Therapy Tailored to Public Safety Personnel: Longitudinal Observational Study (e27610)
Heather Hadjistavropoulos, Hugh McCall, David Thiessen, Ziyin Huang, R Carleton, Blake Dear, Nickolai Titov. 358

Guided Internet-Based Cognitive Behavioral Therapy for Depression: Implementation Cost-Effectiveness Study (e27410)
Jordi Piera-Jiménez, Anne Etzelmueller, Spyros Kolovos, Frans Folkvord, Francisco Lupiáñez-Villanueva. 371

Internet-Based Cognitive Behavioral Therapy for Patients Reporting Symptoms of Anxiety and Depression After Myocardial Infarction: U-CARE Heart Randomized Controlled Trial Twelve-Month Follow-up (e25465)
Sophia Humphries, John Wallert, Fredrika Norlund, Emma Wallin, Gunilla Burell, Louise von Essen, Claes Held, Erik Olsson. 400

Intelligent Personalized Exercise Prescription Based on an eHealth Promotion System to Improve Health Outcomes of Middle-Aged and Older Adult Community Dwellers: Pretest–Posttest Study (e28221)
Ting Sun, Yang Xu, Hui Xie, Zuchang Ma, Yu Wang. 414

A Social Media Organizational Productivity Model: Insights From Public Health Professionals (e23792)
Hamad Dailah Sr, Muhammad Naeem. 428

Sleep Disturbances in Frontline Health Care Workers During the COVID-19 Pandemic: Social Media Survey Study (e27331)
Nancy Stewart, Anya Koza, Serena Dhaon, Christiana Shoushtari, Maylyn Martinez, Vineet Arora. 441

Developing an Automatic System for Classifying Chatter About Health Services on Twitter: Case Study for Medicaid (e26616)
Yuan-Chi Yang, Mohammed Al-Garadi, Whitney Bremer, Jane Zhu, David Grande, Abeed Sarker. 451

Information-Seeking Patterns During the COVID-19 Pandemic Across the United States: Longitudinal Analysis of Google Trends Data (e22933)
Tichakunda Mangono, Peter Smittenaar, Yael Caplan, Vincent Huang, Staci Sutermaster, Hannah Kemp, Sema Sgaier. 464

Mining and Validating Social Media Data for COVID-19–Related Human Behaviors Between January and July 2020: Infodemiology Study (e27059)
Ashlynn Daughton, Courtney Shelley, Martha Barnard, Dax Gerts, Chrysm Watson Ross, Isabel Crooker, Gopal Nadiga, Nilesh Mukundan, Nidia Vaquera Chavez, Nidhi Parikh, Travis Pitts, Geoffrey Fairchild. 480

Detecting Impending Stroke From Cognitive Traits Evident in Internet Searches: Analysis of Archival Data (e27084)
Sigal Shaklai, Ran Gilad-Bachrach, Elad Yom-Tov, Naftali Stern. 494

The Uptake and Use of Telemonitoring in Chronic Care Between 2014 and 2019: Nationwide Survey Among Patients and Health Care Professionals in the Netherlands (e24908)
Martine Huygens, Helene Voogdt-Pruis, Myrah Wouters, Maaike Meurs, Britt van Lettow, Conchita Kleijweg, Roland Friele. 504

The Costs and Cardiovascular Benefits in Patients With Peripheral Artery Disease From a Fourth-Generation Synchronous Telehealth Program: Retrospective Cohort Study (e24346)
Jen-Kuang Lee, Chi-Sheng Hung, Ching-Chang Huang, Ying-Hsien Chen, Hui-Wen Wu, Pao-Yu Chuang, Jiun-Yu Yu, Yi-Lwun Ho. 515

Characteristics of Citizens and Their Use of Teleconsultations in Primary Care in the Catalan Public Health System Before and During the COVID-19 Pandemic: Retrospective Descriptive Cross-sectional Study (e28629)
Oscar Solans, Josep Vidal-Alaball, Pasqual Roig Cabo, Núria Mora, Ermengol Coma, Josep Bonet Simó, Eduardo Hermosilla Pérez, Francesc Saigí-Rubió, Carmen Olmos Domínguez, Jordi Piera-Jiménez, Mercè Abizanda González, Francesc López Seguí. 533

Perceived Utility and Characterization of Personal Google Search Histories to Detect Data Patterns Proximal to a Suicide Attempt in Individuals Who Previously Attempted Suicide: Pilot Cohort Study (e27918)
Patricia Areán, Abhishek Pratap, Honor Hsin, Tierney Huppert, Karin Hendricks, Patrick Heagerty, Trevor Cohen, Courtney Bagge, Katherine Comtois. 544

Patient Monitoring Alarms in an Intensive Care Unit: Observational Study With Do-It-Yourself Instructions (e26494)
Akira-Sebastian Poncette, Maximilian Wunderlich, Claudia Spies, Patrick Heeren, Gerald Vorderwülbecke, Eduardo Salgado, Marc Kastrup, Markus Feufel, Felix Balzer. 557

Integrating Option Grid Patient Decision Aids in the Epic Electronic Health Record: Case Study at 5 Health Systems (e22766)
Peter Scalia, Farhan Ahmad, Danielle Schubbe, Rachel Forcino, Marie-Anne Durand, Paul Barr, Glyn Elwyn. 569

Patient Portal Use, Perceptions of Electronic Health Record Value, and Self-Rated Primary Care Quality Among Older Adults: Cross-sectional Survey (e22549)
Dori Cross, Zachary Levin, Minakshi Raj. 583

Evaluating the Effectiveness of NoteAid in a Community Hospital Setting: Randomized Trial of Electronic Health Record Note Comprehension Interventions With Patients (e26354)
John Lalor, Wen Hu, Matthew Tran, Hao Wu, Kathleen Mazor, Hong Yu. 596

Patient Rationales Against the Use of Patient-Accessible Electronic Health Records: Qualitative Study (e24090)
Hanne Valeur, Anne Lie, Kåre Moen. 608

Testing a Novel Web-Based Neurocognitive Battery in the General Community: Validation and Usability Study (e25082)
Riley Capizzi, Melissa Fisher, Bruno Biagianti, Neelufaer Ghiasi, Ariel Currie, Karrie Fitzpatrick, Nicholas Albertini, Sophia Vinogradov. 618

Effects of an Animated Blood Clot Technology (Visual Clot) on the Decision-Making of Users Inexperienced in Viscoelastic Testing: Multicenter Trial (e27124)
Sadiq Said, Tadzio Roche, Julia Braun, Micheal Ganter, Patrick Meybohm, Johannes Herrmann, Kai Zacharowski, Florian Raimann, Florian Piekarski, Eva Rivas, Manuel López-Baamonde, Donat Spahn, Christoph Nöthiger, David Tscholl. 631

WeChat as a Platform for Problem-Based Learning Among Hematological Postgraduates: Feasibility and Acceptability Study (e16463)
Ping Luo, Wenwen Pang, Yingying Wang, Minghui Liu, Shu Zhou, Shuai Liu, Xian Zhang, Li Liu, Yanan Liu, Fuling Zhou. 643

Influences of Medical Crowdfunding Website Design Features on Trust and Intention to Donate: Controlled Laboratory Experiment (e25554)
Xing Zhang, Wenli Hu, Quan Xiao. 660

Willingness to Adopt Health Information Among Social Question-and-Answer Community Users in China: Cross-sectional Survey Study (e27811)
PengFei Li, Lin Xu, Tingting Tang, Xiaoqian Wu, Cheng Huang. 675

A Clinical Prediction Model to Predict Heparin Treatment Outcomes and Provide Dosage Recommendations: Development and Validation Study (e27118)
Dongkai Li, Jianwei Gao, Na Hong, Hao Wang, Longxiang Su, Chun Liu, Jie He, Huizhen Jiang, Qiang Wang, Yun Long, Weiguo Zhu. 688

Automatic Classification of Screen Gaze and Dialogue in Doctor-Patient-Computer Interactions: Computational Ethnography Algorithm Development and Validation (e25218)
Samar Helou, Victoria Abou-Khalil, Riccardo Iacobucci, Elie El Helou, Ken Kiyono. 701

Usability of Rapid Cholera Detection Device (OmniVis) for Water Quality Workers in Bangladesh: Iterative Convergent Mixed Methods Study (e22973)
Theresa Rager, Cristian Koepfli, Wasif Khan, Sabeena Ahmed, Zahid Mahmud, Katherine Clayton. 715

Patient Recruitment Into a Multicenter Clinical Cohort Linking Electronic Health Records From 5 Health Systems: Cross-sectional Analysis (e24003)
Wendy Bennett, Carolyn Bramante, Scott Rothenberger, Jennifer Kraschnewski, Sharon Herring, Michelle Lent, Jeanne Clark, Molly Conroy, Harold Lehmann, Nickie Cappella, Megan Gauvey-Kern, Jody McCullough, Kathleen McTigue. 729

Emotional Reactions to Cybersecurity Breach Situations: Scenario-Based Survey Study (e24879)
Sanja Budimir, Johnny Fontaine, Nicole Huijts, Antal Haans, George Loukas, Etienne Roesch. 740

Understanding Barriers to Novel Data Linkages: Topic Modeling of the Results of the LifeInfo Survey (e24236)
Holly Clarke, Stephen Clark, Mark Birkin, Heather Iles-Smith, Adam Glaser, Michelle Morris. 754

HIV Information Acquisition and Use Among Young Black Men Who Have Sex With Men Who Use the Internet: Mixed Methods Study (e22986)
Megan Threats, Keosha Bond. 773

Validation of 4D Components for Measuring Quality of the Public Health Data Collection Process: Elicitation Study (e17240)
Hong Chen, Ping Yu, David Hailey, Tingru Cui. 790

Feasibility, Acceptability, and Efficacy of Virtual Reality Training for Older Adults and People With Disabilities: Single-Arm Pre-Post Study (e27640)
Pui Chau, Yan Kwok, Mee Chan, Ka Kwan, Kam Wong, Ying Tang, Kan Chau, Sheung Lau, Yan Yiu, Mei Kwong, Wai Lai, Mun Leung. 806

Effect of Cognitive Training in Fully Immersive Virtual Reality on Visuospatial Function and Frontal-Occipital Functional Connectivity in Predementia: Randomized Controlled Trial (e24526)
Jae Kang, Nambeom Kim, Sook Lee, Soo Woo, Geumjin Park, Byeong Yeon, Jung Park, Jung-Hae Youn, Seung-Ho Ryu, Jun-Young Lee, Seong-Jin Cho. 822

Assessing the Feasibility of an Open-Source Virtual Reality Mirror Visual Feedback Module for Complex Regional Pain Syndrome: Pilot Usability Study (e16536)
Andrea Won, Ariana Barreau, Mark Gaertner, Tristan Stone, Joshua Zhu, Cheng Wang, Sean Mackey. 840

Virtual Reality for Sedation During Atrial Fibrillation Ablation in Clinical Practice: Observational Study (e26349)
Thomas Roxburgh, Anthony Li, Charles Guenancia, Patrice Pernollet, Claire Bouleti, Benjamin Alos, Matthieu Gras, Thomas Kerforne, Denis Frasca, François Le Gal, Luc Christiaens, Bruno Degand, Rodrigue Garcia. 848

Digitization of Measurement-Based Care Pathways in Mental Health Through REDCap and Electronic Health Record Integration: Development and Usability Study (e25656)
Steve Hawley, Joanna Yu, Nikola Bogetic, Natalia Potapova, Chris Wakefield, Mike Thompson, Stefan Kloiber, Sean Hill, Damian Jankowicz, David Rotenberg. 867

Guided Internet-Based Cognitive Behavioral Therapy for Insomnia: Health-Economic Evaluation From the Societal and Public Health Care Perspective Alongside a Randomized Controlled Trial (e25609)
Claudia Buntrock, Dirk Lehr, Filip Smit, Hanne Horvath, Matthias Berking, Kai Spiegelhalder, Heleen Riper, David Ebert. 895

Medical Specialty Recommendations by an Artificial Intelligence Chatbot on a Smartphone: Development and Deployment (e27460)
Hyeonhoon Lee, Jaehyun Kang, Jonghyeon Yeo. 910

Addressing Biodisaster X Threats With Artificial Intelligence and 6G Technologies: Literature Review and Critical Insights (e26109)
Zhaohui Su, Dean McDonnell, Barry Bentley, Jiguang He, Feng Shi, Ali Cheshmehzangi, Junaid Ahmad, Peng Jia. 920

Personalization of Conversational Agent-Patient Interaction Styles for Chronic Disease Management: Two Consecutive Cross-sectional Questionnaire Studies (e26643)
Christoph Gross, Theresa Schachner, Andrea Hasl, Dario Kohlbrenner, Christian Clarenbach, Forian Wangenheim, Tobias Kowatsch. 936

The Patterns and Impact of Social Media Exposure of Journal Publications in Gastroenterology: Retrospective Cohort Study (e25252)
Austin Chiang, Loren Rabinowitz, Javid Alakbarli, Walter Chan. 969

Evaluating Scholars' Impact and Influence: Cross-sectional Study of the Correlation Between a Novel Social Media–Based Score and an Author-Level Citation Metric (e28859)
Lucas Oliveira J e Silva, Graciela Maldonado, Tara Brigham, Aidan Mullan, Audun Utengen, Daniel Cabrera. 977

Leveraging Genomic Associations in Precision Digital Care for Weight Loss: Cohort Study (e25401)
Ranjan Sinha, Dashyanng Kachru, Roshni Ricchetti, Simitha Singh-Rambiritch, Karthik Muthukumar, Vidhya Singaravel, Carmel Irudayanathan, Chandana Reddy-Sinha, Imran Junaid, Garima Sharma, Patricia Francis-Lyon. 987

Analysis of COVID-19 Transmission Sources in France by Self-Assessment Before and After the Partial Lockdown: Observational Study (e26932)
Fabrice Denis, Anne-Lise Septans, Florian Le Goff, Stephan Jeanneau, François-Xavier Lescure. 1038

Using a Secure, Continually Updating, Web Source Processing Pipeline to Support the Real-Time Data Synthesis and Analysis of Scientific Literature: Development and Validation Study (e25714)
Uddhav Vaghela, Simon Rabinowicz, Paris Bratsos, Guy Martin, Epameinondas Fritzilas, Sheraz Markar, Sanjay Purkayastha, Karl Stringer, Harshdeep Singh, Charlie Llewellyn, Debabrata Dutta, Jonathan Clarke, Matthew Howard, PanSurg REDASA Curators, Ovidiu Serban, James Kinross. . . . 1045

Associations Between Health Literacy, eHealth Literacy, and COVID-19–Related Health Behaviors Among Chinese College Students: Cross-sectional Online Study (e25600)
Shaojie Li, Guanghui Cui, Atipatsa Kaminga, Sixiang Cheng, Huilan Xu. . . . 1059

Understanding Behavioral Intentions Toward COVID-19 Vaccines: Theory-Based Content Analysis of Tweets (e28118)
Siru Liu, Jialin Liu. . . . 1072

Influence of COVID-19 Lockdowns on the Usage of a Vision Assistance App Among Global Users With Visual Impairment: Big Data Analytics Study (e26283)
Gang Luo, Shrinivas Pundlik. . . . 1082

The Efficacy of Computerized Cognitive Behavioral Therapy for Depressive and Anxiety Symptoms in Patients With COVID-19: Randomized Controlled Trial (e26883)
Zhifen Liu, Dan Qiao, Yifan Xu, Wentao Zhao, Yang Yang, Dan Wen, Xinrong Li, Xiaoping Nie, Yongkang Dong, Shiyou Tang, Yi Jiang, Ying Wang, Juan Zhao, Yong Xu. . . . 1092

Factors Influencing Anxiety Among WeChat Users During the Early Stages of the COVID-19 Pandemic in Mainland China: Cross-sectional Survey Study (e24412)
Changqing Zou, Weiyu Zhang, Kristin Sznajder, Fengzhi Yang, Yajing Jia, Ruqing Ma, Can Cui, Xiaoshi Yang. . . . 1107

Experiences and Attitudes of Elementary School Students and Their Parents Toward Online Learning in China During the COVID-19 Pandemic: Questionnaire Study (e24496)
Shu Cui, Chao Zhang, Shijiang Wang, Xingong Zhang, Lei Wang, Ling Zhang, Qiuyu Yuan, Cui Huang, Fangshuo Cheng, Kai Zhang, Xiaoqin Zhou. . . . 1125

Utilizing Health Behavior Change and Technology Acceptance Models to Predict the Adoption of COVID-19 Contact Tracing Apps: Cross-sectional Survey Study (e25447)
Samuel Tomczyk, Simon Barth, Silke Schmidt, Holger Muehlan. . . . 1137

Tweet Topics and Sentiments Relating to COVID-19 Vaccination Among Australian Twitter Users: Machine Learning Analysis (e26953)
Stephen Kwok, Sai Vadde, Guanjin Wang. . . . 1156

Characterizing Health Care Delays and Interruptions in the United States During the COVID-19 Pandemic: Internet-Based, Cross-sectional Survey Study (e25446)
Elizabeth Papautsky, Dylan Rice, Hana Ghoneima, Anna McKowen, Nicholas Anderson, Angie Wootton, Cindy Veldhuis. . . . 1172

Capturing COVID-19–Like Symptoms at Scale Using Banner Ads on an Online News Platform: Pilot Survey Study (e24742)
Brian Dixon, Sumit Mukherjee, Ashley Wiensch, Mary Gray, Juan Ferres, Shaun Grannis. . . . 1188

An App-Based Intervention to Support First Responders and Essential Workers During the COVID-19 Pandemic: Needs Assessment and Mixed Methods Implementation Study (e26573)
Stacie Vilendrer, Alexis Amano, Cati Brown Johnson, Marissa Favet, Nadia Safaeinili, Jacqueline Villasenor, Jonathan Shaw, Attila Hertelendy, Steven Asch, Megan Mahoney. . . . 1202

Abstract

Background: The use of information and communication technology (ICT) in suicide prevention has progressed rapidly over the past decade. ICT plays a major role in suicide prevention, but research on best and promising practices has been slow.

Objective: This paper aims to explore the existing literature on ICT use in suicide prevention to answer the following question: what are the best and most promising ICT practices for suicide prevention?

Methods: A scoping search was conducted using the following databases: PubMed, PsycINFO, Sociological Abstracts, and IEEE Xplore. These databases were searched for articles published between January 1, 2013, and December 31, 2018. The five stages of the scoping review process were as follows: identifying research questions; targeting relevant studies; selecting studies; charting data; and collating, summarizing, and reporting the results. The World Health Organization suicide prevention model was used according to the continuum of universal, selective, and indicated prevention.

Results: Of the 3848 studies identified, 115 (2.99%) were selected. Of these, 10 regarded the use of ICT in universal suicide prevention, 53 referred to the use of ICT in selective suicide prevention, and 52 dealt with the use of ICT in indicated suicide prevention.

Conclusions: The use of ICT plays a major role in suicide prevention, and many promising programs were identified through this scoping review. However, large-scale evaluation studies are needed to further examine the effectiveness of these programs and strategies. In addition, safety and ethics protocols for ICT-based interventions are recommended.

Introduction

Background

Information and communication technology (ICT) has been used for suicide prevention over the past decade. Moreover, there is a growing body of evidence supporting the use of ICT in the development of promising suicide prevention practices [1,2]. ICT can be used to screen individuals at risk of suicide on the web; offer information and help regarding suicidal thoughts and behavior; and offer web-based assessment, interventions, and follow-up [1-6]. The use of ICT widens accessibility to hard-to-reach individuals who do not always seek help in person and offers treatment opportunities to communities with lower access to care, such as rural communities. The use of ICT in suicide prevention can also help professionals offer better care to their patients by combining multiple approaches, such as using mobile apps to monitor symptoms or providing web-based therapeutic programs [7,8].

Many opportunities arise when using ICT to expand suicide prevention strategies. However, the pace at which ICT is advancing makes it difficult to keep up with, especially from a research perspective. To make better use of these different web-based suicide prevention strategies, a better understanding of these different uses of ICT is necessary. We identified 3 major questions. First, a better understanding of how to emphasize the technical aspects of ICT regarding the development, maintenance, privacy, and life cycle of the technology would help make better choices regarding which ICT to use in what context. For example, machine learning offers many possibilities for identifying at-risk individuals, but major technical and ethical considerations must be described and taken into account. Second, we need to improve our understanding of ICT use in suicide prevention. To support adequate decision making, it is important to know whether ICT-based suicide prevention strategies reach different clienteles or if we are reaching the same individuals differently. Third, a better understanding of the structure and efficacy of various types of current web-based assessments and interventions is also important. For instance, can artificial intelligence (AI) and machine learning be used to optimize and accelerate the assessment of individuals at risk? Is a suicide crisis intervention by chat as effective as talking over the phone or in person? Are web-based cognitive behavioral therapy (CBT) programs as effective for suicide prevention as face-to-face CBT programs? Before shifting toward using and recommending the use of these different ICT-based assessments and interventions, it should be noted that their effectiveness has yet to be demonstrated in the literature.

Current Study

The available literature often refers to a specific type of ICT as opposed to a general overview of existing ICT-based strategies in mental health and suicide prevention. More precisely, existing literature reviews have focused on specific ICTs such as smartphone tools [1], web-based interventions [3], mobile apps [4], and social media [5] or specific age groups such as youth [6]. Based on this background and a rapidly evolving corpus of research, we set out to review the evidence supporting the use of all types of ICTs in different levels of suicide prevention strategies. More precisely, we carried out a scoping review to identify the best and most promising practices for ICT use at all levels of suicide prevention, which are described by the World Health Organization as the universal (entire population), selective (specific subpopulations), and indicated (high-risk individuals) levels [9]. ICT was defined as all materials, software, or services used to collect, process, and transmit information; this includes electronic, computer, telecommunications, multimedia, and internet technologies [10]. AI was defined as all theories and techniques used to develop machines capable of simulating intelligence [7].

Methods

Scoping Review Framework

We used the 5-stage scoping framework developed by Arksey and O'Malley [11] and adapted by Levac et al [12] to review peer-reviewed publications. These stages are (1) identifying research questions; (2) identifying relevant studies; (3) selecting studies; (4) charting data; and (5) collating, summarizing, and reporting results. A scoping review allows researchers to explore the available data on various aspects of a theme instead of just one [11,12]. This provides an overview of the relevant literature that helps to identify the various ICT and suicide prevention strategies examined by researchers since 2013 and to document their effects. The Center for Research and Intervention on Suicide, Ethical Issues, and End-of-Life Practices decided to better understand the use of ICT in suicide prevention as of 2013 following the publication of the book *Suicide prevention and new technologies: Evidence-based practice* [13]. This book provides an overview of new technologies in suicide prevention and demonstrates the need for further research in this area. As ICT tools, contents, and use evolve rapidly, a 5-year timeframe seems relevant to address the current state of ICT preventive practices and research. For example, major social networks have changed their policies toward content related to suicidality. During the 2019 International Suicide Prevention Day, Facebook revised its policy of preventing self-harm and suicide by banning graphic representations of suicidality, which could change the level of exposure of individuals vulnerable to suicide. At the same time, the rapid development of scientific knowledge and technology has been noted many times. For example, a review of the scientific literature published in 2013 identified 5 scientifically evaluated mobile apps for child and adolescent mental health [14], whereas Grist et al [15] identified 19 more. In addition, web-based platforms such as Parler or 4Chan were not as widely known and used 10 years ago. Including older technologies and neglecting to consider the rapid content change of internet content over the years may skew results toward obsolete prevention strategies.

Summary of Search Strategy

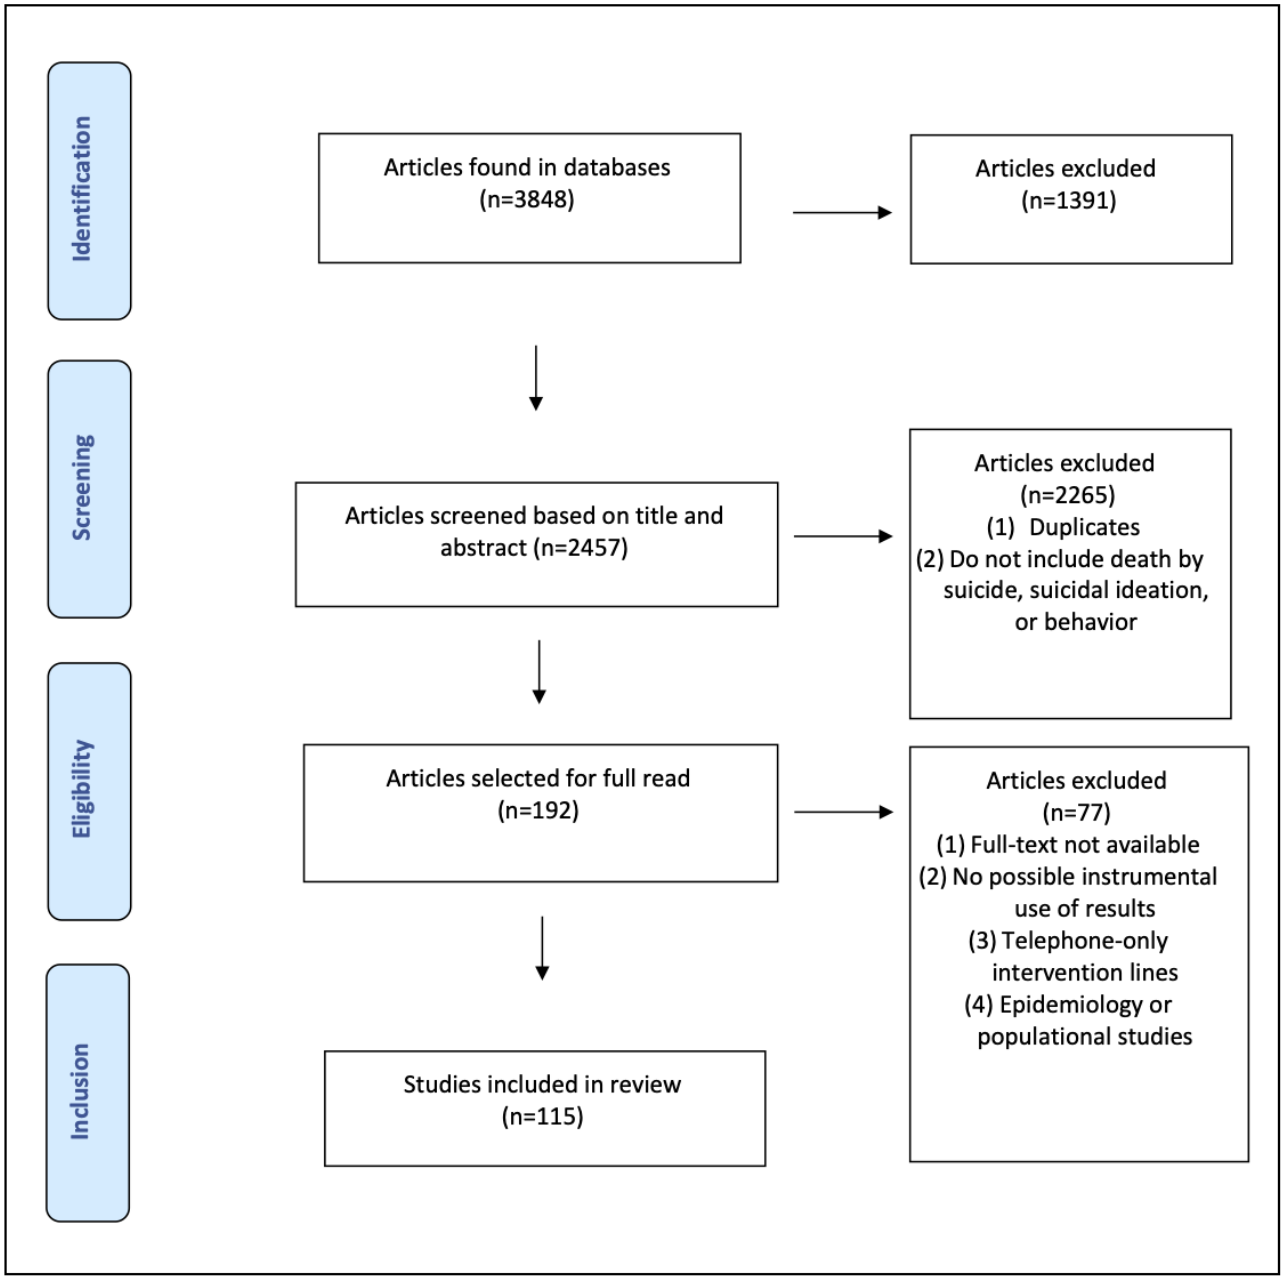
Identifying the Research Question

The research question identified for this scoping review aims to guide future program development and implementation by establishing an inventory of strategies using ICT that have been the subject of research in recent years. Following the PRISMA

XSL•FO
RenderX

(Preferred Reporting Items for Systematic Reviews and Meta-Analyses) recommendations, the research question was developed using the PICO (population, intervention, comparison, and outcomes) conceptual tool [16]. Note that an adaptation of PICO was made through an amalgamation with the SPIDER (sample, phenomenon of interest, design, evaluation, research type) tool by Methley et al [17] to facilitate the consideration of the psychosocial nature of the research object. Consequently, the research question was "How information and communication technology (ICT) can be used in intervention and prevention of suicide among the general population, people at risk, or suicidal people of all ages and conditions combined to contribute to the reduction of any indicators relating to suicidality?" This question was selected to promote the instrumental use of the research results [18].

Identifying Relevant Studies



The search strategy consisted of identifying key concepts related to ICT-based suicide prevention and intervention, developing a provisional syntax specific to each database for pretesting, and determining the definitive syntax based on the pretest results. The keywords used to construct research syntaxes were extracted from natural (everyday vocabulary) and controlled (indexer terms) language terms and based on the central concepts associated with the research questions. The researched concepts were suicidal behavior, ICT (AI, machine learning, application, social network, and mobile technology), intervention (information, education, prevention, decision making, and intervention), and program evaluation. The final syntax based on these keywords and used with each database searched is presented in Multimedia Appendix 1. PubMed, PsycINFO, Sociological Abstracts, and IEEE Xplore were searched for publications from January 1, 2013, to December 31, 2018. The selection of each database was carefully thought out by the research team (2 senior researchers in suicidology, 2 ICT experts, 1 postdoctoral student, 1 doctoral student, and 1 specialized librarian who provided support) to include data in the medical field, psychology, social and behavioral sciences, and ICT. The number of databases chosen was in line with that of other reviews that focused on specific ICTs and mental health [5,19]. In addition, the choice of databases was based on the following 2 criteria: the number of documents they contain and the degree of overlap of the content indexed in each database [20]. The final choice was made to select high quantities of indexed documents in databases and databases with less content overlap to maximize the completeness of the retrieval process.

Selecting Studies

The final search syntax identified 3848 publications that were imported for EndNote selection. From these, 1391 duplicates were removed. The remaining 2457 publications were then sorted according to the inclusion and exclusion criteria applied by 5 research assistants against titles and abstracts only. Interrater reliability was assessed for 100 publications. Agreement reached 89% and a Cohen κ statistic of 0.704 was achieved, which is considered substantial by Cohen [21]. The studies covered in our review used various methods (qualitative, quantitative, and mixed methods) and were drafted in English or French. They had to provide original empirical or descriptive data. Literature reviews, editorials, theoretical articles, and studies focused only on ethical or legal issues surrounding ICT-based suicide prevention were excluded. The included articles had to directly address suicide prevention strategies using ICT. All studies that used death by suicide, suicidal ideation, or suicide behavior as outcomes were considered. The PRISMA flow chart [16] of our study presented in Figure 1 provides an overview of our study selection process.

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.

Charting, Collating, Summarizing, and Reporting Data

A form was developed in Microsoft Excel to retrieve pertinent information from selected qualitative, quantitative, and mixed methods studies to optimize data charting. A research team tested the form before use. It included 10 items: title, objectives, research design, instruments of measure, type of suicide prevention (universal, selective, or indicated), technology category, participant characteristics, results associated with effects and benefits regarding lowering suicidal behavior, clinical and scientific contributions, and recommendations. The research team thoroughly examined 5 independent studies with 10 items and then compared the results. Following this analysis, precision was applied to the exclusion criteria of the studies. Verbal telephone interventions were excluded from this review. Considering the large quantity of data available on suicide prevention telephone interventions [22-24], studies addressing these types of interventions were excluded from this scoping review. However, interventions based on text messaging and smartphone apps were included as new ICT-based interventions relevant to this review. After criteria validation, a summary of pertinent information was prepared for each study included. No systematic methodological quality evaluation was carried out in accordance with the scoping review methodology [11].

Results

General Information

Our search of PubMed, PsycINFO, Sociological Abstracts, and IEEE Xplore yielded 3848 articles. After removing 1391 duplicates and 2265 articles based on a perusal of title and abstract, 192 texts were read in full for the final screening. This allowed us to remove an additional 77 articles, leaving 115 articles for the scoping review. We also noticed through our

XSL•FO
RenderX

analysis that the number of publications increased in 2016 and 2017, and the scientific articles focused more on selective and indicated suicide prevention strategies.

Classification of Interventions' Efficacy

In the context of this scoping review, we aim to provide a general portrait of existing suicide prevention strategies based on ICT. It does not aim to determine the quantitative effectiveness of such interventions. Therefore, a prevention strategy is considered effective when it is based on rigorous theory and when it has been evaluated by a minimum of 2 studies with a quasi-experimental approach [25]. Typically, in traditional systematic reviews, identifying *evidence-based practices* requires a weighting of the methodological quality of primary studies, unlike the scoping review [12]. If the relevant studies are randomized trials, the body of evidence begins with high certainty. If the relevant studies are observational, the body of evidence begins with low certainty [26]. Certain strategies may, however, be presented as *promising* when at least one observational or randomized study supports its efficacy. Therefore, we considered all interventions that have demonstrated effectiveness in any type of research design (qualitative, quantitative, or mixed studies).

Universal Suicide Prevention Strategies

In total, 10 of the studies selected referred to universal suicide prevention strategies (Table 1). These addressed 2 main program categories: (1) health promotion and suicide prevention through the use of educational websites and (2) health promotion and suicide prevention through awareness campaigns and social media psychoeducation. These programs were accessible to all participants. The types of websites identified were information-based, interactive, forums, and chats. Social media platforms included Facebook, Twitter, and personal and professional blogs. In general, the effects of these programs on perceptions and knowledge have been poorly evaluated. Universal suicide prevention strategies included the *SUPREME* (Suicide Prevention through Internet and Media-Based Mental Health Promotion) project [27], the *Storytelling* project [28], the *It Gets Better* project [29], the *Live Through This* project [30], and *Media-Based Prevention Messages* [31]. Although these different universal strategies could have some effects on the negative emotions of participants [32], they primarily play a potential role in reducing the stigma associated with suicide [30,33] and suicidal ideation and behavior [27,30,32] and increasing web-based suicide prevention knowledge [31,34,35], mental health literacy [32,33], and web-based help seeking [33,34]. Table 1 presents a description of the studies that referred to universal suicide prevention strategies.

Table 1. Universal suicide prevention strategies.

Type of program	Identified studies	Objectives	Programs, n	ICT[a] used	Targeted population	Examples	Results and comments
Health promotion and suicide prevention through the use of educational websites	[27,28,30,32]	• Improve mental health and well-being • Educate and increase awareness of young people of mental health and suicide prevention • Prevent stigma • Encourage help seeking and service use by young people • Promote protective factors	2	• Websites • Interactive modules • Forums	• Young people • Young adults • At-risk groups	"SUPREME[b]" project [27] and "Live Through This" [30]	Results in terms of reducing suicidal ideation and behavior, increasing mental health literacy, and increasing web-based help seeking seemed promising.
Health promotion and suicide prevention through awareness campaigns and social media psychoeducation	[29,31,33-36]	• Increase social media users' awareness of the existence of and issues associated with suicide and its prevention	4	• Presenting, broadcasting and sharing messages on social media	• Young people • At-risk groups	"It Gets Better" project [29] and "Media-Based Prevention Messages" [31]	Results in terms of reducing suicidal ideation and behavior and improving knowledge, attitudes, and asking for help on the web seemed promising. However, further research was needed.

Selective Suicide Prevention Strategies

We identified 53 studies that dealt with selective suicide prevention strategies (Table 2). From these, 9 different selective suicide prevention program categories emerged, and each had multiple different outcomes. These strategies ranged from identifying people at risk to web-based self-management and training programs. Some were designed to be used alone, whereas others were part of a larger intervention program involving direct contact between suicidal individuals and suicide prevention resources. The programs targeted distressed individuals and groups at risk, that is, health professionals. ICT use varied according to the desired outcome. For example, algorithms were used to identify individuals at risk for suicide on the web, as advertised by Google AdWords, which is now known as Google Ads [37,38]; interactive websites were used to support the assessment and management of mental health disorders in collaboration with a mental health professional [39]; and training modules, web-based exercises, and multimedia presentations were used to enhance knowledge, understanding, and attitudes regarding suicide prevention and intervention [40-42]. Programs using algorithms to identify at-risk individuals seemed most promising for identifying people at risk for suicide versus those not at risk [37,38,43-58]. These algorithms analyzed suicide risk on the basis of different elements, including speech and linguistic characteristics, medical notes, search engine ad clicks, and profiles from web-based chat sessions or social media [37,38,43-58]. Although these algorithms helped identify individuals at risk for suicide, a clinical application of these algorithms is yet to be developed, as little is known about the effectiveness of these programs in increasing actual web-based and in-person help-seeking behaviors.

XSL•FO
RenderX

Table 2. Selective suicide prevention strategies.

Type of program	Identified studies	Objectives	Programs, n	ICT[a] used	Targeted population	Examples	Results and comments
Identifying at-risk individuals through automatic analysis of their linguistic characteristics during face-to-face consultations	[44-47]	• Identify individuals at risk for suicide and qualify risk level based on speech characteristics	2	• Analysis of characteristics from observation of spoken language	• Individuals presenting risk factors at assessment interviews	Analysis of speech and sound characteristics program [45-47]	This technology seems effective in distinguishing suicidal from nonsuicidal individuals. A clinical use of this technology is yet to be developed.
Identifying at-risk individuals through automatic analysis of medical file notes and/or research data	[54-57]	• Identify individuals at risk for suicide and qualify risk level based on data (medical file or research data) from clinical observations by clinicians or researchers	1	• Analysis of written language	• Individuals presenting risk factors during assessment interviews	The "SafetyNet" program [56]	This technology seems effective in distinguishing suicidal from nonsuicidal individuals. A clinical use of this technology is yet to be developed.
Identifying at-risk individuals through automatic analysis of their linguistic characteristics during chat sessions or on written forms	[43,58]	• Identify individuals at high risk for suicide based on characteristics of their words or responses	0	• Analysis of written language	• Individuals presenting risk factors during written exchanges	Suicide meaning making applied in specific contexts [58]	This technology seems promising. A clinical use of this technology is yet to be developed.
Identifying at-risk individuals through automatic analysis of their linguistic characteristics on social media	[48-53,59-62]	• Examine writings of social media users to automatically identify individuals at risk for suicide and offer them proactive help	4	• Analysis of written language	• Social media users	Program to screen suicidal individuals based on tweets [52,59]	This technology is innovative. Further research is needed.
Identifying at-risk individuals through targeted ads on search engines	[37,38]	• Identify suicidal individuals through their queries on search engines • Suggest help resources	2	• Search engine algorithm and targeted ads	• General public	Web-based sentinel program [37]	The number of clicks on targeted ads serves as an indicator. There are too few results to date to evaluate these programs' effectiveness in increasing the web-based help-seeking behaviors of suicidal individuals.
Web-based identification programs tailored to different groups	[63-69]	• Identify vulnerable groups using mailing lists or websites to direct them toward help resources	3	• Web-based standardized risk assessment questionnaires with response algorithms adapted to assessment results	• Individuals at risk for suicide	EMPATHY[b] [63] and HEAR[c] for nurses [69]	This type of program allows identifying individuals at risk who have no contact with health services. Utilization rates for proposed resources seem encouraging.

XSL•FO
RenderX

Type of program	Identified studies	Objectives	Programs, n	ICT[a] used	Targeted population	Examples	Results and comments
Web-based mental health self-evaluation programs	[39,70]	• Support evaluation and management of mental health problems in conjunction with a mental health professional	1	• Interactive website • Web-based evaluation tool • Algorithm tool for redirecting to resources • Development of a web-based personalized intervention plan	• Individuals receiving support from a health professional	myGRaCE decision support system [39] and YouthCHAT [70]	Improves patient engagement in understanding their situation and in managing their treatment.
Web-based mental health self-management program with measures of impact on suicide risk	[71-81]	• Facilitate web-based mood self-management and improve quality of life through a cognitive behavioral intervention	5	• Interactive website • Psychoeducation module • Multimedia presentation • Web-based exercises • Discussion and consultation forum	• Individuals with low-intensity mental health problems	MindSpot Clinic [77]	Program membership rates are relatively low. Individuals tend more often to experience a decrease in suicidal ideation and depression symptoms. Programs are offered alone or in conjunction with clinical follow-up by a professional. Results are hard to compare.
Web-based suicide prevention training programs	[40-42,82-87]	• Improve knowledge, attitudes and suicide prevention practices of professionals and sentinels	5	• Website • Training modules • Multimedia demonstration • Web-based exercises	• Professionals • Sentinels	Question, Persuade, Refer, and Treat program [40,84]	These programs allow improving knowledge and attitudes. They seem less effective in changing intervention practices if not offered along with certain forms of face-to-face practices.

[a]ICT: information and communication technology.

[b]EMPATHY: Empowering a Multimodal Pathway Toward Healthy Youth.

[c]HEAR: Healer Education Assessment and Referral.

Using ICT to identify individuals at risk for suicide in school (from elementary school to medical school) or community settings has been associated with increased mental health literacy, help-seeking behavior, and use of help resources [63-65]. For example, in the Health Education Assessment and Referral (HEAR) program, medical students anonymously responded to a web-based questionnaire on suicide risk and various mental health issues. The program allowed identifying students at risk for suicide and referring them to a medical school psychiatrist or psychologist through a web-based platform. As a result, the use of medical schools' mental health services increased from 11.5% to 15% over 4 years [64].

Our review also identified web-based self-assessment and self-management programs. For example, myGRaCE is a decision-making support system that combines service user self-assessment and practitioner expertise by comparing the user's self-assessment against a practitioner's assessment [39]. Most of the participants in this study agreed that myGRaCE helped them assess their personal security, understand what puts them in danger, and what areas they should change in their lives. Self-assessment programs are also a way to engage young people and adults by helping them understand their situation and identify ways to take control of their health [39,70]. As for web-based self-management programs, results showed that many programs could, in some cases, significantly reduce suicidal ideation [71-74] and increase chances of resorting to mental health interventions [75,76]. However, the rate of adherence to these types of programs remains low. Examples of these include MoodGYM [71], MindSpot Clinic [77], different types of internet-based cognitive behavioral therapy (iCBT), Thrive [73], the Sadness program [78], and CATCH-IT (Competent Adulthood Transition with Cognitive, Behavioral,

XSL•FO
RenderX

Humanistic and Interpersonal Training) [74]. These programs were offered either alone or in combination with clinical follow-up. Users seemed to appreciate the mobile apps used for self-management and suicide prevention training. Many web-based suicide prevention programs have been tested for their efficacy. These programs were intended for gatekeepers who work with adolescents [82], gatekeepers in school settings [83], mental health professionals [40], health professionals in general [41,42,84], Veterans Affairs providers [85], and graduate students [86]. In some cases, face-to-face training developed more knowledge and suicide prevention skills than web-based training [84]. In addition, an increase in suicide prevention knowledge was often observed within the first months post training but often decreased over time [82]. Details of the studies that referred to selective suicide prevention strategies are presented in Table 2.

Indicated Suicide Prevention Strategies

Regarding the indicated suicide prevention strategies, we selected 52 studies for our review and identified 9 program categories. These programs, presented in Table 3, were offered by health professionals or psychosocial help services and covered suicide risk assessment triage and monitoring, crisis intervention, low-intensity psychological interventions, psychotherapy for individuals at risk for suicide, and technological tools to support face-to-face interventions. The ICTs used for these programs included classification algorithms, chats and text messages, mobile apps, and interactive clinical intervention websites. Examples of these programs include the Mental Health eClinic [55], a web-based assessment and self-management program; Reframe-IT [88], an internet-based CBT program for high school students at risk for suicide; MYPLAN [89], a mobile phone safety plan app for supporting people at risk for suicide; dialectical behavioral therapy Coach Mobile [90], a CBT support intervention mobile phone app; and RAFT (Reconnecting After a Suicide Attempt) [91], a brief web-based outreach intervention for people who attempted suicide and who lost contact with services. In general, ICT-based self-assessment tools have been reported to be as effective in person as in hardcopy format in identifying suicide risk warning signs [92].

XSL•FO
RenderX

Table 3. Indicated suicide prevention strategies.

Type of program	Identified studies	Objectives	Programs, n	ICT[a] used	Targeted population	Examples	Results and comments
Development of web-based suicide risk assessment tools	[92-97]	• Propose suicide risk assessment tools administered electronically in clinical contexts	4	• Electronic clinical instrument • Response selection algorithm based on assessment results	• Individuals at risk for suicide in contact with health services	Web-based Columbia Suicide Severity Rating Scale [93]	Electronic assessment tools seem as effective as hardcopy versions. They allow internet users at times to reveal their suicidal behaviors more easily
Use of artificial intelligence and machine learning to optimize completion time for suicide risk assessment tools	[98]	• Reduce completion time for suicide risk assessment tools	1	• CAT[b]	• Individuals at risk for suicide in contact with health services	CAT [98]	This type of algorithm allows reducing the number of items needed to assess suicide risk.
Use of triage systems by ICT to assess suicide risk	[99]	• Improve triage of individuals at risk for suicide who use health services	1	• On-lining of clinical suicide risk assessment tools • Risk-level classification algorithm based on scores • Targeted offer of resources • Automatic alert to the clinical team	• Individuals at risk for suicide in contact with health services	Mental health eClinic [99]	This type of program allows identifying young people at risk for suicide and offering them clinical treatment more rapidly.
Crisis intervention via text messaging or internet chatting	[68,69,84,85]	• Intervene in a crisis situation via text messaging or internet chatting	3	• Text messaging • Internet chatting • Computerized system for processing text messages and chat exchanges	• Young people are the priority target group of these interventions. They can, however, be used to reach other age groups	Kids Help Phone LIVECHAT Project [100] and RAFT[c] [91]	Text messages and internet chat interventions seem a viable alternative to telephone interventions for certain groups. However, intervention strategies adapted to these modes of communication need to be developed.
Use of web-based publications by patients as intervention support material	[101,102]	• Assess suicide risk and intervene using a person's web-based discourse	1	• Content of posts written on social networks	• Suicidal individuals receiving mental health services	Patient's social networking sites as a clinical tool [101]	The use of content written on social networks by patients allows a better understanding of the situation and helps perform a suicide risk assessment, especially in the case of patients who deny such behaviors.

XSL•FO
RenderX

Type of program	Identified studies	Objectives	Programs, n	ICT[a] used	Targeted population	Examples	Results and comments
Web-based management and low-intensity intervention for individuals at risk for suicide	[1,31,63,68,88,102-114]	• Intervene with individuals at risk for suicide using a cognitive behavioral approach	7	• Interactive website • Web-based exercise module • Discussion forum • Multimedia presentation	• General population • Individuals referred to programs by clinicians	Reframe-IT [88], Fitmindkit [102], EMPATHY[d] [63], and SMART[e] Mental Health Project [110,113]	These programs bring about a small decrease in suicide risk among participants.
Mobile apps used as part of treatment follow-up with suicidal individuals	[90,115-121]	• Support face-to-face clinical intervention • Support aboriginal young people by complementing face-to-face intervention	2	• Interactive mobile app • Algorithm for providing responses and offering resources based on information provided by the user	• Individuals receiving mental health services • Aboriginal young people	DBT[f] Coach Mobile [90] and AIMhi Stay Strong iPad [101]	These apps seem to help reduce the danger of suicide and the urgency of self-harm. Perceptions are positive, and apps allow reaching young people in isolated communities.
Use of web-based monitoring tools to improve psychological follow-up of individuals at risk for suicide	[107,122,123]	• Conduct regular evaluations of individuals and their symptoms to inform and adjust intervention	3	• Digitalization of screening tools • Mobile app • Contact with intervention team via automated alerts • Automated sending of text messages	• Individuals diagnosed with a mood disorder and receiving mental health services	Depression Project [123]	The use of an app facilitates disclosure of suicidal and self-harm behaviors. Regular monitoring of symptoms helps adjust intervention strategies.
Follow-up program by automatic text messages for individuals at risk for suicide	[91,124-126]	• Offer tailored follow-up following a suicide attempt to increase treatment use and reduce suicidal behaviors and self-harm	3	• Automated sending of predrafted text messages, including encouragement and appointment date reminders	• Suicidal individuals receiving mental health services	Postattempt follow-up program by text messaging [124]	Users appreciate the text messages and deem them a good way of keeping in touch with care services. Help-seeking behaviors increase, and self-harm behaviors decrease.

[a]ICT: information and communication technology.

[b]CAT: computerized adaptive testing.

[c]RAFT: Reconnecting After a Suicide Attempt.

[d]EMPATHY: Empowering a Multimodal Pathway Toward Healthy Youth.

[e]SMART: Systematic Medical Appraisal, Referral and Treatment.

[f]DBT: dialectical behavioral therapy.

In some cases, web-based self-assessment tools, as opposed to face-to-face tools, seemed to facilitate the disclosure of suicidal behavior [93]. AI has also been shown to be effective in optimizing the web-based assessment of suicide behavior by using an item response-based computer-adaptive simulation to reduce the length of a suicide risk assessment tool [98]. As for ICT-based triage systems, the use of the Synergy Online System allowed young people to complete a web-based clinical

XSL•FO
RenderX

assessment before a face-to-face or web-based clinical appointment, who were to be prioritized and contacted immediately in case of high suicide risk [99]. Web-based crisis interventions by chat or SMS text messaging have been on the rise and seem to be an alternative to phone interventions for some groups. Studies comparing chat services with SMS text messaging have shown similar results [127]. However, users of chat services, such as 113Online [128], were more likely to be at a high level of suicide crisis, had more mental health problems, were younger, and were more often to be women compared with crisis hotline users. In addition, interventions delivered through chat services were longer and more complicated, and fewer changes were observed in the individual's emotional state [127,128]. Interventions have yet to be developed and adapted to this type of technology; the fact that interventions designed to be delivered by telephone were delivered by chat or SMS text messaging without being adapted to these other media was considered a major limitation [128]. Some studies also analyzed content posts by suicidal patients on social networking sites to better assess suicide risk, especially in patients denying suicidal behavior [101,129]. Although social media content helped with better understanding a person's situation, there were many ethical concerns regarding this data collection method [129].

Self-management and iCBT programs seemed to reduce suicidal ideation. Unlike iCBT and self-management interventions addressing general mental health in the selective suicide prevention section, these interventions specifically addressed user suicide behaviors. Examples of these programs included Empowering a Multimodal Pathway Toward Healthy Youth [63], Reframe-IT [88], Fitmindkit [102], Safe conversation [103], Latitudes [103] and PrevenDep [104]. Intervention goals included developing basic problem-solving skills [88] and cognitive restructuring [105] to reduce suicide risk. Other ICT suicide prevention interventions include using computer alerts or mobile apps to apply a safety plan. These ranged from a system alerting the clinician not to forget to use the safety plan with a patient [130] to a mobile app of a personalized safety plan that patients could have on their phones at all times [89,115]. Research has demonstrated a good level of acceptability [131] for these interventions, but further evaluation of their effects on suicidal behaviors is necessary. Mobile apps have also been used to support therapeutic follow-up for suicidal patients [90,115,116], including for specific groups such as Aboriginals and Torres Strait Island Australians [117]. These mobile apps seemed to help reduce suicidal danger and self-harm [90,118], reach young people in isolated communities [132], and increase adherence to face-to-face follow-ups [119].

Discussion

Limitations

The rapid expansion of ICT use in suicide prevention has preceded the development of theoretical models to orient its methods and content and the accumulation of sufficient empirical research to indicate what is most helpful and what is not helpful. In this context, common sense has been the guiding principle, resulting in a plethora of suicide prevention activities being implemented with limited research evaluations of their effectiveness slowly following. Many of the most widely used ICT suicide prevention services have never been evaluated. Therefore, the published studies concern a small nonrandom sample of select interventions that a few researchers have been interested in studying. When little or no research has been published on ICT programs, this does not mean that they are not effective. Similarly, when there are promising empirical data on the benefits of a program, this does not mean that it is better or more useful than programs that have not been studied. Furthermore, we do not know if the *promising* results reported will stand the test of time, as more research is conducted using more rigorous research methodologies. Therefore, any conclusions drawn from the limited scientific publications must be considered preliminary and hopefully will be subject to verification in the future.

Contributions

This scoping review on ICT use in suicide prevention shows that a large number of studies have been published in the past few years [1,3,5]. Our findings shed light on the use of ICT in different types of universal, selective, and indicated suicide prevention strategies.

Amid publications with the potential to reach a large population, there are only a few publications on the use of ICT in universal suicide prevention [27-35,133]. Our findings reveal that there are around 85% fewer studies on universal prevention strategies than those on selective and indicated strategies. The 10 publications we identified describe health promotion and suicide prevention through educational websites, web-based awareness campaigns, and social media [27-35,133]. The limited empirical findings suggest that these programs may play a role in increasing general mental health literacy and the incidence of help-seeking behavior, which are associated with reduced suicidal ideation and behavior. However, the effects of these programs on perceptions and knowledge have rarely been investigated. It is important to identify which characteristics of educational websites, awareness campaigns, and postings on social media are associated with positive changes in help seeking and reductions in suicidal ideations and behaviors. Furthermore, it is essential to develop effective means for identifying sites and postings that are helpful and notifying users about or orienting them toward internet content that may be of help to them.

Selective suicide prevention strategies using ICT consist of programs that identify specific subpopulations to offer specialized support to reduce suicide risk. They particularly targeted young people and various at-risk groups (eg, the lesbian, gay, bisexual, transgender, queer, and other community; sexual minorities; and aboriginal communities) through their profiles and linguistic characteristics (eg, chat sessions, web-based written forms, and social media) or by analyzing their medical records and research data. They also include targeted web-based advertising, web-based self-assessment and self-management, and web-based training. A larger published body of research indicates that these approaches are promising, particularly in controlled environments such as schools. School programs using ICT, such as HEAR, have been shown to have a positive impact

XSL•FO
RenderX

on mental health help seeking and service use in youth [64]. Programs targeting specific subgroups of the general population have been shown to increase mental health literacy and the chances of using mental health services, but this effect seems to decrease over time [71,73,74,77,92]. Therefore, it is important to focus on the sustainability of the effects of programs that have an initial positive impact. The novelty of an intervention may be associated with greater effects. If novelty is a key feature of programs' success, then either the programs need to be constantly changed and renewed to sustain their impact or the programs need to be continually replaced by new and different activities to ensure that people will continue to be helped over time. Therefore, both approaches may be proven to be unsustainable over time. This rapid effect can also give a false sense that resorting to web-based strategies is sufficient. However, web-based help does not replace face-to-face or direct support and care from trained professionals. These different selective suicide prevention strategies should only be used in addition to face-to-face type of help and interventions. Moreover, our empirical findings show that more research is required to better distinguish between false positives and false negatives in these web-based identification techniques. It is of utmost importance to help identify at-risk groups and avoid discarding individuals who are assessed as false negatives too quickly. A false impression of security can put these individuals at a greater risk.

Where indicated suicide prevention strategies are concerned, programs vary, including using ICT in suicide risk assessment triage, monitoring suicide risk, crisis intervention activities, and psychotherapy. The programs were offered on the web only (eg, websites, mobile phone apps, and chats), but they were sometimes supported by face-to-face interventions. In some instances, they were found to be efficient (eg, shortened web-based assessments), and sometimes they were time-consuming (eg, interventions were longer in chat sessions). ICT-based and self-management interventions seem promising, as they address suicidal behaviors directly and offer alternatives for coping with suicidal thoughts by developing problem-solving skills [88,90-92]. In addition, specific at-risk groups in isolated communities where other services are not available may benefit from mobile apps used for patient follow-up.

Ethical Considerations to Address in the Future

Many of the studies included in this review raised security and ethical concerns regarding web-based suicide prevention practices. Ethical concerns range from a lack of training and web-based moderators' skills to the lack of an evidence-based framework providing guidelines for the secure use of ICT [35]. As mentioned by Robinson et al [35], it is ethically necessary to provide security protocols and a clear code of ethics for safe web-based intervention. Another ethical concern is that all individuals have the right to privacy, including web privacy [101,129]. Thus, there is reason to question whether the content analysis of web-based social media posts, emails, and other web-based sources of information is an ethical research endeavor if informed consent is not obtained from the individuals who have posted the information [101,129]. Beyond security and privacy, there are many other ethical concerns regarding web-based surveillance, informed consent, communication, controls, and disclosure [134,135]. For example, a proper ethical assessment of risks and benefits to the use of different ICT strategies is rarely, if almost never, considered in the development process. There is also a major ethical concern regarding reducing or eliminating in-person services and replacing them with insufficient web-based solutions that may appear to present better cost-effectiveness without proper in-depth assessment. With this concern, web-based interventions should always be combined with in-person formal help and intervention services. This raises many concerns and provides plenty of grounds for further research aimed at ensuring safer and more ethical use of ICT in suicide prevention.

Conclusions

As the number of studies on ICT use in suicide prevention is growing, the published literature needs to be reviewed regularly. This scoping review shows that ICT use in suicide prevention provides an interactive, personalized, readily available, and accessible approach to reach various populations for identification of at-risk individuals and to provide support. ICT may provide a sense of *being connected* to people who are otherwise isolated and reluctant to use offline services. Promising published findings on web-based intervention content includes psychoeducation and skills training. As digital help proliferates, one should consider whether this means that help-seeking and suicide prevention activities will replace traditional offline services. However, in some areas where radical changes were expected, existing modalities continue to be used (eg, individuals did not stop using in-person services when telephone phone crisis lines appeared, and these telephone lines reached a different audience and complemented existing services). The extent to which ICT will become the main source of suicide prevention activities will depend upon its efficacy in helping people, compared with and as a complement to existing services and activities.

Although there is a growing body of evidence regarding ICT use in suicide prevention, program evaluation is still lacking. There is a need for more research evaluating and comparing the impacts of various ICT strategies in different contexts, understanding the profiles of individuals at risk of suicide who use ICT, and web-based help-seeking behaviors. We also need to better understand the impact of ICT on individuals who are bereaved by suicide. Moreover, ethics and security concerns regarding web-based suicide prevention have been the focus of very limited research and need to be addressed in future studies.

Furthermore, service users, providers, and managers from private or public systems should be informed as of now and updated regularly on the benefits and risks of ICT use in health and social services. This information should include (1) effectiveness in various well-described contexts and potential unexpected iatrogenic effects, (2) cost-benefit relationship to the best comparator, (3) access, (4) acceptability and ethical concerns, (5) security, and (6) implementation. Concerning implementation, quality standards should be similar to those of Improving Access to Psychological Therapies standards set by the United Kingdom for access to psychotherapy. These standards are (1) a model of care, (2) access, (3) evidence-based interventions, (4) outcome-based measurement, and (5) the

XSL•FO
RenderX

provider's training and supervision. International health and social technology assessment agencies should therefore consider developing guidelines and a system of voluntary accreditation for ICT use in suicide prevention. National and regional public health and social services may require that, before commissioning an ICT for suicide prevention or mental health care, their Health Technology Agency recommends ICT based on its efficacy, efficiency, safety, acceptability, and feasibility in the context of jurisdiction.

Acknowledgments

The authors would like to thank Brian Mishara, Alain Lesage, Jérôme Gaudreault, and the Association Québécoise de prevention du suicide for their valuable and constructive suggestions during the planning and development of this study. A grant was awarded for the completion of the study to RL and CB by the Canadian Institutes of Health Research, Institute of Population and Public Health (grant 385 708). JR received a postdoctoral grant from the Quebec Network on Nursing Intervention Research and the project from the Quebec Network on Suicide, Mood Disorders and Related Disorders.

Abstract

Background: Machine learning systems are part of the field of artificial intelligence that automatically learn models from data to make better decisions. Natural language processing (NLP), by using corpora and learning approaches, provides good performance in statistical tasks, such as text classification or sentiment mining.

Objective: The primary aim of this systematic review was to summarize and characterize, in methodological and technical terms, studies that used machine learning and NLP techniques for mental health. The secondary aim was to consider the potential use of these methods in mental health clinical practice

Methods: This systematic review follows the PRISMA (Preferred Reporting Items for Systematic Review and Meta-analysis) guidelines and is registered with PROSPERO (Prospective Register of Systematic Reviews; number CRD42019107376). The search was conducted using 4 medical databases (PubMed, Scopus, ScienceDirect, and PsycINFO) with the following keywords: machine learning, data mining, psychiatry, mental health, and mental disorder. The exclusion criteria were as follows: languages other than English, anonymization process, case studies, conference papers, and reviews. No limitations on publication dates were imposed.

Results: A total of 327 articles were identified, of which 269 (82.3%) were excluded and 58 (17.7%) were included in the review. The results were organized through a qualitative perspective. Although studies had heterogeneous topics and methods, some themes emerged. Population studies could be grouped into 3 categories: patients included in medical databases, patients who came to the emergency room, and social media users. The main objectives were to extract symptoms, classify severity of illness, compare therapy effectiveness, provide psychopathological clues, and challenge the current nosography. Medical records and social media were the 2 major data sources. With regard to the methods used, preprocessing used the standard methods of NLP and unique identifier extraction dedicated to medical texts. Efficient classifiers were preferred rather than transparent functioning classifiers. Python was the most frequently used platform.

Conclusions: Machine learning and NLP models have been highly topical issues in medicine in recent years and may be considered a new paradigm in medical research. However, these processes tend to confirm clinical hypotheses rather than developing entirely new information, and only one major category of the population (ie, social media users) is an imprecise cohort. Moreover, some language-specific features can improve the performance of NLP methods, and their extension to other languages should be more closely investigated. However, machine learning and NLP techniques provide useful information from

XSL•FO
RenderX

unexplored data (ie, patients' daily habits that are usually inaccessible to care providers). Before considering It as an additional tool of mental health care, ethical issues remain and should be discussed in a timely manner. Machine learning and NLP methods may offer multiple perspectives in mental health research but should also be considered as tools to support clinical practice.

machine learning; natural language processing; artificial intelligence; data mining; mental health; psychiatry

Introduction

Machine Learning

Machine learning (ML) systems automatically learn models from data to make better decisions. As such, they are part of a major subfield of artificial intelligence (AI). There are 3 main approaches to learning from data: supervised, unsupervised, and reinforcement learning. In supervised learning, a target attribute is predicted, and ML algorithms infer a model from labeled input data (ie, a training data set that provides examples described by predictive attributes and values for the target attribute). The goal is to make target predictions on new data to obtain good generalization performance. In contrast, there is no target attribute in unsupervised learning, and thus no labeled data. Unsupervised learning consists of inferring a model to describe hidden patterns from unlabeled data. Under circumstances in which labeled data acquisition proves to be difficult, (eg, costly), semisupervised ML methods can use both labeled and unlabeled data for learning. The third main category of ML is reinforcement learning, in which the ML model uses feedback that acts as a reward or punishment to maximize its performance.

ML is limited to certain capacities. For one, it relies on collections of data that may be incomplete, noisy, or subject to systematic bias, all of which can lead to erroneous predictions. In addition, ML algorithms may introduce bias. Interesting questions to be addressed in ML are discussed in an article by Domingos [1]. However, when carefully conducted, ML can have great utility.

AI and ML have many applications, many of which are encountered in daily life. Supervised ML, for example, is widely used for spam filtering (ie, classifying incoming email as spam or not spam) [2]. It is also used to classify credit applicants based on their probabilities of default [3]. Unsupervised ML, such as algorithm clustering, is able to group customers with similar characteristics and their likelihood to purchase. This is widely used by banks for market segmentation [4]. Finally, automatic document clustering that organizes similar documents into classes (for purposes of improving information retrieval, for example) is gaining importance due to the increasing number of documents on the internet [5].

The application of ML in health is also of concern. Indeed, ML is widely used in critical disease models in cardiology, neurology, and diabetes research [6] to automatically identify heart disease risk factors [7], to classify primary progressive aphasia subtypes [8], and for the characterization and diagnosis of cognitive impairments [9], diabetes, and cardiovascular disorders [10-17].

ML is also challenging the traditional epidemiologic approach of evidence-based medicine owing to its high processing speed and ability to handle large volumes of data with heterogeneous variables (electronic health records, administrative data sets, wearable sensors, genomic and proteomic databanks, and social media) [18]. In fact, AI and ML have huge potential to build inferences and find patterns in vast volumes of patient histories, medical images, epidemiological statistics, and other particulars such as natural language data. For example, they can help doctors improve their diagnoses, forecast disease outbreaks, and customize treatments [19,20], provide better patient care [21], and predict the splicing activity of individual exons and chromatin marks from DNA sequences [22]. From a mental health perspective, the prevention of suicidal risk has recently been substantially studied [23-26].

Indeed, mental health care is also benefiting from the advancements in ML [27-29]. Classical ML with only mixed data (observations described by a mixture of numerical and categorical variables) is widely used, but language-based deficits are common symptoms of depression, bipolar disorder, autism spectrum disorder (ASD), personality disorder, and schizophrenia [30]. This implies that computational linguistics could have a great role in forming new insights into individuals' mental health and emotions.

Language in both spoken and written forms plays an important role in ML mental health applications. It is therefore essential to understand what natural language processing (NLP) is before discussing the joint applications of ML and NLP in mental health.

NLP

NLP is a subdiscipline of computer science that emerged in the 1960s. In 1967, the first published book on the subject, *Introduction to Computational Linguistics* [31], clearly considers language from a symbolic point of view: it describes techniques such as syntax parsing using dependency trees or Chomsky transformational grammars and statistical methods (word counting) are only hinted at. At that time, computing resources were sparse and had to be carefully managed; hence, a whole chapter of the book is dedicated to the storage of grammars in memory. The situation changed in the 1990s when personal computers became largely available and increasingly powerful. A new approach to NLP based on statistical methods emerged. The book by Manning and Schütze, *Foundations of Statistical Natural Language Process* [32], is a landmark of this evolution [32]. The 3 main sections of the book are dedicated to (1) methods at the word level (collocations, *n*-grams, and word sense disambiguation), (2) methods at the sentence level (morphosyntactic parsing using Markov models, and

XSL•FO
RenderX

probabilistic context-free grammars), and (3) clustering, classification, and information retrieval. Probabilistic context-free grammars are a typical example of the evolution of NLP methods: the symbolic approach by Chomsky—or at least a simplified version—is endowed with probabilities attached to productions, and the ambiguity of natural language is reflected in the coexistence of several syntax trees with different probabilities.

During the same period, symbolic methods evolved as well. The 1990s witnessed the emergence of the World Wide Web, the Semantic Web, and ontology engineering. First, the 2 research directions seemed contradictory. Knowledge representation was aimed at structuring knowledge in an exhaustively precise symbolic manner, whereas the statistical viewpoint considered language in the same way as physics considers natural phenomena: by analyzing them through various heteroclitic methods, identifying general laws by numerical indicators, and proving them using statistical methods. An example illustrating the latter is the distributional semantic hypothesis (originally stated in the paper by Harris titled, Distributional structure [33]) asserting that "Words occurring in the same contexts will tend to have related meanings." According to this hypothesis, one does not need to identify the precise meaning of a word, as a symbolic method would require, but simply to find the word's cooccurrences in a corpus and consider these as semantics of the word. A very popular method called latent semantic analysis (LSA) is based on the following: the matrix of occurrences of words in documents (contexts) is reduced so that the dimensions of the new matrix represent aggregates of words and aggregates of documents where each dimension is not interpretable per se, but when words or documents are represented as vectors in this new *latent* system of coordinates, the scalar product of vectors can be used as a semantic relatedness measure [34]. LSA is also an example of a typical ML method, with a learning phase (when the frequencies of words in the corpus are counted and the word or document matrix is reduced) to perform a specific task (evaluating the similarity between documents).

Since the 2000s and 2010s, a new evolution has occurred in NLP with the emergence of convolutional, recurrent, and recursive neural networks (NNs) [35]. By using large corpora and sophisticated learning approaches, these methods provide good performance in tasks of statistical nature, such as text classification or sentiment mining. In the past 3 years, they have been much more frequently used for learning higher syntactic or semantic structures (syntax graphs or concept mining, respectively).

In the future, hybrid methods may be used more frequently, which combine symbolic and statistical approaches. The presence of ML methods in NLP systems is a trend that will undoubtedly remain integral to contemporary methods through the foreseeable future.

Applications of ML and NLP to Mental Health

Applications of ML and NLP to mental health can be classified according to the following axes:

- The corpus: as one of the topics is NLP, the corpus necessarily has a textual component. The most common corpora are records or reports (electronic health records [EHRs], Psychological Evaluation Reports, and Coroner Reports), social media (Reddit, Twitter, etc), or transcribed patient interviews.
- Corpus processing: depending on the nature of the corpus, one can either extract medical terms and match them with unified medical language system (UMLS) concept unique identifiers (CUIs) or process blocks of text in natural language and perform specific searches (eg, to detect terms related to suicide).
- Classification methods: many ML techniques are used, such as decision trees, support vector machines, conditional random fields, random forests, and NNs.
- Goal: the goal is usually to validate a hypothesis or to study the behavior of a given population of patients.

Corpora can be of a very large volume. For instance, Sinnenberg et al [36] published a systematic review about Twitter as a tool for health research that included 137 different studies and analyzed over 5 billion tweets using ML; Castro et al [37] have processed 4.2 million EHRs spanning a period of over 20 years. Corpora can also be small, as demonstrated in the study conducted by Carson et al [38], who treated 73 respondents' unstructured clinical notes, or in the study by Bedi et al [39], in which only 34 participants' 1-hour-long narrative interviews were considered. Sometimes, corpora are created specifically for a project. For example, in a study by Roy et al [40], volunteers had written 182 abusive texts, annotated by researchers and abuse victims, and these texts were then analyzed and provided a model for detecting abusive texts.

Extraction of the UMLS CUIs is mainly applied to EHRs because the latter are semistructured and constitute a special document type. The specificities of this document type are reflected in its structure, the syntax of text, and, most importantly, the vocabulary used. The extraction of medical terms is achieved through information extraction algorithms and matching these terms with UMLS CUIs is performed through knowledge representation methods. Once these concepts have been extracted from an EHR, the latter is represented by the former and concepts become features used for classification.

On corpora other than EHRs, rather than extracting the UMLS CUIs, more general NLP methods are applied to textual data to obtain features that are then classified by ML algorithms. These NLP methods are often frequency counts of words or *n*-grams in a specific set, which can be manually curated or obtained out of a corpus. In other cases, methods such as LSA or latent Dirichlet allocation (LDA) are used for topic detection. The initial set of words can be explicit. For example, Doan et al [41] collected tweets containing the hashtags #relax and #stressed and classified them by theme and location. In other cases, calculations are performed at a higher level and words involved in the process are not explicitly known. For example, Luo et al [42] attempted to characterize autism by analyzing textual descriptions of closely related individuals written by patients or members of a control group. Nevertheless, most NLP applications in mental health rely on words (using the bag-of-words method, that is, ignoring word order and keeping

XSL•FO
RenderX

only their frequencies). Some take word order into account in a limited way (by using *n*-grams, ie, contiguous sequences of words of length *n*), but very few take syntax into account by the use of dependency trees [18,43,44]. With respect to their applications, it should be noted that ML and NLP tools are invaluable in alleviating data issues such as data overflow in modern medicine. Forsting et al [45] acknowledge that ML and NLP techniques can be useful for optimism bias (eg, the difference between a person's expectation and the actual outcome or the concept that a clinician may think that his or her patient's problem falls solely into a specific discipline in which the physician works) because the machine has a generalist approach unlike the specialist clinician. Within the last two decades, these techniques have emerged in mental health, following the success of social media to act as an informative source of data [46].

In addition, NLP is essential in psychiatry because language-based deficits are common symptoms of depression, behavioral disorder, ASD, personality disorder, and schizophrenia [30]. It can provide insight into individuals' mental health and emotions, their use of narrative, subjective, and structured speech styles, and their lifestyle, specifically their educational level, socioeconomic status, living conditions, and cultural background [47], all of which are routine in mental status examinations.

Using ML in general and NLP methods in particular, one can create semiautomated systems (operating under human supervision) aiming to improve the specificity of diagnosis, knowledge of psychophysiology, speed of diagnosis, and more accurate estimations of disease severity [48]. Through analyses of Twitter posts, O'Dea et al [49] identified the importance of creating real-time campaigns to increase help-seeking behaviors and reduce the stigma attached to mental health. Moreover, automated programs can be more cost-effective and time-efficient than their traditional counterparts. Ly et al [50] proposed using interventions based on an automated self-help system as a way to make mental health promotion tools more widely accessible. In addition, Lucas et al [51] demonstrated through a clinical trial that when people believed they were interacting with a computer rather than an actual clinician, they reported less fear of self-disclosure, reported reduced impression management behaviors, experienced more ease in expressing the severity of their emotions, and were rated by observers as more willing to disclose. However, these findings may not be generalizable, as they were potentially biased by their sample selections and/or system design itself.

Although ML and NLP provide new tools and strategies for psychiatric research and practice [52], it should be kept in mind that their use frequently raises ethical and legal concerns over consent to personal data use and data anonymization. Similarly, studies using AI for predictive analyses are challenging the balance between beneficence and respect for patients' autonomy. McKernan et al [53] suggest that efforts be made to communicate AI methods to obtain free and informed consent from patients. Moreover, prospective studies should be conducted to evaluate the use of AI tools [53].

The primary aim of this systematic review is to summarize and characterize studies that used ML and NLP techniques for mental health in methodological and technical terms. Hence, the secondary aim is to consider the potential use of these methods in mental health clinical practice, such as the contributions that they may offer in areas of diagnosis and prognosis, the establishment of risk factors, impacts of psychotherapy, treatment adherence, and side effects.

Methods

This systematic review is grounded in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analysis) guidelines [54]. Searches were carried out as specified by the standard protocol for PROSPERO (Prospective Register of Systematic Reviews; registration number CRD42019107376).

Literature Search Strategy

A systematic, computerized literature search was conducted using 4 databases: PubMed (via MEDLINE), Scopus, ScienceDirect, and PsycINFO. Each database was explored from August 21, 2018, through February 1, 2020, with no publication date limit. The search was carried out using the following keywords: "natural language processing" AND "machine learning" AND ("psychiatry" OR "mental health" OR "mental disorder"). The same search was performed on the element (data mining) instead of (machine learning). When the full text was not available, the abstract was used to extract the necessary information to avoid selection bias. Case studies, conference papers, and reviews were excluded.

Study Selection and Eligibility Criteria

After removing duplicates, 2 collaborators independently screened all titles and abstracts that were relevant to this systematic review. A third reviewer was consulted when disagreement arose between the first 2 collaborators. The process is depicted in Multimedia Appendix 1. Only studies available in English were selected. We deliberately excluded studies about the anonymization process to focus on the articles investigating the clinical use of ML and NLP in psychiatry (eg, contribution to diagnosis, prognosis, establishment of risk factors, impact of psychotherapy, treatment adherence, and side effect). No limitations on publication dates were imposed. A total of 58 articles were included in the review.

Included Studies

All studies were thoroughly screened, and their main ideas are summarized in individual tables (Multimedia Appendix 2 [37-41,43,47,48,55-104]). These tables provide information on qualitative and quantitative features: authors, year of publication, precise topic of mental health (eg, autism, psychotic spectrum disorder, etc), population characteristics, and types and volume of recorded data. The second part of these tables summarizes the objectives, methods, and results.

XSL•FO
RenderX

Results

Study Selection

The database search resulted in 222 studies identified using the (machine learning) keyword and 105 studies using the (data mining) keyword. After merging them, 238 unique studies were considered for review, based on the title and abstract. A total of 84 papers were excluded because (1) they were not about psychiatry or mental health (52 cases), (2) they were not written in English (1 case), and (3) the keywords (machine learning), (natural language processing), or (data mining) did not appear in the title or abstract (8 cases). As a second filter, 33 studies about data anonymization were excluded. Furthermore, 7 studies were excluded because ML or NLP were not their main subject but were only quoted as background information. In addition, 96 papers were excluded because they were reviews, case studies, or conference papers. Finally, 58 articles were included in this review.

Topics and Population

Topics are heterogeneous. The most frequently mentioned topics are depression and suicide with 17 studies [38,55,57,60-62,77-79,82,83,87,88,91,92,99,104]. Other psychiatric diagnoses were addiction to alcohol or illicit drugs (6 cases) [43,65,66,75,84,86]; posttraumatic stress disorder (PTSD; 3 cases) [47,63,64]; neurodevelopmental disorders (3 cases) [42,58,93]; psychotic spectrum disorders, including schizophrenia (3 cases) [39,95,100]; anxiety (2 cases) [41,98]; personality disorder (1 case) [85]; eating disorders (2 cases) [89,96]; and bipolar disorder (2 cases) [37,102]. A total of 3 studies were on violence and cyber harassment [40,80,94]. Treatment issues such as adherence or misuse are also depicted (6 cases) [56,72,74,81,101,103]. Only 1 study on mechanical restraints [90] and 1 on cognitive troubles [97] were found. A total of 8 studies were transnosographic [59,67-71,73,76]: 6 met the CEGS N-GRID 2016 Center of Excellence in Genomic Science Neuropsychiatric-Genome-Scale and Research Domain Criteria (RDoC) Individualized Domains 2016 Shared Task in Clinical NLP criteria, which will be developed further in our results.

In total, 3 distinct categories of population were found:

1. Patients whose EHRs were available in science-based research databases such as the Partners HealthCare electronic medical record (EMR), a collection of data from patients at Massachusetts General Hospital and Brigham and Women's Hospital [55,56]. These records extended beyond psychiatric records and included other medical records as well.
2. Patients seen in emergency or psychiatry departments who had additional clinical characteristics in their records (eg, clinical observation, laboratory tests, diagnostic and therapeutic interventions, typed specialists' notes).
3. Social media networks (Facebook, Twitter, and Instagram): The authors of these studies have selected specific hashtags such as #stress or #depression and have screened a multitude of public messages using a streaming platform.

Objectives

In total, 5 main categories of objectives were found: to extract clinical symptoms, to classify severity of illnesses, to compare different therapies, to provide psychopathological clues in mental health, and to challenge the current nosography.

The principal objectives of these studies were to extract and record clinical symptoms, establish a diagnosis, or monitor changes over time. A total of 2 studies targeted automated epidemiological monitoring: Metzger et al [57] provided a method of detecting suicide attempts from EHRs and Leroy et al [58] achieved automatic extraction of criteria for ASD from EHRs with an accuracy of 76%. The latter study stated that an increasing prevalence of given symptoms (nonverbal behavior, social and emotional reciprocity, and adherence to routine disabilities) occurred from 2000 through 2010. Data extraction was also used for diagnosis: He et al [47] diagnosed PTSD with an accuracy of 82% after analyzing free texts written by trauma survivors.

In addition to extraction, an important aim was to measure the severity of psychiatric disorders in psychological evaluation record corpora. Goodwin et al [59] classified symptoms of patients with psychosis into 4 different levels of severity (absent, mild, moderate, and severe) using statistical analyses. Fernandes et al [60] studied EHRs from a cohort of individuals with a history of suicide attempts and a cohort of individuals with a history of suicidal ideation only. Their algorithm of detecting suicidal ideation or suicide attempts had a sensitivity of 98.2% and a positive predictive value of 82.8% [57]. Other studies found that ML and NLP techniques performed well, although they were not necessarily better than a practitioner's ability to predict the clinical risk of suicide in their patients [61,62]; thus, the authors proposed statistical NLP approaches to be used in collaboration with clinical practice.

ML and NLP methods are also used to measure and compare the effectiveness of different types of psychotherapy [63,64]. Tanana et al [43] investigated 2 statistical NLP techniques to code motivational interviewing sessions. Motivational interviewing is a psychotherapy method used for substance use disorders and other behavioral problems to strengthen personal motivation for change [105]. Motivational interviews can be manually coded to assess therapy adherence and gather feedback for subsequent sessions. The authors found that the discrete sentence feature model (a sentence classifier based on *n*-gram models) had accuracy similar to the manual coding of therapeutic sessions. Maguen et al [63] used statistical NLP techniques to distinguish evidence-based psychotherapy, including cognitive processing therapy and prolonged exposure notes from unstructured psychotherapy notes for a population of veterans with PTSD. They found that almost 20% of veterans observed an improvement in their symptoms after one or more sessions of evidence-based psychotherapy.

Another objective was to provide psychopathological clues for understanding mental health disorders by analyzing language features. This objective sometimes involves the processing of previously unexplored data, such as chat groups or social networks. The following are some examples of studies that pursue this objective: Baggott et al [65] found that MDMA

XSL•FO
RenderX

(3,4-méthylènedioxy-N-méthylamphétamine; Ecstasy) altered individuals' speech patterns more frequently than the placebo and led to an increase in both positive and negative social and sexual language use (others, public, camaraderie, and outgoing). Chary et al [66] analyzed posts on Lycaeum, a popular web forum known for being one of the most frequently cited platforms with respect to drug use. They discovered new combinations of drugs that were not mentioned in the medical literature. Luo et al [42] differentiated the social interactions between adults with ASD and healthy adults. They confirmed the hypothesis regarding differences in language and social interactions in adults with ASD: typical participants had more connected semantic links than the ASD group and the words with the largest number of connections were different between the 2 groups. Doan et al [41] noticed that American Twitter users are more likely to express their source of stress on Twitter than in their day-to-day experiences. The main causes of stress that emerged from the Twitter data were education, work, and social relationships. They also found that individuals' expressions of stress and relaxation differed based on the city of residence (Los Angeles, New York, San Diego, and San Francisco). Moreover, Mowery et al [106] revealed that less than 2% of the tweet corpus (a corpus of 9300 annotated tweets containing depression-related keywords) included more than one depression-related reference, suggesting that there may be different forms of expression when it comes to depression.

Finally, AI in mental health research challenges the current practice and nosography. In 2010, Insel et al [107] initiated a project called the RDoC, a research framework for mental health disorders that aims to constitute an alternative to the DSM (Diagnostic and Statistical Manual of Mental Disorders). The former includes data on genetics and neuroscience in its classification of mental health disorders, whereas the latter is solely based on clinical data [107]. The RDoC is a matrix in which the columns and rows represent constructs (genes, molecules, cells, circuits, physiology, behaviors, self-reports, and paradigms) and subconstructs of each of the following 6 domains: negative valence, positive valence, cognitive systems, systems for social processes, arousal or regulatory systems, and sensorimotor systems. Pro-RDoC practitioners argue that DSM syndromes have significant limitations when used as phenotypes for identifying biomarkers and specific genetic variants associated with mental illness [108]. A concrete application of this new system used statistical NLP methods to create a phenotypic homogenous cohort that allowed a better comparison [109]. In 2016, the CEGS N-GRID (Centers of Excellence in Genomic Science Neuropsychiatric-Genome-Scale and RDoC Individualized Domains) proposed 3 challenging tasks using NLP methods: (1) data anonymization, (2) predicting symptom severity in the positive valence domain from neuropsychiatric clinical records, and (3) novel data use case (eg, predicting the presence of common mental conditions in patients) [67]. This research on NLP and ML processing identified 6 articles [59,67-71] that met these challenge tasks, although only 1 study dealt with task 3 [67]. As mentioned earlier, studies on anonymization were excluded; thus, the RDoC framework links the neuro-biological basis of mental processes with phenotypical manifestations [110]. The CEGS N-GRID shared task provided usable data for investigating ML and NLP techniques, which could lead to new psychiatric nosology.

Type of Data Used

As can be seen in Table 1 (in which no hapaxes are displayed), the most frequent corpus type is that of EHRs (to which EMRs can be added). EHRs (and EMRs) are convenient data sources because of their heterogeneity: they combine structured, semistructured, and free data, and they often use a significantly controlled language containing medical terms that allow the extraction of CUIs (Methods Section). The second most frequent sources of data are clinical notes and clinical records, which share the convenient properties of EHRs or EMRs, but are not standardized in the same way.

Table 1. Corpus type.

Characteristics	Values
EHRs[a]	22.9508
ClinNotes	16.3934
ClinRecords	11.4754
Interviews	8.1967
Tweets	8.1967
Questionnaires	6.5574
Reddit	6.5574
Web	4.918
EMRs[b]	3.2787

[a]EHR: electronic health record.

[b]EMR: electronic medical record.

The data described earlier share an important property: the corpora are generated by practitioners and therefore can be used for medical term extraction with satisfactory results.

A different category of data is generated by the patients. This category can be divided into 2 subcategories: data generated with the help of practitioners (eg, interviews and questionnaires)

XSL•FO
RenderX

and data freely generated by patients on social media (tweets, posts on Reddit, web blogs, etc).

Interviews and (textual parts of) questionnaires are technically free text but practitioners still have some amount of control over the content, and the environment in which the data are collected influences the degree of informality of texts. For these reasons, traditional NLP methods can be applied to them with satisfactory results.

Data collected from social media, because of their high degree of informality, loose spelling and syntax, and use of abbreviations and emojis, can only be superficially processed by standard NLP methods. Typical examples are in studies by Doan et al [41] and Jackson et al [73], in which tweets were selected because they contained the hashtags #stress and #relax and their words were used in a bag-of-words without any further linguistic treatment [41] or tweets were selected based on the presence of terms denoting opioids [72]. Although the authors lemmatized tweet contents, the main feature of tweets taken into account was their geographical origin.

Methodology

Two phases of NLP projects were distinguished: (1) preprocessing, which consists of analyzing the data to obtain numeric or categorical features, and (2) classification.

Preprocessing

Table 2 (in which no hapaxes are displayed) represents the frequency of use of various preprocessing methods that can be of different natures. Some methods apply to words or word groups: *lemma (*lemmatization, ie, replacing a word by a base form such as the singular for nouns or the infinitive for verbs), *POS* (part of speech, ie, attaching to a word a label denoting its grammatical function), *cTAKES* or *CUIs* (mapping a word or a noun phrase to concept in an ontology, such as the UMLS, and therefore unambiguously defining its semantics), *tf-idf* (attaching to a word or a term a value representing its significance in characterizing a given document or class it belongs to), *embedding* (representing a word by a vector in a high-dimensional space), *named-entity recognition* (deciding whether a given word or noun phrase is a named entity), *LIWC* (Linguistic Inquiry and Word Count, a commercial tool advertised as being “based on solid science” providing various “social and psychological insights” of words). Other methods combine words into higher structures: *n-grams* (considering an *n*-gram, ie, a sequence of *n* subsequent words, as an entity and measuring the frequencies of these entities). Finally, other methods are applied to entire sentences, paragraphs, or documents: *SentiAna* (analyzing sentiments or emotions), *LDA* and *LSA* (calculating sets of topics, detecting the significance of each topic for a given document, and providing representative words for each topic). The most frequent preprocessing methods are the standard methods of NLP (lemmatization, part-of-speech tagging, *n*-grams, and tf-idf), and methods specific to medical texts such as CUI extraction (keywords cTAKES and CUIs in Table 2). The embedding method is related almost exclusively to NNs and therefore is relatively recent. Finally, the tail of the graph in Table 2 contains methods applied primarily to free texts such as topic detection, named-entity recognition, sentiment or emotion analysis.

Table 2. Preprocessing methods.

Classification

Once the classification phase is reached, linguistic data are entirely converted into numeric data, and therefore, the choice of classifier depends on factors other than corpus type. Some of these factors include (1) the volume of data, (2) the type of classification (supervised vs unsupervised), (3) the explicability level, and (4) the platform used. In Table 3 (where hapaxes are not displayed), we have shown decision tree, association rules, and C4.5 (also a decision tree algorithm) that are *transparent* methods, that is, the user can follow the classification process in a step-by-step manner and understand the reason a given individual belongs to a particular class. They are not the most frequent classifiers, probably because explicability is not a major concern of most studies. Instead, the most frequently used classifiers such as support vector machine (SVM), LogiR (logistic regression), RF (random forest), and LinR (linear regression) are solid, fast legacy classifiers with small parameter sets and good performance. In the middle of Table 3 are NNs that belong to the deep learning tendency of ML: they are opposite to DT/AR/C4.5 when it comes to explicability and they rely heavily on certain parameters (type and geometry of NN, number of layers, size of layers, optimizer, learning rate, loss function, etc). The causes of the relatively low frequency of NNs in publications may be (1) the fact that they have been implemented in user-friendly frameworks (such as Theano or Keras) only recently, (2) the necessity to fine-tune a large number of parameters, and (3) the relatively high requirements in terms of memory, central processing unit, and graphical processing unit. This is likely to change in the near future.

Table 3. Classifier type.

Characteristics	Values
SVM[a]	22.6804

[f]NN: neural network.
[g]LinR: linear regression.
[h]AR: association rules.

Platforms

As can be seen in Table 4 (hapaxes are not represented), the 2 most common platforms are Python and R. Python is a *universal* programming language, in the sense that it is not specific to a given domain: more than 120,000 packages allow the user to perform specialized tasks in any possible field. Furthermore, it is open-source and high-quality documentation abounds. R is also an open-source programming language and compiler, but contrary to Python, it is oriented toward statistics. Although many classifiers have been implemented efficiently both in Python and R, the domain of NLP is better represented in Python, in credit to packages such as NLTK (Natural Language ToolKit), spaCy, and Stanza. The third bar, titled *Unknown*, represents publications that do not mention the platform used. The fourth bar indicates the General Architecture for Text Engineering General Health platform, an open-source Java application that provides an environment for processing textual data in a user-friendly manner. The *Apache* bar gathers different tools distributed by the Apache Software Foundation. Stata is a commercial statistics software from College Station, Texas, first released in 1985. Weka is an open-source programming environment for ML.

Figure 1 shows the use of platforms in chronological order. The use of Python and R started after 2015, while Stata, Weka, and Apache were already in use in 2011.

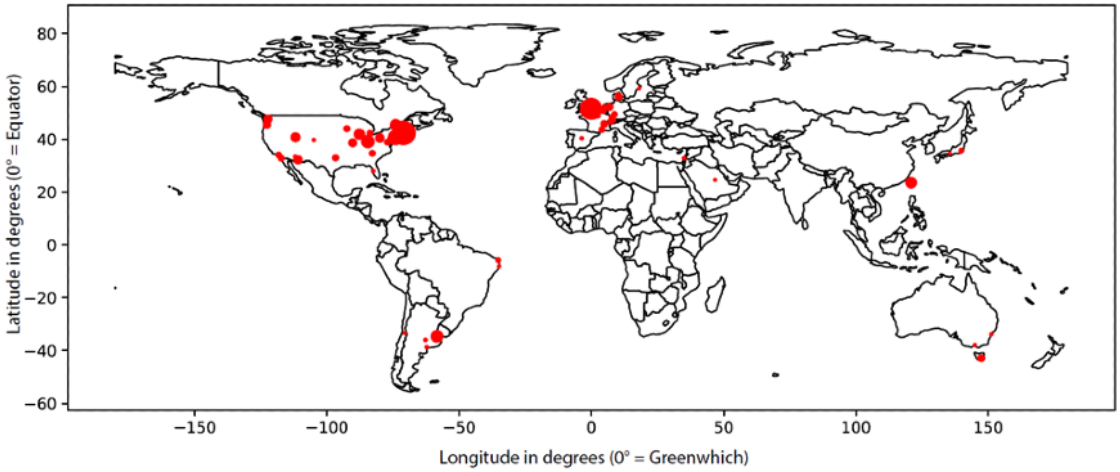
Correspondence Analysis of Data, Methods, Classifiers, Platforms, and Publications

The correspondence analysis is a dimension reduction technique that maps the data into a factorial space where each dimension is a combination of the initial variables. Figure 2 represents the principal coordinates of the publications and the various entities considered in their study.

On the right, a cluster of publications is surrounded by data type *ClinNotes*, method *cTAKES*, and platform *R*. In the upper left quadrant, some publications gather with method *embedding* and classifier *NN*. Toward the left of the diagram and close to the horizontal axis, publications with an *unknown* platform using the *NB* classifier are present along with a big cluster whose center includes *tf-idf*, *LogiR*, *SVM*, *Python*, and *n-grams*: the legacy methods, most used classifiers, and the most used platform.

Figure 2. Correspondence analysis.

With regard to publications, *Filannino_17* is an obvious outlier because it has no method, classifier, or platform and because it describes a task and how this task has been treated by others. *Clark_17* is at the extreme upper left, as it uses NNs and k-means (the latter is not displayed because only entities appearing at least 5 times are included). *Coppersmith_18* also uses embeddings and NNs, whereas *Tran_17* (which is closer to the central cluster) uses both NNs and SVMs. On the right side, *Shiner_13* and *Vaucheret_19* use clinical notes and R, whereas *Hart_20* and *Moessner_18* use R and methods that



XSL•FO
RenderX

have not been taken into account in the calculation. In the bottom left, *Iqbal_15* uses EHRs in the General Architecture for Text Engineering General Health (which is not displayed). At the extreme left and close to the horizontal axis, *Pestian_16* and *Yu_11* use an unknown platform.

Geographical Distribution of Authors

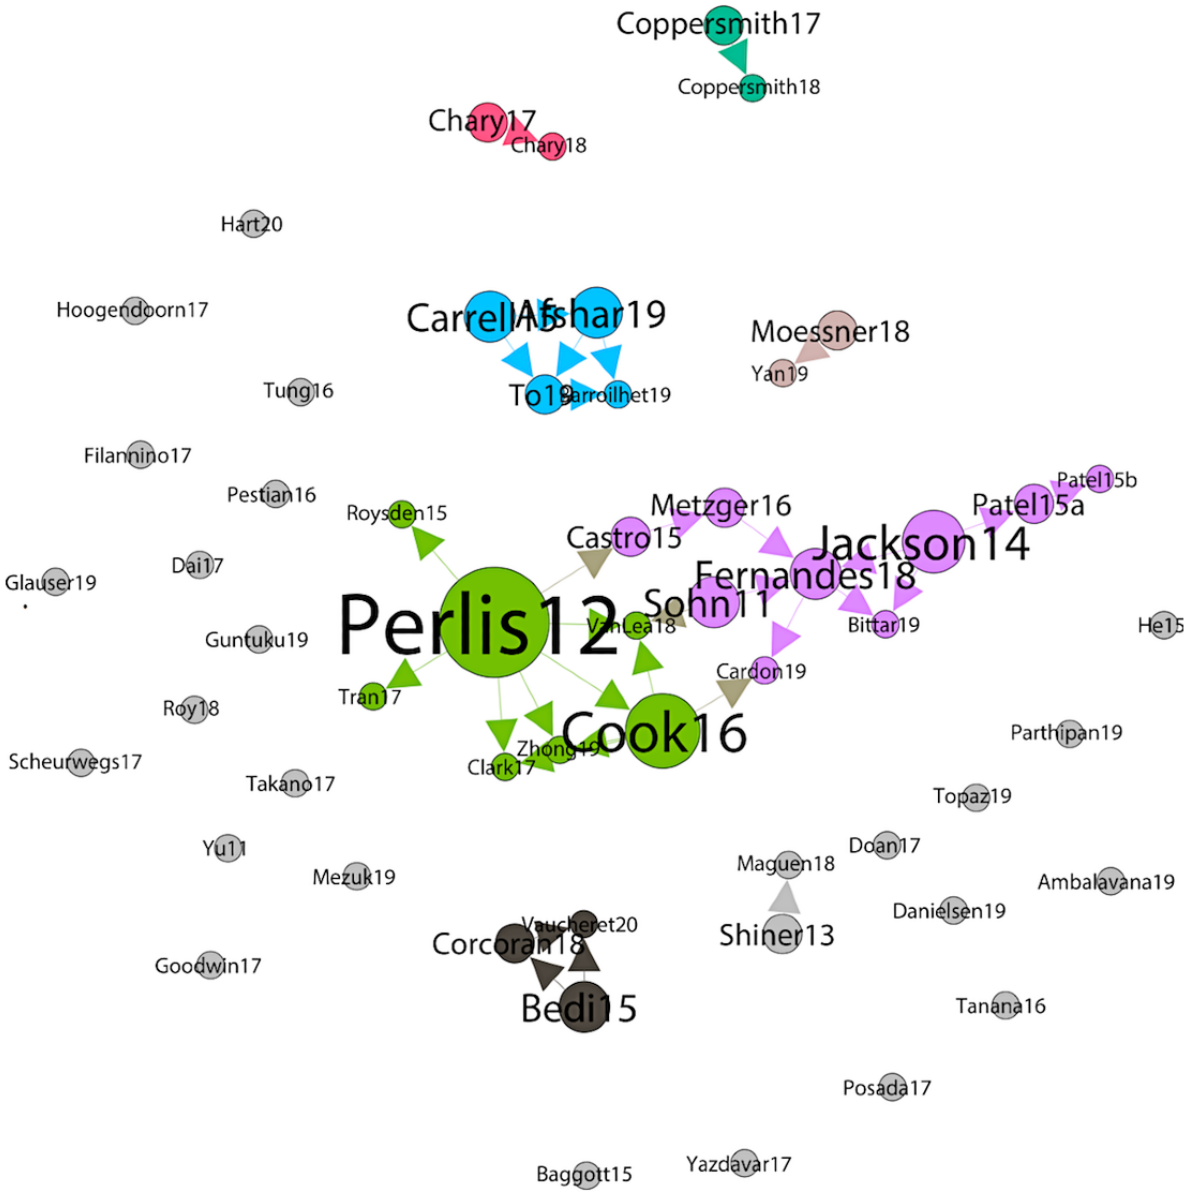
In the map in Figure 3, the diameter of the red marks is proportional to a score calculated as follows: we added 1 unit for the geographical origin of the affiliation of each author of each paper. The cities with scores greater than 10 were Boston (54), London (44), New York (21), Cincinnati (15), Buenos Aires (13), Cambridge, Massachusetts (12), San Francisco (11), and Taiwan (11).

Figure 3. Geographical distribution of authors.

Citations and Cocitations

Figure 4 represents the citations of the papers in our list by other papers on the same list. The size of the nodes of a paper is proportional to the number of papers citing it. The colors of the nodes and edges represent communities. Each community has a central node: Perlis et al [55] are cited in 7 other papers, Jackson et al [73] are cited in 4 other papers, Carrell et al [74] and Afshar et al [75] are cited in 2 other papers, and Bedi et al [39] are cited in 2 other papers. In total, 22 papers are singletons: they are neither cited nor cite any other paper in our list.

Although mutual citations show influences between papers in our list, we can also measure the number of cocitations (ie, common references between 2 papers in the list). In Figure 5, the edges between papers indicate that they have at least 3 common references. The edge width is proportional to the number of references.



The edge of the greatest width is the one between the papers by Coppersmith et al [76] and Coppersmith et al [77], which is normal—the 2 papers share the same first author, have been released within less than a year, and have 26 common references.

The second case, in descending order of edge width, is between Shiner et al [64] and Maguen et al [63]. This is also normal—the first author of the former is also the last author of the latter and the latter is presented as an extension of the former: “In this study, our goal was to extend Shiner and colleagues’ work by applying automated coding to a large national pool of mental health treatment notes in order to identify the use of cognitive processing therapy and prolonged exposure.” The 2 papers share 14 common references.

The size of nodes in the graph is proportional to the degree. Zhong et al [78] have the highest degree: this paper has more than three common references with as many as eight other papers, in fact, with 8 references. The color of the nodes and edges corresponds to the connected components. There are 19 singleton nodes that share ≤2 references with every other paper of the list.

Discussion

Strengths and Limitations of the Review

This study reviews ML and NLP models in the field of mental health, which has been a highly topical issue in recent years. The methodology was elaborated to screen a maximum number of specific medical studies by expanding the research to 4 medical databases (PubMed, Scopus, ScienceDirect, and PsycINFO). Furthermore, the characterization of the selected studies has been done very precisely in a qualitative manner to simultaneously depict the populations, methods, data sources, and technical aspects.

The primary limitation of this study is the lack of quantitative comparisons between the selected studies. It is indeed not feasible to compare highly heterogeneous studies that do not share common research patterns. In addition, the selected works were not scored on their risk of bias. Despite this shortcoming, their limitations and strengths are outlined in the individual tables in Multimedia Appendix 2.

Methodological and Technical Limitations of the Selected Studies

ML and NLP methods may be considered as a new paradigm in medical research in which it becomes practical to analyze every possible, even unexpected, and innovative parameter of a topic to discern new clinical patterns. This new paradigm involves reconsidering the standard methodology, which consists of formulating a sound hypothesis, defining objectives, and collecting results to either uphold or reject the hypothesis. However, in practice, the selected studies tend to confirm clinical hypotheses based on fundamental clinical intuitions, namely language abnormalities in adults with ASD [42].

Other methodological limitations and potential bias sources have been noted. As stated in the Results section, one of the 3 main population categories is *social network or chat users* [40,41,66,77,79], whose members are predominantly young. Owing to this, Coppersmith et al [76,77] cautioned that these results may not be generalizable to other populations [77,106]. In addition, when Chary et al [66] focused on *Lycaeum users* and Coppersmith et al [76] mentioned *participants from a company*, the lack of precise information on the participants of a cohort was obvious. An exception to this is the group of OurDataHelps.org users [77] who volunteered to participate in

XSL•FO
RenderX

scientific research and filled out a questionnaire to provide information about themselves. Even when participants volunteer to provide personal information, there is a high likelihood that personality bias plays a role, especially in studies on suicide and depression.

Similarly, studies rarely consider cultural or ethnic differences within a sample [80]. For example, in a study on violent behavior, researchers should acknowledge that *spanking children for discipline purposes* is considered inappropriate in some cultures but appropriate in others. In some cases, language-specific features can improve the performance of NLP methods. For example, in the case of Takano et al [62], the distribution of morphemes is used to distinguish between specific and nonspecific memories in the Autobiographical Memory Test. As shown in the paper, among the most important distinctive factors are grammatical particles that are specific to the Japanese language, such as た/だ (past tense), ない (negation), は (topic marker), and で (place or method). In languages with different structures, the same method may be less efficient and other indicators may need to be investigated.

Is There an Advantage in Using ML and NLP for Mental Health Clinical Practice?

The hallmark ML principle is to simultaneously analyze large quantities of data; however, this sometimes leads researchers to the implicit assumption that *the more data they input, the more accurate will be the results*. ML and NL allow the analysis of large amounts of data and the comparison of broad groups and patients. For example, Roysden et al [56] screened administrative data and EHRs from a population of 12,759 patients; Maguen et al [63] compared over 8,168,330 clinical notes collected over 15 years; and Yazdavar et al [79] analyzed posts authored by 4000 Twitter users. At the same time, even though thousands of papers have been published using medical data, very few have made meaningful contributions to clinical practices [111].

Twitter and other social networks, with almost 3 billion users globally, have become significant sources of information for medical use and research [112]. Moreover, the analysis of social media–based platforms can generate valuable details about people's mental health and social or professional interactions. The alteration of daily habits is one of the core criteria for the diagnosis of a mental health disorder (in general, criterion B of DSM-5). A recent study by Fagherazzi and Ravaud [113] illustrates the idea that AI can be implemented in the so-called *digitosome* (data generated online and by digital technologies) that constitutes a powerful agent for detecting new digital markers and risk factors in medicine. By analyzing a global cohort of more than 85,000 tweets per week authored by people with diabetes, they were able to discuss different illness-related stress patterns of patients with type 1 or type 2 diabetes. By analyzing tweets, Mowery et al [106] found that there may be alternative ways in which people express depression. These findings indicate that there may be new ways for people to express mental illness.

From this perspective, different expressions of psychological distress (whether people are addressing health care professionals, relatives, or digital friend networks) could be accessible and useful to care providers. ML and NLP may be valuable in psychiatry for identifying people with clinical risks for depression, suicide attempts, anxiety, or even psychosis based on digital data or clinical notes.

Ethical Reflections

AI in psychiatry and more broadly in medicine raises ethical issues and requires prudence in its application. As mentioned earlier, ML and NLP techniques have valuable advantages in psychiatry for analyzing large amounts of data with high diagnostic and prognostic validity. These tools, which have been groundbreaking in medicine and psychiatry, should receive more attention for their promising results with regard to clinical practice and medical research. In addition, recent studies suggest that people are becoming more comfortable when speaking with a machine compared with a clinician: Lucas et al [51] state that in a clinical trial, people who (believed they) were interacting with a computer disclosed information more openly than people who thought that an individual was controlling the computer. Perhaps the machine is viewed as being more objective than a human and therefore reduces the fear of judgment from a practitioner. The introduction of a computer in medical practice as a new type of clinician leads to a profound change in the physician-patient relationship and promotes the idea of having a new clinical model involving a third party. The relationship is crucial to psychiatric clinical practice, and the use of data processing should be discussed. Sassolas [114] questioned this *technological psychiatry* as a practice that is likely to avoid what he called the "psychic privacy proximity." Technological psychiatry could generate an operative encounter whose unique purpose is to normalize the patient's symptoms and reduce the fear of disclosure.

In addition to improved relationships, the application of ML and NLP in psychiatry should be done with special precautions to avoid clinical abuse. This review includes 2 studies about the prediction of psychosis in patients at high risk of this disease. One even introduced a model of ML+NLP that had a 100% accuracy in predicting psychosis among the latter patient sample [39], which was better than a simple clinical evaluation. Nevertheless, these results should be treated with caution because of the small sample size and the lack of detail on the statistical techniques used. The risk of overfitting needs to be considered. Although further research should be continued to improve technical issues, ethics should be taken into account. Martinez-Martin et al [115] questioned whether it is ethical to use prognostic estimates from ML to treat psychosis, as it is not known whether variables are present in the local context (such as differences in psychiatric practice and social support) that would affect the model's validity. Moreover, when programming an ML algorithm, investigators can choose to strengthen the criteria they esteem to be more relevant, such as clinical criteria instead of socioeconomic factors. This could result in loss of opportunity for some patients when the automated machine analysis gives the illusion of greater objectivity. These adjustments should be done to respect the principle of equity.

In the case of predicting psychosis, the study involved only patients who consented to both psychiatric care and the completion of interviews. This was not the case in studies on

XSL•FO
RenderX

suicide prevention, where researchers tracked information on patients by using social media. This could be considered a violation of confidentiality. Should information from social media be used to identify symptoms? Applying AI in this context raises significant ethical concerns, particularly in balancing beneficence and respecting confidentiality [53]. ML and NLP can help identify people at clinical risk for depression or suicidal ideation, who most likely do not have access to mental health providers and/or a primary care doctor [61]; however, this reduces confidentiality protection and can lead to increased vulnerability in certain populations [21]. To obtain informed consent from patients and protect their privacy, McKernan et al [53] proposed some recommendations: patients should be informed that (1) algorithms can be imperfect or wrong; (2) algorithm data should be considered highly sensitive or confidential; (3) algorithm data might recommend actions that are not immediately apparent; and (4) algorithms might prompt unnecessary intervention from the provider. Therefore, psychiatrists should be trained in ML and NLP techniques and be able to explain to patients their main characteristics and why they may require certain recommendations. This last point underlines the need for an explainable AI that goes further than black box methods.

Finally, ML and NLP should not lead to disempowerment of psychiatrists or replace the clinician-patient pair. On the contrary, the combination of ML with NLP should be considered as a *tool* to support clinical practice and medical research.

Conclusions

In the past decade, the use of ML and NLP has become increasingly widespread in medicine and more specifically in psychiatry. Hence, this review aimed to summarize and characterize studies that used ML and NLP techniques for mental health in methodological and technical terms. The secondary aim was to consider the potential use of these methods in mental health clinical practice (eg, contribution to diagnosis, prognosis, establishment of risk factors, impact of psychotherapy, treatment adherence, and side effects).

Although the selected studies were heterogeneous in terms of topics and mental disorders, common features were found in terms of population categories (patients included in medical databases, patients presenting to the emergency room, and social media network users) and objectives (ie, symptom extraction, severity classification, comparison of therapies, findings of psychopathological clues, and challenges to the current nosography). The type-of-data-used analysis identified 2 major corpora: data collected by care providers (EHR, clinical notes, or EMR) and data from social media. Finally, the method analysis indicates that the authors privileged certain techniques. The standard methods of NLP (such as lemmatization, POS tagging, or n-grams) are most frequently used for preprocessing, in addition to CUI extraction dedicated to medical texts. The classification analysis specifies that classifiers with good performance (SVM, LogIR, and RF) are preferred to those with *transparent* functioning. The use of the universal programming language platforms such as Python and R is verified; Python turned out to be the most frequently and recently used. The correspondence analysis of data, methods, classifiers, platforms, and publications reveals a cluster of publications associating clinical notes data with cTAKES methods and the R-Python platform.

ML and NLP methods may sometimes be impressive with their huge amount of data screening and the multiple perspectives they offer. This has led some authors to consider it to be a new paradigm in mental health research. However, these processes tend to confirm clinical hypotheses rather than developing new information, and some results should be treated with caution (eg, results from social media users' cohorts or the impact of language-specific features on NLP methods performance). On the contrary, ML and NLP techniques provide information from unexplored data and on patients' daily habits that are usually inaccessible to care providers. It may be considered as an additional tool in every step of mental health care: diagnosis, prognosis, treatment efficacy, and monitoring. In this regard, ethical issues, such as predicting psychiatric troubles or implications in the physician-patient relationship, remain and should be discussed in a timely manner. Therefore, ML and NLP methods may offer multiple perspectives in mental health research, but they should be considered as a tool to support clinical practice.

Abstract

Background: Electronic visits (e-visits) involve asynchronous communication between clinicians and patients through a secure web-based platform, such as a patient portal, to elicit symptoms and determine a diagnosis and treatment plan. E-visits are now reimbursable through Medicare due to the COVID-19 pandemic. The state of evidence regarding e-visits, such as the impact on clinical outcomes and health care delivery, is unclear.

Objective: To address this gap, we examine how e-visits have impacted clinical outcomes and health care quality, access, utilization, and costs.

Methods: We conducted a systematic review; MEDLINE, Embase, and Web of Science were searched from January 2000 through October 2020 for peer-reviewed studies that assessed e-visits' impacts on clinical and health care delivery outcomes.

Results: Out of 1859 papers, 19 met the inclusion criteria. E-visit usage was associated with improved or comparable clinical outcomes, especially for chronic disease management (eg, diabetes care, blood pressure management). The impact on quality of care varied across conditions. Quality of care was equivalent or better for chronic conditions, but variable quality was observed in infection management (eg, appropriate antibiotic prescribing). Similarly, the impact on health care utilization varied across conditions (eg, lower utilization for dermatology but mixed impact in primary care). Health care costs were lower for e-visits than those for in-person visits for a wide range of conditions (eg, dermatology and acute visits). No studies examined the impact of e-visits on health care access. It is difficult to draw firm conclusions about effectiveness or impact on care delivery from the studies that were included because many used observational designs.

Conclusions: Overall, the evidence suggests e-visits may provide clinical outcomes that are comparable to those provided by in-person care and reduce health care costs for certain health care conditions. At the same time, there is mixed evidence on health care quality, especially regarding infection management (eg, sinusitis, urinary tract infections, conjunctivitis). Further studies are needed to test implementation strategies that might improve delivery (eg, clinical decision support for antibiotic prescribing) and to assess which conditions can be managed via e-visits.

KEYWORDS

telemedicine; telehealth; e-visits; electronic visits; digital care; outcome; delivery; review; access; utilization; cost; patient portal; eHealth

Introduction

Telemedicine—or the delivery of health care at a distance—can improve health care access and quality while reducing health care utilization and costs [1]. For instance, telemedicine can improve access to specialists for patients in rural areas or in underresourced care settings by increasing the convenience and availability of health care (eg, extended hours, decreased wait times) [2-4]. Studies have also demonstrated that telemedicine may achieve comparable clinical outcomes to in-person care across a variety of conditions, such as stroke care [5], heart failure [6,7], hepatitis C [8], and diabetes [8]. Telemedicine can also reduce the utilization of in-person care and reduce health care costs [3,4,9]. Furthermore, some telemedicine types have demonstrated cost-effectiveness [10,11]. Studies have shown that the impact of telemedicine on health care delivery and patient outcomes varies across telemedicine types. Some forms of telemedicine, such as telestroke [12-14], have a strong evidence base while other forms of telemedicine, such as electronic visits (e-visits), are understudied.

E-visits involve asynchronous communication between clinicians and patients through a secure web-based platform, such as a patient portal. Generally, patients answer questions about their medical history and symptoms through a structured questionnaire and upload photos (if relevant). The data are then reviewed by a clinician, who develops a diagnosis and treatment plan. Although e-visits often involve clinicians who the patient is familiar with, they can also involve a third-party clinician through direct-to-consumer telemedicine. E-visits offer notable benefits, such as allowing patients and clinicians to communicate at a convenient time (ie, eliminating scheduling barriers) and improving documentation of patient-clinician communication (eg, patients can review clinician's instructions) [15,16]. However, e-visits have a number of implementation barriers, such as those regarding workflow integration (eg, having dedicated clinician time to respond to messages) [16-18], those regarding lack of reimbursement [15,16,19,20], and concerns about the quality of communication from patients (eg, failing to submit sufficient information for diagnosis) [21]. Health care organizations have also raised concerns about the quality of care provided through e-visits, such as the potential for inappropriate antibiotic prescribing and difficulties with providing care without being able to see the patient face-to-face [22-29]. Despite these challenges, studies have reported positive effects of e-visits on health care delivery, such as lower costs [24], comparable follow-up rates to those of in-person care (ie, a proxy for diagnostic accuracy) [30], and comparable or improved patient outcomes (eg, lower uric acid level for patients with gout) [31].

Because of COVID-19, e-visits are being implemented more frequently and are now reimbursable by Medicare and other payers in the United States [32,33]. As the nation moves forward in telemedicine implementation and health care systems decide whether to integrate telemedicine into future care delivery, it is critical to determine the costs and benefits of telemedicine models, such as e-visits. To date, a systematic review has not been conducted to assess the state of the evidence regarding e-visits. To address this gap, the objective of this review is to summarize the findings of studies examining the association of e-visits with clinical outcomes, quality of care, access to care, utilization, and costs.

Methods

We conducted a systematic review based on PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analysis) guidelines [34].

Data Sources and Searches

MEDLINE, Embase, and Web of Science were searched to locate peer-reviewed studies published from January 2000 through October 2020. The start date for the search was chosen because electronic visits were developed recently, and the authors did not anticipate any studies published prior to 2000 (when web-based, patient portal studies emerged). A preliminary search was done to confirm this. Studies were limited to those in the United States as systemic factors, such as reimbursement, may influence the results. All reference lists for included studies were cross-searched. Duplicate studies were removed. Multimedia Appendix 1 lists the search terms used for this search after consultation with a health sciences librarian at the University of Florida.

Study Selection

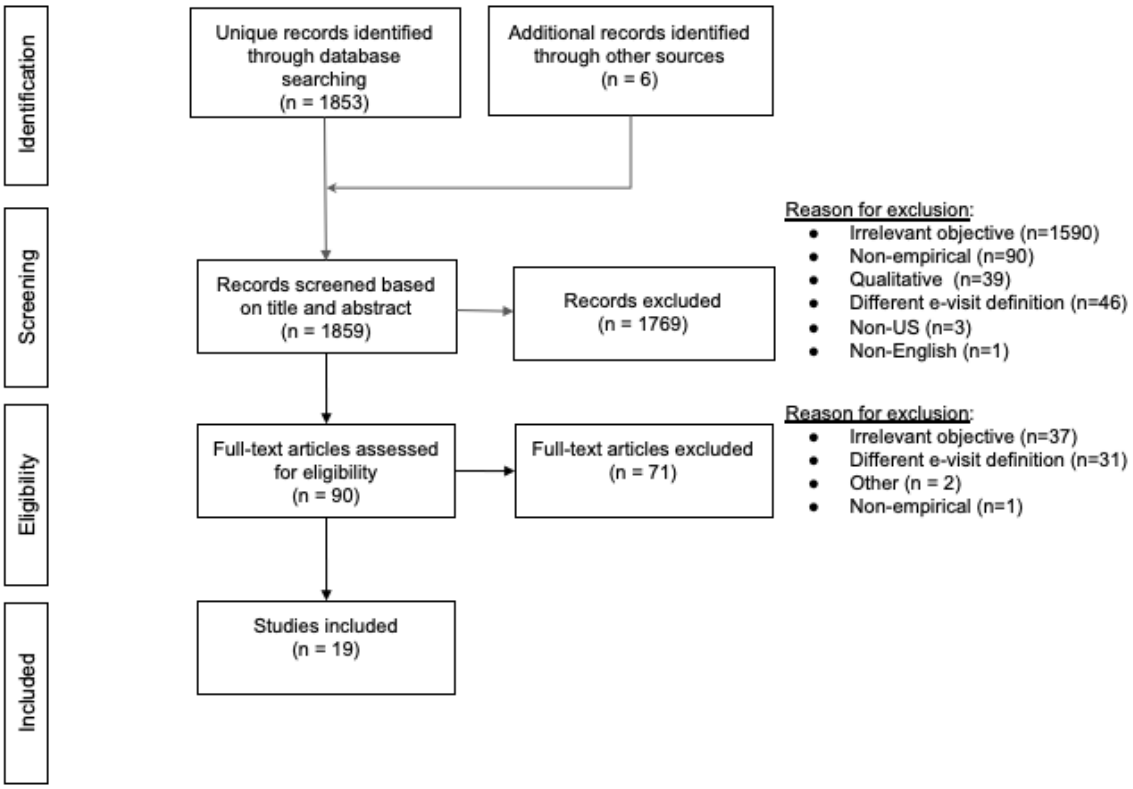
Two reviewers (KT, OTN) independently screened papers identified from the search strategy, and assessed each for inclusion eligibility using a spreadsheet (Excel 2013, Microsoft Inc). Any discrepancy encountered was discussed until a consensus was reached.

E-visits were defined as any asynchronous electronic visit where a clinician assesses a patient's health status, makes a diagnosis, and develops a treatment plan via a secure messaging system (eg, patient portal) [24,35]. This definition was based on how recent studies have defined e-visits [24,35]. Studies that defined an e-visit differently were excluded (eg, defines e-visit as real-time, 2-way communication). Studies were included that reported on the impact of e-visits on clinical outcomes, health care quality, access, utilization or costs. Included studies also had to be written in English, empirical (ie, reporting original research), quantitative, and peer reviewed.

Data Extraction and Quality Assessment

For each included study, 2 investigators (KT, OTN) noted study design, outcome measurements, care setting, medical conditions studied, sample size, and major findings. Since most of the studies included were observational, the authors used the Risk of Bias Assessment Tool for Nonrandomized Studies to assess criteria specific to observational studies [36]. A *P*-value <.05 was considered significant.

XSL•FO
RenderX



Data Synthesis and Analysis

Due to the heterogeneity of outcome measures used in our included studies, it was infeasible to conduct a meta-analysis. Consequently, findings were qualitatively grouped by outcome type (eg, clinical outcomes, costs).

Results

After reviewing 1859 studies, a total of 19 studies met our inclusion criteria. Figure 1 shows our study selection process.

Figure 1. PRISMA [34] flowchart.

Study Characteristics

Most studies assessed clinical outcomes, quality of care, health care utilization, and costs. None reported access outcomes. Most studies were observational in design, with one study using a randomized experimental design, another study using a case study design, and another 2 studies employing quasi-experimental designs. Sixteen studies used cross-sectional or pooled cross-sectional data. Three studies used a panel design. Table 1 summarizes the study characteristics of included studies, and Table 2 summarizes findings with respect to clinical outcomes, quality of care, access to care, health care utilization, and costs.

Table 2. Effects of asynchronous e-visits on clinical outcomes, quality, utilization, and costs.

Outcome type and citations	Specific measures	Impact
Clinical outcomes		
Hawes et al [44]	Abnormal international normalized ratio	E-visits were associated with lower abnormal international normalized ratios than in-person visits (P<.05).
Hawes et al [44]	HbA_{1c}[a]	E-visits were associated with lower HbA_{1c} values than in-person visits (P<.001).
Hawes et al [44]	Amount of diabetic patients with controlled blood pressure	Compared to the preimplementation period, more diabetic patients were observed with controlled blood pressure in the postimplementation period (P<.001).
Hawes et al [44]	Amount of diabetic patients with HbA_{1c} levels of less than 8%	Compared to the preimplementation period, more diabetic patients with HbA_{1c} levels of less than 8% were observed in the postimplementation period (P<.0001).
Hawes et al [44]	Amount of diabetic patients with HbA_{1c} levels of less than 7%	Compared to the preimplementation period, more diabetic patients with HbA_{1c} levels of less than 7% were observed in the postimplementation period (P<.001).
Levine et al [45]	Systolic blood pressure	Equivalent outcomes
Watson et al [38]	Total inflammatory lesion counts	Equivalent outcomes
Watson et al [38]	Frontal inflammatory lesion counts	Equivalent outcomes
Watson et al [38]	Leeds score	Equivalent outcomes
Penza et al [47,51]	Mortality rate	Penza et al reported only descriptive statistics in both studies, so it is unclear if there are differences in mortality rates between e-visits and in-person visits.
Murray et al [50]; Penza et al [51]	Hospitalizations	Murray et al [50] and Penza et al [51] reported only descriptive statistics, so it is unclear if there are differences in the number of related hospitalizations between e-visits and in-person visits.
Murray et al [50]	Antibiotic retreatment rate	Equivalent outcomes
Yokose et al [31]	Proportion of patients serum urate levels of less than 6.0 mg/dL	E-visits had greater proportions of patients with optimal control of serum urate levels when compared to in-person visits (P<.01).
Quality of care		
Hawes et al [44]	Amount of diabetic patients receiving aspirin, if clinically indicated	Equivalent outcomes
Hawes et al [44]	Amount of diabetic patients receiving moderate-intensity statins	Equivalent outcomes
Hawes et al [44]	Amount of diabetic patients receiving high-intensity statins	Equivalent outcomes
Heyworth et al [42]	Medication discrepancy discovery rate	It is unclear what the impact is on the rate of discovering medication discrepancies as no P value was reported.
Mehrotra et al [24]	Order rate of diagnostic test	E-visits had a lower order rate of diagnostic tests when compared to in-person visits (P<.001).
Mehrotra et al [24]	Order rate of preventive care services	E-visits had a lower order rate of preventive care services when compared to in-person visits (P<.01).
Yokose et al [31]	Rate that serum urate levels were checked	E-visits had more frequent checks of serum urate levels when compared to in-person visits (P<.05).
Murray et al [50]; Penza et al [46,51]; Mehrotra et al [24]; Courneya et al [40]	Antibiotic prescribing rate	Mehrotra et al [24] reported that the rate of prescribing antibiotics was higher during e-visits than in-person visits for sinusitis (P<.001) but not for e-visits for urinary tract infections. However, Penza et al [46] and Murray et al [50] saw equivalent outcomes. Penza et al [51] reported e-visits had lower antibiotic prescribing rates than in-person visits (P<.001). Courneya et al [40] also investigated the association but did not report a P value, so the impact on antibiotic prescribing rate is unclear.
Health care utilization		
Levine et al [45]	Overall primary care visit utilization	Equivalent outcomes

XSL•FO
RenderX

Outcome type and citations	Specific measures	Impact
Levine et al [45]	Overall specialist visit utilization	Equivalent outcomes
Levine et al [45]	Overall emergency department utilization	Equivalent outcomes
Levine et al [45]	Overall inpatient admissions	Equivalent outcomes
Rajda et al [49]	Number of specialist procedures done 60- and 90-days after initial consultation	E-visits were associated with a lower number of specialist procedures performed 60 and 90 days after an initial consultation when compared to in-person visits (P<.01)
Murray et al [50]; Penza et al [51]	30-day follow-up rate (planned and unplanned)	Equivalent outcomes
Penza et al [46]; Pathipati et al [43]; Albert et al [39]; Player et al [48]; Adamson et al [19]	Rate of patients who need planned follow-up visits	Penza et al [46] reported that e-visits were associated with higher rates of planned follow-up visits than in-person visits (P<.001). Pathipathi et al [43], Albert et al [39], Player et al [48], and Adamson et al [19] reported only the proportion of e-visits that required follow-up visits, so it is unclear what the association of e-visit usage and rate of planned follow-up visits is.
Penza et al [47]; Mehrotra et al [24]; Courneya et al [40]; North et al [41]; Hertzog et al [30]	Unexpected follow-up encounter rate after initial encounter	Hertzog et al [30] reported that e-visits were associated with higher unexpected follow-up rates when compared to in-person visits (P<.05). However, Mehrotra et al [24], Courneya et al [40], and North et al [41] found equivalent outcomes. Penza et al [47] reported only descriptive statistics, so it is unclear if there are differences in unexpected follow-up encounter rates between e-visits and in-person visits.
Health care costs		
Rajda et al [49]; Courneya et al [40]; Rohrer et al [37]	Treatment costs	Courneya et al [40] and Rajda et al [49] reported e-visits were associated with lower treatment costs (P<.001). Rohrer et al [37] reported a lower median of costs associated with e-visits than in-person visits (P<.01).

[a]HbA_{1c}: hemoglobin A_{1c}.

Study Quality Assessment Results

Detailed results of the quality assessment are summarized in Multimedia Appendix 2. Each column describes the quality criterion we assessed. Briefly, most (12/19, 63.2%) studies reported a strategy for minimizing selection bias. Less than half of studies (9/19, 47.4%) reported methods to control for confounders. All studies measured outcomes for e-visits separately from other forms of telemedicine, making it possible to evaluate the unique impact of e-visits on the outcome of interest. Problems with low response rate (<50%) or attrition bias (>10% dropout) were less common (2/19, 10.5%).

Clinical Outcomes

Associations between e-visit usage and clinical outcomes were reported by 7 studies. A total of 13 different measures were used among the studies. Overall, the studies reported an association with improved outcomes or null findings across the medical conditions examined.

Among diabetic patients, one study (n=36 patients) found that e-visits were associated with significantly improved glucose over a 6-month period (–3.4 percentage points in HbA_{1c}, P<.001) [44]. In the same study, e-visits for anticoagulant management were associated with less frequent instances of abnormal international normalized ratio values compared to in-person care (5/104, 5% vs 1/198, 0.5%, P<.05) [44]. An additional study (n=62) reported that patients with gout who received care through e-visits were more likely to have optimal serum rate levels (>6.0 mg/dL) (63.8% vs 33.9%, P<.01) and lower mean serum urate levels (5.5 mg/dL vs 6.7 mg/dL, P<.01) compared to historical controls [31]. In the context of acne and hypertension management, equivalent outcomes were reported between e-visits and in-person visits [38,45].

Quality of Care

Across the 8 studies that examined the association of e-visit usage on quality of care, 8 unique measures were observed. Overall, there were mixed effects on the association of e-visit usage on quality of care.

Mixed results were observed in some quality of care measures of several health care conditions between e-visits and in-person visits [44]. For example, one study (n=36) [44] reported comparable prescribing rates for statins among patients with diabetes across e-visits and in-person visits. One study [24] found that e-visit usage was associated with significantly lower rates of diagnostic procedures for sinusitis (0/475, 0% vs 40/4690, 1%, P=.04) and lower rates of diagnostic procedures for urinary tract infections (8/99, 8% vs 1501/2855, 53%, P<.001) than those for historical controls. The same study [24] also reported that preventive screenings were lower among sinusitis patients receiving an e-visit (1/475, 0.2% vs 155/4690, 3%; P<.001) and urinary tract infection patients' receiving an e-visit (0/99, 0% vs 214/2855, 7%, P=.005) than in those receiving in-person visits.

When examining management of acute infections (eg, urinary tract infections), the definitive impact was less clear. One study [24] found that e-visits resulted in higher antibiotic prescribing rates for sinusitis (471/475, 99% vs 4408/4690, 94%, P<.001)

XSL•FO
RenderX

but no association for urinary tract infections (98/99, 99% vs 1299/2855, 92%, *P*=.07), compared to those for historical control. Another study [46] reported that e-visits for conjunctivitis resulted in a significantly lower antibiotic prescribing rate than that of phone visits (26/101, 26% vs 84/202, 42%, *P*=.006), and a third study [51] found that e-visits for sinusitis resulted in a significantly lower antibiotic prescribing rate (84/150, 56% vs 108/150, 72%, *P*=.01) than that of in-person visits. Lastly, one study (n=450) [50] reported no difference in antibiotic prescribing rates for treatment of urinary tract infections across e-visits, phone encounters, and in-person visits.

Access to Care

No studies investigated the association between e-visits and access to care.

Health Care Utilization

Fourteen studies assessed health care utilization associated with e-visits. An overall mixed impact was observed across these studies.

Some studies evaluated the impact of e-visits on subsequent health care utilization, such as primary care, specialty care, and emergency care [45,49-51]. For example, one study [45] matched 893 e-visits and 893 in-person visits for hypertension and found that e-visits resulted in fewer primary care visits (–0.8 visits, 95% CI 0.3-1.2) compared to in-person visits. The same study [45] also found that usage of specialist visits, emergency department visits, and inpatient admissions were not significantly different across in-person and e-visits. Another study [49] evaluating a teledermatology program found that e-visits were associated with significantly fewer specialty visits at 60-day (15 vs 46, *P*=.005) and 90-day follow-up (26 vs 74, *P*=.001) compared to those associated with in-person visits. Another study [40] examining a direct-to-consumer telemedicine program found that the rate of visits that did not require a follow-up visit (ie, resolution rate) was similar for e-visits for sinusitis (90% vs 91%) and conjunctivitis (94% vs 95%) to those for in-person visits.

Some studies [24,40,41] reported no differences in health care utilization. For example, one study [24] found that e-visits for sinusitis and urinary tract infections had equivalent rates of follow-up visits, phone calls, and emails within 3-week follow-up. Some studies [30,46] reported a higher rate of health care utilization with e-visits. For example, one study [30] found that the rate of follow-up visits was higher for primary care e-visits (59/490, 12%) compared to that for in-person visits (198/2201, 9%; *P*=.04).

Health Care Costs

Three studies [37,40,49] found e-visit usage was associated with lower overall treatment costs than those for in-person visits. One study utilizing claims data found that e-visits for dermatology resulted in lower mean costs at the initial visit (US $59 vs $113, *P*<.001), at 30-day follow-up ($70 vs $202, *P*=.03), and at 60-day follow-up ($78 vs $221, *P*=.02) than those of in-person visits; however, at the 90-day follow-up, costs were comparable to those of an in-person visit ($86 vs $307, *P*=.08) [49]. One study [40] of a direct-to-consumer e-visit platform reported lower costs for a wide-range of conditions, including sinusitis, conjunctivitis, acne, and ear, nose, and throat infections. As an example, that study (n=9551 visits) used claims data to report that the cost per visit for e-visits was significantly lower for acne management ($178 vs $361, *P*<.001) compared to in-person care [40]. A third study [37] calculated total reimbursable costs and descriptively reported the median cost per visit was lower for e-visits ($161 vs $219) compared to in-person visits for acute conditions (eg, conjunctivitis, sore throat, bronchitis, viral illness, cough).

Discussion

This was a systematic review that assessed the impact of e-visits on clinical outcomes and health care delivery. To our knowledge, this is the first systematic review to assess the state of evidence for asynchronous e-visits. Most studies found that e-visits were associated with lower treatment costs and comparable clinical outcomes to in-person visits. Studies reported mixed effects on health care utilization, and no studies evaluated the impact of e-visits on health care access, suggesting future research is needed in this area. We provide implications for research and practice below.

Our review found that e-visits may be an adequate substitute for in-person care for chronic disease management. Studies showed that e-visits were effective for the treatment of diabetes, hypertension, and gout. Our findings are consistent with those of previous studies [52] that suggest that other forms of asynchronous communication with providers (eg, secure messaging without a formal e-visit) can improve chronic disease management. Further study, however, is needed to determine the ideal conditions for e-visit implementation. For example, many chronic conditions co-occur with other conditions (eg, diabetes and hypertension), and current studies were not designed to determine whether e-visits are effective for complex patients, such as patients with multiple chronic conditions and older adults who are frail. Additionally, it is important to note that not all types of medical issues may be appropriate for asynchronous management and health care systems may need to implement safeguards to ensure that the right patient is using an e-visit [53]. For example, if patients send a message about an urgent condition, e-visit technology could be harnessed to flag certain keywords (eg, chest pain, breathing difficulties) and display automated pop-up alerts to patients to instruct them to seek care in-person at the office or emergency department [54]. Some health care systems have also implemented guidelines, such as requiring at least one in-person visit prior to an e-visit to ensure that a patient has an established relationship with a clinician [55]. Additional research is needed to determine how e-visits should be implemented (eg, how to prevent inappropriate usage and for which patients does it work best).

Our review found mixed evidence for the effect of e-visits on quality of care. For example, prior studies [22,24-29] have raised concerns that telemedicine usage can increase inappropriate antibiotic prescribing, but this review found mixed evidence on whether comparable antibiotic prescribing rates were observed between e-visits and in-person visits. This inconsistency may

XSL•FO
RenderX

stem from differences in the acute infection that was studied (ie, acute sinusitis, urinary tract infections, ear infections, conjunctivitis). Further research is needed to better understand when e-visits can be used effectively for managing acute infections and what implementation strategies can be used to ensure appropriate antibiotic prescribing (eg, use of clinical decision support). Furthermore, additional research is needed to compare the receipt of low-value care (eg, overutilization of services for sinusitis and urinary tract infections across e-visits and in-person visits). Future studies should examine guidelines, such as the Choosing Wisely guidelines [56,57], to see whether e-visits reduce low-value care compared to in-person visits. One study [24] included in this review found that e-visits were associated with lower rates of diagnostic procedures for sinusitis and urinary tract infections and may offer an advantage in terms of reducing unnecessary health care utilization. Studies in this review did report other quality problems, such as lower use of preventive care services in e-visits compared to in-person visits. This may stem from a lack of practice guidance on how e-visits should be implemented (eg, should providers use e-visits as an opportunity to reinforce messages about preventive care?). Prior studies [16] have noted that lack of practice guidance or standard procedures as barriers to e-visit implementation. These differences in quality of care suggest additional implementation research is needed to test implementation strategies for ensuring quality of care delivered through e-visits is consistent across clinicians.

Our review found that e-visits had mixed effects on health care utilization compared to in-person visits. These findings are consistent with those of reviews on other forms of telemedicine [6,58-62]. Specifically, telemedicine can reduce health care utilization in certain instances (eg, reduce the need for in-person visits) or it can increase utilization (eg, meet an unmet demand for a patient that was not previously accessing in-person care). Variation in health care utilization may stem from other various factors that are unaccounted for. For example, if a patient did not submit sufficient information to be evaluated through an e-visit, this could lead to greater health care utilization compared to an initial in-person visit where information exchange is synchronous. Future research is needed to determine strategies for ensuring that complete information is elicited from the patient (eg, structured symptom questionnaires). Additional research should test strategies for optimizing patient data collection and patient-clinician communication through e-visit platforms.

The findings on favorable cost implications align with those of other works that evaluated the effects that synchronous alternatives for care (eg, telemedicine via teleconferencing software) had on cost outcomes for patients [63-70]. Notably, 2 [40,49] of 3 studies used claims data to estimate health care costs; however, insurers commonly include in their contracts with health care organizations contractual adjustments (ie, slightly lower reimbursement rates in exchange for including the health care organization in-network) [71], suggesting that using claims data may underestimate the true cost savings potential of e-visits. Furthermore, many of these studies did not evaluate cost comprehensively (eg, only examined costs of dermatology visits and not visits to providers outside of that delivery system, analyzing average costs per visit instead of average costs of an episode of illness). Additionally, we did not identify any studies that assessed cost-effectiveness, which considers costs relative to outcomes. Future cost-effectiveness studies may also help health care systems make decisions about whether e-visits are worth the investment.

Additional research is also needed on how e-visits impact health care access and the digital divide. There is growing evidence that patient-level disparities exist across adoption and usage patterns of patient portals [72-76]. Similarly, several studies in this review reported differences in usage based on sex [19,30,39,41,42,48], age [30,42,47], employment status [41,48], and ethnicity [19,41]. Since many patients access e-visits through the patient portal, which has known disparities in uptake [72-76], future studies are needed to test strategies for overcoming disparities in patient portal adoption. Since the Pew Research Center reports 81% of Americans in 2019 owned a smartphone [77], there have been studies that have recently tested whether smartphone access to a patient portal could improve access [78,79]. Future studies should test whether strategies, such as smartphone access, could improve uptake of e-visits.

Some of the included literature cited implementation barriers in their discussion that should be further explored in future studies (eg, lack of integration into workflow). Clinicians may need assistance with adjusting their workflows when being trained on e-visits [80]. Best practices should be researched and disseminated to help alleviate concerns on increased workload [81]. Furthermore, the adoption of payment models by insurers that reimburse for e-visits may be a crucial facilitator of e-visit uptake [20,82,83]. Since the COVID-19 pandemic has spurred the introduction of insurance coverage of e-visits among Medicare and some private payers, case studies have been published that suggest e-visits are being used more frequently during the COVID-19 pandemic. For example, one health care system reported that the use of e-visits increased by 4000% during the COVID-19 pandemic and that the majority of e-visits were used for remotely managing patients with COVID-19 [84-86]. Further work is needed to evaluate if the reimbursement policies have led to higher utilization of e-visits by patients and health care organizations.

This systematic review has several limitations. First, a majority of the studies used an observational design, limiting our ability to draw causal conclusions on the effect of using e-visits on quality of care, access to care, costs or clinical outcomes. Second, we found heterogeneity in how studies measured the impact of e-visits, making it impossible to quantitatively pool study estimates. Third, we excluded non-English studies, which may limit our ability to determine the effect of e-visits outside of English-speaking regions. Fourth, the follow-up periods among the studies varied (eg, 2 weeks vs 1 month), limiting our comparisons of findings between studies. Fifth, a majority of the studies examined e-visits that are hosted by the health care delivery organization rather than by a direct-to-consumer vendor or insurer, limiting the generalizability of our results to e-visit programs sponsored by entities external to the health care delivery organization. Lastly, most e-visits occurred in outpatient

XSL•FO
RenderX

ambulatory and academic medical center contexts, limiting our ability to comment on inpatient settings.

Overall, the evidence suggests that e-visits can provide equivalent outcomes to in-person care and reduce health care costs for certain health care conditions. There are still notable quality concerns (eg, inappropriate antibiotic prescribing, underutilization of preventive care) that warrant further study. It is also unknown how e-visits have affected access to care. Furthermore, many studies in the review lacked a rigorous design, making it difficult to draw firm conclusions about the state of evidence regarding e-visits. Future trials should be conducted to test the effectiveness of e-visits and determine what factors drive effective implementation.

Acknowledgments

We owe many thanks to Nancy Schaefer for providing her expertise as a health science librarian by providing us a framework on how to search for relevant articles and suggesting search terms to supplement our original search strategy.

Authors' Contributions

KT conceptualized the study. OTN and KT drafted the manuscript. All authors participated in the analysis and interpretation of data. AAT, JH, KH, CMS, and KT provided critical revisions to the manuscript. All authors approved the submission.

Abstract

Background: People who have migrated or with a language barrier may face significant hurdles in accessing health care. Some apps have been specifically developed to facilitate the dialogue between health care professionals and people who have migrated who have low-level language proficiency or to promote health among people who have migrated.

Objective: We conducted a systematic review to investigate development, acceptability, and effectiveness of these types of apps.

Methods: We conducted a search of PubMed, Scopus, and Embase databases. We included all study designs (qualitative, quantitative, mixed) reporting development, evaluation of efficacy, or acceptability of apps facilitating dialogue with a health professional or promoting health for people who have migrated, minorities, or tourists with a language barrier, using any outcome. Two researchers selected the studies independently. We collected general information about the app, information about health literacy and cultural adaptation, information about the development of the app, evidence on acceptability or efficacy, and information on app use. Data were collected by 2 researchers independently and results were reviewed to verify agreement and reported according to PRISMA (Preferred Reporting Items for Systematic Review and Meta-analysis).

Results: Positive results for translation apps included better communication, but with possible limitations, and reduced consultation time. Positive results for health promotion apps included improved quality of life and better management of chronic illnesses.

Conclusions: Overall, the apps had good levels of acceptability, though only half had their efficacy evaluated. In those evaluations, the endpoints were mostly related to reported behavior change and knowledge improvement, which is common for evaluations of health promotion programs. In the future, as more health apps are created, it is essential that apps that claim to have a public health objective undergo a rigorous evaluation of their acceptability, efficacy, and actual use. Indicators of outcomes beyond changes in behavior and knowledge should be reported; change in health status or access to care should also be reported. This systematic review has helped us note the characteristics associated with improved acceptability and efficacy, which can be helpful for the development of future apps.

Introduction

People who have migrated may face significant delays and barriers in accessing health care, especially those who do not fluently speak the language of the host country. Research has been conducted to investigate language barriers in accessing care and prevention among people who have migrated and its health consequences. Pregnant women who have migrated and with low proficiency in the language of their new country of residence have found it more difficult to access care [1], had less knowledge about the benefits of folic acid and had lower folic acid intake [2], and had a higher risk of obstetric trauma [3]. A study [4] showed that a language barrier is significantly associated with a higher occurrence of serious medical events in pediatrics. Cancer studies show less screening for colorectal cancer [5,6], cervical cancer [6], and breast cancer [6,7] among people who have migrated who had low English proficiency. Others have found that adding an interpreter to a consultation where the patient has a language barrier (any type of interpretation) results in the reduction of obstetric interventions [8], better clinical outcomes in people with diabetes [7,8], a higher rate of breast cancer and colorectal cancer screening [7], and a higher rate of influenza vaccination [7]. Overall, it has also been shown that patients with a low proficiency in the language of the country of residence receive more preventive advice and more prescriptions and have fewer emergency visits if they use interpretation services [9].

Health care professionals commonly use several solutions to communicate with people who have migrated with low language proficiency, including printed guides and brochures, informal interpreters, professional interpreters in person, professional interpreters on phone or video conference, and general translation apps. Some apps or electronic tools have been specifically developed to be used in medical consultations to facilitate dialogue between health care professionals and people who have migrated who have low language proficiency or to promote health among people who have migrated. In the last decade, there has been a sharp increase in the number of medical apps developed [10], but their impact on patients or public health should be established.

We conducted a systematic review to examine the evidence related to the development, adaptation, acceptability, and effectiveness of electronic tools designed to help health care providers communicate with or promote health among people who have migrated and who have low levels of proficiency in the language of their country or low levels of health literacy. The aim of this review was to describe the existing tools and gather evidence about features that increase the acceptability and efficacy of such tools. Our work is part of a larger project designed to develop and evaluate an app to facilitate communication between people who have migrated who face a language barrier and health professionals regarding testing for HIV and different forms of viral hepatitis [11]. Lessons learned and evidence from similar apps could help design an app that has a significant impact on public health.

Methods

Search Strategy, Databases, and Keywords

We wrote a protocol prior to starting the systematic review and reported the results according to the PRISMA reporting guideline [12] (Multimedia Appendix 1). We conducted a search of 3 databases of scientific publications: PubMed, Scopus, and Embase. The keywords varied according to the database used. To determine keywords, we undertook a broad preliminary search and selected some articles (between 5 and 10) identified as meeting inclusion criteria determined by the authors. After selecting these articles, we searched for their related keywords, MeSH terms (Medical Subject Headings), terms in titles or abstracts, and EmTree terms. Then the selection of keywords was tested and different combinations were tested so that the total number of results was manageable and yielded relevant articles. The final selection of keywords was critically reviewed by a university librarian. The keywords for each database are detailed in Multimedia Appendix 2.

Inclusion and Exclusion Criteria

We used the inclusion and exclusion criteria detailed in Table 1. Although the primary focus of this review was people who have migrated, the preliminary search yielded articles reporting apps that helped bridge the language barrier for other populations, such as tourists needing emergency care and not speaking the language of the country visited or indigenous people whose primary language is different from the official language. Since these apps help health care providers communicate with patients with a language barrier, we decided to include them because we found they were relevant.

XSL•FO
RenderX

Table 1. Inclusion and exclusion criteria.

Criteria type	Inclusion criteria	Exclusion criteria
Publication		
Language	• Written in English or French	• Other languages
Date range	• Published after 1998	• Published before 1998
Type	• Original article, review, protocol, conference abstract, book chapter	• Other types of publications: editorial, letter, notes, etc
Study		
Design	• Studies reporting the development of an electronic tool, including qualitative or quantitative studies of people who have migrated or health providers, mixed methods, literature reviews • Studies evaluating the acceptability of electronic tools, including qualitative or quantitative studies, usability studies, randomized or nonrandomized trials • Studies evaluating the efficacy of electronic tools, including randomized or nonrandomized trials, qualitative or quantitative studies, economic evaluations	• Articles lacking information about the development or evaluation of an electronic tool • Studies exploring only the perceptions of users (people who have migrated or health professionals) related to e-health or a health issue
Population		
Language	• International people who have migrated not fluent with the language of the country they reside	• People with no language barrier (internal people who have migrated, ethnic minorities, people who have migrated with no language barrier)
Communication barriers	• Cultural minorities having a language barrier (eg, indigenous people whose first language is different from the official language) • Tourists	• People with other type of communication barriers: deaf or hard-hearing people, people with a learning disability
Technology		
	• Website, mobile (smartphone or tablet) apps, other electronic technology that allows interaction with user text message or email-based services	• Tools using only print material, audio, or video
Intervention	• Technology designed to help communication between health care providers (eg, doctors, nurses, midwifes) and people who have migrated in any health care setting (eg, hospital, primary care) • Technology designed to promote healthy behavior among people who have migrated	• Technology that aims to facilitate communication or translation in general settings but not designed specifically for the medical setting (eg, Google Translate, apps for tourists).
Outcome		
Development of an electronic tool	• Themes emerging from interviews or focus groups, results from participants consultations	• None
Acceptability	• Comments from participants,, satisfaction surveys, data in app use or consultations	• None
Efficacy	• Changes in health outcomes (self-reported or measured with biomedical measures), changes in knowledge, attitudes, practices, and beliefs	• None

Study Selection

A list of articles retrieved from all 3 journal databases was compiled. After excluding duplicates, 2 researchers (FT and SP) independently reviewed the title and abstracts of all documents for preselection. Articles were then reviewed in full for inclusion or exclusion; if an article was excluded, the reason was documented. We managed the selection of articles with Rayyan [13]. Differences of opinion regarding the inclusion of an article were managed by a third researcher (ORT). We also

XSL•FO
RenderX

subsequently included relevant articles that were cited by articles that had been initially selected.

Data Collection

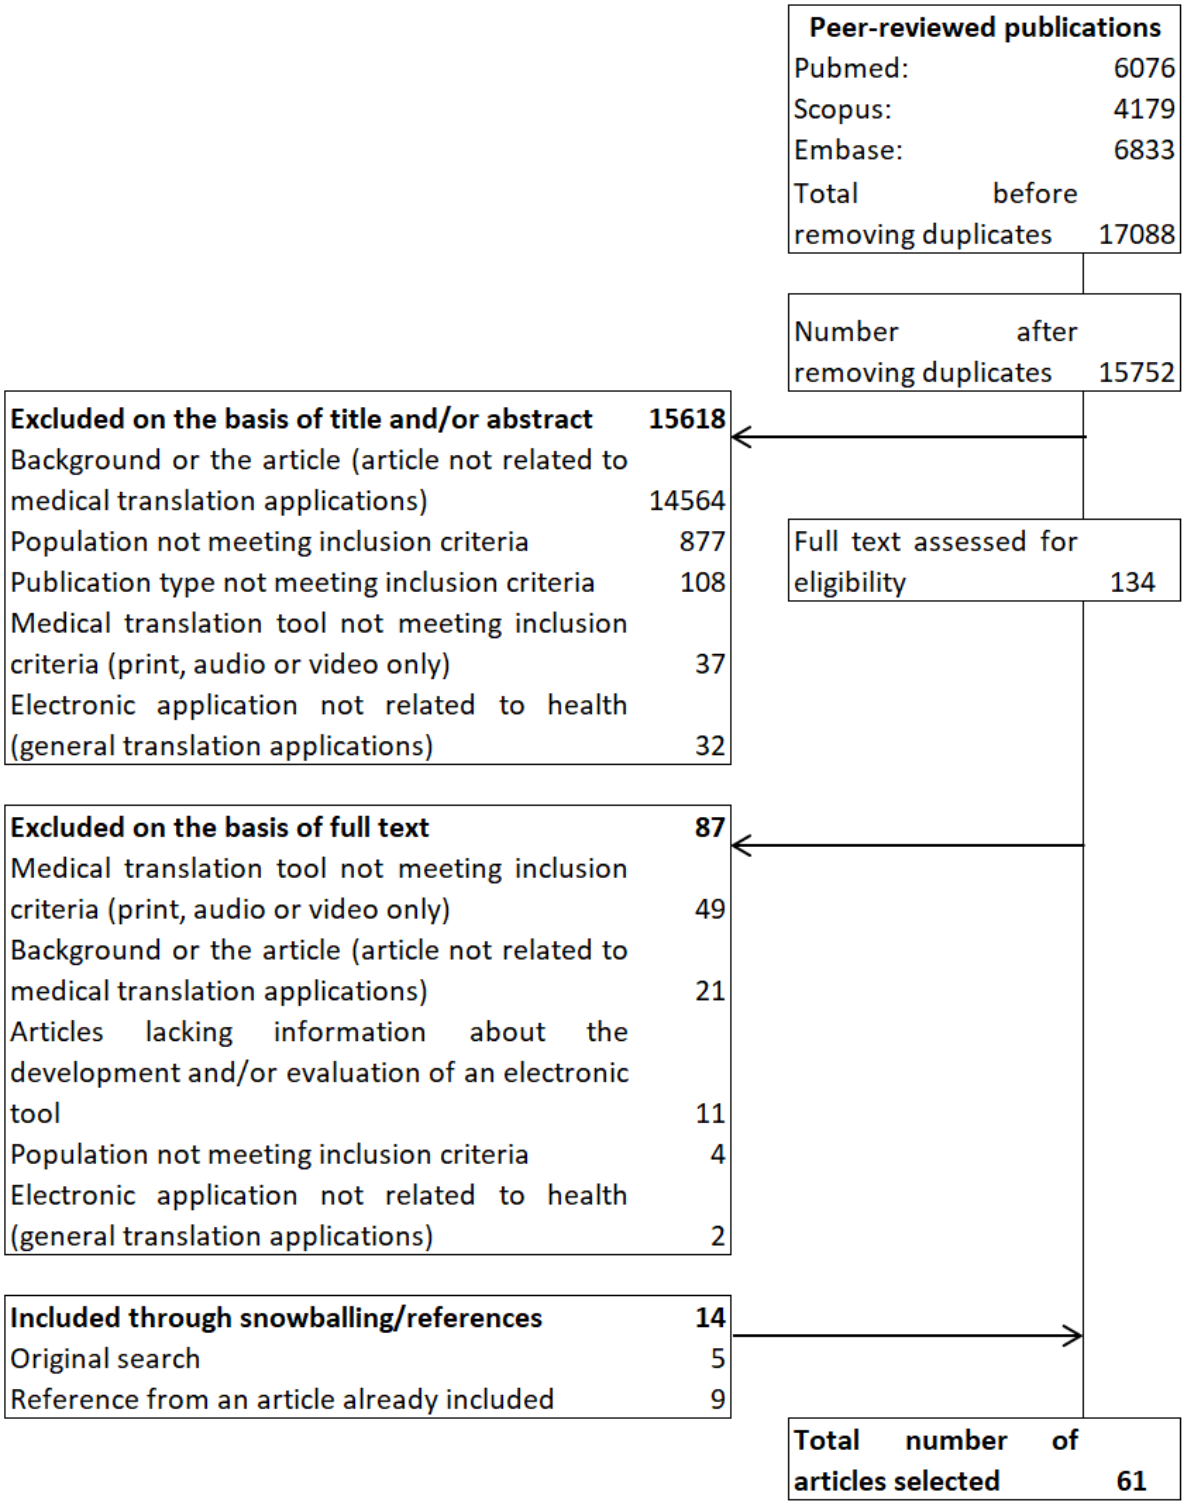
We used 2 data collection coding sheets (Google Forms): one for each article (type of publication, year of publication, and journal) and one for each app studied (general information about the app or electronic tool, information about health literacy and cultural adaptation, information about the development of the app or electronic tool, evidence about the acceptability or efficacy of the app or electronic tool, information about the use of the app or electronic tool). All articles were read by FT, and to improve the validity of results, we performed data triangulation by having a second author read articles independently.

When articles presented additional sources of information regarding an app, such as gray literature or a website, we retrieved data about the app from this source and noted the references of this additional source of information but did not use them in the article selection.

Quality and Risk of Bias Assessment

We evaluated the articles using ICROMS (Integrated Quality Criteria for Review of Multiple Study Designs) [14], which can be used for public health reviews that include several study designs, such as randomized controlled trials, controlled before-after, controlled interrupted times series, cluster randomized controlled trial, noncontrolled before-after, cohort studies and qualitative studies. This tool consists of 33 indicators grouped in 7 dimensions: (1) clear aims and justification; (2) managing bias in sampling or between groups, (3) managing bias in outcome measurement and blinding, (4) managing bias in follow-ups, (5) managing bias in other study aspects; (6) analytical rigor; and (7) managing bias in reporting or ethical considerations. Each indicator receives a score of 2 if the criteria for the indicator are met, 0 if this is not the case, or 1 if it is unknown whether the criteria were met. Where specified, we also found that it was necessary to use CHEERS (Consolidated Health Economic Evaluation Reporting Standards [15]), noting if the information required was available, incomplete, or not available using the same scoring system as ICROMS. It should be noted that this scoring system for protocols or medicoeconomic studies is not validated, nor is it part of the ICROMS tool.

Many articles related to eHealth are information technology usability studies. Usability studies are studies that aim to explore usability requirements, discover usability problems, and design solutions [16]. To our knowledge, there is no published article proposing a tool to evaluate the quality or bias of such studies. Usability studies mainly use either qualitative or quantitative methodologies [16], however, due to the usually small sample of participants [17] and approaches used, such as participants being asked to perform tasks and give oral feedback [18], they are closer to qualitative studies than they are to quantitative studies. Therefore, we assessed the quality and risk of bias of most of usability studies using the ICROMS tool adapted to qualitative studies, except usability studies using quantitative-only methodology, which were assessed as noncontrolled before-after. We also used the ICROMS tool to evaluate research protocols; we simply disregarded the questions that were not applicable.



Results

Selection

The database search was carried out in October 2019. We retrieved a total of 15,752 articles from 3 databases after removing duplicates, of which 15,618 were excluded on the basis of title or abstract content. We assessed the full texts of 134 articles and excluded 87, most because the electronic tool described did not meet the inclusion criteria. We subsequently added 14 articles, because they were found either in the original background search or cited by articles that had been initially selected. In total, we included 61 articles (Figure 1). The difference between the very high number of articles originally retrieved and the number of articles selected can be explained by the fact that the original search yielded a number of articles related to translational research. The 61 selected articles were all read and analyzed by FT, and 51 (84%) were read and analyzed by a second reviewer (35 by SP and 16 by AVY).

XSL•FO
RenderX

Figure 1. Flowchart of article selection.

Characteristics

The majority of articles were original research articles (55/61, 90%); 4 were published research protocols, and 2 were proceedings of scientific conferences. Of the 61 articles, most articles (27/61, 44%) were published in journals that specialized in medical information technology, 14 (23%) were published in journals related to a disease or medical specialty, 11 (18%) were published in journals that specialized in health promotion, 6 (10%) were published in general health journals, and 3 (5%) were published in nonmedical journals that specialized in information technology. All articles were published in English. The countries of affiliation of the first authors were USA (n=40), Germany (n=5), Australia (n=5), New Zealand (n=2), United Kingdom (n=2), Italy (n=1), Nigeria (n=1), China (n=1), Switzerland (n=1), Japan (n=1), Norway (n=1), and Spain (n=1).

Of the 61 articles, 21 articles reported qualitative studies (34%), 18 articles reported usability studies (30%), 9 articles reported

XSL•FO
RenderX

nonrandomized interventional studies (15%), 7 articles reported randomized controlled trials (11%), 4 articles were protocols for either randomized controlled trials (n=3, 5%) or a mixed methods study (n=1, 2%), and 2 articles reported other types of studies (1 medicoeconomic study; 1 case study).

Quality and Risk of Bias

One article was a health economic study, for which CHEERS was used. We could not evaluate the quality of one article [19], as it is was a description of the tool and a single case study of its use on a patient. This article was included in our review because of its practical description of the tool.

The full results are available in Multimedia Appendix 3. Among the 7 randomized controlled trial articles, the mean score was 22 and the median score was 24 (the score ranges from 0 to 30, and the minimum score required for a study to be considered of robust quality is 22); 1 article did not meet the criterion to be considered of robust quality. Among the 21 qualitative studies, the average and median score were 18 and 18, respectively (the score ranges from 0 to 26, and the minimum required for a study to be considered of robust quality is 16); 7 articles did not meet the minimum to be considered of robust quality. Among the 9 noncontrolled before-after studies, the mean score was 22 and the median score was 23 (the score ranges from 0 to 30 and the minimum required for a study to be considered of robust quality is 22); 4 studies did not meet the minimum to be considered of robust quality. Among the 18 usability studies, 6 did not meet the minimum required for either qualitative or noncontrolled before-after studies to be considered of robust quality.

For the randomized controlled trials, the lowest scores were found on questions regarding allocation blinding and measurement blinding, and to a lower extent, reliability of primary outcome measures (lack of objectivity of outcome variables). For the qualitative studies and usability studies, the lowest scores were found for items of critically assessing researcher bias and lack of agreement. For noncontrolled before-after studies, the lowest scores were found regarding justification for and attempts to mitigate the lack of control group and, to a lower extent, lack of objectivity of outcome measures.

General Characteristics of Apps

In the 61 articles, a total of 48 apps were presented (Table 2). Approximately two-thirds of the electronic tools (n=30, 63%) were developed in the USA. Other countries represented were Germany (4 apps), Australia (4 apps); New Zealand (2 apps) and Italy, United Kingdom, Nigeria, China, Switzerland, Japan, Norway, and Spain (1 app each).

Of the 48 apps, 20 apps (42%) were designed for health promotion or prevention, rather than for one specific health care setting: 11 were designed for hospital care, 8 were designed for primary care, 5 were designed for therapeutic or patient education, 3 were designed for both primary care and hospital care, and one was designed for both health promotion and primary care; 14 apps (29%) were health promotion apps that were not related to one specific medical specialty or condition, and the most represented medical specialties were cancer (9/48, 19%), mental health (6/48, 13%). Health promotion is defined as the process of enabling people to increase control over and to improve their health [20].

One-third of apps (16/48, 33%) were designed solely to facilitate interactions between people who have migrated and health care providers during a consultation, while the remaining two-thirds (32/48, 67%) were designed to promote health among people who have migrated who face a language barrier. Of those 32 apps designed to promote health, 9 were adaptations for people who have migrated of existing apps, while 23 were new apps developed specifically for people who have migrated.

Most electronic tools (38/48, 79%) were in the form of a mobile app, while other types (text messaging, website) were less common. It should be noted that 2 electronic tools (2/48, 4%) included both a mobile app and a text messaging service. Almost two-thirds of apps (31/48, 65%) were interactive, meaning that they allowed feedback from the user, either to another user or to the app.

More than three-quarters (38/48, 79%) were specifically targeted to a group of people who have migrated, and mostly for people who have migrated from specific nationalities (24/38, 63%). Over two-thirds (33/48; 69%) had 1 language in addition to the source language, nine apps had 3 to 9 languages, five had 10 to 19 languages, and one app had over 20 languages. Information about the funding of the app was available for 33 (69%) out of the 48 apps: 30 apps (63%) had received a funding from either a public source, charitable source or crowd-funding, while 2 apps (4%) had received a funding from a mix of private and public or charitable source, and 1 app (2%) had received a private or industry funding.

[a]Of the 32, 9 were adaptations of existing apps.

Health Literacy and Cultural Adaptation

There was information about how the translation was performed for only half of the apps (n=24); translation was performed by a professional translator (16/48, 33%); informally (4/48, 8%), usually by nonprofessional native speakers; or by a mix of professional and personal translation (4/48, 8%). Some form of quality control of the app was mentioned for 18 apps (38%), usually forward-backward translation or translation being checked by a native speaker. The translation included cultural adaptation on 23 apps (48%), half of the apps included pictures or pictograms (n=24). Two-thirds of apps had either an audio or video feature (32/48, 67%).

Information About the Development of the App or Electronic Tool

Of the 48 apps, 33 (69%) reported using scientific methods to develop the content of the app: qualitative studies (interviews or focus groups) for 15 (45%), use of a theoretical framework such as behavioral theories for 8 (24%), use of existing guidelines of curriculums (n=5, 15%), a mix of qualitative and quantitative methods for 4 (12%), and a mix of survey and use of theoretical framework for 1 (3%).

Of the 48 apps, less than half (22/48, 46%) reported involving users (people who have migrated) in the development, 18 apps (38%) reported involving health professionals in the development, and 5 apps (10%) reported involving other stakeholders such as charities.

Evidence About the Acceptability and Efficacy of the App or Electronic Tool

Many apps (32/48, 67%) had their acceptability evaluated (translation apps: 14/16, 88%; health promotion apps: 18/32, 56%). Of the 14 translation apps that had their acceptability evaluated, 3 were evaluated among people who had migrated only, 6 were evaluated among people who had migrated and health professionals, and 5 were evaluated among health professionals alone. Of the 18 apps designed to promote health among people who had migrated that have been evaluated for acceptability, 14 were evaluated among people who had migrated alone, 3 were evaluated among people who had

XSL•FO
RenderX

migrated and health professionals, and 1 was evaluated among health professionals alone. Acceptability studies used mixed methods (20/32, 63%), used quantitative methods only (8/32, 25%), used qualitative methods only (7/32, 22%), were pilots (5/32, 16%), and randomized controlled trials (2/32, 6%). The endpoints used to measure acceptability were comments from participants (12/32, 38%), results from satisfaction survey (9/32, 28%), length of time of a consultation and satisfaction survey (4/32, 13%), data on the use of the app (3/32, 9%), a mix of survey and qualitative comments (2/32, 6%), and other outcomes (2/32, 6%). The Systems Usability Scale was mentioned in 5 evaluations. Other evaluation systems mentioned were the Technology Acceptance Model and the Stanford Communication with Physicians Scale. Among the 32 apps that had their acceptability evaluated, 25 (78%) reported an overall good or very good acceptability; 1 (3%) reported an adequate acceptability; for 3 apps (9%), the study was ongoing; and for 3 others, the results cannot be reported as they consisted of comments from participants or choice of a design. Of the 25 apps that reported a good or very acceptability, 8 had been developed involving users in the process.

Half of the apps (n=24) had their efficacy evaluated (translation apps: 2/16, 13%; health promotion apps: 22/32, 69%). Study designs were randomized controlled trials (9/24, 38%), nonrandomized trials (7/24, 29%), survey (3/24, 13%), qualitative (2/24, 8%), mixed methods (2/24, 8%), and economic analysis (1/24, 4%). The endpoints or outcomes used for those evaluations were reported behavior change (10/24, 42%), knowledge improvement (7/24, 29%), self-reported health markers, such as improved quality of life, better sleep, less anxiety (4/24, 17%), biometric health markers (2/24, 8%), cost-effectiveness (2/24, 8%), and accuracy of medical information (n=2, 8%). The total exceeds 100% as 11 apps used several different endpoints. Among the 24 apps that had their efficacy evaluated, 12 (50%) had significant positive results; 5 (12%) had partially positive results, meaning that the app showed significant efficacy in some measured outcomes but not all, or was effective in some population and not all; and 2 apps had nonsignificant results (8%); 5 studies were ongoing (21%). Details of the efficacy and acceptability studies are in Multimedia Appendix 4.

Positive outcomes (Table 3) reported for translation apps includes reducing the need to call an interpreter, especially in emergency situations [21], reduced consultation time [22,23], and reduced patient anxiety [24]. Negatives that were reported included limitations in the dialogue between health professionals and patients [25-27] and concerns about hindering the therapeutic relationship [28]. Health promotion apps had positive results in terms of acceptability and efficacy. Positive outcomes included improved quality of life and better management of chronic illnesses such as diabetes [29-31], cancer [32-34], HIV [35], depression [19,36], and addiction [37,38].

Table 3. Characteristics of health apps linked to better acceptability or efficacy.

App type	Important points noted during the development	Characteristics linked to better acceptability or efficacy
Translation	Many experts recommend that culturally tailored materials be created de novo or in tandem, rather than as variations on existing materials	• Speech is generally preferred to text • Including a button, equivalent to the patient's "I do not understand the question" • Including a phrase for health care practitioners "I don't understand your answer" • Integrating an option to directly call an interpreter in the app • Integrating a list of nearby hospitals for follow-up care • Including the option for patients to respond with pictures • Including the option for health care practitioners to save the conversation with a patient (with respect to data protection and confidentiality)
Health promotion	Addressing both motivation as well as linguistic and sociocultural barriers and reassuring participants of confidentiality	• Apps that personalize the experience for users are preferred • Including a help function and a tutorial • Include a tutorial provided by a virtual human rather than text • Culturally appropriate, with photos of a multigenerational family • Colorful and eye catching, but also professional, with easy-to-access information • Easy to navigate with simple and easy-to-understand information • Interactive with immediate feedback • Audio, videos and pictures • Provision of links for further information about a health issue • Use of humor considered very effective by target audiences • Including a list of frequently asked questions for users • Including the option for people who have migrated to learn medical terms in the language of the country they live in

Discussion

Main Results

We synthesized evidence regarding the development, acceptability, and efficacy of health apps and electronic tools created to overcome the language barriers. Acceptability was evaluated in almost two-thirds of the apps and was generally high. Although health promotion or prevention programs specifically targeting people who have migrated might be complex to integrate into a health system, they are generally well accepted [39] and are a way to elevate health for all individuals.

Efficacy evaluations were only conducted for half of the apps. In those evaluations, the endpoints were mostly related to

XSL•FO
RenderX

reported behavior change and knowledge improvement. Knowledge improvement, however, does not systematically lead to behavior change and the reported behavior change may not be long lasting. Changes in health outcomes are rarely measured in health promotion programs or health promotion research; this should be included as a goal of health communication tools. Indeed, a survey of researchers in health promotion highlighted that the majority of assessment measures changes in awareness, knowledge, skills, policy changes, changes in behavior, changes in community capacity, changes in organizational capacity, but changes in health outcomes are not cited [40]. In addition, several systematic reviews [41-43] examining the literature related to health promotion programs have shown that programs are rarely evaluated in terms of health outcomes. It seems, therefore, that assessments of health promotion apps are in line with current practices for assessments of health promotion programs, which focus on knowledge and reported practices but rarely on final health outcomes. Given the difficulty of measuring the health outcomes of health promotion programs or apps, it is necessary to develop new methods.

Although we could only retrieve information about the funding of 69% of apps (33/48), we found that the majority had either public or charitable funding, while only 2 apps received industry funding. Additionally, only 5 apps reported charging users a fee. That seems to suggest that both health promotion and medical translation apps mostly have a noncommercial purpose and were designed with a public health goal.

Only half of the apps had their efficacy evaluated, of which half had a significant positive result. Efficacy was evaluated more often for health promotion apps than for medical translation apps. As we have mentioned, communication difficulties between health providers and individuals with language barriers can have several negative consequences, such as less satisfaction with care [7], longer consultation time [44], lower adherence to treatment protocols [45], less health education messages delivered [9], and worse clinical outcomes [8]; therefore, it is of tremendous importance that medical translation apps are rigorously assessed, not only for their acceptability but also for their efficacy.

Comparison With Literature

Several literature reviews [46-48] have been conducted of health apps and multimedia-based health promotion programs; however, none has specifically examined apps that are focused specifically on language barriers. Two reviewed the use of mobile health technology use and implications in historically underserved and minority populations in the United States [46] and mobile health interventions to promote physical activity for Black and Hispanic women [47] but scarcely addressed language barriers. We found one systematic review evaluating consumer health information technology interventions toward US Spanish-speaking populations [48]. The study [48] focused on one specific population in a specific country (USA), for a very wide scope of electronic interventions (eg, radio, videos, text messages services) that is different from the scope of our article. In that systematic review, the most commonly used evaluation metrics were behavior, attitude change, usability, and knowledge retention. The results of the study [48] and of our own were similar.

Strengths and Limitations

We conducted an extensive search of the literature using 3 different databases of publications. The selection of articles was conducted by two researchers working independently; results were compared and differences were settled by a third party. Most articles were read and their data extracted by two researchers independently, and results were compared when analyzing data. This enabled us to have a higher quality of data and a reduced risk of bias. We extended the scope of our systematic review to both electronic tools designed for translation and those designed to promote health among people who have migrated with a language barrier. Although the electronic tools have seemingly different objectives, it is likely that, in the future, there will be hybrid apps that will be developed to integrate both objectives. Indeed, many primary care consultations include health education and advice from a health provider, and hospitals have been advised to include health promotion activities into their activities [49]. Development of new hybrid apps that includes both objectives will be able to learn from the evidence from the both types of apps we examined.

In this systematic review, we only included apps that were referred to in a scientific journal. Our analysis did not include the plethora of apps designed to promote heath or facilitate consultation for people who have migrated with a language barrier that were not the topic of published peer-reviewed articles. Since the objective of our review was to evaluate the evidence related to the development or evaluation of these types of apps, it was not relevant to include these other sources. In our review, we did not assess the technical characteristics of the apps studied. Indeed most articles included in this review did not give information about the technical characteristics of the apps. Many scales and evaluations systems have been created to that end [50-53]. Assessing the technical characteristics is time-consuming and not always possible as many of those apps are not available for public use. We suggest that when new apps are developed, they strive to achieve the technical qualities measured by such scales. Other systematic reviews [54] have examined an extensive range of apps designed to help communication between health care providers and people who have migrated beyond those published in peer-reviewed articles, which focus on technical characteristics, and which provide different types of information that are complementary to that provided herein.

Implication for Policy and Conclusion

As previously mentioned, people who do not speak the language of the country have poorer access to care, longer and less satisfactory consultations, and worse clinical outcomes. In this review, we found that translation apps showed good user satisfaction but had less data on changes in the process of care (consultation length, renouncing medical care) and no data on possible changes in clinical outcomes or medicoeconomic benefits. The evaluations of health promotion apps had positive results in terms of acceptability and efficacy; however the trials on efficacy mostly used self-reported outcomes, such as

XSL•FO
RenderX

self-reported behavior changes or quality of life, rather than clinical outcomes. Most trials lacked randomization or control groups, blinding, or objective measures. This lower quality makes it difficult to draw clear conclusions on efficacy.

Future apps that are developed should include evaluation of clinical and possibly medicoeconomic benefits to draw clear recommendations on their use. The apps that were the most acceptable were those that integrated features beyond simple translation, such as making appointments with health professionals on the platform or entering basic information to prepare a visit. We recommend that future translation apps are created for medical visits integrate such. In both translation and health promotion apps, including audio and video features was most appreciated by users. We recommend integrating such features in the development of new apps.

In the future, more and more health apps will be created. Given the high cost of development [55], it is essential that apps that claim to have a public health objective undergo a rigorous evaluation of their acceptability, and efficacy. Future studies should also use strong epidemiological indicators as outcomes, such as changes in health status or access to care, rather than only using reported changes in behavior and knowledge.

The aim of this systematic review was to examine the evidence related to the development, adaptation, acceptability, and effectiveness of electronic tools designed to help health care providers communicate with or promote health among people who have migrated having a low proficiency in the language of the country of origin or a low level of health literacy. Our results, especially development and characteristics associated with a better acceptability and efficacy, should be of help to public health professionals who develop new apps.

Acknowledgments

We sincerely thank Corinne H Miller, Clinical Informationist at Galter Health Sciences Library & Learning Center of Northwestern University, Chicago, USA, for her help in the developing the search strategy and keywords.

The study was funded by the *Agence Nationale de Recherches sur le SIDA et les Hépatites virales* (grant ECTZ109287) and by *Office Français de l'Immigration et de l'Intégration* (20191104122918510), whom we thank for their support. The funders had no role in study design, data collection or analysis, manuscript writing, or decision to publish. JWG was supported in part by the National Institutes of Health (R01MD010440).

Authors' Contributions

FT, ORT, MD, SP, JWG, and OC designed the study. FT and SP developed the search and selection strategy, developed the data extraction form, and collected data. AVY collected data. FT, ORT, MD, and OC performed critical evaluation and discussion of results. FT drafted the manuscript. All authors reviewed the manuscript.

Abstract

Background: Health care organizations are increasingly working with eHealth. However, the integration of eHealth into regular health care is challenging. It requires organizations to change the way they work and their structure and care processes to be adapted to ensure that eHealth supports the attainment of the desired outcomes.

Objective: The aims of this study are to investigate whether there are identifiable indicators in the structure, process, and outcome categories that are related to the successful integration of eHealth in regular health care, as well as to investigate which indicators of structure and process are related to outcome indicators.

Methods: A systematic literature review was conducted using the Donabedian Structure-Process-Outcome (SPO) framework to identify indicators that are related to the integration of eHealth into health care organizations. Data extraction sheets were designed to provide an overview of the study characteristics, eHealth characteristics, and indicators. The extracted indicators were organized into themes and subthemes of the structure, process, and outcome categories.

Results: Eleven studies were included, covering a variety of study designs, diseases, and eHealth tools. All studies identified structure, process, and outcome indicators that were potentially related to the integration of eHealth. The number of indicators found in the structure, process, and outcome categories was 175, 84, and 88, respectively. The themes with the most-noted indicators and their mutual interaction were inner setting (51 indicators, 16 interactions), care receiver (40 indicators, 11 interactions), and technology (38 indicators, 12 interactions)—all within the structure category; health care actions (38 indicators, 15 interactions) within the process category; and efficiency (30 indicators, 15 interactions) within the outcome category. In-depth examination identified four most-reported indicators, namely “deployment of human resources” (n=11), in the inner setting theme within the structure category; “ease of use” (n=16) and “technical issue” (n=10), both in the technology theme within the structure category; and “health logistics” (n=26), in the efficiency theme within the outcome category.

Conclusions: Three principles are important for the successful integration of eHealth into health care. First, the role of the care receiver needs to be incorporated into the organizational structure and daily care process. Second, the technology must be well attuned to the organizational structure and daily care process. Third, the deployment of human resources to the daily care processes needs to be aligned with the desired end results. Not adhering to these points could negatively affect the organization, daily process, or the end results.

KEYWORDS

eHealth; digital health; blended care; quality; integration; health care organization; structure; process; outcome

Introduction

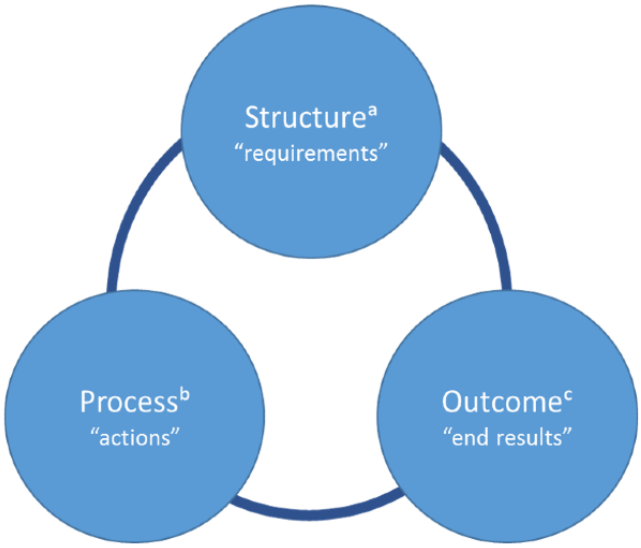
Health care is changing, whereby patient empowerment, democratization of the internet, and an increasing burden on health care professionals play influential roles [1-3]. In line with these trends, innovations such as eHealth are required to maintain high quality of care [4-6]. eHealth includes a wide range of web-based interventions, for example e-consults, telemonitoring, and web-based viewing of medical records [1,7,8]. However, eHealth is more than a technology; it is another way of working and thinking and requires a change in attitude, which goes beyond the boundaries of a local health care organization [9,10].

The most comprehensive definition of eHealth with reference to the organizational context is that provided by Eysenbach [11]:

> *e-health is an emerging field in the intersection of medical informatics, public health and business, referring to health services and information delivered or enhanced through the Internet and related technologies. In a broader sense, the term characterizes not only a technical development, but also a state-of-mind, a way of thinking, an attitude, and a commitment for networked, global thinking, to improve health care locally, regionally, and worldwide by using information and communication technology.*

In other words, the integration of eHealth into traditional health care requires organizational and behavioral changes for both health care professionals and patients [9,10].

Organizations are increasingly working with eHealth; however, implementing eHealth into the regular health care system requires organizations to change the way they work [9-11]. eHealth enables patients to have a more active role in managing their health [7,12,13], which affects interactions between the patient and health care professional [14-17]. Furthermore, working with eHealth technology requires workflow adjustments for health care professionals [18,19]. The organization's structure and care processes need to be adapted to ensure that eHealth supports the attainment of desired outcomes [20,21].



The challenge of optimally integrating eHealth into health care is thus a complex organizational issue. Several studies have identified elements to promote eHealth adoption, such as the degree of complexity, adaptability of the technology, costs, and stakeholder value [20,22], but uncertainty remains on how digital and traditional health care can blend successfully in the long term. With different definitions of eHealth available in the literature [10,11,23], and unclear barriers for facilitators in the application of eHealth [19], there is a need for further research on how eHealth can successfully be integrated into health care.

The aim of this study is to analyze how the integration of eHealth can be organized optimally by reviewing studies evaluating real-world eHealth interventions. The Donabedian framework of Structure-Process-Outcome (SPO) [24] was used, allowing the identification of relevant indicators that demonstrate how effective the integration of eHealth is in the organization.

According to the Donabedian model, the quality of health care can be assessed by three components that are relevant for organizations: structure (ie, requirements of the organization), process (ie, actions to be taken), and outcome (ie, end results), as shown in Figure 1 [24,25]. *Structure* is defined as the setting in which health care is provided (eg, facilities, equipment, numbers, and qualification of personnel); *process*, as what is actually done in giving and receiving care (eg, patient and doctor activities, doctor-patient communication and information); and *outcome*, as the consequence of the provided health care (eg, health status, satisfaction, and costs) [24-26]. Quality of health care is based on different aspects of these three categories and their relationships. As Donabedian eloquently puts it: "A good structure increases the likelihood of good process, and good process increases the likelihood of good outcomes" [24]. The interaction between the categories can be bidirectional, and it is not a simple separation between cause and effect [25]. The movement is an "unbroken chain of antecedents, followed by intermediate ends, which are themselves the means to still further ends" [25].

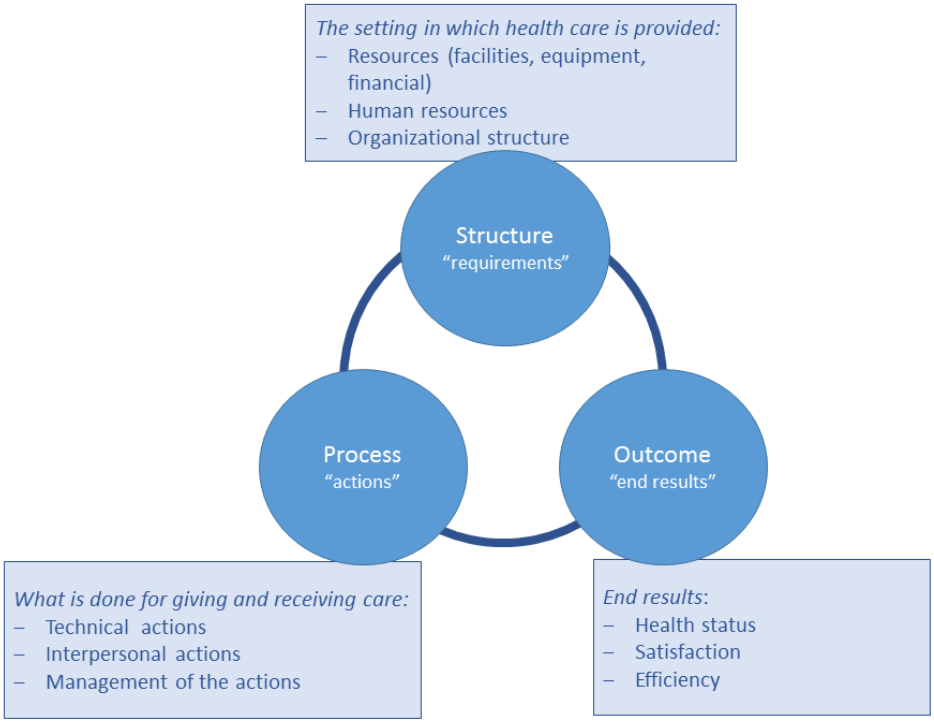
RenderX

Figure 1. Donabedian Structure-Process-Outcome framework.

a. What an organization needs to have to provide health care
b. The actions in giving and receiving health care
c. End results as a consequence of providing care

The aim of this systematic review is twofold: (1) to investigate whether there are identifiable indicators in the structure, process, and outcome categories related to the successful integration of eHealth in regular health care and (2) to investigate which indicators of structure and process are related to outcome indicators.



Methods

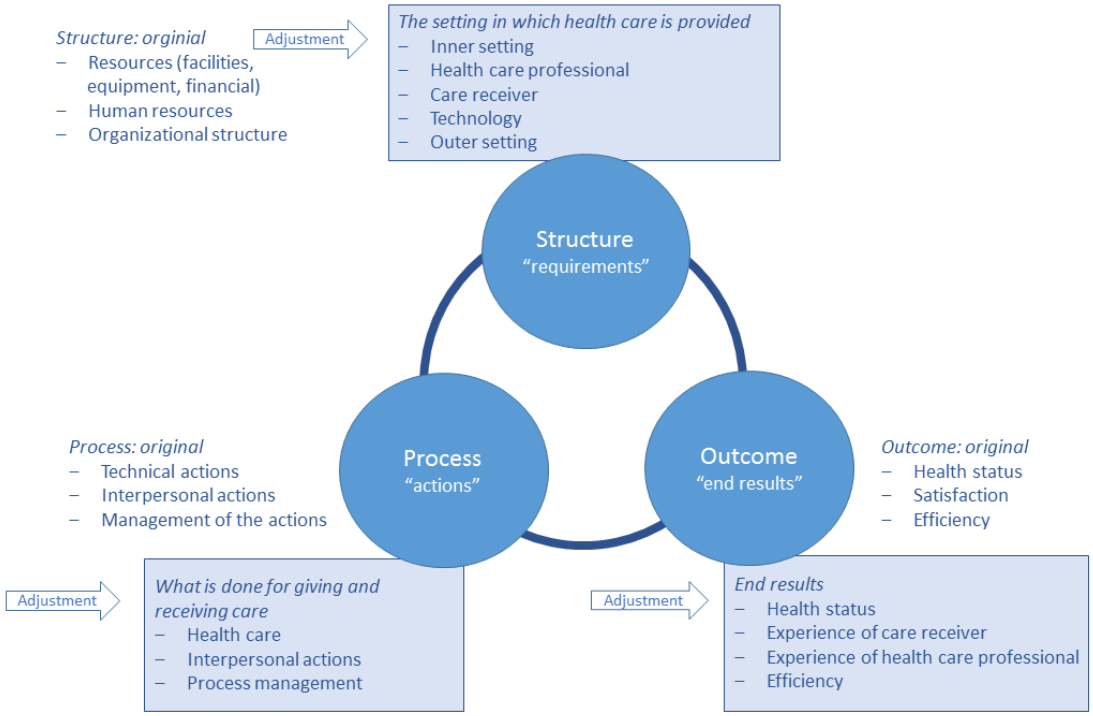
Theoretical Framework

The Donabedian SPO framework was used to identify the indicators of structure, process, and outcome that potentially affect the integration of eHealth into health care organizations. The Donabedian framework covers all relevant aspects of an organization's structure, process, and outcome and their interrelations, and it combines these aspects with health and social factors. Therefore, it is a suitable model to evaluate the organization of eHealth within health care organizations. The SPO categories are thematically explained in Figure 2 [24,25].

XSL•FO
RenderX

Figure 2. Explanation of the Structure-Process-Outcome categories of the Donabedian model.

The Donabedian SPO framework was designed in the 20th century before the introduction of eHealth. For this review, the SPO framework was adjusted to be compatible with the current time and incorporated the application of eHealth. The adjustments are described in the themes presented in Textbox 1.



The adjustments to the SPO framework are shown in Figure 3.

Textbox 1. Adjustment of the Structure-Process-Outcome framework into themes, to integrate the application of eHealth into the health care system.

- **Structure**: The *setting* of provided care can be internal and/or external. Therefore, a distinction was made between *inner* and *outer settings*. With regard to *resources*, *technology* was added as a separate theme to cover eHealth. This was done because the focus of this research was eHealth. The remaining parts of the *resources* are covered under inner setting. *Human resources*, besides *health care professionals*, included *care receivers*. Their mutual involvement is required and is therefore also considered a conditional human resource [1]. *Organizational structure* was split into *inner setting* and *outer setting*, in line with the reasons given above, and to take the external stakeholders into account [27].
- **Process**: Instead of *technical actions*, the term *health care actions* was used, to avoid confusion with the term *technology* in the structure. *Interpersonal actions* remained unchanged. *Management of the actions* was shortened to *process management*.
- **Outcome**: *Health status* was retained as *health status*. *Satisfaction* was broadened to include *experience of the health care receiver* and *experience of the health care provider*, as both are pivotal outcome parameters in the *health care* process [28,29]. *Efficiency* remained unchanged.

XSL•FO

Figure 3. Adjustment to the themes of the Structure-Process-Outcome framework, considering eHealth integration.

Search Strategy

This systematic review followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) guidelines. The research question was as follows: "How are structure indicators and/or process indicators related to eHealth or blended health care outcome indicators?"

Two authors (RT and MK) searched PubMed, EMBASE, Web of Science, Cochrane, and Emcare databases for relevant studies published up to December 12, 2019. They searched for the following terms in the titles, abstracts, and keywords of the published papers: structure* indicators* or process* indicators* or outcomes* indicators* and [blended care or eHealth* or telehealth*]. Multimedia Appendix 1 contains the full search details. After the search, two authors (RT and AV) screened the titles and abstracts of the relevant articles. Studies were included if they mentioned (1) the use of eHealth or blended care for diagnostics or treatment and (2) structure, process, or outcome indicators. Quantitative, qualitative, and mixed method study designs were included. A study was excluded if (1) it was a protocol, review, meta-analysis, grey literature, book chapter, oral presentation, or poster presentation; (2) it was published in a language other than English or Dutch; (3) full-text of the article was not available; (4) the intervention was not implemented (eg, conducted research regarding the users' expectations towards a prototype); or (5) the intervention used an analog application via plain-old-telephone lines. Of the remaining articles, RT reviewed the full texts. To ensure reliability, AV randomly selected about 10% of the fully reviewed articles for a blind review. Discrepancies were resolved by discussion. In case of uncertainty, a third author (MK) was consulted.

Data Extraction

Data extraction sheets were designed to provide an overview of the (1) study characteristics (eg, title, author, study aim, setting, disease, and quality appraisal); (2) characteristics of the eHealth intervention (eg, technology and function) and description of the intervention; (3) distribution of indicators into themes and categories related to the integration of eHealth into health care; and (4) interaction among the indicators, presented as themes.

RT designed the first concepts of the data extraction sheets. Authors RT, MK, NC, and ET discussed the design of the data extraction sheets to ensure their usability. Improved sheets were developed accordingly. The blind reviewer (AV) did not discuss the data extraction sheets. The included articles were reread by RT to check whether data clustering was complete and logical and for purposes of data pooling itself. AV selected a sample of 10% of the included articles for data extraction. Discrepancies were resolved by discussion.

Quality Appraisal

The Mixed Methods Appraisal Tool (MMAT) was used to appraise the quality of eligible studies in mixed methods systematic reviews—that is, reviews that included qualitative research, randomized controlled trials, nonrandomized studies, quantitative descriptive studies, and mixed methods studies [30]. The MMAT allows determination of the quality of different empirical study designs by using the same measure of five criteria in the chosen category. MMAT scores range on a scale of 1 to 5, with 1 indicating the lowest quality and 5 indicating the highest quality.

XSL•FO
RenderX

Classification of eHealth Interventions

eHealth interventions were ordered by type of technology and functionality. For technology, the classification proposed by Nictiz was used, distinguishing websites, apps, video communication, sensors, and wearables, domotics, robotics, and big data (ie, artificial intelligence) [31]. This classification is based on international studies [10,32]. For the present study, eHealth only concerns digital interventions and not analog ones such as analog applications via plain-old-telephone lines; this is in line with the classification proposed by Nictiz. For labelling the functionality, the second and third tiers of the National Institute for Health and Care Excellence (NICE) [33] were used, because these functionalities measure patient outcomes (Tier one consists of system services with no measurable patient outcomes). The functions were classified as communication, self-management, clinical calculation, active monitoring, diagnosis, and treatment [33].

Organization of Indicators and (Sub)themes of the SPO Framework

Indicators that had a potential impact on the integration of eHealth in health care were extracted and organized by the relevant theme according to the adjusted SPO framework (Textbox 1). In addition, the reported interactions between the indicators were extracted and organized by the relevant categories and themes. For a clear overview, the indicators within each theme were further divided into two subthemes by RT and ET (Table 1). The creation of subthemes was an iterative process. When reading the full texts, we found some definitions that sharpened some of the subthemes. The full definitions of the themes and subthemes are provided in Multimedia Appendix 2.

For each of the extracted indicators, the relevant impact on the integration of eHealth was noted. As there is no general standard for when eHealth is successful or effective [3,19], nor did the included studies specify such standards, these indicators were labeled as *advantage*, *disadvantage*, or *neutral*. An advantage in the structure and process categories indicates a positive effect on the integration and/or a positive effect on the outcome. A disadvantage in the structure and process categories indicates a negative effect on the integration and/or a negative effect on the outcome. An indicator that did not turn out to be an advantage nor a disadvantage was labeled neutral. The extracted indicators were noted as *advantage*, *disadvantage*, or *neutral*, in line with the evaluation performed in the corresponding study.

The following results are presented in this paper: (1) distribution of the indicators into (sub)themes and categories, and the impact on the integration of eHealth into health care; (2) most frequently reported indicators (ie, reported 10 times or more); and (3) interaction among indicators organized into themes and categories.

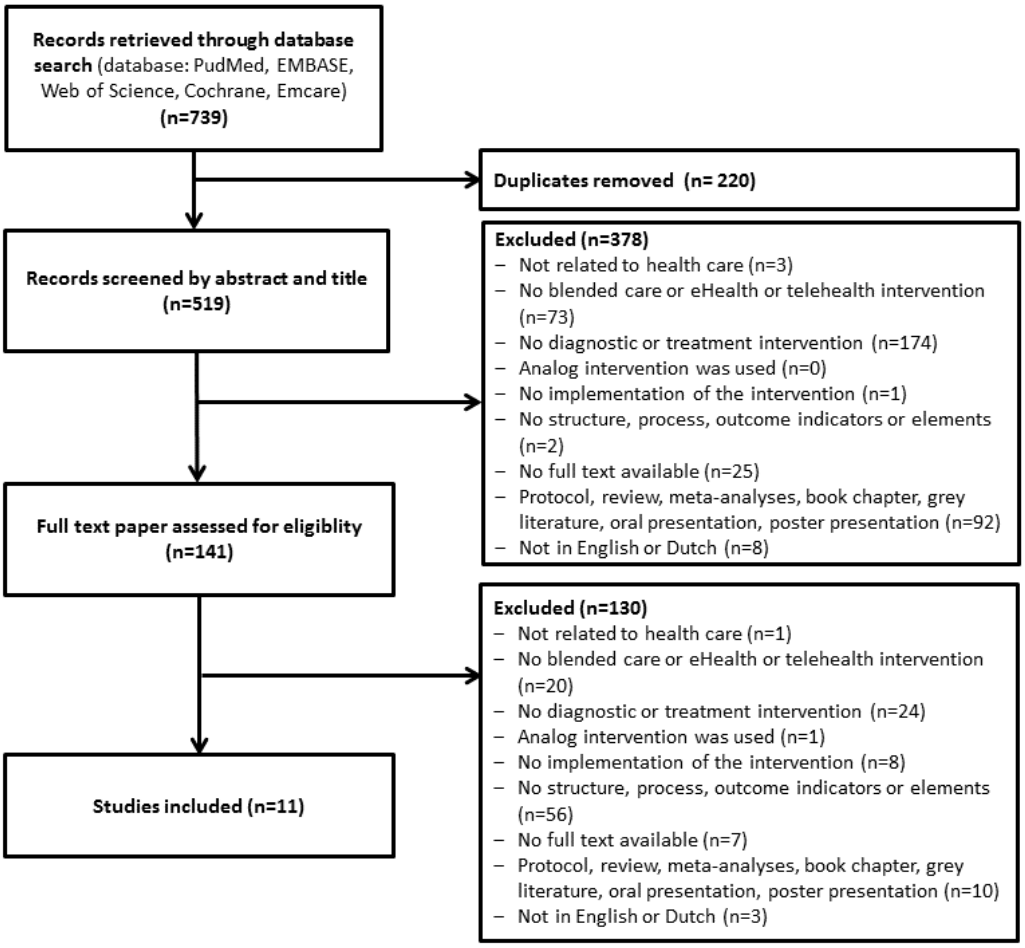
Table 1. Themes and subthemes in the structure, process, and outcome categories.

Category and theme	Subtheme
Structure	
Inner setting	• Support of primary process • Culture and leadership
Health care professional	• Skills • Attitude
Care receiver	• Daily life • Baseline characteristics
Technology	• Usability and functionality • Interaction with electronic health record
Outer setting	• Finance and legislation • Involvement of stakeholders
Process	
Health care actions	• Workflow • Patient-centered
Interpersonal actions	• Personal • Shifting roles
Process management	• Quality improvement • Mistake-proofing
Outcome	
Health status	• Clinical or functional • Intrapersonal
Experience of care recipient	• Satisfaction • Convenience
Experience of health care professional	• “What’s in it for me” • “What’s in it for them”
Efficiency	• Operations • Revenues



Results

Study Selection

The systematic search led to the identification of 11 eligible articles, selected from a total of 739 articles shortlisted initially (Figure 4).

Data Results: Study and eHealth Characteristics

Study Characteristics

The included studies cover various study designs, diseases, and health care settings. Most studies were published after 2017 [27,34-41] and were of high quality [27,34,36,37,39,40,42]. Table 2 shows a detailed description of the characteristics of the included studies.

Title, author (year)	Aim of the study	Study design	Setting and country	Disease	Sample size (N) and participant type	Quality of study[a]
Implementation of the blended care self-management program for caregivers of people with early-stage dementia, Boots et al (2017) [34]	To assess the internal and external validity of the trial and its implementation to inform effect analysis	Mixed methods, nested in an RCT[b]	Elderly care, home setting, the Netherlands	Early-stage dementia	N=62; Informal caregivers, psychologists, nurses	4.5
Lack of adoption of a mobile app to support patient self-management of diabetes and hypertension in a Federally Qualified Health Centre, Thies et al (2017) [35]	To understand why the trial was unsuccessful	Qualitative (interview) analysis	Primary care, USA	Uncontrolled diabetes and hypertension	N=13; Patients, primary care provider, nurses, research assistants	3.0
"Sounds a bit crazy, but it was almost more personal:" A qualitative study of patient and clinician experiences of physical therapist-prescribed exercise for knee osteoarthritis via skype, Hinman et al (2017) [36]	To explore the experience of therapists and patients using Skype for exercise management of knee osteoarthritis	Qualitative study, nested in an RCT	Rehabilitation at home, Australia	Knee osteoarthritis	N=20; Patients, physical therapists	5.0
The challenge of real-world implementation of web-based share care software, Lycett et al (2014) [43]	To highlight the challenges of implementing software and reporting on the extent to which the software met its implementations and user aims	Mixed methods study, nested within an RCT	Children's Hospital, General Practices, Australia	Obesity	N=27; General Practitioners	2.5
Implementation of a multicomponent telemonitoring intervention to improve nutritional status of community-dwelling older adults, Van Doorn-van Atten et al (2018) [37]	To study how PhysioDom Home Dietary Intake Monitoring was delivered and received by participants and nurses, and to study the intervention's mechanism of impact	Mixed methods study	Home care and/or lived in a service flat in sheltered accommodation, the Netherlands	At risk of undernutrition	N=105; Patients, nurses	4.5
Implementation of internet-delivered cognitive behaviour therapy within community mental health clinics, Hadjistavropoulos et al (2017) [27]	To understand facilitators and barriers impacting the uptake and implementation of internet cognitive behavior therapy	Mixed methods study	Community Mental Health Clinic, Canada	Depression and anxiety	N=33; Therapists, managers	4.5
Implementation and evaluation of the safety net specialty care program in the Denver Metropolitan Area, Fort et al (2017) [38]	To describe the program, identify aspects that work well, areas for improvement, and offer lessons learned	Mixed methods study	Safety-net: a non-profit integrated health care system, USA	Uninsured patients	N=43; Patients, primary care clinicians, specialists	3.5
Perceived improvement in integrated management of childhood illness implementation through use of mobile technology, Mitchell et al (2012) [42]	To examine health care provider and carer perceptions of electronic Integrated Management of Childhood Illness (eIMCI) in diagnosing and treating childhood illnesses	Qualitative study (semi-structured interviews)	Health centers, Tanzania	Childhood illness in children 5 years or younger	N=31; Carers, health care providers	4.5

High level of integration in integrated disease management leads to higher usage in the e-Vita Study, Talboom-Kamp et al (2017) [39]	To analyze the factors that successfully promote the use of a self-management platform for chronic obstructive pulmonary disease patients	Quantitative, nonrandomized, parallel cohort design	Primary care, the Netherlands	Chronic obstructive pulmonary disease	N=215; Patients	4.0
What drives adoption of a computerised, multifaceted quality improvement intervention for cardiovascular disease management in primary healthcare settings? Patel et al (2018) [40]	To identify and explain the underlying mechanisms by which the intervention did and did not have an impact	Mixed methods study	Primary care, Australia	Cardiovascular disease	N=19; Patients, general practitioners, nurses, aboriginal health workers	4.5
Exploring the challenges of implementing a web-based telemonitoring strategy for teenagers with inflammatory bowel disease, Dijkstra et al (2019) [41]	To evaluate whether the telemonitoring strategy could move from a demonstration project to one that is sustained within existing sites	Mixed methods study, nested within an RCT	Pediatric gastroenterology centers, the Netherlands	Inflammatory bowel disease	N=27; Researchers, clinicians, hospital decision makers, web designer	2.5

[a]Methodological quality of studies assessed with MMAT, ranging from 0 (lowest) to 5 (highest).

[b]RCT: randomized controlled trial.

eHealth Intervention Characteristics, Descriptions, and Results

The most frequently used digital technology was websites (n=7) [27,34,37-41], and the most frequently reported functions [33] of the technology were self-management (n=6) [34-37,39,41] and communication (n=6) [35,37,39-41,43]. Table 3 shows an overview of the eHealth intervention characteristics, descriptions, and the study results. A detailed description of indicators, sorted according to the structure, process, outcome categories and their respective (sub)themes, are highlighted in the next paragraph.

XSL•FO
RenderX

Table 3. eHealth intervention characteristics, descriptions of the intervention, and study results.

First author	Technology; intervention name	eHealth function	Intervention	Study results (findings)[a]
Boots [34]	Website; Partner in Balance	Self-management	Face-to-face coaching with tailored web-based modules.	The participation rate of eligible caregivers was 51.9% (80/154). Recruitment barriers included lack of computer and need for support. Young age and employment were considered recruitment facilitators. All coaches attended training and supervision in blended care self-management. Deviations from the structured protocol were reported on intervention time, structure, and feedback. Coaches described an intensified relationship with the caregiver post-intervention. Caregivers appreciated the tailored content and positive feedback. The blended structure increased their openness. Overall, personal goals were attained after the program (t>50). Implementation barriers included lack of financing, time, and deviating target population.
Thies [35]	App; Undisclosed	Self-management, communication	Platform for active collaboration between patients and their primary care teams.	There was a poor fit between the app, end-users, and recruitment and treatment approaches in the setting. Usability testing might have revealed this prior to launch, but this was not an option. There was not sufficient time during routine care for clinical staff to familiarize patients with the app or to check clinical data and messages, which are unreimbursed activities. Some patients did not use the app appropriately. The lack of integration with the electronic health record was cited as a problem for both patients and staff who also said the app was just one more thing to attend to.
Hinman [36]	Video communication; Telerehabilitation via Skype	Self-management, treatment	Individualized home-based training strengthening program via Skype delivered physiotherapy.	Six themes arose from both patients and therapists. The themes were Structure: technology (ease of use, variable quality, set-up assistance helpful) and patient convenience (time-efficient, flexible, increased access); Process: empowerment to self-manage (facilitated by home environment and therapists focusing on effective treatment) and positive therapeutic relationships (personal undivided attention from therapists, supportive friendly interactions); and Outcomes: satisfaction with care (satisfying, enjoyable, patients would recommend, therapists felt Skype more useful as adjunct to usual practice) and patient benefits (reduced pain, improved function, improved confidence and self-efficacy). A seventh theme arose from therapists regarding process: adjusting routine treatment (need to modify habits, discomfort without hands-on, supported by research environment).
Lycett [43]	Website, HIE[b]; Shared-Care Obesity Trial in Children (HOPSCOTCH)	Communicate	Children attended a tertiary appointment with a pediatrician and dietician specializing in childhood obesity, followed-up by general practitioner consultations over the following year, supported by shared-care web-based software.	Software implementation posed difficult and at times disabling technological barriers. The software's speed and inability to seamlessly link with day-to-day software was a source of considerable frustration. Overall, general practitioners rated software usability as poor, although most (68%) felt that the structure and functionality of the software was useful.
Van Doorn-van Atten [37]	Website; PhysioDom HDIM[c]	Self-management, communication	Nutritional telemonitoring, education, a follow-up of telemonitoring measurement by a nurse.	About 80% of participants completed the intervention. Drop-outs were significantly older, had worse cognitive and physical functioning, and were more care-dependent. The intervention was largely implemented as intended and was received well by participants, but less well by nurses. Participants adhered better to weight telemonitoring than to telemonitoring by means of questionnaires, for which half the participants needed help. Intention to use the intervention was predicted by performance expectancy and social influence. No association was found between process indicators and intervention outcomes.

RenderX

First author	Technology; intervention name	eHealth function	Intervention	Study results (findings)[a]
Hadjistavropoulos [27]	Website; ICBT[d]	Treatment	Web-based lessons that provide psychoeducation and instructions and therapist support via email or telephone.	ICBT implementation was perceived to be most prominently facilitated by intervention characteristics (namely, the relative advantages of ICBT compared to face-to-face therapy, the quality of the ICBT program that was delivered, and evidence supporting ICBT) and implementation processes (namely the use of an external facilitation unit that aided with engaging patients, therapists, and managers and ICBT implementation). The inner setting was identified as the most significant barrier to implementation as a result of limited resources for ICBT combined with greater priority given to face-to-face care.
Fort [38]	Website; Safety Net Specialty Care Program	Diagnosis, treatment	E-consults between primary care clinicians and specialist, face-to-face visits to the patients from a specialist, and continuing medical education for the primary care clinicians.	In the first 20 months of the program, safety-net clinicians at 23 clinics made 602 e-consults to specialists, and 81 patients received face-to-face specialist visits. Of 204 primary care clinicians, 103 made e-consults; 65 specialists participated in the program. Aspects facilitating program use were referral case managers' involvement and the use of clear, concise questions in e-consults. Key recommendations for process improvement were to promote an understanding of the different healthcare contexts, support provider-to-provider communication, facilitate hand-offs between settings, and clarify program scope.
Mitchell [42]	App; Electronic Integrated Management of Childhood Illness (eIMCI)	Diagnosis, treatment	An electronic handheld device or personal digital assistant, to guide the health care provider through IMCI protocols.	Providers expressed positive opinions on eIMCI, noting that the personal digital assistants were faster and easier to use than were the paper forms and encouraged adherence to IMCI procedures. Carers also held a positive view of eIMCI, noting improved service from providers, a more thorough examination of their child, and a perception that providers who used the personal digital assistants were more knowledgeable.
Talboom-Kamp [39]	Website; e-Vita COPD[e]	Self-management, communication	Insight into personal health data, self-monitoring of health values, education, and a coach for attaining personal goals.	Use of a self-management platform was higher when participants received adequate personal assistance about how to use the platform. Blended care, where digital health and usual care are integrated, will likely lead to increased use of the web-based program.
Patel [40]	HIE, website; HealthTracker	Communication, monitoring	Real-time decision support integrated with electronic medical records; CVD[f] risk communication tool between provider and patient; clinical audit tool; web portal providing peer-ranked performance trends.	A complex interaction was found between implementation processes and several contextual factors affecting uptake of the intervention. There was no clear association between team climate, job satisfaction, and intervention outcomes. There were four spheres of influence that appeared to enhance or detract from normalization of the intervention: organizational mission and history, leadership, team environment, and technical integrity of the intervention.

XSL•FO
RenderX

First author	Technology; intervention name	eHealth function	Intervention	Study results (findings)[a]
Dijkstra [41]	Website, IBD-live	Monitoring, self-management, communication	Flarometer, platform for direct communication with the IBD[g] team, module with study questionnaires (Quality of life, absenteeism, health care utilization).	The technology and the linked program allowed selection and targeting of teenagers who were most likely to benefit from a face-to-face encounter with their specialist. The value proposition of the technology was clear, with a distinct benefit for patients and an affordable service model, but health providers had plausible personal reasons to resist (double data entry). The organization was not yet ready for the innovation, as it required a shift to new ways of working. Dutch health insurers agreed that screen-to-screen consultations will be reimbursed at a rate equivalent to face-to-face consultations. The technology was considered easy to adapt and evolve over time to meet the needs of its users.

Indicators Organized by (Sub)themes of the SPO Framework

Overview

In total, an indicator was reported 347 times: 175 times in the structure category, 84 times in the process category, and 88 times in the outcome category. Of the 347 indicators, 111 were unique indicators (Multimedia Appendix 3). In the structure category, most indicators were labeled as neutral (65/175, 37.1%) or as a disadvantage (70/175, 40%). In the process category, most indicators were labeled as an advantage (30/84, 36%) or neutral (33/84, 39%). In the outcome category, the indicators were mostly classified as a realized advantage (49/88, 56%), as shown in Figure 5.

Table 4 shows the total distribution of the indicators organized by themes and subthemes of the structure, process, and outcome categories and the extent to which it was reported as an advantage, disadvantage, or neutral to the integration of eHealth and its outcome in regular health care. The themes and subthemes containing the most reported indicators are described below.

Figure 5. Number of indicators reported in the structure, process, and outcome categories. Advantage: in the structure and process categories, advantage indicates a positive effect on the integration. In the outcome category, it indicates a positive effect on the outcome. Disadvantage: in the structure and process categories, disadvantage indicates a negative effect on the integration. In the outcome category, it indicates a negative effect on the outcome. Neutral: Indicator was neither an advantage nor a disadvantage.

Distribution of Indicators Within the Themes and Subthemes of the Structure Category

In the structure category, most indicators were reported in the inner setting (51/175, 29.1%), care receiver (40/175, 22.9%), and technology (38/175, 21.7%) themes. The indicators in the inner setting (n=22) and technology (n=23) themes were mainly classified as a disadvantage to the integration, whereas those in the care receiver theme (n=23) were mainly classified as neutral. Regarding the subthemes, most indicators were reported in the support of the primary process subtheme within the inner setting theme (34/175, 19.4%), the baseline characteristics subtheme within the care receiver theme (22/175, 12.6%), and the usability and functionality subtheme within the technology theme (33/175, 18.9%), as shown in Table 4.

Distribution of Indicators Within the Themes and Subthemes of the Process Category

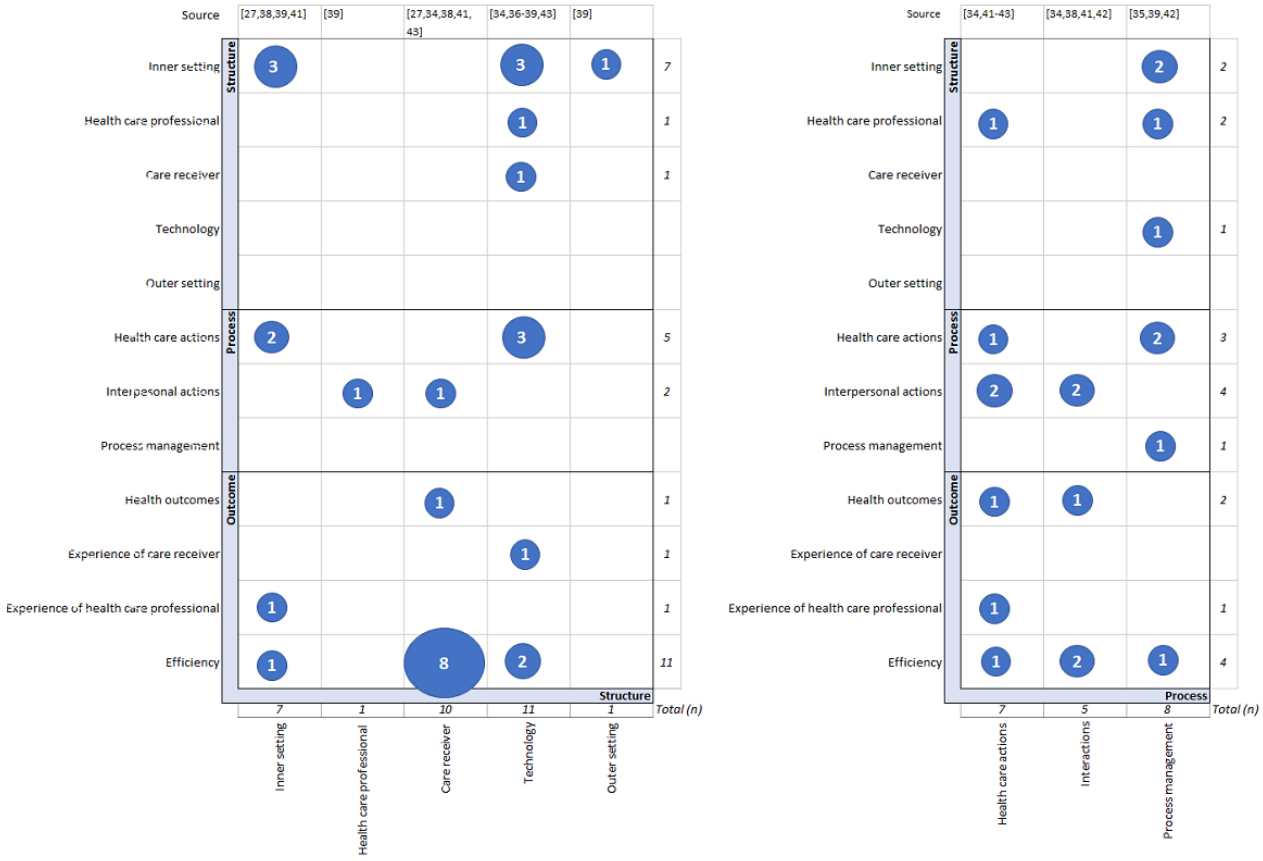
Almost half of the indicators were organized within the health care actions theme (38/84, 45%), which were diversely reported as an advantage (n=13), disadvantage (n=11), and neutral (n=15). The subthemes with the most reported indicators were workflow (18/84, 21%), patient-centered (20/84, 24%), both within the health care actions theme, and the personal subtheme (19/84, 23%) within the interpersonal actions theme (Table 4).

Distribution of Indicators Within the Themes and Subthemes of the Outcome Category

In the outcome category, the most frequently reported indicators were from the efficiency theme (30/88, 34%), with advantages (n=5) reported for very few indicators. The "experiences" themes of care receivers and health care professionals together accounted for 55% (48/88), both predominated by advantages (n=37). The highest number of indicators were reported in the operations subtheme (n=27/88, 31%; Table 4).

Most Reported Indicators

An in-depth examination of the distribution of the indicators showed that the following four indicators were the most reported (ie, reported 10 times or more) among the included studies: "deployment of human resources" (n=11) of the inner setting theme in the structure category; "ease of use" (n=16) and "technical issue" (n=10), both belonging to the technology theme in the structure category; and "health logistics" (n=26) of the efficiency theme in the outcome category. An overview of all indicators is presented in Multimedia Appendix 3.



Interactions Among Indicators Organized into Themes and Categories

Overview

Of the 11 included studies, 10 (91%) reported interactions among indicators organized by themes within the structure, process, and outcome categories. The most frequently reported interaction among indicators at the category level was between the structure and outcome categories (14 times). The most frequently reported interaction among indicators at the theme level was between the care receiver theme within the structure category and the efficiency theme within the outcome category (8 times), as shown in Figure 6.

XSL•FO
RenderX

Figure 6. Interactions among indicators within themes and categories. The numbers within the blue circles represent the number of noted interactions among indicators within the themes. The x-axis represents the antecedent, and the y-axis represents the (intermediate) result.

Interactions With Themes in the Structure Category

All themes in the structure category contained indicators as an antecedent to, or as an intermediate result of other indicators. The inner setting (n=16), technology (n=12), and care receiver (n=11) themes represented the highest number of interactions with other themes. Inner setting was noted 7 times as an antecedent and 9 times as an intermediate result. Technology was noted 11 times as an antecedent and once as an intermediate result. Care receiver was noted 10 times as an antecedent and once as an intermediate result. The health care professional (n=3) and outer setting (n=1) themes were noted less frequently (Figure 6).

Interactions With Themes in the Process Category

In all themes in the process category, the indicators displayed interactions with indicators of other themes; specifically, health care theme (n=15), noted 7 times as an antecedent and 8 times as an intermediate result; interpersonal actions theme (n=11), 5 times as an antecedent and 6 times as an intermediate result; process management theme (n=9), 8 times as antecedent and once as an intermediate result (Figure 6).

Interactions With Themes in the Outcome Category

In the outcome category, the efficiency theme (n=15) contained most of the interacting indicators, all as an intermediate result. The other themes, including health status (n=3), experience of health care receiver (n=1), and experience of health care provider (n=2), were noted less frequently as (intermediate) results (Figure 6).

Examples of interactions among the indicators and the associated themes are illustrated in Textbox 2.

XSL•FO
RenderX

Textbox 2. Illustrations of reported interactions among indicators and their themes. Indicator names are written in italics as reported in the published studies (followed by the corresponding themes and categories in parentheses).

- *Technical and usability issues* (technology theme, structure category) experienced by the health care professional negatively impacted the *engagement* and the *internal collaboration* (inner setting theme, structure category) [40] and the health care workflow by causing *extra steps* and *workarounds* (health care actions theme, process category) [37,41,43].
- *Technical and usability issues* (technology theme, structure category) experienced by the care receiver challenged the care receiver to *fit the application of eHealth into their daily lives* (care receiver theme, structure category) and caused increased *dropouts* (efficiency theme, outcome category) [34,39]. Conversely, one study [36] showed that technology that is *easy to use* (technology theme, structure category), can contribute positively to its application, and *fit into the patient's daily life* (care receiver theme, structure category).
- Insufficient attention to the *patient's burden* (care receiver theme, structure category), *health literacy* (care receiver theme, structure category), and whether the plan *fits into their daily life* (care receiver theme, structure category) caused *dropouts* (efficiency theme, outcome category) [36,37,39], and *nonadherence to care plans* (efficiency theme, outcome category) [34].
- *High workload* (inner setting theme, structure category) hindered the *incorporation of the application into daily practice* (inner setting theme, structure category) [40].
- *Lack of time* (inner setting theme, structure category) discouraged health care professionals from their *intention to (re)*use (experience health care professional theme, outcome category) [37] and health care professionals did not *experience an added value for themselves* (experience health care professional theme, outcome category) [37].
- *Communicated added value* (inner setting theme, structure category) on a corporate level positively influenced the *collective engagement* (inner setting theme, structure category) [40].
- *Guidelines on the work process* (process management, process category) made the *work process easier and faster for health care professionals* (health care actions theme, process category) but *limited the adaptability of the technology for certain recipients* (technology theme, structure category) [42].
- Limited *feedback about the quality of care* (process management theme, process category) made specialists feel *uncertain about the suitability of the technology* (health care professional theme, structure category) [38], whereas *sharing information* (process management theme, process category) to improve program efficiency allowed the program *to be a part of the workflow* (health care actions theme, process category) [38].
- *Face-to-face contact* (health care actions theme, process category) benefitted the *personal connection between care receiver and professional* (interpersonal actions theme, process category) and the *engagement of the care receiver with the treatment* (interpersonal actions theme, process category) [34].
- *Personal assistance* (health care actions theme, process category) and *personalized therapy* (health care actions theme, process category) increased the *usage of the intervention by the care receiver* (efficiency theme, outcome category) [39].
- *Personalized therapy* (health care actions theme) also increased the *satisfaction of the care receiver* (experience of care receiver theme, outcome category) [36].
- *Exceptions to the operational process* (health care actions theme, process category) were made too often, such as *providing extra support to patients* (health care actions theme, process category), or *providing less care* (health care actions theme, process category), *creating new administrative workarounds* (health care actions theme, process category) caused by *technical issues* (technology theme, structure category) [35,37,38,41,43] or *high workloads* (inner setting theme, structure category) [27].
- An increase in *questioning* by professionals (interpersonal actions theme, process category) made carers feel more *engaged and knowledgeable* (health status theme, outcome category) [42].
- Recipients' *detailed input* (interpersonal actions theme, process category) on the assignments enabled professionals *to empathize with their situation* and *focus on their feedback* (interpersonal actions theme, process category) [34].

Discussion

Principal Findings

This literature review analyzed how eHealth can be organized optimally by using the Donabedian SPO framework. General organizational developments were identified, regardless of the type of illness, setting, or the eHealth application used. A review of the literature of selected cases highlighted three important findings. First, the role of the care recipient needs to be incorporated into the organizational structure and daily care process. Second, the technology must be well attuned to the structure of the organization and daily care process. Third, the deployment of the human resources to the daily processes needs to be aligned with the desired end results. Not adhering to these points could negatively affect the organization, daily process, or the end results. Findings from this research using the Donabedian framework corresponds to the conclusions of other studies using different research methodologies, which is explained below.

First, the SPO analysis showed that the care recipient plays a crucial role in the successful integration of eHealth. Patient-centered interaction and communication are important, to activate patients in managing their health care and to improve health outcomes in the application of eHealth [5,31,44-46]. Kuipers et al [44] and Rathert [45] demonstrated with systematic literature reviews that patient-centered care and co-creation are positively associated with the physical and social well-being of patients and with satisfaction of patients and health care professionals. These findings are in line with the review of Wildevuur and colleagues [46], demonstrating that organizations that are more patient centered with eHealth interventions achieve better outcomes with regard to patient health and quality of life.

XSL•FO
RenderX

Although most health care professionals embrace more patient involvement and engagement, delegating power and responsibilities could be a challenge for health care professionals' authority [47,48]. Another important issue is knowing who the customers are, what they want, and how the customer's demand is answered [49]. A previous study reported that eHealth is not suitable for all care receivers [18,50]. Therefore, identifying who benefits most from which kind of therapy is an essential addition to the screening process, and it could lead to more effective targeting and resourcing [51]. Furthermore, insufficiently incorporating the patients' family, work, and life goals into care plans will likely result in dropouts or nonadherence to care plans [50].

The second noteworthy finding is the essential role of excellent technology in the integration of eHealth. The way technology is set up has an influence on the working environment of health care professionals [52]. Inflexibility and complexity of the technology comes at the expense of effective daily processes and their quality [53,54]. Several studies demonstrated that the adaptability of eHealth technologies to fit to the local context, its ease of use, and its integration into clinical workflow benefit the users' acceptance and meaningful use [22,55,56]. This was also reflected in the early phase of the COVID-19 pandemic, where rapid scalable technologies were the easiest to use and quickly implementable [53]. However, the health care system continued to face challenges in adopting digital technology after the first emergency phase of the COVID-19 pandemic, due to inadequate information and communication technology infrastructure and a bad fit of the technology into the clinical workflow that is primarily designed for face-to-face care [53]. Granja et al [54] demonstrated that the application of eHealth is often not fitted to the existing workflow due to time and space constraints and breaking of traditions. Although eHealth is seen as an innovative solution for alleviating the increasing burden for health care professionals [2], it could have a counterproductive effect on the working conditions for employees if the technology is not properly adapted to the structure and processes [57,58]. Third, integrating eHealth into a health care organization requires adjustments of the care processes and utilization of the human resources, with appropriate process monitoring. Working with eHealth also poses logistical challenges; for example, a clear understanding is needed of the expected achievements, processes, and staffing requirements in order to bring about changes and create new capabilities [59]. Vissers and De Vries [49] pointed out that it is necessary to know how the logistical capacities should be assigned to the process, how the processes are measured, and who is responsible for the management of the process. Changes in the workflow are inevitable and necessary for eHealth interventions to be successful [54]. However, integrating eHealth technology into daily care processes is complex, and it needs coordination and process communication [19]. For example, a living laboratory experiment conducted over 3 years with patients, health care professionals, enterprises, and researchers to accelerate the integration of eHealth in daily practice showed that workflow, responsibilities, and roles needed to change, but health care professionals did not know how to approach this and had difficulties in integrating eHealth into their daily care processes [18].

Strength and Limitations

The strengths of this research are that international studies were included and represented a wide range of patient groups and settings. The findings were representative for the included studies, and they were not dependent of the study design, disease, target population, setting, or type or function of the eHealth application used. The wide range of settings of the included studies is supportive of a broader application of the present study's findings. In the *Methods*, we stated that there is no clear consensus on what constitutes as *good eHealth* and how it is best organized [3,19]. Nevertheless, we believe that our findings make a significant contribution to improving the integration of eHealth in regular health care by identifying the most common indicators in the organization's structure, processes, and outcomes. Thus, this research contributes to a new model for integrating organizational, health, and social factors.

A limitation of this study is that the health outcomes were rarely mentioned in this review. We hypothesized that this is because the main method used in the included studies was process evaluation. Therefore, although the health outcomes played a major role in earlier RCTs, this was not the case in process evaluation studies. The included studies did not define clear standards for the indicators to determine their quality. However, an indicator only becomes meaningful if a standard is specified [60,61]. There are also limitations in the selection procedure. The interrater reliability was not calculated. Due to this complex, broad topic, the predefined inclusion and exclusion criteria were sharpened at the time of selection. It was an iterative process, with a lot of consultation and coordination. In the process, full consensus was reached for all inclusion and exclusion criteria for selection at each step of the research. Another limitation is the classification of indicators into subthemes and themes at the discretion of the authors. It is conceivable that different classifications would reach different conclusions. Yet, the conclusions of each included study fit with the overall conclusion; therefore, the chance of this bias seems to be small. However, the findings of this literature review are dependent on the results of the included studies and may be subject to publication bias. Even though the included publications contain either positive or negative results (eg, a failed randomized trial [35] or interventions with no or less impact [40,43]), a chance of publication bias cannot be precluded automatically [62,63].

It is also noted that the Donabedian framework itself was designed before the introduction of eHealth and may not include the latest prevailing ideas on the organization of health care. For this reason, the model has been adapted in order to represent eHealth. By doing so, an attempt has been made to reduce the limitation as far as possible. Nevertheless, this literature review confirmed that it is still useful to analyze what contributes to the successful integration of eHealth into traditional health care. Additionally, there are other reputable models for evaluating eHealth interventions, such as the nonadoption, abandonment, scale-up, spread, sustainability (NASSS) framework [20]; Consolidated Framework for Implementation Research (CFIR) [64]; and the holistic framework to improve the uptake and impact of eHealth technologies [19]. These models describe the different phases from the design of the intervention to its

XSL•FO
RenderX

adoption and implementation. This literature review focused on quality improvement of the way eHealth is organized, that has already passed the initial phase (of design and adoption). The Donabedian framework covers all relevant aspects for sustaining the integration of eHealth into health care and the interrelations of organization's structure, processes, and outcomes, as well as integrating these aspects with human and social factors, after the adoption and uptake phase of eHealth.

Conclusions

For optimal integration of eHealth into health care, the following main principles should be considered and approached simultaneously. First, the role of the care recipient needs to be incorporated in the organizational structure and daily care process. Second, the technology must be well attuned to the structure of the organization and daily care process. Third, the deployment of human resources to the care process needs to be aligned with the desired end results.

Thus far, no study has presented a complete overview of the successful and effective organization of eHealth. Therefore, it is desirable to supplement this research with knowledge from other sources, such as in-depth research into the experiences from different perspectives, as this can help us to obtain a complete overview of how eHealth can be successfully integrated into health care organizations.

Abstract

Background: Social media has been widely used for health-related purposes, especially during the COVID-19 pandemic. Previous reviews have summarized social media uses for a specific health purpose such as health interventions, health campaigns, medical education, and disease outbreak surveillance. The most recent comprehensive review of social media uses for health purposes, however, was conducted in 2013. A systematic review that covers various health purposes is needed to reveal the new usages and research gaps that emerge in recent years.

Objective: This study aimed to provide a systematic review of social media uses for health purposes that have been identified in previous studies.

Methods: The researchers searched for peer-reviewed journal articles published between 2006 and 2020 in 12 databases covering medicine, public health, and social science. After coding the articles in terms of publication year, journal area, country, method, social media platform, and social media use for health purposes, the researchers provided a review of social media use for health purposes identified in these articles.

Results: This study summarized 10 social media uses for various health purposes by health institutions, health researchers and practitioners, and the public.

Conclusions: Social media can be used for various health purposes. Several new usages have emerged since 2013 including advancing health research and practice, social mobilization, and facilitating offline health-related services and events. Research gaps exist regarding advancing strategic use of social media based on audience segmentation, evaluating the impact of social media in health interventions, understanding the impact of health identity development, and addressing privacy concerns.

(J Med Internet Res 2021;23(5):e17917) doi:10.2196/17917

KEYWORDS

social media; health communication; health researchers; health practitioners; health institutions; systematic review

Introduction

Social media has been widely used in health contexts by various users. For individuals, social media is a primary source of COVID-19 information for patients [1]. Social media is used by 80% of cancer patients to connect with peers [2]. For health organizations, more than 80% of US state health departments have social media accounts [3]. Among health professionals, 65% of radiologists across the United States and Europe use social media for various health-related reasons [4]. A review of the state of the art can provide guidance for practitioners who intend to use social media and for researchers who intend to advance our understanding of social media use for health purposes.

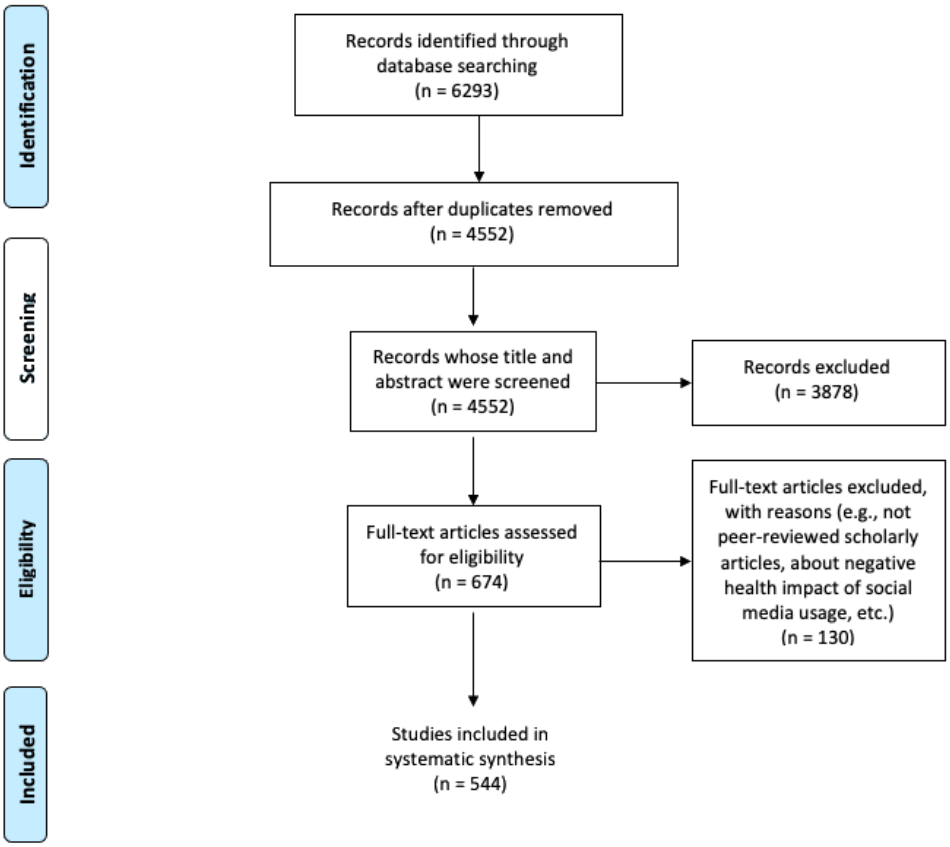
Before reviewing social media use for health purposes, it is necessary to outline the scope of social media and health purposes. Social media has been defined in different ways. Some definitions focus on the technological features of social media that distinguish it from traditional technologies. For example, Kaplan and Haenlein [5] emphasized that social media is a type of application based on the internet and web 2.0 technology. Other definitions focus on the communication features of social media that distinguish it from traditional media. For example, McGowan et al [6] defined social media as an online

XSL•FO
RenderX

environment where users can contribute to the content and consume content mostly generated by other users. They also emphasized that content being "created by users for users" is an important feature that distinguishes social media from traditional media [6]. From a communication perspective, this paper emphasizes the communication features of social media and considers social media as a web 2.0–based platform for individuals to get access to, share, and generate content. Health purposes include health-related goals such as health promotion, medical service and administration, health research, medical education and training, and health-related social movements. This review focuses on users purposively getting access to, sharing, and generating content on social media in order to achieve various health purposes.

Previous reviews about social media use for health mostly focused on using social media for a single health purpose. These reviews summarized social media as a tool for health interventions [7], health campaigns [8], medical education [9], disease outbreak surveillance [10], and health promotion and behavior change [11]. The most recent comprehensive review of social media use for various health-related purposes was conducted by Moorhead et al [12] and included studies published between 2002 and 2012. However, multiple new uses have emerged between 2013 and 2020 given the rapid development of social media and the need for effective communication and infodemiology practice in the face of emerging health risks. Following Moorhead et al [12], this study reviewed articles published between 2006 and 2020 and categorized social media uses for health purposes in terms of user types, namely, health institutions, health researchers and professionals, and the public. By conducting a systematic review, we aimed to summarize social media use for health purposes, identify new uses that have emerged since 2013 as compared with Moorhead et al [12], and discuss research gaps and future directions for research in social media use for health purposes.

Methods



Searching Strategy and Inclusion Criteria

This review followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) guideline [13] to search and screen articles as shown in Figure 1. In the first step, the researchers searched 12 databases through ProQuest and EBSCO, including important databases in public health, medical, and social science areas such as MEDLINE, Academic Search Complete, PsycINFO, CINAHL, Psychology and Behavioral Science Collection, and Coronavirus Research Database. The search string was "AB(health) AND AB("social media" OR "social network" OR Facebook OR LinkedIn OR Twitter OR Instagram OR Pinterest OR WeChat OR Weibo)." Additional restrictions (ie, published between 2006 and 2020, peer-reviewed scholarly journal article, full text available, and written in English) were added to the search requirement. The time range was set from 2006 to the end of 2020 because most of the current popular social media platforms such as Twitter and Facebook have been created or open to the public since 2006. The initial search retrieved 6293 articles.

In the next step, the two researchers screened items retrieved from the databases. An article was included if the study identifies at least one social media use for health purposes (eg, a study that finds that parents use social media to seek information about breastfeeding), examines the impact of using social media for health purposes (eg, a study that examines the effectiveness of a social media–based health intervention), or explores how to use social media for health purposes (eg, a study that examines how to detect mental health risk through analyzing social media posts). After reviewing the titles, abstracts, and full text, the researchers included 544 articles in the final sample. Articles were excluded for reasons such as not being scholarly journal articles, focusing on the negative health impacts of using social media such as depression and obesity, describing social media networks or social media post characteristics without discussing how to intentionally use social media for health purposes, examining health promotion within an offline social network, or examining social media use in general context rather than health context.

XSL•FO
RenderX

Figure 1. Article search and screening process.

Coding Process

The preliminary coding scheme was developed by one researcher based on an initial review of 20% of the articles included. The two researchers coded 20 articles using the preliminary coding scheme and met to discuss the applicability of the preliminary coding categories and possible additional coding categories. The coding scheme was finalized after the two researchers reached an agreement after the discussion. The finalized coding scheme included 8 dimensions: publication year, journal area (eg, public health and medical area, communication, psychology), the country where the study was conducted (eg, United States, United Kingdom, China), type of article (eg, empirical studies, review paper, protocol), methodology used in empirical studies (eg, experiment, survey, interview), type of social media users (ie, health institution, health researcher and professional, publics), and social media use for health purposes. Social media use for health purposes were grouped under social media users. There are 4 usages by health institutions (ie, infoveillance, disseminate health information and combat misinformation, health intervention, and social mobilization), 3 usages by health researchers and professionals (ie, health-related research, professional development, and facilitate doctor-patient communication and offline services), and 3 usages by the public (ie, seek and share health information, exchange social support in an online community, and track and share one's health statuses or activities). The intercoder reliability indicated by Krippendorff alpha ranged from a low of 0.86 to a high of 1.00. The reliability is satisfactory compared with the 0.80 criterion [14].

Results

Characteristics of the Studies

All articles were published between 2016 and 2020. There were 25 articles published in 2016, 42 in 2017, 28 in 2018, 185 in 2019, and 264 in 2020. The number of publications continuously increased during the 5 years, showing that social media use for health purposes received growing attention from researchers.

Regarding methodology, most of the articles were empirical studies (n=399). Among the empirical studies, 294 used a quantitative method including experiment, survey, content analysis, and network analysis, and 74 studies used a qualitative method including interview, focus group, and discourse/thematic analysis. There were 15 studies using a mixed method and 16 studies used other methods such as data mining and describing social media metrics of campaign messages (eg, number of likes and views). The rest of the articles were review papers (n=78), commentaries (n=37), protocols (n=22), and theoretical and methodological papers (n=8).

Regarding fields of publication, most articles were published in journals in medical and public health (n=489) followed by journals in communication (n=26), psychology (n=7), sociology (n=6), information science (n=5), interdisciplinary journals (n=5), and journals of other fields (n=6) such as technology, computing, and behavior research method.

Most of the articles featured social media use in the United States (n=170) followed by China (n=64), United Kingdom (n=20), Australia (n=14), Canada (n=7), South Africa (n=6),

XSL•FO
RenderX

Iran (n=5), Malaysia (n=4), Ghana (n=4), and India (n=4). A total of 43 articles featured social media use in other countries such as Jordan, South Korea, Denmark, and Sweden. Some studies featured social media use in more than one country or internationally (n=27). There were 176 studies that did not specify the geographic scope of social media use. For example, there were studies that analyzed all the English written posts related to a disease on social media or reviewed all the relevant literature about social media–based health intervention.

Regarding the social media platforms used for health purposes, most studies (n=231) examined social media in general without specifying use on certain social media platforms. Other studies featured Twitter (n=79) followed by Facebook (n=76), WeChat (n=33), online forums (n=16), Sina Weibo (n=13), Reddit (n=8), YouTube (n=8), WhatsApp (n=6), Instagram (n=6), and other platforms such as Pinterest, Yelp, and Yahoo! Answer (n=10). There were also 58 studies that featured more than one social media platform.

Social Media Use for Health Purposes

This review summarized 10 uses of social media for health purposes. Uses were grouped into 3 categories according to the type of social media users, namely, health institution, health researcher and professional, and the public. The following sections summarize social media uses by each type of user and the benefits and challenges related to each use.

Health Institution

Health institutions include government health agencies and nongovernmental health organizations such as the World Health Organization. The review shows that health institutions mainly used social media for infoveillance (n=94), disseminating health information and combating misinformation (n=76), health intervention (n=168), and social mobilization (n=7).

Infoveillance

Infoveillance is the application of infodemiology with a primary aim of surveillance, which refers to surveilling and analyzing the unstructured information available on the internet in order to inform public health and public policy [15]. In this review, we focused on the surveillance of information available on social media in order to inform public health. Specifically, articles in this category analyzed social media data to (1) surveil potential public health risks including the onset of individual illnesses and disease outbreaks in a population (n=70) and (2) monitor public responses to health issues (n=25).

First, social media data have been analyzed to predict the future illness onset for individual users. For example, the language used in users' posts such as life stress and anxiety can predict future occurrence of mental illness and distinguish different types of mental illness [16]. In addition, special characters used in social media posts such as emojis can also help identify illness syndromes such as asthma and difficulty breathing syndrome [17]. The use of social media to detect individual illness is especially beneficial for people who are at risk but less motivated to seek diagnosis and treatment; social media surveillance can supplement the traditional doctor-patient interaction method for illness detection [17] and can be combined with social media–based interventions to proactively provide health advice to those who are less likely to seek help [18].

Second, social media data can be analyzed to predict infectious disease outbreaks among a population such as in the COVID-19 outbreak [19]. The studies showed that social media data can provide an accurate prediction of disease outbreak case count [19]. In addition to outbreak prediction, demographic and geographic data obtained from social media can inform medical research and practice of the characteristics of people who are at risk of being infected [20]. Consistent with a recent systematic review of social media–based surveillance systems for health care [21], this study found that Twitter was the most used social media platform for individual illness and disease outbreak surveillance.

Third, user-generated social media posts can provide insights about the public's cognitive and behavioral responses to health-related issues. Studies have analyzed social media posts to understand public concerns and sentiments about ongoing disease outbreaks such as Zika [22] and COVID-19 [23], investigated public attitudes toward and actual implementation of recommended disease prevention actions [20,24], monitored public discussion about controversial health topics such as vaccination [25] and e-cigarettes [26], and gauged public support of health-related policies [27]. Assessing social media data to understand public responses to health issues not only yields results comparable to national survey data but also provides insights for health-related theoretical models [25]. More importantly, traditional public surveys may take weeks and are expensive, while social media provides real-time and inexpensive data to evaluate the effectiveness of public health communication, which allows communication practitioners to adapt timely communication strategies to public needs [23].

Disseminate Health Information and Combat Misinformation

With the ability to disseminate information quickly and widely, social media can be used by health institutions to post health information and share information with the public. Health institutions can inform the public about common health topics such as healthy living, immunization, and smoking [7]; communicate the risk of disease outbreaks [28]; quickly provide instructions about prevention behaviors to a broad audience during disease outbreaks [29]; and share the latest news and inform the public of the government's handling of disease outbreaks [28,30]. Research efforts have been devoted to exploring strategies for generating health content on social media and increasing retransmission [31,32].

Social media has several advantages over other media outlets when used for disseminating health information. First, social media is seen as the fastest among available channels to share alerts and updates about disease outbreaks [28]. Second, social media allows leveraging various media forms to engage the public. For example, by integrating hyperlinks, social media posts can direct the public to other online resources for additional health information [28,33]. Health institutions can also share podcast audios and YouTube videos on various social media platforms to deliver health information [34,35]. Third, social media can provide a communication platform for

XSL•FO
RenderX

stakeholders during disease outbreaks. Government social media accounts may become official information sources that provide content about disease outbreaks for local agencies and journalists in a timely manner [28,33].

With the increased volume of misinformation during the COVID-19 pandemic, many studies focused on the concern of rapid misinformation transmission on social media and proposed approaches to combat misinformation through social media. For example, researchers suggested health institutions increase efforts to monitor and enforce fact-checking of dubious information on social media [36,37], promote strategic and timely refutation to misinformation on social media [38], share personal experiences on social media to refute rumors [39], and use search optimization strategies within the social media platforms to redirect users who ask health-related questions to reliable information sources [40]. In addition to combating misinformation through social media, health institutions may also encourage health professionals to establish interpersonal relationships with patients and invite patients to conversations about misinformation that they may encounter online [41]. Although the effectiveness of the approaches proposed by articles in this review have not been formally tested, there have been many studies testing the effectiveness of different message design features in correcting misinformation. For example, Gesser-Edelsburg and colleagues [42] found that a theory-based correction message posted on Facebook by health authorities was more effective in correcting vaccination misinformation than a common correction message. Practitioners may design and post misinformation-correcting messages on social media based on the strategies suggested by these message design studies.

Health Intervention

Social media has been widely integrated into health interventions and can perform multiple functions. First, social media was used to offer health resources including delivering health information to audiences [43], motivating participation in health-related events [44], and directing campaign audiences and intervention participants to other health resources [45,46]. Second, social media was used to support interaction with audience including engaging campaign audiences in 2-way communication with the institutions and health professionals [47,48] and providing platforms for peer support group discussion [49]. Third, social media was used to motivate health behavior change; intervention participants used social media to document and share their own progress of health behavior change such as uploading a picture of an everyday healthy meal [50] and sharing virtual awards of weekly achievement in physical activities [51], setting group challenges toward health goals [52], and engaging in health behavior competition with peers [53]. Last, at the preparing stage of an intervention, social media was also used to reach broader and more varied populations, including hard-to-reach populations [54,55].

Research effort has also focused on improving the design and evaluation of social media–based health interventions. Studies have examined approaches to evaluating campaign outcomes [56], proposed theoretical frameworks for effective health interventions design [57], explored social media user segments to inform intervention development [58], and examined user acceptance and suggestions of receiving social media–based interventions [59]. In general, empirical evidence shows that integrating social media in health interventions is accepted by target populations [59] and effective in increasing health knowledge, reducing risky behaviors, and adopting health behaviors [60]. Researchers have also discussed challenges and raises concerns regarding social media–based health intervention; for example, researchers must rigorously evaluate social media–based interventions throughout the stages of development and implementation, involve populations experiencing health disparities in the studies, and address privacy concerns [61].

Social Mobilization

Since social media can reach varied stakeholders and a wide audience in society, nongovernmental health organizations can use social media to mobilize social resources. Studies found that these organizations leveraged social media to advocate for change in public policies related to health issues such as HIV/AIDS [62] and mental health [63], raise funds for individual medical care and health-related research [64,65], and raise awareness and promote actions to address health problems such as medical equipment shortages [66]. Although a formal test of the effectiveness of using social media for social mobilization is lacking, the successful cases described in the articles show that social media provides a platform for nongovernmental health organizations to effectively mobilize resources and advocate for collective actions to achieve their goals [62].

Health Researchers and Practitioners

Social media use by health researchers includes facilitating health-related research (n=45), professional development (n=34), and doctor-patient communication and offline services (n=36).

Facilitate Health-Related Research

Social media can facilitate health-related research in two ways: provide additional data to learn about patients' disease experience and recruit research participants. First, by analyzing patients' conversations on social media, researchers can gauge patients' understanding of the disease and their coping strategies [67], identify their concerns about the disease [68], understand their barriers to health behavior change [69], identify symptoms related to the disease [70], and assess patients' experience after recovery [71]. Because patient self-reported illness experience is not routinely reported to and recorded by physicians, analyzing patient discussions on social media may enhance health researchers' and professionals' understanding of patient experiences beyond what can be learned from traditional sources of health data [72].

Second, social media can help researchers recruit participants for health-related research. Studies found that social media performs as well as or even better than traditional recruiting methods in terms of cost and number of participants enrolled [73]. Social media is also useful in recruiting hard-to-reach populations such as immigrants [74]. Social media recruitment can generate a representative sample; a study comparing a social media–recruited sample with the underlying population found

XSL•FO
RenderX

that the sample was representative in 8 of the 13 characteristics studied including demographics and health-related factors [75].

Professional Development

Health professionals and researchers may use social media for their own professional development such as learning, collaboration, and career advancement. Social media can be used to collaborate on research projects and practices [76], access and share trending research findings and medical knowledge [77,78], broaden their exposure to funders and publishers [79], conduct a job search [80], follow medical conferences remotely [81], market their team and services, and discuss interesting or difficult cases with colleagues [4]. Studies found that different social media platforms serve different roles in the professional development of health professionals and researchers; Pinterest was mostly used for health care–quality education [82], Twitter for gathering news and information on conferences, and LinkedIn for career advancement [81]. Nearly 85% of health professionals agreed that social media can be an effective tool for educational purposes [82], and 71% of health professionals, researchers, and businesspeople in the urology discipline agreed that social media is useful for career development [83].

Facilitate Doctor-Patient Communication and Offline Health Services

Health professionals use social media for doctor-patient communication including responding to questions posted by patients [84], offering online consultation [85], and proactively providing advice and health information to social media followers [86]. In addition, social media can be used to support offline health services. Health professionals can use social media to inform patients of the results of their examination [4], encourage compliance with medication [87], receive feedback from patients about their health services [4], and collect information from patients after discharge to inform future practices [88]. Encouraging interactions between health practitioners and patients on social media may benefit both patients' well-being and patient-physician relationships [89]. In addition, social media can also be used to provide medical services such as appointments, medical inquiries, personal information management, and medical charge payment, which can increase the accessibility of medical care and improve patient experiences [90].

However, increasing use of social media by health professionals and researchers is accompanied by concerns and challenges. Many studies raised concerns about risks to patients' privacy and confidentiality [80] and health professionals lacking knowledge about social media [4]. Studies also discussed challenges such as protecting content generators' intellectual property [91] and managing negative comments from patients [4]. Most of these articles called for developing a guideline or a regulation regarding ethical, legal, and technological issues [4,80] and providing training for health professionals and researchers on the proper use of social media [91,92].

Public

The public includes healthy people and those with health concerns, including patients with known diagnoses and populations at risk of certain health problems, such as men who have sex with men, first-time pregnant mothers, and LGBTQIA+ (lesbian, gay, bisexual, transgender, queer, intersex, asexual) youth. The reviews show that the public uses social media to seek and share health-related information (n=108), exchange social support in online communities (n=95), and track and share health statuses or activities (n=10).

Seek and Share Health-Related Information

Seeking and sharing health information is the most common use by the public. The public uses social media to follow and share news about trending health issues such as flu [93] and COVID-19 [1], find information on daily health behaviors such as fitness and healthy food choices [94-96], search for health advice for their own health concern such as pregnancy-related information [97], request a crowd diagnosis or second opinion after seeing a health care professional about their illness [98], access health care law [70], follow social media accounts of health organizations and professionals [99,100], and learn about physicians and hospitals to inform their choices [101]. Social media has become a primary information source for the public with varying information needs [1,102].

However, many studies raised concerns of social media information quality and its impact on individual health outcomes [103]. Indeed, empirical studies provided grounds for the concern. Sallam et al [104] found that people who relied on social media for health information had a lower COVID-19 knowledge score compared with those who relied on doctors and scientific journals for information. In addition, people who sought information on social media did not confirm its accuracy with health professionals, and health professionals disagreed with the information found on social media on 36.7% of occasions when people checked the information accuracy with health professionals [105]. This evidence calls for efforts to reduce misinformation on social media and improve the ability of the public to find reliable information sources on social media.

Exchange Social Support in Online Communities

Social support includes informational support, emotional support, esteem support, network support, and tangible support [106]. Except for tangible support, other types of social support were widely found in interactions in the online health community.

People with certain health concerns can receive and provide informational support content. They may read the experience of others diagnosed with the same illness, share details of their own medication and diagnosis [107,108], share and access medical knowledge such as treatment options and self-care activities [109], learn about health laws [110], and solicit recommendations of doctors and hospitals [99]. They may also proactively request health information and advice [111] and validate health information with others [112].

Emotional and esteem support, expressions that convey love and caring (emotional support) and respect and confidence in ability (esteem support), were considered as one category [106]. People with health concerns may express their disease feelings to mitigate their stress and appeal for sympathy [113], offer

XSL•FO
RenderX

hope and a sense of empowerment to each other [114], and encourage peers' engagement in medical care [115].

Network support content refers to expressions that communicate belonging to a group of people who have the same concerns or interest [106]: individual users use social media to build community with people who have similar health concerns or health goals [116], foster a group identity [116], enhance a sense of belonging [117], achieve shared health goals together [118], get connected with peer patients [119], and get involved in social events such as swimming lessons with peers [120]. Network support also empowered people with health concerns to influence health awareness at the societal level such as raising awareness of queer and trans issues [121].

People with health concerns may benefit from participating in online communities in several ways. First, they do not have to reveal personal identity and thus are free from the risk of being stigmatized when participating in online communities [107]. Second, online communities as an information channel supplement offline communication channels in terms of content and time. Peers may provide more information on treatment options not raised by health professionals because of time constraints [109]. Also, people can get answers and emotional support from online communities 24/7, while other social networks may not be able to provide such timely support [122]. Third, people have a sense of control over the help-seeking process when participating in online communities, which may fulfill patients' need of autonomy and reduce treatment avoidance [123]. Last, engaging in online communities may benefit health outcomes; studies found that perceived social support predicted subjective well-being [124].

Track and Share Health Statuses or Activities

Social media enables users to track and share their health statuses or activities and view those of others in the community. The public can document and share their illness experiences such as a breast cancer journey [125] or experience with chronic disease [126], achievements in health behavior change [127], and fitness activities [128] such as cycling and walking [129]. By self-tracking and sharing their physical activities, users can build networks with other users and discuss their activity performances [129]. Writing about and sharing their illness experiences may help patients cope with illness [125] and achieve health goals [126]. Other users may also benefit from such sharing as they can easily find peers who have similar experience to get advice on lifestyle changes and discuss treatment options [130].

Discussion

We reviewed articles published between 2006 and 2020 and identified 10 uses of social media for health purposes. The review found new social media uses for health purposes that emerged after 2013 as well as research gaps that need future research. The following sections will discuss the new uses and gaps.

New Social Media Uses for Health Purposes

Several new usages have emerged since 2013 compared with the usages summarized by Moorhead et al [12]. First, recent studies have begun to explore social media use for health purposes beyond the scope of patients, the general public, and health professionals. Studies have paid attention to social media use by health institutions including government agencies such as US federal, state, and local health departments [3,28,131] and nongovernmental health organizations [62]. Social media use identified in Moorhead et al [12] mostly benefits individuals who are experiencing illness or with the need for health information, while the use of social media by government agencies may benefit the whole society, especially during disease outbreaks. These articles also mentioned the limitations of government agencies using social media for health purposes such as lack of conversation with the public [131] and a disconnect between the health-related content generated by government agencies on social media and the actual health conditions that affect the population [2].

Second, studies in recent years have started to pay attention to social media use by health professionals and researchers to advance their practices and research. Social media is not only a communication channel that facilitates their conversation with patients [85] but also a tool for professional development [132] and health-related research [75]. Social media can provide opportunities for professional development from job searches to learning about trending research findings [77,80]. In addition, although studies have long been using social media for recruitment as a research tool, research efforts have been made to investigate the effectiveness of using social media for recruitment in recent years (ie, 2019-2020) and found social media promising as a recruitment tool [75].

Third, studies in recent years have found that social media can be used for social mobilization. Social media provides new opportunities for nongovernmental organizations to build community, mobilize resources, and extend discourse about sensitive issues beyond mainstream media coverage [47]. Although social mobilization was often initiated by nonprofit health organizations, people with heath concerns can form a community and collectively use social media to raise awareness of a disease or minority population. For example, patients with brain injuries can use social media to increase awareness of brain injury in society [133]. Social media was also used by LGBTQIA+ youth in the United States to increase the visibility of that population's voice and promote civic engagement on public issues related to the population [121].

Last, as social media incorporates more functions such as sending reminders, registering for events, and linking payment methods, social media becomes useful in facilitating offline health-related services and events such as making appointments and providing visiting guides [90]. In this sense, social media not only serves as a communication tool but also a tool for medical service and administration. However, this emerging usage may not be applicable to all social media platforms, as different platforms may incorporate functions not suitable for administrative uses. Moreover, this usage poses challenges to health organizations as they need to concern about the privacy issue and the need of additional workforces to manage their social media accounts [90].

XSL•FO
RenderX

Research Gaps in Social Media Uses for Health Purposes

There are several gaps existing in this research on using social media for health purposes. First, future studies should explore and test strategies to motivate engagement based on evidence of audience segmentation. There have been research efforts devoted to examining the audience segments on social media based on network characteristics in a health campaign [58], the extent to which users produce and consume health-related user-generated content [134], and users' motivation for participating in an online community [135]. Although these studies on audience segmentation provide implications on strategies to engage different types of audiences, we need more studies to formally test the effectiveness of strategies derived from audience segmentation research.

In addition, future research should develop a dynamic audience segment–detecting tool that can monitor audience characteristics and integrate these characteristics to predict audience segments on social media. Multiple factors may collaboratively determine audience types such as offline support [134], sentiment about the health issue [58], illness stage, need for support [135], and availability of spare time [136]. Some of these factors may change over time resulting in a transitioning of audience types [135]. As a result, changes in social media users' health status and social environments may lead to changes in their engagement pattern on social media. By predicting the change in user engagement patterns, practitioners can develop tailored engagement strategies for different types of social media users and adapt the strategies according to individual changes as an intervention goes on.

Second, more studies are needed exploring the relative impact of different applications of social media in health interventions on health outcomes, a research gap identified by Moorhead et al [12] that remains unresolved. Although the general impact of integrating social media in health interventions on promoting health knowledge and behavior is promising, it is unclear if different uses of social media in health interventions have different impacts. Social media can be integrated into an intervention in multiple ways and used for peer discussion with or without discussion leaders [137], conversations between participants and health professionals [138], delivering real-time and adaptive intervention messages [139] or regular intervention messages [45], delivering information in texts or more attractive formats such as video and infographics [138], intervention monitors to acknowledge achievements in participant health behavior changes [51], or participants to share their achievements with each other [127], etc. Using social media in these different manners may result in different effects on participant health behaviors and outcomes. For example, Garett et al [140] found that participants in the intervention group (ie, a Facebook group with peer leaders) acquired more knowledge about sexual health services and felt more comfortable with connecting with peers than those in the control group (ie, a Facebook group without peer leaders). Experimental studies and meta-analyses may be helpful to examine if and how using social media in an intervention in different ways affect health behavior change differently.

Third, social media enables users with similar health issues to develop health-related identities in a community. However, under which conditions identity building leads to positive or negative health behaviors and health outcomes is unclear [141]. Although developing identities may foster mutual support and decrease a sense of isolation [116], building an identity with a certain patient group can reinforce negative health behaviors such as disordered eating behaviors [142], and being part of a healthy community may pose pressures for users to consistently present an optimal identity as a healthy role model under persistent self- and community surveillance [128]. Researchers should explore approaches to using the identity-building function of social media to improve health outcomes and avoid negative impacts.

Last, privacy concerns were raised in articles on using social media for various health purposes including disease surveillance [21], health interventions [60], participation in online communities [143], and professionals communicating with colleagues and patients [76]. Researchers have consistently called for efforts to address privacy concerns related to using social media for health purposes [12,61,144]. Indeed, research effort has been made such as developing models to filter patients and caregivers and match them with trusted peer patients and caregivers in a privacy-preserving way [85] and developing social media privacy guide for health professionals [145]. However, gaps still exist in research and practice such as lacking an official guideline about privacy issues related to using social media in health research recruitment [73,146], lacking an approach to guarantee online informed consent [140], and researchers and potential participants lacking the awareness of the privacy risks of social media research recruitment [146]. Future studies should explore research methods and form practice guidelines that can address privacy issues associated with using social media for health research, intervention, and patient-doctor interaction.

Limitations

The review has several limitations. First, the review does not include conference papers, dissertations, and grey literature. However, given the large number of peer-reviewed journal articles included in the review and overlaps on social media uses identified in the articles, we expect that there will not be many other social media uses left unidentified by the review.

Second, we only searched keywords in abstracts instead of full texts. This may render the review missing articles that mentioned social media uses for health purposes only in the main text and not in the abstract. Indeed, some articles were not included in this review but were included in previous reviews; all articles included in this study were published between 2016 and 2020, while the previous review conducted by Moorhead and colleagues [12] included articles published before 2013. However, although the scope of this review may be limited due to the restrictive search strategy, the uses identified in the review cover most social media uses found by Moorhead and colleagues [12], meaning this study provides a comprehensive overview of the social media uses identified in existing literature. In addition, this review contributes to the literature by identifying social media uses for health purposes emerging after 2013.

Conclusions

This review summarized 10 social media uses for health purposes identified in previous literature and categorized the social media uses in terms of user types. Public health practitioners and organizations may use the summary as a starting point to explore applying social media in their daily practice. In addition, the review contributes to the literature by identifying research gaps in social media use for health purposes, providing guidance for future research in this area.

Abstract

Background: Digital health interventions are increasingly being used as a supplement or replacement for face-to-face services as a part of predictive prevention. They may be offered to those who are at high risk of cardiovascular disease and need to improve their diet, increase physical activity, stop smoking, or reduce alcohol consumption. Despite the popularity of these interventions, there is no overall summary and comparison of the effectiveness of different modes of delivery of a digital intervention to inform policy.

Objective: This review aims to summarize the effectiveness of digital interventions in improving behavioral and health outcomes related to physical activity, smoking, alcohol consumption, or diet in nonclinical adult populations and to identify the effectiveness of different modes of delivery of digital interventions.

Methods: We reviewed articles published in the English language between January 1, 2009, and February 25, 2019, that presented a systematic review with a narrative synthesis or meta-analysis of any study design examining digital intervention effectiveness; data related to adults (≥18 years) in high-income countries; and data on behavioral or health outcomes related to diet, physical activity, smoking, or alcohol, alone or in any combination. Any time frame or comparator was considered eligible. We searched MEDLINE, Embase, PsycINFO, Cochrane Reviews, and gray literature. The AMSTAR-2 tool was used to assess review confidence ratings.

Results: We found 92 reviews from the academic literature (47 with meta-analyses) and 2 gray literature items (1 with a meta-analysis). Digital interventions were typically more effective than no intervention, but the effect sizes were small. Evidence on the effectiveness of digital interventions compared with face-to-face interventions was mixed. Most trials reported that intent-to-treat analysis and attrition rates were often high. Studies with long follow-up periods were scarce. However, we found that digital interventions may be effective for up to 6 months after the end of the intervention but that the effects dissipated by 12 months. There were small positive effects of digital interventions on smoking cessation and alcohol reduction; possible effectiveness in combined diet and physical activity interventions; no effectiveness for interventions targeting physical activity alone, except for when interventions were delivered by mobile phone, which had medium-sized effects; and no effectiveness observed for interventions targeting diet alone. Mobile interventions were particularly effective. Internet-based interventions were generally effective.

XSL•FO
RenderX

Conclusions: Digital interventions have small positive effects on smoking, alcohol consumption, and in interventions that target a combination of diet and physical activity. Small effects may have been due to the low efficacy of treatment or due to nonadherence. In addition, our ability to make inferences from the literature we reviewed was limited as those interventions were heterogeneous, many reviews had critically low AMSTAR-2 ratings, analysis was typically intent-to-treat, and follow-up times were relatively short.

Introduction

Background

The National Health Service (NHS) Long Term Plan sets out the UK government's vision for preventing health problems and supporting the self-management of conditions [1]. A major target is cardiovascular disease (CVD), which causes 28% of all deaths in the United Kingdom and is the largest cause of premature death in deprived areas [2,3]. England's primary large-scale intervention for CVD prevention is the NHS Health Check program [1,2], which was introduced in 2009 [4]. It is one of the largest public health prevention programs in the world, with over 6 million people in England having a check between 2013 and 2018 [5]. The NHS Health Check is a CVD risk assessment, which should be offered every 5 years to all adults aged between 40 and 74 years with no pre-existing vascular condition. As a result, people with previously undiagnosed conditions can be put on a clinical pathway and those who are at risk of developing a condition can be offered lifestyle support and advice to manage their risk. In particular, cardiovascular risk can be reduced by modifying 4 types of behavior: diet [6], physical activity [7], smoking [8], and alcohol consumption [9].

A key pillar of the Long Term Plan is *predictive prevention*—the use of technology and digital tools to identify health risks, make early diagnoses, and support positive health behaviors of those most at need through targeted treatments [3]. Predictive prevention, including the NHS Health Check, involves risk communication and behavior change. Evidence shows that risk communication alone does not lead to behavior change [10-13]. Therefore, we need to support behavior change. Digital tools are an increasingly important part of that landscape, and digital behavior change interventions may be offered to people after their NHS Health Check to manage their risk by helping them modify their diet, physical activity, smoking, or alcohol consumption.

Digital tools may be used either to supplement face-to-face services or to replace them. Replacement is particularly germane, since there is anecdotal evidence that face-to-face services are increasingly being defunded. In addition, services may need to shift from face-to-face to digital in response to the COVID-19 pandemic, which occurred after we had completed the review. Providers may hope that digital tools will offer a low-cost solution, with the potential to reach more people than traditional face-to-face services; however, the research base needs to be evaluated to see if there is sufficient evidence [14].

Aims and Objectives

The first step is to establish whether digital interventions are effective. We also need to know which modes of delivery are most effective in order to allocate resources to develop the most promising digital tools or to know where research is needed, if the evidence base is lacking. In this systematic review of reviews, we aim to summarize the evidence on the effectiveness of digital interventions in improving dietary, physical activity, smoking, and alcohol consumption behaviors in nonpatient adult populations in high-income countries.

Methods

Overview

The study protocol was registered with PROSPERO (registration number: CRD42019126074). All deviations from the protocol are explained in the Methods section. We followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines for reporting (see Multimedia Appendix 1 for the checklist) [15].

Data Sources

Relevant reviews were obtained through an internet-based search and a manual search. First, 4 internet-based databases (MEDLINE, Embase, PsycINFO, and Cochrane Reviews) were searched for peer-reviewed review articles published in English between January 1, 2009, and February 25, 2019. We limited our search dates, only starting in January 2009, to make our study manageable and also because we expected reviews published in the last decade to capture earlier papers. Publications were restricted to English due to the absence of translation expertise. Gray literature searches were conducted in OpenGrey, ProQuest Dissertations and Theses, Google, and targeted websites (see Multimedia Appendix 2 for search terms and the gray literature search strategy). More articles were identified by manual searches of the reference lists from excluded reviews of reviews. We did not search in study registries, as we were looking for systematic reviews. We did not conduct full hand searches or consult experts to ascertain the literature for pragmatic and logistical reasons.

XSL•FO
RenderX

Review Selection

The reviews were screened using a three-stage process. A total of 2 reviewers (NG and AY) examined titles and discarded reviews that did not meet the inclusion criteria (Textbox 1). Each reviewer then independently screened the abstracts of 10% of the remaining reviews to identify studies that potentially met the inclusion criteria. Interreviewer agreement on inclusion was also assessed. Reviewers disagreed on 11 of 41 decisions. All disagreements were resolved through discussion. AY screened all the remaining abstracts. The relevant review articles were then obtained in full and screened independently for eligibility by NG and AY. Any disagreement over eligibility was resolved through discussion with a third reviewer (TC or BR).

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

1. Study type: systematic reviews (whose reporting of the evidence could be either by narrative synthesis or by meta-analysis) that reported on the effectiveness of digital interventions in changing health-related behavior and/or health outcomes. We did not restrict by study design of the included studies within the systematic reviews.
2. Population: this included adult nonclinical populations. We aimed to assess the effectiveness of digital interventions in relation to CVD prevention relevant to the NHS Health Check program, which is offered to adults aged between 40 and 74 years (England, United Kingdom). Where populations were mixed, we included the review if the population of interest could be isolated. Where impossible to isolate the population of interest, reviews were included if ≥50% of the studies were of relevant populations.
3. Intervention: we included digital interventions targeting behaviors related to diet, physical activity, smoking, and/or alcohol consumption. Digital interventions include interventions delivered over the internet (web-based or websites), mobile telephone interventions (including texts and mobile apps), social media, computer-delivered interventions, and wearable technology. Interventions incorporating both digital and face-to-face components were also included.
4. Comparator: there were no restrictions. We extracted information about the comparators where available, allowing us to review effectiveness compared with both nondigital interventions and nonintervention controls.
5. Outcome: this included behavioral or health outcomes related to diet, physical activity, alcohol consumption, and smoking. Reviews that considered these areas of behavior, either individually or in combination, were included.
6. Time frame for follow-up: any time frame.

Exclusion criteria

1. Study type: reviews of reviews, conference abstracts, protocols, opinion pieces, and commentaries. We excluded reviews of reviews because we expected that most of the reviews gathered in a review of reviews would already be included in our study. Therefore, including reviews of reviews would have led to double counting of some information.
2. Population: reviews that only considered any of the following in ≥50% of included studies: children and adolescents, students, adults aged <40 years, pregnant women, management of existing CVD or other health conditions, and low- to middle-income countries. These criteria were selected to protect the ecological validity of this review, as relevant to the NHS Health Check.
3. Intervention: reviews of nondigital interventions. We did not consider television, radio, or telephone calls to be digital, as they are not often used in digital interventions for public health.
4. Comparator: no exclusion criteria.
5. Outcome: feasibility, acceptability, participation, and engagement only.
6. Superseded: this included reviews updated by subsequent reviews that included all the same studies as the original.

Study Quality Assessment

Review confidence was critically appraised independently by 2 reviewers (NG and AY) for a 10% subsample of the included publications, using the AMSTAR-2 tool [16]. The findings were discussed to check for consistency. The remaining articles were divided and assessed by NG or AY. Any uncertainty was resolved through discussion with a third reviewer (BR).

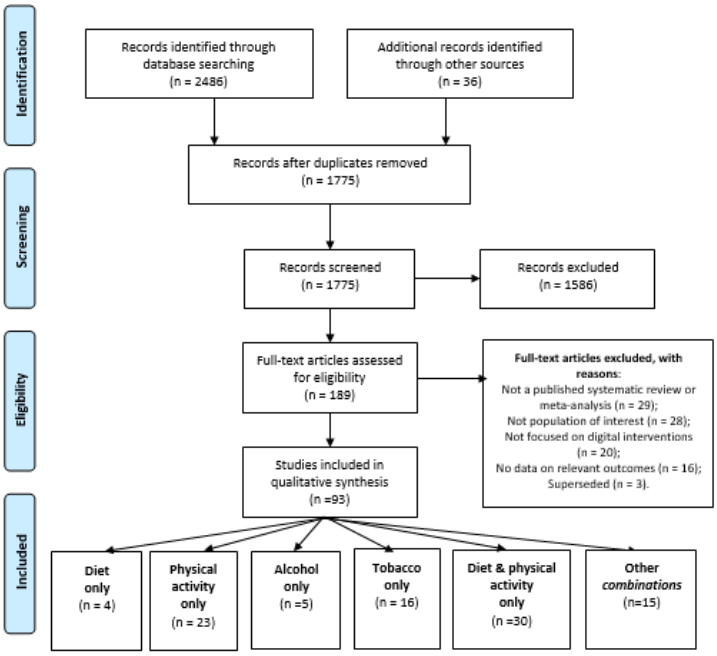
Data Extraction

Data were extracted using a standardized form (Multimedia Appendix 3). We extracted data on the following predefined review components: objective, population, inclusion and exclusion criteria, search date, included studies (number, type, and countries), follow-up, method of synthesis, results and findings, and comparator. A total of 2 reviewers (NG and AY) extracted the data independently for 10% of the publications. Discrepancies were resolved through discussion. The remaining publications were divided among both reviewers. During data extraction, we also noted information about the control condition and any information on a comparison of effectiveness of no-intervention versus active controls. Data on adherence and attrition were also recorded, where available. The data extraction form has been presented in Multimedia Appendix 3.

Analysis

We conducted a systematic narrative synthesis using extracted data from included articles. No statistical analyses were conducted and meta-analysis was not possible with the included articles. We have presented results in the following categories: diet, physical activity, diet and physical activity combined, smoking, alcohol consumption, and multiple areas of behavior (all combinations other than diet and physical activity). Where there were enough reviews, we grouped by mode of delivery,

XSL•FO
RenderX



especially internet (including email and interventions that require accessing a website) and mobile phone (including apps and SMS text messaging interventions); social media was categorized separately from internet, mainly because there are enough papers to make the subdivision worthwhile but also because the social aspect may differentiate social media interventions from other forms of internet interventions, so that it is appropriately considered a subclass [17]. When reporting effect sizes, for Cohen *d*, Hedges *g*, and other measures of standardized mean difference (SMD), we followed the convention that 0.2 is a small effect size, 0.5 is a medium effect size, and 0.8 is a large effect size [18]. For risk ratios (RRs), we classified 1.22 as small, 1.86 as medium, and 3.00 as large; for odds ratios (ORs), these were 1.32, 2.38, and 4.70, respectively [19].

Results

Overview

Searches identified 1739 potentially relevant records. After screening the titles and abstracts, 154 articles were retrieved in full. An additional 36 articles were identified through hand searches and gray literature searches. In total, 94 reviews met the inclusion criteria (Figure 1). A list of reviews excluded after full-text screening is provided in Multimedia Appendix 4. We were unable to retrieve one gray literature item by May 13, 2019, and it was therefore excluded.

Figure 1. PRISMA flowchart. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

Review Characteristics

The included reviews examined the effectiveness of digital interventions on diet only [20-23], physical activity only [24-46], diet and physical activity combined [47-76] (for some it was possible to extract separate results about diet and physical activity behaviors, whereas some reported more general results on weight loss outcomes), alcohol consumption [77-82], and smoking cessation [83-98]. A further 15 reviews examined the effectiveness of digital interventions on a combination of our 4 target areas of behavior (not diet and physical activity; again, sometimes it was possible to extract separate information for each target area but other times, the results were only reported in combination) [99-113]. Some reviews covered a number of areas of behavior because their research questions focused on a health outcome (eg, CVD) or a mode of intervention delivery (eg, internet interventions) rather than a behavior. Where extracting information on an area of behavior from a combination review was possible, we included the relevant data in the results for that area. For a breakdown of the reviews, with the number found in each area, for each mode of intervention and type of control see Multimedia Appendix 5.

The populations reviewed were general (nonclinical) adult populations. However, the diet and physical activity reviews were often restricted to populations of individuals with overweight or obesity. The alcohol reviews were often restricted to *problem drinkers*, defined with reference to local guidelines [77,79,80], questionnaire scores [81], or reduced productivity at work [78]. There was a range of modes of delivery, including mobile app, SMS text messaging, social media, pedometer, wearable, and interactive computer program. The reviews included both active and nonactive or minimal intervention controls, many pooling both types, but where possible, we tried to extract separate information about effectiveness of active compared with nonactive controls. We regarded the provision of educational materials as a nonactive or minimal control. More reviews included behavioral outcomes (such as fat consumption, fruit and vegetable consumption, physical activity, alcohol consumption, smoking cessation, and smoking abstinence) than health outcomes (such as weight loss, BMI, and waist

XSL•FO
RenderX

circumference). Multimedia Appendix 6 provides the key characteristics of all included studies.

Review Confidence Ratings

The confidence rating of each review is presented in the study characteristics table in Multimedia Appendix 6, and a summary of confidence ratings is provided in Table 1; 84% (79/93) of reviews were rated as critically low. During the completion of the AMSTAR-2 tool, reviewers noted that most reviews failed to satisfy items 4 (including and justifying a publication language inclusion criterion) and 7 (providing a list of excluded reviews and justifications). Both items are considered critical for systematic reviews but not for meta-analyses. A modified rating was produced alongside the original AMSTAR-2 rating, which did not classify either of these flaws as critical, to see whether a variation among reviews would be revealed. However, little change was observed, with only 5 reviews moving from a rating of critically low to low.

Table 1. Risk of bias: a summary of AMSTAR-2 confidence ratings.

Category	Confidence rating (modified rating)			
	High	Moderate	Low	Critically low
Diet	0 (0)	0 (0)	1 (1)	3 (3)
Physical activity	0 (0)	1 (1)	0 (1)	20 (19)
Diet and physical activity	0 (0)	1 (1)	1 (3)	28 (26)
Alcohol	0 (0)	0 (0)	1 (1)	4 (4)
Smoking	0 (0)	2 (2)	4 (4)	10 (10)
Other	0 (0)	1 (1)	2 (4)	14 (12)
Total	0 (0)	5 (5)	9 (14)	79 (74)

Effectiveness of Interventions

Table 2 summarizes the effectiveness of the different types of interventions.

XSL•FO
RenderX

Table 2. Summary of the effectiveness of different types of interventions.

Findings	Behavioral categories				
	Diet	Physical activity	Diet and physical Activity	Smoking	Alcohol	Other combinations
Number of reviews	• 20 reviews, of which 4 were diet-only	• 45 reviews, of which 22 were physical activity-only	• 35 reviews, of which 29 were on weight loss, specifically combining diet and physical activity, and 3 where results on weight loss were extractable from other combinations	• 28 reviews, of which 16 were smoking-only	13 reviews, of which 6 were alcohol-only	11
Effectiveness compared with mixed (active and nonactive) controls	• Small effect of internet interventions on pooled behaviors but heterogenous outcome measures and effect sizes • Some small effects of mobile phone interventions on behavior, but no effects on weight loss • Mixed effects of social media but no effects on weight loss • Mixed effects of computer-delivered interventions, and positive effects were not clinically significant	• Mixed evidence for the effect of internet interventions on physical activity; where there were effects, they were small and there was heterogeneity between studies • Mixed effects of social media, with meta-analyses not finding significant effects • Better evidence for effects of mobile phone interventions, with most studies in narrative reviews showing effectiveness, with effect sizes for SMS text messaging interventions ranging from small to medium • Mixed evidence for the effect of exergaming • Mixed evidence on computer-delivered interventions (2 reviews); the meta-analysis found small effects • There was favorable evidence from reviews assessing a variety or a combination of interventions	• Positive effects of internet interventions for weight loss and BMI, especially when part of blended interventions • Mixed effects of social media interventions • Medium-sized effects of mobile interventions on weight loss • Mixed results from reviews covering a variety of interventions, around half of the interventions were found to be effective	• Small positive effects for internet, mobile, and computer-delivered interventions. Mixed evidence about interventions from reviews that covered multiple types of digital technologies	Small and medium positive effects	Small positive effects on behavior and on health outcomes for internet, computer-delivered, SMS text messaging, and prompts delivered by all methods; however, results were not favorable for apps

XSL•FO
RenderX

Findings	Behavioral categories					
	Diet	Physical activity	Diet and physical Activity	Smoking	Alcohol	Other combinations
Comparison to no or minimal intervention	Little evidence available and it was mixed: • One meta-analysis of voice-response interventions found no effect • One meta-analysis of computer-tailored interventions found a small effect	Mixed results: • Mixed results for internet and mobile interventions • One review of social media interventions, finding increased in steps taken but not energy expenditure, total physical activity, or moderate-to-vigorous physical activity • Small positive effect of interactive voice response and computer-delivered interventions	• More effective than minimal controls for internet and computer-based interventions, but effect sizes were small	• Small positive effects for internet-based interventions and for digital interventions not broken down by mode of delivery), mobile interventions more effective than completely passive controls and as effective as minimal controls	Effective compared with no-intervention controls	Effective compared with no-intervention controls, with small effects for internet and medium effects for SMS text messaging interventions
Comparison with active controls	• Mixed; in narrative syntheses (of internet, mobile, and combinations of interventions), less than 50% of studies in each review found significant improvements	• Increase in physical activity for internet-based interventions • Mixed results for mobile interventions • Promising results about wearables	• Internet-based interventions not more effective than active controls, unless as a part of blended interventions • Computer-delivered interventions led to less weight loss than in-person treatment	• No evidence that digital interventions are any more effective than active controls	No evidence that digital interventions are any more effective than active controls; mixed evidence about whether active controls are more effective than digital	Very small effects for internet and small effects for computer-delivered and SMS text messaging interventions
Sustainability	• Relatively few studies with follow-ups • Digital interventions were largely effective over a 3- to 6-month period • Evidence was more mixed in the long term (>12 months)	• Relatively few studies with follow-ups • Some evidence for sustainability of internet and combinations of digital interventions at 6-month follow-up • Some evidence that the effect of mobile interventions is short lived	• Few studies, but those found that effectiveness declined over time		Mixed results about whether the effect was sustained. No follow-ups exceeded 12 months. Evidence suggests effects have diminished by this point	Mixed evidence on when the effect size peaks (short or medium term); effects decrease but still exist at 12 months

XSL•FO
RenderX

Findings	Behavioral categories					
	Diet	Physical activity	Diet and physical Activity	Smoking	Alcohol	Other combinations
				Mixed evidence: • Effects of internet-based interventions sustained up to 6 months, but there is disagreement about whether effects are maintained at the 12-month follow-up • Mixed evidence on the sustainability of mobile interventions • No evidence of sustainability of computer-delivered interventions • Reviews that surveyed a range of digital interventions without differentiating by mode of delivery found sustained effects, even at the 18-month follow-up		

Diet

Review Characteristics

A total of 20 reviews reported findings on diet behaviors or a weight loss outcome that resulted from an intervention that only targeted diet. The breakdown of their characteristics is shown in Table S1.

Effectiveness of Digital Interventions on Diet Compared With Mixed (Active and Nonactive) Controls for Diet Behaviors

The effectiveness of digital interventions in improving results related to diet was at best mixed, for both behavioral and health outcomes (Table 3); where improvements were reported, the effect sizes were typically small. This was the case across all modes of delivery.

XSL•FO
RenderX

Table 3. Results of reviews on diet, ordered by type of control and mode of delivery of intervention.

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Dietary outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Mixed (active and nonactive) controls							
Afshin et al (2016) [99]	20 (224)	Narrative synthesis of RCTs[a] and quasiexperimental studies	Internet and mobile	Various dietary behaviors, fruit and veg intake	1 week-2 years	70% (14/20) studies found significant dietary improvements. Effect sizes varied due to heterogeneity in dietary targets. The intake of fruit increased by approximately 1 serving/day. Two RCTs assessed mobile - based interventions and fruit or vegetable intake; each found significant improvement (by 2 and 4 servings/day)	Critically low
Aneni et al (2014) [100]	9 (29)	Narrative synthesis of RCTs	Internet	Dietary intake	6-24 months	44% (4/9) high-quality studies demonstrated improvements in diet	Critically low
Hou et al (2013) [108]	7 (38)	Narrative synthesis of studies with comparison or control groups	Internet	Dietary intake and fruit and vegetable intake	Not reported	All the studies examining nutrition alone and nutrition and other factors in addition to PA[b] reported increases in healthy dietary behaviors in the intervention groups. Interventions showed promising effects at 12 months for reductions in body fat, weight, and dietary fat intake	Critically low
Lustria et al (2013) [110]	10 (40)	Meta-analysis of experimental and quasiexperimental studies	Internet-tailored interventions	Fruit and vegetable intake and saturated fat intake	6 weeks-6 months	Small effect sizes, Cohen d=0.223 (k=4; 95% CI 0.11 to 0.33; P<.001)	Critically low
Maon et al (2012) [63]	8 (26)	Narrative synthesis of RCTs	Internet	Fruit and vegetable consumption	6 weeks-2 years	50% (4/8) studies investigating healthy eating habits reported positive changes such as increased fruit or vegetable consumption	Critically low
Webb et al (2010) [113]	10 (85)	Meta-analysis of RCTs	Internet	Dietary behavior	Not reported	Small effect sizes on behavior were observed for interventions that targeted only dietary behavior (Cohen d_+=0.20; k=10; 95% CI 0.02 to 0.37)	Critically low
DiFillipo et al (2015) [21]	3 (3)	Narrative synthesis of RCTs	Mobile	Weight loss	8 weeks-6 months	100% (3/3) of studies found a numerical tendency to weight loss compared with the control; only 33% (1/3) of studies was statistically significant; this study showed an increase in self-monitoring	Critically low
McCarroll et al (2017) [23] (diet only)	21 (23)	Narrative synthesis of RCTs	Mobile	Healthy eating and weight loss (diet only)	1-24 months	Small positive effects of interventions on healthy eating (5/8, 63% of trials) and weight loss (5/13, 38% of trials), but studies were judged to be of poor quality	Critically low

XSL•FO
RenderX

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Dietary outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Lyzwinksi et al (2014) [60]	5 (14)	Meta-analysis of RCTs	Mobile	Fruit and veg intake, energy density	8 weeks-12 months	100% (3/3) of studies found an improvement in fruit and vegetable intake; 100% (2/2) studies found an improvement in energy density and eating behavior	Critically low
Palmer et al (2018) [111]	3 (71)	Meta-analysis of RCTs	Mobile	Saturated fat intake, BMI, salt intake, weight from diet-only interventions	Not reported	2 (100%) studies showed no effect of interventions on weight or dietary intake	Moderate
Elaheebocus et al (2018) [56]	20 (134)	Narrative synthesis of RCTs	Social media	Body weight	6-48 months	75% (15/20) of studies using web-based social networks had positive results for dietary outcomes	Critically low
Mita et al (2016) [65]	12 (16)	Meta-analysis of RCTs	Social media	Body weight and fruit and vegetable intake	Not reported	No significant differences (SMD[c] −0.14; 95% CI −0.28 to 0.01), with similar findings for body weight (SMD 0.07; 95% CI −0.17 to 0.20) and fruit and vegetable intake (SMD 0.39; 95% CI −0.11 to 0.89)	Moderate
Williams et al (2012) [75]	5 (22)	Meta-analysis of RCTs	Social media	Body weight and dietary fat	3-24 months	No significant differences in changes in weight (SMD 0; 95% CI −0.19 to 0.19; 10 studies) however, pooled results from 5 studies showed a significant decrease in dietary fat consumption with social media (SMD −0.35; 95% CI −0.68 to −0.02)	Critically low
Wieland et al (2012) [74]	18 (18)	Meta-analysis of RCTs, quasi-RCTs, cluster RCTs, and quasi-experimental studies	Interactive, computer-based	Fat intake, calorie intake, total fiber, fruit and vegetable intake; weight, BMI, and waist circumference	4 weeks-30 months	Computer-based interventions led to greater weight loss than minimal interventions (MD[d] −1.5 kg; 95% CI −2.1 to −0.9) but less weight loss than in-person treatment (MD 2.1 kg; 95% CI 0.8 to 3.4; one trial); in the 3- to 6-month follow-up, there was a significant decrease in percentage calories from fat (MD −1.1%), and improved fiber intake (dietary fiber score MD 1.3); there was no significant effect on energy intake at 30 months	Critically low

XSL•FO
RenderX

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Dietary outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Harris et al (2011) [22] (diet only)	25 (43)	Meta-analysis of RCTs	Interactive, computer based	Fat intake, fruit and vegetable consumption, fiber intake, and energy intake	0-12 months	Interventions did not produce clinically significant changes in dietary behavior: fruit and vegetable intake had a weighted MD of 0.24 servings per day (95% CI 0.04 to 0.44 servings; *P*=.02), total energy consumed from fat had a weighted MD of –1.4% (95% CI –2.5% to –0.3%; *P*=.01); there were no significant weighted MDs in intake of total fat, saturated fat, daily dietary fiber, or daily energy; there were no significant effects on fruit and vegetable consumption and BMI at 12 months	Low
Carvalho de Menzes et al (2016) [53]	15 (18)	Narrative synthesis of all designs	Various	Fat consumption and fruit and vegetable consumption	1-36 months	Among the changes in eating habits, statistically significant reductions were observed in the consumption of fat (total fat, saturated fat, and transfat), and there was an increase in the ingestion of fruit and vegetables	Critically low
Nonactive controls							
Krebs et al (2010) [109]	51 (76)	Meta-analysis of RCTs	Computer-tailored	Dietary intake of fat, vegetables, and fruits	1-24 months	The mean effect size for dietary fat reduction was *g*=0.22 (95% CI 0.18 to 0.26); mean effect size for fruit and vegetable intake was *g*=0.16 (95% CI 0.10 to 0.21).	Low
Tsoli et al (2018) [73]	2 (15)	Meta-analysis of RCTs	Interactive voice response	Diet	6 weeks-12 months	No statistically significant effect on behaviors related to diet (Hedges *g*=0.130; 95% CI −0.088 to 0.347; k=2; *P*=.24)	Critically low
Active controls							
Burke et al (2011) [20] (diet only)	5 (24)	Narrative synthesis of RCTs and descriptive studies	Personal digital assistants	Weight loss (diet only)	3-24 months	In all studies, self-monitoring was significantly associated with weight loss, but there was minimal evidence to support the use of personal digital assistants over other methods of self-monitoring; they may result in long-term reduced risk of weight regain after 18 months	Critically low

RenderX

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Dietary outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Covolo et al (2017) [104]	18 (40)	Narrative synthesis of RCTs	Mobile	BMI and waist circumference; fruit and vegetable intake, and high-sugar food intake	6 months-2 years	56% (10/18) of RCTs found no difference between intervention and control group; 33% (6/18) studies showed a significant increase in the consumption of fruit and vegetables and reduced sugar-sweetened beverage consumption	Critically low

[a]RCT: randomized controlled trial.

[b]PA: physical activity.

[c]SMD: standardized mean difference.

[d]MD: mean difference.

Of the 6 reviews covering internet interventions, 2 meta-analyses found small, favorable effects of internet interventions on dietary behavior, Cohen *d*=0.223 [110] and Cohen *d*+=0.20 [113]. A total of 4 narrative syntheses found mixed results with heterogeneous target outcomes [63,99,100,108]. The most common dietary target across the studies was fruit intake, which increased by approximately 1 serving per day [99].

Across 6 reviews of mobile interventions, there was some evidence of positive effects on dietary behaviors, especially fruit and vegetable intake, but no statistically significant effects on weight loss [21,23,60,99,104,111]. One of these reviews [99] reported a previous systematic review (not covered in this paper) that found no significant change in calorie intake or the consumption of sugar-sweetened beverages in 4 trials evaluating diet.

A total of 3 social media reviews had mixed findings on dietary outcomes, such as fruit and vegetable intake and fat intake, but the 2 reviews with meta-analyses found no differences in weight [65,75].

The effects of interactive computer interventions were equivocal and not clinically significant [22,74].

Effect of Digital Interventions on Diet Compared With Nonactive Controls

There was little evidence about the effectiveness of digital interventions on diet compared with no intervention or minimal intervention controls, and the available evidence was mixed (Table 3). One meta-analysis found small effects on fruit and vegetable intake (g=0.16) and dietary fat reduction (g=0.22) [109], but another meta-analysis found no statistically significant effects on dietary behaviors [73].

Effect of Digital Interventions on Diet Compared With Active Controls

The relative effectiveness of digital interventions on diet compared with active comparators was mixed, with approximately half of the studies or less in narrative syntheses, showing that digital interventions were effective compared with active controls (Table 3). This was true across all modes of delivery: internet [99], mobile [99,104], and combined interventions [99].

Sustainability of Effects on Diet at Follow-Up

Reviews included studies that ranged from single-contact interventions to 5-year follow-ups (Table 3). Relatively few reviews reported on follow-ups; of those that did, about half reported follow-ups in the medium term (3-6 months) and half in the long term (≥12 months).

Where reported, digital interventions were generally found to be effective for over 3 to 6 months. Several reviews have found positive results at 6 months [20,21,74]. However, this finding is not universal [111].

Long-term findings were more mixed in the 5 reviews that investigated them. Two reviews suggested promising effects at 12 months [108] and 18 months [20]. However, 3 reviews found no significant effects at 12 months [22], 24 months [111], and 30 months [74].

Physical Activity

Review Characteristics

We included the findings on physical activity–related outcomes from 45 systematic reviews. The breakdown of their characteristics is shown in Multimedia Appendix 6.

Effectiveness of Digital Interventions on Physical Activity Compared With Mixed (Active and Nonactive) Controls

The effectiveness of digital interventions was mixed across all modes of delivery, apart from mobiles, for which the evidence was consistently positive (Table 4).

XSL•FO
RenderX

Table 4. Results of reviews on physical activity, ordered by type of control and further ordered by mode of delivery of intervention.

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Mixed controls (active and nonactive)							
Aalbers et al (2011) [47]	2 (10)	Narrative synthesis of randomized and nonrandomized pre-post controlled trials	Internet	Total PA[a] and MV-PA[b]	1.5-6.5 months	2 studies reported the effects of digital interventions, one was less effective on MVPA than a nonactive control and the other demonstrated a small positive effect on total PA[b] (*P*=.001).	Critically low
Aneni et al (2014) [100]	9 (29)	Narrative synthesis of RCTs[c]	Internet	PA measures	6-24 months	No improvement was seen in virtually all the studies with PA outcome, only 11% (1/9) of studies demonstrated a significant intervention effect on PA.	Critically low
Bottorf et al (2014) [26] (PA only)	8 (35)	Narrative synthesis of all study types	Internet	Changes in PA; step count; self-reported walking; BMI; waist circumference; weight	3-12 months	63% (5/8) of studies demonstrated that PA significantly increased in the internet-based interventions, 2 studies showed a nonsignificant difference, and one showed that the effects were indeterminable.	Critically low
Davies et al (2012) [29] (PA only)	34 (34)	Meta-analysis of experimental design studies	Internet	PA	2-52 weeks	The estimated overall mean effect of internet-delivered interventions on PA was Cohen *d*=0.14 (*P*<.001). Homogeneity tests from the fixed-effect analysis revealed significant heterogeneity across studies (*Q*=73.75; *P*<.001). The overall mean effect for sustained PA at least 6 months postintervention (n=11) resulted in a small but significant effect size Cohen *d*=0.11 (*P*<.01).	Critically low
George et al (2012) [33] (PA only)	2 (14)	Narrative synthesis of all study types	Internet	Step count; health status; BMI; weekly PA	2-8 months	Increase in PA in 100% (2/2) of online interventions where participants were in competitive teams, including one that showed an increase in step count. Poor quality evidence.	Critically low
Hou et al (2013) [108]	7 (38)	Narrative synthesis of trials with comparison or control group	Internet	Level of physical activity	0-12 months	86% (6/7) of interventions were successful in the studies focusing primarily on PA.	Critically low
Jahangiry et al (2017) [35] (PA only)	21 (22)	Meta-analysis of controlled trials	Internet	MVPA; walking; step count (pedometer)	1-20 weeks	36% (5/14) of rials reporting MVPA, 50% (3/6) of trials reporting step count, and 29% (4/14) of studies reporting minutes walking showed significant increases. The interventions were influenced by the age of participants and trial length.	Critically low
Lustria et al (2013) [110]	12 (40)	Meta-analysis of experimental and quasiexperimental studies	Internet	Levels of PA	4 weeks-24 months	The sample size–weighted mean effect size for studies on PA was not significant Cohen *d*=0.059 (k=12; 95% CI −0.02 to 0.14).	Critically low

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Maon et al (2012) [63]	13 (26)	Meta-analysis and narrative synthesis of RCTs	Internet	PA levels, sedentary behavior, and MV-PA	6 weeks-2 years	54% (7/13) of studies showed statistically significant effects on PA levels, such as increased walking or decreased sedentary behavior. However, a meta-analysis on 4 studies with extractable data for the outcome of moderate-to-vigorous weekly PA found a not statistically significant improvement: SMD[d] 0.15 (95% CI 20.06 to 0.35; *P*=.16) Duration of studies and effects: 10% (3/30) of studies showed positive effects when outcomes were measured immediately after the end of the interventions. In total, 37% (11/30) of studies that lasted 3 months or less demonstrated positive outcomes; 43% (13/30) of studies with an intervention of 3-6 months showed positive results; and only 10% (3/30) interventions that lasted longer than 6 months were reported to have positive results.	Critically low
Webb et al (2010) [113]	20 (85)	Meta-analysis of RCTs	Internet	Level of PA	3-12 months	Small effects on behavior were observed for interventions that targeted only PA (Cohen *d*+=0.24; k=20; 95% CI 0.09 to 0.38).	Critically low
Buchholz et al (2013) [27] (PA only)	10 (10)	Narrative synthesis of RCTs, quasiexperimental and, single groups	Mobile (SMS text messaging)	Self-reported frequency or pedometer-reported steps and level of PA	3-52 weeks	Effect sizes across all studies were positive; the median effect size was 0.5 (medium) but heterogeneous. Sample sizes were small.	Critically low
Elavsky (2018) [31] (PA only)	50 (52)	Narrative synthesis of RCTs and pre-post studies	Mobile	PA and sedentary behavior	<3 months	59% (17/29) of RCTs and 62% (13/21) of pre-post studies supported the effectiveness of mobile interventions to improve PA, and 9 (5 of 10 RCTs and all 4 pre-post) of 14 (64%) studies reduced sedentary behavior.	Critically low
Lyzwinksi et al (2014) [60]	9 (14)	Meta-analysis of RCTs	Mobile	Levels of PA	8 weeks-12 months	Trials mostly found that PA levels increased in the intervention groups relative to the control groups.	Critically low
Maher et al (2014) [61]	4 (10)	Narrative synthesis of studies with comparator group (control or within subject)	Mobile	Levels of PA	8 weeks-24 months	25% (1/4) of studies demonstrated a significant change in PA Cohen *d*=0.84 (95% CI −0.49 to 1.19).	Critically low
Muntaner et al (2015) [41] (PA only)	11 (11)	Narrative synthesis of all study types	Mobile	PA; exercise	2-24 weeks	55% (6/11) of articles included in this review reported significant increases in PA levels.	Critically low

XSL•FO

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
O'Reilly et al (2013) [42] (PA only)	12 (22)	Narrative synthesis of RCTs	Mobile	PA; sedentary behavior; BMI; blood lipids; blood pressure; QoL[e]; adverse effects	Not reported	75% (9/12) of studies reported significant changes in PA or sedentary behavior.	Critically low
Palmer et al (2018) [111]	15 (71)	Meta-analysis of RCTs	Mobile	Level of PA	3 months	Trials of PA interventions reporting outcomes at 3 months showed no benefits.	Moderate
Schoeppe et al (2016) [68]	10 (27)	Narrative synthesis of RCTs, randomized trials, controlled trials, and pre- and poststudies	Mobile	PA; sedentary behavior	1-24 weeks	59% (13/22) of studies reported significant improvements in levels of PA; 20% (1/5) of studies reported a significant change in sedentary behavior.	Critically low
Elaheebocus et al (2018) [56]	25 (134)	Narrative synthesis of RCTs	Social media	Body weight	6-48 months	76% (19/25) of studies using online social networks had positive results.	Critically low
Mita et al (2016) [65]	11 (16)	Meta-analysis of RCTs	Social media	PA; weight change	1-12 months	For PA, significant mean difference 0.07; 95% CI −0.25 to 0.38; k=11.	Moderate
Williams et al (2012) [75]	12 (22)	Meta-analysis of RCTs	Social media	PA	3-24 months	Meta-analysis showed no significant differences in changes in PA (SMD 0.13; 95% CI −0.04 to 0.30; k=12).	Critically low
Willis et al (2017) [76]	3 (5)	Narrative synthesis of all study types	Social media	Total PA	8 weeks-6 months	Only one study reported significant changes in levels of PA, when the web-based social network intervention included an online support group.	Critically low
Johnson (2017) [37]	10 (19)	Narrative synthesis of RCTs	Active gaming	Behavioral and cognitive outcomes	Not reported	Findings were largely positive for behavioral impacts, specifically the impact of gamification for PA: 80% (8/10) positive and 20% (2/10) mixed.	Critically low
Peng et al (2012) [43] (PA only)	4 (12)	Narrative synthesis of all study designs	Active gaming	Heart rate; energy expenditure; and oxygen uptake	6-12 weeks	Evidence does not support active video games as an effective tool to significantly increase PA or exercise attendance.	Critically low

XSL•FO
RenderX

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Street et al (2017) [46] (PA only)	9 (9)	Narrative synthesis of studies with comparison or control groups	Active gaming	PA; maximum oxygen uptake; power; blood pressure; body mass; body weight; body fat; BMI; balance; speed; and strength	6-12 weeks	Moderate-to-high exergaming participation was associated with statistically significant improvements in anthropometric outcomes but low participation was not associated with anthropometric changes. 38% (3/8) studies that investigated anthropometric outcomes, including BMI and body fat, found a statistically significant improvement, all 3 studies showed positive health outcomes associated with moderate-to-high participation in exergaming; 100% (3/3) of studies that reported on PA frequency reported higher frequency in the exergaming condition; however, a different 100% (3/3) of studies that reported on overall PA found no statistically significant increases.	Critically low
Wieland et al (2012) [74]	4 (18)	Meta-analysis of RCTs, quasi-RCTs, cluster RCTs, and quasiexperimental studies	Computer-delivered	Steps per day and minutes walked continuously	4 weeks-30 months	No studies demonstrated statistically significant effects on PA.	Critically low
Afshin et al (2016) [99]	33 (224)	Narrative synthesis of RCTs and quasi-experimental studies	Various: internet and mobile	Level of PA	1 week-5 years	88% (29/33) of studies reported significant improvement in PA; 83% (5/6) of phone interventions were effective, including 66% (2/3) of SMS text messaging interventions, 100% (2/2) of apps, and 100% (1/1) of automated voice response.	Critically low
Carvalho de Menzes et al (2016) [53]	13 (18)	Narrative synthesis of all study designs	Various: email, telephone, websites	Level of PA	1-36 months	Most studies demonstrated statistically significant improvements in the level of PA.	Critically low
Hakala et al (2017) [34] (PA only)	13 (23)	Meta-analysis of RCTs	Various: mobile, text messages, pedometers, wearables, email	PA: self-reported or using an accelerometer or pedometer	3 weeks-24 months	No differences were observed between the experimental and control groups (risk ratio 1.03; 95% CI 0.92 to 1.15; *P*=.57).	Critically low
Muellmann et al (2018) [39] (PA only)	13 (20)	Narrative synthesis of experimental designs and quasiexperimental studies	SMS text messaging and internet	PA and number of steps per day	4 weeks-24 months	75% (3/4) of studies using mobile phones demonstrated significant differences in the level of PA or steps per day (mixed controls). In 100% (9/9) of studies, internet interventions significantly increased PA compared with nonactive controls.	Critically low
Muller and Khoo (2014) [40] (PA only)	4 (16)	Narrative synthesis of RCTs and quasiexperimental studies	Various: internet and mobile	PA	1 week-18 months	75% (3/4) of studies reported significant improvements in PA; 25% (1/4) of studies reported nonsignificant decrease in PA.	Critically low

XSL•FO
RenderX

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Stephenson et al (2017) [45] (PA only)	15 (17)	Meta-analysis of RCTs	Various: mobile messaging, mobile apps, website, wearable technology	Sedentary behavior	5 days-24 months	Interventions using computer and mobile and wearable technologies can be effective in reducing sedentary behavior. Effectiveness appeared most prominent in the short-term and lessened over time. Meta-analysis of 88% (15/17) of RCTs suggested that computer, mobile, and wearable technology tools resulted in a mean reduction of −41.28 min/day of sitting time (95% CI −60.99 to −21.58; I^2=77%). The pooled effects showed mean reductions at short (≤3 months), medium (>3 to 6 months), and long-term (>6 months) follow-up of −42.42 min/day, −37.23 min/day, and −1.65 min/day, respectively.	Critically low
Nonactive controls							
Jenkins et al (2009) [36] (PA only)	5 (22)	Narrative synthesis of RCTs	Internet	PA	0-24 months	Results were mixed; internet interventions can be effective, compared with control conditions, although poor compliance was an issue. 50% (2/4) studies reported an increase in PA compared with nonactive controls while 2 studies found no difference.	Critically low
Bock et al (2014) [24] (PA only)	4 (50)	Narrative synthesis of RCTs and quasiexperimental studies	Internet or computer	Weekly PA, proportion of sufficiently active persons; step counts	0 weeks-3 years	Interventions had a nonsignificant, positive effect on PA (*P*=.88).	Critically low
Krebs et al (2010) [109]	25 (76)	Meta-analysis of RCTs	Computer-delivered	Minutes of PA	1-18 months	The mean effect size was *g*=0.16 (95% CI 0.10 to 0.21).	Low
Bort-Roig et al (2014) [25] (PA only)	5 (26)	Narrative synthesis of comparative and pre-postdesign	Mobile	PA (steps); energy expenditure; body weight and body fat; blood pressure and cholesterol; QoL	2 weeks-6 months	80% (4/5) of studies assessing PA intervention effects reported PA increases, with mean PA increases ranging from 800 to 1104 steps/day. Studies were small with differences in baseline characteristics.	Critically low
Direito et al (2017) [30] (PA only)	17 (21)	Meta-analysis of RCTs	Mobile	PA, MVPA, walking and sedentary behavior	1-52 weeks	Not effective for MVPA outcomes, based only on adult studies SMD 0.14 (95% CI −0.10 to 0.37). For sedentary behavior outcomes, SMD −0.21 (95% CI −0.59 to 0.18).	Critically low
Freak-Poli et al (2013) [32] (PA only)	4 (4)	Narrative synthesis of RCTs and cluster RCTs	Wearable technology	PA; sedentary behavior; BMI; blood lipids; blood pressure; QoL; adverse effects	3-8 months	Overall, there was insufficient evidence to assess the effectiveness of pedometer interventions in the workplace. 75% (3/4) of studies compared with a minimal control group, 33% (1/3) of studies observed an increase in PA under a pedometer program, but the other two did not find a significant difference.	Moderate

XSL•FO
RenderX

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
An et al (2017) [49]	21 (22)	Meta-analysis of RCTs, pre-post studies, and cohort studies	Social media	PA, sedentary behavior	3-102 weeks	Interventions increased daily number of steps taken by 1530 (95% CI 82 to 2979). However, they were not associated with energy expenditure, total PA, or MVPA.	Critically low
Tsoli et al (2018) [73]	3 (15)	Meta-analysis of RCTs	Interactive voice responses	PA	6 weeks-12 months	Interventions led to a small but statistically significant increase in PA (g=0.254; 95% CI 0.068 to 0.439; k=3; P=.007).	Critically low
Active controls							
Beishuizen et al (2016) [102]	5 (57)	Meta-analysis of RCTs	Internet	Level of PA	4 weeks-3 months	Interventions led to an increase in PA (SMD 0.25; 95% CI 0.10 to 0.39).	Low
Covolo et al (2017) [104]	23 (40)	Narrative synthesis of RCTs	Mobile apps	Daily steps, frequency, and intensity of PA	6 months-2 years	30% (7/23) of RCTs showed a significant increase in PA in the intervention group (measured in daily steps, frequency of PA, or level of intensity), 48% (11/23) of studies did not show a significant increase, and in 21% (5/23) studies, outcome measures were inconsistent in whether there was a significant difference between intervention and control.	Critically low
Mateo et al (2015) [38] (PA only)	10 (11)	Meta-analysis of controlled trials	Mobile apps	PA, MVPA, and steps	6 weeks-9 months	Compared with the control group, use of a mobile phone app was associated with significant changes in body weight and BMI of −1.04 kg (95% CI −1.75 to −0.34; I^2=41%) and −0.43 kg/m^2 (95% CI −0.74 to −0.13; I^2=50%), respectively (k=9); however, a nonsignificant difference in PA was observed between the intervention and comparison groups (SMD 0.40; 95% CI −0.07 to 0.87; I^2=93%).	Critically low
Song et al (2018) [44] (PA only)	6 (8)	Narrative synthesis of all study types	Mobile	PA (frequency and step count); BMI; blood glucose	4 weeks-6 months	Significant effects on frequency of PA in 80% (4/5) of studies (though the effect was reported to have disappeared after the 12-week follow-up), step count in 66% (2/3) of studies, BMI in 50% (2/4) of studies, and reduction in glucose in 100% (2/2) studies.	Critically low

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Cheatham et al (2018) [28] (PA only)	25 (25)	Narrative synthesis of controlled clinical trials	Wearable technology	PA; BMI; weight; blood pressure; Resting Energy Expenditure; body composition; cardiovascular fitness; work productivity and absenteeism; waist circumference; blood parameters	3 weeks-24 months	An activity tracker combined with a comprehensive weight loss program may provide superior short-term (≤6 months) results than a standard weight loss program in middle aged or older adults. 80% (20/25) of studies reported higher weight loss when an activity tracker was used with a weight loss intervention.	Critically low

[a]PA: physical activity.

[b]MVPA: moderate-to-vigorous physical activity.

[c]RCT: randomized controlled trial.

[d]SMD: standardized mean difference.

[e]QoL: quality of life.

Evidence for the effectiveness of internet interventions on physical activity has been mixed. In total, 5 out of 10 reviews were positive [26,29,33,108,113], including 2 meta-analyses that found small but significant effects of internet interventions: Cohen *d*=0.14 [29] and Cohen *d*+=0.24 [113]. However, there was significant heterogeneity across studies [29]. In contrast, 5 studies were not positive [35,47,63,100,110], one of which was very unfavorable, with only 1 of 9 (11%) studies demonstrating an effect of the intervention [100]. Two meta-analyses found that the effect of internet interventions on physical activity was not significant [63,110].

A total of 4 reviews of social media interventions were mixed. In total, 2 meta-analyses of social media interventions found no significant difference in changes in physical activity [65,75], and a narrative synthesis reported mixed results [76]. However, one narrative synthesis found that 76% of studies using web-based social networks had positive results for physical activity [56].

The results of the mobile interventions to improve health were more positive. In total, 8 of 10 (80%) narrative syntheses reported a majority of positive results [25,27,31,39,41,42,60,99], with one reporting an increase of 800 to 1104 steps per day [25]. One review noted that effective interventions used SMS text messaging communication or self-monitoring [42]. A review that was specifically on SMS text messaging reported that effect sizes were all greater than 0.20, and the median was 0.50, a medium effect size [27]. In contrast, 2 narrative syntheses reported that most mobile trials did not show any benefits [61,111].

There was mixed evidence of active gaming across 3 reviews. One review found that gamification has a positive impact on physical activity and found evidence that gamification can increase motivation to exercise [37]. However, another review found a positive effect on attendance but not on physical activity or BMI [46]. A third review found that active gaming did not support increases in either physical activity or attendance [43].

Computer-delivered interventions in physical activity behaviors did not have consistent results in either weight loss or weight maintenance trials [74].

In total, 4 of the 5 reviews assessing a variety of interventions found favorable results [40,45,53,99]. One of the narrative syntheses reported a wide range of values for improvement, from 1.5 to 153 extra minutes of physical activity a week and 1000 to 2600 steps per day [99]. A meta-analysis found that computer, mobile, and wearable technology led to a mean change of −41.28 minutes per day of sitting time (a reduction in sitting time) [45]. However, one meta-analysis found no difference between the experimental and control groups [34].

Effectiveness of Digital Interventions on Physical Activity Compared With Nonactive Controls

Compared with minimal controls, evidence for the effectiveness of digital interventions has been mixed.

For internet interventions, one review found favorable evidence [39], another found unfavorable evidence [24], and a third found mixed evidence [36].

The 3 reviews of mobile interventions have also provided mixed evidence. One narrative synthesis found that interventions were effective, with 4 studies (3 pre-post and 1 comparative) reporting increases of 800 to 1104 steps per day [25]. However, another study found that mobile interventions were not effective in increasing physical activity of moderate-to-vigorous intensity or in decreasing sedentary behavior [30]. Wearables were also not very effective, with only 1 of 3 (33%) studies comparing a pedometer with a minimal control showing increased physical activity [32].

Social media–based interventions increased the daily number of steps taken by 1530 steps per day [49]. However, they were not associated with energy expenditure, total physical activity, or moderate-to-vigorous physical activity.

There were small effect sizes for both computer-delivered interventions (*g*=0.16) [109] and interactive voice response–based interventions (*g*=0.254) [73].

XSL•FO
RenderX

Effectiveness of Digital Interventions on Physical Activity Compared With Active Controls

There were mixed results compared with active controls.

A meta-analysis of internet interventions found an increase in physical activity with an SMD of 0.25 compared with active controls [102].

In total, 3 reviews of mobile phones had active controls, and there were mixed results. A meta-analysis found that the use of a mobile phone app was associated with significant changes in body weight (−1.04 kg) and BMI (−0.43 kg/m^2); however, there was no significant difference in physical activity between the 2 groups [38]. A narrative synthesis app was also not favorable for assessing changes in physical activity, with less than half of the studies showing a significant increase in physical activity in the intervention group [104]. However, another narrative synthesis of general mobile interventions found that most studies had interventions that led to changes in body weight, increases in step count, and increases in frequency of physical activity [44].

There were also promising results from a review on wearables: when an activity tracker is combined with a comprehensive weight loss program, it may provide superior short-term (≤6 months) results than a standard weight loss program in middle-aged or older adults (>30 years) [28].

Sustainability of Effects on Physical Activity at Follow-Up

There was little evidence on sustainability, as many physical activity studies did not have follow-up assessment postintervention or only had follow-ups relatively soon after the intervention end point.

There is some evidence that digital interventions can have sustained effects. A meta-analysis assessing combinations of digital technologies found that the pooled effects showed mean changes (reductions) at short (≤3 months), medium (3 to 6 months), and long-term follow-up (>6 months) of −42.42 minutes per day, −37.23 minutes per day, and −1.65 minutes per day, respectively [45]. A meta-analysis of internet interventions also found a small but significant effect on physical activity for follow-ups at least six months postintervention (Cohen *d*=0.11) [29]. The sustainability of internet interventions was also supported by a narrative synthesis that found that only 12 of 35 (34%) studies had follow-up assessments, which ranged from 7 weeks to 15 months postprogram; 10 out of 12 (83%) studies demonstrated successful maintenance of physical activity and/or secondary measures indicative of positive changes in physical activity; however, follow-up durations were primarily shorter: in 9 studies, follow-up was conducted at less than 12 months [26]. However, for mobile interventions, 2 reviews found evidence that effects tended to decrease in the long term [31], with effects disappearing after as little as 12 weeks [44].

Diet and Physical Activity (Weight Management)

Review Characteristics

A total of 35 reviews reported on both diet and physical activity. The breakdown of their characteristics is shown in Multimedia Appendix 6.

Effectiveness of Digital Interventions on Diet and Physical Activity (Weight Loss) Compared With Mixed (Active and Nonactive) Controls

Overall, digital interventions were generally found to be effective, with mobile phone interventions in particular having consistently positive results (Table 5).

XSL•FO
RenderX

Table 5. Results of reviews on diet and physical activity combined, ordered by type of control and further ordered by mode of delivery of intervention.

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Mixed (active and nonactive) controls							
Aalbers et al (2011) [47]	5 (10)	Narrative synthesis of RCTs[a] and nonrandomized pre-post controlled trials	Internet	Body weight and body weight regain	1.5-6.5 months	40% (2/5) of studies reported effect sizes on body weight with small-to-medium significant effects; 1 study reported weight regain but did not reach significance.	Critically low
Aneni et al (2014) [100]	20 (29)	Narrative synthesis of RCTs	Internet	Weight, BMI, waist circumference, and body fat	6-24 months	Modest improvements were observed in more than half of the studies with weight-related outcomes; 20 studies reported on body weight: 75% (15/20) of high quality and 5 of 20 (25%) low quality); 47% (7/15) high-quality studies reported significant improvement.	Critically low
Beishuizen et al (2016) [102]	7 (57)	Meta-analysis of RCTs	Internet	Systolic blood pressure, diastolic blood pressure, HbA_{1c}[b] level, cholesterol level, weight, and level of physical activity	3-60 months	There was a significant reduction in systolic blood pressure (MD[c] –2.66 mm Hg; 95% CI –3.81 to –1.52), diastolic blood pressure (MD –1.26 mm Hg; 95% CI –1.92 to –0.60), HbA_{1c} level (MD –0.13%; 95% CI –0.22 to –0.05), LDL[d] cholesterol level (MD –2.18 mg/dL; 95% CI –3.96 to –0.41), weight (MD –1.34 kg; 95% CI –1.91 to –0.77), and an increase in physical activity (SMD[e] 0.25; 95% CI 0.10 to 0.39).	Low
Fry et al (2009) [57]	8 (19)	Narrative synthesis of all study types	Internet	Diet and physical activity	8 weeks-30 months	There were generally positive effects of prompts; there was not enough evidence to know whether the medium in which prompts were sent through affected their effectiveness but personal contact with a counsellor did enhance effectiveness.	Critically low
Hou et al (2013) [108]	7 (38)	Narrative synthesis	Internet	Body fat, weight, and dietary fat intake	0-12 months	In 71% (5/7) of studies, intervention groups lost more body fat, body weight, and dietary fat intake and maintained higher weight loss at 12 months.	Critically low
Manzoni et al (2011) [62]	26 (26)	Narrative synthesis of all study types	Internet	Weight loss and weight loss maintenance	3-24 months	Internet-based weight loss interventions enhanced by professional feedback provided through the internet are more effective for weight loss than website-only programs but less effective than telephone counselling. 93% (13/14) of studies showed a further improvement in mean weight loss (weight maintenance) after the end of the trials.	Critically low

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Seo et al (2015) [69]	31 (31)	Meta-analysis of RCTs	Internet	Waist circumference	4 weeks-2 years	Internet-based interventions showed a significant reduction in waist circumference (mean change –2.99 cm; 95% CI −3.68 to −2.30; I^2=93.3%) and significantly better effects on waist circumference loss (mean loss 2.38 cm; 95% CI 1.61 to 3.25; I^2=97.2%) than minimal interventions such as information-only groups; no differences with respect to waist circumference change between internet-based interventions and paper-, phone-, or person-based interventions (mean change −0.61 cm; 95% CI −2.05 to 0.83; *P*=.42; k=31).	Critically low
Sherrington et al (2016) [70]	12 (12)	Meta-analysis of RCTs	Internet	Weight loss	3-24 months	The internet-delivered weight loss interventions providing personalized feedback resulted in an MD of 2.13 kg (*P*<.001) greater weight loss in comparison with control groups receiving no personalized feedback. Heterogeneity levels showed considerable and significant heterogeneity (I^2=99%; *P*<.001) between control groups not receiving personalized feedback and the internet-delivered weight loss interventions providing personalized feedback.	Critically low
Elaheebocus et al (2018) [56]	11 (134)	Narrative synthesis of RCTs	Social media	Body weight	6-48 months	82% (9/11) of studies using web-based social networks had positive results for weight loss.	Critically low
Maher et al (2014) [61]	5 (10)	Narrative synthesis	Social media	Weight	8 weeks-24 months	Findings were mixed, from negligible to large effect sizes for weight loss.	Critically low
Mita et al (2016) [65]	10 (16)	Meta-analysis of RCTs	Social media	Weight change	1-12 months	Meta-analysis of all trials showed no significant differences for body weight (significant mean difference 0.07; 95% CI −0.17 to 0.20).	Moderate
Williams et al (2012) [75]	10 (22)	Meta-analysis of RCTs	Social media	BMI; body weight; diet	3 months-24 months	Meta-analysis showed no significant differences in changes in weight (SMD 0; 95% CI −0.19 to 0.19; 10 studies); however, pooled results from 5 studies showed a significant decrease in dietary fat consumption with social media (SMD −0.35; 95% CI −0.68 to −0.02).	Critically low

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Willis et al (2017) [76]	5 (5)	Narrative synthesis of all study types	Social media	Body weight; body composition; blood pressure; and blood markers	8 weeks-6 months	100% (5/5) of studies reported a reduction in baseline weight. 60% (3/5) of studies reported significant decreases in body weight when online social networks was paired with health educator support. Only one study reported a clinically significant weight loss of 55%.	Critically low
Bacigalupo et al (2013) [50]	5 (7)	Narrative analysis of RCTs	Mobile	Weight loss and BMI	9-52 weeks	Strong evidence for weight loss in the short term with moderate evidence for the medium term.	Low
Covolo et al (2017) [104]	21 (40)	Narrative synthesis of RCTs	Mobile	BMI and waist circumference	6-12 months	62% (13/21) of studies did not find a statistical difference in changes in weight. 24% (5/21) of studies found that a mobile app was more effective compared with controls (P<.05). In 3 studies, this did not differ significantly between the 2 groups.	Critically low
Head et al (2013) [107]	3 (19)	Meta-analysis of RCTs	Mobile (SMS text messaging)	Weight	Mean 81.26 days	The weighted mean effect size for weight loss was Cohen d=0.255 (95% CI .056 to .455; P=.01; k=3).	Critically low
Liu et al (2015) [59]	9 (14)	Meta-analysis of RCTs	Mobile	Weight and BMI	3-30 months	Compared with the control group, mobile phone intervention was associated with significant changes in body weight and body mass index (weight [kg]/height (m^2) of −1.44 kg (95% CI −2.12 to −0.76) and −0.24 units (95% CI −0.40 to −0.08), respectively; no differences between shorter and longer trials (< or ≥6 months; k=22).	Critically low
Lyzwinksi et al (2014) [60]	8 (17)	Meta-analysis of RCTs	Mobile	Body weight and BMI	8 weeks-12 months	75% (6/8) of studies of mobile phone interventions found significant changes in weight favoring the mobile phone intervention groups over the controls; the meta-analysis generated a medium, significant effect size of 0.430 (95% CI 0.252 to 0.609; P≤.01), favoring mobile interventions.	Critically low

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Palmer et al (2018) [111]	3 (71)	Meta-analysis of RCTs	Mobile	Body weight and triglyceride levels	24 hours-6 months	There were, at best, modest benefits of diet and physical activity interventions. The effect of SMS text messaging–based diet and physical activity interventions on incidence of diabetes was pooled (risk ratio 0.67; 95% CI 0.49 to 0.90; I^2=0.0%); end point weight was pooled (MD −0.99 kg; 95% CI −3.63 to 1.64; I^2=29.4%); percentage change in weight was pooled (MD −3.1; 95% CI −4.86 to −1.3; I^2=0.3%); and triglyceride levels was pooled (MD −0.19 mmol/L; 95% CI −0.29 to −0.08; I^2=0%).	Moderate
Schoeppe et al (2016) [68]	10 (27)	Narrative synthesis of RCTs, randomized trials, controlled trials, and pre- and poststudies	Mobile	Physical activity; diet; weight status; BMI; blood pressure; sedentary behavior; and fitness	1-24 weeks	40% (4/10) of studies that measured weight reported significant improvement in weight status; apps were more successful when used alongside other intervention components than when used alone.	Critically low
Siopis et al (2015) [71]	6 (14)	Meta-analysis of RCTs, quasi-RCTs, and pre-post studies	Mobile	Body weight and BMI	8 weeks-12 months	The weighted mean change in body weight in intervention participants was −2.56 kg (95% CI −3.46 to −1.65) and in controls, −0.37 kg (95% CI −1.22 to 0.48).	Critically low
Wieland et al (2012) [74]	18 (18)	Meta-analysis of RCTs, quasi-RCTs, and quasiexperimental studies	Computer based	Weight	4 weeks-30 months	At 6 months, computer-based interventions led to greater weight loss than minimal interventions (MD −1.5 kg; 95% CI −2.1 to −0.9; 2 trials) but less weight loss than in-person treatment (MD 2.1 kg; 95% CI 0.8 to 3.4; 1 trial). At 6 months, computer-based interventions were superior to a minimal control intervention in limiting weight regain (MD −0.7 kg; 95% CI −1.2 to −0.2; 2 trials) but not superior to infrequent in-person treatment (MD 0.5 kg; 95% −0.5 to 1.6; 2 trials).	Critically low
Afshin et al (2016) [99]	35 (224)	Narrative synthesis and meta-synthesis for RCTs and quasiexperimental studies	Various: internet and mobile	Weight	3-30 months	69% (24/35) of studies reported significant improvements in adiposity following the intervention. 81% (13/16) of RCTs reported significant reductions in adiposity; using the internet in the weight loss program resulted in 0.68 kg (95% CI 0.08 to 1.29 kg) additional weight reduction over a period of 3 to 30 months; in studies finding significant weight reduction, the magnitude of weight change ranged from 1 to 6 kg after 6 months of follow-up.	Critically low

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Allen et al (2014) [48]	38 (39)	Narrative synthesis of randomized trials	Various: internet, messaging, chat rooms, and mobile	Weight loss	5 weeks-24 months	53% (21/39) of RCTs reported statistically significant weight loss in the intervention group as compared with the control group; the proportion varied by mode of delivery, the highest proportion of successful trials involving SMS text messaging or email (67%), followed by online chat rooms (50%), web-based (48%), and self-monitoring with technology (43%).	Critically low
Bassi et al (2014) [51]	8 (28)	Narrative analysis of RCTs	Various: internet and mobile	BMI and weight	12 months	Results were mixed; 2 studies reported significant improvements with weight loss; however, effects were typically short lived, and more weight is regained in a primarily technology-based approach, as compared with personal contact.	Critically low
Carvalho de Menzes et al (2016) [53]	18 (18)	Narrative synthesis of all study types	Various: email, telephone, face-to-face, and websites	Fat consumption, fruit and vegetable consumption, and physical activity	1-36 months	Approximately half the studies showed weight loss in the intervention group.	Critically low
Coons et al (2012) [54]	13 (13)	Narrative synthesis of RCTs	Various: PDA[f], web-based, and wearables	Body mass; BMI; BP[g]; waist circumference; RHR[h]; physical activity; body fat percentage; energy intake; and EE[i]	12 weeks-24 months	50% (6/12) of weight loss trials reported significantly greater weight loss among individuals randomized to technology interventions compared with controls; insufficient evidence to determine the effectiveness of interventions for weight maintenance.	Critically low
Dutton et al (2014) [55]	18 (22)	Narrative synthesis of all study types	Various: mobile, internet, and podcasts	Weight	3 weeks-24 months	67% (12/18) of trials found significant differences in weight loss at one or more assessments.	Critically low
Maxwell (2015) [64]	Not reported	Narrative synthesis of all study types	Technology interventions, including web-based and mobile	Healthy eating and active living	Not reported	Men participate in technology-based healthy lifestyle interventions less than women; maintenance of behavior is challenging.	Critically low
Podina and Fodor (2018) [66]	43 (47)	Meta-analysis of RCTs	Various: mobile messaging, mobile app, and website	Weight, BMI, waist circumference, and percentage of body fat	3-24 months	Standard active treatment was more effective than eHealth interventions with regard to weight (g=−0.31; 95% CI − 0.43 to −0.20). There was a statistically significant, albeit small effect size favoring eHealth interventions relative to passive control groups for weight (g=0.34; 95% CI 0.24 to 0.44) and behavioral outcomes (g=0.17; 95% CI 0.07 to 0.27).	Critically low

XSL•FO
RenderX

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Ryan et al (2019) [67]	6 (6)	Narrative synthesis of randomized trials	Various: mobile or internet	Weight loss	5 weeks-24 months	Tailored interventions were found to be more effective in supporting weight loss than generic or waitlist controls in 66% (4/6) of articles. Effect sizes were very small to moderate, with evidence of fluctuations in effect sizes and differences of effect between tailored and non-tailored interventions, and between tailoring types, over time.	Critically low
Nonactive controls							
An et al (2017) [49]	21 (22)	Meta-analysis of RCTs, pre-post studies, and cohort studies	Social media	Physical activity; sedentary behavior; diet; BMI; hip-waist ratio; body fat; and waist circumference	2-102 weeks	Social media–based interventions were found to reduce body weight by 1.01 kg (95% CI 0.45 to 1.57), BMI by 0.92 kg/m^2 (95% CI 0.29 to 1.54), and waist circumference by 2.65 cm (95% CI 0.86 to 4.43).	Critically low
Tang et al (2016) [72]	18 (27)	Meta-analysis of RCTs	Various	Body weight; BMI; and waist circumference	1-24 months	Participants receiving internet-based, self-directed interventions lost significantly more weight than those receiving minimal intervention or no treatment (MD −1.72 kg; 95% CI −2.60 to −0.84; significant mean difference −0.45; 95% CI −0.67 to −0.23; I^2=80%; *P*<.001) and a significantly greater reduction in BMI levels than those receiving no treatment or minimal intervention (MD −0.47 kg/m^2; 95% CI −0.81 to −0.14; significant mean difference −0.32; 95% CI −0.61 to −0.03; I^2=90%; *P*=.03; 13 evaluations). There was a greater reduction in BMI (MD 0.54 kg/m^2) and waist circumference (2.81 cm) at 0-4 months follow-up than at later times (k=27).	Critically low
Active controls							
Beleigoli et al (2019) [52]	11 (11)	Meta-analysis of RCTs	Internet	Weight and BMI	3-12 months	Compared with offline interventions, digital interventions led to a greater short-term (<6 months follow-up) weight loss (MD −2.13 kg; 95% CI −2.71 to −1.55; 393 participants; high-certainty evidence) but not in the long-term (MD −0.17 kg; 95% CI −2.10 to 1.76; 1104 participants; moderate-certainty evidence).	Critically low

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Kodama et al (2012) [58]	23 (23)	Meta-analysis of RCTs	Internet	Weight loss	3-30 months	Using the internet had a modest but significant additional weight loss effect compared with non-web user control groups (−0.68 kg; *P*=.03). Internet-based interventions were effective for weight loss (−1.00 kg; *P*<.001) but not a substitute for face-to-face support (+1.27 kg; *P*=.01). An additional effect on weight control was observed when the aim of using the internet was initial weight loss (−1.01 kg; *P*=.03) but was not observed when the aim was weight maintenance (+0.68 kg; *P*=.26); furthermore, it was effective to use the internet as an adjunct to face-to-face care (−1.00 kg; *P*<.001) but adverse effects on weight loss were found when it was used as a substitute (+1.27 kg; *P*=.01). The weight loss effect was insignificant (−0.20 kg; *P*=.75) in studies with educational periods ≥12 months and was significant in studies with an educational period <6 months (−1.55 kg; *P*=.001).	Critically Low

[a]RCT: randomized controlled trial.

[b]HbA_{1c}: glycated hemoglobin.

[c]LDL: low-density lipoprotein.

[d]MD: mean difference.

[e]SMD: standardized mean difference.

[f]PDA: personal digital assistant.

[g]BP: blood pressure.

[h]RHR: resting heart rate.

[i]EE: energy expenditure.

Internet interventions were found to be somewhat effective. A total of 5 narrative syntheses found them to be effective in approximately half of the studies [47,62,99,100,108]. In total, 3 meta-analyses quantified weight loss and other health effects. A total of 3 reviews found a significant reduction in weight: mean difference –1.34 kg [102], SMD 2.13 kg [70], and a 0.68-kg additional weight reduction over a period of 3 to 30 months [99]. A fourth review found that internet interventions significantly reduced waist circumference (mean change −2.99 cm) [69]. However, stratified analysis suggested that internet interventions were effective when used in combination with in-person counseling (−1.93 kg), rather than as a substitute [98]. This finding was supported by a narrative synthesis, which reported that internet interventions were more effective when they were enhanced to offer more than just educational resources (several studies found medium effect sizes) [62].

There were mixed results regarding the effectiveness of social media interventions. A total of 2 reviews were favorable [49,56], including a meta-analysis that found that social media–based interventions reduced body weight by 1.01 kg, BMI by 0.92 kg/m^2, and waist circumference by 2.65 cm but did not find significant changes in body fat or body fat percentage [49]. A total of 2 narrative syntheses found effects that were small and not meaningful [61,76]. Two meta-analyses found no significant effects on the diverse primary outcomes of the studies or on body weight [65,75].

Most reviews of mobile phone interventions found that they were effective in achieving weight loss via diet and physical activity. One meta-analysis found a statistically significant medium effect size (Cohen *d*=0.430) in favor of mobile phone interventions [60]. Two others quantified the change in terms of body weight: mobile phone interventions were associated with significant changes in body weight of −1.44 kg and in BMI of $-0.24\ kg/m^2$ compared with controls [59]; the weighted mean body weight change in intervention participants was −2.56 kg compared with −0.37 kg in controls [71]. These results were supported by 3 narrative syntheses, which found evidence that

XSL•FO
RenderX

mobile interventions led to weight loss [50,68,99]. However, one review of apps to promote healthy lifestyles found that most trials did not show significant differences [104], and one of the reviews that looked at the use of apps for diet, physical activity, and sedentary behavior, which concluded that apps led to weight loss, also concluded that the apps were more successful when used alongside other intervention components than when used alone [68].

In total, 4 of 5 narrative syntheses that ranged over a variety of digital interventions found that around half of the interventions were effective compared with controls [48,51,53,54], with only one finding that a large majority (81%) reported a significant reduction in adiposity [99]. One of these studies found that most trials reported within-group weight loss, even when there was no difference between digital interventions and controls [54]. Another study compared the success of different modes of delivery, finding the highest proportion of successful trials involving SMS text messaging or email (67%), followed by online chat rooms (50%), web-based (48%), and self-monitoring with technology (43%) [48].

Effectiveness of Digital Interventions on Diet and Physical Activity (Weight Loss) Compared With Nonactive Intervention Controls

A total of 6 reviews that reported results for digital interventions for diet and physical activity to no intervention or minimal intervention controls all agreed that digital interventions were more effective [66,67,69,70,72,74]. Table 5 provides a summary of the results.

Internet interventions were more effective than nonactive controls according to 3 meta-analyses and 1 narrative synthesis [67,69,70,72]. Internet interventions led to a greater reduction in waist circumference (mean change –2.99 cm, 95% CI −3.68 to −2.30, I2=93.3% vs 2.38 cm, 95% CI 1.61 to 3.25, I2=97.2%) [69]; internet-delivered personal feedback led to greater weight loss (mean difference 2.14 kg) [70]; and self-directed internet interventions led to significantly more weight loss (mean difference −1.56 kg) and showed a significantly greater reduction in BMI (mean difference −0.41 kg/m^2) [72].

Similar effects were observed for computer-based interventions, which led to greater weight loss at 6 months (mean difference −1.5 kg) and were superior to limiting weight regain (mean difference −0.7 kg) [74].

A narrative review of tailored internet interventions found that effect sizes ranged from very small to moderate [67]. This was supported by a meta-analysis that covered various digital interventions, which found small effect sizes favoring digital interventions for weight (g=0.34) and behavioral outcomes (g=0.17) [66].

Effectiveness of Digital Interventions on Diet and Physical Activity (Weight Loss) Compared With Active Controls

The effects of digital interventions on diet and physical activity (with regard to weight loss) compared with active controls were mixed. A total of 2 meta-analyses found no differences between web-based interventions and active offline interventions for weight loss outcomes [52,69]. One meta-analysis of a range of interventions found that standard active treatment was more effective for weight loss (g=0.31) [66]. However, one meta-analysis found that using the internet had a modest but significant additional weight loss effect compared with offline control groups (−0.68 kg; P=.03), with a subgroup analysis showing that the internet was effective compared with controls for achieving weight loss (weight change=−1.01 kg) but not weight maintenance [58]. The same meta-analysis also found that it was effective to use the internet as an adjunct to face-to-face care (−1 kg; P<.001) but that adverse effects on weight loss were found when it was used as a substitute (+1.27 kg; P=.01) [58].

Computer-based interventions led to less weight loss than in-person treatment (mean difference 2.1 kg) and were not superior to infrequent in-person treatment in limiting weight regain at 6 months [74].

Sustainability of Effects on Diet and Physical Activity (Weight Loss) at Follow-Up

Although technology-related health interventions may be effective, the maintenance of behavior is challenging [64], and there is insufficient evidence to determine the effectiveness of digital interventions on weight maintenance [54]. One review of internet interventions reported that, in studies finding significant weight reduction, the magnitude of weight change ranged from 1 to 6 kg after 6 months of follow-up [99].

Many studies included in the reviews had short follow-ups. Where longer follow-ups were reported, effectiveness typically diminished over time. Examples of the diminishing effects are clear in the 2 reviews. One meta-analysis of internet-delivered personal feedback found a greater reduction in BMI (mean difference 0.54 kg/m^2) and waist circumference (2.81 cm) at 0 to 4 months follow-up than at later times compared with undefined control groups [72]. A narrative synthesis supports these findings, concluding from multiple high-quality randomized controlled trials (RCTs) that weight loss occurs for a short term through mobile interventions, with moderate evidence for the medium term [50]. Two other meta-analyses reported significantly greater weight loss in favor of digital interventions in the medium term only (<6 months): 2.13 kg [52] and 1.55 kg [58]. One meta-analysis assessed differences between trials of different lengths, reporting no differences between shorter and longer trials (<6 or ≥6 months) [59].

Smoking

Review Characteristics

There were 28 reviews on smoking (see Multimedia Appendix 6 for summary characteristics).

Effectiveness of Digital Interventions on Smoking Compared With Mixed (Active and Nonactive) Controls

Digital interventions were generally effective across different modes of delivery (Table 6).

XSL•FO
RenderX

Table 6. Results of reviews on smoking, ordered by type of control and further ordered by mode of delivery of intervention.

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Mixed (active and nonactive) controls							
Afshin et al (2016) [99]	22 (224)	Narrative synthesis of RCTs[a] and quasiexperimental studies	Internet and mobile interventions	Abstinence	1 week-2 years	77% (17/22) of studies reported a significant increase in abstinence. In studies reporting benefits, the OR[b] for 7-day abstinence at 6 months ranged from 1.6 (95% CI 1.1 to 2.4) to 2.7 (95% CI 1.8 to 4.0).	Critically low
Boland et al (2016) [83] (Smoking only)	13 (13)	Meta-analysis of RCTs	Various: website or computer program and SMS text messaging	Abstinence	1 week-18 months	Interventions increased the odds of smoking cessation for disadvantaged groups at 1 month (OR 1.70; 95% CI 1.10 to 2.63), 3 months (OR 1.30; 95% CI 1.07 to 1.59), 6 months (OR 1.29, 95% CI 1.03 to 1.62) and 18 months postintervention (OR 1.83, 95% CI 1.11 to 3.01).	Low
Aneni et al (2014) [100]	3 (29)	Narrative synthesis of RCTs	Internet	Cessation	12 months	3 follow-up studies that measured smoking cessation showed significant intervention effects, although they were assessed to be of low quality.	Critically low
Chebli et al (2016) [103]	9 (16)	Narrative synthesis of RCTs	Internet	Cessation and reduction	1-12 months	Internet-based interventions may have a positive effect on smoking cessation. Several studies found that web-based use and number of log-ins was positively associated with quit outcomes.	Critically low
Cheung et al (2017) [85] (Smoking only)	6 (45)	Narrative synthesis and meta-analysis of RCTs and quasi-RCTs	Internet	Cessation	>4 weeks	Only 13% (6/45) of studies provided data on effectiveness, with 66% (4/6) of studies demonstrating effectiveness. Smokers using a web-based cessation intervention were 1.15 to 2.84 times more likely to become a former smoker compared with the control condition (with a pooled RR[c] 1.39; 95% CI 1.18 to 1.65).	Critically low
Gainsbury and Blaszczynski (2010) [87] (Smoking only)	7 (9)	Narrative synthesis of RCTs and pre-experimental studies	Internet	Abstinence, tobacco use, smoking status, compliance, nicotine dependence, carbon monoxide markers, and toxicity	3-12 months	86% (6/7) of studies reported significantly greater self-reported smoking quit rates or abstinence at the end of the treatment trial for participants in the internet intervention compared with controls. Several trials found improvements at 3, 6, and 12 months.	Critically low
Graham et al (2016) [88] (Smoking only)	40 (40)	Meta-analysis of RCTs	Internet	Abstinence	7 days-3 months	Pooled results from 15 trials (24 comparisons) found a significant effect in favor of experimental internet interventions (RR 1.16; 95% CI 1.03 to 1.31; I^2=76.7%).	Critically low

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Hutton et al (2011) [90] (Smoking only)	15 (21)	Narrative synthesis of RCTs	Internet	Cessation	>1 month	Two RCTs found that a multicomponent intervention with web and nonweb-based elements was more efficacious than a self-help manual, and one of the 2 RCTs found that web-based interventions may be more effective than no treatment. Three trials provided insufficient evidence to demonstrate whether web-based interventions were more efficacious than counselling. Tailored websites in 2 RCTs and greater website exposure in 86% (6/7) of RCTs were associated with higher rates of abstinence.	Critically low
Lustria et al (2013) [110]	8 (40)	Meta-analysis of experimental and quasiexperimental studies	Internet	Abstinence	30 days-6 months	Web ‐ based, tailored interventions had significantly greater improvement in smoking outcomes compared with control conditions, with small effects, Cohen *d*=0.151 (k=8; 95% CI 0.11 to 0.19; *P*<.001).	Critically low
McCrabb et al (2019) [91] (Smoking only)	45 (45)	Meta-analysis of RCTs	Internet	Abstinence	1-18 months	Interventions were effective in the short term (OR 1.29, 95% CI 1.12 to 1.50; *P*=.001) and long term (OR 1.1.9, 95% CI 1.06 to 1.35; *P*=.004).	Low
Shahab and McEwen (2009) [95] (Smoking only)	10 (11)	Meta-analysis of RCTs	Internet	Cessation	>1 month	Interactive interventions were effective compared with untailored booklets or emails (RR 1.8; 95% CI 1.4 to 2.3) increasing 6-month abstinence by 17% (95% CI 12 to 21%); no evidence was found of a difference between interactive and static interventions.	Critically low
Taylor et al (2017) [97] (Smoking only)	61 (67)	Meta-analysis of RCTs and quasi-RCTs	Internet	Cessation	6-12 months	Interactive and tailored internet-based interventions with or without additional behavioral support are moderately more effective than nonactive controls at 6 months or longer, but there was no evidence that these interventions were better than other active smoking treatments.	Moderate
Webb et al (2010) [113]	12 (85)	Meta-analysis of RCTs	Internet	Smoking abstinence	12 months	Interventions that targeted smoking abstinence tended to have small effects on behavior that did not reach statistical significance (Cohen *d*+=0.07; k=12; 95% CI −0.04 to 0.18).	Critically low
Head et al (2013) [107]	5 (19)	Meta-analysis of RCTs	SMS text messaging	Smoking cessation	Mean 81.26 days	The weighted mean effect size for smoking cessation, Cohen *d*=0.447 (95% CI .367 to .526; *P*=.001; k=5).	Critically low

XSL•FO
RenderX

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Scott-Sheldon et al (2016) [94] (smoking only)	18 (20)	Meta-analysis of RCTs	SMS text messaging	Abstinence, cigarette use, quit attempts, and nicotine dependence	Not reported	SMS text messaging was associated with significantly greater odds of abstinence compared with controls: 7-day point prevalence (OR 1.38, 95% CI 1.22 to 1.55; k=16) and continuous abstinence (OR 1.63, 95% CI 1.19 to 2.24; k=7); interventions were also more successful in reducing cigarette consumption (Cohen d_+=0.14; 95% CI 0.05 to 0.23; k=9).	Critically low
Spohr et al (2015) [96] (smoking only)	10 (13)	Meta-analysis of RCTs	SMS text messaging	Cessation	3 and 6 months	Interventions generally increased quit rates compared with controls (OR 1.36, 95% CI 1.23 to 1.51). Intervention efficacy was higher in studies with a 3-month follow-up compared with a 6-month follow-up.	Critically low
Palmer et al (2018) [111]	18 (71)	Meta-analysis of RCTs	Mobile	Abstinence and cessation (verified biochemically)	24 hours-6 months	The effect of SMS text messaging–based smoking cessation support on biochemically verified continuous abstinence was pooled relative risk, RR 2.19 (95% CI 1.80 to 2.68; I^2=0%) and on verified 7-day point prevalence of smoking cessation was pooled RR 1.51 (95% CI 1.06 to 2.15; I^2=0%).	Moderate
Whittaker et al (2016) [98] (smoking only)	12 (12)	Meta-analysis of RCTs and quasi-RCTs	Mobile	Cessation	6 months	Smokers who received support programs were 1.7 times more likely to stay quit than smokers who did not receive the programs (9.3% quit with programs compared with 5.6% who quit with no programs). Most of the studies were of programs relying mainly on text messages.	Moderate
Danielsson et al (2014) [86] (smoking only)	21 (74)	Narrative synthesis of RCTs	Various	Abstinence	>3 months	The studies showed mixed results regarding internet interventions and smoking, with some positive effects for the smoking cessation program that combined the use of both the internet, mobile phones (SMS text messaging), and email.	Critically low

XSL•FO

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
HIQA (2017) [89] (smoking only)	12 (143)[d]	Network meta-analyses of RCTs	Various: internet and mobile	Cessation	6-12 months	Internet-based interventions are superior to control (brief advice or written materials; RR 1.43, 95% CI 1.02 to 2.00; *P*=.04; k=5); Internet-based interventions are superior to doing nothing (RR 1.46, 95% CI 1.18 to 1.81; *P*<.001; k=3); mobile phone–based interventions appear to have similar effectiveness to control (RR 1.18, 95% CI 0.88 to 1.60; *P*=.27; k=3); no evidence of difference between mobile phone–based interventions and internet (RR 1.43, 95% CI 0.88 to 2.31; *P*=.15; k=1).	Low
Hou et al (2013) [108]	5 (38)	Narrative synthesis of studies with comparison or control groups	Web-based computer programs	Cessation	Not reported	2 studies found higher cessation rates in intervention groups than control. 3 studies found no significant differences in quit rates at the end of the intervention or at follow-ups.	Critically low
Myung et al (2009) [92] (smoking only)	22 (22)	Meta-analysis of RCTs	Various: internet or computer based	Abstinence and biochemical markers	>3 months	Intervention groups had a significant effect on smoking cessation (RR 1.44; 95% CI 1.27 to 1.64). Similar findings were observed in web-based interventions (RR 1.40; 95% CI 1.13 to 1.72) and in computer-based interventions (RR 1.48; 95% CI 1.25 to 1.76).	Critically low
Naslund et al (2017) [93] (smoking only)	7 (7)	Narrative synthesis of all study types	Social media	Cessation	30-365 days	71% (5/7) of studies reported significant effects on smoking-related outcomes such as greater abstinence, reduction in relapse, and an increase in quit attempts.	Critically low
Elaheebocus et al (2018) [56]	7 (134)	Narrative synthesis of RCTs	Social media	Cessation	6-48 months	100% (7/7) of studies on smoking cessation using web-based social networks had positive results.	Critically low
Rooke et al (2010) [112]	13 (34)	Meta-analysis of RCTs	Computer based	Abstinence and reduction	1-156 weeks	The weighted average effect size (Cohen *d*) was 0.14; *P*<.001 for studies addressing tobacco use.	Critically low
Nonactive controls							
Chen et al (2012) [84] (smoking only)	60 (60)	Meta-analysis of RCTs and quasi-RCTs	Various: computer and other electronic aids	Cessation	2 days-30 months	Computer and other electronic aids increase the likelihood of cessation compared with no intervention or generic self-help materials but the effect is small (prolonged abstinence: RR 1.32; 95% CI 1.21 to 1.45).	Low
Krebs et al (2010) [109]	32 (88)	Meta-analysis of RCTs	Computer tailored	Abstinence	24 hours-9 months	Mean effect for the 32 studies reporting point prevalence outcome was *g*=0.16 (95% CI 0.12 to 0.19); mean effect for the 16 studies reporting prolonged abstinence measures was *g*=0.24 (95% CI 0.20 to 0.31).	Low
Active controls

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Covolo et al (2017) [104]	2 (40)	Narrative synthesis of RCTs	Mobile apps	30-day point prevalence cessation	30 days	1 trial compared 2 apps and found no evidence of any difference; the other found text messaging produced more abstinence than an app (P<.05).	Critically low

[a]RCT: randomized controlled trial.

[b]OR: odds ratio.

[c]RR: risk ratio.

[d]In total, 12 relevant studies were included in the meta-analysis.

Internet interventions were generally found to be effective (Table 6). A total of 3 relevant meta-analyses found small or small-to-medium effects [85,89,91]: pooled RR 1.39 [85]; RR 1.40 [92], and RR 1.43 [88] and a short-term (≤6 months) OR 1.29 (95% CI 1.12 to 1.50; P=.001) [91]; the latter showed that internet interventions were also successful for the individual outcomes of *prolonged abstinence*, that is, not smoking since a quit date (OR 1.43) and *30-day point prevalence abstinence*, that is, not smoking one or more days before the follow-up (OR 1.75) [91]. However, one narrative synthesis noted that although the 3 studies that measured smoking cessation all showed significant intervention effects, they were all assessed to be of low quality [100].

The 3 reviews of mobile interventions that focused on SMS text messaging found it to be effective, again with small effects: Cohen d=0.14 [94]; OR 1.36 [96]; and OR 1.36 [98]. A fourth meta-analysis differentiated between specific outcomes and found a medium effect (RR 2.19) on biochemically verified continuous abstinence, and a small-to-medium effect (RR 1.51) on verified 7-day point prevalence of smoking cessation was pooled [111]. However, 2 reviews (including 1 meta-analysis) with information on mobile interventions in general did not find that they were effective [89,99].

A meta-analysis of computer-delivered interventions also found a small but significant effect size associated with studies addressing tobacco use (Cohen d=0.14) [112].

There is mixed evidence from reviews that cover a variety of digital technologies. One narrative synthesis [99] and one meta-analysis found that they were effective, with interventions increasing the odds of smoking cessation at 1 month (OR 1.70) [83]. However, another narrative synthesis that included both phone and internet interventions found that there were mixed results [86].

A total of 2 reviews of social media interventions with narrative syntheses both found favorable effects of the interventions on outcomes related to smoking cessation [56,93].

As seen above, separate reviews of internet, mobile, and computer-delivered interventions found small effects for each. One meta-analysis looked for differences in effect sizes between different modes of intervention and found no statistically significant evidence of any differences in effect sizes of internet interventions, intensive advice, telephone support, individual counseling, or group behavior therapy [89].

Effectiveness of Digital Interventions on Smoking Compared With Nonactive Controls

There were small effects of digital interventions compared with nonactive controls for all modes of delivery (Table 6). Meta-analyses found small effects for pooled modes of digital interventions compared with controls: 1 month OR 1.70 (k=13) [83]; pooled estimate for prolonged abstinence, RR 1.32 (k=60) [84], and pooled estimate for point prevalence abstinence, RR 1.14 [84]. Internet interventions were more effective than nonactive controls [88-90,92,97], with 3 meta-analyses finding small effects compared with nonactive controls: RR 1.15 [97], RR 1.46 [89], and RR 1.60 [88]. Computer-tailored interventions had effects sizes of g=0.16 for point prevalence outcomes and g=0.24 for prolonged abstinence [109]. Mobile phone–based interventions appeared to have similar effectiveness to minimal controls (RR 1.18) and were more effective than no intervention (typically either waiting list control or no further contact until follow-up) [89].

Effectiveness of Digital Interventions on Smoking Compared With Active Controls

Most reviews concluded that internet interventions were not more effective than active controls, with 3 reviews (including 2 meta-analyses) not finding differences [88,90,97]. This included a meta-analysis that found no significant effects of internet interventions compared with face-to-face counseling or telephone counseling [88]. However, one narrative synthesis was more positive about the greater effect of internet interventions compared with conventional ones [99].

There was no information on mobile interventions compared with active controls, but one meta-analysis with mixed controls noted that the summary effect sizes favored the treatment groups even when 18 of the 20 (90%) controlled trials used an active control and 12 (66%) of these active controls included some smoking-related content, including smoke-free websites, self-help guidebooks, and smartphone apps [94].

Sustainability of Effects on Smoking at Follow-Up

There was agreement that the effects of internet interventions were sustained for up to 6 months [83,87,91,95]. This was quantified as interventions increasing the 6-month abstinence by 17% [95], increasing the odds of cessation at the 6-month

XSL•FO
RenderX

follow-up (OR 1.29) [83], and increasing the likelihood of *prolonged abstinence* (ie, not smoking since a quit date; OR 1.19) [91]. However, there was disagreement about whether there were significant effects at 12-month follow-ups, with 2 reviews in favor [87,89], one quantifying the quit rate at 12 months as 8% [89] but another reporting that the positive results of internet interventions were not generally maintained at 1-year follow-up assessments [103].

There is mixed evidence on the sustainability of the effects of mobile interventions. A total of 2 meta-analyses found that mobile interventions were effective in the medium term, with a quit rate of 13% [89] and effects on biochemical measures of quitting at 6 months (RR 1.83) [98]. However, a study of SMS text messages suggested that any effect was not sustained [96].

Regarding computer-delivered interventions, one meta-analysis found that computer programs increased the odds of cessation at the 3-month (OR 2.04), 12-month (OR 1.68), and 18-month follow-up (OR 1.83) [83]. A meta-analysis of computer-delivered interventions did not find evidence of differential effects depending on the length of follow-up or number of sessions [112].

A total of 2 reviews that considered a range of different technologies found evidence of sustained effects. A narrative synthesis of internet and mobile interventions found that the OR for 7-day abstinence at 6 months ranged from 1.6 to 2.7 [99]. A meta-analysis found that digital interventions increased the odds of smoking cessation at 3 months (OR 1.30), 6 months (OR 1.29), and 18 months (OR 1.83) postintervention [83].

In a pooled analysis of web-based and computer-based interventions, the smoking cessation rate was 14.8% in the intervention group and 14.3% in the control group at the short-term 3-month follow-up (P=.42), 11.7% and 7.0% at the midterm 6- to 10-month follow-up (P<.001), and 9.9% and 5.7% at the long-term 12-month follow-up (P<.001), respectively [92].

One meta-analysis that covered multiple intervention types found that SMS text messaging had the highest OR (2.81) at the 1-month follow-up, followed by the use of computer programs at the 3-month follow-up (OR 2.04), 12-month follow-up (OR 1.68), and 18-month follow-up (OR 1.83) and websites at 6 months (OR 1.37), while a DVD intervention and integrated videotelephony did not increase the odds of cessation compared with no intervention [83].

Alcohol

A total of 13 papers covered alcohol [73,77-82,99,103,104,111-113]. Multimedia Appendix 5 presents a breakdown of the study characteristics.

Effectiveness of Digital Interventions on Alcohol Consumption Compared With Mixed (Active and Nonactive) Controls

In total, 7 of 8 (88%) reviews with mixed controls reported favorable evidence that digital interventions were effective in decreasing alcohol consumption (Table 7), although one review noted that the controls were just as effective [103]. A total of 2 meta-analyses reported small effect sizes (Cohen d=0.26 [112] and Cohen d=0.14 [113]). A narrative synthesis of interventions using novel technologies found that, in studies finding benefits and reporting compliance with drinking recommendation as an outcome, the OR for drinking within the recommended limit ranged from 1.7 to 3.7 (small/medium to medium/large effects) [99]. In contrast, the sixth review, which surveyed mobile phone interventions, reported that the results were inconclusive for alcohol reduction, and the authors declined to perform a meta-analysis because the results were self-reported and therefore at risk of overstating the benefits [111].

XSL•FO
RenderX

Table 7. Effectiveness of digital interventions on alcohol consumption, sorted by controls and further ordered by intervention type.

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Mixed (active and nonactive) controls							
Afshin et al (2016) [99]	47 (224)	Narrative synthesis of RCTs[a] and quasiexperimental studies	Various: internet, mobile, computer software, and sensors	Alcohol frequency and quantity, binge drinking, estimated blood alcohol concentration, alcohol dependency, and Alcohol Use Disorder Identification Test scores	1 week-2 years	34% (39/47) of studies, 41 RCTs and 6 quasiexperimental, reported a significant decrease in alcohol use; 83% (33/41) of RCTs reported statistically significant benefits.	Critically low
Chebli et al (2016) [103]	2 (16)	Narrative synthesis of RCTs	Internet	Cessation and reduction of alcohol	1-12 months	Both studies demonstrated positive treatment outcomes in both arms, but there were no differences between internet intervention and control.	Critically low
Kaner et al (2017) [77] (Alcohol only)	57 (57)	Narrative synthesis and meta-analysis of RCTs	Computer and mobile	Alcohol consumption and frequency	1-12 months	Alcohol consumption reduced by approximately 23 g per week (95% CI 15 to 30) at follow-up (1-12 months; based on 41 studies). Frequency of consumption reduced (based on 15 studies): participants who engaged with digital interventions had less than one drinking day per month fewer than no intervention controls (moderate - quality evidence); had about one binge drinking session less per month in the intervention group (moderate - quality evidence); and drank one unit per occasion less than no intervention control participants (moderate - quality evidence). Compared with face-to-face interventions, there was no difference in alcohol consumption at the end of follow-up (mean difference 0.52 g/week; 95% CI −24.59 to 25.63; low - quality evidence).	Low
Kolar et al (2015) [78] (Alcohol only)	2 (18)	Narrative synthesis of all studies	Internet	Alcohol quantity and frequency	1 month	100% (2/2) of studies found reduced alcohol consumption in both arms but no significant differences between arms.	Critically low
Palmer et al (2018) [111]	8 (71)	Narrative synthesis of RCTs	Mobile	Self-report alcohol consumption	Not reported	The effects of alcohol reduction interventions were inconclusive.	Moderate
Rooke et al (2010) [112]	9 (34)	Meta-analysis of RCTs	Computer-delivered	Abstinence and reduction of alcohol	1-156 weeks	The weighted average effect size (Cohen *d*) was 0.20 (*P*<.001).	Critically low
Vernon et al (2010) [81] (Alcohol only)	15 (15)	Narrative synthesis of all studies	Computer-delivered	Alcohol consumption	30 days-12 months	All but one intervention showed significant improvement in at least one drinking-related outcome. However, interventions were heterogenous and preintervention alcohol consumption was not standardized.	Critically low

XSL•FO
RenderX

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Webb et al (2010) [113]	9 (85)	Meta-analysis of RCTs	Internet	Alcohol consumption	Not reported	Small effects were observed for alcohol consumption (Cohen d_+=0.14; k=9; 95% CI 0.00 to 0.27).	Critically low
Nonactive controls							
Black et al (2016) [82] (Alcohol only)	93 (93)	Meta-analysis of RCTs	Computer delivered	Alcohol consumption: total consumption over a period of time; average alcohol consumption per drinking occasion or drinking day; peak consumption—max consumed on one occasion. Frequency of heavy episodic drinking and of any alcohol consumption	Up to 2 years	Small effects averaging across timepoints, Cohen *d*=0.007 (heavy episodic drinking frequency) to Cohen *d*=0.15 (total consumption); in the short term, there were small-to-medium effects (Cohen *d*+=0.16 to 0.31) and significant effects on all outcomes except drinking frequency; in the medium-to-long term, they produced small (Cohen *d*+=0.07 to 0.12), significant effects on all outcomes.	Critically low
Covolo et al (2017) [104]	1 (40)	Narrative synthesis of RCTs	Mobile	Alcohol frequency	0-2 years	Contrary to expectation, it was found that the mobile app significantly increased the frequency of drinking occasions compared with the control group (*P*=.001).	Critically low
Riper et al (2011) [79] (Alcohol only)	9 (9)	Meta-analysis of RCTs	Internet	Alcohol consumption	Up to 12 months	An overall medium effect size (*g*=0.44; 95% CI 0.17 to 0.71; random effect model) in favor of the intervention groups was found.	Critically low
Riper et al (2014) [80] (Alcohol only)	16 (16)	Meta-analysis of RCTs	Internet	Alcohol consumption	1 to 12 months	A small but significant overall effect size in favor of internet interventions (*g*=0.20; 95% CI 0.13 to 0.27; *P*=.001) was found. Participants in internet-based interventions consumed approximately 22 g of ethanol less and were more likely to adhere to low-risk drinking guidelines (risk difference 0.13; 95% CI 0.09 to 0.17; *P*=.001).	Critically low
Tsoli et al (2018) [73]	4 (15)	Meta-analysis of RCTs	Interactive voice responses	Alcohol consumption	6 weeks-12 months	The meta-analysis of included studies demonstrated that interactive voice response–based interventions had no statistically significant effect on alcohol consumption (*g*=−0.077; 95% CI −0.162 to 0.007; k=4; *P*=.07).	Critically low

[a]RCT: randomized controlled trial.

Effectiveness of Digital Interventions on Alcohol Consumption Compared With Nonactive Controls

In total, 4 of 6 (67%) reviews with nonactive controls found an effect of the intervention (Table 7). Of the 4 meta-analyses, 2 found a medium effect on alcohol consumption (*g*=0.44 [80] and *g*=0.44 [79]). A third found a small-to-medium effect on total alcohol consumption (Cohen *d*+=0.31), small effects on 2 other consumption measures, and a measure of frequency of heavy drinking episodes (Cohen *d*+=0.16-0.19) and no effect on drinking frequency [82]. The fourth review found no effect [73].

Two studies quantified the effect on alcohol consumption, finding a reduction in weekly consumption of 22 g of alcohol [80] and 23 g of alcohol [77], approximately 3 UK units. However, when studies with a high risk of bias were excluded, this number decreased to 11 g of alcohol (or 1.5 UK units) per week [77]. With regard to frequency of consumption, participants who were given digital interventions had less than one drinking day per month, which is fewer compared with

XSL•FO
RenderX

no-intervention controls (moderate-quality evidence); had approximately 1 binge-drinking session less per month in the intervention group compared with no-intervention controls (moderate-quality evidence); and drank 1 unit per occasion, which is less than the no-intervention control participants (moderate-quality evidence) [77]. Participants in internet interventions were significantly more likely to adhere to low-risk drinking guidelines at the immediate posttreatment follow-up, compared with the no-intervention controls [80].

Only one review was negative. A narrative synthesis of mobile apps reported that there was a single RCT on alcohol reduction where, contrary to expectation, the frequency of drinking occasions was higher in the intervention group [104].

Effectiveness of Digital Interventions on Alcohol Consumption Compared With Active Controls

In total, 2 reviews that separated active controls found that there were no significant differences between the intervention and control groups [77,99], one of which was specifically compared with face-to-face controls (Table 7) [77].

Sustainability of Effects on Alcohol Consumption at Follow-Up

The effectiveness of the interventions seemed to decrease over time (Table 7). One meta-analysis, which reported small-to-medium effects in the short term (Cohen *d*+=0.16-0.19), found that in the medium to long term, there were small (Cohen *d*+=0.07-0.12), significant effects on all outcomes [82]. A total of 2 reviews reported that, for internet-based intervention studies where there were 3-, 6-, or 12-month follow-up data, no significant differences in effect remained in later follow-up [80,103]. In contrast, one review of computer- or mobile-delivered interventions found that positive differences in measures of drinking were seen at 1, 6, and 12 months [77], and one review of internet interventions found a medium effect size (*g*=0.39), lasting up to 6 or 9 months posttreatment, as compared with no intervention; the effects of the interventions beyond 9 months could not be assessed, but 2 studies in the review suggested that they had faded out by 12 months [79].

Other Combinations

Review Characteristics

A total of 11 reviews covered a number of areas of behavior [101-107,109,110,112,113]. The breakdown of their characteristics is shown in Multimedia Appendix 5.

Effectiveness of Other Digital Combination Interventions Compared With Mixed (Active and Nonactive) Controls

All 5 reviews of internet interventions concluded that they were effective in changing behavior (Table 8). A total of 3 meta-analyses found small effects: Cohen *d*=0.19 [105], Cohen *d*=0.139 [110], and Cohen *d*=0.16 [113]. However, one study reported that the effect sizes were heterogeneous [113]. The fourth meta-analysis quantified the effects on health outcomes, finding statistically significant reductions in systolic blood pressure (mean difference –2.66 mm Hg), diastolic blood pressure (mean difference –1.26 mm Hg), glycated hemoglobin level (mean difference –0.13%), and low-density lipoprotein cholesterol level (mean difference –2.18 mg/dL) [102].

Table 8. Effectiveness of digital interventions on other combinations of outcomes, sorted by controls and further sorted by intervention type.

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Mixed (active and nonactive) controls							
Beishuizen et al (2016) [102]	15 (57)	Meta-analysis of RCTs[a]	Internet	Systolic blood pressure, diastolic blood pressure, HbA_{1c}[b] level, cholesterol level, weight, and level of physical activity	3-60 months	Intervention groups had a reduction in systolic blood pressure (mean difference –2.66 mm Hg; 95% CI –3.81 to –1.52), diastolic blood pressure (mean difference –1.26 mm Hg; 95% CI –1.92 to –0.60), HbA_{1c} level (mean difference –0.13%; 95% CI –0.22 to –0.05), and LDL[c] cholesterol level (mean difference –2.18 mg/dL; 95% CI –3.96 to –0.41). There were larger effects in internet interventions that combined the internet application with human support (blended care).	Low
Chebli et al (2016) [103]	11 (16)	Narrative synthesis of RCTs	Internet	Cessation and reduction (for both alcohol and smoking)	1-12 months	Internet-based interventions may have a positive effect on smoking cessation. Several studies found that web-based use and number of logins were positively associated with quit outcomes. Both studies on alcohol demonstrated positive treatment outcomes in both arms, but there were no differences between the internet-based intervention and control.	Critically low
Cugelman et al (2011) [105]	30 (30)	Meta-analysis of experimental, quasiexperimental, and correlational studies	Internet	Behavioral outcomes	1 day-7 months	Effect sizes were small but statistically significant (standardized mean difference effect size Cohen *d*=0.19; 95% CI 0.11 to 0.28; *P*<.001; number of interventions, k=30); however, there was a lot of heterogeneity, Cochran's Q test 64.125 (*P*<.001) and I^2=54.776; the largest effect size was observed when interventions were compared with waitlists and placebos (Cohen *d*=0.28; 95% CI 0.17 to 0.39; *P*<.001; k=18); there was no significant difference compared with sophisticated print interventions (Cohen *d*=–0.11; *P*>.05; k=29).	Critically low
Webb et al (2010) [113]	85 (85)	Meta-analysis of RCTs	Internet	Smoking abstinence, level of physical activity, alcohol consumption, and dietary behavior	3-12 months	Interventions had a statistically small but significant effect on health-related behavior (Cohen *d*+=0.16; 95% CI 0.09 to 0.23). The effect size of interventions targeting a single area of health behavior was not significantly different to the effect size of those targeting multiple areas of health behaviors, but the numerical difference was in favor of single-area studies (Cohen *d*+=0.17 versus Cohen *d*+=0.12).	Critically low

XSL•FO

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Lustria et al (2013) [110]	40 (40)	Meta-analysis of experimental and quasiexperimental studies	Tailored internet-based interventions	Levels of physical activity, fruit and vegetable intake, saturated fat intake, and abstinence from smoking and alcohol consumption	1-24 months	Web ‐ based, tailored interventions effected significantly greater improvement in health outcomes as compared with control conditions immediately post intervention, Cohen *d*=0.139 (95% CI 0.111 to 0.166; *P*<.001; k=40). The effect remained at follow ‐ up, Cohen *d*=0.158 (95% CI 0.124 to 0.192; *P*<.001; k=21), and the correlation between follow ‐ up time point and effect size was r_{39}=.004 (*P*=.98, for posttest effects) and r_{20}=−.176 (*P*=.50, for follow ‐ up effects), which suggests that length of follow ‐ up did not significantly influence intervention outcomes. Interventions using tailored websites had a larger weighted mean effect size when compared with nontailored websites (Cohen *d*=0.188) than when they were compared with no ‐ treatment control conditions (Cohen *d*=0.07; *P*<.01). There was an extremely small effect of tailored websites frompared to no-treatment control conditions (Cohen *d*=0.08; k=4) and of tailored websites compared with sophisticated print interventions (Cohen *d*=–0.11; *P*>.05; k=29).	Critically low
Covolo et al (2017) [104]	39 (40)	Narrative synthesis of RCTs	Mobile apps	BMI and waist circumference; various physical activity levels; fruit and vegetable intake, high-sugar food intake, smoking cessation, and number of drinking days	6 months-2 years	Only 25% (10/40) of RCTs found statistical differences between intervention and control groups.	Critically low
Armanasco et al (2017) [101]	35 (51)	Meta-analysis of RCTs and quasiexperimental studies	Text messaging	Weight, level of physical activity, and smoking cessation	1 to 66 weeks	The overall pooled effect of interventions was Cohen *d*=0.24 (95% CI 0.16 to 0.32; *P*<.001; k=35) using outcome data collected most proximal to the intervention end. 7 studies collected data following a no-intervention maintenance period and showed a small but significant pooled maintenance effect (Cohen *d*=0.17; 95% CI 0.03 to 0.31; *P*=.017; k=7).	Critically low

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Head et al (2013) [107]	12 (19)	Meta-analysis of RCTs	Text messaging	Smoking cessation, weight loss, and level of physical activity	Mean 81.26 days	The overall weighted mean effect size representing the impact of these interventions on health outcomes was Cohen *d*=0.329 (95% CI 0.274 to 0.385; *P*<.001). Correlations between effect size and follow-up (r_{18}=−.12; *P*=.62) and effect size and retention (r_{18}=.14; *P*=.56) were not statistically significant. Effect sizes for interventions that employed no-treatment control groups (Cohen *d*=0.369), however, were significantly larger than those that employed alternative comparisons (Cohen *d*=0.226; Q_B=.5.16, df=1; *P*=.02).	Critically low
De Leon et al (2014) [106]	55 (55)	Narrative synthesis of RCTs	Text messages and emails (prompts)	Smoking cessation, diet intake, and physical activity level	3 weeks-9 months	76% (42/55) of articles found statistically significant positive behavioral outcomes of prompts, the mode by which the prompt was sent did not seem to impact its success.	Critically low
Rooke et al (2010) [112]	34 (34)	Meta-analysis of RCTs	Computer delivered	Abstinence and reduction for both smoking and alcohol	1-156 weeks	The weighted average effect size (Cohen *d*) was 0.20 (*P*<.001); however, lower effect sizes were associated with studies addressing tobacco use (Cohen *d*=0.14). There was significant heterogeneity between studies targeting tobacco versus alcohol use (*Q*=5.65; *P*=.02), with studies on alcohol consumption producing significantly higher effect sizes than tobacco studies (Cohen *d*=0.26 and 0.12, respectively). Effect sizes were higher for studies in which the comparison condition was an attention/placebo (Cohen *d*=0.22) relative to studies in which the comparison condition was an active comparison (Cohen *d*=0.10); studies employing active treatments as the comparison condition mainly produced effect sizes close to zero.	Critically low
Nonactive controls

Review	Relevant studies, n (total studies)	Method of synthesis	Interventions	Outcomes	Follow-up	Summary of findings	AMSTAR-2 rating
Krebs et al (2010) [109]	76 (88)	Meta-analysis of RCTs	Computer-tailored interventions	Dietary intake of fat, vegetables, fruit; various levels of physical activity, and smoking abstinence over various timescales	1-24 months	The overall effect size was *g*=0.17 (95% CI 0.14 to 0.19) using a fixed effects model and *g*=0.17 using a random effects model (95% CI 0.14 to 0.20). Effects peak from 4 to 12 months postbaseline with a mean effect size of *g*=0.20, and while they decline after 12 months postbaseline, the mean effect size at long-term follow-up (*g*=0.12) remains to be statistically significant (95% CI 0.08 to 0.16). The meta-analysis found a trend for increasing effect sizes across studies that intervened on 1 (*g*=0.15), 2 (*g*=0.21), and 3 (*g*=0.24) areas of behavior, but this trend did not continue with the 1 study that intervened on 4 areas (*g*=0.12).	Low

[a]RCT: randomized controlled trial.

[b]HbA_{1c}: glycated hemoglobin.

[c]LDL: low-density lipoprotein.

Of the 3 reviews of mobile interventions, a review of SMS text messaging concluded that they were effective, but the narrative synthesis of apps was the only review in the other combinations category that did not find a preponderance of positive results [104]. The effect sizes for the SMS text messaging interventions were small (Cohen *d*=0.24 [101] and Cohen *d*=0.329 [107]), and the effect sizes in the meta-analysis were heterogeneous [107].

Other modes of intervention continued in the pattern of positive, albeit small, effects. Computer-delivered interventions had a small effect (Cohen *d*=0.20) [112]. Prompts delivered by SMS text messaging or email were effective in changing diet, physical activity, and smoking behaviors [106].

Relative Effect of Interventions by Number of Behaviors Targeted

A total of 3 meta-analyses that compared interventions targeting single versus multiple areas of behaviors found that both types of interventions were effective but they differed in whether they found interventions with single or multiple targets to be more effective. A total of 2 meta-analyses of internet-based interventions found that the effect size of interventions targeting a single area of health behavior was not significantly different to the effect size of those targeting multiple areas of health behaviors, but the numerical difference was in favor of single-area studies (Cohen *d*=0.146 vs Cohen *d*=0.121 for multiple-behavior studies [110]; Cohen *d*+=0.17 vs Cohen *d*+=0.12 [113]). However, the computer feedback–based meta-analysis found a trend for increased effect sizes across studies that intervened in 1 (*g*=0.15), 2 (*g*=0.21), and 3 (*g*=0.24) areas of behavior, but this trend did not continue with the one study that intervened in 4 areas (*g*=0.12) [109]. The review covered diet, physical activity, smoking cessation, and mammography.

Relative Effect of Intervention by Area of Behaviors Targeted

The review of SMS text messaging interventions found that interventions targeting smoking cessation and physical activity were more successful than interventions targeting other areas of health behavior, including alcohol and weight loss [107]. In contrast, a review of computer-delivered interventions found that interventions targeting smoking had statistically significantly lower effect sizes than those targeting alcohol (Cohen *d*=0.26 and 0.12, respectively) [112].

Effect of Other Combination Interventions Compared With Nonactive Controls

Digital interventions had their largest effect sizes when compared with nonactive controls; however, the effect sizes were generally small. Internet interventions had the largest effect size when compared with waitlists and placebos, but the effect sizes were small: Cohen *d*=0.28 [105] and Cohen *d*=0.22 [107]. Tailored websites had extremely small effect sizes when compared with no-treatment control conditions (Cohen *d*=0.07), and the effects were not statistically significant compared with nontailored print materials [110]. There were medium effect sizes for SMS text messaging interventions that employed no-treatment control groups (Cohen *d*=0.369) [107].

Effect of Other Combination Interventions Compared With Active Controls

The effects of digital interventions compared with active controls were very small or nonexistent.

A total of 2 meta-analyses found that there was an extremely small effect size (Cohen *d*=0.08) [110] or no significant difference [105] when internet-based interventions were compared with sophisticated print interventions. There were larger effects in internet-based interventions that combined

XSL•FO
RenderX

internet application with human support (blended care) [102]. Computer-delivered interventions had very small effect sizes when the comparison condition was an active comparison (Cohen *d*=0.10); studies employing active treatments as the comparison condition mainly produced effect sizes close to zero [112]. SMS text messaging interventions had small effect sizes compared with active comparisons (Cohen *d*=0.226), which was statistically significantly smaller than their effect size compared with the no-treatment control groups [107].

Although digital feedback was effective, it seems that it was no more effective than feedback delivered by nondigital means, and 2 reviews that examined feedback interventions found that the medium did not affect behavior change (SMS text messaging, print, email, telephone, newspaper articles [106] and print, computer, telephone, etc [109]).

Sustainability of Effects at Follow-Up

There was mixed evidence on the sustainability of interventions. A meta-analysis of internet-based interventions found the largest effect size at 1 month to 4 months [105], but a meta-analysis of computer-tailored interventions found that effects peaked from 4 months to 12 months postbaseline [109]. A total of 3 meta-analyses found that the correlation between effect size and follow-up was not significant for internet-based [110], SMS text messaging [107], or computer-delivered interventions [112].

The effects did seem to decline in the long run, and the 2 meta-analyses that explicitly examined effectiveness 1 year postintervention (for internet-based and computer-delivered interventions) found that the effect size declined, although it remained statistically significant [102,109].

Adherence (Considered for All Behavioral Areas)

Typically, adherence data were not reported. Where reported, there were generally decreases in program usage over the intervention period [75]. Rates of attrition were variable and sometimes very high, for instance, in one diet review, it was 0% to 84% [61] and in 2 smoking reviews it was ≥60% [86] and 35% to 84% (median 70%) [93]. Bucking the trend, a couple of reviews reported high adherence to digital physical activity interventions [46,60]. Many reviews found a dose-response relationship, whereby the effectiveness of the intervention was positively associated with dietary usage [20,21,61], weight loss [47], smoking [87,90,93,103], and alcohol [79]. However, there was no unanimity, for instance, one combination review found that the attrition rate was lower in internet-based interventions than in face-to-face settings [103] and 2 others found no evidence that retention influenced outcomes [107,110].

Discussion

Principal Findings

We reviewed 94 systematic reviews and meta-analyses that examined the effectiveness of digital interventions in changing health-related behavior and improving health outcomes in the areas of diet, physical activity, diet and physical activity combined, alcohol consumption, and smoking cessation, alone or in any other combination. The effectiveness of digital interventions differed according to the area of health behavior reviewed. Small positive effects were evident in smoking- and alcohol-related interventions. Similar findings were observed in the combined diet and physical activity interventions, as well as in other outcome combinations. However, there was little evidence of the effectiveness of stand-alone diet interventions, and evidence of the effectiveness of physical activity interventions was mixed, with some consistently positive evidence for mobile interventions and some promising evidence for exergaming. Digital interventions were most effective in the short-to-mid term (approximately 3 to 6 months), but there was insufficient evidence about their long-term effect. Typically, they were more effective than no intervention. There is mixed evidence on their effectiveness compared with nondigital interventions.

Our secondary objective was to identify differences in effectiveness between the modes of delivery of digital interventions. We identified internet-based interventions to be one of the more effective interventions for each area studied, except for physical activity alone. Mobile interventions were particularly effective for diet and physical activity combined (medium effects), but they were also effective for alcohol and smoking (small effects) and physical activity alone. Social media interventions were not effective for diet and physical activity combined (weight loss interventions), they had mixed effects for diet, and there was limited evidence for other areas. Computer-delivered technologies had small effects for smoking and alcohol consumption, but the effects for diet and physical activity were mixed.

The effect sizes reported in the reviews were generally below the National Institute for Health Care Excellence (NICE) guidelines for effectiveness of interventions, although it was often difficult to compare results with NICE guidelines, as different measures were used.

For weight management, NICE guideline PH53 (Recommendation 13) states that commissioned lifestyle weight management programs should have at least a 60% completion rate and should be likely to lead to an average weight loss of at least 3%, with at least 30% of participants losing at least 5% of their weight [114]. It should be noted that this is based on all participants, that is, those who attend at least one session. For those *completing* the service, that is, attending at least 75% of sessions, the key performance indicator of 50% losing at least 5% has been set [115]. In contrast, most reviews reported changes in weight in kilograms or changes in BMI, rather than percentage weight loss. The highest effect sizes for BMI in our review were −0.92 kg/m^2 [49] and −0.43 kg/m^2 [38], which are extremely unlikely to represent a 3% or 5% weight loss in individuals with overweight or obesity. The largest changes in weight found in the reviews of digital interventions were −2.71 kg in one study [72] and −2.56 kg in one meta-analysis [71]. In comparison, the Hartman-Boyce evidence review that supports NICE guideline PH53 found an average effect size of −2.59 kg for face-to-face services at 12 months (intention-to-treat analysis) [116]. Most effect sizes from digital interventions did not reach the effect size of face-to-face services.

For smoking, the national outcome measure for stop smoking services is 4-week quits. Smokers attempting to stop without

XSL•FO
RenderX

additional support generally have a success rate of 25% at 4 weeks for carbon monoxide–validated quits and a success rate of about 35% at 4 weeks for self-reported quits [117]. Therefore, to show an impact, services must achieve success rates equivalent to or in excess of these rates that smokers achieve without support. Patients who receive stop smoking service support (behavioral support and pharmacotherapy) are 3 times more likely to quit than those with no support [118], and there is a cessation rate of 35% for brief intervention services but only at the 4-week point [117]. It is difficult to compare the results of our review with these services because the outcomes of digital smoking interventions are often expressed as ORs for smoking cessation rather than cessation rates. The only available review that used cessation rates demonstrated a cessation rate of 14.8% [92]. This is lower than the observed rate from stop smoking services or brief advice, but the follow-up point was considerably later and cessation rates decreased over time.

For alcohol, the average weekly reduction in drinking from brief advice interventions is 20 g of alcohol (about 2.5 UK units) [119], so the reductions in weekly alcohol consumption achieved by digital alcohol interventions are comparable when including all interventions (22 g of alcohol or 3 UK units) but lower if one restricts attention to high-quality evidence (11 g of alcohol or 1.5 UK units) [77].

To the extent that the effectiveness of digital interventions is below the NICE guidelines, doctors and organizations should be cautious about recommending them to patients who would benefit from behavior change in the 4 areas of our review. However, it may be valuable to recommend them to people who refuse a face-to-face intervention. On the basis of the evidence that we found, digital interventions for weight loss should combine diet and exercise unless they are mobile interventions targeting physical activity.

For digital interventions for both smoking and combined diet and physical activity, there were studies showing significant health effects but not significant behavioral effects. This seems paradoxical. However, it is possible that even a small increase in physical activity or a small improvement in diet, which may not be statistically significant, can improve health markers over an intervention period, particularly in the most inactive and less fit individuals. Light physical activity is beneficial for health outcomes, including cardiometabolic risk factors [120]. We also noted that, although statistically significant, the health effects are small and possibly not meaningful.

Limitations

Owing to the rapid nature of our review, we did not perform full hand searches or consult experts. This may mean that we overlooked some reviews. At the other end of the spectrum, by reviewing reviews, there is the possibility that some studies were double counted if they were covered in more than one review.

Our ability to make inferences from the literature reviewed is limited for the following reasons.

Heterogeneity was consistently high across reviews. Heterogeneity of effects probably reflects heterogeneity of interventions, which could be a consequence of rapid advances in digital devices and systems. There were also heterogeneous outcome measures. As the reviews covered different types of digital interventions and outcome measures, it was difficult to make comparisons. Differing outcome measures may have differentially impacted the effectiveness of modes of intervention or the general effectiveness of interventions in the areas we investigated. For instance, smaller effect sizes were reported in studies addressing smoking use than in studies on alcohol consumption, possibly because studies addressing alcohol use tended to use reductions in drinking behavior as their outcome variable, while studies addressing smoking use tended to apply the more stringent standard of abstinence [112].

Follow-up times were relatively short, so we cannot know if behavior change would be sustained in the long term. Some trials only provided behavioral data, so we cannot be sure of health outcomes. A review of physical activity found that the average rate of sustained use of digital health interventions over 10 weeks was 50% [64]. This is consistent with the findings of another systematic review on physical activity apps, which concluded that apps are effective in the short term (up to 3 months) but not longer [121].

Most trials reported intent-to-treat analysis, and typically, adherence data were not reported. This makes it difficult to assess nonsignificant effects to determine whether they resulted from ineffectiveness of treatment or from nonadherence. Where attrition rates were reported, they were often high.

Anecdotally, digital interventions are being used both to supplement and replace face-to-face services. However, most reviews did not discriminate between these functions. In the domain of weight loss, 5 reviews reported enhanced effects on weight loss in interventions that incorporated personal contact or counseling [51,54,57,62,74]. One meta-analysis showed that infrequent in-person treatment was superior in limiting weight gain to computer-based interventions (mean difference 0.5 kg). Digital interventions that particularly benefit from involving people alongside are thought to include sensitive tailoring of feedback [57,62] and social support [54].

Confidence ratings were critically low in 79 of 93 reviews (85%). However, when isolated, those reviews that were rated critically low presented findings that were consistent with the overall findings: equivocal evidence on effectiveness for diet or physical activity outcomes but consistent findings of short-term effects for alcohol, smoking, and other combined outcomes.

Even when the AMSTAR-2 [16] ratings were moderated (so that justifying any publication language inclusion criterion and providing a list of justifications for excluding reviews were no longer considered critical flaws), 74 of 93 (80%) reviews were rated critically low. During the generation of confidence ratings, it was noted that many reviews failed to satisfy items 2 and 13. These are considered critical items for all review types. Item 2 specifies that, as a minimum, reviews state that a protocol containing research questions, search strategy, inclusion/exclusion criteria, and a risk of bias assessment was completed before conducting the review. Item 13 dictates that reviews should account for the risk of bias in individual studies when interpreting/discussing the results of the review. The

XSL•FO
RenderX

inclusion of these items in the AMSTAR-2 rating may represent an aspiration to improve standards. Our AMSTAR-2 quality ratings are consistent with other evidence that suggests that it is possible to satisfy PRISMA standards yet still have poor methodological quality [122]. However, judging reviews according to such high standards, such that they are virtually all rated as being very low, masks the differences in quality.

Future Research Work

This is the first review of reviews on the effectiveness of digital interventions with such a large scope. It summarizes the state of our knowledge of digital interventions for health improvement behaviors in nonclinical populations. However, the literature could be developed to be more helpful for professionals and organizations who need to decide whether to promote digital interventions, which ones to promote, which areas of behaviors to promote them for, and who to promote them to.

For policy purposes, reviews with mixed controls are of limited use. It matters whether a digital intervention is being compared with no intervention or an active nondigital control. It also matters whether the intervention is a stand-alone digital intervention or whether digital is being used as an adjunct to face-to-face services. We cannot assume that a digital intervention that is successful as an adjunct will also be successful as a stand-alone intervention. Therefore, reviews are needed to separately summarize the evidence base for these different ways of using digital interventions. It could be helpful to have well-structured and coordinated reviews that collate a high-level picture for each area of behavior, which can be updated on a regular basis. We need comparisons with national measures of effectiveness, such as the NICE guidelines, to more easily influence policy.

We also need reviews that can help us determine which interventions are most effective. In the future, it would be helpful to conduct comparative research on the mode of delivery of digital interventions (including comparisons of effect sizes), so that we can determine the most promising interventions for further development. There was also a lack of evidence about the long-term effects of interventions, and more studies on the sustainability of behavior change after digital interventions are needed. It would be especially useful to have this information in comparison with active controls.

Professionals also need to know who should be recommended digital interventions. Therefore, it would also be useful to know whether effect sizes are consistent across various subgroups of the population or whether digital interventions have different effects in different subgroups. We were not specifically looking for this information, but the reviews that were surveyed had mixed findings about whether the effectiveness of digital interventions varied with sex and age. Three meta-analyses found no significant association between sex and effect size or age and effect size [102,109,110]. However, one study found that the effect of interventions declined as age increased [105]. There may also be sex-based differences in adherence, and it is plausible, though not proven, that adherence moderates effect size. One narrative synthesis found that women and middle-aged participants were more likely to use web-based intervention services than men and younger participants, and women were more adherent to the overall intervention [103]. There is even less information about differential effects according to socioeconomic status (SES). In the domain of smoking, one review found that the relative effectiveness of technology-based interventions appeared to be comparable between low- and high-SES groups [83].

The acceptability of digital interventions to their target users also warrants further study. In one review of digital interventions of addictive behaviors, participants expressed a preference for internet-based services because of the convenience and increased confidentiality, and individuals who might not otherwise seek treatment said they would consider an internet-based intervention [103].

Providers may be drawn to digital tools in the hope that they are cost-effective. While not the purpose of our review of reviews, we noted insufficient evidence in the reviews to draw any preliminary inferences about the cost-effectiveness of digital interventions. The evidence from the reviews was mixed. There was evidence in favor (internet-based health interventions [41]), evidence against (adaptive e-learning interventions [22]), and mixed evidence: 1 of 3 (33%) web-based interventions was cost-effective compared with in-person interventions at 6 months [52]. Cost-effectiveness may also depend on whether digital interventions supplement or replace face-to-face interventions. Cost-threshold analyses indicated that some form of electronic intervention is likely to be cost-effective when added to nonelectronic behavioral support, but there is substantial uncertainty with regard to determining the most effective (thus most cost-effective) type of electronic intervention, which warrants further research [84]. Future work will need to investigate cost-effectiveness to allocate resources to developing the most promising digital tools.

Conclusions

Our review of reviews summarizes the state of our knowledge of digital interventions for health improvement behaviors in nonclinical populations. We found positive but small effects for digital interventions that targeted diet and physical activity combined, greater effects—but still small—for smoking and alcohol consumption, and positive, medium-sized effects for mobile interventions for physical activity alone. More high-quality research is needed to assess the sustainability of the effects of digital interventions in the long term, the differences between modes of delivery for digital interventions, their effect on different population subgroups, their cost-effectiveness compared with existing behavior change approaches, and in particular whether they are better used as an adjunct to or replacement for face-to-face treatment. We need the answers to these questions to be able to make an informed decision about whether digital behavior change tools should be integrated into the NHS Health Check program.

Abstract

Background: Many current research needs can only be addressed using very large cohorts. In such studies, traditional one-on-one phone, face-to-face, or paper-based engagement may not be feasible. The only realistic mechanism for maintaining engagement and participation at this scale is via digital methods. Given the substantial investment being made into very large birth cohort studies, evidence for optimal methods of participant engagement, participation, and retention over sustained periods without in-person contact from researchers is paramount.

Objective: This study aims to provide an overview of systematic reviews and meta-analyses evaluating alternative strategies for maximizing participant engagement and retention rates in large-scale studies using digital methods.

Methods: We used a rapid review method by searching PubMed and Ovid MEDLINE databases from January 2012 to December 2019. Studies evaluating at least 1 e-engagement, participation, or retention strategy were eligible. Articles were screened for relevance based on preset inclusion and exclusion criteria. The methodological quality of the included reviews was assessed using the AMSTAR-2 (Assessing the Methodological Quality of Systematic Reviews 2) measurement tool, and a narrative synthesis of the data was conducted.

Results: The literature search yielded 19 eligible reviews. Overall, 63% (n=12) of these reviews reported on the effectiveness of e-engagement or participation promotion strategies. These evaluations were generally not conducted within very large observational digital cohorts. Most of the contributing reviews included multipurpose cohort studies (with both observational and interventional elements) conducted in clinical and research settings. Email or SMS text message reminders, SMS text messages or voice notifications, and incentives were the most commonly used design features to engage and retain participants. For parental outcomes, engagement-facilitation interventions influenced uptake and behavior change, including video feedback, goal setting, and intensive human facilitation and support. Participant-stated preferences for content included new knowledge, reminders, solutions, and suggestions about health issues presented in a clear, short, and personalized way. Perinatal and postpartum women valued self-monitoring and personalized feedback. Digital reminders and multiple SMS text messages were specific strategies that were found to increase adherence to medication and clinic attendance, respectively.

Conclusions: This review adds to the growing literature evaluating methods to optimize engagement and participation that may apply to large-scale studies using digital methods; it is promising that most e-engagement and participation promotion strategies appear to be effective. However, these reviews canvassed relatively few strategies, suggesting that few alternative strategies have been experimentally evaluated. The reviews also revealed a dearth of experimental evidence generated within very large observational digital cohort studies, which may reflect the small number of such studies worldwide. Thus, very large studies may need to proactively build in experimental opportunities to test engagement and retention approaches to enhance the success of their own and other large digital contact studies.

Introduction

Background

Adult cohort studies (such as the UK Biobank, recruiting 500,000 participants and costing approximately £250 million (US $349 million) to date [1]) have demonstrated the power of mega-cohorts to transform the speed, precision, and capacity for high-value new knowledge for health and health care delivery. Unfortunately, high-profile *early life* initiatives of similar size and ambition, such as the US National Children's Study and UK Life Study, were withdrawn despite £0.8 billion (US $1.2 billion) and £38 million (US $59 million) funding, respectively [2,3], in large part because they stumbled at the first hurdle of engagement and uptake. Others, though successful in recruitment, have had substantial attrition over time [4]. Thus, a limited science of engagement and retention poses a critical hurdle to such studies in meeting their vision of advancing human health.

Engagement is defined as "the extent to and manner in which people actively use a resource and has been operationalized as a multistage process involving the point of engagement, a period of sustained engagement, disengagement, and reengagement" [5]. Many factors may influence the engagement process at different time points. In a research study, indicators of poor engagement may include low initial uptake from the first point of contact or reduced interaction over time, in some cases leading to complete disengagement or dropout. Engagement strategies have been developed to enable cohort studies—both observational and interventional—to meet their aims (eg, improving health behaviors and outcomes) by allowing regular, sustainable engagement with large numbers of participants via remote or digital-only studies [6].

e-Engagement incorporates the participation, recruitment, and retention of participants through digital platforms. Factors that may improve participant e-engagement include its technical features, content, frequency of waves, and engagement-facilitation interventions (EFIs) [7]. User characteristics and digital platform features should also be considered. Ritterband et al [8] simplified this in their internet intervention model, hypothesizing that behavior change is influenced by the stepwise progression of environmental factors, support, and website characteristics affecting adherence, which then affect behavior change (ie, sustained participant engagement) through various mechanisms of change. Thus, maximizing e-engagement can improve the efficiency of research processes and reduce both administration costs [9] and the validity and power costs of significant and systematic nonuptake and attrition [10] in major studies.

Given the expense of longitudinal cohort studies, effective strategies that engage and retain cohort participants are critical to the integrity of research outcomes [11,12]. The retention of study participants is vital to ensure the power and internal validity of longitudinal research [13-15], whereas participant engagement is important for evaluating the efficacy and generalizability of the program under study. A review of randomized controlled trials [16] suggests that delays in participant recruitment or high dropout rates postrandomization may lead to uncertainty in treatment effectiveness and possibly confound results. For example, in the case of technology-based intervention studies, the technology may change over time if recruitment is prolonged, potentially leading to artifacts or differential effects on treatment outcomes. Proposed retention strategies involving (1) contact and scheduling methods, (2) visit characteristics, (3) study personnel, (4) nonfinancial incentives, (5) financial incentives, (6) reminders, (7) special tracking methods, (8) study description, (9) benefits of study, (10) reimbursement, (11) study identity, and (12) community involvement [17,18] may influence participant retention rates. However, there is limited experimental evidence and data for the in-depth exploration of retention strategies and their implementation.

With the recent growth in experimental research on the optimization of digital methods in longitudinal cohort research studies, there is a need for the literature to be collectively synthesized at a pace reflecting the rapid evolution of technology.

Objective

The objective of this review is to provide an overview of strategies that enhance engagement, participation, and retention rates in large-scale digital contact studies, comparing digital methods with alternative (digital and nondigital) methods. This work has been undertaken as part of the design of the forthcoming Generation Victoria (GenV) study [19]. GenV is a whole-of-state birth and parent cohort being planned in the state of Victoria, Australia. After initial face-to-face recruitment, the majority of contact with study participants will be via digital methods. The findings of this review are expected to inform GenV and other very large birth cohort studies in planning.

Methods

Protocol Registration

The protocol of this rapid review was registered with PROSPERO (International Prospective Register of Systematic Reviews; registration number CRD42020155430). We followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement to report our systematic review [20].

Research Questions and Definitions

In the context of the administration of large-scale digital contact cohort studies, we investigated the following research questions:

XSL•FO
RenderX

1. What technical design features aid engagement, participation, and retention?
2. What EFIs aid engagement, participation, and retention?
3. What feedback is valued by parents with young children?
4. How effective are e-engagement, participation, and retention interventions?

We used the following definitions throughout:

- Engagement: the proportion of participants who receive, open, and actively engage in a survey or an assessment wave. Incorporates the study being able to contact the participant, and the participant being motivated to start the activity.
- EFI: the approach used to increase the acceptability of a web-based program.
- Participation: the proportion of participants who completed a survey or an assessment. Incorporates the participant having time to complete the activities, understanding how to complete the activities, and being willing to provide information about themselves and their family.
- Retention: the proportion of participants who participate across successive waves. Incorporates the study being able to contact the participant and the participant wanting to continue to participate.
- Review: reporting on overall findings of an included systematic review.
- Study: reporting on findings of an individual study reported within a systematic review.

Electronic Searches

Four authors (MW, JN, SAC, and YW) developed the search strategy and refined the searches with an experienced librarian. The search queries used to retrieve our systematic reviews and meta-analyses are presented in Multimedia Appendix 1. Literature searches were performed in PubMed and Ovid MEDLINE databases using both MeSH and free-text words. The results from each search engine were downloaded into an EndNote (Clarivate Analytics) reference library and saved in Covidence (Veritas Health Innovation Ltd). Duplicate studies across the combined groups were removed. We also consulted experts and manually searched for relevant studies.

Selection of Reviews

Two authors (selected from JN, YW, and LC) independently screened each paper title and abstract for relevance. The full text of the remaining papers was independently screened by two of the authors (selected from JN, YW, SAC, and LC). Any disagreements were resolved by consensus. To ensure a standardized process for our review, the author's pilot-tested titles and abstracts, and full-text screening with a sample of papers. This information helped refine the inclusion and exclusion criteria.

Inclusion Criteria

Study Types

As this was a rapid review, we examined only systematic reviews and meta-analyses (not individual source studies) pertinent to large-scale cohort studies. We included studies with observational and/or interventional elements conducted in clinical and research settings. As digital technology is moving so rapidly, we limited our search to reviews published between January 2012 and December 2019, reasoning that these would include relevant older studies while being most technologically relevant to the needs of cohorts being planned in the 2020s.

Studies were eligible if they evaluated at least one of the following e-engagement, participation, or retention strategies (note that testing these strategies could occur in the context of a trial of therapeutic intervention):

1. Alternative contact metrics: for example, frequency per month or year; time of the month, week, or day; duration of each contact; and reminder content and frequency.
2. Reimbursement and gifts or penalties: for example, payments for survey completion, small gifts, or store discount codes.
3. Feedback features: for example, presented as participant's responses or performance at the point of completion; progress over time (with or without comparison with the population); a report sharable with care providers; and thank you certificates.
4. Content features: for example, assessments relevant to the life course approach or development stage of participants and/or their child; the balance of positive and negatively framed questions; ease of understanding; cognitive burden of assessment or survey items; and interest.
5. Technical and design features: for example, native or web app, can leave and return to assessment, the appearance of the interface, gamified interface, and visual progress tracker.
6. Study design features: for example, messages personalized with participant names and study staff contactable to answer questions.
7. Target participant characteristics: for example, demographic, motivation, or burden of disease.
8. Communication modes: for example, visual, auditory, text, and real person or avatar.

Participants

As the respondents in large birth cohorts are usually parents for the first decade of life, our primary focus was adults aged <50 years. Where evidence existed, we considered parents of children aged between 0 and 5 years.

Comparators

Alternative *standard* delivery strategies such as mail, fax, and other digital interventions (DIs).

Outcome Measures

Participant engagement in, completion of, and retention in digital study (survey and assessment) waves throughout short and long periods.

Exclusion Criteria

For initial title and abstract screening, we excluded the following publications: the primary focus (participant) was adults ≥50 years or children as the primary respondents; publications not written in English; and publications with full text not accessible through the University of Melbourne library.

XSL•FO
RenderX

Additional criteria for the full-text review screening were not reporting our outcome metrics of engagement, participation, or retention; focusing on low-income countries; and focusing on rare or uncommon conditions such as HIV or cancer.

Data Extraction

A data extraction template was developed and piloted by the authors (JN, YW, SAC, and LC) in 3 reviews. The template contained general review information (author and search dates), characteristics of included studies (number of relevant studies, study designs, health topics, population age, and geographic area), e-engagement, participation, and retention promoting strategies, the methodological quality of systematic reviews, and a summary of review results and conclusions.

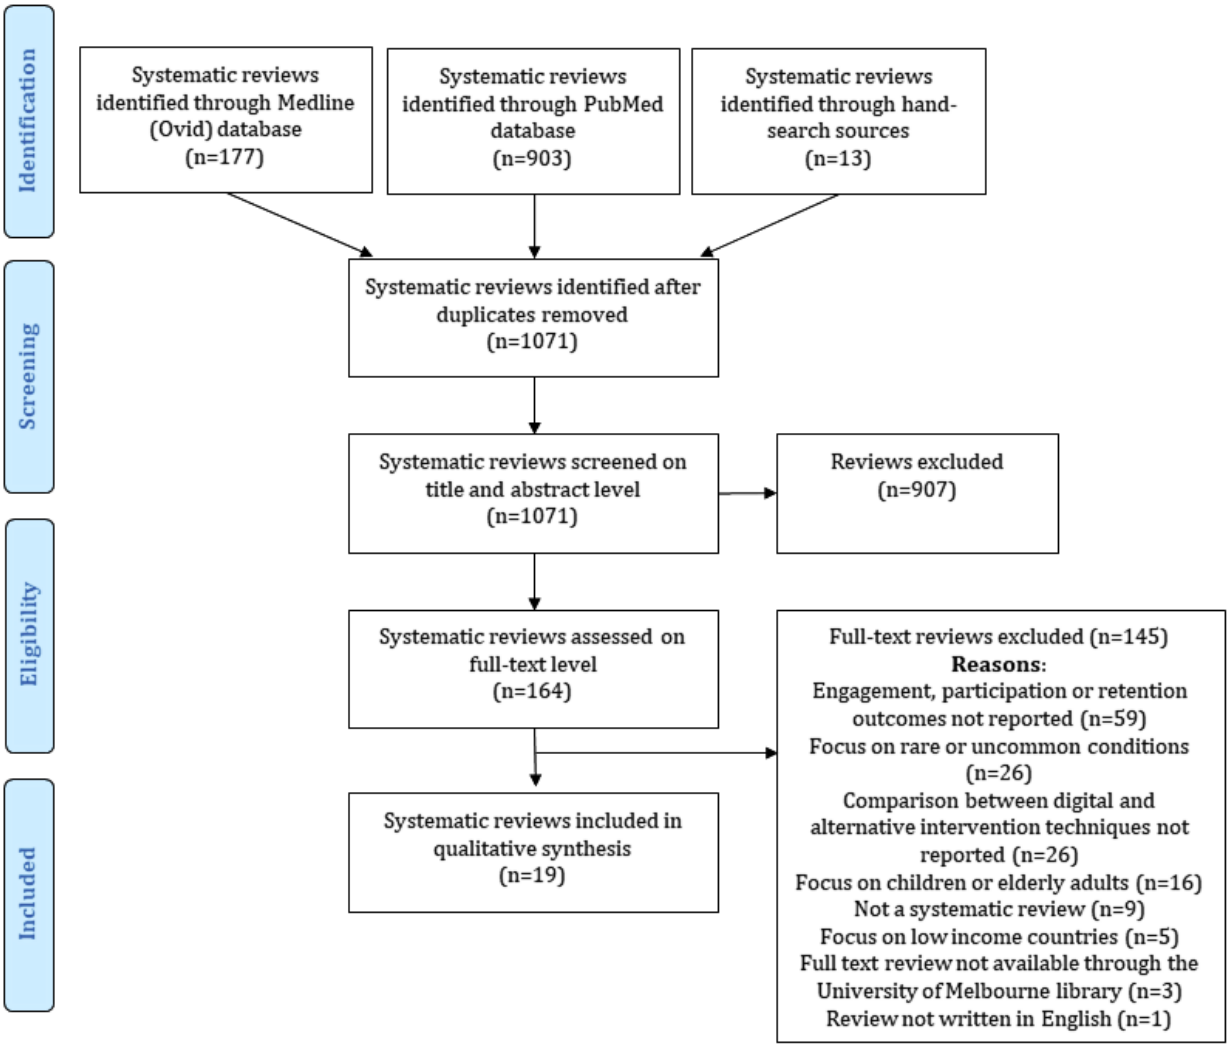
Data were extracted independently by 2 of the authors (selected from JN, YW, SAC, and LC), and any discrepancies were resolved by consensus.

Data Synthesis

A meta-analysis was not performed because of the heterogeneity of intervention types, study designs, study populations, and outcome variables among the included studies. Instead, a narrative summary of the findings across studies was created based on study outcomes (ie, participant engagement, participation, completion, and retention) and strategies promoting these study outcomes.

Methodological Quality of Included Reviews

Two authors (JN and YW) independently assessed the quality of the included review methodology using AMSTAR-2 (Assessing the Methodological Quality of Systematic Reviews 2; a measurement tool to assess systematic reviews) [21]. The appraisal tool of AMSTAR-2 included 16 domains: whether there was a description of the PICO (population, intervention, control group, and outcome) components in the research questions and the inclusion criteria; the protocol of systematic review or meta-analysis; study design rationale; the literature searching strategy; study selection; data extraction; specific details of inclusion and exclusion criteria; adequate detail of the included studies; bias risk assessment of the included studies; the funding sources; appropriate statistical methods; the impact evaluation of the individual study's risk of bias (RoB); the explanation of RoB in individual studies; a satisfactory explanation for any heterogeneity; adequate investigation of publication bias; and potential conflicts of interest. The answer options for the AMSTAR-2 were yes, partial yes, and no. *Yes* denoted a positive result. *No* represented that there was not enough information about the domain. *Partial yes* represented that it partially adhered to the standard. Discrepancies were resolved by consensus.



Results

Search and Screening Results

The search strategy yielded 1080 systematic reviews. An additional 13 reviews were identified through a manual search of publications' reference lists. Following the removal of duplicates, 1071 publications were screened. The title and abstract screening excluded 907 reviews. A total of 164 articles underwent full-text review, of which 19 publications [22-40] met the inclusion criteria. Figure 1 summarizes the search and screening process presented in the PRISMA format.

XSL•FO
RenderX

Figure 1. Search and screening process.

Characteristics of Included Reviews

On simple summing, the 19 reviews contained 437 studies and more than 556,000 participants (4 studies did not report the number of participants). Some studies and therefore participants are included in more than one review. Given that we aimed to identify strategies that may influence the outcomes of interest rather than synthesize an overall estimate (as per meta-analytic techniques), we did not see an overlap as problematic.

The characteristics of the included reviews are summarized in Table 1. Most reviews contained studies of varying designs, spanning quantitative and qualitative analyses.

The 19 systematic reviews included studies conducted in both research (8 reviews) and clinical or health care (11 reviews) settings. Of these reviews, 4 examined young people and adults with mental disorders, anxiety, and depressive symptoms. Others examined engagement, participation, and/or retention in digital contact studies among perinatal and postpartum women, patients with chronic diseases, parents in neonatal intensive care units, human papillomavirus vaccine uptake in young children, vaccinations in adults, pregnant women, and uptake of preschool vaccinations.

XSL•FO

Table 1. Systematic review characteristics.

Study	Objective	Studies in review	Participants	Population	Regions	Designs of included studies
Research setting						
Alkhaldi, 2016 [23]	Evaluate the effectiveness of tech-based prompts (eg, SMS text messages or calls) for promoting engagement with digital interventions	14	8774	Adults participating in digital interventions for physical and/or mental health	Europe, United States, and Australia	RCTs[a]
Baumeister, 2014 [26]	Investigate the impacts of guidance (human support) on the effectiveness of web-based mental health interventions	14	Not stated	Adults with clinical or subthreshold mental disorders	Not stated	RCTs
Lattie, 2019 [32]	Evaluate factors associated with the effectiveness of web-based mental health interventions	89	15,857	Postsecondary (eg, university) students targeted by universal prevention or treatment intervention programs	Europe, United States, Canada, China, Mexico, Australia, and New Zealand	RCTs, nonrandomized studies, and qualitative
Lim, 2019 [33]	Explore postpartum women's and health professionals' perspectives of digital health interventions for lifestyle management in postpartum women	9	484	Postpartum women	United Kingdom, United States, Bangladesh, and Australia	Qualitative (focus groups or interviews), questionnaire, and observational
Thakkar, 2016 [37]	Investigate the effect of SMS text messaging on medication adherence in chronic disease	16	2742	Adults with chronic diseases, including HIV infection, cardiovascular disease, asthma, diabetes, and epilepsy	Europe, South America, United States, Asia, and Africa	RCTs
Tromp, 2015 [38]	Investigate motivations of children and their parents to participate in clinical drug research	42	Not stated	Children with health conditions (eg, cancer, respiratory diseases, or diabetes) or no health conditions and their parents or guardians	Not stated	Quantitative (questionnaires or registries) and qualitative (interviews, focus groups, or case study)
Valimaki, 2017 [39]	Summarize the content and effectiveness of web-based interventions for depression and anxiety	27	7786	Young people (aged 10-24 years) with symptoms and/or diagnosis of depression or anxiety	Europe, United States, Canada, China, Australia, and New Zealand	RCTs
Whitaker, 2017 [40]	Describe the extent and effectiveness of using Facebook to recruit participants for health research	35	Median 264 per study	People (aged ≥13 years) targeted for recruitment into health studies and interventions, most commonly smoking cessation, human papillomavirus vaccination, and healthier lifestyle interventions	Germany, United States, Canada, Japan, and Australia	Quantitative and qualitative
Clinical or health care setting						
Adams, 2015 [22]	Provide evidence on the effectiveness, acceptability, economic costs, and consequences of parental financial incentives and quasi-mandatory schemes for increasing the uptake of preschool vaccinations	11	334,476	Parent of preschool children living in high-income countries; member of any relevant stakeholder group living in high-income countries	United Kingdom	RCTs and controlled pre-post and time-series analyses

XSL•FO
RenderX

Study	Objective	Studies in review	Participants	Population	Regions	Designs of included studies
Ames, 2019[24]	Describe clients' experiences of receiving health information via their mobile phone	35	Not stated	Adolescent and adult clients of pregnancy, newborn, and child health, sexual health, and family planning health services receiving communication via their mobile devices	United Kingdom, United States, Canada, Southeast Asia, Australia, South America, and Africa	Qualitative study
Atkinson, 2019 [25]	Evaluate the effectiveness of digital push interventions in improving vaccine uptake and series completion compared with nondigital interventions	13	24,224	Adults receiving vaccines themselves, including pregnant women, or parents of adolescents and children eligible for vaccination	United States, Lebanon, Zimbabwe, and Guatemala	RCTs
Belisario, 2015 [27]	Compare the quality of survey responses collected using mobile apps vs other methods	14	2272	Smartphone and tablet apps as a delivery mode in clinical patients. Data collected from participants completing health-related, self-administered questionnaires	Western Europe, United States, Canada, and Korea	RCTs, crossover, and paired repeated measures studies
Dol, 2017 [28]	Examine the effect of eHealth interventions used in neonatal intensive care units on parents and infants	8	Not stated	Parents in neonatal intensive care units	United States, Singapore, the Netherlands, South Korea, and Israel	RCTs, quasi-experimental, pre-post, observational studies, descriptive studies, and prospective studies
Dubad, 2017 [29]	Evaluate the efficacy and usability of mobile mood-monitoring apps in young people	25	110,051	Healthy participants, participants from clinical populations, including youth with a range of mental health, emotional, or behavioral problems	Western Europe, United States, and Australia	RCTs, secondary analyses, nonexperimental studies, and quasi-experimental
Garrido, 2019 [30]	Examine the effectiveness of digital mental health interventions for depression and anxiety in young people	41	16,874	Young people with depression and anxiety	Northern Europe, United States, South America, Asia, and Australia	RCTs, single cohort (including pre-post design), and case studies
Kang, 2017 [31]	Evaluate the impacts of digital interventions on human papillomavirus vaccination	5	14,107	Young adults (males and females) who had received their first human papillomavirus vaccine dose	United States	RCTs
Mertens, 2019 [34]	Evaluate the effects of technology-supported lifestyle interventions on gestational weight gain and postnatal weight loss	9	2603	Perinatal women during pregnancy or within the first postnatal area	United States, Australia, and Iran	RCTs
Parsons et al, 2017 [35]	Evaluate the remotely delivered interventions for children with autism spectrum disorder living outside of urban areas: systematic review	9	197	Families having a child with autism spectrum disorder, living outside of urban areas, and having limited access to services	United States, Canada, and Australia	Pre-post, multiple-base design, RCTs, and quasi-experimental studies
Robotham, 2016 [36]	Assess the impact of digital notifications to improve attendance in clinics	21	16,076	Patients attending health care services	Europe, United States, Asia, Africa, and Australia	RCTs

[a]RCT: randomized controlled trial.

Research Question 1: Technical Design Features That Aid Engagement, Participation, and Retention

We found 4 reviews [22,25,31,32] reporting on several technical design features to aid engagement, participation, and retention, including financial incentives (including gifts), digital pushes (SMS text message alerts), voice notifications, and email or SMS text message reminders and studies' technical feasibility and usability (ie, informed consent). Email or SMS text message reminders and SMS text message notifications were reported

XSL•FO
RenderX

in 4 reviews [31,32,36,37] as the most commonly used technical design feature to improve participation and completion rates. Two reviews reported the use of email or SMS text message reminders and voice notifications [36,37] to enhance study participation. Robotham et al [36] compared zero, one, and multiple SMS text message notifications and voice notifications.

Research Question 2: EFIs That Aid Engagement, Participation, and Retention

The following EFIs were reported by 5 reviews [24,26,28,30,35] as a means to aid uptake and participant engagement.

SMS Text Messages and Interactive Voice Response Messages

The review by Ames et al [24] examined perceptions and experiences of digital targeted client communication (ie, SMS text messages and interactive voice response messages) via mobile devices in the areas of reproductive, maternal, newborn, and adolescent health. The results suggested that many clients liked receiving messages from health services using mobile phones. Content preferences included new knowledge, reminders, solutions, and suggestions about health issues presented in a clear, short, and personalized way.

Intensive Guidance (Web-Based Interventions With Human Facilitation, Support, or Coaches)

According to the review by Baumeister et al [26], in treating mental health disorders, guidance, as a retention strategy, improved rates of completion (pooled completer rate: odds ratio 2.76, 95% CI 1.68-4.53; n=6) and the number of completed modules (pooled mean number of completed modules: standardized mean difference 0.52, 95% CI 0.37-0.067; n=7). Lim et al [33] reported on the use of lifestyle coaching as an EFI to aid DI uptake. DIs were perceived as positive, user-friendly, and acceptable. Engagement strategies employed in DIs were monitoring and feedback, goal setting, health professional input, and social support.

Videoconferencing and Video-Feedback Interventions

The review by Dol et al [28] reported the following EFIs to aid uptake across included studies: Baby CareLink (an educational and emotional support system for parents with children in the neonatal intensive care unit) [41], Skype, and FaceTime. In this review, no significant differences were found between parents who participated in an e-intervention or received standard care in terms of their reported anxiety and/or stress, possibly because of the greatly varied study design and type of eHealth technology across studies.

Garrido et al [30] summarized the use of web-based modules, learning materials, or activities; group chats or courses; online forums; web-based chat facilities with a mental health professional; games; and psychoeducational computer programs as EFIs to aid participant uptake. The pooled effect size on depression compared with a nonintervention control was small (Cohen *d*=0.33; 95% CI 0.11-0.55), whereas the pooled effect size of studies comparing an intervention group with an active control showed no significant differences (Cohen *d*=0.14; 95% CI −0.04 to 0.31). In addition, pooled effect sizes were higher when supervision was involved (for studies comparing digital mental health interventions with high human interaction vs no intervention: Cohen *d*=0.52, 95% CI 0.23-0.80; for studies comparing digital mental health interventions with high human interaction vs active controls with no supervision: Cohen *d*=0.49; 95% CI −0.11 to 1.01).

Web-Based Training Intervention in Behavioral Interventions and Video Training Materials

Parsons et al [35] reported that using video training materials compared with face-to-face training improved parent knowledge, parent intervention fidelity, social behavior, and communication skills of children with autism spectrum disorders.

Research Question 3: Feedback Valued by Participants With Younger Children

Feedback was valued by perinatal and postpartum women and parents in neonatal intensive care units, as reported by 4 reviews [24,28,33,34].

In the review by Merten et al [34], participants valued visual and personalized feedback, information, and tools for physical activity and dietary intake tailored to their self-monitored data during pregnancy. This feedback reinforced successes and/or offered motivational support and recommendations to achieve their goals. Ames et al [24] reported that the opportunity to offer feedback about needs, preferences, and experiences during pregnancy helped develop or improve the study intervention. In the review by Dol et al [28], parents valued a video-feedback intervention that guided them to reflect on their own successful interactions through recordings of parent-infant interaction and feedback from a video interaction guidance professional. According to Lim et al [33], many of the characteristics of DIs that postpartum women valued included feedback and goal setting. Women valued setting realistic goals through video consultation with their dietitian and tracking daily weight, exercise, and blood glucose levels in a web-based intervention, consistent with known key strategies for behavior change.

Research Question 4: Effectiveness of Engagement, Participation, and Retention Promotion Strategies

Overall, 63% (12/19) of reviews reported the effectiveness of e-engagement or participation promotion strategies. Table 2 summarizes the effectiveness of the various e-engagement, participation, and retention strategies reported in the reviews. Most findings were reported as relative rather than absolute differences, where numerical syntheses were provided (refer to Multimedia Appendix 2 [22,23,25,27,29,31,32,34,36,37,39,40] for further details on the answered research questions and strategies).

XSL•FO
RenderX

Table 2. Interventions, main outcomes, and results of included systematic reviews.

Study	Condition or sample	Intervention vs control	Outcome	Study statistics: number of studies, effect size (95% CI), heterogeneity	Results
Alkhaldi, 2016 [23]	Digital interventions	Study design features: (1) Technology-based engagement strategies (email, phone call, and SMS text messages) to promote engagement with digital interventions vs no strategy (11 studies); postal mail strategy (1 study); fewer technology-based strategies than the intervention group (2 studies).	Engagement—engagement with the digital intervention. Dichotomous outcomes: number of log-ins or visits, page views, sessions completed, digital interventions features used. Continuous outcomes: time spent on the digital intervention.	(1) • Dichotomous outcomes (n=8): RR[a]=1.27 (−1.01 to 1.60) favoring strategy group; I^2=71%.[b] • Continuous outcomes (n=4): SMD[c] 0.19 (−0.11 to 0.48) favoring strategy group; I^2=20%.	(1) Engagement in a digital intervention was higher with engagement strategy, compared with no strategy.
Baumeister, 2014 [26]	Mental health disorders	Study design features: (1) Guided interventions (with human support) vs nonguided interventions (self-guided) (2) Guided interventions with a higher qualified e-coach vs guided interventions with a lesser qualified e-coach (3) Intensive guidance (at least three email conversations per week) vs less-intensive guidance (one email contact per week).	Completion—number of completed modules, number of people completing the intervention.	(1) • Number of completed modules (n=7): SMD 0.53 (0.37 to 0.67), higher in a guided group. • Number of completers (n=6): OR[d] 2.76 (1.68 to 4.53). Higher for a guided group; I^2=42%. (2) • Number of completed modules (n=4): SMD −0.15 (−0.36 to 0.05). No significant difference between groups; I^2=0%. • Number of completers (n=4): OR 0.85 (0.54 to 1.35). No significant difference between groups; I^2=0%. (3) • Completer rate: OR 1.40 (0.41 to 4.71). Higher in intensive guidance group. • Mean completed modules: SMD 0.11 (−0.41 to 0.63). Higher in intensive guidance group.	(1) Completion was higher in guided interventions than self-guided interventions. (2) No difference in completion by coach qualification level. (3) Completion was higher with intensive guidance than less-intensive guidance.
Garrido, 2019 [30]	Internet or web-based interventions	Communication modes: (1) Web-based module learning materials or activities, group chats or courses, online forums, and web-based chat facilities with a mental health professional vs face-to-face counseling (2) Computer-based programs including games and psychoeducational computer programs vs waitlist control group.	Completion—proportion of commencing participants who completed the intervention.	(1) Not stated.	(1) and (2) Engagement and adherence rates were low with participants completing less than half of the intervention components.

XSL•FO
RenderX

Study	Condition or sample	Intervention vs control	Outcome	Study statistics: number of studies, effect size (95% CI), heterogeneity	Results
Parsons, 2017 [35]	Internet or web-based parent training programs for autism spectrum disorder	Communication modes: (1) Web-based training intervention in behavioral interventions vs written training materials (2) Video training materials vs completing the same training face-to-face within families' homes.	Completion—completion and adherence.	(1) and (2) Not stated.	(1) and (2) Interventions delivered via videos were more effective and accepted by parents than those delivered via written information.
Mertens, 2019 [34]	Telehealth	Communication modes: (1) Mobile apps, SMS text messages, and e-intervention vs standard care including brief information brochures with healthy eating and physical activity advice.	Participation—efficacy, feasibility, acceptability, use of e-intervention.	(1) Not stated.	(1) Email, app alerts, or SMS text message notifications are well accepted for health interventions.
Whitaker, 2017 [40]	Internet or web-based interventions	Communication modes: (1) Recruitment via Facebook advertisements vs recruitment via traditional methods or national data.	Engagement—number of participants recruited, conversion rate.	(1) Not stated.	(1) Facebook can be successfully used to recruit young and hard-to-reach populations. Facebook-recruited samples were generally representative to the target demographic, but some reported overrepresentation of young White women.
Atkinson, 2019 [25]	Vaccinations	Communication modes: (1) Digital push notifications (eg, SMS text message alerts) vs nondigital interventions (eg, appointment card). (2) Digital push notifications (eg, SMS text message alerts) vs nondigital pull interventions	Participation—vaccination uptake (1 dose) or completion (all doses in series).	(1) • 1 dose (n=9): OR 1.17 (1.10 to 1.23); I^2=89%. • Completion of all doses (n=4): OR 1.53 (1.13 to 2.08); I^2=82%. (2) • 1 dose or completion of all doses (n=10): OR 1.22 (1.15 to 1.30); I^2=79%.	(1) and (2) There were increased odds of participants being vaccinated or completing the vaccination series with digital alerts compared with nondigital interventions.
Dubad, 2018 [29]	Delivery mode	Communication modes: (1) Mobile mood-monitoring apps vs paper diary or in person.	Participation—completion rate of diary entries and mood assessments, engagement with the app.	(1) Not stated.	(1) Participation rates ranged between 30% and 99%.
Belisario, 2015 [27]	Delivery mode	Communication modes: (1) Smartphone app questionnaire vs paper questionnaire.	Completion—data completeness.	(1) Not stated.	(1) Higher data completeness in app than paper reported by individual studies.
Dol et al, 2017 [28]	eHealth intervention	Communication modes: (1) Videoconferencing (Skype or FaceTime), Baby CareLink (an internet-based application), video-feedback intervention, and internet-based telemedicine program vs standard care.	Completion—parents completed demographic and feasibility surveys postintervention.	(1) Not stated.	(1) Parents generally found eHealth interventions useful and acceptable for neonatal intensive unit care for their infant.

XSL•FO
RenderX

Study	Condition or sample	Intervention vs control	Outcome	Study statistics: number of studies, effect size (95% CI), heterogeneity	Results
Valimaki, 2017 [39]	Internet or web-based interventions	Communication modes: (1) Web-based interventions for depression and anxiety, computers, tablets, or mobile phones vs wait-list, other intervention method or program.	Completion—attrition, number of participants leaving the study early.	(1) • Attrition of web-based interventions compared with a control group for short-term effectiveness (n=11): OR 1.31 (1.08 to 1.58). • Attrition in midterm (follow-up measurements after 3-5 months) effectiveness (n=3): OR 1.65 (1.09 to 2.49).	(1) Adolescents in the intervention group left the study early more often, both in short-term studies and midterm studies.
Robotham, 2016 [36]	Patients attending various health care services	Contact metrics: (1) One SMS text message notification vs no SMS text message notifications. (2) 2+SMS text message notifications vs no SMS text message notification. (3) SMS text message notifications vs voice notifications.	Participation—attendance, cancellation, and "no shows" at a health care service appointment.	(1) • Attendance (n=13): RR 1.23 (1.10 to 1.38) in favor of the SMS text message group; I^2=82%. • Cancellation (n=3): RR 1.37 (*P*=.34) with no difference between groups; I^2<1%. • "No shows" (n=16): RR 0.75 (0.68 to 0.82); I^2=21%. (2) • Attendance (n=13): RR 1.49 (1.17 to 1.88) in favor of 2+notifications group; I^2=66%. 19% risk difference • "No shows": (n=15): RR 0.75 (0.57 to 0.99) with "no shows" lower in the 2+notifications group or I^2=35%. 0.3% risk difference between 1 and 2+notification groups. (3) • Attendance (n=3): RR 0.90 (0.82 to 0.98) in favor of voice notifications, I^2<1%; "No shows" (n=4): RR 1.12 (0.90 to 1.38), I^2=73% • Between 1 and 2+notification groups. "No shows": (n=15): RR 0.75 (1.17 to 1.88) with "no shows" lower in the 2+notifications group; I^2=35%. 0.3% risk difference between 1 and 2+notification groups. • Attendance (n=3): RR 0.90 (0.82 to 0.98) in favor of voice notifications, I^2<1%. "No shows" (n=4): RR 1.12 (0.90 to 1.38); I^2=73%.	(1) Patients who received SMS text message notifications were 23% more likely to attend, equally likely to cancel, and less likely to *no show* a clinic appointment than those who received no notification. (2) Participants who receive 2+SMS text message notifications are 19% more likely to attend compared with one SMS text message notification but equally likely to *not show* at a clinic appointment, compared with those who received 1 SMS text message. (3) Voice notifications may increase clinic attendance slightly compared to SMS notifications, but no difference was found for "no shows"
Thakkar, 2016 [37]	Various chronic conditions	Contact metrics: (1) SMS text message reminder vs no SMS text message reminder.	Participation—medication adherence.	(1) • Adherence to medication schedule (n=not stated): OR 2.11 (1.52 to 2.93). Weighted mean effect size (n=not stated): Cohen d=0.41 (0.23 to 0.59).	

XSL•FO
RenderX

Study	Condition or sample	Intervention vs control	Outcome	Study statistics: number of studies, effect size (95% CI), heterogeneity	Results
					(1) The odds of medication adherence more than doubled with SMS text message reminders, compared with no reminders. Assuming baseline medication adherence was 50%, this translates to an improvement to 67.8%, or an absolute increase of 17.8%.
Lattie, 2019 [32]	Participation reminders	Contact metrics: (1) Email reminders vs no email reminders.	Completion—number of sessions or assessments or prompts completed.	(1) • Number of sessions completed (n=not reported): Reminder group mean 2.9, SD 2.5; no reminder group mean 3.6, SD 2.3; t=0.88.	(1) Email reminders were not associated with completing more sessions in a web-based intervention. There were also notable rates of participant attrition and early program discontinuation in many of the studies.
Kang, 2017 [31]	Reminders	Contact metrics: (1) 7 email or SMS text message reminders vs paper appointment card.	Completion—completion of three-dose human papilloma virus vaccine schedule.	(1) • Number of people completing the vaccine schedule (n=86): email or SMS text message reminder group 34%, paper card reminder group 32%; *P*=.76.	(1) Completion rates of a vaccine schedule did not differ by reminder format (email or SMS text message, compared with paper card).
Adams, 2015 [22]	Incentives	Reimbursement and gifts or penalties: (1) Cash lottery tickets for attendance vs usual care (no incentives). (2) Loss of US $40 welfare benefits for not vaccinating vs usual care (no incentives). (3) Loss of some welfare benefits for not vaccinating vs usual care (no incentives).	Engagement or uptake—uptake of preschool vaccinations; up to date with 0-2–year vaccinations; up to date with child vaccinations.	(1) • At each follow-up time point, attendance for any reason and for vaccination was higher in incentives group. (2) • No difference in up-to-date rates at 1 or 2-years follow-up. (3) • Welfare deduction group had higher vaccination rates at 1, 2, 3, and 4 years. At age 2 years, the welfare deduction group had higher vaccine series completion.	(1) The incentives group had higher attendance. (2) No difference between the groups. (3) The welfare deduction group had higher vaccination rates.

[a]RR: relative risk.

[b]I^2 statistic: percentage of variation due to heterogeneity between studies.

[c]SMD: standardized mean difference.

[d]OR: odds ratio.

RoB for Included Systematic Reviews

The assessment of the 16 items of AMSTAR-2 from each included review is demonstrated in Multimedia Appendix 3 [22-40]; 11 systematic reviews were rated as critically low [22,23,25,26,30-36] and 8 [24,27-29,37-40] were rated as low quality. Items 7 and 10, as indicated in Table 3, were rated as particularly low quality. All systematic reviews except 1 [29] reported potential sources of conflicts of interest, including any funding they received for conducting the review, but no review reported on the sources of funding for the studies included in the review. It is important to note that AMSTAR-2 does not evaluate the quality of the primary studies. Its objective is to evaluate the methodological quality of the systematic reviews, considering how well the systematic review was conducted (eg, literature searching and data pooling). Therefore, if a systematic review included primary studies with a high RoB but the review itself was well conducted, the review tended to be rated as *high quality*.

XSL•FO
RenderX

In Table 3, we detailed the overall confidence in the results of each included systematic review. Reviews performed poorly with respect to (1) reporting sources of funding for included studies (0/19, 0%), (2) adequately investigating publication bias (small study bias) and discussing its likely impact on the results of the review (4/19, 21%), and (3) providing a list of excluded studies and justifying their exclusions (6/19, 32%).

Table 3. Overall confidence assessment (Assessing the Methodological Quality of Systematic Reviews 2 tool) of the 19 included systematic reviews.

AMSTAR-2[a] items	Yes, n (%)	Partial yes, n (%)	No, n (%)	No MA[b], n (%)
1. Did the research questions and inclusion criteria for the review include the components of PICO[c]?	13 (68)	0 (0)	6 (32)	0 (0)
2. Did the report of the review contain an explicit statement that the review methods were established before the conduct of the review and did the report justify any significant deviations from the protocol?[d]	7 (37)	8 (42)	4(21)	0 (0)
3. Did the review authors explain their selection of the study designs for inclusion in the review?	12 (63)	0 (0)	7 (37)	0 (0)
4. Did the review authors use a comprehensive literature search strategy?[d]	3 (16)	14 (74)	2 (11)	0 (0)
5. Did the review authors perform study selection in duplicates?	13 (68)	0 (0)	6 (32)	0 (0)
6. Did the review authors perform data extraction in duplicates?	12 (63)	0 (0)	7 (37)	0 (0)
7. Did the review authors provide a list of excluded studies and justify the exclusions?[d]	6 (32)	0 (0)	13 (68)	0 (0)
8. Did the review authors describe the included studies in adequate detail?	13 (68)	3 (16)	3 (16)	0 (0)
9. Did the review authors use a satisfactory technique for assessing the RoB[e] in individual studies that were included in the review?[d]	9 (47)	6 (32)	4 (21)	0 (0)
10. Did the review authors report on the sources of funding for the studies included in the review?	0 (0)	0 (0)	19 (100)	0 (0)
11. If meta-analysis was performed, did the review authors use appropriate methods for statistical combination of results?[d]	7 (37)	0 (0)	4 (21)	8 (42)
12. If meta-analysis was performed, did the review authors assess the potential impact of RoB in individual studies on the results of the meta-analysis or other evidence synthesis?	6 (32)	0 (0)	5 (26)	8 (42)
13. Did the review authors account for RoB in individual studies when interpreting/discussing the results of the review?[d]	10 (53)	0 (0)	9 (47)	0 (0)
14. Did the review authors provide a satisfactory explanation for and discussion of any heterogeneity observed in the results of the review?	10 (53)	0 (0)	9 (47)	0 (0)
15. If they performed quantitative synthesis, did the review authors carry out an adequate investigation of publication bias (small study bias) and discuss its likely impact on the results of the review?[d]	4 (21)	0 (0)	8 (42)	7 (37)
16. Did the review authors report any potential sources of conflict of interest, including any funding they received for conducting the review?	18 (95)	0 (0)	1 (5)	0 (0)

[a]AMSTAR-2: Assessing the Methodological Quality of Systematic Reviews 2.

[b]MA: meta-analysis.

[c]PICO: population, intervention, control group, outcome.

[d]Items considered as critical domains in the AMSTAR-2.

[e]RoB: risk of bias.

Out of the 19 reviews, 10 (53%) accounted for such bias in individual studies when interpreting and discussing the results of the review and 9 (47%) reviews used a satisfactory technique for assessing the RoB in individual studies included in the review. For reviews that used a satisfactory technique for assessing RoB, most [23,26,27,29,35,36] suggested that e-engagement, participation, and retention promotion strategies were effective.

Discussion

Principal Findings

This study reviewed the current state of research comparing alternative strategies to maximize participant engagement, participation, and retention in large digital studies (as held in narrative and systematic reviews). We explored EFIs and study design features that aid engagement, participation, and retention.

XSL•FO
RenderX

For reviews that met the inclusion criteria, there was substantial heterogeneity across studies in terms of e-strategies.

Most reviews show that e-engagement and participation promotion strategies are effective, which is promising. However, these reviews canvassed relatively few experimentally tested strategies, suggesting that the myriad of alternative strategies that may have been tested have not yet been the subject of reviews. Many studies have reported these features as a secondary goal of objectives such as adherence to therapy rather than as a primary goal in and of itself. From the 19 reviews, few contained very large digital studies that directly compared alternative strategies to examine impacts on engagement and retention; this may reflect the small number of such mega-studies worldwide. However, contributing reviews contained multipurpose (observational and interventional) cohort studies conducted in clinical and research settings. Motivation for study engagement, participation, and retention may differ somewhat between observational and clinical intervention studies where the participant can potentially directly benefit from participation, although the successful strategies make sense and at face value seem likely to generalize to both settings. In the absence of more tailored evidence, engagement strategies successful in intervention studies may be the best evidence we have, though they should be cautiously applied.

In the context of technical study design features, evidence suggests that using email or SMS text message reminders and voice notifications enhanced participant attendance to health care clinics. Although promising, these results should be interpreted with caution given the short duration of the e-intervention and reliance on self-reported medication adherence measures. Future studies need to determine the features of text message interventions that improve success and appropriate patient populations, sustained effects, and influences on clinical outcomes.

Human facilitation or support was important in influencing the uptake, engagement, and outcomes of digital technologies [26]. As illustrated by completion modules and completer rates, the larger effect sizes found in guided interventions suggested increased intervention adherence.

Reviews examining the effectiveness of e-engagement, participation, and retention interventions in the context of a health care intervention (rather than a cohort study) suggested the following:

1. Visual and personalized feedback seemed effective, for example, for recordings of parent-child interaction in the neonatal intensive care setting [42,43]. This reinforces successes and/or offers motivational support to achieve an individual's goals and is consistent with known key strategies for behavior change.
2. In e-intervention studies, goal setting has mostly been used as a behavior change strategy [44-46], such as the Fishbein and Yzer Integrative Model of Behavioral Prediction and Fogg Behavior Model for Persuasive Design [44], Theory of Planned Behavior and Fun Theory [47], the Social Cognitive Theory [48,49], and the Coventry, Aberdeen, and London-Refined taxonomy of behavior change techniques [50].
3. Using digital push interventions for vaccine uptake and series completion supported the idea that digital technologies could be a useful adjunct in improving vaccination rates. Reminder interventions for vaccinations have improved the completion of vaccination schedules.
4. There was higher uptake when parental financial incentives or rewards were offered in quasi-mandatory schemes to increase the uptake of preschool vaccinations. Universal gifts were more acceptable than targeted parental financial incentives.
5. Mental health apps were effective or partially effective in producing beneficial changes in psychological outcomes among young adolescents (ie, among college students). This is consistent with past meta-analyses of digital mental health programs for similar populations [51,52].
6. Intensive guidance (with a human coach) was more efficacious than unguided interventions and a beneficial design feature, particularly for mental health studies. It is considered an adherence-facilitating measure in large digital research studies.
7. Electronic text notifications improved attendance and reduced nonattendance (no-shows) across health care settings. Sending multiple notifications improved attendance rates.

Overall, no specific e-intervention strategy was identified as being superior. However, more interactive methods of delivery, such as videos and regular e-therapist contact for training, (1) improve adherence, (2) increase completion rates, and (3) improve fidelity. Further research is needed to understand the strategies that improve retention in longitudinal studies.

Limitations

We limited our search to systematic reviews published between 2012 and 2019. These reviews should give good reach into source studies during the preceding decade while encompassing the rapid evolution of technology and the explosion of digital methods in this period and thus relevant to the new studies of the 2020s. However, we acknowledge that this is an arbitrary choice. Although all of the literature sourced reported on studies using partial or fully digital contact with participants, much was in the context of interventions and may not be wholly applicable to observational cohort studies. Nonetheless, those strategies found to be successful in interventional settings seem worthwhile to explore in cohort studies. We obtained low-quality ratings for some systematic reviews. We also note that although high engagement and retention are the best strategies to obtain powerful representative data sets, statistical techniques such as multiple imputation are vital adjuncts.

Conclusions

Although all studies want to maximize the recruitment and retention of study participants, the best methods to do this, particularly in digital settings, are understudied. This review adds to the small but growing literature on methods for optimizing engagement and participation in digital contact cohort studies. Evidence-based recruitment and retention methods are particularly important to the success of the next generation of very large birth cohorts, which are very expensive but have low funding per participant and require high retention

XSL•FO
RenderX

throughout decades despite participants having no or very little in-person contact with the study team. Ideally, such studies will not only use existing evidence-based methods but will also build on experimental studies of alternative engagement and retention methods to build the evidence base of *the science of science*.

Acknowledgments

This study was funded by GenV. GenV is supported by the Paul Ramsay Foundation, the Victorian Government, the Murdoch Children's Research Institute, and the Royal Children's Hospital Foundation (2019-1226). Research at the Murdoch Children's Research Institute was supported by the Victorian Government's operational infrastructure support program.

MW is supported by Australia's National Health and Medical Research Council (NHMRC) Principal Research Fellowship 1160906. FKM is supported by NHMRC Career Development Fellowship 1111160.

Authors' Contributions

MW conceived the study. MW, JN, and SAC designed the study. JN, SAC, YW, and LC conducted the review. JN drafted the first version of this manuscript. All authors contributed to writing the manuscript and read and approved the final review.

Conflicts of Interest

Abstract

Twitter is a free, open access social media platform that is widely used in medicine by physicians, scientists, and patients. It provides an opportunity for advocacy, education, and collaboration. However, it is likely not utilized to its full advantage by many disciplines in medicine, and pitfalls exist in its use. In particular, there has not been a review of Twitter use and its applications in the field of neurology. This review seeks to provide an understanding of the current use of Twitter in the field of neurology to assist neurologists in engaging with this potentially powerful application to support their work.

(J Med Internet Res 2021;23(5):e25229) doi:10.2196/25229

KEYWORDS

Twitter; neurology; tweet chats; research; tweetorials; contemporary issues

Introduction

Twitter is a free-to-use social networking and microblogging platform, enabling registered users to post (ie, tweet), read, and repost (ie, retweet) short messages known as tweets. Tweets are limited to 280 characters—previously 140—and users can share photos, short videos, or website URLs [1]. The limited character count is an important consideration when tweeting, and encourages succinct delivery of concepts or acts as the starting point for a conversation. Messages from profiles the user has *followed*, using their @handles, appear in a curated *feed*, which is updated with new tweets at different intervals. Though Twitter has been widely used in medicine by physicians, scientists, and patients, its application in the field of neurology remains relatively uncharted.

Here we explore the powerful potential of Twitter in promoting research, education, and health care activities in neurology to relevant stakeholders. We also examine the risks and limitations of Twitter use in a professional capacity.

XSL•FO
RenderX

Search Strategy and Selection Criteria

References for this review were identified by searching PubMed, Google Scholar, Embase, MEDLINE, and the Twitter site between March 2006 (ie, when Twitter was founded) and July 2020 as well as searching references from relevant articles. The search terms "Twitter," "neurology," "journal clubs," "tweetorials," "tweet chats," "misuse," "unprofessional," "social media," "health care," and "medicine" were used. The search was restricted to English-language articles. The final reference list was generated on the basis of relevance to the topics covered in this review.

Neurology and Twitter

Twitter has become an appealing platform for the scientific community to exchange ideas, information, research insights, teaching and career achievements, and opportunities. Many academic Twitter hot spots garner a huge following (eg, #AcademicChatter, #PhDChat, #Medtwitter, @OpenAcademics, and #Epitwitter). As with other social media platforms, neurologists, neurology residents, neuroscience researchers, advocacy groups, journals, professional societies, and funding agencies have all asserted their presence in the *Twitterverse* over the past few years (Tables 1 and 2 [2-4]). Tweets addressed to neurologists are often tagged #neurotwitter, and users might post anything ranging from introductions to recently published papers from their institutions to pictures of electroencephalogram (EEG)–adorned cakes.

Table 1. Selected neurology journals, professional associations, and medical funding agencies with a strong Twitter presence.

Journal, professional association, or funding agency	Twitter handle	Approximate follower count
Journal		
Green Journal	@GreenJournal	44,900
Lancet Neurology	@TheLancetNeuro	26,900
American Academy of Neurology (ANN)	@AANMember	23,200
Brain	@Brain1878	19,800
Nature Reviews Neurology	@NatRevNeurol	28,100
Nature Neuroscience	@NatureNeuro	86,400
JAMA Neurology	@JAMANeuro	35,700
Neurology Today	@NeurologyToday	44,000
Association		
Motor Neuron Disease (MND) Association	@mndassoc	31,000
Stroke Association	@TheStrokeAssoc	107,000
Alzheimer's Research UK	@AlzResearchUK	78,000
American Stroke Association	@American_Stroke	19,100
Brain and Life Magazine	@BrainandLifeMag	34,300
Dementia UK	@DementiaUK	106,200
International Parkinson and Movement Disorder Society	@movedisorder	7157
World Muscle Society	@WorldMuscleSoc	800

Table 2. Examples of patient support groups for neurological disorders that have a Twitter presence.

Support group	Support group Twitter handle	Activity
The Brain Charity	@TheBrainCharity	Offers emotional support, practical help, and social activities to anyone with a neurological condition
Multiple Sclerosis Foundation	@MS_Focus [3]	Helps people with multiple sclerosis (MS) live their best lives through free programs, services, and education
Stroke Association	@TheStrokeAssoc	Supports people in rebuilding their lives after stroke with their #RebuildingLives campaign
Alzheimer's Society	@alzheimerssoc	Provides information and support for people affected by dementia (#UnitedAgainstDementia)
FSHD Society	@FSHDSociety [4]	A research-focused patient organization for facioscapulohumeral muscular dystrophy (FSHD)
Amyloidosis Support Groups	@AmyloidosisSupp	Official Twitter account of Amyloidosis Support Groups; dedicated to the support of amyloidosis patients, caregivers, and former caregivers
Parkinson's Foundation	@ParkinsonDotOrg	Strives to make life better for people with Parkinson disease through expert care and research
FND Action	@FNDAction	A charity organization for raising awareness of functional neurological disorders (FNDs) [2], including nonepileptic attack disorder (#NEAD), and supporting those diagnosed with FNDs (#action4FND)
Muscular Dystrophy Association	@MDAorg	Strives to transform the lives of people affected by muscular dystrophy (MD), amyotrophic lateral sclerosis, and related neuromuscular diseases through innovations in science and in care
Friedreich's Ataxia Research Alliance	@CureFA_org	Works to direct and focus the resources and relationships needed to treat and cure Friedreich's Ataxia (FA)
Hereditary Neuropathy Foundation	@CMTNeuropathy	Supports patients and families with updated relevant information and is dedicated to funding Charcot-Marie-Tooth disease (CMT)–related research

Promoting Research

Enhance Research Visibility and Recruitment

Twitter hashtags (ie, #) help connect people with topics of interest. By following specific profiles and hashtags and reading the associated threads, one can quickly establish an overview of the most up-to-date research activities, clinical advances, and future perspectives. This effect is particularly apparent in rare diseases, where following key handles (ie, @) and hashtags ensures that researchers, physicians, and patients can establish connections; for example, #ALSResearch (amyotrophic lateral sclerosis, ALS), @Phelan_McDermid and #PMSF (Phelan McDermid Syndrome Foundation), @thetinman_org (help and awareness for stiff-person syndrome), @yaya4HL (Yaya Foundation for 4H leukodystrophy, 4HL), @fragilexsyndrom, and numerous others. Such social media cross talk is often helpful in building clinical registries and biorepositories and may facilitate higher-quality clinical and translational research.

Twitter can help promote the visibility of clinical trials, enhancing both recruitment and inclusivity via links to enrollment websites [5]. Some such examples are as follows:

1. The Emergency Laparotomy and Frailty (ELF) study achieved a target enrollment of 500 participants by utilizing a Twitter handle (@ELFStudy) and eye-catching logos on its Twitter profile [6].
2. The AVERT DOSE trial (@AVERTDOSEtrial) posts regular updates on their work evaluating rehabilitation after stroke via their Twitter profile [7], ensuring sustained visibility.
3. Novartis is recruiting participants with advanced malignancies for US clinical trials, and its Twitter profile (@NovartisOncCT) shares the following link for potential participants to join: "http://bit.ly/2LhfJIk! #ClinicalTrialsSM" [8].
4. Wasilewski et al, in the context of a caregiver study, conducted a secondary analysis of their Twitter recruitment and found that out of the 71 caregivers, 27 were recruited via Twitter. General recruitment tweets were most frequently shared by users [9].

In a study by Sedrak et al, while the majority of the tweets (86.3%) had embedded links to news articles, one tweet led to a patient recruitment site (ie, ClinicalTrials.gov; row 7 of the second table of the study) [5]. Harnessing Twitter in this way can result in novel and larger networks.

Facilitate International Connections, Networks, and Visibility

Twitter enables users from around the world to interact with individuals at the forefront of academic research or clinical practice. This interaction may be via tweets, comments, or both—an engagement that might not otherwise have been possible. Conference organizers can also enhance the influence of conference-related discussions beyond those attending in person through social media, including Twitter [10]. Following the people you met at a conference can also be a convenient way of light-touch networking long after a conference has ended.

XSL•FO
RenderX

Some fellowship training programs use Twitter to advertise; in the United States, neurosurgery programs have the highest social media presence compared to neurology and neuroradiology [11], especially in terms of advertising residency programs [12]. Since the onset of the COVID-19 pandemic, there has been at least a 216% (from n=24 to n=76) increase in the number of neurology residency accounts on Twitter, as noted by Zelikovich et al in a blog post in Neurology [13].

Within specialties, there are focused spaces for discussion on specific topics or diseases—a global connection for users with a small area of shared interest. For instance, @Microbleeds discusses microbleed research and @ScienceofPD highlights Parkinson disease research [14]. Many also use Twitter to disseminate collaborative subspecialty education, such as neuropathology and neuroradiology, to broader audiences.

Rapid Communication of Research

Twitter provides a platform where opinions, queries, and comments on recently published research can be posted, and reacted to, in real time facilitating easy access for clinical neurologists to recent advances. Examples of highly followed journals and societies can be seen in Table 1. Connecting clinicians and researchers is vital, as research data with translational potential may be helpful in management decisions. Moreover, input from physicians may prompt research in novel and impactful fields. Patient or public comments on research topics may also provide new perspectives and relevant research questions. Thus, Twitter can facilitate mutually beneficial, multichannel communication [15].

Capturing a Wider Audience, Faster: #Power

Twitter facilitates patient involvement in care and has the capacity to remove barriers to understanding complex medical conditions through sharing information. By using Twitter, a patient can connect to support groups pertaining to his or her illness, such as the Motor Neuron Disease (MND) Association (@mndassoc) [16] and Parkinson's Foundation (@ParkinsonDotOrg) [17]. Patients may interact with others who have the same disease, share experiences, and discuss treatment facilities and trials, advances in disease management, prevention, and potential sources of financial support, all of which enhance patient care. Twitter also provides a forum for all parties vested in health care to interact, including physicians, allied health care providers, patients, carers, advocacy groups, policy makers, and the pharmaceutical industry. Tagging using hashtags (ie, #) helps identify and, therefore, rapidly disseminate information to others, creating a mechanism for online multidisciplinary and interdisciplinary feedback, which may improve coordination among all relevant health care stakeholders [18].

Role as a Search Engine: Hashtags and Handles

Twitter allows for focused reading on a particular topic of interest by providing links to research articles. For instance, someone interested in clinical genetics can follow #GeneTherapy, browse through tweets, and obtain links to pertinent websites, such as the following tweet:

> *Standardizing Cell and #GeneTherapy Remains Bioindustry Goal -- Please Read: http://ow.ly/3fJu50AQgLP; @AVROBIO about characterizing stem cells for gene therapy.*

Individuals who have or research a specific disease can keep up to date at the level of the individual gene; for example, the inherited neuropathy gene PMP22 has its own hashtag: #PMP22.

Conference Updates and Participation

Conference updates are shared through individual Twitter handles (eg, @SfN2020 and @abnconf) and via broader platforms using hashtags (eg, #BBIConf2018, #TheNeuroNetwork, #NeuroConference, and #AANAM). For future conferences, links can be utilized for abstract submission (eg, #Neurology2021), resulting in broader coverage and reach. It is possible to share the latest research presented during and after a conference, increasing accessibility to those unable to travel and attend in person. Consider a neurologist at a conference who replies to a tweet from @GreenJournal; others may respond in real time with critiques and may share related papers, real-life experiences, and links to related conference presentations or other research. This intertwining of experience, expertise, and communication has the potential to advance the reach of health care delivery systems. Virtual conferences have found renewed popularity in the context of the COVID-19 pandemic and benefit from advertising via Twitter; for instance, @WorldStrokOrg recently tweeted the following:

> *#ESOWSO2020 will run as a fully virtual event from 7-9 November. Virtual sessions will allow live interaction and will be available on-demand in the weeks following the Conference.*

Another example from the Movement Disorder Society (MDS) Twitter handle @movedisorder is as follows:

> *New in #MDSMovingAlong: Looking Forward to the First MDS Virtual Congress. Read more from the MDS Virtual Congress Task Force on plans for this year's big event. There is still time to register at no charge before it begins on September 11. #MDSCongress.*

Platform for Journal Club and Research Review

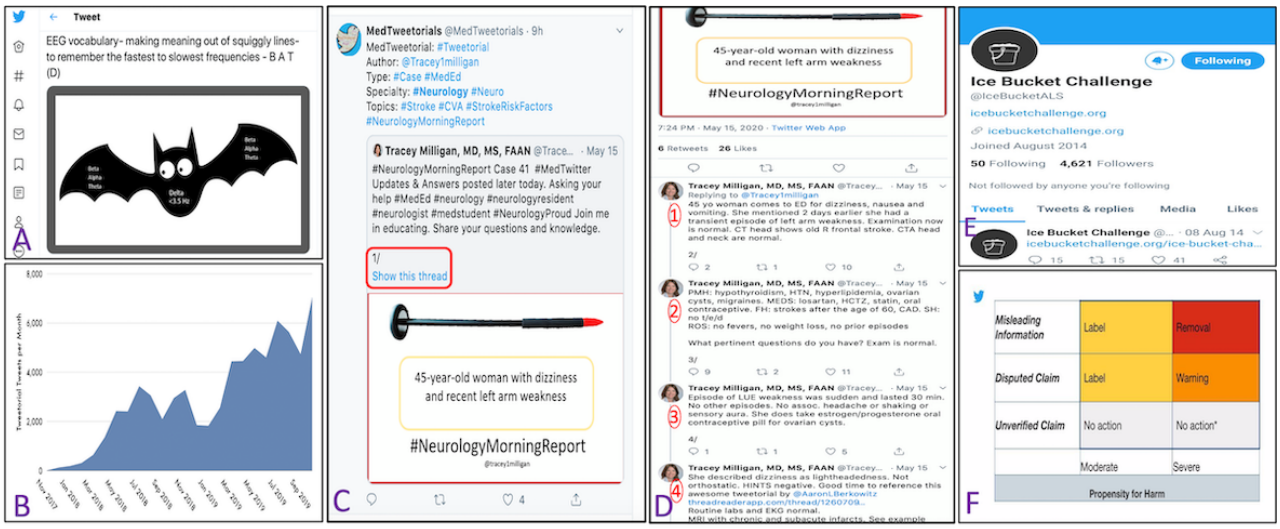
Journal clubs on Twitter are an emerging alternative to in-person journal clubs, which are limited by time or geographical location. Twitter provides accessibility and flexibility to involve people globally, without the added pressure of hierarchy, ensuring a broader audience. For example, #NCSTJC is the Twitter hashtag for the Neurocritical Care Society's journal club. Similar to an in-person journal club, at a Twitter journal club, a paper is selected, sometimes using crowdsourcing to ascertain participant interest. At a specific time, participants log on to Twitter, and there may be a facilitator similar to an in-person setting. Preselected questions and polls may be posted via handles or hashtags to the participants. Though there is potential for textual discussion, it is limited by the 280-character limit, unless a thread is used [19].

Traditionally, journals provide a restricted and moderated platform for research review and comments on recently

XSL•FO
RenderX

published data. Twitter provides a more open platform for instant, multidimensional feedback on research quality and validity. On an individual level, reading through such comments may help broaden knowledge and enhance analytical skills. On a larger canvas, it may identify research flaws and knowledge gaps, ultimately leading to better designed and focused research. One can even seek comments from a particular organization or individual using their Twitter handle. Furthermore, there is a distinct advantage of obtaining varied views across the globe for one's research, rather than the tunnel vision that can exist within smaller communities.

An Alternative to Publishing Powerhouses



Academics and the public can be biased toward publications in high-impact journals, which may result in excellent research work that is published in less "prestigious" journals, thereby gaining less visibility. Social media outlets, such as Twitter, offer individuals and organizations such as universities a platform to publicize their work. However, expression of one's expertise and research work through social networking sites, instead of through conventional platforms like journals, can be considered as less thorough or pertinent [20].

Education and Learning

Case Discussions

Twitter has opened up new dimensions to education and learning. For example, Tracy Milligan (@Tracey1milligan), through #NeurologyMorningReport [21], shares clinically relevant neurology cases via interactive, stepwise reasoning. Twitter provides a platform to tweet bite-sized informative pearls, and by the virtue of the opportunity for interaction, the chance to learn from each other's varied clinical expertise and experience. Short, snappy, and humorous posts (eg, picture of a bat as a tool to remember EEG wave frequencies; Figure 1, A) result in a fun-filled learning experience. Thus, Twitter enhances traditional teaching by making it more interactive, exciting, and practical.

Figure 1. Examples of various aspects of Twitter that can be applied to neurologists. A. A representative tweet depicting a pictorial mnemonic on how to remember electroencephalogram (EEG) wave frequencies shared on Twitter. B. Monthly volume of tweetorials showing exponential growth; data were taken from Healthcare Social Graph using keyword and hashtag versions of tweetorials from November 2017 to October 2019. C and D. Examples of the use of tweetorials in neurology. C. Tracey Milligan shares an interesting clinical scenario and clicking on "show this thread" (red rectangle) opened up all the discussions pertinent to this case (D, 1), numbered here as 1, 2, 3, 4, and so on. E. A snapshot of the Ice Bucket Challenge movement on Twitter that was started to garner donations for amyotrophic lateral sclerosis (ALS) research. F. Brightly colored labels that Twitter is contemplating adding directly beneath lies and misinformation posted by users.

Tweetorials

Developed in late 2017 by Mike Thompson and Vinay Prasad, *tweetorials* have seen explosive growth (Figure 1, B) [22] and have recently been accepted by the New England Journal of Medicine as a type of publication under the handle @MedTweetorials [23]. A tweetorial is a series of educational tweets posted in quick succession or a long or extended tweet, made by stringing together a series (ie, thread) of tweets [24]. Stringing together tweets, or composing a thread, allows the educator to get around the 280-character limit per tweet [25]. Because they are typically *tagged* with a keyword or hashtag and the tweets numbered by the convention 1/n, tweetorials are easy to retrieve (Figure 1, C and D). As clinical reasoning forms the backbone of neurology teaching, the structure of tweetorials has become immensely popular. For example, Crystal Yeo (@CrystalYeoMDPhD) shares tutorials on neuromuscular conditions as tweetorials.

Tweet Chats

Tweet chats are public Twitter conversations around a unique hashtag. This hashtag allows one to track and participate in discussions as well as to connect with health care personnel and laypersons with specific interests [26]. For instance, the World Stroke Organization's (@WorldStrokeOrg) campaign through tweet chats on COVID-19 helped spread much-needed awareness on challenges and workflow modifications during the pandemic. A representative tweet is as follows:

> *In the meantime, mark your calendar for the next #WSOwebinar on August 18: #Stroke Guidelines in the setting of #COVID19 with @patrice_lindsay,*

XSL•FO
RenderX

@sheilambrasiland Jeyaraj Pandian, @gsaposnik @neurologija @WorldStrokeEd @IntJStroke @WStrokeCampaign @BelsonSarah.

Recently, NeurologyLive and the Women Neurologists Group hosted a tweet chat on mental health in neurology, with topics addressing mental health issues and available resources from the clinician's perspective; relevant tweets were tagged with #MindMoments. Recent tweets concerning #MindMoments have generated a staggering 1.1 million impressions [27].

Learning and Training Opportunities

Twitter can be used to advertise and access training opportunities across all aspects of neuroscience. Examples include @NeurologistJobs, @ABNTrainees, @GetNeurologJobs, and, for the US match system, @NMatch2021. Scholars can identify and connect to potential mentors. Users of the #PhDChat network [28], created by UK doctoral students (>12,000 followers), offer advice on identifying best-fit training programs, exchange resources, and extend support via sharing experiences in academia. During the COVID-19 pandemic, PhD writing rooms, such as those hosted by @PhDForum, have evolved to help candidates focus. Curating one's feed by following those providing relevant material can result in daily educational snippets with minimal effort. Some notable examples are as follows: (1) case- and image-based discussion on EEG hosted by Rebecca Fasano, @RebeccaFasanoMD (eg, Emory EEG Case of the Day #79 [29]); (2) @TheNotoriousEEG hosted by M Scott Perry MD [30]; (3) @ClinicalNeuroph [31], which provides news from Clinical Neurophysiology, Clinical Neurophysiology Practice, and International Federation of Clinical Neurophysiology; and (4) @MDedgeNeurology [32], which gives an overview of the most recent research and clinical developments in neurology and neuroscience.

Workplace and Professional Concerns

Work-life balance and healthy working environments are prioritized by health care institutions. Recent studies have shown burnout to be very common among all neurology practice settings and subspecialties, with one study reporting that 60% of respondents had at least one symptom of burnout [33], and another study reporting burnout to be as high as 73% and 55% among neurology residents and fellows, respectively [34]. A study on Canadian physicians reported that more than a quarter of the physicians had mental health concerns, mostly depressed mood [35]. However, sharing of professional or workplace challenges is not always straightforward and should be approached with careful judgement and with the social media policies of relevant organizations in mind. Twitter provides a platform for individuals to connect with others with shared experiences or concerns and enables discussion that is centered on coping strategies and suggestions; the platform can act as an online *professional support group* of sorts. Examples include #BlackInNeuro, @WNGtweets (Women Neurologists Group), @LGBT_PsychNeuro, and others. Such groups have the potential to reduce isolation and enhance connectivity and visibility, and act as one of the spaces for people to discuss how to best manage the inherent challenges of the working and academic worlds.

Community Health Care–Related Activities

Support Groups

Many community-centric health care activities are shared through the Twitterverse. Support groups for a variety of common and, importantly, rare neurological disorders enable relationships beyond the traditional physical space (Table 2).

Awareness Campaigns

Public awareness campaigns that use Twitter can reach a broader audience within a shorter time frame than more traditional advertising platforms. For instance, the ALS Ice Bucket Challenge (@IceBucketALS) [36] was conceived to promote awareness of ALS and to encourage donations to research. It went on to become *viral* [37] on social media during July and August 2014 (Figure 1, E), resulting in donations of US $227.6 million for ALS research in 2014 and the subsequent 4 years [38].

A study conducted in 2011 uncovered the stigma associated with epilepsy on Twitter, as 41% of tweets related to "seizure" were seen to be derogatory in nature [39]. Similar studies have also noted the use of pejorative tweets referring to psychogenic nonepileptic seizures, even by professionals [40]. Sirven et al called for a Twitter revolution to alter the way in which we perceive seizures [41]. Today, many epilepsy patient advocacy groups like the Epilepsy Foundation of America (@EpilepsyFdn; >34,000 followers) and Epilepsy Action (@epilepsyaction; >28,000 followers) regularly tweet content aiming to raise public awareness and knowledge of seizures. Only a few years later in their 2017 analysis, Meng et al found that within epilepsy and seizure accounts, verified foundations and support groups had the greatest number of accounts and users on Twitter and Facebook, with 48% of their posts aiming to provide information or to dispel common misconceptions and stigma surrounding epilepsy [42].

Patients as a Part of Focus Groups

Twitter has been adopted by patient-focused groups (eg, NeuroImmunology Club: @NeuroImmunology [43]; MuscularDystrophyUK: @MDUK_News [44]; and Sign Against Stroke: @signagnststroke [45]) for enabling interactions between clinicians and patients, using tweet replies, and following particular handles or hashtags. This allows patients suffering from a particular illness to directly connect with their clinicians and get clarification on their illness and further treatment prospects. In the longer term, this primarily addresses patients' main concerns but also improves the clinical community's awareness of understanding of the disease and its management, thus bridging critical care gaps.

Pitfalls: Ethical and Legal Concerns

Overview

The legal and ethical issues surrounding Twitter are no less complex than those affecting the internet in general. Currently, Twitter takes some precautions in identifying the authenticity of individual users. If one chooses to make bad decisions with

XSL•FO
RenderX

the information they are sharing, such as defamatory, harassing, malicious, menacing, deceptive, impersonating, or threatening tweets, they may be held liable for legal action [46]. However, regulations remain porous. Many professional bodies have issued formal guidance, such as the General Medical Council ethical guidance in the United Kingdom, Twitter Guidelines & Best Practices by the US Centers for Disease Control and Prevention, Twitter Best Practices & Tips for Physicians by Johns Hopkins Medicine, and numerous others. Some critical concerns are discussed in the following sections.

Misrepresentation of Credentials

Individuals posing as physicians may post information that tends to be taken at face value by an unsuspecting user.

Misinformation

Misleading messages may be widely retweeted and, hence, gain traction. No structured system currently exists to filter out misinformation on Twitter, potentially allowing inaccurately informed persons, nonprofessionals, and those with commercial interests to frame their views as facts. This can pose serious problems for trainees and patients alike, who may struggle to identify genuine and credible posts. Various groups may use the same hashtag, which confuses hashtag followers. Individuals or organizations may use a hashtag to either spread misinformation or to "bog down" a hashtag with irrelevant or unhelpful posts, which makes it harder to find the desired posts. In the nascent stages of the COVID-19 pandemic, there was a "flood of misinformation" [47] on Twitter, such that the World Health Organization termed it a "massive infodemic" [48].

Shahi et al undertook an exploratory study on COVID-19 misinformation on Twitter. Analysis of 1500 tweets relating to 1274 false and 276 partially false claims revealed that verified Twitter handles, including organizations and celebrities, were also involved in either creating or spreading the misinformation via new tweets or retweets, respectively. They also noted that false claims propagated faster than partially false claims (χ^2_3=10.2; P<.001; N=1500) [49]. Controversial posts were taken down only after large-scale objections [2,50]. In October 2020, Twitter removed a tweet by Scott Atlas, a controversial US scientist, in which he had wrongly stated that masks fail to protect against coronavirus: "Masks work? NO" [51]. In the same month, then–US President Donald Trump tweeted that the United States had "learned to live with" flu season, "just like we are learning to live with Covid, in most populations far less lethal!!!" Twitter added a caveat the same message with a warning about "spreading misleading and potentially harmful information" [52].

Twitter is experimenting with adding brightly colored labels directly beneath lies or misinformation posted by famous users (Figure 1, F), in addition to a community reports feature where inaccurate and misleading information posted by public figures is corrected directly beneath a tweet by verified fact checkers and journalists. While this may benefit the medical community [53], it may be worthwhile to explore strategies that favor dissemination of evidence-based information.

Commercial Influences

Twitter posts with biased information may be promoted by parties with commercial interests. During the COVID-19 infodemic, the US Food and Drug Administration had to issue warnings to individuals to refrain from promoting or selling colloidal silver on social media profiles [54]. Twitter may be potentially misused by individuals and companies peddling unproven, investigational, and controversial medications, and by organizers of predatory conferences [55].

In June 2020, an Indian-based Ayurveda pharmacy claimed that it had discovered a potential cure for COVID-19, with an "80 per cent cure rate" [56]. A tweet from the chief executive officer of the pharmacy, apparently suggesting that it had obtained approval from the Ministry of AYUSH (Ayurveda, Yoga and Naturopathy, Unani, Siddha, and Homeopathy) for the drug as a "cure for COVID-19," went viral on Twitter [57-60]. The combined drug preparation and its individual components together recorded sales of over 85 lakh units within 4 months of its launch, garnering an estimated 241 crore Indian rupees (~US $32.5 million) for the pharmacy [61]. These record sales occurred despite the fact that soon after its launch, the Ministry of AYUSH ordered the Ayurveda pharmacy to stop advertising the product as a COVID-19 cure due to the absence of appropriate clinical trial data to back its claim [61].

Similarly, predatory conferences aggressively solicit conference abstract submissions [62] and combine broad topics from multiple disciplines to cast a larger net and bring more physicians into their fold [63]. Social media, including Twitter, allows them easy access to a broad audience. Cress et al collated a list of confirmed predatory conference organizers [63]. Individuals often share their experience of receiving invitations for predatory conferences on Twitter; for example, Wim Crusio, the editor-in-chief of the journal Behavioral and Brain Functions (@WimCrusio) once shared the following [64]:

> *Just got an invitation for "Neurology 2019", a world-wide meeting that attracted no less than 60 participants last year in Paris! This gem is organized by @Euroscicon. #Avoid #PredatoryConferences #FakeConferences.*

Strategies to avoid such commercial misuse may include identifying and calling out suspicious activity or insisting on *identifier* hashtags.

Exposure Bias

It is possible to be highly influenced by a small group of opinions. Users should take time to consider whether what they see is unbiased, as algorithms suggest potential profiles of interest and posts based on the interests users have already demonstrated. Twitter is an enviable educational resource, but users must always ensure that their practice is appropriately evidence based.

Patient Confidentiality Breaches and Privacy Concerns

Twitter provides easy access to potential *research participant* data sets, which raises some concerns. In one study, 60% of Twitter users surveyed were unaware that publicly available tweets can be used for research, and 65% felt researchers should

XSL•FO
RenderX

not be able to use public tweets without user permission [65-67]. There are numerous examples of patient-identifiable information being inadvertently or inappropriately shared by professionals [68].

Unprofessional Behavior

Previous studies on verified medical Twitter users have reported a worrying trend of "unprofessional" tweets, including patient privacy violations, profanity, sexually explicit content, discriminatory statements, inaccurate information, and self-promotion [69]. While most of the violations were clearly not in keeping with a professional code of conduct, the interpretation of unprofessional was variable. Recently, a paper called *Prevalence of unprofessional social media content among young vascular surgeons* was retracted by the Journal of Vascular Surgery [70]. The researchers classified "pictures in a bikini, posted on Twitter" as unprofessional, leading to a backlash from the scientific community that was centered upon interpretation and boundaries of unprofessionalism. While some professional bodies have published ethical guidelines for doctors' use of social media, the field remains largely unregulated [71,72]. Twitter users should keep in mind that individuals have been dismissed from their professional positions as their tweets were deemed as "unprofessional behavior" by their institutions [73].

Breach of Intellectual Property

Sharing of prepublished content, speaker slides, and pictures taken during lectures beg the question of whether this may qualify as a breach of intellectual property. For users, it may be best to ask for permission from the primary source prior to posting information on Twitter.

Trolling

Trolling refers to deliberate acts of making controversial comments in order to provoke internet users to respond emotionally. Trolls have used tweets to target patients with photosensitive epilepsy with flashing images intended to provoke seizures in the recent past [74,75]. Before posting, users should consider whether their posts might be considered provocative.

Confusing Hashtag Use

Various groups may use the same hashtag and confuse hashtag followers. People may also use a hashtag incorrectly or to spread false information. In addition, people may bog down a hashtag with many posts that are not necessarily relevant or helpful. All of these make it harder to find the desired posts.

Tips for Using Twitter

There are numerous other ethical concerns associated with physicians' use of Twitter. One critical question is, "Who will regulate its use and how could regulations be enforced?" While Twitter has initiated, and will initiate, changes based on real-life experiences, the onus of patient confidentiality and professionalism lies with individual users. The challenges can be much higher in countries with lower English literacy, since the vast majority of information in the aforementioned resources is presented in English. The issue of language translation should be considered, as the message could be lost or transformed by translation. With this in mind, we propose some tips for using Twitter in Textbox 1.

XSL•FO
RenderX

Textbox 1. Tips for Twitter use in order to maintain a healthy, informative, and interactive Twitter profile.

How should I use Twitter?:

1. Consider operating separate personal and professional accounts.
2. Make an honest, representative Twitter profile. Identities are periodically verified by Twitter.
3. Before sharing or retweeting, check the authenticity of the information and source. If you should reference another user's work or tweet, use the retweet function and add a comment or use the relevant hashtag or handle to credit them. Alternatively, provide a reference or a URL to the source material.
4. Healthy critique is positive. Even if offence is not intended, comments that could be interpreted as bullying or discriminatory are ill advised. Consider whether foul language is truly necessary.
5. Educate yourself with the social media guidelines of your institution and strictly adhere to them. Remember that employers often review social media accounts—never tweet anything that could affect your professional standing or employability. In case of complaints and discrepancies, employers, regulatory bodies, or legal agencies can become involved.
6. Use meaningful hashtags. Follow a large number of other accounts and follow your followers back to maximize the number of people who see your tweets.
7. Proudly share your work. If people learn from you, they may like, follow, or retweet you.
8. When following, posting, and retweeting, endeavor to show good judgment and consider why you are saying what you are—ensure it reflects well on you and your colleagues.
9. Carefully choose the people and groups you follow or share information with. Review the privacy settings to regulate who can view your posts.
10. If you are a victim of targeted harassment or abuse, unfollow and end any communication with that user. If the behavior continues, it is recommended to block the user and report them to Twitter.

How to maintain social media professionalism:

1. Avoid advertising.
2. Avoid sharing any patient-identifiable information; even if anonymized, ensure you have the proper consent.
3. Demonstrate good judgement—if you should not say it in your workplace, it should remain untweeted. Avoid posting and sharing misinformation, racist or discriminatory statements, or unpleasant or explicit content. Think carefully before tweeting: if necessary, compose your tweet and review it after a short period before posting.

Conclusions

The Twitterverse is a vast and exponentially growing expanse of information. Neurologists have taken to Twitter to educate, promote research, share information rapidly, and reach a broader potential global audience. Twitter has added a new dimension to learning and education in neurology in a practical and interactive manner. Multichannel interactions have furthered improvements in patient care and other health care–related activities. This has been particularly beneficial in promoting, furthering, and communicating research. In addition, there is enhanced support available to patients, particularly in the fields of rare and orphan diseases. However, the pros of the Twitterverse must be balanced with the potential risks, which are common to all social media platforms. Greater reach means that misinformation and promotion of vested interests can be too easily and widely disseminated. Unregulated use can result in inappropriate and unprofessional conduct whether intentional or not, highlighting the urgent need for designing and implementing institutional, national, or specialty-specific ethical and legal guidelines on appropriate social media use. Nonetheless, with judicious use, the benefits of Twitter for a neurologist or neuroscientist outweigh the risks; a graphical rendering is provided in Figure S1 in Multimedia Appendix 1.

Acknowledgments

The authors acknowledge Dr Lara J Cooke, Department of Clinical Neurosciences, Cumming School of Medicine, University of Calgary, for her immense help in supervision of the work during the entire time period, writing assistance, language editing and proofreading, and providing intellectual content. RP is supported by a Medical Research Council Clinician Scientist Fellowship (MR/S002065/1). RP, PT, and VV are supported by a Medical Research Council strategic award to establish an International Centre for Genomic Medicine in Neuromuscular Diseases (MR/S005021/1). CD is supported by funding from the Muscular Dystrophy Association of the United States.

Conflicts of Interest

None declared.

Abstract

Background: Adherence rates of preventative medication for cardiovascular disease (CVD) have been reported as 57%, and approximately 9% of all CVD events in Europe are attributable to poor medication adherence. Mobile health technologies, particularly mobile apps, have the potential to improve medication adherence and clinical outcomes.

Objective: The objective of this study is to assess the effects of mobile health care apps on medication adherence and health-related outcomes in patients with CVD. This study also evaluates apps' functionality and usability and the involvement of health care professionals in their use.

Methods: Electronic databases (MEDLINE [Ovid], PubMed Central, Cochrane Library, CINAHL Plus, PsycINFO [Ovid], Embase [Ovid], and Google Scholar) were searched for randomized controlled trials (RCTs) to investigate app-based interventions aimed at improving medication adherence in patients with CVD. RCTs published in English from inception to January 2020 were reviewed. The Cochrane risk of bias tool was used to assess the included studies. Meta-analysis was performed for clinical outcomes and medication adherence, with meta-regression analysis used to evaluate the impact of app intervention duration on medication adherence.

Results: This study included 16 RCTs published within the last 6 years. In total, 12 RCTs reported medication adherence as the primary outcome, which is the most commonly self-reported adherence. The duration of the interventions ranged from 1 to 12 months, and sample sizes ranged from 24 to 412. Medication adherence rates showed statistically significant improvements in 9 RCTs when compared with the control, and meta-analysis of the 6 RCTs reporting continuous data showed a significant overall effect in favor of the app intervention (mean difference 0.90, 95% CI 0.03-1.78) with a high statistical heterogeneity (I^2=93.32%). Moreover, 9 RCTs assessed clinical outcomes and reported an improvement in systolic blood pressure, diastolic blood pressure, total cholesterol, and low-density lipoprotein cholesterol levels in the intervention arm. Meta-analysis of these clinical outcomes from 6 RCTs favored app interventions, but none were significant. In the 7 trials evaluating app usability, all were found to be acceptable. There was a great variation in the app characteristics. A total of 10 RCTs involved health care professionals, mainly physicians and nurses, in the app-based interventions. The apps had mixed functionality: 2 used education, 7 delivered reminders, and 7 provided reminders in combination with educational support.

Conclusions: Apps tended to increase medication adherence, but interventions varied widely in design, content, and delivery. Apps have an acceptable degree of usability; yet the app characteristics conferring usability and effectiveness are ill-defined. Future large-scale studies should focus on identifying the essential active components of successful apps.

KEYWORDS

mobile health care applications; medication adherence; cardiovascular disease; systematic review; mobile phone

Introduction

Cardiovascular diseases (CVDs) are responsible for almost one-third of all deaths worldwide, leading to an estimated 17.9 million deaths each year [1]. A long-term use of cardiovascular medications significantly reduces the risk of morbidity and mortality [2,3], but their full therapeutic potential cannot be achieved if patients are nonadherent [4]. Approximately 9% of all CVD events in Europe are attributed to poor medication adherence [5], with adherence rates of only 57% [6].

Developing interventions to tackle medication nonadherence is important for improving health outcomes. A recent network meta-analysis of many different interventions showed that those with a technology-based approach had a positive, but short-lived, effect on medication adherence [7]. The escalating inclusion of technology into everyday life has witnessed the introduction of mobile health (mHealth) interventions, such as mobile apps, to support patients and health care professionals (HCPs) in disease management [8,9]. These reviews were not confined to app-based interventions. Some of the wide-ranging interventions included apps, whereas other mHealth interventions, such as text messaging and emails, were common. Several systematic reviews have indicated that apps may play a role in improving medication adherence in patients with CVD. For example, one systematic review included smartphone app-based interventions to promote lifestyle and behavior changes, reporting them as effective at improving medication adherence and increasing physical activity behavior [10]. For secondary prevention in patients with cerebrovascular disease, another systematic review showed improved medication adherence, a better maintenance of blood pressure (BP) and lipids within target ranges, and decreased episodes of angina, transient ischemic attack, and stroke with mHealth interventions, several of which included apps [11]. In contrast, a systematic review of internet-based interventions, which included apps, improved dietary outcomes, quality of life (QoL), and physical activity but reported a lack of evidence for their effect on medication adherence [12].

Published evidence for the beneficial effects of apps on medication adherence is often lacking or inconclusive. This study evaluates the effectiveness of app-based interventions on medication adherence in patients with CVD. Furthermore, this study explores the effects of app-based interventions on health-related outcomes, the functionality and usability of apps for patients, and the involvement of HCPs in the delivery of the intervention.

Methods

Search Strategy and Study Selection

This review followed the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [13]. The protocol was registered in the PROSPERO database (CRD42019121385) [14].

MEDLINE (Ovid), PubMed Central, Cochrane Library, CINAHL Plus, PsycINFO (Ovid), Embase (Ovid), and Google Scholar databases were searched from inception to January 2020 using a 3-domain search strategy to include terms related to CVD, apps, and medication adherence (the search strategy is presented in Multimedia Appendix 1). Studies were selected if they were randomized controlled trials (RCTs), if they were published in English, if they were for patients with CVD (eg, atrial fibrillation, coronary heart disease, heart failure, hypercholesterolemia, hypertension, myocardial infarction, and stroke), and if the intervention included an app to improve medication adherence. A 2-stage process was used to select studies for inclusion in this review. First, 1 author (SA) screened titles and abstracts for relevance and removed duplicate records. Where ambiguities arose from the screening process, 1 of 2 different authors (JM and ZJ) independently assessed the title and abstract for relevance. For the second stage of screening, 2 authors (SA and ZJ) independently reassessed the full-text studies matching the prespecified criteria for eligibility. Bibliographies of selected studies were hand searched for additional references.

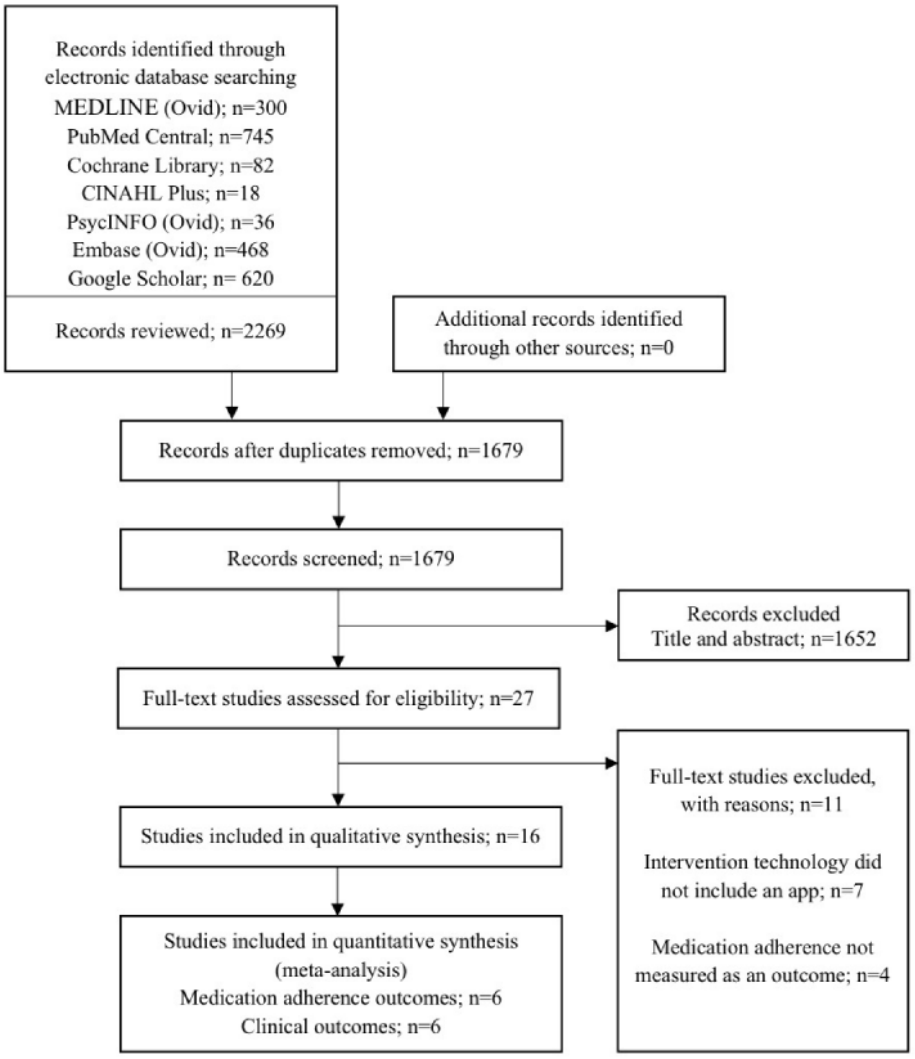
Data Extraction and Quality Assessment

Data extraction was conducted using a standardized form developed specifically for this review. Extracted data included the characteristics of the study and details of the intervention strategy. Quality assessment was conducted independently by 2 authors (SA and ZJ), and consensus was reached through discussion. The risk of bias was guided by the Cochrane Collaboration tool for RCTs [15], with the bias broadly categorized as selection, performance, attrition, or other bias. Once categorized, each bias domain was further categorized as low, high, or unclear risk of bias. Agency for Healthcare Research and Quality standards [15] were then applied, and an overall summary was generated using Review Manager (RevMan. version 5.4, The Cochrane Collaboration) [16].

Data Synthesis and Statistical Analysis

The outcome data were extracted from each trial. The authors were contacted for raw data where follow-up points for individual trials were identified but outcomes not reported in the published manuscripts. Four main analyses were conducted: (1) a series of meta-analyses of intervention effects on medication adherence at different time points of intervention duration; (2) a univariable meta-regression analysis, regressing the app intervention across trials on intervention duration; (3) a meta-analysis of intervention effects on medication adherence across all included trials at the final time point of intervention duration; and (4) a series of meta-analyses of intervention effects on systolic blood pressure (SBP), diastolic blood pressure (DBP), total cholesterol (TC), and low-density lipoprotein cholesterol (LDL-C) levels at the third month of the intervention. For the meta-analyses, trials reporting continuous data, means, SD, and sample sizes were included. Where SE or CI were

XSL•FO
RenderX



reported, the SD was manually calculated. A random-effects model was used to allow for differences in the true intervention effect across trials. The Q test was used to assess heterogeneity, with a significant result (P<.05) indicating heterogeneity across trials. The I^2 statistic was computed to describe the percentage of variability effect estimates due to heterogeneity. I^2 values of 25%, 50%, and 75% were assigned as low, moderate, and high heterogeneities, respectively [17]. The statistical package STATA (StataCorp, Stata Statistical Software: Release 16) was used for the meta-analysis [18].

Results

Search Results

Searches yielded 2269 citations, of which 590 duplicates were removed. The title and abstract screening resulted in 27 full-text review studies. Of these, 11 studies were excluded. No additional citations were identified by hand searching. Therefore, 16 RCTs were included in this review [19-34]. A PRISMA flowchart summarizing the study selection is shown in Figure 1.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram depicting study selection.

Study Characteristics and Design

All the included studies were published between 2013 and 2019. They all compared 1 or more interventions (app alone or app in conjunction with a package of participant support) with a control arm described as usual care. A total of 10 studies randomized patients to parallel intervention or control groups [20,21,23,25-28,31-33]; 2 had a crossover design [19,30]; and 4 were cluster randomized by the trial site [22,24], researcher [29], or physician [34]. Study sample sizes ranged from 24 [30] to 412 [31], and interventions ranged in duration from 1 [23,30,32] to 12 [29] months. The definition of usual care in the control groups differed among the studies. It was defined as follow-up without the use of the app in 7 trials [22,24,26,27,29,31,33]; the use of the app with limited functionality in 1 trial [32]; and an alternative intervention not including apps, for example, the use of a SMS text message [20,28,34], follow-up phone calls [21], use of a pillbox [23], and use of an e-diary [25] in 6 trials. For the 2 crossover trials, nondigital technology methods were used [19,30] (Table 1).

Table 1. Characteristics of the included randomized controlled trials.

Source; country	RCT[a] design	Number of randomized participants	Intervention and control arm	Length of intervention	Primary and secondary outcomes measures
Brath et al [19]; Austria	Crossover 2-arm	77	• Intervention: monitoring phase using app • Control: control phase using paper diary	20 weeks	• Primary: medication adherence • Secondary: changes in SBP[b], DBP[c], HbA1c[d], LDL-C[e], and usability of the app
Chandler et al [20]; United States	Parallel 2-arm	54	• Intervention: SMASH[f] app • Control: SMS text messages on lifestyle tips unrelated to medication adherence	9 months	• Primary: change in SBP • Secondary: change in DBP, medication adherence, and patients' satisfaction with using the app
Fang and Li [21]; China	Parallel 3-arm	280	• Intervention: 2 arms: (1) SMS text messages using an app and (2) SMS text messages using an app plus micro letter • Control: phone	6 months	• Primary: medication adherence • Secondary: none
Frias et al [22]; United States	Parallel 3-arm, clustered by study site	118	• Intervention: a DMO[g] system designed to provide feedback about taking medication to both patients and providers consisted of an ingestible sensor, sensor patch, and app, 2 arms: (1) 4-week DMO and (2) 2.12-week DMO • Control: no system use	12 weeks	• Primary: change in SBP • Secondary: changes in SBP, DBP, HbA1c, and LDL-C; medication adherence; and satisfaction with using the app
Goldstein et al [23]; United States	Parallel 2×2 arm	60	• Intervention: 2 arms: (1) mHealth[h] app reminder and (2) mHealth app silent • Control: 2 arms: (1) telehealth (pillbox reminder) and (2) telehealth (pillbox silent)	28 days	• Primary: medication adherence • Secondary: acceptance of the app
Guo et al [24]; China	Parallel 2-arm, clustered by study site	209	• Intervention: mAF app • Control: no app use	3 months	• Primary: medication adherence, usability of the app, PAM[i], patients' knowledge, anticoagulation satisfaction, and QoL[j] • Secondary: none
Johnston et al [25]; Sweden	Parallel 2-arm	174	• Intervention: interactive patient support tool (web-based app) • Control: no app use, only simplified tool	6 months	• Primary: medication adherence • Secondary: change in SBP and LDL-C; QoL; and usability of the app
Kim et al [26]; Republic of Korea	Parallel 2-arm	95	• Intervention: Wireless Self-Monitoring, an app with enrolled in the HealthyCircles Platform • Control: no app use	6 months	• Primary: medication adherence, PAM, SBP, and DBP • Secondary: none
Labovitz et al [27]; United States	Parallel 2-arm	28	• Intervention: artificial intelligence app • Control: no daily monitoring	12 weeks	• Primary: medication adherence • Secondary: medication adherence for patients receiving DOACs[k] and usability of the app

Participant Characteristics

The included trials covered a range of different CVDs and risk factors: atrial fibrillation [24], coronary heart disease [21,30,32,33], diabetes [19,22], heart failure [23], hypercholesterolemia [19], hypertension [19,20,22,26,29,31], myocardial infarction [25,28,30], and stroke [27,34]. The mean age of participants varied depending on the disease and ranged from 46.5 (SD 9.9) [20] to 73.8 (SD 7.5) years [30]. All studies recruited outpatients from secondary care [19,21,23-28,30,32,34], primary care [20,22,29], tertiary care [33], or web-based patient communities [31].

App Characteristics

The characteristics of the trialed apps are shown below. Each study used a different app developed by different organizations: 8 were academic or government institutions [20,21,23,24,26,28-30], whereas others were commercial organizations. A total of 7 apps were supported by platforms [19-22,24,26,27]. The functionality of the apps and platforms varied across the different trials and the interactions needed by patients. All but 2 apps [24,26] delivered medication reminders to promote medication adherence. For the majority, this was their primary function, with 4 apps using one-way SMS text message reminders [21,27,28,32] and 5 delivering a mobile device alert [23,29-31,33]. Others had a primary focus on self-monitoring alone [26] or with a medication reminder [25], patient education [24], or delivery of a tailored motivational SMS text message based on medication adherence levels [20,34]. Two trials used the app to transmit patients' adherence data to the associated platform to be monitored by HCPs [19,22].

Involvement of HCPs

Half of the trials involved physicians and/or nurses in app use [19,21,24,25,29,30,32,34] (Table 2). A trial involved pharmacists in blinding study medication, whereas the health care team, whose professions remained unspecified, used the app and monitored the data transmitted to the associated platform [22]. One trial permitted the sharing of patients' data with families and caregivers as well as with HCPs [26]. A total of 6 trials did not specify the type of HCPs involved in app use [20,23,27,28,31,33]. The involvement of HCPs varied; most of the trials involved HCPs to monitor patients' data [19,22,24-26,30,34], instruct patients on how to use the app [29], and send educational materials to patients via the app [21,32].

XSL•FO
RenderX

Table 2. Mobile app characteristics in the included randomized controlled trials.

Source	App name and functionality	Platform used with the app and functionality	Overall system functionality	Involvement of HCP[a]
Brath et al [19]	Name not specified, referred to as a mobile phone–based data gateway. Reader and transmitter of data from electronic medication blister to a remote database	Remote telemonitoring service: data sent from the app to platform and then analyzed for timing and number of pills taken, and an automatic reminder is sent to patients via SMS text messages	Reminder	Physician
Chandler et al [20]	SMASH[b] app: medication reminders via signals (blinking light, intermittent chime, automated SMS text messages, or phone call) and BP[c] monitor reminders via SMS text messages. The app provided timely tailored motivational and reinforcement SMS text messages based on the levels of medication adherence and SMS text message reminders to monitor BP with a Bluetooth-enabled BP device. The app also provided a cumulative table of average BP displayed in categories of daily, weekly, and/or monthly progress reports	HIPAA[d]-compliant servers: BP data sent from the app to platform, then analyzed for processing with timestamps, providing information for the calculation of adherence levels to the BP protocol	Reminder	Not stated
Fang and Li [21]	Name not specified, referred to as a messaging app: medication reminders via an SMS text messaging app, educational materials via micro letter	Huaxi-gold card: the platform sent SMS text messages, images, media content related to disease and other information at regular intervals	Reminder and education	Physician and nurse
Frias et al [22]	Proteus Discover app: reader and transmitter of the patient's adherence data from patch to the cloud and prompted the patient to take their medication doses as scheduled. Patients could visualize their data on their mobile devices via the app	Provider web portal: provider views summaries of the DMO[e] data for the patients on the web portal	Reminder and education	Clinic staff, pharmacist had a role in set up (coencapsulation of ingestible sensor and medication)
Goldstein et al [23]	Name not specified, referred to as a medication adherence app. Medication reminders provided via alert, patients could view list of medications with instructions, and they were able to record taking their medication	No platform	Reminder and education	Not stated
Guo et al [24]	mAF app: educational app used by both patients and physicians: For patients, personal health record (CHA_2DS_2-VASc[f], HAS-BLED[g], and SAMe-TT_2R_2[h] scores), patient educational programs (knowledge of atrial fibrillation and learn how to manage themselves at home), patient involvement in self-care items (monitor their heart rate, BP, and their quality of life), and structured follow-up consultation via a sent alert reminder. For physicians, clinical decision support	Cloud platform: data management	Education	Physician
Johnston et al [25]	Name not specified, referred to as an interactive patient support tool app: medication reminders via SMS text messages (e-diary) to register daily ticagrelor intake. Secondary prevention educational modules (exercise module, BMI module, and BP module)	No platform	Reminder and education	Physician and nurse
Kim et al [26]	HealthyCircles: an educational app that allowed patients and nurses to access the patient's reading recorded on the BP monitor devices. The BP measurements are wirelessly uploaded from BP devices to the HealthyCircles account	HealthyCircles platform: the platform sent reminders for self-monitoring BP, education information about the disease condition, and general health behavior recommendations	Education	Families, caregivers, and HCPs (profession not specified)

XSL•FO
RenderX

Source	App name and functionality	Platform used with the app and functionality	Overall system functionality	Involvement of HCP[a]
Labovitz et al [27]	Artificial intelligence app: medication reminders and dosing instructions via SMS text messages. Late doses generated notifications within the hour and before the end of the dosing window	Artificial intelligence platform: the platform sent an automatic SMS text message or emails to clinical staff if doses were missed, late, or based on incorrect use	Reminder	Clinic staff (profession not specified)
Liu et al [28]	HeartGuardian app: medication reminders via SMS text messages. The app provided educational materials; medication recording and daily feedback; and self-empowerment via automatic intelligent, real-time video feedback based on the subjects' medication adherence	No platform	Reminder and education	Not stated
Márquez Contreras et al [29]	AlerHTA app: medication and appointments reminders via alerts. The app recorded patients' personal data, the physician's advice about the prescribed treatment, and the results of the BP measurement. The app recommended BP levels as objectives	No platform	Reminder and education	Physician
Mertens et al [30]	iNephro medication plan app: medication reminders via alert, to support the drug intake needs of patients with chronic conditions on polypharmacy	No platform	Reminder	Physician
Morawski et al [31]	Medisafe app: medication reminders via alert. The app provided alerts to remind patients when it is time to take medications and generate weekly adherence reports, the app also allowed for tracking of BP and other biometric measurements	No platform	Reminder	Not stated
Ni et al [32]	BB reminder app and WeChat app: medication reminders via SMS text messages through the BB reminder app. Educational materials through the WeChat app	No platform	Reminder and education	Physician and nurse
Santo et al [33]	No specified name. Referred to as a medication reminder app. Medication reminders provided via alert. In the basic app, the reminders were noninteractive and occurred 1 time only, whereas the advanced app provided interactive and customizable features including daily reminders, which could be snoozed, rescheduled, and/or marked as a taken or missed dose; medication refill reminders; adherence statistics; and ability to share information with others such as family members, if the patient missed a medication dose	No platform	Reminder	Not stated

XSL•FO
RenderX

Source	App name and functionality	Platform used with the app and functionality	Overall system functionality	Involvement of HCP[a]
Sarfo et al [34]	No specified name. Referred to as medical regimen assistance app. Medication reminders provided via SMS text messages. The app reported BP measurements and medication intake and sent written and oral information on adherence criteria to take the medications within 2 hours of designated times and to measure BP every 3 days in the morning and evening	No platform	Reminder	Nurse

[a]HCP: health care professional.

[b]SMASH: Smartphone Medication Adherence Stops Hypertension.

[c]BP: blood pressure.

[d]HIPAA: Health Insurance Portability and Accountability.

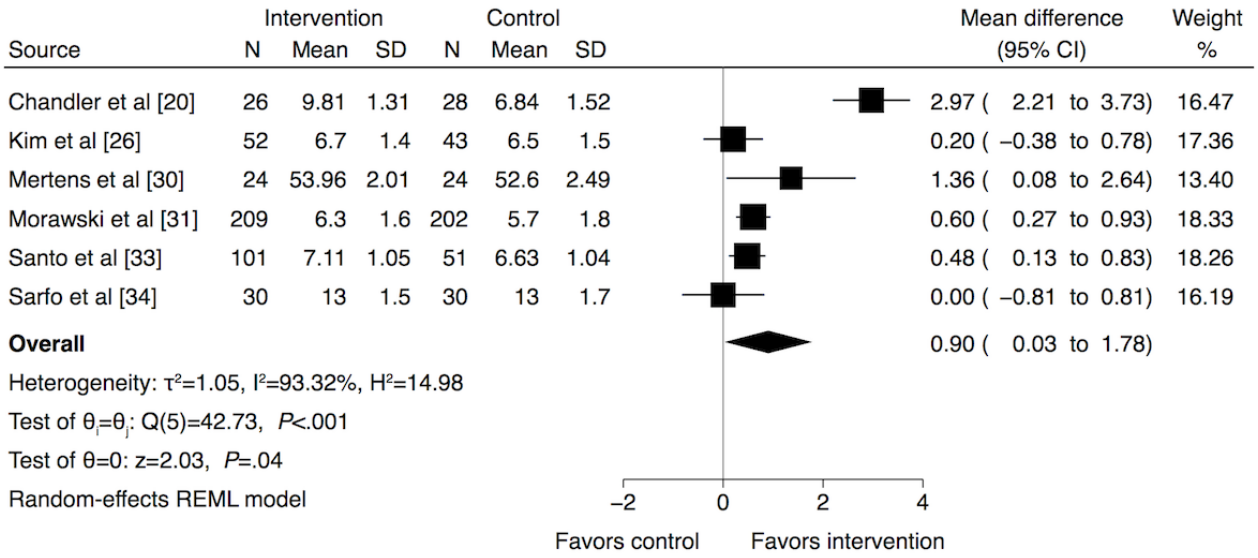
[e]DMO: digital medicine offering system.

[f]CHA_2DS_2-VASc: congestive heart failure, hypertension, age>75 years (doubled), type 2 diabetes mellitus, previous stroke, transient ischemic attack or thromboembolism (doubled), vascular disease, age of 65-75 years, and sex.

[g]HAS-BLED: Hypertension, abnormal renal or liver function, stroke, bleeding history or predisposition, labile international normalized ratio, age>65 years, drugs or alcohol concomitantly.

[h]SAMe-TT_2R_2: sex, age, medical history, treatment, tobacco use, and race.

Assessment of Medication Adherence



Adherence measures varied among studies (Multimedia Appendix 2 [19-34]). Most used questionnaires to include the validated 8-item Morisky Medication Adherence Scale [20,26,31,33] and the 4-item Morisky Medication Adherence Scale [21,28] and nonvalidated self-report questionnaires [24,25,30,32]. Other adherence measures included medication event monitoring systems (MEMSs) [29] and a digital medicine offering with an ingestible sensor taken alongside medication [22]. Other trials used a combination of measures; 2 trials combined 2 different measures, one for each arm. One trial used the remote medication adherence measurement system for the intervention and pill count for the control [19]. Another trial used an electronic self-report for the intervention and pillbox openings for the control [23]. Only 2 trials combined 2 different measures for both arms (pill counts and plasma samples [27] and pill counts and 8-item Morisky Medication Adherence Scale [34]).

Effect on Medication Adherence

Overall, 12 trials reported apps to enhance medication adherence rates [20,21,24,25,27-34], with 9 demonstrating significant improvement [20,24,25,28-31,33,34]. In the remaining 4 trials, 3 did not find a significant difference [22,23,26] and 1 reported a significant difference, with only 1 of the 4 medicines being monitored [19] (Multimedia Appendix 2 [19-34]). Six trials reporting continuous data were included in the meta-analysis of medication adherence [20,26,30,31,33,34]. Trials with the same duration of follow-up for the intervention were subjected to a separate meta-analysis and all favored the intervention, mean difference for month 1, 1.52 (95% CI 0.89 to 2.15); 2 trials [20,30] for month 3, 0.46 (95% CI 0.21 to 0.71); 4 trials [20,31,33,34], for month 6, 1.46 (95% CI −1.02 to 3.95); 2 trials [20,26], and for month 9, 1.49 (95% CI −1.42 to 4.40); 2 trials [20,34]. Meta-regression analysis for these 6 studies showed that the duration of intervention (ie, the follow-up month) did not exert a statistically significant impact on the effect of the app on medication adherence (P=.65). Thus, a combined meta-analysis (Figure 2) over the different trial durations was performed, thereby demonstrating a significant effect in favor of the app intervention (mean difference 0.90, 95% CI 0.03 to 1.78) with a high statistical heterogeneity (I^2=93.32%).

XSL•FO
RenderX

Figure 2. Meta-analysis results and forest plot of the effect of app-based interventions on medication adherence. Mean difference (95% CIs) are denoted by black boxes (black lines). The combined mean difference estimate for all studies is represented by a black diamond, where diamond width corresponds to 95% CI bounds. REML: restricted maximum likelihood.

Effect on Other Nonclinical Outcomes

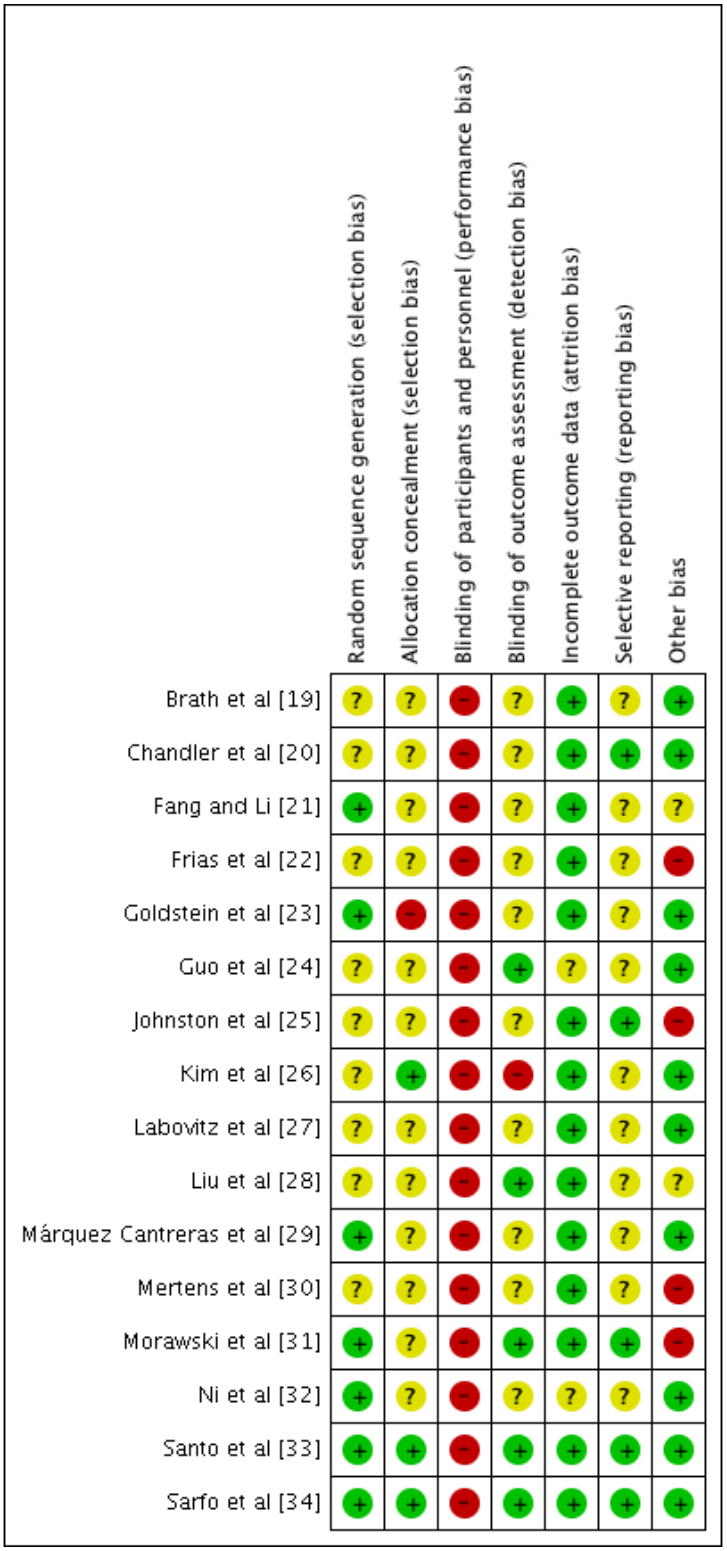
An array of nonclinical outcomes was measured across the trials. Two trials have reported patient activation measures (PAMs) [22,26]. One trial reported a higher increase in PAM scores mean change for the intervention arm 7.9 (SE 2.4) when compared with control 1.7 (SE 3.3); mean difference 6.2 (SE 4.6), (95% CI −2.8 to 15.2) [22]. However, for the other trial, there was no significant difference in the average PAM score over the trial period (baseline: 78.0; end of trial: 76.0; *P*=.34) [26]. Patients' knowledge of their CVD was only reported in 2 trials [24,34], despite 9 of the 16 trials involving apps with an educational function [21-26,28,29,32]. Interestingly, one trial showed not only a significant improvement in knowledge with app use but also in medication adherence [24]. In the same trial, the benefits and burden of anticoagulation therapy were explored using a patient satisfaction questionnaire. Patients using the app expressed more anticoagulant *benefits*, whereas the control declared more *burden*: benefit (intervention: mean 15.6, SD 2.73 vs control: mean 14.21, SD 3.37; *P*=.05) and burden (intervention: mean 15.57, SD 6.57 vs control: mean 19.30, SD 6.39; *P*=.008) [24]. In the other trial, the knowledge questionnaire scores increased at the end of the trial but not significantly (intervention: mean 10.8, SD 0.8 vs control: mean 11.1, SD 1.1; *P*=.23) [34]. The QoL was assessed in 2 trials using the European Quality of Life–5 Dimensions measure [24,25]. One trial reported significantly higher QoL in the intervention arm compared with the control (*P*<.05; exact *P* value not quoted in original paper) [24], whereas in the other trial, QoL scores increased with app use over the duration of the trial but not significantly (*P*=.06) [25].

Effect on Clinical Outcomes

Clinical outcomes measured included BP, blood cholesterol, and blood glucose (Multimedia Appendix 3 [19,20,22,25,26,28,29,31-34]). Eight trials reported positive effects of apps on both SBP and DBP [19,20,22,25,26,29,33,34], and 4 reported significant results [19,20,22,29]. In total, 4 trials reported improvements in TC [19,22,28,33] and 3 were significant [19,22,28]. A reduction in LDL-C was observed with app-based interventions [19,22,25,28,33], but it was only significant in 2 trials [22,25]. Only 2 trials reported glycated hemoglobin (HbA_{1c}) as an outcome, with no significant change [19,22]. Meta-analysis for clinical outcomes was only possible at 3 months duration of intervention for SBP, DBP, TC, and LDL-C; all favored the use of an app in disease management, but not all were significant (Multimedia Appendix 4 [22,25,28,31,33,34]). Meta-analysis for HbA_{1c} was not possible because of the lack of reported outcomes.

App Usability, Acceptability, and Patient Satisfaction

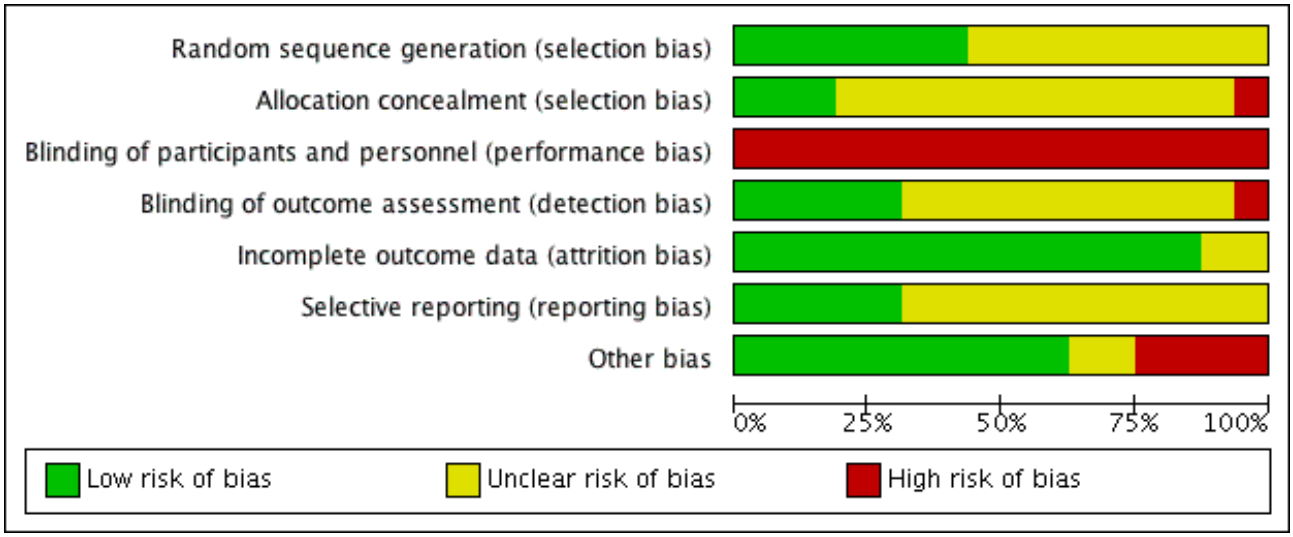
Various questionnaires were used to evaluate the app usability for patients, but this was only done in 4 trials [19,24,25,27]. One study used a validated System Usability Scale to demonstrate greater usability in the app intervention arm than in the control arm (intervention: mean 87.3, SD 13.9 vs control: mean 78.1, SD 18.9; *P*=.001) [25]. Three trials evaluated app usability with nonvalidated questionnaires and obtained positive feedback from 80% or more of the participants [19,24,27]. Patients with stroke rated the app *extremely good* as a medication management tool and as means to improve physician-patient rapport [27]. Patients with atrial fibrillation agreed that the study app was user-friendly and helpful with additional positive feedback from physicians [24].



Four different trials explored app acceptability in patients [23,30,32,33]. Acceptance rates measured by nonvalidated questionnaires found the app to be more acceptable than the control [23], and most patients reported that the app was useful and helpful [33]. Interviews conducted within 2 studies revealed that patients accepted and appreciated receiving reminders and educational materials via the app [32] and that most patients (22/24) reported wanting to use the app in everyday life [30]. Three trials evaluated patient satisfaction with the apps being trialed by nonvalidated questionnaires, with more than 90% reporting the app as easy to use [20,22,34].

XSL•FO
RenderX

Risk of Bias of Included Trials



Only 7 trials reported sufficient random sequence generation [21,23,29,31-34], and only 3 trials reported allocation concealment [26,33,34]. Although these types of interventions are problematic to blind, outcome assessors could have been blinded, but only 5 trials clearly stated that this was done [24,28,31,33,34]. In total, 14 trials had a low risk of incomplete outcome data [19-23,25-31,33,34], whereas only 5 had a low risk of selective outcome reporting [20,25,31,33,34]. Ten trials had no other sources of risk of bias [19,20,23,24,26,27,29,32-34]. According to the Agency for Healthcare Research and Quality standards, most trials were considered to be of poor quality [19-32], with only 2 rated as fair [33,34]. Figures 3 and 4 present the risk of bias judgment.

Figure 3. Authors' judgments about each risk of bias item for each included trial. Green: low risk of bias; yellow: unclear risk of bias; red: high risk of bias.

Figure 4. Authors' judgments about each risk of bias item presented as percentages across all included trials.

Discussion

Principal Findings

This study included 16 RCTs that assessed the effectiveness of mobile app–based interventions on medication adherence [19-34]. A total of 9 trials showed a statistically significant improvement in medication adherence in the intervention arm [20,24,25,28-31,33,34]. The meta-analysis of 6 trials revealed that app interventions exert a significant positive effect on medication adherence with meta-regression, showing no statistically significant impact for the duration of use over a maximum of 9 months. However, the statistical and methodological heterogeneity was high [20, 26, 30, 31, 33, 34]. Ten trials assessed health-related outcomes and generally reported an improvement with intervention over control [19,20,22,24-26,28,29,33,34]. The apps used had mixed functionality, including reminders [19,20,27,30,31,33,34], education [24,26], or both [21-23,25,28,29,32]. Regarding the involvement of HCPs, most involved physicians and/or nurses [19,21,24,25,29,30,32,34]. The usability of apps was mainly assessed with questionnaires, with most participants reporting acceptance and ease of use [19,24,25,27]. The effectiveness of app interventions could not be assigned to particular app components or characteristics. Half of the trials were small-scale studies, that is, pilot studies [19,22,24,34] and feasibility studies [21,23,27,32], and most trials were classified as having poor quality of evidence because of the high risk of bias or insufficient reporting of information [19-32].

Relationship With Previous Published Literature

Previous systematic reviews have assessed the effectiveness of health care apps in the management of several different long-term conditions, including asthma [35], obesity and diabetes [36], and CVD [37]. Most included small-scale studies, with insufficient or low-quality evidence to support app use. Despite this, many reviews have reported beneficial trends, for example, in the promotion of positive behavior changes such as medication adherence [37].

A network meta-analysis of different interventions showed that technology-based interventions exert a major effect on the long-term management of medication adherence in patients with CVD [38]. The World Health Organization categorizes medication adherence measurements as either subjective or objective [39]. More than half of the trials in this systematic review used subjective self-report questionnaires to measure medication adherence [20,21,24-26,28,30-33], with a potential to overestimate adherence. Although there is no gold standard measure of medication adherence, a multi-measure approach is highly recommended to reduce subjectivity [40]. Therefore, the results of improved adherence from the trials included in this review should be interpreted with caution.

This review shows that objective measures can be improved with expected app use. For example, some of the trials included in this review assessed BP and showed improvements for participants in the intervention arms [19,20,22,25,26,29,33,34], a similar result to a previous systematic review assessing the effects of mobile apps designed for BP management [9]. Another systematic review and meta-analysis of 21 RCTs showed a reduction in HbA_{1c} levels in patients with diabetes [41]. In this review, the effectiveness of apps to support patients with diabetes was inconclusive, as only 2 included trials evaluated HbA_{1c}, and both the trials reported no significant difference in the change in HbA_{1c} between the intervention and control arms [19,22].

Although few trials included in this review investigated nonclinical outcomes other than adherence, those that did demonstrated a meaningful, but not always significant, improvement in PAM [22,26], patients' disease knowledge [24,34], anticoagulation satisfaction [24], and QoL [24,25]. These results align with existing systematic reviews of smartphone-based health care technologies, which demonstrate that apps could play an important role in patient education, self-management, and remote monitoring [42] and improvements in patients' QoL [37]. Furthermore, 2 pilot studies examining the feasibility of app use to enhance safe anticoagulation therapy and knowledge acquisition by patients showed a significant increase in anticoagulation knowledge after 3 months of app use [43,44]. The beneficial effects of apps on medication adherence will likely depend on the nature of the support needed

XSL•FO
RenderX

by different patients. To improve medication adherence, the literature suggests that some patients may need only reminders, whereas others need a greater knowledge and understanding of their disease and the medication prescribed [45,46]. There is a long history of reminders and patient education to improve medication adherence, and the introduction of app technology has seen these strategies incorporated into mHealth interventions. In this review, most of the included trials used apps with mixed functionality, including reminders, education, or both. All but 2 of the apps [24,26] included reminders [19-23,25,27-34]; of these, significant improvements in medication adherence were only reported in about half of the trials [20,24,25,28-31,33,34]. Thus, it remains impossible to assign success to a single component within a multifunctional intervention.

App design, user interface, and evaluation of these factors are often under-reported. In this review, 4 trials that assessed app usability demonstrated that the apps were user-friendly, and users were interested and engaged with the technology [19,24,25,27]. Three of these studies featured commercially developed apps [19,25,27]. The measures of app success for developers of commercial, academic, or government origins may explain why only 1 app developed by an academic institution [24] investigated usability. A systematic review of app usability in patients with diabetes also reported moderate to good usability, but users expressed preference for apps developed for tablet computers rather than smartphones due to their larger display and better illustrations [47]. Usability is a key factor in the uptake of mHealth apps [48,49], and it would make sense to conclude that a more user-friendly app might be more effective. In this review, significant improvements in medication adherence rates were found in only 2 of the 4 trials reporting a good usability [24,25]. This may, in part, be because usability outcomes measure ease of use (ie, user-friendliness) rather than motivation, engagement, and continued use. Motivating components, such as social contracts with family members and gamification, have been incorporated into some apps to improve their effectiveness [43]. Several studies highlight the importance of using theory to develop and design behavioral change interventions [50-52], which should also be considered in mHealth app intervention design. Only 3 of the trials in this review [20,28,34], reported the use of behavioral change theories to inform their app intervention, and it is of note that only one of the app interventions purported to involve social support or interactions outside of HCPs [26]. This review revealed that HCPs' involvement in app interventions for CVD health care mainly involved physicians and nurses [19,21,24,25,28-30,32,34], with 1 trial reporting pharmacist involvement; however, that did not include the administration of the app intervention [22]. With the widening clinical patient-facing roles of pharmacists within primary care [53,54] and reports of their effectiveness in both CVD management [55-57] and successful efforts to improve CVD medication adherence [58,59], it is potentially surprising that pharmacists were not more involved in any of these studies. The involvement of any HCP in the administration and concomitant use of apps with patients requires careful consideration. Such apps have the potential to increase HCP workload, and it remains unclear whether the cost of that involvement outweighs the benefits observed. Of the RCTs included in this review, 5 of the 9 that included HCPs in the administration of the app reported significant improvements in medication adherence, but no cost-benefit analysis was conducted [24,25,29,30,34]. In the current climate, with a growing choice of apps, a more important role for HCPs may be in the recommendation of safe, user-friendly, and effective mHealth apps for patients depending on their disease and apps chosen specifically to meet their patients' needs and motivations.

Strengths and Limitations

This review did not consider the differences in adherence between the medications included in the trials. Some medications might have a higher rate of nonadherence than others because of the adverse effects and taste of the formulation. The heterogeneity of the trials' methodologies, apps, and outcome measures studied made quantitative comparisons problematic. Different measures of medication adherence were used among the trials, which made it impossible to calculate the exact adherence rates. For several of the included trials, control groups were also subjected to an intervention aimed at improving medication adherence, meaning that the impact of the app intervention was not comparable with standard care. This, coupled with the potential for wide variations in standard care more generally, suggests that the findings of many of the included studies need to be interpreted with caution. Finally, this review included only RCTs; thus, other relevant studies and reports from the gray literature were excluded. However, RCTs are considered the cornerstone of clinical research to determine the efficacy of interventions and the highest level of evidence.

Implication for Practice and Policy

Health care apps have the potential to enhance medication adherence, leading to improvements in clinical and nonclinical outcomes in patients with CVD. However, the use of this technology to support medication adherence is in its infancy, and apps require robust testing to demonstrate its effectiveness. The trials included in this review provided inconsistent data regarding their effectiveness. Overall, user engagement and usability were rated positively, demonstrating interest in the concept. However, it is difficult to make strong, unrestricted recommendations for practice, especially with the methodological limitations of the included trials.

Implication for Research

This review indicates the need for further large-scale studies to determine whether mobile apps are effective in improving medication adherence among patients with CVD. There is a paucity of data to differentiate the effects of individual app intervention characteristics on behavioral change, and the most effective app functionality remains unknown. The involvement of HCPs in the use of mobile apps needs to be investigated further, needs to undergo cost-benefit analysis, and needs to be compared with the effectiveness standalone apps that do not require HCP input. Finally, a standard validated approach for medication adherence measurement is recommended for future studies to enable the comparison of findings and/or pooling of adherence data.

XSL•FO
RenderX

Conclusions

Mobile apps appear to enhance medication adherence and improve health-related outcomes. Apps have an acceptable degree of usability; yet the app characteristics conferring usability and effectiveness are often indeterminate due to their multifactorial design. Existing evidence is currently insufficient to unreservedly recommend the use of health care apps to improve adherence to CVD medications because of the generally small sample sizes; clinical and methodological heterogeneity between studies; and disparity in app features, content, and delivery, but they may enhance medication adherence as part of a package of care.

Authors' Contributions

SA, JM, and ZJ conceived and designed the study. SA, JM, and ZJ completed the screening and selection of studies, data extraction, and critical appraisal. SA, JM, and ZJ initially analyzed the data, with review and further interpretation from all other authors. SA, JM, and MSH performed the statistical data analysis. SA, JM, and ZJ drafted the manuscript. All authors contributed the manuscript review, revision, and final approval.

Conflicts of Interest

DAL is a coauthor of the mAF app but reports no other conflicts of interest in relation to this manuscript. LF has received institutional research grants from the European Union (for the design of mobile health apps for patient education), the British Heart Foundation, Medical Research Council (UK), and German Research Foundation. The Institute of Cardiovascular Research, University of Birmingham, has received an Accelerator Award by the British Heart Foundation (AA/18/2/34218) during the conduct of the study. LF is listed as an inventor on 2 patents held by the University of Birmingham (Atrial Fibrillation Therapy [WO 2015140571] and Markers for Atrial Fibrillation [WO 2016012783], not related to medical adherence or apps). LF has received grants from EU Horizon 2020 (CATCH ME Characterizing Atrial fibrillation by Translating its Causes into Health Modifiers in the Elderly (633196), and MAESTRIA Machine Learning Artificial Intelligence Early Detection Stroke Atrial Fibrillation [(965286) to fund WC). No other disclosures were reported.

Abstract

Background: Nearly 90% of deaths due to cervical cancer occur in low- and middle-income countries (LMICs). In recent years, many digital health strategies have been implemented in LMICs to ameliorate patient-, provider-, and health system–level challenges in cervical cancer control. However, there are limited efforts to systematically review the effectiveness and current landscape of digital health strategies for cervical cancer control in LMICs.

Objective: We aim to conduct a systematic review of digital health strategies for cervical cancer control in LMICs to assess their effectiveness, describe the range of strategies used, and summarize challenges in their implementation.

Methods: A systematic search was conducted to identify publications describing digital health strategies for cervical cancer control in LMICs from 5 academic databases and Google Scholar. The review excluded digital strategies associated with improving vaccination coverage against human papillomavirus. Titles and abstracts were screened, and full texts were reviewed for eligibility. A structured data extraction template was used to summarize the information from the included studies. The risk of bias and data reporting guidelines for mobile health were assessed for each study. A meta-analysis of effectiveness was planned along with a narrative review of digital health strategies, implementation challenges, and opportunities for future research.

Results: In the 27 included studies, interventions for cervical cancer control focused on secondary prevention (ie, screening and treatment of precancerous lesions) and digital health strategies to facilitate patient education, digital cervicography, health worker training, and data quality. Most of the included studies were conducted in sub-Saharan Africa, with fewer studies in other LMIC settings in Asia or South America. A low risk of bias was found in 2 studies, and a moderate risk of bias was found in 4 studies, while the remaining 21 studies had a high risk of bias. A meta-analysis of effectiveness was not conducted because of insufficient studies with robust study designs and matched outcomes or interventions.

Conclusions: Current evidence on the effectiveness of digital health strategies for cervical cancer control is limited and, in most cases, is associated with a high risk of bias. Further studies are recommended to expand the investigation of digital health strategies for cervical cancer using robust study designs, explore other LMIC settings with a high burden of cervical cancer (eg, South America), and test a greater diversity of digital strategies.

KEYWORDS

cervical cancer; digital health; mobile phones; low- and middle-income countries; colposcopy; uterine cervical neoplasms; telemedicine or mobile apps; cell phones; developing countries

Introduction

Background

Annually, 311,000 women die from cervical cancer worldwide, with 90% of the deaths occurring in low- and middle-income countries (LMICs). [1]. To reduce this high burden of mortality, it is critical to implement and scale sustainable and effective cervical cancer control programs in LMICs. However, cervical cancer control programs in LMICs must overcome individual-, provider-, and health system–level bottlenecks to health service delivery, access, and utilization [2-5]. In the last decade, health systems in LMICs have taken advantage of the increasing prevalence of digital technologies, particularly mobile phones, to circumvent some of the bottlenecks in cervical cancer control. However, systematic reviews of the effectiveness of such digital health strategies in LMIC settings are lacking, especially regarding how such strategies may improve the delivery, access, and utilization of cervical cancer control programs [4].

Primary prevention strategies for cervical cancer control focus on vaccination against human papillomavirus (HPV), whereas secondary prevention strategies focus on early screening and treatment of precancerous lesions [6,7]. Where implementation of preventive services is inadequate, cervical cancers are typically detected at advanced stages, further contributing to high mortality rates [8,9]. Commonly used screening methods include visual inspection with acetic acid (VIA), visual inspection with Lugol iodine, and HPV DNA testing [10,11]. Although an initial cervical cancer screening is possible at primary health facilities, or even at the community level by frontline health workers, follow-up procedures, diagnosis, and treatment require access to trained medical providers (eg, expert colposcopists). The treatment of invasive cancer also requires secondary or tertiary health facilities with specialized equipment for surgery, chemotherapy, and radiation [11]. The management of invasive cancer includes long-term retention of women in care, with regular follow-ups and palliative care as applicable. To be effective, cervical cancer control programs must not only achieve high rates of screening coverage among eligible women but also ensure that women who screen positive receive timely treatment and support for long-term management [12]. There is a lack of systematic reviews to understand how digital health strategies affect cervical cancer control in LMICs across the continuum spanning from prevention to palliative care.

There is growing interest from local, national, and global stakeholders in integrating digital health strategies with cervical cancer control programs in LMICs. For instance, the Global Action Plan for the Prevention and Control of Noncommunicable Diseases 2013-2020 highlights the use of digital health strategies for health education, promotion, and communication, especially in populations with low literacy and health awareness [13]. Examples of using digital health for cervical cancer control include the World Health Organization and the International Telecommunications Union's *Be he@lthy, Be mobile* initiative, which launched a mobile phone text messaging campaign to improve the awareness of cervical cancer screening in Zambia [14]. In another instance, the Ministry of Health in Peru successfully completed a national pilot program of using text messages to notify women about their HPV screening results [15]. In light of the expanding local, national, and global efforts, evidence of successful implementation and impact is needed to drive further research on and development of digital strategies for cervical cancer control in LMICs.

Currently, much of the published literature describing the use of digital strategies for cervical cancer control comes from high-income settings [16-19]. However, a previous systematic review examined the effectiveness of digital strategies for cervical cancer control in LMICs [20]. In this review, authors identified 8 eligible studies, most of which lacked rigorous study designs and evidence. With the increasing use of digital health strategies in LMICs, an updated review is necessary to evaluate the contextual effectiveness of such strategies for cervical cancer control as compared with high-income settings. Furthermore, the synthesis of key implementation challenges and opportunities for future research is needed to prioritize and increase the success of digital health strategies for cervical cancer control in LMICs.

Objectives

The primary objectives of the review were to assess the effects of using mobile devices on the following:

- Facilitate task shifting for cervical cancer screening, treatment of precancerous lesions, and management of LMICs as compared with usual care.
- Reduce delays in postscreening treatment initiation among women in LMICs as compared with usual care.
- Assess and improve cervical cancer knowledge or awareness among women in LMICs as compared with usual care.

The secondary objectives were to describe the following:

- Digital health strategies used for cervical cancer control, including those used to visualize the cervix using a mobile device at the point of care in LMICs.
- Challenges associated with the implementation of digital health strategies for cervical cancer control in LMICs.

Methods

Protocol and Registration

The review protocol was registered with the PROSPERO database for prospectively registered systematic reviews (protocol #CRD42017071560). Deviations from the registered protocol and unused methods are included in Multimedia Appendix 1. The findings of this systematic review are reported

XSL•FO
RenderX

in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) checklist and are specified in Multimedia Appendix 2 [21].

Eligibility Criteria

Participants

For the assessment of the primary and secondary review objectives, we included studies of all cadres of health care workers (eg, medical doctors, nurses, midwives, community health workers) providing any cervical cancer screening, treatment, and management services, as well as women (of all ages) receiving any cervical cancer education, screening, treatment, and management services.

Interventions

For the assessment of primary and secondary review objectives, we included any intervention wherein mobile devices were used in the screening, treatment, and management of cervical cancer. These included studies in which mobile devices were used to do the following:

- Facilitate the visualization of the cervix (cervicography).
- Facilitate communication between health care providers for diagnosis, consultation, or referral.
- Provide training or support to health care providers, especially in the context of task shifting.
- Communicate with patients to provide appointment reminders, test results, disease progression monitoring, coordinate services, etc.
- Improve cervical cancer knowledge or awareness among women.
- Facilitate cervical cancer screening, treatment of preinvasive lesions or cervical cancer management.

We excluded the following types of studies:

- Where the intervention used a nonmobile phone device (eg, digital camera, television) to visualize the cervix.
- Where the intervention exclusively focused on the use of mobile devices for providing education about HPV vaccination or to improve its coverage, because these activities generally fall within the purview of immunization programs. In addition, other published systematic reviews have examined the efficacy of mobile phone interventions for HPV vaccination [22-24].
- Where the intervention was only described or conceptualized without actual implementation or evaluation.
- Where abstracts were only published in languages other than English and for which published English translations were not available.
- Where full texts were not available.
- Where the publications were reviews, systematic reviews, conference proceedings, blogs, reports, or other nonpeer-reviewed sources.

Comparators

Details of the comparator group were extracted from the studies and included in the analysis of primary and secondary review objectives. The comparison was usual care, which could include the use of traditional colposcopy and nondigital, paper-based strategies for data collection, communication, and dissemination in cervical cancer control programs.

Outcomes

For the review of the primary review objectives, the outcomes of interest were as follows:

1. Coverage and timeliness of cervical cancer screening, treatment, and management.
2. Cervical cancer knowledge or competency (ie, training) of health worker.
3. Cervical cancer knowledge or awareness among women.

Outcome data were not reviewed quantitatively because of the descriptive nature of the secondary review objectives.

Study Design

We included randomized and nonrandomized controlled study designs (controlled before-and-after studies with at least 2 intervention sites or interrupted time-series studies) in the qualitative synthesis and meta-analysis of the primary review objectives. We included all study designs for a narrative review of the secondary review objectives.

Settings

For both the primary and secondary review objectives, we included studies from any country listed as low or middle income according to the World Bank Group classification [25].

Information Sources

Electronic Searches

The following 5 electronic databases were searched for studies published in English: PubMed, Embase, Web of Science, Scopus, and CINAHL. We included studies from January 1, 1992, to September 19, 2020 (date of search), with 1992 being the year the first commercial text message was sent.

Search Strategy

A systematic search strategy (Multimedia Appendix 3) was developed, including a detailed search string comprising terms from 3 broad categories, namely, digital health, cervical cancer, and LMICs. The search terms were customized for each of the 5 electronic databases. A Google search was conducted with an abbreviated search string, as described in Multimedia Appendix 3, and the first 100 search results were analyzed.

Study Selection

Search records were imported into the reference management software and duplicates were removed. The titles and abstracts of the records were screened according to the predefined eligibility criteria. For each record, 2 reviewers discussed and resolved any ambiguities in screening outcomes during abstract and full-text screening. Interrater reliability was assessed by 2 reviewers independently screening a 10% sample of sources for inclusion based on abstract evaluation. A Cohen κ value of 0.6 was predetermined as an acceptable interrater agreement.

Data Collection Process and Items

We used a structured template, which was adapted based on the template from Cochrane, to extract relevant data from each

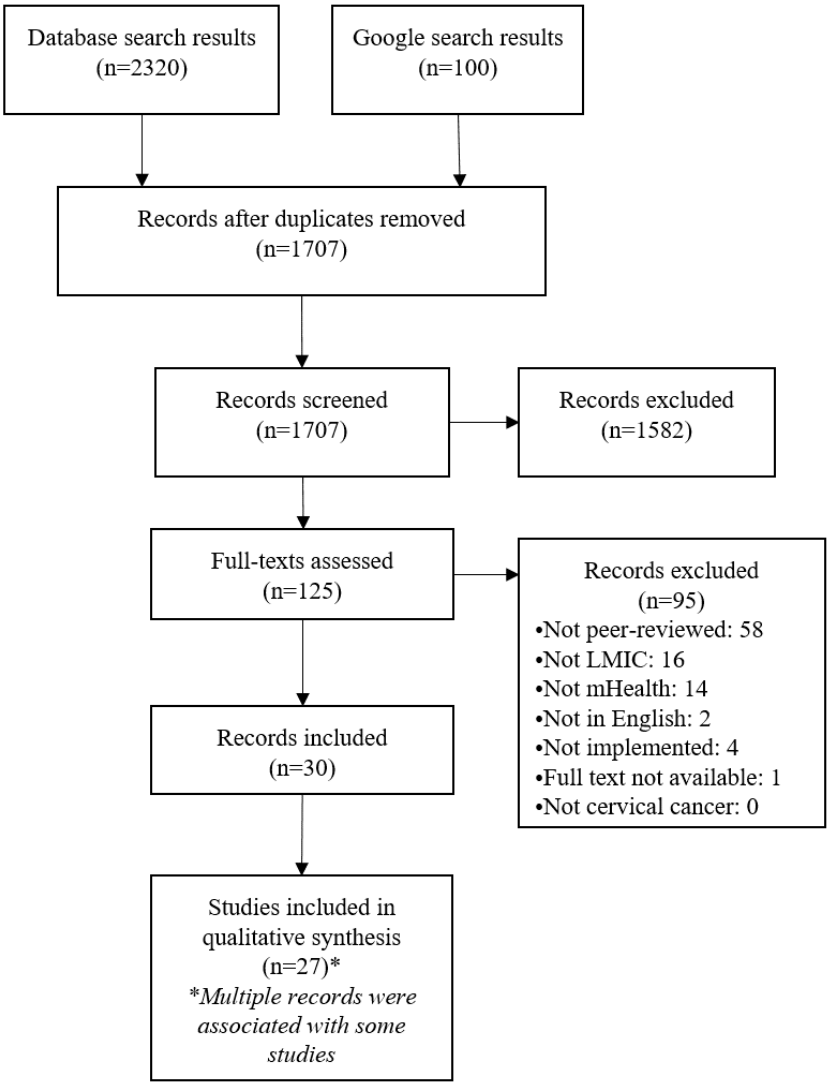
XSL•FO
RenderX

included study [26]. Primary data items extracted using the template included study location, sample size, population, study duration and design, cervical cancer service or procedure, the description of digital health intervention, conclusions, study limitations, and information for assessing the risk of bias. In addition, quantitative outcome data were extracted from the studies included in the review of the primary objectives.

Risk of Bias in Individual Studies

We assessed the risk of bias for all studies using the Effective Public Health Practice Project's Quality Assessment Tool for Quantitative Studies [27].

Additional Analyses



We assessed the quality of data reporting for each included study using the mobile health (mHealth) evidence reporting and assessment (mERA) checklist [28]. This 16-item checklist aims to enhance the replicability of mHealth interventions by promoting the complete reporting of content, context of implementation, and technical features in peer-reviewed publications.

Results

Study Selection

Figure 1 shows the results of the study selection process. The systematic search yielded 1707 nonduplicate studies. The overall interrater agreement for screening a 10% sample was 98.8%, which corresponded to a Cohen κ value of 0.76 [29]. Following the abstract screening, 125 records were evaluated using their full text and 95 of those were excluded. Records were excluded after full-text review mainly because they did not describe a peer-reviewed study or because the intervention was conducted in a non-LMIC setting. In total, 30 records corresponding to 27 unique studies [30-59] were included in the final review.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart of systematic search results. LMIC: low- and middle-income country; mHealth: mobile health.

Study Characteristics

Characteristics of included studies are summarized in Multimedia Appendix 4 [30-59].

Study Design

In total, 4 included studies were randomized controlled trials (RCTs) [38,40,47-49,59]. These studies met the criteria for inclusion in the review of the primary objectives, that is, the

XSL•FO
RenderX

effect of digital health strategies on cervical cancer control. A fifth study by Lima et al [41] used random allocation but was excluded from the review of the primary objectives because of the lack of a control group. Huchko et al [39] reported findings of a mixed methods analysis from a cluster RCT; however, the assignment of the digital health strategy was not randomized; thus, it did not meet the criteria for inclusion in the review of primary objectives. All 27 studies were included in the review of the secondary objectives, that is, to describe the digital health strategies used for cervical cancer control in LMICs and the challenges associated with their implementation. Nonrandomized studies used quasi-experimental [32-34,41], cross-sectional [30,31,35-37,46,50,51,53,56,57], or other [52,54,55] study designs. In total, 4 studies [42-45] described program implementation.

Participants

The studies included 23,393 women and 152 health care workers. Types of health care workers included clinicians (eg, gynecologists, colposcopists, and assistant medical officers), facility-based nurses, and community health nurses.

Intervention

Many interventions targeted health workers and implemented the use of mobile phones for digital cervicography (ie, imaging of the cervix) or for digital patient data collection [30-32,35-37,42-46,50,51,53-57]. Interventions targeting women were focused on building knowledge or awareness about cervical cancer, delivering reminders to promote the uptake of cervical cancer services or for the notification of test results [33,34,38-41,47-49,52,58,59].

Comparators

Most of the included studies lacked a parallel control group. Apart from the 4 RCTs and the cluster randomized trial, the only other studies with a control group were Caster et al and Romli et al [34,58].

Outcomes

Studies using digital cervicography primarily reported diagnostic reliability outcomes such as interrater agreement and sensitivity or specificity as compared with a gold standard diagnostic test such as histology [30,31,35,46,50,51,53-57]. Among the 4 RCTs included in the review of primary objectives, 1 study [40] measured improvement in patient knowledge and all 4 [38,40,47-49,59] measured the uptake of cervical cancer services postintervention. One RCT study [49] included a cost-effectiveness analysis. For the secondary review objectives, all 27 studies included a description of the digital health strategy used and implementation challenges.

Settings

The review focused on LMICs: 19 studies were conducted in sub-Saharan Africa [30,31,34-39,42-46,50,52,54-56,59], 7 in Asia [32,33,40,47-49,51,53,58], and 1 in South America [41].

Risk of Bias Within Studies

The analysis results of the risk of bias within the studies are presented in Table 1 (Effective Public Health Practice Project Quality Assessment tool for quantitative studies). Most of the studies (21/27, 78%) were assessed to have a high risk of bias. A total of 2 studies (Erwin et al [38] and Romli et al [58]) were assessed to have a low risk of bias, whereas 4 other studies [34,40,53,59] were assessed to have a moderate risk of bias.

[a]Scores of 1, 2, and 3 indicate low, moderate, and high risks of bias, respectively. The risk of bias was assessed cumulatively for studies with multiple sources, for example, Asgary et al [30,31].

[b]N/A: not applicable.

[c]Criteria were not applicable based on a skip pattern in the Effective Public Health Practice Project tool.

Results of Individual Studies

The study outcomes included in the review of the primary objectives are presented in Table 2.

XSL•FO
RenderX

Table 2. Outcomes of randomized controlled trial studies included in the review of primary objectives.

Study and participants	Outcome	Result	Summary of risk of bias[a]
Erwin et al (2019) [38], N=851 women			
• 281 controls • 272 SMS messaging • 298 SMS messaging+e-voucher	Cervical cancer screening attendance within 60 days of randomization (combined for women from rural and urban settings)	• Women in the SMS messaging group had 3.0 higher adjusted odds of attendance as compared with women in the control group • Women in the SMS messaging+e-voucher group had 4.7 higher adjusted odds of attendance as compared with women in the control group • Women in the SMS messaging+e-voucher group had 1.5 times higher adjusted odds of attendance compared with women in the SMS messaging group	The overall risk of bias was assessed to be low
Khademolhosseini et al (2017) [40], N=95 women			
• 47 control • 48 intervention	Mean difference in pre- and posttraining knowledge among women in the intervention group as compared with those in the control group measured immediately and 3 months after SMS messaging–based training	• Women in the intervention group had a mean increase in the knowledge of 8.18 points from baseline as compared with a mean increase of 0.27 points from baseline in the control group immediately posttraining • Women in the intervention group had a mean increase in the knowledge of 8.35 points from baseline as compared with a mean increase of 0.17 points in the control group at 3 months of posttraining	The overall risk of bias was assessed to be moderate
• 47 control • 48 intervention	Uptake of Pap test within 3 months of training in the intervention group compared with control group	• At 3 months of posttraining, only 4 (5.8%) participants of the control group as compared with 23 (47.9%) participants of the intervention group had received a Pap test	The overall risk of bias was assessed to be moderate
Linde et al (2020) [59], N=705 women			
• 347 standard of care (control) • 358 standard of care+text message	The attendance rate of follow-up cervical cancer screening among HPV[b]-positive women	• Compared with standard of care, a written appointment card, the addition of one-way text messages had no effect on follow-up cervical cancer screening among HPV-positive women	The overall risk of bias was assessed to be moderate
Rashid and Dahlui (2013) [48], N=1000 women			
• 250 letters • 250 registered letters • 250 SMS messaging • 250 phone calls	The uptake of Pap test in response to recall through phone call as compared with recall by letter	• Compared with women receiving recall by letter, those receiving recall by phone call had 2.38 times higher odds of receiving a Pap smear	The overall risk of bias was assessed to be high
• 250 letters • 250 registered letters • 250 SMS messaging • 250 phone calls	The uptake of Pap test in response to recall through SMS messaging as compared with recall by letter	• Compared with women receiving recall by letter, those receiving recall by SMS messaging had no significant change in the odds of receiving a Pap smear	The overall risk of bias was assessed to be high

[a]Assessed using the Effective Public Health Practice Project risk of bias assessment tool for quantitative studies.

[b]HPV: human papillomavirus.

Synthesis of Results

Findings From the Review of Primary Objectives: Effectiveness of Digital Health Strategies for Cervical Cancer Control

We did not conduct a meta-analysis of the included studies because of variations in the nature of the interventions, outcome measures, and small number of studies included in the primary review of the effect of mobile devices. The only included study with a low risk of bias found that SMS behavior change communication messaging in conjunction with transportation e-voucher led to an increased uptake of cervical cancer screening (Table 2) [38].

XSL•FO
RenderX

Findings From the Review of Secondary Objectives: Description of Strategies Used

We adapted a published mHealth framework for noncommunicable diseases to facilitate the narrative synthesis of the digital health strategies used in the included studies [4,60]. Framework adaptation allowed for the mapping of included studies to various stages of the cervical cancer control cascade (primary prevention, secondary prevention, treatment, and palliation) as well as the key individual, provider, and health system challenges (knowledge, access, quality, and continuity of care) addressed by the included studies. The mapping results are presented in Table 3. Only the digital health components of the study interventions were mapped and any nondigital components (community sensitization, paper educational booklets administered before digital reminders, etc) were excluded. Many studies addressed multiple challenges; hence, digital health strategies were mapped to all the applicable challenges in the framework.

Table 3. Landscape of digital health strategies for cervical cancer prevention and control.

Individual-, provider- and health system–level challenges in cervical cancer control	Stages in cervical cancer prevention and control				
	Primary prevention	Secondary prevention		Treatment and palliative care	
	HPV[a] vaccination	Screening (study)	Treatment of precancerous lesions (study)	Treatment	Palliative care
Knowledge and awareness					
Low knowledge of HPV or cervical cancer	Not within the scope of this review	5 [34,38,40,58,59]	1 [34]	0	0
Low knowledge of cervical cancer screening or treatment services	Not within the scope of this review	6 [34,38,40,41,58,59][b]	1 [34]	0	0
Access to care					
Low access to health facilities or cervical cancer services	Not within the scope of this review	1 [38]	0	0	0
Low availability of appropriate and accurate screening or treatment methods	Not within the scope of this review	15 [30,31,35,36,42-46,50,51,53-57][c]	0	0	N/A
Low access to experts	Not within the scope of this review	15 [30,31,35,36,42-46,50,51,53-57]	0	0	0
Financial barriers	Not within the scope of this review	1 [38]	0	0	0
Continuity of care					
A low uptake of follow-up services	Not within the scope of this review	7 [33,39,41,47-49,52,58,59]	0	0	N/A
Quality of care					
A lack of training opportunities for health workers	Not within the scope of this review	10 [30,31,35,36,42-44,46,51,56,57][c]	0	0	0
Poor data availability	Not within the scope of this review	19 [30-32,35-37,39,42-46,50-57]	2 [32,45]	0	0

[a]HPV: human papillomavirus.

[b]Represents the number of included studies mapped to each category. For example, we found 3 studies that aimed to increase the demand for screening by increasing women's knowledge of human papillomavirus or cervical cancer.

[c]Some studies were associated with multiple records, for example, Asgary et al [30,31].

A majority of the included studies used digital health strategies for secondary prevention; only Caster et al [34] focused on educating women about treatment, whereas Bhatt et al [32] and Peterson et al [45] collected data related to postscreening treatment. None of the included studies focused on cervical cancer treatment or palliative care. Studies related to primary prevention (HPV vaccination) were not within the scope of the study. Although most included studies focused on increasing screening or treatment among all eligible women, some studies focused on high-risk populations, and in particular, HPV-positive women [35-37,50,53,54,59].

1. *Knowledge and awareness*: in total, 6 studies mapped to this domain and included digital health strategies to educate women about HPV, cervical cancer, and cervical cancer prevention or treatment services. These studies

XSL•FO
RenderX

[34,38,40,41,58,59] focused primarily on increasing the screening uptake: Khademolhosseini et al [40] used an educational intervention delivered via an instant messaging platform called Telegram. They used a diverse range of content including text messages, posters, infographics, podcasts, and video tutorials. Lima et al [41] tested a telephone intervention focused on increasing the patient's knowledge of cervical cancer and Pap smears. In the study by Erwin et al [38], women in one study arm received 15 behavior change communication messages via SMS messages that were designed to increase their knowledge and awareness about cervical cancer screening. Caster et al [34] implemented a tablet-based cervical cancer education program to facilitate patient education about screening. Opportunities for interaction with the educational content were through quizzes, or while navigating the content on the tablet. Caster et al [34] also included educational content related to treatment and was the only study to do so.

2. *Access to care*: only one study, by Erwin et al [38], used digital health to reduce transportation and financial barriers to health care access. Women randomized to one of the study arms received e-vouchers through their mobile phone, which covered the costs of a return trip to the health facility. In total, 15 studies used smartphones for facilitating digital cervicography and visualizing the cervix during VIA at the point of care [30,31,35,36,42-46,50,51,53-57]. In total, 7 studies included visual inspection with Lugol iodine images in addition to VIA images [35-37,50,53-55]. Although most studies used the mobile phone camera for image acquisition, Peterson et al [45] and Taghavi et al [53] used smartphone attachments for enhanced cervix visualization. These studies allowed for task shifting, as mobile devices were used to acquire cervical images, record diagnosis, and receive or compare diagnoses with remote experts. Images and relevant patient data were shared with the experts via a text/multimedia message service or by uploading data to a web-based database. Parham et al [44] used an automated text messaging system to reduce the time between screening, diagnosis, and treatment by sending a text message requesting expert review of an image while the patient was still in the clinic. Yeates et al [56,57] used WhatsApp to send patient images, nurse diagnosis, and treatment plans for expert review and subsequently developed the SEVIA app to accomplish these tasks.
3. *Continuity of care*: in total, 7 studies tested digital strategies for reminding or recalling patients for follow-up services [33,39,41,47-49,52,58,59]. These studies focused on women who had already received some cervical cancer services. All 7 studies tested SMS-based reminders or recall messages. In total, 3 studies [39,47-49,52] also tested phone calls. Other nondigital modalities included letters, registered letters, home visits, and return visits to the clinic.
4. *Quality of care*: studies mapped to this domain focused on 2 key applications: training health workers and improving data availability. In most cases, the training covered the acquisition of good-quality images using cervicography and expert feedback to improve the accuracy of diagnosis [30,31,35,36,42-44,46,51,56,57]. In Botswana, Littman-Quinn et al [42] provided additional ongoing medical education content to health workers via tablet devices to complement in-service training. Studies using digital cervicography were also mapped to this domain as the documentation of cervical images during VIA can improve data availability for patient management, and hence, improve the quality of care. Two studies, Bhatt et al [32] and Peterson et al [45], collected treatment information in addition to information about screening results. In the study by Bhatt et al [32], a SIM-based app was loaded on feature phones provided to trained nurses. The nurses used a menu-based protocol on the feature phone for entering data.

Findings From the Review of Secondary Objectives: Implementation Challenges

In the included studies, the authors described several technical challenges in implementing digital health strategies for cervical cancer control in LMICs. These challenges were based on *lessons learned* and, in a few cases [31,32], on formal qualitative data collected during the study. In addition to the technical challenges, many studies described inadequacies in the underlying health system resources (eg, availability of pelvic exam rooms and lack of supplies for cryotherapy in community health centers [30]), which impacted study implementation. Digital health strategies were not implemented in a vacuum; several studies described the need for increasing the community knowledge and awareness of cervical cancer as well as reducing stigma and fear related to cancer screening/diagnosis in parallel with the implementation of digital health strategies [30,32,37,38,41,44,45,51]. One study also described negative attitudes toward cervical cancer screening among health care workers as an issue [51]. Some authors emphasized the need for strong partnerships and stakeholder support for the success and future sustainability of digital health strategies [42,43,45,51]. Table 4 shows the technical challenges in implementing digital health strategies for cervical cancer control.

XSL•FO
RenderX

Table 4. Description of implementation challenges for digital health strategies for cervical cancer control.

Implementation challenge	Included studies	Description and examples

High training requirements	[30,31,34,35,43,44,51,54]	• Pretraining lasting several weeks, providing supplemental training for augmenting skills, refresher training to minimize loss of skills, and the availability of experts to provide ongoing feedback for using digital cervicography
		  • Catarino et al [35]: 5 weeks of training on digital cervicography to medical students
		  • Asgary et al [30,31]: additional one-on-one training to community health nurses in cases where the digital image quality was low
		  • Ndlovu et al [43]: high training requirements on the touchscreen features
		  • Caster et al [34]: Users had limited previous experience with technology (but needed very little support for using the tablet device).

Technology-specific challenges	[30,32,36,42-44,46,50,54,55]	• Procurement of appropriate technology
		  • Challenges with the availability of technology options in the study area in preparation for and during the study [30,32]
		  • Considerations related to finding mobile phone cameras with high image quality and zoom capabilities [30,43,46,54,55]
		  • The use of high-pixel smartphone cameras were associated with better reported quality of images [50]; however, Tran et al [54] suggested that the quality was inferior to colposcopy images.
		  • Parham et al [44]: need to send cameras out of the country for repairs was a challenge
		• Software and hardware issues: software "bugs," crashing of apps, device malfunctions, and an insufficient battery life [36,42-44]
		  • Gallay et al [36]: loss of patient data due to the unexpected crash of their data collection app
		• Data security issues
		  • Littman-Quinn et al [42]: security breach (attack by an anonymous hacker) lead researchers to increase data security to the level of compliance described in the Health Insurance Portability and Accountability Act
		• Software updates
		  • Bhatt et al [32]: challenges in updating a SIM-based app requiring project staff to collect all SIM cards to update the app
		  • Littman-Quinn et al [42]: challenges with communication when the technical team was based in a different country and did not speak the same language as the end users, reflecting the need for local technology development capacity for the sustainability of digital health strategies

Infrastructure challenges	[31,32,42,43,45,46]	• Issues with network coverage and electrical outages as limitations to widespread implementation
		  • Bhatt et al [32]: challenges faced by nurses from hillier communities in sending patient data and receiving acknowledgment of report submission
		  • Yeates et al [56]: health care workers given solar-powered chargers and light sources for anticipated power outages and to allow use of digital cervicography in off-site settings

Challenges with technology reach	[39,47-49]	• Rashid et al [47-49]: letters were more likely to be successfully and reliably delivered to patients than phone text messages or calls because of connectivity and coverage issues (incorrect phone numbers and nonresponse) • Rashid et al [47-49] and Huchko et al [39]: direct communication through phone call encouraged more women to seek screening (both studies had a high risk of bias, limiting our confidence in their findings)
Inequitable access to technology	[38,39,52]	• Exclusion of women without mobile phones from digital health intervention components in some studies

Additional Analysis: Quality of Digital Health Reporting

The quality of reporting scores according to the mERA checklist is summarized in Multimedia Appendix 5 [30-59]. The mERA scores ranged from 1 to 10, out of a maximum possible score of 16. The mERA checklist items frequently described in the studies included the technology platform and details of intervention delivery. Poorly described items were related to digital health infrastructure necessary for implementation, interoperability with other existing digital health systems, usability testing during development, and intervention

XSL•FO
RenderX

replicability, with 6 or fewer included studies describing these characteristics.

Discussion

Summary of Evidence

Our review findings show that the majority of the studies in LMICs used digital health strategies to facilitate the screening and treatment of precancerous lesions (ie, secondary prevention) as compared with the treatment of invasive cancer or palliative care. Even though our search attempted to include any relevant studies since 1992, the date of the earliest included study was 2010. Within the realm of secondary prevention, strategies focused on improving women's knowledge and awareness about cervical cancer, increasing access to cervical cancer services, improving the training of health workers and availability of data, and ensuring the continuity of care. Key challenges in implementing digital health strategies for cervical cancer control were related to the high burden of training, technology-specific issues, infrastructure challenges, challenges with technology reach, and inequitable access to technology among target users. We were unable to determine the quantitative effect of digital health strategies on cervical cancer control because of the small numbers and inadequate quality of studies for meta-analysis. Only one randomized controlled study identified in this review with a low risk of bias found that SMS behavior change communication messaging in conjunction with a transportation e-voucher leads to an increased uptake of cervical cancer screening. Most of the studies included in the review had a high risk of bias and were rated poorly in terms of the quality of reporting of the digital health strategy.

Implications for Research and Practice

This review identified several gaps in the literature. These gaps are summarized below, along with their implications for research and practice:

1. Improve the evidence base for the effectiveness of digital health strategies for cervical cancer control: there is insufficient evidence related to the effectiveness of digital health strategies for cervical cancer screening and treatment. The included studies implemented digital health strategies mostly for secondary prevention, and there are opportunities to investigate the use of digital health for cervical cancer treatment and palliative care. Other bottlenecks in the cervical cancer control cascade that may benefit from using digital health include improving access to health facilities (eg, through the use of digital telemedicine), reducing financial barriers (eg, provision of phone vouchers), and supporting disease management among women diagnosed with invasive cancer (eg, using digital knowledge interventions).
2. Use more rigorous study designs: among the 27 included studies, only 4 studies used an RCT design [38,40,47-49,59] and only one of these studies had a low risk of bias [38]. The high or moderate risk of bias among the remaining studies limited our confidence in their findings. Future studies should consider using rigorous study designs that minimize the risk of bias.
3. Improve the reporting of digital health strategies in the literature: in our review, only 5 studies [35-37,39,54,57,59] met the mERA checklist item on replicability, indicating that many of the digital health strategies identified in this review would be difficult to replicate and re-evaluate based on published information. The use of reporting checklists ensures that all relevant information is presented to readers to assist with study reproducibility.
4. Expand research on LMIC settings in Asia and South America: a majority (70%) of the included studies took place in sub-Saharan Africa, indicating an opportunity to expand research to other LMIC settings with a high burden of cervical cancer.

Limitations

Our synthesis of the literature is limited by the availability of peer-reviewed reports of digital health strategies for cervical cancer control. We tried to mitigate this limitation by using a systematic search strategy and searching 5 large databases and Google to identify relevant studies. We did not search any trial databases for ongoing studies or to examine other gray literature sources. Hence, we may have missed ongoing implementations and emerging data on using digital health for cervical cancer control.

Conclusions

There is insufficient evidence to determine the effectiveness of digital health strategies for cervical cancer control in LMICs. The only RCT study identified in this review with a low risk of bias found that SMS behavior change communication messaging in conjunction with a transportation e-voucher led to an increased uptake of cervical cancer screening. Future efforts are needed to investigate the use of digital health strategies across the cervical cancer control continuum and in LMIC settings outside of sub-Saharan Africa.

Acknowledgments

The authors would like to thank Patricia G Moorman, PhD, for providing feedback on the early drafts of the manuscript and Christina Makarushka, MPH, for coordinating this review. This study was funded by a pilot grant from the Duke Cancer Initiative and 1R01CA195500 Quick Trials: a viable solution for a see and treat paradigm for cervical precancer in Africa, and 1R01CA19338001 AIP: Culturally Appropriate Screening and Diagnosis of Cervical Cancer in East Africa to NR. HWR and LV receive funding from the National Center for Advancing Translational Sciences of the National Institutes of Health under award numbers TL1TR002555 and KL2TR002554, respectively. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

XSL•FO
RenderX

Authors' Contributions

LV conceived the study and protocol. AHR, LV, and MVI developed the search terms. The medical librarian (MVI) conducted the systematic search. AHR, LV, CM, and HWR screened studies for inclusion, and AHR, LV, MMP, CM, and HWR extracted data and completed the bias analysis. AHR developed figures and tables. AHR and LV cowrote the first draft of the manuscript. All authors have revised the manuscript and approved the final version for submission.

Conflicts of Interest

One review author (MJH) was listed as an author on 2 included studies and did not participate in the risk of bias assessment of any included study. The authors declare no other conflicts of interest.

Abstract

Background: As social media are increasingly used worldwide, more and more scientists are relying on them for their health-related projects. However, social media features, methodologies, and ethical issues are unclear so far because, to our knowledge, there has been no overview of this relatively young field of research.

Objective: This scoping review aimed to provide an evidence map of the different uses of social media for health research purposes, their fields of application, and their analysis methods.

Methods: We followed the scoping review methodologies developed by Arksey and O'Malley and the Joanna Briggs Institute. After developing search strategies based on keywords (eg, social media, health research), comprehensive searches were conducted in the PubMed/MEDLINE and Web of Science databases. We limited the search strategies to documents written in English and published between January 1, 2005, and April 9, 2020. After removing duplicates, articles were screened at the title and abstract level and at the full text level by two independent reviewers. One reviewer extracted data, which were descriptively analyzed to map the available evidence.

Results: After screening 1237 titles and abstracts and 407 full texts, 268 unique papers were included, dating from 2009 to 2020 with an average annual growth rate of 32.71% for the 2009-2019 period. Studies mainly came from the Americas (173/268, 64.6%, including 151 from the United States). Articles used machine learning or data mining techniques (60/268) to analyze the data, discussed opportunities and limitations of the use of social media for research (59/268), assessed the feasibility of recruitment strategies (45/268), or discussed ethical issues (16/268). Communicable (eg, influenza, 40/268) and then chronic (eg, cancer, 24/268) diseases were the two main areas of interest.

Conclusions: Since their early days, social media have been recognized as resources with high potential for health research purposes, yet the field is still suffering from strong heterogeneity in the methodologies used, which prevents the research from being compared and generalized. For the field to be fully recognized as a valid, complementary approach to more traditional health research study designs, there is now a need for more guidance by types of applications of social media for health research, both from a methodological and an ethical perspective.

Introduction

Social Media Background

Social media (SM) refer to new forms of media that involve interactions between users [1] in personal (eg, Facebook) or more professional (eg, LinkedIn) ways. In 2010 in the United States, 80% of adults used the internet to search for health-related information, and 11% of SM users posted comments, queries, or information about health or medical content [2]. Every user activity on the internet generates a unique digital footprint that can be collected for health research [3]. However, SM are not only used in a personal way. Indeed, academics are also increasingly using SM to share their work and disseminate their findings [4].

Opportunities for Health Research

Since the creation of SM in 2004-2005 and with 3.81 billion active social media users in April 2020 [5], concepts like infodemiology and infoveillance have emerged. The term "infodemiology" refers to the science of using the internet to improve public health, while "infoveillance" refers to the science of syndromic surveillance using the internet [6]. These opportunities have been seized through the years in order to create new methodologies for health research to cope with the issues raised by traditional methods (eg, difficulty of recruitment [7]).

Scoping Review Contextualization

Previous scoping and systematic reviews have already been published about the different uses of SM for health research. However, they were either focusing on a specific type of SM (eg, blogs [8]), on a specific field of health research (eg, child maltreatment [9]), or on a specific methodology (eg, recruitment of study participants [10,11]). Other reviews discussed the overall use of SM for health research [12,13] but did not provide any insights on the analysis techniques or the ethical issues. Besides, the COVID-19 pandemic has sped things up and pushed research to be done online, leveraging existing data for disease surveillance purposes, which makes the present work particularly timely and needed for better structuration of the field [14]. The research field on social media and health is relatively young and therefore lacks structures and guidelines. In the light of the above, it seemed important to map the different uses of social media for health research. Our work will directly contribute to the general effort of acknowledging the potential of this research field and will help to identify the main limitations to tackle in the future.

Review Questions

The overall research questions were as follows: (1) How have SM modified or complemented traditional health research? (2) What are the different fields of application of this approach? (3) What are the different methodologies for SM data analysis?

Methods

Overview

This scoping review followed the methodological framework introduced by Arskey and O'Malley in 2005 [15] and the methodology manual published by the Joanna Briggs Institute for scoping reviews [16]. It is reported in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-analyses Extension for Scoping Review (PRISMA-ScR) guidelines [17]. The methods have been previously detailed in a research protocol [18].

Search Strategy

An initial literature search was first manually conducted on PubMed/MEDLINE to identify the health research fields in which SM are mostly used and developed. We searched for the term "social media" in the Medical Subject Headings (MeSH) Terms (words or phrases selected to represent particular biomedical concepts) as it gathers all papers discussing the use of at least one example of social media. For instance, this MeSH Term also includes articles that mention Facebook or Twitter without referring directly to "social media." We considered the term "health research" as all kinds of research performed to learn more about human health, prevent or treat disease, test ideas, improve treatments, and answer questions. Then, the literature search was performed through PubMed/MEDLINE and Web of Science. The search strategy, highlighted in Textbox 1, included two sets of search terms: (1) one linked with SM (eg, social media) and (2) one linked with research (eg, health research, biomedical research). In order to capture the evolution of SM uses for health research over the years, databases were searched between January 1, 2005, and April 9, 2020. The term "social network" was also searched, as it is often misused as a synonym of SM. An additional list of 5 relevant articles [19-23] was manually searched to identify any other potentially relevant articles not yet captured. These articles were chosen in order to retrieve more articles about infodemiology, ethical issues, or the use of SM data. A snowball searching technique was adopted with these 5 articles in which citations within articles were searched and kept if relevant to the review.

Textbox 1. Inclusion criteria, exclusion criteria, and search strings.

Inclusion criteria

- written in English
- published between January 1, 2005, and April 9, 2020
- dealt with the use of social media by researchers

Exclusion criteria

- not about health research
- not related to social media (eg, social network analysis)
- not about human subjects
- no relevant information (eg, methodology) about the use of social media for health research
- no relevant characteristics of social media

Search string in PubMed

Eligibility Criteria

This review was guided by the “Population, Concept, Context” framework suggested by the Joanna Briggs Institute [24]. We did not have any restriction about the population; we took any relevant publications regardless of the age, the origin, or the gender of the studied populations. The concept was the use of social media and the context was health research. The eligibility criteria were any journal article that described the use of social media platforms or social media data for health or medical research purposes. We excluded articles that were not directly related to research from our review, such as those on the use of social media among patients, patient associations or communities, organizations, or health care professionals for their day-to-day practice. Grey literature and studies about nonhuman subjects were excluded as well. Documents related to the mining of social media data to detect prescription drug misuse and abuse as well as those related to the use of machine learning methodologies to analyze data were eligible for inclusion. We included full texts that reported on at least one of the following outcomes: (1) SM data analysis, (2) recruitment through SM, (3) methodology for SM research, and (4) ethical issues of using SM for health research. Only English-language articles were retained. The inclusion and exclusion criteria and the search strings are summarized in Textbox 1.

Study Selection Process

A 2-step screening was performed after duplicate removal. First, titles and abstracts were screened in order to define the eligibility of each article. Publications with title or abstract not meeting the eligibility criteria were excluded. Then, the full texts having passed the first step were screened, and only articles meeting the eligibility criteria were kept. All screening levels were conducted with CADIMA [25], a free web tool to facilitate the conduct and documentation of literature reviews [26]. Two reviewers screened articles (GF, CB) independently, and consistency checks were performed thanks to CADIMA.

Data Extraction

Data were abstracted on (1) the country of origin, (2) the aims of the study (eg, to map ethical issues when using SM for health research), (3) the type of study (eg, recruitment feasibility assessment), (4) the research field (eg, mental health research), (5) the studied population (eg, adolescents), (6) the type of SM (eg, Facebook), (7) the methodology (eg, paid advertisement), (8) the outcomes of the study (eg, efficiency of recruitment via SM), and (9) the key findings for our scoping review (eg, possibility to recruit on SM). Data were extracted and cleaned by a first reviewer (CB), then verified and approved by a second reviewer (GF).

Methodological Quality Appraisal

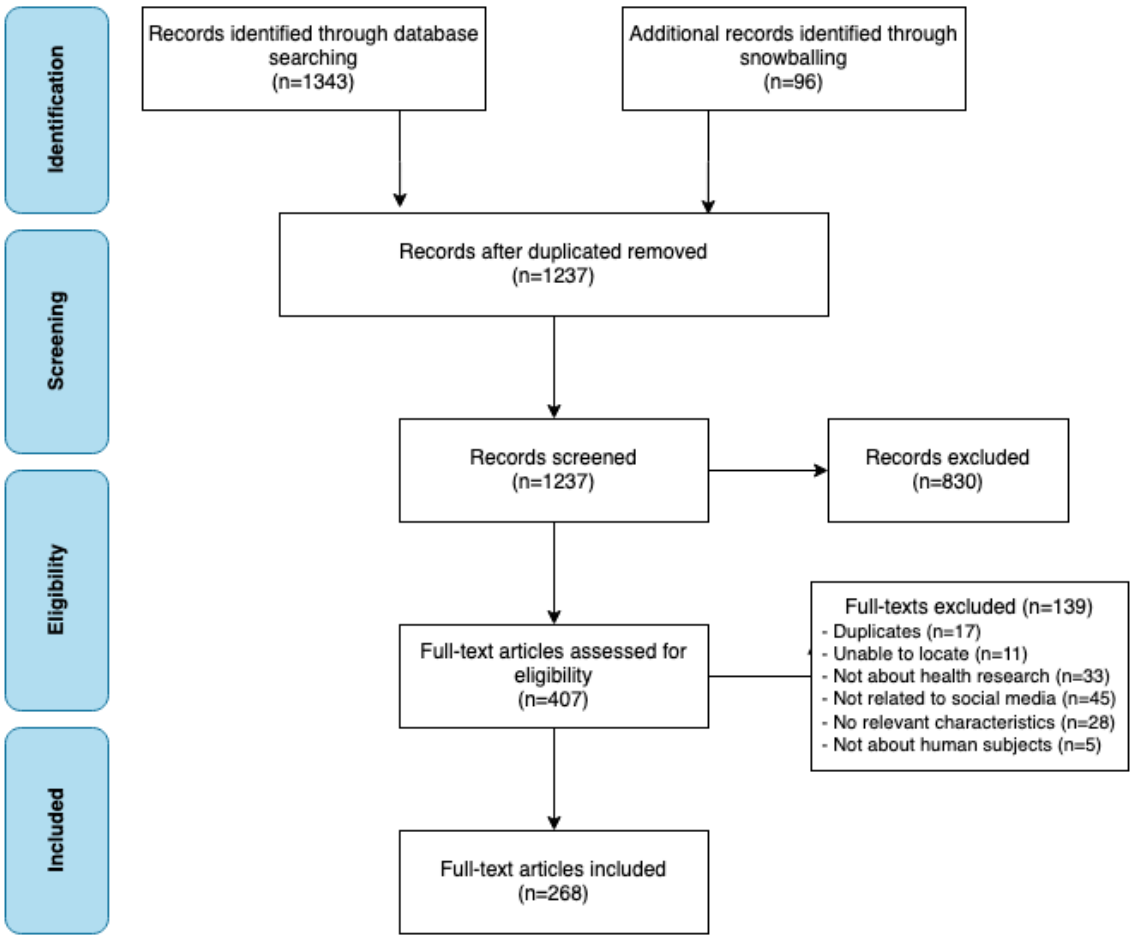
Because this is a scoping review, we did not appraise methodological quality or risk of bias of the included articles.

Analysis and Presentation of Results

We conducted a descriptive analysis of the characteristics of the included literature. We described the included articles according to the journal of publication, publication date, country of origin (location of the corresponding author), Altmetric score (automatically calculated weighted count of all of the attention a research output has received) [27], type of SM, type of population, and type of disease studied. We decided to focus on Altmetric score rather than citation counts; as the SM

XSL•FO
RenderX

research field is still relatively young, traditional citation counts provide a quite conservative approach of a paper's "influence" that is influenced by the size of the research community working on the topic. Thus, Altmetric might be less influenced by the relatively "young" aspect of this research field by giving weight to other dimensions (record of dissemination, influence, impact). All these measures are more nuanced than citation counts alone are able to be [28,29]. However, Altmetric scores also have some limitations, as they do not take comparability across journals and platforms into account, and this system can be gamed [30,31].



We categorized the diseases in 7 categories: (1) chronic diseases (eg, diabetes), (2) communicable diseases (eg, influenza), (3) alcohol/smoking (eg, vaping), (4) mental health (eg, depression), (5) lifestyle (eg, nutrition outcomes), (6) drug/medication (eg, drug use disorder), and (7) other (eg, child maltreatment). Descriptive statistics and corresponding plots were computed (n, means, frequencies) with R (version 3.6.3; R Foundation for Statistical Computing).

Results

Search Results

The initial search conducted in April 2020 revealed 1343 results. An additional 96 articles were retrieved through a snowballing technique based on 5 relevant articles [16-20]. This resulted in a total of 1439 articles, and duplicates (n=202) were removed. Then, 1237 titles and abstracts were screened, which led to the exclusion of 830 articles. Overall, 407 studies were included to screen as full - text papers, of which 139 were excluded. The main reasons for exclusion were that the study (1) did not contain relevant characteristics of SM for health research (n=28), (2) did not relate to SM (n=45), or (3) was not about health research (n=33). 268 studies were included in the analyses. Figure 1 shows the flow diagram of the article selection. Lastly, Multimedia Appendix 1 displays the characteristics of the 268 included studies (author or authors, year of publication, country, title, aim of the study, type of social media, studied population and disease).

Figure 1. Flow diagram of the included studies.

Distribution of Studies

In all, we included 268 unique records from 155 different journals. Table 1 displays the 10 most common journals in which the included studies were published: 55 (20.5%) articles were published in the *Journal of Medical Internet Research* or sister journals *JMIR Research Protocols* and *JMIR Public Health and Surveillance*. *PLoS ONE* is the second most common journal with 10 (3.7%) articles.

XSL•FO
RenderX

Table 1. Top 10 most common journals publishing work using social media for health research purposes.

Name of the journal	Articles, n (%)
Journal of Medical Internet Research	39 (14.6)
PLoS ONE	10 (3.7)
JMIR Research Protocols	9 (3.4)
JMIR Public Health and Surveillance	7 (2.6)
American Journal of Public Health	5 (1.9)
The American Journal of Bioethics	5 (1.9)
BMC Medical Informatics and Decision Making	4 (1.5)
International Journal of Environmental Research and Public Health	4 (1.5)
PLoS Computational Biology	4 (1.5)
Digital Health	3 (1.1)

A total of 1025 authors took part in the writing of the included studies. Figure S1 in Multimedia Appendix 2 provides the coauthorship network of all these authors. The largest set of connected authors included 57 authors and shown in Figure S2 in Multimedia Appendix 2).

Even though our research date range was from 2005 to 2020, none of the 268 included articles are dated before 2009. In Table 2, it can be seen that the number of publications is growing through the years, corresponding to an average annual growth rate of 32.7% for the 2009-2019 period. This suggests that the field of health research supplemented by SM has gained interest for the last 11 years. Earlier studies concentrated more on the use of SM for health research in general and the opportunities for the study of communicable diseases. The most recent studies more frequently included recruitment strategies and methodologies. Table 3 displays the distribution of articles by the continent of publication. Most articles were from the Americas (173/268, 64.6%, including 151/173, 87.3% from the United States), 18.7% were from Europe (50/268), 11.6% were from Oceania (31/268), 4.9% were from Asia (13/268), and 0.4% were from Africa (1/268).

Social Media

Among all the retrieved articles, 57.8% (155/268) used or described at least one specific type of SM. From these articles, as can be seen in Table 4, 42.6% (66/155) were based on Twitter, 34.2% (53/155) on Facebook, and 11.0% (17/155) on several SM (eg, combining Facebook, Instagram, and Snapchat [32]). The remaining 12.3% (19/155) were distributed between Instagram, Reddit, forums, blogs, Weibo, and YouTube.

Table 4. Distribution of publications by social media (N=155).

Type of social media	Publications, n
Blogs	2
Facebook	53
Forums	3
Instagram	5
Reddit	5
Several types	17
Twitter	66
Weibo	2
YouTube	2

Focused Populations

A total of 80.2% (215/268) of included articles did not focus on any specific population. In articles that studied a specific subpopulation (n=53), youth was the most common one (34/53, 64%), followed by women (7/53, 13%), families (5/53, 9%), men (1/53, 2%), and other (6/53, 11%), as shown in Table 5. The "Other" category gathered adults (2/6), Chinese migrants (1/6), elderly people (1/6), emergency nurses (1/6), and researchers (1/6).

Table 5. Distribution of publications per studied population (N=53).

Studied population	Publications, n
Youth	34
Women	7
Families	5
Men	1
Other	6

Domain of Health Research

In addition, 45.1% (121/268) of publications dealt with a specific disease or condition (the remaining articles usually dealt with the use of SM for health research in general or with methodology). Indeed, as shown in Table 6, 33.1% (40/121) of articles studied communicable diseases, 19.8% (24/121) studied chronic diseases, 15.7% (19/121) studied lifestyle (eg, nutrition outcomes), 13.2% (16/121) studied other conditions (eg, drug use disorder), 9.9% (12/121) studied alcohol/smoking (eg, vaping), and 8.3% (10/121) studied mental health (eg, depression).

Table 6. Distribution of publications by studied disease type (N=121).

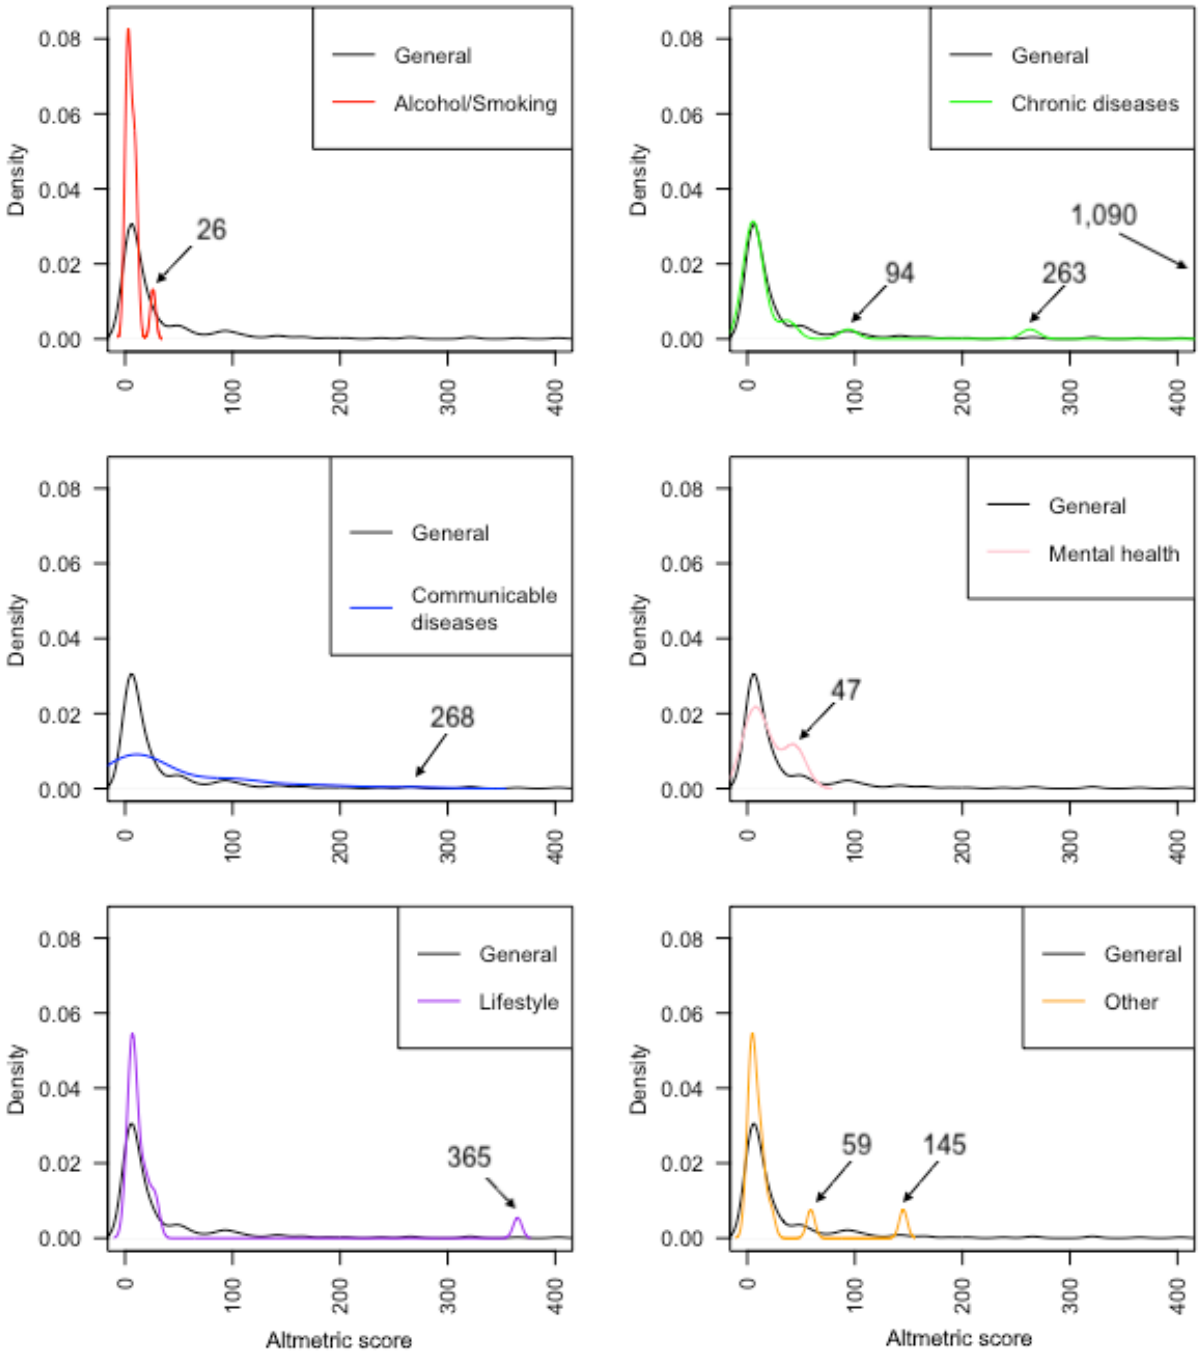
Studied disease type	Publications, n
Alcohol/smoking	12
Chronic diseases	24
Communicable diseases	40
Lifestyle	19
Mental health	10
Other	16

Communicable Diseases

Among articles that discussed communicable diseases, influenza was the primary studied disease (18/40, 45%), followed by HIV (8/40, 20%) and human papillomavirus (3/40, 8%).

Chronic Diseases

Among articles that discussed chronic diseases, a quarter studied cancer (6/24, 25%), followed by diabetes (5/24, 21%),



XSL•FO
RenderX

cardiovascular diseases (eg, congenital heart disease, 3/24, 12%), and obesity (2/24, 8%).

Dissemination

As highlighted in Figure 2, some papers stood out and could be considered important in the recent field of health research on social media.

Figure 2. Distribution of Altmetric scores by health research area. Corresponding publications to the indicated Altmetric scores: Alcohol/Smoking: 26 [33]; Chronic diseases: 94 [34], 263 [35], 1090 [36]; Communicable diseases: 268 [37]; Mental health: 47 [38]; Lifestyle: 365 [39]; Other: 59 [40], 145 [41]. General corresponds to the Altmetric scores of all studies.

Type of Studies

Among all included studies, 22.4% (60/268) described the use of machine learning and data mining techniques, 22.0% (59/268) discussed the opportunities and limitations of the use of SM for research, 16.8% (45/268) assessed the feasibility of recruitment strategies on SM, 6.0% (16/268) discussed the ethical issues when using SM for health research, 5.2% (14/268) gave methodologies for health research, and 4.9% (13/268) illustrated the use of SM for dissemination. Guidelines for recruitment (9/268, 3.4%), interventions of prevention (6/268, 2.2%), crowdfunding (4/268, 1.5%), sentiment analysis (4/268, 1.5%), data anonymization (2/268, 0.7%), and crowdsourcing (2/268, 0.7%) were also considered.

Machine Learning and Other Techniques

Machine learning techniques included text mining (17/60, 28%), natural language processing (15/60, 25%), data mining (12/60,

XSL•FO
RenderX

20%), classification (10/60, 17%), topic modelling (4/60, 7%), deep learning (1/60, 2%), and social network analysis (1/60, 2%). In particular, support vector machine (17/60, 28%), logistic regression (11/60, 18%), latent Dirichlet allocation (5/60, 8%), convolutional neural network (5/60, 8%), random forests (4/60, 7%), decision trees (4/60, 7%) and n-grams (64/60, 7%) are the most used models. Stacked linear regression, Bayesian network algorithm, nonnegative matrix factorization, stochastic gradient, learning vector quantization, and recurrent neural networks represent 2% (1/60) each. Lastly, these techniques were mostly used for data coming from Twitter (38/60, 63%) and Reddit (3/60, 5%).

Recruitment Strategies

Studies assessing recruitment strategies' feasibility applied paid advertisement (36/45, 80%), free advertisement (eg, posting in relevant Facebook groups [42]) (6/45, 13%), and the combination of both advertisements (3/45, 7%). Paid recruitment strategies included designing the ad, targeting the right audience with Facebook Ads Manager and measuring the impacts with Facebook Analytics [43]. Moreover, 64% (29/45) of studies considered SM recruitment to be effective (time-effective and efficient to recruit populations). Paid advertisement was evaluated as cost-effective in 83% (30/36) of studies and too costly in 6% (2/36). We found out that 80% (36/45) of recruitment was carried out on Facebook, 9% (4/45) on both Facebook and Twitter, and 9% (4/45) on more than two types of SM (eg, Facebook, Twitter, Craigslist, Tumblr, LinkedIn [44]). Lastly, a third of recruitment strategies included providing incentives to participants (eg, gift cards).

Ethical Issues

Ethical issues were usually mentioned but not investigated in detail. When the article focused on ethical issues (n=16), the main ethical issues raised were getting consent of online users (15/16, 94%), protecting the privacy of users (14/16, 88%), preserving confidentiality (9/16, 56%), potential harms to participants (9/16, 56%), preserving of anonymity (8/16, 50%), securing data (7/16, 44%), transparency of the research (7/16, 44%), application of guidelines (7/16, 44%), representativeness and self-selection bias (5/16, 31%), and the risk of double accounts (2/16, 12%).

Discussion

Principal Findings

The overarching aim of this review was to scope the literature for evidence on the use of SM for health research. We were able to include 268 studies. Most of the included articles in this scoping review are dated from 2013 onwards, which is consistent with the worldwide growth of SM use over the last decade [45]. We identified three main SM used for health research: Twitter, Facebook, and Instagram, the most popular platforms in 2020 [46]. The most studied populations are young adults and adolescents. This could be related to the elevated proportion of young people active on SM. In 2018 in the United States, 51% of teens were on Facebook, 69% on Snapchat, 72% on Instagram, and 85% on YouTube; thus, SM seems to have great potential to focus on the young generations [47]. The majority of the included works focused on both communicable and chronic diseases. The field of SM research is still very young, and this can be seen in the impact that publications have (via the Altmetric score), with the exception of 9 articles. However, it is set to evolve rapidly, and it will be necessary to follow the evolution of the Altmetric scores of the field in the coming years to identify the new major articles.

The fields of application of SM in health research are broad and constantly evolving: as earlier studies concentrate on the study of communicable diseases, most recent studies include recruitment strategies and data collection for infoveillance. First, SM can be used to complement traditional methods. Traditional procedures can meet several limitations. When recruiting a specific population, traditional methods (eg, fliers, advertising) can be expensive or limited in reach [7,48-50]. Complementing them with SM advertisements can cope with these limitations. Second, SM alone show high potential. Studies have concluded that SM paid advertisements can be an efficient and cost-effective tool to recruit [11,51-56]. SM appear not only to facilitate and complement traditional recruitment strategies to reach specific populations but to be efficient as well when used alone [52,57-59], especially to reduce time constraints or to target a large population [60]. Particularly, Facebook can be used to recruit participants of all ages and allows researchers to obtain participant samples similarly representative to those recruited via traditional recruitment methods [11]. Facebook, together with Facebook Ads Manager and Facebook Analytics, are particularly useful to develop and adjust such strategies. Traditional disease surveillance, population surveillance, and epidemiology methodologies can be improved by SM [21,50,61]. Pharmacovigilance and the detection of adverse drug reactions on SM proved to be efficient and to reduce time between the online report of an incident and its discovery [62-64]. As the number of SM users is increasing, generated data, or "big data," is expanding. Such data can be collected and studied to improve disease and public health surveillance [65-67] to forecast diseases [68] or to improve research in a medical field [69,70]. Along with big data growth, machine learning and data mining techniques such as text mining and natural language processing are constantly evolving and are thus increasingly used in the field of public health research based on SM [71-73]. These techniques can be particularly interesting to analyze social media data and, for instance, to develop sentiment or topic analysis among a specific population [19,74] or to predict epidemics [75]. Twitter is mainly used for such work because Twitter developed a streaming application programming interface. This is a free application that allows easy access to 1% of all Twitter data in real time, filtered by specific criteria (eg, keywords) [76,77]. Lastly, SM can be directly used by health researchers to support prevention interventions to raise awareness and engage populations [78] and to crowdfund by promoting their research on SM. Indeed, crowdfunding can be eased by establishing professional contacts through SM and sharing campaigns [79].

The digitization of public health and clinical research is likely to grow in the years to come. The COVID-19 pandemic has already played a major role in this dynamic. Indeed, social media were not only efficient to spread information and to share

XSL•FO
RenderX

diagnostic, treatment, and even follow-up protocols [80-82] but also to develop infoveillance studies to help characterize disease distribution and behaviors critical to the early stages of an outbreak [83,84] and to recruit participants in order to collect large-scale data within a short time period [85].

Still, the use of SM features and SM data for health research induces several ethical issues and limitations. Online data, such as those from Twitter, are often considered to be public, and user consent is not provided for collecting it. Moreover, ensuring privacy protection of a data set when anyone has access to vast amounts of public information is difficult because data could be reidentified [86,87]. Safety features should be used to protect users' personal and sensitive information [20] and to protect users from dangerous or fake content posted by detractors, chatbots, or social media trolls (people who purposely provoke other SM users) [88]. These kinds of behaviors can also be oriented to researchers themselves and demotivate them. Moreover, data can represent only certain users' characteristics due to researchers' self-selection or to coverage issues of underserved populations or minority groups who are disproportionately absent online (eg, older adults). This can bias the representativeness of the sample and consequently bias the findings and prevent from any generalizability [89,90]. However, it is possible to multiply platforms (cross-platforms) or to combine with other recruitment methods to minimize such bias [91]. When recruiting and providing incentives, users might be tempted to participate multiple times. Researchers should ensure that the study allows only one response from a given IP address [92,93]. A few guidelines and frameworks have already been created to guide health researchers in using social media and prevent such issues [94-98].

Strengths and Limitations of This Scoping Review

The present work used a rigorous scoping review methodology from the manual by the Joanna Briggs Institute [16] throughout the entire process. It was guided by a previously published protocol [18]. To ensure a broad search of the literature, the search strategy included two electronic bibliographic databases and the snowball technique. There are some limitations to our scoping review process. We may not have identified all relevant articles in the published literature despite attempts to be as comprehensive as possible. We limited our review to documents written in English, which may have led to missed relevant studies. Data were abstracted by one reviewer and verified by a second reviewer because of the important number of included publications.

Conclusion and Recommendations

Our findings suggest that SM hold high potential to improve and complement existing health research studies. Indeed, some SM features can complement traditional research strategies, and the growing amounts of SM data hold great opportunities in the evolution of infoveillance and infodemiology. For researchers, SM can be an effective tool at almost every step of a study, from the development, ideation, recruitment, and crowdsourcing to the dissemination of findings. Researchers should determine which type of SM best fits their objectives, as Facebook might be better for recruitment and Twitter for data collection, in order to gain time and efficiency. Last but not least, we have observed strong heterogeneity in the approaches used. We therefore recommend taking the existing guidelines into account and carefully thinking about the different ethical issues highlighted in this work before using SM for research.

Acknowledgments

This work is supported by the Luxembourg Institute of Health.

Authors' Contributions

CB and GF conducted title, abstract, and full-text screening. CB performed data extraction and data cleaning. GF performed data verification. CB and GF drafted the manuscript. CB, SS, CD, GF, AA, and CP contributed to review and final approval of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Theory-guided approaches to implementation science have informed translation efforts and the acceptance of eHealth (digital health) interventions in clinical care. However, there is scarce evidence on which theories are best suited to addressing the inherent complexity of eHealth implementation.

Objective: The objectives of this systematic review are to identify theories that inform and explain eHealth implementation and to classify these theories using the typology by Sovacool and Hess for theories of sociotechnical change.

Methods: An electronic search was conducted in the PsycINFO, MEDLINE, Embase, CINAHL, Scopus, Sociological Source Ultimate, Web of Science, ABI/INFORM, EBSCO, and ProQuest databases in June 2019. Studies were included if they were published between 2009 and June 2019; were written in English; reported on empirical research, regardless of study or publication type; reported on one or more theories in the context of eHealth implementation; and were published in a peer-reviewed journal. A total of 2 reviewers independently assessed the titles, abstracts, and full texts. Theories identified were classified using a typology for theories of sociotechnical change, which was considered a useful tool for ordering and analyzing the diverse theoretical approaches as a basis for future theory building.

Results: Of the 13,101 potentially relevant titles, 119 studies were included. The review identified 36 theories used to explain implementation approaches in eHealth. The most commonly used approaches were the Technology Acceptance Model (TAM) (n=33) and the Unified Theory of Acceptance and Use of Technology (UTAUT) (n=32). These theories were primarily concerned with individual and interpersonal elements of eHealth acceptance. Less common were theories that reflect the various disorderly social processes and structural dimensions of implementation, such as the normalization process theory (n=17) and the structuration theory (n=6).

Conclusions: Theories currently informing the implementation of eHealth interventions predominantly focus on predicting or explaining end-user acceptance. Theoretical perspectives that capture the dense and intricate relationships and structures required to enact sustainable change are less well represented in the eHealth literature. Given the growing acknowledgment of the inherent complexity of eHealth implementation, future research should develop and test models that recognize and reflect the multidimensional, dynamic, and relational nature of this process.

Introduction

In recent years, technological innovation in health care has developed exponentially, and eHealth is now widely viewed as a significant potential contributor to improved quality of care [1,2]. However, despite much policy-level and scholarly discussions of triggering a revolution in health service delivery, problems of implementation and uptake of eHealth among both patients and service providers persist [1,3,4].

Poor uptake of eHealth (a term with contested definitions [5] but, broadly speaking, "health services and information delivered or enhanced through the internet and related technologies" [6]) is often explained in terms of barriers and facilitators [1]. In a recent study, Schreiweis et al [7] identified 77 barriers and 292 facilitators in implementing eHealth services. Similarly, a systematic review by Granja et al [8] identified 27 factors that determine the success or failure of eHealth interventions. Although studies about barriers and facilitators are important, they tend to fall short of capturing the complexity of the implementation process and the multiple *interrelated* factors that determine the translation and uptake of eHealth [1,9].

Evidence suggests that theory-informed approaches to implementation science can enhance the translation and acceptance of eHealth into clinical care [1,10-18]. Theories offer explanatory frameworks and formal heuristic devices that have the potential to move beyond the basic listing of individual facilitators and barriers to implementation, to capture *the dynamic interaction between them* [1]. As Damschroder [19] notes, theory "enables knowledge to emerge out of seeming chaos," facilitating exploration of complex relationships and interdependencies between variables that unfold in diverse and changing contexts [20]. This is of paramount importance in eHealth settings [1,18], which are characterized by a complicated interplay between patients, clinicians, the health care system, and the eHealth technology.

Many theories and models have been articulated to inform and explain eHealth implementation [15]. Despite this abundance, findings from several reviews show that only a small number of select theories have been used repeatedly across multiple publications and by several authors [21-24]. For example, a recent review by Harst et al [23] of 24 studies of end-user acceptance of telemedicine found that 2 theories accounted for 20 instances of theory use: the technology acceptance model (TAM) and the unified theory of acceptance and use of technology (UTAUT). Similarly, a review on the use of theory in eHealth weight management interventions by Willmott [24] identified 18 studies referencing a theory, of which 16 mentioned either the social cognitive theory or the transtheoretical model.

Theories most commonly used in the literature tend to emphasize individual factors, such as motivation, attitudes, and behavior, rather than the broader social and environmental factors impacting implementation [21,22,25]. This is despite evidence highlighting the multilevel nature of technology implementation in health care and the importance of targeting variables at different levels [1,26]. As Glanz and Bishop [22] noted, social and environmental factors may constrain individuals' behavior even when they are highly motivated. Therefore, the authors recommend complementing individually oriented theories with theories of social, policy, or organizational change [22].

One hindrance to this is that the current eHealth implementation literature is fragmented across multiple specialty areas and disciplines, making it difficult to locate the range of theories available [27]. To improve the selection and application of theory, it is necessary to identify an array of theories, across diverse disciplines, that have the potential to inform eHealth implementation. A further issue is that many theories contain overlapping constructs but use different terms to describe them [26]. Synthesizing theories according to their similarities would facilitate their selection and application at different levels [27].

To address these issues, we conducted a systematic review and classification of eHealth implementation theories. The review aims to address the following question: "What theories exist across disciplines that have been used to inform or explain eHealth implementation?" Theories identified by our review were classified using the typology by Sovacool and Hess [28] for theories of sociotechnical change. This typology provides an accessible and useful framework for organizing and selecting diverse theoretical options that target variables at different levels. Its use also allows the identification of areas where further theoretical development is required.

Methods

Overview

This systematic review was conducted by members of the review team in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [29]. A PRISMA checklist is available in Multimedia Appendix 1 [29]. The authors adopted a flexible approach by continuing to apply the core principles of systematic review methodology but tailoring the PRISMA guidelines to the needs of this review [30]. As such, formal quality assessment was not conducted for this review, as the perceived validity or trustworthiness of the included studies did not address the overall research question, which sought to identify the existence of theories across a broad and varied body of literature.

Search Strategy

Electronic searches of PsycINFO, MEDLINE, Embase, CINAHL, Scopus, Sociological Source Ultimate, Web of Science, ABI/INOFORM, EBSCO, and ProQuest Databases were conducted by the review team in June 2019 to identify studies that applied one or more theoretical frameworks to inform eHealth implementation. For this review, implementation was defined as "the scientific study of methods to promote the systematic uptake of research findings and other EBPs (evidence-based practices) into routine practice, and, hence, to improve the quality and effectiveness of health services." [31]. These databases were chosen because they were deemed to be likely to catalog studies and disciplines relevant to the eHealth context and the specific research question. The search was limited to studies published in the last 10 years (from 2009 to June 2019) and yielded 21,704 abstracts for initial consideration. A full list of key search terms used can be found in Multimedia

XSL•FO
RenderX

Appendix 2. All records were converted into an EndNote library and reduced to 13,101 following deduplication. Papers were then title-checked for relevance to the topic and research questions and aims before further screening by 2 independent reviewers (MH and HW) in accordance with the detailed inclusion and exclusion criteria outlined below.

Eligibility Criteria

Individual studies were included in the review if they were (1) published in the last 10 years (from 2009 to June 2019), (2) published in English, (3) outputs of empirical research or theoretical papers reporting on one or more theories in the context of eHealth implementation (this included all study types and populations), or (4) published in a peer-reviewed journal. Studies were excluded if they were (1) published before 2009, (2) not written in English, (3) studies that did not report on one or more theories applied in the context of eHealth implementation, (4) gray literature not published in a peer-reviewed journal, (5) dissertations, theses, conference proceedings, or abstracts, or (6) any form of literature review. The full eligibility criteria for this review are provided in Textbox 1.

Textbox 1. Eligibility criteria for the review.

Inclusion criteria

- Publication date from 2009 (inclusive) to June 2019
- Australian and international literature in English language
- Papers reporting on one or more theories in the context of eHealth implementation (any study type and population)
- Empirical studies (both quantitative and qualitative)
- Position, discussion, or theoretical papers
- Peer-reviewed articles

Exclusion criteria

- Publication before 2009
- Literature in non-English language
- Papers not reporting on one or more theories in the context of eHealth implementation
- Gray literature or not published in a peer-reviewed journal
- Dissertations or theses or conference proceedings or abstracts
- Literature reviews (narrative, scoping, and systematic)

Identification and Selection of Studies

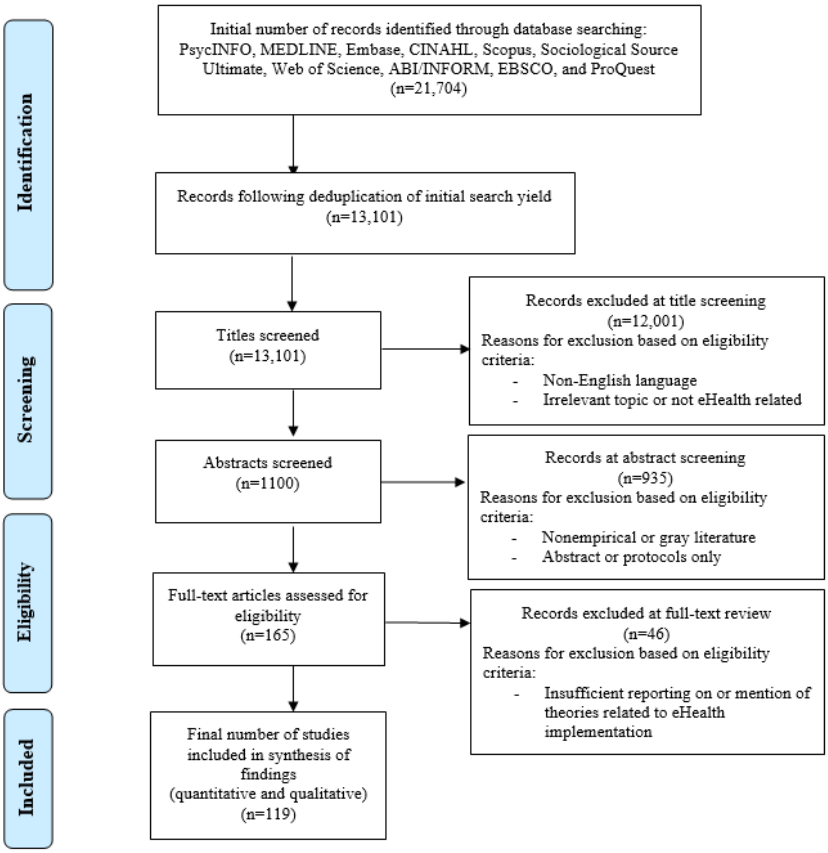
A total of 2 reviewers (MH and HW) independently applied the predefined inclusion and exclusion criteria to screen for relevant studies from those obtained through database searching. To ensure accuracy, record titles and abstracts were screened manually in EndNote, and documents that did not meet the selection criteria outlined above were excluded by the reviewers. Following 2 rigorous rounds of title and abstract screening, full texts of all potentially eligible studies were examined and further screened by the 2 independent reviewers (MH and HW) using the Covidence web-based software (Veritas Health Innovation Ltd), an effective tool for assisting research teams when performing systematic reviews or meta-analyses [32]. Articles that failed to meet the selection criteria were excluded and then cross-checked to ensure transparency and accuracy surrounding the reasons given for exclusion. Any conflicts in decision making during the screening phase were resolved via discussion between reviewers or, if needed, with the research coordinator (FKL) until consensus was reached.

Data Extraction and Presentation

As the standardized extraction tool in Covidence did not meet the specific needs of this review, a modified extraction form was developed and piloted by the 2 reviewers (MH and HW) with 10 included studies tabulated and refined accordingly. The modified extraction form was tailored to include characteristics relevant to the research question. The characteristics extracted by the reviewers included (1) name of theory, (2) description, (3) instances of theory use, (4) examples of theory application, and (5) theory type. Instances of theory use refer to the number of occurrences in which a theory was used. As several studies used more than one theory, the total number of theory instances exceeded the number of papers included in the review. Examples of theory application were drawn from the literature to specify how each theory informed eHealth implementation. The reviewers then determined each theory type by drawing on the typology by Sovacool and Hess [28] for theories of sociotechnical change. This typology categorizes theories according to where they tend to *center* their analysis. The term *center* is intended to convey that a theory may involve elements of multiple types but that it approximates one ideal type above all. This typology was considered a useful tool for ordering and analyzing the diverse theoretical approaches identified, as a basis for future theory building [33].

The typology includes 5 categories: agency, structure, relations, meaning, and norms. *Agency-centered* theories relate to people's individual actions, beliefs, and attitudes, and assume that these can be explained without deeper consideration of broader social and systemic elements [28,34,35]. In contrast, *structural* theories propose that people are influenced largely by external forces

XSL•FO
RenderX



beyond their control, such as their organizational, political, or macrosocial environments [28,35]. *Relational* theories attempt to interpret the interactional processes that influence the circulation of knowledge throughout different social networks. They view technology and society as coproduced and coconstructed, with no single dimension creating change by itself [28,36]. *Meaning-centered* theories focus on language, ideas, symbolism, narratives, rhetorical visions, and other cognitive dimensions that both orient action and are changed by it. *Normative* theories offer criteria by which to assess the positive or negative impact of technology on society or on a specific group. A sixth category, *combined* theories, was added to these 5 categories. This included meta-theories that explored a combination of individual, structural, or relational frameworks. All authors (MH, JW, JC, HW, CT, and FKL) reviewed and agreed upon the classification of theories using this typology.

Results

Search Results

The electronic search of key databases resulted in 21,704 potentially eligible articles (Figure 1). This number was reduced to 13,101, following deduplication. Of these, 12,001 papers were excluded based on title screening and application of the eligibility criteria previously outlined. Key reasons for exclusion of papers at title screening included eliminating those that were in non-English language or those that reported on an irrelevant topic to the research question, for example, non-eHealth or theory-related papers. The abstracts of the remaining 1100 papers were then independently screened by reapplying the inclusion and exclusion criteria, and a further 935 papers were excluded. Key reasons for exclusion at abstract screening included nonempirical or gray literature and papers that reported abstracts or protocols only. Following a full-text review of the remaining 165 articles, an additional 46 articles were excluded because of insufficient reporting on or mention of theories related to eHealth implementation. In total, 119 articles met the full, predefined eligibility criteria and were included for data extraction and synthesis of findings. The PRISMA flowchart in Figure 1 details the process of eligibility and study selection.

Figure 1. Flowchart of studies included and excluded from the systematic review.

Theory Summary and Classification

The summary (including theory name, description, instances of theory use, and examples of application to implementation) and classification of all theories used to inform and explain eHealth implementation is provided in Table 1. In total, 36 distinct theories were identified. Classification of these theories using the typology by Sovacool and Hess [28] showed that the theories used in the literature were predominantly agency centered (19/36, 53%), followed by relational (7/36, 20%), structural (6/36, 16%), meaning (3/36, 8%), and combined theory types (1/36, 4%). No normative theories were identified.

XSL•FO
RenderX

Table 1. Summary and classification of eHealth implementation theories.

Theory	Description	Instances of theory use	Examples of theory application	Type
TAM[a]	Proposes that technology acceptance and use are affected by an individual's perceived ease of use, perceived usefulness, and subjective norms	33	• "This study tested an extended version of TAM and used this to explain the attitude of nursing staff towards using electronic patient record. The addition of external variables was shown to increase the predictive value of the model." (de Veer and Francke, 2010) [37] • "Our research introduces new variables to the TAM model in order to suit this particular study. These new variables include staff information technology experience, technical infrastructures, security concerns, and information sharing. These additional independent factors enhance the TAM's predictive power." (Zayyad and Toycan, 2018) [38]	Agency centered
UTAUT[b]	Proposes that behavioral intention to use eHealth interventions is affected by individual effort expectancy, performance expectancy, social influence, facilitating conditions, and habit	32	• "We extended the UTAUT model to investigate further context-related predictors of acceptance and postulated that eHealth literacy, which means the ability to find, evaluate, and utilize internet-based health information to health problems, and knowledge of and experience with eHealth interventions were positively related with eHealth acceptance, based on previous evidence." (Henneman et al, 2017) [39] • "To assess prospects for broad adoption of Electronic Integrated Antenatal Care, we trained midwives in the use of the system and then used the UTAUT survey to assess their intention to adopt the tool." (Markam et al, 2018) [40]	Agency centered
NPT[c]	Explains the social processes (eg, coherence, participation, collective action, and reflexive monitoring) through which eHealth interventions are operationalized	17	• "Deductive thematic and content analyses were undertaken by two independent coders [on data derived from semistructured interviews]. The NPT coding framework was used...A coding protocol was developed, trialled and refined using an additional transcript from each network." (Bagot et al, 2017) [41] • "In this paper we present a simplified set of 16 statements that express key elements of NPT, but which can be applied without a detailed knowledge of the underlying theory...we sought to better understand the ways that potential users of NPT could apply it to real world problems. Between 2006 and 2009 we engaged with multiple potential users. Engaging potential users included presentations to researchers and practitioners that linked NPT's core constructs to practical research and development problems" (May et al, 2011) [42]	Relational
DOI[d] theory	Explains how an eHealth innovation gains momentum and diffuses through a specific population. This process is affected by the innovation itself, time, channels of communication, and an individual's social system	16	• "The semistructured interview built upon Rogers' Diffusion Theory and examined the five general stages of diffusion (knowledge, persuasion, decision, implementation, and confirmation) that occurred during the clinic development. We asked respondents to describe the local mental health services before telehealth was introduced; the process by which the telehealth was introduced to—and adopted by—their organization; and the acceptance of telehealth by the community." (Brooks et al, 2012) [43] • "We used Rogers' DOI theory framework for how new innovations are adopted by organizations and Greenhalgh's subsequent work adapting the framework for health care settings. We used these frameworks to deductively explore factors that might help intervention better diffuse in each clinic setting...The analysis mapped themes identified in the qualitative data to the DOI framework described above." (Lin et al, 2016) [44]	Agency centered

XSL•FO
RenderX

Theory	Description	Instances of theory use	Examples of theory application	Type
Structuration theory	Models the relationship between agency and structure. In eHealth implementation, interventions are configured and coconstructed over time and can be adapted or revised to better accommodate different settings and needs	6	• "This study represents an empirical example of how AST[e] coupled with literature on organizational change offer a better understanding of technology implementation practices. Our findings complement past AST research, claiming that implementation success and users' change attitudes are two important outcomes associated with appropriation." (Barrett and Stephens, 2017) [45]	Relational
CFIR[f]	A meta-theoretical framework that provides an overarching typology of constructs relating to implementation, including intervention characteristics, outer setting, inner setting, and individual characteristics	6	• "The main results presented subsequently address identified barriers and facilitators influencing the implementation of internet-based patient-provider communication in 5 hospital units using CFIR to identify determinants distinguishing between high and low implementation success." (Varsi et al, 2015) [46] • "Semistructured interviews were developed based on the constructs of the CFIR which provides a pragmatic organization of theory-informed constructs known to impact implementation success across five domains...Interview transcripts were analyzed by two independent investigators using the Framework Method. This involved a largely deductive thematic analysis using a codebook based on the constructs of the CFIR." (Ware et al, 2018) [47]	Combined
ANT[g]	Posits that objects have agency and that a combination of network components (both human and nonhuman) helps create and/or influence social effects (such as implementation)	4	• "This is a qualitative study, in which ANT was used as a theoretical reference. The ANT proposes to follow and map actant' movements and the influences traversing their reciprocal connections...Our methodological reference was the 'cartography of the controversies,' considered a set of techniques to explore and visualize controversies and discussions, observing and describing social debate, especially—but not exclusively—around technical and scientific problems." (Cavalcante et al, 2019) [48]	Relational
TPB[h]	Extends the theory of reasoned action to incorporate actors' perceived control over the outcomes of their behaviors	3	• "This study integrated the Technology Acceptance Model and TPB frameworks to evaluate patient acceptance of e-health services. The Technology Acceptance Model and TPB frameworks were developed based on the theory of reasoned action." (Albar and Hoque, 2019) [49]	Agency centered
Institutional theory	Posits that an organization's environment is capable of strongly influencing the development, acceptance, and use of eHealth interventions	3	• "Due to the unique and highly institutionalized healthcare environment in the US, we therefore focus on EHR[i] adoption as an isomorphic institutional change that leads to the decision to acquire and make available electronic records for use in ambulatory services...we believe that institutional theory is a useful framework for analyzing EHR adoption." (Sherer et al, 2016 [50])	Structural
SCT[j]	Posits that the acquisition of new knowledge and perceived self-efficacy in using interventions is influenced by observing others in the context of social interactions and experiences (including the media)	3	• "The research framework encompasses three categories. The proposed bidirectional interaction between the belief types associated to these categories is based on SCT's assumption that individual behaviour is shaped by outcome expectations (behavioural factors), self-perception (personal factors) and the social and physical environment (environmental factors)." (Weeger and Gewald, 2015) [51]	Agency centered
Theory of reasoned action	A social-psychological attitude-behavior model that examines normative social influences on behavioral intention	2		Agency centered

XSL•FO
RenderX

Theory	Description	Instances of theory use	Examples of theory application	Type
			• "The theoretical background of this study focuses on the Theory of Reasoned Action...to analyze the influence of smartphones at tertiary hospitals. This study also applies the Technology Acceptance Model...Based on the accumulated knowledge from Kim and Chang, and Chang, the research model was derived..." (Moon and Chang, 2014) [52]	
IT[k]	Posits that the identity associated with a particular role is likely to drive individual decision making about eHealth interventions	2	• "We briefly reviewed the existing state of research on health IT adoption in information science and the medical informatics literatures. This is followed by a discussion of identity theories and their application to unique aspects of the healthcare context." (Mishra et al, 2012) [53]	Agency centered
PMT[l]	Explains how the perceived threat of a new eHealth intervention affects individual adoption and implementation attitudes and behaviors	2	• "To study the influence of PMT components on users' mobile health adopt intentions, we developed an integrated model based on the PMT theory and the moderating role of gender, age, and education." (Guo et al, 2015) [54]	Agency centered
Health belief model	Suggests that a personal threat, together with belief in the effectiveness of the proposed behavior, predicts the likelihood of engaging in that behavior	2	• "We applied a new adoption model that combines 3 different theories, namely, extended unified theory of acceptance and use of technology, health belief model, and the diffusion of innovation; all the 3 theories provided relevant contributions for the understanding of EHR portals. To test the research model, we used the partial least squares causal modelling approach." (Tavares and Oliveira, 2018) [55]	Agency centered
BMHSU[m]	A model for predicting and explaining factors that lead to the use of eHealth services. These can include predisposing, enabling, and needs factors	2	• "We used a multiphase, longitudinal study design. The four objectives were addressed in the four proposed stages of use. Applying Venkatesh's UTAUT and Anderson's BMHSU, we conceptualized that caregivers will go through the stages of consideration, initiation, utilization, and outcomes." (Chiu and Eysenbach, 2010) [56]	Agency centered
Sociotechnical systems theory	Proposes an interdependent relationship between the social and technical aspects of an organization (eg, human-computer interface). It suggests that these must be viewed congruently to optimize the implementation of new eHealth interventions	1	• "Drawing insight from the theoretical lens of Sociotechnical theory, the seven clusters of factors required for health-risk assessments implementation could be read as belonging to three overarching aspects: Technical (cluster 1, 2 and 3), Social-Patient (cluster 4 and 5), and Social-Provider (cluster 6 and 7)." (Ahmad et al, 2012) [57]	Relational
ECT[n]	Posits that expectations, coupled with perceived performance of an eHealth intervention, lead to post-purchase satisfaction	1	• "The conceptual framework of this research was cited from ECT. This theory was adopted extensively in the field of Marketing and Management Information System since the 1980s, though rarely applied to the healthcare field. We also used all the constructs derived from Oliver's ECT model in our research to present the original concept of this model." (Chou et al, 2012) [58]	Meaning centered
PCT[o]	Posits that past experiences of using eHealth technologies and individual assumptions in relation to the design, impact, ownership, and value of these technologies can strongly influence acceptance or reluctance toward an eHealth intervention	1	• "Arguably, PCT is a very useful framework for making more visible what lies below the surface of human problems in organisations...Consequently, this paper employs PCT as a theoretical lens to understand clinicians' reluctance to accept and use new IT systems in the NHS." (Fernando et al, 2012) [59]	Meaning centered
Resource dependence theory		1		Structural

XSL•FO
RenderX

Theory	Description	Instances of theory use	Examples of theory application	Type
	Asserts that acquiring and maintaining resources (eg, eHealth interventions) is key to organizational survival. Scarce resource availability or uncertainty about the environment motivates managers to act in ways to secure more resources and reduce their uncertainty		• "This study used the resource dependence theory to understand how the environment influences hospitals' investments in health information technology." (Tarver and Menachemi, 2018) [60]	
Theory of middle managers' role	Hypothesizes that middle managers promote implementation by fulfilling 4 roles: diffusing information, synthesizing information, mediating between strategy and day-to-day activities, and selling intervention implementation	1	• "Although the theory has received some empirical support, the extent to which it aligns with middle managers' experience in practice is unclear. The objectives of this study were to (1) assess alignment between middle managers' experience and the theory's hypothesized roles and activities and (2) elaborate on the theory with examples from middle managers' experience." (Birken et al, 2016) [61]	Structural
PAD[p] emotional state theory	Asserts that all emotional responses to physical and social environmental stimuli can be captured in 3 dimensions: pleasure (enjoyment), arousal (alertness), and dominance (control), which subsequently influence human behavior	1	• "It is the first attempt at integrating UTAUT and PAD theories to account for cognitive and affective factors in explaining technology adoption. The theory enhances the theoretical base of technical communication research by enabling theory-driven design and development of wireless health communication systems." (Alaiad and Zhou, 2017) [62]	Agency centered
Information behavior theory	Posits that information systems serve as a bridge between users and information resources. They consist of mediators (people who help users seek information and share the same social norms) and technologies (techniques and tools) that help users with the search	1	• "In this study, a critical inquiry approach was used to theorize usage behaviour through an analytic integration of three theoretical models. In our model, the driving question was as follows: What usage behaviour can be explained by Anderson's BMHSU, Venkatesh's UTAUT, and Wilson's and Chatman's information behaviour theories? We answered this question by constructing a concept map that integrates the theoretical and empirical findings. The concept map and five subthemes that influence usage and non-usage behaviour will be reported." (Chiu and Eysenbach, 2011) [63]	Agency centered
JDRM[q]	Suggests that strain is a response to imbalance between demands on individuals and the resources they have to deal with these demands	1	• "To answer our research questions, we took guidance from 2 theoretical models to ultimately derive the model...Based on the JDRM and UTAUT, we hypothesized that each of the 4 factors will positively impact provider satisfaction, and inversely relate to intention to quit." (Hysong et al, 2014) [64]	Agency centered
Cultural dimension theory	Shows the effects of a society's culture on the values of its members and how these values relate to implementation behaviors	1	• "To explore the influence of culture on e-health adoption, both TAM and Hofstede's cultural dimension model are incorporated in this study." (Hoque and Bao, 2015) [65] • "The second section [of the survey questionnaire] consists of subject perception of each variable in the model. The measurement items were adopted from prior research and modified based on the e-health context in Bangladesh." (Hoque and Bao, 2015) [65]	Meaning centered
Affect theory	Claims that there are 3 primary types of affect or emotion, including positive (joy, interest, and excitement), neutral (surprise), and negative (anger, terror, and disgust). These affective states may be advantageous or disadvantageous in users' acceptance of new information systems	1	• "Grounded in current theories of affect this study examines the role positive and negative moods play on the acceptance of a specialized telemedicine system for microbiology consultation and diagnostics, referred to as telepathology." (Djamasbi et al, 2009) [66] • "Using cognitive theories of affect, we propose an extension to TAM by arguing that users' affect plays a significant role in influencing their attitude towards a new healthcare information system." (Djamasbi et al, 2009) [67]	Agency centered

Theory	Description	Instances of theory use	Examples of theory application	Type
Activity theory	Focuses on understanding the mental capabilities of individuals by analyzing the cultural and technical aspects of human actions	1	• "We propose an integrated research model for exploring and understanding critical factors influencing physicians' intention to use computerized Clinical Practice Guidelines by incorporating activity theory (three dimensions of factors) with TAM concepts (intention as dependent variable)." (Hsiao and Chen, 2016) [68]	Agency centered
Social capital theory	Contends that social relationships are resources that can lead to the development and accumulation of human capital	1	• "This study integrated social capital theory, social cognitive theory, and TAM to develop a comprehensive behavioral model for analyzing the relationships among social capital factors (social capital theory), technological factors (TAM), and system self-efficacy (social cognitive theory) in telehealth." (Tsai, 2014) [69]	Agency centered
Contingency theory	Claims that there is no best way to organize or lead an organization or to make decisions. Instead, the optimal course of action is dependent upon the internal and external situation	1	• "In this study, we use contingency theory as a base to hypothesize how contingent factors, above and beyond traditionally considered 'dominant' factors often associated with supply-side adoption, may affect the adoption of patient portals by ambulatory-care clinics." (Baird et al, 2012) [70]	Structural
Social information processing theory	Predicts that technology-related attitudes and behaviors are not individually laden but socially constructed	1	• "When relating social information processing theory and the social influence model to organizational change situations, we see that both theories provide a framework for understanding previous scholars' arguments advocating the noteworthy role informal, coworker communication plays in effective organizational and healthcare change." (Barrett and Stephens, 2017) [71]	Relational
Consequence of modernity	Suggests that use of technologies is influenced by trust and sense of security in the absence of complete information from face-to-face interactions	1	• "Our research uses concepts from Giddens's structuration theory and consequence of modernity to understand clinical users view on telehealth service when first introduced in their work setting." (Sharma et al, 2010) [70]	Agency centered
Social worlds theory	Proposes that social worlds are self-organizing units in which people share resources, information, and assumptions about what is important and ideas about what types of activities are desirable	1	• "Using the notions of social worlds, trajectories, and boundary objects enables us to show how mobile information technology innovation in Danish home care can facilitate negotiation and collaboration across different social worlds in one setting while becoming a source of tension and conflicts in others." (Nielsen and Mengiste, 2014) [72]	Relational
Boundary objects	Boundary objects serve as interfaces between multiple social worlds and facilitate the interaction; communication; and flow of information, concepts, skills, and materials between diverse social actors	1	• "This article contributes to this emerging research domain by using notions of social worlds, trajectories, and boundary objects and applying these constructs in an empirical investigation in Danish elderly home care. Our discussion therefore focuses on two key issues: to what extent different interests among multiple social worlds have been negotiated in the trajectory of adopting and diffusing mobile IT and to what extent boundary objects have aligned the interests of stakeholders from different social worlds." (Nielsen and Mengiste, 2014) [72]	Relational
Adult learning theory	Posits that one's learning context influences learning outcomes. Thus, knowledge evolves not only through formal learning activities, such as training programs, but also through the context and culture in which they are delivered	1	• "We drew on concepts from social cognitive theory and situated cognition theory (from adult learning theory) to frame our study of training practices within the ambulatory EHR system implementation process. These theories helped us develop five propositions related to the importance of training in promoting meaningful use of EHR systems." (McAlearney et al, 2012) [73]	Agency centered
Social contagion theory		1		Agency centered

XSL•FO
RenderX

Theory	Description	Instances of theory use	Examples of theory application	Type
	A theory of collective behavior that explains how ideas and opinions spread in a social network. It holds that actors' behaviors are a function of their exposure to others' behaviors		• "Based on extensive literature review and drawing upon two theories—social contagion theory and task technology fit theory—I argue that the adoption of EHR system is contagious among health care providers; however, the contagion effect depends on the fit between the characteristics of EHR system and the characteristics of health care providers." (Gan, 2015) [74]	
TTF[r] theory	Explains how technology interacts with the tasks or activities of an organization and impacts their performance	1	• "The findings also suggest that the two factors (TTF and social contagion) are not independent and the interaction of them plays a more important role that either of them alone." (Gan, 2015) [74]	Structural
Technology organization environment theory	Predicts that technology adoption is influenced by factors relating to technological, organizational, and environmental dimensions	1	• "To investigate the factors influencing the adoption of HIS[s] in the hospitals' work processes, this study proposed the initial theoretical framework based on the combined Technology Organization Environment, institutional theory, and Human Organization Technology fit model." (Ahmadi et al, 2017) [75]	Structural

In total, 53% (19/36) of theories were classified as *agency centered*. Individual theories that occurred most frequently in the literature were the TAM by Davis and Venkatesh [76] (33 instances), UTAUT by Venkatesh [77] (32 instances), and Diffusion of Innovations Theory by Rogers [78] (16 instances). These theories were found to be primarily concerned with the individual and interpersonal elements of eHealth implementation. Although they did, to some extent, appear to consider the influence of organizational and social factors on eHealth adoption, individual attitudes, behaviors, and motivations remained the core focus of theoretical analysis. Theories classified as individual examined the adoption of eHealth either before or soon after the implementation of an intervention. However, they did not emphasize any form of user involvement in the development of an intervention. These theories tended to depict adoption as a temporally discrete and relatively immediate event, rather than as one stage in a larger multistage process. They often focused on what people were going to do soon, a decision they are about to make, or a behavior they need to alter. The diffusion of innovations theory provides an exception, as this theory considers time to be an essential factor influencing adoption [79].

A total of 20% (7/36) of theories identified in the literature were classified as *relational*. Of these, the normalization process theory (NPT) by May et al [80] occurred most frequently in the literature (17 instances), followed by structuration theory (ST) [81] (6 instances) and actor-network theory (ANT) [82,83] (4 instances). Sociotechnical systems theory, social information processing theory, social worlds theory, and boundary object theory occurred only once each in the literature. Relational theories emphasize social relations and interactions at the human-technology interface. They highlighted the complex networks of social structure and meaning in which people are embedded, proposing that the translation of knowledge is

XSL•FO
RenderX

facilitated by processes of circulation both within and across different social worlds. Some relational theories, such as ANT and ST, emphasized the role of nonhuman actors, such as computer software or programs, in transforming and mediating social relationships. These theories tended to view technology and society as coconstructed or coproduced, with no single dimension dictating change by itself. Within these theories, coproduction and implementation were often described as continuous processes, in which eHealth interventions were adapted to better accommodate different end-user settings and needs.

A total of 16% (6/36) of theories were classified as *structural*. The most common structural theory was institutional theory (IT) [84] (3 instances). Resource dependence theory, theory of middle managers' role, contingency theory, task technology fit theory, and technology organization environment theory occurred only once each in the literature. These theories conceptualized *structure* as including institutional or organizational systems as well as political, cultural, and other macrosocial environments. They often assumed that people are constrained or influenced by external forces frequently beyond their comprehension or control. For example, IT posits that organizational structures and cultural norms drive eHealth implementation, despite strong political influence.

A total of 8% (3/36) of theories were classified as *meaning centered*: expectation confirmation theory, personal construct theory, and cultural dimension theory. Each of these theories occurred only once in the literature. These theories tended to focus on the cognitive dimensions (expectations, perceptions, and beliefs) that explain people's willingness to accept the use of new health technologies. Although some meaning-centered theories, such as cultural dimension theory, have considered the influence of cultural values on the adoption and use of eHealth, these theories nonetheless centered their analysis at the individual level and were often used in combination with agency-level theories.

The Consolidated Framework for Implementation Research (CFIR) [85] was the only theory to be classified as a *combined* theory type. This theory is a meta-theoretical framework that provides a comprehensive listing of individual, social, and organizational constructs thought to influence eHealth implementation. However, it does not consider how these factors might be interrelated or how changes occur.

Discussion

Principal Findings

Evidence from a range of disciplines suggests that theory-informed approaches to implementation science are integral to the translation and implementation of eHealth into clinical care [1,10-18]. Analysis of the 119 studies included in this review identified 36 distinct theories that inform or explain eHealth implementation. However, only a few selected theories (UTAUT and TAM) were dominant, which is consistent with the findings from previous reviews [21-24]. Although these theories have been empirically proven to explain or predict certain aspects of implementation, Willmott et al [24] and Davis et al [21] caution that overreliance on *common* or *favorite* theories without direct questioning of their underlying assumptions limits progress in the field.

The typology by Sovacool and Hess [28] facilitated a closer examination of the assumptions underlying eHealth implementation theories. The findings revealed that the majority of theories were agency centered, emphasizing individual factors rather than the broader social and environmental factors impacting implementation. Although these findings were consistent with previous reviews [21,22,24,86], the wider net cast for this review provided the needed validation that this trend can be observed across multiple specialty areas and disciplines [27]. This calls into question whether theories currently being used to inform and explain the eHealth implementation adequately address the multiple and complex factors that influence the implementation process, and highlights the need for more dynamic, multilevel models of eHealth implementation [21,23,87].

This review identified a number of theories classified as relational or structural, which, to varying degrees, capture the complexity and multilevel nature of eHealth implementation. The most commonly cited relational theories were NPT, ST, and ANT. These theories recognize the important role of actors, relationships, and networks in mobilizing knowledge and embedding interventions into everyday practice. For ANT, networks are made up of both human and nonhuman *actors*, and technologies are understood to have agency and the potential to transform human interactions [88,89]. From this perspective, it may be a particularly useful theory for examining the implementation of eHealth technologies and the impacts these technologies have on human behavior. A criticism of ANT is that it has a *flat* ontology and refuses to consider institutional sources of power and inequality. Here, NPT and ST offer a possible extension, as both theories recognize the inseparable intersection between individual agents and wider social and organizational structures and norms. Structural theories also consider the influence of external forces on individual behavior and decision making. For example, IT, the most commonly used structural theory in this review, posits that an organization's environment is capable of strongly influencing the development, acceptance, and use of eHealth interventions. This theory is considered particularly relevant for application in eHealth environments, which are highly institutionalized and subject to multiple regulatory forces, high levels of professionalism, and growing network externalities that can influence adoption decisions [50].

Of particular interest was the lacuna of normative theories identified in this review. Normative theories attempt to answer whether a technology is a net positive or negative for society and individuals [28]. To do so, they often rely on evaluative criteria determined by ethics, moral studies, political ecology, or social justice. Social justice theory and sustainable development are 2 common examples of normative theories. The absence of normative theories in eHealth implementation studies is emblematic of the broader tendency of implementation science to overlook the importance of contextual factors, such as economic, social, historical, and political forces, that perpetuate inequalities in the delivery of health care services

XSL•FO
RenderX

[90]. This omission is concerning in the context of eHealth, as digital technologies have been found to exacerbate inequalities associated with older age, lower level of educational attainment, and lower socioeconomic status [91]. Future research should not shy away from normative questions of equity, justice, and sustainability and should find ways to incorporate theoretical approaches that enable exactly that.

When incorporating or combining theories, Sovacool and Hess [28] highlight the need for careful consideration of the *epistemological baggage* of different approaches. Combining multiple theoretical approaches may offer a more complete understanding or explanation, yet such combinations may mask contrasting assumptions regarding key issues [92]. For instance, are people driven primarily by their individual attitudes and motivation or do pervasive organizational cultures and social systems impose norms and values that shape people's behavior, making individual characteristics relatively unimportant? These challenges may account for the tendency of theories to target variables at the same level. One exception was the CFIR framework, which was the sole theory that provided a *menu* of constructs at different levels for researchers to choose from. However, although CFIR recognizes the multilevel nature of eHealth implementation, it does not consider the relationship between constructs or how change takes place, leading Nilsen [92] to contend that it should not be considered a theory at all. Further research is needed to explore how diverse theoretical perspectives can be brought together in ways that capture the dynamic interaction between constructs [1], while avoiding disconnects and incompatibilities [28].

Limitations

This study has several limitations. First, papers not published in English were excluded, which may indicate a selection bias. The decision to keep the research question and inclusion criteria for this review broad resulted in a high yield of papers and, to some extent, reduced the specificity of search results. This decision was made to ensure the identification of the full spectrum of theories being used to inform and explain eHealth implementation. Restriction of inclusion criteria in previous systematic reviews [24] led to the omission of a number of key theories that provide a more comprehensive explanation of the various constituents of the implementation processes. A further limitation is that the protocol for this systematic review was not registered. However, every care was taken to ensure compliance with the core principles of the systematic review methodology. As Mallett [30] noted, systematic reviews do not constitute a homogenous approach, and researchers may adopt a more flexible approach that better suits their research purpose while continuing to comply with the principles for conducting a systematic review. Finally, the literature search for this review was conducted in June 2019. Given the rapid rate of publication in the field of eHealth, it is likely that recent relevant articles have not been included. As completing an updated search was not feasible for the research team, we suggest that future studies must continue to identify theories used to inform and explain the implementation of eHealth interventions.

Conclusions

This systematic review identified 36 theories that are being used to inform and explain eHealth implementation and classified these theories using the categories adapted from the typology by Sovacool and Hess [28] for theories of sociotechnical change. The results highlight the dominance of theories that focus mainly on individual readiness to accept health technologies rather than the various disorderly social processes or systemic dimensions of implementation. This calls into question whether theories currently being used to inform and explain eHealth implementation adequately address the multiple and multilevel factors that influence the implementation process. Nonetheless, this review identified a number of theories classified as relational, structural, or combined, which, to varying degrees, capture the complex interactions within a wider organization and policy system. Although less prominent in the literature, these theories may be particularly applicable to the implementation of eHealth in health settings and services.

Acknowledgments

This systematic review is part of the eCliPSE (Electronic Clinical Pathways to Service Excellence) project, which is funded by a National Health and Medical Research Council partnership project grant (APP117181) and Beyond Blue.

Abstract

One of the most at-risk groups during the COVID-19 crisis is older adults, especially those who live in congregate living settings and seniors' care facilities, are immune-compromised, and/or have other underlying illnesses. Measures undertaken to contain the spread of the virus are far-reaching, and older adults were among the first groups to experience restrictions on face-to-face contact. Although reducing viral transmission is critical, physical distancing is associated with negative psychosocial implications, such as increased rates of depression and anxiety. Promising evidence suggests that participatory digital co-design, defined as the combination of user-centered design and community engagement models, is associated with increased levels of engagement with mobile technologies among individuals with mental health conditions. The COVID-19 pandemic has highlighted shortcomings of existing technologies and challenges in their uptake and usage; however, strategies such as co-design may be leveraged to address these challenges both in the adaptation of existing technologies and the development of new technologies. By incorporating these strategies, it is hoped that we can offset some of the negative mental health implications for older adults in the context of physical distancing both during and beyond the current pandemic.

(J Med Internet Res 2021;23(5):e21864) doi:10.2196/21864

KEYWORDS

social isolation; mental health; COVID-19; technology; older adult; psychology; digital health

Older adults constitute one of the most at-risk groups during the ongoing COVID-19 crisis, especially those who live in congregate living settings and seniors' care facilities, are immune-compromised, and/or have other underlying illnesses [1]. Measures undertaken to contain the spread of the virus are far-reaching, and older adults were among the first groups to have experienced restrictions with regard to face-to-face contact. Although reducing viral transmission is critical, physical distancing is known to have significant negative psychosocial implications, such as increased rates of depression and anxiety, particularly for older adults [2].

Apart from the COVID-19 outbreak, older adults, in general, experience the highest rates of social isolation and loneliness, which are associated with a range of negative mental health outcomes [3]. Physical distancing measures may have negative impacts on older adults living in the community, especially for those who rely on formal or informal support and care from family and/or friends, those who utilize religious or community centers as social hubs, as well as those who live in supportive or assisted living centers (where gathering in common spaces used for meals and other activities must cease as a result of physical distancing measures). This double burden of age-related diminishing social spheres and the implementation of measures that require physical distancing and enforced isolation presents significant mental health risks for older people.

RenderX

In response to "stay at home" orders, sweeping transitions to web-based communication platforms have been adopted as a means of fostering and maintaining social connectedness; however, older adults use these technologies at disproportionately lower rates than younger individuals, both during and beyond the COVID-19 pandemic. This digital divide, which involves barriers to digital technologies [4], is a major inhibitive force in facilitating digital social connectedness among older adults while following the stay-at-home orders. The first level of the digital divide includes barriers to uptake and access to technology (eg, financial limitations), whereas the second level concerns barriers to the usage of these technologies (eg, functional impairments in manual dexterity) [5]. Most videoconferencing or communication platforms have not been developed with the older adult in mind, thereby leading to low rates of uptake before the COVID-19 pandemic and difficulty in accessing and using these platforms during the pandemic.

Consequently, we find ourselves in a catch-22 situation where negative mental health implications of social isolation and loneliness among older adults could potentially be mitigated by the use of digital solutions, but only if the person already has the technological knowledge, desire, and access to use these technologies. Furthermore, without the capacity to interact face-to-face with older adults during the COVID-19 outbreak, it can be challenging, albeit possible, to provide guidance on how to use technologies, an issue further compounded by physiological challenges (eg, reduced visual acuity, manual dexterity, and cognitive impairment). Despite its huge potential, the impact of implementing technologies to reduce social isolation and loneliness has been limited in terms of real-world products and services [6]. Unfortunately, it is often the individuals who would benefit most from digital solutions who are the most vulnerable and least likely to access these technologies. Moving forward, there is a need for a major shift in research culture away from a researcher- and technology-driven agenda to one that focuses on real-world problems and solutions [6,7]. The digital divide spans a considerable breadth of issues within the context of the pandemic; therefore, we will focus on the challenge of technology development that is not inclusive of older adults' perspectives.

In the short term, we must aim to foster the uptake of existing technologies through trainings designed for older adults and address normal age-related changes that impede technology use (ie, changes to memory, eyesight, or mobility), with longer-term objectives to incorporate older adults throughout the software development lifecycle of new technologies. Within the context of the current challenges presented by physical distancing, repurposing or reframing existing technologies may be effective in mitigating social isolation and feelings of loneliness among the older population. For example, the telephone may not be the leading edge of innovation, but a landline phone call is a demonstrated and effective means of communication and human connection [8]. With respect to new technologies—that may be critical in addressing future pandemics—incorporating digital peer support is one of the best ways to foster technology engagement [9]. Through these live or automated peer support services that can be delivered through various digital platforms, such as peer-to-peer networks on social media or peer-delivered interventions supported with smartphone apps, older adults can develop the tools needed to actively engage with technology. The similarity, bond, and trust within this relationship supports reciprocal accountability and engagement, which may promote engagement as older adults model and teach others how to use technology. For example, older adult peer support specialists with lived experience of aging with a mental health condition (and commonly a physical health condition), who are trained and accredited by their respective state to provide Medicaid and/or Medicare reimbursable telehealth services, can use their personal experiences to help address challenges of normal aging and technology use (eg, changes to eyesight, fine motor skills, and hearing). Through such support from individuals with lived experiences of aging, it is hoped that greater technology use and uptake can be fostered.

Promising evidence suggests that participatory digital co-design, defined as the combination of user-centered design and community engagement models, shows high levels of engagement with mobile technologies among individuals with mental health conditions [9]. The COVID-19 pandemic has certainly highlighted the shortcomings of existing technologies and challenges in their uptake and usage [10]; however, strategies such as co-design may be leveraged to address these challenges both in the adaptation of existing technologies and the development of new technologies.

In populations where individuals are not living with mental illness, participatory digital co-design has led to promising developments with the potential for more relevant research with wider impact, better internal validity, and rapid translation of research into practice—and greater engagement [9]; therefore, it has the potential to reduce the digital divide [11]. By incorporating the aforementioned strategies, it is hoped that we can offset some of the negative mental health implications for older adults in the context of physical distancing, both during and beyond the COVID-19 pandemic.

Abstract

Digital technology has been widely used in health care systems and disease management, as well as in controlling the spread of COVID-19. As one of the most successful countries in combating the COVID-19 pandemic, Taiwan has successfully used digital technology to strengthen its efforts in controlling the COVID-19 pandemic. Taiwan has a well-established National Health Insurance System (NHIS), which provides a great opportunity to develop a nationwide data linkage model in an agile manner. Here we provide an overview of the application of data linkage models for strategies in combating COVID-19 in Taiwan, including NHIS centralized data linkage systems and "from border to community" information-driven data linkage systems during the COVID-19 pandemic. Furthermore, we discuss the dual role of digital technologies in being an "enabler" and a "driver" in early disease prevention. Lastly, Taiwan's experience in applying digital technology to enhance the control of COVID-19 potentially highlights lessons learned and opportunities for other countries to handle the COVID-19 situation better.

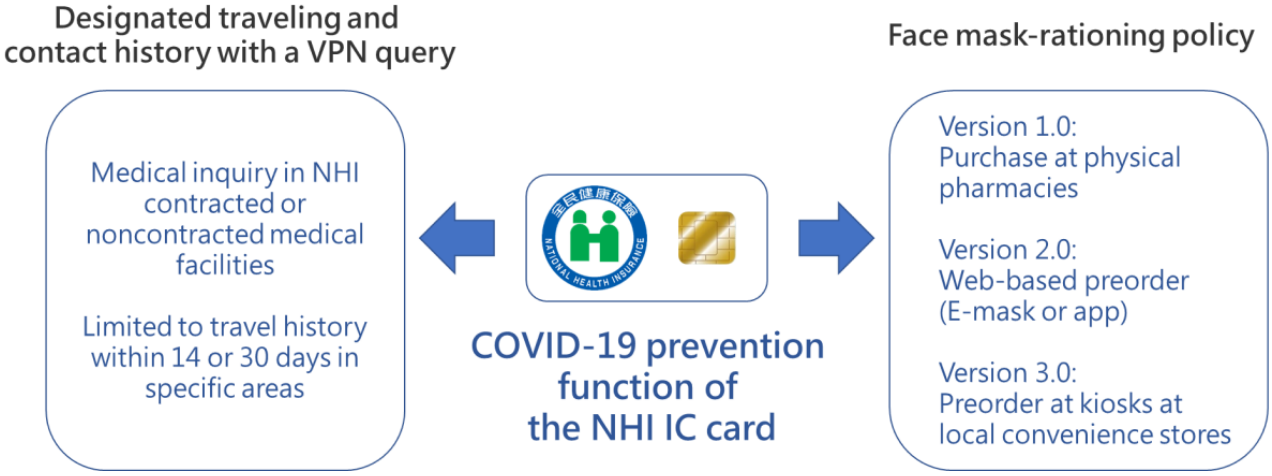
Introduction

Worldwide, there have been 60 million confirmed cases of COVID-19 and 1.4 million confirmed deaths as of November 30, 2020, and the numbers are still rising to date. When China reported its first COVID-19 outbreak, an early study conducted by Johns Hopkins University in January had forecasted the number of imported cases arriving at each airport inside and outside mainland China, and reported that Taiwan would be the second most affected country by COVID-19 owing to the close economic and transportation links with mainland China [1]. However, Taiwan has defied those expectations. Until November 30, 2020, Taiwan reported only 679 COVID-19 cases, 7 confirmed deaths, and only a 1.03% case fatality rate. Taiwan has been performing well in combating COVID-19 thus far; this may be attributed to the hard lessons learned from the severe acute respiratory syndrome (SARS) outbreak in 2003. The SARS experience had prepared the government and citizens of Taiwan

XSL•FO
RenderX

to respond to the COVID-19 pandemic more promptly and cautiously. Countries with a prior experience with SARS prevention (with over 100 confirmed cases and a >10% case fatality rate) also performed well in combating the current COVID-19 outbreak [2,3].



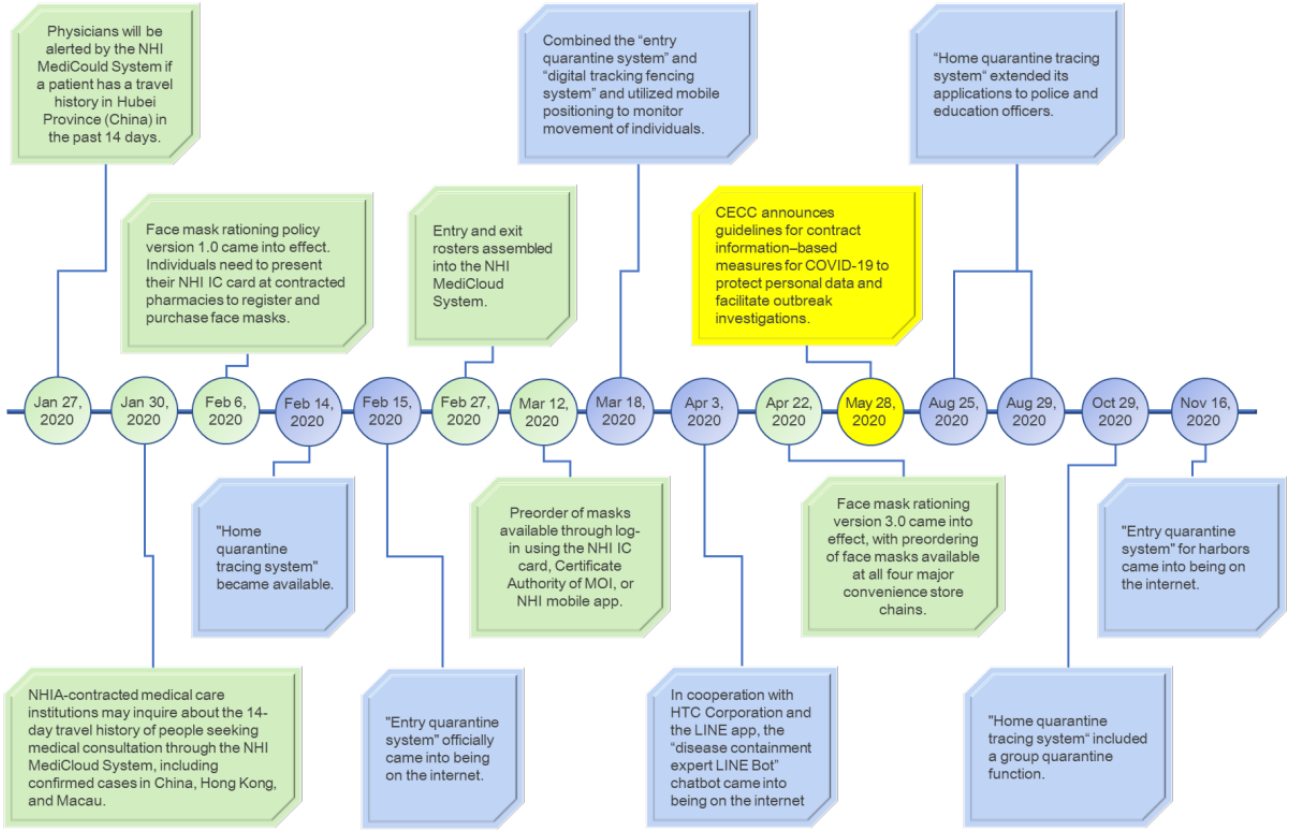
During the SARS outbreak of 2003 in Taiwan, the infected persons did not disclose their history of travel to outbreak areas in order to escape the quarantine; this was a loophole in border control. Furthermore, there was no regulation to prevent potentially infected people from entering hospitals without declaring their risk, resulting in the shutdown of a regional hospital and partial service closure at a medical center [4,5]. Furthermore, the face mask supplies in the market decreased and caused panic related to the purchase of face masks in the community. The devastating experience with the SARS outbreak had led Taiwan to be extremely cautious when China initially announced its COVID-19 outbreak on January 20, 2020. Taiwan quickly established the Central Epidemic Command Center (CECC). The well-developed infrastructure of the CECC has allowed for quick strategic planning, epidemic analysis, and disease prevention, as well as unifying medical resources to successfully contain the outbreak and minimize infections [6]. Meanwhile, digital technology (DT) has played an essential role in combating the COVID-19 pandemic (especially considering its dual roles as an "enabler" and a "driver") and provided tremendous help in containing SARS-CoV-2, which was not well-exploited during the SARS pandemic.

During the current COVID-19 pandemic, all countries worldwide deployed public health strategies including border control, control of community transmission, enhancement of personal hygiene, and prevention of nosocomial infection, and Taiwan was no exception. Here we elucidate how data linkage was used to strengthen disease prevention and to explore the role of DT in public health and disease control strategies. Based on Taiwan's successful experience with COVID-19 control, 2 major data linkage models are proposed herein for COVID-19 control. Furthermore, we have discussed the application of data linkage models.

Applications of the Current National Health Insurance System to Enhance COVID-19 Prevention and Control

Taiwan's National Health Insurance System (NHIS) was initially rolled out in 1995, with the National Health Insurance Administration (NHIA) being the only insurer. Since the NHIS was completely information-driven, 90% of the hospitals and clinics had used the electronic reporting systems to claim medical expenses. Currently, these services are fully automated and have been running smoothly for years. For security reasons, a virtual private network is used to strengthen data security while the information is being processed on the internet. Once the NHIA had collected, reported, and complied all medical expenses into the "centralized database," big data were used to automatically review and process all medical claims received from hospitals and clinics. As a benefit, Taiwan's NHIS has the lowest administrative cost worldwide [7,8]. In addition, NHIA issues National Health Insurance IC cards (NHI IC cards) as an insurance certificate. In general, Taiwanese citizens present the NHI IC card during medical visits. The NHI IC card enables physicians to obtain the most recent medical records of the patient. Moreover, detailed past medical records and medication use can also be accessed by linking this information with a medical cloud information exchange system, the MediCloud. Under the NHIS, two important pandemic prevention features were established: travel history tracking and the mask-rationing plan for purchase (Figure 1).

Figure 1. Diagrammatic representation of the NHI IC card usage in COVID-19 prevention policies. NHI: National Health Insurance, VPN: virtual private network.



Travel History Tracking

At the early stage of CECC establishment, the presence of fever, cough, as well as other respiratory symptoms, travel history, occupation, contact history, and cluster exposure were used as the criteria for case reporting and screening. In addition to the existing pandemic reporting and screening procedures, toward the end of January 2020 (also known as Lunar New Year for Asian-Pacific regions), the CECC decided to utilize the MediCloud system from NHIS to provide inquiry services for travel history. MediCloud system (previously known as "PharmaCloud") had been expanding its services and functions

XSL•FO
RenderX

to provide patient information (ie, disease diagnosis, examinations, laboratory testing, and medication) to hospitals and clinics since its initiation in 2015. After years of promotion and system advancement, the usage of MediCloud is currently over 99%, and MediCloud has become the essential platform for information sharing among medical institutions. Once interface linkage was established between the National Immigration Agency (part of the Ministry of the Interior of Taiwan) and the NHIA, the travel information database was integrated with medical records within just a few days. Now the NHIA has been able to provide inquiry services for travel history among infected countries or regions. In response to the progression of the COVID-19 pandemic, the features of querying wider ranges of travel history and occupations were included (Figure 2). These features contribute greatly to the prevention of nosocomial infections and enable timely screening to prevent COVID-19 outbreaks. Front-line medical workers are able to identify potentially infected individuals on the basis of their travel history and have reported symptoms with the aid of real-time alerts from the integrated information system and taken appropriate steps to adequately protect themselves from COVID-19.

Figure 2. Timeline of technology usage in COVID-19 prevention in Taiwan. Green blocks represent the launching date of the travel history inquiry system and the name-based mask-rationing system, blue blocks represent the procedures and services for border control and the home quarantine system, and the yellow block represents the date when CECC announced guidelines for contact information–based measures and data collection. CECC: Central Epidemic Command Center, MOI: Ministry of the Interior, NHI: National health Insurance, NHIA: National Health Insurance Administration.

Name-Based Mask-Rationing System for Purchase

At the beginning of February 2020, the CECC announced that the daily production of face masks was approximately 2 million, which was markedly lesser than the total population of Taiwan (approximately 23 million). Meanwhile, China also proceeded with purchasing large amounts of face masks in response to the COVID-19 pandemic. Since the people of Taiwan have had experiences with the SARS pandemic, people in some areas started stocking up face masks at home to avoid shortage [9]. In response to the face mask shortfall, the government began to increase face mask production to ensure all citizens have equal access to high-quality face masks. The policy that the government deployed, the "name-based mask-rationing system," inevitably ensured fair distribution of face masks in the community. Since all insurees (including legal foreign workers in Taiwan) obtain an NHI IC card, the CECC instructed the NHIS to contract pharmacies to link with the MediCloud system such that the policy of "three face masks per week per individual" can be executed for all insured individuals. The policy utilized the information that the NHI IC card provides to verify and control the allocation of face masks to ensure that everyone has access to face masks for basic protection against COVID-19. Furthermore, at the beginning of March, the CECC had announced a payment mechanism where the public can utilize kiosks to reserve face masks, pay the fees, and collect them at either local convenience stores or pharmacies per their preference. Local manufacturers in Taiwan have been able to increase face mask production; hence, the purchasing policy was modified by the CECC to "nine face masks every two weeks per individual" in early May. Starting on June 1, 2020, the public was allowed to make more purchases if needed, other than the primary rationing.

XSL•FO
RenderX

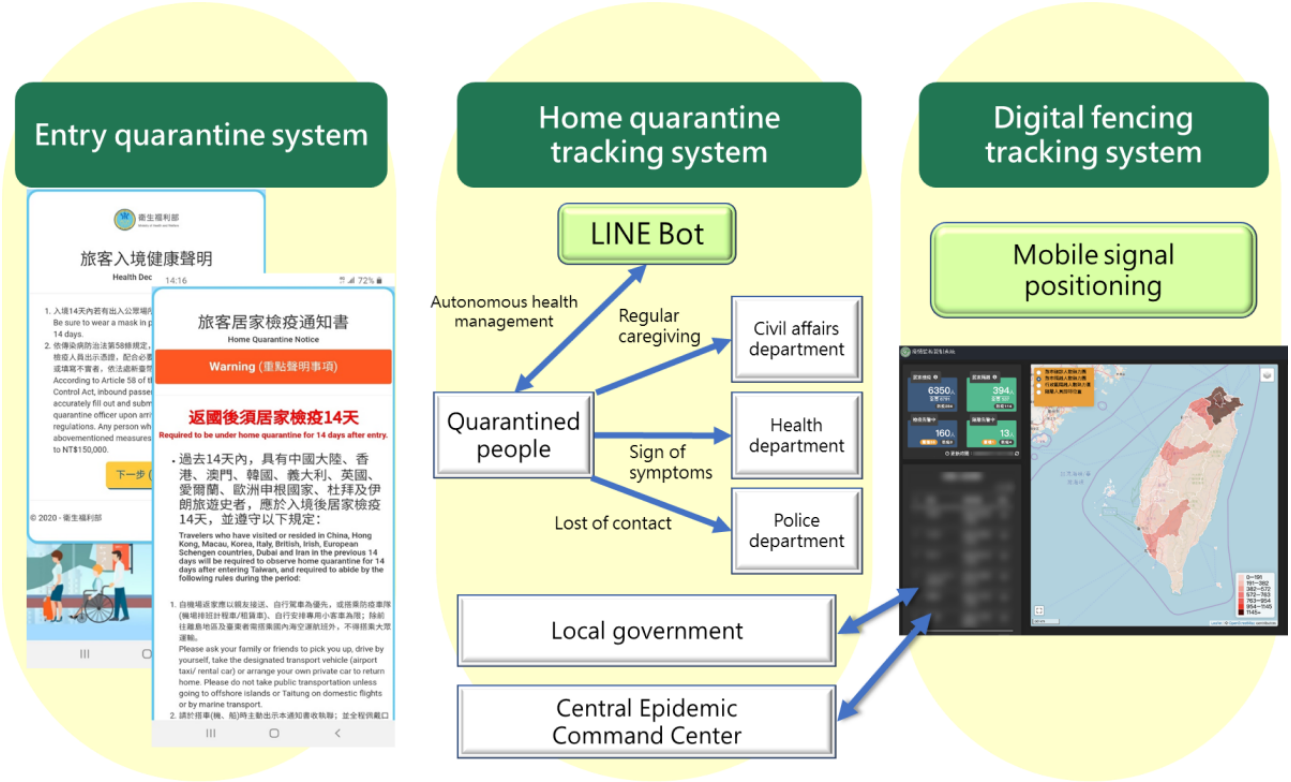
The current infrastructure of the NHIS allows the aforementioned functions such as travel history tracking and executing a "name-based mask-rationing system" policy; thus, all pandemic prevention strategies postulated by the CECC can be implemented in a timely manner. The establishment of the NHI IC card, MediCloud, and a virtual private network were mostly completed after the SARS outbreak in 2003. The original purpose was not pandemic control, but rather for Taiwan's citizens to utilize medical services at their convenience. The original purpose of establishing the NHI IC card was to avoid the misuse of medical services by the public and to enhance medication safety by using information technologies to share information among hospitals, clinics, and pharmacies rather than for pandemic control. Meanwhile, this "centralized" data linkage structure has become the key enabler for the government to implement pandemic prevention strategies.

Establishment of a Pandemic Prevention System from the Border to the Community

Toward the end of January 2020, the CECC decided to instruct passengers arriving from China, Hong Kong, and Macau to follow home quarantine procedures. The procedure required passengers to receive a home quarantine notice once they entered Taiwan (both by air and sea). Both the civil affairs department and the health department could be informed with lists of people who require home quarantine in their responsible areas. The civil affairs personnel would then monitor those who are in home quarantine with regard to basic living and health needs, and the health department would arrange for medical treatments if needed.

Information-Driven System Planning

Owing to the lack of assistance from DT, the manpower required to carry out those surveillance duties was tremendous and ineffective in the beginning. For instance, the airport staff needed to identify those who require home quarantine from among 70,000 passengers entering Taiwan each day. Therefore, airports needed to recruit a large number of health officers or temporary assistants to carry out verification duties. According to the infectious disease prevention and treatment law, the duty of performing home quarantine is fulfilled by civil affairs personnel of the Ministry of Home Affairs and the local government. Health officers who are responsible for COVID-19 testing at the airport collected all the information on paper, performed web-based data entry, and the information was sent out from the health department to the Ministry of Home Affairs and then passed on to the local government. The local government passed on the information regarding the results of COVID-19 testing to the chief of the village, who in turn would check and assist those who are in home quarantine. Those who violate home quarantine procedures are subject to administrative penalties by the health administrative system. Many government employees are under extreme pressure with regard to mishandling of COVID-19–related tasks and the creation of loopholes in the disease prevention system during the pandemic. The delay in information received by the local government employees, misinformation regarding personal data (such as telephone numbers and addresses), quality of information, and efficiency may all contribute to the pressure felt by the government employees.



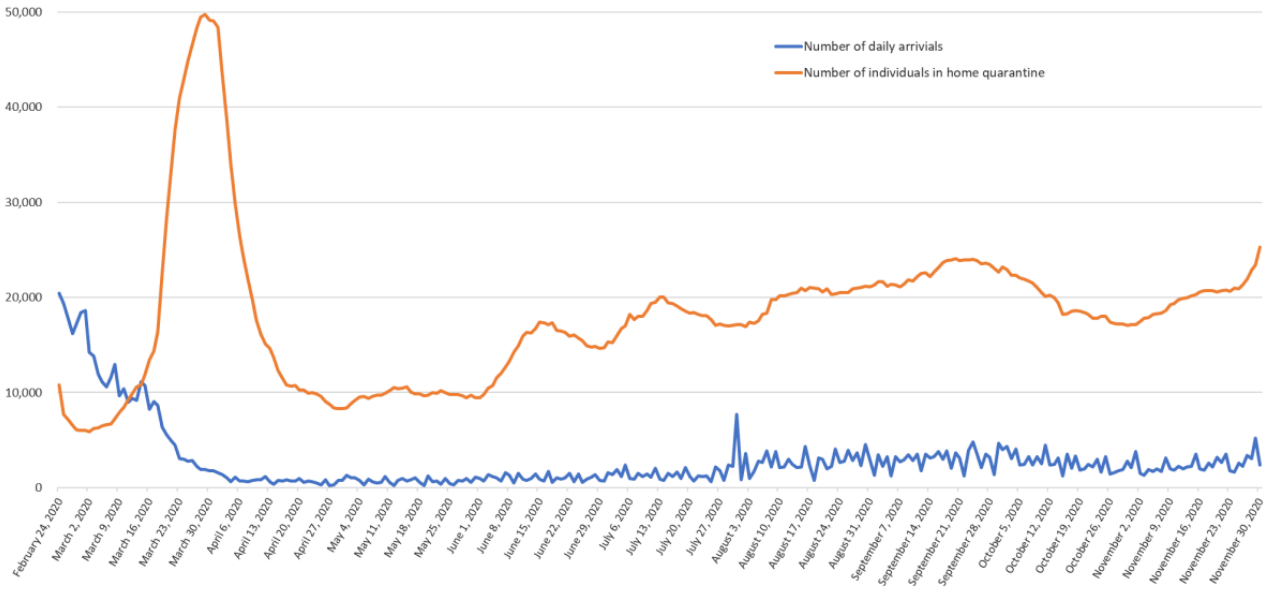
By the end of January 2020, the CECC had begun to improve data quality and efficiency and attempted to improve the sharing of correct personal information such as residential addresses, telephone numbers, cellphone numbers, and the start date of home quarantine among different government departments. As an information center, the CECC has established both the information flow and a relevant application system to allow for the circulation of information from the border to the community. Because 80% of the people of Taiwan are smartphone users, smartphones were being used as the main tool to keep track of individuals. A mobile app was not considered a viable option regardless of the smartphone's operating system (iOS or Android) since it may take considerable time for approval. Nevertheless, more time may be required for program correction. Therefore, the option of using a mobile app was eliminated as it was time-consuming during the critical outbreak.

Establishment of the Information-Driven System

The information-driven system was ready for launch after 2 weeks of brainstorming ideas to the completion of the entire system. In mid-February 2020, the information system became available and allowed data linkage among border control and local government services with the Advance Passenger Information System from the National Immigration Agency and Household Registration Information from the department of household affairs (also part of the Ministry of the Interior of Taiwan) for the management of home quarantine cases (Figure 3). For instance, the information system would ask all inbound passengers to use smartphones to scan a specific QR code prior to their departure and fill out personal information, health status, travel history, cellphone number, and public transportation needs. Before the aircraft reaches the gate, passengers will receive text messages regarding information on home quarantine notice and health declaration certificates. If passengers report symptoms related to COVID-19 under health status, the health personnel would proceed to test them immediately and arrange for medical treatment. If passengers indicate the need for public transportation, arrangements would be made. At present, there are on average 40,000 travelers arriving in Taiwan every day, and our information system has been functioning well in entry control.

XSL•FO
RenderX

Figure 3. Diagrammatic representation of the border control and home quarantine systems.



Immigration information can be delivered in a timely manner to the home quarantine management system, which is based on the regional joint defense concept to directly assign people who require home quarantine to the village, which prevents delays in information transfer. Initially, when the system was established, issues such as the submission of incorrect contact information were reported. The village-based civil affairs personnel (such as village officials) are responsible for confirming whether the individual has returned to the correct home quarantine location; if not, all the other possible addresses or telephone numbers may be used to track the individual down. If needed, the civil affairs personnel would check on the individual in person to ensure the individual stays at the designated quarantine location. The civil affairs personnel from different villages would also assist one another to carry out the surveillance duty. During the 14-day home quarantine period, the civil affairs personnel would provide home care services to the quarantined individuals on the basis of the address and contact number that appears in the system. Home care services provided by the civil affairs personnel are often delivered to the individual through smartphones, which will allow tracing of records for future reference. If there is an incidence of violation of home quarantine, the CECC would coordinate with telephone service providers to send out timely text messages to remind the concerned individual to return to their designated home quarantine location.

Merging of Information-Driven Systems and Instant Messaging Apps

As the system functions better each day and the accuracy of information continues to improve, the initiation of complete border control still remains a challenge. On March 19, 2020, the CECC announced that all travelers entering Taiwan will need to fulfill the home quarantine requirement. Although on average only approximately 7000 travelers entered Taiwan each day, the number of home quarantine cases still increased significantly (maximum 50,000 people/day to be monitored), and this certainly adds tremendous pressure on the local civil affairs personnel (Figure 4). The CECC used the media as a channel to advocate and invite the citizens to use the instant messaging app LINE and add the LINE Bot as a friend. On obtaining a consensus from home quarantine cases, the local civil affairs personnel could use the LINE app to follow up on home-quarantined individuals with regard to self-health management and personal needs on a daily basis. According to a survey performed in mid-May 2020, 7100 home-quarantined people in Taiwan who used the LINE app were sampled. The data revealed that chatting with LINE Bot and chatting with local civil affairs personnel scored 8.68 and 8.56, respectively, on a scale of 10 (0=completely unsatisfactory and 10=very satisfied).

XSL•FO
RenderX

Figure 4. Number of daily arrivals and home quarantine management in Taiwan (data were collected until November 30, 2020).

Until June 30, 2020, form among 447 confirmed cases of COVID-19, 356 (80%) were imported, and only 55 (12%) local cases and 36 (8%) confirmed cases were from navy clusters. For the imported cases, 141 infected individuals tested positive on arrival at the Taiwan border, 150 infected individuals tested positive during the 14-day quarantine, and the remaining 65 individuals tested positive during cluster quarantine, home quarantine, or isolation (Table 1). The information-based disease control system was the main "driver" to successfully block the spread of COVID-19 at the border and away from the community. The local rate of penalization for violating the home quarantine policy was lower than 0.5% (n=720/175,720 people).

Table 1. Source of confirmed COVID-19 cases in Taiwan as on November 30, 2020.

Records	Quantity
Tests performed, n	110,685
Confirmed cases (positive rate), n (%)[a]	679 (0.6)
Imported cases	588 (86.6)
Immigration testing	232 (39.5)
During home quarantine	207 (35.2)
Others	149 (25.3)
Locally acquired infections	55 (8.1)
Navy crew members aboard the Panshi Fast Combat Support Ship	36 (5.3)

[a]Imported cases, locally acquired infections, and navy crew members aboard the Panshi Fast Combat Support Ship are calculated relative to the number of confirmed cases.

Recommendation and Discussion

From the perspective of using data linkage to enhance pandemic control, the success of COVID-19 control in Taiwan was analyzed and could be attributed to 2 main data linkage models. These 2 main models enhance and improve 4 key public health strategies in Taiwan, including border control, prevention of community outbreaks, enhancement of personal hygiene, and prevention of nosocomial infections. Through data linkage between the NHIS and other departments, Taiwan was able to secure the supply of face masks and avoid nosocomial infections, which have been reported in previous studies [10,11]. The efficiency of the "centralized" data linkage model can be optimized as long as the integrity of the database is sufficient. Moreover, the range of travel history and the traveler's identity can be expanded as the pandemic progresses. The amount of allowance to purchase face masks and participating vendors can also be adjusted as needed. Overall, it is quite feasible to have the aforementioned flexibilities in a country such as Taiwan where the NHIS has demonstrated great functionality and performance. Unlike Taiwan, the United States has multiple insurance systems. Nevertheless, it is still feasible to use existing web-based medical networks to create similar data linkages through additional effort. From the border to the community, the information-oriented prevention system is considered a type of "downstream supply chain" of data linkage, and the key to

XSL•FO
RenderX

its success is attributed to the accuracy and timeliness of data collection [6,12]. For instance, for people who require home quarantine, within the first hour or 2 hours of arrival, the information should be sent directly to the civil affairs personnel of the appropriate residential area. This process can significantly ensure that information is received in a timely manner and can avoid any flaws in disease prevention. It is essential to implement the correct system at the right time to reinforce border management and prevent community outbreaks. Therefore, using the agile approach instead of the traditional approach in building the correct system is preferable during the COVID-19 outbreak.

Similar to other countries that rely heavily on information technologies, it is essential to establish a balance between disease prevention and personal data protection. However, the public generally agrees with and follows the necessary pandemic control policies despite the concern of personal data protection. Unlike Taiwan, South Korea has implemented a law allowing the government to reduce the level of personal data protection during the critical phase of the pandemic [13]. The government of Taiwan applies the current Infectious Disease Control Act and Personal Data Protection Act and openly discloses the prevention measures that are required to be followed by all travelers on entering Taiwan. On May 28, 2020, the CECC announced guidelines for contact information–based measures and data collection in response to the COVID-19 outbreak to ensure personal data protection and facilitate outbreak investigations. On the other hand, Taiwan chose to use a less privacy-sensitive DT approach, such as using smartphone-based station tracking instead of real-time GPS technology to monitor people who are in home quarantine or home isolation. Furthermore, a proposal has been approved, endorsed, and authorized by the legislature to eliminate all the unnecessary electronic records and linkages after the pandemic, which can also be adopted by other countries.

Currently, Taiwan has been free from local COVID-19 transmission for more than 200 days. The CECC has cautiously reopened the economy in a stepwise manner. As the restrictions on social activities are being lifted gradually, the “from border to community” information-driven prevention system continues to strengthen border control, ensuring that imported cases can be isolated immediately to minimize contact with others and information on the number of screenings performed and the number of confirmed cases can be compiled at the airport on a daily basis. Furthermore, the system can also help analyze and understand the changes in the number of confirmed cases overseas once border restrictions are lifted and adjustments are made to border control policies accordingly. Furthermore, in the post–COVID-19 era, new technology-driven practices will now form a part of “the new normal.” The government and organizations need to adopt new DT systems during the pandemic and devise methods to normalize these new practices. These new technology-driven work practices are usually implemented during the most severe times under high-pressure conditions and often without former experience or training. Taiwan’s experience can therefore be considered a valuable reference for other countries to further the current understanding of how DT can be embedded within government practices and form the “new normal” in the post–COVID-19 era.

In conclusion, the integrity, accuracy, and timeliness of data linkage and DT infrastructure ensure that essential public health interventions, such as border control, quarantine, case detection, contact tracing, and universal surgical mask–wearing can be effectively implemented and become the foundation of the highly successful COVID-19 pandemic response in Taiwan.

Acknowledgments

We appreciate the support from the Department of Information Management and Centers for Disease Control at the Ministry of Health and Welfare, Department of Cyber Security of the Executive Yuan, and the National Immigration Agency at the Ministry of the Interior of Taiwan.

Authors' Contributions

All authors contributed substantially to this study. IMP and HYC conceived and designed the study, and contributed to the manuscript equally. FCW, HWJ, HCW, and YLH prepared the figures and tables. WCL, FCW, and LYL drafted the manuscript. All authors contributed to the interpretation of data, critically revised the manuscript, and approved the final manuscript.

Abstract

Background: The emergence of SARS-CoV-2 in late 2019 and its subsequent spread worldwide continues to be a global health crisis. Many governments consider contact tracing of citizens through apps installed on mobile phones as a key mechanism to contain the spread of SARS-CoV-2.

Objective: In this study, we sought to explore the suitability of artificial intelligence (AI)–enabled social media analyses using Facebook and Twitter to understand public perceptions of COVID-19 contact tracing apps in the United Kingdom.

Methods: We extracted and analyzed over 10,000 relevant social media posts across an 8-month period, from March 1 to October 31, 2020. We used an initial filter with COVID-19–related keywords, which were predefined as part of an open Twitter-based COVID-19 dataset. We then applied a second filter using contract tracing app–related keywords and a geographical filter. We developed and utilized a hybrid, rule-based ensemble model, combining state-of-the-art lexicon rule-based and deep learning–based approaches.

Results: Overall, we observed 76% positive and 12% negative sentiments, with the majority of negative sentiments reported in the North of England. These sentiments varied over time, likely influenced by ongoing public debates around implementing app-based contact tracing by using a centralized model where data would be shared with the health service, compared with decentralized contact-tracing technology.

Conclusions: Variations in sentiments corroborate with ongoing debates surrounding the information governance of health-related information. AI-enabled social media analysis of public attitudes in health care can help facilitate the implementation of effective public health campaigns.

Introduction

SARS-CoV-2 is a major global threat to public health. Many governments worldwide are using mobile apps for contact tracing of citizens to contain the spread of SARS-CoV-2 [1]. The contact tracing applications used vary within and between countries, but they generally track movements of individuals and aggregate data to communicate to users when they may have been exposed to the virus, and if they need to be tested and/or self-isolated.

The higher the user base of contact tracing apps, the larger the anticipated impact on reducing the estimated effective reproduction number of the virus [2,3]. However, there is inconsistent and incomplete uptake of these technologies, especially in individualistic societies where intended users may perceive such apps to be of limited personal benefit or infringing on personal privacy and where the use of such apps is difficult to mandate [4,5]. To understand what public health measures may promote the use of contact tracing apps in the United Kingdom, policy makers need to understand the reasons why members of the public may be hesitant to use them. The empirical literature shows how attitudes of prospective users influenced by their individual backgrounds, technological features of the app in question, and perceived benefits and trade-offs can be a key barrier to the effective implementation of such apps (see Textbox 1) [6-9].

More than half of the world's population, and around two-thirds of the UK population, currently use social media platforms, with significantly increased engagement levels during the ongoing pandemic [10]. We here sought to explore how analyzing public attitudes on these forums can provide insights into low levels of adoption of contact tracing apps in the United Kingdom. Our recent work has demonstrated the value of artificial intelligence (AI)–based sentiment analysis of social media data [11].

Textbox 1. Factors likely to impact the use of contact tracing apps identified in the literature.

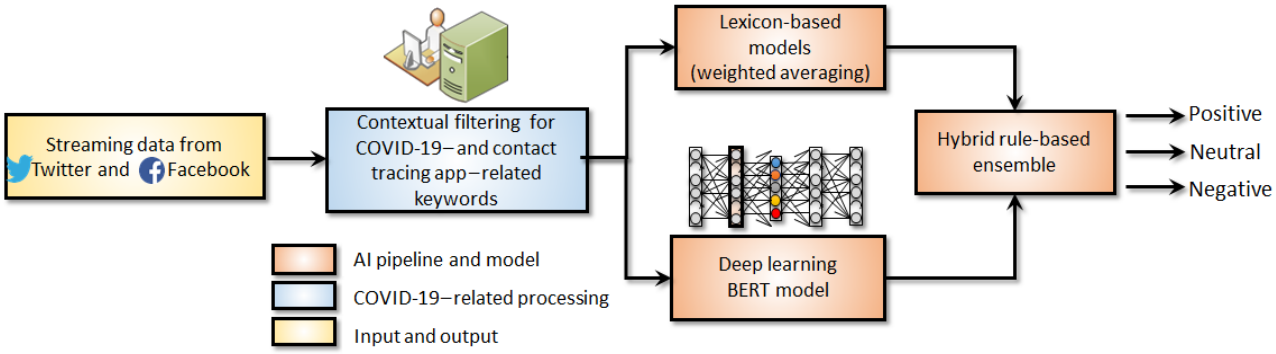
- **Individual backgrounds:** demographics, health status, involvement with COVID-19, and previous experiences (technology, health, and other factors associated with COVID-19).
- **Technological features:** effectiveness, privacy, security, cost, trust in system vendor, performance and reliability (eg, false-positive or false-negative alerts), compatibility with installed base, interoperability, and architecture of systems (eg, centralized vs decentralized).
- **Perceived benefits:** self, society, research, epidemiology, mediators (eg, if the user or others will take action based on risk, if they care about the environment or society, if they believe data will be used effectively), and tension between perceived benefit to the user and altruistic benefit to the whole population.
- **Perceived trade-offs, risks, and limiting factors:** data collected (who will know what about the user), risk of marginalization of certain demographic groups, level of control of who sees what aspects of data and who can retain it for how long, and transparency of app.

Methods

Data Sources

To assess the potential of an AI-based sentiment analysis to understand public views and concerns, we analyzed data from two popular social media platforms—Facebook and Twitter. Facebook posts were extracted using the CrowdTangle platform [12], and Twitter posts were extracted from the COVID-19 Twitter chatter dataset, constructed by Panacea Lab (using a publicly available Twitter application programming interface) [13]. English-language Facebook posts and tweets posted in the United Kingdom from March 1 to October 31, 2020, were extracted, and thematically filtered using a two-step process, for keywords related to both COVID-19 and contact tracing apps. The Twitter dataset was already filtered with predefined COVID-19–related keywords as detailed previously [13], and the same keywords were used to apply an initial filter to the Facebook data. The following contract tracing app–related keywords for the second step filtering were selected by our interdisciplinary team: "covid app," "tracing app," "contact tracing," "privacy," "security," "app security," "app privacy," "contain virus spread," "movement tracking," "tracking," and "surveillance." Following geographical filtering for the United Kingdom, a total of 2000 tweets and 8000 Facebook posts were obtained for the analysis.

Analysis



A novel ensemble-based AI model developed by the authors in a recent study [14] was adapted and utilized for this study, by combining lexicon rule-based and deep learning (DL)–based approaches. Specifically, an average-weighting ensemble [15] of lexicon-based models, including Valence Aware Dictionary and Sentiment Reasoner (VADER) [16] and TextBlob [17], was combined with a state-of-the-art DL-based model Bidirectional Encoder Representations from Transformers (BERT) [18]. The overall hybrid rule-based ensemble method is illustrated in Figure 1.

The hybrid rule-based ensemble model was hyperparameter tuned based on manual validation by using 1000 randomly selected posts and labelled by the team. Specificity and sensitivity analyses showed that the lexicon-based model demonstrated better performance accuracy for positive sentiment and that the DL-based BERT model demonstrated enhanced accuracy for neutral and negative sentiments, as shown in the confusion matrices (Multimedia Appendix 1). The TextBlob lexicon-based model utilizes a higher weight (0.52) than the VADER model, as it demonstrated marginally better accuracy (VADER × 0.48 + TextBlob × 0.52) for positive sentiments. For the ensemble, weighted averaging was utilized to combine the two lexicon-based models. The output of the weighted average lexicons was combined with the DL-based BERT model through a rule-based approach. For positive sentiments, the weighted average output of the lexicon models was selected as

XSL•FO
RenderX

the final output. For neutral and negative sentiments, the output of the DL-based BERT model was chosen as the final output. If-else logical constructs were used to determine the final sentiment class based on the base model outputs.

Figure 1. Hybrid rule-based ensemble model for sentiment classification of social media data. AI: artificial intelligence; BERT: Bidirectional Encoder Representations from Transformers.

Ethics

No ethical review was necessary since the data analyzed was fully in the public domain. A thorough assessment of the privacy risk to individuals posed by our research was conducted to ensure compliance with relevant sections of the General Data Protection Regulation (GDPR). We have also striven to comply with best practices for user protection to ensure no nonpublic material was included in our dataset.

Data Availability

The code and data used for data analysis and generation of figures are openly available on GitLab [19] for reproducibility and transparency of the analysis. Due to the computationally expensive nature of the code, we recommend using a high-performance computing resource.

Results

Figure 2 shows the average weekly sentiment trends on using contact tracing apps on Facebook and Twitter. The sentiments were computed by utilizing our ensemble-based AI model to predict the *overall* polarity of each post as positive, negative, or neutral. Due to the relatively small number, sentiments extracted from Facebook and Twitter posts were combined using weighted weekly averages. Sentiment word clouds were used to explore the topics being discussed at different time points of interest (Figure 2). Overall, the average positive sentiments were found to far outnumber the negative sentiments. We observed a six-fold difference between the sentiment type, with 76% positive and 12% negative sentiments. These were found to broadly corroborate with findings from independent surveys that show strong support for contact tracing apps. For example, an Ipsos MORI survey of 1983 UK adults conducted in May 2020 found that two-thirds (67%) of the population was in support and 12% was against the government's plans to use a smartphone app to track and trace new cases of COVID-19 [20]. However, the public's attitudes were found to be heavily influenced by demographics and the digital divide [12,21]. Several new survey studies are currently underway to explore public attitudes towards contact tracing apps.

Figure 2 illustrates some of the key events that are likely to have influenced changes in the public's sentiments toward using contact tracing apps. Following the successful implementation of contact tracing strategies in several East Asian countries and high-profile research reporting that app-based contact tracing was likely to be effective in curbing the spread of the virus [22-24], Apple and Google partnered on developing a decentralized COVID-19 contact tracing technology [25]. Shortly after, the UK government released contact tracing guidance with plans to develop a *home-grown* app and deploy it through a centralized model, implying that individual information would be shared with health services [26,27]. This model was controversial, primarily driven by public concerns around privacy and security of the app, its incompatibility with iPhones, and potential breaches of the Data Protection Law [28]. In June 2020, the centralized UK app was abandoned [29]. In August 2020, the UK government decided to implement the decentralized contact tracing system developed by Apple and Google [30], launching the app in September 2020 [31]. Since then, there have been concerns around high rates of false-positive COVID-19 cases reported via the app, hindering its uptake among the public [32].

We also carried out spatial mapping of the sentiments extracted from geo-tagged tweets to counties in the United Kingdom (see Figure 3). Most tweets had an overall positive sentiment toward COVID-19 contact tracing. The counties with the most positive sentiment included Lincolnshire, Norfolk, Nottinghamshire, Leicestershire, and Northamptonshire in England, and Stirling, Fife, Dumfries and Galloway, East Ayrshire, and West Lothian in Scotland. Counties with the most negative sentiment were Suffolk, Somerset, Devon, and North Yorkshire—all in England.

Discussion

Principal Findings

This study has provided insights into some of the underlying issues and concerns surrounding contact tracing apps, and particularly how decisions surrounding system architecture (eg, centralized vs decentralized) can influence public attitudes.

More fine-grained spatiotemporal variation in sentiments across the United Kingdom, and globally, should be further studied. Failure to pay timely attention to negative attitudes and resistance to emerging technologies in population health can have potentially damaging consequences, whereas an understanding of barriers can facilitate the development of effective interventions.

Limitations of our preliminary analysis include that social media platform users are largely not representative of the total UK population (eg, users are younger, more left-wing, and have higher incomes) [33]. Only about 15% of UK adults are regular Twitter users, with activity levels varying among passive and active users, and the demographics of users do not reflect the demographics of the general population [34]. It has also been shown that sentiments of tweets can vary across geographical locations and may therefore reflect the demographics of the population being studied [35]. Variations in sentiments can occur at an individual level, influenced by personal experiences and changes not necessarily related to the subject of the tweet [36]. The developed ensemble-based sentiment analysis approach can be optimized by using additional labelled data for transfer learning and fine-tuning the BERT base model. Adaptive neuro-fuzzy inferencing [37] can also be utilized to replace the current nonadaptive (weighted-average and logical rule-based) constructs.

The current focus on selected social media platforms, outstanding issues around the accuracy of AI techniques (eg, around deceptive language), and the limited number of tweets and Facebook posts due to the specific search strategy used, as well as given that only geo-tagged tweets were used, may limit the generalizability of these findings. Thus, there is a need for a more refined and comprehensive search strategy using multiple social media and web platforms, as well as linked analysis with data from external trustworthy sources such as polls, census, surveys, and clinical notes. Considering the limitations, the proposed approach should currently only be used alongside other methods to assess public sentiment, including public consultations, surveys, and qualitative studies.

In future, mobility trends [38] can be integrated into this approach and demographic determinants can also be inferred [39] and included to provide further insights. Furthermore, subgroup analysis could explore reasons for low uptake in certain populations or communities (eg, anti-vaxxers [40]), which can inform the design of vaccine deployment strategies, including public messaging campaigns. The approach may help promote a learning public health policy cycle, where ideas can be tested against public attitudes before they are implemented, thereby maximizing their effectiveness and real-world applicability [41].

Conclusions

We advocate for future work on AI-enabled social media analysis of public attitudes in health care, which we believe has the potential to help facilitate the implementation of effective public health campaigns. Through this preliminary analysis, we show how such innovative methods may complement findings using conventional methods to monitor public sentiments (eg, surveys) while also providing greater spatiotemporal granularity.

Abstract

Background: The use of technology to support health and health care has grown rapidly in the last decade across all ages and medical specialties. Newly developed eHealth tools are being implemented in long-term management of growth failure in children, a low prevalence pediatric endocrine disorder.

Objective: Our objective was to create a framework that can guide future implementation and research on the use of eHealth tools to support patients with growth disorders who require growth hormone therapy.

Methods: A total of 12 pediatric endocrinologists with experience in eHealth, from a wide geographical distribution, participated in a series of online discussions. We summarized the discussions of 3 workshops, conducted during 2020, on the use of eHealth in the management of growth disorders, which were structured to provide insights on existing challenges, opportunities, and solutions for the implementation of eHealth tools across the patient journey, from referral to the end of pediatric therapy.

Results: A total of 815 responses were collected from 2 questionnaire-based activities covering referral and diagnosis of growth disorders, and subsequent growth hormone therapy stages of the patient pathway, relating to physicians, nurses, and patients,

XSL•FO
RenderX

parents, or caregivers. We mapped the feedback from those discussions into a framework that we developed as a guide to integration of eHealth tools across the patient journey. Responses focused on improved clinical management, such as growth monitoring and automation of referral for early detection of growth disorders, which could trigger rapid evaluation and diagnosis. Patient support included the use of eHealth for enhanced patient and caregiver communication, better access to educational opportunities, and enhanced medical and psychological support during growth hormone therapy management. Given the potential availability of patient data from connected devices, artificial intelligence can be used to predict adherence and personalize patient support. Providing evidence to demonstrate the value and utility of eHealth tools will ensure that these tools are widely accepted, trusted, and used in clinical practice, but implementation issues (eg, adaptation to specific clinical settings) must be addressed.

Conclusions: The use of eHealth in growth hormone therapy has major potential to improve the management of growth disorders along the patient journey. Combining objective clinical information and patient adherence data is vital in supporting decision-making and the development of new eHealth tools. Involvement of clinicians and patients in the process of integrating such technologies into clinical practice is essential for implementation and developing evidence that eHealth tools can provide value across the patient pathway.

Introduction

eHealth Implementation

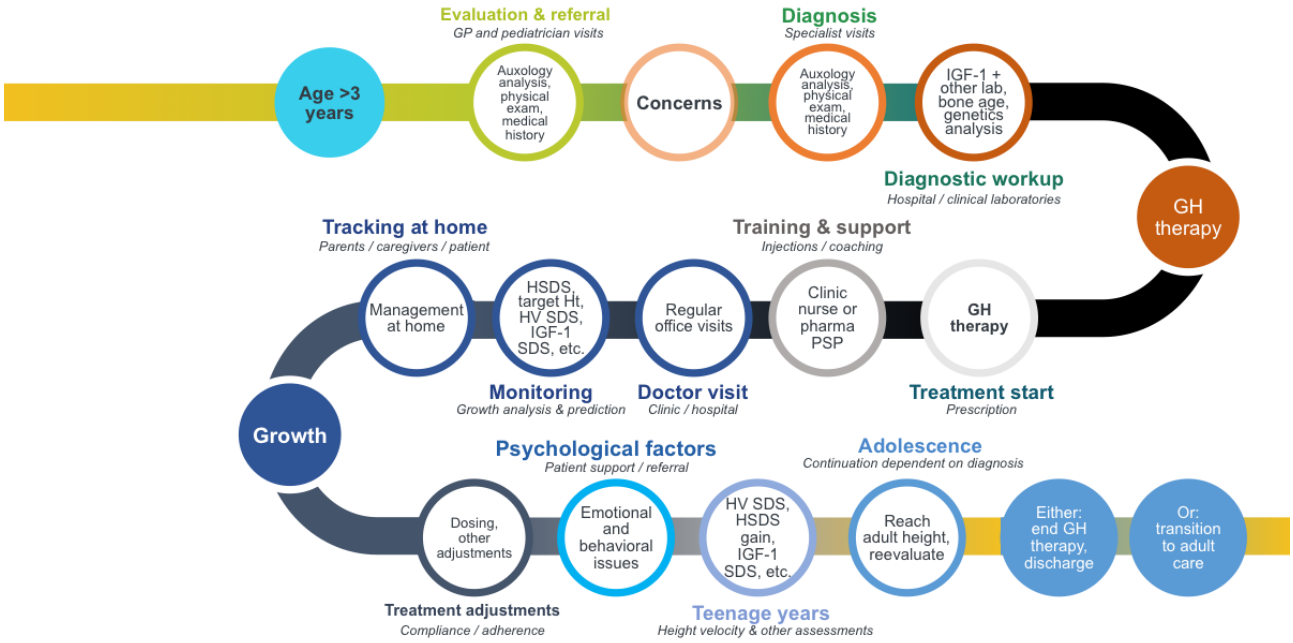
The implementation of eHealth solutions in clinical practice is growing rapidly [1]. Digitalization of the health sector is bringing many opportunities, such as the collection of patient-generated data [2] and the provision of health services over distance, also known as telehealth [3]. These technological advances are supporting a paradigm shift towards more integrated health care [4]. However, implementing technologies in the highly complex setting of health care delivery faces many challenges, which include both technical and human factors (eg, organizational issues, service integration, usability, legal frameworks, privacy) [5].

Opportunities of eHealth for Patient Empowerment in Growth Hormone Therapy

Pediatric endocrinology (the management of endocrine disorders in children) has adopted eHealth solutions for decades. For example, diabetes mellitus education uses game-based interventions [6,7], and more recent advanced technologies, such as augmented reality [8] and robotics [9], have been integrated into education and assistive care in diabetes mellitus. These approaches have traditionally looked at chronic conditions that require intensive lifestyle modifications, where lack of adherence to medication has a negative impact, with an increased risk of health complications and hospitalization.

Similarly, one of the areas that may benefit from implementation of novel eHealth tools is the long-term use of growth hormone therapy in the management of childhood growth failure. Growth hormone therapy is indicated for a heterogeneous set of growth disorders; in addition to growth hormone deficiency, approved pediatric indications include Turner syndrome, short stature after being born small for gestational age, Noonan syndrome, Prader-Willi syndrome, *SHOX* (short stature homeobox-containing gene) deficiency, chronic renal failure, and idiopathic short stature, although licensed indications vary by country and growth hormone formulations [10,11].

Importantly, growth hormone affects not only growth of children, but also metabolism, cardiovascular health, bone strength, and quality of life in the short and long term [12-14]. These effects continue into adult life, and a proportion of patients treated as children continue to require growth hormone therapy as adults. During the transition from pediatric to adult care, eHealth tools have been shown to be important in supporting patients to achieve positive outcomes and enhance ongoing engagement with health care [15,16].



The case of growth hormone therapy is somewhat different from that of diabetes because patients do not require intensive or large-scale lifestyle modifications. Because growth hormone therapy is administered by daily injection, the most important self-management behavior is adherence to medication, which affects long-term outcome. Growth hormone therapy for children with short stature must be administered consistently and with a high level of adherence over many years for an effective gain in height and optimal adult height [17]. Therapy is required from early childhood to adolescence; therefore, support and involvement of the patient's family and caregivers are crucial to achieving the best outcomes. Thus, eHealth tools to support growth hormone therapy must be developed with a holistic approach that involves the family and must also take into consideration physiological, psychological, and developmental changes as children grow, with a view to using these tools over many years [18,19]. Additionally, some of the conditions that are supported with growth hormone therapy are classified as rare diseases (incidence <1 in 2500 [20]), posing extra challenges. Physicians' knowledge may be limited, which can often lead to delayed referral and diagnosis, and the small number of patients creates difficulties in collection of data to generate large and meaningful data sets unless performed on an international scale. The collection of adherence data is of crucial importance [21] to optimizing adherence and improving adult height [22,23].

An optimal adult height is attained through the early recognition and understanding of the different causes of growth failure, thus leading to early referral, diagnosis, and growth hormone therapy

XSL•FO
RenderX

initiation. As mapped out in Figure 1, outcomes can be improved at all stages of the patient journey through comprehensive monitoring of growth, education, and clinical support to achieve a high level of therapy adherence. We surmised that eHealth tools could play a significant role in the management of growth disorders and growth hormone therapy through additional and comprehensive support and monitoring.

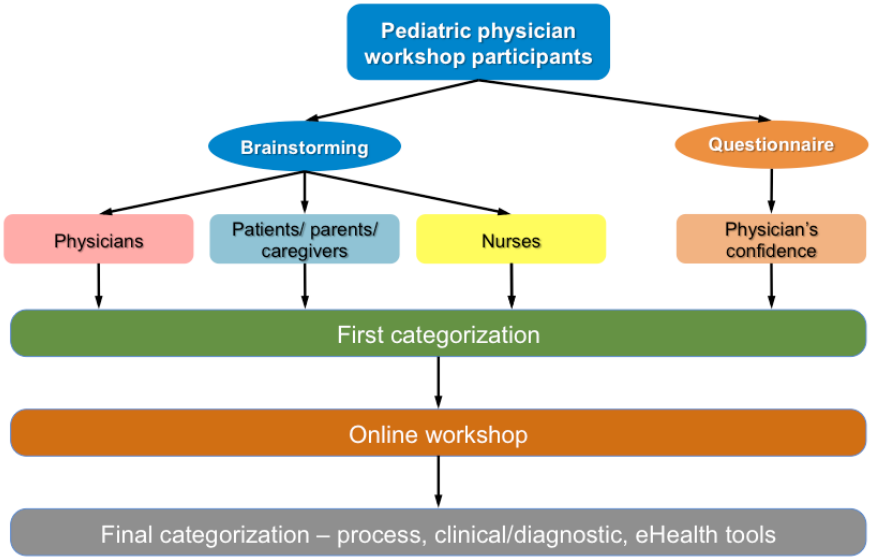
Objective

We aimed to develop a framework for using eHealth tools in the identification, investigation and diagnosis of growth failure and the management of growth hormone therapy in pediatric patients. Development of this framework was carried out as a multistep process, guided by the principles of participatory research involving key informants across a series of workshops and virtual activities. Similar approaches have been widely applied in medical informatics to identify implementation challenges of digital health tools [24], including the application of the Delphi method [25] in other endocrine disease areas [26] and eHealth for pediatrics [27].

Methods



Initially, we conducted 3 online webinars with presentations and interactive discussions around key concepts and issues of eHealth, including data science and use in pediatric patients with growth failure and growth hormone therapy. Based on active involvement in this initial step, a group of 12 participants were subsequently invited to more detailed discussions. This report describes the approach that was adopted for these online detailed discussion workshops and is outlined (Figure 2) and explained in more detail in the following sections.

The 12 participants were pediatric endocrinologists who have experience in the treatment of growth disorders. Convenience sampling was used to select participants on the basis of previous participation, interest or experience in eHealth activities, and patients' use of connected injection devices for growth hormone therapy. Sampling also considered participants on the basis of providing worldwide geographical representation, with participants from Argentina, Brazil, Finland, France, Germany, Malaysia, Sweden, Spain, Taiwan, and the United Kingdom, encompassing a wide base of health care and socioeconomic conditions. The participants completed preparation activities that included reading relevant publications [28-30], brainstorming activities (see Multimedia Appendix 1), and completing an adapted version of the eHealth literacy scale (eHEALS) survey [31] related to digital health literacy (see Multimedia Appendix 2).

The brainstorming activities solicited opinions of the participants on opportunities, challenges, and established or potential eHealth tools relating to 3 stakeholder groups: (1) pediatric endocrinologists, (2) patients and their parents/caregivers, and (3) nurses. Simultaneously, the pediatric endocrinologists completed a survey about their perception of eHealth tools in aiding clinical decisions and their confidence in use of such tools, with results quantified as proportions of respondents agreeing or disagreeing with the statements on a 5-point scale. The brainstorming activities and surveys were designed using the SurveyMonkey tool (SVMK Inc).

XSL•FO
RenderX

Figure 2. Workshop participation methodological steps. Each step was carried out twice, first in relation to referral and diagnosis stages and second in relation to all stages from growth hormone therapy initiation to completion.

For the first online workshop, the physicians completed the brainstorming exercise and eHealth literacy questionnaire with respect to the first part of the patient journey (Figure 1), through referral and diagnosis. For the second online meeting, the exercise and questionnaire were completed with respect to the subsequent stages of the patient journey from start of growth hormone therapy, through monitoring, tracking, and assessment of outcomes, to either growth hormone discontinuation or into the transition phase from pediatric to adult care for patients still requiring growth hormone therapy.

In each case, the brainstorming responses were initially categorized according to common themes, which were then discussed in the online workshops under the moderation of PD who was the key facilitator and with additional availability of textual responses. The brainstorming responses for each of the 3 categories of opportunities, challenges, and eHealth tools were finally categorized as relating to process, clinical pathway (including diagnostics for the first meeting), or education. These 3 main categories reflected important aspects for the implementation of eHealth solutions in clinical practice and formed the basis for the framework for best practices: (1) process—responses that related to everyday tasks that aided the distance and time logistics required by the specified people for delivery of health care; (2) clinical—responses relating to the medical condition, including those relating to establishing diagnosis; and (3) education—responses relating to digital technologies that can enhance learning and understanding of the condition, and therapy for either health care specialists or the patients and families.

Results

Survey Responses

A total of 815 responses were received from the 2 brainstorming exercises, comprising 419 in relation to referral and diagnosis stages and 396 relating to growth hormone therapy stages. In each case, the responses were grouped and categorized; Figure 3 shows the grouped responses relating to physicians for the referral and diagnosis stages, while Figure 4 shows the growth hormone therapy stages (responses relating to patients/parents/caregivers can be found in Multimedia Appendix 3 for referral/diagnosis and Multimedia Appendix 4 for growth hormone therapy, and responses relating to nurses in Multimedia Appendix 5 for referral/diagnosis and Multimedia Appendix 6 for growth hormone therapy). In the following subsections we describe the responses provided, assigned to each group in turn.

Brainstorming Responses Relating to Physicians

Growth Monitoring and Screening

For the referral and diagnosis stages, the perceived opportunities for physicians largely concerned process, particularly regarding digital reminders to record growth. It was noted that this could be done by primary care personnel, such as in Finland where children's height is routinely monitored and data immediately entered and integrated into electronic health records. Machine learning or artificial intelligence algorithms could be used to identify faltering growth and be followed by notification of health care professionals of this issue. Although such a system may overestimate referrals, it could support earlier diagnosis of conditions such as Turner syndrome and *SHOX* deficiency; it was noted that physicians may lack knowledge of these types of conditions, and pediatricians may not readily associate signs or symptoms with a diagnosis, resulting in late referral and therapy delay. Algorithms that have been developed to follow through symptomatic characteristics to identify the cause of growth failure could be incorporated into eHealth tools to aid physicians through the early stages of the referral and diagnostic process. Streamlining the screening, referral, and diagnostic process may expedite subsequent genetic testing, particularly for rare conditions associated with growth failure, thus identifying patients eligible for growth hormone therapy at an earlier stage.

XSL•FO
RenderX

Automated Height Measurements

At each stage of the patient journey, during referral, diagnosis, and monitoring of response to growth hormone therapy, the ability to accurately measure height electronically was cited as a significant area of development that could overcome the labor-intensive challenge of manually measuring height and inputting this into the patient record. There is potential for height and height velocity to be determined using electronic devices, such as mobile phones or tablet computers, which could be used by health professionals and parents or caregivers. Development of digital techniques for height measurement outside of the clinic would be very helpful in countries with remote rural communities where primary care is lacking, and data could be incorporated directly by linking to electronic health records. A tool that could be used by patients or caregivers to measure height electronically and be linked to artificial intelligence-based technology could increase the frequency of height measurements and provide a signal to health care providers about faltering growth to support earlier intervention.

Growth Hormone Response Prediction Models

The response to growth hormone therapy can be determined using validated prediction models that estimate potential adult height by incorporating parameters related to growth. These parameters include bone age, which is a determination of skeletal physiological maturity relative to chronological age through use of hand radiographs that can be evaluated with an automated digital method. There are multiple prediction models and a current lack of consensus regarding which of these is the gold standard. Clinicians wished to see a more unified international approach to growth prediction, which could subsequently lead to the incorporation of a model into an eHealth platform to aid clinicians in determining adult height.

Incorporation of prediction models into apps was considered a challenge, particularly given the lack of consensus on which model to use. It was, however, considered to be an important tool to allow identification of those patients who would most benefit from growth hormone therapy. Moreover, by using a digital device to measure height and then linking this to an electronic patient record, adult height prediction could be provided in a more seamless way through the integration of a prediction model into the process.

Communication, Logistics, and Engagement

Remote Delivery of Care and Communication

Communication between primary care and pediatric endocrine specialists, and others in multidisciplinary teams, was identified as an opportunity for eHealth tools to improve service provision. Multidisciplinary teams require good videoconferencing facilities; current platforms require improvements, such as increased bandwidth, to facilitate greater use of telemedicine. Guidelines for physicians that augment their ability to carry out online consultations are required, and education facilities for this could be provided through online workshops and video recordings.

One of the biggest challenges mentioned was constraints of time and distance when patients have to attend a hospital or clinic in order for assessments to be made. This may involve considerable travel over long distances (particularly for those in rural settings) and a large amount of time for both patients and health care personnel to ensure that appointments can be initiated and kept. Thus, the refinement of telecommunication systems will help to overcome this barrier.

Participants proposed that electronic health records could be used for automating appointments, referrals, and data reporting. As consultations improve efficiency, more information could be made available for each patient, giving interoperability greater importance in order that data entry does not require additional time. Overall, eHealth tools need to be efficient to use if they are to gain acceptance.

Patient Engagement

Digital technologies that can seamlessly record adherence with the therapy regimen allow of evaluation and timely intervention if adherence decreases over time. Adding adherence data to growth prediction models was considered a potential aid to the assessment of patients that would benefit from therapy and could be used as an additional variable in prediction of adult height.

Interactive games that motivate and engage the patient may also increase the long-term adherence to growth hormone therapy, and their development requires involvement of families, nurses, and physicians as key stakeholders.

Psychological Well-Being

One challenge for physicians is dealing with the psychological impact of growth hormone therapy. As patients move through different stages of their therapy journey, with evolving physical and emotional maturity, variations in therapy adherence are expected. Digital tools to evaluate the psychological status of patients could enable the identification and assessment of anxiety related to the condition and long-term therapy. Participants suggested that therapy-related psychology could be assessed using short online questionnaires, with standardization across different clinics. In addition, as online and digital tools are developed to deliver psychological interventions, these could be used to support patient care, thus reinforcing therapy adherence.

Evaluation of psychological status is particularly important at the end of pediatric care when patients who remain growth hormone–deficient transition to adult care in order to continue growth hormone therapy to optimize benefits of therapy beyond growth. Digital tools can be used to explain the pathway changes and specific needs to children and young adults, and can also provide feedback to refine care pathways.

Safety Assessments

Medical devices should also enable and encourage safety, with mechanisms built into the reporting platforms to individualize according to the specific diagnosis, therapy device, and condition of the patient. The reporting mechanism for safety concerns needs to be carefully considered to determine who should receive and respond to reports. Physicians could also be alerted to any problems in order to differentiate between

XSL•FO
RenderX

background symptoms of the condition and adverse events potentially related to therapy.

Brainstorming Exercise Responses From the Patient/Parent/Caregiver Perspective

Patient Education

Physician perspectives on opportunities and eHealth tools relating to patients, parents, or caregivers predominantly focused on education, largely concerning patient awareness, access to trusted information, and increased remote training. Videoconferencing tools are already being used for this to some extent, but more online tools involving apps, websites, medical portals, and search resources are needed to provide information that is accurate, trustworthy (ie, endorsed or produced by reputable sources with knowledge in the area), and easily understood. These tools could also be used to increase access to and interaction with health care personnel; however, access may need to be limited to avoid out-of-hours timing, but this could be mitigated by use of technologies such as virtual assistants or “chatbots ” to provide automated answers.

Patient-Reported Outcomes

Digital techniques to accurately measure height at home would enable growth to be monitored without the need for clinical review. These methods could also detect growth deceleration, with integration into electronic health records and prompting alerts sent to patients, parents, or caregivers. Therapy-related anxiety and psychological problems could be aided through games to generate interest in diagnosis and therapy, and to reduce needle anxiety. Appropriate tools could be developed to enhance psychological care, although it was noted that language barriers and digital access problems would need to be overcome to avoid digital exclusion and polarization of patients. Behavioral management may be enhanced through educational tools with a holistic approach, incorporating factors such as good nutrition and exercise to improve metabolic and physical outcomes beyond growth.

Brainstorming Exercise Responses From the Clinic Nurse Perspective

Responses in regard to nurses, similar to those from physicians, were more often related to process, including support for adherence, and on the medical devices used for therapy delivery. These patient-support tasks are frequently the responsibility of specialized nurses. Difficulties were noted in the delivery of roles, including patient testing, education. and ongoing support, which could be made easier by improved digitalization of and access to records, telemedicine technologies, and remote monitoring; eHealth tools could relieve nurses of some duties, yielding more time for personal interaction with the patient.

Responses also indicated challenges in the receipt and delivery of training and education to nurses around the management of growth failure and therapy, with limited opportunities for learning. In some counties, clinics do not have specialist nurses, and responsibilities may be inadequately defined, with no clear career paths. In such situations, online interactive learning resources could support training.

During growth hormone therapy, virtual reality or augmented reality immersive experiences could help with training and distraction during injections and blood sampling. During transition from pediatric to adult care, digital tools can assist nurses in providing psychological support and education for patients.

eHealth Literacy Survey

The questionnaire results indicated that the majority of the participants felt that eHealth tools were useful, but some were uncertain about evidence for their usefulness. There was also some uncertainty about what eHealth tools are currently available and how to use them. Most felt that digital tools are important and that they had the skills to use them, but many lacked confidence in their use largely due to the perceived lack of evidence. The respondents indicated that more data on the effectiveness of eHealth tools need to be presented for mainstream use in clinical practice, and interoperability would be required for routine clinical use.

Pediatric Growth Disorders and Growth Hormone Therapy Management Framework

From the workshop and questionnaire information, we devised a framework for developing eHealth tools for growth disorders and growth hormone therapy, as shown in Figure 5. The framework was devised to support integration of new eHealth tools into health care systems and assist health care professionals, patients, and families throughout the patient journey.

Discussion

Principal Findings

We are not aware of any similar studies and, to the best of our knowledge, this is the first time global experts in pediatric endocrinology have come together to consider possible eHealth solutions for the care of children and young people with growth disorders. Our work has led to greater understanding of the acceptability, confidence, and knowledge of the use of eHealth tools in growth disorders, and has opened up digital health care options to improve current clinical management.

Several key themes arose, which were aligned across the themed stakeholder groups considered: physicians, patients/parents/caregivers, and nurses. It was agreed that communication through established and novel technologies are likely to provide significant opportunities to improve interactions between clinicians across the health sector and to facilitate diagnosis, referral, and patient management. Importantly, telecommunication has the potential to improve management of patients who may be in isolated communities or rural areas remote to the central health care provider and to enable parents and caregivers to rapidly communicate with health care professionals when problems arise [32]. Connected digital systems will reduce travel time for families and reduce time of missed education, in turn supporting cost and efficiency savings for families and health services [33]. Integration of these systems into electronic patient records would optimize this process. Additionally, physicians suggested that parents and caregivers would value electronic processes to help them manage appointments, that administration tasks should be automated, and that improved interoperability between systems and within and across centers would allow sharing and integration of vital patient information.

Rapid development of technology could also facilitate the earlier identification of growth disorders through electronic screening programs, with the proviso that the input of height data is accurate. Thus, the development of a mobile phone or tablet-based tool that can accurately measure height in the home environment and that could link with a centralized electronic system may accelerate the identification and referral of patients with short stature and poor growth, reducing the prevalence of late diagnosis of rare disorders of growth where other comorbidities may exist [34-36]. However, a reliable electronic system for early identification of growth disorders is complex and will depend on the integration of systems that monitor height at home and in the clinical environment, with a high sensitivity and specificity [37].

Once a diagnosis of growth failure has been established, an accurate and validated digital tool to monitor height will provide a means of assessing response to growth hormone therapy. Response to growth hormone therapy and improved adherence are both predictors of adult height [23,38,39]. Fundamental to this is the use of artificial intelligence to understand and analyze patient growth data, which can be fed into an electronic health record. When patients become established on growth hormone, clinicians would value a unified means of predicting adult height, encompassing the diverse growth prediction models currently available [40-43]; identifying the impact of growth hormone through prediction models on digital platforms that link to or are embedded in patient records can aid optimization of therapy.

Education was identified as a key area to which eHealth tools could add significant value. Physicians, nurses, and families (including the patients) require relevant and trusted information delivered in an engaging, and developmentally and professionally appropriate way to support the rapid acquisition in knowledge [44,45]. Recent advances in medical education for patients and clinicians have focused on using immersive virtual and augmented reality (AR/VR), app-based interactive training, virtual assistants to answer questions in real-time, 3D modeling, and online real-time education [8,46,47]. In particular, virtual assistants or chatbots have been identified as a technology suitable for supporting patient groups with focused information available in real time [48-50]. One of the challenges in using novel technology-based education is ensuring that hard-to-reach and vulnerable groups have appropriate access to and understanding of these tools [51,52].

Participants also suggested that eHealth tools could be developed to support adherence to growth hormone therapy through the identification of therapy-related psychological and medical issues, potentially via access to data on patient-reported outcome measures [53] or ecological momentary assessments [54]. Given

XSL•FO
RenderX

the psychological and physiological changes that take place during growth and puberty, these tools will need to be versatile and responsive, supporting patients and their families during the transition from pediatric to adult health care settings [55]; furthermore, to mitigate the risk of future health complications, such tools need to reiterate education and prevent disengagement from health care [15,16,56]. Importantly, eHealth tools were also cited as an option to address some of the psychological issues identified, with digital platforms providing online psychological support; technologies including VR or AR could provide a means of reducing anxiety during painful procedures such as growth hormone injections, similar to the application of VR and AR as distraction tools in other conditions [8,46,56,57].

Although there was clear support for eHealth solutions to address challenges in the diagnosis and management of patients with growth disorders, results from the e-literacy questionnaire identified a need to ensure that the development and implementation of these tools is supported by a well-established evidence base and that integration within a clinical or home-based setting is supported by education and training.

The workshops and questionnaires have provided information that has led us to devise a framework to support the development of eHealth tools for growth disorders, which may also be relevant to other long-term conditions. The framework (Figure 5) has been devised as an eHealth overlay for the patient journey from identification of a problem, to diagnosis, implementation of therapy, and subsequent monitoring and support. The framework maps directly onto the patient pathway and thus will provide the relevant context for those developing novel technologies. It will support appropriate service and health care integration of new eHealth tools for health care professionals, patients, and families, which in turn will provide reassurance that technology development has appropriately addressed unmet needs for growth disorders.

Limitations

Participants in this study were chosen for their experience in childhood growth disorders and active interest and involvement in use of eHealth tools. However, participation was limited to physicians, albeit with significant experience in this field of medicine; thus, the views relating to patients, parents, caregivers, and nurses may be skewed by personal reflections and opinions, but responses were perhaps more directed and uniform. The relatively small number that provided responses and opinions may not be wholly representative of the pediatric endocrine community although they represented a wide geographical distribution, allowing us to consider the variation in health care systems in different countries. Due to logistic reasons, face-to-face meetings were not ideal, and we decided to conduct the workshops online, which might have restricted some activities that could have been better conducted through a face-to-face format. Although all participants were highly experienced pediatric endocrinologists, their differing backgrounds meant that there was an inherent variation in cultural perspectives, health care system setups, funding arrangements, and governmental priorities; however, this broad range of experiences could be viewed as reflective of real-world scenarios. Despite all participants having a strong interest in the use of digital techniques, eHealth tools may sometimes be seen to be purely theoretical, as they encompass technologies that could potentially be devised but are not yet established. The integration and adoption of our proposed eHealth framework into clinical practice remains to be assessed and rigorously tested in future studies.

Conclusions

By bringing together established and experienced pediatric endocrinologists from across the world, we have developed a framework for the implementation and integration of eHealth tools to support the identification and ongoing referral of children with growth disorders, and the subsequent management and monitoring of growth hormone therapy. Integration of eHealth tools in the management of patients with growth disorders will support height screening and regular height monitoring; improve communication; facilitate the delivery of and access to training and education for health care providers, patients, parents, and caregivers; improve therapy adherence; enable the earlier identification of problems; and support patients and families during their journey. Digitalization can enhance the collection of data from multiple sources to support research in low prevalence diseases, such as those treated with growth hormone, to build on best practice by providing an additional incentive for research collaboration using eHealth tools. The use of eHealth tools in the patient pathway has the potential to increase efficiency in care delivery while introducing cost benefits. The involvement of both service providers and service users is of crucial importance for the successful design and implementation of eHealth solutions. The credibility of these eHealth tools will be dependent on appropriate clinical evaluation of established and emerging digital tools. Moreover, training health care professionals and patients and their families in the use of eHealth tools while ensuring successful service integration and ongoing support will prevent the misuse or rejection of eHealth tools and unintended negative health consequences.

We conclude that novel eHealth tools have considerable potential for supporting patients and their families, and for health care providers in the detection and management of growth disorders. We envisage that our work may provide a blueprint for other chronic conditions that could benefit from eHealth tools in supporting long-term adherence.

Acknowledgments

This research is supported by Merck KGaA (Darmstadt, Germany). PD is also in receipt of research support for this study from the National Institute of Health Research (NIHR) Children and Young People MedTech Co-operative; the views expressed are those of the author and not necessarily those of the NHS (National Health Service) the NIHR, or of the Department of Health. The authors would like to thank Dr Peter Bates (Cambridge Medical Writing Services, United Kingdom) for medical writing

Abstract

As of March 2021, the SARS-CoV-2 virus has been responsible for over 115 million cases of COVID-19 worldwide, resulting in over 2.5 million deaths. As the virus spread exponentially, so did its media coverage, resulting in a proliferation of conflicting information on social media platforms—a so-called “infodemic.” In this viewpoint, we survey past literature investigating the role of automated accounts, or “bots,” in spreading such misinformation, drawing connections to the COVID-19 pandemic. We also review strategies used by bots to spread (mis)information and examine the potential origins of bots. We conclude by conducting and presenting a secondary analysis of data sets of known bots in which we find that up to 66% of bots are discussing COVID-19. The proliferation of COVID-19 (mis)information by bots, coupled with human susceptibility to believing and sharing misinformation, may well impact the course of the pandemic.

Introduction

Globally, 2020 has been characterized by COVID-19, the disease caused by the SARS-CoV-2 virus. As of March 2021, the COVID-19 pandemic has been responsible for over 115 million documented cases, resulting in over 2.5 million deaths. The United States accounts for 24.9% of the world’s COVID-19 cases, more than any other country [1].

As the virus spread across the United States, media coverage and information from online sources grew along with it [2]. Among Americans, 72% report using an online news source for COVID-19 information in the last week, with 47% reporting that the source was social media [3]. The number of research articles focusing on COVID-19 has also grown exponentially; more research articles about the disease were published in the first 4 months of the COVID-19 pandemic than throughout the entirety of the severe acute respiratory syndrome (SARS) and Middle East respiratory syndrome (MERS) pandemics combined [4]. Unfortunately, this breadth, and the speed with which information can travel, sets the stage for the rapid transmission of misinformation, conspiracy theories, and “fake news” about the pandemic [5]. One study found that 33% of people in the United States report having seen “a lot” or “a great deal” of false or misleading information about the virus on social media [3]. Dr Tedros Adhanom Ghebreyesus, the Director-General of the World Health Organization, referred to this accelerated flow

XSL•FO
RenderX

of information about COVID-19, much of it inaccurate, as an "infodemic" [6].

Though the pandemic is ongoing, evidence is emerging regarding COVID-19 misinformation on social media. Rumors have spread about the origin of the virus, potential treatments or protections, and the severity and prevalence of the disease. In one sample of tweets related to COVID-19, 24.8% of tweets included misinformation and 17.4% included unverifiable information [7]. The authors found no difference in engagement patterns with misinformation and verified information, suggesting that myths about the virus reach as many people on Twitter as truths. A similar study demonstrated that fully false claims about the virus propagated more rapidly and were more frequently liked than partially false claims. Tweets containing false claims also had less tentative language than valid claims [8].

This trend of misinformation emerging during times of humanitarian crises and propagating via social media platforms is not new. Previous research has documented the spread of misinformation, rumors, and conspiracies on social media in the aftermath of the 2010 Haiti earthquake [9], the 2012 Sandy Hook Elementary School shooting [10], Hurricane Sandy in 2012 [11], the 2013 Boston Marathon bombings [12,13], and the 2013 Ebola outbreak [14].

Misinformation can be spread directly by humans, as well as by automated online accounts, colloquially called "bots." Social bots, which pose as real (human) users on platforms such as Twitter, use behaviors like excessive posting, early and frequent retweeting of emerging news, and tagging or mentioning influential figures in the hope they will spread the content to their thousands of followers [15]. Bots have been found to disproportionately contribute to Twitter conversations on controversial political and public health matters, although there is less evidence they are biased toward one "side" of these issues [16-18].

This paper combines a scoping review with an unpublished secondary analysis, similar in style to Leggio et al [19] and Zhu et al [20]. We begin with a high-level survey of the current bot literature: how bots are defined, what technical features distinguish bots, and the detection of bots using machine learning methods. We also examine how bots spread information, including misinformation, and explore the potential consequences with respect to the COVID-19 pandemic. Finally, we analyze and present the extent to which known bots are publishing COVID-19–related content.

What Are Bots?

Before addressing issues surrounding the spread of misinformation, we provide a definition of bots, describe their typical features, and explain how detection algorithms identify bots.

Definition and Identification

Bots, shorthand for "software robots," come in a large variety of forms. Bots are typically automated in some fashion, either fully automated or human-in-the-loop. There is a common conception that all bots spam or spread malware, but this is not the case. Some bots are benign, like the Twitter account @big_ben_clock, which impersonates the real Big Ben clock by tweeting the time every hour [21]. Others have even been used for social good, such as Botivist, which is a Twitter bot platform used for recruiting volunteers and donations [22]. Groups of bots can function in coordination with each other, forming what are called botnets [23]. One botnet of roughly 13,000 bot accounts was observed tweeting about Brexit, with most of these bot accounts disappearing from Twitter shortly after the vote [24]. Bots of all types are ubiquitous on social media and have been studied on Reddit [25,26], Facebook [27], YouTube [28], and Twitter [29], among other platforms.

Given their large variety, bots are often organized into subclasses, a selection of which we discuss here. Content polluters are one subclass; these are "accounts that disseminate malware and unsolicited content." Traditional spambots, another subclass, are "designed to be recognizable as bots" [30]. Social bots—a newer, more advanced type of bot [31-33]—use "a computer algorithm that automatically produces content and interacts with humans on social media, trying to emulate and possibly alter their behavior." There are also hybrid human-bot accounts (often called cyborgs) [34], which "exhibit human-like behavior and messages through loosely structured, generic, automated messages and from borrowed content copied from other sources" [35]. It is not always clear which category a bot may fall into (eg, if a given social bot is also a cyborg).

Various methods have been used to identify bots "in the wild," so as to build the data sets of known bots used to train bot-detection algorithms. One method, the "social honeypot" [36], mimics methods traditionally used by researchers to monitor hacker activity [37] and email harvesting [38]. Specifically, social honeypots are fake social media profiles set up with characteristics desirable to spammers, such as certain demographics, relationship statuses, and profile pictures [39]. When bots attempt to spam the honeypots (by linking malware-infested content or pushing product websites), researchers can easily identify them.

Technical Features of Bots

Overview

Features that distinguish bots from humans roughly fall into three categories: (1) network properties, such as hashtags and friend/follower connections, (2) account activity and temporal patterns, and (3) profile and tweet content. These feature categories have the advantage of being applicable across different social media platforms [27].

Network Properties

Networks based on friend/follower connections, hashtag use, retweets, and mentions have been used in a number of studies that seek to identify social bots [40-43], exploiting network homophily (ie, humans tend to follow other humans and bots tend to follow other bots). As bots become more sophisticated, network properties become less indicative of them; studies have found groups of bots that were able to build social networks that mimic those of humans [44].

XSL•FO
RenderX

Account Activity and Temporal Patterns

Patterns of content generation can be good markers of bots. Bots compose fewer original tweets than humans, but retweet others' tweets much more frequently, and have a shorter time interval between tweets [40]. Ferrara et al [31] found that humans are retweeted by others more than are bots, suggesting that bots may struggle to compose convincing or interesting tweets. However, many others have found this not to be the case [15,16,33]. Finally, humans typically modify their behavior during each online session; as the session progresses, the density of new tweets decreases. Bots do not engage in these "sessions" of social media usage, and accordingly do not modify their behavior [45].

Profile and Tweet Content

Profile metadata such as account age and username can be used to identify social bots. Ferrara et al [31] showed that bots have shorter account age (ie, the accounts were created more recently), as well as longer usernames. Automatic sentiment analysis of tweet content has also been studied as a means of distinguishing bots from humans. One study found humans expressed stronger positive sentiment than bots, and that humans more frequently "flip-flopped" in their sentiment [42].

Detection of Bots

Over the past decade, several teams have sought to develop algorithms that successfully identify bots online. Social media platforms use similar algorithms internally to remove accounts likely to be bots. These algorithms originated in early attempts to identify spam emails [46], social phishing [47], and other types of cybercrimes [37]. With the advent of online communities, cybercriminals turned their attention to these sites, eventually creating fake, automated accounts at scale [48]. Table 1 provides a summary of several prominent papers on bot identification. We note that the details of specific machine learning algorithms are beyond the scope of this paper and therefore are not included in this manuscript.

Table 1. Review of state-of-the-art detection of bots on Facebook and Twitter.

Type and reference	Platform	Number of accounts	Features			Model	Metric	Predictive accuracy
			N[a]	T[b]	C[c]			
Human judgment (manual annotation)								
Cresci et al (2017) [33]	Twitter	928				Manual annotation	F1-score	0.57
Automatic methods								
Ahmed and Abulaish (2013) [27]	Facebook and Twitter	320 (Facebook), 305 (Twitter)			✓	Naïve Bayes, decision trees, rule learners	Detection rate	0.96 (Facebook), 0.99 (Twitter)
Dickerson et al (2014) [42]	Twitter	897	✓	✓	✓	Gradient boosting	Area under the curve	0.73
Cresci et al (2017) [33]	Twitter	928		✓		Digital DNA sequences	F1-score	0.92
Varol et al (2017) [41]	Twitter	21,000	✓	✓	✓	Random forests	Area under the curve	0.95
Kudugunta and Ferrara (2018) [49]	Twitter	8386			✓	AdaBoost	Area under the curve	>0.99
Mazza et al (2019) [50]	Twitter	1000		✓		Long short-term memory networks	F1-score	0.87
Santia et al (2019) [51]	Facebook	1000			✓	Support vector machines, decision trees, Naïve Bayes	F1-score	0.72
Yang et al (2020) [52]	Twitter	137,520		✓	✓	Random forests	Area under the curve	0.60-0.99

[a]N: network properties.

[b]T: account activity and temporal patterns.

[c]C: profile and tweet content.

The first reference in Table 1 involved a manual annotation task in which raters were asked to label a Twitter account as human or bot. The fourth study listed in the table is the same as the first study; in this study, the same data set was evaluated by both human annotators and machine learning methods [33]. There was a large discrepancy in predictive accuracy (F1-score) between the two methods: 0.57 for the human annotators versus 0.92 for the automated method. Stated another way, human participants correctly identified social bots less than 25% of the time, though they were quite good at identifying genuine (human) accounts (92%) and traditional spambots (91%). These results suggest that social bots have a very different online presence from traditional spambots, or "content polluters"—and that this presence is convincingly human. Even if the human annotators are compared to the lowest scoring automated method (which we note is in a different domain and, thus, not directly comparable), the machine learning algorithm still provides a considerable boost in F1-score (0.57 versus 0.72).

XSL•FO
RenderX

There is no good way to compare all automated methods directly, as data sets are typically built in a single domain (ie, a single social media platform) and rapid advances in machine learning techniques prevent comparisons between models published even a few years apart. Furthermore, results suggest that models trained on highly curated bot data sets (eg, groups of accounts promoting certain hashtags or spamming a particular honeypot) may not perform well at detecting bots in other contexts. Yang et al [52] used a large number of publicly available bot data sets, training machine learning models on each set and testing them on those remaining. The result was a wide range of predictive accuracies across different bot data sets.

How Do Bots Amplify and Spread Misinformation?

We adopt the definition of misinformation used by Treen and colleagues: "misleading [or false] information that is created and spread, regardless of intent to deceive" [53]. For the purposes of this paper, we include fake news and false conspiracy theories under this umbrella term.

Many features of bots likely enable them to be "super-spreaders" of misinformation. Bots have been shown to retweet articles within seconds of their first being posted, contributing to the articles going viral [15]. Moreover, the authors of this study found that 33% of the top sharers of content from low-credibility sources were likely to be bots, significantly higher than the proportion of bots among top sharers of fact-checked content. Similarly, in a study of bots and "anti-vaxxer" tweets, Yuan et al [18] found that bots were "hyper-social," disproportionately contributing to content distribution. Bots also employ the strategy of mentioning influential users, such as @realDonaldTrump, in tweets linking to false or misleading articles, and are more likely to do so than their human counterparts [15]. The hope is that these users will share the article with their many followers, contributing to its spread and boosting its credibility. "Verified" (blue check) Twitter users, often celebrities, have been shown to both author and propagate COVID-19–related misinformation [54]. Interestingly, the frequency of false claims about the 2020 election dropped dramatically in the week after former president Donald Trump was removed from the platform [55].

In light of findings that humans are largely unable to distinguish social bots from genuine (human) accounts [33], it is likely that humans unknowingly contribute to the spread of misinformation as well. Accordingly, one study found that in regard to low-credibility content, humans retweet bots and other humans at the same rate [15]. Similarly, Vosoughi et al [56] found that "fake news" articles spread faster on Twitter than true news articles because humans, not bots, were more likely to retweet fake articles. Given human susceptibility to both automated accounts and "fake news," some have warned that intelligent social bots could be leveraged for mass deception or even "political overthrow" [57].

There is reason to believe that bots have already infiltrated political conversations online. Leading up to the 2016 presidential election in the United States, 20% of all political tweets originated from accounts that were likely to be bots [16]. While it did not specifically implicate bots, one study found that a majority of "fake" or extremely biased news articles relating to the 2016 election were shared by unverified accounts—that is, accounts that were not confirmed to be human [58]. There is also evidence that bots spread misinformation in the 2017 French presidential election, though ultimately the bot campaign was unsuccessful, in part because the human users who engaged with the bots were mostly foreigners with no say in the election outcome [59]. Bot strategies specifically relevant to political campaigns include "hashtag hijacking," in which bots adopt an opponent's hashtags in order to spam or otherwise undermine them, as well as flagging their opponent's legitimate content in the hopes it gets removed from the platform [60].

Where Do Bots Come From?

The origin of social bots is a challenging question to answer. Given the aforementioned concerns of political disruption by social bots, one may assume that foreign actors create social bots to interfere with political processes. Indeed, the Mueller report found evidence of Russian interference in the 2016 US election via social media platforms [61], and Twitter reports removing over 50,000 automated accounts with connections to Russia [62]. However, locating the origin of a social media account is difficult, as tweets from these accounts are rarely geotagged. Rheault and Musulan [63] proposed a methodology to identify clusters of foreign bots used during the 2019 Canadian election using uniform manifold approximation and projection combined with user-level document embeddings. Simply put, the authors constructed communities of users via linguistic similarities, and identified members significantly outside these communities as foreign bots.

Of note, studies have shown that a majority of social bots focusing on election-related content originate domestically [63]. Reasons for a candidate or their supporters to employ social bots may be relatively benign, such as boosting follower counts or sharing news stories, or they may involve smear campaigns [64].

While the ability to investigate the origin and motive of social bots is difficult, the means to create a social bot are fairly easy to access. Social bots are available for purchase on the dark web, and there are tens of thousands of codes for building social bots on free repositories like GitHub [65]. Of note, the top contributors of bot-development tools for mainstream social media sites are the United States, the United Kingdom, and Japan. The authors of this paper also note the intelligence and capabilities of these freely available bots may be overstated.

Are Bots Tweeting About COVID-19?

In light of the COVID-19 "infodemic" and findings that social bots have contributed to misinformation spread in critical times, we sought to assess the number of known Twitter bots producing COVID-19–related content. To this end, we gathered a number of publicly available bot data sets from the Bot Repository [66]. These data sets include both traditional spambots and social

XSL•FO
RenderX

bots that were first identified through a number of different methods (see the original papers for more details).

Using the open-source Python package TwitterMySQL [67], which interfaces with the Twitter application programming interface (API), we were able to pull all tweets from 2020 for each bot in the combined data set. Of note, Twitter's API limits access to tweets and account information available at the time of collection. Tweets and accounts that have been deleted or made private since originally appearing in one of the above papers are not made available, meaning we had less data than what was reported in the original papers. Our final data set consisted of 3.03 million tweets from 3953 bots, with an average of 768.9 (SD 1145.4) tweets per bot, spanning January 1, 2020, to August 21, 2020.

From these data, we pulled tweets using a set of 15 COVID-19–related keywords, which have previously been used to identify COVID-19 tweets in a study tracking mental health and psychiatric symptoms over time [68]. Sample keywords include #coronavirus, #covid19, and #socialdistancing. We then counted the number of accounts that mentioned these keywords in tweets since January 2020. Table 2 shows the percentage of bot accounts in each data set currently tweeting about COVID-19. Original sample size refers to the number of bots identified in this data set, while current sample size is the number of currently active bots (ie, tweeting in 2020). Between 53% (96/182) and 66% (515/780) of these bots are actively tweeting about COVID-19.

Table 2. Open-source data sets of bots discussing COVID-19[a].

Reference	Year	Original sample size, n	Current sample size, n	Bots discussing COVID-19, n (%)
Lee et al [36]	2011	22,223	2623	1427 (54)
Varol et al [41]	2017	826	292	164 (56)
Gilani et al [69]	2017	1130	780	515 (66)
Cresci et al [33]	2017	4912	77	48 (62)
Mazza et al [50]	2019	391	182	96 (53)

[a]Original sample size is the number of bot IDs publicly released on the Bot Repository, while current sample size is the number of active accounts tweeting in 2020. Percentage discussing COVID-19 is the percentage of bots with at least one tweet containing a COVID-19 keyword out of those active in 2020.

Implications for the COVID-19 Pandemic

Here we have shown that a majority of known bots are tweeting about COVID-19, a finding that corroborates similar studies [68,70]. Early in the pandemic, one study found that 45% of COVID-19–related tweets originate from bots [71], although Twitter has pushed back on this claim, citing false-positive detection algorithms [72]. Another study showed that COVID-19 misinformation on Twitter was more likely to come from unverified accounts—that is, accounts not confirmed to be human [7]. In an analysis of 43 million COVID-19–related tweets, bots were found to be pushing a number of conspiracy theories, such as QAnon, in addition to retweeting links from partisan news sites [73]. Headlines from these links often suggested that the virus was made in Wuhan laboratories or was a biological weapon.

One limitation of our study is that we did not investigate the validity of COVID-19–related claims endorsed by bots in our analyses. It may be that bots are largely retweeting mainstream news sources, as was the case in a recent study of bots using #COVID19 or #COVID-19 hashtags [68]. However, previous research has connected bots to the spread of misinformation in other public health domains, such as vaccines [30] and e-cigarettes [74], and unsubstantiated medical claims surrounding the use of marijuana [75].

Such misinformation can have detrimental consequences for the course of the COVID-19 pandemic. Examples of these real-world consequences include shortages of hydroxychloroquine (a drug that is crucial for treating lupus and malaria) due to increased demand from people who believe it will protect them from COVID-19 [76,77]. This drug has been promoted as a preventative against COVID-19 on social media, even though several randomized controlled trials have found it ineffective, [78,79], and the National Institutes of Health recently halted its own trial due to lack of effectiveness [80]. Moreover, belief in conspiracy theories about COVID-19 is associated with a decreased likelihood of engaging in protective measures such as frequent handwashing and social distancing, suggesting that misinformation may even contribute to the severity of the pandemic [81]. In addition, exposure to misinformation has been negatively correlated with intention to take a COVID-19 vaccine [82].

We are certainly not the first to express concern with viral misinformation; in May 2020, Twitter began labeling fake or misleading news related to COVID-19 in an effort to ensure the integrity of information shared on the platform [83]. Facebook introduced even more controls, such as organizing the most vetted articles at the top of the news feed, banning antimask groups, and sending antimisinformation messages to users who have shared fake news [84]. However, these measures are designed to target humans. In light of the numerous viral rumors relating to COVID-19 and the US response to the pandemic, we believe that bots likely contributed to their spread.

Major social media platforms like Twitter and Facebook do have methods to curtail suspected bots. In 2018, Twitter banned close to 70 million suspicious accounts in a matter of months [85]. Facebook banned 1.3 billion suspicious accounts in the third quarter of 2020. The platform estimates these accounts represent 5% of its worldwide monthly active users. The vast

XSL•FO
RenderX

majority of suspicious accounts were identified using automated detection methods, but 0.7% were first flagged by human users, suggesting that everyday Facebook users concerned about malicious activity on the platform can contribute to efforts to ban these accounts [86].

Mitigation of the harmful effects of social bots can also occur at the policy level. In 2018, California became the first and only state to pass a law requiring social bots to identify themselves as such [87]. In 2019, Senator Dianne Feinstein proposed a similar bill federally; the bill would allow the Federal Trade Commission to enforce bot transparency and would prohibit political candidates from incorporating social bots in their campaign strategy [88]. The United States Congress has brought top executives from Facebook, Twitter, and Google to testify before Congress about Russian influence on their platforms in advance of the 2016 election [89]. Scholars have interpreted these actions as a sign that the government wishes to maintain the right to regulate content on social media—a prospect that brings concerns of its own [90]. Presently, content problems on social media platforms are almost exclusively dealt with by the owners of those platforms, usually in response to user complaints, but in the coming years we may see an increase in government oversight on these platforms, fueling concerns about state-sponsored censorship [91,92]. More fundamentally, some have argued that, before any actionable policy or automatic interventions can be enabled, ambiguities in both bot definitions and jurisdiction and authority need to be addressed [90].

Even as citizens, social media platforms, and policy makers converge on the notion that bots and misinformation are urgent problems, the methods used to address the issue have had mixed results. When social media platforms crack down on bots and misinformation, either through automated techniques or manual content moderation, they run the risk of censoring online speech and further disenfranchising minority populations. Content promotion and moderation can lead to arbitrary policy decisions that may be inconsistent across or even within platforms [93]. In one example, Facebook ignited a controversy when their moderators flagged a breastfeeding photo as obscene, leading to a large number of protests on both sides of the debate [94]. Automated methods suffer from similar drawbacks, with multiple studies showing that biases in machine learning models can have unintended downstream consequences [95]. For example, algorithms designed to detect hate speech were more likely to label a post as “toxic” when it showed markers of African American English [96].

Finally, there is a continued arms race between bot-detection algorithms and bot creators [21,33]. As bots inevitably become more intelligent and convincingly human, the means for identifying them will have to become more precise. We observed that the majority of known bots in a sample of publicly available data sets are now tweeting about COVID-19. These bots, identified between 2011 and 2019, were discovered before the pandemic and were originally designed for non–COVID-19 purposes: promoting product hashtags, retweeting political candidates, and spreading links to malicious content. The COVID-19 pandemic will eventually end, but we have reason to believe social bots, perhaps even the same accounts, will latch on to future global issues. Additionally, we can expect bot generation techniques to advance, especially as deep learning methods continue to improve on tasks such as text or image generation [97,98]. Bot creators will continue to deploy such techniques, possibly fooling detection algorithms and humans alike. In the end, we should not expect current detection techniques, self-policing of social media platforms, or public officials alone to fully recognize, or adequately address, the current landscape of bots and misinformation.

Acknowledgments

This work was supported in part by the Intramural Research Program of the National Institutes of Health, National Institute on Drug Abuse. MHW wrote the manuscript, with help from SG and AD. SG conceptualized the paper, with input from BC, HAS, and LU. SG performed the analyses on Twitter bots and created Tables 1 and 2. MHW, SG, AD, and MR all contributed to the literature review. LL and DHE provided crucial edits. All authors reviewed and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Real-world data are crucial to continuously improve the management of patients with rheumatic and musculoskeletal diseases (RMDs). The German RheumaDatenRhePort (RHADAR) registry encompasses a network of rheumatologists and researchers in Germany providing pseudonymized real-world patient data and allowing timely and continuous improvement in the care of RMD patients. The RHADAR modules allow automated anamnesis and adaptive coordination of appointments regarding individual urgency levels. Further modules focus on the collection and integration of electronic patient-reported outcomes in between consultations. The digital RHADAR modules ultimately allow a patient-centered adaptive approach to integrated medical care starting as early as possible in the disease course. Such a closed-loop system consisting of various modules along the whole patient pathway enables comprehensive and timely patient management in an unprecedented manner.

Current Challenges in Rheumatology

The efficacy and safety of treatments for patients with rheumatic and musculoskeletal diseases (RMDs) have continuously improved during previous decades. However, the combination of a declining number of rheumatologists [1] on the one hand and a rising life expectancy in developed countries on the other imposes a significant challenge to rheumatology care nowadays. The growing need for a professional evaluation of common symptoms, such as joint pain [2,3], can hardly be met by the number of available rheumatologists. Besides the lack of the latter, multiple factors contribute to the omnipresent diagnostic delay in rheumatology. Unspecific rheumatic symptoms are challenging to patients [4], general practitioners [5], and experienced rheumatologists [6] alike. Even the most advanced and innovative therapies cannot reverse the health impairment that manifests due to diagnostic delay. “Time is joint” depicts the concept of a timely diagnosis as an indispensable goal in rheumatology. Focusing on this goal could be more cost-effective and generate better outcomes than the development of new RMD drugs.

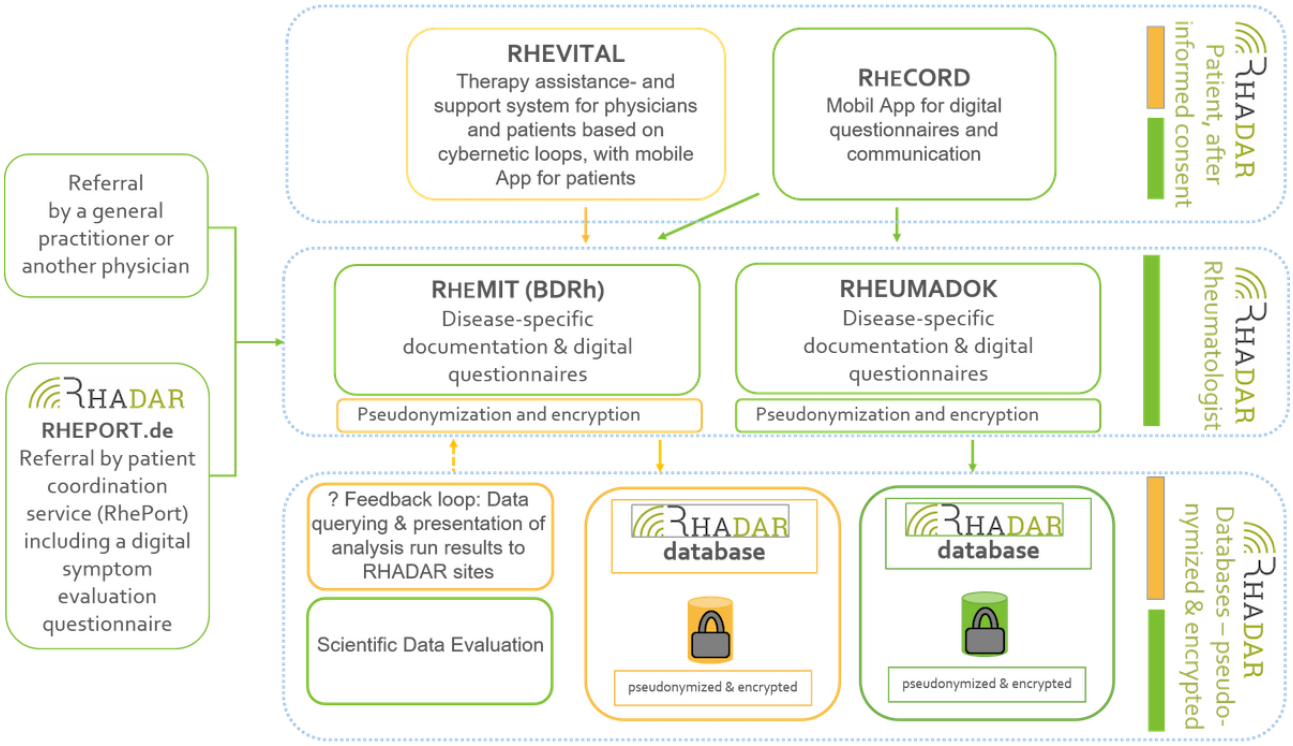
The shortage of rheumatologists translates to reduced doctor-patient time, especially for follow-up appointments. On average, patients have appointments every 3 to 6 months, while rheumatologists spend 15 minutes for each consultation. In complex diseases like RMDs, the long-term treatment effectiveness cannot be deduced from a single laboratory result like HbA_{1c} in diabetes mellitus. The current monitoring approach in rheumatology relies mainly on the collection of laboratory, clinical, and anamnestic snapshots. This “black box” monitoring approach hardly represents modern personalized medicine. Apart from diagnostic delay, timely treatment adaptions are hampered by the status-quo approach.

Rheumatology encompasses various rare diseases, with limited evidence aiding clinicians in their treatment decisions. Despite the growing number of therapeutic options and treatment guidelines, patients frequently feel like guinea pigs, with prescribed anti-inflammatory treatments not showing the expected therapeutic effect. Thus, clinical evidence supported by real-world data is needed to improve personalized evidence-based treatment decisions.

Potential of a Digital Patient Pathway in Rheumatology

The potential of digitalization in rheumatology has been depicted in recent publications [7-14]. The European League Against Rheumatism (EULAR) recommends that patients experiencing morning stiffness, joint pain, or swollen joints should see a rheumatologist no later than 6 weeks after symptom onset [15]. A symptom-based, patient-centered, digital screening approach could allow the successful implementation of this guideline. This low burden approach could effectively cut diagnostic delay. The omnipresence of smartphones in the RMD population [14] (irrespective of age) and instinctive digital symptom-based search for solutions [2,3,11,14] represent an immense potential to guide and triage patient streams effectively.

Electronic patient-reported outcomes (ePROs) allow for an individual, continuous, flexible, asynchronous, and need-adapted patient follow-up. Only few rheumatologists are currently using ePROs in clinical routine, mainly due to unawareness of suitable software solutions [13]. Similarly, only few RMD patients are aware of useful rheumatology-specific medical applications [14]. However, rheumatologists and patients are motivated to use ePROs and rheumatology-specific applications in the future [9,13,14,16]. A randomized controlled trial could show that an ePROs-based telehealth follow-up strategy can achieve similar disease control as conventional follow-up [17]. This need-adapted follow-up strategy could set precious resources free, which could thus reduce the diagnostic and monitoring delay in RMD patients. A parallel collection of ePROs may facilitate the integration of ePROs into the daily routine. Importantly, wearable-based ePROs produce continuous data sets and can accurately predict disease flares in patients with rheumatoid arthritis and axial spondyloarthritis [18].



Digital registries are crucial for RMD research. Only in a collaborative effort [19] significant amounts of data can be gathered to improve knowledge among rheumatologists. Registries are urgently needed to support RMD patients’ management based on evidence. Registries have helped to provide knowledge for rare diseases, such as myositis [20], specific patient scenarios, such as pregnancy [21], and the safety of biologic therapy [22]. Unfortunately, the data collection approach of most patient registries relies on cumbersome active and redundant manual data entry, which frequently lacks precision or completeness [23]. Values can be inconsistent, out of range, or even completely made up. Most importantly, data entry and employment often stop with the end of financial support [24]. Fortunately, most RMD patients are willing to share their data for research purposes [14].

RheumaDatenRhePort Patient Pathway

The RheumaDatenRhePort (RHADAR) registry (Figure 1) is based on a framework of complementary software modules covering the patient pathway from symptom onset through the disease course.

XSL•FO
RenderX

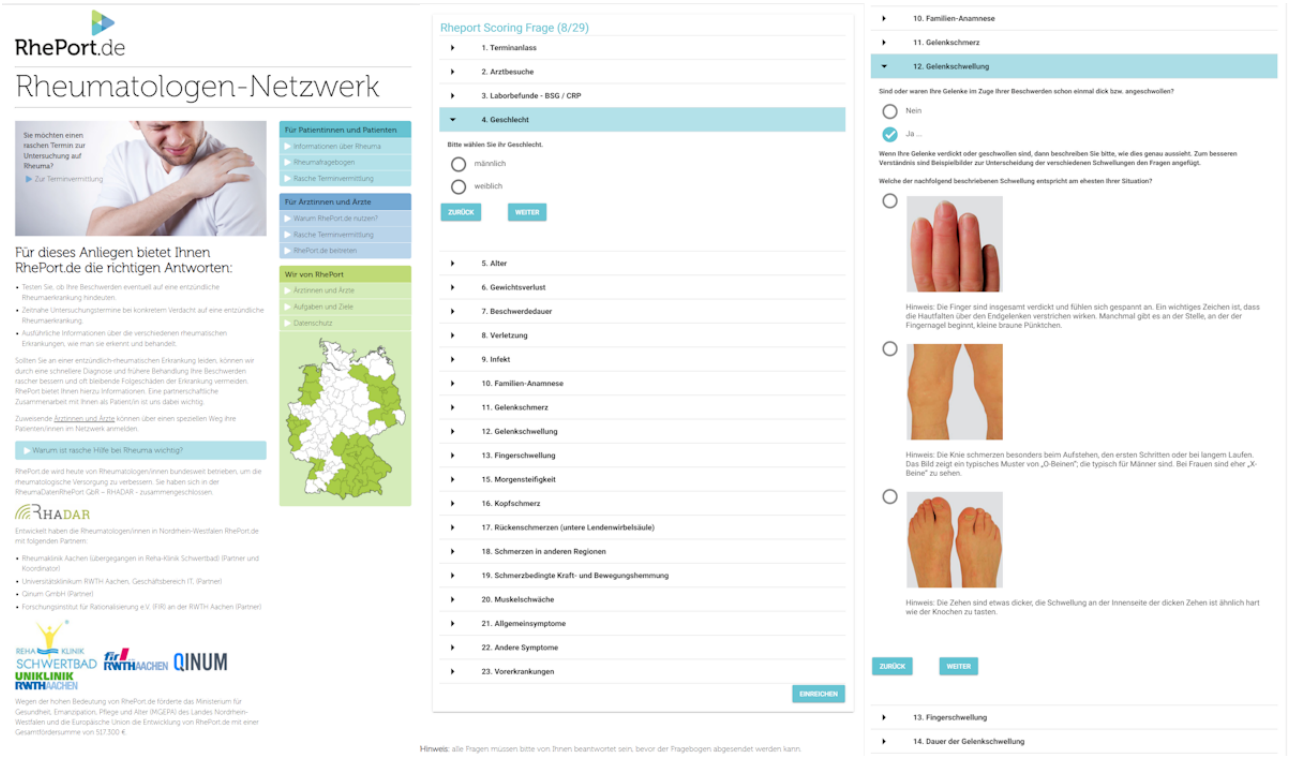


Figure 1. RHADAR patient and data pathway. Green boxes resemble established parts of the RHADAR network. Orange boxes are in preparation. RHADAR: RheumaDatenRhePort.

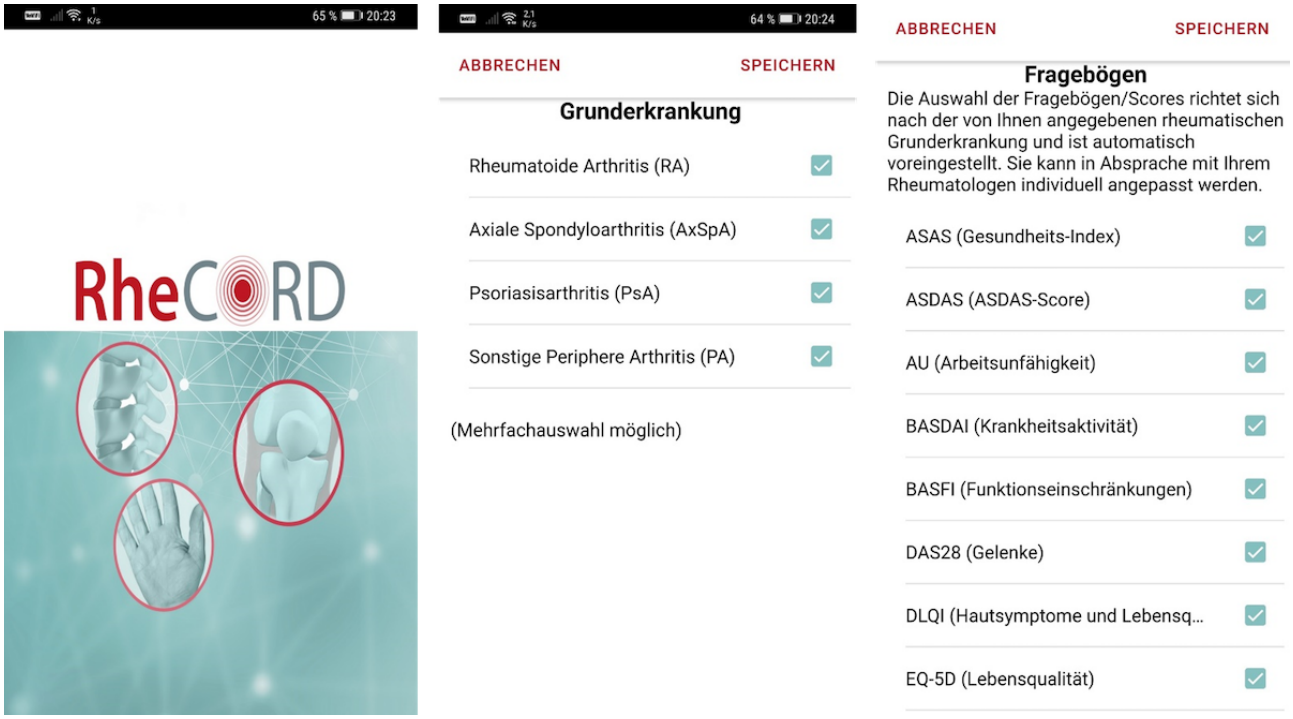
RhePort: Digital Gate to Rheumatology Care

RHADAR provides low burden direct digital access to a growing network of participating rheumatology sites. The gate module toward RHADAR rheumatology care is RhePort (Figure 2) [25]. Online registration is necessary to use RhePort, and users need to actively consent to the addition of their data to the RHADAR registry.

Figure 2. Screenshots of RhePort.

RhePort currently consists of a questionnaire that takes on average 9 minutes to complete [26]. It includes necessary demographic information, current symptoms, and already collected laboratory reports. Based on the patient's answers, RhePort calculates the RMD risk. The implemented algorithm refers to a weighted sum score. Individual weights were derived

XSL•FO
RenderX



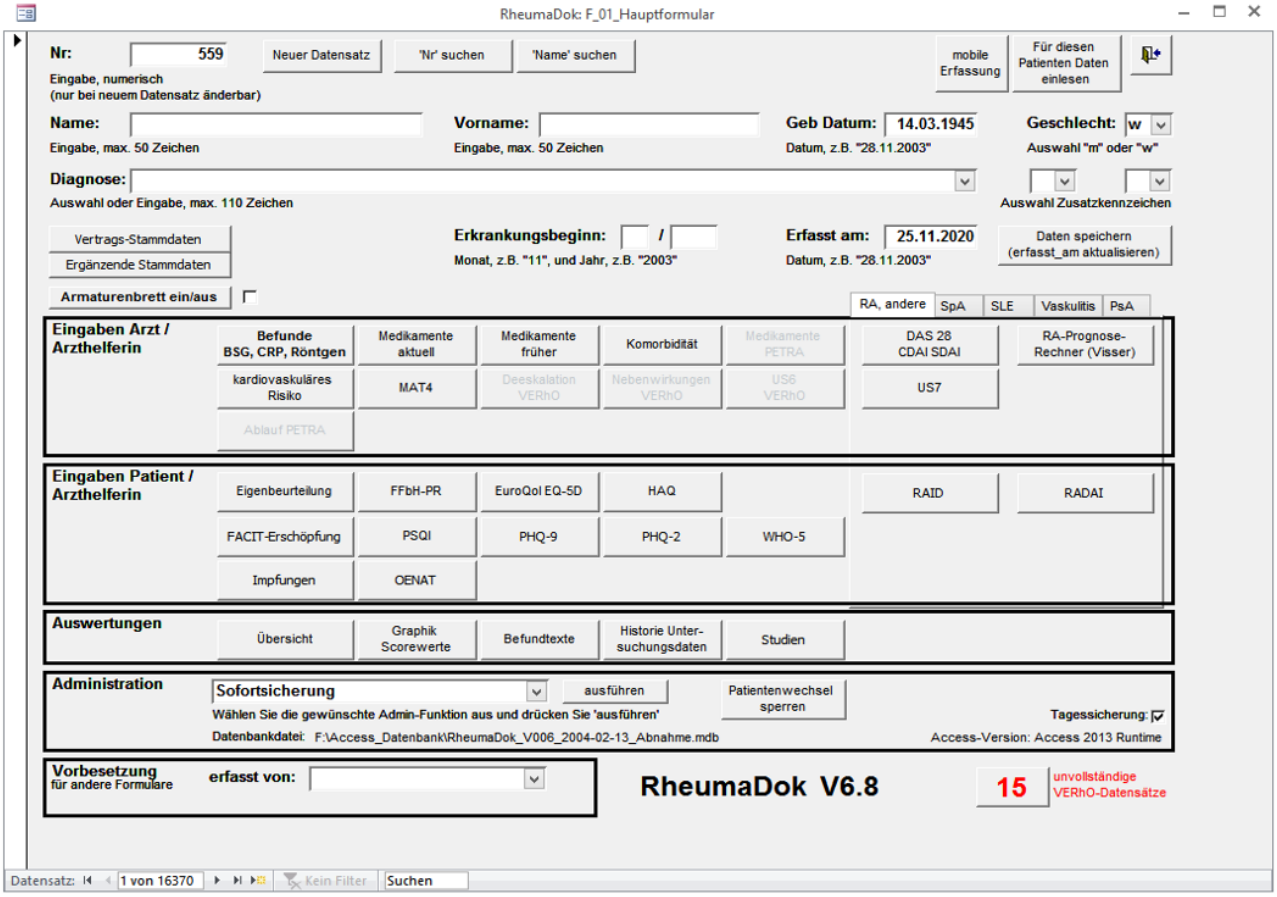
by consensus and the work experience of the RhePort founders. Based on the RhePort RMD risk score, an individual triage level is determined. Currently, there are four triage levels as follows: (1) very urgent, (2) urgent, (3) intermediate, and (4) unlikely. Based on the corresponding level, the patient gets access to locally available RHADAR rheumatology site appointments.

The questionnaire threshold focuses on sensitivity, that is, omitting false-negative ratings. Furthermore, participating rheumatology sites are encouraged to use RhePort only on a complimentary basis. Proft et al recently showed that an online self-referral strategy can successfully be used in addition to the traditional physician-based referral [27]. By including patients based on symptoms, at-risk RMD patients are included in the registry as well. In an interim analysis of a head-to-head randomized controlled trial, the diagnostic accuracy of RhePort was similar to an artificial intelligence–based symptom checker regarding the presence of RMDs [26].

RheCORD: Digital Companion App

RheCORD (Figure 3) [28] is a rheumatological medical app currently being developed to enable the collection of ePROs. RheCORD gives insights into the patient's symptom state between consultations or before an upcoming appointment on the same day. The ePROs to be collected can individually be determined by the patient [14,29] and local rheumatology site [13] via shared decision-making. The app provides multiple optional secondary features, such as medication and appointment reminders. Feature selection and app development are carried out with respect to guidelines [30,31], app analysis [31], and patient insights [14,29]. RheCORD is based on the previous CE-certified medical apps RheumaLive, AxSpALive, and PsALive. RHADAR sites provide a free soft token and password to the patient via a QR code to enable encrypted data transfer to the site.

Figure 3. Screenshots of RheCORD.

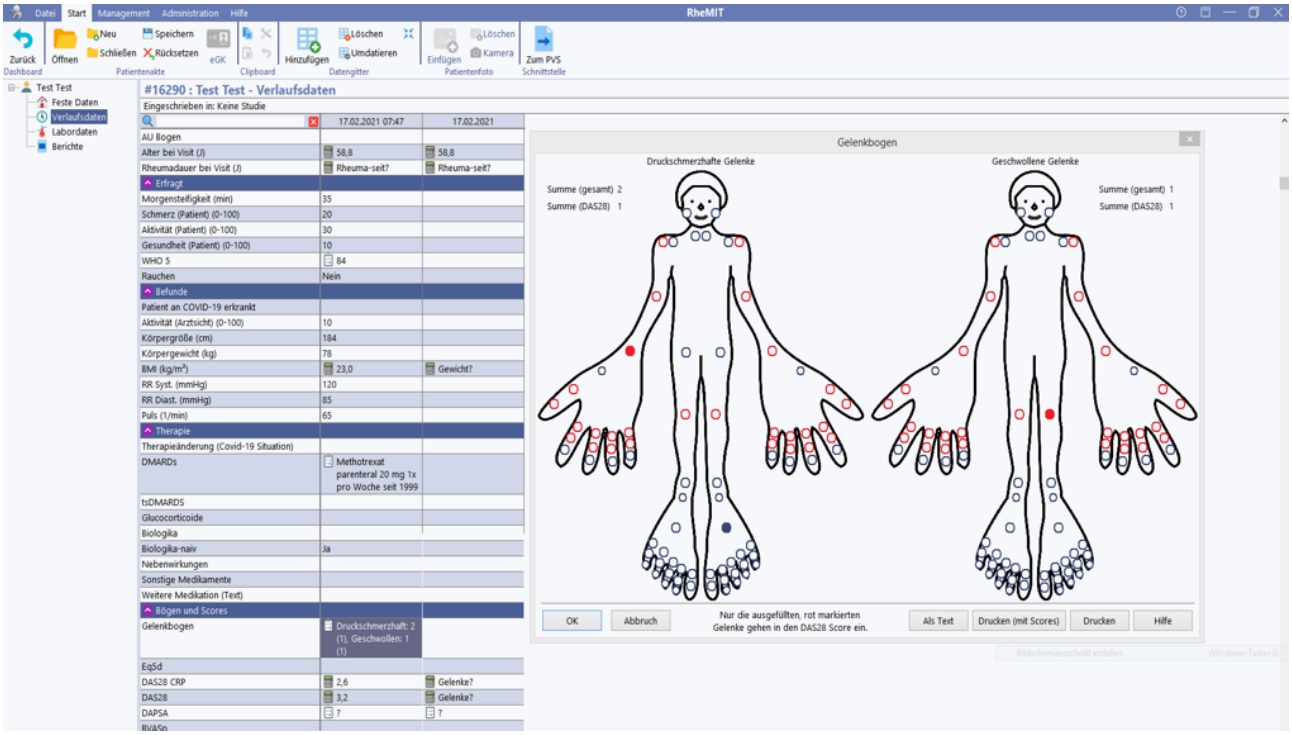


RheumaDok

RheumaDok (Figure 4) is the current core application used by the RHADAR system for patient data collection. It is a Microsoft Access (Microsoft Corp) database developed in Visual Basic for Applications and is available free of charge for rheumatologists in Germany who are members of the German Rheumatologists' Professional Association (Berufsverband Deutscher Rheumatologen [BDRh]). This database was developed by the Nils Körber und Joachim Elgas GbR. In the months ahead, RheumaDok will be replaced by RheMIT.

XSL•FO
RenderX

Figure 4. Screenshot of RheumaDok.



RheMIT: Clinical Documentation Software

RheMIT (Figure 5) is currently becoming the standard clinical documentation software for rheumatologists in Germany. The software has been developed and adapted by itc-ms.de for the German Rheumatologists' Professional Association (BDRh) [7]. The software offers standardized entry masks to document the patient's disease course at each consultation, including standard disease activity measures, general or disease-specific PROs, demographic characteristics, comorbidities, and current as well as previous antirheumatic treatments. If patients provide their consent, pseudonymized information will be uploaded to the RHADAR registry.

XSL•FO
RenderX

Figure 5. Screenshot of RheMIT.

RHADAR Registry

All information from RheCORD and local RheumaDok database instances are pseudonymized at each participating site. Subsequently, data are merged in a mutual database. The responsible data protection authority approved the current RHADAR database environment to ensure data privacy according to legislation. Patients participating in the RHADAR network have to complete an informed consent form before their initial data entry. Participation is voluntary for each patient. Participants and patients refusing to participate are treated equally, following national guidelines and rheumatologic care standards in Germany. As of September 2020, 22 rheumatologists at eight sites provided data to the RHADAR registry, including a total of 15,908 patients.

RHADAR Outlook

RHADAR software modules are continuously being improved based on new technological standards, user preferences, and scientific literature. For instance, a machine-learning approach to improve the triage performance of the RhePort algorithm is being evaluated based on current data. The implementation of an objective, standardized, and evidence-based triage algorithm seems crucial. Additionally, a complementary software module, RheVITAL [32], is under development in cooperation with the largest German patient organization, the German Rheumatism League (“Deutsche Rheuma-Liga”), to facilitate RMD disease management. Several registry analyses are being carried out and are set to directly impact future RMD management. A new database is currently under construction, and it will include data from all current and future software modules. Growing awareness of the integrative RHADAR system and its distribution will foster networking of rheumatology sites.

Acknowledgments

The authors thank all patients, partners, and collaborators for their support of the RHADAR registry. The authors would especially like to thank Monika Ronneberger, Praxedis Rapp, Jörg Wendler, Sonja Baltrusch, Florian Popp, Patrizia Sternad, Alexandra Edhofer, Ernestina Guillen Poveda, Yella C Rottländer, Sybille Kramer, Benjamin Schulte, Ramona Merkle, and Dorthe Gruber for their support in the data acquisition process and during data completion. The authors would like to thank Nils Körber, the developer of the initial RHADAR database, for his support and consultation during the project roll out; Michael Schumann, the developer of the successor RHADAR database, for his support and cooperation; and Achim Fricker, the cooperation partner developing RhePort with the founders, for his support. This study was funded by the RheumaDatenRhePort GbR, Bahnhofstr. 32, 82152 Planegg, Germany.

The members of the RHADAR Group, Planegg, Germany includes Monika Ronneberger, Praxedis Rapp, Jörg Wendler, Sonja Baltrusch, Florian Popp, Patrizia Sternad, Alexandra Edhofer, Ernestina Guillen Poveda, Yella C Rottländer, Sybille Kramer, Benjamin Schulte, Ramona Merkle, Dorthe Gruber, Nils Körber, and Achim Fricker.

Authors' Contributions

All authors wrote, reviewed, and approved the final manuscript.

Conflicts of Interest

WV, CD, SK, PB-B, and MW are members of RheumaDatenRhePort. WV, CD, and PB-B were involved in the development of Rheport. JK, AZ, TW, and SPF are members of the scientific board of RheumaDatenRhePort.

RhePort was developed and provided by the Verein zur Förderung der Rheumatologie eV, Würselen, Germany, and QINUM GmbH, Cologne, Germany. The development was supported by the government of Northrhine-Westfalia, Germany, and by the European Union (EFRE; AZ: 005-GW02-075A). The maintenance of this service has been supported by AbbVie, Novartis, Chugai, UCB, and Sanofi-Aventis. RheVITAL was developed and provided by the Verein zur Förderung der Rheumatologie eV, Würselen, Germany; QINUM GmbH, Cologne, Germany; and the Martin-Luther- Universität Halle, Halle, Germany. The development was supported by the government of Northrhine-Westfalia, Germany, and by the European Union (EFRE; Förderkennzeichen: EFRE-0800750). RheumaDok and the RHADAR database were developed and technically implemented by Nils Körber and Joachim Elgas GbR, Erlangen, Germany. RheMIT has been developed for the German Rheumatologists' Professional Association (Berufsverband Deutscher Rheumatologen) by itc-ms.de, Marburg, Germany. The app RheCORD is the property of the RheCordHealthCare GmbH. It was preceded by AxSpALive, PsALive, and RheumaLive. The latter three were sponsored by UCB Pharma GmbH, Monheim, Germany. All apps were developed and technically implemented by Star Healthcare Management GmbH, Cologne, Germany. JK has received research support from Novartis Pharma GmbH to evaluate RhePort.

GG receives speaker and consulting fees from Abbvie, Celgene, Chugai, Gilead, Novartis, and UCB. CK, KK, and SS-M are members of RheumaDatenRhePort GbR that had part of the software developed as described in this publication. FS is part of the advisory board at Abbvie, Gilead, Novartis, and Sanofi Aventis. ME has received remunerations from RheumaDatenRhePort GbR for statistical data analyses & consultation.

The RHADAR GbR has received honoraria from UCB Pharma GmbH, Sandoz Deutschland/Hexal AG, and Lilly GmbH, and research support from Novartis Pharma GmbH.

Abstract

Artificial intelligence–driven voice technology deployed on mobile phones and smart speakers has the potential to improve patient management and organizational workflow. Voice chatbots have been already implemented in health care–leveraging innovative telehealth solutions during the COVID-19 pandemic. They allow for automatic acute care triaging and chronic disease management, including remote monitoring, preventive care, patient intake, and referral assistance. This paper focuses on the current clinical needs and applications of artificial intelligence–driven voice chatbots to drive operational effectiveness and improve patient experience and outcomes.

artificial intelligence; conversational agent; COVID-19; virtual care; voice assistant; voice chatbot

Review of Voice Assistants in Health Care

A cutting-edge development in the field of artificial intelligence (AI) and machine learning has enabled verbal communication interfaces between users and voice assistants (VAs), which are synonymously termed “voice chatbots” or “conversational agents.” VAs, exemplified by Apple’s Siri, Amazon Alexa, and Google Assistant, are a software layer embedded in a standalone smart speaker, such as Home Pod, Amazon Echo, Google Home, or smartphones, allowing for the interpretation of human speech. Technically, conversational agents are cloud-based services performing speech-to-text and text-to-speech tasks that are initiated by a person evoking a wake-word followed by a voice command [1]. The implementation of VAs in health care has the potential to support the delivery of care in a routine clinical setting, especially when functionalized by a computerized clinical decision support system (CDSS). These robotic process automation (RPA) chatbots have the decision-making ability of a human health care professional to perform rule-based tasks (ie, digital patient triaging) [2]. Voice technology has already been tested in various applications to support everyday clinical activities [3-12]. Its applications include the following:

1. Education-level services answering frequently asked questions based on a knowledge database (eg, first aid instructions).
2. Optimization of processes (eg, medication reminders, prescription refills, appointment scheduling, bedside assistants, and paperless documentation).
3. Patient support with personalized rule-based clinical instructions (eg, instructions to reduce carbohydrate intake among patients with diabetes mellitus).
4. Data collection services (eg, collection of patient-reported outcomes, biometric tracking, and identification of health status changes exemplified by the collection of medical history or remote home monitoring; classified by the Food and Drug Administration [FDA] as Medical Device Data Systems [13,14]).

XSL•FO
RenderX

5. Medical device–grade solutions designed to diagnose, treat, cure, mitigate, or prevent disease, termed "Software as a Medical Device" by the FDA [15], combining voice interface and CDSS.

Education-level VA services have been implemented by health care organizations and provide guidelines, instructions, and navigation for patients, such as WebMD [16], Cleveland Clinic's Tip of the Day [17], Boston Children's KidsMD [18], Mayo Clinic's First Aid [19], American Red Cross' First Aid [20], Mayo Clinic's News Network [21], Boston Children's My Children's Enhanced Recovery After Surgery [22], Ohio Health [23], or New Hanover Regional Medical Center [24]. For example, Mayo Clinic's First Aid application deployed on Amazon Alexa provides self-care instructions for everyday mishaps. Through a voice interface, users can ask for guidance on how to treat fever or what to do in case of spider bites or burns. These examples confirm the applicability of conversational systems for responding to health-related search activities. Moreover, the Livongo Blood Sugar Lookup app is designed for patients with diabetes mellitus, which supports them to keep track of their blood sugar levels logged via Livongo meter [25]. This solution provides recent blood glucose readings through verbal input.

The optimization of processes and workflow with VAs has proved useful for patients in the pharmacotherapy management at home. The Alexa-based Giant Eagle Pharmacy app allows users to set reminders and helps refill prescriptions through home delivery services [26]. Similar functionality is available through the Express Scripts app [27]. Furthermore, Swedish Health Connect by Providence St Joseph Health allows for scheduling of medical visits by suggesting the next available appointments near the patients' homes [28]. Similarly, the Atrium Health app provides information about the nearest urgent care service and hospital wait times, hours of operation, and contact details, thus allowing patients to schedule a same-day visit with a care provider [29]. OrbitaASSIST voice technology was also implemented as a bedside assistant to optimize communication with care teams and smart routing of requests [30]. Moreover, researchers from the Nationwide's Children Hospital (Columbus, Ohio) designed the SpeakHealth voice interactive service for the care coordination of children with complex medical problems [3], which confirms the applicability of voice-enabled technology in pediatrics. Conversational agents have been also shown to optimize hospital operations at Cedars-Sinai Medical Center (Los Angeles, California), supporting health care professionals in time-consuming paperwork tasks and automating medical data collection and documentation through the electronic health record (EHR)–integrated CardioCube voice app (accuracy=97.5%) [7].

Personalized clinical instructions are an important component of a holistic medical approach allowing for the continuity and coordination of care. Answers by Cigna tracks patient incentive programs, provides wellness tips, and enables health coach programs to navigate treatment plans [31]. OrbitaCONNECT provides a virtual health assistant for chronic, pre-, and postvisit care continuity [32]. Furthermore, with Talkspace Alexa skill, users can access mental health assessments and a library of mental health tools [33].

End-to-end solutions powered by voice AI can be used for routine clinical care. CardioCube allows for the collection of patient-reported outcomes and biometric data captured at patients' homes. At the appointed time, the voice assistant has a medical conversation with the patient by asking him/her, "What's your blood pressure?" Accordingly, the patient measures his/her blood pressure by using a standard monitor and reads out the results to the voice assistant. CardioCube also asks about dyspnea, quality of life, or prompts for tasks including, "Let's check your ischemic and bleeding risk again," in reference to CHA_2DS_2-VASc/HAS-BLED scores. Afterward, CardioCube automatically transmits the results to a proprietary server integrated with the EHR system and red-flags any alarming reports. This solution, which complies with the Health Insurance Portability and Accountability Act of 1996 (HIPAA) and the General Data Protection Regulation, was validated at Cedars Sinai Medical Center [7] and classified by the FDA as a Medical Device Data System. CardioCube was also implemented for remote home monitoring of adult patients with heart failure and diabetes at the Family Care Network (Bellingham, Washington) (Multimedia Appendix 1 and Figure 1 exemplify the utility of the CardioCube voice app for patients with diabetes mellitus and a medical report automatically generated from the conversation with the virtual assistant, respectively).

XSL•FO

Figure 1. Medical report generated automatically from the artificial intelligence–driven CardioCube voice app for patients with diabetes.

#	Question	Patient response	Date
1.	In the past week, have you missed any doses of your medication?	NO	03/04/20 8:56 AM
2.	Are you needing a medication refill?	NO	03/04/20 8:56 AM
3.	Do you have any medication related questions that you need your care team to answer?	YES	03/04/20 8:56 AM
4.	A caring reminder, eating more carbohydrates increases your blood sugar. All sugary foods contain carbohydrates, as do bread, rice, pasta and potatoes. Have you been carefully managing your carbohydrate intake in the past week?	YES	03/04/20 8:56 AM
5.	And what about exercise, how many times in the past week have you exercised?	2	03/04/20 8:57 AM
6.	As for this past week, were you able to check your sugar levels with a glucometer?	YES	03/04/20 8:57 AM
7.	And how many times in the past week did you check your blood sugar level?	7	03/04/20 8:57 AM
8.	Were the majority of your readings in a good range?	YES	03/04/20 8:57 AM

Kind regards,
CardioCube Team

1411 4th Ave, Seattle, WA 98101

Furthermore, focusing on cardiovascular diseases, Shara et al [34] at Medstar Health Research Institute conducted a clinical trial using Amazon Alexa as an automated personal health care assistant for patients with heart failure to optimize clinical care (trial registration# NCT03707275). Outcome measures included the change in the number of hospitalizations and medication adherence during a 3-month follow-up period (upon study completion, when awaiting for publication of the results). VAs have been also implemented in other fields of medicine. For example, Beaman et al [5] at the Oklahoma State University Center for Health Sciences initiated a study to examine whether verbal responses collected through Amazon Alexa is effective in capturing participant depression levels, using Patient Health Questionnaire-9 (trial registration# NCT04609267) [5].

The most advanced medical software solutions are defined to be SaMD, which, under the Federal Food, Drug, and Cosmetic Act include services designed to diagnose, treat, cure, mitigate, or prevent disease. Interestingly, regulatory authorities tend to facilitate the implementation of chatbot technology into clinical practice, especially in the context of the current pandemic. For example, the Danish COVID-19 RPA triaging chatbot that incorporates if-then branching logic was evaluated as being of “lower risk” by the FDA despite featuring a diagnostic component when the Federal Food, Drug, and Cosmetic Act was not enforced [35]. To our knowledge, none of the current VA-deployed health care apps are classified as SaMD.

Gaps in Health Care Delivery Exposed by the COVID-19 Pandemic

The surge in COVID-19 cases has placed unprecedented strain on health care systems, requiring adjustments in treatment delivery to patients. Despite the fact that the traditional clinical approach was partially substituted with web-based visits, the mismatch between demand and resources is a realistic challenge. The capacity of health care systems to adjust is limited by the incremental rate at which systems can grow by training new health care providers and reorganization of the structure [36]. However, the exponential increase in COVID-19 cases has highlighted gaps in the current organizational systems at a global scale [37]. As a result of the number of COVID-19 cases, health care providers have been required to work on the front line, shifting the human resources available for routine care services. Clinical institutions underwent extraordinary reorganizations to accommodate for the surge in COVID-19 cases. The focus was on emergency care, scaling up beds in intensive care units, and reassigning roles among the clinical staff. Parallelly, nonurgent procedures and elective surgeries were postponed. Furthermore, shortages of personal protective equipment, especially in the early phase of the pandemic, exposed health care workers to the infection and the incapability to combat the COVID-19 pandemic [38-40]. Subsequently, we observed an unprecedented health care crisis having a direct and indirect impact on medical patients with and those without COVID-19. Combined with a high number of deaths and serious illness among patients with COVID-19 [41], there were reductions in accident, emergency, and hospital admissions for urgent conditions, such as myocardial infarctions [42], which reflects patients who decided not to seek medical care owing to the fear of becoming infected. Disruptions due to the pandemic affected people with chronic conditions who could not access routine medical services. It let to postponed elective procedures, on-site visits, and reduced rates of hospitalization during the COVID-19 emergency. This will likely result in an extensive workload in the postpandemic period.

XSL•FO
RenderX

The health care crisis magnified the problem among socioeconomic statuses and racial groups [43]. Furthermore, as pointed out by the World Health Organization, public health gaps impacted the security and economic situation [44], thus revealing deep underlying problems in the insurance coverage system in the United States. A sudden wave of unemployment caused many people to lose employer-sponsored insurance coverage, thus limiting access to care in low-income populations. The COVID-19 pandemic also impacted employers who faced several challenges when operating in a difficult organizational situation. Some institutions including hospitals were required to screen all employees and visitors for COVID-19 symptoms prior to entrance. For example, University of California San Francisco Health was posed with a tremendous logistical challenge, which was solved by using a chatbot technology [45].

How Can Voice Technology Fill the Gaps?

The inability to provide in-person clinical consultations owing to the COVID-19 pandemic has fast-tracked the implementation of telehealth services. The use of virtual care solutions increased up to 10-fold within a few weeks, thus enabling patients to access clinical care remotely [46], with the majority including real-time, synchronous communication between patients and health care providers [47]. Of note, this approach is time- and resource-intensive and is thus inefficient for large patient populations. In mature telehealth systems, one telenurse can monitor up to 250 patients remotely; however, a single patient can be contacted via the telephone only periodically [48]. The COVID-19 pandemic forced an immediate implementation of new digital technologies [49,50], particularly AI-driven medical chatbots. These chatbots have the potential to improve access to health care through acute care triaging. This is favorable for COVID-19 screening and chronic disease management (long-term follow-up at home, scheduling of medical visits, and preventive care) [51]. Numerous health care systems have already utilized interactive voice response systems and chatbots to run hotlines helping to triage patients during the COVID-19 pandemic [45,52] for organizational optimization, including Massachusetts General Hospital and Brigham and Women's Hospital (Boston, Massachusetts; >40,000 digital encounters/week) [2,52], OSF Healthcare (Peoria, Illinois; >50,000 digital encounters) [53], and Providence (Seattle, Washington; >150,000 messages exchanged each day between the chatbot and users) [44].

With a user-friendly and accessible interface, voice AI chatbots provide a tool for prehospital triaging at the digital front door, assessing the clinical status of patients before they make direct contact with a health care provider. McGill University Health Centre is testing the application of a COVID-19 screening tool that uses Amazon Alexa to automatically survey patients visiting Cardiology Heart Failure Clinic (trial registration# NCT04508972) [54]. Apple's Siri provides a self-assessment tool that allows users to survey for potential COVID-19 symptoms. An automatic COVID-19 triaging service, developed on Amazon's Alexa platform, was generated by the Mayo Clinic (Rochester, Michigan) in accordance with the guidelines of the Centers for Disease Control and Prevention and fielding a substantial number of digital encounters about COVID-19 [4]. Furthermore, Apple, Amazon, and Google have removed unofficial COVID-19–related voice apps, thus preventing potential misinformation from being spread [55].

As indicated above, a mobile-responsive, web-based interface chatbot was successfully used to screen health system employees at University of California San Francisco Health, which conducted over 270,000 digital screenings within 2 months of operation. Digital solutions have optimized organizational workflow and reduced wait times for employees entering the hospital building and prevented at-risk people from coming to work [45]. OrbitaENGAGE is a voice and chat virtual assistant solution that automates critical patient engagement workflows at the so-called "digital front door" of health care. Patients interact with a voice or chatbot VA to obtain answers to health-related questions, find locations and specialists, and access symptom screening and monitoring tools for COVID-19 or other conditions including anxiety and depression [56].

Voice chatbots can potentially help patients easily communicate their health status by providing them with any disease management data. This approach allows for remote monitoring of medical patients without COVID-19 and those with COVID-19 who are mildly ill. The implementation of RPA technology integrating medical data collected through a conversational interface with the hospital database and alert-based CDSS delivers a powerful architecture that can function hand-in-hand with health care providers. Automatic clinical follow-up services provide access to up-to-date information about the individual's health status for informed medical decision-making [57] and reduce the risk of exposure and infection during face-to-face contact. More efficient patient care may help prevent unnecessary exposures due to decreased use of personal protective equipment (as exemplified by the web-based chatbot at Massachusetts General Hospital and Brigham and Women's Hospital) [2].

The implementation of innovative strategies based on VAs provides support to traditional telehealth approaches and may help reduce costs of health care services by lowering the entry bar for uninsured individuals. Direct-to-consumer digital health is a growing industry that can address unmet health care needs bypassing the traditional model (eg, that used by insurance companies), thus linking patients directly with services and providers without copays and deductibles [58]. Voice AI–supported virtual health care based on video consultations could be an alternative for people who lost employer-sponsored insurance during the COVID-19 pandemic. Virtual Care by CardioCube tests the aforementioned solution in Washington [59].

Advantages of VAs

From a user's perspective, the advancements in the field of voice-enabled technology allow for a human-like verbal communication between users and chatbots. In contrast to text-based mobile or web-based equivalents, voice chatbots have personalized speaking styles and emotions, thus providing

XSL•FO
RenderX

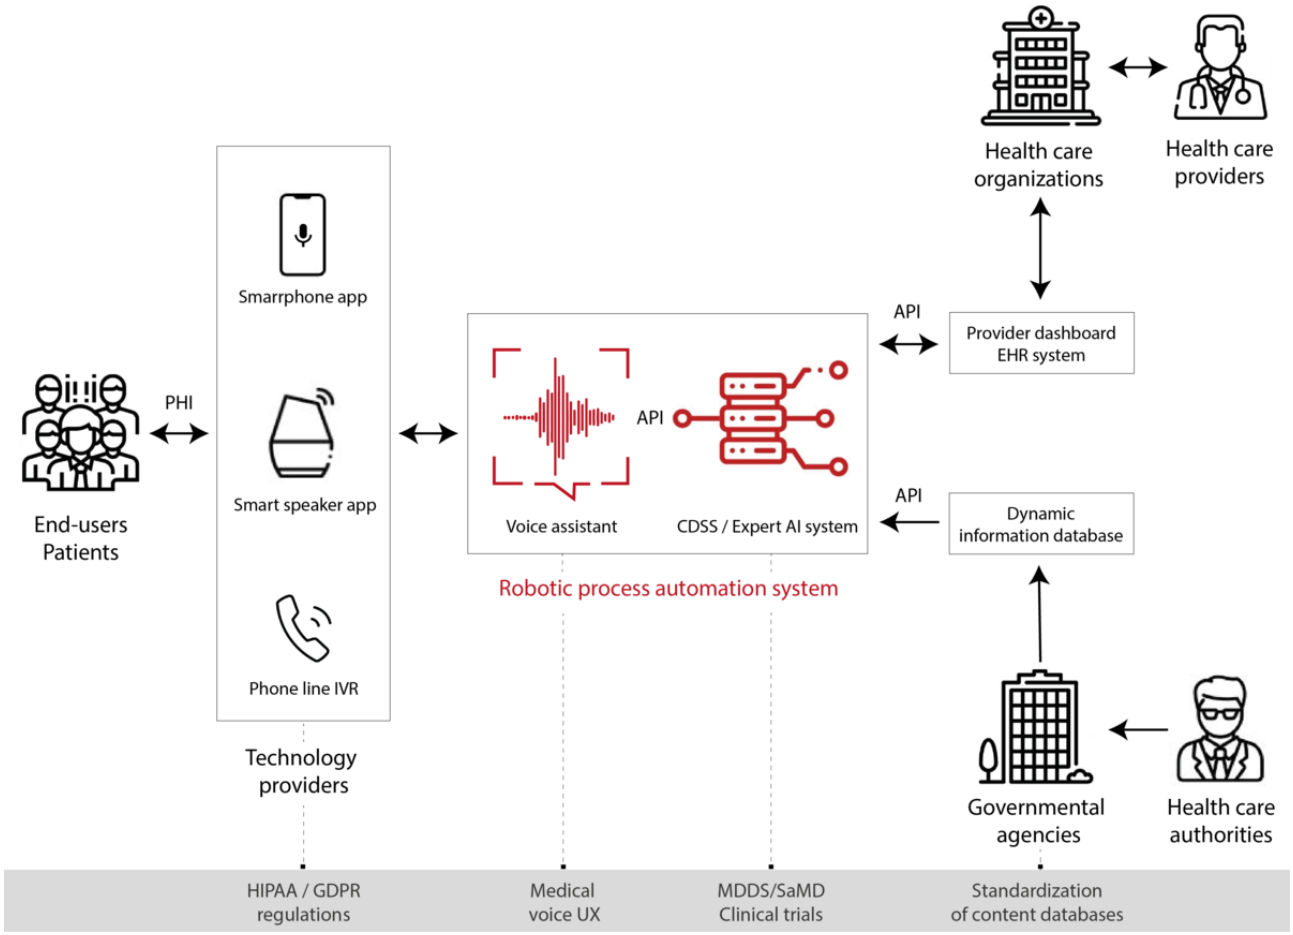
a more natural and intuitive experience, which is an important advantage over conventional chatbots [60,61]. Exchanging a smartphone screen with a hands-free VA might remove technological barriers. Senior users were found to prefer a conversational interface to touchscreens in a smart home environment [62]. It is also important to consider patient privacy when designing these tools. Developing multimodal solutions allows the user to choose the input modality to best suit their immediate surroundings. The user may not be comfortable speaking to VAs while in the presence of others. Having the option to provide and receive data on screen would enable them to adhere to their protocols in public environments. A strong example for the acceptance of VAs is the Healthy Coping voice bot deployed on Google Home. It is specifically targeted to patients with type 2 diabetes mellitus. The majority of users (80%) selected the voice interface over mobile solutions. Healthy Coping was assessed as easy to use and physically convenient with understandable language and communication [63]. According to Slavik et al [64], audible user interfaces are promising solutions for people with special needs for information access and control. Summarizing the advantages of voice technology, Fisher presented 5 main reasons why conversational agents may emerge as the next operating system: versatile, omnipresent, innate, contextual, and efficient characteristics (summarized as "VOICE") [65].

From a practical perspective, VAs can automate traditional telehealth services that require human providers to operate. Using conversational agents, it is possible to collect and share information at the levels of public health and individual patients. Voice chatbots can support routine care through automatic at-home monitoring, triaging, screening, providing medical recommendations and guidelines, and improving operational workflow. It is possible to help hospitals reduce their infection risk and exposure of medical staff by automatic paperless and hands-free scripting services including dictating of visit notes, charting, and patient onboarding [66].

In regard to rapid implementation, chatbot solutions are nearly off-the-shelf products that do not require substantial information technology and server infrastructure if applied with a dedicated dashboard for clinicians. The relatively low cost and rapid adoption is another important advantage of conversational agents for web-based care delivery [2].

Commercial adoption of voice technology confirms customer acceptability and provides strong grounds for the scalability and implementation of medical applications. The supportive evidence comes from the National Public Radio and Edison Research's "Smart Audio Report," which shows that there are 157 million voice devices in US households [67]. Moreover, Statista projected that the number of digital VAs in use will rise to 8 billion worldwide by 2023 [68].

Risks and Challenges



Health care systems have been working on implementing telemedicine programs for a number of years [69,70]. This leads to the question of why the uptake of web-based care solutions has been limited despite their salient clinical and economical potential. Key barriers that delay the adoption of new solutions and practice patterns exist at many levels in the chain of health care delivery [71,72]. Patient-specific obstacles include difficulties interfacing with the technology and the lack of motivation to follow through with computer-derived advice and instructions. Both patients and physicians may not wish to adopt telemedicine, as it is an imperfect surrogate for building human relationships between patients and physicians. Furthermore, both physicians and payors may be resistant to invest in web-based health platforms until these platforms have been proven to improve patient outcomes and cost-effectiveness metrics.

Initial implementation of VAs showed discordance between the quality of COVID-19–related content and guidelines by public health authorities, which have caused the dissemination of imprecise information [57]. Learning from this example, it is crucial to ensure the deliverability of reliable content through close collaboration among technology providers, developers, and health care experts. Apart from the distribution of verified information, VAs processing medical data must comply with the HIPAA to protect health information reported by end-users. Importantly, the US Department of Health and Human Services, Office for Civil Rights, waived penalties for HIPAA violation against medical providers who use everyday communication technologies to help patients remotely during the COVID-19 pandemic [39]. Furthermore, the FDA announced that the Federal Food, Drug, and Cosmetic Act will not be enforced for low-risk applications developed to combat COVID-19 [57]. These regulations supported the deployment of voice technology in clinical settings [73]. Nevertheless, it is important to establish clear regulations and guidelines for the application of voice chatbots for medical purposes. Thus far, Alexa's HIPAA-Eligible Skills program allows covered entities to design and launch HIPPA-compliant medical apps that use protected health information; these are available only in the United States [74]. However, the implementation of voice technology into clinical practice requires further regulation. In this context, guidelines and policies for telehealth (ie, those of the American Telemedicine Association) should include rules describing the utilization of medical VAs. This topic is directly associated with security, privacy, and hacking issues [75,76]. Edu et al [77] reviewed a wide range of elements that expose smart speakers at the risk of the attack surface, particularly those associated with the interaction between the user and the smart home personal assistants [77].

Amid this rapidly changing landscape, it is important to build relationships amongst the different stakeholders working to implement telemedicine innovations. These stakeholders include retail companies selling the telemedicine technology, software companies interfacing the telemedicine technology with health care systems, health care systems and their providers, payors, patients, and government health agencies (Figure 2).

XSL•FO
RenderX

Figure 2. Workflow of the AI-driven voice chatbot in health care delivery. AI: artificial intelligence; API: application programming interface; CDSS: clinical decision support systems; HER: electronic health record; GDPR: General Data Protection Regulation; HIPAA: Health Insurance Portability and Accountability Act of 1996; IVR: interactive voice response; MDDS: Medical Device Data System; PHI: protected health information; SaMD: Software as a Medical Device; UX: user experience.

Close collaboration should focus on the following:

1. Risk-based classification and verification process for VAs including assessment using FDA software as a Medical Device Guidance [15] and Medical Device Data Systems, Medical Image Storage Devices, and Medical Image Communications Devices Guidelines [14].
2. Early clinical validation; that is, using the FDA Early Feasibility Studies Program.
3. Protected health information security including voice patterns and pin-code user verification; currently implemented in HIPAA-eligible Alexa voice apps.
4. Interoperability of the systems to integrate voice-first devices, peripheral devices, and wearables with EHR systems through application programming interfaces; a feasibility study confirmed the integration of the Amazon Alexa-deployed CardioCube app with Centricity (GE Healthcare), OpenEMR, and Epic through an Fast Healthcare Interoperability Resources protocol (Cedars-Sinai Medical Center; under the Cedars-Sinai Accelerator) [78].
5. Harmonization and standardization of medical content databases providing up-to-date information through established data flow channels for quality assurance.
6. Alternative information delivery methods in case of failure in capturing or understanding questions asked by a user. Palanica et al [79] showed that VAs have different comprehension accuracy for drug names from 54.6% to 91.8% for Amazon Alexa and Google Assistant, respectively. Furthermore, Alagha and Helbing [80] showed that VAs have high variability in information quality about vaccines; hence, it is essential to secure a "safe-mode," redirecting the user to another source of information in case of delivery failure.
7. Segregation and personalization of relevant information in accordance with end-user profiles, taking into consideration determinants including demographics (especially older individuals [81,82] who showed high readiness for voice technology [83]), geographic localization, and spoken languages (voice interfaces are available in a limited number of languages) [84].
8. User experience to optimize how users who seek health information interact with VAs, preferably dedicated medical voice user designers with expertise in health care to understand patients' needs.
9. Context-aware method of delivery dependent on end-user characteristics and the digital ecosystem; for example, voice-only as a stand-alone smart speaker, smartphone- or computer-deployed app (more applicable for users with broadband internet access), or the telephone (useful for rural areas with limited internet access) vs voice and video devices (ie, Google Nest). In this aspect, VAs might be

XSL•FO
RenderX

used for provider-patient audio calls, while devices with embedded video cameras allow audio-visual communication.

Reimbursement for VAs is an important factor determining its adoption. Even though chatbots are not currently eligible for billing both in Europe and in the United States, Keesara et al [50] proposed that the payment structure could be based on time-based models or fixed fee-for-service monetization. Furthermore, the reimbursement for evaluation and management billing codes could be adjusted for digital services, while the Centers for Medicare and Medicaid Services could remove restrictions on in-person consultations under evaluation and management services [50]. Alternatively, having well-established distribution, supply chain, and AI services, software companies developing VAs could become a key player in the health care ecosystem. Interestingly, Amazon Care provides app-based health services to its employees bypassing health plans and brokers. Furthermore, Amazon has enabled patients to order and have their medications delivered home through Amazon Pharmacy. Subsequently, with Amazon's Pillo Health, an interactive drug dispenser with voice-first technology, patients can optimize pharmacological treatment at home [85]. In the case of health care organizations, Amazon released HealthLake, a HIPAA-eligible data management service functioning as a cloud EHR system [86].

Future Directions

VAs could be applied to capture human voice utilized as a digital biomarker. The analysis of vocal characteristics is a promising research field that combines AI and clinical medicine. Maor et al [87] reported an independent association between voice signal analysis and hospitalization as well as mortality among patients with heart failure. Furthermore, quantitative voice analysis was shown to be applicable in the diagnosis of neurodegenerative diseases [88] and COVID-19 [89].

Conclusions

In summary, with the growing demand for telehealth services, VAs could extend the workforce of medical care providers by using AI-powered interfaces to ensure the safety of patients and medical staff. Conversational agents have the potential to become a regular component of health care systems, thereby multiplying medical capacities during the current COVID-19 pandemic and reducing the spread of COVID-19. Moreover, clinical-grade voice AI chatbots can sustainably supplement routine clinical work in the postpandemic period. Voice technology implements synergistic and practical solutions, which have the potential to optimize health care systems and increase preparedness for future COVID-19–like pandemics. Currently, the Amazon Alexa HIPAA-eligible environment enables VAs implemented in the United States to be applied as a professional medical tool.

Abstract

In this paper, we describe techniques for predictive modeling of human-computer interaction (HCI) and discuss how they could be used in the development and evaluation of user interfaces for digital health systems such as electronic health record systems. Predictive HCI modeling has the potential to improve the generalizability of usability evaluations of digital health interventions beyond specific contexts, especially when integrated with models of distributed cognition and higher-level sociotechnical frameworks. Evidence generated from building and testing HCI models of the user interface (UI) components for different types of digital health interventions could be valuable for informing evidence-based UI design guidelines to support the development of safer and more effective UIs for digital health interventions.

KEYWORDS

digital health; human-centered design; usability; human-computer interaction; predictive modeling

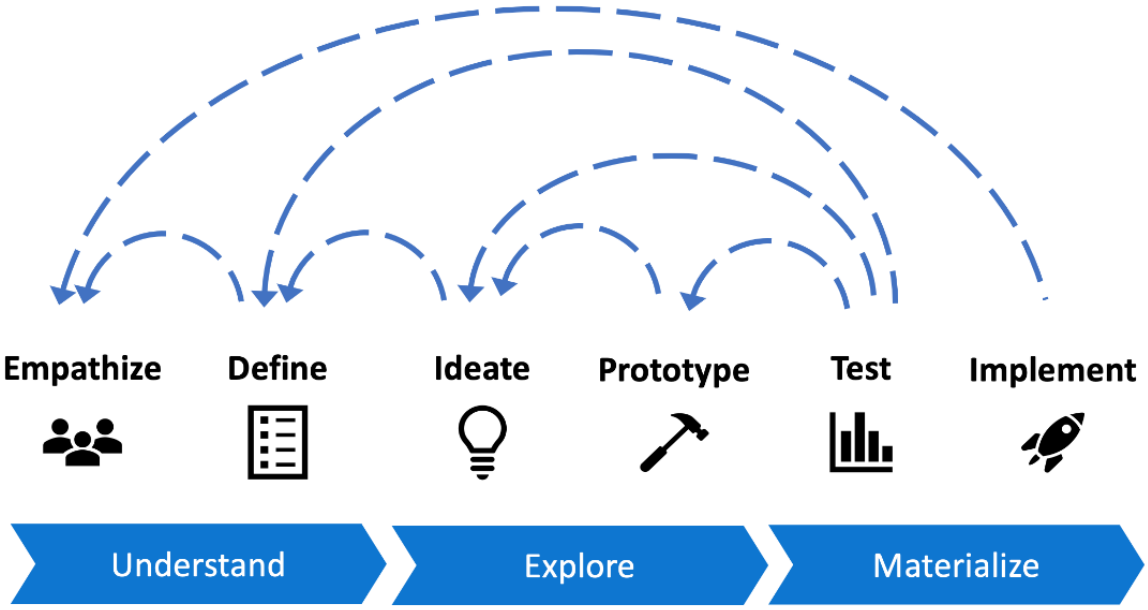
Introduction

User interfaces for digital health systems such as electronic health records (EHRs) or clinical decision support systems should be designed so that clinicians can accomplish tasks efficiently without making errors that could compromise patient safety. Designers of digital health systems should be able to use the best research evidence currently available, drawn from systematic reviews and meta-analyses, to inform their designs. However, the evidence base for designing user interfaces (UIs) of digital health systems has been difficult to establish, as evaluations of UIs are often subjective and difficult to generalize to new clinical contexts [1]. Recent systematic reviews of usability issues with different types of digital health systems (such as computerized physician order entry [2] and electronic medical records [3]) highlight some common issues identified across different studies but also describe the difficulties in generalizing guidance from context-specific evaluations. This evidence is of use to designers but does not offer specific design patterns or quantitatively demonstrate the trade-offs between efficiency and effectiveness that may be involved in different approaches to making designs more usable. Partly due to the weakness of the scientific evidence base, usability guidelines have therefore generally recommended adopting a human-centered design (HCD) approach and the use of expert heuristics to guide the design of interfaces rather than quantitatively validated design patterns.

In this paper, we examine how the use of human-computer interaction (HCI) predictive models can contribute to building a more robust and generalizable evidence base for UI designs for digital health interventions. This evidence base could then be used to advance UI design guidelines and could be

XSL•FO
RenderX

incorporated in the human-centered design process to accelerate innovation and improve clinical safety.



HCI modeling was used to develop the first computer mouse [4,5] and the modern window-based graphical UIs in wide use today [6]. As digital health systems become widely (albeit often reluctantly) adopted in health care, HCI modeling could have an important role in ensuring that the systems we use to care for patients are as safe and effective as other medical innovations such as drugs and diagnostics.

To discuss this approach, we provide a summary of the historical origins of predictive HCI modeling, show examples of how it can be used in modern digital health system design, and show how HCI modeling can be integrated into the human-centered design process.

The Digital Health Design Evidence Gap

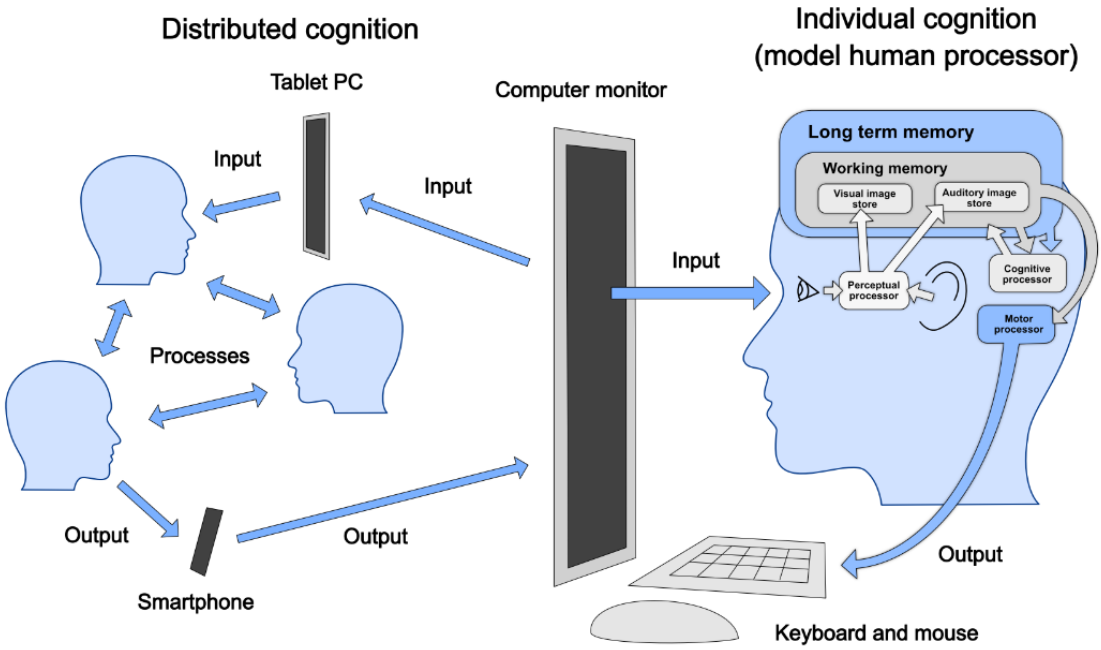
The current best practice for designing UIs for digital health systems is to use a human-centered design (HCD) approach such as "design thinking" [7], in which designers and developers move through an iterative and flexible process of understanding, exploring, and materializing the end product (Figure 1). This process is often guided by design heuristics ("rules of thumb") that include such guidance as keeping the UI simple and aesthetically pleasing and ensuring that help and documentation are readily available (see Textbox 1 for the 10 Nielsen heuristics) [8,9,10]. Iterative design thinking methods attempt to ensure that systems are aligned with users' behaviors and needs and allow for improvements to be made throughout the course of the design process.

Figure 1. Human-centered design helps designers move from computer code to real-world use. Adapted from Gibbons [7].

Textbox 1. The 10 Nielsen usability heuristics.

1. Visibility of system status
2. Match between system and the real world
3. User control and freedom
4. Consistency and standards
5. Error prevention
6. Recognition rather than recall
7. Flexibility and efficiency of use
8. Aesthetic and minimalist design
9. Help users recognize, diagnose, and recover from errors
10. Help and documentation

HCD has been developed to ensure that UIs work well for specific contexts but does not provide the kind of evidence normally expected for medical interventions. HCD should be part of the design process; however, additional methods are



XSL•FO
RenderX

needed with a more scientific basis to be confident that digital health UI designs are suitable for use in high-risk settings such as hospitals.

Predictive Models of HCI

Predictive HCI models have the potential to explain how users interact with digital health interventions at the level of individual human cognition. For more than 50 years, empirically derived predictive HCI models have been used for ensuring the safety and usability of information systems (physical and digital) for industrial and commercial applications ranging from avionics to power plant control systems. These models informed the designs of the first desktop computers, with innovations such as the computer mouse and windows-based graphical UIs. The "classic" HCI model was called the "model human processor," in which the different components of human cognitive systems were modeled and combined with models of the interactions (inputs and outputs) between the human and the computer system (see Figure 2).

Figure 2. The model human processor: a model of how long it takes to process information (from perception to action) and how we can use the limited "chunks" of information in working memory. Building on the idea of a model human processor is the concept of "distributed cognition," with multiple humans and devices working together. Adapted from Card et al [11].

There are now several types of HCI predictive models that can be used depending on the context or type of tasks analyzed. For example, the Fitts law is used for mouse pointing [12], the Hick-Hyman law is used for reviewing a sorted list [13,14], and goals operators methods and selection rules (GOMS) [15] is a high-level model that is used to describe the cognitive processes and methods involved in using a computer to achieve specific goals. The keystroke-level model (KLM) is a more specific type of GOMS model that is used for compositions of tasks that fit how an experienced user interacts with the interface [11]. KLM has also recently been updated for touch interfaces [16]. Although individuals will vary in their performance speed, these models give a good indication of the relative effort required to accomplish a task. For example, Warren et al and others [17-19] have used such models for simulation-based evaluation of split-menu designs (placing commonly accessed options at the top of a list) for clinical information systems. These models are primarily aimed at reducing the time needed to complete tasks by eliminating unnecessary clicks and ensuring that UI elements are easy to navigate. In the health care domain, simplifying designs and increasing efficiency is also likely to reduce errors that can cause patient harm, such as choosing incorrect items from unnecessarily long menus or clicking through lengthy screens too quickly [20,21].

Limitations of HCI Modeling

Although the abovementioned models proved useful and effective in the design of early graphical UIs and input devices, the ways in which teams of people began to use computer systems in the 1990s prompted a move in HCI research communities away from the micro-level interactions to meso-level systems of "distributed cognition" [22] (Figure 2) and "situated action" [23]. These systems included the described cognitive models by attempting to place them within a social context, with human-human interaction playing a role in addition to machine-machine interaction (Figure 2 shows how distributed cognition can be integrated with micro-level HCI modeling). In the health care domain, Borycki and Kushniruk [20,24-26] led the development of an integrative cognitive-sociotechnical model for characterizing user interactions with health care systems at multiple levels.

The field of cognitive science has also moved on since HCI modeling was first proposed. The human cognitive system

XSL•FO
RenderX

processes information in a highly complex manner, with dynamic feedback loops that are not included in the ways that HCI models are traditionally described. Therefore, HCI modeling has been more recently viewed as a useful tool for assisting in the development of systems rather than the scientific pursuit originally envisaged by Card, Moran, and Newell in their classic text "The Psychology of Human-Computer Interaction" [15]. However, recent work, such as on the representation of "M" (for "mentally prepare") in the KLM model, shows that more nuanced and complex models can be created where more fidelity to human cognition is required.

Example of the "Combined" Layered Approach to Collecting Evidence About HCI

In their study of electronic whiteboards across Denmark, Rasmussen and Kushniruk [27] incorporated the KLM model; however, this work was initially driven by a naturalistic study to locate workflow issues associated with deployment of a new electronic whiteboard across several hospitals across Denmark. The naturalistic study identified areas where optimization might be needed, as evidenced by observation of seemingly inefficient user interactions with the whiteboard (identified from review of the screen recordings of user interactions), and the KLM experimental approach was then used to test hypotheses on applying different changes to create efficiencies.

The research team video recorded 2863 entries from video analysis of live user interactions with the whiteboard and identified potential inefficient sequences from observing and timing the video (eg, the task "add new patient" took an average of 12.3 seconds). They then conducted GOMS-KLM analysis producing the following predictive model (H=move hands; M=mentally prepare; K=tap key or button; P=point):

H+M+P+K+M+P+K+H+M+ (K*10) +H+M+P+K+P+K+H+M+ (K*30)+H+M+P+K+M+P+K+M+P+K+M+P+K+M+P+K+M+P+K+M+P+K+M+P+K+M+P+K+M+P+K+M+P+K+M+P+K+M+P+K+M+P+K = 54.6 seconds

They then modified the "add new patients" task so that instead of opening new dialog boxes, information could be directly entered into text boxes or from menus, modeled thus:

H+M+P+K+M+P+K+H+M+K+ (K*10) +H+M+P+K+H+M+ (K*30) +H+M+P+K+M+P+K+M+P+K+M+P+K=31.25 seconds

The results of the project led to a reduction in time to task completion of 44.6% and illustrated the benefits of considering HCI at multiple levels (ie, including the use of naturalistic observation and video coding of those data for the use of KLM to predict more optimal user designs for improving inefficient user interaction sequences).

HCI Model Patterns for Different Types of Digital Health Systems

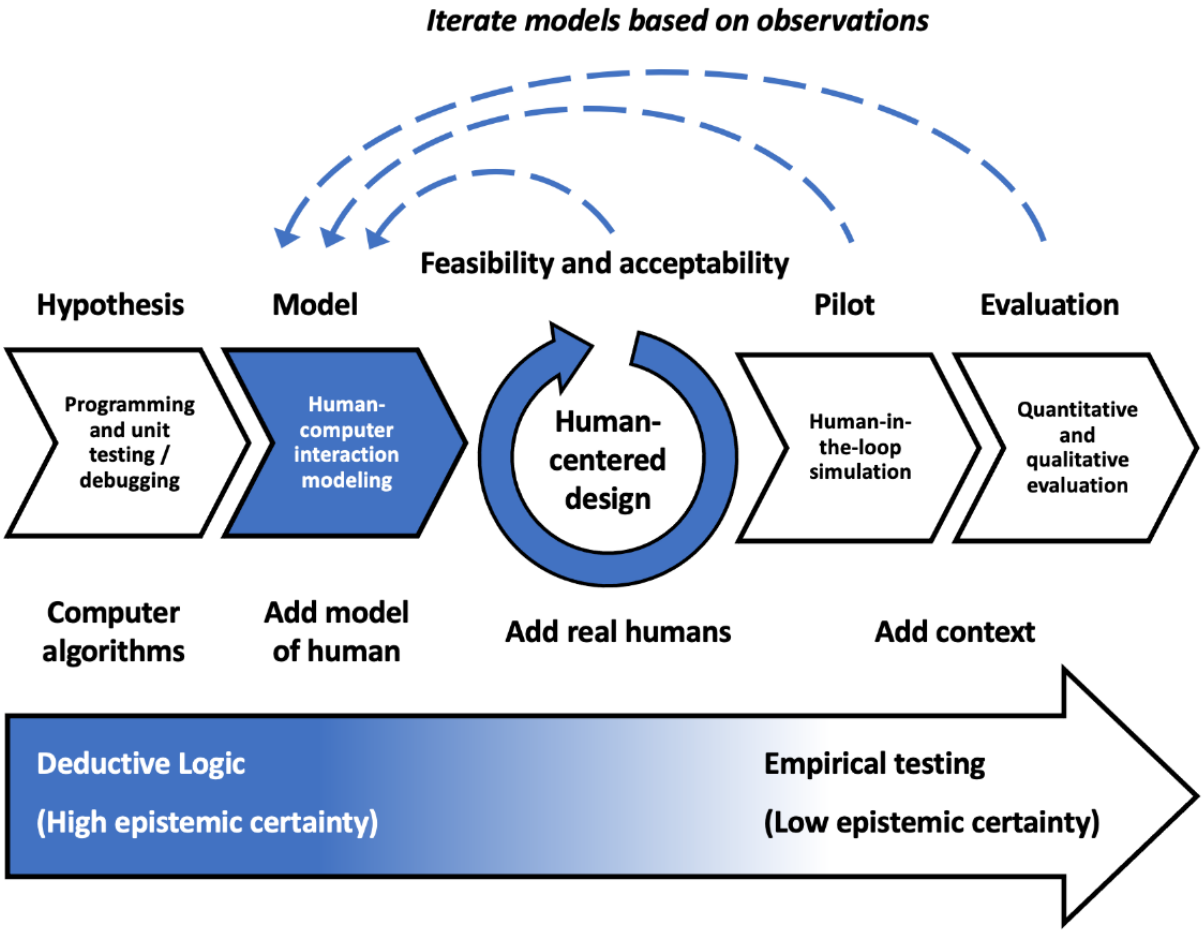
Digital health applications may have common usability and resultant patient safety issues that can be modeled using predictive HCI approaches as shown above. However, specific types of digital health interventions may also have type-specific UI patterns that, if modeled as a common function of a particular type of system, may make it easier to develop more general models. Using the World Health Organization Digital Health Intervention (DHI) classification system [28], it could be envisaged that each type of system, such as a telemedicine system (DHI 2.4) or health care provider training system (DHI 2.8), would have a common HCI predictive model that takes into account the cognitive processes involved in using that type of system. For example, a training system would include cognitive models of how the system enables the user to learn how to manage a clinical problem, retain the knowledge over time (perhaps by repeatedly "topping up" their knowledge), and recall the information when needed.

Implications for Developing Guidelines and Standards for Digital Health Systems

Safety issues with large-scale EHR systems have now started to be reported in the literature. Recent work by Ratwani et al [29,30] has highlighted a wide range of usability issues in currently used digital health systems. The analysis by Pacheco et al [31] of the Certified Health IT Product List database of usability attestation, for example, revealed that 3.7% of the products surveyed had a certified capability nonconformity issue that was coded as being associated with possible patient harm. Despite these ongoing issues with clinical usability, current guidance on digital health system development has largely taken a heuristic approach [32], building on and adapting the Nielsen heuristics for health care contexts [3]. Several large-scale projects have been undertaken to develop UI guidelines; however, without establishing an evidence-based approach to guideline development, it has been difficult to maintain or build on these guidelines as technology develops. For example, in the United Kingdom, the National Health Service commissioned Microsoft to develop a "Common User Interface" for EHR systems designed as part of the National Programme for Information Technology; however, this guidance was recently withdrawn without replacement [33]. In the United States, the Department of Health and Human Services created "Research-Based Web Design and Usability Guidelines" [34].

Although these approaches can aid the design of systems that adhere to industrial usability standards, they represent a broad-brush approach that lacks the kind of scientific rigor required by other health care interventions, such as new pharmaceuticals.

Greater consideration and use of predictive models integrated into an HCD approach may be needed to ensure that evidence-based UI design guidelines can be developed over time. The results of modeling-based studies could ensure that systematic reviews and meta-analyses of usability studies generate evidence that is generalizable beyond the specific contexts of the studies.



Integrating Predictive Modeling With HCD

Using predictive models to inform the HCD process could accelerate the design of digital health systems. By having a

XSL•FO
RenderX

validated evidence base of UI designs to draw on, designers could eliminate a large number of potential designs that might meet basic usability heuristics or that could be appealing to early testers but that could be shown through predictive modeling to have poor usability. Figure 3 shows how HCI modeling could fit into the process of designing the UI for a digital health application. The design process moves from implementing the computer algorithms needed for the software to function (developed using deductive logic with a high level of epistemic certainty) to modeling how users would interact with the UI of the system using HCI cognitive models. Once designs that show poor results with modeling are weeded out, the project will then enter a human-centered design phase in which the system is trialed with real users (for example, nurses and physicians who will use a digital health system on the wards) and repeatedly iterated until the software is sufficiently acceptable to pilot. At this stage, human-in-the-loop simulations can be conducted as the system is piloted. Finally, more formal quantitative and qualitative evaluations in clinical contexts can provide higher-level empirical evidence (albeit with lower epistemic certainty than with in-silico HCI modeling). At each stage, in keeping with the design thinking approach, the development team can move back to modeling and HCD to improve the design if needed. In addition to showing whether a particular application works, real-world evaluations based on HCI models will show which models work in the real world, building the evidence base for future design guidelines.

Figure 3. Predictive human-computer interaction modeling could augment the human-centered design process and help us understand how an application achieves real-world effectiveness.

Conclusion

UIs for digital health applications are currently designed using techniques developed for commercial software applications based on human-centered design processes and heuristics. Predictive HCI modeling of applications may help improve the design process and allow for more scientific progress toward safer and more effective digital health systems. We have described in this paper how predictive HCI modeling has developed from individual cognitive modeling to distributed cognitive models and provided examples of how these models can be integrated into sociotechnical modeling approaches. Although predictive HCI modeling has fallen out of favor in recent years, as the demand for more evidence of the safety and effectiveness of digital health systems increases, it is worth re-evaluating whether HCI modeling can contribute to the science of evidence-based digital health system design. Future research on the integration of predictive modeling with usability and software engineering approaches (such as usability testing and human-in-the-loop simulations) is both needed and warranted.

Abstract

Background: Clinical data in social media are an underused source of information with great potential to allow for a deeper understanding of patient values, attitudes, and preferences.

Objective: This tutorial aims to describe a novel, robust, and modular method for the sentiment analysis and emotion detection of free text from web-based forums and the factors to consider during its application.

Methods: We mined the discussion and user information of all posts containing search terms related to a medical subspecialty (oculoplastics) from MedHelp, the largest web-based platform for patient health forums. We used data cleaning and processing tools to define the relevant subset of results and prepare them for sentiment analysis. We executed sentiment and emotion analyses by using IBM Watson Natural Language Understanding to generate sentiment and emotion scores for the posts and their associated keywords. The keywords were aggregated using natural language processing tools.

Results: Overall, 39 oculoplastic-related search terms resulted in 46,381 eligible posts within 14,329 threads. Posts were written by 18,319 users (117 doctors; 18,202 patients) and included 201,611 associated keywords. Keywords that occurred ≥500 times in the corpus were used to identify the most prominent topics, including specific symptoms, medication, and complications. The sentiment and emotion scores of these keywords and eligible posts were analyzed to provide concrete examples of the potential of this methodology to allow for a better understanding of patients' attitudes. The overall sentiment score reflects a positive, neutral, or negative sentiment, whereas the emotion scores (anger, disgust, fear, joy, and sadness) represent the likelihood of the presence of the emotion. In keyword grouping analyses, medical signs, symptoms, and diseases had the lowest overall sentiment scores (−0.598). Complications were highly associated with sadness (0.485). Forum posts mentioning body parts were related to sadness (0.416) and fear (0.321). Administration was the category with the highest anger score (0.146). The top 6 forum subgroups had an overall negative sentiment score; the most negative one was the *Neurology* forum, with a score of −0.438. The *Undiagnosed Symptoms* forum had the highest sadness score (0.448). The least likely fearful posts were those from the *Eye Care* forum, with a score of 0.260. The overall sentiment score was much more negative before the doctor replied. The anger, disgust, fear, and sadness emotion scores decreased in likelihood, whereas joy was slightly more likely to be expressed after doctors replied.

Conclusions: This report allows physicians and researchers to efficiently mine and perform sentiment analysis on social media to better understand patients' perspectives and promote patient-centric care. Important factors to be considered during its application include evaluating the scope of the search; selecting search terms and understanding their linguistic usages; and establishing selection, filtering, and processing criteria for posts and keywords tailored to the desired results.

Introduction

Understanding patient attitudes and expectations toward health care is an important component of promoting patient-centric care and patient satisfaction. However, studies have shown that physicians have difficulties in understanding patients' health beliefs and concerns [1]. Strategies to improve the understanding of patient attitudes have traditionally required the development of specialized survey instruments, which may nonetheless be limited in scope, or focus groups, which can be very time consuming and laborious [2].

The internet has now become a rich additional source of information regarding patients' attitudes and expectations toward health care. Recent decades have seen a rapid increase in internet engagement, with an estimated 5 billion people using mobile devices [3], and more than half of the global population actively using the internet [4]. In 2012, 72% of American internet users sought health information on the web [5] and many also increasingly expressed their medical concerns on the web [6,7]. These web-based communication outlets include social networks (eg, Facebook, Twitter, or Instagram), doctor review websites (eg, Healthgrades, Vitals, or RateMDs), and health web forums (eg, MedHelp, Health245, or Patient info). Analyzing people's health-related queries and reports on the internet to better inform public health and public policy is an increasingly popular field known as infoveillance [8]. Although Twitter is a common and popular platform based on which many infoveillance studies are conducted, its space-limited format contrasts with web-based health forums, which are a particularly rich resource for understanding patient attitudes toward medical issues by supporting patients in directly seeking medical advice, sharing their medical experiences, and discussing their symptoms at length [9-15].

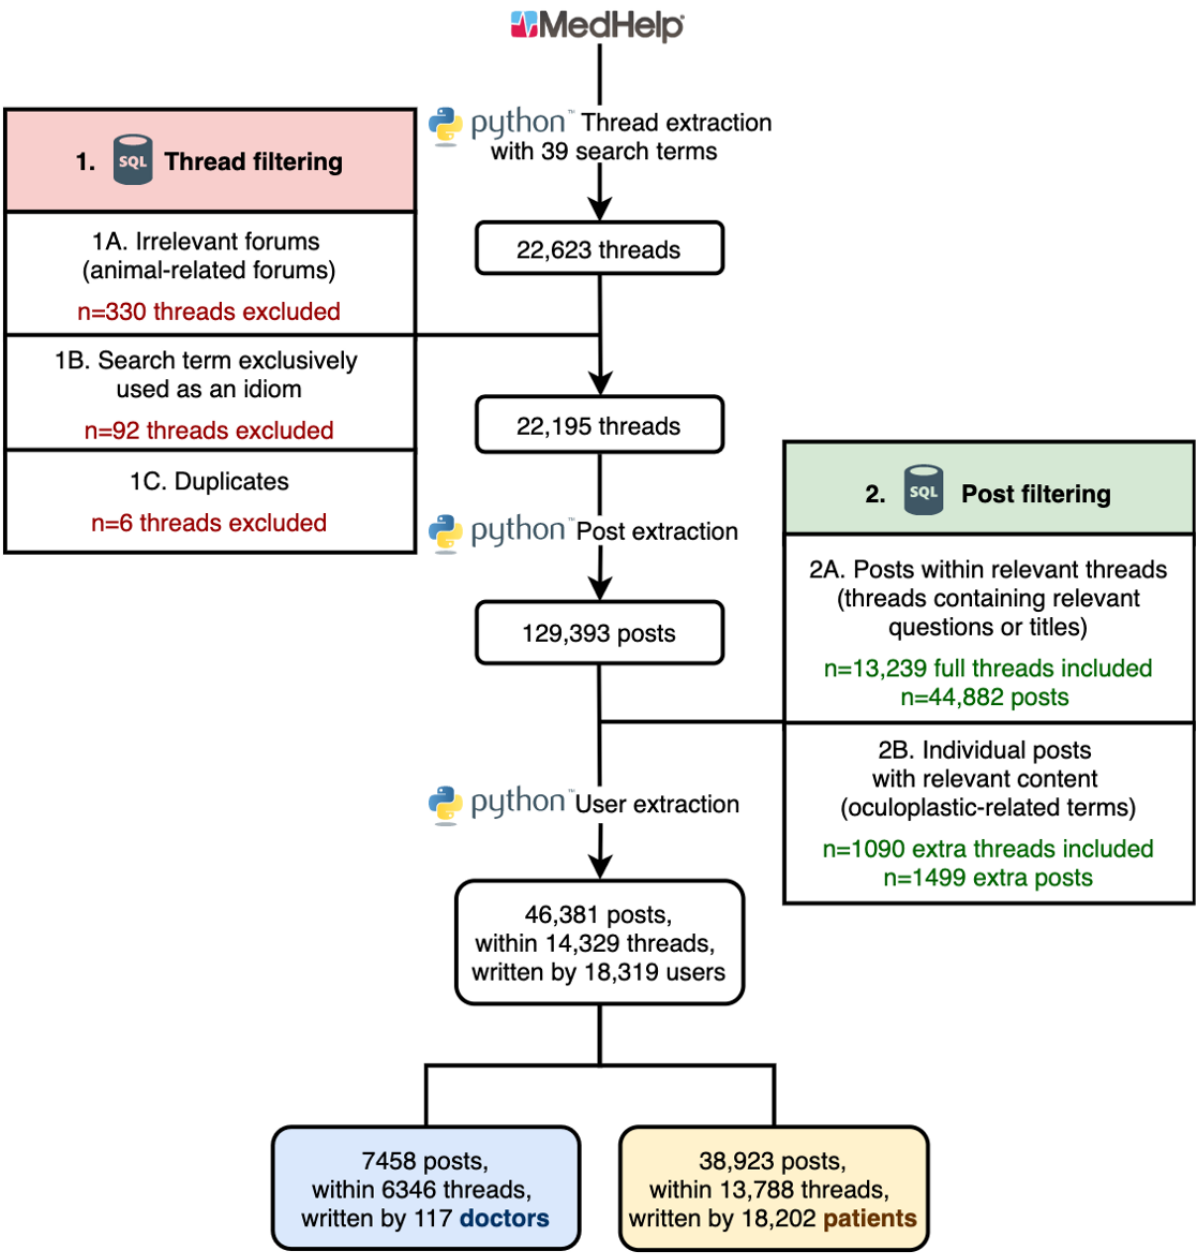
Understanding unstructured clinical data on social media requires natural language processing (NLP), a well-established branch of artificial intelligence that has been applied in a variety of fields and has emerging applications in medicine [16,17]. Sentiment and emotion analyses, which are subbranches of NLP, can identify and quantify positive, neutral, and negative sentiments and can detect emotions such as anger, disgust, fear, joy, and sadness in free text [18,19]. The data mining and sentiment analysis of social media, especially web-based medical discussion forums, can provide a fast and effective way to better understand patients' attitudes, expectations, and experiences [18], which can better guide patient-centric care [20]. The literature shows that health care professionals can, with the sentiment analysis of web-based medical forums, discover new outlooks of patient issues and recurrent complications related to specific treatment uses and drugs [19,21,22] and administrative burden and access to care [23]. By analyzing forum posts, physicians can further understand patients' attitudes and experiences and assess their needs and concerns, which can result in better patient-centric care [24].

We examined all oculoplastics-related posts on MedHelp, which included questions from patients and replies written by patients and doctors. Oculoplastics is a subspecialty in ophthalmology that involves the eyelids, face, tear ducts, and orbit and is both highly specialized and interdisciplinary as a clinical domain, often at the intersection of ophthalmology, plastic surgery, dermatology, and otolaryngology. Our study illustrates the challenges of identifying and distinguishing text related to specialized medical subdomains, such as ophthalmology, in the context of patient-centric idiomatic language and of web-based discussion forum analysis, where the relevance of text must be filtered on multiple structural levels and physician and patient posts must be distinguished from physicians' posts. We provide all scripts and describe a detailed approach toward web-based patient forum sentiment analysis, which includes data collection; rigorous data processing, cleaning, and selection; and in-depth data analysis. This methodology allows for a variety of applications, notably the identification and analysis of the main topics related to the chosen field (eg, symptoms, complications, and medication) and their associated quantified sentiment (positive, neutral, or negative) and the likelihood of the presence of certain emotions (joy, anger, disgust, sadness, and fear). This methodology can also be used as a means to measure patient satisfaction and perspective by comparing patients' sentiment and emotions before, during, and after their interaction with health care professionals. This paper aims to guide physicians and researchers to mine and perform sentiment analysis on web-based clinical data in a chosen field and highlights the challenges and approaches to consider in the process.

Methods

Data Source and Study Population

Founded in 1994, MedHelp is the world's largest web-based health community [25]. With more than 15 million visits per month, it allows users (patients and doctors) to discuss issues related to various health and wellness topics on a daily basis [18]. Currently, this platform contains 299 official support communities, including a wide variety of well-established medical discussion forums. The main oculoplastic discussion forum is the *Eye Care Community*, which encourages patients to discuss eye-related issues. Another vision-related forum was the *Ask a Doctor-Eye Care Forum*, which benefited from a collaboration with ophthalmologists from the American Academy of Ophthalmology from 2007 to 2014 [25,26]. In addition to these forums, MedHelp has more than 1000 user-made groups.



Each community or group, also referred to as *a forum*, encompasses various discussion *threads*. Discussion threads comprise a question asked by a user (the initial *post*), followed by replies written by individual users, which are also considered *posts* [19].

XSL•FO
RenderX

Approach to Data Extraction

The approach to data extraction from MedHelp is summarized in Figure 1. Discussion threads related to oculoplastic surgery were identified from MedHelp using a list of oculoplastics-relevant search terms created by consensus between 2 specialized ophthalmologists, AYW and SYW, and AXN (Multimedia Appendix 1).

Figure 1. Flowchart for the data extraction of discussion threads and posts on web-based medical forums. SQL: Structured Query Language.

Each discussion thread was parsed using a Python script (Python Software Foundation, version 3.8.6) [27] and the Python package *Beautiful Soup* [28] to yield the full text of each post (including the initial question and all replies) and the relevant metadata, including the MedHelp user for each post and the forum that each thread belonged to.

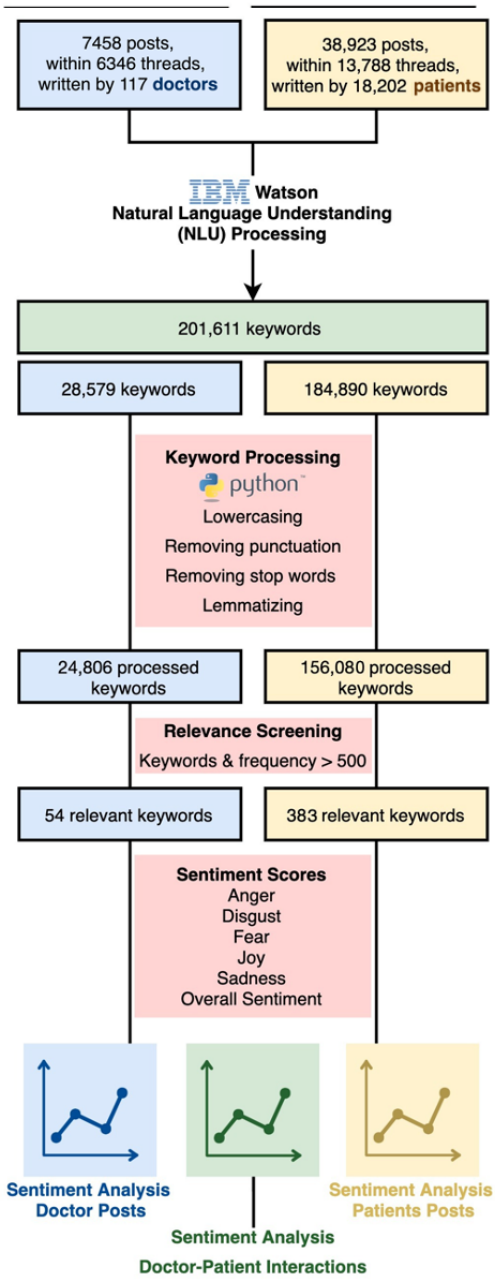
An initial review of the search results demonstrated that not all results appeared to be relevant, and it was noted that the details of the exact algorithm used by MedHelp's proprietary search engine could not be known. Thus, we performed additional filtering of the search results to remove irrelevant discussion threads. Threads in animal forums, duplicate threads, and threads where the search terms were mentioned in purely idiomatic ways were removed.

In addition, we noted that many threads were returned as search results because search terms appeared in different posts within the same thread, for example, the search term "double eye lid" could return a thread containing the use of "double," "eye," and "lid" in separate posts, which could result in many irrelevant posts.

Therefore, to further filter the posts to include those that were most highly relevant to oculoplastics, we developed additional lists of related terms and text patterns and identified all the posts that contained exact matches to these patterns (Multimedia

XSL•FO
RenderX

Appendices 2-3) after lowercasing all the posts. Posts were deemed relevant and included for analyses if they were (1) in a thread whose title or initial question contained an exact pattern match (Multimedia Appendix 2) or (2) the post itself contained an exact pattern match to a very specific oculoplastics-related term (Multimedia Appendix 3). Posts that were not part of a relevant thread were subject to more stringent inclusion criteria because the original topic of the thread did not necessarily pertain to oculoplastics. This filtering algorithm ensures that the data set is relevant and tailored and is not influenced by the proprietary search algorithm of the platform.



Patterns required for inclusion of posts allowed for some variability in human language, for example, the two patterns "%upper lid%eye" and "eye%upper lid%" ("%" denotes 0 or more of any character) match a subset of posts expressing one's upper eyelid, such as "my eye hurts, and my upper lid..." and "my upper lid droops, and my eye keeps twitching," without deeming posts containing solely "upper lid" as relevant, such as "the upper lid of my jar...." After excluding irrelevant posts, we extracted the username, user type (doctor or patient), self-reported age, sex, registration date to the MedHelp community, and user location from each user profile. All data were stored in an SQLite relational database [29]. The scripts used to extract threads, posts, and users and the detailed instructions on how to use them can be found in our repository [30].

Approach to Natural Language Understanding Processing

The approach to NLP and sentiment analysis is presented in Figure 2 [31]. We used IBM's Watson Natural Language Understanding (NLU; IBM Cloud Natural Language Understanding V1, version 2019-07-12) [32] to perform sentiment and emotion analyses on the free text of every included forum post. The Watson machine learning system reads and understands the semantics of free text by breaking down sentences structurally, grammatically, and contextually through various linguistic models and algorithms. The results that were returned included a sentiment score for the full document (ie, the full text of a single post) and for each keyword extracted by the IBM Watson algorithm and emotion scores for anger, sadness, joy, fear, and disgust at both the post and keyword levels. These keywords include important words, entities, and phrases from each post. Sentiment scores ranged from −1 to +1 on an arbitrary linear scale of intensity and were negative (less than 0), neutral (0), or positive (greater than 0). For each emotion, a score was given in the form of a percentage of likelihood, ranging from 0 to 1, where 0 represents the certain absence of the emotion in question and 1 represents the definite presence of the emotion.

XSL•FO
RenderX

Figure 2. Flowchart describing keyword processing and sentiment analysis.

NLU Keywords Processing

Related keywords generated by the IBM Watson NLU program were processed using a Jupyter Notebook [33] with Natural Language Toolkit (NLTK) [34], NumPy [35], and Pandas [36] libraries. The following transformations were applied to each keyword: lowercasing, punctuation removal, stop word deletion (eg, prepositions and conjunctions), and lemmatization [37] (morphological destructuring that allows words to be stripped down to their root word, eg, “oculoplastics” into “oculoplastic”).

NLU Keywords Selection and Categorization

Among the keywords with a frequency higher than 500, manual verification was performed to merge the keywords with the same semantic meaning. These keywords were then classified into various categories (groups and subgroups). For example, the “people” group encompasses multiple subgroups including the “eye care provider” subgroup, which in turn contains the fully processed keywords “ophthalmologist” and “optometrist.” However, keywords with a questionable relevancy to the clinical field and keywords with a general meaning (eg, “thing,” “thought,” and “name”) were excluded from the analysis.

Sentiment Scores Statistical Analysis

We used Python to aggregate and calculate the mean and standard deviation of each keyword’s associated sentiment and emotion scores (sentiment, sadness, fear, anger, joy, and disgust scores). Three examples of the analyses were performed with the results. We performed a summary of statistics by keyword grouping to determine significant trends among the chosen clinical categories. We also analyzed the data by forum subgroups (eg, posts in the *Eye Care* forum vs posts in the *Neurology* forum). We also compared the sentiment associated

XSL•FO
RenderX

with the posts written by the patient before a doctor replied with the patient's posts written after a doctor replied.

Results

Results From Data Extraction

Threads Extraction and Filtering

Searching the 300 forums (including ongoing communities, discontinued forums, and user-made groups) on MedHelp using 39 oculoplastics-related search terms resulted in 22,623 discussion threads (Multimedia Appendix 1). The screening for irrelevant threads resulted in the exclusion of 6 duplicate threads, 330 threads found in animal-related forums, and 92 threads containing the search term used exclusively as an idiom. Table 1 highlights threads containing the common idioms associated with the initial search term lists and excluded forums (*Animal Health—General*, *Animal Lovers Group*, *Animal-Surgery*, *Birds*, *Cats*, *Dogs*), as well as example text from the excluded threads and the associated number of threads deleted.

Table 1. Examples of excluded posts because of idiomatic language or reference to animals.

Idiom or forum name	Description	Threads deleted, n (%)	Example text from excluded threads
Idiom			
(1) Raise an *eyebrow*[a]; (2) raise an *eye brow*; (3) raise *eyebrows*	This idiom is used to convey awe, consternation, or disbelief.	(1) 51 (100); (2) 2 (100); (3) 18 (64)	"I may be just freaking out but it does raise an *eyebrow.*"
(1) Bat an *eyelid*; (2) bat an *eye lid*	This idiom is used to show an emotional reaction.	(1) 20 (100); (2) 1 (100)	"And the doctor, like me, has seen so many she's not going to bat an *eyelid*!"
Forum			
Animal Health—General	This forum is used to answer questions related to general pet health (treatment, parasites, infectious disease, etc).	56 (100)	"My 3 year old boxer has one *eye* that seems to droop and is a little redder than normal. [...] It has always been that way it could be a congenital abnormality such as *entropion*."
Animal Lovers Group	This forum was previously used to chat about anything related to pets and animals.	1 (100)	"Birds are wonderful. In this state, they seem to *frown* on folks feeding them in the park too, it really irritates me, what would our world be like without those lovely creatures singing their happy song to us, I love them."
Animal-Surgery	This forum was previously used to have questions answered by a veterinarian from PetDocsOnCall on all questions regarding animal surgery.	2 (100)	"My dog has ingrown *eyelashes*"
Birds	This forum was used to answer questions about pet birds.[b]	5 (100)	"My three year old peacock has cloudy *eyes*. One *eye* in particular, the lid seems to linger and appears to bulge (slightly) when looking at him straight."
Cats	This forum was used to answer questions about pet cats.[b]	113 (100)	"I don't know what my cat has got into but his left *eye* has been watering really bad and is red inside. It is now red on the right *eye* but just around where the *lashes* would be."
Dogs	This forum was used to answer questions about pet dogs.[b]	153 (100)	"Lumps on dogs *eye lid*"

[a]Words referring to ophthalmology are italicized.

[b]These forums used to have questions answered by a veterinarian.

Posts Extraction and Filtering

After filtering the threads, 129,393 posts associated with the resulting 22,195 threads remained, which then underwent additional layers of filtering for inclusion and exclusion (Figure 1). Posts from 13,239 of the 22,195 threads were considered relevant and were therefore included because the thread title or question contained a relevant oculoplastic term (Multimedia Appendix 2), which resulted in 44,882 included posts. An additional 1499 individual posts from 1090 other discussion threads also contained oculoplastic-related keywords (Multimedia Appendix 3) and were therefore included in the analysis. The final corpus was composed of 46,381 posts within 14,329 threads, which were written between January 1, 1995, and December 18, 2019, in 273 forums.

User Extraction

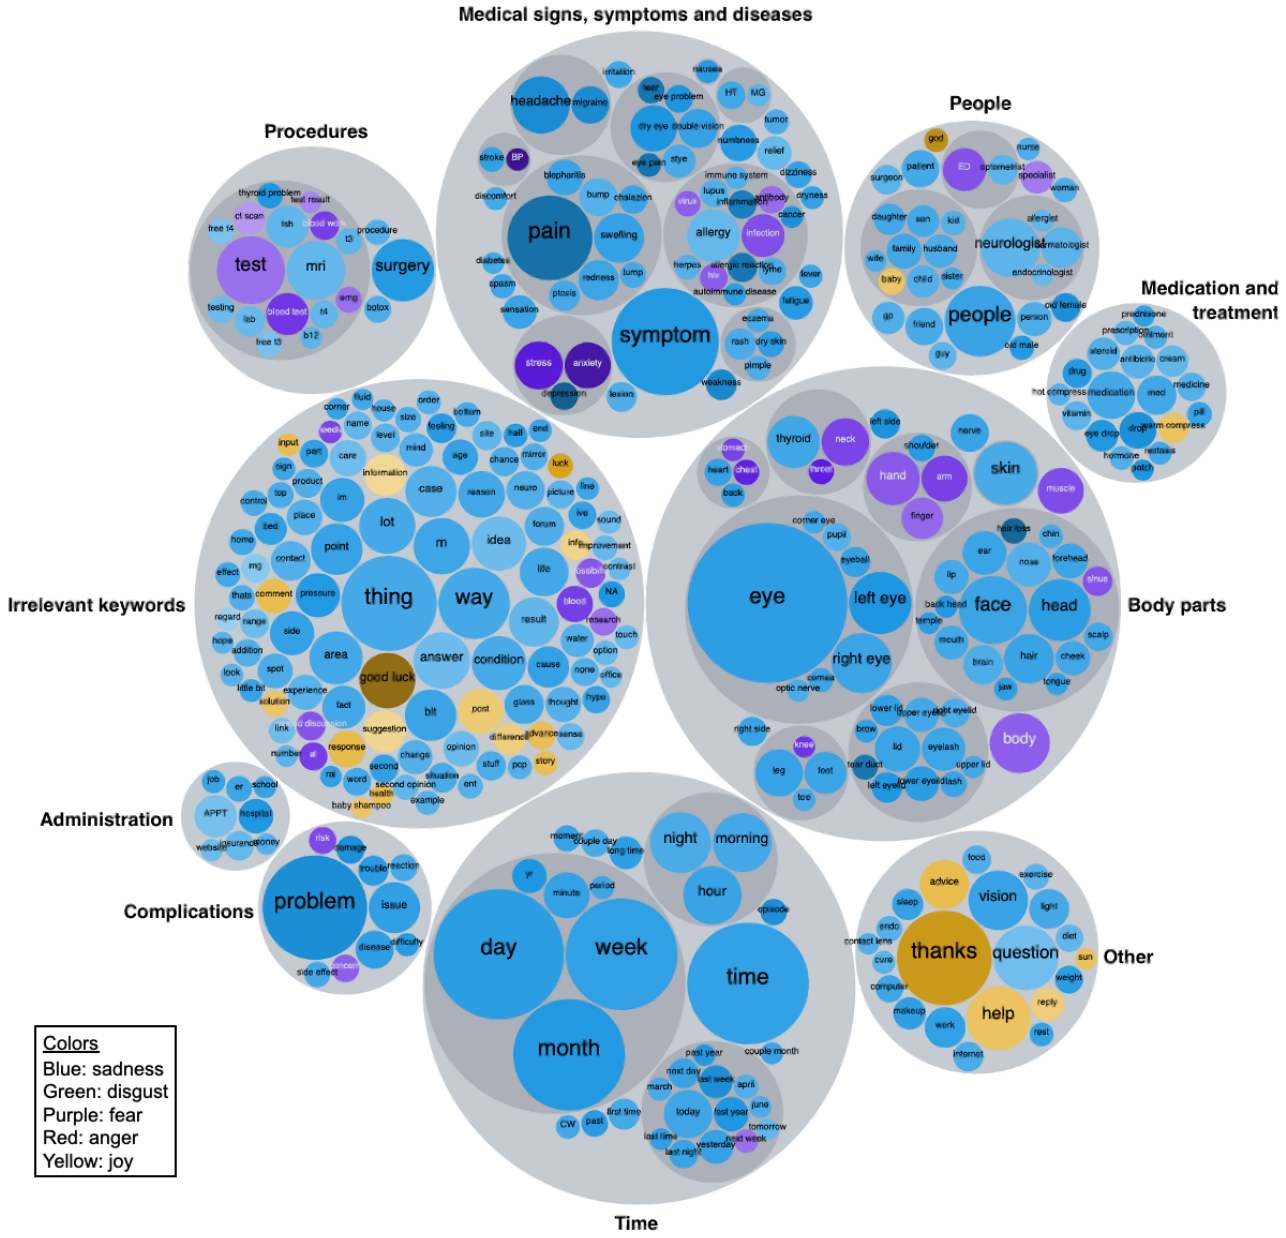
These 46,381 posts were written by 18,319 users from 1995 to 2019. More specifically, 7458 posts (within 6346 threads) were written by 117 doctors, and 38,923 posts (within 13,788 threads) were written by 18,202 patients. Overall, 20.19% (3699/18,319) of users were male patients, 38.33% (7022/18,319) were female patients, 40.84% (7481/18,319) of the patients did not specify their sex, 0.41% (75/18,319) were male doctors, and 0.23%

XSL•FO
RenderX

(42/18,319) were female doctors. A total of 5642 patients were included in this study. Their ages varied from 10 to 96 years, with an average of 44.8 years. A total of 6704 patients indicated their location (city, state, and/or country).

Results From Keyword Processing

Keyword Extraction



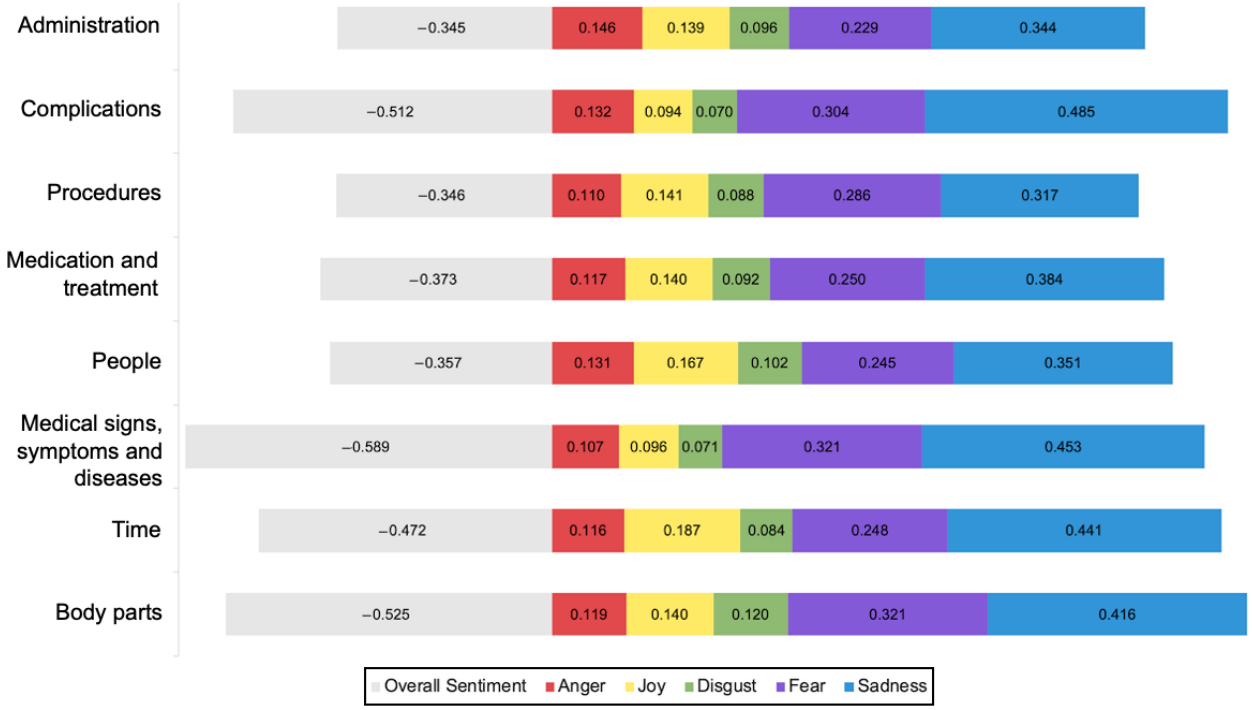
Keyword extraction, sentiment analysis, and emotion analysis were performed using the IBM Watson NLU service, which generated 201,611 unique raw keywords, including 28,579 keywords from posts written by doctors and 184,890 keywords from posts written by patients, with some keywords common to both sets of posts (Figure 2). Further processing using the NLTK Python library grouped related keywords, resulting in 24,806 keywords from doctors' posts and 156,080 keywords from patients' posts. For instance, "eyes" became "eye," "eyelids" became "eyelid," and "eye lashes" became "eye lash."

Keyword Selection and Categorization

Keywords that occurred at least 500 times in the corpus were included for analysis; 383 keywords were from patients' posts and 54 keywords were from doctors' posts. We grouped these keywords into nine relevant categories: body parts; medical signs, symptoms, and diseases; people; medication and treatment; procedures; complications; administration; aggravating and relieving factors; and others. Some of these categories were then subdivided into more precise clinical concepts. For example, the broad category *body parts* contained keywords related to the head, neck, upper limbs, thorax, and lower limbs. The category *medical signs, symptoms, and diseases* was subdivided by specialty (oculoplastics, ophthalmology, psychiatry, neurology, endocrinology, integumentary, immunology, cardiology, and gastroenterology). The *people* category contained references to eye care doctors, nonocular medical specialists, surgeons, family doctors, family members, friends, and other health care professionals (Figure 3) [38].

XSL•FO
RenderX

Figure 3. Nested bubble chart showing the top 500 keywords associated with patient posts and grouped into clinically relevant categories. The size of each bubble is proportional to the frequency of the keyword. The color of each bubble represents the most likely emotion associated with the keyword. The shade of each bubble is proportional to the likelihood of the emotion score; emotions that are more likely are in darker bubbles. APPT: appointment; BP: blood pressure; ED: eye doctor; HP: hypothyroidism; MG: myasthenia gravis.



Similar keywords that were aggregated include the following examples: “itch” encompassing both “itch” and “itching,” “diagnosis” replacing “dx” and “diagnosis,” “eyelid” including both “eyelid” and “eye lid,” “eyebrow” (“eye brow” and “eyebrow”), “twitch” (“twitch” and “twitching”), “treatment” (“tx” and “treatment”), “non specified doctor” (“doctor,” “doc,” “dr,” “physician,” and “md”), and “ophthalmologist” (“ophthalmologist” and “ophthamologists” [sic]).

Sentiment and Emotion Analysis

Summary statistics were therefore performed using keyword groupings (Figures 3 and 4). Medical signs, symptoms, and diseases had the lowest overall sentiment scores (−0.598). Complications were highly associated with sadness (likelihood sadness score of 0.485). Forum posts mentioning body parts were related to sadness (likelihood sadness score of 0.416) and fear (likelihood fear score of 0.321). Administration was the category with the highest anger score (0.146).

XSL•FO
RenderX

Figure 4. Top 8 groupings and their respective overall sentiment and emotion scores. The overall sentiment score reflects a positive, neutral, or negative sentiment, whereas the emotion score (anger, disgust, fear, joy, and sadness) represents how likely (%) the emotion is to be present.

We further analyzed sentiments and emotions by the forum subgroup. We compared the most popular forums among each other by analyzing the sentiment and emotion scores of their posts (Multimedia Appendix 4). All 6 forums had an overall negative sentiment score; the most negative one being the *Neurology* forum with a score of −0.438. The *Undiagnosed Symptoms* forum had the highest sadness score (0.448). The least likely fearful posts were those from the *Eye Care* forum, with a score of 0.260.

We also analyzed all the posts from users who asked questions (ie, initiated new threads) on MedHelp. These posts were divided into two categories: the pre–doctor reply group and the post–doctor reply group. The pre–doctor reply group included all the questions, the self-replies, and replies to other users written by the initial user before a doctor replied. The post–doctor reply group included all the other posts written by the initial user after the first doctor replied. As seen in Table 2, the overall sentiment score is much more negative before the doctor replied. We can also see shifts in the emotion scores: anger, disgust, fear, and sadness decreased in likelihood whereas joy was expressed slightly more likely after the doctor replied.

Table 2. Difference in sentiment and emotion scores between the posts written before and after a doctor replied.

Posts analyzed	Pre–doctor reply group	Post–doctor reply group	Difference (post − pre)
Posts expressing the following sentiment			
Negative, n (%)	1553 (92.22)	1260 (49.55)	−42.67%
Neutral, n (%)	11 (0.65)	110 (4.33)	+3.67%
Positive, n (%)	120 (7.13)	1172 (46.09)	+38.97%
Scores			
Overall sentiment	−0.557	0.0268	+0.584
Anger	0.143	0.109	−0.0334
Disgust	0.126	0.0740	−0.0505
Fear	0.364	0.233	−0.130
Joy	0.308	0.348	+0.0391
Sadness	0.5210	0.335	−0.186

Discussion

Innovation

This is the first paper providing a detailed methodology for preparing unstructured text data from web-based health discussion forums related to ophthalmology for sentiment and emotion analyses. We detailed the steps performed to quantify patients' and doctors' sentiments from web-based discussion forums: searching results, extracting a data corpus of threads and posts, cleaning the data, analyzing text using IBM Watson NLU, and aggregating and processing the important keywords from each post. Our goal was to explain these key steps and highlight the applicability of our methods to the field of medicine and the factors to consider in the process, notably the selection of search terms; understanding the latter's different linguistic usages (eg, idioms); the adequate consideration of different forums; and the establishment of robust criteria for data cleaning, aggregation, and grouping of posts and keywords (eg, lowercasing, punctuation removal, and lemmatization). Our approach highlights the importance of considering the unique structure of discussions within web-based health forums, distinguishing between physician and patient posts and analyzing idiomatic language usage to determine text relevance in infoveillance studies, which we found to be important steps not commonly detailed in previous studies of web-based health forums [39,40].

Medical Application

Analyses examining groupings (eg, administration; complications; procedures; medication and treatment; people; medical signs, symptoms, and diseases; time; and body parts), forum subgroups (eg, eye care, neurology, dermatology, thyroid disorders, multiple sclerosis, and undiagnosed symptoms), and patient-doctor interactions can enable researchers to provide key recommendations to physicians. In the oculoplastics data set, patients had a highly negative overall sentiment score and emotion score (anger, disgust, fear, and sadness) before the doctor replied (Table 2). To improve patient satisfaction, health care professionals can address their concerns by adapting their responses to the patients' sentiments and emotions. These sentiments and emotions can be further broken down by grouping and forums. Each grouping can be addressed with different solutions, such as reducing appointment and waiting time; explaining medical signs, symptoms, and diseases; and reassuring patients' concerns regarding specific procedures and body parts (Figure 4). Each forum's scores indicate how the corresponding health care team (eg, neurology, endocrinology, and ophthalmology) must communicate with patients to better manage different emotions, different emotions by predominantly addressing patients' sadness, disgust, fear, or even joy (Multimedia Appendix 4).

Challenges and Factors to Consider

Several issues must be carefully considered when gathering data from internet sources and unstructured free text to ensure relevance to the desired topic. First, the selection of the search terms is critical when analyzing web-based content. A deep understanding of the chosen field along with its related terms (eg, symptoms, complications, and subfields) is crucial to establish a complete list that encompasses all the possible relevant thread discussions. Second, a thorough understanding of the linguistic usages of the search terms is critical for establishing adequate data cleaning algorithms (eg, removal of threads containing the search terms exclusively used as idioms and consideration of human speech variance in the filtering algorithm). There are many eye-related idioms in the English language that must be considered when analyzing web-based text for ophthalmology-related insights (eg, "bat an eyelid"); every specialty will have its own unique set of idioms related to anatomical parts or functions (eg, "break my heart" and "take my breath away") that must be taken into consideration. The results can also differ according to the terms' specificity: broader terms (eg, eyelids, eyebrows, and oculoplastics) encompass the oculoplastics field, whereas more specific terms (eg, blepharitis, entropion, and ectropion) refer to specific medical conditions in this field. It is recommended to choose all relevant search terms (broad and specific) to ensure exhaustive results. However, a robust and tailored filtering algorithm must be established to ensure a relevant data set that is not influenced by the initial results returned by any proprietary search algorithm for any platform.

Indeed, every social media platform will have individual and proprietary search functions that may retrieve information irrelevant to the original query. Therefore, a careful and tailored process for further filtering is required to remove irrelevant results. Key decisions must be made on the filtering process (filtering by topic title, discussion thread, and/or individual post content). Establishing these filtering guidelines is crucial to ensure that the content of the posts selected is relevant and that the posts discarded do not contain relevant information. Basing the filtering algorithm on the relevancy of the thread topic allows for this methodology to be applied to many other social media platforms that often contain similar data structures (eg, on Facebook, Twitter, and Instagram, a main post (topic or title) is followed by comments (replies) related to the initial topic).

Furthermore, the scope of the search must also be evaluated. Depending on the topic selected, forums outside of those dedicated to the primary specialty may also need to be included. In our study, we considered a wide variety of MedHelp forums outside the eye care forums as oculoplastics is a field at the intersection of ophthalmology and plastic surgery. The *Eye Care* forum is only one of the 273 forums that contained our relevant threads and posts (ie, the *Cosmetic Surgery*, *Dermatology*, *Neurology*, and *Thyroid Disorders* forums). As we took all MedHelp forums into account during the extraction process, more constraints had to be established. For example, all forums related to animal care needed to be excluded.

After carefully selecting individual posts on which sentiment analysis is performed, the keywords extracted by the program will be numerous and lexically repetitive. Therefore, care must be taken to normalize the results originally sourced from free text. Using NLP tools to process and group the keywords with the same clinical meaning is a crucial step to ensure that the analysis is performed on uniform and clean data. To facilitate the grouping of related processed keywords, following a systematic method, such as ours (all keywords with a frequency greater than 500 and keyword categorization by 2 reviewers),

XSL•FO
RenderX

prevents biases from being induced into the sentiment analysis and results.

Limitations

Although the effects of users' spatiotemporal characteristics on sentiment analyses in MedHelp have not been evaluated yet, studies have shown that these features can bias the results of sentiment analysis derived from tweets. Gore et al showed that sentiment analysis can yield biased measures related to population demographics at the municipal, state, and national levels [41]. Another study demonstrated that an individual's location throughout the day can also affect their tweets' sentiment [42]. These issues can be addressed by assessing the population represented by posts on the web. In the case of Twitter, only 15% of adults on the web regularly use Twitter, and those aged 18-29 years and minorities tend to be more highly represented on Twitter than in the general population [43]. Although it is unclear what effect these spatial, temporal, and demographic effects may have on sentiment and emotion reflected in forum posts, they have the potential to affect these findings. We acknowledge that not all patients will rely on web-based forums to discuss their medical concerns or receive expert advice, especially the most vulnerable (older adults, minority, and socioeconomic groups).

Conclusions

Despite these limitations, the internet is a major source of health-related information that is underused [44]. In this paper, we describe an accessible, quick, and robust approach to sentiment analysis of patient data in social media that is relevant to a chosen medical topic, such as oculoplastics, and highlight the technical challenges encountered when preparing and analyzing the data. Regardless of the clinical questions examined, important factors to be considered during the application of this methodology include assessing the scope of the research; determining search terms and understanding their different linguistic usages; and implementing selection, filtering, and processing criteria for posts and keywords tailored to the results. This emerging methodology can be used as a valuable guide for clinicians and researchers who want to better understand patient attitudes toward and patient satisfaction with particular fields and procedures. The analysis of web-based forum discussions can be a quick, efficient, and robust method for gathering unstructured, diverse, and detailed opinions relevant to a chosen medical topic such as oculoplastics.

Acknowledgments

The authors thank Jerry Kurian for his expert opinion on the code and the reviewers for their valuable comments. Abstract

Background: Authorship teams in the health professions are typically composed of scholars who are acquainted with one another before a manuscript is written. Even if a scholar has identified a diverse group of collaborators outside their usual network, writing an article with a large number of co-authors poses significant logistical challenges.

Objective: This paper describes a novel method for establishing and facilitating large-scale manuscript collaborations via social media.

Methods: On September 11, 2020, I used the social media platform Twitter to invite people to collaborate on an article I had drafted. Anyone who wanted to collaborate was welcome, regardless of discipline, specialty, title, country of residence, or degree completion. During the 25 days that followed, I used Google Docs, Google Sheets, and Google Forms to manage all aspects of the collaboration.

Results: The collaboration resulted in the completion of 2 manuscripts in a 25-day period. The International Council of Medical Journal Editors authorship criteria were met by 40 collaborators for the first article ("Documenting Social Media Engagement as Scholarship: A New Model for Assessing Academic Accomplishment for the Health Professions") and 35 collaborators for the second article ("The Benefits of Using Social Media as a Health Professional in Academia"). The authorship teams for both articles were notably diverse, with 17%-18% (7/40 and 6/35, respectively) of authors identifying as a person of color and/or underrepresented minority, 37%-38% (15/40 and 13/35, respectively) identifying as LGBTQ+ (lesbian, gay, bisexual, transgender, gender non-conforming, queer and/or questioning), 73%-74% (29/40 and 26/35, respectively) using she/her pronouns, and 20%-23% (9/40 and 7/35, respectively) identifying as a person with a disability.

Conclusions: Scholars in the health professions can use this paper in conjunction with the tools provided to replicate this process in carrying out their own large-scale manuscript collaborations.

Introduction

In the health professions, we typically collaborate with people we already know or are at least acquainted with. There is a practical reason for this: We have to know someone exists in order to think of them as a potential collaborator. However, this can lead to authorship teams that lack diversity. Even if a scholar has identified a diverse group of collaborators outside their usual network, writing an article with a large number of co-authors can be a logistical nightmare. This paper describes a novel method for establishing and facilitating large-scale manuscript collaborations via social media.

Methods

Finding Collaborators

On September 11, 2020, I posted a series of tweets (a "thread") on the social media platform Twitter, inviting people to collaborate with me on an article I had drafted [1]. Textbox 1 shows the transcript of the tweets in the thread.

The first tweet in the thread was shared with the >7400 people who follow me on Twitter; 2330 people engaged with the first tweet in the thread: 1991 people viewed the details about this tweet, 161 people clicked on my profile, 122 people clicked a heart icon to indicate they "liked" the tweet, 29 people replied to the tweet, and 27 people shared the tweet with their followers by retweeting it.

Less than 24 hours after I posted the thread inviting people to collaborate with me, 31 people had entered their names and affiliations onto the title page of the Google Doc to indicate their desire to serve as co-authors [2].

Textbox 1. Transcript of the tweets in the thread.

Publication opportunity for MD, NP, and RN tweeps! I'm writing a piece on how to document social media engagement as public scholarship on CVs and dossiers in medicine and nursing. Target Journal = @AcadMedJournal There's no widely-accepted format for how to do this so I thought it was about time we fixed that. :) Since the article is about social media engagement, I decided to take a risk and use social media to recruit co-authors and add to/revise the draft manuscript. Academic Medicine uses the ICMJE definition of authorship: "Authorship is based on (1) substantial contributions to conception and design, or acquisition of data, or analysis and interpretation of data, (2) drafting the article or revising it critically for "...important intellectual content, (3) final approval of the version to be published, and (4) agreement to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately "...investigated and resolved. Authors must meet conditions 1, 2, 3, and 4." If you're willing to meet conditions 1, 2, 3, and 4, AND you're willing to turn around your edits in the next 7 days -- a timeframe I picked solely because I want to see how fast we can actually do this -- here's how you can co-author this paper with me. Step 1. Go to the Google Doc and type in your name and affiliation on the title page in a blue highlighted spots (you can add more spots if you need to). ** Rest assured your name will NOT be included on the submission unless you give approval of the final version.** Step 2. Make the article better. Work your magic. Don't insert comments -- add to or revise the actual text of the article. You have good ideas -- your ideas will make this article much better! Next Friday I'll take whatever edits have been made and will create a final version of the submission. I'll email it to everyone who listed their name on the title page. If you're happy with the final version and you meet the authorship criteria, bingo - you're a co-author. For a control-freak like me this is absolutely terrifying, BTW. So, here's the link to the Google Doc: [link to original Google Doc]. It's a rough draft, y'all -- like, ROUGH. If we pull this off, we can change the way CVs and dossiers look at med schools and nursing schools. The last person who did that was Ernest Boyer 30 years ago. How cool is that? In terms of the co-authors, I *really* want to have a diverse group. We can't have a bunch of white, cis, heterosexual, able-bodied folx writing this. If you're white, cis, heterosexual, and able-bodied, I'd still love for you to be a coauthor. Just saying that I'm hoping for a diverse group overall. I'm excited to see what comes of this. Thanks for being open to being part of this adventure! Here's the link to the Google Doc if you missed it earlier: [link to original Google Doc]. Thanks everybody!"

Coordinating the Collaboration

To manage the large number of potential co-authors, I created a Google Sheet and posted a link to it at the top of the title page of the Google Doc containing the draft article. With the link to the Google Sheet, I included a note encouraging co-authors to indicate in the Google Sheet whether they identified as someone who is LGBTQ+ (lesbian, gay, bisexual, transgender, gender non-conforming, queer and/or questioning), a person of color/under-represented minority, and/or a person with a disability because this would be helpful info for us to have collectively so that we have a sense of the diversity of our authorship team (I have created a blank version of the Co-Author Info Sheet for anyone interested in replicating the process described in this innovation report) [3]. There was no screening process for who could or could not join in the collaboration. Anyone who wanted to collaborate was welcome, regardless of discipline, specialty, title, country of residence, or degree completion.

Over the next 7 days, the article grew and changed considerably. Students, residents, fellows, and more senior scholars joined as collaborators, and no contributions to the article were viewed as more or less important based on the status of the collaborator making the contribution. Collaborators made edits to the article and inserted comments or questions that were then answered by other collaborators, occasionally in real time when multiple people were working on the document simultaneously. By September 18, 2020 — my original target date for completing the article — it was clear the article had expanded to have 2 foci rather than 1. I pulled content from Article #1 into a second Google Doc to build an outline for Article #2, then shared the link to the outline with all collaborators.

To keep things simple throughout the collaboration process, the first page of the original Google Doc was where I posted messages to the collaborators as well as links to the revised Article #1 (guidelines for documenting social media contributions) and what had become a draft of Article #2 (the benefits of social media for health professionals in academia). This approach preserved the comments made by collaborators on the original draft so that we could maintain a history of everyone's contributions.

Ensuring the Integrity of Authorship Designation

With such a large team of potential co-authors, I recognized that I would need to build several checkpoints into the collaboration process to ensure that individuals who met the International Council of Medical Journal Editors (ICMJE) criteria for authorship would be credited as such on the manuscript. The ICMJE defines authorship as follows: "The ICMJE recommends that authorship be based on the following 4 criteria: 1. Substantial contributions to the conception or design of the work; or the acquisition, analysis, or interpretation of data for the work; AND 2. Drafting the work or revising it critically for important intellectual content; AND 3. Final approval of the version to be published; AND 4. Agreement to be accountable for all aspects of the work in ensuring that

XSL•FO
RenderX

questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved. In addition to being accountable for the parts of the work he or she has done, an author should be able to identify which co-authors are responsible for specific other parts of the work. In addition, authors should have confidence in the integrity of the contributions of their co-authors. All those designated as authors should meet all four criteria for authorship, and all who meet the four criteria should be identified as authors. Those who do not meet all four criteria should be acknowledged" [4].

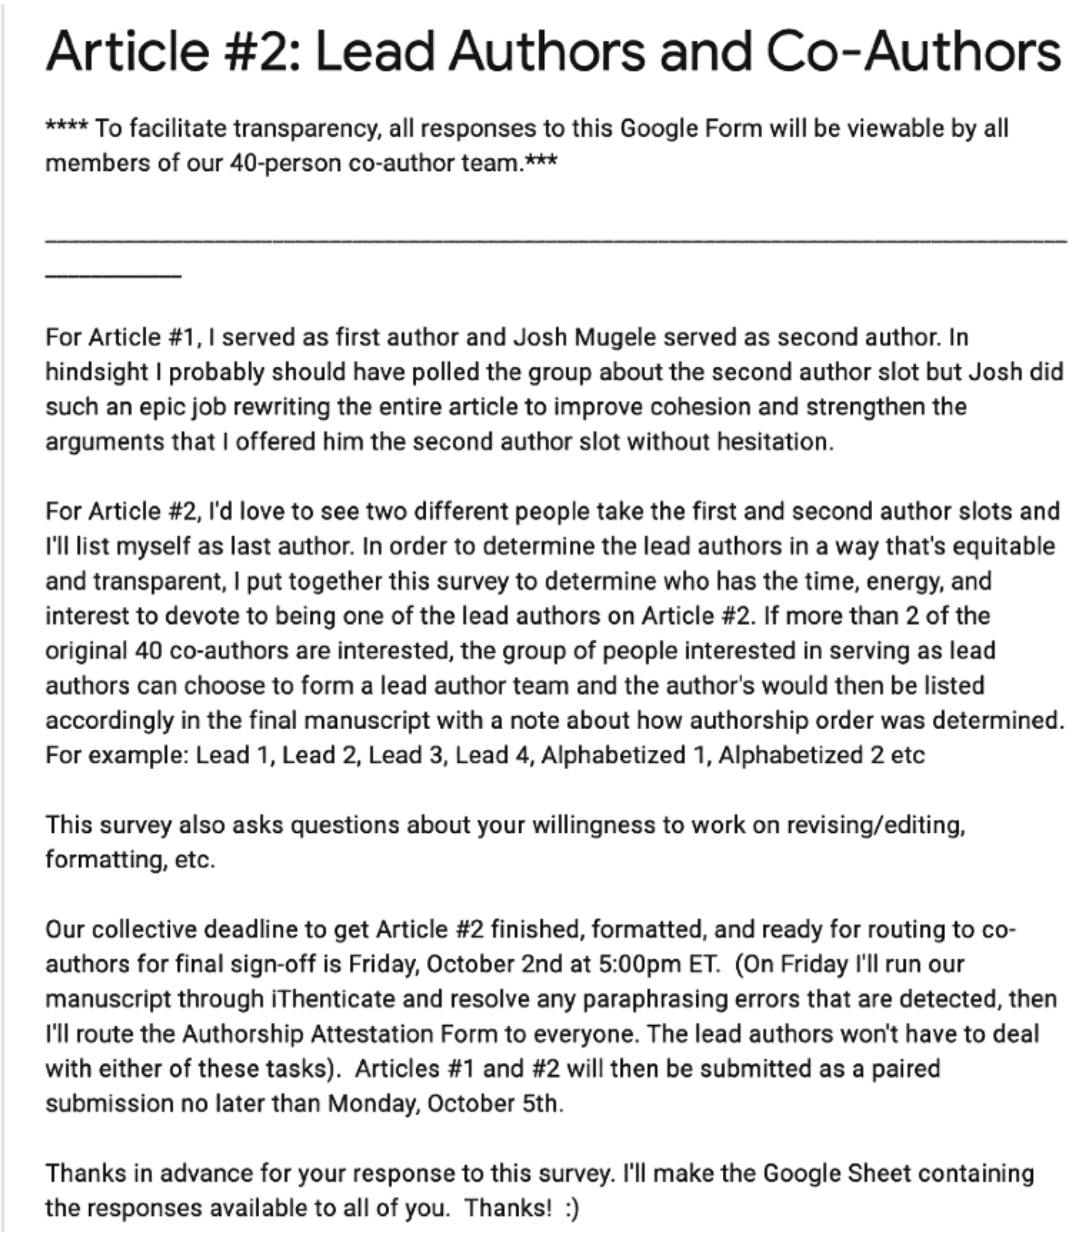
To address this, I asked co-authors to describe their specific contributions to each manuscript in a Google Sheet; then, I sent them a "Co-Author Attestation Form" at 2 different points in the manuscript preparation process. This form asked them to attest to having met all 4 of the ICMJE authorship criteria. All members of the authorship team were able to see one another's contributions to the manuscript in the Google Doc as well as their descriptions of those contributions in the Google Sheet, so there was ample opportunity for concerns to be raised if an individual was not pulling their weight as a co-author. No such concerns were raised. In a few cases, individuals recognized during the co-author attestation checkpoints that they themselves did not meet the ICMJE authorship criteria, and as such, they requested being moved to the acknowledgements. Overall, this process seems to have been both efficient and effective.

Revising, Rewriting, and Negotiating

On September 18, 2020, one collaborator (J Mugele) took the lead in completely rewriting Article #1 to improve flow and cohesion. This collaborator's contributions were substantial in reshaping the way in which Article #1 was conceptualized, so I asked him to serve as second author. Although none of the co-authors expressed concerns about this, in hindsight, I should have asked the other collaborators if they supported this decision. At the time, I was struggling to manage what had grown into a team of 45 active, engaged collaborators; Mugele's leadership in revising the article was a life buoy, and I grabbed it. Mugele sent me the revised article on September 19, 2020, and I posted it to the rest of the collaborators later that day as a link from the original Google Doc. I asked all collaborators to make final edits by Friday, September 25, 2020 and asked them to indicate their preference in the Google Sheet for listing co-authors after the first 2 authors (Acquaviva and Mugele).

Between September 19, 2020 and September 25, 2020, I followed up with collaborators via Twitter direct message to remind them to finish entering their info on the Google Sheet. The vast majority of collaborators indicated a preference for listing co-authors after Acquaviva and Mugele in alphabetical order, so I edited the title page of the manuscript accordingly. On September 25, 2020, when the article was finalized and all edits had been received, I put together 2 different Google Forms to send to collaborators. I emailed "Co-Author Attestation v. 1" to collaborators who had already documented in the Google Sheet that they met the first 2 ICMJE authorship criteria. The form asked them to indicate they approved the final version of the article and met the last 2 ICMJE authorship criteria. I emailed "Co-Author Attestation v. 2" to collaborators who had not yet documented in the Google Sheet that they met the first 2 ICMJE authorship criteria. The form asked them to describe how they met the first criteria and then indicate whether they met the other 3 criteria. I have created blank versions of the Co-Author Attestation v.1 [5] and Co-Author Attestation v.2 [6] for readers who are interested in replicating the approach described in this innovation report. The last Co-Author Attestation form for Article #1 was received on September 29, 2020. In keeping with the practice I follow with all co-authored manuscripts I write, I ran the manuscript through iThenticate prior to submission to ensure that it was free of plagiarism. None was found.

Article #2



With Article #1 finalized, I then began the process of moving Article #2 toward completion. On September 27, 2020, I sent a Google Form to the 40 original co-authors and one individual who received an acknowledgement in Article #1 but made substantial contributions to the draft of Article #2. Because all 41 of these individuals had made significant contributions to the draft of Article #2, I wanted to give each person in the group the opportunity to take a lead role on the manuscript. The Google Form contained the message shown in Figure 1.

The Google Form contained 3 questions (Figure 2).

As responses to the Google Form were received, they automatically fed into a Google Sheet that was viewable by all members of the 41-person team. I created additional tabs in the Google Sheet labeled "Lead Author Team," "Revising/Editing Team," "Formatting Team," and "Move to Acknowledgements" and then copied individual responses into these sheets. On the evening of September 27, 2020, I posted the message shown in Figure 3 as both a comment and a cell in the Lead Author Team sheet.

XSL•FO
RenderX

Figure 1. Message contained within the authorship interest form.

Article #2: Lead Authors and Co-Authors

**** To facilitate transparency, all responses to this Google Form will be viewable by all members of our 40-person co-author team.***

For Article #1, I served as first author and Josh Mugele served as second author. In hindsight I probably should have polled the group about the second author slot but Josh did such an epic job rewriting the entire article to improve cohesion and strengthen the arguments that I offered him the second author slot without hesitation.

For Article #2, I'd love to see two different people take the first and second author slots and I'll list myself as last author. In order to determine the lead authors in a way that's equitable and transparent, I put together this survey to determine who has the time, energy, and interest to devote to being one of the lead authors on Article #2. If more than 2 of the original 40 co-authors are interested, the group of people interested in serving as lead authors can choose to form a lead author team and the author's would then be listed accordingly in the final manuscript with a note about how authorship order was determined. For example: Lead 1, Lead 2, Lead 3, Lead 4, Alphabetized 1, Alphabetized 2 etc

This survey also asks questions about your willingness to work on revising/editing, formatting, etc.

Our collective deadline to get Article #2 finished, formatted, and ready for routing to co-authors for final sign-off is Friday, October 2nd at 5:00pm ET. (On Friday I'll run our manuscript through iThenticate and resolve any paraphrasing errors that are detected, then I'll route the Authorship Attestation Form to everyone. The lead authors won't have to deal with either of these tasks). Articles #1 and #2 will then be submitted as a paired submission no later than Monday, October 5th.

Thanks in advance for your response to this survey. I'll make the Google Sheet containing the responses available to all of you. Thanks! :)

Over the next 7 days, the members of the Lead Author Team and Co-Author Team made considerable revisions to the manuscript. On October 3, 2020, I posted a link at the top of the manuscript Google Doc to a Google Form. The Google Form asked members of the authorship team if they happened to know the reference for 2 sentences that had been entered into the draft, as well as asked them about their contributions to the manuscript and their preferences for author order if they were a member of the Lead Author Team. Responses to the Google Form quickly yielded answers to the 2 reference questions but did little to answer the question of what order the lead author team members should be listed. On October 4, 2020, I asked a member of the Lead Author Team (Christopher Carroll) if he would take the lead on communicating with the rest of the lead author team via email to reach consensus on author order. Within 12 hours, the members of the Lead Author Team had reached consensus on the order their names should be listed on the final manuscript. Without exception, members of the Lead Author Team were generous in recognizing the contributions of other members and humble in conveying their own.

On October 5, 2020, I repeated the authorship attestation process followed with Article #1. I emailed the Co-Author Attestation Google Form along with a link to the final manuscript to all 39 collaborators. The last Co-Author Attestation form for Article #2 was received on October 5, 2020. In keeping with the practice I follow with all co-authored manuscripts I write, I ran the manuscript through iThenticate prior to submission to ensure that it was free of plagiarism. None was found.

Results

Article #1: Documenting Social Media Engagement as Scholarship: New Model for Assessing Academic Accomplishment for the Health Professions [7]

Of the 45 collaborators who had originally entered their names into the title page of the Google Doc as potential co-authors, 40 collaborators ended up meeting the ICMJE authorship criteria, 4 collaborators decided that their contributions were more appropriate for recognition in an acknowledgement, and 1 collaborator dropped out because they were unable to contribute. The authorship team was notably diverse (Table 1).

Table 1. Authorship team composition for article #1.

Article #1	Identifies as a person of color and/or an under-represented minority, n (%)	Identifies as LGBTQ+[a], n (%)	Uses she/her pronouns	Identifies as a person with a disability
Authorship team (40 people)	7 (18)	15 (38)	29 (73)	9 (23)

[a]LGBTQ+: lesbian, gay, bisexual, transgender, gender non-conforming, queer and/or questioning.

To view the diverse array of degrees, licenses, and certifications held by the authorship team, you can view the article online [7].

After submitting the manuscript to Academic Medicine, we received a rejection within a matter of days. No feedback was provided. The authorship team revised the manuscript for submission to the Journal of Medical Internet Research (JMIR) and opted for open peer review. We received a revise-and-resubmit decision and then revised the manuscript to address the reviewers' comments and suggestions. The manuscript was then accepted for publication and published in December 2020. The day the article was published online, one of the members of the authorship team noticed that their name was not listed on the article: Apparently, I had made an error during the process of entering the metadata into the journal's online submission system. I was mortified. I immediately owned up to the error publicly on Twitter and contacted the authorship team to alert them directly. Because a correction to the list of authors in a journal article requires the approval of every member of the authorship team, I routed the corrigendum to every author for their review and signature. The error was corrected in the list of authors within a matter of days.

Article #2: The Benefits of Using Social Media as a Health Professional in Academia

Of the 41 collaborators from Article #1 who were surveyed at the beginning of the Article #2 revision process to determine their interest in serving as a lead author or co-author on the second manuscript, 2 individuals asked to be moved to the acknowledgements section of Article #2. Of the remaining 39 collaborators, 7 indicated interest in serving on the lead author team. When the manuscript was formatted and finalized and the Authorship Attestation Form was routed on October 3, 2020, 35 collaborators ended up meeting the ICMJE authorship criteria, and 4 collaborators agreed to be moved to the acknowledgements section. The authorship team for Article #2 was as diverse as Article #1, with marked diversity among the Lead Author Team in particular (Table 2).

Table 2. Authorship team composition for article #2.

Article #2	Identifies as a person of color and/or an under-represented minority, n (%)	Identifies as LGBTQ+[a], n (%)	Uses she/her pronouns, n (%)	Identifies as a person with a disability, n (%)
Lead authorship team (7 people)	2 (29)	3 (43)	3 (43)	2 (29)
Authorship team (35 people)	6 (17)	13 (37)	26 (74)	7 (20)

[a]LGBTQ+: lesbian, gay, bisexual, transgender, gender non-conforming, queer and/or questioning.

After submitting the manuscript to Academic Medicine, we received a rejection accompanied by helpful feedback for revising the paper for submission to another journal. The overarching theme running through the reviewers' comments was that we needed to focus the article more narrowly — a valid criticism with which the members of the authorship team agreed. The authorship team is in the process of revising the manuscript to address the issues raised by the Academic Medicine reviewers. Because Academic Medicine did not invite us to resubmit a revised manuscript, we plan to submit the paper to another journal that is better aligned with the subject matter.

Relationship Between the Three Manuscripts

Congruent with the ICMJE's "Recommendations for the Conduct, Reporting, Editing, and Publication of Scholarly Work in Medical Journals" [4], this manuscript is not "…reporting work that has already been reported in large part in a published article or is contained in or closely related to another paper that has been submitted or accepted for publication elsewhere." This manuscript is narrowly focused on describing the method used to establish and facilitate a large-scale collaboration using social media. The manuscript titled "Documenting Social Media Engagement as Scholarship: A New Model for Assessing Academic Accomplishment for the Health Professions" [7] presents the guidelines created through the process described in this manuscript, while the manuscript titled "The Benefits of Using Social Media as a Health Professional in Academia" (unpublished) examines the benefits of social media engagement.

Conclusion

This paper and the 2 manuscripts described therein are evidence that it is possible to establish and facilitate large-scale manuscript collaborations via social media. Open collaboration

XSL•FO
RenderX

on manuscripts in the health professions is one way to ensure diverse authorship teams and facilitate collaboration across disciplines. Scholars can use this innovation report in conjunction with the tools provided to replicate this process in carrying out their own large-scale manuscript collaborations.

Abstract

Background: Canadian public safety personnel (PSP) experience high rates of mental health disorders and face many barriers to treatment. Internet-delivered cognitive behavioral therapy (ICBT) overcomes many such barriers, and is effective for treating depression, anxiety, and posttraumatic stress disorder (PTSD) symptoms.

Objective: This study was designed to fill a gap in the literature regarding the use of ICBT tailored specifically for PSP. We examined the effectiveness of a tailored ICBT program for treating depression, anxiety, and PTSD symptoms among PSP in the province of Saskatchewan.

Methods: We employed a longitudinal single-group open-trial design (N=83) with outcome measures administered at screening and at 8 weeks posttreatment. Data were collected between December 5, 2019 and September 11, 2020. Primary outcomes included changes in depression, anxiety, and PTSD symptoms. Secondary outcomes included changes in functional impairment; symptoms of panic, social anxiety, and anger; as well as treatment satisfaction, working alliance, and program usage patterns.

Results: Clients reported large symptom reductions on measures of depression and anxiety, as well as moderate reductions on measures of PTSD and secondary symptoms, except for social anxiety. Most clients who reported symptoms above clinical cut-offs on measures of depression, anxiety, and PTSD during screening experienced clinically significant symptom reductions. Results suggested good engagement, treatment satisfaction, and working alliance.

Conclusions: Tailored, transdiagnostic ICBT demonstrated promising outcomes as a treatment for depression, anxiety, and PTSD among Saskatchewan PSP and warrants further investigation.

Trial Registration: Clinicaltrials.gov NCT04127032; https://www.clinicaltrials.gov/ct2/show/NCT04127032

Introduction

Public safety personnel (PSP) include border security personnel, communications officials (eg, emergency response dispatchers), correctional workers, firefighters, paramedics, police officers, and others whose work keeps communities safe [1]. Through their work, PSP frequently experience or witness potentially traumatic events such as motor vehicle collisions and acts of violence [2-4]. Research shows that such events put individuals at risk of developing several emotional disorders, including posttraumatic stress disorder (PTSD), major depressive disorder, and panic disorder [5-10]. In Canada, a large survey study indicated that 44.5% of PSP report clinically significant symptoms of one or more mental health disorders [11]. PSP have also reported high rates of mental health problems in other countries [12-14]. PSP face many barriers to treatment, such as stigma, distance from services, and time constraints [15]. Stigma appears to be a particularly prohibitive barrier to treatment among PSP [15,16].

Internet-delivered cognitive behavioral therapy (ICBT) is a treatment wherein traditional cognitive behavioral therapy skills are taught via online learning platforms and is poised to help overcome these barriers to treatment for PSP. ICBT can be accessed privately and conveniently, and it is cost-effective because it requires less therapist time per client than traditional face-to-face treatments [17,18]. Meta-analyses have shown that ICBT is effective for treating symptoms of a range of mental disorders, including depression, anxiety, and PTSD [19,20]. There have been several recent calls for internet interventions to be tailored to the unique needs of their target users to facilitate greater treatment engagement [21,22]. As one group stated, this process begins with establishing "a deep understanding of user needs and preferences, and actively involving users in design processes from the outset" [21]. Tailoring ICBT may be particularly important for PSP, who have reported several unique needs such as the need for flexible treatment timelines, diverse preferences for frequency of therapist support, specialized therapists with knowledge of unique PSP issues and culture, and a focus on exposures to potentially psychologically traumatic events [15]. Canadian PSP appear receptive to therapist-supported ICBT, which was ranked as their most preferred mental health treatment after face-to-face psychological services [23].

The Government of Canada recently announced a $10 million investment into developing, delivering, and evaluating ICBT tailored specifically for PSP [24]. Our research unit, PSPNET, was contracted to carry out this work. We conducted extensive interviews with PSP stakeholders to better understand their needs and preferences [15] and, drawing upon their feedback, tailored a transdiagnostic ICBT program that previously demonstrated positive outcomes for a range of conditions to meet the needs of PSP. The tailored course of treatment is called the PSP Wellbeing Course, which is described in detail below.

This paper presents the initial outcomes of the PSP Wellbeing Course among the first 83 PSP enrolled in the course during the first 7 months of availability in Saskatchewan. The study objectives were to evaluate the initial (a) effectiveness, (b) treatment satisfaction and working alliance, and (c) program usage patterns of the PSP Wellbeing Course. We hypothesized high completion rates, high satisfaction, and moderate to large effect sizes for symptom change. This study is the first, as far as we are aware, to evaluate the tailored ICBT approach for treating mental health problems among PSP.

This study's sample represents only the first third of the sample described in our trial protocol (N=250; Clinicaltrials.gov NCT04127032). This early evaluation of outcomes is important for three reasons. First, it is important to ensure that the development and delivery of the PSP Wellbeing Course is a fruitful use of Canadian tax dollars. Second, evaluation of early outcomes is consistent with the learning health system approach, which is characterized by a continuous cycle of gathering data from practice, transforming data into knowledge, and implementing knowledge into practice [25]. Third, our preliminary findings may be helpful for others involved in the development, provision, evaluation, and funding of mental health services for PSP.

Methods

Study Design

We employed a longitudinal single-group open-trial design. This study was approved by the local institutional research ethics board (2019-157) and registered on Clinicaltrials.gov (NCT04127032). This article presents the initial study outcomes for the first 83 clients who enrolled in the PSP Wellbeing Course (one third of the total expected sample of 250). We have followed the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement in preparing the article [26].

Setting

This study was performed in the Canadian province of Saskatchewan. There was no specialized ICBT for PSP in Saskatchewan prior to this study. ICBT has been available to Saskatchewan residents through the Online Therapy Unit [27] since 2010, but the numbers of PSP using this service have not been systematically tracked.

Clients

All clients who enrolled in the PSP Wellbeing Course between December 5, 2019 and July 2, 2020 consented to our use of their data for research and were included in this study. Enrollment in the PSP Wellbeing Course required clients to (a) be 18 years or older, (b) currently or formerly employed as a PSP (as defined above), (c) have access to a computer and internet service, (d) provide an emergency medical contact, and (e) reside in the province of Saskatchewan (although we later began offering the PSP Wellbeing Course in English and French to residents of Quebec as well). Prospective clients were excluded and referred to appropriate services if they (a) reported a high suicide risk; (b) had attempted suicide or had been hospitalized for a high suicide risk within the past year; (c) reported a primary problem with psychosis, mania, or alcohol and drugs; (d) reported receiving psychological treatment more than twice per month; or (e) reported concerns about ICBT and requested referral to other services in the community.

XSL•FO
RenderX

Intervention

The PSP Wellbeing Course was adapted from a transdiagnostic ICBT program called the Wellbeing Course, which was developed for use in the general population by eCentre Clinic at Macquarie University, Australia [28-32]. The PSP Wellbeing Course is designed to treat symptoms of depression, anxiety, and PTSD. The course consists of five sequential lessons, which are presented in a slideshow format and focus on (1) introducing the cognitive behavioral model and symptom identification, (2) monitoring and challenging maladaptive thoughts, (3) managing physical symptoms, (4) graded exposure, and (5) relapse prevention. Lesson content is relayed through instructive text, diagrams, and illustrative case stories about PSP. Clients are also given access to downloadable materials, weekly homework assignments, and supplementary resources related to issues not addressed in the lessons (eg, assertiveness, communication, sleep problems). Therapists hold graduate degrees in psychology or social work and provide support to clients by phone or secure email up to twice per week, depending on each client's preference. Each week, clients complete symptom questionnaires and a reflection questionnaire including both open-ended and closed-ended questions designed to gauge response to the treatment program (eg, what clients worked on; any challenges they encountered; and ratings of helpfulness, understanding, and difficulty). The course is designed to be completed in 8 weeks, but clients are provided with therapist support for up to 16 weeks based on symptoms and preference, and are given access to the course materials for 1 year. We tailored the PSP Wellbeing Course using extensive feedback from PSP stakeholders gleaned through 112 interviews [15] and 132 survey responses [23] (eg, replacing generic case stories and examples used to illustrate treatment concepts with case stories and examples about PSP).

Procedure

Prospective clients completed a two-stage eligibility screening process consisting of an online screening questionnaire (demographics, clinical history, and the measures described below) and a screening interview by phone. Clients then began the PSP Wellbeing Course. Clients were automatically administered brief weekly questionnaires and a longer battery of questionnaires at 8 weeks, as detailed below. Questionnaires were embedded in the course. Members of our research team followed up with clients by phone or email to encourage them to complete posttreatment measures.

Measures

Primary Outcome Measures

Patient Health Questionnaire-9

The Patient Health Questionnaire-9 (PHQ-9) measures symptoms of depression and includes one item to assess suicidality [33]. It includes nine items rated from 0 (not at all) to 3 (nearly every day), with total scores ranging from 0 to 27. A score greater than 9 is typically used to identify a likely diagnosis of major depressive disorder [34]. The PHQ-9 has demonstrated excellent psychometric properties [33,35,36]. Cronbach α for the PHQ-9 in this study ranged from .84 to .88.

Generalized Anxiety Disorder-7

Generalized Anxiety Disorder-7 (GAD-7) is a brief measure of general anxiety symptoms [37]. It includes seven items rated from 0 (not at all) to 3 (nearly every day) for a total score ranging from 0 to 21. The GAD-7 has demonstrated strong psychometric properties, and a score of 10 or greater is typically used to identify a likely diagnosis of generalized anxiety disorder [36,37]. Cronbach α for the GAD-7 in this study ranged from .86 to .92.

Posttraumatic Stress Disorder Checklist for DSM-5

The Posttraumatic Stress Disorder Checklist for the DSM-5 (PCL-5) measures symptoms of PTSD and includes 20 items rated from 0 (not at all) to 4 (extremely) [38]. A cut-off of 33 was recommended by several groups to indicate a likely diagnosis of PTSD [39,40]. The PCL-5 has shown good psychometric properties [39]. Cronbach α for the PCL-5 in this study ranged from .95 to .96.

Secondary Outcome Measures

Panic Disorder Severity Scale Self-Report

The Panic Disorder Severity Scale Self-Report (PDSS-SR) is a psychometrically sound 7-item measure assessing symptoms of panic disorder [41]. Items are rated from 0 to 4 for a total score of 0 to 28. It is common practice to employ a cut-off score of 8 on the PDSS-SR [42-44], based on the cut-off initially established for the nonself-report PDSS [45]. Cronbach α for the PDSS-SR in this study was .89-.91.

Six-Item Social Phobia Scale and Six-Item Social Interaction Anxiety Scale

The 6-item Social Phobia Scale (SPS-6) and 6-item Social Interaction Anxiety Scale (SIAS-6) are brief measures of social anxiety that are psychometrically sound when administered together or separately [46]. Items are rated from 0 to 4 for total scores of 0 to 24 on each measure or a combined total of 0 to 48, with a clinical cut-off of 2 on the SPS-6 and of 7 on the SIAS-6 [46]. Cronbach α for the measures combined in the current study was .91 and .94.

Dimensions of Anger Reactions Scale

The Dimensions of Anger Reactions Scale (DAR-5) is a 5-item measure of anger that has demonstrated good psychometric properties [47]. Scores range from 5 to 25 with a cut-off of 12 [48]. Cronbach α for the DAR-5 in this study was .88 and .89.

Sheehan Disability Scale

The Sheehan Disability Scale (SDS) is a psychometrically sound 3-item measure assessing respondents' functioning in their home lives, social lives, and work/school lives [49].

Treatment Satisfaction Questionnaire

We administered a bespoke questionnaire to explore treatment satisfaction.

Working Alliance Inventory-Short Revised

The Working Alliance Inventory-Short Revised (WAI-SR) is a 12-item measure of working alliance with goal, task, and bond subscales that has demonstrated good psychometric properties [50,51]. The Cronbach α for the WAI-SR in this study was .94

XSL•FO
RenderX

for the goal subscale, .93 for the task subscale, and .95 for the bond subscale.

Administration of Measures

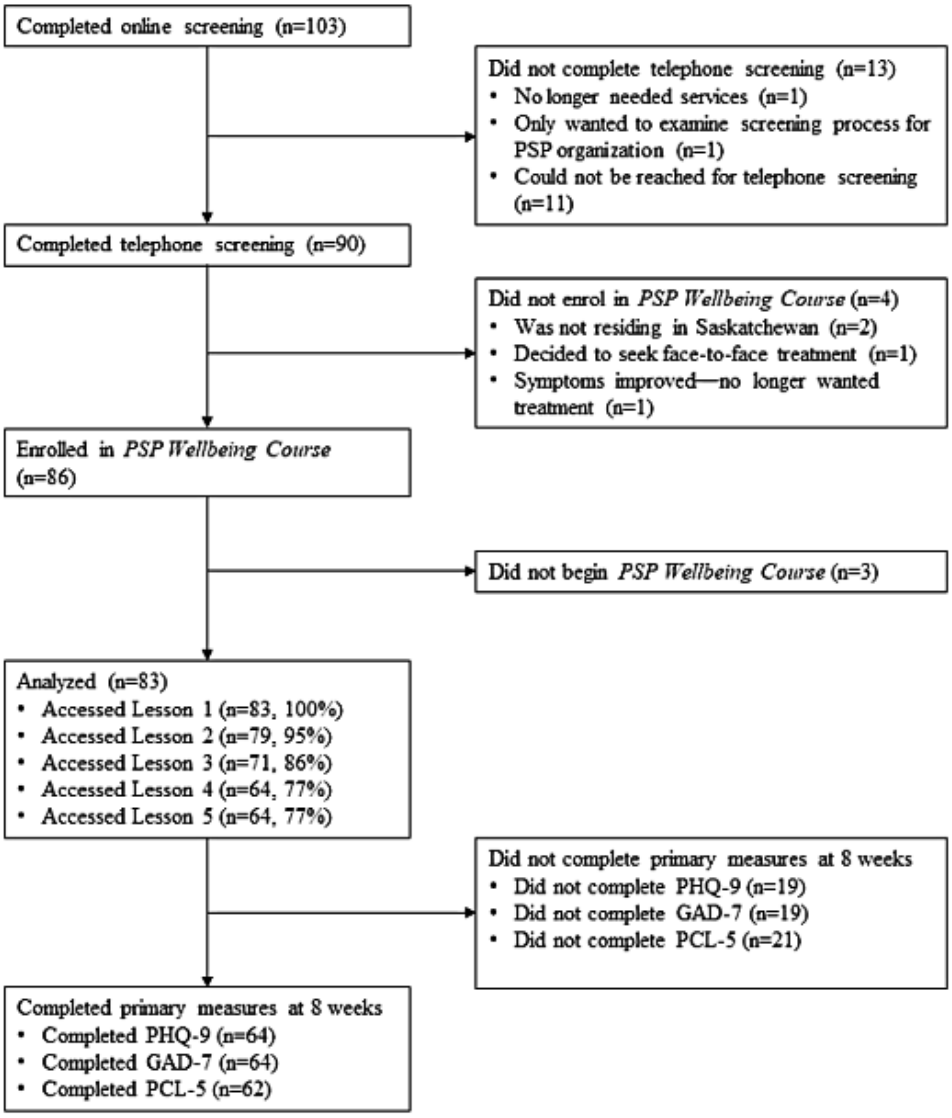
At screening and posttreatment, clients were administered the PHQ-9, GAD-7, PLC-5, PDSS-SR, SPS-6, SIAS-6, DAR-5, and SDS. Additionally, at posttreatment, clients were administered the Treatment Satisfaction Questionnaire and WAI-SR. Certain measures were administered weekly during treatment, and at 6 months and 1 year postenrollment. These time points are not included in the present analyses but will be reported in the future once more data are available.

Analyses

Following intention-to-treat principles, we first created multiple imputations for missing data using predictive mean matching. Imputations for missing data were modeled controlling for lesson completion rates, pretreatment symptom measures, and, if available, weekly symptom measures. We used generalized estimating equations (GEEs) to model the change in symptoms from pretreatment to posttreatment [52]. A gamma distribution with a log-link function was used to model changes between pretreatment and posttreatment as proportional and to accommodate the skewed response distribution [53]. We ran the imputations and GEE models in R version 4.0.3 using the mice [54] and geepack [55] packages.

The effectiveness of the PSP Wellbeing Course was evaluated by examining Hedges *g* and proportional reductions in symptoms. Hedges *g* is calculated as the difference in means between pretreatment and posttreatment divided by the pooled SD and multiplied by a small-sample bias correction. It is interpreted similarly to Cohen *d* but was considered to be a more appropriate measure of effect size for this study given the small size of our clinical subsamples. Some researchers have recommended calculating Hedges *g* using the SD of the control or pretreatment group instead of the pooled SD when pretreatment and posttreatment SDs are unequal [56]. Indeed, we noted that in the subsets of clients scoring above clinical cut-offs at pretreatment, the pretreatment SDs were much lower than the posttreatment SDs. However, because these subsets represented a restricted range of pretreatment scores, a greater SD at posttreatment would be expected—even in the absence of a treatment effect—due to regression toward the mean [57]. Therefore, we used pooled SDs in calculating Hedges *g* in the clinical subsets to avoid overestimating effect sizes.

We also examined clinically significant deterioration and recovery for the PHQ-9, GAD-7, and PCL-5. Following the UK National Health Service guidelines, deterioration was defined as an increase of at least 6 points on the PHQ-9 [58]. Following precedents set in previous research using the same outcome measures, deterioration was defined as an increase of 5 points on the GAD-7 [59,60] or 10 points on the PCL-5 [61]. Recovery was defined as a decrease of at least 6 points on the PHQ-9, 5 points on the GAD-7, or 10 points on the PCL-5 that resulted in the patient moving from the clinical range to the nonclinical cut-off scores described in the Measures section above. We examined the uptake, treatment satisfaction and acceptability, and program usage patterns using descriptive statistics in SPSS version 23.



Results

Client Characteristics

There were 83 clients included in this study. The flow of clients through the study process is shown in Figure 1. Client characteristics are summarized in Table 1.

Effectiveness

The effect sizes for each scale, along with the percentage changes and reliable change rates for primary symptom measures are detailed in Table 2. The results indicated large effect sizes on the PHQ-9 and GAD-7, and a moderate effect size on the PCL-5. When examining effect sizes for each primary measure only among clients reporting clinically significant symptoms on that measure at screening, we found large effect sizes on all three measures. In general, we found moderate effect sizes on secondary symptom measures in the entire sample and moderate to large effect sizes when examining only clients reporting clinically significant symptoms at screening; however, the results indicated small effect sizes on the combined SIAS-6 and SPS-6 among all clients and for those with clinically significant SIAS-6 and SPS-6 scores at screening.

[a]PHQ-9: Patient Health Questionnaire-9.

[b]GAD-7: Generalized Anxiety Disorder Questionnaire-7.

[c]PCL-5: Posttraumatic Stress Disorder Checklist for DSM-5.

[d]PDSS-SR: Panic Disorder Severity Scale Self-Report.

[e]N/A: not applicable; reliable recovery and deterioration were only calculated for primary measures because the magnitude of the score change required to determine reliable score changes for several secondary measures was unknown.

[f]SIAS-6/SPS-6: 6-item Social Interaction Anxiety Scale/6-item Social Phobia Scale.

[g]DAR-5: Dimensions of Anger Reactions-5.

[h]SDS: Sheehan Disability Scale.

[i]For each measure, estimated means, effects sizes, and percentage change are calculated based on those who scored in the clinical range on the measure at pretreatment.

Treatment Satisfaction and Working Alliance

Of the 62 clients who completed the WAI-SR and questions related to treatment satisfaction, 54/62 (86%) indicated that the PSP Wellbeing Course had increased or greatly increased their confidence in their ability to manage their symptoms, and 61/62 (98%) indicated that the PSP Wellbeing Course was worth their time. Mean scores on the bond, goal, and task subscales of the WAI-SR were 16.11 (SD 4.64), 14.50 (SD 4.72), and 14.63 (SD 4.07), respectively. To our knowledge, there are no formal guidelines for interpreting WAI-SR scores, but these participant scores fall in the “high/positive” range according to the interpretation of one group of ICBT researchers [62].

Program Usage Patterns

All 83 clients included in the analyses accessed Lesson 1 of the PSP Wellbeing Course. Most clients also accessed Lesson 2 (79/83, 95%), Lesson 3 (71/83, 86%), Lesson 4 (64/83, 77%),

XSL•FO
RenderX

and Lesson 5 (64/83, 77%). Of the 60 clients who completed 8-week measures, at the time they did so, all had accessed Lesson 1 and Lesson 2, and most had accessed Lesson 3 (58/60, 97%), Lesson 4 (54/60, 90%), and Lesson 5 (45/60, 75%). Across the entire sample, most clients who accessed each lesson also accessed the accompanying DIY guides (92% or more for each lesson), FAQs (84% or more), and stories about PSP (84% or more). Many clients accessed additional resources; the most frequently accessed resources were on relationships with significant others (46/83, 55%), anger (42/83, 51%), communication skills (40/83, 48%), and problem solving and worry time (40/83, 48%). Most clients opted to receive therapist support once per week (74/83, 89%), but some opted to receive therapist support twice per week (6/83, 7%) or only on an as-needed basis (3/83, 4%). On average, clients sent 4.98 messages (SD 5.53) to their therapists and received 9.80 (SD 4.71) messages.

Some clients reported using the PSP Wellbeing Course concurrently with other treatments. At prescreen, some clients reported currently taking one or more medications for their mental health (18/83, 22%) or receiving mental health care from one or more providers (19/83, 23%), the most common of which were family doctors (13/83, 16%), psychologists (6/83, 7%), psychiatrists (4/83, 5%), and counsellors (3/83, 4%). Per the eligibility criteria described above, none of these clients were receiving mental health treatments from these providers more than twice per month. Several clients (4/83, 5%) indicated that they were on a waitlist to see a mental health care provider.

Discussion

Principal Findings

Canadian PSP experience high rates of mental health problems and face several barriers to mental health care [15,16]. ICBT is a promising solution for effectively managing symptoms of common mental disorders [19,20] in a private and convenient fashion that allows clients to overcome key barriers for care [15,17]. PSPNET has developed a tailored ICBT program for PSP called the PSP Wellbeing Course. This article presents the initial program outcomes.

The results indicated that the PSP Wellbeing Course is effective for treating symptoms of depression, anxiety, PTSD, panic disorder, and anger, and also improves clients' functioning across three domains of life. The course appeared to be only slightly effective for treating symptoms of social anxiety, but this should be interpreted with caution because the subsample reporting clinically significant social anxiety was small (n=27). Nonetheless, in keeping with the learning health system approach [25], PSPNET will explore the possibility of providing additional resources to help clients manage social anxiety symptoms. This is important because approximately 15% of Canadian PSP—and 33% in this study's treatment-seeking sample—struggle with clinically significant social anxiety [11]. Results concerning treatment satisfaction, working alliance, and engagement were promising. Although in our interviews with PSP stakeholders [15], most had expressed a preference for a flexible treatment duration, it was encouraging that most clients completed all lessons within 8 weeks. It was also very encouraging that working alliance was high because many PSP we interviewed previously [15] reported negative attitudes toward mental health care providers (eg, distrust, discomfort, beliefs that service providers do not understand PSP). Most clients accessed multiple additional resources, suggesting that they found them helpful and lending some support to recommendations for modularized, optional treatment elements in internet interventions [21].

Descriptively, these outcomes are comparable to the most recent published outcomes of the Wellbeing Course offered by the Online Therapy Unit to the general population of Saskatchewan [63]. Effect sizes, percentage changes, and reliable change rates were comparable for all available symptom measures with the possible exception of the SIAS-6/SPS-6, which appeared to show better outcomes for the Wellbeing Course. However, mean pretreatment social anxiety symptoms were considerably less severe in the present sample than in the Online Therapy Unit's clients [63], and the smaller change in symptoms found in this study may be due, in part, to a floor effect. Of note, the present findings show that the PSP Wellbeing Course was moderately effective for treating anger, which has not been measured in research on the Wellbeing Course. PSP participating in this study reported concurrent use of psychotropic medication less frequently than clients of the Wellbeing Course [63]. Results concerning treatment satisfaction, working alliance, and engagement were similar across the two courses.

Limitations

This study has several limitations. First, the data were collected during the COVID-19 pandemic, and the impact of the pandemic on outcomes is unclear. Second, there was no control condition and therefore no direct evidence that symptom change can be attributed to the PSP Wellbeing Course. However, it has been argued that the literature on digital mental health interventions would benefit from more research evaluating such interventions in real-world settings [64,65], as we did in this study. Third, at 8 weeks, we were missing PHQ-9 and GAD-7 data for 23% of clients and PCL-5 data for 25% of clients. A conservative approach was used to manage missing data, but it is possible that clients for whom data were missing may represent a unique subset of clients (eg, clients who experienced less positive outcomes).

Future Directions

Further research can extend these findings in several ways. This article describes the results for only the first third of the sample (83 of 250) specified in our trial protocol; full results will be reported when available, including outcomes at 1-year follow-up and for PSPNET clients in Quebec. Further research will also be required to explore demographic and clinical predictors of treatment response for the PSP Wellbeing Course and to identify new ways to tailor and improve ICBT for PSP. Finally, although this study suggests that the PSP Wellbeing Course benefits the PSP who access it, economic evaluation will be required in the future.

Conclusions

Preliminary results indicate that the PSP Wellbeing Course is a promising and effective method for treating symptoms of

XSL•FO
RenderX

depression, anxiety, and PTSD among Saskatchewan PSP. Our results also suggest that the course improved clients' functioning and reduced their symptoms of panic and anger, but not social anxiety. Clients reported good working alliance and treatment satisfaction, and they demonstrated good engagement. Consistent with the concept of learning health systems, PSPNET will continue applying research results to iteratively improve tailored ICBT services, such as by investigating ways to better treat symptoms of social anxiety among PSP. Our findings may also be helpful for other groups involved in researching, providing, funding, or otherwise supporting mental health care for this unique and underserved population.

Acknowledgments

We would like to acknowledge the contributions of all PSP who have participated and the members of the PSPNET team for their support with this project. We would also like to acknowledge the many stakeholders and organizations who have assisted us in tailoring the PSP Wellbeing Course and distributing information about PSPNET to PSP. Acknowledgements are due to the Online Therapy Unit for their support in setting up PSPNET. The authors are indebted to Information Services at the University of Regina, especially Max Ivanov, for his pivotal role in developing the Online Therapy Unit platform that is used to host PSPNET. This research was performed by PSPNET, which is funded by the Canadian Government's Ministry of Public Safety and Emergency Preparedness. The funders had no involvement in the design of the study, or in the collection, analysis, and interpretation of the data. NT and BD are funded by the Australian Government to operate the MindSpot Clinic. NT and BF developed the Wellbeing Course but derive no financial benefit from it.

Conflicts of Interest

HH is the Director of PSPNET and Executive Director of the Online Therapy Unit, and declares funding as noted above. BFD and NT are authors and developers of the Wellbeing Course, but do not derive any personal or financial benefit from it. The other authors have no conflicts of interest to declare.

Abstract

Background: Major depressive disorder is a chronic condition; its prevalence is expected to grow with the aging trend of high-income countries. Internet-based cognitive-behavioral therapy has proven efficacy in treating major depressive disorder.

Objective: The objective of this study was to assess the cost-effectiveness of implementing a community internet-based cognitive behavioral therapy intervention (Super@, the Spanish program for the MasterMind project) for treating major depressive disorder.

Methods: The cost-effectiveness of the Super@ program was assessed with the Monitoring and Assessment Framework for the European Innovation Partnership on Active and Healthy Ageing tool, using a 3-state Markov model. Data from the cost and effectiveness of the intervention were prospectively collected from the implementation of the program by a health care provider in Badalona, Spain; the corresponding data for usual care were gathered from the literature. The health states, transition probabilities, and utilities were computed using Patient Health Questionnaire–9 scores.

Results: The analysis was performed using data from 229 participants using the Super@ program. Results showed that the intervention was more costly than usual care; the discounted (3%) and nondiscounted incremental cost-effectiveness ratios were €29,367 and €26,484 per quality-adjusted life-year, respectively (approximately US $35,299 and $31,833, respectively). The intervention was cost-effective based on the €30,000 willingness-to-pay threshold typically applied in Spain (equivalent to approximately $36,060). According to the deterministic sensitivity analyses, the potential reduction of costs associated with intervention scale-up would reduce the incremental cost-effectiveness ratio of the intervention, although it remained more costly than usual care. A discount in the incremental effects up to 5% exceeded the willingness-to-pay threshold of €30,000.

Conclusions: The Super@ program, an internet-based cognitive behavioral therapy intervention for treating major depressive disorder, cost more than treatment as usual. Nevertheless, its implementation in Spain would be cost-effective from health care and societal perspectives, given the willingness-to-pay threshold of €30,000 compared with treatment as usual.

Introduction

Population aging is a global trend and is expected to be one of the most significant societal challenges worldwide in upcoming years [1]. The profound impact that this aging trend is likely to cause on our societies and economies has prompted significant efforts in turning the challenges of this scenario into opportunities for rethinking the way we design and organize our society, including the delivery of health and social care services [2-5].

Depression is a significant contributor to morbidity during entire lifespans and has been among the 3 leading nonfatal causes of disability globally for nearly three decades [6]. Although often underdiagnosed, depression is the most prevalent mental health condition among adult population and across cultural settings resulting in an aggregate point prevalence of 12.9%, 1-year prevalence of 7.2%, and lifetime prevalence of 10.8% (years 1994-2014) [7-9].

The burden of depression is specifically high among the elderly, irrespective of the presence of cognitive impairment, particularly in long-term care settings [8,10,11]. Various factors may increase the risk of depression among older people, including physiological factors (eg, cardiovascular disease, diabetes, or immunological changes) and psychosocial factors (eg, low economic status, social isolation, or relocation) [12-14]. Once established, depression in older people increases the risk of suicide and may trigger dementia [10].

While the efficacy of psychotherapy in the treatment of depression has been proven [15], the availability of evidence-based interventions constitutes a persistent challenge given the lack and unequal distribution of qualified practitioners, delayed provision of treatment, and inadequacy of treatment [16,17]. Given the limitations and health care costs associated with treating depression (eg, US $7638, according to a study conducted in Singapore [18]), there is growing interest in alternative therapies to routine care. Among them, a plethora of internet-based cognitive behavioral therapies for depression treatment have been introduced, many showing efficacy in treating major depressive disorder [19-21]. Although costs associated with the implementation of these therapies have been assessed, most studies are based on descriptive approaches, and formal cost-effectiveness analysis of internet-based cognitive behavioral therapy interventions are scarce [22].

While randomized controlled trials and accompanying cost-effectiveness analysis can be considered the gold standard in exploring the cost-effectiveness of mental health interventions, the idealized and controlled nature of these trials limits the generalizability of findings to routine care populations [23-25]. Establishing the cost-effectiveness of an intervention and its implementation under routine care conditions is an important part of the evaluation before wide-scale adoption. So far, establishing the cost-effectiveness of implementation projects in routine care provides a methodological challenge.

MasterMind was a European cofunded project aimed at scaling-up the implementation of evidence-based internet interventions (eg, internet-based cognitive behavioral therapy) for the treatment of adults experiencing depressive symptoms across Europe [26]. In this study, we assessed the cost-effectiveness of the Super@ intervention as part of its implementation within the MasterMind project in a pilot site in Spain. The current analysis was performed using the Monitoring and Assessment Framework for the European Innovation Partnership on Active and Healthy Ageing (MAFEIP) tool, developed for monitoring the financial sustainability of initiatives for promoting a healthy lifespan of European citizens [27,28]. Provided as a free-to-access tool for economic evaluations, MAFEIP has gained relevance over the years, and its usage is expanding, particularly within the European project landscape.

Methods

Overview of Study Design

As part of the MasterMind project for implementing an internet-based cognitive behavioral therapy for treating depression, we designed a pragmatic within-group trial to assess the cost-effectiveness of the intervention [29,30]. The evaluation framework applies the Model for Assessment of Telemedicine applications [31], which helped to define the data collection tools and instruments according to 3 levels of stakeholders involved within the implementation process: (1) patients, (2) professionals, and (3) organizations.

This analysis corresponds to the experience of the MasterMind project in the BSA (*Badalona Serveis Assistencials*) consortium, implemented under a program named *Super@ tu depresión* ("Get over your depression"). The BSA consortium provides primary and specialized care to a catchment population of 433,175 inhabitants in the most densely populated suburban area of Barcelona and has a long tradition in integrated care and the adoption of digital health solutions [32-38]. The implementation and data collection process for the Badalona pilot site was carried out between March 2015 and June 2017. The outcomes and costs of the intervention were compared with those of usual care in previously published data from the same area [39].

The local study protocol was approved by the Ethics Committee of the Hospital *Germans Trias i Pujol* (reference PI-15-069), and all participants provided informed consent before entering the study.

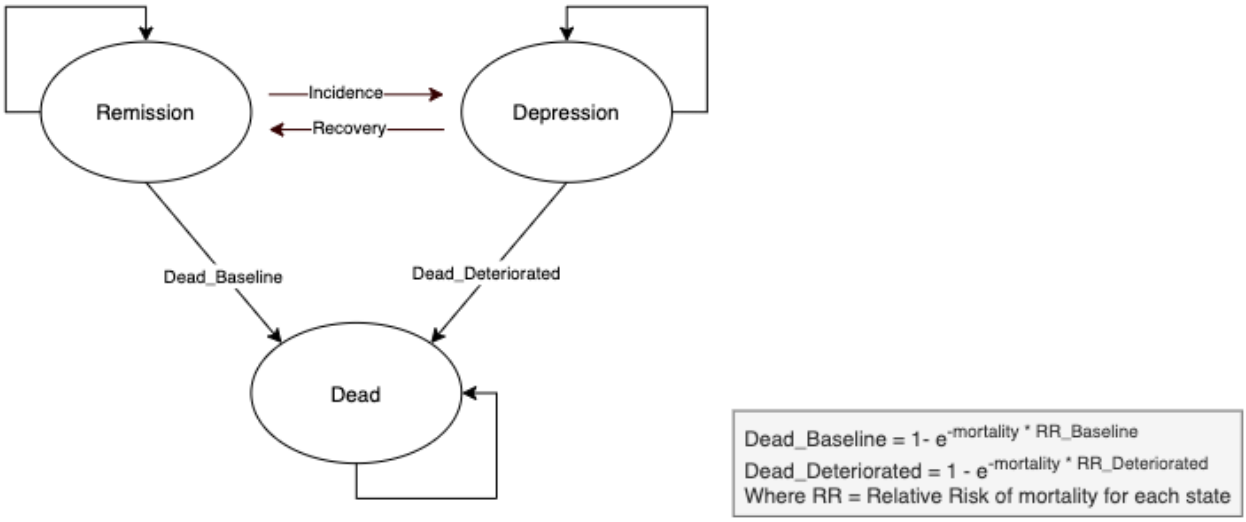
Participants

Study candidates included health care recipients and were screened for eligibility after general practitioner referral in the primary care setting. All consecutive patients who visited their general practitioners during the study period and met the selection criteria were offered the opportunity to participate in the Super@ program. Patients included in the study were adults (ie, 18 years or older) diagnosed with mild, moderate, or severe major depressive disorder based on the Patient Health Questionnaire 9 (PHQ-9; with score cutoffs of 10, 15, and 20 for mild, moderate, and severe major depressive disorder, respectively), living in Badalona and who, according to their general practitioner, had a certain level of technological literacy and internet connection. The main exclusion criteria were having

XSL•FO
RenderX

comorbidities that may interfere with the treatment, having a nonpsychiatric disease that could explain depressive symptoms, receiving structured face-to-face psychological therapy at the time of inclusion, and reporting a high suicidal risk or ideation (item 9 of the PHQ-9). After checking all selection criteria and obtaining written informed consent, the general practitioner referred participants to the internet-based cognitive behavioral therapy service, provided a comprehensive explanation about the intervention, and enrolled participants in the platform, which automatically provided a username and a password to the participant.

Intervention



The Super@ program (Multimedia Appendix 1) consisted of 9 modules (8 regular and 1 extra) composed of videos, text content, and questionnaires to monitor the progression of symptoms and adherence to the intervention. Therapists provided guidance and project management within the BSA team to ensure patient follow-up and activation of the appropriate resources upon an increase of depressive symptoms. A project management team facilitated the project and its implementation process. Table S1 (Multimedia Appendix 1) summarizes the main activities performed in the project and the different professional profiles and teams involved in each. Intervention completion (ie, minimal adequate dose) was defined as engaging in a minimum of 3 modules of internet-based cognitive behavioral therapy.

Cost-Effectiveness Assessment

Model Structure, Transition Probabilities, and Utility Estimates

The cost-effectiveness of the Super@ program was assessed using the MAFEIP tool, which computes costs and utilities using a Markov model of health states and corresponding transition probabilities [40]. Based on previous economic evaluations of treatments for major depressive disorder, we defined a 3-state Markov model, with remission (PHQ-9 score <10), depression (PHQ-9 score ≥10), and death [41] (Figure 1). Transitions between the 3 states of the Markov model included recovery (ie, the probability of going from depression to remission) and relapse (ie, the probability of going from remission to depression); death was used as an absorbing state. The transition probabilities for the intervention group were calculated based on the changes between the health states at baseline and after the intervention. Given the lack of a control group, the corresponding probabilities for treatment as usual were obtained from a recent meta-analysis [41] assessing the usual care effects on major depressive disorder, which included 38 studies with pooled a remission rate (adjusted for publication bias) of 33% (95% CI 26%-40%). As suggested elsewhere [42], the risk of all-cause mortality was derived from life tables—in this case, the Human Mortality Database [43], which is stratified by gender and provides mortality rates at concrete years of age—and adjusted for depression [44].

Figure 1. Diagram of the 3-state Markov model of health states and transition probabilities designed for the Super@ intervention.

In accordance with standard guidelines for estimating quality-adjusted life-years in economic evaluations, the MAFEIP tool recommends computing utilities based on measures of health-related quality of life, preferably the EuroQoL 5-dimension (EQ-5D) questionnaire [45]. However, no estimates of health-related quality of life were collected during the assessment of the Super@ program. Alternatively, based on the relationship between utility scores derived from (including the EQ-5D score) and depression health states reported by Kolovos et al [46], we estimated the remission utility from the results of the PHQ-9 measure: the values proposed for 4 clinical categories of major depressive disorder severity were adapted to the 3-state model by estimating the weighted average of utilities of patients in the remission state (ie, PHQ-9 score <10) and those in the depression state (PHQ-9 score ≥10) (Multimedia Appendix 1).

Cost Estimate

The MAFEIP tool considers 3 types of costs: one-off costs, which represent the total cost incurred only once at the implementation point (ie, implementation support, training provision of professional staff, and cost of devices), health care costs (ie, health care resources consumption such as costs associated with the time spent by health care professionals on service provision, hospitalizations, pharmacy, etc), and societal

XSL•FO
RenderX

costs (ie, related to the time spent by either patients or informal caregivers such as the time spent using the technology or traveling to the hospital).

One-off costs were the main costs of implementing the Super@ services and included the support given to therapists to implement the intervention in their daily routine, the training of professional users, and the costs of development and adaptation of Super@ to the existing information and communication technology platform. Based on the annual gross salary of technical staff in Spain and the number of hours devoted to the project (ie, part-time 50%), we estimated €158 per patient (approximately US $190; an exchange rate of approximately €1 to US $1.20 is applicable at the time of publication). The costs of development and adaptation of Super@ to the existing information and communication technology platform were €237 per patient (US $285). Recurring costs, which included direct costs of each internet-based cognitive behavioral therapy session, amounted to €2439 (US $2927) per patient. For the control group, the typical situation is setting the one-off and recurrent costs at 0, because in most cases, the intervention would mean an additional investment.

Health care and societal costs were not collected in the MasterMind project. These costs were gathered from a previous study [39] that described the costs associated with major depressive disorder in the same area. Based on this study [39], we established the health care costs for patients in remission and depression as €451 and €826, respectively (US $542 and US $993). Correspondingly, the costs due to loss of labor productivity were €991 and €1842 for patients in remission and depression, respectively (US $1191 and US $2214). Health care and societal costs were assumed to be the same for the intervention and control groups.

In accordance with recommendations from local health technology assessment authorities in Spain, we applied a discount factor of 3% for both health care outcomes and costs [47]. The willingness-to-pay threshold was established at €30,000 per quality-adjusted life-year, the threshold most frequently used in Spain (equivalent to approximately $36,060).

The cycle length of the Markov model was set at 1 year (ie, the maximum allowed in the MAFEIP tool). Given the chronic nature of major depressive disorder [48], we established the number of cycles necessary to cover the time lapse between the average age of study participants (ie, 46 years) and a theoretical lifespan time of 100 years.

Analysis

The cost-effectiveness analysis was performed on the intention-to-treat sample, which included all participants who started at least 1 module of the treatment. The clinical and demographic characteristics of study participants were described with R software (version 3.5.3; The R Project) using the frequency percentage and the mean and standard deviation for categorical and quantitative variables, respectively. Variables of time were described as the median and interquartile range. The cost-effectiveness analysis was conducted using the MAFEIP tool including health states, transition probabilities, utility scores, and costs. All participants started on the state *depression* in the 3-state Markov model.

In addition to the base-case analysis, we conducted deterministic sensitivity analyses for 2 scenarios: reduction in session cost (up to 25%) associated with a lower professional-to-patient ratio expected for a scaling up of the intervention, and 0% to 5% discount in utilities, as recommended by local guidelines for economic evaluations [49]. Sensitivity analyses were nondiscounted.

Transition probabilities were computed using R software, whereas costs and utilities were calculated using a spreadsheet (Excel, version 2013; Microsoft Inc).

Results

Study Population and Intervention Conduct

Of the 253 patients recruited for the study, 229 participants (90.5%) started at least one module of the treatment (intention-to-treat sample), of whom 1 participant (0.4%) did not provide data on posttreatment status, and 81 participants (35.4%) did not complete treatment; therefore, 147 participants completed the treatment (Multimedia Appendix 1). All participants had been recruited during a clinical interview after referral by their general practitioner, and all completed the PHQ-9 questionnaire. Table 1 summarizes demographic and clinical characteristics of the intention-to-treat sample at baseline. Participants in the intention-to-treat sample remained under the Super@ program a median of 96 days (IQR 70-321); 147 participants (64.2%) were considered to have completed the study. At the end of the intervention, 98 participants (66.7%) had achieved the remission state. No adverse events related to the intervention or the major depressive disorder were reported.

Depression	1.68	1.68

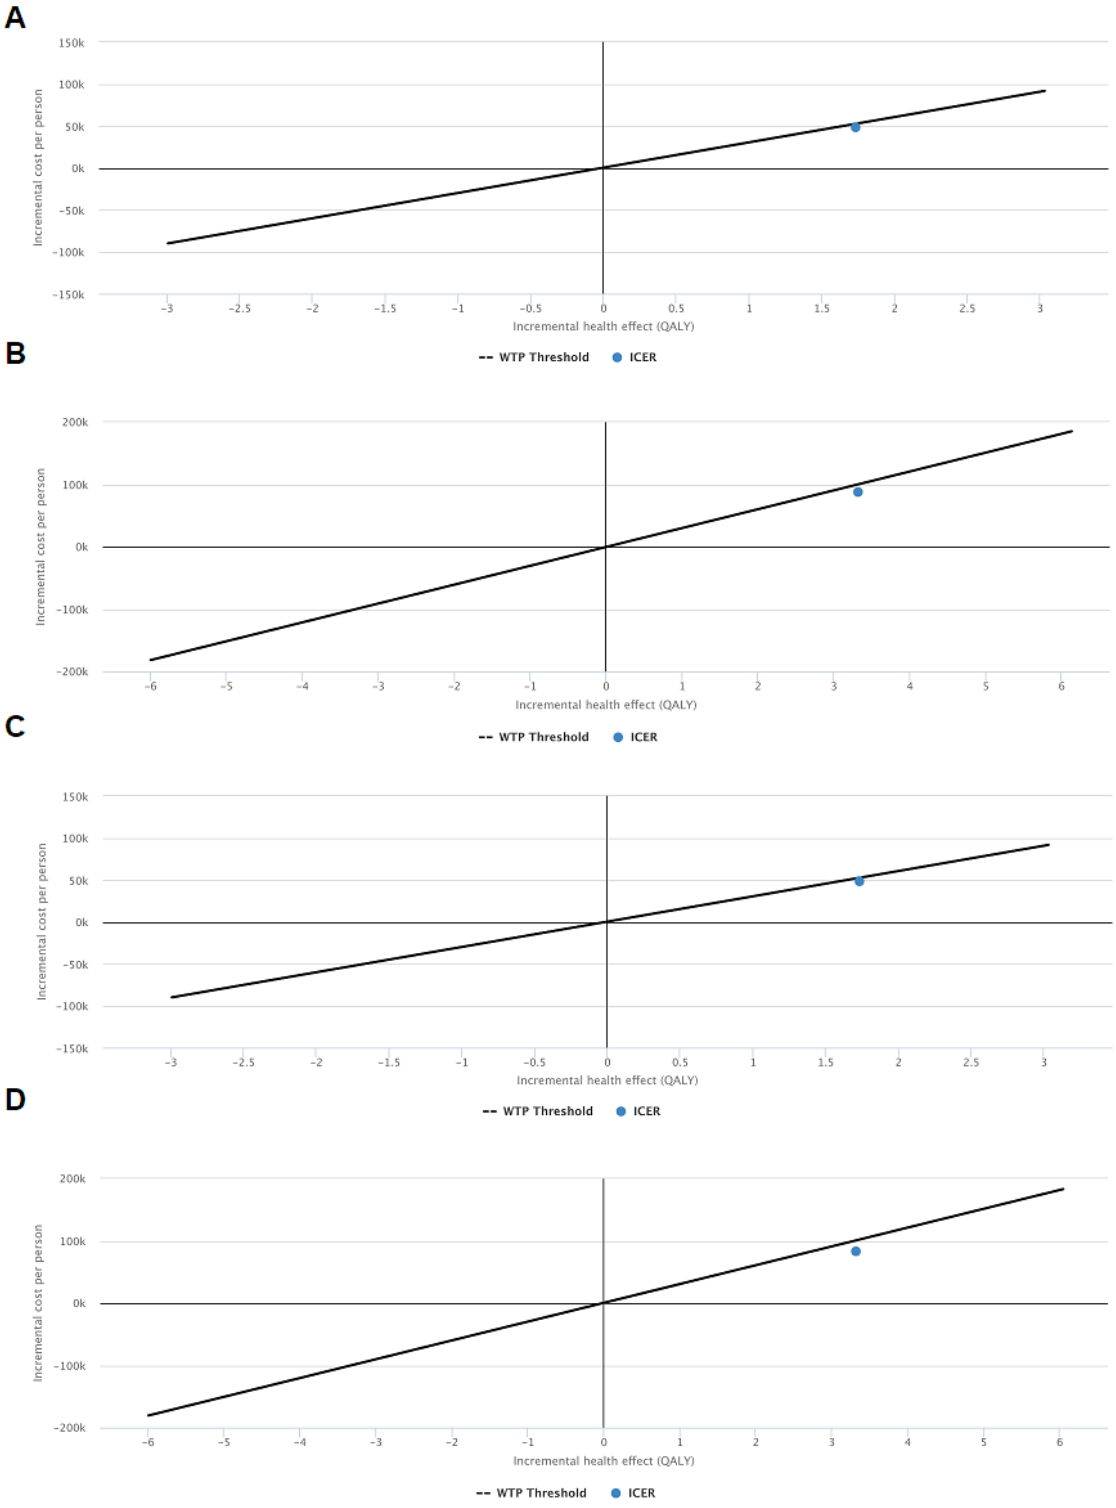
[a]An exchange rate of approximately €1 to US $1.20 is applicable at the time of publication.

[b]N/A: not applicable.

Table 3. Incremental costs, effects, and cost-effectiveness ratio from health care and societal perspectives.

Perspective	Incremental cost (€[a])	Incremental effects (QALY[b])	Incremental cost-effectiveness ratio (€/QALY)
Health care perspective			
Discounted (3% for both costs and effects)	50,924.53	1.734	29,366.92
Nondiscounted	87,807.06	3.315	26,484.27
Societal perspective			
Discounted (3% for both costs and effects)	48,178.53	1.734	27,783.38
Nondiscounted	83,181.81	3.315	25,089.21

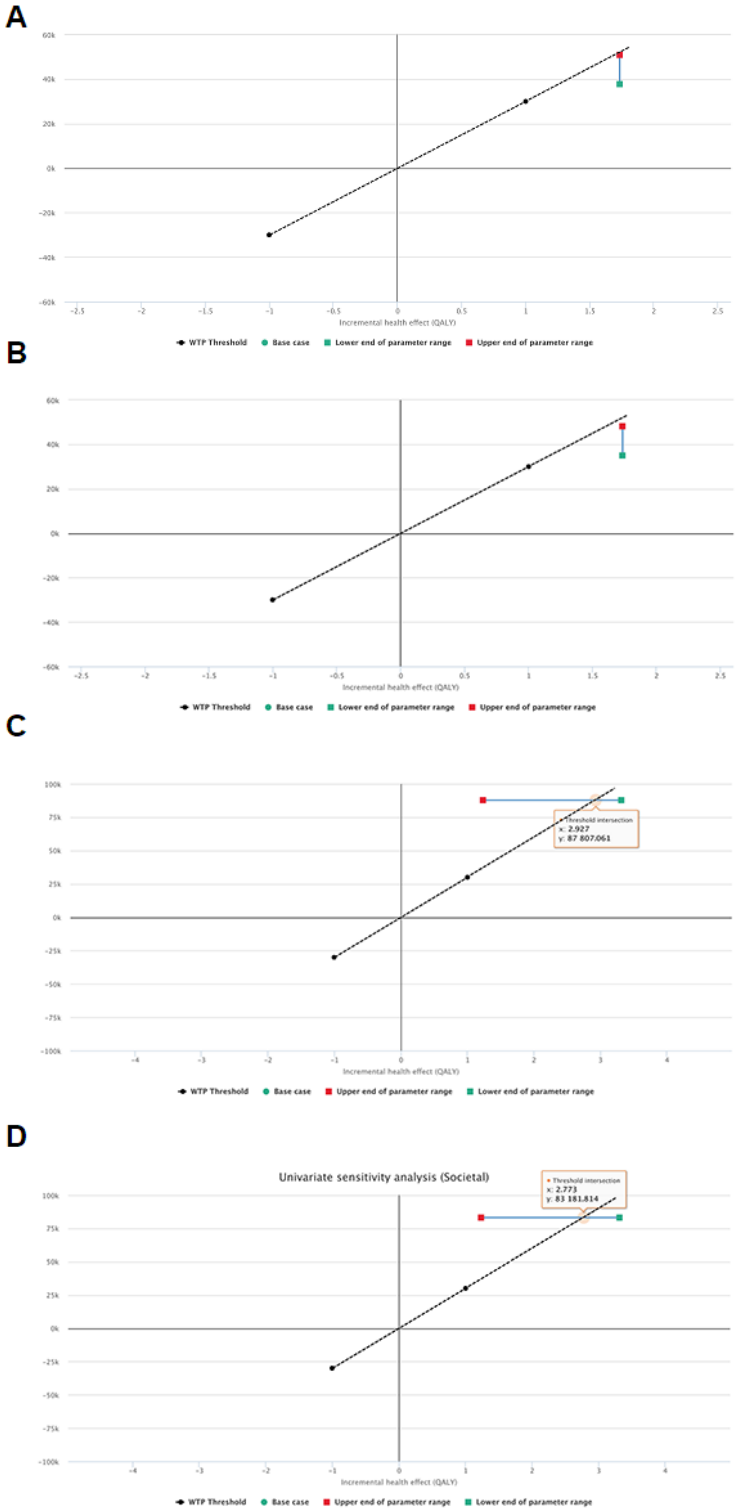
[a]An exchange rate of approximately €1 to US $1.20 is applicable at the time of publication.



[b]QALY: quality-adjusted life-year.

The nondiscounted incremental cost-effectiveness ratios were below the willingness-to-pay threshold of €30,000 (Figure 2): €26,484 and €25,089 for health care and societal perspectives, respectively (US $31,833 and $30,162). The discounted incremental costs and effects were higher, although the incremental cost-effectiveness ratios remained below the willingness-to-pay threshold of €30,000.

In addition, we conducted a deterministic sensitivity analysis assuming that a greater number of participants to the program would results in a reduction of cost per session. A 25% reduction in the cost per session would reduce the incremental cost-effectiveness ratio from €26,484 to €19,623 (US $31,833 to $23,591) in the health care perspective analysis and from €25,089 to €18,228 (US $30,162 to $21,914) in the societal perspective analysis (Figure 3A and 3B). From the health care perspective (Figure 3C), the incremental cost-effectiveness ratio at the 5% discount in utility (worst-case scenario of the sensitivity analysis) was €71,041 (US $85,405). The corresponding intersection and lowest incremental cost-effectiveness ratio values for the societal perspective were 2.773 quality-adjusted life-years and €30,000 (Figure 3D).



XSL•FO
RenderX

Figure 2. Cost-effectiveness plane of the Super@ intervention Healthcare perspective discounted (3% for both costs and health effects) (A) and non-discounted (B) analyses. Societal perspective discounted (3% for both costs and health effects) (C) and non-discounted (D) analyses. The solid line shows the 30,000 €/QALY willingness-to-pay threshold (equivalent to approximately US $36,060; an exchange rate of approximately €1 to US $1.20 is applicable at the time of publication). QALY: quality-adjusted life-year. WTP: willingness-to-pay.

Figure 3. Cost-effectiveness planes of sensitivity analyses. A reduction of up to 25% in cost per session (A and B for healthcare and societal perspectives, respectively), and 0% to 5% discount in effects (C and D for healthcare and societal perspectives, respectively). The dotted black line shows the 30,000 €/QALY willingness-to-pay threshold (equivalent to approximately US $36,060; an exchange rate of approximately €1 to US $1.20 is applicable at the time of publication). The solid green line shows the range of the incremental cost-effectiveness ratio, with the red and green squares indicating the range extremes for the worse (more costly or less effective) and best (less costly or more effective) scenario, respectively. QALY: quality-adjusted life-year. WTP: willingness-to-pay.

Discussion

In this analysis of the cost-effectiveness of an internet-based cognitive behavioral therapy intervention for mild or moderate major depressive disorder, we found that the intervention was more effective than treatment as usual, with incremental costs of €87,807 and €83,181 (nondiscounted from the health care and societal perspectives, respectively; US $105,561 and $99,999), according to costs reported for routine care of patients with mild-to-moderate major depressive disorder in our area

(Badalona, Spain). Despite the higher cost of the internet-based cognitive behavioral therapy intervention, it remained below the willingness-to-pay threshold of €30,000 typically used in Spain for making decisions in health care policies. According to the sensitivity analyses, the internet-based cognitive behavioral therapy would remain more expensive and more effective than treatment as usual in the onset of the cost reduction expected when scaling up the intervention (with the consequent decrease of the professional-to-patient ratio), with an incremental cost-effectiveness ratio below the willingness-to-pay threshold. When considering a 5% reduction in utility (ie, as suggested by local guidelines for economic evaluations), the intervention remained more effective than treatment as usual, although with an incremental cost-effectiveness ratio above the willingness-to-pay threshold.

In the last decade, many studies [50-53] have investigated the costs associated with internet-based cognitive behavioral therapy interventions, including therapies for major depressive disorder; however, most are based on descriptive approaches, which preclude drawing conclusions that can be used for making decisions on their implementation. More recently, Paganini et al [22] reviewed economic evaluations of internet-based cognitive behavioral therapy interventions for major depressive disorder that fulfilled preselected quality criteria, including the presence of comparator groups such as treatment as usual, another intervention, or wait-list controls. The case-mix of these interventions and heterogeneity of analyses precludes direct comparisons regarding the cost-effectiveness of each intervention. Nevertheless, they found that guided interventions (such as the Super@ program) tended to be more cost-effective than self-help ones, despite the higher cost associated with professional honoraria [22]. The incremental cost-effectiveness ratio of our intervention for the base-case health care perspective (€26,484 per quality-adjusted life-year) was in the lower zone of the wide range of values reported for guided interventions (ie, €19,616 [54] to €157,900 [55]; approximately US $19,616 and $189,825, respectively) and below that of unguided interventions (ie, €40,412 [56] to €178,700 [57]; approximately US $48,583 and $214,831, respectively).

Additionally, such studies [51,52] can only report on cost-effectiveness measures in controlled settings. Our study focused on the assessment of cost-effectiveness under real-world conditions free from biases possibly being introduced within efficacy studies such as a stricter application of protocolized procedures, eligibility criteria, and randomization [23-25]. Nevertheless, this approach resulted in some disadvantages, and our results should be interpreted with caution due to several limitations.

The lack of a comparator group has been considered among the limitations of economic evaluations of internet-based cognitive behavioral therapy interventions for major depressive disorder [22]. The pragmatic approach of our study, which took advantage of the implementation of the Super@ program by the local health care provider to assess its cost-effectiveness, precluded collecting treatment-as-usual data in parallel with those collected for the internet-based cognitive behavioral therapy intervention; however, the MAFEIP tool allowed us to rely upon literature for gathering these data. Of note, the source of cost-estimate data of treatment as usual for major depressive disorder corresponded to the same area in which the Super@ program was deployed [39]. Hence, the costs attributed to treatment as usual are expected to be similar to those we would have observed in a control group.

The MAFEIP tool also allowed us to bypass the unavailability of EQ-5D scores of health-related quality of life, a widely accepted measurement for computing utilities in cost-effectiveness analyses [45,58]. Other measures, such as disease severity scores, have been proposed as a proxy for health-related quality of life [59]. Taking advantage of the analysis by Kolovos et al, who established a relationship between health-related quality of life and PHQ-9 score for major depressive disorder severity [46], we computed the utility of the remission state of our 3-state Markov model using the PHQ-9 scores at the cutoff for minor depressive symptoms in the 5-state scale defined by the American Psychiatric Association [60] and the National Institute for Clinical Excellence [61].

Readers should take into consideration some limitations of the study design. First, the pragmatic approach constrained the number of participants to the implementation capacity, rather than the adequate sample size to achieve precision in our estimates. Second, like many other information and communication technology-based solutions, the success of an internet-based cognitive behavioral therapy intervention requires minimal technological literacy, which in our intervention was measured in an unstructured way at each general practitioners discretion. Technological literacy and keenness for the use of digital gadgets are expected to influence not only adherence but also the benefit that the patient may obtain from the intervention; the unstructured assessment of digital literacy may have introduced heterogeneity in the intervention outcomes. Third, the transferability of the results to other settings should be considered carefully. There are many reasons why cost-effectiveness analysis of health technologies may differ across jurisdictions and researchers and implementers should always refer to national guidelines in order to shed some light on the applicability of the results emerging from other contexts [62].

Our results suggest that the Super@ program provided benefits to patients at a cost that would allow its implementation in Spain, where interventions below €30,000 per quality-adjusted life-year are accepted. Costs associated with the intervention are expected to decrease in a scaling-up scenario; however, the sensitivity analysis of utility indicates that small reductions in effects would place the intervention at a nonacceptable incremental cost-effectiveness ratio based on the €30,000 threshold. Future studies should explore the patient profile that can benefit most from the intervention so that general practitioners have more information to target the therapy adequately.

Acknowledgments

The authors would like to thank Gerard Carot-Sans for providing medical writing support during the preparation of the manuscript. The authors would also like to thank the MasterMind project consortium partners for their contribution along the project.

The MasterMind project was partially funded under the Information and Communication Technology Policy Support Programme as part of the Competitiveness and Innovation Framework Programme by the European Community (grant agreement 621000).

The continuous development of the MAFEIP tool is funded by the European Commission's Horizon 2020 program under the projects WE4AHA (grant number 769705) and DigitalHealthEurope (grant number 826353).

The funders had no role in data collection or analysis, the decision to publish, or the preparation of the manuscript.

Authors' Contributions

JPJ was the principal investigator at the Badalona pilot site for the MasterMind project. JPJ and AE contributed to the study design and data collection. JPJ and AE conducted the statistical analyses. JPJ drafted the manuscript. AE and SK contributed to the different versions of the paper. FLV and FF supervised the study. All authors critically revised and approved the final version of the manuscript.

Conflicts of Interest

Author AE is employed by the Institute for health training online as research coordinator. All other authors declare no competing interests.

Abstract

Background: The risk of development of chronic diseases related to poor nutrition increases with age. In the face of an aging population, it is important for health care sectors to find solutions in delivering health services efficiently and effectively to middle-aged and older adults.

Objective: The aim of this systematic review and meta-analysis was to consolidate the literature that reported the effectiveness of eHealth apps in delivering nutritional interventions for middle-aged and older adults.

Methods: A literature search from five databases (PubMed, CINAHL, Cochrane, Web of Science, and Global Health) from the past 5 years was performed. Studies were selected for inclusion that used eHealth to deliver nutritional interventions to adults aged 40 years and above, and reported health and behavioral outcomes. Two independent reviewers searched for research articles and assessed the eligibility of studies to be included in the review. A third reviewer resolved disagreements on study inclusion. We also assessed the quality of the included studies using the CONSORT 2010 checklist.

Results: A total of 70 studies were included for analysis. The study quality ranged from 44% to 85%. The most commonly used eHealth intervention type was mobile apps (22/70, 31%). The majority of studies (62/70, 89%) provided multicomponent health interventions, which aimed to improve nutrition and other health behaviors (eg, exercise, smoking cessation, medication adherence). Meta-analysis results indicated high and significant heterogeneity; hence, conclusions based on these results should be considered with caution. Nonetheless, the results generally showed that eHealth interventions improved anthropometric and clinical outcomes, but not behavioral outcomes such as fruit and vegetable consumption.

Conclusions: The use of eHealth apps to deliver health interventions has been increasing in recent years, and these apps have the potential to deliver health services to a larger group of people. Our findings showed that the effectiveness of eHealth apps to deliver health interventions for middle-aged to older adults was supported by the improvement of anthropometric and clinical outcomes. Future work could aim to develop research frameworks in administering eHealth interventions to address heterogeneity in this field of research.

Introduction

The world is aging rapidly as people live longer and fertility rates decline. An aging population poses challenges to society as it is accompanied by a declining labor force and an increase in government spending in health care, thereby increasing the burden of health care management and delivery [1]. Moreover, the risk of developing chronic diseases such as hypertension, diabetes, and coronary heart diseases increases with age [2]. In fact, studies have shown that the risk of developing chronic diseases linked to a poor diet not only increases with age [3,4], but the onset of chronic diseases was also found to increase rapidly among the middle-aged population [5]. To delay the onset of these chronic conditions that are often related to poor diet and nutrition in middle-aged and older adults, it is important to improve diet and nutrition [6,7]. The need for an adequate, healthy, and well-balanced diet is thus essential, not only for the management of chronic diseases but also for their prevention [8,9].

To support the management of a healthy diet and lifestyle, many have turned to eHealth services. eHealth is an emerging field in health care that utilizes various technologies for the management and delivery of health services to users. eHealth encompasses mobile health (mHealth), which focuses on mobile devices and apps. eHealth technologies are invaluable in providing health care services that are personalized, timely, and efficient [10]. The use of eHealth technologies in the health care sector has been increasing in recent years [11,12]. In turn, there has been great interest in the research community for evaluating the efficacy of eHealth technologies in delivering health services and achieving positive health outcomes for users [11,13-15].

eHealth nutritional technologies typically aim to provide nutrition-related services that focus on aiding people with weight loss, in maintaining a healthy diet, and in supporting the self-management of nutrition-related chronic diseases and abating further regression of chronic conditions. Although studies have reported the success of eHealth nutritional interventions in targeting weight loss and promoting healthy eating habits [13,16-18], the study populations typically comprised mainly younger adults or adults. To our knowledge, the use of eHealth and evaluation of its effectiveness in providing nutrition-related services for older adults is much less frequently reported in the literature. A systematic review [19] did explore the use of eHealth among older adults aged 50 years and above, but with greater focus on the use of these technologies as a means for health promotion and primary prevention. The authors reported that the use of eHealth technologies was generally accepted among the older population in health promotion and primary prevention of diseases. Most of the studies reviewed involved older adults with weight problems, who used eHealth technologies that aimed to improve physical activity and diet. However, the authors did not report how successful the reviewed eHealth technologies were in improving the health of the study groups.

Therefore, the aims of this systematic review and meta-analysis were to consolidate the results of published research studies on the use of eHealth technologies for nutrition- and diet-related services for middle-aged and older adults. The onset of chronic diseases related to poor lifestyle habits increases with age [20], which could lead to higher stress and burden on health care systems in the face of an aging society [21]. Furthermore, eHealth was suggested to be advantageous in administering health care services to older adults owing to its efficiency and cost-effectiveness, but more research is needed to evaluate the effectiveness of eHealth on improving or maintaining health, which can strengthen evidence to support its use in administering health services in an effective and cost-effective manner [22,23]. Thus, the purpose of this systematic review and meta-analysis was to evaluate the effectiveness of eHealth nutritional interventions for the prevention and management of chronic diseases among middle-aged and older adults.

To address this aim, we established the following research questions: (1) Which eHealth technologies (eg, mobile phone, wearables) are most commonly used in eHealth nutritional interventions for middle-aged and older adults? (2) What are the common types of eHealth features provided by eHealth nutritional technologies? (3) Compared to non-eHealth interventions/standard care, does eHealth result in improvements to health and behavioral outcomes related to nutrition and diet? (4) Does the duration of eHealth interventions lead to better overall improvements in health and behavioral outcomes related to nutrition?

We define eHealth nutritional interventions as those using technologies such as mobile devices, telephones, wearables, sensors, and mobile and web-based apps to support users in achieving nutritional-related outcomes such as weight reduction, or changes in dietary intake or behavior. This support could be in the form of a reminder system, coaching calls, sharing of educational content, or sending motivational messages with the primary aim to support users in various activities such as setting and achieving nutritional health goals, recording dietary behavior, monitoring food intake, regulating eating habits, or tracking physical activity.

We performed a systematic review to consolidate the literature on the use of eHealth technologies in providing nutrition-related services to answer research questions 1 and 2. Additionally, meta-analyses were performed to evaluate the effectiveness of eHealth nutritional interventions in improving outcomes, addressing research questions 3 and 4. The strengths and limitations of employing such eHealth nutritional interventions in older adults are also discussed to provide considerations for future research in developing and implementing eHealth nutritional technologies.

Methods

Literature Search

This systematic review was performed in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses for Protocols 2015 (PRISMA-P 2015) guidelines [24]. Systematic searches were performed in May 2020 using five databases: PubMed/Medline, CINAHL, Cochrane, Web of Science, and Global Health. We considered that these databases are sufficiently extensive to cover the literature on eHealth,

XSL•FO
RenderX

mHealth, public health, and health systems. In addition, manual searches for relevant studies were also performed from the reference lists of retrieved articles and directly in Google Scholar. Systematic searches were limited to the English language literature, human research, and year of publication between 2014 and 2019. We limited the search to articles published in the last 5 instead of 10 years, as technology is rapidly outdated and findings published more than 5 years ago might not be up to date or of high relevance to the current and future context of eHealth nutritional interventions. We identified the search categories based on the purpose of the systematic review. The search term "eHealth" was selected as it is the type of intervention of interest to our research questions, "nutrition" was selected since the purpose of the eHealth interventions of interest is to improve nutrition, and the search terms "middle-aged" and "elderly" were selected as these were our target populations. These search terms were entered in the Cochrane Library medical subject heading (MeSH) browser, and the relevant MeSH terms and synonyms were selected. MeSH terms represent a controlled vocabulary thesaurus maintained by the National Library of Medicine, which are used to index research articles for the PubMed and Medline databases. As shown in Table 1, the selected MeSH terms were used to perform full-text literature searches in the respective databases. Additionally, we used Boolean operators (eg, AND, OR, NOT) in our search strategy to provide a narrower and more productive search. More detailed information about the search strategies used for each database are presented in Multimedia Appendix 1.

Table 1. Medical subject heading (MeSH) search terms used for the literature search.

Search terms	MeSH terms
eHealth	eHealth OR telemedicine OR telehealth OR mhealth OR mobile health
Nutrition	Nutrition, diet, food, eating, food intake, ingestion, diet habit
Middle-aged and elderly	middle aged OR aged OR "aged, 80 and over" OR elderly

Inclusion Criteria and Selection of Studies

Studies were selected to be included in the systematic review based on the following inclusion criteria: (1) used a form of eHealth nutritional intervention for disease prevention and/or management; (2) involved adults aged 40 years and above; and (3) reported data regarding anthropometric measures (eg, weight, BMI, blood pressure readings), dietary behaviors, and other health outcomes (eg, self-report of physical and mental well-being).

Based on our definition, an eHealth nutritional intervention should encompass technologies that aid participants in losing weight, in maintaining a healthy diet, and in supporting the self-management of nutrition-related chronic diseases and abating further regression of chronic conditions. The use of eHealth to improve diet and nutrition among older adults could either be the primary or secondary aim of the intervention. Likewise, the intervention could be a stand-alone nutrition-only intervention or part of a multicomponent intervention such as those that aimed to improve other health behaviors (eg, physical activity).

We compiled a comprehensive list of outcome measures from the literature pertaining to nutrition, diet, and health outcomes that we could expect to be reported as the results of eHealth interventions, including: (1) anthropometric outcomes such as weight, BMI, waist circumference, hip circumference, body adiposity, and waist-to-hip ratio; (2) clinical outcomes such as liver enzyme and lipid profile, cholesterol level, blood pressure level, fasting blood glucose level, hemoglobin A_{1c} (HbA_{1c}) level, urinary sodium level, triglycerides level, fat mass or body fat, pulse pressure, insulin level, C-reactive protein, alkaline phosphatase, total white blood cell, alanine aminotransferase/aspartate aminotransferase, and serum creatinine; (3) behavioral outcomes such as dietary attitudes, dietary behavior, adherence to a Mediterranean diet, adherence to health behaviors, physical activity level, nutritional status, low salt content of purchased foods, low saturated fat and energy content of purchased foods, and the Framingham Heart Study cardiovascular disease (CVD) risk score [25,26]; (4) educational outcomes such as nutritional knowledge and health literacy; and (5) other outcomes such as psychological outcomes, quality of life, and app usage.

A study was excluded from the review if it (1) implemented a nonexperimental study design (eg, observational and case studies, study protocol); (2) was not a peer-reviewed research article (eg, conference proceedings, letters, commentaries); (3) did not report any health outcomes as aforementioned in the inclusion criteria; and (4) used an eHealth intervention as a follow-up intervention to observe maintenance of outcome changes from a previously administered health intervention that did not use eHealth.

Titles and abstracts of studies were first screened by an independent reviewer. During the first round of screening, studies that did not meet the eligibility criteria for selection were excluded from the review. Two independent researchers reviewed and screened the remaining studies based on the inclusion and exclusion criteria, and any disagreements were discussed and resolved with a third independent reviewer. Data and references were managed using EndNote software.

Data Extraction

The process of data extraction followed a standardized procedure as reported in previous systematic reviews [13,19,27]. This systematic review adhered to the guidelines proposed by Cochrane Handbook for Systematic Review of Interventions [28]. Data were extracted based on our research aims, and the inclusion and exclusion criteria. Multimedia Appendix 2 presents the relevant characteristics and data that were extracted from the included studies. With the aim to answer our research questions, we extracted data on the study design, participant

XSL•FO
RenderX

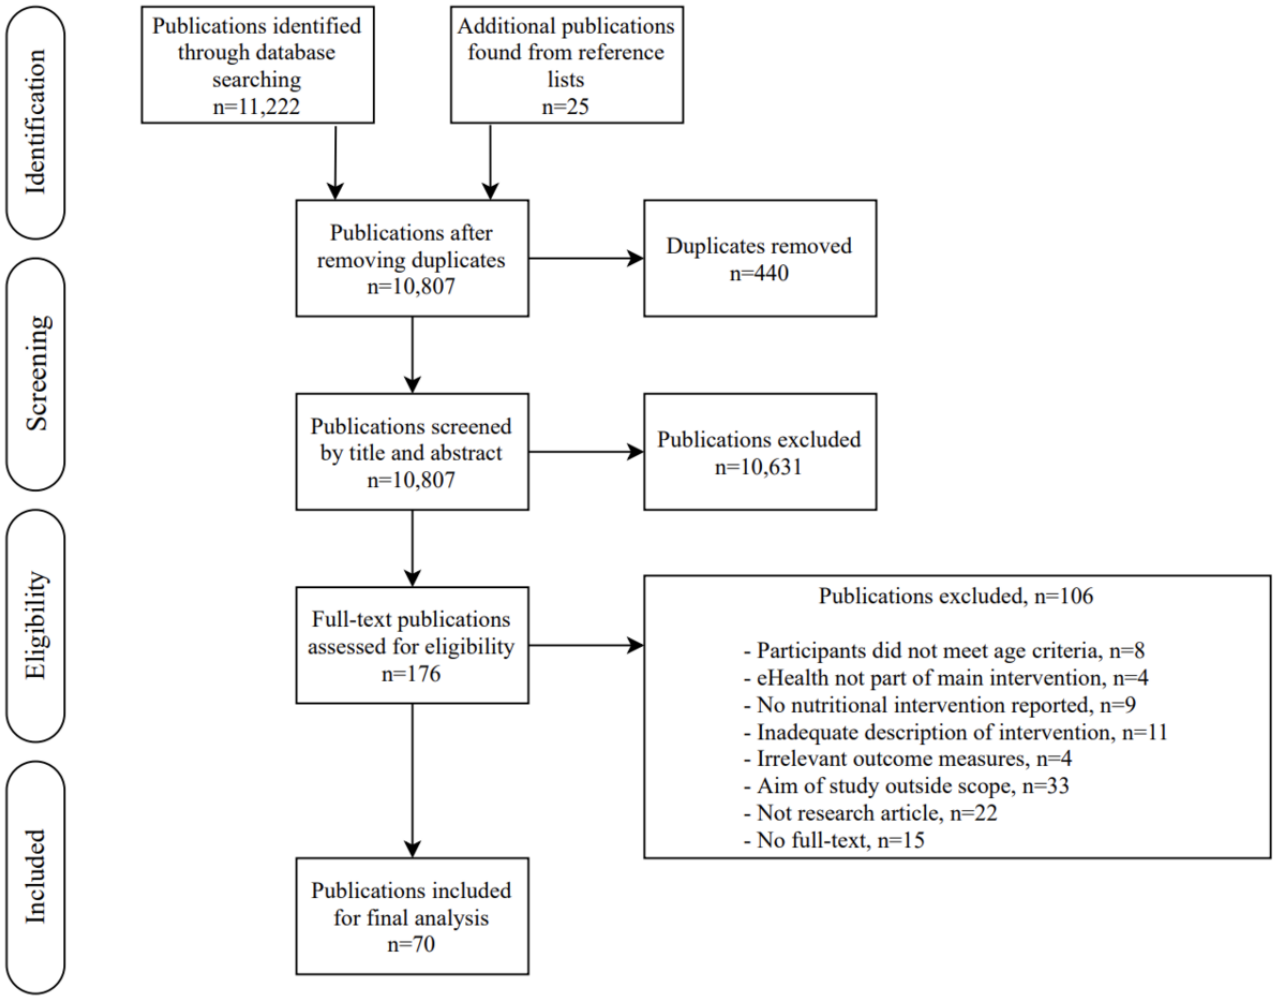
information, intervention description, outcome measures, and results. Study design comprised the study method or design, information regarding the groups involved in the study, duration of the intervention, measurement time points, and attrition rate. Participant information included sample size and sample selection criteria such as demographics, disease or health condition, mean age, and gender distribution. Interventions are described as a brief overview of the intervention and eHealth features. Outcome measures included the primary and secondary outcomes measured in the study. Results are described as an overview of the main primary and secondary findings of the study, including details on mean or percentage changes in outcomes, as well as significance levels where possible.

Quality Assessment

The quality of all included studies in the systematic review was assessed using the CONSORT (Consolidated Standards of Reporting Trials) 2010 checklist for reporting randomized controlled trials (RCTs) [29]. The CONSORT checklist includes a 25-point evaluation for RCTs. Although it is mostly used to assess RCTs, most of the criteria in the CONSORT checklist are applicable to other study designs. Quality assessment using the CONSORT checklist has also been adopted in other systematic reviews [13,27]. To assess quality, points were allocated to each criterion: 1 point was given to a fulfilled criterion, 0.5 points to a partially fulfilled criterion, 0 points to an unfulfilled criterion, and NA was indicated for criteria that were not applicable to the study. The quality of the systematic review was checked in accordance with the PRISMA-P 2015 checklist and reported in Multimedia Appendix 3.

Meta-analysis

A meta-analysis was performed using Cochrane Review Manager version 5.3 [30]. Only studies with an RCT design were included in the meta-analysis, as scores at baseline and postintervention are not independent [31]. Mean change scores from baseline to postintervention were included as the dataset for analysis. Postintervention results were treated as the scores or values collected at the end of the intervention period. SD values of the mean change scores were obtained as reported or calculated from the standard error or 95% CI if the study did not report the SD values [28]. Studies were excluded from the meta-analysis if they did not provide sufficient data for computing the mean change and SD values, or if the methodology and instruments used to measure the outcomes were not standardized and similar to the majority of studies in the meta-analysis. Our meta-analysis was performed using a random-effects model, with mean difference for outcomes that were measured and reported in a standardized manner (eg, weight in kilograms), and standardized mean difference for outcomes that were measured using different scales or measurements [26]. Publication bias for each outcome was assessed with funnel plots (Multimedia Appendix 4). Subgroup analyses based on the duration of the intervention period (ie, ≤3 months, 4-6 months, 7-12 months) were performed on outcomes that had at least three studies per subgroup to evaluate whether the intervention duration had differential effects on the outcomes.



Results

Study Selection

Figure 1 presents the flowchart of the study selection process. A total of 11,247 studies were identified from database searches and additional reference lists. After the removal of 440 duplicates, 10,807 studies were screened by title and abstract. Among these, 176 full-text publications were considered to be potentially eligible for inclusion. We had several reasons for the exclusion of publications. Studies whose recruited participants were aged 39 years and below were excluded as they did not meet the age criterion of our target population. Publications were excluded that did not focus on eHealth as part of their main intervention. Publications were excluded that reported an eHealth intervention, but not related to nutrition. Publications that did not describe what the eHealth devices aimed to achieve in the nutritional intervention (eg, whether they comprised an educational component) were excluded due to the inadequate description of the intervention. Publications were also excluded for studies that did not measure any eHealth nutritional outcomes. Some publications were excluded because the study did not aim to administer an eHealth nutritional intervention to improve health outcomes of the participants but rather to, for example, compare methodologies or to evaluate the cost-effectiveness of eHealth programs, and were thus outside of the scope of this analysis. We only included full-text research articles. Of the full-text articles identified, 70 studies were finally included in the systematic review, having fulfilled our study inclusion criteria and having clearly indicated the effectiveness of implementing eHealth nutritional interventions on nutrition-related health outcomes.

XSL•FO
RenderX

Figure 1. Flowchart of publication selection procedure.

Study Characteristics

The characteristics of the included studies for the systematic review are presented in Multimedia Appendix 2. This systematic review adheres to the Cochrane guidelines for reporting characteristics of studies that were included in the review [28]. Thirteen studies were performed in the Asia-Pacific region [32-44], 3 studies were performed in the Middle East [45-47], 35 studies were performed in North America [48-82], 1 study was performed in South America [83], and 18 studies were performed in Europe [84-101]. The majority of the studies included were RCTs, with 38 studies that performed two-group RCTs [33-36,38-41,43,44,47-51,53,55,57-60,69,70,74-77,80,83,85,88,92,93,95-97,100,101] and 12 studies that performed three-group RCTs [45,46,54,56,61,79,86,87,90,91,94,99]. Nineteen studies involved a pre-post study design [32,37,42,52,63-68,71-73,78,81,82,84,89,98] and one study involved a pragmatic trial design [62].

Participant Information

The most common target population group was patients with chronic diseases. Of the 38 studies that recruited patients with chronic diseases, 25 recruited patients with diabetes mellitus or who were in a prediabetic state [32,40-44,46,47,50-52,55,60,62,65,66,70-72,75,82,83,86,90,93], 7 studies recruited patients with CVD [33,34,36,39,45,49,53], 1 study recruited patients with liver disease [48], 2 studies recruited patients with hypertension [61,69], and 3 studies recruited patients who reported any form of chronic disease [38,94,95]. Seventeen studies recruited patients with other clinical disorders such as individuals at risk of breast cancer [58], cancer survivors [64,92], those with obesity [57,59,63,67,68,73,76,77,89,101], and those who had obesity along with other health conditions [56,74,91,100]. The remaining 14 studies recruited healthy older adults [35,37,54,78-80,84,85,87,88,96-99]. With respect to gender, 47 studies recruited more female participants [32,34,37,44,48,52,54-59,62-66,68-72,76-78,80-87,89,91-93,95-97,99-101], 5 of which recruited only female participants [56,58,63,64,79]. One study recruited equal numbers of male and female participants [42]. The remaining 22 studies recruited more male participants for their intervention [33,35-41,43,45-47,49-51,53,60,61,67,74,90,94], 3 of which recruited only male participants [35,37,74]. Most of the studies (38/70, 54%) included participants with mean ages ranging from 50 to 59 years [32,33,39-43,45,46,48,51,53-55,58,60,61,64-66,69-71,73-75,79,81,82,84,86,88,90,92,94,96,97,100]. There were 18 studies that recruited participants with mean ages ranging from 40 to 49 years [34,35,37,47,57,59,63,68,72,76,77,80,85,87,89,91,99,101]. Eleven studies recruited participants with mean ages from 60 to 69 years [36,38,44,49,50,52,56,62, 67,83,93], and two studies recruited participants aged 70 and above [95,98]. Das et al [78] recruited participants with ages that ranged from

XSL•FO
RenderX

40 to 70 years and above. Recruitment ranged from 19 to 2305 participants, with reported attrition rates ranging from 0% to 67.4%.

eHealth Interventions

The purpose of using eHealth as a health intervention varies from the self-management of chronic diseases to the prevention or delay of their onset. The majority of the included studies (39/70, 56%) used eHealth interventions for the self-management of chronic conditions [32-34,36,39-50,53,55,60-62,65,66,69-71,74-76,78,79,82,83,86,90,93-95,100]. With healthy older adults as participants, 14 studies utilized eHealth as an intervention for the prevention of chronic diseases [35,37,54,77,80,84,85,87,88,96-99,101]. Additionally, 17 studies implemented eHealth interventions to support the progression of diseases [38,51,52,56-59,63,64,67,68,72,73,81,89,91,92].

The interventions were most commonly performed for a duration of 3-6 months. Twenty-nine studies performed the intervention for 3 months or less [32,34,36,40,41,45,46,57,59,60,63-65,70,74,76,78,80,82,86-88,91,93,96,97,101], 24 studies were performed for 4-6 months [33,37-39,42,44,47,48,51,53-56,58,61,68,73,75,81,84,92,98-100], 13 studies involved interventions for a duration of 7-12 months [35,43,52,62,67,69,70,84,85,89,90,94,95], and 3 studies performed the intervention for more than 12 months [66,70,79].

The studies included in this review reported the use of different technologies as their interventions, with the most common (22/70, 31%) being the use of mobile apps [36,40-42,44,47,53,57,63,64,66,68,75,77,84,89-91,96,97,99,101]. Twelve studies used a web-based app [34,43,62,65,67,69,70,78,79,87,92,100], 9 studies used phone calls [49,50,56,59,60,74,81,83,93], and 12 studies used wearable technology in conjunction with other eHealth technologies [37,38,52,55,58,76,79,80,86,88,94,100]. Two studies used an automated program [51,98] and the remaining studies used email [61,70,79], text messages [33,39,45,46,48,82], or videoconferencing [54,73,76,78,95]. As shown in Multimedia Appendix 2, the eHealth focused on nutritional intervention only in 8 studies [32,36,43,60,71,72,74,77,92,99,101]. The remaining studies administered an intervention on nutrition and other health behaviors such as exercise, smoking cessation, medication adherence, and behavioral change techniques for a better lifestyle.

Multimedia Appendix 5 presents the types of features implemented by the eHealth apps for the studies included in the systematic review. Most of the studies implemented several types of features in their eHealth app to deliver the intervention to participants. The most common feature of the eHealth interventions was the distribution of educational content for health behaviors. The second most common feature was to allow users to record their health behaviors such as dietary behavior, clinical and anthropometric data, or physical activity levels, and included health reports generated to assess their adherence or performance during the intervention. Thirty-six studies allowed participants to set their own health goals, which they would aim to achieve by the end of the intervention. Motivational messages would be sent to participants to further encourage them to adopt or maintain health behaviors, or to continue to adhere to the intervention. Fifteen studies implemented a reminder system in the mHealth app to send reminders to users to input their health data, and some included a point-based system whereby participants would receive incentives when they successfully attained a health goal.

Effectiveness of eHealth Interventions

A summary of the intervention findings that included anthropometric, clinical, behavioral, educational, and psychological outcomes is provided in Multimedia Appendix 6. In general, the studies found overall positive effects of the intervention in measured outcomes. The most commonly measured outcomes were weight (n=44), dietary behavior (n=30), BMI (n=27), HbA_{1c} levels (n=24), and physical activity levels (n=23). Among outcomes reported by five or more studies, adherence to health behaviors, Framingham CVD risk score, dietary behavior, weight, and BMI were those that showed the most common improvements in favor of the eHealth intervention group. Specifically, 5/7 (71%) of studies that reported adherence to health behaviors, 3/5 (60%) studies for Framingham CVD risk, 14/30 (47%) studies for dietary behavior, 20/44 (45%) studies for weight, and 11/27 studies (41%) for BMI showed improvements in favor of the intervention group. Multimedia Appendix 6 presents a summary of results for each included study at the latest measurement time point (ie, end of intervention or last follow-up), showing positive, negative, or no change to outcomes measured for all included studies in the intervention and control or comparison groups. Multimedia Appendix 7 presents a more comprehensive overview of the results for each study included in the systematic review. There are several cautionary notes about the results reported in some of the included studies. Bentley et al [86] did not perform inferential analyses of secondary outcomes (weight and HbA_{1c} level) due to a small sample size. Thus, positive results in favor of the eHealth intervention group should be interpreted with caution. Recio-Rodriguez et al [97] did not provide follow-up results on secondary outcomes (blood pressure, waist circumference, and BMI).

Meta-analysis

Summary of the meta-analysis findings are reported in Table S1 in Multimedia Appendix 8, including heterogeneity, mean differences and 95% CIs, as well as the significance of the intervention effect. The forest plots for each variable reported in Table S1 are shown in Figures S1-S12 in Multimedia Appendix 8. The *P* values for heterogeneity showed significance for nearly all variables included in the meta-analysis. This indicates significant clinical heterogeneity [102] among the studies, possibly due to variability in the eHealth nutritional interventions administered. The forest plots also show the diverse effects of the eHealth nutritional interventions on the outcomes reported in the meta-analysis. Nonetheless, we considered it to still be worthwhile to summarize the results quantitatively with a random-effects model [102]. The effects of eHealth interventions on weight, BMI, waist circumference, low-density lipoprotein-cholesterol, systolic blood pressure, and HbA_{1c} level favored the intervention group (all $P<.001$) as compared to the control group, whereas the effects on fruit and vegetable consumption favored the control group ($P=.01$). addition, the effects of the eHealth intervention on body fat, triglyceride level, Framingham CVD risk, and calorie intake favored neither the intervention nor the control group (all $P>.05$). Subgroup analyses based on the duration of the intervention period (ie, ≤3 months, 4-6 months, 7-12 months) on the outcomes of weight, waist circumference, and HbA_{1c} levels indicated high and significant heterogeneity for many variables (Figures S1, S3, and S7 in Multimedia Appendix 8); thus, the conclusions based on these results should be considered with caution.

eHealth Usage

The majority of the studies included in the systematic review neither reported participants' adherence to the eHealth app nor the participants' perceptions and satisfaction toward the eHealth intervention. Only two studies reported higher adherence to the mHealth interventions among the intervention group when compared to control groups [33,82,97]. A few studies reported that overall, the eHealth apps were well-received by participants, as they found it to be useful [36], easy to use [32,33,36,37,55,68,86], and were satisfied with their respective eHealth apps [33,68]. Interestingly, two studies found that older participants were more likely to use the eHealth intervention app more frequently than younger participants [88,90]. However, Fukuoka et al [55] raised the issue of decreasing adherence to the mHealth intervention due to technical issues with the mobile app and pedometer. Similarly, Mundi et al [68] found a decrease in mobile app usage over the study period, even though participants reported that they were generally satisfied with the mobile app.

Study Quality Assessed by the CONSORT 2010 Checklist

Multimedia Appendix 9 presents a detailed quality assessment of each study, with their raw and percentage scores indicated. The percentage scores for all included studies ranged between 44% and 85%. Overall, the quality for all included studies was judged to be "fair," with a mean percentage score of 65.85%. Two studies were assessed to have low quality [40,63] with percentage scores below 50%. Ten studies were ranked as fair with percentage scores between 50% and 59% [34,38,41,49,58,64,74,84,94,95]. Twenty-five studies with percentage scores ranging from 60% to 69% were assessed as good quality [32,35,39,45,52-54,56,57,60,63,65,67,70,71,83,85,86,89-93,96,98], and 18 studies were ranked as very good quality with a score of 70% and above [33,36,37,48,50,51,55,59,61,62,66,69,72,73,75,87,88,97].

Discussion

Principal Results

The findings of the studies included in this systematic review and meta-analysis provided varying evidence for the effectiveness of eHealth interventions in improving health and other related outcomes for the prevention and management of chronic diseases related to poor nutrition. Results from the systematic review demonstrated that eHealth interventions were highly successful in significantly improving adherence to health behavior, Framingham CVD risk, dietary behavior, weight, and BMI.

The results of the meta-analysis revealed overall positive within-group improvements in favor of the intervention group for anthropometric (ie, weight, BMI, waist circumference) and clinical (ie, low-density lipoprotein-cholesterol, systolic blood pressure, HbA_{1c} level) outcomes. No within-group improvements were found in fasting blood glucose, body fat, triglyceride level, Framingham CVD risk, and calorie intake. Subgroup analyses based on the intervention duration were performed for outcomes of weight, waist circumference, and HbA_{1c} levels. Regardless of the intervention duration, there were significant improvements in weight. However, the highest improvement in weight was found for interventions administered for 4-6 months. Similarly, interventions that were administered for exactly 4-6 months improved waist circumference and had the largest improvement on HbA_{1c} levels compared with other intervention durations. In other words, interventions offered for less than 4 months and for more than 6 months showed no significant improvements in waist circumference, and improvements in weight and HbA_{1c} level were lower as compared to those achieved when interventions were delivered for 4-6 months. This could most likely be due to the effectiveness of eHealth interventions often only being measurable after a minimum intervention duration. Moreover, studies with longer intervention durations could show less effectiveness possibly due to unsustainable rates of adherence and drops in compliance of the study participants over time. Nevertheless, interpretation of these results requires caution owing to the significant heterogeneity among studies included in the meta-analysis. With regard to behavioral outcomes, improvements in fruit and vegetable consumption were more apparent in the control group. However, caution is also needed in interpreting this finding as the meta-analysis only included three studies that measured fruit and vegetable consumption. Indeed, it is also important to consider that not all studies in the systematic review were included in the meta-analysis, as some studies reported insufficient data, or used very diverse instruments or methods to measure their outcomes. Therefore, caution is also required in interpreting the results related to the effectiveness of eHealth on health and behavioral outcomes.

Furthermore, discrepancies in the findings of the meta-analysis (ie, improvements in anthropometric and clinical outcomes, but not behavioral outcomes) suggest that the improvements found in eHealth intervention groups could be due to the fact that many studies not only focused on nutrition but also on other lifestyle behaviors. Moreover, several studies [32,33,36,57] found improvements in dietary behavior or adherence to health behavior, but did not find any improvements in anthropometric outcomes or clinical outcomes (eg, weight, BMI, blood pressure, cholesterol). This contrast in findings begs the question as to whether improvements in health outcomes were brought about by improvements in dietary behavior. Therefore, future studies should further evaluate the relationship between improvements in behavioral and health outcomes, and whether such relationships will lead to longer-lasting effects. This would help

XSL•FO
RenderX

validate the efficacy of the eHealth intervention, and its effectiveness in improving and maintaining health.

The implementation of eHealth technologies to deliver nutritional interventions provides great convenience and potential for health care systems, as participants are able to receive efficient, timely, and personalized health services. Previous research acknowledged the advantages of using eHealth in providing health services to older adults in a cost-effective and convenient manner [20,23]. Moreover, Kampmeijer et al [19] demonstrated that eHealth services are generally widely accepted among the older population. As these findings suggested that future work is needed to evaluate the effectiveness of eHealth on health outcomes, our current work bridges this gap in the literature by providing further evidence and considerations on the relevance of using eHealth for middle-aged and older populations.

Future Considerations

Due to the exploratory nature of our review, we included a considerably broad range of eHealth interventions, target outcomes, as well as population groups. To address concerns of heterogeneity found in the meta-analysis, future meta-analyses should focus on specific types of eHealth interventions (eg, mobile apps), specific primary outcomes (eg, weight or BMI), or specific population groups (eg, patients with hypertension). With heterogeneity addressed in this way, results and conclusions drawn upon these studies would then be able to offer insight into the efficacy of eHealth interventions on specific outcomes. Subgroup analyses could also be performed to evaluate if different intervention durations have differential effects on target outcomes.

The vast majority of the included studies used a multicomponent intervention, whereby the eHealth technologies were most commonly used to provide nutritional and physical exercise intervention. In fact, we found only six studies that solely delivered nutritional interventions, and reported mixed results on the efficacy of eHealth to participants' health outcomes [32,36,60,71,74,92]. The meta-analysis further showed that the intervention duration did not have a significant impact on health outcomes, suggesting that there could be other factors (eg, types of eHealth used or target population groups) that contributed to the effectiveness of such interventions. Having multicomponent interventions delivered through eHealth apps would understandably be more effective as compared to stand-alone nutritional interventions. Previous systematic reviews on mHealth app usage by adolescents and adults found similar favorable results for multicomponent interventions [13]. Moreover, for one to achieve a healthy and balanced lifestyle, it would be necessary to make positive changes to both diet and exercise simultaneously, rather than focusing on diet or exercise alone [103]. Thus, future developments of eHealth apps could consider having multicomponent intervention features to improve the health outcomes of users.

By and large, participants were reportedly satisfied with the eHealth technologies in helping them to achieve their health goals. However, a large number of studies did not systematically measure participants' adherence, perception, and satisfaction toward the eHealth technologies. Future studies on the efficacy of eHealth interventions should measure these aspects, as it is important to have a better understanding of participants' evaluation of the eHealth technologies from a qualitative and quantitative perspective. Otherwise, if the interventions provided are not widely accepted by participants, this might reduce their efficacy. Furthermore, if we consider the lack of a scientific theory and framework for app development [104], it would be imperative for future studies to consider participants' engagement and evaluation of eHealth technologies, which might effectively improve future app development.

Strengths and Limitations

One of the limitations of this systematic review was the search strategy employed to obtain relevant research articles. We searched for articles from five databases, which might have led us to miss relevant articles in the literature. However, we considered that the databases used for our search were sufficiently extensive in covering topics on eHealth and health services. We also manually searched articles that were not found in our selected databases. In addition, there are many ways to describe the search terms, which we might not have exhaustively included in our search strategy. However, we do consider the inclusion of MeSH terms, and general terms such as "telemedicine" and "nutrition" should suffice in comprising the main terms and concepts of interest. Nevertheless, the large number of articles identified, screened, and excluded does indicate that the search query could have been more specific. In addition, the use of Boolean operators (OR, AND) in our search query might have led to different interpretations by the various databases. Another limitation of our search strategy was the timeframe of searching for articles published in the last 5 years. We considered a 5-year timeframe as sufficient, as technologies used in eHealth tend to change and improve rapidly, and therefore become outdated in a short period. As such, studies using older technologies might already be outdated. We encountered important clinical heterogeneity in our meta-analysis; however, we still decided to report our findings in the appendices to illustrate that although these studies aimed to measure the same outcomes, there was high heterogeneity due to the diverse ways the interventions were administered (eg, mobile apps vs web-based tools). In addition, due to the different types of interventions administered across studies, the issue of clinical heterogeneity [102] makes it difficult to conclude consistent and convincing meta-analysis findings. Finally, we did not account for the quality of studies in our subgroup analyses. Variability in study quality may overestimate positive results, especially if studies with poorer quality are included in the meta-analysis. Nonetheless, the majority of our studies were ranked as being of good or very good quality; thus, we might expect less variability on the effect of study quality on subgroup analyses.

One strength of our study was that we had two independent reviewers performing the selection process and a third independent reviewer solving any disagreements in study inclusion. In addition, we followed the PRISMA-P 2015 guidelines for reporting a systematic review, and checked the quality of each included study using the CONSORT 2010 checklist in a standardized manner. We did consider additional ways to assess study quality, such as using the Cochrane risk

XSL•FO
RenderX

of bias tool [105], which assesses each study outcome. However, we found that due to the exploratory nature and scope of our research aims, we were considering a rather large number of studies (70 in total), each having multiple primary and secondary outcomes. This made it challenging to assess the risk of bias for each outcome across all studies. Although the CONSORT checklist does not explicitly assess risk of bias, it does score and assess whether studies have adequately designed, analyzed, interpreted, and reported their results and methods, which we believe is an acceptable and valid way of assessing study quality and risk of methodological bias [13,27].

Conclusion

We found varying evidence for the effectiveness of eHealth in providing nutrition-related interventions for middle-aged and older adults. Studies included in the systematic review generally reported positive support for the use of eHealth technologies in improving health and behavioral outcomes. Apps that delivered multicomponent interventions for improving nutrition and other health behaviors were more commonly used in health interventions as compared to stand-alone apps. The use of eHealth technologies has been increasing over the years, and has great potential in effectively delivering health services to a large group of people. Meta-analysis findings, although based on heterogeneous data and with quality limitations, generally demonstrated improvements in weight and BMI for eHealth users. To address heterogeneity in this field of research, future studies could look into developing a research framework or consensus in administering studies that involve eHealth interventions. Nevertheless, more research is needed to measure participants' engagement with the technologies, and to provide structural and scientific frameworks for the development of future apps, which can provide a better understanding of their effectiveness and encourage app adherence among users.

Abstract

Background: The U-CARE Heart trial was one of the first randomized controlled trials to evaluate the effect of internet-based cognitive behavioral therapy on self-reported symptoms of anxiety or depression for patients with a recent myocardial infarction. While the effects of internet-based cognitive behavioral therapy on Hospital Anxiety and Depression Scale (HADS) scores at 14 weeks postbaseline were not significant, in this study, we investigated possible long-term effects of treatment.

Objective: The aim of this study was to evaluate the long-term effectiveness of internet-based cognitive behavioral therapy on self-reported symptoms of anxiety and depression in patients 12 months after a myocardial infarction and to explore subsequent occurrences of cardiovascular disease events.

Methods: Shortly after acute myocardial infarction, 239 patients (33% female, mean age 59.6 years) reporting mild-to-moderate symptoms of anxiety or depression were randomized to 14 weeks of therapist-guided internet-based cognitive behavioral therapy (n=117) or treatment as usual (n=122). Data from national registries were used to explore group differences in clinical outcomes such as cardiovascular disease and cardiovascular-related mortality for a follow-up period of up to 5 years: group differences in HADS total score 1 year post–myocardial infarction, the primary outcome, was analyzed using multiple linear regression. Secondary outcomes, such as HADS anxiety and depression subscales and the Cardiac Anxiety Questionnaire total score (CAQ), which measures heart-focused anxiety, were analyzed in the same way. Multiple imputation was used to account for missing data, and a pooled treatment effect was estimated. Adjusted Cox proportional hazards models were used to estimate hazard ratios (HRs) for data pertaining to registry outcomes.

Results: Both groups reported lower HADS total scores 1 year after myocardial infarction than those at baseline. HADS total scores were not significantly different between the treatment and control groups 1 year after myocardial infarction (β=–1.14, 95% CI –2.73 to 0.45, *P*=.16). CAQ was the only measure improved significantly by internet-based cognitive behavioral therapy when compared with treatment as usual (β=–2.58, 95% CI –4.75 to –0.42, *P*=.02) before adjusting for multiple comparisons. The composite outcome of nonfatal cardiovascular events and cardiovascular-related mortality did not differ between groups but was numerically higher in the internet-based cognitive behavioral therapy group, who were at slightly greater risk (HR 1.8, 95% CI

XSL•FO
RenderX

0.96 to 3.4, *P*=.07). Adjusting for previous myocardial infarction and diabetes attenuated this estimate (HR 1.5, 95% CI 0.8 to 2.8, *P*=.25).

Conclusions: Internet-based cognitive behavioral therapy was not superior in reducing self-reported symptoms of depression or anxiety compared to treatment as usual at the 1-year follow-up after myocardial infarction. A reduction in cardiac-related anxiety was observed but was not significant after adjusting for multiple comparisons. There was no difference in risk of cardiovascular events between the treatment groups. Low treatment adherence, which might have affected treatment engagement and outcomes, should be considered when interpreting these results.

Introduction

Myocardial infarction continues to be the leading cause of death worldwide [1]. The risk increases with age and is associated with behavioral factors such as smoking and reduced physical activity [2]. For over one-third of patients after myocardial infarction, symptoms of anxiety, depression, or both remain elevated 3 months after hospital discharge [3], and similar levels have even been reported up to 1 year after myocardial infarction [4]. A preexisting history of mental illness, such as depression, is associated with a 31% increased risk of a recurrent myocardial infarction [5] and a 30% higher mortality rate in the 18 months following myocardial infarction than among those without a history of depression [6]. Mortality rates increase with severity of depression, according to one study [7] and, depressive symptoms are reported to be more prevalent among patients with more cardiovascular risk factors (eg, smoking and obesity) [8]. This combination of increased risk for morbidity following a myocardial infarction and lower reported quality of life [9,10] makes therapy that is aimed at reducing symptoms of anxiety and depression likely a beneficial treatment option. In a recent meta-analysis [11], psychological treatment for patients with coronary heart disease was linked to a reduction in self-reported symptoms of anxiety and depression and reduced risk of cardiac-related mortality compared to treatment as usual.

Web-based interventions offer remote access to treatment which are sometimes otherwise inaccessible [12] and have been evaluated against face-to-face therapy in randomized controlled trials with varying yet promising results [12-14]. Some trials have used therapy conducted online, often in the form of internet-based cognitive behavioral therapy, to treat depression in patients with heart failure [15], cardiovascular disease [16], and with high-cardiovascular disease risk [17], but before the U-CARE Heart trial [18], no study had offered internet-based cognitive behavioral therapy specifically to patients after myocardial infarction. A more recent study [19] of internet-based cognitive behavioral therapy for symptoms of anxiety and depression in patients who had experienced an acute coronary event, including myocardial infarction, demonstrated a strong effect of treatment on reduction of these symptoms that was sustained at a 4-week follow-up.

The U-CARE heart trial [18] was, to the authors' knowledge, the first randomized controlled trial to offer internet-based cognitive behavioral therapy to patients experiencing mild to moderate self-reported symptoms of anxiety or depression after a myocardial infarction. Posttreatment follow-up at 14 weeks found an overall reduction in symptoms of anxiety and depression, according to the Hospital Anxiety and Depression Scale (HADS) [20] compared to those at baseline, yet no differences were found between the intervention and control group. Long-term treatment follow-up of the study population was intended to gather more information about the sustainability of general improvements in anxiety and depression and whether group characteristics (symptoms of anxiety and depression, myocardial infarction and stroke events, and cardiovascular-related mortality) differed at follow-up. The ultimate goal of a psychological intervention post–myocardial infarction would be, not only to reduce symptoms of anxiety and depression long-term but also, to reduce cardiovascular morbidity and mortality, although this was not the main purpose of the U-CARE Heart trial.

The purpose of this follow-up study was thus to investigate whether patients with mild-to-moderate symptoms of anxiety or depression, self-reported within 2 months following myocardial infarction and treated with internet-based cognitive behavioral therapy, had (1) improvements in self-reported mental health at 12 months after the myocardial infarction, and (2) reduced risk for cardiovascular events including cardiovascular-related mortality, for a period of up to 5 years, compared to those receiving treatment as usual.

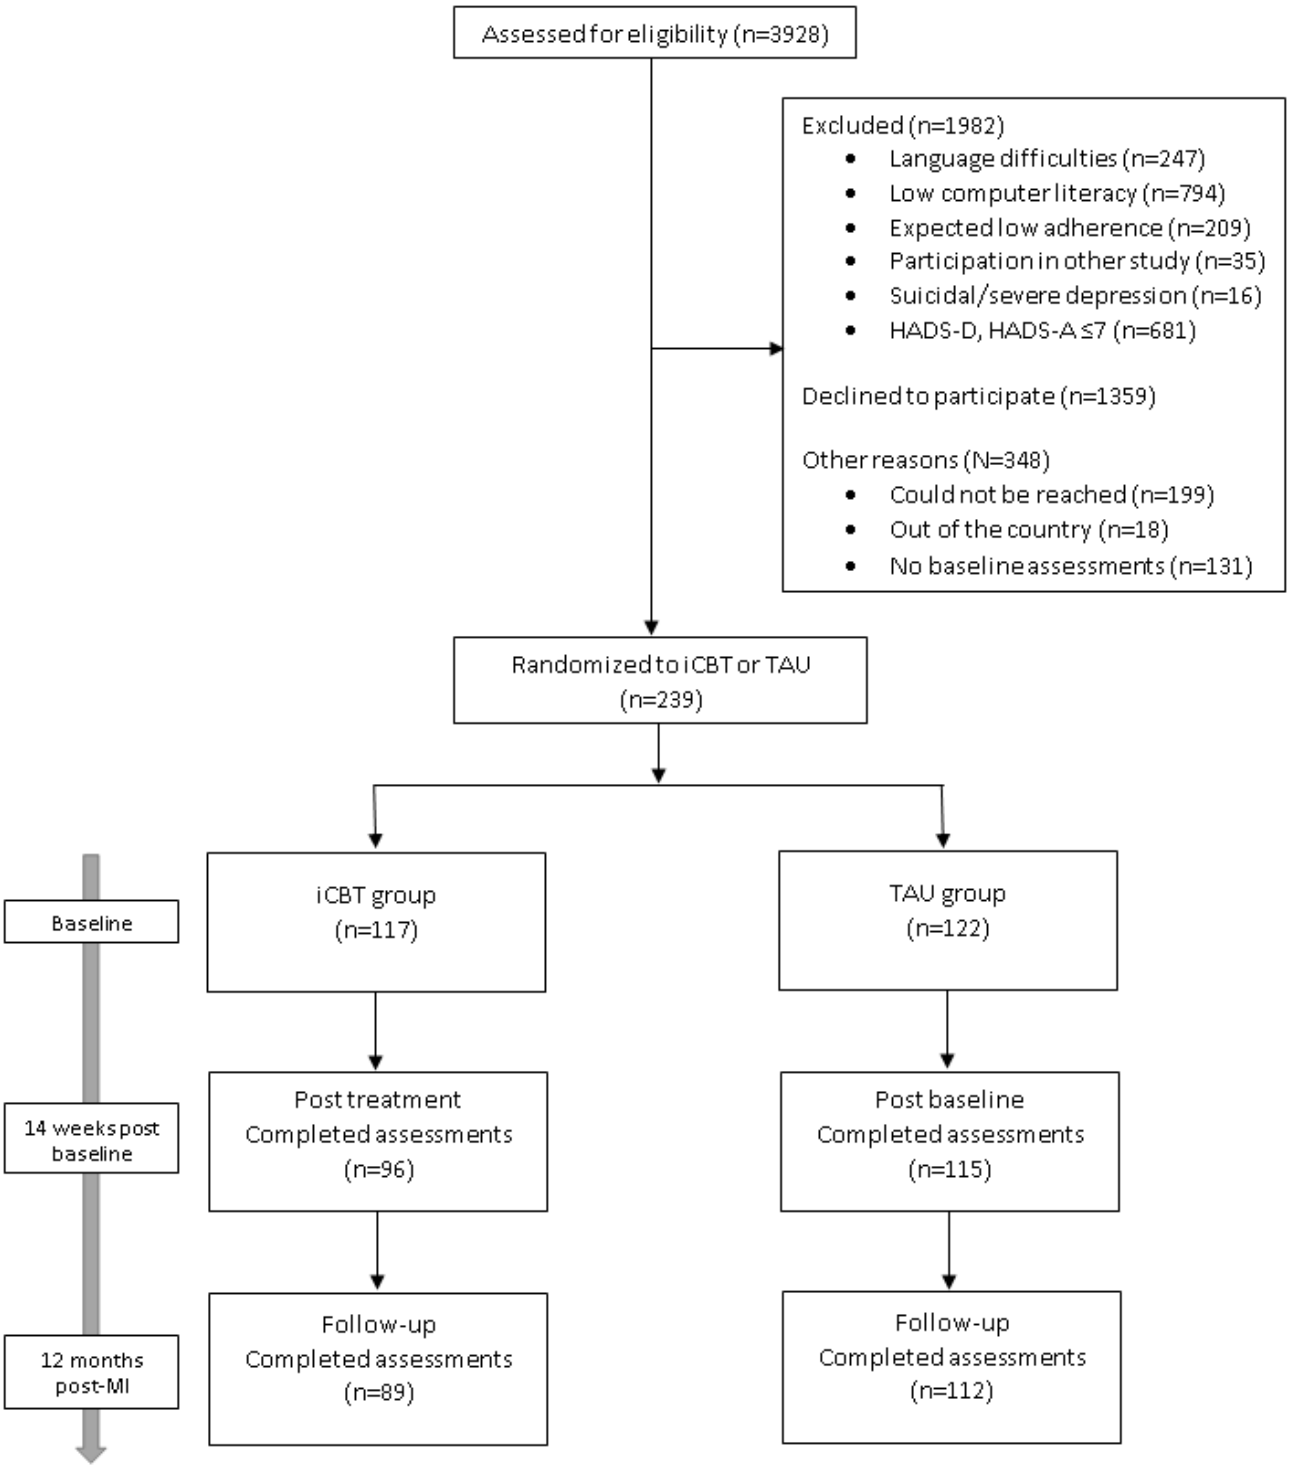
Methods

Study Design and Participants

This follow-up study (1) evaluated the effect of internet-based cognitive behavioral therapy on self-reported symptoms of anxiety and depression 12 months after the myocardial infarction, and (2) explored whether internet-based cognitive behavioral therapy had an effect on nonfatal cardiovascular events or cardiovascular-related mortality up to 5 years after study inclusion. The study design, procedure, intervention, and results of the posttreatment follow-up of the U-CARE Heart trial have been reported [18,21].

XSL•FO
RenderX

In brief, the U-CARE Heart trial was a multicenter study that recruited participants <75 years of age, reporting symptoms of anxiety or depression (scoring >7 on any of the 2 HADS anxiety and depression subscales) within 3 months following their myocardial infarction. Myocardial infarction was defined according to International Statistical Classification of Disease Tenth Revision (ICD-10) code I21 and diagnosed by a cardiologist. Patients scheduled for coronary artery bypass surgery, with low adherence (such as missing appointments with the cardiac nurse or substance use), or expected to live <1 year, as judged on-site by the recruiting nurse, were not eligible. Patients who met eligibility criteria (n=239) were randomized to receive either internet-based cognitive behavioral therapy (n=117) or treatment as usual (n=122). This study received ethical approval by the regional ethics committee in Uppsala (2011/217) and is registered on ClinicalTrials.gov (NCT01504191).



Procedure

Screening for eligible participants took place across in Sweden from September 2013 to December 2016 in 25 cardiac clinics during routine visits between 1 and 8 weeks following their myocardial infarction. Consenting participants were sent an email and password login to a secure internet-based portal (Multimedia Appendix 1) where they completed baseline assessments and would subsequently receive the internet-based cognitive behavioral therapy (if applicable). Eligibility (Figure 1) was assessed in the baseline questionnaires and those scoring >7 on any or both of the HADS subscales were randomized automatically in the internet-based portal 1:1 to internet-based cognitive behavioral therapy or treatment as usual. The full recruitment procedure has previously been reported [18].

Trial-specific outcomes were measured 14 weeks postbaseline, which corresponded to treatment completion for those in the internet-based cognitive behavioral therapy group, and again at follow-up 12 months after myocardial infarction. Participants in both the intervention and treatment-as-usual groups were sent automatic SMS texts and email reminders asking them to fill in the web-based questionnaires at each observation point and were subsequently reminded via telephone by one of the research staff (blind to treatment allocation) if initially unresponsive. Figure 1 details the patient flow through the study.

Intervention

The internet-based cognitive behavioral therapy intervention [18,21] delivered via the U-CARE portal (a secure web-portal) was therapist guided and partly customizable. This meant that after a compulsory introduction module, patients could choose their treatment modules. The intervention was developed for cardiac patients and consisted of 11 modules: Introduction, Managing Worry, Fear and Avoidance, Behavioral Activation, Problem Solving, Communication Skills, Applied Relaxation Training, Managing Negative Thoughts, Coping With Insomnia, Values in Life, and Relapse Prevention. Homework assignments were included in each module, and the portal also included a library that was accessible at all times with content and material including media such as videos and informational text.

All participants received standard protocol secondary prevention and cardiac rehabilitation offered by the regional health care system. This usually includes, but is not limited to, preventive medications, education about cardiovascular risk-factors, smoking cessation, organized and tailored physical exercise, and in some areas, access to counseling or psychosocial support.

Measures

Sociodemographic and Psychological Measures

Sociodemographic data were self-reported at baseline. The primary outcome measure was HADS total score, measuring self-reported symptoms of both anxiety and depression (subscales). The HADS is a useful tool in the screening of depression in cardiac patients [22,23], and there is support of its validity for online use [24].The 2 subscales are divided equally between 14 questions, with 7 questions pertaining to each subscale. Questions are answered on a 4-point scale (0-3), with a score >7 on either subscale indicating at least mild symptoms [20].

Secondary outcome measures included the Cardiac Anxiety Questionnaire (CAQ) [25], which assesses self-reported heart-related anxiety; Montgomery-Åsberg Depression Rating Scale–Self-rated (MADRS-S) [26], which measures depression; and the Behavioral Activation for Depression Scale Short–Form (BADS-SF), which assesses depression-related behaviors [27]. In contrast to the other scales, for which a high score denotes more severe symptoms, a high score on the BADS-SF is favorable as it indicates higher activation of change to depression-related behaviors.

Register Data

Data on cardiovascular events and mortality during follow-up were obtained from the Patient Registry and the Causes of Death Registry of the National Board of Health and Welfare in Sweden [28]. ICD-10 diagnostic codes were used [29]. A composite cardiovascular event outcome was created comprising hospitalization for any of the following diagnoses between time of randomization and point of data censoring: cardiovascular death (ICD cause of death code I), acute coronary syndrome (ICD codes I20, I21, and I22), heart failure (ICD codes I50 and I11.0), stroke (ICD codes I61, I62, I63, and I64), and revascularization (intervention codes FNG00, FNG02, FNG05, FNG10, and FNC). Background data for medical history were taken from the Swedish Web-System for Enhancement and Development of Evidence-Based Care in Heart Disease Evaluated According to Recommended Therapies (SWEDEHEART) registers [30]: RIKS-HIA (the National Register for Information and Knowledge on Heart Intensive Care Admission) and SEPHIA (the Registry for Secondary Prevention after Heart Intensive Care Admission). These sources of data are linked via a personal identification number that is unique to every registered resident in Sweden, matched to the study cohort with codes, and handled in accordance with current data protection standards.

Statistical Analysis

Statistical analysis was planned in line with CONSORT (Consolidated Standards of Reporting Trial) before treatment allocation was disclosed and before the trial database was locked.

Main analysis investigated potential differences in HADS total scores 12 months post–myocardial infarction, with subsequent analyses of the HADS anxiety and HADS depression subscale scores. Secondary analyses focused on potential differences between groups in MADRS-S total score, CAQ total score, and BADS-SF total score.

Linear modeling was used to estimate treatment effects. As with the posttreatment analysis [18], analyses were conducted based on intention to treat. Treatment was an independent variable and 12-month follow-up HADS total score as the dependent variable, while controlling for baseline HADS total score, sex, and age. This adjustment for covariates was applied to all analyses. The HADS subscales were analyzed in the same way but only with patients included in the study based on the specific subscale. Thus, it was possible for patients to be included in both analyses for both subscales if they scored >7 on both at baseline.

To account for missing values and analyze according to intention to treat, data were imputed by multiple imputation using chained equations and predictive mean matching [31]. Variables used in the imputation model were the same as those in the posttreatment analysis [18], which were chosen on the basis of potential association with the main outcome and with input from cardiologist and psychologist recommendations. Unless specified, reported results are based on imputed data.

HADS total score sensitivity analyses were conducted on observed data (ie, nonimputed). Supplementary analyses of HADS total score were based on per protocol data, including only those in the model who had completed at least one homework assignment. Only the analyses according to intention to treat (with imputed data) were applied to the secondary outcomes. Effect estimates are reported as pooled adjusted point estimates β with 95% confidence intervals. Paired *t* tests were conducted with outcomes pre- vs posttreatment to assess change over time across the full sample. Level of significance, α, for all separate comparisons was set to $P<.05$. For familywise testing of the multiple hypotheses, a Bonferroni-corrected *P* value=.008 (6 hypotheses) was used.

Multivariable Cox regression analysis was performed to estimate adjusted hazard ratios (HR) with 95% confidence intervals with time (in days) to first cardiovascular event as the outcome event. The exposure was treatment group, with time under risk starting from the date of randomization during follow-up and censoring at the time of any cardiovascular event, end of follow-up (December 31, 2018), or the date of noncardiovascular death, whichever came first.

The first participant was randomized in September 2013. The longest period of follow-up spanned 1898 days, and the shortest spanned 719 days; the mean follow-up period was 1139.3 days. Any incidence of cardiovascular death or cardiovascular disease event was used as the primary outcome for time-to-event analysis. There were no missing data for these outcomes. Adjustments for age and sex were performed for higher precision. Posthoc exploratory analyses were conducted with previous myocardial infarction and diabetes as additional covariates since previous medical history of these appeared to be more prevalent in the treatment group. All statistical analyses were performed using R statistical software (version 4.0.2, The R Project).

XSL•FO
RenderX

Missing Data

Of 239 patients who were enrolled, 24% (28 participants) from the internet-based cognitive behavioral therapy group and 8% (10 participants) from the treatment-as-usual group had missing data on the HADS questionnaire at the 12-month follow-up. In the internet-based cognitive behavioral therapy and treatment-as-usual groups 26% (31 participants) and 9% (11 participants), respectively, had missing data on MADRS-S; 26% (30 participants) and 8% (10 participants), respectively, had missing CAQ values; and 30% (35 participants) and 11% (13 participants) respectively, had missing data on the BADS-SF.

Data were considered missing if (1) the entire questionnaire was left unanswered (ie, the participant skipped the questionnaire or the participant did not log in or respond to any of the questionnaires at follow-up) or (2) items were skipped within a questionnaire that were required in order to compute a value for the total score (eg, missing items within the HADS questionnaire, which made it impossible to compute a total score from the observed data).

Results

Patient Characteristics

Baseline characteristics are presented in Table 1. Overall, patients were a mean age of 59.6 years (SD 8.49), and 33.5% were women (80/239). At baseline, 24.3% (58/239) reported to be receiving other forms of counseling and 18.0% (39/239) of the study sample reported taking psychotropic medications. At baseline, there was no difference between the groups in the mean HADS total score (P=.57).

All primary and secondary measures (Figure 2, Multimedia Appendix 2) at posttreatment and follow-up displayed changes from baseline, indicating a reduction of self-reported anxiety or depression symptoms.

Figure 2. (a) Hospital Anxiety and Depression Scale total score, (b) Montgomery-Åsberg Depression Scale–Self-rated total score, (c) Cardiac Anxiety Questionnaire total score, and (d) Behavioral Activation for Depression Scale–Short Form total score mean (observed data) values at baseline, posttreatment, and 1-year follow-up. Error bars indicate 95% CI. iCBT: internet-based cognitive behavioral therapy; TAU: treatment as usual.

Main Analysis

HADS total scores from baseline to the 12-month follow-up visit after myocardial infarction showed a consistent reduction across the total study sample (mean difference 5.7; t_{200}=13.57, *P*<.001). Figure 2 shows changes in mean scores over the 3 time points (baseline, posttreatment, and 12-month follow-up) of the observed (nonimputed) data.

The main model showed no difference of internet-based cognitive behavioral therapy on HADS total scores at follow-up (β=–1.14, 95% CI –2.73 to 0.45, *P*=.16). There was no effect of internet-based cognitive behavioral therapy on HADS depression (β=–1.08, 95% CI –2.31 to 0.16, *P*=.09) or anxiety (β=–0.64, 95% CI –1.65 to 0.37, *P*=.21) subscale scores.

Secondary Outcomes

The CAQ was the only additional outcome to show a significant reduction at the 12-month follow-up (β=–2.58, 95% CI –4.75 to –0.42, *P*=.02) for internet-based cognitive behavioral therapy; however, this was not significant after adjusting for multiple comparisons (Bonferroni-corrected level of significance *P*<.008). Further details on outcomes are available in Multimedia Appendix 2.

Sensitivity analysis of observed data (β=–1.3, 95% CI –2.96 to 0.27, *P*=.10) and per protocol analysis (β=–1.3, 95% CI –2.90 to 0.41, *P*=.14) showed no effect of internet-based cognitive behavioral therapy on HADS total score.

Cardiovascular Clinical Outcomes

Compared to those in the treatment-as-usual group, participants receiving internet-based cognitive behavioral therapy had a numerically but not significantly higher risk of experiencing a cardiovascular event (HR 1.8, 95% CI 0.96 to 3.4, *P*=.07). Posthoc analysis showed this estimate was attenuated when previous myocardial infarction and diabetes, as indicators of baseline health status, were entered in the model (HR 1.5, 95% CI 0.8 to 2.8, *P*=.25). Cardiovascular events included in the analysis are shown in Table 2.

Discussion

Principal Findings

Primary analysis did not detect a significant difference in HADS total score between the treatment and control groups at follow-up 12 months after the myocardial infarction. These findings were in line with those of the original paper (presenting posttreatment results, ie, 14 weeks after baseline [18]). Of the secondary measures, the CAQ was the only outcome to show an effect of treatment in mean scores between the internet-based cognitive behavioral therapy and treatment-as-usual group at the 12-month follow-up, and occurrences of cardiovascular-related events did not differ significantly between the groups, although statistical power was limited.

Possible explanations to why there was no difference observed between the groups are low activity-levels among patients in the internet-based cognitive behavioral therapy arm and the low number of completed treatment modules. Just over half of those in the internet-based cognitive behavioral therapy group completed the first introductory module, and only 15% continued to work through any of the remaining 10 modules [18]. Interviews with patients from this study in a follow-up study [32] identified several factors that potentially contributed to low treatment adherence: lack of time, technical aspects (eg, insufficient computer literacy), and unpleasant emotions evoked by the intervention.

The intervention design may have contributed to low adherence. Creating an internet-based cognitive behavioral therapy intervention is technically challenging and complex and must be made with the characteristics and demographics, such as age, of the population in mind. Despite excluding individuals not able or willing to use a computer, the internet, email, or a mobile device, participants still reported low computer literacy as a contributing factor to why they did not engage more with the intervention [32]. A study [16] that reported high adherence to internet-based cognitive behavioral therapy for patients with cardiovascular disease (60% completed all modules) used nurses with experience of cardiovascular disease care to guide the intervention and suggested that this was beneficial as it allowed the participants to ask cardiovascular disease-related questions and health-related concerns. Providing a similar option for patients in our study could have likewise improved adherence. Moreover, age is one of the most well-known risk factors for myocardial infarction [33] so it is not unexpected that patients are older on average than other patient populations treated with internet-based cognitive behavioral therapy; it is important to understand how demographic characteristics of myocardial infarction patients might affect treatment engagement, particularly as it has been found that one-third of adults aged over 65 years who were average or modest internet users report feeling anxious around technology [34]. Therefore, studies with low treatment attrition and high participant satisfaction that have tailored certain aspects towards populations that may be less familiar with digital technology, should be used as design examples. For example, a recent pilot study [35] of treatment for depression in healthy older adults provided tablet-device training to the participants beforehand, required no internet connection, and used a stylus to operate the touch screen. Applying these elements to the intervention may improve results.

A well-discussed issue in intervention literature that applies to this study concerns how participants are recruited into a study that offers treatment. Patients were approached by hospital staff in participating hospitals and asked if they would be interested in participating rather than responding to an open-advertisement or actively seeking care themselves. Similar studies have also suggested that clinical recruitment might have contributed to low internet-based cognitive behavioral therapy adherence [36]. It is likely that self-referring patients would be more motivated to complete psychological treatments. A meta-analysis [37] found a more favorable effect of internet-based cognitive behavioral therapy (vs waitlist control) on anxiety outcomes for studies that deployed open community recruitment strategies as opposed to clinical service recruitment. One could speculate that this favorable difference was due to greater treatment adherence of self-referring patients and stricter inclusion and exclusion criteria.

More recent trials have had better success in maintaining participant retention, particularly when patients could self-identify as needing help with symptoms related to their coronary event and when there were fewer treatment modules to work through [19].

Of note, secondary analyses revealed significant long-term improvement on the CAQ scale in the internet-based cognitive behavioral therapy group compared to that of the treatment-as-usual group (P=.02). Interestingly, this parameter did not differ between groups at 14 weeks postbaseline [18].

XSL•FO
RenderX

One possible explanation might be that treatment was tailored relatively well to cardiac-specific scenarios and provided examples that were well-suited to someone with a recent myocardial infarction. Machine learning modeling with the U-CARE Heart trial data has since shown that high CAQ total score predicts participants' adherence to the treatment [38] and that the CAQ fear subscale was the strongest predictor of participant adherence. The group differences observed on these variables might explain the intrinsic motivation of some participants to adhere more than others, and thus, may explain the findings in the CAQ outcome. Since so few participants adhered to the treatment, however, we cannot conclude that this was the reason for better CAQ scores. Previous research [4,39] has demonstrated that a treatment effect might appear at a later follow-up period despite that no effect being observed immediately posttreatment. This may explain why these effects were not present 14 weeks postbaseline. Multiple hypothesis testing can also become a problem as some results may appear by chance. After adjusting multiple comparisons, the CAQ *P* value (*P*=.02) was not significant.

The risk of cardiovascular events did not differ across groups at long-term follow-up. Unexpectedly, the hazard ratio indicated a slightly negative effect of the treatment. This effect was not significant (*P*=.07); this was a small study, with few events and lacking power for this exploratory analysis. Despite this, such an analysis is arguably justified as the knowledge gained thereof, and its potential benefits could contribute to the literature of internet-based cognitive behavioral therapy effects on cardiovascular events. Since we included a rather broad range of cardiovascular events, it is possible that those in the internet-based cognitive behavioral therapy group experienced more but milder incidences such as heart failure; the number of events were too few to adequately explore this, but upon counting the different event types in the 2 groups, no particular pattern emerged. It could also be that the treatment group was less healthy at baseline as randomization does not necessarily make groups similar. When adding indications of baseline health differences (previous myocardial infarction and diabetes), the effect was attenuated. A similar recent study [40] also found no difference in clinical outcomes between a control group and a cognitive behavioral therapy/well-being therapy group. In our study, one participant in each group died, but since neither death was the first event experienced by each respective participant, these deaths were excluded from analysis. However, as noted above, since adherence was low, it is difficult to conclude whether any effects were due to the treatment. One could speculate that it is distressing for some people to participate in a treatment study where activity is expected as it can engage feelings of guilt due to low adherence. Increased distress was the main interpretation of the negative effect on mortality in women in the nurse-led intervention in the M-HART trial [41].

Limitations

The inclusion of participants with a rather low level of self-reported anxiety or depression (HADS anxiety or HADS depression subscale scores >7) meant that patients with only mild symptoms were included, which could be considered a disadvantage—this may have contributed to the lack of difference in the primary outcome both immediately posttreatment and at the 1-year follow-up. Spontaneous improvement over time in anxiety and depression has been observed in patients with acute myocardial infarction [42,43]. At 2 months post–myocardial infarction, it may have been too early to know which patients would still report problematic symptom levels versus those whom would recover over time, particularly as some high anxiety–reporting myocardial infarction patients have been found to steadily improve between 3 and 6 months post–myocardial infarction [44]. As previously reported [21], problems with recruitment were the initial reason for lowering the HADS anxiety and HADS depression inclusion scores from >10 to >7, and more stringent exclusion criteria (ie, a higher HADS anxiety or HADS depression threshold value for inclusion) may have allowed stronger treatment effects to be observed.

As previously reported [18], the HADS was developed largely as a screening measure for anxiety and depression and might not have been sensitive enough to detect minor changes across the measurement time points, although the inclusion of multiple secondary measures may have somewhat made up for this. Using a diagnostic interview technique is arguably one of the most robust methods to screen for anxiety and depression; however, this would have required a lot more time and therapist involvement, been more expensive, and been further from the digitalization goals around which this treatment was structured.

One challenge in this study, as is often the case in long-term follow-up studies, was the amount of missing data due to nonresponses. There was also more attrition in the internet-based cognitive behavioral therapy group than in the treatment-as-usual group at the 1-year follow-up. While this would need to be explored further to fully understand the reasons for the differences between the groups, one could speculate that it was partly because of the perceived burden by those in the internet-based cognitive behavioral therapy group of completing so many additional web-based forms and exercises, which was not experienced by those in the treatment-as-usual group. Alternatively, patients assigned to the internet-based cognitive behavioral therapy intervention could have been randomly more ill from the start, a factor which could contribute to more attrition and explain higher risk for cardiovascular events in this group.

Conclusion

Therapist-guided internet-based cognitive behavioral therapy developed for patients with a recent myocardial infarction was not superior to treatment as usual at the 1-year follow-up in the U-CARE Heart trial; however, the CAQ scale did detect a possible trend (*P*<.02, which was not significant when corrected for multiple comparisons) toward improvement in the treatment group. This may indicate a differential effect of the internet-based cognitive behavioral therapy on cardiac anxiety that requires further research. The internet-based cognitive behavioral therapy was not associated with an increased time-to-event risk for cardiovascular events. The low adherence rates should be considered when interpreting these results.

Acknowledgments

This study is part of U-CARE, which is a strategic research environment funded by the Swedish Research Council (2009-1093). The Swedish Heart and Lung Association (E 148/11); the Uppsala-Örebro Regional Research Council (22 86 61); Swedish Research Council for Health, Working Life, and Welfare (2014-4947); and the Vårdal foundation (2014-0114) are also responsible for funding U-CARE Heart. The authors would like to thank all patients who participated in this study for their time and contribution; participating hospitals; nurses and doctors involved who helped them in the recruitment process; Kata Bordas and Malin Fridlund, who helped out with the study recruitment and informing patients; Amanda Romppala, for the administrative help and contribution; and Ronnie Pingel, Maria Bertilsson, and Lars Lindhagen from Uppsala University for statistical support.

Abstract

Background: A scientific, personalized, and quantitative exercise prescription that has the potential to be an important therapeutic agent for all ages in the prevention of chronic disease is highly recommended. However, it is often poorly implemented, as clinicians lack the necessary knowledge and skills while participants have low adherence due to design defects (eg, prescriptions fail to take individual willingness, the appeal of exercise, and complex physical conditions into account). Intelligent personalized prescription is thus worth exploring.

Objective: The aim of this study was to investigate whether a year-long cloud platform–based and intelligent personalized exercise prescription intervention could improve Chinese middle-aged and older adult community dwellers' health outcomes.

Methods: A total of 177 participants (aged 52-85 years; mean 67.93, SD 7.05) were recruited from 2 Chinese community health service centers in Anhui Province, China. The exercise intervention was delivered over 12 months with a single-group pretest–posttest design. After being assessed in terms of physical activity, health-related lifestyle, history of chronic diseases and drug use, family history of disease and cardiovascular function, body composition, bone mineral density, and physical fitness through an eHealth promotion system, participants with relative contraindications for exercise were personally prescribed the health care exercise mode by an intelligent system, while those without relative contraindication and who had a regular exercise habit were prescribed the scientific fitness mode. Paired *t* tests were used for the analysis.

Results: A total of 97 participants were classified into the health care mode, and the remaining 80 participants were assigned to the scientific fitness mode. Significant changes in heart rate (mean difference [MD] 2.97; 95% CI 1.1-4.84; *P*=.002), subendocardial viability ratio (MD –0.13; CI: –1.19 to –0.63; *P*<.001), weight (MD 0.99; CI 0.29-1.69; *P*=.006), BMI (MD 0.38; CI 0.11-0.64; *P*=.006), body fat rate (MD 0.88; CI 0.24-1.51; *P*=.007), fat mass (MD 0.92; CI 0.33-1.53; *P*=.003), and brachial-ankle pulse wave velocity (MD: –0.72; CI –1.17 to –0.27; *P*=.002) were observed among participants with the health care mode exercise prescriptions at the 12-month postintervention versus the baseline assessment, while no changes in systolic blood pressure, diastolic blood pressure, muscle mass, bone mineral density, *t* value, *z* value, balance, or ability were discerned. The results showed a functional decline in the physical fitness of both groups, including in handgrip strength (healthcare mode: MD 4.41; scientific fitness mode: MD 3.11), vital capacity (healthcare mode: MD 261.99; scientific fitness mode: MD 250.78), and agility (healthcare mode MD=–0.35; scientific fitness mode: MD=–0.39) with all *P* values <.001, except handgrip strength in the scientific fitness mode (*P*=.002). There were no significant differences in other parameters among participants with scientific fitness mode exercise prescriptions.

XSL•FO
RenderX

Conclusions: The observations suggest that our exercise prescription intervention program might promote certain health outcomes in Chinese middle-aged and older adult community dwellers, yet we are unable to recommend such a program given the existing limitations. Future randomized controlled trials with diverse samples are warranted to confirm our findings.

exercise prescription; cardiovascular function; body composition; bone mineral density; physical fitness

Introduction

Physical activity is defined as any bodily movement produced by skeletal muscle [1]. Exercise is one form of delivery for physical activity and has been defined as a structured activity to maintain essential physiological systems, such as the skeletal muscular and metabolic systems [2], and to improve physical function and quality of life [1,3-5]. Resistance training is considered a very effective method for the development of skeletal muscle [6], and aerobic exercise training performed at an appropriate level of intensity has beneficial effects on cardiopulmonary function [7]. As middle-aged and older adults experience functional decline and often suffer from one or more noncommunicable chronic diseases (NCDs), many people have become aware of the health benefits of regular exercise. Consistent evidence confirms the benefits of exercise: prevention of injurious falls, sarcopenia, cognitive decline, and frailty [3,8,9]; a reduction of morbidity (eg, coronary heart disease, type 2 diabetes) [2,3,10,11]; and at least a 20%-30% reduction for more than 25 chronic symptoms (eg, depression or hypertension,) and 10% reduction in premature mortality [10,12]. Furthermore, a lack of exercise not only leads to an increase in NCDs, but also increases medical costs and the economic burden on the state and individuals [4], which is estimated to be at about US $68 billion worldwide annually [10]. The benefits of exercise for everyone are obvious. Even for middle-aged and older adults with NCDs, exercise is one of the best medicines, being cheap, accessible, and providing a complex, whole-body impact with very few side effects [13]. Therefore, exercise training is a cornerstone in the management of NCDs [14].

Although the value of regular exercise is well known, many people still do not include exercise in their daily routines [15]. A global pandemic of physical inactivity has been described [10]. For example, 50% of American adults and 49% of New Zealand adults are nonactive or insufficiently active [2,12]. The situation for older people may be worse as a result of complex physical conditions [16]. Older individuals may struggle to exercise because of pain or other symptoms [17].

Exercise prescription is cost-effective and can increase physical activity by 10% in relatively inactive patients [1]. It is recommended and defined by the World Health Organization (WHO) as follows: an exercise prescription given by physicians to help patients engage in physical exercise, according to the medical examination data (including exercise and physical tests) and based on the patient's specific health, physical strength, and cardiovascular function status. The type of exercise, exercise intensity, exercise time, and exercise frequency are specified in the prescription, and any associated precautions when undertaking the exercise are detailed [18]. The American College of Sports Medicine (ACSM) introduced an exercise prescription guideline in 1990 to guide the design of exercise prescriptions for the general population and people with chronic diseases [19].

Exercise prescription is highly recommended by the current guidelines on the prevention and management of chronic disease, but its implementation remains poor [20]. Many clinicians—especially primary care staff [1]—experience difficulties in prescribing exercise in the presence of different concomitant chronic diseases and risk factors within the same patient because of a lack of expert knowledge and skills [21,22]. Although the scientific effectiveness of exercise prescriptions is supported by a substantial amount of experimental data, studies have also demonstrated that adherence to this "scientific" and "best health–benefit" exercise prescription is not high [23,24]. This is likely because the prescription design does not take into account factors such as individual willingness to exercise, the appeal of exercise, and the conditions under which exercise occurs. In short, personalized exercise prescription is not simple and comprises many challenges, such as time constraints, complex comorbidities, perceived lack of patient engagement, and a lack of physician training or education on the particulars of physical activity [1,13]. To provide an effective and safe exercise program for patients with multiple comorbidities, an advanced intelligent exercise prescription that can calculate the complex physical condition of a patient and combine this with the patient's exercise preferences to give the best prescription, is required [25]

The purpose of this year-long program was to verify the effectiveness of intelligent personalized exercise prescriptions for middle-aged and older adult community dwellers and support the next research stage: exercise prescription using the smartphone with intervention and procedural monitoring through wearable devices. Ultimately, we envision a new protocol that includes 3 characteristics: (1) an individual assessment of needs, motivation, habits, preferences, and barriers; (2) valid behavior change approaches; and (3) proper follow-up, self-monitoring, and social support.

Methods

Design

This study included a single-group pretest–posttest design with blind pre- and postoutcome assessment and the collector of participant information being unaware of the purpose of the experiment.

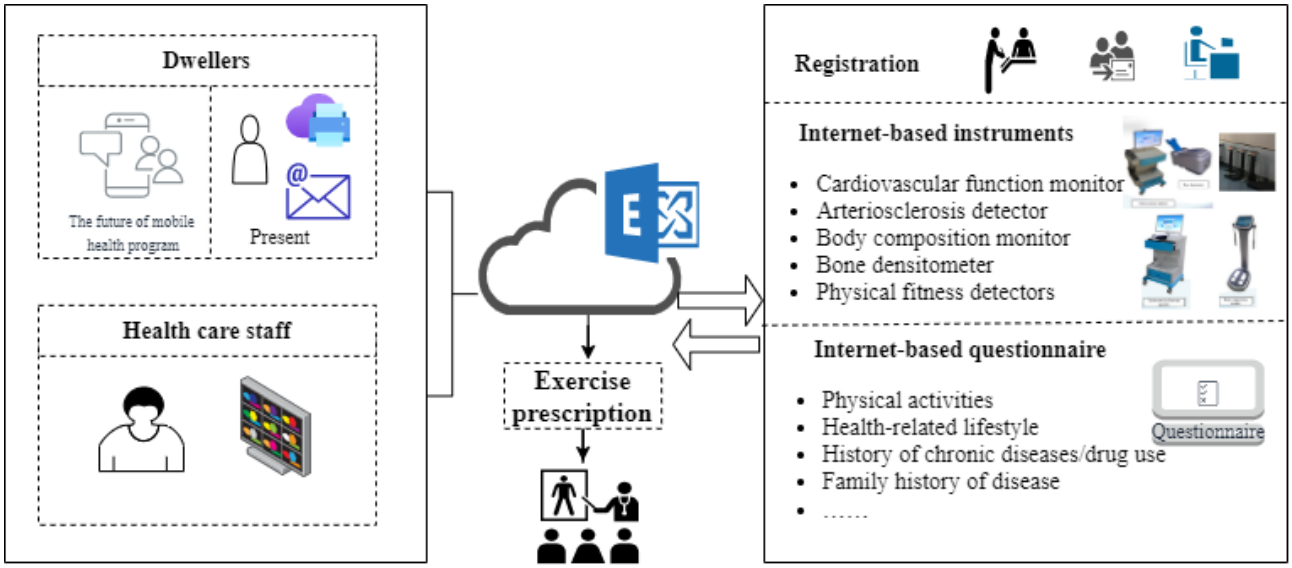
RenderX

Study Sample and Recruitment

Between January 2019 and November 2019, middle-aged and older adult community-dwelling individuals were recruited via 2 community health service centers in Bengbu in the Anhui Province of China. They were invited by center staff through telephone or verbal invitation, and those interested were asked to contact staff members for further information. Eligible participants were then scheduled to be pre-examined one by one. When they finished the entire year-long intervention program, the time of the postintervention evaluations was booked, and they were reassessed one by one until the last participant finished in November 2020. There were 3 modes available for the intervention, but because of difficulties in meeting requirements for the "exercise habit formation" mode, we only recruited participants for the "health care" and "scientific fitness mode" groups. The participants were required to be more than 50 years of age, be community dwellers, have no regular exercise habits (total number of physical activities of various intensity per week ≥3 times; total physical activity time per week ≥90 minutes) for inclusion into the health care mode group, and have regular exercise habits for inclusion into the scientific fitness mode group. Participants were excluded if they had serious cardiovascular or cerebrovascular diseases; lung or kidney diseases or related complications, according to their self-reported hospitalization experience; severe diabetes or related complications, such as fundus lesion, peripheral neuropathy, diabetic foot, or renal dysfunction; a fasting blood glucose ≥13.3 mmol/L and urine ketone positive, or postprandial blood glucose ≥19.4 mmol/, with resting blood pressure ≥180/110 mmHg; or severe cognitive impairment and diagnosed mental disorders, such as moderate to severe depression, schizophrenia, and mania.

Ethical Considerations

In accordance with ethical guidelines, the participants were fully informed about the positive effects of exercise prescription and the details of the procedures. All participants provided written informed consent to participate in this study and agreed to their data being used. The study protocol was approved by the Ethics Committee of Bengbu Medical College (Anhui, China; no. 2018045).



Sample Size

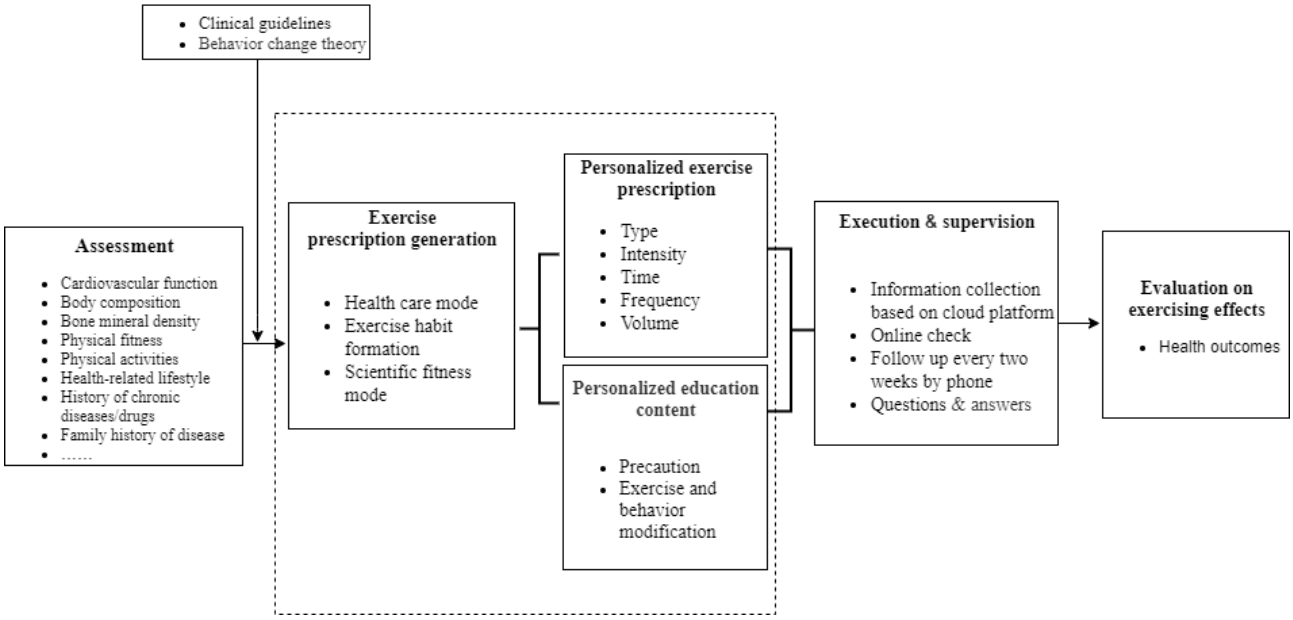
We calculated the sample size of the mean difference (MD) of the before and after comparison of each index, as reported in similar literature [26], using MedSci sample size tools with α=.05 and 1-β=.8 resulting in a sample range of 11-67. A sample size of 70 was decided upon for both groups.

Intervention

This intelligent personalized exercise prescription program (IPEPP) is a preliminary experiment for a mobile health intervention, based on an eHealth promotion system (Figure 1). At present, it includes 4 elements: (1) registration system (typically participants are invited to participate in the program by a family-contracted physician); (2) cloud platform (all data are stored and calculated in the cloud platform, through which community health care staff and researchers can monitor an individual's data online); (3) internet-based instruments (including cardiovascular function monitor, arteriosclerosis detector, body composition monitor, bone densitometer, and physical fitness detectors used to assess cardiovascular function, body composition, bone mineral density, and physical fitness of participants before and after intervention); (4) an internet-based questionnaire to collect data about physical activity, health-related lifestyle, history of chronic diseases or drug use, and family history of disease. In the future, a mobile health app currently under development will be combined with wearable devices for monitoring the process of exercise to increase the adherence of intervention based on theories of health behavior change.

Figure 1. Components of the eHealth promotion system.

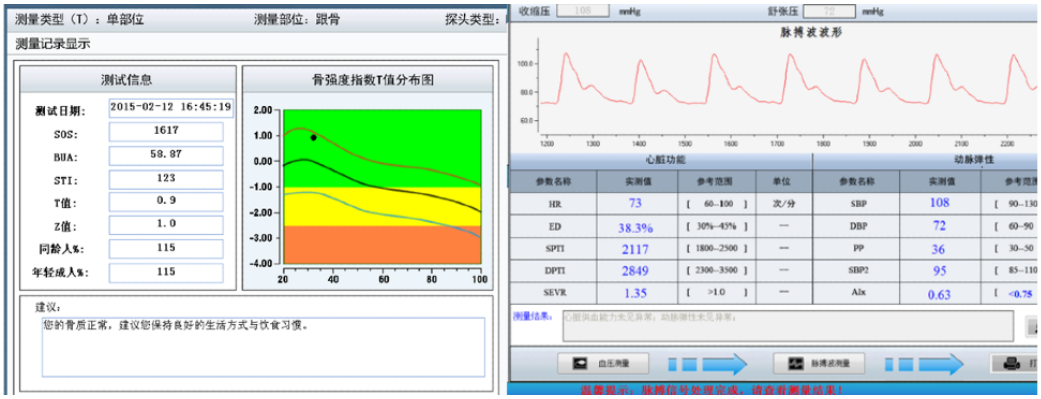
The IPEPP comprised 4 processes: (1) assessment (using internet-based instruments and an internet-based questionnaire to collect integrated information and analyze the situation of the individuals to support decision-making about individualized exercise prescription), (2) exercise prescription generation (based on the assessment of the integrated information and the



XSL•FO
RenderX

individual's exercise habits, 3 types of personalized exercise prescription are generated: a health care mode, an exercise habit-formation mode, and a scientific fitness mode), (3) execution and supervision (health care staff print exercise prescriptions or send them to participants by email, explain the instructions, precautions, and content of exercise and behavior modification, and follow up with participants every 2 weeks by telephone), and (4) evaluation of exercising effects (cardiovascular function, body composition, bone mineral density, and physical fitness).

Assessment



According to the ACSM's guidelines for exercise testing and prescription, pre-exercise screening is indispensable [19]. The generation of our exercise prescription was based on the assessment of baseline data. It consisted of information collected by an internet-based questionnaire system, including the individual's current level of physical activity, history of chronic diseases (eg, cardiovascular and cerebrovascular diseases, diabetes and hypertension) and drug use (eg, types, dosage, and times), symptoms of the disease (eg, exercise dysfunction, hypoglycemia, and hypotension symptoms), health-related lifestyle (eg, eating, smoking and drinking habits), and family history of disease (Figure 2; other details are published elsewhere [27]); and information collected by internet-based instruments, which included physiological parameters (cardiovascular function, body composition, bone mineral density, and physical fitness) as obtained from a body composition monitor (BX-BCA-100, Institute of Intelligent Machines), a cardiovascular function monitor (BX-CFTI-100, Institute of Intelligent Machines), an arteriosclerosis detector (BX-AS-100, Institute of Intelligent Machines), a bone densitometer (BX-BDI-500A, Institute of Intelligent Machines), and physical fitness detectors, including a handgrip strength meter (TSN100-WL, Physical Fitness Sports Technology Company), a reaction time meter (TSN100-FY, Physical Fitness Sports Technology Company), a 1-leg stand meter with closed eyes (TSN100-ZL, Physical Fitness Sports Technology Company), a spirometer (TSN100-FH, Physical Fitness Sports Technology Company), and a flexion measurement instrument of sitting position (TSN100-TQ, Physical Fitness Sports Technology Company). Figure 3 displays examples of screenshots showing examination results of the bone densitometer and cardiovascular function monitor. The details of the assessment procedure are shown in Multimedia Appendix 1, and other related information has been published elsewhere[27].

XSL•FO
RenderX

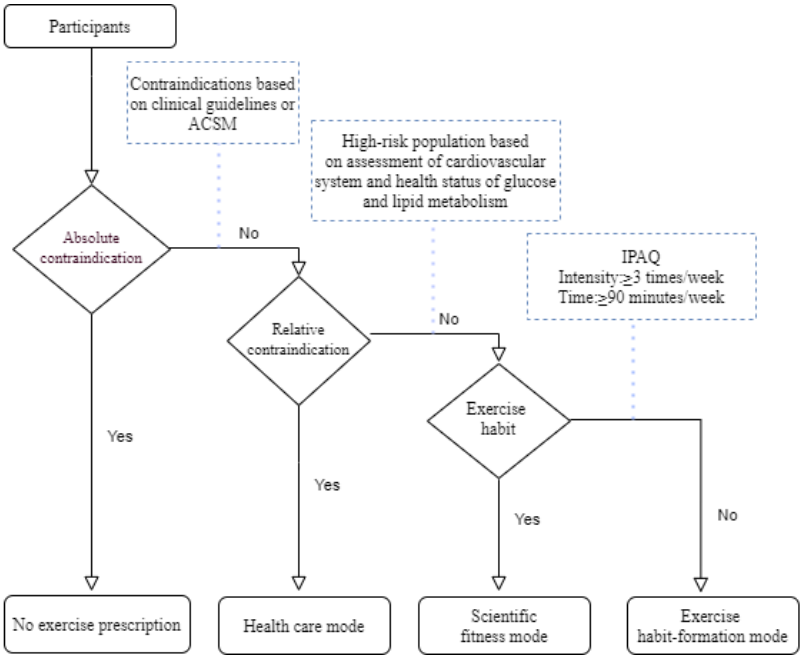

Figure 3. Examples of screenshots of the examination reports of bone mineral density and cardiovascular function.

Exercise Prescription Generation

All exercise prescription recommendations were based on clinical guidelines and the ACSM. Participants for whom exercise was absolutely contraindicated were excluded, while those with relative contraindications were given the health care mode as their prescription. Relative contraindications included the following: suspected symptoms or target organ damage, as indicated by subendocardial viability ratio (SEVR) ≤0.9; ankle/brachial systolic pressure index (ABI) ≥1.4 or 0.6 ≥ ABI >0, brachial-ankle pulse wave velocity (baPWV) ≥21.1 m/s; central arterial pressure ≥145 mmHg; and abnormal blood pressure, as indicated by systolic blood pressure (SBP) ≥160 mmHg or diastolic blood pressure (DBP) ≥100 mmHg, and SBP <90 mmHg or DBP <60 mmHg with hypotensive symptoms. After being confirming of having no relative contraindications, participants with or without adequate and regular physical activities were given the scientific fitness mode or exercise habit-formation mode exercise prescriptions (Figure 4).

Figure 4. Algorithms for 3 modes of exercise prescription. ACSM: The American College of Sports Medicine. IPAQ: International Physical Activity Questionnaire.

The system automatically generated 3 kinds of exercise prescriptions with pictures of the recommended exercise type (Figure 5) and notes of exercise precautions corresponding with the screened risks and incorrect exercise-related health behaviors. The health care mode recommended low-intensity aerobic gymnastics and other simple types of low-intensity exercise, including basic self-massage exercises (randomly drawn from the system). Compared with the health care mode, the exercise habit-formation mode recommended an unstructured prescription to cultivate individuals' exercise consciousness. It encouraged individuals to choose their exercise type and intensity according to their subjective feelings, and exercises were recommended with low requirements for skills or physical fitness, such as walking, leisure cycling, and slow dances. It is generally recommended that a single effective exercise time should not be less than 10 minutes and that the frequency of exercise should not be less than twice a week. The scientific fitness mode recommended a structured prescription following the frequency, intensity, type, time, volume, and progression principle, which includes aerobic exercise and resistance training (Table 1). Examples of exercise prescriptions and algorithms for various exercise categories are presented in Multimedia Appendices 2 and 3.

XSL•FO

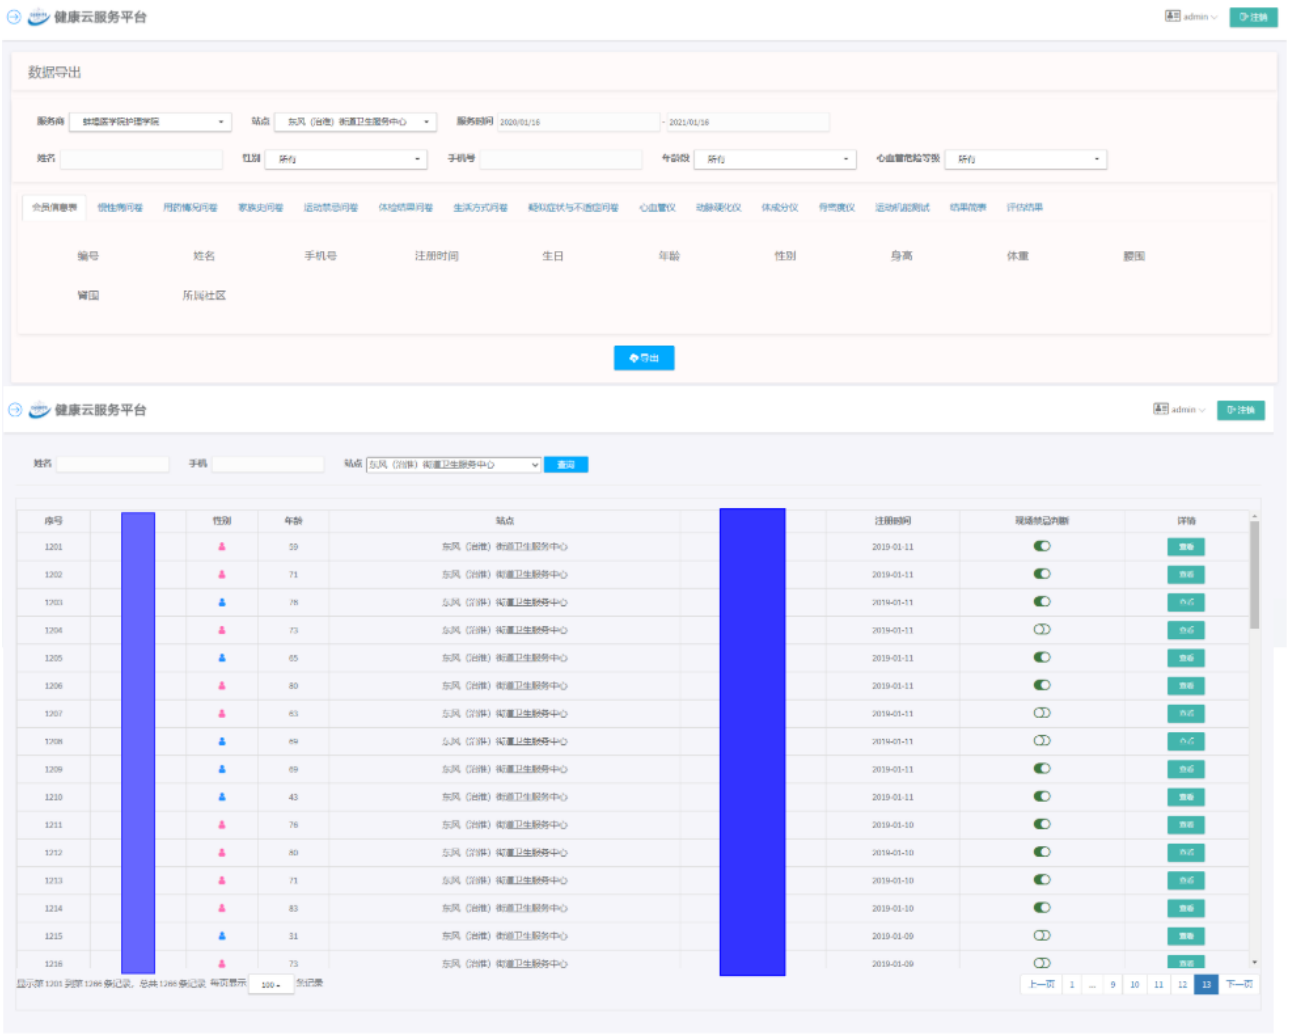
Prescription type	Aerobic exercise	Resistance training	Flexibility exercise	Special exercise[a]	Low-intensity aerobic gymnastics
Health care mode	√[b]				√
Exercise habit-formation mode	√		√	√	
Scientific fitness mode	√	√	√	√	

[a]Special exercise is recommended by prescription when a related health problem is detected in the exercise habit-formation mode and scientific fitness mode.

[b]√: The type of exercise recommended by prescription.



The exercise habit-formation mode and scientific fitness mode include recommendations for flexibility exercises before and after either aerobic exercise or resistance training (Figure 5). Special exercises were recommended for any currently detected health problems (eg, knee pain, neck discomfort), and the system recommended a suitable set of health care exercises from the special sports library as guidance. Only when relevant problems were detected in the participants during the assessment process would these special exercises be recommended (Table 1).

Execution, Supervision, and Evaluation of Exercising Effects

Participants were given their exercise prescription in the community health center after a detailed explanation, which culminated in them taking away printed color papers or receiving emails. Researchers visited the cloud platform online to find each individual's information (Figure 6), and they followed up participants every 2 weeks by telephone to remind them to exercise according to their prescription (keeping the same prescription for a year) and to help them solve any problems encountered.

XSL•FO
RenderX

Figure 6. Website with cloud platform screenshot.

After 12 months, the participants were reevaluated to check if there were any changes in the following health outcomes: cardiovascular function, body composition, bone mineral density, and physical fitness. Participants were asked to report whether they changed their medication use or related lifestyle (eg, diet change).

Statistical Analyses

Data were analyzed using SPSS 23.0 software (IBM Corp). Continuous variables are expressed as mean and SD. Paired *t* tests for independent samples and Pearson chi-squared test were used to assess the significance of differences in baseline characteristics between the health care mode and scientific fitness mode. Paired *t* tests were also used to analyze the difference in health outcomes before and after intervention. A *P* value <0.05 was considered statistically significant.

Results

Participants

A total of 232 participants agreed to participate in the study. Of this number, 27 participants were excluded due to not meeting inclusion criteria, and 28 participants did not complete the entire program including those who changed medication. These 28 participants were excluded due to inadequate adherence, an inability to finish the postassessment, changes in health status unrelated to the study and thus cessation of the intervention, withdrawal, or loss of contact. Overall, 177 participants (105 women and 72 men; mean age 67.93 years, SD 7.05 years) were included in the final analysis, with 97 in the health care mode group and 80 in the scientific fitness mode group. All participants reported they did not change their related lifestyle.

Baseline Data

Baseline characteristics are presented in Table 2. Epidemiological data of the 2 groups showed no difference except for gender, but participants with an exercise prescription in the health care mode had a poorer baseline condition for heart rate, SEVR, baPWV, body fat rate, fat mass, and vital capacity compared with those in the scientific fitness mode group. Other baseline characteristics did not differ between participants allocated to the 2 exercise prescriptions.

Treatment Effect

Results of the health care mode group at baseline and posttest on health outcomes are shown in Table 3. Some domains of cardiovascular function and body composition, including heart rate, SEVR, weight, BMI, body fat rate, and fat mass, showed significant improvement. Compared with the scientific fitness mode group (Multimedia Appendix 4), no significant changes were observed in these parameters in the health care mode group. Noticeably, baPWV (MD –0.72; CI –1.17 to –0.27; *P*=.002) changed from 17.31 m/s to 18.03 m/s during the intervention periods in the health care mode participants, while no change was discerned in those following the scientific fitness mode.

For bone mineral density, no significant improvements were shown in either the health care (*P*=.682) or scientific fitness mode groups (*P*=.55). The results showed functional decline in the physical fitness of both groups, including handgrip strength (healthcare mode MD 4.41; scientific fitness mode: MD 3.11), vital capacity (healthcare mode: MD 261.99; scientific fitness mode: MD 250.78), and agility (healthcare mode: MD –0.35; scientific fitness mode: MD –0.39) with all *P* values <.001 except that of handgrip strength in the scientific fitness mode (*P*=.002).

Discussion

We found a few improvements in cardiovascular function and body composition of participants with exercise-related contraindications but without good exercise habits. However, for participants already in the habit of exercising, there were no changes in these 2 domains.

Cardiovascular function and body composition improvements were important outcomes in our study. For cardiovascular function, we detected that heart rate and SEVR were significantly improved following a 12-month unstructured exercise prescription intervention among middle-aged and older adult dwellers with related exercise contraindications. This is consistent with previous studies, in which exercise improved cardiovascular and arterial function [5] for healthy populations, and even sedentary individuals aged more than 50 years gained the benefit of improved maximal oxygen consumption after exercise [28]. Few studies have reported on improvement in SEVR among older adults, but Huang et al [29] found an augmentation in SEVR after a 6-week exercise intervention in obese adolescents. We suspect our low-intensity, unstructured exercise prescription with associated precautions and tips was a major contributor to adherence of participants who have doubts about how to exercise because of their disease symptoms. Our recommended low-intensity special aerobic gymnastics with instruction through pictures gave participants guidelines, and the unstructured prescription provided tools and cues for participants to take safety into consideration while choosing the physical activity they prefer. For body composition, those participants prescribed the health care mode changed their weight, BMI, body fat rate, and fat mass significantly, but their muscle mass was unchanged. Unsurprisingly, this is in line with results of other interventions with or without calory restriction, implemented in a variety of populations [25-30]. Most of these were short-term intervention programs (6 to 12 weeks), and evidence of long-term effectiveness of exercise intervention in middle-aged and older adults is insufficient. It can therefore be concluded that even low-intensity, aerobic exercise and unstructured physical activity is beneficial in the long-term for middle-aged and older adults without exercise habits. Essentially, starting to exercise is the most important thing.

Corresponding parameters of cardiovascular function and body composition in the scientific fitness mode group showed no statistically significant changes. We expected that the structured and combined exercise of aerobic and resistance training would improve cardiovascular function and body composition in participants with exercise habits. However, a possible ceiling effect might have prevented further improvements in functioning, even though these participants had completed more scientific exercise [17]. Theresa et al [30] reported that individuals with more “favorable” values at baseline (eg, lower submaximal heart rate) may potentially show a low subsequent training response if a “ceiling effect” limits further improvement in that parameter. Similar research showed low exercise doses can effectively reduce cardiovascular disease or cardiovascular risk factor prevalence, but higher exercise doses do not yield additional benefits [31].

Our present work showed an increase in baPWV for the health care mode group and unchanged results for the scientific fitness mode group. These changes differed from those reported in previous studies [32-35]. However, studies included in meta-analyses investigating the effects of exercise on arterial stiffness also report positive evidence [36-38] for aerobic exercise, with patients with isolated systolic hypertension being the exception. Resistance exercise has different effects on arterial stiffness depending on type and intensity, and there seem to be no unfavorable effects on arterial stiffness if the training is of low intensity or performed in a slow concentric manner or in the lower limbs of healthy individuals [37]. Furthermore, combined training has no significant effects on arterial stiffness [36]. In our study, more than half of the participants in with healthcare mode (56/97, 58%) and nearly half of the participants in the scientific fitness mode(36/80, 45%) were diagnosed with hypertension, and those in the health care mode group were given a low-intensity aerobic exercise prescription. This partly explains the lack of improvement in baPWV, as blood pressure is affected by many confounding factors (eg, medication). Another explanation might be age. Aging reduces arterial elasticity and has been suggested to be the main precursor of arterial stiffness in different populations [39,40], with this change being more significant in older adults. Noticeably, in our present work, arterial elasticity became worse in participants engaging in aerobic exercise only, but there was no significant difference in baPWV among community dwellers engaging in both aerobic exercise and resistance training. Given the undifferentiated baseline data, it may be that the potential effectiveness of this intelligent, personalized, structured exercise prescription intervention has been demonstrated. However, additional well-designed randomized controlled trials are needed before any final recommendations can be formulated.

This 12-month intervention study showed no difference before and after intervention in bone mineral density for either group. Although some previous trials have reported the effectiveness of intervention [41], there is currently insufficient evidence to recommend exercise for improving bone mineral density [42]. One meta-analysis reported that the positive results were small, nonsignificant, and with a large and statistically significant amount of heterogeneity. There were also some consistent results detecting no significant changes in breast cancer survivors [43], or overweight and obese older adults [44].

Evidence does consistently suggest that exercise leads to significant improvements in physical fitness, increased flexibility, agility, and strength [32,41,45-48]. However, in our present work, physical fitness showed a decline in both exercise prescription groups. The inclusion of older participants may partly explain this. Reduction in physical fitness, including reduction of muscle strength in both the upper and lower limbs, and changes in flexibility, agility, and endurance, were equal for both men and women and was likely due to the aging process, which was discussed in a previous study [49].

No adverse events were reported for any of the interventions. Although our prescription included step-by-step instructions with pictures and participants could call community health center staff to report any uncomfortable conditions during exercise, there are safety aspects worth considering that should

XSL•FO
RenderX

be more strictly monitored. We should strengthen the monitoring of exercises so that harmful execution of exercises can be quickly noted and addressed.

There were several limitations to this research. First, this study was conducted in 1 geographic location, which limits the generalizability of observations and hinders the ability to identify population differences. Second, we only studied a single group of middle-aged and older adults and did not include a control group, impeding any ability to draw conclusions on initial intervention effectiveness. Third, the adherence to exercise prescription was only based on a self-report of participants. We lacked a objective and scientific means of monitoring the entire program. Fourth, as a feasibility and single-arm study, we failed to control age and disease-related confounding factors, which might have potentially influenced our observations. Future studies using a randomized controlled intervention protocol and employing app-based, wearable devices are encouraged to expand on this effort.

The observations suggested that our exercise prescription intervention program might promote certain health outcomes, such as cardiovascular function and body composition in middle-aged and older adult Chinese community dwellers. However, we are unable to recommend this program because of the existing limitations. Nonetheless, we recommend that older adults with a range of diseases begin exercise under supervised instruction when initiating training. The benefit is clear, and “start to exercise” should be the top priority for all older adults.

Acknowledgments

The authors thank Lan Xie and Lin Liu at the Community Health Service Centre for administrative assistance. Abstract

Background: Many previous studies have explored socialization-oriented social media (SM), but their reach has been limited to the context of information exchange for common personal interests. This study focuses on work-oriented SM, which can enhance organizational networking and productivity levels in the context of public hospitals.

Objective: This study aims to provide a theoretical framework to explain how the use of SM can enhance the skills of health professionals and levels of organizational productivity in uncertain environments.

Methods: A total of 2 distinct forms of data collection techniques were combined: focus groups and semistructured interviews. Both were conducted with doctors and nurses in Saudi public sector hospitals.

Results: The findings reveal that the use of SM can create professional socialization at the level of the institution, and this can enhance skills, knowledge, decision making, and the overall level of organizational productivity. The increasing use of SM creates collaboration between health experts (particularly endocrinologists and pulmonologists in this case) who arrange video calls to share best practices in terms of medication, diet, and health care plans for patients with multiple diseases. Many of these patients are particularly vulnerable, given the wider context of the current global pandemic.

Conclusions: This study culminates in the Social Media Organizational Productivity model, which provides insights into how SM has increased the accessibility of health professionals through the use of technology. Access to such professionals creates a patient-centric approach and a culture of shared communication for dealing with high-risk patients during the current global pandemic.

Introduction

Background

The flexible, agile, collaborative, informal, unstructured, and spontaneous nature of social media (SM) platforms has given rise to more and better social interactions, social support, knowledge sharing, and social expectations [1,2]. There are various kinds of SM, such as personal platforms (ie, Skype and WhatsApp) and organizational SM platforms (ie, Microsoft Yammer). Thus, SM is heterogeneous at both the personal and organizational levels. However, contemporary employees cannot differentiate between personal and corporate SM. On the basis of this heterogeneity and motivated by the influence of the SM world, workplaces have begun to embrace SM for socialization and work-oriented purposes [3,4]. Work-oriented SM types include web-based platforms that can be used in the workplace to facilitate collaboration. These forms of SM can also generate resources and facilitate the sharing of work-related content and information. They can support internal organizational communication and can be used to track events and

XSL•FO
RenderX

workstreams. They are also reliable forms of support for task management [5,6]. However, socialization-oriented SM includes web-based platforms that facilitate the sharing of personal and social information and that enable people to develop expressive links that can shape identities through normative expectations and emotional and social forms of support [6,7].

Existing literature on SM has tended to focus on exploring socialization-oriented SM, which is limited to information exchange for personal common interests. However, this study focuses on work-oriented SM that can influence organizational productivity in the setting of Saudi public sector hospitals. SM plays a very important role in supporting communication among employees in organizations [8]. A key previous study highlighted the importance of relationships and social interactions to achieve common objectives [8]. Virtuality theory advocates the use of SM if it is required to alter patterns of social exchange ties. However, it overlooks the consequences of such social exchange ties in organizational settings. Previous studies have measured the impact of patient tweets on hospital quality improvements, but these studies failed to produce the expected results [6,9,10]. Approximately 60% of physicians use SM to monitor patient health and education. Furthermore, these physicians use SM sites to inform patient drug adherence and behavioral changes that can enhance the level of patient compliance and positive outcomes [6,9,10]. Conversely, a survey of 480 physicians revealed that 68% of physicians hesitate to use SM sites for patient, personal, and professional connections. However, there is little research on how the use of SM for communication purposes influences organizational productivity in the Saudi health sector setting. High-quality SM relationships make a significant contribution to employee performance, but there is little understanding of this contribution in public hospitals in Saudi Arabia [11].

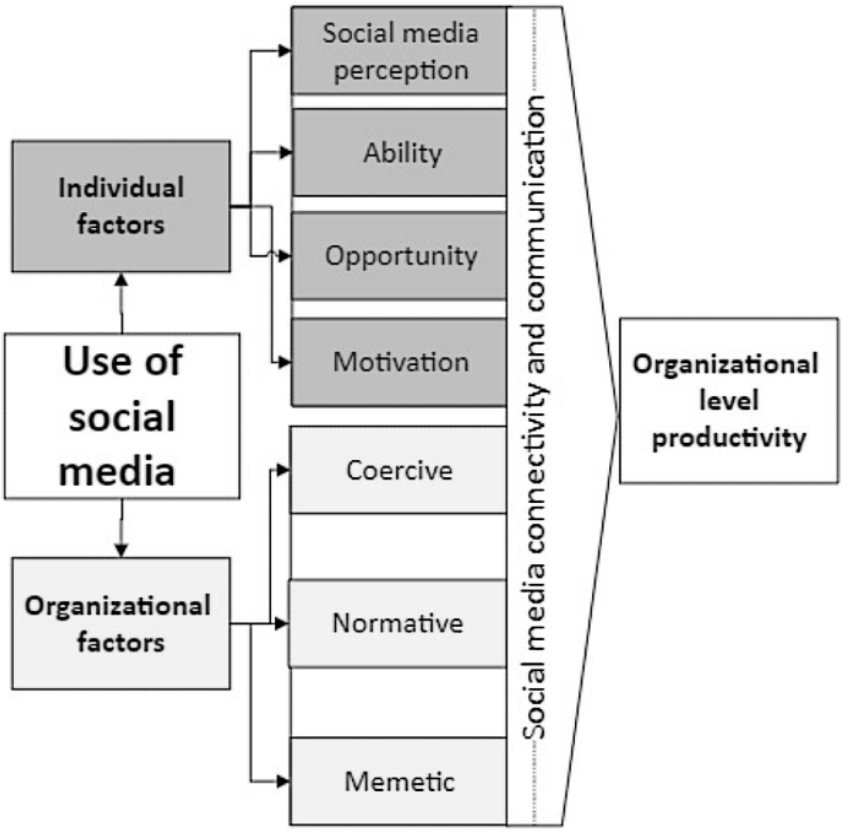
There is evidence of the popularity of SM among Saudi men and women, as approximately 41% of the Saudi population actively uses various SM platforms [2]. According to recent statistics, some 9.9 million Saudi Arabians regularly use Twitter. Saudi Arabians are the fourth highest users of Twitter in the world [12]. Facebook, WhatsApp, and Twitter are used to exchange audio, videos, text, views, and information and to meet personal and organizational interests. The Saudi government has restricted the use of some SM platforms because of social campaigns by SM activists between 2013 and 2017 [13]. However, after this time, the Saudi government lifted the ban and allowed the use of the SM platforms [13]. Public hospitals in Saudi Arabia are under the control of the Saudi Ministry of Health. It is therefore interesting to analyze the specific rules, regulations, policies, hierarchal structure, and power uses that can influence the use of SM platforms, even for productive purposes in Saudi public sector hospitals.

Although an ample body of literature has explored the effective use of SM at individual levels as well as in the organizational communication context in Western culture [14,15], there is evidence that Arab public organizational culture is unique and different from Western public organizational culture. This might be because of some inherent cultural attributes, such as authoritative management styles, hierarchal structures, a preference for top-down communication, low staff empowerment, and strong social networking among those with sufficient resources. Work overload and favoritism might also be factors. These are some of the unique features of Saudi public sector organizations that strongly influence the use of SM platforms at both the individual and organizational levels. There is little understanding of how public hospitals in Arab countries such as Saudi Arabia manage SM use. This study introduces a theoretical framework to guide how SM can drive productivity in Saudi public sector hospitals.

Literature Review

Deep penetration of SM has been observed in many workplaces. Nowadays, there is an increasing trend among companies to strategically implement such tools to improve their organizational activities and support their workforces [16]. Leading organizations regularly use personal, public, and popular SM such as LinkedIn, Twitter, and Facebook to improve employee engagement, customer service, talent recruitment, marketing, and knowledge sharing [17,18]. Research has described SM use in health information management as “the activities that people perform to acquire, organize, maintain, share, retrieve, and use health information items to complete healthcare tasks and fulfil their needs” [19]. The increasing use of SM in the workplace has led to the emergence of various socially connected software that companies commonly use to pursue their business activities and goals [5]. In addition, where the aim is to support employees, such use is considered promising for excellent organizational performance [9,20].

In addition to extending access to public and general SM platforms such as Twitter and Facebook in workplaces [10,20], more emphasis is being placed on developing and implementing professional and more specific SM technologies. Examples include IBM connections, Slack, Jive, Facebook Workplace, DingTalk, and Microsoft Yammer. Consequently, it has become possible for different types of SM platforms to coexist in organizations. These can be used by workers for work and/or during work time for information exchange and effectiveness in workplaces. However, companies and executives may sometimes perceive SM as controversial [16]. This begs the question: How does the utilization of different kinds of SM platforms in the workplace influence organizational productivity, and what can be learned specifically from public sector hospitals in Saudi Arabia? Ability, motivation, and opportunity (AMO) theory holds that if employees are competent, skilled, and motivated, then they can create more opportunities at the personal and organizational levels. Therefore, organizations should provide training and career advancement opportunities to employees, as this can enhance their skills and motivation and can drive organizational productivity.



There are various fields in which institutional theory has been applied, such as political science, economics, organizational theory, and sociology. However, there is little understanding about the application of institutional theory in public hospital settings. In the context of institutional theory, organizations embed themselves within different environments in which they may acquire legitimacy from imitative, coercive, or other kinds of institutional forces. Moreover, institutional theory implies that corporate decisions are partially driven by rational

XSL•FO
RenderX

effectiveness goals and partially by legitimacy concerns and cultural and social factors. Companies adhere to different institutional values or norms to acquire a *fit* and/or to integrate into the surrounding environment. Isomorphism provides an in-depth understanding of the institutional environment. By incorporating institutional rules within their own structures, organizations become more homogeneous and similar in structure over time. This is particularly the case within particular institutional environments and contexts, such as how public hospitals in Arab countries, such as Saudi Arabia, manage SM use.

The 3 common methods of isomorphism identified by DiMaggio and Powell are coercive isomorphism (firms are either compelled to adhere to rules or adopt to structures), normative isomorphism (firms adopt forms as professionals within the firm who claim their superiority over others), and mimetic isomorphism (one firm copies another firm, often because of uncertainty). Institutionalization is a process that involves modifying behaviors to fulfill social expectations that are derived from different norms such as regulatory structures, professions, laws, cultural practices, and government agencies. All these actors exert pressure on firms to operate in a particular manner. Institutional theory is considered a powerful and popular explanatory tool for any analysis of organizational behavior that seeks to address different forms of organizational change. In contrast, the concept upon which most classical approaches are based is that organizations are dominated mainly by role, personal preferences, and the interest of individuals, as well as by rational actors. Likewise, new institutionalism primarily focuses on the formative role of organizations. In this sense, the core postulate is that rational actors within organizations always look out for their personal interests and exploit particular institutional limitations in pursuit of these. This view suggests that patterns of organizational actions are not shaped by instrumental calculations, but by institutional forces, such as cultural scripts and norms. The deep penetration of organizations in social environments could expedite or compromise their use of SM platforms for organizational productivity purposes (Figure 1). This suggests that organizational procedures and structures often reflect the environmental expectations that are required to enhance the use of SM to make the organization more successful. Institutional theory is based on the idea that organizations always want to respond to their environmental demands with the purpose of leveraging competitive advantage.

Figure 1. Theoretical framework based on institutional and ability, motivation, and opportunity theories.

Methods

Overview

There is an increasing trend among researchers to use social constructivism to understand and synthesize the different realities of multiple disciplines, including the health sciences, philosophy, sociology, and psychology [1,21,22]. In particular, health science researchers extensively use social constructivism to gain in-depth insights into how health care professionals obtain and integrate new knowledge. They also tend to explore the kinds of behaviors they can develop to improve their own decision-making performance [22]. According to social constructivists, the social world in which we live has unique

XSL•FO
RenderX

local, cultural, and social contexts, and all these contexts vary from location to location, from individual to individual, and from nation to nation [17,23]. Unique and different knowledge insights are, thus, produced through the lens of social constructivism because they critique shared beliefs, shared meaning, shared language, collective cultures, values, and social norms [21,23]. Social constructivists construct knowledge on the basis of cultural and social values. Therefore, they prefer to understand, see, and shape things in accordance with the viewpoints of social actors. The researchers were highly involved in this study to capture and better understand the issues under investigation. Institutional forces, national cultures, individual capabilities and abilities, social structures, organizational policies, the sharing and exchanging of knowledge, and SM are all subjective realities. Each of these influences the organizational productivity of public hospitals. Through the research process, this study clearly shows how social constructivism, analytical techniques, and data collection are interconnected.

There is limited literature available that has sought to uncover the influence of SM on employee work productivity in a public sector hospital. Therefore, this study is exploratory in nature because it aims to capture rich insights using social constructivism and interpretive methods. Social constructivists believe that there are multiple environmental and biological factors that have different impacts on individuals [17,21]. Interpretive methods are considered important where the researcher seeks to understand the social and *real* context of networking technologies and how social networking technologies influence organizational productivity in health care workplaces. Interpretive methods are thus recognized as important, especially when people are interested in knowing how the use of technology influences various institutional, government, cultural, and social structural factors [24,25]. Indeed, interpretive studies are more focused on understanding social contexts (ie, social relationships, peer influence, the division of labor, and the structure of an organization) that are impacted by the actions of individuals [17,21]. Previous studies have indicated that interpretive methods can capture subjective realties, such as individual levels of information and levels of knowledge, expectation, experience, and understanding [17,23]. Other studies have suggested that interpretive or qualitative methods are more useful for capturing the exploratory elements of subjects with the support of single or multiple theories [22]. These methods are usually useful for understanding individual perceptions about and sense-making in particular situations.

Sampling and Population

This study primarily focuses on Saudi public sector (government) hospitals, as they are strongly influenced by institutional, cultural, and social forces. Multiple hospitals were selected to gain insights from health care professionals in a variety of government hospitals in Jazan, Saudi Arabia. The hospitals selected for this study included Jizan Hospital, Prince Mohammed Bin Abdul Aziz Hospital, and King Saud Medical City. All these public sector hospitals have a rich technological and institutional history, and many health professionals want to work in them to gain valuable experience.

As many of the doctors in these hospitals are visiting professionals, it was not possible to fully describe the sampling framework. Moreover, although 2 of the hospitals were willing to provide a sampling framework, the others declined to provide any sampling framework. To address this issue, we decided to use a nonprobability sampling method. In health sciences, purposive sampling is common and is particularly useful when researchers are aware of the sampling framework and when they want to choose informants who have rich knowledge about the study objectives. Therefore, purposive sampling was used to collect data for this study. The 30 participants selected for data collection included nurses and head nurses working in government hospitals. Moreover, the 20 participants selected for focus group interviews included emergency doctors, surgeons, and hospitalists. Multimedia Appendices 1 and 2 indicate the demographic attributes of the selected informants. Their selection was based on the following inclusion criteria:

- Working within public sector hospitals for at least two years
- Older than 18 years
- Willing to voluntarily provide research data
- Had at least one active account on SM

Data Collection Technique

To collect qualitative data, 2 distinct forms of data collection techniques were used: focus group interviews and semistructured interviews. Data collection took about 7 months, and 3 different methods were used to gain in-depth insights into the expectations and experiences of professionals who use SM in the workplace. Semistructured interviews were undertaken because this type of method ensures the maximum participation of respondents throughout the research process. Moreover, “researchers have realized [for] quite some time that researchers are not invisible neutral entities; rather they are part of the interactions they seek to study and influence as well as observe those interactions.” Of real interest here were the experiences of nurses and their perceptions of the different realities of organizational productivity and SM use. Doctors were seen as key sources for verifying and conceptualizing these shared realities.

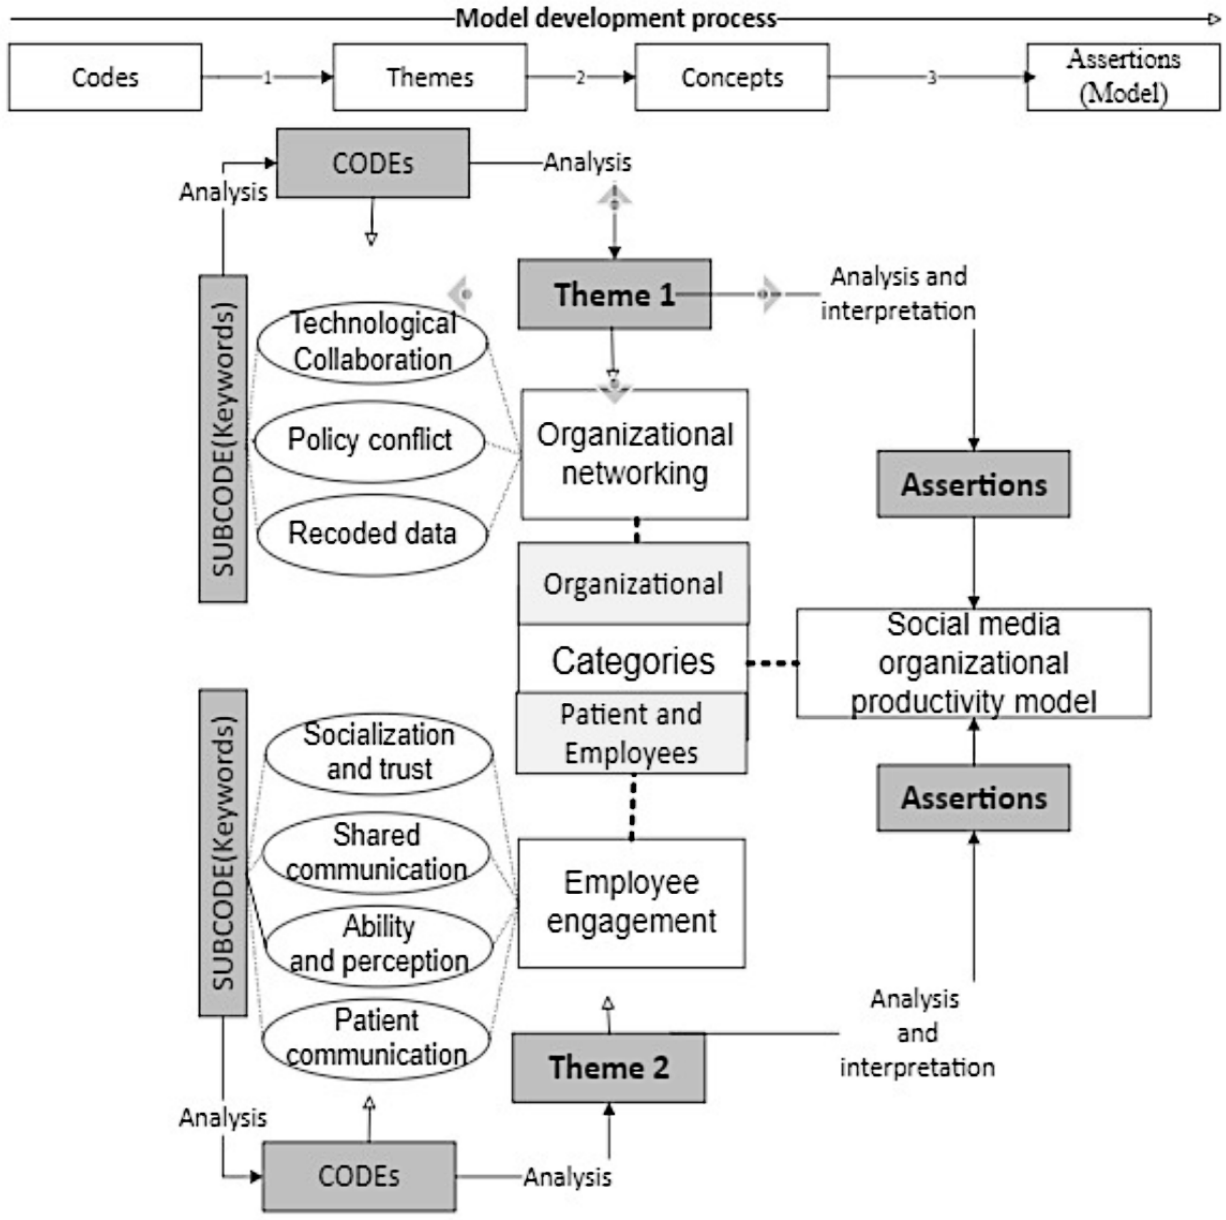
Interpretative methods are useful for gaining rich insights through observations, semistructured interviews, stories, diaries, and narratives [24,25]. Semistructured interviews are one of the most commonly used interpretative methods among interpretivists because they can elicit rich insights and generate answers to multiple questions such as *what, how, and why* [22,26]. Moreover, the flexibility of semistructured interviews means that it is possible to add or modify the interview questions. Contrary to structured or open-ended interviews, semistructured interviews focused on obtaining particular answers [24,25]. Semistructured interviews were conducted in a face-to-face setting. The following questions were asked during semistructured interviews: How do you see the role of SM in relation to organizational productivity in the workplace? What socialization factors appear useful for increasing your productivity? What are your organizational and individual perceptions of SM use within hospitals? What challenges negatively influence SM use within this hospital? What are the specific public sector policies or factors that influence the use of SM in public sector hospital settings?

XSL•FO
RenderX

Focus group interviews are widely used by researchers interested in accessing the opinions and life stories of individuals in specific situations. Many researchers recommend conducting focus group interviews whenever there is a need to handle discourse in which the image of the research participants is continuously regenerated. Health professionals were invited to participate in focus group interviews. The sample comprised 20 doctors and 30 nurses (Multimedia Appendices 1 and 2). This sample resonates with previous qualitative studies wherein the data saturation point was reached before the 30th interview [24,25]. To maintain social distancing, the social networks of health professionals and the researcher played an important role in identifying respondents with knowledge of SM technologies. Initially, the participants were asked if they would like to volunteer to participate in the interviews. In addition, some health professionals were contacted via SM (such as Twitter, Facebook, and WhatsApp). The researchers sent reminder emails to contact any participants who had not yet confirmed their interview schedule either by Skype or telephone. Interviews through Skype and telephone took place to maintain social distancing during the COVID-19 pandemic.

Interviews with nurses and head nurses lasted between 30 and 60 minutes. Skype videoconferencing calls were initiated to conduct focus group interviews with the selected health professionals. Participants preferred to take calls in their private offices in the hospitals in which they worked. Interview questions were developed based on the expectations and experiences of health professionals in relation to technology. This is an efficient way through which episodic memory can be accessed and complementary insights can be induced [22,26]. During interviews, episodic memory in individuals' neurocognitive memory systems can be activated by asking them about specific and ordered occasions [22,26], such as employee performance and SM, in this study. Moreover, the researcher used the past tense while developing interview questions to ensure the collection of complete data. Technical questions were also used in this study, whenever required. Many studies have recommended using tactical questions, particularly when managing participants seems quite difficult [22,26]. Indeed, tactical questions represent the summary of questions that were initially asked and are also very useful when it comes to addressing the risks identified earlier.

By asking different forms of interview questions, the researcher can optimize conversations with health professionals on the topic of internal generalizability [22]. Moreover, in the context of social constructivism, internal generalizability was possible with the help of data gathered from different respondents in terms of gender, occupation, and age [22]. The sample drawn for this study contained 30 female respondents of different ages (19-50 years) and experiences (Multimedia Appendix 1). The sample contained 20 doctors (Multimedia Appendix 2). Regardless of the sample composition (more males and fewer female participants), no screening questions preceded the interviews to avoid any intentional demographical influence on an otherwise diverse sample. The respondents were also provided with verbatim transcripts of the interviews to enable cross-examination, increase data validity, and improve internal generalizability.



Thematic Analysis

This study used thematic analysis to explore data and to develop a common set of themes or patterns. The researcher also used transcripts of the interviews to develop different initial codes to support the main themes of organizational networking and patient engagement. A total of 3 codes emerged around organizational networking: technological collaboration, policy conflict, and recorded data. In total, 4 codes of employee engagement emerged: socialization and trust, shared communication, ability and perception, and patient communication. After the construction of the main themes, keywords, and codes, the researchers reviewed them to increase both external and internal homogeneity [24,25]. Figure 2 illustrates the thematic analytical procedure of the Social Media Organizational Productivity (SMOP) model.

Data were organized into a verbatim transcript spanning 218 pages. The data were analyzed across 3 key phases. The responses of doctors, head nurses, and nurses were analyzed in the first phase of this process. Next, words that were repeatedly used throughout the interviews were identified. To group these repeated words into codes, the researcher visited them iteratively. Subsequently, the researcher assigned themes to these codes based on their meanings. Further analysis of responses was performed in the second phase. As a result, SM social practices are described. The integration of the experiences of doctors and head nurses was carried out in the third phase, so that a holistic outlook of organizational productivity and SM as a joint experience could be disclosed.

XSL•FO
RenderX

Figure 2. Thematic analysis process.

Trustworthiness of Qualitative Findings

Qualitative studies use confirmability, credibility, dependability, and transferability to maintain rigor and trustworthiness, whereas quantitative studies use reliability, objectivity, and validity to ensure rigor and trustworthiness. *Internal validity should be replaced by credibility, external validity by transferability, reliability by dependability, and objectivity by confirmability.* Although conducting qualitative studies, it is assumed that no *truth* is absolute in nature, but rather multiple realities are accessed. Consequently, generalizing the qualitative findings is not possible. However, credibility, confirmability, transferability, and dependability are, however, very useful measures of rigor and research validity for qualitative studies. Moreover, qualitative studies can improve the transferability of their findings by providing rich descriptions of the research process. This study, for example, produces transferable findings by highlighting the research process and providing a detailed justification for every qualitative data gathering method used. The extent to which the researchers or participants in qualitative studies can evaluate both the recommendations and interpretation of study findings is termed dependability. In this study, the researchers evaluated the data many times to ensure the rigor and trustworthiness of interpretations. Semistructured interviews were conducted to ensure the confirmability of the findings. The use of different qualitative data collection techniques with different respondents increased the credibility of the qualitative findings. In this study, the researcher ensured the credibility of the findings by using focus groups and semistructured interviews with a variety of participants.

Results

Main Theme 1: Organizational Networking

Organizational networking involves exchanging, governing, and organizing sociotechnical networks that can enhance information exchange and social relationships within a formal organization [27]. This study of organizational networking provides ideas about how knowledge, information, communication, and decision making can be carried out in a formal setting. For example, Saudi public sector hospitals operate under the authority of the Ministry of Health. Therefore, these authorities can influence the level of knowledge, information, communication, and decision making, which ultimately influence the level of organizational productivity. To understand organizational networking in Saudi public sector hospitals, this study summarizes the findings into 3 codes: technological collaboration, policy conflict, and recorded data.

Code 1: Technological Collaboration

Technology collaboration refers to the systems and tools that help stakeholders to coordinate and complete tasks effectively, whether working remotely or in an office environment. It is found that nurses use SM instant messaging and video calls to increase interpersonal collaboration. As a result, they can enhance their knowledge, influence the speed at which they work, and increase their organizational productivity. For example, interviewee 19 noted:

> *social media increased peer to peer support as I can consult with my senior nurses through video call and messages and their shared knowledge is always helpful as now, I can be able to complete multiple tasks in limited time.*

There is evidence that SM increases real-time communication, as video calls help health professionals manage patients in intensive care units (ICUs). Specialist doctors cannot be available at all times to deal with critical patients in ICUs. Therefore, SM provides them with the opportunity to manage situations through nurses so that they can assess the condition of multiple patients. For example, interviewee 22 noted:

> *I am working in ICU and many times I faced severe situation as I have to deal with emergency patients who have multiple diseases so we need sometimes urgent video call to different experts so they can advise what I should do until they physically visit to ICU.*

There is evidence that SM has increased the virtual connectivity of different health professionals (ie, endocrinologists and pulmonologists), which means they are in a position to join group discussions with vulnerable patients. This could drive the need for emergency visits to assess vulnerable patients. For example, focus group interviewee 19 stated:

> *Social media helped to virtually connected with my patients as sometimes patients are more critical such as old (unable to visit hospitals) as well as having both diabetes and asthma at the same time so different medical experts (endocrinologist and pulmonologist) can now arrange video call for proper guidance of patients.*

The COVID-19 pandemic has increased many risks to health professionals, patients, and communities. However, SM platforms such as WhatsApp and Skype help users to control situations, especially when there are limited health resources. Therefore, these SM platforms contribute to the care of COVID-19 patients. For example, focus group interviewee 5 noted:

> *Dealing with vulnerable patients has become more complicated, especially when they have the virus, so using Skype and WhatsApp video calls means we can coordinate with each other in a safe community.*

Code 2: Policy Conflict

Policy conflict occurs when there is no professional code of conduct regarding the use of SM platforms. As a result, these social platforms cannot deliver maximum benefits at the organizational level. For example, interviewee 5 noted:

> *The Saudi ministry of health did not develop any organizational policy to use social media in workplace as a result we have not top management support otherwise we can practice it effectively to enhance the speed and collaborative care for patients.*

There is evidence that although the use of SM helps professionals to collaborate and coordinate activities, there is no Saudi government policy to positively use these platforms in the workplace. Therefore, some health professionals use these social platforms, whereas others do not. For example, focus group interviewee 9 said:

> *I am working in public hospitals since 26 years but I experienced when we started to use social media then it saved our time, energy, financial resources, and use of physical infrastructure.*

Some nurses felt that SM platforms really helped them to educate their patients so that they could control emergency situations and find the best way to deliver medicine and diet plans. Furthermore, many used SM to share relevant health care materials with patients, even in the absence of organizational support for the use of SM in public hospital settings. For example, interviewer 18 noted:

> *It is our duty to educate patient so that they can self-manage their diseases and reduce work overload and utilization of human and financial resources. Social media provided us this opportunity to share health care material with patients but there is no organizational policy and leadership support for using these best interactive communication platforms.*

Code 3: Recorded Data

Recorded data refer to SM channels such as YouTube providing facilities to health professionals to record, store, and share data to save time, energy, and resources. In the past, health professionals have tended to verbally communicate to organize tasks that have no official record. As a result, many did not later accept responsibility if anything serious happened to the patients that were being discussed. For example, interviewer 2 noted:

XSL•FO
RenderX

> *Social media helps to generate evidence of communication as, in the past verbal communication is not recorded and sometimes our seniors decline to take responsibility for their recommendations/actions.*

Participants felt more engaged and connected with vulnerable patients and were able to manage emergency situations. As a result, they were able to deal with high numbers of patients, even when they were not at work. For example, focus group interviewee 19 highlighted:

> *I am a diabetes expert and sometimes I receive calls about my diabetes patients and how to clean wounds and stop bleeding in emergency situations...so social media really helps (me) to share YouTube videos of experts, so that these patients can self-manage in emergency situations.*

Recording exchanges on SM also helped professionals to support parents and community education stakeholders by sharing knowledge about, for example, the care of infants among new mothers. For example, focus group interviewee 17 said:

> *I am working in the maternity department so we always share videos to educate the first-time parents about how they should lift their babies...the best positions for burping, and how they should use infant car seats to effectively care for their new-borns.*

Main Theme 2: Employee Engagement

Employee engagement is an increasingly well-researched concept, and many have sought to understand this phenomenon through qualitative and quantitative methods. However, there is less understanding of how engaged health professionals and patients can influence organizational-level productivity, especially in the context of Saudi public sector hospitals. Employee engagement can be explained as motivated and enthusiastic employees involved in positive actions to improve health care services, reputations, and levels of organizational productivity. Although previous studies have provided an understanding of employee engagement from motivational, emotional, and cognitive perspectives, this study examines how SM can increase engagement among health professionals by building socialization and trust and by relying on shared communication, abilities and perceptions, and patient communication.

Code 1: Socialization and Trust

Socialization refers to the enhancement of information exchange to support learning and to improve competencies that can enhance productivity in hospitals. Socialization can promote effective communication among health professionals, and it is therefore useful for building trust in the workplace. For example, interviewee 23 noted:

> *WeChat, Facebook, WhatsApp, and twitter are common social media platforms that we use to communicate and learn from doctors and colleagues. Therefore, we are not more effective and productive compared to the past.*

Socialization promotes the use of social networking platforms (ie, Twitter, WhatsApp, Facebook, and WeChat) for effective communication and is, therefore, an informal, popular, and optimal way of maintaining professional trust in intensive health care settings. The analysis suggests that doctors and nurses are now more connected and engaged and that SM is useful for celebrating individual and organizational achievements. These professionals are now more familiar with SM and can use it in emergency situations. For example, focus group interviewee 13 noted:

> *Nurses and doctors of a particular department are connected through instant messaging apps for celebration of new appointments, promotions, personal educational achievements, parties, and helping others during excessive work overload.*

Some argue against the use of social networking platforms and believe that these have reduced productivity. For example, interviewee 18 noted:

> *I noticed many of my colleagues and seniors even using social media in ICU and operation theatres when they have to focus on their work, so I believe its wastage of time and reduce the work productivity.*

Code 2: Shared Communication

Shared communication refers to explaining, questioning, listening, understanding, acting, advocating, and negotiating over tasks, roles, and responsibilities to enhance organizational productivity. For example, interviewee 13 said:

> *During this global pandemic, both nurse and doctors are extremely busy in ICU and critical operations, but the use of social media increase their interaction, coordination and collaboration especially when health resources are become limited due to increasing the number of patients.*

It is evident that the use of SM has driven coordination and collaboration among doctors and nurses, and they are able to manage more tasks within a limited time frame. The findings also suggest that mental and behavioral issues are heightened among children and older people. Therefore, using SM, doctors and nurses can more effectively discuss health care plans with patients during a global pandemic. For example, focus group interviewee 3 noted:

> *The global pandemic has increased the issues of children and old people who have behaviour and psychological issues. So, the use of social media facilitates shared communication so parents and other people may know what care should be more effective without visiting in hospitals.*

The findings suggest that multiple doctors now collaborate through SM to discuss health care plans with patients who have various diseases and who are vulnerable during global pandemics. For example, focus group interviewee 4 said:

> *I have some patients who have type 2 diabetes, cancer, asthma issues and they are older therefore it is not risk free to meet with them physically. Therefore, sometimes multiple doctors (Trauma surgeon, Endocrinologist, and Pulmonologist)*

XSL•FO
RenderX

conduct conference call for discussing the medication and health care plan.

Code 3: Ability and Perception

Ability refers to the particular skills that we elicit from sharing practical knowledge and experiences through SM platforms. The interviewees had mixed views, and some acknowledged how groups on SM updated their skills and performance, whereas others complained that SM platforms increased expectations when it came to response times. For example, interviewee 9 noted:

> *Our hospital IT department is not very skilled, so we got lower motivational and technical support. Some of our colleagues also have perception that use of these social media platforms created more stress and pressure from our seniors who always demand quick response and action.*

However, focus group interviewee 14 said:

> *Our profession is required to continuously learn and improve our ability, so I have joined many YouTube channels and WhatsApp groups where we are getting opportunities to learn, knowledge exchange, and improve our performance.*

SM has, therefore, connected professionals who have relevant, rich experiences and practical knowledge of the different workplaces at national and international levels. Therefore, there are opportunities for junior staff to increase their skills by learning through experience. For example, interviewee 14 noted:

> *We (head nurses of different hospitals and countries) are now connected with WhatsApp and Facebook groups where we sharing content related to advance healthcare techniques, so we experienced that our level of performance is now more improved.*

Code 4: Patient Communication

Keywords: patient communication, health care, high risks, education, awareness, skills, knowledge.

SM helps to create better health services and patient-centered care. Therefore, doctors are more engaged, particularly with patients who require immediate help to recover from critical situations (ie, pneumonia, chest infections, and asthma). For example, focus group interviewee 9 noted:

> *Instant messaging apps have created direct communication (audio, video, text messaging) between doctors and patients. So now I can more effectively work on asthma patients regarding diet plan, smoking/alcohol habit, inhaler use, and how to control stress in emergency situations.*

In the presence of COVID-19, both public and private hospitals have insufficient resources to provide health care to every mother. Therefore, doctors often only engage with mothers who are struggling because of high-risk pregnancies. For instance, focus group interviewee 6 highlighted:

> *Due to the spread of Covid-19, we cannot ask every patient to come in hospital therefore those mothers who have high risks birth and pregnancies may only contact us through social media and telephone when they need caesareans and interventions.*

The findings highlight that the global pandemic has increased the responsibilities of nurses and doctors who are now less able to provide high standard health care services. However, SM platforms provide them with an opportunity to disseminate educational materials about chronic diseases so that emergency visits can be reduced. For example, focus group interviewee 5 noted:

> *Every asthma patient has different level of complications, education, awareness, and knowledge so social media provided me more opportunity to share relevant material with those asthma patients who have low knowledge as they do more emergency visits and increase work overload during global pandemic.*

Discussion

Principal Findings

The findings show that the increased use of SM has helped to enhance both networking and connections among health professionals outside and within public hospitals. Due to the advent and use of SM sites, management in public hospitals can more quickly share the medical histories of critical patients and can ask for advice from experts in other hospitals. SM promotes knowledge and information exchange among health professionals. As a result, they have become more knowledgeable and competent. There is evidence that various global environmental changes and the increasing consumption of petrol have increased the level of air pollution in Saudi Arabia. Therefore, the number of chronic diseases, especially the number of asthma patients, has increased in recent years. Furthermore, the number of patients with type 2 diabetes has increased because of the high use of red meat and junk foods. These chronic patients have lower levels of education and awareness about chronic diseases, including how to avoid them. Health professionals and the Ministry of Health in Saudi Arabia have started to use YouTube and Twitter platforms to educate patients with chronic diseases. This can reduce work overload, emergency visits, and resource utilization. YouTube videos educate patients about medication, healthy diets, the use of inhalers, exercise plans, and methods to inject insulin to control diabetes.

There is a need to further enhance the productive use of SM as it enhances collaboration and socialization among health professionals and patients. For example, when a health professional is linked to patients with type 2 diabetes through SM, a shared video on YouTube can provide fruitful advice about exercise, the use of medication, the use of inhalers, healthy diets, and other ways to control diabetes. For example, if nurses and doctors are engaged through SM, they can manage emergency situations better, especially during public health crises when all patients cannot receive the same level of care and attention from doctors. Therefore, SM use enhances the level of information sharing. It facilitates learning, knowledge exchange, and patient education about healthy lifestyles. Using SM, patient engagement can enhance the experiences and

XSL•FO
RenderX

knowledge of health professionals, which is useful for improving individual and organizational performance. Furthermore, SM helps to educate and activate patients and can therefore reduce the workload of health organizations as patients are able to control critical situations. Within the organizations in question, the increasing use of SM among nurses and doctors is beneficial for multitasking, as health professionals can ask, guide, or instruct others on routine and emergency tasks. Therefore, it can be argued that the use of SM enhances information sharing, knowledge, skills, and time efficiency for health professionals who are now more productive as a result.

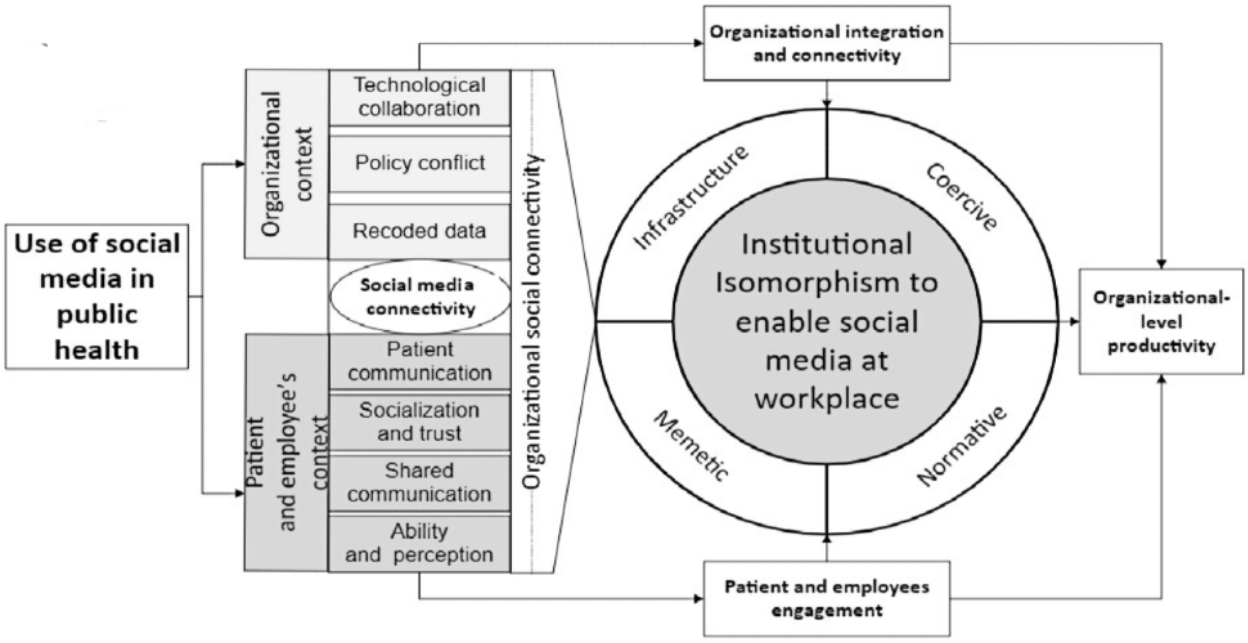
The analysis revealed that Saudi hospitals operate under the control of the Saudi Ministry of Health. Therefore, this ministry can create policies, rules, and regulations that can influence communication, decision making, and the level of productivity of health professionals. It is evident that the use of SM drives collaboration and coordination among health professionals and patients. However, unfortunately, there is no Saudi Health Ministry Policy to positively use these platforms in the workplace. Therefore, when health professionals use these platforms, there is no training or technical, motivational, or organizational support for them. This is counterintuitive, given that SM can save professionals' time, energy, and resources. The findings reveal that the use of SM enhances peer-to-peer support, as newly appointed nurses and young doctors can consult with head nurses and senior doctors through video calls. Their shared knowledge can help them, especially when patients are in emergency situations. However, analysis also suggests that the use of SM has created a culture of quick responses and actions among junior professionals, which ultimately increases the stress and pressure they face to fit more work into limited timeframes. Both nurses and doctors use instant messaging and video calls to increase interpersonal and professional collaboration. As a result, they are able to enhance their level of knowledge, speed of work, and overall organizational productivity. Therefore, it is recommended that the Saudi Ministry of Health and government should specify regulations and policies that can increase the use of SM platforms as evidence-based practices that help health professionals communicate and collaborate to manage critical patients.

A key finding of this study is that the use of SM has promoted the exchange of recorded data and technological collaboration among health professionals. This has improved patient-centric communication, health care services, and the overall level of productivity. For example, diabetes experts can now conduct conference calls with their diabetes patients and advise them on how to clean wounds and stop bleeding in emergency situations. YouTube videos of health experts meant that these patients could self-manage in emergency situations, especially when visiting a hospital is risky. These SM support technological collaboration among different health professionals when it comes to diabetes and asthma health experts (endocrinologists and pulmonologists) who can now arrange video calls to share best practices in terms of medication, diets, and health care plans. This is especially useful for patients with multiple diseases. There is evidence that nurses use SM to share videos to educate first-time parents about infant childcare. Indeed, the data sharing facility provided by SM saves nurses' time so that they can prioritize clinical care and balance it with educating parents and patients.

The use of SM enhances employee engagement by building socialization and trust. It supports shared communication and better patient communication, especially during a global pandemic when health resources are limited, and it is less common for doctors to see patients in person. The findings also reveal that both nurses and doctors engage with instant messaging apps to join appointments. They also use these to share information about promotions, personal educational achievements, parties, and mutual self-help. Therefore, socialization through SM increases social interactions, knowledge exchange, and trust building, and such media can help with emergency situations. Such shared communication is facilitated through SM as doctors and nurses can discuss health care plans and behavioral issues in relation to patients during global pandemics. During global pandemics, both nurses and doctors are unable to provide high standards of health care services because of limited human capital and health resources. However, SM platforms provide them with the opportunity to disseminate educational materials about chronic diseases so that emergency trips to hospitals can be reduced, whereas awareness and self-care can be increased.

Contribution

Previous researchers have applied various models and theories to understand the adoption of technology or SM in the workplace. Examples include the likelihood model [28,29], the technology acceptance model [30-32], the unified theory of acceptance and use of technology 2 [33], the diffusion of innovation theory [34], the social cognitive theory [15], the theory of planned behavior model [35], social exchange theory [3], and social influence theory [25]. However, none of these models have been tested when people are practicing social distancing and are restricted to their homes because of a pandemic. This is the first study to explore how SM practices are developed at the institutional level with the purpose of enhancing technological collaboration among health professionals and patient-centric approaches during the COVID-19 pandemic.



In terms of the first theoretical contribution, this study applied institutional and AMO theories to understand how health professionals experience instant messaging apps. The results could be used to improve professional socialization, trust building, data recording, knowledge exchange, collaboration, health service delivery, and organizational productivity. For example, institutional theory offers knowledge about how to use accessible technology to deal with uncertainty, whereas the ability and motivation of health professionals to use SM provides them with the opportunity to cope with uncertainty during a global pandemic. It empowers them to educate patients and, subsequently, lowers emergency visits.

The second theoretical contribution is the use of institutional theory through the lens of health professionals' motivations and opportunities that are explored in the specific context of Saudi public sector hospitals. For example, institutional theory offers an understanding of professional networking and collaboration, whereas the AMO theory provides an understanding of how

XSL•FO
RenderX

both diabetes and asthma health experts (endocrinologists and pulmonologists) can arrange video calls to share best practices in terms of medication, diet, and health care plans for patients who have multiple diseases and who are vulnerable during a global pandemic. The third and most significant theoretical contribution is that the SMOP model was developed in this study. This model suggests that, even in the absence of institutional policies and in the context of uncertainty, the use of SM platforms at the individual level provides the motivation to develop health professionals and patient interactions with the purpose of creating health care plans during a global pandemic (Figure 3). This model provides an understanding of how to use SM to increase the accessibility of health care professionals at the institutional level. This way, shared communication can be used to manage patients who are at high risk (eg, older and children who live with psychological and behavioral issues).

Figure 3. Social Media Organizational Productivity model.

Practical Implications

This study has provided useful insights regarding how health professionals can make the best use of SM platforms to deal with uncertainty during global pandemics and can reduce the number of emergency visits patients make to hospitals. The second practical contribution is that the use of SM has created a means to record data on how, for example, new parents should care for newborns and how patients with asthma and patients with type 2 diabetes can manage emergency situations. SM can also decrease the workload of professionals during a global pandemic. These data and the technological collaboration between health professionals and patients can reduce the necessity for hospital admissions, and it is useful to ensure the safety of families, communities, and working environments during global pandemics. The third practical contribution is how the use of SM creates an opportunity, regardless of circumstances, to enhance the productive use of SM during a global pandemic. Therefore, it is recommended that the Saudi Ministry of Health and Saudi government should create institutional policies that support the use of SM platforms in public and private hospital settings.

Limitations and Future Directions

Although this study provides unique theoretical and practical contributions, it is not free from limitations. For example, previous studies have highlighted that although qualitative methods can provide rich insights to develop theoretical frameworks, they cannot test the validity of theoretical frameworks [24,25]. Therefore, future studies may test the validity of the SMOP model by collecting data from health professionals in private and public hospitals using statistical methods. Future studies might also test the effectiveness of the SMOP model in different environments and contexts where there are institutional policies and skilled leadership teams that can create more motivation and opportunities to use SM platforms to increase organizational productivity.

Abstract

Background: During the COVID-19 pandemic, health care workers are sharing their challenges, including sleep disturbances, on social media; however, no study has evaluated sleep in predominantly US frontline health care workers during the COVID-19 pandemic.

Objective: The aim of this study was to assess sleep among a sample of predominantly US frontline health care workers during the COVID-19 pandemic using validated measures through a survey distributed on social media.

Methods: A self-selection survey was distributed on Facebook, Twitter, and Instagram for 16 days (August 31 to September 15, 2020), targeting health care workers who were clinically active during the COVID-19 pandemic. Study participants completed the Pittsburgh Sleep Quality Index (PSQI) and Insomnia Severity Index (ISI), and they reported their demographic and career information. Poor sleep quality was defined as a PSQI score ≥5. Moderate-to-severe insomnia was defined as an ISI score >14. The Mini-Z Burnout Survey was used to measure burnout. Multivariate logistic regression tested associations between demographics, career characteristics, and sleep outcomes.

Results: A total of 963 surveys were completed. Participants were predominantly White (894/963, 92.8%), female (707/963, 73.4%), aged 30-49 years (692/963, 71.9%), and physicians (620/963, 64.4%). Mean sleep duration was 6.1 hours (SD 1.2). Nearly 96% (920/963, 95.5%) of participants reported poor sleep (PSQI). One-third (288/963, 30%) reported moderate or severe insomnia. Many participants (554/910, 60.9%) experienced sleep disruptions due to device use or had nightmares at least once per week (420/929, 45.2%). Over 50% (525/932, 56.3%) reported burnout. In multivariable logistic regressions, nonphysician (odds ratio [OR] 2.4, 95% CI 1.7-3.4), caring for patients with COVID-19 (OR 1.8, 95% CI 1.2-2.8), Hispanic ethnicity (OR 2.2, 95% CI 1.4-3.5), female sex (OR 1.6, 95% CI 1.1-2.4), and having a sleep disorder (OR 4.3, 95% CI 2.7-6.9) were associated with increased odds of insomnia. In open-ended comments (n=310), poor sleep was mapped to four categories: children and family, work demands, personal health, and pandemic-related sleep disturbances.

Conclusions: During the COVID-19 pandemic, nearly all the frontline health care workers surveyed on social media reported poor sleep, over one-third reported insomnia, and over half reported burnout. Many also reported sleep disruptions due to device use and nightmares. Sleep interventions for frontline health care workers are urgently needed.

Introduction

Since March 2020, the pandemic of SARS-CoV-2, the virus that causes COVID-19, has impacted people's lives on a global scale, especially the lives of health care workers on the front lines. During the pandemic, health care workers have used social media to share their experiences serving on the front lines, such as lack of personal protective equipment, mental anguish, burnout [1], and the toll of caring for patients with COVID-19. Repeatedly, health care workers have reported concerns that include sleep loss and other sleep disturbances [2]. Although these sleep issues certainly can be attributed to long working hours, they may also occur for other reasons. Social media posts suggest that health care workers are suffering from nightmares, insomnia, and using mobile devices at night to review social media ("doomscrolling") [3,4]. Given the increased professional and personal responsibilities of health care workers during the pandemic, it is possible that sleep loss or disturbances will be compounded by additional worries during the pandemic. Moreover, mounting evidence is demonstrating that inadequate physician sleep is associated with burnout and medical errors [5,6].

Several studies in various countries have described the sleep of health care workers during the COVID-19 pandemic. Most notable are two meta-analyses on sleep in health care workers during the initial months of the COVID-19 pandemic, with studies mostly focusing on the experience of health care workers in China. Pappa et al [7] reviewed 5 cross-sectional studies conducted among Chinese health care workers prior to April 17, 2020, and reported a prevalence of insomnia (38.9%) among them. Salari et al [8] reviewed 7 cross-sectional studies from Asia and the Middle East conducted among nurses and physicians prior to June 24, 2020, and they reported a prevalence of sleep disturbances of 34.8% and 41.6% in nurses and physicians, respectively. Additionally, several other studies reported on sleep loss in health care workers from countries such as Oman [9], Bahrain [10], and Spain [11].

Prior to the COVID-19 pandemic, studies reported that nearly 1 in 2 physicians admitted experiencing symptoms of burnout [12]. In 2004, researchers described the profound impact of perceived sleep loss on trainee well-being [13]. That same year, Lockley et al [14] demonstrated that reduction of intern work hours improved sleep and decreased attention failures. In 2015, the American Thoracic Society published an official statement affirming that good quality and quantity of sleep is imperative for healthy physicians [15].

To date, few studies of the sleep experience among frontline health care workers during the COVID-19 pandemic in the United States have been conducted. These studies did not utilize validated measures of sleep and were limited to a single institution [3,16]. In the United States, to our knowledge, no study has yet evaluated sleep using standardized measures in clinically active frontline health care workers during the COVID-19 pandemic. Despite anecdotal observations of sleep loss described via social media platforms, no study has yet explicitly explored the sleep of frontline health care workers during the COVID-19 pandemic utilizing social media, an increasingly important and influential mode of communication during the pandemic. The aim of this study was to describe the sleep disturbances of a sample of predominantly US frontline health care workers during the COVID-19 pandemic with validated instruments through a survey distributed on social media. A secondary aim of this study was to examine the association between the demographic and career characteristics of health care workers and their reported sleep disturbances and burnout.

Methods

From August 31 to September 15, 2020, we recruited frontline health care workers from across the world to complete the web-based R.E.S.T. (Recommending Essential Sleep Time) survey. The restricted, self-selection survey (respondents chose to participate by clicking on the survey link) was distributed through Twitter, Facebook, and Instagram social media accounts created specifically for the study. A river sampling method was used to recruit participants anonymously [17]. This web-based sampling technique redirected interested participants to the survey link via digital promotion (eg, banners, advertisements, flyers, offers) [17]. A unique bit.ly link was created for the social media accounts to enable tracking of views and clicks. Participation in the study was voluntary, and participants could opt out at any time while responding to the survey questions. Participants included physicians, physician assistants, nurse practitioners, nurses, pharmacists, physical/ occupational/ respiratory therapists, health care trainees, and allied health care workers (eg, medical technologists, therapists, certified nursing assistants). The University of Chicago Institutional Review Board reviewed and approved the protocol.

Survey Design

Study data were collected and managed using Research Electronic Data Capture (REDCap), hosted at the University of Chicago. REDCap is a secure, web-based software platform that supports data capture for research studies [18,19]. Qualifying participants for our study were at least 18 years of age and were frontline health care workers who were clinically active during the COVID-19 pandemic. The survey automatically terminated for respondents who did not meet these inclusion criteria. We asked the participants to frame all their responses for 1 month in the pandemic in which they experienced the greatest clinical intensity and risk of COVID-19 transmission. This time frame was selected as the most representative of the sleep of respondents while they were

XSL•FO
RenderX

clinically active on the front lines caring for patients with COVID-19.

The survey contained the following categories: Sleep, Well-being, Career, and Baseline Demographics. The Sleep section included the Pittsburgh Sleep Quality Index (PSQI) [20] and the Insomnia Severity Index (ISI) [21]. The PSQI is a 19-item validated questionnaire that measures sleep quality over 1 month, generating 1 global score [20]. The ISI is a 7-item validated questionnaire that assesses the nature, severity, and impact of insomnia in adults [21]. The Sleep section also included questions about sleep disturbances due to device use. The Well-being section included the Mini-Z Burnout Survey, an 8-item validated questionnaire that investigates health care burnout and job satisfaction [22]. The Mini-Z also includes a 1-item burnout measure that is validated against the longer Maslach Burnout Inventory [23]. Other questions in this section related to pandemic-related worries, changing responsibilities, living situation, and health status. The Career section collected data on each participant's job role, level of training, specialty, and career setting prior to the pandemic and whether they cared for patients with COVID-19 directly. Baseline demographics were collected on marital status, age, gender, race, ethnicity, type of practice, location of practice, and type of community served (eg, urban, suburban, rural). Two open-ended questions were also included in the survey: "What was the cause of your sleep disruption(s) during your reported month?" and "Is there anything else you would like to share?"

Upon completion of the survey, participants were invited to submit their email address to enter a daily raffle for a US $25 Amazon gift card (14 gift cards in total). Before deployment, the survey was piloted with a few health care workers who were not affiliated with the study. Changes made included deleting duplicate questions and removing one sleep scale to abbreviate the time to complete the survey to 10 minutes or less.

Social Media Distribution Strategy

To disseminate the survey link, we created a Facebook page and a Twitter and Instagram account on behalf of the R.E.S.T. study. This enabled the use of engagement tracking built into these social media platforms to calculate the response rate. To market our survey through Instagram, we used paid advertisements. On Facebook, we posted on health care–specific social media groups (eg, Women Physician Wellness, StyleMD, and the Physician Collective). On Twitter, we tagged colleagues and organizations and employed health care–specific hashtags (eg, #MedTwitter, #NurseTwitter). Although the authors re-shared the R.E.S.T. survey posts on their personal Twitter accounts to increase visibility, the link remained connected to the original posts of the R.E.S.T. accounts to preserve the ability to track engagement. To promote the survey, an infographic was posted each day on the study's social media accounts. Survey links were also placed in the biography of each social media account. To draw attention to the survey post and the account, we linked each post to standard information from national organizations (eg, the American Academy of Sleep Medicine and the Sleep Research Society) and to articles about sleep and the pandemic through the study's social media accounts.

One of our study authors (SRD) used a customized *bit.ly* link [24] to track user engagement daily on Facebook, Twitter, Instagram, and email. The metrics analytics from the social media platforms enabled us to view specific metrics on reach (the total number of individuals who viewed the content) and link clicks (the number of times individuals chose to open the survey). At midnight on each day, we calculated the reach and link clicks of the study on each social media website. This enabled us to compare the performance of each platform and track our progress. We also calculated the number of survey responses per day while the survey was active.

Statistical Analysis

Descriptive statistics were used to quantify the participants' demographics and profession. Primary outcomes were poor sleep quality and moderate to severe insomnia. Poor sleep quality was defined as a PSQI score ≥5 [20]. Moderate-to-severe insomnia was defined as an ISI score of >14.21. The Mini-Z Burnout Survey was used to measure burnout [22]. Multivariate logistic regression was used to test for independent associations between age, gender, race (Black vs non-Black), ethnicity (Hispanic vs non-Hispanic), and profession (physician vs. nonphysician), with odds of each of the outcomes, after controlling for those with a preexisting sleep disorder. All statistical analyses were conducted using Stata Statistical Software, Release 16 (StataCorp LLC), with $P<.05$ used to indicate statistical significance.

Coding Open-ended Comments

There were two open-ended questions in the survey. For participants who responded to one or both questions, open coding of comments was used [25]. Sleep disturbance was mapped to four main themes: (1) children and family; (2) work demands affecting sleep; (3) personal health conditions; and (4) pandemic-related sleep disturbances. Subthemes were created for each of these themes.

Results

Our social media posts were seen by 87,061 unique individuals and resulted in 976 clicks on our survey link. Our final sample contained 963 submitted surveys. The most common ways people discovered the survey were through Twitter (372/944, 39.4%), in a private Facebook group (199/944, 21.1%), and through a colleague (103/944, 10.9%).

Participants were mostly female (707/963, 73.4%), White (894/963, 92.8%), aged 30-49 years (692/963, 71.9%), and physicians (620/963, 64.4%) (Table 1).

[a]Reference group for race: non-Black.

[b]Reference group for ethnicity: non-Hispanic.

Poor sleep quality, defined as a PSQI score ≥5, was identified in 95.5% (920/963) of all health care workers (Table 2). Rates of moderate and severe insomnia were 249/963 (28.5%) and 39/963 (4.5%), respectively (Table 2). Average sleep duration was 6.1 hours per day (SD 1.2) (Table 2).

Many respondents (554/910, 60.9%) reported sleep disruptions due to device use or due to nightmares at least once per week (420/929, 45%). Those with a sleep disorder were more likely to report burnout (52.1% vs 63.2%, χ^2_4=116.4; P<.001). In unadjusted analyses, being Black (31.0% vs 59.4%), having Hispanic ethnicity (27.9% vs 59.6%), being single (44.6% vs 27.1%), and being a non-physician (50.7% vs 23.2%) were significantly associated with risk of moderate-to-severe insomnia. Non-Hispanic ethnicity was the reference group. In

XSL•FO
RenderX

the multivariable logistic regressions, not being a physician (odds ratio [OR] 2.4, 95% CI: 1.7-3.4), caring for patients with COVID-19 (OR 1.8, 95% CI 1.2-2.8), Hispanic ethnicity (OR 2.2, 95% CI 1.4-3.5), and being female (OR 1.6, 95% CI 1.1-2.4) were associated with increased odds of insomnia (Table 3). Having a sleeping disorder also increased the odds of insomnia compared to those without one (OR 4.3, 95% CI 2.7-6.9) (Table 3). With respect to confounders, we did not focus on low socioeconomic status; however, we did evaluate geography, and we noted no major impact on geography.

Table 2. Prevalence of poor sleep and insomnia in health care workers working during the COVID-19 pandemic (N=963).

Variable	Value
Poor sleep quality[a], n (%)	920 (95.5)
Insomnia[b], n (%)	
Absent	220 (25.1)
Subthreshold	367 (41.9)
Moderate	249 (28.5)
Severe	39 (4.5)
Sleep duration (hours)[c], average (SD)	6.1 (1.2)

[a]As measured by the Pittsburgh Sleep Quality Index (PSQI); poor sleep quality was defined as a PSQI score ≥5 [20].

[b]As measured by the Insomnia Severity Index (ISI); insomnia was qualified by ISI score, interpreted as absent (0-7), subthreshold (8-14), moderate (15-21), or severe (22-28) [21].

[c]Average hours of sleep duration was defined by the PSQI [20].

Table 3. Risk factors for insomnia among frontline health care workers during the COVID-19 pandemic (N=963).

Characteristic	Insomnia[a], odds ratio (95% CI)	*P* value
Age group (years)		
18-29	Reference	N/A[b]
30-49	1.1 (0.7-1.8)	.63
≥50	1.3 (0.7-2.4)	.49
Gender		
Male	Reference	N/A
Female	1.6 (1.1-2.4)	.02
Black race	1.5 (0.8-2.7)	.24
Hispanic ethnicity	2.2 (1.4-3.5)	<.001
No significant other	1.3 (0.9-1.9)	.18
Career role		
Physician	Reference	N/A
Nonphysician	2.4 (1.7-3.4)	<.001
Prior sleep disorder	4.3 (2.7-6.9)	<.001
Cared for patients with COVID-19	1.8 (1.2-2.8)	.008

[a]As measured by the Insomnia Sleep Index (ISI); insomnia was defined by ISI scores qualifying as moderate to severe insomnia (>14) [21].

[b]N/A: not applicable.

A total of 310 open-ended comments regarding factors affecting sleep were categorized into the following four themes: (1) children and family; (2) work demands affecting sleep; (3) personal health conditions; and (4) pandemic-related sleep disturbances. The most frequently reported non–pandemic-related theme was children and family (n=59) (“COVID plus home stress plus stress over my kids, my job, my marriage”) (Table 4). Other non–pandemic-related sleep disturbances included work demands affecting sleep (n=48) (“The volume of calls and messages from my patient and caregiver population is through the roof and I’m sleeping 4-5 hours per night”) and personal health (n=41) (“Insomnia predating COVID, but worsened with COVID”) (Table 4). Pandemic-related sleep disturbances (n=48) (“I never had sleep issues prior to the COVID-19 pandemic; suddenly I had issues with sleep initiation”) were also noted (Table 4).

XSL•FO
RenderX

Table 4. Themes, subthemes, and example quotes from the open-ended comments (n=310).

Theme	Subthemes	n (%)	Example quote
Sleep disruptions not due to the pandemic			
Children and family (n=59)	Child care (1-18 years)	27 (46)	"6 year old who wakes 2-3 times per night (some secondary to COVID related anxiety for him), 2.5 year old who wakes about 2-3 nights per week"
	Infant care	18 (31)	"Both COVID and my usual sleep disturbances plus my infant daughter"
	Concerns about family affecting sleep	8 (17)	"COVID plus home stress plus stress over my kids, my job, my marriage"
	Pregnancy affecting sleep	6 (10)	"I was pregnant with twins and carried to term. COVID increased my anxiety and work-related stress. I had to lay off employees and reduce my salary, right before maternity leave."
Work demands affecting sleep (n=48)	Shift work	18 (38)	"Mostly schedule fluctuations each week - late evening shifts followed by early morning shifts"
	Work-life interference	18 (38)	"Extra work at home [charting] due to increased patient volumes"
	Residency training	6 (13)	"Switching schedules with residency (days/nights and 28-hour calls), overall sleep debt, and fatigue"
	Volume of calls/pages	6 (13)	"The volume of calls and messages from my patient and caregiver population is through the roof…sleeping 4-5 hours [per night]."
Personal health conditions (n=41)	Poor sleep prior to the pandemic	18 (44)	"I have never been a great sleeper."
	Chronic medical issue	12 (29)	"Possibly COVID-19 related.... I had an onset of Obsessive-Compulsive Disorder this summer and have been adjusting to antipsychotic medication, intervention, and prescription sleep aids."
	Formal sleep disorder	8 (20)	"Insomnia pre-dating COVID, but [it] worsened with COVID"
	Female hormones	3 (7)	"In vitro fertilization side effects"
Sleep disruptions due to the pandemic			
Pandemic-related sleep disturbances (n=48)	Pandemic affecting sleep	17 (35)	"I never had sleep issues prior to the COVID-19 pandemic. Suddenly I had issues with sleep initiation."
	Nightmares about the pandemic	8 (17)	"The only thing that has changed with my sleep is an increase in nightmares and night terrors primarily regarding work situations."
	Pandemic-related exhaustion	8 (17)	"In the last 1-2 months, I am EXHAUSTED and fall asleep easily, often on the couch right after dinner."
	Medication/substance use to cope with the pandemic	7 (15)	"Alcohol plays a role in my sleep deprivation and 'coping' during COVID."
	Worry about pandemic response	4 (8)	"I worry about how COVID is being managed by the President of the United States and I don't believe he is doing a good job; I worry things will get even worse if he is elected to a second term. This does keep me awake at night."

Discussion

Principal Findings

To our knowledge, this is the first study to evaluate self-reported sleep disturbances among a sample of predominantly US frontline health care workers during the COVID-19 pandemic with validated instruments using a survey distributed on social media. Our study demonstrates that nearly all (96%) of the surveyed health care workers reported poor sleep, over 30% reported moderate to severe insomnia, and over 50% reported burnout. A majority of respondents also reported sleep disruptions due to personal technology device use (eg, cell phone, iPad) or nightmares at least once per week. Additionally, survey participants reported a mean sleep duration of 6.1 hours per day, which is less than the recommended 7 hours of sleep for US adults [26]. Our study demonstrated that health care workers at highest risk of insomnia included those who were not physicians, were not male, were Hispanic, and directly cared for patients with COVID-19. We also demonstrate that sleep disturbances in health care workers during the pandemic are related not only to work demands and personal health but also to children and family as well as to the pandemic itself, including worry about the response to the COVID-19 pandemic. Given the strong association between sleep and burnout among health professionals, it is not surprising that a high number of the surveyed health care workers reported burnout [5].

XSL•FO
RenderX

The results of this study are consistent with prior studies demonstrating a high prevalence of insomnia in nurses and physicians caring for patients with COVID-19 on the front lines [8]. In a systematic review and meta-analysis, Salari et al [8] reported on the increase of insomnia in frontline nurses near 35% and in frontline physicians near 42%, however they did not report on a subgroup analysis of insomnia in women. In the meta-analysis by Pappa et al [7], the prevalence of insomnia in health care workers during the COVID-19 pandemic was near 40%, and the authors did not specifically report the prevalence of insomnia in women frontline health care workers. Our data are also in accord with those in a study by Trockel et al [5], who demonstrated that sleep-related impairment is an occupational hazard associated with increased medical-related errors and burnout. In comparing our sample to the general US physician population, we found higher rates of sleep disturbances and insomnia risk than in the general population of practicing physicians [12,27,28]. Our study findings of sleep disruption due to device use are consistent with findings demonstrating increased nightly screen time in health care workers and reports of doomscrolling [3,4].

Our findings have many clinical implications. Frontline health care workers involved in the direct care of patients with COVID-19 report decreased sleep time, increased insomnia, nightmares, fears for their safety, increased clinical workload, and concerns for their family, which reportedly impact their sleep. Health care workers are at high risk for the development of psychological distress and medical errors [5,29]. The professional environment for health care workers has drastically changed during the pandemic, which has brought challenges related to increased workload, reduced protective equipment and resources, rapidly evolving protocols, relocation of intensive care settings, fear of viral transmission, and social isolation from supportive networks [30,31]. Given this unfolding environment, the findings of sleep disturbances of frontline health care workers are not surprising.

The study findings are particularly concerning given the natural course of insomnia and potential for long-term psychological impact, as seen in health care workers during prior severe acute respiratory syndrome (SARS) outbreaks [32-34]. In a recently reported longitudinal study on insomnia, nearly half (42%) of patients who had insomnia initially (as measured by the ISI) also had insomnia 5 years later, demonstrating a persistent course [35]. Likewise, studies on the mental health of health care workers who were active during the 2003 SARS epidemic suggest the psychological consequences may persist months to years after the epidemic ends [34]. While noting long-term impacts of mental health, it is also important to consider the implication of potential medical errors due to sleep loss by these health care workers [6]. Studies of sleep disorders in health care workers during prior infectious outbreaks are in concert with our study findings, and they forecast the potential longitudinal psychological impact on the sleep health of our frontline health care colleagues.

Limitations

Although social media platforms are widely used, a limitation of this study may be that a sample recruited through social media platforms may not be representative of health care workers in the US and around the world. To combat time period bias, we asked participants to complete the survey while thinking of the month in which they were most clinically active in caring for patients with COVID-19. Although this approach may lead to biased results, we felt it would provide results that were most representative of the respondents' experiences while they were serving on the front lines during the COVID-19 pandemic. Due to the nature of a worldwide pandemic, the incidence of COVID-19 is distributed differently across geographic areas; therefore, the time frame of reflection may differ between respondents. Because the focus of our survey was on sleep, it is possible that health care workers who were more likely to experience sleep disturbances completed the survey. Given the prevalence of sleep disorders in the general US population of 8%-19% [36,37], our sample does not appear to overrepresent people with sleep disorders. Our sample did not contain a sufficient number of nonphysician health care workers to characterize the sleep quality of nonphysician workers (eg, physician assistants, nurse practitioners, nurses, pharmacists, allied health workers) during the COVID-19 pandemic. We also asked the participants to complete the survey questions by reflecting on a time when they experienced the greatest clinical intensity and risk of COVID-19 transmission; this may have led to inconsistencies in our data. All data were self-reported, and we do not have objective measures of sleep duration and quality in this sample. We also do not have longitudinal data on our sample, limiting our ability to draw longitudinal conclusions. Furthermore, when using data obtained from social media, it is difficult to capture the accurate outreach and link clicks; for example, if an individual shares the link but not our original post, we cannot calculate the outreach and metrics. Therefore, the actual metrics may be higher than we were capable of measuring.

Prior to the pandemic, sleep and burnout issues existed among health care workers; however, strategies to improve and implement change are lagging behind. The reporting of these issues by frontline health care workers caring for patients with COVID-19 during the pandemic is not surprising. Studies demonstrating successful interventions to impact sleep and burnout are increasing, and they recommend interventions focused both at the individual and the organizational level. Examples of these recommendations include reducing work hours while maintaining the same salary, allowing schedule flexibility, behavioral wellness, and curricular interventions [38-41].

Conclusion

During the COVID-19 pandemic, almost all the health care workers we surveyed on social media reported poor sleep, with nearly half of respondents reporting moderate to severe insomnia and over half reporting burnout. Immediate interventions to improve the sleep and well-being of health care workers, discourage nocturnal social media use, and discourage doomscrolling are needed to strengthen the ability of these workers to continuously meet the daily demands of the COVID-19 pandemic. Concerns regarding clinician well-being are not new. Moreover, health systems and national organizations are placing greater emphasis on systemic change

XSL•FO
RenderX

[38]. Practical frameworks for creating wellness exist; however, senior-level champions are critical for implementation [42]. Considering that sleep is a modifiable factor of our physical and mental health, prioritizing it may help mitigate the health risks associated with the pandemic and its potential longitudinal impacts on sleep and health.

Abstract

Background: The wide adoption of social media in daily life renders it a rich and effective resource for conducting near real-time assessments of consumers' perceptions of health services. However, its use in these assessments can be challenging because of the vast amount of data and the diversity of content in social media chatter.

Objective: This study aims to develop and evaluate an automatic system involving natural language processing and machine learning to automatically characterize user-posted Twitter data about health services using Medicaid, the single largest source of health coverage in the United States, as an example.

Methods: We collected data from Twitter in two ways: via the public streaming application programming interface using Medicaid-related keywords (Corpus 1) and by using the website's search option for tweets mentioning agency-specific handles (Corpus 2). We manually labeled a sample of tweets in 5 predetermined categories or *other* and artificially increased the number of training posts from specific low-frequency categories. Using the manually labeled data, we trained and evaluated several supervised learning algorithms, including support vector machine, random forest (RF), naïve Bayes, shallow neural network (NN), k-nearest neighbor, bidirectional long short-term memory, and bidirectional encoder representations from transformers (BERT). We then applied the best-performing classifier to the collected tweets for postclassification analyses to assess the utility of our methods.

Results: We manually annotated 11,379 tweets (Corpus 1: 9179; Corpus 2: 2200) and used 7930 (69.7%) for training, 1449 (12.7%) for validation, and 2000 (17.6%) for testing. A classifier based on BERT obtained the highest accuracies (81.7%, Corpus 1; 80.7%, Corpus 2) and F_1 scores on consumer feedback (0.58, Corpus 1; 0.90, Corpus 2), outperforming the second best classifiers in terms of accuracy (74.6%, RF on Corpus 1; 69.4%, RF on Corpus 2) and F_1 score on consumer feedback (0.44, NN on Corpus 1; 0.82, RF on Corpus 2). Postclassification analyses revealed differing intercorpora distributions of tweet categories, with political (400778/628411, 63.78%) and consumer feedback (15073/27337, 55.14%) tweets being the most frequent for Corpus 1 and Corpus 2, respectively.

Conclusions: The broad and variable content of Medicaid-related tweets necessitates automatic categorization to identify topic-relevant posts. Our proposed system presents a feasible solution for automatic categorization and can be deployed and generalized for health service programs other than Medicaid. Annotated data and methods are available for future studies.

natural language processing; machine learning; Twitter; infodemiology; infoveillance; Twitter; social media; Medicaid; consumer feedback

Introduction

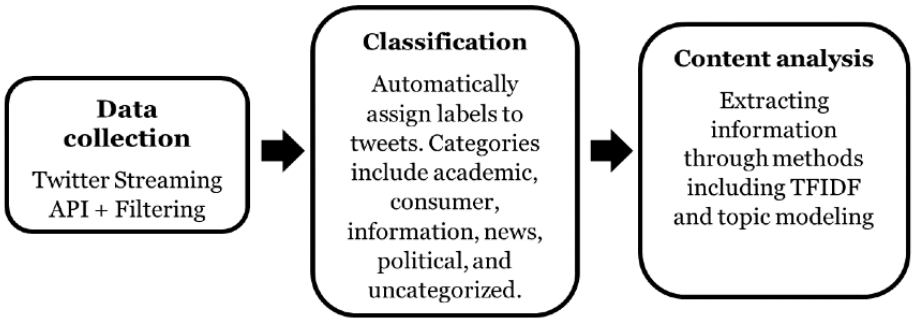
Consumers' perspectives and feedback are crucial for improving products or services. Over the last two decades, widespread adoption and use of the internet has led to its use as a major platform for collecting targeted consumer feedback. Businesses often allow consumers to rate specific products and services and provide detailed comments or reviews, and this has become a key feature of e-commerce platforms. For example, consumer-generated reviews and ratings of products play an important role in the differentiation on Amazon's e-commerce site, which currently has a global presence [1,2]. There are also companies, such as Yelp, that focus specifically on crowdsourcing consumer feedback [3-6]. Similarly, as social media has become the primary platform of communication for many people, many companies have started maintaining and communicating via social media accounts, often enabling direct communications, both private and public, with consumers. Not only do consumers provide comments or seek assistance through these social media accounts, they also often engage in discussions about products or services within their own social networks. Consequently, such consumer-generated chatter is often used to assess perceptions about specific topics, which may range from products or services to social programs, legislation, and politics.

Social media is a rich resource for obtaining perspectives on public health, as it enables the collection of large amounts of data directly and in real time. It is commonly used for sentiment analysis—a field of study that analyzes opinions, sentiments, attitudes, and emotions from written language. Sentiment analysis research involving social media data has covered a wide range of topics, events, individuals, issues, services, products, and organizations [7,8]. However, the use of social media has not been limited to sentiment analysis in open domains. In recent years, research within the broader medical domain has embraced social media, and it is currently being used for conducting real-time public health surveillance, including for topics such as influenza surveillance, pharmacovigilance, and toxicovigilance [9-11]. Meanwhile, similar to corporate businesses in the United States, health service providers such as local health departments and hospitals have also started adopting social media specifically as a consumer-facing communication channel [12,13]. Prior studies in this area have investigated how social media data linked to such health services accounts reflect the consumers' perspectives about them. The simplest studies have focused on using structured or numeric information, such as likes or ratings, associated with the accounts belonging to hospitals or nursing homes, and these metrics have been compared with traditional quality reports and ratings [14-16]. Building on the advances in open-domain natural language processing (NLP), some studies within the broader health domain have attempted to use unstructured data, including postings related to patients' experiences about hospitals, to infer consumer sentiments [17,18] or extract topics that summarize content [19].

Extracting knowledge from social media data is notoriously difficult for NLP methods because of factors such as the presence of misspellings, colloquial expressions, lack of context, and noise. These problems are exacerbated for health-related data because of the complexities of domain-specific terminologies, the lack of expert knowledge among common social media users, and the uniqueness of health-related topics. Consequently, there is considerably less research using the free-text data on social media for health-related tasks. Past studies closely related to ours have focused on analyzing sentiments toward attributes of health insurance plans [20] and social media users' responses to public announcements about health policies [21]. However, to the best of our knowledge, there has been no near real-time automatic system that provides comprehensive data collection and analysis on social media chatter about health services and insurance coverage provided by large public insurers such as Medicaid and Medicare.

Nevertheless, such a system is essential for analyzing the public's perspective toward public insurers and their governance and policies from social media. For example, the customers using Medicaid might provide their feedback based on their experiences or even engage in discussion of their experiences, which they might not have a chance or even willing to reveal to the Medicaid providers' customer service representatives. Analyzing such chatter could provide researchers and policy makers with information complementary to traditional customer feedback channels and possibly help improve the services and related policies. However, chatter associated with an entity such as Medicaid contains discussions about politics and legislation; academic research, statistics, and factual information; consumer feedback; and so on. Chatter related to politics can be very different in terms of content, compared with chatter related to consumer feedback. Thus, properly categorizing these tweets based on content is crucial for providing accurate information. Furthermore, sentiment may also have different meanings for these 2 broad categories of chatter—negative sentiment in political chatter may represent a user's emotions associated with a political decision about the health service (eg, changes in policies related to insurance coverage or covered benefits within Medicare or Medicaid) rather than the service itself.

Therefore, there is a need to identify and categorize the content of the chatter before it can be used for targeted analyses. A good categorization scheme can not only help in bringing forth good analysis but can also help to avoid contaminating the chatter with irrelevant content. To achieve this and effectively use social media big data, automatic classification and analysis systems based on machine learning methods are required. This, together with the promise of social media data and the lack of past research in this specialized area, served as the primary motivation for this study. We chose Medicaid as our target health service because it is the single largest public insurance



XSL•FO
RenderX

program in the country [22] and contains large volumes of related chatter on social media.

The specific objectives of this paper are as follows:

- To assess if a social media platform, specifically Twitter, contains sufficient volumes of chatter about health services so that it can be used to conduct large-scale analyses, using Medicaid as our target service
- To develop and discuss a data-centric system involving NLP and machine learning to automatically collect, categorize, and analyze Twitter chatter associated with Medicaid, as shown in Figure 1
- To describe the manual annotation of a Twitter-Medicaid data set and its composition
- To describe supervised classification strategies for automatically classifying Medicaid-related tweets into broad categories and evaluating the performances of several machine learning models, with particular emphasis on tweets that potentially represent consumer feedback
- To conduct postclassification content analyses to verify the potential utility of our data-centric system

Figure 1. Workflow of the natural language processing system for automatic data collection, classification, and content analysis of the Medicaid chatter on Twitter. API: application programming interface; TFIDF: term frequency-inverse document frequency.

The main contributions of this paper are as follows:

- We present the methods and results of collecting Medicaid-related Twitter data, analyzing a sample of the data manually, and developing an annotation guideline suitable for preparing a large data set for training classification algorithms.
- We present details of automatic supervised classification experiments, including methods, results, and evaluations, and provide suggestions on how to further improve the performance.
- We discuss the postclassification analyses of the collected data, including data distribution and content analyses.
- We make the NLP and machine learning scripts in this study publicly available, along with the labeled training data set and a larger set of unlabeled Medicaid-related data.

Methods

Data Collection

To develop our models for analyses of Twitter data related to Medicaid, we collected 2 sets of publicly available data from the network, which we labeled Corpus 1 and Corpus 2. Corpus 1 contains tweets mentioning the term "Medicaid," or Medicaid agency (MA) and managed care organization (MCO, an organization that provides Medicaid-related health services under contracts from the agency) names that are branded and thus easily distinguishable on Twitter (eg, *Medi-cal*: California's Medicaid program, and *TennCare*, Tennessee's Medicaid program). These tweets were collected via Twitter's public streaming application programming interface from May 1, 2018, to October 31, 2019, and were limited to only English tweets. It has been reported that misspellings appear frequently on social media platforms [23], particularly Twitter; hence, we used an automatic spelling variant generator to generate common misspellings for "medicaid" and used them to capture tweets referring "medicaid" as one of the misspellings [24]. This can increase the retrieval rate and increase the volume of streaming data. The full list of keywords, including misspellings, is shown in Table S1 in Multimedia Appendix 1. We then identified and removed tweets whose contents were not directly related to Medicaid and tweets with repeated or duplicated contents (eg, fundraising or political campaigns). To focus on tweets expressing personal opinions, we removed retweets, which were deemed as duplicates of the original tweets. The final data set consisted of 628,411 tweets for Corpus 1.

Although most of the chatter regarding Medicaid posted by consumers only included the term "medicaid" (or its variants), some directly tagged or mentioned relevant Twitter handles associated with MAs or the MCOs (eg, "@organization_name"). Corpus 2 is composed of such tweets, and the MA and MCO Twitter handles were identified in a previous study [25]. The full list of the handles used in data collection is presented in Table S2 in Multimedia Appendix 1. These tweets were retrieved by targeted searching (eg, "to:organization_name") on Twitter. These tweets were posted between December 12, 2008, and the time of search (January 9, 2020). We filtered the tweets using the same approaches used for Corpus 1. Overall, there were 27,337 tweets in the corpus. Additional notes regarding our data are provided in Multimedia Appendix 1.

Tweet Contents and Manual Annotations

To better understand the contents of the tweets posted by users and to develop methods to automatically characterize the posts, we first performed manual inspections of the contents of the posts and identified commonly occurring themes. We used the grounded theory approach to conduct a thorough analysis [26]. We analyzed a random sample of tweets to identify recurring topics and then grouped the topics into broader categories and themes. The analysis was conducted by multiple authors of this

XSL•FO
RenderX

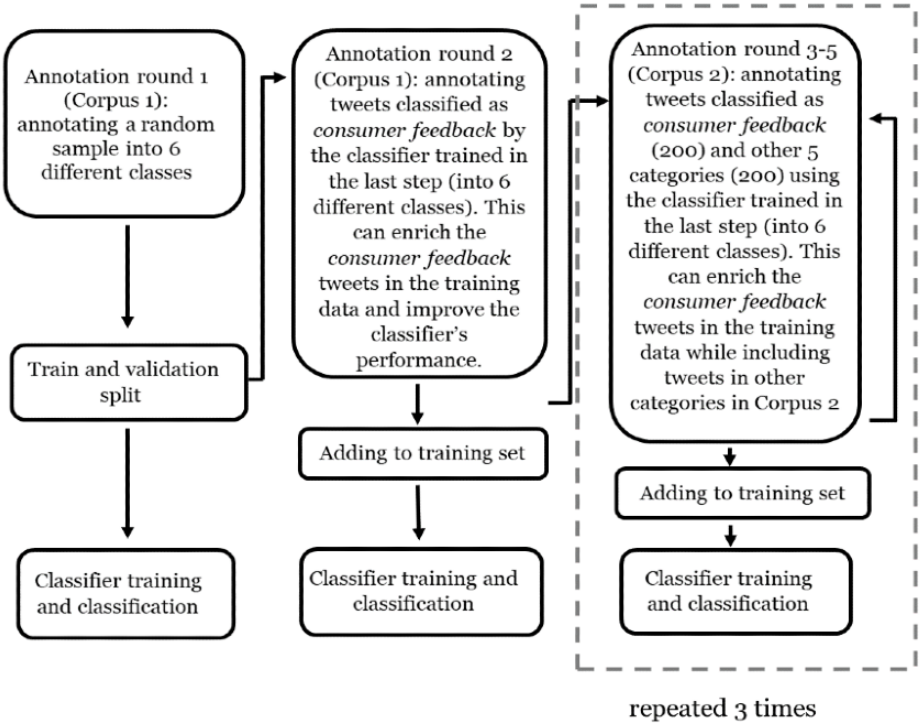
paper, and the topics discovered initially were discussed. The discovered topics were either merged into broader themes (eg, combining *information* and *outreach*), discarded from our consideration (eg, for topics that were observed rarely or only once), or split into multiple themes (eg, splitting of *information* tweets into *academic*, *information*/*outreach*, and *news*). Following iterative discussions and finalization by the domain expert authors of this paper (JMZ and DG), we classified tweet contents into 5 broad categories: (1) academic, (2) consumer feedback, (3) information/outreach, (4) news, and (5) political opinion/advocacy. Tweets that could not be categorized as any of these were labeled as *other*. The descriptions of these classes are as follows:

- *Academic* (*academic*)—tweets related to research on Medicaid. These included tweets by persons or organizations with academic affiliations or think tanks that expressed the perspective from the affiliated organizations or any tweet relating to education, scholarship, and thought, including (links to) journal publications and reports.
- *Consumer feedback* (*consumer*): These included tweets related to consumers' experiences or questions related to Medicaid services, coverage, benefits, or health issues. The tweets were typically from Medicaid consumers or family members of consumers and also included discussions with others.
- *Information/outreach* (*information*): These included tweets directed at consumers and beneficiaries of Medicaid to convey information including agency services, programs, events, enrollment, eligibility criteria, etc. Tweets containing information about general health or public health reminders were also included.
- *News* (*news*): These included news and announcements, including any tweets from a news agency or organization. Tweets that explicitly expressed political opinions and tweets from Medicaid agencies or plans were excluded.
- *Political opinion/advocacy* (*political*): These included comments, personal opinions, and feedback about politics related to Medicaid.
- *Other* (*other*): These included tweets that were not relevant, typically the noise that is not captured by the initial screening.

Following the establishment of the desired categories and the development of annotation guidelines by JMZ, 2 trained annotators performed the first round of annotations (for the data in Corpus 1) in multiple iterations, developed annotation guidelines, and resolved ambiguities via discussions. Following the completion of this round of annotations, the annotation disagreements were resolved by AS and WH. We found the class distribution to be very imbalanced, with most of the tweets annotated as *news*, *political*, and *other*, whereas only a small portion were in *academic*, *consumer*, and *information* categories (Table 1). Examples of each category are provided in Table S3 in Multimedia Appendix 1. To understand how this imbalanced distribution affected the classifier performances on the smaller classes, particularly the consumer class, we performed preliminary automatic classification experiments using 3 classifiers: naïve Bayes (NB), support vector machine (SVM), and random forest (RF). We split the data into training (5795/7244, 80%) and validation (1449/7244, 20%) sets and found the best performance on consumer feedback to be low for all the classifiers, with the best F_1 score=0.3 (SVM). Tweets belonging to the consumer feedback class were of particular importance to our overarching project objectives, so we devised 2 strategies for improving performance for this class: the first involved additional annotations of targeted tweets from the same data set and the second focused on collecting an additional data set (Corpus 2, as described earlier).

Table 1. Distribution (counts and percentages) of annotated data in the first round of annotations (rows 2 and 3) and the final data sets (Corpus 1 for rows 4 and 6; Corpus 2 for rows 5 and 7).

Data set	Academic, n (%)	Consumer, n (%)	Information, n (%)	News, n (%)	Political, n (%)	Other, n (%)	Total, n (%)
Training set (first round)	61 (1.05)	158 (2.73)	198 (3.42)	1288 (22.23)	3613 (62.34)	477 (8.23)	5795 (100)
Validation set (first round)	35 (2.42)	37 (2.55)	49 (3.38)	317 (21.88)	897 (61.90)	114 (7.86)	1449 (100)
Training set (Corpus 1)	83 (1.23)	355 (5.27)	429 (6.37)	1299 (19.30)	3710 (55.13)	854 (12.69)	6730 (100)
Training set (Corpus 2)	9 (0.75)	709 (59.08)	94 (7.83)	40 (3.33)	10 (0.83)	338 (28.17)	1200 (100)
Test set (Corpus 1)	20 (2)	46 (4.60)	49 (4.90)	199 (19.90)	603 (60.30)	83 (8.30)	1000 (100)
Test set (Corpus 2)	6 (0.60)	579 (57.90)	80 (8.00)	21 (2.10)	6 (0.60)	308 (30.80)	1000 (100)
Total	153 (1.34)	1726 (15.17)	701 (6.16)	1876 (16.49)	5226 (45.93)	1697 (14.91)	11,379 (100)



For the first strategy, we conducted another round of annotation of tweets from Corpus 1 to increase the number of tweets for the consumer class. Owing to the very low number of consumer class tweets in the original data set, we realized that it would not be feasible to annotate sufficient numbers of these tweets by drawing random samples because of budgetary and other constraints. Therefore, rather than randomly drawing tweets for the next round of annotations, which would again lead to finding a small number of tweets belonging to the consumer feedback category, we attempted to artificially increase the number of tweets for this category. We achieved this by running our above-described weak classifier on a larger set of unlabeled tweets and only picking tweets classified as consumer feedback by the SVM classifier. This significantly increased the number of consumer feedback tweets in the data to be annotated. The

XSL•FO
RenderX

new set of annotated data was then added to the training set, and the data distribution is presented in Table 1.

We followed the same annotation strategy for Corpus 2 (ie, annotating tweets classified as consumer feedback by the classifier trained on the previously annotated data), but this time, we also annotated equal amount of nonconsumer tweets. This is because Corpus 2 is rich in consumer feedback tweets, and we would also like to include tweets in other categories to improve performance. An outline of the overall annotation process is presented in Figure 2. Although we tried to decrease the class imbalance in the training sets of the 2 corpora, to ensure that our evaluations represented the classifier performances on real-world distributions of the data, we did not artificially balance the validation set. We also annotated the test set randomly generated from the 2 corpora, 1000 tweets each, so they would reflect the data composition of the original corpora, allowing us to evaluate how the classifier would perform when deployed for streaming data.

Figure 2. Flowchart for the entire annotation process (for the training and validation set) involving multiple rounds.

Classification

We experimented with 5 traditional classification algorithms, including Gaussian NB [27,28], SVM [29,30], RF [31], k-nearest neighbor (KNN) [28], and shallow neural network (NN), and 2 advanced classification algorithms, bidirectional long short-term memory (BLSTM) [32,33] and bidirectional encoder representations from transformers (BERT) [34,35]. Although the origin and distributions of tweets in the 2 corpora were different, we decided to combine them as our previous research suggests that multicorpus training, or distant supervision, leads to performance improvements for social media text classification [36]. The feature extraction and classification training for traditional classifiers was done using the "Scikit-learn" package in Python [37], the BLSTM classification was implemented using package "Keras" in Python [38], and the BERT classification approach was implemented using package "simpletransformers," which is based on the package "transformers" [39]. The performance on the validation set and the test set from Corpus 1 and Corpus 2 are shown in Table 2.

XSL•FO
RenderX

Table 2. Classification performances of the classifiers on the test sets of Corpus 1 and Corpus 2.

Data set and classification algorithm	F_1 score (0.XX)[a]						Percentage accuracy (95% CI)
	Academic	Consumer (95% CI)	Information	News	Political	Other	
Validation set							
NB[b]	11	17 (11-24)	24	55	70	34	55.0 (52.4-57.6)

Test set (Corpus 2)							
NB	0	72 (69-75)	30	11	3	21	47.3 (44.2-50.3)
SVM	0	76 (73-78)	2	21	7	18	56.4 (53.3-59.4)
RF	0	*82 (80-84)*	7	16	11	66	69.4 (66.6-72.3)
KNN	0	38 (33-42)	0	7	0	50	42.2 (39.1-45.3)
NN	0	79 (76-82)	40	24	5	66	66.0 (63.0-69.0)
BLSTM	0	81 (79-84)	34	21	4	55	67.3 (64.4-70.2)
BERT	50	*90 (89-92)*	49	37	21	79	*80.7 (78.2-83.1)*

[a]The number represents the first two decimal points. For example, the F1 score for SVM on Consumer is 0.53 with 95% CI 0.38-0.66.

[b]NB: naïve Bayes.

[c]SVM: support vector machine.

[d]The best scores are highlighted in italics.

[e]RF: random forest.

[f]KNN: k-nearest neighbor.

[g]NN: shallow neural network.

[h]BLSTM: bidirectional long short-term memory.

[i]BERT: bidirectional encoder representations from transformers.

The tweets were preprocessed by lowercasing and anonymizing the URLs and user names. For the traditional classifiers, the non-English characters were further removed (keeping underline), and each word was stemmed by the Porter stemmer. The features were the unnormalized counts of the 3000 most frequent n-grams (contiguous sequences of words with n ranging from 1 to 3, with 1380 unigrams, 1296 bigrams, and 324 trigrams). We also introduced a "word cluster" feature, which are clusters or generalized representations of semantically similar words or phrases learned from Twitter chatter [10,40]. The word clusters were represented as bag-of-word vectors, and the feature space consisted of 972 word clusters. We used the Twitter word clusters, "50mpaths2," provided by Owoputi et al [41]. For the advanced classifiers, each word or character sequence was replaced with a dense vector, and the vectors were then fed into the relevant algorithms for training.

We performed hyperparameter tuning using the validation set to improve the classification task on the imbalanced data set. Specifically, we focused on improving the F_1 score for consumer

XSL•FO
RenderX

feedback. For traditional classifiers, we optimized the number of nearest neighbors for KNN, the number of estimators (trees) for RF, and the c parameter and weights for SVM. We also experimented with oversampling using the synthetic minority oversampling technique, but the performance was not improved (provided in Table S4 in Multimedia Appendix 1). The optimal hyperparameters for the traditional classifiers are listed in Table S5 in Multimedia Appendix 1. We used the Twitter GloVe word embeddings for the BLSTM [42] classifier, where each word was converted to a 200-dimensional vector. BLSTM was then trained with 40 epochs and dropout regularization, and the best model was selected based on the accuracy of the validation data. We chose RoBERTa-large for the BERT algorithms [35], trained with 3 epochs. The technical details are provided in Table S5 in Multimedia Appendix 1.

Postclassification Analyses

To assess the utility of our classification approaches and gain an understanding of the data, we used the best-performing classifier (the classifier based on BERT) to label all collected unlabeled data and compute the data distribution. We then performed content analysis using the term frequency-inverse document frequency (TFIDF) method [43], focusing on the tweets in Corpus 1 that contained the term “medicaid” and its misspellings, and using the latent Dirichlet allocation (LDA) for topic modeling [44], focusing on consumer feedback tweets. Our first intent was to qualitatively assess whether the classifier was capable of distinguishing tweets based on contents that were manually verifiable. Second, we wanted to obtain a basic understanding of the content of each category by identifying the top rated TFIDF words. The TFIDF method adjusts the term frequencies with inverse document frequency so that the high-frequency terms unique in one category would rank higher than the high-frequency words that are common across the categories. This helps identify important terms unique to the target category. Our third objective was to summarize consumer feedback chatter using LDA topic modeling, going beyond the TFIDF method. For all content analyses, the text was first preprocessed by lowercasing and removing URLs, user names, non-English characters (keeping underline and hyphen), stopwords, and any word with less than 4 characters. For LDA topic modeling, we experimented with different hyperparameters (number of topics=5, 10, 20, 50, and 100) and selected the model with the highest coherence score.

Results

Annotation and Class Distributions in Test Sets

We annotated a total of 9179 tweets from Corpus 1 and 2200 tweets from Corpus 2. We obtained substantial interannotator agreement (Cohen κ=0.734) [45,46] over 892 double-annotated tweets. The test data sets were randomly selected from the corpora, and therefore, they can be considered a sample of the collected data. For Corpus 1, the test data contained 1000 tweets, among which political discussion was the dominant class (603/1000, 60.30%), followed by news (199/1000, 19.90%), whereas consumer feedback comprised 4.60% (46/1000) of the tweets. In contrast, consumer feedback comprised 57.90% (579/1000) of the tweets in Corpus 2, and 30.80% (308/1000) of the tweets could not be categorized, most of which were part of conversations and could not be understood without full context.

Classification Results

The F_1 scores for each class and the accuracies of the classifiers on the validation set and the test sets are presented in Table 2, including CIs estimated using bootstrapping, whereas the precisions and recalls are given in Table S6 of Multimedia Appendix 1. For the validation and test sets from Corpus 1, the classifiers showed high performance for political discussion, but relatively low performance for consumer feedback. This was expected based on the large imbalance described earlier. Among all the traditional classifiers tested, SVM performed the best on the validation set, with an F_1 score of 0.53 on the consumer feedback. However, the F_1 score on the consumer feedback on the test set from Corpus 1 was only 0.38. In contrast, we found that the BERT classifier had the highest F_1 scores on consumer feedback for both the validation set (0.61) and the test set from Corpus 1 (0.58).

For the test set from Corpus 2, most of the classifiers performed well on the consumer feedback. Among the traditional classifiers, RF performed the best, with an F_1 score of 0.82 on consumer feedback. On the other hand, BERT still performed the best, with a consumer feedback F_1 score of 0.90.

As the BERT classifier performed the best in terms of accuracy and the consumer feedback F_1 score on the validation set and the 2 test sets, we used the BERT classification for postclassification analysis.

Error Analysis

We conducted a brief analysis of the errors made by the BERT-based classifier. We first calculated the confusion matrix for both test sets (Table 3). In Table 4, we provide examples of the most frequent classification errors, omitting unnecessary details. For Corpus 1, we highlighted that the classifier frequently misclassified political tweets as news or consumer feedback, and vice versa. This is not surprising because users sometimes commented on and discussed politics with personal experience, and some news content was related to opinions about the policy. We also highlighted that the uncategorized tweets, whose content is often not directly related to Medicaid or lack of information, are frequently misclassified as consumer feedback or political. The confusion between consumer feedback and political or uncategorized tweets, along with the low volume of consumer feedback, contributes to the low performance of consumer feedback. We also observed that some news tweets were confused with the information tweets because information is frequently spreading as news or blog articles.

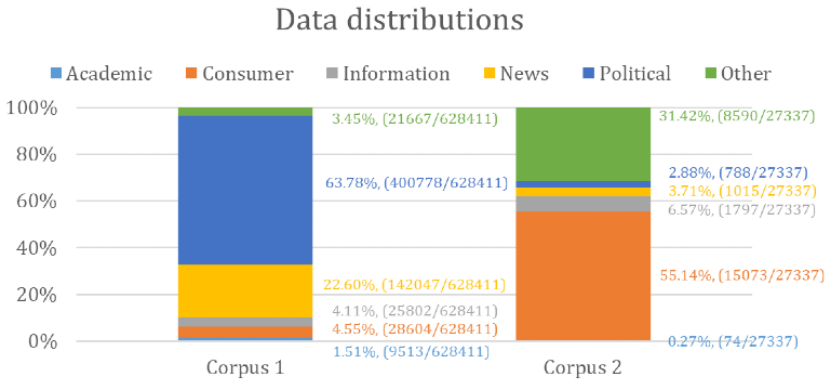
Table 3. The BERT classifier's confusion matrix on the test set

Data set and true value	Predicted value					
	Academic	Consumer	Information	News	Political	Other
Test set (Corpus 1)						
Academic	13	0	1	4	2	0
Consumer	0	26	0	0	18	2
Information	0	0	27	9	10	3
News	1	0	9	169	17	3
Political	2	5	3	39	549	5
Other	0	12	4	4	30	33
Test set (Corpus 2)						
Academic	3	0	0	1	2	0
Consumer	1	512	1	2	26	37
Information	1	5	33	15	1	25
News	0	0	5	11	3	2
Political	0	0	0	1	5	0
Other	1	36	15	7	6	243

Table 4. Examples of misclassified tweets by the BERT classifier on Corpus 1 and Corpus 2.

Data set, Tweets	True class (prediction)	Comments
Test set (Corpus 1)		
I need this government shutdown to end because no one is going to call me to set up my Medicaid while it's shutdown	Political (consumer)	Discussion about politics with personal experience
"This is just cruelty and exclusion": Amid Trump's attack on poor, one million fewer kids receiving Medicaid and CHIP–Raw Story <URL>	Political (news)	Opinion on Medicaid policy presented as a news title
<USERNAME> So do I! But I totally understand why some people really hate it. And yes... lack of Medicaid providers is a problem everywhere (I do accept it, but only have a mobile practice). Maybe contact your local health department and ask!	Consumer (political)	Customer's discussion about Medicaid services. It may have been misclassified because of similarity to political discussion regarding Medicaid
Thanks to <USERNAME> for this story about the bill ... Ohio leaving some military families with special needs children waiting for answers <URL>	News (political)	News about Medicaid policy reformation bill
States that been successful in lowering substance use disorder rates have increased access to medicaid & private insurance, and to MAT and naloxone. Thank you, NYT Editorial Board @NYTOpinion. <URL>	News (information)	News about information related to Medicaid
3 Ways to increase Missouri Medicaid EMOMED Reimbursement <URL>	Information (news)	Information for Medicaid beneficiaries, presented as a blog article
The Medicaid office I'm going to tomorrow opens at 7:30 am. I won't be there that early, but ugh.	Other (consumer)	Uncategorized because it is not about experience or question, but content indicates the user to be a customer
<USERNAME> I hope someone will ask him "What's the difference between Medicaid and Medicare?"	Other (political)	Uncategorized because of lack of related content but is similar to political discussion
Test set (Corpus 2)		
<organization_name> poorly worded	Consumer (other)	Most likely comment on customer service but hard to pick up by algorithm
<organization_name> My pleasure!	Other (consumer)	Classified as others because of lack of information, but the algorithm might recognize that it could be a conversation between a customer and a customer representative



XSL•FO
RenderX

For Corpus 2, the dominant classes were consumer feedback and uncategorized tweets, and they were most frequently misclassified as each other. We suspect they were misclassified because tweets sometimes lacked context, making their meanings ambiguous and difficult for the machine to understand. For example, the tweet "<organization_name> poorly worded," though ambiguous, might be understood as that some document for the customer or the customer service representative's expression was poorly worded, and thus, we categorized it as consumer feedback. However, the machine learning algorithms were not capable of deciphering such implicit contexts: "poorly worded" is usually associated with a feedback and, in tweets directed to the agency's handle, it is likely related to customer service. Similarly, the tweet "<organization_name> My pleasure!," may belong to a conversation between a customer and a representative, but the lack of information renders it to the other class. However, machine learning could not capture this understanding.

Postclassification Analyses: Data Distribution

We applied the best-performing classifier (BERT) to label both corpora. The obtained class distributions are shown in Figure 3. We found that the majority of tweets in Corpus 1 were news (142047/628411, 22.60%) and political discussion (400778/628411, 63.78%), whereas consumer feedback accounted for only 4.55% (28604/628411), consistent with the data distribution of the test set of Corpus 1. The data distribution indicates that this corpus is suitable for analyzing chatter regarding political discussion or news. For Corpus 2, the majority of the tweets were labeled as consumer feedback (15073/27337, 55.14%) and uncategorized (8590/27337, 31.42%), which is also consistent with the data distribution in the test set.

Figure 3. Postclassification class distributions among 2 corpora, as per the automatically classified tweets.

Postclassification Analyses: Content of Each Class in Corpus 1

We now briefly summarize the findings from content analyses of the tweets in Corpus 1 that contain the terms associated with "medicaid" to understand, from a high-level perspective, the contents within each category. The 10 highest ranking bigrams and trigrams detected by the TFIDF method are listed in Table S7 of Multimedia Appendix 1 [43]. Not surprisingly, the academic tweets are dominated by terms starting with "study..." and terms indicating research finding. Similarly, the information tweets contain terms related to "service," "care,"... etc, consistent with information outreach. For the news tweets, we found that many tweets were about news on medicaid work requirements in Kentucky and Arkansas (blocked by the federal judge on March 27, 2019). In addition, "social security" and "Trump..." are also highly ranked among the news and political classes. For the tweets belonging to the consumer feedback, some of the high-ranking terms were shared with other classes (eg, "... insurance," "social security," or "... care"), whereas some were specific to this class ("make much" or "doesn cover") and potentially indicated comments about Medicaid income cap and coverage.

We did not know the compositions of the 2 data sets that we had collected a priori. Thus, the results of our classification experiments provided us with very important knowledge about which type of Twitter data to use when conducting targeted studies about Medicaid or health services in general. For example, when studying consumer feedback, it is best to use data from Corpus 2 (ie, tweets containing Twitter handles of the MA or MCO); for studying public perceptions of political decisions, Corpus 1 would be more useful. Detailed content analyses of the tweets in each category, such as their temporal and geolocation-specific distributions, are likely to reveal more relevant information. However, such analyses are outside the scope of this study, and we plan to build on the NLP system described in this paper to conduct more thorough content analyses in the future.

Postclassification Analyses: LDA Topic Modeling on Consumer Feedback

We found that the model with 20 topics achieved the highest coherence score. The top 20 words in each topic are listed in Multimedia Appendix 1, Table S8. We now summarize the main findings based on these top words, with example top words provided in parentheses. We deduced that this chatter contains discussion related to (1) applying for Medicaid, either for oneself or even family members (eg, *deny*, *apply*, *family*, and *child*); (2) Medicaid coverage for dentists, specialists, prescription medications, emergency department visits (eg, *cover*, *dentist*, *therapist*, *prescription*, *medication*, and *emergency*); (3) interacting with customer representatives, especially through phone (eg, *call*, *phone*, *hour*, *hold*, *tell*, and *wait*); (4) hospital-related bills (eg, *hospital*, *bill*, and *copay*); and (5) comparing different insurance plans (*switch*, *insurance*, *private*,

XSL•FO
RenderX

and *plan*). The list of topics can be a guide to further categorize the consumer feedback chatter, which could lead to a more detailed analysis and even provide recommendations on how to further improve the Medicaid program. A more in-depth analysis is left for future work.

Discussion

Principal Findings

As many classification errors occur because the tweets lie in the boundary between 2 classes, we note that a multilabel classification scheme might improve the performance [47]. However, in the experiments conducted earlier in this project, we found that the multilabel scheme only improved the classification performance by a small margin, while making the annotation process more difficult. Thus, we focused on the single-label classification scheme in this work, leaving the development of multilabel models to future work.

In addition to multilabel classification models, the classification error might also be remedied by creating new categories for tweets lying at the boundary of current categories. For example, we can further divide the political discussion into 2 categories: discussion of policy without personal experiences or experiences from friends or relatives and discussion of policy with experiences as supporting evidence. The classification performance may be further improved by including more user profile information. For example, we can include features such as whether the account belongs to a news agency or if the user is affiliated with an academic organization or think tanks, which could improve the classification performance on the news class or the academic class. As the 2 corpora have very different distributions, developing a corpus-specific classifier might further improve the performance.

Although our content analysis is limited to the high-ranking TFIDF terms and LDA topic modeling on consumer feedback, additional analyses could include topic modeling of other chatter [44] or sentiment analysis to understand sentiments toward Medicaid in general or to specific aspects of the Medicaid program [8]. The manual analysis of selected samples can deepen the understanding of these topics and potentially generate recommendations toward policy change. We also note that content analysis can not only help researchers further understand the Medicaid chatter but it can also improve the classification performance in reverse.

Limitations

This analysis has limitations related to the quality of Twitter data, which contain high volumes of noise that may affect the accuracy and generalizability of our content analyses and annotation guidelines. In addition, Twitter users may not be representative of Medicaid enrollees. Older age groups tend to be underrepresented among Twitter users [48], and more vulnerable populations who rely on Medicaid may not use this platform to discuss their health coverage.

Conclusions

We have developed a social media mining system, involving NLP and machine learning, for continuously collecting and categorizing Twitter chatter about the Medicaid program. Our study demonstrates that it is possible to collect data about large, complex health services and coverage programs such as Medicaid using Twitter to obtain near real-time knowledge about consumer perceptions and opinions. The automatic classification of streaming data is crucial, specifically for smaller classes, such as consumer feedback, for studying targeted topics.

Our analysis can inform public health researchers on how to use public discussions about health programs and services, such as Medicaid. Similarly, our system can be deployed by research groups or Medicaid agencies for continuous, ongoing research on the evolution of public opinions on social media (eg, the impact of certain policy changes or rulings). We also note that although this work focuses on Medicaid, our methods and open source code can readily be applied to other health services. Annotated data and methods are available for future studies [49].

Acknowledgments

This study was conducted with partial support from the Robert Wood Johnson Foundation (#76158, JMZ and DG).

Authors' Contributions

YY conducted and directed the machine learning experiments, evaluations, and data analyses with assistance from MAA, AS, and WH. YY, AS, MAA, and WH contributed to data collection, annotation, and analyses. JMZ and DG provided their expertise in preparing the annotation guidelines and categories and helped formulate the overarching objectives of the project. AS, JMZ, and DG supervised various aspects of the study. YY drafted the manuscript, and all the authors contributed to the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The COVID-19 pandemic has impacted people's lives at unprecedented speed and scale, including how they eat and work, what they are concerned about, how much they move, and how much they can earn. Traditional surveys in the area of public health can be expensive and time-consuming, and they can rapidly become outdated. The analysis of big data sets (such as electronic patient records and surveillance systems) is very complex. Google Trends is an alternative approach that has been used in the past to analyze health behaviors; however, most existing studies on COVID-19 using these data examine a single issue or a limited geographic area. This paper explores Google Trends as a proxy for what people are thinking, needing, and planning in real time across the United States.

Objective: We aimed to use Google Trends to provide both insights into and potential indicators of important changes in information-seeking patterns during pandemics such as COVID-19. We asked four questions: (1) How has information seeking changed over time? (2) How does information seeking vary between regions and states? (3) Do states have particular and distinct patterns in information seeking? (4) Do search data correlate with—or precede—real-life events?

Methods: We analyzed searches on 38 terms related to COVID-19, falling into six themes: social and travel; care seeking; government programs; health programs; news and influence; and outlook and concerns. We generated data sets at the national level (covering January 1, 2016, to April 15, 2020) and state level (covering January 1 to April 15, 2020). Methods used include trend analysis of US search data; geographic analyses of the differences in search popularity across US states from March 1 to April 15, 2020; and principal component analysis to extract search patterns across states.

Results: The data showed high demand for information, corresponding with increasing searches for *coronavirus* linked to news sources regardless of the ideological leaning of the news source. Changes in information seeking often occurred well in advance of action by the federal government. The popularity of searches for unemployment claims predicted the actual spike in weekly claims. The increase in searches for information on COVID-19 care was paralleled by a decrease in searches related to other health behaviors, such as urgent care, doctor's appointments, health insurance, Medicare, and Medicaid. Finally, concerns varied across the country; some search terms were more popular in some regions than in others.

Conclusions: COVID-19 is unlikely to be the last pandemic faced by the United States. Our research holds important lessons for both state and federal governments in a fast-evolving situation that requires a finger on the pulse of public sentiment. We suggest strategic shifts for policy makers to improve the precision and effectiveness of non-pharmaceutical interventions and recommend the development of a real-time dashboard as a decision-making tool.

Introduction

Problem Statement

Over a period of a few months, the COVID-19 pandemic dramatically and rapidly changed the lives of most Americans. With the spread of SARS-CoV-2, people faced extreme uncertainty due to evolving information, calls for behavior change, and economic shocks. As US states move through different stages of the response and plan a path back to normalcy, it is important to develop ways to gather and measure insights into how Americans are responding to the challenges and uncertainties posed by the pandemic [1]. These insights will help policy makers know what to focus on as the United States continues to navigate the COVID-19 outbreak. In particular, it is important to understand the changes and patterns in the information seeking of Americans over the course of the pandemic, both as a window into key concerns as they emerge and as potential signals of actual behavior change.

Collecting data on population responses to a crisis poses a host of methodological challenges [2,3]. Surveys are a commonly used way to gather information on how people are reacting to a health crisis [4]. Several surveys have been deployed to measure Americans' reactions to COVID-19, and they offer insights into the concerns and behaviors of many Americans [5,6]. However, traditional large-scale surveys are expensive and time-consuming; also, due to the rapidly changing nature of the pandemic, it is difficult to capture time-sensitive relevant data [4]. Further, surveys require a baseline understanding of the context of the participants before the events of interest. However, recent research [7] shows that many surveys administered during the COVID-19 pandemic either do not have a baseline or have an inaccurate baseline that relies on the participants' limited ability to recall the answers to retrospective questions. Another option is to use health information systems, generating insights from existing large-scale health data such as electronic patient records and surveillance systems [8]. However, working with this type of data also has limitations: it requires multiple data sets that cannot easily be merged, it relies at times on outdated data, and it requires complex methodological approaches to analysis [9].

An alternative approach to data collection on pandemic response is to examine web-based information-seeking behavior through Google Trends, a source of data on trends in web-based information-seeking [10].

Background

Google Trends and Health Phenomena

Google Trends data have been leveraged extensively in health behavior research by using trends in web-based search queries as proxies for changes in human behavior [11]. Released in 2006, these data became more influential when Ginsberg et al [12] showed a predictive approach that could "make it possible to use search queries to detect influenza epidemics in areas with a large population of web search users." Since then, there have been suggestions to improve the predictive approaches after an overestimation of influenza metrics during the 2012-2013 season [13]. Outside of influenza predictions, Google Trends data have also been used to analyze a wide array of health behavior topics, such as the relationship between media coverage and information seeking around major infection events, the impact of local abortion policies on information seeking about abortion, the influence of influenza concerns on travel, and temporal patterns in interests in healthy behaviors such as dieting [14-17]. In 2014, Nuti et al [3] found that 60% of Google Trends research was focused on infectious diseases and general population behavior, which suggests that it may be a good tool to investigate COVID-19 trends.

Google Trends data are also useful for studying health information- and care-seeking patterns. Initial research using Google Trends data in the United States showed declining interest in imaging diagnostics [18] and surgeries [19] alongside a steady rise in interest in telehealth and telemedicine [20]. Other studies focused on COVID-19 and Google Trends data showed increases in general virus information seeking; however, to date, most studies have explored a singular issue over time or in a specific geographic region, without examining comprehensive search pattern correlations or geographical heterogeneity and their potential implications [21-23]. Recent research also shows "statistically significant correlations between Google Trends and COVID-19 data" [24]. Thus, Google Trends offers immense potential for generating temporally and geographically specific insights into the beliefs, behaviors, and actions of various communities in their response to the COVID-19 pandemic.

Health Information Seeking

Health information seeking is an important step in the care seeking journey, given that "one in three US adults use the internet to diagnose or learn about a health concern" [25]. Health information seeking has been extensively studied, with several studies identifying antecedents and reasons for individual health information-seeking behaviors. Factors that influence health information seeking include the subjective norms of a society or group of which the individual is a member [26], emotional responses and social context [27], and media-driven triggers [28]. Research on web-based health information seeking suggest certain reasons why individuals seek information on the web, including preparing for a doctor's appointment [29] and anxiety about their health [30]. These studies are useful for some applications, such as improving the quality of information campaigns; however, they are general frameworks and are not disease specific.

In this work, we address information seeking from an infodemiology perspective, following seminal work by Eysenbach [30,31] that defines infodemiology as "the science of distribution and determinants of information in an electronic medium, specifically the Internet, or in a population, with the

XSL•FO
RenderX

ultimate aim to inform public health and public policy". We focus on the topics people search for (the demand side of infodemiology, in this case represented by Google Trends search queries) as opposed to what people write on the web (the supply side). Some infodemiology demand research focuses only on specific groups of people, such as the information-seeking behavior of clinical providers [32]. Our work instead examines the information seeking of the general population as measured by web-based search activity to capture wider public health implications. We also include a diverse set of socioeconomically related queries to address the multidimensional nature of the effect of COVID-19 and its intersection with nonpharmaceutical interventions. Analytically, we address three of four categories of analysis identified in a systematic review of Google Trends infodemiology by Mavragani et al [33]; we (1) measure the general web-based interest of several COVID-19– related themes, (2) detect variations and seasonality across geographic regions with comparisons to actual events, and (3) correlate search queries among them to understand the underlying patterns. The fourth category involves actual prediction and forecasting, which we do not address in this paper. In addition to specific public health and policy proposals, we emphasize the potential of an infoveillance [34] approach—using web-based information for public health surveillance—and propose a dashboard informed by this work.

Research Questions

We created a curated list of search queries and used Google Trends to analyze changes in information seeking related to the COVID-19 pandemic over time and across geographic areas in the United States. We answered four broad questions regarding information seeking around COVID-19:

First, how is information seeking changing over time? Specifically, what is the relationship between the COVID-19 outbreak and internet searches related to health care seeking, government support programs, media sources of different ideologies, planning around social activities, travel, and food, and new COVID-19–specific behaviors and concerns? We would expect certain types of searches (eg, health care–related inquiries, government safety net programs, web-based food delivery) to become more popular, while others would be expected to fall in popularity (eg, nearby bars, travel plans). These trends provide clear contextual information on the changing interests and concerns of Americans as the pandemic progresses, and we can also compare the timing of these changes with real-world actions and events such as policy announcements.

Second, what geographic variation exists in information-seeking behavior? Specifically, how does the popularity of search terms differ across states and regions? Given the immense heterogeneity across the United States, both culturally and in terms of COVID-19 caseload and response, we would expect states to differ in the most-sought information. Observed geographic differences in information seeking add granularity to the information-seeking context and provide an opportunity to develop hypotheses around why these differences exist.

Third, do states have particular and distinct patterns in information seeking? Specifically, which searches correlate with each other at the state level? Using machine learning methods, specifically unsupervised learning, we can construct different typologies of geographic areas so that those whose search trends provoke concern for public health can be better targeted with information and other interventions.

Fourth, do Google Trends data correlate with and potentially precede real-life events? If Google Trends data can be "predictive" of real-life events (eg, unemployment rates), it provides further validation for this method as a window into the behaviors of Americans during the pandemic.

Methods

Google Trends is a free web-based source of data on trends in web-based information seeking across geographies (country, region, city, and designated market area/metropolitan area where this exists) and over time (since 2004). In 2019, a comprehensive methodological framework was published to standardize approaches to Google Trends research [35]. This work follows that framework, which provides specific criteria for selecting the keywords, geographical regions, and time period for analysis. We also combine several keywords that represent a similar topic into a single query.

Keywords and Search Queries

Google Trends accepts a single word or a phrase, and several of these can be combined into a single Trends query by joining with a "+", which functions like an "OR." This study used 38 queries of up to 5 words/phrases each (Table 1). We generated and curated search terms and evaluated the popularity/relevance and data quality of each query in representing different aspects of the response to and impact of COVID-19–related search activity on Google Trends. The list of search terms was derived from the most commonly searched terms associated with COVID-19 on Google Trends [10] and was refined to be more specific as recommended by Tran et al [36].

Each query was then categorized into one of six emergent themes: care seeking, government programs, health programs, news and influence, outlook and concerns, and social and travel (Table 1). These themes were developed to comprehensively capture the effects of and responses to the pandemic: care seeking and health programs capture how people look for care; news and influence captures the sources of information; and outlook and concerns and social and travel capture the economic and nonpharmaceutical preventive intentions. For the news and influence theme, we selected media outlets that are representative of both sides of the ideological spectrum based on a Pew Research survey conducted in 2014 that measured the ideological leanings (left or right) of the audiences of different news media sources [37]. All search data were extracted on April 15, 2020.

XSL•FO
RenderX

Table 1. Final list of search queries grouped into emergent themes (38 queries with 1-5 combined terms).

Category/ theme	Queries
Care seeking	• *coronavirus symptoms* • *coronavirus testing near me + coronavirus testing center near me + coronavirus test* • *doctor appointment* • *coronavirus afford doctor + coronavirus uninsured + coronavirus medical bill* • *Coronavirus can i see a doctor + coronavirus can i get a test + coronavirus are tests available* • *doctor open + doctor office open* • *urgent care near me*
Government programs	• *disability benefits + apply benefits + food stamps + wic* • *government aid* • *recession + stock market crash + economic downfall + bear market* • *small business loans* • *stimulus check* • *paycheck protection program*
Health programs	• *health insurance* • *health insurance + medicare + medicaid* • *medicaid* • *medicare*
News and influence	• *chinese virus* • *coronavirus cnn + coronavirus msnbc + coronavirus nbc news + coronavirus cbs news* • *coronavirus hoax + coronavirus fake news* • *coronavirus infowars + coronavirus breitbart + coronavirus glenn beck + coronavirus the blaze* • *coronavirus washington post + coronavirus new york times + coronavirus npr* • *coronavirus fox news + coronavirus drudge report*
Outlook and concerns	• *can't pay rent + how pay rent + behind on rent + can't pay mortgage* • *hoarding + hoard* • *how can i stop coronavirus* • *how to make coronavirus mask* • *how to stockpile + buy in bulk + bulk order* • *sick days + sharing sick days + no sick days + sick leave + paid time off* • *social distancing* • *sold out + stock out + stockout + stockpil* • *unemployment benefits + unemployment application + file unemployment + apply unemployment + layoffs*
Social and travel	• *bar closed + restaurant closed* • *bar near me + restaurant reservation + local happy hour + ladies' night* • *bar + restaurant + happy hour + pub + house party + party ideas* • *cheap flights + travel destinations + flight deals + vacation deals* • *food delivery + grocery deliveries + takeout + curbside + online food order* • *house party + party ideas*

Data Collection

Data from Google Trends [10] were extracted through an open-source third party Python application programming interface, PyTrends. Google provides the relative search values (RSVs) for each query on a scale from 0 to 100, representing a normalized value.

Three primary data sets were developed from Google Trends: one at the national level and the other two at state level, capturing all 50 states and the District of Columbia.

The national data set contained weekly RSVs for the United States for each of 38 queries for the 224 weeks between January 1, 2016, and April 15, 2020. This enabled us to conduct trend analysis for each query independently, tracking its relative popularity in the entire United States compared with its most popular week over these 224 weeks. For each query, the week when the query was most popular (as a percentage of all queries in that week) was scored as 100 by Google Trends, and all other weeks were scored relative to this week.

One of the state-level data sets contained weekly RSVs for each query for each state for the 16 weeks between January 1 and April 15, 2020, while the other contained aggregated RSVs for each query for each state over the whole period of March 1 to April 15, 2020. For each of these data sets, RSVs for a specific query were always expressed as search popularity relative to other weeks, other states, or both, but never relative to other search queries (ie, our approach factored out absolute differences in popularity between queries).

Finally, two additional, secondary data sets were referenced, comparing Google Trends against new monthly Medicaid applications and weekly initial unemployment claims, from the public Medicaid web-based database (June 2017 to January

XSL•FO
RenderX

2020) [38] and US Department of Labor data (January 2016 to April 2020) [39], respectively.

Analysis

Geographically, states were grouped by federal region and division based on US census data [40]. We used Python for data processing and Tableau for exploratory data analysis and visualization [41]. We used the packages of Python and R (R Foundation for Statistical Computing) to perform pairwise correlations (Pearson, pairwise complete) and unsupervised learning by principal component analysis (PCA), respectively [42]. We conducted pairwise correlations to visualize and quantify associations between the individual queries at the state level; we then applied dimensionality reduction through PCA to reveal groups of queries that are often searched together and to identify top states with search patterns of interest, either supporting or undermining the fight against the COVID-19 epidemic. Missing values were removed for correlation and PCA analysis (ie, we retained all 51 geographies and removed any queries that had missing values for any states). Nine queries had missing values: *coronavirus infowars + coronavirus breitbart + coronavirus glenn beck + coronavirus the blaze, how can I stop coronavirus, coronavirus can I see a doctor + coronavirus can I get a test + coronavirus are tests available, coronavirus afford doctor + coronavirus uninsured + coronavirus medical bill, bar closed + restaurant closed, government aid, doctor appointment, doctor open + doctor office open*, and *can't pay rent + how pay rent + behind on rent + can't pay mortgage*. This reduced the number of queries for analysis from 38 to 29.

For pairwise correlations, we filtered for any correlations of low to very high (positive or negative) correlation (ie, >0.3 or <–0.3) according to the guideline proposed by Mukaka [43]. We then focused only on the most prominent (moderate and high) scales. For PCA, only loadings with loading scores higher than 0.2 or lower than –0.2 were used to explain each component (PCA loadings take values from 0 to 1).

To calculate the increase in search popularity between January and March 2020, we took the mean RSV for March 2020 and divided this by the mean RSV for January 2020 and expressed this ratio as a percentage change. We chose January and March to capture the largest shifts in RSV based on the progression of the SARS-CoV-2 virus. Data for the extra 2 weeks in April were used to monitor which trends persisted or dissipated after large shifts in March.

Finally, to compare Google Trends to real-life phenomena, we visualized data on actual weekly initial unemployment claims and new applications for Medicaid, then quantified the correlations between each phenomenon and the corresponding Google Trends query.

Results

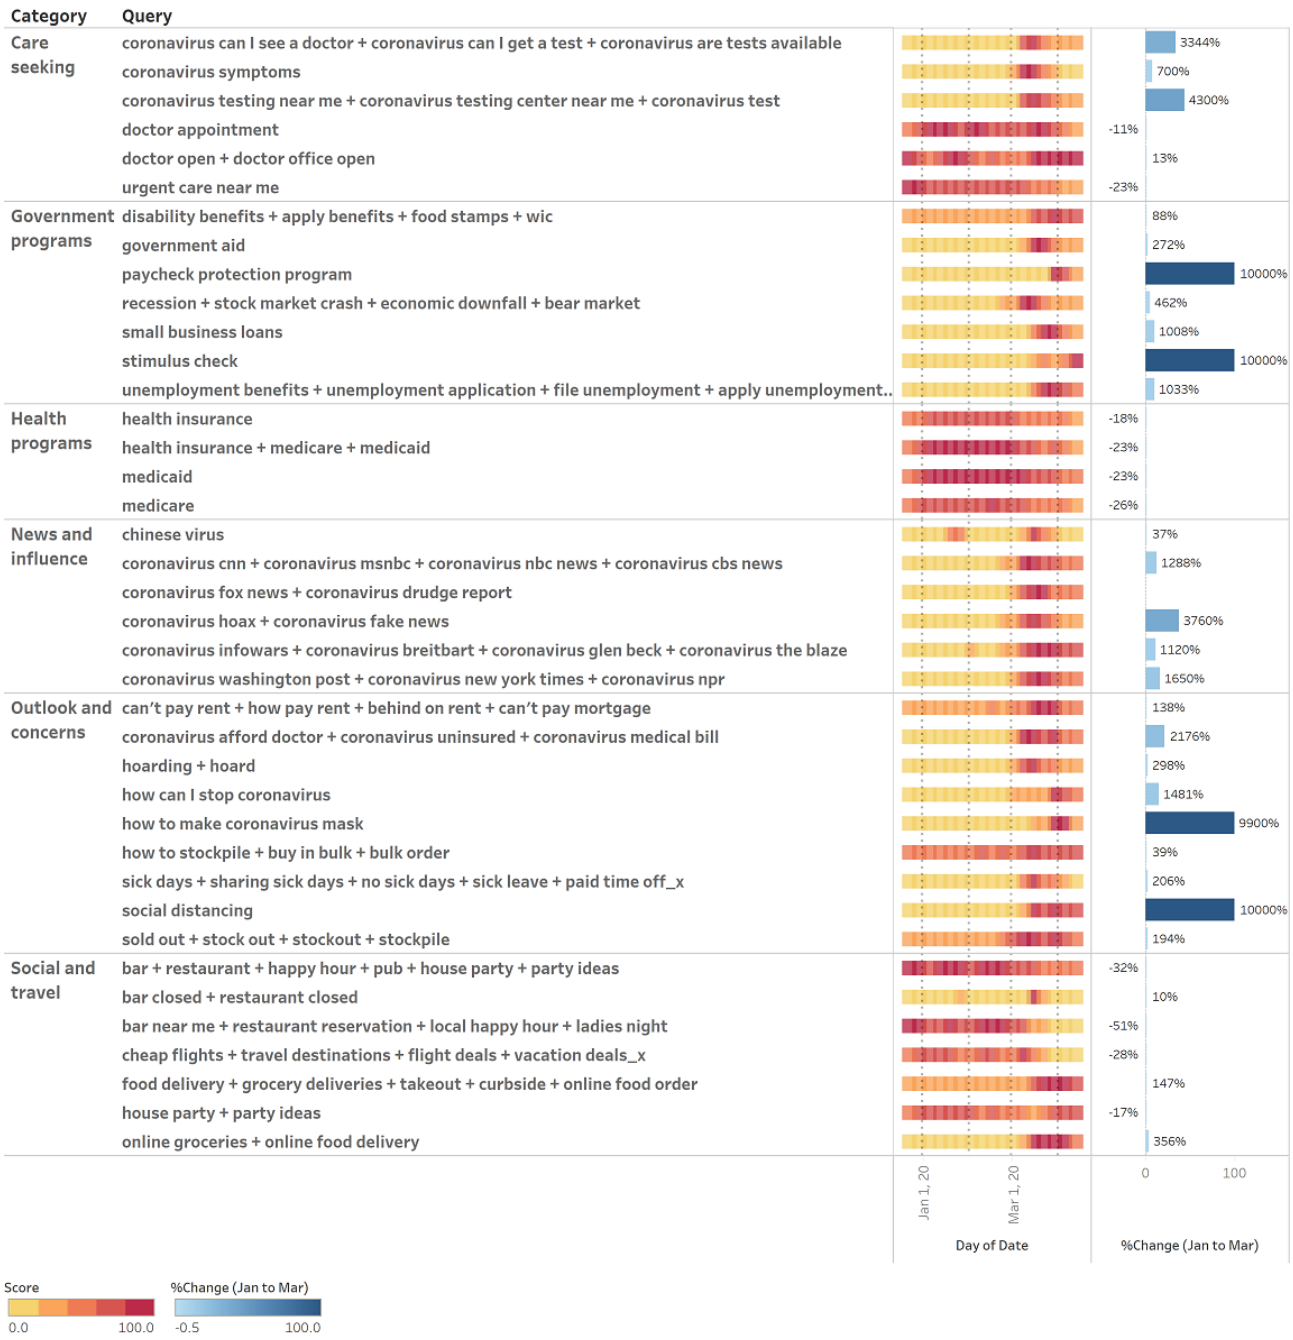
Magnitude of Shifts in Information Seeking

National trends show shifts in information seeking related to health and lifestyle activities.

Analysis of all queries showed substantial shifts in RSVs across all thematic categories (Figure 1) predominantly in March 2020, with trends persisting or stabilizing in early April.

For the care seeking theme, the RSVs of COVID-19–related queries increased substantially (*coronavirus symptoms* and *testing centers*) while the RSVs of general health-seeking queries (*urgent care* and *doctor appointments*) declined in late March/early April, suggesting a nuanced story of care seeking (Figure 1). This trend was matched by a decline in the RSVs for all queries in the health programs theme (*health insurance*, *medicaid*, and *medicare*) by 18%, 23%, and 26%, respectively. Comparison with the same time window in preceding years confirmed that this finding was an anomaly against historical seasonality, where health program searches peak and drop in November and December, not in March and April.

News and influence searches related to COVID-19 saw notable hikes in RSV for both left-leaning and right-leaning media. RSV for far-right/alt-right media outlets (see the *Methods* section for definitions based on the Pew Research survey) also increased. Simultaneously, RSV for *coronavirus fake news* and *coronavirus hoaxes* surged 38-fold (Figure 1).



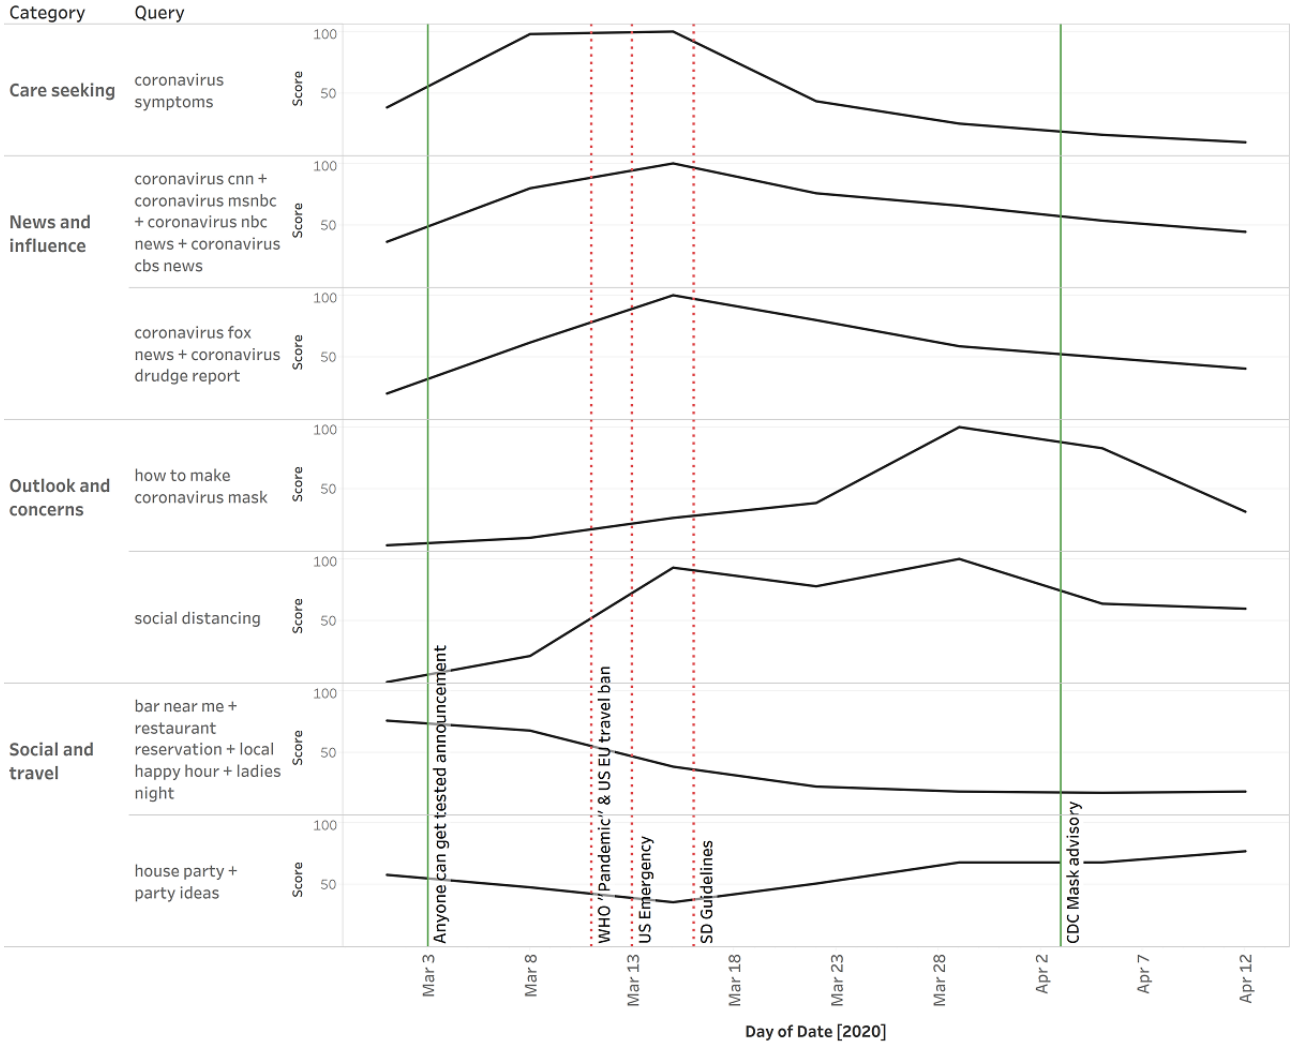
For the outlook and concerns theme, RSVs for new behavioral concepts gained immense popularity: *social distancing* and *how to make masks* spiked by 100-fold and peaked in March, as did time-sensitive concerns such as *hoarding* and *can't pay rent*. In contrast, searches for *stock outs/sold out* and *coronavirus medical bill/affordability* remained at high levels into early April, hinting at potential differences in long-term versus short-term concerns (Figure 1).

Within the social and travel theme, search trends were aligned with the new norm of social distancing and also signaled potential drops in business for the travel and service industries. The RSVs for *online groceries + food delivery* and *food delivery + grocery deliveries + takeout + curbside + online food order* tripled and doubled, respectively, while the RSVs for *party ideas*, *nearby bars and restaurants*, and *cheap flights/travel* all dropped by between 17% and 51%. This shift is noteworthy for *nearby bars and restaurants*, as it is a reversal of an upward trajectory that had recently peaked in December 2019 (Figure 1).

For the government programs theme, its relative popularity increased for new COVID-19–specific packages (*stimulus check* and *small business loans*) as well for unemployment benefits, which is a more mature program. Notably, the RSVs for *disability/food stamps* and *government aid* had the lowest increases in RSVs among government programs. However, relative interest in programs focused on individuals—*stimulus check* and *unemployment application*—maintained momentum through April 15 (Figure 1).

XSL•FO
RenderX

Figure 1. National search pattern for each query in every theme by relative search value for 16 weeks between January 1 and April 15, 2020. The right panel shows the change in monthly average relative search value between January and March, capped at 10,000% for queries with extremely high changes.



Timing of Shifts in Information Seeking

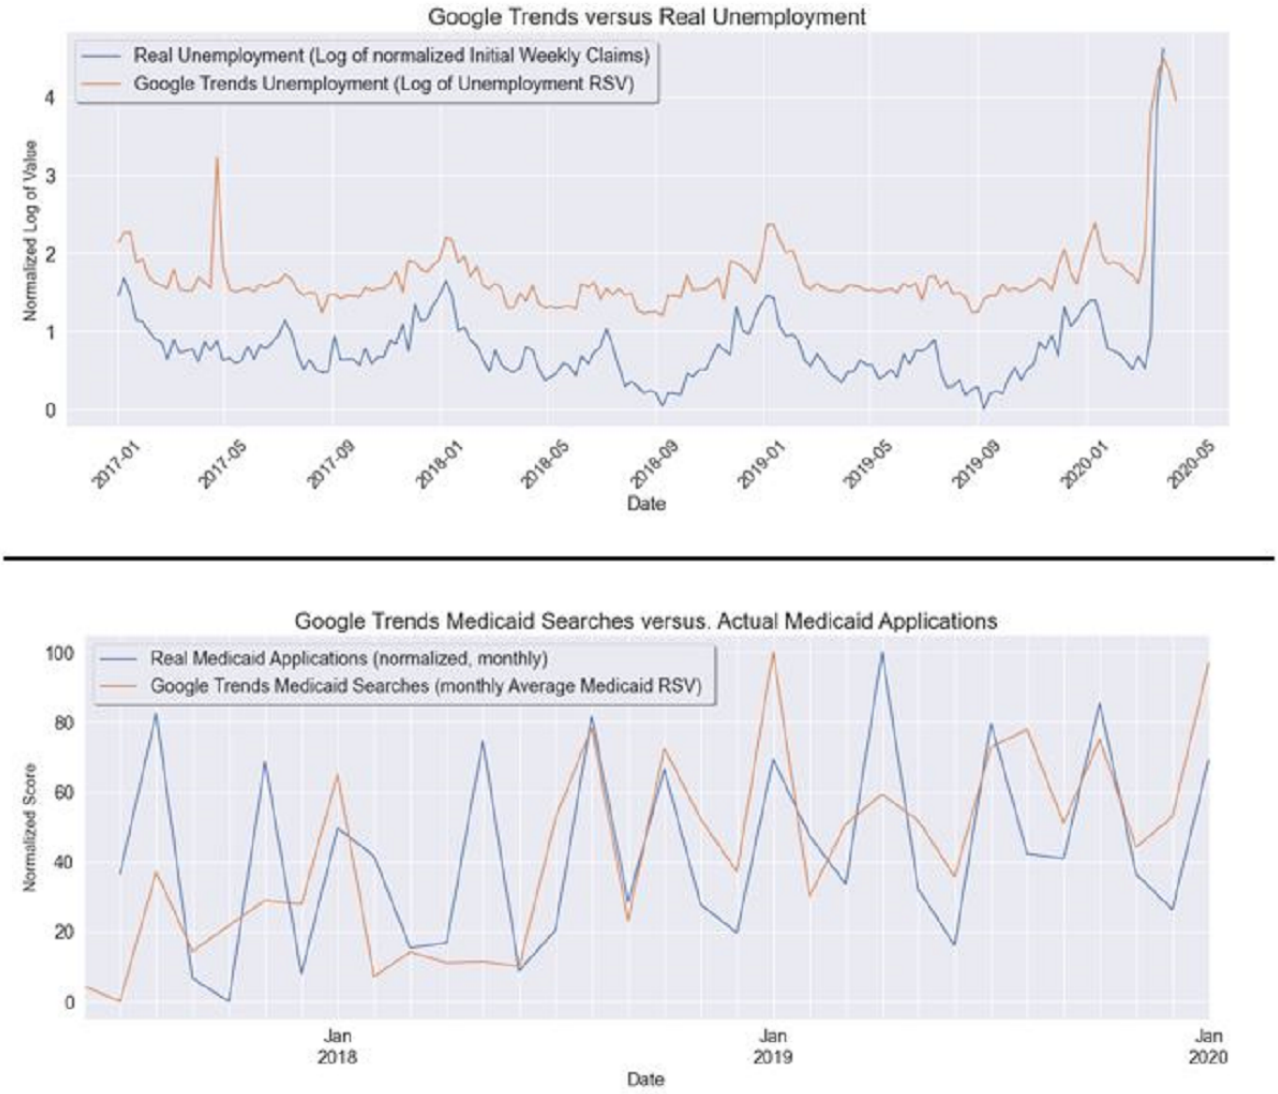
Shifts in information seeking occurred earlier than federal government policy action. We would have expected the directives from the federal government, which formulates national policies, to be issued early and to precede changes in search patterns and behaviors. However, the Google Trends data show that the relative popularity of queries related to non-pharmaceutical interventions (NPIs) was already shifting substantially, and in some cases peaking, several days ahead of major federal government policies and NPI action (Figure 2). For example, RSVs for *social distancing* and *bar/restaurant nearby* were quickly increasing and decreasing, respectively, by March 8—3 days before the World Health Organization declared COVID-19 a pandemic, 5 days before the US federal government's national emergency declaration, and 8 days before the government released official social distancing guidelines. Furthermore, *how to make a coronavirus mask* was already relatively popular (RSV >50) by March 23, exactly 12 days before the US Centers for Disease Control and Prevention issued an advisory promoting the use of masks for the general public.

On the other hand, the RSV trends for news on COVID-19 and COVID-19 symptoms were in sync, matching each other regardless of the ideological leaning of the news source. This suggests that searches for disease characteristics were highly correlated with searches for news coverage of the disease.

XSL•FO
RenderX

Figure 2. National trends for Google Trends nonpharmaceutical intervention–related queries compared to actual government and public health nonpharmaceutical interventions at the US federal level between March 1 and April 15, 2020. CDC: US Centers for Disease Control and Prevention; EU: European Union; SD: social distancing; WHO: World Health Organization.

Correlation Between Information Seeking and Unemployment and Medicaid Claims



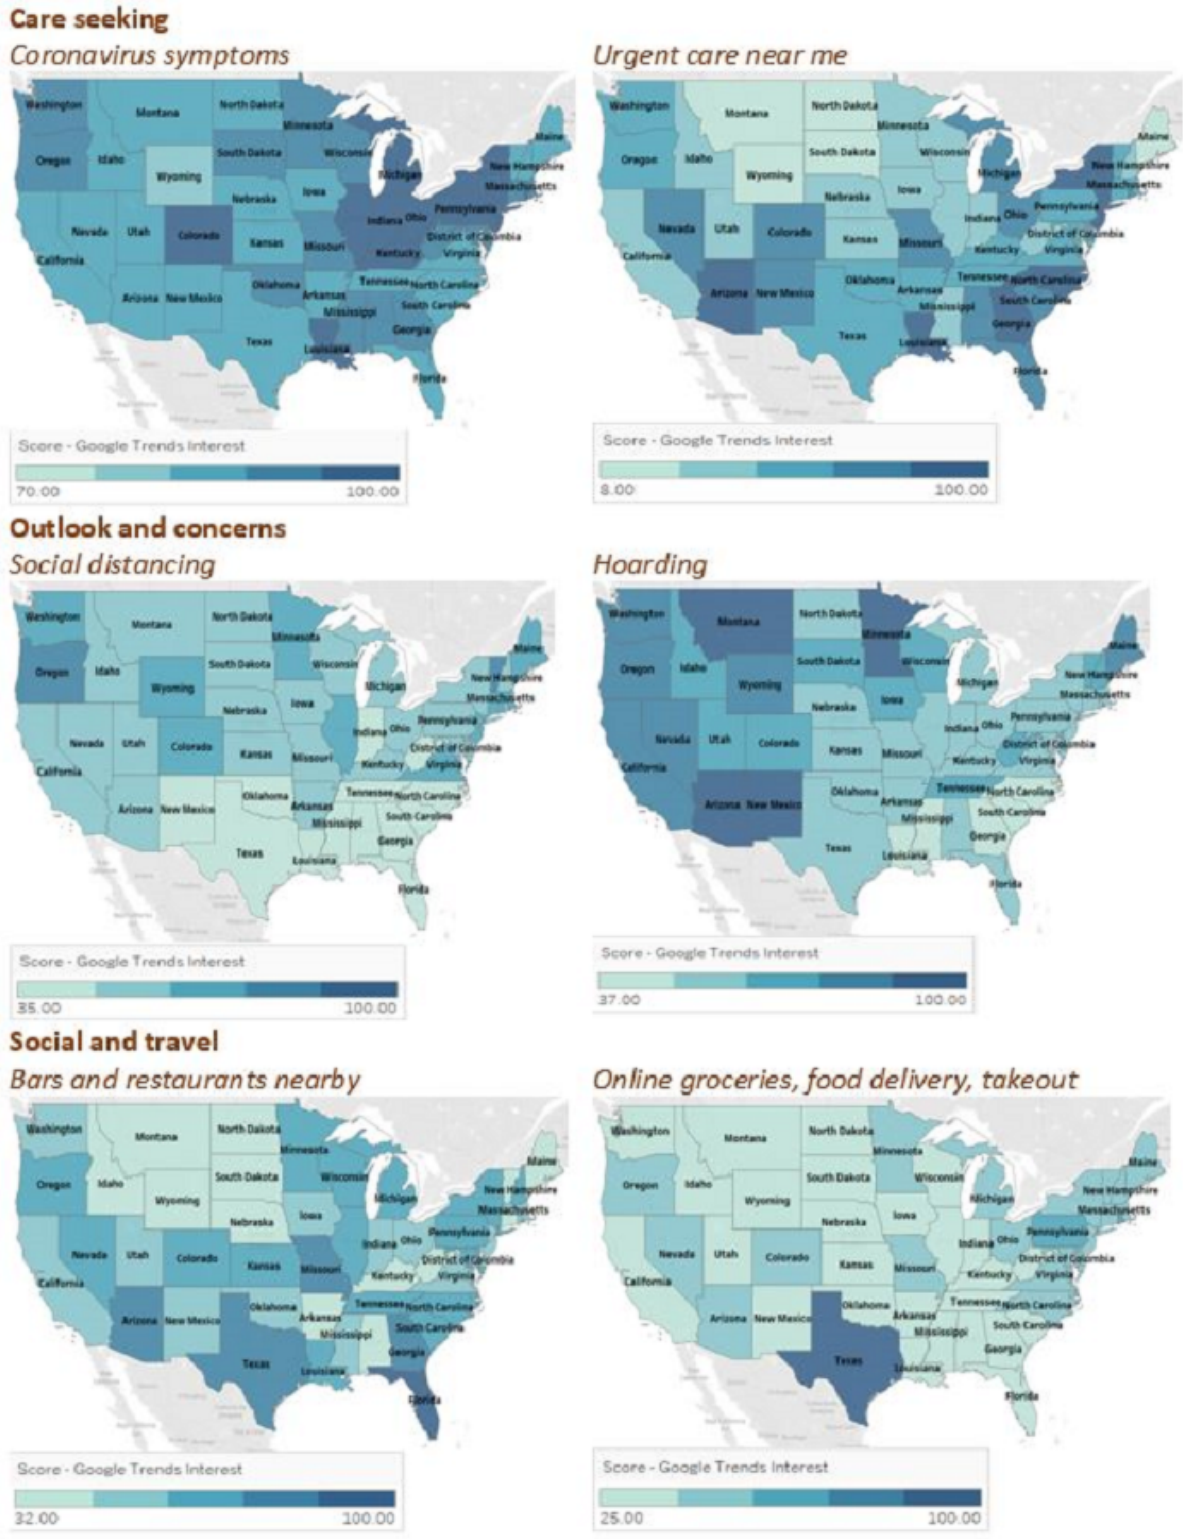
Google Trends were correlated with unemployment claims and Medicaid applications. We found high correlations between specific Google Trends queries and corresponding phenomena in the real world both before the epidemic (for unemployment and Medicaid) and during the epidemic (for unemployment). Two examples were selected: initial weekly unemployment claims and new monthly Medicaid applications. Figure 3 shows the comparative results with corresponding Google Trends queries over time.

There was a very high positive correlation of 0.96 between the previous week's Google Trends RSV for unemployment applications and the actual weekly initial unemployment claims normalized to 0-100 (seasonally adjusted as recommended by the Bureau of Labor Statistics to eliminate seasonal spikes and enable easy detection of nonseasonal anomalies such as COVID-19–related spikes). For Medicaid, there was a moderate positive correlation of 0.55 between the average monthly Google Trends RSV for Medicaid, lagged one month, and the number of new applications for Medicaid each month.

However, we noted that this approach was only modestly successful for more complex cases in which the link between search popularity and actual behavior is more difficult to imagine. A notable example is stock market prices (Dow Jones Industrial Average) and the Google Trends query for *recession/stock market crash*, which showed no correlation.

XSL•FO
RenderX

Figure 3. National-level multivariate trends for new weekly unemployment (January 2016 to April 2020) [39] and new monthly Medicaid applications (July 2017 to January 2020) [38]. Top: Google searches for unemployment applications and actual initial weekly unemployment claims normalized from 0-100 over time (with seasonal adjustment). Bottom: Monthly average Google searches for Medicaid and actual new applications for Medicaid normalized from 0-100 (lagged by 1 month). RSV: relative search value.



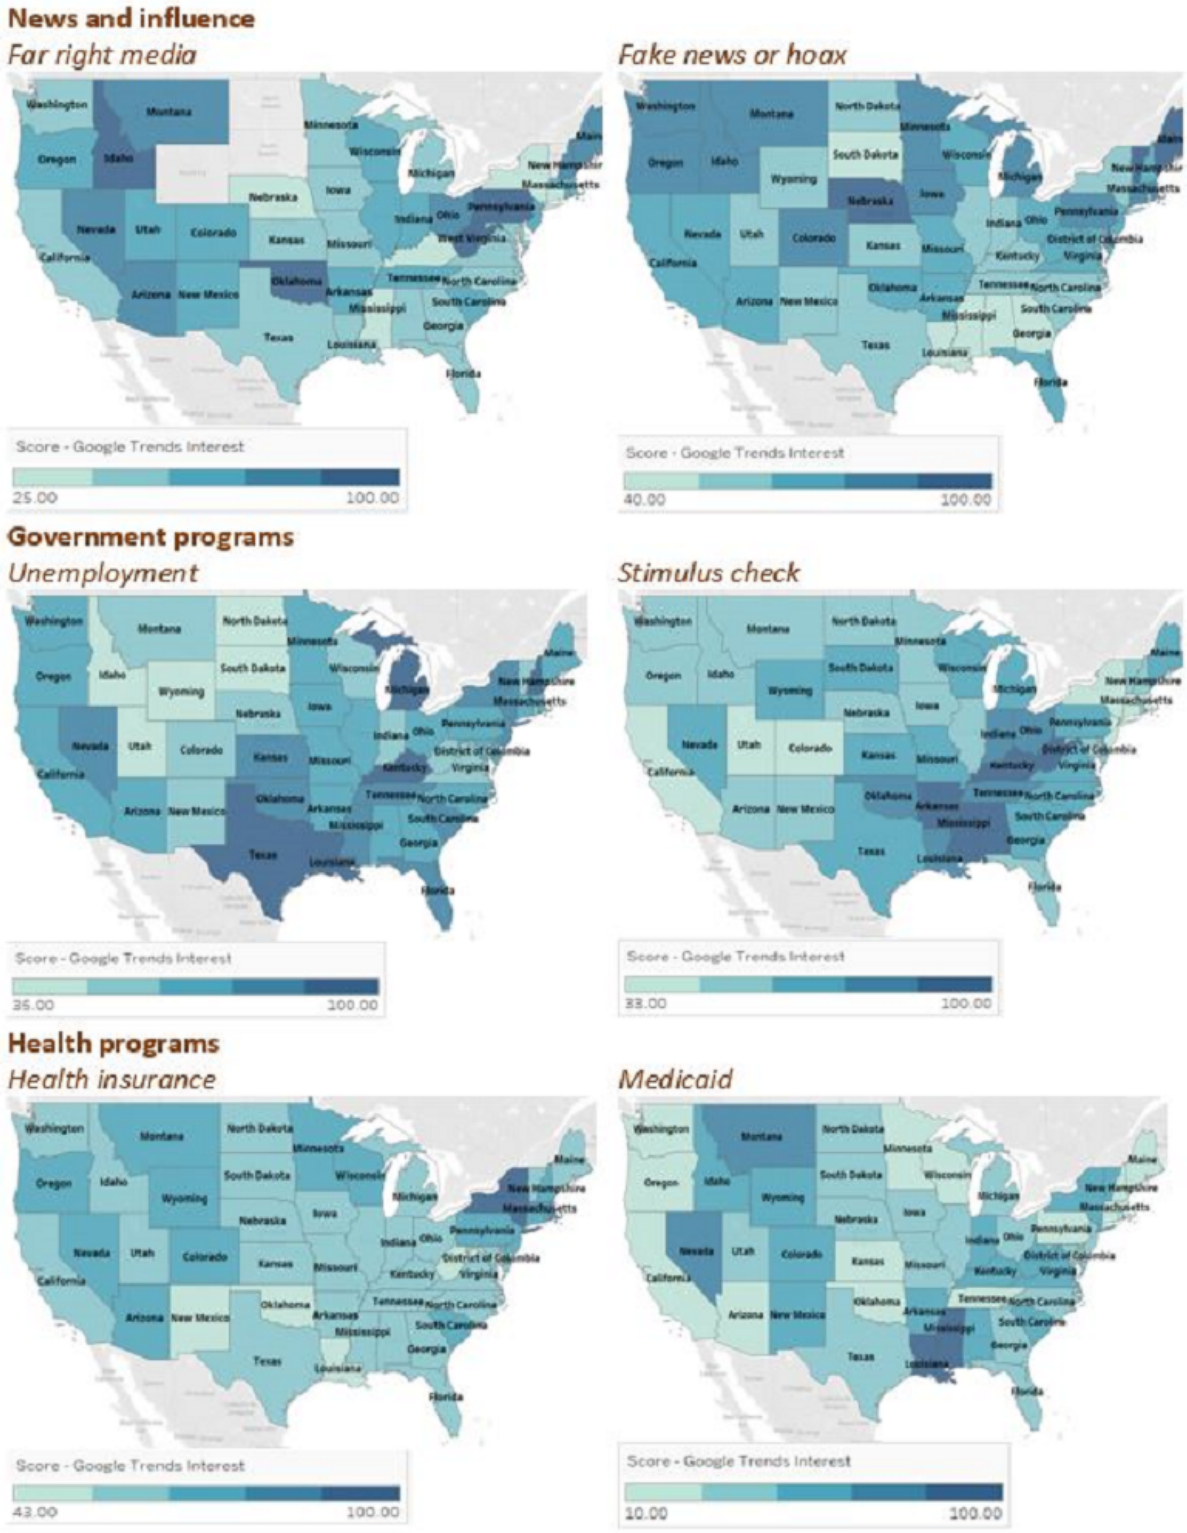
Differences in Search Patterns Across States and Regions

Differences in search patterns suggest varied responses to COVID-19 across states and regions. Nationally, the largest jumps in RSV were concentrated between March 1 and April 15; therefore, we focused on this window to investigate state-by-state differences in information seeking. Here, we compared the relative popularity of a search query across states in a single time period rather than across time.

The findings showed similar levels of popularity of searches for *urgent care near me* in the South and Northeast but a difference in the relative popularity of searches for health programs (*health insurance*, *Medicare*, and *Medicaid*). Care seeking searches were most popular in the South (Louisiana, Georgia, and North Carolina); the Northeast (New York and New Jersey); and in Indiana, Illinois, and Arizona during this specific window (Figure 4). Although New York and New Jersey were already COVID-19 hotpots, this period also coincided with sharp increases in the number of cases for Louisiana, Georgia, and North Carolina.

XSL•FO
RenderX

Figure 4. Geographical variations across states from March 1 to April 15, 2020, for the care seeking, outlook and concerns, and social and travel themes. The figure shows the two queries that were most representative of each category.



RSVs for *social distancing* were generally high in the Northeast and West but generally low in the South, while searches for *hoarding* were relatively more popular in Alaska, New Mexico, Minnesota, Arizona, and Montana than in other states during this period.

Regarding the news and influence theme, searches for *far-right/alt-right* and *coronavirus* were most popular in West Virginia, Oklahoma, Idaho, and Pennsylvania, while *fake news coronavirus* searches were most popular in DC, Vermont, Alaska, Maine, and Nebraska (Figure 5). Additionally, *stimulus check* had particularly high RSVs in Southern states (Figure 5). Although *health insurance* had a high RSV in the Northeast (New York, Massachusetts, and Vermont), *Medicaid* had higher RSVs in Southern states, including Louisiana and Mississippi (Figure 5).

XSL•FO
RenderX

Figure 5. Geographical variations across states from March 1 to April 15, 2020, for the news and influence, government programs, and health programs themes. The figure shows the two queries that were most representative of each category.

Summarizing Differences in Search Patterns Using Correlation and PCA

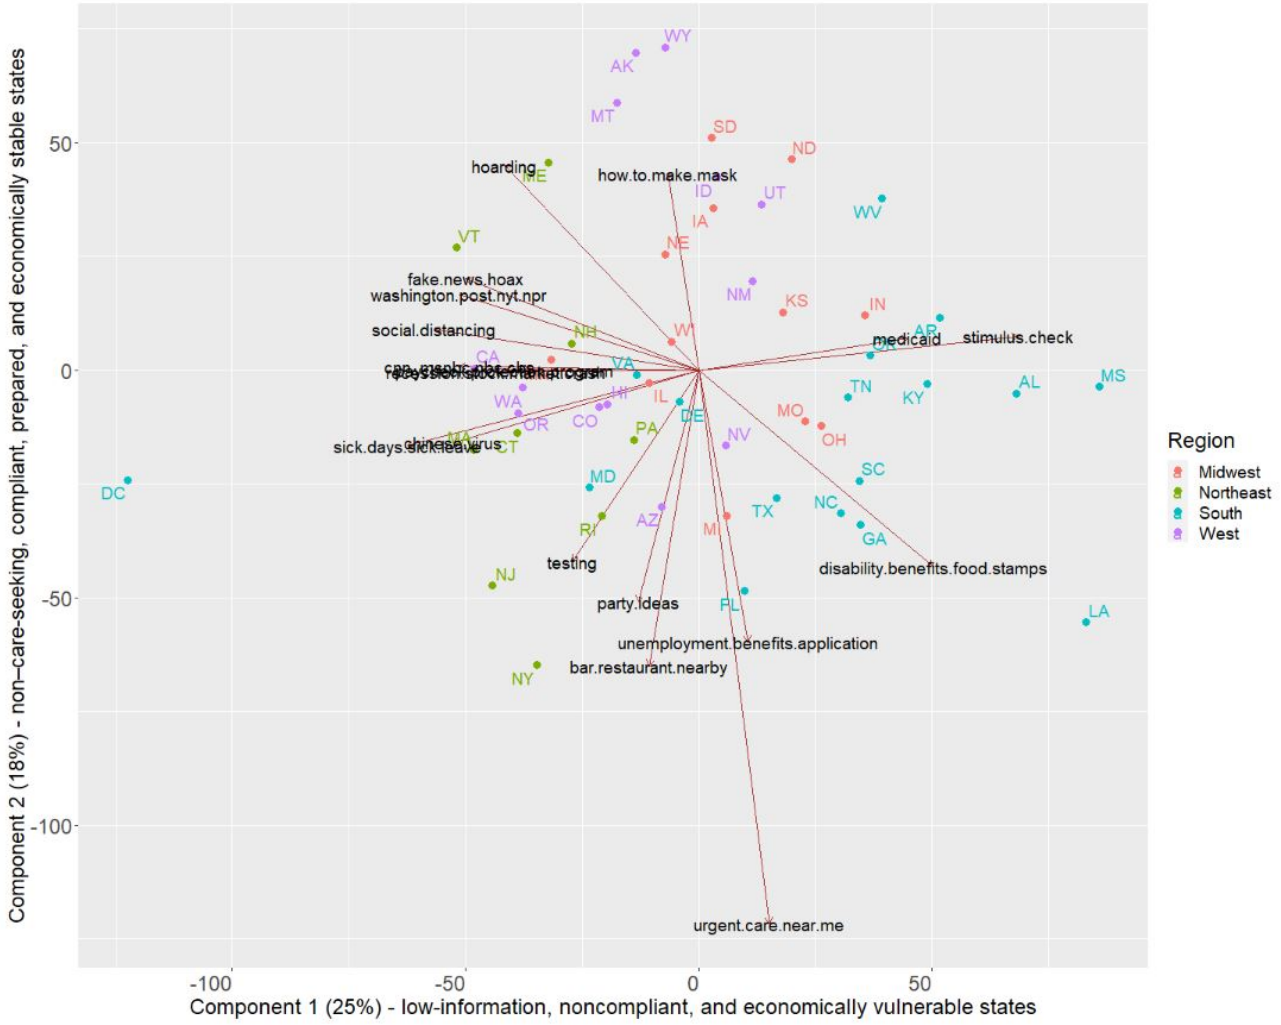
Much variability in information seeking between states can be explained by a few components.

Although the thematic categories in the above analysis give insights on the relative popularity of queries over time and across geographic regions, we also conducted pairwise correlation and PCA analyses to understand how the queries were correlated. First, correlation analysis showed that states with high RSVs for *coronavirus symptoms* also tended to have high RSVs for *urgent care* and *test centers*, suggesting a relationship between awareness of the disease and potential intention to seek care. Second, the correlation showed that states with high RSVs for *social distancing* also tended to have high RSVs for *coronavirus* and all types of news media regardless

XSL•FO
RenderX

of ideological leaning, *recession/stock market crash*, and *sick days/leave*, while tending to have low RSVs for safety net programs such as *medicare* and *stimulus check*. This finding suggests that news sources and economic factors play a role in the levels of interest in, awareness of, and potential adoption of social distancing behavior.

The PCA results are shown in Figure 6, with all 38 queries summarized as the top two components that explain 43% of the variation (differences or patterns) in the data—25% from Component 1 and 18% from Component 2. The two components were assigned labels based on the search patterns they showed.



PCA revealed search patterns related to economic vulnerability and searching for information from news and media sources. It also highlighted how state search patterns were related to other concepts, such as compliance with social distancing or related policies such as mask wearing; preparation for emergencies (hoarding); and care-seeking concepts, such as searching for urgent care.

Specifically, Component 1 explained 25% of the variation in the data (Figure 6). This component represented potentially low-information, noncompliant, and economically vulnerable states. These terms are defined as follows: *low-information*: low association with searches for any news source, whether real or fake; *noncompliant*: low association with searches for *social distancing*; and *economically vulnerable*: high association with searches for *disability/food stamps* and *stimulus check*. The states with the highest scores (ie, those that exhibited this search pattern most strongly) were Mississippi, Louisiana, Alabama, Arkansas, and Kentucky. Additional clusters of states within Component 1 also had high scores for *urgent care nearby* and *unemployment application* (Florida and Michigan) as well as *disability/food stamps* (Georgia, North Carolina, and South Carolina).

Component 2 explained 18% of the variation in the data (Figure 6). This represented potentially non–care-seeking, compliant, prepared, and economically stable states. These terms are defined as follows: *non–care-seeking*: low association with searches for *urgent care nearby*; *compliant*: low association with searches of *nearby bars/restaurants*; *prepared*: high association with searches for *how to make a mask* and *hoarding*; and *economically stable*: low association with searches for *unemployment* and *disability/food stamps*. The states exhibiting this trend were Wyoming, Alaska, Montana, North Dakota, and South Dakota.

XSL•FO
RenderX

Figure 6. Scatterplot of state principal component analysis loadings and scores for the first two components, with the top queries shown as arrow vectors. Each arrow represents the relative weight of each query, and the direction indicates the points to the states that most exhibit this search pattern. The arrow direction measures correlation; arrows in the same direction are highly positively correlated, while divergent arrows in opposite directions are highly negatively correlated. Component 1 (x-axis) and Component 2 (y-axis) explain 25% and 18% of the variation (differences or patterns) in the data, respectively.

Discussion

Principal Findings

We studied the demand side of the infodemiology [31] of COVID-19 using a curated set of queries from Google Trends grouped into emergent themes. Our findings show substantial changes in COVID-19 information seeking at the national level, particularly in March 2020, suggesting a hyperawareness and desire for information about both COVID-19 and its corresponding novel behavioral concepts, namely social distancing and mask wearing. This is in line with other studies showing spikes in information seeking during disease outbreaks [44]. The trends also mirrored the rapid changes in the way people eat, travel, and socialize. The high demand for information corresponded with increasing searches for news sources and coronavirus, regardless of ideological leaning, including searches for *coronavirus fake news* + *coronavirus hoax*. It is not conclusive whether this indicates curiosity or an earnest belief in the existence of "fake news." Still, this finding underscores the critical and timely role that news sources play in providing information during a pandemic and why this information must be correct and trustworthy. This complements other Google Trends studies [45,46] that showed that information seeking and collective attention toward COVID-19 can, at times, be driven by media coverage more than epidemic trends.

Effective communication during health crises is critical and, if not done well, leads to "public confusion and misunderstanding" with negative public health consequences, as happened with COVID-19 in the United States [47,48]. Our study found that changes in information seeking often occurred well in advance of action by the federal government. Tracking search patterns for social distancing or mask wearing could show public health authorities what interventions people are aware of and might accept, as well as the best time to start talking about them, especially in rapidly evolving situations. Previous studies showed that attention paid to COVID-19–related information spiked sharply but quickly saturated despite high media coverage [44] as the pandemic continued to spread. Therefore, the right interventions, if poorly timed, could be too early to be acceptable, or, as occurred in the case of the COVID-19 pandemic, too late to be optimally effective.

RenderX

The decrease in popularity of searches related to urgent care, doctors' appointments, and health insurance/Medicare/Medicaid is consistent with the decline in health seeking that occurs during pandemics: prospective patients for other diseases have higher risk perception of hospital-based transmission of COVID-19, which reduces their health-seeking behavior [49]. This was especially true in the United States, where hospitals prioritized COVID-19 and relegated other services [50]. This finding can be an early-warning indicator of reduced health-seeking behavior, especially for vulnerable communities with underlying health risks. It can be used to prioritize and target these communities with messages about the continued importance of health care for conditions and symptoms not related to COVID-19.

State-level differences in search patterns confirmed the trajectory of the pandemic and informed our potential hypotheses about the regional and structural drivers of these differences. For example, in New York and New Jersey, two states where the pandemic quickly accelerated and where, coincidentally, health insurance marketplaces are state-run rather than federally run, people were performing searches related to urgent care and health insurance [51]. Residents of southern states tended to search for several potentially worrying factors in the fight against COVID-19, including searches related to urgent care and Medicaid and searches for stimulus checks, indicating the need for a financial safety net. The search for *hoarding* was popular in states with either large land areas (and less dense populations) or especially extreme weather conditions—Alaska, New Mexico, Minnesota, Arizona, and Montana. This may reflect heightened expectations of scarcity of the populations of these states during a pandemic, as these factors likely make these states hard to reach in the case of disrupted supply chains. These hypotheses need to be validated; however, they provide a starting point for anticipating the trajectory of the next pandemic or national emergency.

Using correlation and PCA, we identified economic and financial factors, access to information, and interest in social distancing as key variables in describing states' information-seeking patterns on COVID-19. Using this premise, Mississippi, Louisiana, Alabama, Arkansas, and Kentucky were identified as low-information, noncompliant, and economically vulnerable states during the time window of the analysis (March and April 2020). Thus, the states that are most vulnerable economically or in terms of the social safety net are also the least informed and show the least search-related interest in social distancing, a key intervention to prevent COVID-19. This insight can be used to increase awareness of social distancing and its benefits while targeting and prioritizing resources to support these states, including increased testing, health system capacity support, and economic relief measures.

To capture the evolving information and insights available through Google Trends, we propose a real-time dashboard to track trends, geographical variations, and patterns of interest regarding the epidemic. This proposal is in line with evidence that Google Trends data are statistically significantly correlated with COVID-19 data [24]. The queries used in this study can be used as a starting point or baseline, with additional features added if needed. As the epidemic continues and potentially gives way to a second wave, this dashboard will follow how specific queries change over time and which states demonstrate concerning search patterns using the pairwise correlation and PCA approaches. Depending on the search patterns identified, policy makers can then design or improve interventions as well as allocate resources to target states.

Limitations

We made some assumptions and choices that may result in limitations depending on the use case. First, the selection of keywords and queries was an iterative process because it is difficult to know a priori what search terms best capture a desired concept. Analytically, we used weekly RSVs as opposed to daily RSVs, resulting in some loss of granularity. We also used the state as our main unit of analysis and not the city or designated market area level because the COVID-19 response was organized at the state level and lower levels had more missing values. However, at state level, there were a few missing values that were included in the trend and geographical analyses but removed for the pairwise correlation and PCA analyses.

While valuable insights can be derived, a major limitation of Google Trends is that it will always be a measure of search patterns and not the actual corresponding behaviors; therefore, inference and prediction must always come with this caveat. Finally, this analysis is limited by specific assumptions of Google Trends, which include pulling the data from only a sample and not the whole database of searches and providing it in the form of RSV instead of absolute search volumes per geographic region. This requires caution when analyzing results from low-volume queries or geographic regions and when making interpretations and conclusions from analyses.

Conclusion

Our work provides insights into, and potential indicators of, important changes in information-seeking patterns during pandemics such as COVID-19 that can be used to inform public health and public policy. High demand for information corresponding with increasing search popularity for COVID-19 from news sources highlights the importance of public health authorities working with media to ensure that information is correct. Decreases in search popularity for health seeking–related searches can be an early warning indicator for policy makers to target areas with serious underlying health risks with messages about the importance of continuing to seek care for other ailments, even during a pandemic. The emergence of economic and financial factors, access to information, or interest in social distancing as important variables suggests potential interventions to increase awareness of social distancing and its benefits, while targeting and prioritizing resources to support states, including increased testing, health system capacity support, and economic relief measures.

We demonstrated that PCA can explain the variation across several queries and multiple geographies. This work underscores the importance of tracking a well-curated set of queries, customized for the topic, and combined to capture all angles of the problem to improve public health in real time.

Abstract

Background: Health authorities can minimize the impact of an emergent infectious disease outbreak through effective and timely risk communication, which can build trust and adherence to subsequent behavioral messaging. Monitoring the psychological impacts of an outbreak, as well as public adherence to such messaging, is also important for minimizing long-term effects of an outbreak.

Objective: We used social media data from Twitter to identify human behaviors relevant to COVID-19 transmission, as well as the perceived impacts of COVID-19 on individuals, as a first step toward real-time monitoring of public perceptions to inform public health communications.

Methods: We developed a coding schema for 6 categories and 11 subcategories, which included both a wide number of behaviors as well codes focused on the impacts of the pandemic (eg, economic and mental health impacts). We used this to develop training data and develop supervised learning classifiers for classes with sufficient labels. Classifiers that performed adequately were applied to our remaining corpus, and temporal and geospatial trends were assessed. We compared the classified patterns to ground truth mobility data and actual COVID-19 confirmed cases to assess the signal achieved here.

Results: We applied our labeling schema to approximately 7200 tweets. The worst-performing classifiers had F1 scores of only 0.18 to 0.28 when trying to identify tweets about monitoring symptoms and testing. Classifiers about social distancing, however, were much stronger, with F1 scores of 0.64 to 0.66. We applied the social distancing classifiers to over 228 million tweets. We showed temporal patterns consistent with real-world events, and we showed correlations of up to –0.5 between social distancing signals on Twitter and ground truth mobility throughout the United States.

Conclusions: Behaviors discussed on Twitter are exceptionally varied. Twitter can provide useful information for parameterizing models that incorporate human behavior, as well as for informing public health communication strategies by describing awareness of and compliance with suggested behaviors.

Introduction

Health authorities can minimize the impact of an emergent infectious disease through effective and timely risk communication, vaccines and antiviral therapies, and the promotion of health behaviors, such as social distancing and personal hygiene practices [1-4]. Of these, official communication is the earliest available strategy, and its effectiveness will build trust and adherence to the remaining measures [1]. During the H1N1 influenza pandemic in 2009, most countries focused on the promotion of health behaviors [2] such as mask-wearing, avoidance of crowds, and increased disinfection after observing that such protocols contributed substantially to reduced transmission and ultimate control of disease during the SARS outbreak in 2003 [5]. Health authorities have paid less attention to the psychological factors associated with a pandemic [3,4], though such factors play a vital role in subsequent adherence to health behaviors and vaccine uptake [1]. During the emergence of the Zika virus in 2016, public health guidelines focused on preventing sexual transmission by using condoms, avoiding travel to locations with active Zika transmission, and mosquito control [6], with varying levels of compliance [7,8].

Research into the use of social media and internet data for health surveillance is a growing field. Individuals discuss a wide variety of health concerns and health behaviors online, from symptom searching [9] and personal experiences with infectious diseases [2] to dieting [10] and electronic cigarette use [11]. These data have been used to identify prominent points of discussion in relation to health topics [12-14], which can point toward more effective health policies and interventions. In addition, social media and internet data reflect temporal and spatial patterns in health behavior [9-12,15]. The association between internet data and health behavior, topics, and attitudes relevant to the public provides insight into the manner in which individuals receive health information and how that information may translate into behavioral change. Specifically for disease outbreaks, internet and social media data provide opportunities for public health officials to monitor prevalent attitudes and behaviors at a given time to target further interventions and policies.

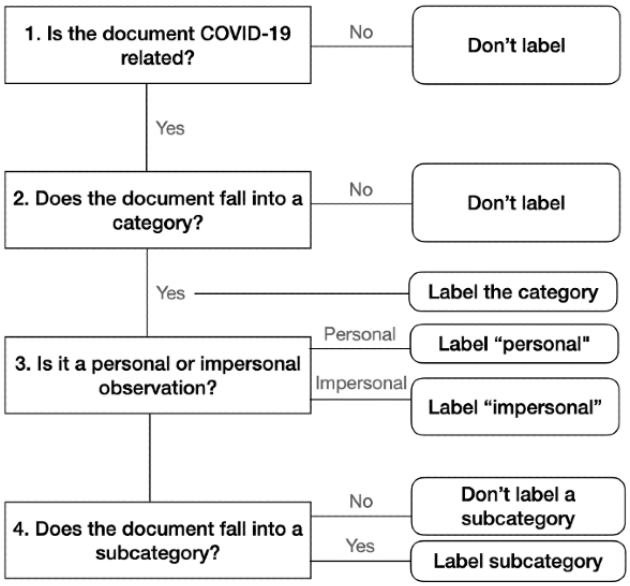
In this work, we used social media data to better understand human behaviors relevant to COVID-19 transmission and the perceived impacts of COVID-19 on individuals. We developed a coding schema for 6 categories and 11 subcategories, which included both a wide number of behaviors as well as codes focused on the impacts of the pandemic (eg, economic and mental health impacts). We applied this schema to approximately 7200 tweets and developed supervised learning classifiers for classes with sufficient labels. We then applied these classifiers to an extensive Twitter data set and showed patterns in human behaviors temporally and spatially across the United States.

We specifically focused on the following research questions:

1. Research Question 1: What behaviors related to COVID-19 are discussed on social media websites, specifically Twitter? Using content analysis techniques similar to other social media studies (eg, Ramanadhan et al [16] and Carrotte et al [17]), we identified behaviors discussed on Twitter that could be relevant to disease transmission or the downstream impacts of COVID-19. At the outset, we were particularly interested in social distancing, hygiene, and personal protective equipment practices, but we were also interested in identifying the breadth of behaviors that might be discussed.
2. Research Question 2: How do patterns in behaviors change geospatially and temporally in the United States? Using labeled data from Research Question 1, we built classification models to identify behaviors in the larger Twitter corpus. We were interested in temporal and geospatial trends in these classified data with the goal of observing regional patterns and temporal changes that occurred in conjunction with real-world events. Prior work has used similar methods to observe patterns during Zika emergence in 2016 [15].
3. Research Question 3: How do these trends compare to other data streams, like mobility data sets? Prior work has shown that social media data are biased in multiple ways [18,19]. One way to validate our findings is to compare results using social media data to other data sources that have been useful to measure human behavior during the COVID-19 pandemic. In particular, several studies have shown that mobility data sets that rely on mobile devices (eg, smartphones) have been useful at accurately gauging reduced mobility [20,21].

Methods

Data



For this work, we used a data set of tweets provided by Chen et al [22]. Data collection started on January 28, 2020, and used Twitter's search application programming interface (API) to get historical tweets as early as January 21, 2020. They started with 14 keywords related to the novel coronavirus, and later expanded both keywords and individual accounts tracked over time. The data relied on Twitter's streaming API, and are thus a 1% sample of tweets that include the keywords. The original repository contained about 270 million tweets as of mid-July 2020 [22]. Of these, we were able to collect 84% (N=228,030,309).

Schema Development

The coding schema was developed by three of the authors (AD, DG, and CS) through iterative analysis of random samples of tweets from our corpus. We started initially with categories of interest (eg, social distancing and personal protective equipment) and added both categories and subcategories as they were identified in tweets, similar to prior work [16,17]. The final schema is hierarchical, where annotators can label categories and, if applicable, subcategories within the category of interest (Figure 1).

Figure 1. Decision tree for labeling.

Personal and impersonal viewpoints were labeled separately from the tweet category. Here, a *personal viewpoint* is a tweet that describes a direct observation of the behavior, meaning the individual tweeting talks about their own behavior, or a person or event that the user can directly observe. For example, the tweet "I am wearing a mask when I go out" is a personal mention of personal protective equipment, specifically mask-wearing. An *impersonal viewpoint*, in contrast, includes actions like sharing articles, retweeting, or expressing an opinion without providing evidence that the user themself engages in the behavior (eg, "Ugh, I wish more people wore masks"). This definition is the same as prior work [15]. Of note, tweets were only labeled as personal or impersonal if they were already labeled with a category. Tweets that were outside the labels of interest were not labeled for viewpoint.

Training Data

Training Annotators and Annotation

To create our training data set, 7278 tweets were selected at random from the English tweets we collected between January and May 2020, as labeling commenced in May. Using the above schema, we then trained three additional annotators. Annotators were trained using the following steps. First, a member of the team (AD) met with each individual prospective annotator and thoroughly described the schema. The prospective annotator and AD first labeled 16 example tweets together using tweets already labeled during schema development. The annotator then individually coded 160 additional tweets previously labeled by the authors. If agreement was sufficiently high (>0.6), the annotator was then given their own section of training data to code. Each tweet in our training data set was coded by two such annotators. All annotators met weekly to discuss questions about labels. All tweets with disagreements were resolved by a third annotator or via group discussion. The workflow to label tweets is given in Figure 1. Tweets can be labeled with more than one label, as applicable.

Annotator Agreement

Annotator agreement varied. Personal and impersonal labels had agreements of 0.41, 0.44, and 0.41 between the three pairs of annotators. Category-level labels had agreements of 0.77, 0.82, and 0.82, and subcategory-level labels had agreements of 0.61, 0.65, and 0.66. Distinguishing between personal and impersonal tweets was the hardest classification task because it is inherently difficult to correctly identify voice in the span of 280 characters, especially without additional context. Prior work has relied on the use of personal pronouns (eg, "I," "we," and "our") to identify personal tweets [15], but it is clear that this method has a high false negative rate because of linguistic patterns like pronoun-drop (eg, the tweet "Went to the store today and nobody was wearing masks" drops the pronoun "I" and leaves it implied) [23]. Thus, despite the difficulty in labeling these tweets, we believe it is preferable to automated methods.

Classification Algorithms

Tweet Preprocessing

Tweet URLs and usernames (@-mentions) were replaced with the tokens "URL" and "USERNAME," respectively. Consecutive characters were truncated (eg, "greaaaaaat" was truncated to "great") and punctuation was removed. Of the training data, 15% were reserved as the test set. Tweets were split using stratified sampling based on the category labels to preserve label proportions. Because of the small number of labels in several categories (Table 1), we only attempted to make classifiers for the following: personal or impersonal, social distancing (category), shelter-in-place (subcategory), monitoring (category), hygiene (category), and personal protective equipment (category).

Because personal and impersonal labels were only assigned to tweets if they fell into a category, the training data for this classifier were only those tweets with an initial label. In contrast, all other classifiers used binary classification and included all tweets that did not include the label of interest, including tweets

RenderX

with no labels. As such, all classification models were built using extremely disproportionate label distributions.

Logistic Regression

Logistic regression models were implemented in Python, version 3.7.7 (Python Software Foundation), using scikit-learn [24] and the elastic net penalty. Features included all unigrams, bigrams, and trigrams of tweet text. To optimize models, grid search was used with all possible combinations of the following parameters: the elastic net penalty varied the L1 ratio from 0 (equivalent to only "L2" penalty) to 1 (equivalent to only "L1" penalty), regularization strength varied in order of magnitude from 0.001 to 1000, and chi-square feature selection was varied from 10% to 100% of the features (ie, no feature selection), in steps of 10%, to explore the impact of feature reduction on model performance.

Random Forest

Random forest models were implemented using scikit-learn's random forest classifier [24]. As in logistic regression, features included all unigrams, bigrams, and trigrams of tweet text. Again, grid search was used to optimize models. The minimum number of samples per leaf node was varied from 2 to 11 (in steps of 3), the minimum number of samples required to split an internal node ranged from 2 to 52 (in steps of 10), and the number of trees per forest was either 50 or 100. Last, we additionally varied the number of features. Because of the larger number of parameters tested here, we tried feature selections of 25%, 50%, 75%, or 100% of features (ie, no feature selection).

Classification and Bias Adjustments

Both types of models performed poorly for classifying monitoring, personal protective equipment, and hygiene. As such, we did not use these models for downstream analysis. Rather, we focus on the personal or impersonal model, the social distancing classifier, and the shelter-in-place classifier.

Though random forest models sometimes produced slightly higher F1 scores, we used the logistic regression models for overall classification and downstream analysis because of the slightly higher precision values. Said another way, in this context, we preferred fewer false positives to slightly more false negatives because we were trying to identify a particular behavior and wanted as few erroneous predictions included in the classifier as possible.

To combat the bias inherent in our classifiers, as it is clear that misclassification will occur, we used the method suggested by Daughton and Paul [25] to create confidence intervals that account for classifier error. The basic principle is to use bootstrapping to generate many samples and to subsequently weight individual classifications by the positive predictive value or negative predictive value of the classifier. The bootstrapped samples are then used to generate a 95% confidence interval around the point estimate (see Daughton and Paul [25] for full details). This method has been successfully applied in similar work focused on identifying travel change behaviors in response to Zika [15]. For this work, we used 100 bootstrapped samples to generate daily confidence intervals.

Geospatial Analysis and Comparison to Mobility and COVID-19 Data
